When enabled and execution of a load or store class instruction results in a data access with an address that meets the criteria specified in the DBCRx, DACx, and DVCx Registers, and the instruction also meets the criteria for generating an Instruction Address Compare event, a Linked Data Address Compare debug event occurs. This event can

occur and be recorded in DBSR regardless of the setting of MSR_{DE}. The normal DAC1 status bit in the DBSR is used for recording these events. The IAC status bit is not set if the corresponding Instruction Address Compare register is linked.

Linking is enabled using control bits in DBCR2 and DBCR8. Note that linking is only available in EDM or IDM. Attempts to use linking otherwise are ignored.

Note

Linked DAC events will not be recorded if a load multiple word or store multiple word type instruction is interrupted prior to completion by a critical input or external input interrupt.

64.2.4 Trap Debug Event

A Trap debug event (TRAP) occurs if Trap debug events are enabled ($DBCR0_{TRAP}$=1), a Trap instruction (**tw**) is executed, and the conditions specified by the instruction for the trap are met. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Trap debug event occurs, the $DBSR_{TRAP}$ bit is set to 1 to record the debug exception.

64.2.5 Branch Taken Debug Event

A Branch Taken debug event (BRT) occurs if Branch Taken debug events are enabled ($DBCR0_{BRT}$=1) and execution is attempted of a branch instruction that will be taken (either an unconditional branch, or a conditional branch whose branch condition is true), and MSR_{DE}=1. Branch Taken debug events are not recognized if MSR_{DE}=0 at the time of execution of the branch instruction and thus $DBSR_{IDE}$ can not be set by a Branch Taken debug event. When a Branch Taken debug event is recognized, the $DBSR_{BRT}$ bit is set to 1 to record the debug exception, and the address of the branch instruction will be recorded in DSRR0.

64.2.6 Instruction Complete Debug Event

An Instruction Complete debug event (ICMP) occurs if Instruction Complete debug events are enabled ($DBCR0_{ICMP}$=1), execution of any instruction is completed, and MSR_{DE}=1. If execution of an instruction is suppressed due to the instruction causing some other exception that is enabled to generate an interrupt, then the attempted execution of that instruction does not cause an Instruction Complete debug event. The ***se_sc*** instruction does not fall into the category of an instruction whose execution is

suppressed, since the instruction actually executes and then generates a System Call interrupt. In this case, the Instruction Complete debug exception will also be set. When an Instruction Complete debug event is recognized, $DBSR_{ICMP}$ is set to 1 to record the debug exception and the address of the next instruction to be executed will be recorded in DSRR0.

Instruction Complete debug events are not recognized if MSR_{DE}=0 at the time of execution of the instruction, thus $DBSR_{IDE}$ is not generally set by an ICMP debug event.

Note

Instruction complete debug events are not generated by the execution of an instruction that sets MSR_{DE} to '1' while $DBCR0_{ICMP}$=1, nor by the execution of an instruction that sets $DBCR0_{ICMP}$ to '1' while MSR_{DE}=1.

64.2.7 Interrupt Taken Debug Event

An Interrupt Taken debug event (IRPT) occurs if Interrupt Taken debug events are enabled ($DBCR0_{IRPT}$=1) and a base-class interrupt occurs. Only base-class interrupts (an interrupt using SRR0/1) cause an Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Interrupt Taken debug event occurs, the $DBSR_{IRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the non-critical interrupt handler.

64.2.8 Critical Interrupt Taken Debug Event

A Critical Interrupt Taken debug event (CIRPT) occurs if Critical Interrupt Taken debug events are enabled ($DBCR0_{CIRPT}$=1) and a critical interrupt occurs. Only critical class interrupts (an interrupt using CSRR0/1) cause a Critical Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Interrupt Taken debug event occurs, the $DBSR_{CIRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the critical interrupt handler.

64.2.9 Return Debug Event

A Return debug event (RET) occurs if Return debug events are enabled ($DBCR0_{RET}$=1) and an attempt is made to execute an **se_rfi** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Return debug event occurs, the $DBSR_{RET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfi** (i.e. before the MSR is updated by the **se_rfi**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfi**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfi** instruction.

64.2.10 Critical Return Debug Event

A Critical Return debug event (CRET) occurs if Critical Return debug events are enabled ($DBCR0_{CRET}$=1) and an attempt is made to execute an **se_rfci** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Return debug event occurs, the $DBSR_{CRET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfci** (i.e. before the MSR is updated by the **se_rfci**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfci**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfci** instruction.

64.2.11 External debug event

An External debug event (DEVT1, DEVT2) occurs if External debug events are enabled ($DBCR0_{DEVT1}$=1 or $DBCR0_{DEVT2}$=1), and the respective **p_devt1** or **p_devt2** input signal transitions to the asserted state while the CPU is not in the Stopped state. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an External debug event occurs, $DBSR_{DEVT\{1,2\}}$ is set to '1' to record the debug exception. This debug event is an asynchronous event, but is only sampled when the CPU **m_clk** is active.

64.2.12 Unconditional debug event

An Unconditional debug event (UDE) occurs when the Unconditional Debug Event (**p_ude**) input transitions to the asserted state. The Unconditional debug event is the only debug event that does not have a corresponding enable bit for the event in DBCR0. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Unconditional debug event occurs, the $DBSR_{UDE}$ bit is set to '1' to record the debug exception. This debug event is an asynchronous event.

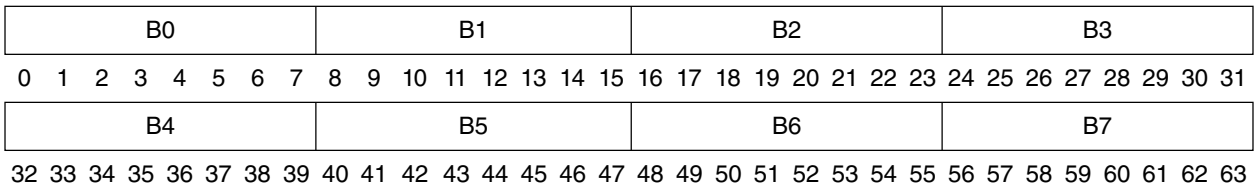
64.2.13 Performance Monitor Interrupt debug event

A Performance Monitor Interrupt debug event (PMI) occurs if Performance Monitor Interrupt debug events are enabled ($PMGC0_{UDI}$=1), and a performance monitor interrupt event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Performance Monitor Interrupt debug event occurs, $DBSR_{PMI}$ is set to '1' to record the debug exception. This debug event is an asynchronous event.

64.3 Debug registers

This section describes debug-related registers that are software accessible. These registers are intended for use by special debug tools and debug software, not by general application code.

Access to these registers (other than DBSR) by software is conditioned by the External Debug mode control bit ($EDBCR0_{EDM}$) and the settings of debug control register EDBRAC0, which can be set by the hardware debug port. If $EDBCR0_{EDM}$ is set and if the bit in EDBRAC0 corresponding to the resource is cleared, software is prevented from modifying debug register values other than in DBSR, since the resource is not "owned" by software. Software always has ownership of DBSR. Execution of a **mtspr** instruction targeting a debug register or register field not "owned" by software will not cause modifications to occur, and no exception will be signaled. In addition, since the external debugger hardware may be manipulating debug register values, the state of these registers or register fields not "owned" by software is not guaranteed to be consistent if accessed (read) by software with a **mfspr** instruction, other than the $DBCR0_{EDM}$ bit itself and the EDBRAC0 register. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control registers as appropriate when hardware modifications to the debug registers is performed.



64.3.1 Debug Address and Value Registers

[SCG_NX_DEBUG_REGS]Instruction Address Compare registers IAC1–8 are used to hold instruction addresses for address comparison purposes. In addition, IAC2 and IAC4 may hold mask information for IAC1 and IAC3 respectively and IAC6 and IAC8 may hold mask information for IAC5 and IAC7 respectively, when *Address Bit Match* compare modes are selected. Note that when performing instruction address compares, the low order bit of the instruction address and the corresponding IAC register is ignored for VLE instructions.

Data Address Compare registers DAC1–4 are used to hold data access addresses for address comparison purposes. In addition, DAC2 and DAC4 may hold mask information for DAC1 and DAC3 respectively when *Address Bit Match* compare modes are selected.

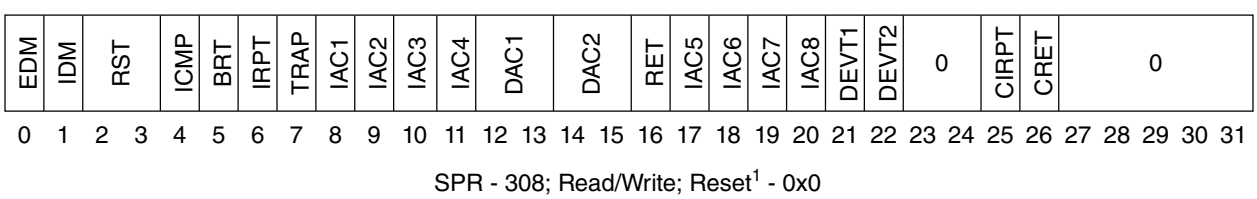
Data Value Compare registers DVC1 and DVC2 are used to hold data values for data comparison purposes. DVC1 and DVC2 are 64-bit registers. Data value comparisons are used to qualify Data Address compare 1 and 2 debug events. Data value comparisons are not available for Data address compare 3–4 events. DVC1 is associated with DAC1, and DVC2 is associated with DAC2. The most significant byte of the DVC1(2) register (labeled B0 in the following figure) corresponds to the byte data value transferred to/from memory byte offset 0, 8, …, and the least significant byte of the register (labeled B7 in the following figure) corresponds to byte offset 7, F, … . When enabled for performing data value comparisons, each enabled byte in DVC1(2) is compared with the memory value transferred on the corresponding active byte lane of the data memory interface to determine if a match occurs. Inactive byte lanes do not participate in the comparison, they are implicitly masked. The Byte Strobe Assertion for Transfers table in the Core (e200z210n3) Core Complex Overview chapter shows active byte lanes for data transfers. Software must also program the DVC1(2) register byte positions based on the alignment of the access. Misaligned accesses are not fully supported, since the data address and data value comparisons are only performed on the initial access in the case of a misaligned access; thus, accesses that cross a 64-bit boundary cannot be fully matched. For address and size combinations that involve two transfers, only the initial transfer is used for data address and value matching.

DVC1 and DVC2 may be read or written using **mtspr** and **mfspr** instructions. The DVC1U and DVC2U SPR numbers (601,602) are used for accessing the upper 32-bit portion of the DVC register. The DVC1 and DVC2 SPR numbers (318,319) are used for accessing the lower 32-bit portion of the DVC register.[end]

SPR - 601 (DVC1U), 318 (DVC1), 602 (DVC2U) 319 (DVC2); Read/Write; Reset - Unaffected

Figure 64-2. DVC1, DVC2 registers

64.3.2 Debug Control and Status registers



Debug Control Registers (DBCR0–8 and EDBRAC0) are used to enable debug events, reset the processor, and set the debug mode of the processor. The Debug Status register (DBSR) records debug exceptions while Internal Debug mode is enabled. The Debug Data Effective Address register (DDEAR) records the effective address of a Data Address Compare event while Internal Debug mode is enabled.

e200z210n3 requires that a context synchronizing instruction follow a **mtspr** DBCR0–8 or DBSR to ensure that any alterations enabling/disabling debug events are effective. The context synchronizing instruction may or may not be affected by the alteration. Typically, an **se_isync** instruction is used to create a synchronization boundary beyond which it can be guaranteed that the newly written control values are in effect.

For watchpoint generation, configuration settings contained in DBCR1–8 are used, even though the corresponding event(s) may be disabled (via DBCR0) from setting DBSR flags.

64.3.2.1 Debug Control Register 0 (DBCR0)

Debug Control Register 0 is used to enable debug modes and controls which debug events are allowed to set DBSR or EDBSR0 flags. e200z210n3 adds some implementation specific bits to this register, as seen in the following figure.

SPR - 308; Read/Write; Reset[1] - 0x0

Figure 64-3. Debug Control Register 0 (DBCR0) register

Note

[1] $DBCR0_{EDM}$ is affected by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**. All other bits are reset by processor reset **p_reset_b** if $DBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $DBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources (other than RST) from reset by **p_reset_b**, and only software-owned resources indicated by EDBRAC0 and the $DBCR0_{RST}$ field will be reset by **p_reset_b**. The $DBCR0_{RST}$ field will always be reset by **p_reset_b** regardless of the value of $DBCR0_{EDM}$.

The following provides bit definitions for Debug Control Register 0.

Table 64-2. DBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug mode. This bit is read-only by software. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset p_reset_b. This allows the debugger to set up hardware debug events that remain active across a processor reset. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned debug events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCR0–8, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0. Hardware-owned events will set status bits in EDBSR0. Programming Notes: It is recommended that debug status bits in the Debug Status Registers be cleared before disabling external debug mode to avoid any internal imprecise debug interrupts. Software may use this bit to determine if external debug has control over the debug registers. The hardware debugger must set the EDM bit to '1' before other bits in this register (and other debug registers) may be altered. On the initial setting of this bit to '1', all other bits are unchanged. This bit is only writable through the OnCE port.
1	IDM	Internal Debug mode 0 Debug exceptions are disabled. Debug events do not affect DBSR. 1 Debug exceptions are enabled. Enabled debug events owned by software will update the DBSR. If MSR_{DE}=1, the occurrence of a debug event, or the recording of an earlier debug event in the Debug Status Register when MSR_{DE} was cleared, will cause a Debug interrupt.
2:3	RST	Reset Control 00 No function 01 **p_dbrstc[1]** pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset 10 **p_dbrstc[0]** pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset. 11 Reserved

64.3.2.2 Debug Control Register 1 (DBCR1)

Debug Control Register 1 is used to configure Instruction Address Compare operation. The DBCR1 register is shown in the following figure.

SPR - 309; Read/Write; Reset[1] - 0x0

Figure 64-4. DBCR1 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 1.

Table 64-3. DBCR1 field descriptions

Bit	Name	Description
0:1	IAC1US	Instruction Address Compare 1 User/Supervisor Mode 00 IAC1 debug events not affected by MSR_{PR} 01 Reserved 10 IAC1 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 IAC1 debug events can only occur if MSR_{PR}=1. (User mode)
2:3	IAC1ER	Instruction Address Compare 1 Effective/Real Mode 00 IAC1 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC1 debug events are based on effective address and can only occur if MSR_{IS}=0 11 IAC1 debug events are based on effective address and can only occur if MSR_{IS}=1
4:5	IAC2US	Instruction Address Compare 2 User/Supervisor Mode 00 IAC2 debug events not affected by MSR_{PR} 01 Reserved 10 IAC2 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 IAC2 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	IAC2ER	Instruction Address Compare 2 Effective/Real Mode 00 IAC2 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC2 debug events are based on effective address and can only occur if MSR_{IS}=0 11 IAC2 debug events are based on effective address and can only occur if MSR_{IS}=1
8:9	IAC12M	Instruction Address Compare 1/2 Mode 00 Exact address compare. IAC1 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC1. IAC2 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC2. 01 Address bit match. IAC1 debug events can occur only if the address of the instruction fetch, ANDed with the contents of IAC2 are equal to the contents of IAC1, also ANDed with the contents of IAC2. IAC2 debug events do not occur. IAC1US and IAC1ER settings are used. 10 Inclusive address range compare. IAC1 debug events can occur only if the address of the instruction fetch is greater than or equal to the value specified in IAC1 and less than the value specified in IAC2. IAC2 debug events do not occur. IAC1US and IAC1ER settings are used.

Table continues on the next page...

Table 64-3. DBCR1 field descriptions (continued)

Bit	Name	Description
		11 Exclusive address range compare. IAC1 debug events can occur only if the address of the instruction fetch is less than the value specified in IAC1 or is greater than or equal to the value specified in IAC2. IAC2 debug events do not occur. IAC1US and IAC1ER settings are used.
10:15	—	Reserved

IAC4 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC4. 01 Address bit match. IAC3 debug events can occur only if the address of the instruction fetch, ANDed with the contents of IAC4 are equal to the contents of IAC3, also ANDed with the contents of IAC4. IAC4 debug events do not occur. IAC3US and IAC3ER settings are used. 10 Inclusive address range compare. IAC3 debug events can occur only if the address of the instruction fetch is greater than or equal to the value specified in IAC3 and less than the value specified in IAC4. IAC4 debug events do not occur. IAC3US and IAC3ER settings are used. 11 Exclusive address range compare. IAC3 debug events can occur only if the address of the instruction fetch is less than the value specified in IAC3 or is greater than or equal to the value specified in IAC4. IAC4 debug events do not occur. IAC3US and IAC3ER settings are used.
26:31	—	Reserved

64.3.2.3 Debug Control Register 2 (DBCR2)

Debug Control Register 2 is used to configure Data Address Compare and Data Value Compare operation.The DBCR2 register is shown in the following figure.

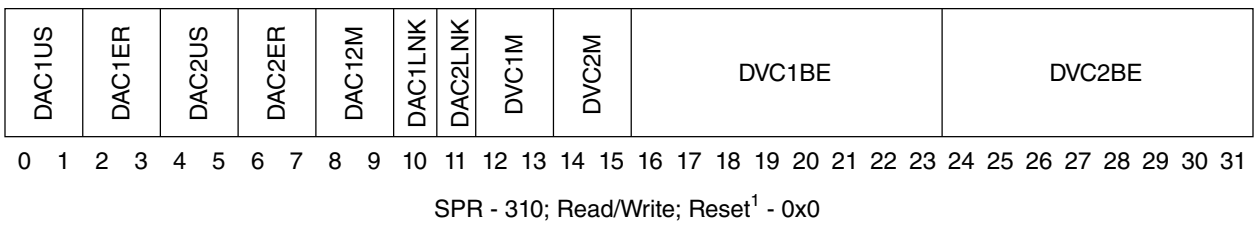

Figure 64-5. DBCR2 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 2.

Table 64-4. DBCR2 Bit Definitions

Bit	Name	Description
0:1	DAC1US	Data Address Compare 1 User/Supervisor Mode 00 DAC1 debug events not affected by MSR_{PR} 01 Reserved 10 DAC1 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC1 debug events can only occur if MSR_{PR}=1 (User mode)
2:3	DAC1ER	Data Address Compare 1 Effective/Real Mode 00 DAC1 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=1
4:5	DAC2US	Data Address Compare 2 User/Supervisor Mode 00 DAC2 debug events not affected by MSR_{PR} 01 Reserved 10 DAC2 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC2 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	DAC2ER	Data Address Compare 2 Effective/Real Mode 00 DAC2 debug events are based on effective address

Table continues on the next page...

Table 64-4. DBCR2 Bit Definitions (continued)

Bit	Name	Description
		01 Unimplemented (Book E real address compare), no match can occur 10 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=1
8:9	DAC12M	Data Address Compare 1/2 Mode 00 Exact address compare. DAC1 debug events can only occur if the address of the data access is equal to the value specified in DAC1. DAC2 debug events can only occur if the address of the data access is equal to the value specified in DAC2. 01 Address bit match. DAC1 debug events can occur only if the address of the data access ANDed with the contents of DAC2, are equal to the contents of DAC1 also ANDed with the contents of DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 10 Inclusive address range compare. DAC1 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC1 and less than the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 11 Exclusive address range compare. DAC1 debug events can occur only if the address of the data access is less than the value specified in DAC1 or is greater than or equal to the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used.
10	DAC1LNK	Data Address Compare 1 Linked. When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC1 debug events are linked to IAC1 debug events. IAC1 debug events do not affect DBSR When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM.
11	DAC2LNK	Data Address Compare 2 Linked. When linked to IAC3, DAC2 debug events are conditioned based on whether the instruction also generated an IAC3 debug event. DAC2 can only be linked if DAC12M specifies Exact Address Compare since DAC2 debug events are not generated in the other compare modes. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC 2 debug events are linked to IAC3 debug events. IAC3 debug events do not affect DBSR
12:13	DVC1M	Data Value Compare 1 Mode When $DBCR4_{DVC1C}$=0: 00 DAC1 debug events not affected by data value compares. 01 DAC1 debug events can only occur when all bytes specified in the DVC1BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC1 debug events can only occur when any byte specified in the DVC1BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC1 debug events can only occur when all bytes specified in the DVC1BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC1 value. **NOTE:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC1C}$=1: 00 Reserved

Table continues on the next page...

Table 64-4. DBCR2 Bit Definitions (continued)

Bit	Name	Description
		01 DAC1 debug events can only occur when any byte specified in the DVC1BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC1 debug events can only occur when all bytes specified in the DVC1BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **NOTE:** Note: Inactive byte lanes of the memory access are automatically masked.
14:15	DVC2M	Data Value Compare 2 Mode When $DBCR4_{DVC2C}$=0: 00 DAC2 debug events not affected by data value compares. 01 DAC2 debug events can only occur when all bytes specified in the DVC2BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC2 debug events can only occur when any byte specified in the DVC2BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC2 debug events can only occur when all bytes specified in the DVC2BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC2 value. **NOTE:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC2C}$=1: 00 Reserved 01 DAC2 debug events can only occur when any byte specified in the DVC2BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC2 debug events can only occur when all bytes specified in the DVC2BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **NOTE:** Inactive byte lanes of the memory access are automatically masked.
16:23	DVC1BE	Data Value Compare 1 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC1. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1xxxxxxx Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC1. x1xxxxxx Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC1. xx1xxxxx Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC1. xxx1xxxx Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC1. xxxx1xxx Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC1. xxxxx1xx Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC1. xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC1. xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC1.

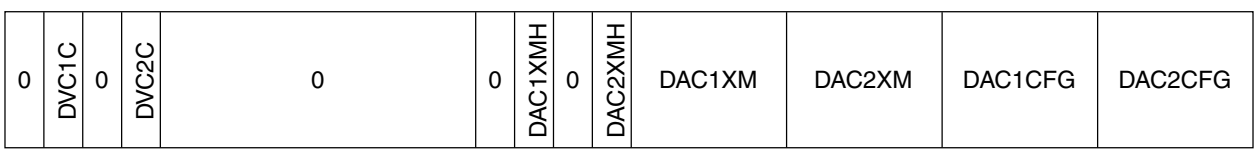

Table continues on the next page...

Table 64-4. DBCR2 Bit Definitions (continued)

Bit	Name	Description
24:31	DVC2BE	Data Value Compare2 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC2. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1xxxxxxx Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC2. x1xxxxxx Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC2. xx1xxxxx Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC2. xxx1xxxx Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC2. xxxx1xxx Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC2. xxxxx1xx Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC2. xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC2. xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC2.

64.3.2.4 Debug Control Register 4 (DBCR4)

Debug Control Register 4 is used to extend data address and value compare matching functionality. DBCR4 is shown in the following figure.

SPR - 563; Read/Write; Reset[1] - 0x0

Figure 64-6. DBCR4 Register

Note

[1] DBCR4 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 4.

Table 64-5. DBCR4 field description

Bit	Name	Description
0	—	Reserved
1	DVC1C	Data Value Compare 1 Control. DVC1C controls whether DVC1 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition. 0 Normal DVC1 operation. 1 Inverted polarity DVC1 operation
2	—	Reserved
3	DVC2C	Data Value Compare 2 Control. DVC2C controls whether DVC2 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition 0 Normal DVC2 operation. 1 Inverted polarity DVC2 operation
4:12	—	Reserved
13	DAC1XMH	Data Address Compare 1 Extended Mask Control High. DAC1XMH extends the range of the DAC1XM field. 0 DAC1XM masks 0–15 low-order address bits 1 DAC1XM masks 16–31 low-order address bits
14	—	Reserved
15	DAC2XMH	Data Address Compare 2 Extended Mask Control High. . DAC2XMH extends the range of the DAC2XM field. 0 DAC2XM masks 0–15 low-order address bits 1 DAC2XM masks 16–31 low-order address bits
16:19	DAC1XM	Data Address Compare 1 Extended Mask Control. DAC1XM allows for binary power of 2 address range compares for DAC1 without requiring the use of DAC2. Value of DAC1XMH || DAC1XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC1 when comparing the storage address with the value in DAC1 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported.
20:23	DAC2XM	Data Address Compare 2 Extended Mask Control Value of DAC2XMH || DAC2XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC2 when comparing the storage address with the value in DAC2 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported. DAC2XM allows for binary power of 2 address range compares for DAC2.
24:27	DAC1CFG	Data Address Compare 1 Configuration 0000 DAC1 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC1}$=00 0001 DAC1 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC1}$=00

Table continues on the next page...

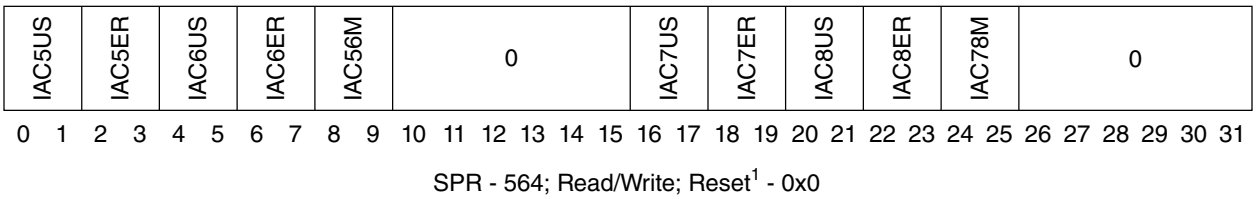

Table 64-5. DBCR4 field description (continued)

Bit	Name	Description
		0010 DAC1 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC1}$=00 0011 Reserved 01xx Reserved 1000 DAC1 address comparisons are used for stack limit checking. DAC1 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC1. When a qualified DAC1 match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC1 watchpoint is generated. $DBCR0_{DAC1}$ and $DBCR2_{DVC1M}$ settings are ignored. 1001 – 1111 Reserved DAC1CFG controls whether DAC1 data address comparisons utilize the normal PowerISA operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint). **NOTE:** unlike the DAC3–4CFG fields, debug event enabling for DAC1 is controlled by the DAC1 field in DBCR0. The DAC1CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC1}$=0; when $DBCR0_{DAC1}$!=00, DAC1 watchpoints will fire whenever a DAC1 debug event occurs.
28:31	DAC2CFG	Data Address Compare 2 Configuration 0000 DAC2 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC2}$=00 0001 DAC2 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC2}$=00 0010 DAC2 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC2}$=00 0011 Reserved 01xx Reserved 1xxx Reserved DAC2CFG controls whether DAC2 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. **NOTE:** Unlike the DAC3–4CFG fields, debug event enabling for DAC2 is controlled by the DAC2 field in DBCR0. The DAC2CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC2}$=00. When $DBCR0_{DAC2}$!=00, DAC2 watchpoints will fire whenever a DAC2 debug event occurs.

64.3.2.5 Debug Control Register 5 (DBCR5)

Debug Control Register 5 is used to configure Instruction Address Compare operation for IAC5–8. The DBCR5 register is shown in the following figure.

.

SPR - 564; Read/Write; Reset[1] - 0x0

Figure 64-7. DBCR5 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 5.

Table 64-6. DBCR5 field descriptions

Bit(s)	Name	Description
0:1	IAC5US	Instruction Address Compare 5 User/Supervisor Mode 00 IAC5 debug events not affected by MSR_{PR} 01 Reserved 10 IAC5 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 IAC5 debug events can only occur if MSR_{PR}=1. (User mode)

		occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC3 watchpoints is generated. 1001 - 1111 Reserved
28:31	DAC4CFG	Data Address Compare 4 Configuration. DAC4CFG controls whether DAC4 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. 0000 DAC4 debug watchpoints are enabled for load-type or store-type data storage accesses 0001 DAC4 debug watchpoints are enabled only for store-type data storage accesses 0010 DAC4 debug watchpoints are enabled only for load-type data storage accesses 0011 Reserved 0100 Reserved 0101 DAC4 debug events and watchpoints are enabled only for store-type data storage accesses 0110 DAC4 debug events and watchpoints are enabled only for load-type data storage accesses 0111 DAC4 debug events and watchpoints are enabled for load-type or store-type data storage accesses 1xxx Reserved

64.3.2.8 Debug Control Register 8 (DBCR8)

Debug Control Register 8 is used to configure Data Address Compare 3 and 4 operation. The DBCR8 register is shown in the following figure.

SPR - 597; Read/Write; Reset[1] - 0x0

Figure 64-10. DBCR8 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 8.

Table 64-9. DBCR8 Bit Definitions

Bit(s)	Name	Description
0:1	DAC3US	Data Address Compare 3 User/Supervisor Mode 00 - DAC3 debug events not affected by MSR_{PR} 01 - Reserved 10 - DAC3 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 - DAC3 debug events can only occur if MSR_{PR}=1. (User mode)
2:3	DAC3ER	Data Address Compare 3 Effective/Real Mode 00 - DAC3 debug events are based on effective address 01 - Unimplemented (Book E real address compare), no match can occur 10 - DAC3 debug events are based on effective address and can only occur if MSR_{DS}=0 11 - DAC3 debug events are based on effective address and can only occur if MSR_{DS}=1
4:5	DAC4US	Data Address Compare 4 User/Supervisor Mode. 00 - DAC4 debug events not affected by MSR_{PR} 01 - Reserved 10 - DAC4 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 - DAC4 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	DAC4ER	Data Address Compare 4 Effective/Real Mode 00 - DAC4 debug events are based on effective address 01 - Unimplemented (Book E real address compare), no match can occur 10 - DAC4 debug events are based on effective address and can only occur if MSR_{DS}=0 11 - DAC4 debug events are based on effective address and can only occur if MSR_{DS}=1
8:9	DAC34M	Data Address Compare 3/4 Mode 00 - Exact address compare. DAC3 debug events can only occur if the address of the data access is equal to the value specified in DAC3. DAC4 debug events can only occur if the address of the data access is equal to the value specified in DAC4.

Table continues on the next page...

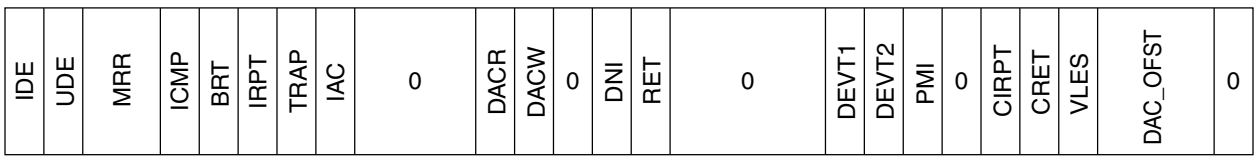

Table 64-9. DBCR8 Bit Definitions (continued)

Bit(s)	Name	Description
		01 - Address bit match. DAC3 debug events can occur only if the address of the data access ANDed with the contents of DAC4, are equal to the contents of DAC3 also ANDed with the contents of DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 10 - Inclusive address range compare. DAC3 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC3 and less than the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 11 - Exclusive address range compare. DAC3 debug events can occur only if the address of the data access is less than the value specified in DAC3 or is greater than or equal to the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used.
10	DAC3LNK	Data Address Compare 3 Linked 0 - No effect 1 - DAC3 debug events are linked to IAC5 debug events. IAC5 debug events do not affect DBSR When linked to IAC5, DAC3 debug events are conditioned based on whether the instruction also generated an IAC5 debug event. Note that linking is only available in EDM or IDM.
11	DAC4LNK	Data Address Compare 4 Linked 0 - No effect 1 - DAC4 debug events are linked to IAC7 debug events. IAC7 debug events do not affect DBSR When linked to IAC7, DAC4 debug events are conditioned based on whether the instruction also generated an IAC7 debug event. Note that linking is only available in EDM or IDM.
12:31	—	Reserved

64.3.2.9 Debug Status Register (DBSR)

The Debug Status Register (DBSR) contains status on debug events and the most recent processor reset. The Debug Status Register is set via hardware, and read and cleared via software. Bits in the Debug Status Register can be cleared using **mtspr***DBSR,RS*. Clearing is done by writing to the Debug Status Register with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write data to the Debug Status Register is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. Debug Status bits are set by Debug events only while Internal Debug Mode is enabled ($DBCR0_{IDM}$=1). When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1, $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR other than MRR, DAC_OFST, or VLES will cause a debug interrupt to be generated. The debug interrupt handler is responsible for clearing DBSR bits prior to returning to normal execution. When resource

sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software, and status bits associated with hardware-owned resources will not be set by hardware in DBSR. The DBSR register is shown in the following figure.

SPR - 304; Read/Clear; Reset - 0x1000_0000

Figure 64-11. DBSR Register

The following table provides bit definitions for the Debug Status Register.

Table 64-10. DBSR Bit Definitions

Bit(s)	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if MSR_{DE}=0 and $DBCR0_{IDM}$=1 and a debug event causes its respective Debug Status Register bit to be set to 1. It may also be set to '1' if an imprecise debug event occurs due to a DAC event on a load or store which is terminated with error.
1	UDE	Unconditional Debug Event Set to 1 if an Unconditional debug event occurred.
2:3	MRR	Most Recent Reset. 00 - No reset occurred since these bits were last cleared by software 01 - A hard reset occurred since these bits were last cleared by software 10 - Reserved 11 - Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if an Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if an Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if an Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a Trap Taken debug event occurred.
8	IAC	Instruction Address Compare Debug Event Set to 1 if an IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event

Table continues on the next page...

Table 64-10. DBSR Bit Definitions (continued)

Bit(s)	Name	Description
		Set to 1 if a write-type DAC debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a Return debug event occurred
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $PMGC0_{UDI}$=1
24	—	Reserved
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if an ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a Power ISA VLE Instruction. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction which took a DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3'b000 and $DBSR_{IDE}$ is set to 1. Normally set to 3'b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

64.3.2.10 Debug Data Effective Address Register (DDEAR)

The Debug Data Effective Address Register (DDEAR) contains address information for data address compare debug events (DAC). DDEAR is update by hardware with the effective address of the load or store operation when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set, in order to capture the first event address.

The DDEAR register is shown in the following table.

Data Effective Address																															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 600; Read/Write; Reset - unaffected

Figure 64-12. DDEAR Register

64.3.3 External Debug Resource Allocation Control Register (EDBRAC0)

The External Debug Resource Allocation Control Register (EDBRAC0) controls resource allocation when $EDBCR0_{EDM}$ is set to '1'. EDBRAC0 provides a mechanism for the hardware debugger to share certain debug resources with software. Individual resources are allocated based on the settings of EDBRAC0 when $EDBCR0_{EDM}$=1. EDBRAC0 settings are ignored when $EDBCR0_{EDM}$=0.

Hardware-owned resources which generate debug events update EDBSR0 instead of DBSR and cause entry into debug mode if the event is not masked in EDBSRMSK0, while software-owned resources which generate debug events if $DBCR0_{IDM}$=1 update DBSR, causing debug interrupts to occur if MSR_{DE}=1. EDBRAC0 is controlled via the OnCE port hardware, and is read-only to software.

The DBSR status register is always owned by software. Debug status bits in DBSR are set by software-owned debug events only while Internal Debug Mode is enabled. When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR by an event which is software-owned (other than MRR, DAC_OFST, or VLES) will cause a debug interrupt to be generated.

Debug status bits in EDBSR0 are set by hardware-owned debug events only while External Debug Mode is enabled ($EDBCR0_{EDM}$=1). When $EDBCR0_{EDM}$=1, a set bit in EDBSR0 by an event which is hardware-owned (other than IDE, DAC_OFST, or VLES) will cause entry into debug mode unless entry is masked via EDBSRMSK0.

If $EDBCR0_{EDM}$=1, DBSR status bits corresponding to hardware-owned debug events are masked from being set by hardware.

Software-owned resources may be modified by software, but only the corresponding control bits in DBCR0–8 are affected by execution of a **mtspr**, thus only a portion of these registers may be affected, depending on the allocation settings in EDBRAC0. The debug interrupt handler is still responsible for clearing DBSR bits for software-owned resources prior to returning to normal execution. Hardware always has full access to all

registers and register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers is performed.

The EDBRAC0 register is shown in the following figure.

0	IDM	RST	UDE	ICMP	BRT	IRPT	TRAP	IAC1	IAC2	IAC3	IAC4	DAC1	DAC34	DAC2	0	RET	IAC5	IAC6	IAC7	IAC8	DEVT1	DEVT2	PMI	0	CIRPT	CRET	DNI	DQM	0
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29 30 31

SPR - 638; Read-only by Software; Reset - Unaffected by **p_reset_b,** reset to 0x00000180 by **m_por** or while in the test-logic-reset OnCE controller state

Figure 64-13. EDBRAC0 Register

Table 64-10 provides bit definitions for the Debug External Resource Control Register. Note that EDBRAC0 controls are disabled when EDBCR0EDM=0.

Table 64-11. EDBRAC0 Bit Definitions

Bit(s)	Name	Description
0	—	Reserved
1	IDM	Internal Debug Mode control 0 - Internal Debug mode may not be enabled by software. $DBCR0_{IDM}$ is owned exclusively by hardware. **mtspr** DBCR0–8 and other debug registers is always ignored. No resource sharing occurs, regardless of the settings of other fields in EDBRAC0. Hardware exclusively owns all resources. 1 - Internal Debug mode may be enabled by software. $DBCR0_{IDM}$ is owned by software. $DBCR0_{IDM}$ is software readable/writable. When $EDBRAC0_{IDM}$=1, software writes to hardware-owned bits in DBCR0–8 via **mtspr** are ignored.
2	RST	Reset Field Control 0 - $DBCR0_{RST}$ owned exclusively by hardware debug. No **mtspr** access by software to $DBCR0_{RST}$ field. 1 - $DBCR0_{RST}$ accessible by software debug. $DBCR0_{RST}$ is software readable/writable.
3	UDE	Unconditional Debug Event 0 - Event owned by hardware debug. 1 - Event owned by software debug.
4	ICMP	Instruction Complete Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{ICMP}$ field. 1 - Event owned by software debug. $DBCR0_{ICMP}$ is software readable/writable.
5	BRT	Branch Taken Debug Event

Table continues on the next page...

Table 64-11. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
		0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{BRT}$ field. 1 - Event owned by software debug. $DBCR0_{BRT}$ is software readable/writable.
6	IRPT	Interrupt Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{IRPT}$ field. 1 - Event owned by software debug. $DBCR0_{IRPT}$ is software readable/writable.
7	TRAP	Trap Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{TRAP}$ field. 1 - Event owned by software debug. $DBCR0_{TRA}$P is software readable/writable.
8	IAC1	Instruction Address Compare 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC1 control and status fields. 1 - Event owned by software debug. IAC1 control fields are software readable/writable.
9	IAC2	Instruction Address Compare 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC2 control and status fields. 1 - Event owned by software debug. IAC2 control fields are software readable/writable.
10	IAC3	Instruction Address Compare 3 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC3 control and status fields. 1 - Event owned by software debug. IAC3 control fields are software readable/writable.
11	IAC4	Instruction Address Compare 4 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC4 control and status fields. 1 - Event owned by software debug. IAC4 control fields are software readable/writable.
12	DAC1	Data Address Compare 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to DAC1 control and status fields. 1 - Event owned by software debug. DAC1 control fields are software readable/ writable.
13	DAC34	Data Address Compare 3 and 4 Debug Events 0 - Events owned by hardware debug. No **mtspr** access by software to DAC3 and DAC4 control and status fields. 1 - Event owned by software debug. DAC3 and DAC4 control fields are software readable/writable.
14	DAC2	Data Address Compare 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to DAC2 control and status fields. 1 - Event owned by software debug. DAC2 control fields are software readable/ writable.
15	—	Reserved
16	RET	Return Debug Event

Table continues on the next page...

Table 64-11. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
		0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{RET}$ field. 1 - Event owned by software debug. $DBCR0_{RET}$ is software readable/writable.
17	IAC5	Instruction Address Compare 5 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC5 control and status fields. 1 - Event owned by software debug. IAC5 control fields are software readable/writable.
18	IAC6	Instruction Address Compare 6 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC6 control and status fields. 1 - Event owned by software debug. IAC6 control fields are software readable/writable.
19	IAC7	Instruction Address Compare 7 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC7 control and status fields. 1 - Event owned by software debug. IAC7 control fields are software readable/writable.
20	IAC8	Instruction Address Compare 8 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC8 control and status fields. 1 - Event owned by software debug. IAC8 control are software readable/writable.
21	DEVT1	External Debug Event Input 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT1}$ field. 1 - Event owned by software debug. $DBCR0_{DEVT1}$ is software readable/writable.
22	DEVT2	External Debug Event Input 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT2}$ field. 1 - Event owned by software debug. $DBCR0_{DEVT2}$ is software readable/writable.
23	PMI	Performance Monitor Interrupt Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to the PMRs. Performance monitor interrupts set $EDBSR0_{PMI}$ regardless of the setting of $PMGC0_{UDI}$ 1 - Event owned by software debug. PMRs are software readable/writable. **Note:** this bit is reset to '1'.
24	—	Reserved
25	CIRPT	Critical Interrupt Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CIRPT}$ field. 1 - Event owned by software debug. $DBCR0_{CIRPT}$ is software readable/writable.
26	CRET	Critical Return Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CRET}$ field. 1 - Event owned by software debug. $DBCR0_{CRET}$ is software readable/writable.
27	DNI	DNI Instruction Debug Control

Table continues on the next page...

Table 64-11. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
		0 - DNI resource owned by hardware debug. Execution of an **e_dni** or **se_dni** instruction results in entry into debug mode. 1 - DNI resource owned by software debug. Execution of an **e_dni** or **se_dni** instruction results in either a debug interrupt ($DBCR0_{IDM}$=1 and MSR_{DE}=1) or a nop ($DBCR0_{IDM}$=0 or MSR_{DE}=0). **Note:** DNI events are not blocked during a debug session
28	DQM	Data Acquisition Messaging Registers 0 - $DEVENT_{DQTAG}$ and DDAM register are exclusively owned by hardware debug. No **mtspr** access by software to $DEVENTD_{QTAG}$ field or DDAM register. Attempted access by software is ignored. 1 - $DEVENT_{DQTAG}$ and DDAM register are owned by software. Software has read/write access to $DEVENT_{DQTAG}$ field and DDAM register.
29:31	—	Reserved

Table 64-12 shows which resources are controlled by EDBRAC0 settings.

1. Note: IDM not required to be set to enable software access.

EDBRAC0 also controls which bits or fields in DBCR0–8 and the PMRs are reset by assertion of **p_reset_b** when $EDBCR0_{EDM}$=1. Only software-owned bits or fields as shown in Table 64-12 are affected in this case, except that $DBCR0_{RST}$ and $DBSR_{MRR}$ are updated by assertion of **p_reset_b** regardless of the value of $EDBCR0_{EDM}$ or EDBRAC0.

64.3.4 Debug Event Select Register (DEVENT)

The Debug Event Select Register allows instrumented software to internally generate signals when a **mtspr** instruction is executed and this register is accessed. The values written to this register determine which of the **p_devnt_out[0:7]** processor output signals are asserted upon access. Writing a '1' to any of these bit positions will cause a one clock pulse to be generated on the corresponding output. For **p_devnt_out[0:3]**, a corresponding **jd_watchpt[x]** output is asserted as well to indicate a watchpoint has occurred. These signals may be used for internal core debug resources as well as for SoC level cross-triggering. See the SoC User's Manual for more information on SoC use cases.

The $DEVENT_{DEVNT}$ register field value is undefined on a read; it may or may not remain set to the last value written. Since it is unconditionally shared by hardware debug and software, software should not rely on any value remaining.

The upper 8 bits of the DEVENT register also provide the DQTAG used to identify channels within Data Acquisition Messages. See the "Data Acquisition ID Tag Field" section in the Core (e200z210n3) Nexus 3 Module chapter for more detail on the DQTAG.

The DEVENT register is shown in the following figure.

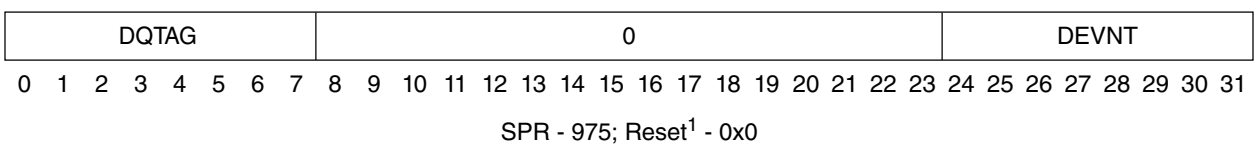

Figure 64-14. DEVENT Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**. Note that DEVNT field is shared by hardware and software but is always reset by **p_reset_b**.

The following table provides bit definitions for the Debug Event Register.

Table 64-13. DEVENT Bit Definitions

Bit(s)	Name	Description
0:7	DQTAG	Data Acquisition Message IDTAG channel identifier (supplied to Nexus 3)
8:23	—	Reserved, should be cleared.
24:31	DEVNT	Debug Event Signals 00000000 - No signal is asserted xxxxxxx1 - **p_devnt_out[0]** and **jd_watchpt[12]** are asserted for one clock xxxxxx1x - **p_devnt_out[1]** and **jd_watchpt[13]** are asserted for one clock xxxxx1xx - **p_devnt_out[2]** and **jd_watchpt[20]** are asserted for one clock xxxx1xxx - **p_devnt_out[3]** and **jd_watchpt[21]** are asserted for one clock xxx1xxxx - **p_devnt_out[4]** is asserted for one clock xx1xxxxx - **p_devnt_out[5]** is asserted for one clock x1xxxxxx - **p_devnt_out[6]** is asserted for one clock 1xxxxxxx - **p_devnt_out[7]** is asserted for one clock

64.3.5 Debug Data Acquisition Message Register (DDAM)

The Debug Data Acquisition Message Register allows instrumented software to generate real-time Data Acquisition Messages (as defined by Nexus 3) via a **mtspr** instruction to this register. See the "Data Acquisition Messaging" section in the Core (e200z210n3) Nexus 3 Module chapter for details.

The DDAM register is shown in the following figure.

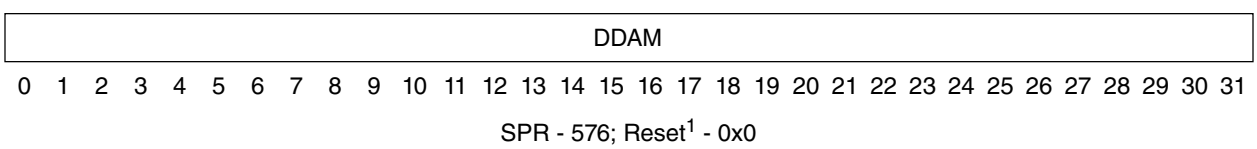

Figure 64-15. DDAM Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for the Debug Data Acquisition Message Register.

Table 64-14. DDAM Bit Definitions

Bit(s)	Name	Description
0:31	DDAM	Value to be transmitted in a Data Acquisition Message (DQM) (supplied to Nexus 3 with strobe)

64.4 Using Debug Resources for Stack Limit Checking

The DAC1,2 and DAC3,4 resources can be used for stack overflow/underflow detection when not being used as a hardware or software debug resource. Stack limit checking is available regardless of EDM or IDM mode, and when resources used for stack limit checking are owned by software, will utilize a DSI or machine check exception. Software-owned stack limit checking does not require IDM to be set. Hardware owned stack limit checking requires EDM to be set.

When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by software, DAC events are not generated for resources configured to perform stack limit checking, and no DBSR DAC status flag will be set due to a detected stack limit violation. Instead, depending on the processor mode, a data storage interrupt or a machine check exception is signaled. When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by hardware, DAC events will be generated for resources configured to perform stack limit checking, and the EDBSR0 DAC status flag will be set due to a detected stack limit violation, causing entry into debug halted mode in the same way as a DAC exception normally does. The only difference is that qualification of the access address is performed as discussed in the next paragraph.

Stack limit checking is implemented in the same way as range compares using DAC1,2 or 3,4, or extended masking using DAC1 or DAC3, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for instructions which indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DAC resources configured to perform stack limit checking are not owned by hardware, if a stack limit violation occurs when performing the load or store, the access is aborted, and an error report machine check is generated, with MCSRR0 pointing to the address of the load or store access which generated the stack overflow/underflow. If DAC resources configured to perform stack limit checking are owned by hardware, then a normal DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event.

Enabling of this functionality is described in more detail in Table 64-5. Note that IDM is not required to be set for software-owned stack limit checking.

In contrast to the normal case of DAC address matching resulting in a debug event, the stack limit check address compare logic operates differently for stack limit checking. When using resources for stack limit checking, a DACn hit to a resource enabled for performing stack limit checking on a stack access indicates a stack limit violation.

When stack limit checking is enabled by the setting of the $DBCR4_{DAC1CFG}$ field to '1000' or the $DBCR8_{DAC3CFG}$ field to '1000' (or both), and the corresponding DACn resources are owned by software, DACn events are not generated and the DBSR DAC status flag will not be set due to a detected stack limit hit. Instead, if stack limit checking is enabled for supervisor mode stack accesses in DAC1 or DAC3, and a compare hit occurs for a supervisor mode stack access (A load or store using GPR R1 in the <EA> calculation), a machine check exception is signaled. If stack limit checking is enabled for user mode accesses, a DSI exception is signaled when a stack limit checking enabled DAC1 or DAC3 compare hit occurs for a user mode access. A watchpoint for DAC1 or DAC3 will be generated when the stack limit violation is detected, even though the instruction does not complete. Stack limit checking for supervisor mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '10', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '10', or both. Stack limit checking for user mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '01', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '01', or both. Note that unlike regular debug DAC events, both halves of a misaligned access are checked for limit violations.

When stack limit checking is enabled for a stack access, and DACn resources are owned by hardware, the EDBSR0 DAC status flag will be set due to a detected stack limit violation, to cause entry into debug halted mode or to generate a watchpoint, or both, in the same way as a DAC event normally does, i.e. after the access has completed. The only difference is that qualification of the access address is performed as discussed in the next paragraph. If the access is aborted due to a DSI or other exception such as machine check condition, the $EDBSR0_{IDE}$ status bit will also be set to indicate that the data access instruction was not completed.

Stack limit checking is implemented in the same way as address compares using DACn, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for instructions which indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DACn resources are not owned by hardware, if a stack limit violation occurs (a hit to a stack limit enabled DAC is detected) when performing the load or store, the access request is

aborted and the access is not performed. Instead, for supervisor mode accesses, an error report machine check exception is generated, with MCSRR0 pointing to the address of the load or store instruction which generated the stack overflow/underflow, and for user mode accesses, a DSI exception is generated, with SRR0 pointing to the address of the load or store instruction which generated the stack overflow/underflow. If all stack limit check enabled DACn resources are owned by hardware, then a DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event. In this case, the instruction and access will normally have completed, in the same manner as a normal DAC event.

Independent limit checks for supervisor and user accesses may be implemented by allocating independent DACn resources to each, or a single limit may be applied using a single DACn resource. Typically, a DAC1,2 pair operating in exclusive address range mode is utilized for stack limit checking for a single shared limit. For separate limits, DAC3,4 may also be utilized. If more than one DACn resource is utilized, a DAC hit on any resource utilized for stack limit checking will cause the corresponding stack limit exception action to occur. If both a hardware-owned and a software-owned resource generate a stack limit exception for a given load or store, the software resource will have priority, since it is detected prior to completion of the access, and the access is aborted, thus the hardware event will not occur.

Enabling of this functionality is described in more detail in the description of the DACnCFG fields in Table 64-5 and Table 64-8 in Debug Control and Status registers. Note that for DAC1 and DAC2, access type (read, write) control is part of DBCR0.

64.5 External Debug Support

External debug support is supplied through the OnCE controller serial interface which allows access to internal CPU registers and other system state while the CPU is halted in debug mode. All debug resources including DBCR0–8, DBSR, IAC1–8, DAC1–4, and DVC1–2 are accessible through the serial OnCE interface in external debug mode. Setting the $EDBCR0_{EDM}$/$DBCR0_{EDM}$ bit to '1' through the OnCE interface enables external debug mode, and unless otherwise permitted by the settings in EDBRAC0, disables software updates to the debug control registers. When $EDBCR0_{EDM}$ is set, debug events enabled to set respective status bits will also cause the CPU to enter Debug Mode if the event is not masked in EDBSRMSK0, as opposed to generating Debug Interrupts, unless the specific events are allocated to software via the settings in EDBRAC0. In Debug Mode, the CPU is halted at a recoverable boundary, and an external Debug Control Module may control CPU operation through the On-Chip Emulation logic (OnCE).

Note that the descriptions of events in the subsections of Software Debug Events and Exceptions refer to setting DBSR status bits, however, when resources are owned by hardware, the events for those resources set the respective status bits in EDBSR0 instead of DBSR.

Note

On the initial setting of $EDBCR0_{EDM}$ to '1', other bits in DBCR0 will remain unchanged. After $EDBCR0_{EDM}$ has been set, all debug register resources may be subsequently controlled through the OnCE interface. The CPU should be placed into debug mode via the OCR_{DR} control bit prior to writing EDM to '1'. This gives the debugger the opportunity to cleanly write to the DBCRx registers and the DBSR to clear out any residual state / control information which could cause unintended operation.

Note

It is intended for the CPU to remain in external debug mode ($EDBCR0_{EDM}$=1) in order to single step or perform other debug mode entry/ reentry via the OCR_{DR}, by performing go+noexit commands, or by assertion of the **jd_de_b** signal.

Note

$EDBCR0_{EDM}$ operation will be blocked if OnCE operation is disabled (**jd_en_once** negated) regardless of whether it is set or cleared. This means that if $EDBCR0_{EDM}$ was previously set, and then **jd_en_once** is negated (this should not occur), entry into debug mode will be blocked, and all *hardware* debug events are blocked. Watchpoints are not blocked.

Due to clock domain design, the CPU clock (**m_clk**) must be active in order to perform writes to debug registers other than the OnCE Command register (OCMD), the OnCE Control register (OCR), External Debug Control Register 0 (EDBCR0), External Debug Status register 0 (EDBSR0), External Debug Status Register Mask 0 (EDBSRMSK0), or the $EDBCR0_{EDM}$ bit. Register read data is synchronized back to the **j_tclk** clock domain. The OnCE Control register provides the capability of signaling the system level clock controller that the CPU clock should be activated if not already active.

Updates to the DBCRx, DBSR, and most other debug registers via the OnCE interface should be performed with the CPU in debug mode to guarantee proper operation. Due to the various points in the CPU pipeline where control is sampled and event handshaking is

performed, it is possible that modifications to these registers while the CPU is running may result in early or late entry into debug mode, and may have incorrect status posted in the DBSR register.

If resource sharing is enabled via EDBRAC0, updates to the EDBRAC0, DBCRx, and DBSR registers must be performed with the CPU in debug mode, since simultaneous updates of register portions could otherwise be attempted, and such updates are not guaranteed to properly occur. The results of such an attempt are undefined.

64.5.1 External Debug Registers

The external debug registers are used for controlling several debug aspects of the core and reporting status while in External Debug Mode.

64.5.1.1 External Debug Control Register 0 (EDBCR0)

EDBCR0 is a control register accessible to an external debugger through the OnCE/Jtag port. An external development tool can write to this register in order to enable external debug mode or to enable Debugger Notify Halt instructions (**e_dnh**, **se_dnh**), as well as to control aspects of Debugger Notify Interrupt instructions (**e_dni**, **se_dni**).

EDBCR0 is not accessible by software, However, the state of $EDBCR0_{EDM}$ is reflected as a read-only bit in $DBCR0_{EDM}$ to software. There is only one physical EDM bit implemented; it is reflected in both the DBCR0 and EDBCR0 registers, and may be written and read using either register by the hardware debugger. For future compatibility, EDBCR0 updates are preferred.

EDBCR0 is shown in the following figure.

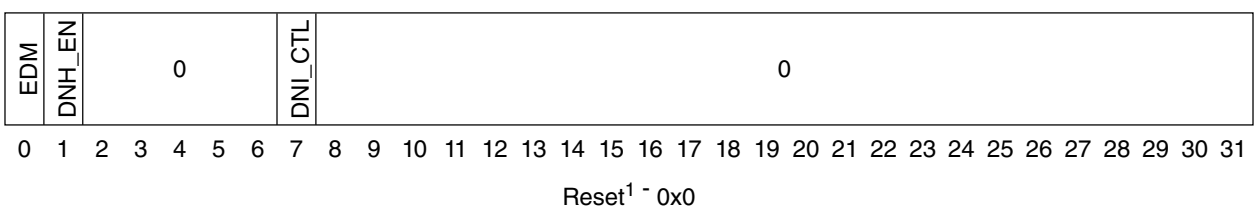

Figure 64-16. EDBCR0 Register

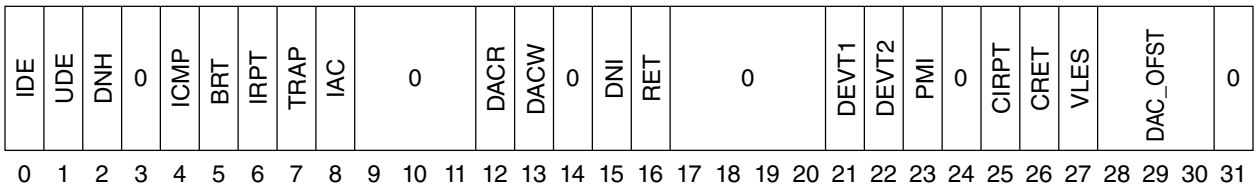
Note

[1] EDBCRO is affected (reset) by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b.**



The following table provides bit definitions for External Debug Control Register 0.

Table 64-15. EDBCR0 Bit Definitions

Bit(s)	Name	Description
0	EDM	External Debug Mode. This bit is also reflected in DBCR0 0 - External debug mode disabled. Internal debug events not mapped into external debug events. 1 - External debug mode enabled. Hardware-owned events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCRx, IAC1-8, DAC1-4, DVC1-2[U]} unless permitted by settings in EDBRAC0. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset **p_reset_b**. This allows the debugger to set up hardware debug events which remain active across a processor reset.
1	DNH_EN	**dnh** Instruction Enable 0 - execution of **e_dnh** and **se_dnh** instructions cause illegal instruction exceptions to occur. 1 - execution of **e_dnh** and **se_dnh** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of EDM.
2:6	---	Reserved
7	DNI_CTL	**dni** Instruction Control 0 - When the **dni** resource is owned by hardware, the MSR_{DE} bit is cared, and when MSRDE=0, execution of **e_dni** and **se_dni** instructions are nop'ed and no entry into debug mode occurs. 1 - When the **dni** resource is owned by hardware, the MSR_{DE} bit is don't-cared, and execution of **e_dni** and **se_dni** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of MSR_{DE}. Note that this control bit is only used when the dni resource is owned by hardware via control in $EDBRAC0_{DNI}$, and thus also only when EDM=1
8:31	---	Reserved

64.5.1.2 External Debug Status Register 0 (EDBSR0)

The External Debug Status Register 0 (EDBSR0) contains status on debug events owned by hardware. The External Debug Status Register 0 is set via hardware, and read and cleared via OnCE access by the debugger. Clearing is done by writing to the External Debug Status Register via the OnCE port, with a '1' in any bit position that is to be cleared and '0' in all other bit positions. The write data to EDBSR0 is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. The EDBSR0 register is shown in the following figure.

Read/Write; Reset[1] - 0x0000_0000

Figure 64-17. EDBSR0 Register

Note

[1] Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while $EDBCRO_{EDM}$=O.

The following table provides bit definitions for External Debug Status Register 0.

Table 64-16. EDBSR0 Bit Definitions

Bit(s)	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if $EDBCR0_{EDM}$=1 and an imprecise debug event occurs for a hardware-owned DAC event due to a load or store which is terminated with error. This bit will not be set for imprecise debug events which are masked via settings in EDBSRMSK0.
1	UDE	Unconditional Debug Event Set to 1 if a hardware-owned Unconditional debug event occurred.
2	DNH	Debugger Notify Halt Event Set to 1 if a debugger notify halt instruction was executed and caused a debug halt.
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if a hardware-owned Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if a hardware-owned Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if a hardware-owned Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a hardware-owned Trap Taken debug event occurred.
8	IAC	Instruction Address Compare 1 Debug Event Set to 1 if a hardware-owned IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a hardware-owned read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a hardware-owned write-type DAC1 debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event

Table continues on the next page...

Table 64-16. EDBSR0 Bit Definitions (continued)

Bit(s)	Name	Description
		Set to 1 if a hardware-owned DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a hardware-owned Return debug event occurred
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a hardware-owned DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a hardware-owned DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $EDBRAC0_{PMI}$=0 regardless of the setting of $PMGC0_{UDI}$
24	—	Reserved
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a hardware-owned Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a hardware-owned Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if a hardware-owned ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a Power ISA VLE Instruction. Also set for execution of an e_dnh or se_dnh instruction when enabled by $EDBCR0_{DNH_EN}$. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction which took a hardware-owned DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3'b000 and $EDBSR0_{IDE}$ is set to 1. Normally set to 3'b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

64.5.1.3 External Debug Status Register Mask 0 (EDBSRMSK0)

The External Debug Status Register Mask 0 (EDBSRMSK0) is used to mask debug events set in EDBSR0 from causing entry into debug halted mode. A '1' stored in any mask bit prevents debug mode entry caused by the corresponding bit being set in EDBSR0. The mask has no effect on DBSR actions or on the setting of EDBSR0 status bits by hardware-owned events, except that the IDE bit will not be set by imprecise hardware-owned debug events which are masked. EDBSRMSK0 may be used to allow debug events owned by hardware to be configured for watchpoint generation purposes

without causing debug mode entry when the watchpoint occurs. EDBSRMSK0 is read and written via OnCE access by the debugger. No software access is provided. The EDBSRMSK0 register is shown in the following figure.

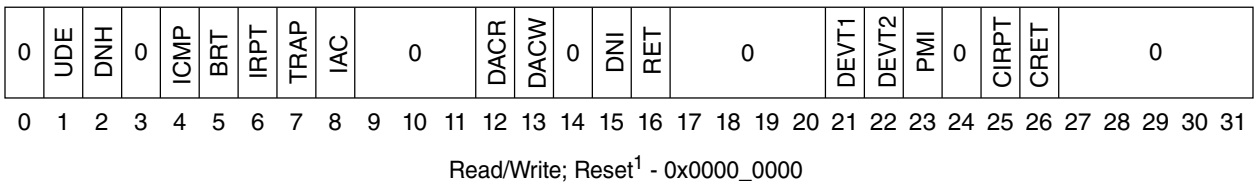


Figure 64-18. EDBSRMSK0 Register

Note

[1] Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while $EDBCRO_{EDM}$=O.

The following table provides bit definitions for External Debug Status Register Mask 0.

Table 64-17. EDBSRMSK0 Bit Definitions

Bit(s)	Name	Description
0	—	Reserved
1	UDE	Unconditional Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{UDE}$
2	DNH	Debugger Notify Halt Event Set to 1 to mask debug mode entry by $EDBSR0_{DNH}$
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{ICMP}$
5	BRT	Branch Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{BRT}$
6	IRPT	Interrupt Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{IRPT}$
7	TRAP	Trap Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{TRAP}$
8	IAC	Instruction Address Compare Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{IAC}$
9:11	—	Reserved
12	DACR	Data Address Compare 1 Read Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DACR}$
13	DACW	Data Address Compare 1 Write Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DACW}$
14	—	Reserved
15	DNI	DNI Debug Event

Table continues on the next page...

Table 64-17. EDBSRMSK0 Bit Definitions (continued)

Bit(s)	Name	Description
		Set to 1 to mask debug mode entry by $EDBSR0_{DNI}$
16	RET	Return Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{RET}$
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DEVT1}$
22	DEVT2	External Debug Event 2 Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DEVT2}$
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{PMI}$
24	—	Reserved
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{CIRPT}$
26	CRET	Critical Return Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{CRET}$
22:31	—	Reserved

64.5.1.4 External Debug Data Effective Address Register (EDDEAR)

The External Debug Data Effective Address Register (EDDEAR) contains address information for hardware-owned data address compare debug events. EDDEAR is update by hardware with the effective address of the load or store operation when an unmasked data address compare event is recorded in EDBSR0 if the previous values of $EDBSR0_{DAC\{R,W\}}$ bits which are unmasked in EDBSRMSK0 are zero. Once an EDDEAR update is performed, these unmasked bits must be cleared by the hardware debugger prior to another EDDEAR hardware update occurring. A subsequent hardware-owned unmasked DAC event will not update the EDDEAR register if either of the $EDBSR0_{DAC\{R,W\}}$ bits are set and are not masked by EDBSRMSK0, in order to capture the first unmasked event address. EDDEAR is read and written via OnCE access by the debugger. No software access is provided.

The EDDEAR register is shown in the following figure.

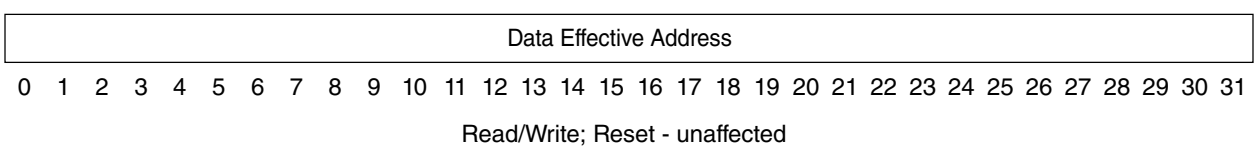

Figure 64-19. EDDEAR Register

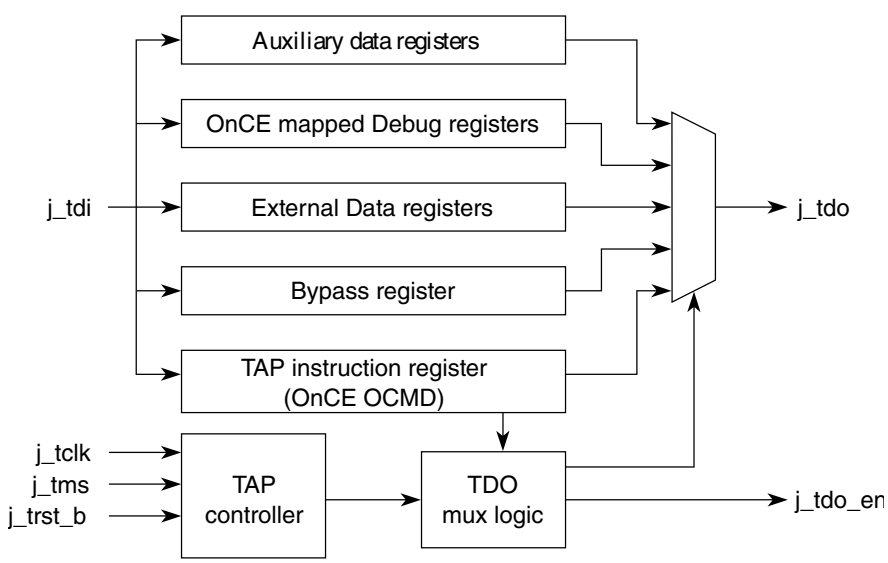
64.5.2 OnCE Introduction

The e200z210n3 on-chip emulation circuitry (OnCE™/Nexus Class 1 interface) provides a means of interacting with the e200z210n3 core and integrated system so that a user may examine registers, memory, or on-chip peripherals facilitating hardware/software development. OnCE operation is controlled via an industry standard IEEE 1149.1 TAP controller. By using public instructions, the external hardware debugger can freeze or halt the CPU, read and write internal state, and resume normal execution. The core does not contain IEEE 1149.1 standard boundary cells on its interface, as it is a building block for further integration. It does not support the JTAG related boundary scan instruction functionality, although JTAG public instructions may be decoded and signaled to external logic.

The OnCE logic provides for Nexus Class 1 static debug capability (utilizing the same set of resources available to software while in internal debug mode).

In order to enable full OnCE operation, the **jd_enable_once** input signal must be asserted. In some system integrations, this is automatic, since the input will be tied asserted. Other integrations may require the execution of the Enable OnCE command via the TAP and appropriate entry of serial data. Exact requirements will be documented by the integrated product specification. The **jd_enable_once** input signal should not change state during a debug session, or undefined activity may occur.

The following figures show the TAP controller state model and the TAP registers implemented by the OnCE logic.



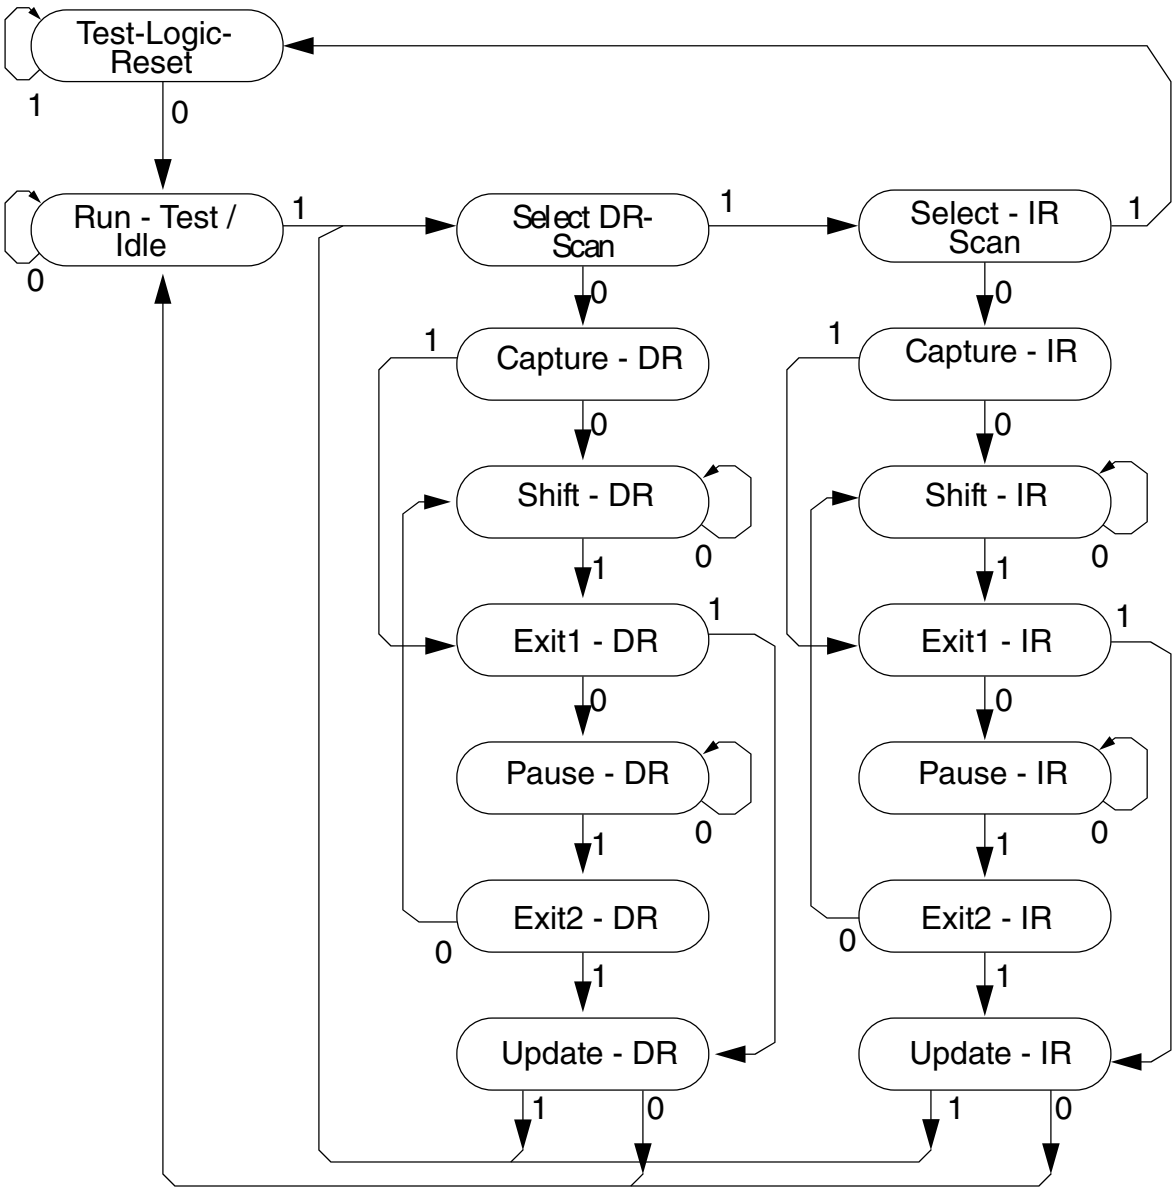


Figure 64-20. OnCE TAP Controller and Registers

The OnCE controller is implemented as a 16-state FSM, with a one-to-one correspondence to the states defined for the JTAG TAP controller.

Access to processor registers and the contents of memory locations are performed by enabling external debug mode (setting $EDBCR0_{EDM}$ to '1'), placing the processor into debug mode, followed by scanning instructions and data into and out of the CPU Scan Chain (CPUSCR); execution of scanned instructions by the CPU is used as the method to access required data. Memory locations may be read by scanning a load instruction into the CPU core which will reference the desired memory location, executing the load instruction, and then scanning out the result of the load. Other resources are accessed in a similar manner.

The initial entry by the CPU into the debug state (or mode) from normal, Waiting, Stopped, or Halted states (all indicated via the OnCE Status Register (OSR), OnCE Status Register) by assertion of one or more debug requests, begins a *debug session*. The **jd_debug_b** output signal indicates that a debug session is in progress, and the OSR will indicate the CPU is in the debug state. Instructions may the be single-stepped by scanning new values into the CPUSCR, and performing a OnCE go+noexit command (See OnCE Command Register (OCMD)). The CPU will then temporarily exit the debug state (but not the debug session) to execute the instruction, and will then return to the debug state (again indicated via the OnCE Status Register (OSR)). The debug session remains in force until the final OnCE go+exit command is executed, at which time the CPU will return to the previous state it was in (unless a new debug request is pending). A scan into the CPUSCR is required prior to executing each go+exit or go+noexit OnCE command.

64.5.3 JTAG/OnCE Pins

The JTAG/OnCE pin interface is used to transfer OnCE instructions and data to the OnCE control block. Depending on the particular resource being accessed, the CPU may need to be placed in the Debug mode. For resources outside of the CPU block and contained in the OnCE block, the processor is not disturbed, and may continue execution. If a processor resource is required, an internal debug request (**dbg_dbgrq**) may be asserted to the CPU by the OnCE controller, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter Debug Mode, and wait for further commands. Asserting **dbg_dbgrq** will cause the chip to temporarily exit the Waiting, Stopped or Halted power management states.

The following table details the primary JTAG/OnCE interface signals.

Table 64-18. JTAG/OnCE Primary Interface Signals

Signal name	Type	Description
j_trst_b	I	JTAG test reset
j_tclk	I	JTAG test clock
j_tms	I	JTAG test mode select
j_tdi[0:31]	I	JTAG test data or parallel input
j_tdo	O	Test data out to master controller or pad
j_tdo_en[1]	O	Enables TDO output buffer
j_parallel_IR_en	I	Enables parallel loading of IR during Shift_IR state
j_parallel_DR_en	I	Enables parallel loading of DR during Shift_DR state

1. j_tdo_en is asserted when the TAP controller is in the shift_DR or shift_IR state.

A full description of JTAG pins is provided in the JTAG Support Signals section of the Core (e200z210n3) Core Complex Overview.

64.5.4 OnCE Internal Interface Signals

The following paragraphs describe the OnCE interface signals to other internal blocks associated with the OnCE controller.

64.5.4.1 CPU Debug Request (dbg_dbgrq)

The **dbg_dbgrq** signal is asserted by the OnCE control logic to request the CPU to enter the debug state. It may be asserted for a number of different conditions, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter the debug mode, and wait for further commands.

64.5.4.2 CPU Debug Acknowledge (cpu_dbgack)

The **cpu_dbgack** signal is asserted by the CPU upon entering the debug state. This signal is used as part of the handshake mechanism between the OnCE control logic and the rest of the CPU. The CPU core may enter debug mode either through a software or hardware event.

64.5.4.3 CPU Address, Attributes

The CPU address and attribute information are used by the Nexus3 unit with information for real-time address trace information.

64.5.4.4 CPU Data

The CPU data buses are used to supply the Nexus3 debug unit with information for real-time data trace capability.

64.5.5 OnCE Interface Signals

The following paragraphs describe additional OnCE interface signals to other external blocks such as a Nexus controller and external blocks which may need information pertaining to debug operation.

64.5.5.1 OnCE Enable (jd_en_once)

The OnCE enable signal **jd_en_once** is used to enable the OnCE controller to allow certain instructions and operations to be executed. Assertion of this signal will enable the full OnCE command set, as well as operation of control signals and OnCE Control register functions. When this signal is disabled, only the Bypass, ID and Enable_OnCE commands are executed by the OnCE unit, and all other commands default to a "Bypass" command. The OnCE Status register (OSR) is not visible when OnCE operation is disabled. In addition, OnCE Control register (OCR) functions are disabled, as is the operation of the **jd_de_b** input. Secure systems may choose to leave the **jd_en_once** signal negated until a security check has been performed. Other systems should tie this signal asserted to enable full OnCE operation. The **j_en_once_regsel** output signal is provided to assist external logic performing security checks.

The **jd_en_once** input must only change state during the Test-Logic-Reset, Run-Test/ Idle, or Update_DR TAP states. A new value will take affect after one additional **j_tclk** cycle of synchronization. In addition, **jd_enable_once** input signal must not change state during a debug session, or undefined activity may occur.

64.5.5.2 OnCE Debug Request/Event (jd_de_b, jd_de_en)

If implemented at the SoC level, a system level bidirectional open drain debug event pin **DE_b** (not part of the e200z210n3 interface) provides a fast means of entering the Debug Mode of operation from an external command controller (when input) as well as a fast means of acknowledging the entering of the Debug Mode of operation to an external command controller (when output). The assertion of this pin by a command controller causes the CPU core to finish the current instruction being executed, save the instruction pipeline information, enter Debug Mode, and wait for commands to be entered. If **DE_b** was used to enter the Debug Mode then **DE_b** must be negated after the OnCE controller responds with an acknowledge and before sending the first OnCE command. The assertion of this pin by the CPU Core acknowledges that it has entered the Debug Mode and is waiting for commands to be entered.

To support operation of this system pin, the OnCE logic supplies the **jd_de_en** output and samples the **jd_de_b** input when OnCE is enabled (**jd_en_once** asserted). Assertion of **jd_de_b** will cause the OnCE logic to place the CPU into Debug Mode. Once Debug Mode has been entered, the **jd_de_en** output will be asserted for three **j_tclk** periods to signal an acknowledge. **jd_de_en** can be used to enable the open-drain pulldown of the system level **DE_b** pin.

For systems which do not implement a system level bidirectional open drain debug event pin **DE_b**, the **jd_de_en** and **jd_de_b** signals may still be used to handshake debug entry.

64.5.5.3 OnCE Debug Output (jd_debug_b)

The OnCE Debug output **jd_debug_b** is used to indicate to on-chip resources that a debug session is in progress. Peripherals and other units may use this signal to modify normal operation for the duration of a debug session, which may involve the CPU executing a sequence of instructions solely for the purpose of visibility/system control which are not part of the normal instruction stream the CPU would have executed had it not been placed in debug mode. This signal is asserted the first time the CPU enters the debug state, and remains asserted until the CPU is released by a write to the OnCE Command Register with the GO and EX bits set, and a register specified as either "No Register Selected" or the CPUSCR. This signal will remain asserted even though the CPU may enter and exit the debug state for each instruction executed under control of the OnCE controller. See OnCE Command Register (OCMD) for more information on the function of the GO and EX bits. This signal is not normally used by the CPU.

64.5.5.4 CPU Clock On Input (jd_mclk_on)

The CPU Clock On input **jd_mclk_on** is used to indicate that the CPU's **m_clk** input is active. This input signal is expected to be driven by system logic external to the e200z210n3 core, is synchronized to the **j_tclk** (scan clock) clock domain, and is presented as a status flag on the **j_tdo** output during the Shift_IR state. External firmware may use this signal to ensure proper scan sequences will occur to access debug resources in the **m_clk** clock domain.

64.5.5.5 Watchpoint Events (jd_watchpt[0:31])

The **jd_watchpt[0:31]** signals may be asserted by the OnCE control logic to signal that a watchpoint condition has occurred. Watchpoints do not directly cause the CPU to be affected. They are provided to allow external visibility only or for triggering purposes. Watchpoint events are conditioned by the settings in the DBCRxx registers, as well as by the DEVENT register, the DTC/DTSA/DTEA registers, and the Performance Monitor control register settings. Refer to Table 64-24 for details of the signal assignments. Note that assertion of most watchpoint outputs is conditioned on being in EDM or IDM. The Performance monitor, DEVENT, and DTC watchpoints are not conditioned however, and

may assert regardless of the state of EDM or IDM. In addition, DAC1 or DAC3 watchpoints may be generated for stack limit violation occurrences when those resources are configured to perform stack limit checking, regardless of the state of EDM or IDM.

64.5.5.6 Update DR w/go+exit (j_ocmd_go_exit)

This signal indicates the TAP controller is in the Update_DR state and that the go and exit bits in the OnCE Command register are high, and RS indicates "no register selected". This signal will assert regardless of whether the CPU is currently in debug mode. It may be monitored by external logic to cause a synchronous exit from debug mode of other modules (but not other CPUs) in the system. A debugger can place all of the CPU tap controllers in parallel, scan in a go+exit command with "no register selected", and sequence through the Update_DR state to cause any CPU currently in debug mode to exit. CPUs which are not it debug mode will ignore the command.

64.5.6 OnCE Controller and serial interface

The OnCE Controller contains the OnCE command register, the OnCE decoder, and the status/control register. The following figure is a block diagram of the OnCE controller. In operation, the OnCE Command register acts as the IR for the TAP controller, and all other OnCE resources are treated as data registers (DR) by the TAP controller. The Command register is loaded by serially shifting in or parallel loading commands during the TAP controller Shift-IR state, and is loaded during the Update-IR state. The Command register selects a resource to be accessed as a data register (DR) during the TAP controller Capture-DR, Shift-DR and Update-DR states.

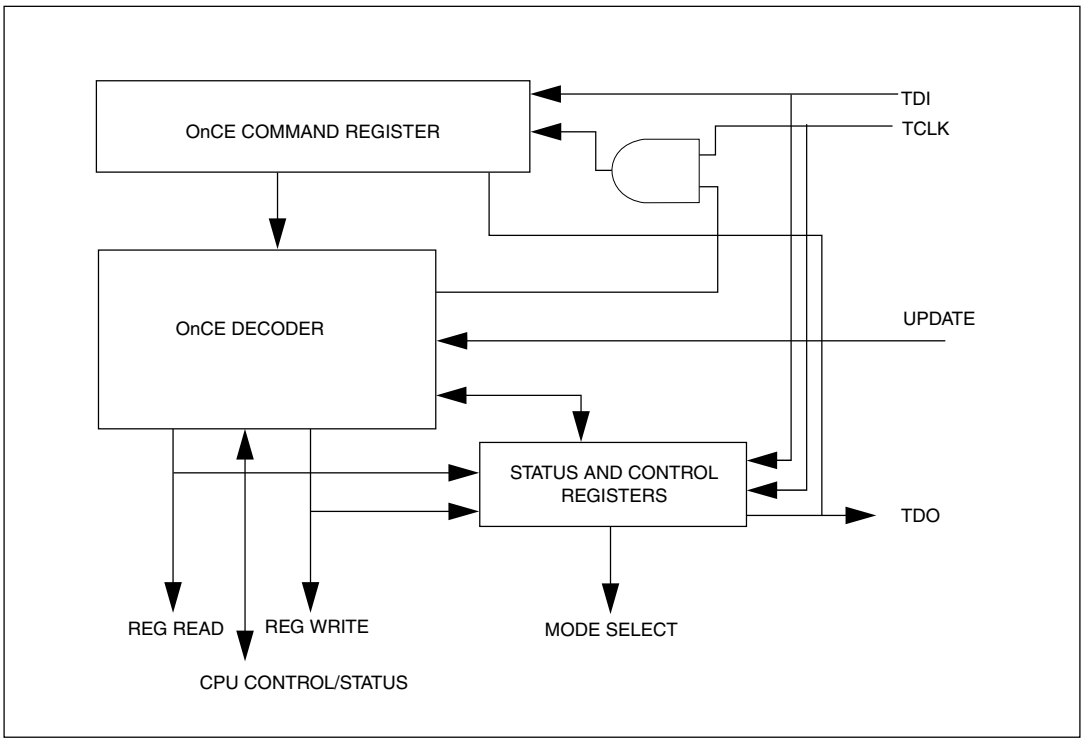

Figure 64-21. OnCE Controller and Serial Interface

64.5.6.1 OnCE Status Register

Status information regarding the state of the CPU is latched into the OnCE Status register when the OnCE controller state machine enters the Capture-IR state. When OnCE operation is enabled, this information is provided on the **j_tdo**[31] output in serial fashion when the Shift_IR state is entered following a Capture-IR. Information is shifted out least significant bit first. Parallel output of the IR status (OSR) is available via the j_tdo[22:31] outputs during the first cycle of the Shift_IR state(s), with j_tdo[22] corresponding to the most-significant bit of the OSR (MCLK).

MCLK	ERR	0	RESET	HALT	STOP	DEBUG	WAIT	0	1
0	1	2	3	4	5	6	7	8	9

Figure 64-22. OnCE Status Register

The following table provides bit definitions for the Once Status Register.

Table 64-19. OnCE Status Register Bit Definitions

Bit(s)	Name	Description
0	MCLK	MCLK **m_clk** Status Bit

Table continues on the next page...

Table 64-19. OnCE Status Register Bit Definitions (continued)

Bit(s)	Name	Description
		0 - Inactive state 1 - Active state This status bit reflects the logic level on the **jd_mclk_on** input signal after capture by **j_tclk**.
1	ERR	ERROR This bit is used to indicate that an error condition occurred during attempted execution of the last single-stepped instruction (GO+NoExit with CPUSCR or No Register Selected in OCMD), and that the instruction may not have been properly executed. This could occur if an Interrupt (all classes including External, Critical, machine check, Storage, Alignment, Program, etc.) occurred while attempting to perform the instruction single step. In this case, the CPUSCR will contain information related to the first instruction of the Interrupt handler, and no portion of the handler will have been executed.
3	RESET	RESET Mode This bit reflects the inverted logic level on the CPU **p_reset_b** input after capture by **j_tclk**.
4	HALT	HALT Mode This bit reflects the logic level on the CPU **p_halted** output after capture by **j_tclk**.
5	STOP	STOP Mode This bit reflects the logic level on the CPU **p_stopped** output after capture by **j_tclk**.
6	DEBUG	Debug Mode This bit is asserted once the CPU is in debug mode. It is negated once the CPU exits debug mode (even during a debug session)
7	WAIT	Waiting Mode This bit reflects the logic level on the CPU **p_waiting** output after capture by **j_tclk**.
8	0	Reserved, set to 0 for 1149.1 compliance
9	1	Reserved, set to 1 for 1149.1 compliance

64.5.6.2 OnCE Command Register (OCMD)

The OnCE Command Register (OCMD) is a 10-bit shift register that receives its serial or parallel data from the TDI pins and serves as the instruction register (IR). It holds the 10-bit commands to be used as input for the OnCE Decoder. The Command Register is shown in Figure 64-23. The OCMD is updated when the TAP controller enters the Update-IR state. It contains fields for controlling access to a resource, as well as controlling single-step operation and exit from OnCE mode.

Although the OCMD is updated during the Update-IR TAP controller state, the corresponding resource is accessed in the DR scan sequence of the TAP controller, and as such, the Update-DR state must be transitioned through in order for an access to occur. In

addition, the Update-DR state must also be transitioned through in order for the single-step and/or exit functionality to be performed, even though the command appears to have no data resource requirement associated with it.

Reset - 10'b1000000010 on assertion of **j_trst_b** or **m_por** , or while in the Test_Logic_Reset state

Figure 64-23. OnCE Command Register

Table 64-20 provides bit definitions for the Once Command Register.

Table 64-20. OnCE Command Register Bit Definitions

Bit(s)	Name	Description
0	R/W	Read/Write Command Bit The R/W bit specifies the direction of data transfer. The table below describes the options defined by the R/W bit. **Note:** The R/W bit generally ignored for read-only or write-only registers, although the PC FIFO pointer is only guaranteed to be update when R/W=1. In addition, it is ignored for all bypass operations. When performing writes, most registers are sampled in the Capture-DR state into a 32-bit shift register, and subsequently shifted out on **j_tdo[31]** during the first 32 clocks of Shift-DR, or on the j_tdo[0:31] outputs during the first clock of Shift-DR. 0 - Write the data associated with the command into the register specified by RS[0:6] 1 - Read the data contained in the register specified by RS[0:6]
1	GO	Go Go Command Bit If the GO bit is set, and the CPU is currently in debug mode, the CPU will execute the instruction which resides in the IR register in the CPUSCR. To execute the instruction, the processor leaves the debug mode, executes the instruction, and if the EX bit is cleared, returns to the debug mode immediately after executing the instruction. The processor goes on to normal operation if the EX bit is set, and no other debug request source is asserted. The GO command is executed only if the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the GO bit is ignored.The processor will leave the debug mode after the TAP controller Update-DR state is entered. On a GO+NoExit operation, returning to debug mode is treated as a debug event, thus exceptions such as machine checks and interrupts may take priority and prevent execution of the intended instruction. Debug firmware should mask these exceptions as appropriate. The OSR_{ERR} bit indicates such an occurrence. If the CPU is not currently in debug mode, then the GO command will be ignored. Note that asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See Exiting Debug Mode and Interrupt Blocking. 0 - Inactive (no action taken) 1 - Execute instruction in IR
2	EX	Exit Command Bit 0 - Remain in debug mode 1 - Leave debug mode

Table continues on the next page...

Table 64-20. OnCE Command Register Bit Definitions (continued)

Bit(s)	Name	Description
		If the EX bit is set, the processor will leave the debug mode and resume normal operation until another debug request is generated. The Exit command is executed only if the Go command is issued, and the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the EX bit is ignored. The processor will leave the debug mode after the TAP controller Update-DR state is entered. Note that if the DR bit in the OnCE control register is set or remains set, or if a bit in EDBSR0 is set and $EDBCR0_{EDM}$=1 (external debug mode is enabled), or if another debug request source is asserted, then the processor may return to the debug mode *without* execution of an instruction, even though the EX bit was set. Note that asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See Exiting Debug Mode and Interrupt Blocking.
3:9	RS	Register Select The Register Select bits define which register is source (destination) for the read (write) operation. Table 64-21 indicates the OnCE register addresses. Attempted writes to read-only registers are ignored.

[SCG_NX_ONCE_REGS]Table 64-21 indicates the OnCE register addresses.[end]

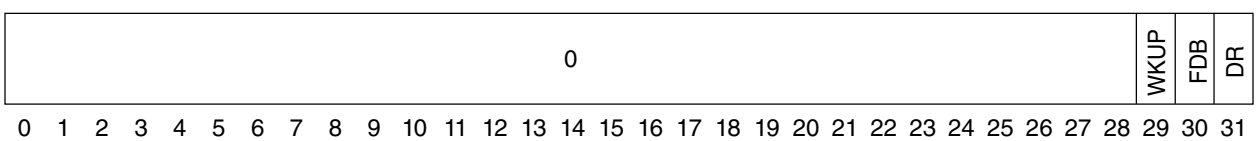
111 1110	Enable_OnCE[1]
111 1111	Bypass

1. Causes assertion of the j_en_once_regsel output.

The Once Decoder receives as input the 10-bit command from the OCMD, and status signals from the processor, and generates all the strobes required for reading and writing the selected OnCE registers.



Single stepping of instructions is performed by placing the CPU in debug mode, scanning in appropriate information into the CPUSCR, and setting the Go bit (with the EX bit cleared) with the RS field indicating either the CPUSCR or No Register Selected. After executing a single instruction, the CPU will re-enter debug mode and await further commands. During single-stepping, exception conditions may occur if not properly masked by debug firmware (interrupts, machine checks, bus error conditions, etc.) and may prevent the desired instruction from being successfully executed. The OSR_{ERR} bit is set to indicate this condition. In these cases, values in the CPUSCR will correspond to the first instruction of the exception handler.

Additionally, the $EDBCR0_{EDM}$ bit is forced to '1' internally while single-stepping to prevent Debug events from generating Debug interrupts. Also, during a debug session, the DBSR register is frozen from updates due to debug events other than execution of a DNI-type instruction, regardless of EDBCR0EDM. DBSR may still be modified during a debug session via a single-stepped **mtspr** instruction, or via OnCE access.

If the CPU is not currently in debug mode, go+exit and go+noexit commands are ignored, although for a go+exit command with "No Register Selected", the j_ocmd_go_exit output will be asserted.

64.5.6.3 OnCE Control Register (OCR)

The OnCE Control Register is a 32-bit register used to force the e200z210n3 core into debug mode and to enable / disable sections of the OnCE control logic. The control bits are read/write. These bits are only effective while OnCE is enabled (**jd_en_once** asserted). The OCR is shown in the following figure.

Reset - 0xo000_0000 on **m_por, j_trst_b,** or entering Test_logic_Reset state

Figure 64-24. OnCE Control Register

The following table provides bit definitions for the OnCE Control Register.

Table 64-22. OnCE Control Register Bit Definitions

Bit(s)	Name	Description
0: 28	—	Reserved
29	WKUP	Wakeup Request Bit (WKUP)

Table continues on the next page...

Table 64-22. OnCE Control Register Bit Definitions (continued)

Bit(s)	Name	Description
		This control bit may be used to force the **p_wakeup** output signal to be asserted. This control function may be used by debug firmware to request that the chip-level clock controller restore the **m_clk** input to normal operation regardless of whether the CPU is in a low power state to ensure that debug resources may be properly accessed by external hardware through scan sequences.
30	FDB	Force Breakpoint Debug Mode Bit (FDB) This control bit is used to determine whether the processor is operating in breakpoint debug enable mode or not. The processor may be placed in breakpoint debug enable mode by setting this bit. In breakpoint debug enable mode, execution of the '**bkpt**' pseudo- instruction will cause the processor to enter debug mode, as if the **jd_de_b** input had been asserted. This bit is qualified with $EDBCR0_{EDM}$, which must be set for FDB to take effect. Note that this bit has no effect on **e_dnh** or **se_dnh** instruction operation.
31	DR	CPU Debug Request Control Bit This control bit is used to unconditionally request the CPU to enter the Debug Mode. The CPU will indicate that Debug Mode has been entered via the data scanned out in the shift-IR state. 0 - No Debug Mode request 1 - Unconditional Debug Mode request When the DR bit is set the processor will enter Debug mode at the next instruction boundary.

64.5.7 Access to Debug Resources

Resources contained in the OnCE Module which do not require the processor core to be halted for access may be accessed while the e200z210n3 core is running, and will not interfere with processor execution. Accesses to other resources such as the CPUSCR require the e200z210n3 core to be placed in debug mode to avoid synchronization hazards. Debug firmware may ensure that it is safe to access these resources by determining the state of the e200z210n3 core prior to access. Note that a scan operation to update the CPUSCR is required prior to exiting debug mode if debug mode has been entered.

Some cases of write accesses other than accesses to the OnCE Command and Control registers, or the EDM bit of DBCR0 require **m_clk** to be running for proper operation. The OnCE control register provides a means of signaling this need to a system level clock control module via the OCR_{WKUP} control bit.

In addition, since the CPU may cause multiple bits of certain registers to change state, reads of certain registers while the CPU is running (DBSR, etc.) may not have consistent bit settings unless read twice with the same value indicated. In order to guarantee that the contents are consistent, the CPU should be placed into debug mode, or multiple reads should be performed until consistent values have been obtained on consecutive reads.

The following table provides a list of access requirements for OnCE registers.

Table 64-23. OnCE Register Access Requirements

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 $_{EDM}$ = 1 for write access	Requires m_clk active for Write Access	Requires CPU to be halted for Read Access	Requires CPU to be halted for Write Access	
Enable_OnCE	N	N	N	N	—	
Bypass	N	N	N	N	N	
CPUSCR	Y	Y	Y	Y	Y	
DAC1–4	Y	Y	Y	N	*[1]	
DBCR0	Y	Y	Y	N	*[1]	*EDBCR0$_{EDM}$ access only requires **jd_en_once** asserted
DBCR1–8	Y	Y	Y	N	*[1]	
DEVENT	Y	Y	Y	N	*[1]	
EDBRAC0 (DBERC0)	Y	N	Y	N	*[1]	
DBSR	Y	Y	Y	N[2]	*[1]	
EDBCR0	Y	N	N	N	N	
EDBSR0	Y	N	Y	N	N	
EDBSRMSK0	Y	N	N	N	N	
IAC1–8	Y	Y	Y	N	*[1]	
JTAG ID	N	N	—	N	—	Read-only
OCR	Y	N	N	N	N	
OSR	Y	N	—	N	—	Read-only, accessed by scanning out IR while **jd_en_once** is asserted
Nexus3-Access	Y	N	N	N	N	
PMR-Access	Y	N	N	N	N	
PMR Registers	Y	Y	Y	N	N	
External GPRs	Y	N	N	N	N	
LSRL Select	Y	N	?	?	?	System Test logic implementation determines LSRL functionality

1. Writes to these registers while the CPU is running may have unpredictable results due to the pipelined nature of operation, and the fact that updates are not synchronized to a particular clock, instruction, or bus cycle boundary, therefore it is strongly recommended to ensure the processor is first placed into debug mode before updates to these registers are performed.

2. Reads of these registers while the CPU is running may not give data that is self-consistent due to synchronization across clock domains.

64.5.8 Methods of Entering Debug Mode

The OnCE Status Register indicates that the CPU has entered the debug mode via the DEBUG status bit. The following sections describe how Debug Mode is entered assuming the OnCE circuitry has been enabled. OnCE operation is enabled by the assertion of the **jd_en_once** input See OnCE Enable (jd_en_once).

64.5.8.1 External Debug Request During RESET

[SCG_NX_EXT_DEBUG_REQ]Holding the **jd_de_b** signal asserted during the assertion of **p_reset_b,** and continuing to hold it asserted following the negation of **p_reset_b** causes the e200z210n3 core to enter Debug Mode. After receiving an acknowledge via the OnCE Status Register DEBUG bit, the external command controller should negate the **jd_de_b** signal before sending the first command. Note that in this case the e200z210n3 core does not execute an instruction before entering Debug Mode, although the first instruction to be executed will be fetched prior to entering Debug Mode in order to properly initialize the CPUSCR.[end]

64.5.8.2 Debug Request During RESET

[SCG_NX_DEBUG_DUR_RESET]Asserting a debug request by setting the DR bit in the OCR during the assertion of **p_reset_b** and then negating **p_reset_b** causes the chip to enter debug mode. In this case the CPU will fetch the first instruction of the reset exception handler in order to properly initialize the CPUSCR, but does not execute an instruction before entering debug mode.[end]

64.5.8.3 Debug Request During Normal Activity

[SCG_NX_DEBUG_NORMAL1]Asserting a debug request by setting the DR bit in the OCR during normal chip activity causes the chip to finish the execution of the current instruction and then enter the debug mode. Note that in this case the chip completes the execution of the current instruction and stops after the newly fetched instruction enters the CPU instruction register. This process is the same for any newly fetched instruction including instructions fetched by the interrupt processing, or those that will be aborted by the interrupt processing.[end]

64.5.8.4 Debug Request During Waiting, Halted or Stopped State

[SCG_NX_DEBUG_DUR_WAIT_HALT_STOP]Asserting a debug request by setting the DR bit in the OCR when the chip is in the Waiting state (**p_waiting** asserted), Halted state (**p_halted** asserted) or Stopped state (**p_stopped** asserted) causes the CPU to exit the state and enter the debug mode once the CPU clock **m_clk** has been restored. Note that in this case, the CPU will negate the **p_waiting, p_halted** and **p_stopped** outputs. Once the debug session has ended, the CPU will return to the state it was in prior to entering debug mode.

To signal the chip-level clock generator to re-enable **m_clk**, the **p_wakeup** output will be asserted whenever the debug block is asserting a debug request to the CPU due to OCR_{DR} being set, or **jd_de_b** assertion, and will remain set from then until the debug session ends (**jd_debug_b** goes from asserted to negated). In addition, the status of the **jd_mclk_on** input (after synchronization to the **j_tclk** clock domain) may be sampled along with other status bits from the **j_tdo** outputs during the Shift_IR TAP controller state. This status may be used if necessary by external debug firmware to ensure proper scan sequences occur to registers in the **m_clk** clock domain.[end]

64.5.8.5 Software Request During Normal Activity

[SCG_NX_DEBUG_NORMAL2]Upon executing a '**bkpt**' pseudo-instruction (for e200z210n3, defined to be an all 0's instruction opcode) when the OCR register's (FDB) bit is set (debug mode enable control bit is true), and $EDBCR0_{EDM}$=1, the CPU enters the debug mode after the instruction following the '**bkpt**' pseudo-instruction has entered the instruction register.[end]

64.5.8.6 Debug Notify Halt Instructions

[SCG_NX_DEBUG_NOTIFY_HALT]The **e_dnh** and **se_dnh** instructions allow software to transition the core from a running state to a debug halted state if enabled by $EDBCR0_{DNH_EN}$, and provide the external debugger with bits reserved in the instruction itself to pass additional information. Entry into debug mode is ***not*** conditioned on $EDBCR0_{EDM}$, allowing for debug of software debug handlers as well as other software. For e200z210n3, when the CPU enters a debug halted state due to a **e_dnh** or **se_dnh** instruction, the instruction will be stored in the CPUSCR[IR] portion, and the CPUSCR[PC] value will point to the instruction. The external debugger should update the CPUSCR prior to exiting the debug halted state to point past the **e_dnh** or **se_dnh** instruction.[end]

64.5.9 CPU Status and Control Scan Chain Register (CPUSCR)

[SCG_NX_CPU_STATUS] A number of on-chip registers store the CPU pipeline status and are configured in a single scan chain for access by the OnCE controller. The CPUSCR register contains these processor resources, which are used to restore the pipeline and resume normal chip activity upon return from the debug mode, as well as a mechanism for the emulator software to access processor and memory contents. The following figure shows the block diagram of the pipeline information registers contained in the CPUSCR. Once debug mode has been entered, it is required to scan in and update this register prior to exiting debug mode.[end]

NOTE

Note that due to the length of this register, parallel JTAG access capability is not provided.

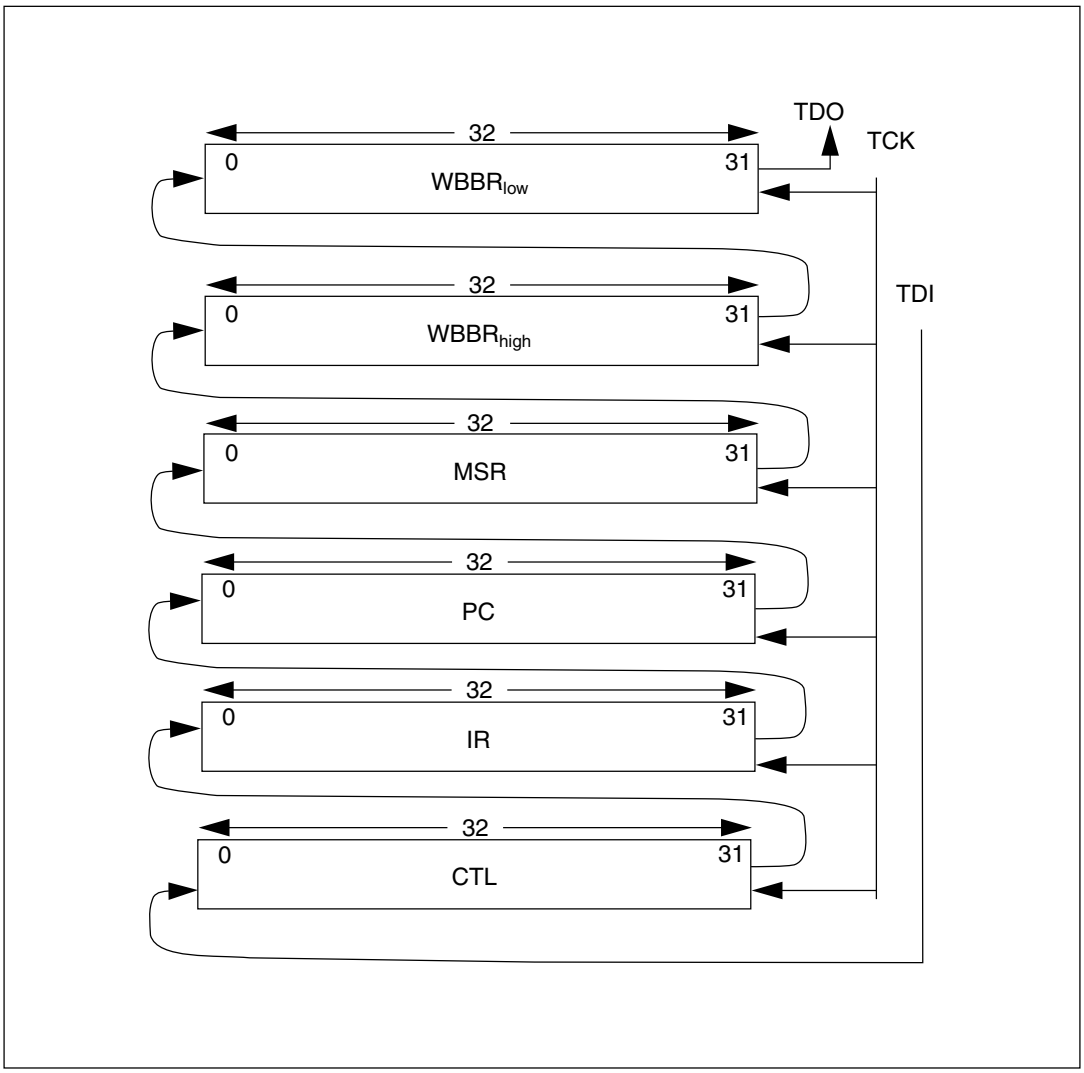


Figure 64-25. CPU Scan Chain Register (CPUSCR)

64.5.9.1 Instruction Register (IR)

The Instruction Register (IR) provides a mechanism for controlling the debug session by serving as a means for forcing in selected instructions, and then causing them to be executed in a controlled manner by the debug control block. The opcode of the next instruction to be executed when entering debug mode is contained in this register when the scan-out of this chain begins. This value should be saved for later restoration if continuation of the normal instruction stream is desired.

On scan-in, in preparation for exiting debug mode, this register is filled with an instruction opcode selected by debug control software. By selecting appropriate instructions and controlling the execution of those instructions, the results of execution may be used to examine or change memory locations and processor registers. The debug

control module external to the processor core will control execution by providing a single-step capability. Once the debug session is complete and normal processing is to be resumed, this register may be loaded with the value originally scanned out.

64.5.9.2 Control State Register (CTL)

The Control State Register (CTL) is a 32-bit register that stores the value of certain internal CPU state variables before the debug mode is entered. This register is affected by the operations performed during the debug session and should normally be restored by the external command controller when returning to normal mode. In addition to saved internal state variables, two of the bits are used by emulation firmware to control the debug process. In certain circumstances, emulation firmware must modify the content of this register as well as the PC and IR values in the CPUSCR before exiting debug mode. These cases are described below.

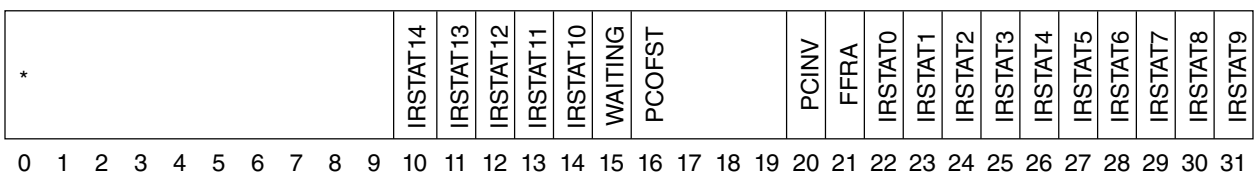

Figure 64-26. Control State Register (CTL)

WAITING — WAITING State Status

This bit indicates whether the CPU was in the waiting state prior to entering debug mode. If set, the CPU was in the waiting state. Upon exiting a debug session, the value of this bit in the restored CPUSCR will determine whether the CPU re-enters the waiting state on a go+exit.

0- CPU was not in the waiting state when debug mode was entered

1- CPU was in the waiting state when debug mode was entered

PCOFST — PC Offset Field

This field indicates whether the value in the PC portion of the CPUSCR must be adjusted prior to exiting debug mode. Due to the pipelined nature of the CPU, the PC value must be backed-up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored into the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction instead of the original IR value, other wise the original value of IR should be restored. (But see PCINV which overrides this field)

0000 - No correction required.

0001 - Subtract 0x04 from PC.

0010 - Subtract 0x08 from PC.

0011 - Subtract 0x0C from PC.

0100 - Subtract 0x10 from PC.

0101 - Subtract 0x14 from PC.

all other encodings are reserved

* — Internal State Bits

Table continues on the next page...

These control bits represent internal processor state and should be restored to their original value after a debug session is completed, i.e when a OnCE command is issued with the GO and EX bits set and not ignored. When performing instruction execution during a debug session. See OnCE Debug Output (jd_debug_b), which is not part of the normal program execution flow, these bits should be set to a 0.

PCINV — PC and IR Invalid Status Bit

This status bit indicates that the values in the IR and PC portions of the CPUSCR are invalid. Exiting debug mode with the saved values in the PC and IR will have unpredictable results. Debug firmware should initialize the PC and IR values in the CPUSCR with desired values prior to exiting debug mode if this bit was set when debug mode was initially entered.

0= No error condition exists.

1= Error condition exists. PC and IR are corrupted.

FFRA— Feed Forward RA Operand Bit

This control bit causes the content of the $WBBR_{lo}$ to be used as the RA operand value (RS for logical, mtspr, mtdcr, cntlzw, and shift operations, RX for VLE se_ instructions, RT for e_{logical_op}2i type instructions, RB for evaddiw, evsubifw, and the value to use as the PC for calculating the LR update value for branch with link type instructions) of the first instruction to be executed following an update of the CPUSCR.

This allows the debug firmware to update processor registers — initialize the $WBBR_{lo}$ with the desired value, set the FFRA bit, and execute a ori Rx,Rx,0 instruction to the desired register.

Note: not all instructions support using the FFRA control. FFRA is mainly intended for use with the ori instruction to allow the debugger to write to a GPR. Support for other instructions is implementation-dependent.

0= No action.

1= Content of $WBBR_{lo}$ used as operand value

IRStat0 — IR Status Bit 0

This control bit indicates a TEA status for the IR.

0= No TEA occurred on the fetch of this instruction.

1= TEA occurred on the fetch of this instruction.

IRStat1 — IR Status Bit 1

This control bit is reserved.

IRStat2 — IR Status Bit 2

This control bit indicates an Instruction Address Compare 1 event status for the IR.

0= No Instruction Address Compare event 1 occurred on the fetch of this instruction.

1= An Instruction Address Compare event 1 occurred on the fetch of this instruction.

IRStat3 — IR Status Bit 3

This control bit indicates an Instruction Address Compare 2 event status for the IR.

0= No Instruction Address Compare 2 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 2 event occurred on the fetch of this instruction.

IRStat4 — IR Status Bit 4

This control bit indicates an Instruction Address Compare 3 event status for the IR.

0= No Instruction Address Compare event 3 occurred on the fetch of this instruction.

1= An Instruction Address Compare event 3 occurred on the fetch of this instruction.

IRStat5 — IR Status Bit 5

This control bit indicates an Instruction Address Compare 4 event status for the IR.

Table continues on the next page...

0= No Instruction Address Compare 4 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 4 event occurred on the fetch of this instruction.

IRStat6 — IR Status Bit 6

This control bit indicates a Parity Error status for the IR.

0= No Parity Error occurred on the fetch of this instruction.

1= Parity Error occurred on the fetch of this instruction .

IRStat7 — IR Status Bit 7

This control bit indicates a Precise External Termination Error status for the IR.

0= No Precise External Termination Error occurred on the fetch of this instruction.

1= A Precise External Termination Error occurred on the fetch of this instruction.

IRStat8 — IR Status Bit 8

This control bit indicates the Power ISA VLE status for the IR.

0= IR contains a BookE instruction. (unused encoding)

1= IR contains a Power ISA VLE instruction, aligned in the Most Significant Portion of IR if 16-bit.

- this bit should not be modified by the debugger, otherwise the resulting operation is boundedly undefined. It should always indicate VLE (=1).

IRStat9 — IR Status Bit 9

This control bit is reserved.

IRStat10 — IR Status Bit 10

This control bit indicates an Instruction Address Compare 5 event status for the IR.

0= No Instruction Address Compare 5 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 5 event occurred on the fetch of this instruction.

IRStat11 — IR Status Bit 11

This control bit indicates an Instruction Address Compare 6 event status for the IR.

0= No Instruction Address Compare 6 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 6 event occurred on the fetch of this instruction.

IRStat12 — IR Status Bit 12

This control bit indicates an Instruction Address Compare 7 event status for the IR.

0= No Instruction Address Compare 7 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 7 event occurred on the fetch of this instruction.

IRStat13 — IR Status Bit 13

This control bit indicates an Instruction Address Compare 8 event status for the IR.

0= No Instruction Address Compare 8 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 8 event occurred on the fetch of this instruction.

IRStat14 — IR Status Bit 14

This control bit is reserved.

Emulation firmware should modify the content of the CTL, PC, and IR values in the CPUSCR during execution of debug related instructions as well as just prior to exiting debug with a go+exit command. During the debug session, the CTL register should be

written with the FFRA bit set as appropriate, and all other bit set to '0', and the IR set to the value of the desired instruction to be executed. IRStat8 will be used to determine the type of instruction present in the IR.

Just prior to exiting debug mode with a go+exit, the PCINV status bit which was originally present when debug mode was first entered should be tested, and if set, the PC and IR initialized for performing whatever recovery sequence is appropriate for a faulted exception vector fetch. If the PCINV bit is cleared, then the PCOFST bits should be examined to determine whether the PC value must be adjusted. Due to the pipelined nature of the CPU, the PC value must be backed-up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored in to the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction (such as **ori r0,r0,0**) instead of the original IR value, otherwise the original value of IR should be restored. Note that when a correction is made to the PC value, it will generally point to the last completed instruction, although that instruction will not be re-executed. The nop instruction is executed instead, and instruction fetch and execution will resume at location PC+4. IRStat8 will be used to determine the type of instruction present in the IR, thus should be cleared in this case. Note that debug events which may occur on the nop (ICMP) will be generated if enabled.

For the CTL register, the internal state bits should be restored to their original value. The IRStatus bits should be set to '0's if the PC was adjusted. If no PC adjustment was performed, emulation firmware should determine whether other IRStat flags should be set to '0' to avoid re-entry into debug mode for an instruction breakpoint request. Upon exiting debug mode with go+exit, if one of these bits is set, debug mode will be re-entered prior to any further instruction execution.

64.5.9.3 Program Counter Register (PC)

The PC is a 32-bit register that stores the value of the program counter which was present when the chip entered the debug mode. It is affected by the operations performed during the debug mode and must be restored by the external command controller when the CPU returns to normal mode. PC normally points to the instruction contained in the IR portion of CPUSCR. If debug firmware wishes to redirect program flow to an arbitrary location, the PC and IR should be initialized to correspond to the first instruction to be executed upon resumption of normal processing. Alternatively, the IR may be set to a nop and the PC set to point to the location prior to the location at which it is desired to redirect flow to. On exiting debug mode, the nop will be executed, and instruction fetch and execution will resume at PC+4.

64.5.9.4 Write-Back Bus Register ($WBBR_{low}$, $WBBR_{high}$)

WBBR is used as a means of passing operand information between the CPU and the external command controller. Whenever the external command controller needs to read the contents of a register or memory location, it will force the chip to execute an instruction that brings that information to WBBR. $WBBR_{low}$ holds the 32-bit result of most instructions including load data returned for a load or load with update instruction. $WBBR_{high}$ holds the updated effective address calculated by a load with update instruction. It is undefined for other instructions.

As an example, to read the 32 bits of processor register **r1**, an **ori r1,r1,0** instruction is executed, and the result value of the instruction will be latched into $WBBR_{low}$. The contents of $WBBR_{low}$ can then be delivered serially to the external command controller. To update a processor resource, this register is initialized with a data value to be written, and an **ori** instruction is executed which uses this value as a substitute data value. The Control State register FFRA bit forces the value of the $WBBR_{low}$ to be substituted for the normal RS source value of the **ori** instruction, thus allowing updates to processor registers to be performed. (Refer to Control State Register (CTL) for more detail on the CTL_{FFRA} bit.)

$WBBR_{low}$ and $WBBR_{high}$ are generally undefined on instructions which do not writeback a result, and due to control issues are not defined on **lmw** or branch instructions as well.

64.5.9.5 Machine State Register (MSR)

The MSR is a 32-bit register used to read/write the Machine State Register. Whenever the external command controller needs to save or modify the contents of the Machine State Register, this register is used.This register is affected by the operations performed during the debug mode and must be restored by the external command controller when returning to normal mode.

64.5.9.6 Exiting Debug Mode and Interrupt Blocking

When exiting debug mode with a Go+Exit, "asynchronous" interrupts are blocked until the first instruction to be executed begins execution. This includes External and Critical input, NMI, and machine check interrupts. Asynchronous debug interrupts are not blocked however, and the CPU will re-enter debug mode without executing an instruction

following Go+Exit, although it may fetch an instruction and discard it. Exceptions due to an illegal instruction or error flags set within the CPUSCR CTL register are not blocked, since they apply to the instruction in the CPUSCR IR.

64.5.10 Reserved Registers (Reserved)

The Reserved Registers are used to control various test control logic. These registers are not intended for customer use. To preclude device and/or system damage, these registers should not be accessed.

64.6 Watchpoint Support

e200z210n3 supports the generation and signalling of watchpoints when operating in internal debug mode ($DBCR0_{IDM}$=1) or in external debug mode ($EDBCR0_{EDM}$=1). Watchpoints are indicated with a dedicated set of interface signals. The **jd_watchpt[0:31]** output signals are used to indicate that a watchpoint has occurred. Certain watchpoints however (DEVENT-based, DTC-based, and Performance Monitor watchpoints) are not qualified with $EDBCR0_{EDM}$ or $DBCR0_{IDM}$.

Each debug address compare function (IAC1–8, DAC1–4), as well as other event types are capable of triggering a watchpoint output. The DBCRx control fields are used to configure watchpoints, regardless of whether events are enabled in DBCR0. Watchpoints may occur whenever an associated event would have been posted in the Debug Status Register if enabled. No explicit enable bits are provided for watchpoints; they are always enabled by definition, although the data address compare watchpoints may be controlled for read and write accesses via configuration fields in DBCR4, 7, and 9. During a debug session, debug events (other than PMI, DEVT1 and DEVT2) with a corresponding DBSR bit are blocked from asserting a watchpoint. The Performance Monitor, DEVNT-based and DTC-based watchpoints are not blocked during a debug session. If not desired, for address-based events the base address values for these events may be programmed to an unused system address. MSR_{DE} has no effect on watchpoint generation.

External logic may monitor the assertion of these signals for debugging or triggering purposes. Watchpoints are signaled in the clock cycle following the occurrence of the actual event. The Nexus3 module also monitors assertion of a portion of these output signals (**jd_watchpt[0:31]**) for various development control purposes. (See the "Watchpoint Trace Messaging" section in the Core (e200z210n3) Nexus 3 Module chapter.)

Note that these signals are **m_clk** domain signals, not **j_tclk** domain signals.

The following table shows the **jd_watchpt[0:31]** output signal assignments to various debug events.

Table 64-24. Watchpoint Output Signal Assignments

Signal Name	Type	Description
jd_watchpt[0]	IAC1	Instruction Address Compare 1 watchpoint Asserted whenever an IAC1 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[1]	IAC2	Instruction Address Compare 2 watchpoint Asserted whenever an IAC2 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[2]	IAC3	Instruction Address Compare 3 watchpoint Asserted whenever an IAC3 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[3]	IAC4	Instruction Address Compare 4 watchpoint Asserted whenever an IAC4 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[4]	DAC1	Data Address Compare 1 watchpoint Asserted whenever a DAC1 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC1CFG}$ settings
jd_watchpt[5]	DAC2	Data Address Compare 2 watchpoint Asserted whenever a DAC2 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC2CFG}$ settings
jd_watchpt[6]	DAC3	Data Address Compare 3 watchpoint Asserted whenever a DAC3 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC3CFG}$ settings
jd_watchpt[7]	DAC4	Data Address Compare 4 watchpoint Asserted whenever a DAC4 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC4CFG}$ settings
jd_watchpt[8]	IAC5	Instruction Address Compare 5 watchpoint Asserted whenever an IAC5 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[9]	IAC6	Instruction Address Compare 6 watchpoint Asserted whenever an IAC6 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[10]	DEVT1	Debug Event Input 1 watchpoint Asserted whenever a DEVT1 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[11]	DEVT2	Debug Event Input 2 watchpoint Asserted whenever a DEVT2 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[12]	DEVNT0	Debug Event Output 0 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[12]
jd_watchpt[13]	DEVNT1	Debug Event Output 1 watchpoint

Table continues on the next page...

Table 64-24. Watchpoint Output Signal Assignments (continued)

Signal Name	Type	Description
		Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[13]
jd_watchpt[14]	IAC7	Instruction Address Compare 7 watchpoint Asserted whenever an IAC7 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[15]	IAC8	Instruction Address Compare 8 watchpoint Asserted whenever an IAC8 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[16]	IRPT	Interrupt watchpoint Asserted whenever an IRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[17]	RET	Return watchpoint Asserted whenever a RET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[18]	CIRPT	Critical Interrupt watchpoint Asserted whenever a CIRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[19]	CRET	Critical Return watchpoint Asserted whenever a CRET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[20]	DEVNT2	Debug Event Output 2 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[20]
jd_watchpt[21]	DEVNT3	Debug Event Output 3 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[21]
jd_watchpt[22]	PMEVENT	Performance Monitor Event input watchpoint Asserted whenever **p_pm_event** transitions from a '0' to a '1' while **m_clk** is running
jd_watchpt[23]	PMC0	Performance Monitor Counter 0 watchpoint Asserted whenever PMC0 triggers an event based on $PMLCa0_{PMP}$
jd_watchpt[24]	PMC1	Performance Monitor Counter 1 watchpoint Asserted whenever PMC1 triggers an event based on $PMLCa1_{PMP}$
jd_watchpt[25]	PMC2	Performance Monitor Counter 2 watchpoint Asserted whenever PMC2 triggers an event based on $PMLCa2_{PMP}$
jd_watchpt[26]	PMC3	Performance Monitor Counter 3 watchpoint Asserted whenever PMC3 triggers an event based on $PMLCa3_{PMP}$
jd_watchpt[27]	—	Reserved
jd_watchpt[28]	TRAP	TRAP watchpoint Asserted whenever an TRAP debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[29]	DTC1	Data Trace Control Range 1 watchpoint

Table continues on the next page...

Table 64-24. Watchpoint Output Signal Assignments (continued)

Signal Name	Type	Description
		Asserted whenever an access meets the conditions for DTC Range 1
jd_watchpt[30]	DTC2	Data Trace Control Range 2 watchpoint Asserted whenever an access meets the conditions for DTC Range 2
jd_watchpt[31]	DTC3	Data Trace Control Range 3 watchpoint Asserted whenever an access meets the conditions for DTC Range 3

64.7 Basic Steps for Enabling, Using, and Exiting External Debug Mode

The following steps show one possible scenario for a debugger wishing to use the external debug facilities. *This simplified flow is intended to illustrate basic operations, but does not cover all potential methods in depth.*

Enabling External Debug Mode and initializing Debug registers

- The debugger should ensure that the **jd_en_once** control signal is asserted in order to enable OnCE operation.
- Select the OCR and write a value to it in which OCR_{DR}, OCR_{WKUP}, are set to '1'. The tap controller must step through the proper states as outlined earlier. This step will place the CPU in a debug state in which it is halted and awaiting single-step commands or a release to normal mode.
- Scan out the value of the OSR to determine that the CPU clock is running and the CPU has entered the Debug state. This can be done in conjunction with a Read of the CPUSCR. The OSR is shifted out during the Shift_IR state. The CPUSCR will be shifted out during the Shift_DR state. The debugger should save the scanned-out value of CPUSCR for later restoration.
- Select the DBCR0 register and update it with the $EDBCR0_{EDM}$ bit set.
- Clear the DBSR status bits.
- Write appropriate values to the DBCR0–8, IAC, and DAC registers. Note that the initial write to DBCR0 will only affect the EDM bit, so the remaining portion of the register must now be initialized, keeping the EDM bit set

At this point the system is ready to commence debug operations. Depending on the desired operation, different steps must occur.

- Optionally, ensure that the values entered into the MSR portion of the CPUSCR during the following steps cause interrupt to be disabled (clearing MSR_{EE} and MSR_{CE}). This will ensure that external interrupt sources do not cause single-step errors.

To single-step the CPU:

- debugger scans in either a new or a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Noexit OnCE Command value.
- The debugger scans out the OSR with "no-register selected", Go cleared, and determines that the CPU has re-entered the Debug state and that no ERR condition occurred.

To return the CPU to normal operation (without disabling external debug mode)

- The OCR_{DR} control bit should be cleared, leaving the OCR_{WKUP} bit set.
- The debugger restores the CPUSCR with a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

To exit External Debug Mode

- The debugger should place the CPU in the debug state via the OCR_{DR} with OCR_{WKUP} asserted, scanning out and saving the CPUSCR.
- The debugger should write the DBCR0–8 registers as needed, likely clearing every enable except the $EDBCR0_{EDM}$ bit.
- The debugger should write the DBSR to a cleared state.
- The debugger should re-write the DBCR0 with all bits including EDM cleared.
- The debugger should clear the OCR_{DR} bit.
- The debugger restores the CPUSCR with the previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

Note

These steps are meant by way of examples, and are not meant to be an exact template for debugger operation.

Chapter 65
Z4 Core Debug Support

65.1 Overview

Internal debug support in the e200z4204n3 core allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. For software based debugging, debug facilities consisting of a set of software accessible debug registers and interrupt mechanisms are provided. These facilities are also available to a hardware based debugger which communicates using a modified IEEE 1149.1 Test Access Port (TAP) controller and pin interface. When hardware debug is enabled, the debug facilities controlled by hardware are protected from software modification.

Software debug facilities are defined as part of *PowerISA 2.06*. e200z4204n3 supports a subset of these defined facilities. In addition to the facilities defined in *PowerISA 2.06*, e200z4204n3 provides additional flexibility and functionality in the form of additional instruction breakpoints, linked instruction and data breakpoints, and extended range and value masking. These features are also available to a hardware-based debugger.

When not being used for debugging purposes, a portion of the debug facilities may be configured to provide a stack limit checking mechanism.

65.1.1 Software Debug Facilities

e200z4204n3 provides debug facilities to enable hardware and software debug functions, such as instruction and data breakpoints and program single stepping. The debug facilities consist of a set of debug control registers (DBCR0–2,4–8, EDBRAC0), a set of address compare registers (IAC1–8, DAC1–4), a set of 64-bit data value compare registers (DVC1, DVC2), a Debug Status Register (DBSR) for enabling and recording various kinds of debug events, a Debug Data Effective Address Register (DDEAR), and a special Debug interrupt type built into the interrupt mechanism.

The debug facilities also provide a mechanism for software-controlled processor reset, and debug mode entry. In addition, the Performance Monitor may be configured to utilize the debug interrupt type.

Software debug facilities are enabled by setting the internal debug mode bit in Debug Control register 0 ($DBCR0_{IDM}$). When internal debug mode is enabled, debug events can occur, and can be enabled to record exceptions in the Debug Status register (DBSR). If enabled by MSR_{DE}, these recorded exceptions cause Debug interrupts to occur. When $DBCR0_{IDM}$ is cleared (and $EDBCR0_{EDM}$ is cleared as well), no debug events occur, and no status flags are set in DBSR unless already set. In addition, when $DBCR0_{IDM}$ is cleared (or is overridden by $EDBCR0_{EDM}$ being set and EDBRAC0 indicating no resource is "owned" by software) no Debug interrupts will occur, regardless of the contents of DBSR. A software Debug interrupt handler may access all system resources and perform necessary functions appropriate for system debug.

65.1.1.1 *PowerISA 2.06* Compatibility

The e200z4204n3 core implements a subset of the *PowerISA 2.06* internal debug features. The following restrictions on functionality are present:

- Instruction address compares do not support compare on physical (real) addresses.
- Data address compares do not support compare on physical (real) addresses.

65.1.2 Additional Debug Facilities

In addition to the debug functionality defined in *PowerISA 2.06*, e200z4204n3 provides capability to link instruction and data breakpoints, provides additional instruction and data breakpoints, extended range and value masking, multiple watchpoint outputs, provides capability for the Performance Monitor to generate debug events, and allows for sharing of debug resources between software and a hardware debugger. (See Sharing Debug Resources by Software/Hardware.) A data trace port is also provided.

65.1.2.1 Data Trace Port

The data trace port interface is provided to assist in implementing extended debug watchpoint/breakpoint/trace capture capability with logic external to the e200z4204n3 core. This port provides information corresponding to each read or write access completed without error by the CPU. In order to report data accesses, the Nexus 3 DTC register DI control bit must be set to trace data accesses, not instruction accesses (i.e. the

normal setting. See the "Data Trace Control Register (DTC)" section in the Core (e200z4204n3) Nexus 3 Module chapter. The data trace port will report aligned accesses and misaligned accesses as one access, unless the two portions of a misaligned access are non-contiguous, such as when the second portion of the misaligned access is to address 0.

65.1.3 Hardware Debug Facilities

The e200z4204n3 core contains facilities that allow for external test and debugging. A modified IEEE 1149.1 control interface is used to communicate with the core resources. This interface is implemented through a standard 1149.1 TAP (test access port) controller.

By using public instructions, the external debugger can freeze or halt the e200z4204n3 core, read and write internal state and debug facilities, single-step instructions, and resume normal execution.

Hardware Debug is enabled by setting the External Debug Mode enable bit in External Debug Control register 0 ($EDBCR0_{EDM}$), which is also aliased to $DBCR0_{EDM}$. Setting $EDBCR0_{EDM}$ overrides the Internal Debug Mode enable bit $DBCR0_{IDM}$ unless resources are provided back to software via the settings in EDBRAC0. When the Hardware Debug facility is enabled, software is blocked from modifying the "hardware-owned" debug facilities. In addition, since resources are "owned" by the hardware debugger, inconsistent values may be present if software attempts to read "hardware-owned" debug-related resources.

When hardware debug is enabled by setting $EDBCR0_{EDM}$=1, the control registers and resources described in Debug registers are reserved for use by the external debugger. The same events described in Software Debug Events and Exceptions are also used for external debugging, but exceptions are not generated to running software. Hardware-owned debug events enabled in the respective DBCR0–8 registers are recorded in the EDBSR0 register (not the DBSR) regardless of MSR_{DE}, and no debug interrupts are generated unless a) the resource is granted back to software via EDBRAC0 settings, and b) debug mode entry is not masked by the corresponding event bit in EDBSRMSK0. Instead, the CPU will enter debug mode when an enabled event causes a EDBSR0 bit to become set. $EDBCR0_{EDM}$, EDBSR0, EDBSRMSK0, EDDEAR, and EDBRAC0 may only be written through the OnCE port.

Access to most debug resources (registers) requires that the CPU clock (**m_clk**) be running in order to perform write accesses from the external hardware debugger.

65.1.4 Sharing Debug Resources by Software/Hardware

Debug resources may be shared by a hardware debugger and software debug based on the settings of debug control register EDBRAC0. When $EDBCR0_{EDM}$ is set, EDBRAC0 settings determine which debug resources are allocated to software and which resources remain under exclusive hardware control. Software-owned resources which set DBSR bits when $DBCR0_{IDM}$=1 will cause a debug interrupt to occur when enabled with MSR_{DE}. Hardware-owned resources which set EDBSR0 bits when $EDBCR0_{EDM}$=1 will cause an entry into debug mode if the event is not masked in EDBSRMSK0. EDBRAC0 is read-only by software. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Hardware-owned resources will set status bits in the EDBSR0 register instead of in DBSR, and will report the effective address of data breakpoints in EDDEAR instead of DDEAR. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers are performed.

65.1.4.1 Simultaneous Hardware and Software Debug Event Handing

Since it is possible that a "hardware-owned" resource can produce a debug event in conjunction with a software-owned resource producing a different debug event simultaneously, a priority ordering mechanism is implemented which guarantees that the hardware event is handled as soon as possible, while preserving the recognition of the software event. The CPU will give highest priority to the software event initially in order to reach a recoverable boundary, and then will give highest priority to the hardware event in order to enter debug mode as near the point of event occurrence as possible. This is implemented by allowing software exception handing to begin internal to the CPU and to reach the point where the current program counter and MSR values have been saved into DSRR0/1, and the new PC pointing to the debug interrupt handler, along with the new MSR updates. At this point, hardware priority takes over, and the CPU enters debug mode.

The following figure shows the e200z4204n3 debug resources.

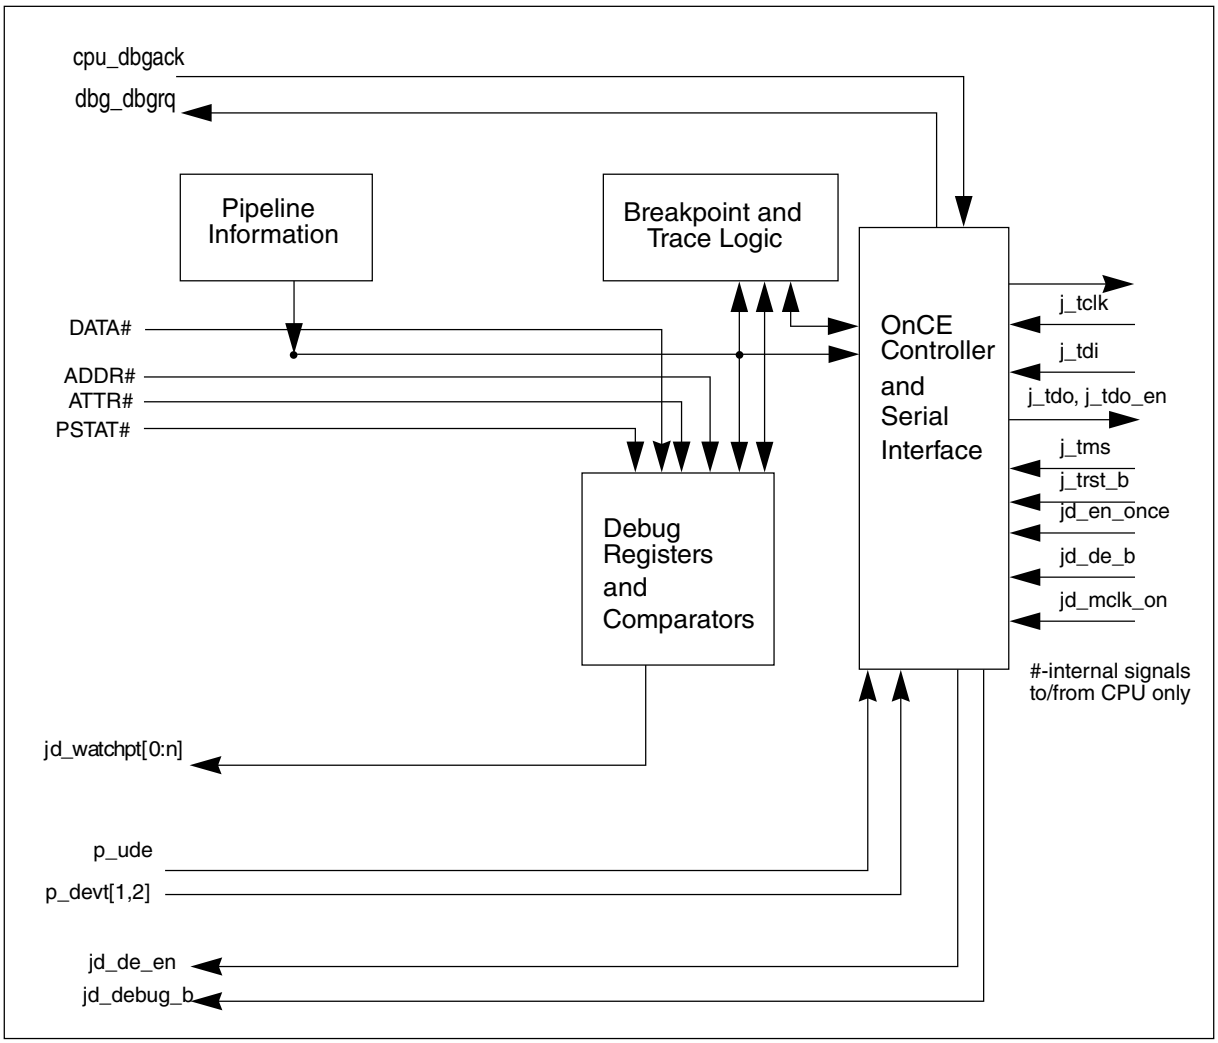

Figure 65-1. e200z4204n3 Debug Resources

65.2 Software Debug Events and Exceptions

Software debug events and exceptions are available when internal debug mode is enabled ($DBCR0_{IDM}$=1) and not overridden by external debug mode ($EDBCR0_{EDM}$ must either be cleared or corresponding resources must be allocated to software debug by the settings in EDBRAC0). When enabled, debug events cause debug exceptions to be recorded in the Debug Status Register. Specific event types are enabled by the Debug Control Registers (DBCR0–8). The Unconditional Debug Event (UDE) is an exception to this rule; it is always enabled. Once a Debug Status Register (DBSR) bit is set by a debug resource which is "owned" by software (other than MRR, DAC_OFST, or VLES), if Debug interrupts are enabled by MSR_{DE}, a Debug interrupt will be generated. The debug interrupt handler is responsible for ensuring that multiple repeated debug interrupts do not occur by clearing the DBSR as appropriate.

Certain debug events are not allowed to occur when MSR_{DE}=0 and $DBCR0_{IDM}$=1. In such situations, no debug exception occurs and thus no DBSR bit is set. Other debug events may cause debug exceptions and set DBSR bits regardless of the state of MSR_{DE}. A Debug interrupt will be delayed until MSR_{DE} is later set to '1'.

When a Debug Status Register bit is set while MSR_{DE}=0, an Imprecise Debug Event flag ($DBSR_{IDE}$) will also be set to indicate that an exception bit in the Debug Status Register was set while Debug interrupts were disabled. Debug interrupt handler software can use this bit to determine whether the address recorded in Debug Save/Restore Register 0 is an address associated with the instruction causing the debug exception, or the address of the instruction which enabled a delayed Debug interrupt by setting the MSR_{DE} bit. A **mtmsr** or **mtdbcr0** which causes both MSR_{DE} and $DBCR0_{IDM}$ to become set, enabling precise debug mode, may cause an Imprecise (Delayed) Debug exception to be generated due to an earlier recorded event in the Debug Status register.

There are eight types of debug events defined by *PowerISA 2.06*:

1. Instruction Address Compare debug events
2. Data Address Compare debug events
3. Trap debug events
4. Branch Taken debug events
5. Instruction Complete debug events
6. Interrupt/Critical Interrupt Taken debug events
7. Return/Critical Return debug events
8. Unconditional debug events

In addition, e200z4204n3 defines additional debug events:

- The External debug events DEVT1 and DEVT2 which are described in External debug event.
- The Performance Monitor Interrupt event PMI which is described in Performance Monitor Interrupt debug event.

The e200z4204n3 debug configuration supports most of these event types. Unsupported *PowerISA 2.06* defined functionality is as follows:

- Instruction Address Compare and Data Address Compare *Real address* mode is not supported

A brief description of each of the event types follows.

65.2.1 Instruction Address Compare Event

Instruction Address Compare debug events occur when enabled and execution is attempted of an instruction at an address that meets the criteria specified in the DBCR0, DBCR1, DBCR5, DBCR6, and IAC1–8 Registers. Instruction Address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. IAC events will not occur when an instruction would not have normally begun execution due to a higher priority exception at an instruction boundary.

IAC compares perform a 31-bit compare for VLE instruction storage accesses. Each halfword fetched by the instruction fetch unit will be marked with a set of bits indicating whether an Instruction Address Compare occurred on that halfword. Debug exceptions will occur if enabled and a 16-bit instruction, or the first halfword of a 32-bit instruction, is tagged with an IAC hit.

65.2.2 Data Address Compare Event

Data Address Compare debug events occur when enabled and execution of a load or store class instruction or a cache maintenance instruction results in a data access that meets the criteria specified in the DBCR0, DBCR2, DBCR4, DBCR7–8, DAC1–4, DVC1, and DVC2 Registers. Data address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. Four address compare values (DAC1–4) are provided.

The effective address of the load, store, or cache control operation is recorded in the DDEAR register when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set.

Note

In contrast to the *PowerISA 2.06* definition, Data Address Compare events on e200z4204n3 do not prevent the load or store class instruction from completing. If a load or store class

instruction completes successfully without a Data Storage interrupt, Data Address Compare exceptions are reported at the completion of the instruction. If the exception results in a precise Debug interrupt, the address value saved in DSRR0 is the address of the instruction following the load or store class instruction. For DVC DAC events, the exception can be imprecisely reported even further past the load or store class instruction generating the event (without necessarily affecting $DBSR_{IDE}$) and the saved address value can point to a subsequent instruction past the next instruction. This occurrence is indicated in the $DBSR_{DAC_OFST}$ field.

If a load or store class instruction does not complete successfully due to a Data Storage exception or a machine check condition for the load or store, and a Data Address Compare debug exception also occurs, the result is an imprecise Debug interrupt, the address value saved in DSRR0 is the address of the load or store class instruction, and the $DBSR_{IDE}$ bit will be set. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note

DAC events will not be recorded if a load multiple word or store multiple word instruction is interrupted prior to completion by a critical input or external input interrupt.

Note

DAC events will occur for cache control instructions without performing data compares, regardless of the settings of the DBCRx registers and DVC registers for data value comparison qualifications, i.e. no data comparisons are performed since these instructions do not have associated data values.

Note

DAC events are not signaled on the second portion of a misaligned load or store that is broken up into two separate accesses.

Note

DAC[1,2] events are not signaled if DVC[1,2]M is non-zero and a DSI exception occurs on the load or store, since the load or store access is not performed. For a **lmw** or **stmw** transfer however, if a DVC successfully occurs on a transfer and a later transfer encounters a DSI exception, the DAC event will be reported, since a successful data value compare took place.

Note

Due to internal pipeline status, for a reported DAC event on a **lmw** or **stmw** transfer, the value stored in the DDEAR/EDDEAR will be the effective address of the first transfer of the sequence, and not necessarily the precise transfer that caused the DAC event.

65.2.2.1 Data Address Compare Event Status Updates

Data Address Compare debug events with Data Value compares can be reported ambiguously in several circumstances involving issuing a sequence of load or store class instructions. Due to the CPU pipeline and the delay in performing the data value compare following completion of the access, if the first load or store class instruction generates a DVC DAC, a second and possibly third load or store class instruction may also generate a DAC or DVC DAC event, or may generate a DSI exception with or without a simultaneous DAC event.

Also, since non-load/store instructions may be dual-issued in combination with a load/store instruction, the actual number of additional instructions that are completed following a recognized DVC DAC on a load/store instruction may vary from 0 to 5. This value will be reported in the $DBSR_{DAC_OFST}$ field when the DVC DAC status is recorded.

Table 65-1 outlines the settings of the DBSR, DSRR0 saved value, and potential updating of the ESR register for various exception cases on sequences of load/store class instructions. Not all exception combinations are covered in the table, such as IAC, ISI, or Alignment exceptions on subsequent instructions. In general these exceptions will cause further instruction issue to be halted, execution of the excepting instruction to be aborted, and reporting of these exceptions will be masked. The saved DSRR0 value will point to this excepting instruction, and the exception(s) may be regenerated after returning from the debug interrupt handler and attempting to re-execute the instruction pointed to by

DSRR0. In addition, in the examples in Table 65-1, the DAC_OFST and DSRR0 values assume no dual issue occurs. If dual-issue occurs with the first, second, or third column, then the DAC_OFST and DSRR0 values will point beyond the values shown.

Table 65-1. DAC events and Resultant Updates

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DSI, no DAC	—	—	Take DSI exception, no DBSR update. Update ESR.
DSI, with DACx	—	—	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST not set. DSRR0 points to 1st load/store class instruction. No ESR update.
DACx	—	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update.
DVC DACx	No exceptions, any instruction	No exceptions, Non-ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. No ESR update.
DVC DACx	No exceptions	No exceptions, Ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b010. DSRR0 points to instruction after 3rd instruction. No ESR update.
DVC DACx	DSI, no DAC	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DSI, with DACy	—	Take Debug exception, DBSR update setting DACx. DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DACy	—	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Normal Ldst	Non-Ldst instruction	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Normal Ldst	Ldst instruction,no exception	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Normal Ldst	DSI Error, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. No ESR update. DSRR0 points to 3rd instruction.

Table continues on the next page...

Table 65-1. DAC events and Resultant Updates (continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
			Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DVC DACy,Normal Ldst	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Ldst multiple (lmw, stmw)	Any instruction including ld/st	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	Any instruction(no exception)	DSI, with or without DAC,Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. No ESR update. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	Any instruction(no exception)	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 65-2 through Table 65-5 show some example updates for specific code sequences of dual issuing of load/store class instructions with non-load/store class instructions and the results of DAC and DVC events on selected ones of the load/store instructions.

Table 65-2. DAC events and Resultant Updates, Dual-issue case 1

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1):	Take DSI exception, no DBSR update, Update ESR.

Table continues on the next page...

Table 65-2. DAC events and Resultant Updates, Dual-issue case 1 (continued)

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) load/store (6) alu	Event(s)	Result
	DSI, no DAC	
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6)
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (5): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. No ESR update. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b100. No ESR update. DSRR0 points to instruction (6).

No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

65.2.3 Linked Instruction Address Compare and Data Address Compare Events

Data Address Compare 1, 2, 3, and 4 debug events may be 'linked' with an Instruction Address Compare event by setting the DAC[1–4]LNK control bits in DBCR2 and DBCR8 to further refine when a Data Address Compare debug event is generated. DAC1

may be linked with IAC1, DAC2 (when not used as a mask or range bounds register) may be linked with IAC3. DAC3 may be linked with IAC5, DAC4 (when not used as a mask or range bounds register) may be linked with IAC7. When linked, a DAC debug event occurs when the same instruction that generates the DAC 'hit' also generates a corresponding linked IAC 'hit'. When linked, the IAC event is not recorded in the Debug Status register, regardless of whether a corresponding linked DAC event occurs, or whether the IAC event enable is set.

When enabled and execution of a load or store class instruction results in a data access with an address that meets the criteria specified in the DBCRx, DACx, and DVCx Registers, and the instruction also meets the criteria for generating an Instruction Address Compare event, a Linked Data Address Compare debug event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. The normal DAC1 status bit in the DBSR is used for recording these events. The IAC status bit is not set if the corresponding Instruction Address Compare register is linked.

Linking is enabled using control bits in DBCR2 and DBCR8. Note that linking is only available in EDM or IDM. Attempts to use linking otherwise are ignored.

Note

Linked DAC events will not be recorded if a load multiple word or store multiple word type instruction is interrupted prior to completion by a critical input or external input interrupt.

65.2.4 Trap Debug Event

A Trap debug event (TRAP) occurs if Trap debug events are enabled ($DBCR0_{TRAP}$=1), a Trap instruction (**tw**) is executed, and the conditions specified by the instruction for the trap are met. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Trap debug event occurs, the $DBSR_{TRAP}$ bit is set to 1 to record the debug exception.

65.2.5 Branch Taken Debug Event

A Branch Taken debug event (BRT) occurs if Branch Taken debug events are enabled ($DBCR0_{BRT}$=1) and execution is attempted of a branch instruction that will be taken (either an unconditional branch, or a conditional branch whose branch condition is true), and MSR_{DE}=1. Branch Taken debug events are not recognized if MSR_{DE}=0 at the time of execution of the branch instruction and thus $DBSR_{IDE}$ can not be set by a Branch Taken

debug event. When a Branch Taken debug event is recognized, the $DBSR_{BRT}$ bit is set to 1 to record the debug exception, and the address of the branch instruction will be recorded in DSRR0.

65.2.6 Instruction Complete Debug Event

An Instruction Complete debug event (ICMP) occurs if Instruction Complete debug events are enabled ($DBCR0_{ICMP}$=1), execution of any instruction is completed, and MSR_{DE}=1. If execution of an instruction is suppressed due to the instruction causing some other exception that is enabled to generate an interrupt, then the attempted execution of that instruction does not cause an Instruction Complete debug event. The ***se_sc*** instruction does not fall into the category of an instruction whose execution is suppressed, since the instruction actually executes and then generates a System Call interrupt. In this case, the Instruction Complete debug exception will also be set. When an Instruction Complete debug event is recognized, $DBSR_{ICMP}$ is set to 1 to record the debug exception and the address of the next instruction to be executed will be recorded in DSRR0.

Instruction Complete debug events are not recognized if MSR_{DE}=0 at the time of execution of the instruction, thus $DBSR_{IDE}$ is not generally set by an ICMP debug event.

One circumstance may cause the $DBSR_{ICMP}$ and $DBSR_{IDE}$ bits to be set. This occurs when a EFPU Round exception occurs. Since the instruction is by definition completed (SRR0 points to the following instruction), this interrupt takes higher priority than the Debug interrupt so as not to be lost, and $DBSR_{IDE}$ is set to indicate the imprecise recognition of a Debug interrupt. In this case, the Debug interrupt will be taken with SRR0 pointing to the instruction following the instruction that generated the EFPU Round exception, and DSRR0 will point to the Round exception handler. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note

Instruction complete debug events are not generated by the execution of an instruction that sets MSR_{DE} to '1' while $DBCR0_{ICMP}$=1, nor by the execution of an instruction that sets $DBCR0_{ICMP}$ to '1' while MSR_{DE}=1.

65.2.7 Interrupt Taken Debug Event

An Interrupt Taken debug event (IRPT) occurs if Interrupt Taken debug events are enabled ($DBCR0_{IRPT}$=1) and a base-class interrupt occurs. Only base-class interrupts (an interrupt using SRR0/1) cause an Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Interrupt Taken debug event occurs, the $DBSR_{IRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the non-critical interrupt handler.

65.2.8 Critical Interrupt Taken Debug Event

A Critical Interrupt Taken debug event (CIRPT) occurs if Critical Interrupt Taken debug events are enabled ($DBCR0_{CIRPT}$=1) and a critical interrupt occurs. Only critical class interrupts (an interrupt using CSRR0/1) cause a Critical Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Interrupt Taken debug event occurs, the $DBSR_{CIRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the critical interrupt handler.

65.2.9 Return Debug Event

A Return debug event (RET) occurs if Return debug events are enabled ($DBCR0_{RET}$=1) and an attempt is made to execute an **se_rfi** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Return debug event occurs, the $DBSR_{RET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfi** (i.e. before the MSR is updated by the **se_rfi**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfi**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfi** instruction.

65.2.10 Critical Return Debug Event

A Critical Return debug event (CRET) occurs if Critical Return debug events are enabled ($DBCR0_{CRET}$=1) and an attempt is made to execute an **se_rfci** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Return debug event occurs, the $DBSR_{CRET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfci** (i.e. before the MSR is updated by the **se_rfci**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfci**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfci** instruction.

65.2.11 External debug event

An External debug event (DEVT1, DEVT2) occurs if External debug events are enabled ($DBCR0_{DEVT1}$=1 or $DBCR0_{DEVT2}$=1), and the respective **p_devt1** or **p_devt2** input signal transitions to the asserted state while the CPU is not in the Stopped state. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an External debug event occurs, $DBSR_{DEVT\{1,2\}}$ is set to '1' to record the debug exception. This debug event is an asynchronous event, but is only sampled when the CPU **m_clk** is active.

65.2.12 Unconditional debug event

An Unconditional debug event (UDE) occurs when the Unconditional Debug Event (**p_ude**) input transitions to the asserted state. The Unconditional debug event is the only debug event that does not have a corresponding enable bit for the event in DBCR0. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Unconditional debug event occurs, the $DBSR_{UDE}$ bit is set to '1' to record the debug exception. This debug event is an asynchronous event.

65.2.13 Performance Monitor Interrupt debug event

A Performance Monitor Interrupt debug event (PMI) occurs if Performance Monitor Interrupt debug events are enabled ($PMGC0_{UDI}$=1), and a performance monitor interrupt event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Performance Monitor Interrupt debug event occurs, $DBSR_{PMI}$ is set to '1' to record the debug exception. This debug event is an asynchronous event.

65.3 Debug registers

This section describes debug-related registers that are software accessible. These registers are intended for use by special debug tools and debug software, not by general application code.

Access to these registers (other than DBSR) by software is conditioned by the External Debug mode control bit ($EDBCR0_{EDM}$) and the settings of debug control register EDBRAC0, which can be set by the hardware debug port. If $EDBCR0_{EDM}$ is set and if the bit in EDBRAC0 corresponding to the resource is cleared, software is prevented from modifying debug register values other than in DBSR, since the resource is not "owned" by software. Software always has ownership of DBSR. Execution of a **mtspr** instruction targeting a debug register or register field not "owned" by software will not cause modifications to occur, and no exception will be signaled. In addition, since the external debugger hardware may be manipulating debug register values, the state of these registers or register fields not "owned" by software is not guaranteed to be consistent if accessed (read) by software with a **mfspr** instruction, other than the $DBCR0_{EDM}$ bit itself and the EDBRAC0 register. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control registers as appropriate when hardware modifications to the debug registers is performed.

65.3.1 Debug Address and Value Registers

Instruction Address Compare registers IAC1–8 are used to hold instruction addresses for address comparison purposes. In addition, IAC2 and IAC4 may hold mask information for IAC1 and IAC3 respectively and IAC6 and IAC8 may hold mask information for IAC5 and IAC7 respectively, when *Address Bit Match* compare modes are selected. Note that when performing instruction address compares, the low order bit of the instruction address and the corresponding IAC register is ignored for VLE instructions.

Data Address Compare registers DAC1–4 are used to hold data access addresses for address comparison purposes. In addition, DAC2 and DAC4 may hold mask information for DAC1 and DAC3 respectively when *Address Bit Match* compare modes are selected.

Data Value Compare registers DVC1 and DVC2 are used to hold data values for data comparison purposes. DVC1 and DVC2 are 64-bit registers. Data value comparisons are used to qualify Data Address compare 1 and 2 debug events. Data value comparisons are

not available for Data address compare 3–4 events. DVC1 is associated with DAC1, and DVC2 is associated with DAC2. The most significant byte of the DVC1(2) register (labeled B0 in the following figure) corresponds to the byte data value transferred to/from memory byte offset 0, 8, …, and the least significant byte of the register (labeled B7 in the following figure) corresponds to byte offset 7, F, … . When enabled for performing data value comparisons, each enabled byte in DVC1(2) is compared with the memory value transferred on the corresponding active byte lane of the data memory interface to determine if a match occurs. Inactive byte lanes do not participate in the comparison, they are implicitly masked. The Byte Strobe Assertion for Transfers table in the Core (e200z4204n3) Core Complex Overview chapter shows active byte lanes for data transfers. Software must also program the DVC1(2) register byte positions based on the alignment of the access. Misaligned accesses are not fully supported, since the data address and data value comparisons are only performed on the initial access in the case of a misaligned access; thus, accesses that cross a 64-bit boundary cannot be fully matched. For address and size combinations that involve two transfers, only the initial transfer is used for data address and value matching.

DVC1 and DVC2 may be read or written using **mtspr** and **mfspr** instructions. The DVC1U and DVC2U SPR numbers (601,602) are used for accessing the upper 32-bit portion of the DVC register. The DVC1 and DVC2 SPR numbers (318,319) are used for accessing the lower 32-bit portion of the DVC register.

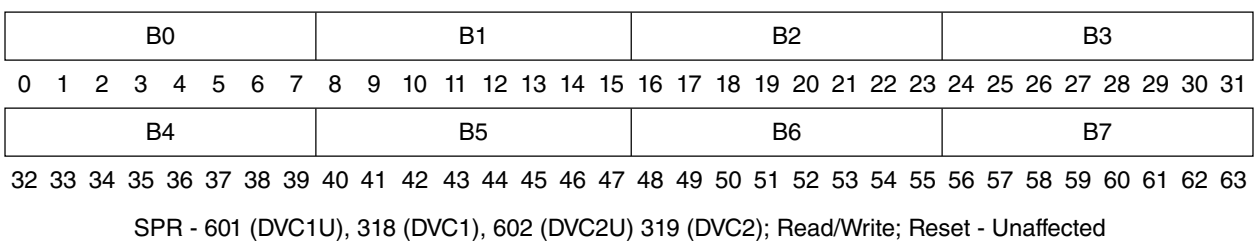

Figure 65-2. DVC1, DVC2 registers

65.3.2 Debug Control and Status registers

Debug Control Registers (DBCR0–8 and EDBRAC0) are used to enable debug events, reset the processor, and set the debug mode of the processor. The Debug Status register (DBSR) records debug exceptions while Internal Debug mode is enabled. The Debug Data Effective Address register (DDEAR) records the effective address of a Data Address Compare event while Internal Debug mode is enabled.

e200z4204n3 requires that a context synchronizing instruction follow a **mtspr** DBCR0–8 or DBSR to ensure that any alterations enabling/disabling debug events are effective. The context synchronizing instruction may or may not be affected by the alteration. Typically, an **se_isync** instruction is used to create a synchronization boundary beyond which it can be guaranteed that the newly written control values are in effect.

For watchpoint generation, configuration settings contained in DBCR1–8 are used, even though the corresponding event(s) may be disabled (via DBCR0) from setting DBSR flags.

65.3.2.1 Debug Control Register 0 (DBCR0)

Debug Control Register 0 is used to enable debug modes and controls which debug events are allowed to set DBSR or EDBSR0 flags. e200z4204n3 adds some implementation specific bits to this register, as seen in the following figure.

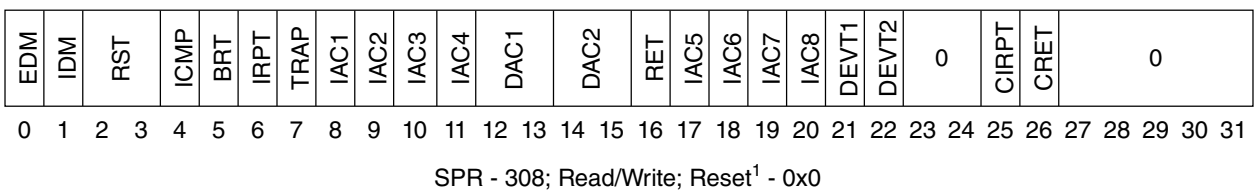

Figure 65-3. Debug Control Register 0 (DBCR0) register

Note

[1] $DBCR0_{EDM}$ is affected by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**. All other bits are reset by processor reset **p_reset_b** if $DBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $DBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources (other than RST) from reset by **p_reset_b**, and only software-owned resources indicated by EDBRAC0 and the $DBCR0_{RST}$ field will be reset by **p_reset_b**. The $DBCR0_{RST}$ field will always be reset by **p_reset_b** regardless of the value of $DBCR0_{EDM}$.

The following provides bit definitions for Debug Control Register 0.

Table 65-6. DBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug mode. This bit is read-only by software. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset p_reset_b. This allows the debugger to set up hardware debug events that remain active across a processor reset. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned debug events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCR0–8, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0. Hardware-owned events will set status bits in EDBSR0. Programming Notes: It is recommended that debug status bits in the Debug Status Registers be cleared before disabling external debug mode to avoid any internal imprecise debug interrupts. Software may use this bit to determine if external debug has control over the debug registers. The hardware debugger must set the EDM bit to '1' before other bits in this register (and other debug registers) may be altered. On the initial setting of this bit to '1', all other bits are unchanged. This bit is only writable through the OnCE port.
1	IDM	Internal Debug mode 0 Debug exceptions are disabled. Debug events do not affect DBSR. 1 Debug exceptions are enabled. Enabled debug events owned by software will update the DBSR. If MSR_{DE}=1, the occurrence of a debug event, or the recording of an earlier debug event in the Debug Status Register when MSR_{DE} was cleared, will cause a Debug interrupt.
2:3	RST	Reset Control 00 No function 01 **p_dbrstc[1]** pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset 10 **p_dbrstc[0]** pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset. 11 Reserved
4	ICMP	Instruction Complete Debug Event Enable 0 ICMP debug events are disabled 1 ICMP debug events are enabled
5	BRT	Branch Taken Debug Event Enable 0 BRT debug events are disabled 1 BRT debug events are enabled
6	IRPT	Interrupt Taken Debug Event Enable 0 IRPT debug events are disabled 1 IRPT debug events are enabled
7	TRAP	Trap Taken Debug Event Enable 0 TRAP debug events are disabled 1 TRAP debug events are enabled
8	IAC1	Instruction Address Compare 1 Debug Event Enable 0 IAC1 debug events are disabled

65.3.2.3 Debug Control Register 2 (DBCR2)

Debug Control Register 2 is used to configure Data Address Compare and Data Value Compare operation.The DBCR2 register is shown in the following figure.

SPR - 310; Read/Write; Reset[1] - 0x0

Figure 65-5. DBCR2 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 2.

Table 65-8. DBCR2 Bit Definitions

Bit	Name	Description
0:1	DAC1US	Data Address Compare 1 User/Supervisor Mode 00 DAC1 debug events not affected by MSR_{PR} 01 Reserved 10 DAC1 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC1 debug events can only occur if MSR_{PR}=1 (User mode)
2:3	DAC1ER	Data Address Compare 1 Effective/Real Mode 00 DAC1 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=1
4:5	DAC2US	Data Address Compare 2 User/Supervisor Mode 00 DAC2 debug events not affected by MSR_{PR} 01 Reserved 10 DAC2 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC2 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	DAC2ER	Data Address Compare 2 Effective/Real Mode 00 DAC2 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=1
8:9	DAC12M	Data Address Compare 1/2 Mode 00 Exact address compare. DAC1 debug events can only occur if the address of the data access is equal to the value specified in DAC1. DAC2 debug events can only occur if the address of the data access is equal to the value specified in DAC2. 01 Address bit match. DAC1 debug events can occur only if the address of the data access ANDed with the contents of DAC2, are equal to the contents of DAC1 also ANDed with the contents of DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 10 Inclusive address range compare. DAC1 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC1 and less than the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used.

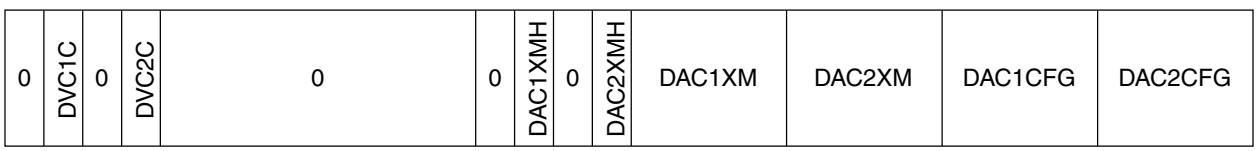
Table continues on the next page...

Table 65-8. DBCR2 Bit Definitions (continued)

Bit	Name	Description
		11 Exclusive address range compare. DAC1 debug events can occur only if the address of the data access is less than the value specified in DAC1 or is greater than or equal to the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used.
10	DAC1LNK	Data Address Compare 1 Linked. When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC1 debug events are linked to IAC1 debug events. IAC1 debug events do not affect DBSR When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM.
11	DAC2LNK	Data Address Compare 2 Linked. When linked to IAC3, DAC2 debug events are conditioned based on whether the instruction also generated an IAC3 debug event. DAC2 can only be linked if DAC12M specifies Exact Address Compare since DAC2 debug events are not generated in the other compare modes. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC 2 debug events are linked to IAC3 debug events. IAC3 debug events do not affect DBSR
12:13	DVC1M	Data Value Compare 1 Mode When $DBCR4_{DVC1C}$=0: 00 DAC1 debug events not affected by data value compares. 01 DAC1 debug events can only occur when all bytes specified in the DVC1BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC1 debug events can only occur when any byte specified in the DVC1BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC1 debug events can only occur when all bytes specified in the DVC1BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC1 value. **NOTE:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC1C}$=1: 00 Reserved 01 DAC1 debug events can only occur when any byte specified in the DVC1BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC1 debug events can only occur when all bytes specified in the DVC1BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **NOTE:** Note: Inactive byte lanes of the memory access are automatically masked.
14:15	DVC2M	Data Value Compare 2 Mode When $DBCR4_{DVC2C}$=0: 00 DAC2 debug events not affected by data value compares. 01 DAC2 debug events can only occur when all bytes specified in the DVC2BE field match the corresponding data byte values for active byte lanes of the memory access.

Table continues on the next page...

Table 65-8. DBCR2 Bit Definitions (continued)



Bit	Name	Description
		10 DAC2 debug events can only occur when any byte specified in the DVC2BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC2 debug events can only occur when all bytes specified in the DVC2BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC2 value. **NOTE:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC2C}$=1: 00 Reserved 01 DAC2 debug events can only occur when any byte specified in the DVC2BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC2 debug events can only occur when all bytes specified in the DVC2BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **NOTE:** Inactive byte lanes of the memory access are automatically masked.
16:23	DVC1BE	Data Value Compare 1 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC1. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1xxxxxxx Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC1. x1xxxxxx Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC1. xx1xxxxx Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC1. xxx1xxxx Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC1. xxxx1xxx Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC1. xxxxx1xx Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC1. xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC1. xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC1.
24:31	DVC2BE	Data Value Compare2 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC2. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1xxxxxxx Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC2. x1xxxxxx Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC2. xx1xxxxx Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC2. xxx1xxxx Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC2. xxxx1xxx Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC2. xxxxx1xx Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC2.

Table 65-8. DBCR2 Bit Definitions

Bit	Name	Description
		xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC2. xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC2.

65.3.2.4 Debug Control Register 4 (DBCR4)

Debug Control Register 4 is used to extend data address and value compare matching functionality. DBCR4 is shown in the following figure.

SPR - 563; Read/Write; Reset[1] - 0x0

Figure 65-6. DBCR4 Register

Note

[1] DBCR4 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 4.

Table 65-9. DBCR4 field description

Bit	Name	Description
0	—	Reserved
1	DVC1C	Data Value Compare 1 Control. DVC1C controls whether DVC1 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition. 0 Normal DVC1 operation. Inverted polarity DVC1 operation
2	—	Reserved
3	DVC2C	Data Value Compare 2 Control. DVC2C controls whether DVC2 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition 0 Normal DVC2 operation.

Table continues on the next page...

Table 65-9. DBCR4 field description (continued)

Bit	Name	Description
		1 Inverted polarity DVC2 operation
4:12	—	Reserved
13	DAC1XMH	Data Address Compare 1 Extended Mask Control High. DAC1XMH extends the range of the DAC1XM field. 0 - DAC1XM masks 0–15 low-order address bits 1 - DAC1XM masks 16–31 low-order address bits
14	—	Reserved
15	DAC2XMH	Data Address Compare 2 Extended Mask Control High. . DAC2XMH extends the range of the DAC2XM field. 0 DAC2XM masks 0–15 low-order address bits 1 DAC2XM masks 16–31 low-order address bits
16:19	DAC1XM	Data Address Compare 1 Extended Mask Control. DAC1XM allows for binary power of 2 address range compares for DAC1 without requiring the use of DAC2. Value of DAC1XMH || DAC1XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC1 when comparing the storage address with the value in DAC1 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported.
20:23	DAC2XM	Data Address Compare 2 Extended Mask Control Value of DAC2XMH || DAC2XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC2 when comparing the storage address with the value in DAC2 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported. DAC2XM allows for binary power of 2 address range compares for DAC2.
24:27	DAC1CFG	Data Address Compare 1 Configuration 0000 DAC1 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC1}$=00 0001 DAC1 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC1}$=00 0010 DAC1 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC1}$=00 0011 Reserved 01xx Reserved 1000 DAC1 address comparisons are used for stack limit checking. DAC1 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC1. When a qualified DAC1 match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC1 watchpoint is generated. $DBCR0_{DAC1}$ and $DBCR2_{DVC1M}$ settings are ignored. 1001 – 1111 Reserved DAC1CFG controls whether DAC1 data address comparisons utilize the normal PowerISA operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint).

Table continues on the next page...

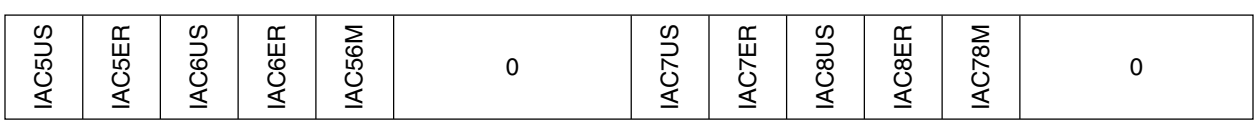


Table 65-9. DBCR4 field description (continued)

Bit	Name	Description
		NOTE: unlike the DAC3–4CFG fields, debug event enabling for DAC1 is controlled by the DAC1 field in DBCR0. The DAC1CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC1}$=0; when $DBCR0_{DAC1}$!=00, DAC1 watchpoints will fire whenever a DAC1 debug event occurs.
28:31	DAC2CFG	Data Address Compare 2 Configuration 0000 DAC2 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC2}$=00 0001 DAC2 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC2}$=00 0010 DAC2 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC2}$=00 0011 Reserved 01xx Reserved 1xxx Reserved DAC2CFG controls whether DAC2 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. **NOTE:** Unlike the DAC3–4CFG fields, debug event enabling for DAC2 is controlled by the DAC2 field in DBCR0. The DAC2CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC2}$=00. When $DBCR0_{DAC2}$!=00, DAC2 watchpoints will fire whenever a DAC2 debug event occurs.

65.3.2.5 Debug Control Register 5 (DBCR5)

Debug Control Register 5 is used to configure Instruction Address Compare operation for IAC5–8. The DBCR5 register is shown in the following figure.

.

SPR - 564; Read/Write; Reset[1] - 0x0

Figure 65-7. DBCR5 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 5.

Table 65-10. DBCR5 field descriptions

Bit(s)	Name	Description
0:1	IAC5US	Instruction Address Compare 5 User/Supervisor Mode 00 IAC5 debug events not affected by MSR_{PR} 01 Reserved 10 IAC5 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 IAC5 debug events can only occur if MSR_{PR}=1. (User mode)
2:3	IAC5ER	Instruction Address Compare 5 Effective/Real Mode 00 IAC5 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC5 debug events are based on effective address and can only occur if MSR_{IS}=0 11 IAC5 debug events are based on effective address and can only occur if MSR_{IS}=1
4:5	IAC6US	Instruction Address Compare 6 User/Supervisor Mode 00 IAC6 debug events not affected by MSR_{PR} 01 Reserved 10 IAC6 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 IAC6 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	IAC6ER	Instruction Address Compare 6 Effective/Real Mode 00 IAC6 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC6 debug events are based on effective address and can only occur if MSR_{IS}=0 11 IAC6 debug events are based on effective address and can only occur if MSR_{IS}=1
8:9	IAC56M	Instruction Address Compare 5/6 Mode 00 Exact address compare. IAC5 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC5. IAC6 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC6. 01 Address bit match. IAC5 debug events can occur only if the address of the instruction fetch, ANDed with the contents of IAC6 are equal to the contents of IAC5, also ANDed with the contents of IAC6. IAC6 debug events do not occur. IAC5US and IAC5ER settings are used. 10 Inclusive address range compare. IAC5 debug events can occur only if the address of the instruction fetch is greater than or equal to the value specified in IAC5 and less than the value specified in IAC6. IAC6 debug events do not occur. IAC5US and IAC5ER settings are used. 11 Exclusive address range compare. IAC5 debug events can occur only if the address of the instruction fetch is less than the value specified in IAC5 or is greater than or equal to the value specified in IAC6. IAC6 debug events do not occur. IAC5US and IAC5ER settings are used.

DAC3 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC3. When a qualified match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC3 watchpoints is generated. 1001 - 1111 Reserved
28:31	DAC4CFG	Data Address Compare 4 Configuration. DAC4CFG controls whether DAC4 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. 0000 DAC4 debug watchpoints are enabled for load-type or store-type data storage accesses 0001 DAC4 debug watchpoints are enabled only for store-type data storage accesses 0010 DAC4 debug watchpoints are enabled only for load-type data storage accesses 0011 Reserved 0100 Reserved 0101 DAC4 debug events and watchpoints are enabled only for store-type data storage accesses 0110 DAC4 debug events and watchpoints are enabled only for load-type data storage accesses 0111 DAC4 debug events and watchpoints are enabled for load-type or store-type data storage accesses 1xxx Reserved

65.3.2.8 Debug Control Register 8 (DBCR8)

Debug Control Register 8 is used to configure Data Address Compare 3 and 4 operation. The DBCR8 register is shown in the following figure.

SPR - 597; Read/Write; Reset[1] - 0x0

Figure 65-10. DBCR8 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 8.

Table 65-13. DBCR8 Bit Definitions

Bit(s)	Name	Description
0:1	DAC3US	Data Address Compare 3 User/Supervisor Mode 00 - DAC3 debug events not affected by MSR_{PR} 01 - Reserved 10 - DAC3 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 - DAC3 debug events can only occur if MSR_{PR}=1. (User mode)
2:3	DAC3ER	Data Address Compare 3 Effective/Real Mode 00 - DAC3 debug events are based on effective address 01 - Unimplemented (Book E real address compare), no match can occur 10 - DAC3 debug events are based on effective address and can only occur if MSR_{DS}=0 11 - DAC3 debug events are based on effective address and can only occur if MSR_{DS}=1
4:5	DAC4US	Data Address Compare 4 User/Supervisor Mode. 00 - DAC4 debug events not affected by MSR_{PR} 01 - Reserved 10 - DAC4 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 - DAC4 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	DAC4ER	Data Address Compare 4 Effective/Real Mode 00 - DAC4 debug events are based on effective address 01 - Unimplemented (Book E real address compare), no match can occur 10 - DAC4 debug events are based on effective address and can only occur if MSR_{DS}=0

Table continues on the next page...

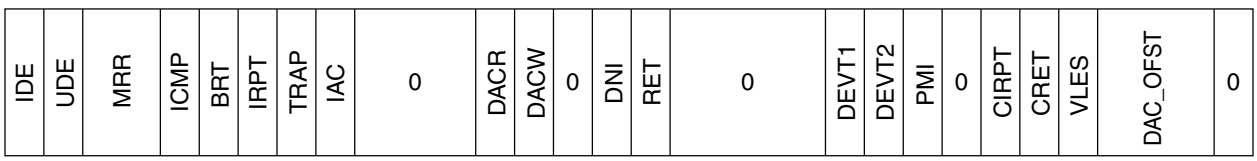

Table 65-13. DBCR8 Bit Definitions (continued)

Bit(s)	Name	Description
		11 - DAC4 debug events are based on effective address and can only occur if MSR_{DS}=1
8:9	DAC34M	Data Address Compare 3/4 Mode 00 - Exact address compare. DAC3 debug events can only occur if the address of the data access is equal to the value specified in DAC3. DAC4 debug events can only occur if the address of the data access is equal to the value specified in DAC4. 01 - Address bit match. DAC3 debug events can occur only if the address of the data access ANDed with the contents of DAC4, are equal to the contents of DAC3 also ANDed with the contents of DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 10 - Inclusive address range compare. DAC3 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC3 and less than the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 11 - Exclusive address range compare. DAC3 debug events can occur only if the address of the data access is less than the value specified in DAC3 or is greater than or equal to the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used.
10	DAC3LNK	Data Address Compare 3 Linked 0 - No effect 1 - DAC3 debug events are linked to IAC5 debug events. IAC5 debug events do not affect DBSR When linked to IAC5, DAC3 debug events are conditioned based on whether the instruction also generated an IAC5 debug event. Note that linking is only available in EDM or IDM.
11	DAC4LNK	Data Address Compare 4 Linked 0 - No effect 1 - DAC4 debug events are linked to IAC7 debug events. IAC7 debug events do not affect DBSR When linked to IAC7, DAC4 debug events are conditioned based on whether the instruction also generated an IAC7 debug event. Note that linking is only available in EDM or IDM.
12:31	—	Reserved

65.3.2.9 Debug Status Register (DBSR)

The Debug Status Register (DBSR) contains status on debug events and the most recent processor reset. The Debug Status Register is set via hardware, and read and cleared via software. Bits in the Debug Status Register can be cleared using **mtspr***DBSR,RS*. Clearing is done by writing to the Debug Status Register with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write data to the Debug Status Register is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no

effect. Debug Status bits are set by Debug events only while Internal Debug Mode is enabled ($DBCR0_{IDM}$=1). When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1, $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR other than MRR, DAC_OFST, or VLES will cause a debug interrupt to be generated. The debug interrupt handler is responsible for clearing DBSR bits prior to returning to normal execution. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software, and status bits associated with hardware-owned resources will not be set by hardware in DBSR. The DBSR register is shown in the following figure.

SPR - 304; Read/Clear; Reset - 0x1000_0000

Figure 65-11. DBSR Register

The following table provides bit definitions for the Debug Status Register.

Table 65-14. DBSR Bit Definitions

Bit(s)	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if MSR_{DE}=0 and $DBCR0_{IDM}$=1 and a debug event causes its respective Debug Status Register bit to be set to 1. It may also be set to '1' if an imprecise debug event occurs due to a DAC event on a load or store which is terminated with error, or if an ICMP event occurs in conjunction with a EFPU FP round exception.
1	UDE	Unconditional Debug Event Set to 1 if an Unconditional debug event occurred.
2:3	MRR	Most Recent Reset. 00 - No reset occurred since these bits were last cleared by software 01 - A hard reset occurred since these bits were last cleared by software 10 - Reserved 11 - Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if an Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if an Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if an Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event

Table continues on the next page...

Table 65-14. DBSR Bit Definitions (continued)

Bit(s)	Name	Description
		Set to 1 if a Trap Taken debug event occurred.
8	IAC	Instruction Address Compare Debug Event Set to 1 if an IAC debug event occurred.
9:11	—	Reserved

13	DACW	Data Address Compare Write Debug Event Set to 1 if a write-type DAC debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a Return debug event occurred
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $PMGC0_{UDI}$=1
24	—	Reserved
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if an ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction which took a DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3'b000 and $DBSR_{IDE}$ is set to 1. Normally set to 3'b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

65.3.2.10 Debug Data Effective Address Register (DDEAR)

The Debug Data Effective Address Register (DDEAR) contains address information for data address compare debug events (DAC). DDEAR is update by hardware with the effective address of the load, store, or cache control operation when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set, in order to capture the first event address.

The DDEAR register is shown in the following table.

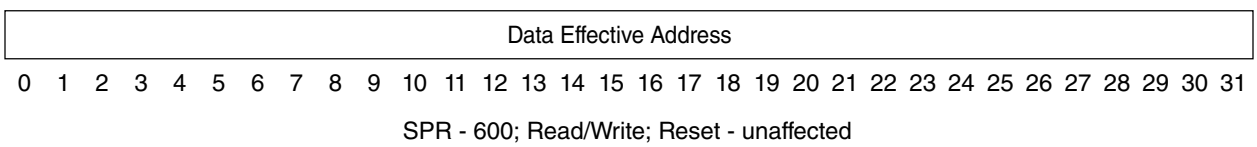

Figure 65-12. DDEAR Register

65.3.3 External Debug Resource Allocation Control Register (EDBRAC0)

The External Debug Resource Allocation Control Register (EDBRAC0) controls resource allocation when $EDBCR0_{EDM}$ is set to '1'. EDBRAC0 provides a mechanism for the hardware debugger to share certain debug resources with software. Individual resources are allocated based on the settings of EDBRAC0 when $EDBCR0_{EDM}$=1. EDBRAC0 settings are ignored when $EDBCR0_{EDM}$=0.

Hardware-owned resources which generate debug events update EDBSR0 instead of DBSR and cause entry into debug mode if the event is not masked in EDBSRMSK0, while software-owned resources which generate debug events if $DBCR0_{IDM}$=1 update DBSR, causing debug interrupts to occur if MSR_{DE}=1. EDBRAC0 is controlled via the OnCE port hardware, and is read-only to software.

The DBSR status register is always owned by software. Debug status bits in DBSR are set by software-owned debug events only while Internal Debug Mode is enabled. When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR by an event which is software-owned (other than MRR, DAC_OFST, or VLES) will cause a debug interrupt to be generated.

Debug status bits in EDBSR0 are set by hardware-owned debug events only while External Debug Mode is enabled ($EDBCR0_{EDM}$=1). When $EDBCR0_{EDM}$=1, a set bit in EDBSR0 by an event which is hardware-owned (other than IDE, DAC_OFST, or VLES) will cause entry into debug mode unless entry is masked via EDBSRMSK0.

If $EDBCR0_{EDM}$=1, DBSR status bits corresponding to hardware-owned debug events are masked from being set by hardware.

Software-owned resources may be modified by software, but only the corresponding control bits in DBCR0–8 are affected by execution of a **mtspr**, thus only a portion of these registers may be affected, depending on the allocation settings in EDBRAC0. The debug interrupt handler is still responsible for clearing DBSR bits for software-owned resources prior to returning to normal execution. Hardware always has full access to all registers and register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers is performed.

The EDBRAC0 register is shown in the following figure.

0	IDM	RST	UDE	ICMP	BRT	IRPT	TRAP	IAC1	IAC2	IAC3	IAC4	DAC1	DAC34	DAC2	0	RET	IAC5	IAC6	IAC7	IAC8	DEVT1	DEVT2	PMI	0	CIRPT	CRET	DNI	DQM	0
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 638; Read-only by Software; Reset - Unaffected by **p_reset_b,** reset to 0x00000180 by **m_por** or while in the test-logic-reset OnCE controller state

Figure 65-13. EDBRAC0 Register

Table 65-14 provides bit definitions for the Debug External Resource Control Register. Note that EDBRAC0 controls are disabled when EDBCR0EDM=0.

Table 65-15. EDBRAC0 Bit Definitions

Bit(s)	Name	Description
0	—	Reserved
1	IDM	Internal Debug Mode control 0 - Internal Debug mode may not be enabled by software. $DBCR0_{IDM}$ is owned exclusively by hardware. **mtspr** DBCR0–8 and other debug registers is always ignored. No resource sharing occurs, regardless of the settings of other fields in EDBRAC0. Hardware exclusively owns all resources. 1 - Internal Debug mode may be enabled by software. $DBCR0_{IDM}$ is owned by software. $DBCR0_{IDM}$ is software readable/writable. When $EDBRAC0_{IDM}$=1, software writes to hardware-owned bits in DBCR0–8 via **mtspr** are ignored.

Table continues on the next page...

Table 65-15. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
2	RST	Reset Field Control 0 - $DBCR0_{RST}$ owned exclusively by hardware debug. No **mtspr** access by software to $DBCR0_{RST}$ field. 1 - $DBCR0_{RST}$ accessible by software debug. $DBCR0_{RST}$ is software readable/writable.
3	UDE	Unconditional Debug Event 0 - Event owned by hardware debug. 1 - Event owned by software debug.
4	ICMP	Instruction Complete Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{ICMP}$ field. 1 - Event owned by software debug. $DBCR0_{ICMP}$ is software readable/writable.
5	BRT	Branch Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{BRT}$ field. 1 - Event owned by software debug. $DBCR0_{BRT}$ is software readable/writable.
6	IRPT	Interrupt Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{IRPT}$ field. 1 - Event owned by software debug. $DBCR0_{IRPT}$ is software readable/writable.
7	TRAP	Trap Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{TRAP}$ field. 1 - Event owned by software debug. $DBCR0_{TRA}$P is software readable/writable.
8	IAC1	Instruction Address Compare 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC1 control and status fields. 1 - Event owned by software debug. IAC1 control fields are software readable/writable.
9	IAC2	Instruction Address Compare 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC2 control and status fields. 1 - Event owned by software debug. IAC2 control fields are software readable/writable.
10	IAC3	Instruction Address Compare 3 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC3 control and status fields. 1 - Event owned by software debug. IAC3 control fields are software readable/writable.
11	IAC4	Instruction Address Compare 4 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC4 control and status fields. 1 - Event owned by software debug. IAC4 control fields are software readable/writable.
12	DAC1	Data Address Compare 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to DAC1 control and status fields.

Table continues on the next page...

Table 65-15. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
		1 - Event owned by software debug. DAC1 control fields are software readable/ writable.
13	DAC34	Data Address Compare 3 and 4 Debug Events 0 - Events owned by hardware debug. No **mtspr** access by software to DAC3 and DAC4 control and status fields. 1 - Event owned by software debug. DAC3 and DAC4 control fields are software readable/writable.
14	DAC2	Data Address Compare 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to DAC2 control and status fields. 1 - Event owned by software debug. DAC2 control fields are software readable/ writable.
15	—	Reserved
16	RET	Return Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{RET}$ field. 1 - Event owned by software debug. $DBCR0_{RET}$ is software readable/writable.
17	IAC5	Instruction Address Compare 5 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC5 control and status fields. 1 - Event owned by software debug. IAC5 control fields are software readable/writable.
18	IAC6	Instruction Address Compare 6 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC6 control and status fields. 1 - Event owned by software debug. IAC6 control fields are software readable/writable.
19	IAC7	Instruction Address Compare 7 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC7 control and status fields. 1 - Event owned by software debug. IAC7 control fields are software readable/writable.
20	IAC8	Instruction Address Compare 8 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC8 control and status fields. 1 - Event owned by software debug. IAC8 control are software readable/writable.
21	DEVT1	External Debug Event Input 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT1}$ field. 1 - Event owned by software debug. $DBCR0_{DEVT1}$ is software readable/writable.
22	DEVT2	External Debug Event Input 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT2}$ field. 1 - Event owned by software debug. $DBCR0_{DEVT2}$ is software readable/writable.
23	PMI	Performance Monitor Interrupt Debug Event

Table continues on the next page...

Table 65-15. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
		0 - Event owned by hardware debug. No **mtspr** access by software to the PMRs. Performance monitor interrupts set $EDBSR0_{PMI}$ regardless of the setting of $PMGC0_{UDI}$ 1 - Event owned by software debug. PMRs are software readable/writable. **Note:** this bit is reset to '1'.
24	—	Reserved
25	CIRPT	Critical Interrupt Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CIRPT}$ field. 1 - Event owned by software debug. $DBCR0_{CIRPT}$ is software readable/writable.
26	CRET	Critical Return Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CRET}$ field. 1 - Event owned by software debug. $DBCR0_{CRET}$ is software readable/writable.
27	DNI	DNI Instruction Debug Control 0 - DNI resource owned by hardware debug. Execution of an **e_dni** or **se_dni** instruction results in entry into debug mode. 1 - DNI resource owned by software debug. Execution of an **e_dni** or **se_dni** instruction results in either a debug interrupt ($DBCR0_{IDM}$=1 and MSR_{DE}=1) or a nop ($DBCR0_{IDM}$=0 or MSR_{DE}=0). **Note:** DNI events are not blocked during a debug session
28	DQM	Data Acquisition Messaging Registers 0 - $DEVENT_{DQTAG}$ and DDAM register are exclusively owned by hardware debug. No **mtspr** access by software to $DEVENTD_{QTAG}$ field or DDAM register. Attempted access by software is ignored. 1 - $DEVENT_{DQTAG}$ and DDAM register are owned by software. Software has read/write access to $DEVENT_{DQTAG}$ field and DDAM register.
29:31	—	Reserved

Table 65-16 shows which resources are controlled by EDBRAC0 settings.

1	-[1]	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	1	$DEVENT_{DQTAG}$, DDAM

1. Note: IDM not required to be set to enable software access.

EDBRAC0 also controls which bits or fields in DBCR0–8 and the PMRs are reset by assertion of **p_reset_b** when $EDBCR0_{EDM}$=1. Only software-owned bits or fields as shown in Table 65-16 are affected in this case, except that $DBCR0_{RST}$ and $DBSR_{MRR}$ are updated by assertion of **p_reset_b** regardless of the value of $EDBCR0_{EDM}$ or EDBRAC0.

65.3.4 Debug Event Select Register (DEVENT)

The Debug Event Select Register allows instrumented software to internally generate signals when a **mtspr** instruction is executed and this register is accessed. The values written to this register determine which of the **p_devnt_out[0:7]** processor output signals are asserted upon access. Writing a '1' to any of these bit positions will cause a one clock pulse to be generated on the corresponding output. For **p_devnt_out[0:3]**, a corresponding **jd_watchpt[x]** output is asserted as well to indicate a watchpoint has occurred. These signals may be used for internal core debug resources as well as for SoC level cross-triggering. See the SoC User's Manual for more information on SoC use cases.

The $DEVENT_{DEVNT}$ register field value is undefined on a read; it may or may not remain set to the last value written. Since it is unconditionally shared by hardware debug and software, software should not rely on any value remaining.

The upper 8 bits of the DEVENT register also provide the DQTAG used to identify channels within Data Acquisition Messages. See the "Data Acquisition ID Tag Field" section in the Core (e200z4204n3) Nexus 3 Module chapter for more detail on the DQTAG.

The DEVENT register is shown in the following figure.

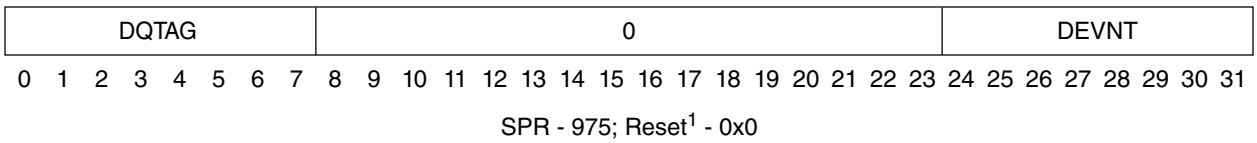

Figure 65-14. DEVENT Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**. Note that DEVNT field is shared by hardware and software but is always reset by **p_reset_b**.

The following table provides bit definitions for the Debug Event Register.

Table 65-17. DEVENT Bit Definitions

Bit(s)	Name	Description
0:7	DQTAG	Data Acquisition Message IDTAG channel identifier (supplied to Nexus 3)
8:23	—	Reserved, should be cleared.
24:31	DEVNT	Debug Event Signals 00000000 - No signal is asserted xxxxxxx1 - **p_devnt_out[0]** and **jd_watchpt[12]** are asserted for one clock xxxxxx1x - **p_devnt_out[1]** and **jd_watchpt[13]** are asserted for one clock xxxxx1xx - **p_devnt_out[2]** and **jd_watchpt[20]** are asserted for one clock xxxx1xxx - **p_devnt_out[3]** and **jd_watchpt[21]** are asserted for one clock xxx1xxxx - **p_devnt_out[4]** is asserted for one clock xx1xxxxx - **p_devnt_out[5]** is asserted for one clock x1xxxxxx - **p_devnt_out[6]** is asserted for one clock 1xxxxxxx - **p_devnt_out[7]** is asserted for one clock

65.3.5 Debug Data Acquisition Message Register (DDAM)

The Debug Data Acquisition Message Register allows instrumented software to generate real-time Data Acquisition Messages (as defined by Nexus 3) via a **mtspr** instruction to this register. See the "Data Acquisition Messaging" section in the Core (e200z4204n3) Nexus 3 Module chapter for details.

The DDAM register is shown in the following figure.

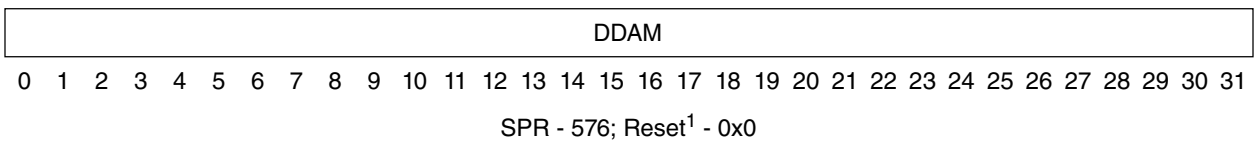

Figure 65-15. DDAM Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for the Debug Data Acquisition Message Register.

Table 65-18. DDAM Bit Definitions

Bit(s)	Name	Description
0:31	DDAM	Value to be transmitted in a Data Acquisition Message (DQM) (supplied to Nexus 3 with strobe)

65.4 Using Debug Resources for Stack Limit Checking

The DAC1,2 and DAC3,4 resources can be used for stack overflow/underflow detection when not being used as a hardware or software debug resource. Stack limit checking is available regardless of EDM or IDM mode, and when resources used for stack limit checking are owned by software, will utilize a DSI or machine check exception. Software-owned stack limit checking does not require IDM to be set. Hardware owned stack limit checking requires EDM to be set.

When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by software, DAC events are not generated for resources configured to perform stack limit checking, and no DBSR DAC status flag will be set due to a detected

stack limit violation. Instead, depending on the processor mode, a data storage interrupt or a machine check exception is signaled. When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by hardware, DAC events will be generated for resources configured to perform stack limit checking, and the EDBSR0 DAC status flag will be set due to a detected stack limit violation, causing entry into debug halted mode in the same way as a DAC exception normally does. The only difference is that qualification of the access address is performed as discussed in the next paragraph.

Stack limit checking is implemented in the same way as range compares using DAC1,2 or 3,4, or extended masking using DAC1 or DAC3, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions which may calculate an EA using GPR R1 such as cache, management instructions, or instructions which indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DAC resources configured to perform stack limit checking are not owned by hardware, if a stack limit violation occurs when performing the load or store, the access is aborted, and an error report machine check is generated, with MCSRR0 pointing to the address of the load or store access which generated the stack overflow/underflow. If DAC resources configured to perform stack limit checking are owned by hardware, then a normal DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event.

Enabling of this functionality is described in more detail in Table 65-9. Note that IDM is not required to be set for software-owned stack limit checking.

In contrast to the normal case of DAC address matching resulting in a debug event, the stack limit check address compare logic operates differently for stack limit checking. When using resources for stack limit checking, a DACn hit to a resource enabled for performing stack limit checking on a stack access indicates a stack limit violation.

When stack limit checking is enabled by the setting of the $DBCR4_{DAC1CFG}$ field to '1000' or the $DBCR8_{DAC3CFG}$ field to '1000' (or both), and the corresponding DACn resources are owned by software, DACn events are not generated and the DBSR DAC status flag will not be set due to a detected stack limit hit. Instead, if stack limit checking is enabled for supervisor mode stack accesses in DAC1 or DAC3, and a compare hit occurs for a supervisor mode stack access (A load or store using GPR R1 in the <EA> calculation), a machine check exception is signaled. If stack limit checking is enabled for user mode accesses, a DSI exception is signaled when a stack limit checking enabled DAC1 or DAC3 compare hit occurs for a user mode access. A watchpoint for DAC1 or DAC3 will be generated when the stack limit violation is detected, even though the instruction does not complete. Stack limit checking for supervisor mode stack accesses is considered

enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '10', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '10', or both. Stack limit checking for user mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '01', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '01', or both. Note that unlike regular debug DAC events, both halves of a misaligned access are checked for limit violations.

When stack limit checking is enabled for a stack access, and DACn resources are owned by hardware, the EDBSR0 DAC status flag will be set due to a detected stack limit violation, to cause entry into debug halted mode or to generate a watchpoint, or both, in the same way as a DAC event normally does, i.e. after the access has completed. The only difference is that qualification of the access address is performed as discussed in the next paragraph. If the access is aborted due to a DSI or other exception such as machine check condition, the $EDBSR0_{IDE}$ status bit will also be set to indicate that the data access instruction was not completed.

Stack limit checking is implemented in the same way as address compares using DACn, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions which may calculate an EA using GPR R1 such as cache, management instructions, or instructions which indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DACn resources are not owned by hardware, if a stack limit violation occurs (a hit to a stack limit enabled DAC is detected) when performing the load or store, the access request is aborted and the access is not performed. Instead, for supervisor mode accesses, an error report machine check exception is generated, with MCSRR0 pointing to the address of the load or store instruction which generated the stack overflow/underflow, and for user mode accesses, a DSI exception is generated, with SRR0 pointing to the address of the load or store instruction which generated the stack overflow/underflow. If all stack limit check enabled DACn resources are owned by hardware, then a DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event. In this case, the instruction and access will normally have completed, in the same manner as a normal DAC event.

Independent limit checks for supervisor and user accesses may be implemented by allocating independent DACn resources to each, or a single limit may be applied using a single DACn resource. Typically, a DAC1,2 pair operating in exclusive address range mode is utilized for stack limit checking for a single shared limit. For separate limits, DAC3,4 may also be utilized. If more than one DACn resource is utilized, a DAC hit on any resource utilized for stack limit checking will cause the corresponding stack limit exception action to occur. If both a hardware-owned and a software-owned resource

generate a stack limit exception for a given load or store, the software resource will have priority, since it is detected prior to completion of the access, and the access is aborted, thus the hardware event will not occur.

Enabling of this functionality is described in more detail in the description of the DACnCFG fields in Table 65-9 and Table 65-12 in Debug Control and Status registers. Note that for DAC1 and DAC2, access type (read, write) control is part of DBCR0.

65.5 External Debug Support

External debug support is supplied through the OnCE controller serial interface which allows access to internal CPU registers and other system state while the CPU is halted in debug mode. All debug resources including DBCR0–8, DBSR, IAC1–8, DAC1–4, and DVC1–2 are accessible through the serial OnCE interface in external debug mode. Setting the $EDBCR0_{EDM}$/$DBCR0_{EDM}$ bit to '1' through the OnCE interface enables external debug mode, and unless otherwise permitted by the settings in EDBRAC0, disables software updates to the debug control registers. When $EDBCR0_{EDM}$ is set, debug events enabled to set respective status bits will also cause the CPU to enter Debug Mode if the event is not masked in EDBSRMSK0, as opposed to generating Debug Interrupts, unless the specific events are allocated to software via the settings in EDBRAC0. In Debug Mode, the CPU is halted at a recoverable boundary, and an external Debug Control Module may control CPU operation through the On-Chip Emulation logic (OnCE).

Note that the descriptions of events in the subsections of Software Debug Events and Exceptions refer to setting DBSR status bits, however, when resources are owned by hardware, the events for those resources set the respective status bits in EDBSR0 instead of DBSR.

Note

On the initial setting of $EDBCR0_{EDM}$ to '1', other bits in DBCR0 will remain unchanged. After $EDBCR0_{EDM}$ has been set, all debug register resources may be subsequently controlled through the OnCE interface. The CPU should be placed into debug mode via the OCR_{DR} control bit prior to writing EDM to '1'. This gives the debugger the opportunity to cleanly write to the DBCRx registers and the DBSR to clear out any residual state / control information which could cause unintended operation.

Note

It is intended for the CPU to remain in external debug mode ($EDBCR0_{EDM}$=1) in order to single step or perform other debug mode entry/ reentry via the OCR_{DR}, by performing go+noexit commands, or by assertion of the **jd_de_b** signal.

Note

$EDBCR0_{EDM}$ operation will be blocked if OnCE operation is disabled (**jd_en_once** negated) regardless of whether it is set or cleared. This means that if $EDBCR0_{EDM}$ was previously set, and then **jd_en_once** is negated (this should not occur), entry into debug mode will be blocked, and all *hardware* debug events are blocked. Watchpoints are not blocked.

Due to clock domain design, the CPU clock (**m_clk**) must be active in order to perform writes to debug registers other than the OnCE Command register (OCMD), the OnCE Control register (OCR), External Debug Control Register 0 (EDBCR0), External Debug Status register 0 (EDBSR0), External Debug Status Register Mask 0 (EDBSRMSK0), or the $EDBCR0_{EDM}$ bit. Register read data is synchronized back to the **j_tclk** clock domain. The OnCE Control register provides the capability of signaling the system level clock controller that the CPU clock should be activated if not already active.

Updates to the DBCRx, DBSR, and most other debug registers via the OnCE interface should be performed with the CPU in debug mode to guarantee proper operation. Due to the various points in the CPU pipeline where control is sampled and event handshaking is performed, it is possible that modifications to these registers while the CPU is running may result in early or late entry into debug mode, and may have incorrect status posted in the DBSR register.

If resource sharing is enabled via EDBRAC0, updates to the EDBRAC0, DBCRx, and DBSR registers must be performed with the CPU in debug mode, since simultaneous updates of register portions could otherwise be attempted, and such updates are not guaranteed to properly occur. The results of such an attempt are undefined.

65.5.1 External Debug Registers

The external debug registers are used for controlling several debug aspects of the core and reporting status while in External Debug Mode.

65.5.1.1 External Debug Control Register 0 (EDBCR0)

EDBCR0 is a control register accessible to an external debugger through the OnCE/Jtag port. An external development tool can write to this register in order to enable external debug mode or to enable Debugger Notify Halt instructions (**e_dnh**, **se_dnh**), as well as to control aspects of Debugger Notify Interrupt instructions (**e_dni**, **se_dni**).

EDBCR0 is not accessible by software, However, the state of $EDBCR0_{EDM}$ is reflected as a read-only bit in $DBCR0_{EDM}$ to software. There is only one physical EDM bit implemented; it is reflected in both the DBCR0 and EDBCR0 registers, and may be written and read using either register by the hardware debugger. For future compatibility, EDBCR0 updates are preferred.

EDBCR0 is shown in the following figure.

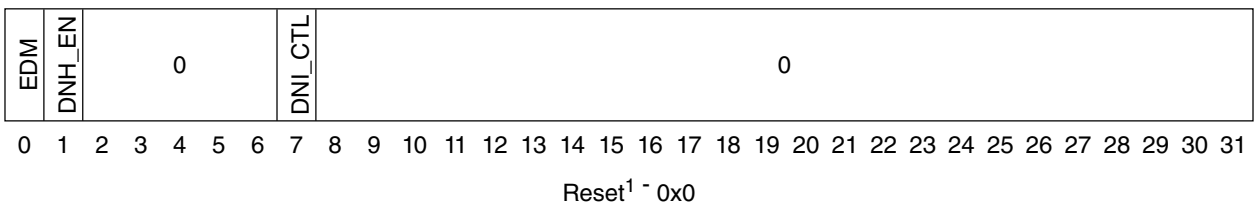

Figure 65-16. EDBCR0 Register

Note

[1] EDBCRO is affected (reset) by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b.**

The following table provides bit definitions for External Debug Control Register 0.

Table 65-19. EDBCR0 Bit Definitions

Bit(s)	Name	Description
0	EDM	External Debug Mode. This bit is also reflected in DBCR0 0 - External debug mode disabled. Internal debug events not mapped into external debug events. 1 - External debug mode enabled. Hardware-owned events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCRx, IAC1-8, DAC1-4, DVC1-2[U]} unless permitted by settings in EDBRAC0. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset **p_reset_b**. This allows the debugger to set up hardware debug events which remain active across a processor reset.
1	DNH_EN	**dnh** Instruction Enable 0 - execution of **e_dnh** and **se_dnh** instructions cause illegal instruction exceptions to occur.

Table continues on the next page...

Table 65-19. EDBCR0 Bit Definitions (continued)

Bit(s)	Name	Description
		1 - execution of **e_dnh** and **se_dnh** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of EDM.
2:6	---	Reserved
7	DNI_CTL	**dni** Instruction Control 0 - When the **dni** resource is owned by hardware, the MSR_{DE} bit is cared, and when MSRDE=0, execution of **e_dni** and **se_dni** instructions are nop'ed and no entry into debug mode occurs. 1 - When the **dni** resource is owned by hardware, the MSR_{DE} bit is don't-cared, and execution of **e_dni** and **se_dni** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of MSR_{DE}. Note that this control bit is only used when the dni resource is owned by hardware via control in $EDBRAC0_{DNI}$, and thus also only when EDM=1
8:31	---	Reserved

65.5.1.2 External Debug Status Register 0 (EDBSR0)

The External Debug Status Register 0 (EDBSR0) contains status on debug events owned by hardware. The External Debug Status Register 0 is set via hardware, and read and cleared via OnCE access by the debugger. Clearing is done by writing to the External Debug Status Register via the OnCE port, with a '1' in any bit position that is to be cleared and '0' in all other bit positions. The write data to EDBSR0 is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. The EDBSR0 register is shown in the following figure.

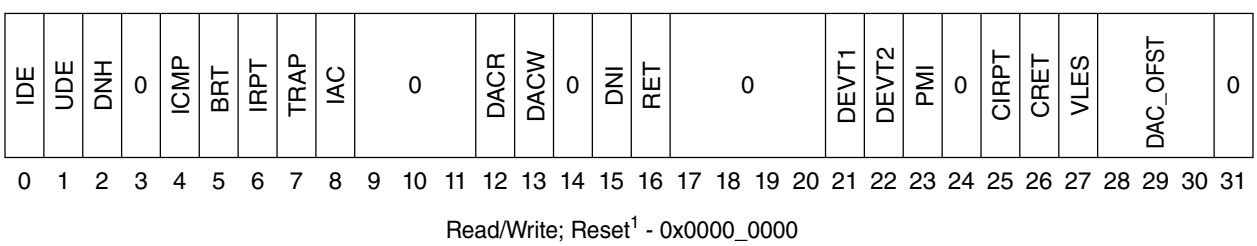

Figure 65-17. EDBSR0 Register

Note

[1] Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while $EDBCRO_{EDM}$=0.

The following table provides bit definitions for External Debug Status Register 0.

Table 65-20. EDBSR0 Bit Definitions

Bit(s)	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if $EDBCR0_{EDM}$=1 and an imprecise debug event occurs for a hardware-owned DAC event due to a load or store which is terminated with error, or if a hardware-owned ICMP event occurs in conjunction with a EFPU round exception. This bit will not be set for imprecise debug events which are masked via settings in EDBSRMSK0.
1	UDE	Unconditional Debug Event Set to 1 if a hardware-owned Unconditional debug event occurred.
2	DNH	Debugger Notify Halt Event Set to 1 if a debugger notify halt instruction was executed and caused a debug halt.
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if a hardware-owned Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if a hardware-owned Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if a hardware-owned Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a hardware-owned Trap Taken debug event occurred.
8	IAC	Instruction Address Compare 1 Debug Event Set to 1 if a hardware-owned IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a hardware-owned read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a hardware-owned write-type DAC1 debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a hardware-owned DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a hardware-owned Return debug event occurred
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a hardware-owned DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a hardware-owned DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $EDBRAC0_{PMI}$=0 regardless of the setting of $PMGC0_{UDI}$
24	—	Reserved
25	CIRPT	Critical Interrupt Taken Debug Event

Table continues on the next page...

Table 65-20. EDBSR0 Bit Definitions (continued)

Bit(s)	Name	Description
		Set to 1 if a hardware-owned Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a hardware-owned Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if a hardware-owned ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Also set for execution of an e_dnh or se_dnh instruction when enabled by $EDBCR0_{DNH_EN}$. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction which took a hardware-owned DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3'b000 and $EDBSR0_{IDE}$ is set to 1. Normally set to 3'b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

65.5.1.3 External Debug Status Register Mask 0 (EDBSRMSK0)

The External Debug Status Register Mask 0 (EDBSRMSK0) is used to mask debug events set in EDBSR0 from causing entry into debug halted mode. A '1' stored in any mask bit prevents debug mode entry caused by the corresponding bit being set in EDBSR0. The mask has no effect on DBSR actions or on the setting of EDBSR0 status bits by hardware-owned events, except that the IDE bit will not be set by imprecise hardware-owned debug events which are masked. EDBSRMSK0 may be used to allow debug events owned by hardware to be configured for watchpoint generation purposes without causing debug mode entry when the watchpoint occurs. EDBSRMSK0 is read and written via OnCE access by the debugger. No software access is provided. The EDBSRMSK0 register is shown in the following figure.

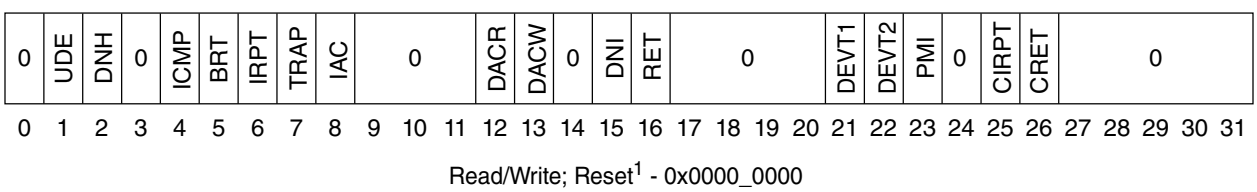

Figure 65-18. EDBSRMSK0 Register

Note

[1] Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while $EDBCRO_{EDM}$=0.

The following table provides bit definitions for External Debug Status Register Mask 0.

Table 65-21. EDBSRMSK0 Bit Definitions

Bit(s)	Name	Description
0	—	Reserved
1	UDE	Unconditional Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{UDE}$
2	DNH	Debugger Notify Halt Event Set to 1 to mask debug mode entry by $EDBSR0_{DNH}$
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{ICMP}$
5	BRT	Branch Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{BRT}$
6	IRPT	Interrupt Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{IRPT}$
7	TRAP	Trap Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{TRAP}$
8	IAC	Instruction Address Compare Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{IAC}$
9:11	—	Reserved
12	DACR	Data Address Compare 1 Read Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DACR}$
13	DACW	Data Address Compare 1 Write Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DACW}$
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DNI}$
16	RET	Return Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{RET}$
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DEVT1}$
22	DEVT2	External Debug Event 2 Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DEVT2}$
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{PMI}$
24	—	Reserved
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{CIRPT}$
26	CRET	Critical Return Debug Event

Table continues on the next page...

Table 65-21. EDBSRMSK0 Bit Definitions (continued)

Bit(s)	Name	Description
		Set to 1 to mask debug mode entry by $EDBSR0_{CRET}$
22:31	—	Reserved

65.5.1.4 External Debug Data Effective Address Register (EDDEAR)

The External Debug Data Effective Address Register (EDDEAR) contains address information for hardware-owned data address compare debug events. EDDEAR is update by hardware with the effective address of the load, store, or cache control operation when an unmasked data address compare event is recorded in EDBSR0 if the previous values of $EDBSR0_{DAC\{R,W\}}$ bits which are unmasked in EDBSRMSK0 are zero. Once an EDDEAR update is performed, these unmasked bits must be cleared by the hardware debugger prior to another EDDEAR hardware update occurring. A subsequent hardware-owned unmasked DAC event will not update the EDDEAR register if either of the $EDBSR0_{DAC\{R,W\}}$ bits are set and are not masked by EDBSRMSK0, in order to capture the first unmasked event address. EDDEAR is read and written via OnCE access by the debugger. No software access is provided.

The EDDEAR register is shown in the following figure.

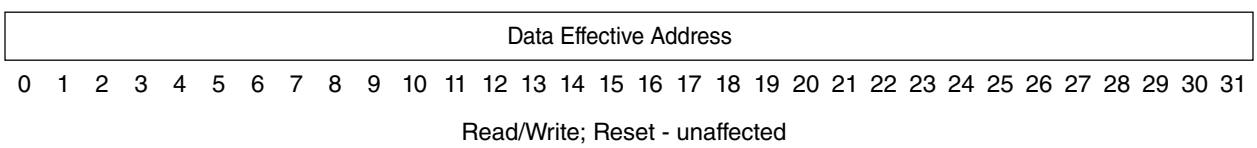

Figure 65-19. EDDEAR Register

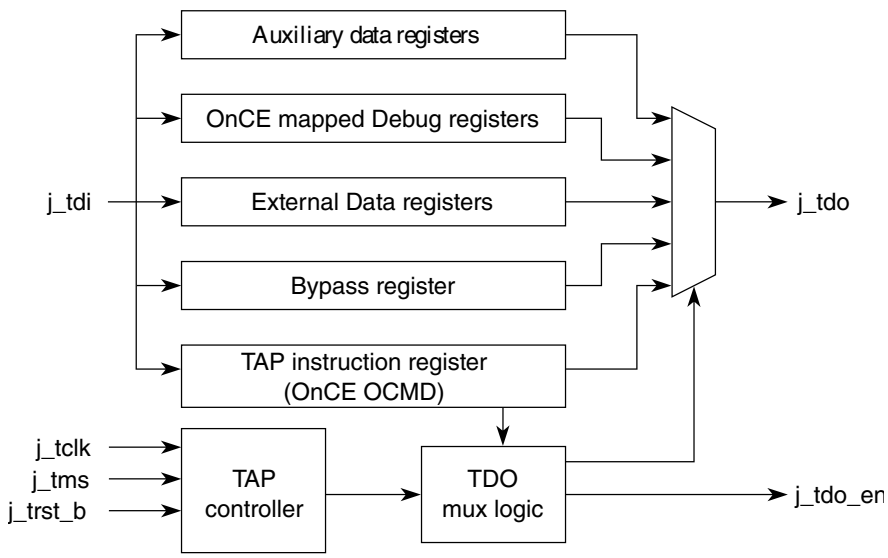
65.5.2 OnCE Introduction

The e200z4204n3 on-chip emulation circuitry (OnCE™/Nexus Class 1 interface) provides a means of interacting with the e200z4204n3 core and integrated system so that a user may examine registers, memory, or on-chip peripherals facilitating hardware/ software development. OnCE operation is controlled via an industry standard IEEE 1149.1 TAP controller. By using public instructions, the external hardware debugger can freeze or halt the CPU, read and write internal state, and resume normal execution. The core does not contain IEEE 1149.1 standard boundary cells on its interface, as it is a building block for further integration. It does not support the JTAG related boundary scan instruction functionality, although JTAG public instructions may be decoded and signaled to external logic.

The OnCE logic provides for Nexus Class 1 static debug capability (utilizing the same set of resources available to software while in internal debug mode).

In order to enable full OnCE operation, the **jd_enable_once** input signal must be asserted. In some system integrations, this is automatic, since the input will be tied asserted. Other integrations may require the execution of the Enable OnCE command via the TAP and appropriate entry of serial data. Exact requirements will be documented by the integrated product specification. The **jd_enable_once** input signal should not change state during a debug session, or undefined activity may occur.

The following figures show the TAP controller state model and the TAP registers implemented by the OnCE logic.



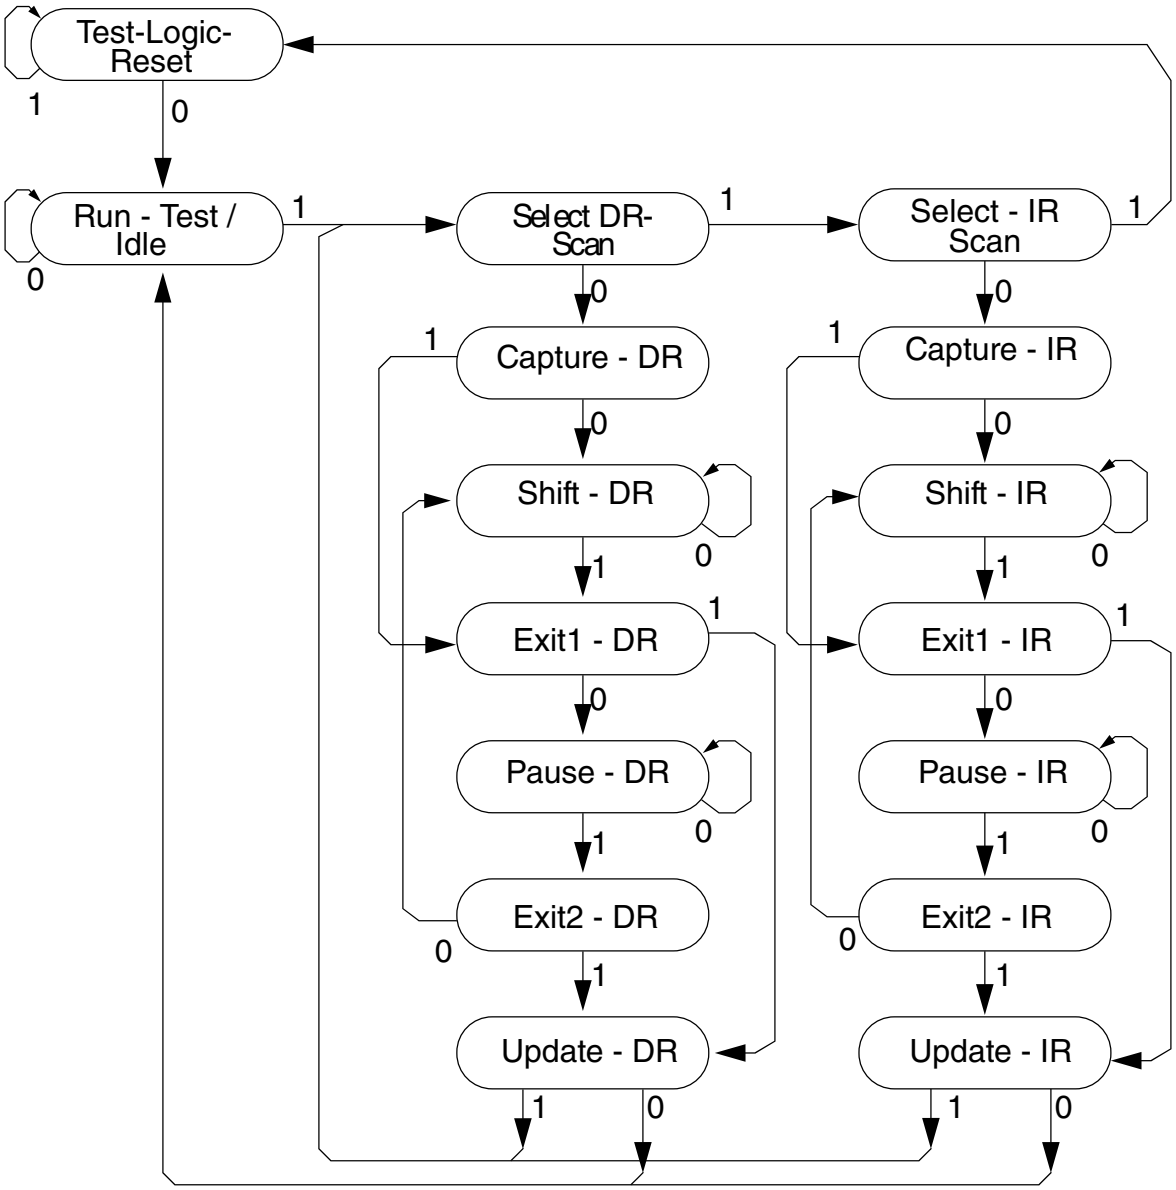


Figure 65-20. OnCE TAP Controller and Registers

The OnCE controller is implemented as a 16-state FSM, with a one-to-one correspondence to the states defined for the JTAG TAP controller.

Access to processor registers and the contents of memory locations are performed by enabling external debug mode (setting $EDBCR0_{EDM}$ to '1'), placing the processor into debug mode, followed by scanning instructions and data into and out of the CPU Scan Chain (CPUSCR); execution of scanned instructions by the CPU is used as the method to access required data. Memory locations may be read by scanning a load instruction into the CPU core which will reference the desired memory location, executing the load instruction, and then scanning out the result of the load. Other resources are accessed in a similar manner.

The initial entry by the CPU into the debug state (or mode) from normal, Waiting, Stopped, or Halted states (all indicated via the OnCE Status Register (OSR), OnCE Status Register) by assertion of one or more debug requests, begins a *debug session*. The **jd_debug_b** output signal indicates that a debug session is in progress, and the OSR will

indicate the CPU is in the debug state. Instructions may the be single-stepped by scanning new values into the CPUSCR, and performing a OnCE go+noexit command (See OnCE Command Register (OCMD)). The CPU will then temporarily exit the debug state (but not the debug session) to execute the instruction, and will then return to the debug state (again indicated via the OnCE Status Register (OSR)). The debug session remains in force until the final OnCE go+exit command is executed, at which time the CPU will return to the previous state it was in (unless a new debug request is pending). A scan into the CPUSCR is required prior to executing each go+exit or go+noexit OnCE command.

65.5.3 JTAG/OnCE Pins

The JTAG/OnCE pin interface is used to transfer OnCE instructions and data to the OnCE control block. Depending on the particular resource being accessed, the CPU may need to be placed in the Debug mode. For resources outside of the CPU block and contained in the OnCE block, the processor is not disturbed, and may continue execution. If a processor resource is required, an internal debug request (**dbg_dbgrq**) may be asserted to the CPU by the OnCE controller, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter Debug Mode, and wait for further commands. Asserting **dbg_dbgrq** will cause the chip to temporarily exit the Waiting, Stopped or Halted power management states.

The following table details the primary JTAG/OnCE interface signals.

Table 65-22. JTAG/OnCE Primary Interface Signals

Signal name	Type	Description
j_trst_b	I	JTAG test reset
j_tclk	I	JTAG test clock
j_tms	I	JTAG test mode select
j_tdi[0:31]	I	JTAG test data or parallel input
j_tdo	O	Test data out to master controller or pad
j_tdo_en[1]	O	Enables TDO output buffer
j_parallel_IR_en	I	Enables parallel loading of IR during Shift_IR state
j_parallel_DR_en	I	Enables parallel loading of DR during Shift_DR state

1. j_tdo_en is asserted when the TAP controller is in the shift_DR or shift_IR state.

A full description of JTAG pins is provided in the JTAG Support Signals section of the Core (e200z4204n3) Core Complex Overview.

65.5.4 OnCE Internal Interface Signals

The following paragraphs describe the OnCE interface signals to other internal blocks associated with the OnCE controller.

65.5.4.1 CPU Debug Request (dbg_dbgrq)

The **dbg_dbgrq** signal is asserted by the OnCE control logic to request the CPU to enter the debug state. It may be asserted for a number of different conditions, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter the debug mode, and wait for further commands.

65.5.4.2 CPU Debug Acknowledge (cpu_dbgack)

The **cpu_dbgack** signal is asserted by the CPU upon entering the debug state. This signal is used as part of the handshake mechanism between the OnCE control logic and the rest of the CPU. The CPU core may enter debug mode either through a software or hardware event.

65.5.4.3 CPU Address, Attributes

The CPU address and attribute information are used by the Nexus3 unit with information for real-time address trace information.

65.5.4.4 CPU Data

The CPU data buses are used to supply the Nexus3 debug unit with information for real-time data trace capability.

65.5.5 OnCE Interface Signals

The following paragraphs describe additional OnCE interface signals to other external blocks such as a Nexus controller and external blocks which may need information pertaining to debug operation.

65.5.5.1 OnCE Enable (jd_en_once)

The OnCE enable signal **jd_en_once** is used to enable the OnCE controller to allow certain instructions and operations to be executed. Assertion of this signal will enable the full OnCE command set, as well as operation of control signals and OnCE Control register functions. When this signal is disabled, only the Bypass, ID and Enable_OnCE commands are executed by the OnCE unit, and all other commands default to a "Bypass" command. The OnCE Status register (OSR) is not visible when OnCE operation is disabled. In addition, OnCE Control register (OCR) functions are disabled, as is the operation of the **jd_de_b** input. Secure systems may choose to leave the **jd_en_once** signal negated until a security check has been performed. Other systems should tie this signal asserted to enable full OnCE operation. The **j_en_once_regsel** output signal is provided to assist external logic performing security checks.

The **jd_en_once** input must only change state during the Test-Logic-Reset, Run-Test/ Idle, or Update_DR TAP states. A new value will take affect after one additional **j_tclk** cycle of synchronization. In addition, **jd_enable_once** input signal must not change state during a debug session, or undefined activity may occur.

65.5.5.2 OnCE Debug Request/Event (jd_de_b, jd_de_en)

If implemented at the SoC level, a system level bidirectional open drain debug event pin **DE_b** (not part of the e200z4204n3 interface) provides a fast means of entering the Debug Mode of operation from an external command controller (when input) as well as a fast means of acknowledging the entering of the Debug Mode of operation to an external command controller (when output). The assertion of this pin by a command controller causes the CPU core to finish the current instruction being executed, save the instruction pipeline information, enter Debug Mode, and wait for commands to be entered. If **DE_b** was used to enter the Debug Mode then **DE_b** must be negated after the OnCE controller responds with an acknowledge and before sending the first OnCE command. The assertion of this pin by the CPU Core acknowledges that it has entered the Debug Mode and is waiting for commands to be entered.

To support operation of this system pin, the OnCE logic supplies the **jd_de_en** output and samples the **jd_de_b** input when OnCE is enabled (**jd_en_once** asserted). Assertion of **jd_de_b** will cause the OnCE logic to place the CPU into Debug Mode. Once Debug Mode has been entered, the **jd_de_en** output will be asserted for three **j_tclk** periods to signal an acknowledge. **jd_de_en** can be used to enable the open-drain pulldown of the system level **DE_b** pin.

For systems which do not implement a system level bidirectional open drain debug event pin **DE_b**, the **jd_de_en** and **jd_de_b** signals may still be used to handshake debug entry.

65.5.5.3 OnCE Debug Output (jd_debug_b)

The OnCE Debug output **jd_debug_b** is used to indicate to on-chip resources that a debug session is in progress. Peripherals and other units may use this signal to modify normal operation for the duration of a debug session, which may involve the CPU executing a sequence of instructions solely for the purpose of visibility/system control which are not part of the normal instruction stream the CPU would have executed had it not been placed in debug mode. This signal is asserted the first time the CPU enters the debug state, and remains asserted until the CPU is released by a write to the OnCE Command Register with the GO and EX bits set, and a register specified as either "No Register Selected" or the CPUSCR. This signal will remain asserted even though the CPU may enter and exit the debug state for each instruction executed under control of the OnCE controller. See OnCE Command Register (OCMD) for more information on the function of the GO and EX bits. This signal is not normally used by the CPU.

65.5.5.4 CPU Clock On Input (jd_mclk_on)

The CPU Clock On input **jd_mclk_on** is used to indicate that the CPU's **m_clk** input is active. This input signal is expected to be driven by system logic external to the e200z4204n3 core, is synchronized to the **j_tclk** (scan clock) clock domain, and is presented as a status flag on the **j_tdo** output during the Shift_IR state. External firmware may use this signal to ensure proper scan sequences will occur to access debug resources in the **m_clk** clock domain.

65.5.5.5 Watchpoint Events (jd_watchpt[0:31])

The **jd_watchpt[0:31]** signals may be asserted by the OnCE control logic to signal that a watchpoint condition has occurred. Watchpoints do not directly cause the CPU to be affected. They are provided to allow external visibility only or for triggering purposes. Watchpoint events are conditioned by the settings in the DBCRxx registers, as well as by the DEVENT register, the DTC/DTSA/DTEA registers, and the Performance Monitor control register settings. Refer to Table 65-28 for details of the signal assignments. Note that assertion of most watchpoint outputs is conditioned on being in EDM or IDM. The Performance monitor, DEVENT, and DTC watchpoints are not conditioned however, and may assert regardless of the state of EDM or IDM. In addition, DAC1 or DAC3 watchpoints may be generated for stack limit violation occurrences when those resources are configured to perform stack limit checking, regardless of the state of EDM or IDM.

65.5.5.6 Update DR w/go+exit (j_ocmd_go_exit)

This signal indicates the TAP controller is in the Update_DR state and that the go and exit bits in the OnCE Command register are high, and RS indicates "no register selected". This signal will assert regardless of whether the CPU is currently in debug mode. It may be monitored by external logic to cause a synchronous exit from debug mode of other modules (but not other CPUs) in the system. A debugger can place all of the CPU tap controllers in parallel, scan in a go+exit command with "no register selected", and sequence through the Update_DR state to cause any CPU currently in debug mode to exit. CPUs which are not it debug mode will ignore the command.

65.5.6 OnCE Controller and serial interface

The OnCE Controller contains the OnCE command register, the OnCE decoder, and the status/control register. The following figure is a block diagram of the OnCE controller. In operation, the OnCE Command register acts as the IR for the TAP controller, and all other OnCE resources are treated as data registers (DR) by the TAP controller. The Command register is loaded by serially shifting in or parallel loading commands during the TAP controller Shift-IR state, and is loaded during the Update-IR state. The Command register selects a resource to be accessed as a data register (DR) during the TAP controller Capture-DR, Shift-DR and Update-DR states.

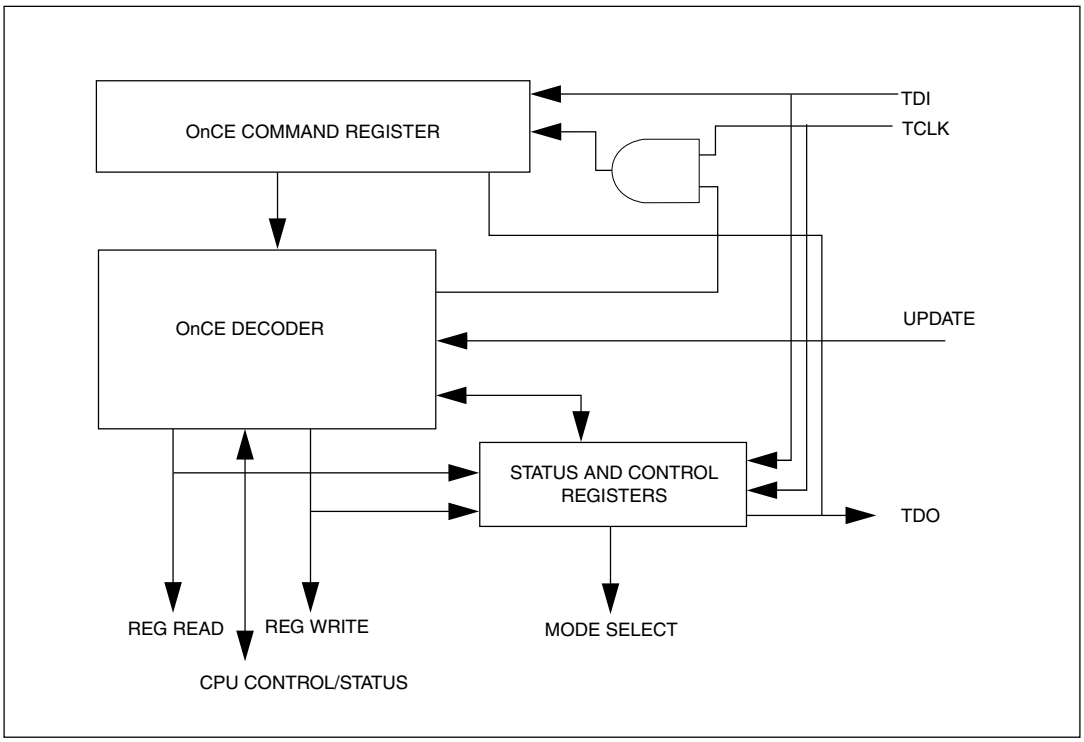

Figure 65-21. OnCE Controller and Serial Interface

65.5.6.1 OnCE Status Register

Status information regarding the state of the CPU is latched into the OnCE Status register when the OnCE controller state machine enters the Capture-IR state. When OnCE operation is enabled, this information is provided on the **j_tdo**[31] output in serial fashion when the Shift_IR state is entered following a Capture-IR. Information is shifted out least significant bit first.

Parallel output of the IR status (OSR) is available via the j_tdo[22:31] outputs during the first cycle of the Shift_IR state(s), with j_tdo[22] corresponding to the most-significant bit of the OSR (MCLK).

MCLK	ERR	0	RESET	HALT	STOP	DEBUG	WAIT	0	1
0	1	2	3	4	5	6	7	8	9

Figure 65-22. OnCE Status Register

The following table provides bit definitions for the Once Status Register.

Table 65-23. OnCE Status Register Bit Definitions

Bit(s)	Name	Description
0	MCLK	MCLK

Table continues on the next page...

Table 65-23. OnCE Status Register Bit Definitions (continued)

Bit(s)	Name	Description
		m_clk Status Bit 0 - Inactive state 1 - Active state This status bit reflects the logic level on the **jd_mclk_on** input signal after capture by **j_tclk**.
1	ERR	ERROR This bit is used to indicate that an error condition occurred during attempted execution of the last single-stepped instruction (GO+NoExit with CPUSCR or No Register Selected in OCMD), and that the instruction may not have been properly executed. This could occur if an Interrupt (all classes including External, Critical, machine check, Storage, Alignment, Program, etc.) occurred while attempting to perform the instruction single step. In this case, the CPUSCR will contain information related to the first instruction of the Interrupt handler, and no portion of the handler will have been executed.
3	RESET	RESET Mode This bit reflects the inverted logic level on the CPU **p_reset_b** input after capture by **j_tclk**.
4	HALT	HALT Mode This bit reflects the logic level on the CPU **p_halted** output after capture by **j_tclk**.
5	STOP	STOP Mode This bit reflects the logic level on the CPU **p_stopped** output after capture by **j_tclk**.
6	DEBUG	Debug Mode This bit is asserted once the CPU is in debug mode. It is negated once the CPU exits debug mode (even during a debug session)
7	WAIT	Waiting Mode This bit reflects the logic level on the CPU **p_waiting** output after capture by **j_tclk**.
8	0	Reserved, set to 0 for 1149.1 compliance
9	1	Reserved, set to 1 for 1149.1 compliance

65.5.6.2 OnCE Command Register (OCMD)

The OnCE Command Register (OCMD) is a 10-bit shift register that receives its serial or parallel data from the TDI pins and serves as the instruction register (IR). It holds the 10-bit commands to be used as input for the OnCE Decoder. The Command Register is shown in Figure 65-23. The OCMD is updated when the TAP controller enters the Update-IR state. It contains fields for controlling access to a resource, as well as controlling single-step operation and exit from OnCE mode.

Although the OCMD is updated during the Update-IR TAP controller state, the corresponding resource is accessed in the DR scan sequence of the TAP controller, and as such, the Update-DR state must be transitioned through in order for an access to occur. In addition, the Update-DR state must also be transitioned through in order for the single-step and/or exit functionality to be performed, even though the command appears to have no data resource requirement associated with it.

Reset - 10'b1000000010 on assertion of **j_trst_b** or **m_por** , or while in the Test_Logic_Reset state

Figure 65-23. OnCE Command Register

Table 65-24 provides bit definitions for the Once Command Register.

Table 65-24. OnCE Command Register Bit Definitions

Bit(s)	Name	Description
0	R/W	Read/Write Command Bit The R/W bit specifies the direction of data transfer. The table below describes the options defined by the R/W bit. **Note:** The R/W bit generally ignored for read-only or write-only registers, although the PC FIFO pointer is only guaranteed to be update when R/W=1. In addition, it is ignored for all bypass operations. When performing writes, most registers are sampled in the Capture-DR state into a 32-bit shift register, and subsequently shifted out on **j_tdo[31]** during the first 32 clocks of Shift-DR, or on the j_tdo[0:31] outputs during the first clock of Shift-DR. 0 - Write the data associated with the command into the register specified by RS[0:6] 1 - Read the data contained in the register specified by RS[0:6]
1	GO	Go Go Command Bit If the GO bit is set, and the CPU is currently in debug mode, the CPU will execute the instruction which resides in the IR register in the CPUSCR. To execute the instruction, the processor leaves the debug mode, executes the instruction, and if the EX bit is cleared, returns to the debug mode immediately after executing the instruction. The processor goes on to normal operation if the EX bit is set, and no other debug request source is asserted. The GO command is executed only if the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the GO bit is ignored.The processor will leave the debug mode after the TAP controller Update-DR state is entered. On a GO+NoExit operation, returning to debug mode is treated as a debug event, thus exceptions such as machine checks and interrupts may take priority and prevent execution of the intended instruction. Debug firmware should mask these exceptions as appropriate. The OSR_{ERR} bit indicates such an occurrence. If the CPU is not currently in debug mode, then the GO command will be ignored. Note that asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See Exiting Debug Mode and Interrupt Blocking. 0 - Inactive (no action taken) 1 - Execute instruction in IR

Table continues on the next page...

Table 65-24. OnCE Command Register Bit Definitions (continued)

Bit(s)	Name	Description
2	EX	Exit Command Bit 0 - Remain in debug mode 1 - Leave debug mode If the EX bit is set, the processor will leave the debug mode and resume normal operation until another debug request is generated. The Exit command is executed only if the Go command is issued, and the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the EX bit is ignored. The processor will leave the debug mode after the TAP controller Update-DR state is entered. Note that if the DR bit in the OnCE control register is set or remains set, or if a bit in EDBSR0 is set and $EDBCR0_{EDM}$=1 (external debug mode is enabled), or if another debug request source is asserted, then the processor may return to the debug mode *without* execution of an instruction, even though the EX bit was set. Note that asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See Exiting Debug Mode and Interrupt Blocking.
3:9	RS	Register Select The Register Select bits define which register is source (destination) for the read (write) operation. Table 65-25 indicates the OnCE register addresses. Attempted writes to read-only registers are ignored.

Table 65-25 indicates the OnCE register addresses.

Table 65-25. OnCE Register Addressing

111 1110	Enable_OnCE[1]
111 1111	Bypass

1. Causes assertion of the j_en_once_regsel output.

The Once Decoder receives as input the 10-bit command from the OCMD, and status signals from the processor, and generates all the strobes required for reading and writing the selected OnCE registers.

Single stepping of instructions is performed by placing the CPU in debug mode, scanning in appropriate information into the CPUSCR, and setting the Go bit (with the EX bit cleared) with the RS field indicating either the CPUSCR or No Register Selected. After executing a single instruction, the CPU will re-enter debug mode and await further commands. During single-stepping, exception conditions may occur if not properly masked by debug firmware (interrupts, machine checks, bus error conditions, etc.) and may prevent the desired instruction from being successfully executed. The OSR_{ERR} bit is set to indicate this condition. In these cases, values in the CPUSCR will correspond to the first instruction of the exception handler.

Additionally, the $EDBCR0_{EDM}$ bit is forced to '1' internally while single-stepping to prevent Debug events from generating Debug interrupts. Also, during a debug session, the DBSR register is frozen from updates due to debug events other than execution of a DNI-type instruction, regardless of EDBCR0EDM. DBSR may still be modified during a debug session via a single-stepped **mtspr** instruction, or via OnCE access.

If the CPU is not currently in debug mode, go+exit and go+noexit commands are ignored, although for a go+exit command with "No Register Selected", the j_ocmd_go_exit output will be asserted.

65.5.6.3 OnCE Control Register (OCR)

The OnCE Control Register is a 32-bit register used to force the e200z4204n3 core into debug mode and to enable / disable sections of the OnCE control logic. The control bits are read/write. These bits are only effective while OnCE is enabled (**jd_en_once** asserted). The OCR is shown in the following figure.

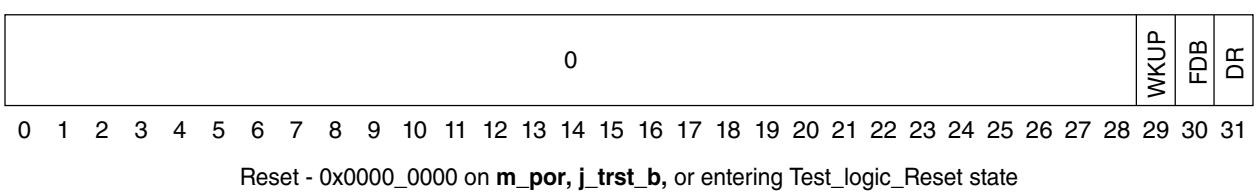

Figure 65-24. OnCE Control Register

The following table provides bit definitions for the OnCE Control Register.

Table 65-26. OnCE Control Register Bit Definitions

Bit(s)	Name	Description
0:28	—	Reserved
29	WKUP	Wakeup Request Bit (WKUP) This control bit may be used to force the **p_wakeup** output signal to be asserted. This control function may be used by debug firmware to request that the chip-level clock controller restore the **m_clk** input to normal operation regardless of whether the CPU is in a low power state to ensure that debug resources may be properly accessed by external hardware through scan sequences.
30	FDB	Force Breakpoint Debug Mode Bit (FDB) This control bit is used to determine whether the processor is operating in breakpoint debug enable mode or not. The processor may be placed in breakpoint debug enable mode by setting this bit. In breakpoint debug enable mode, execution of the '**bkpt**' pseudo- instruction will cause the processor to enter debug mode, as if the **jd_de_b** input had been asserted. This bit is qualified with $EDBCR0_{EDM}$, which must be set for FDB to take effect. Note that this bit has no effect on **e_dnh** or **se_dnh** instruction operation.
31	DR	CPU Debug Request Control Bit This control bit is used to unconditionally request the CPU to enter the Debug Mode. The CPU will indicate that Debug Mode has been entered via the data scanned out in the shift-IR state. 0 - No Debug Mode request 1 - Unconditional Debug Mode request When the DR bit is set the processor will enter Debug mode at the next instruction boundary.

65.5.7 Access to Debug Resources

Resources contained in the OnCE Module which do not require the processor core to be halted for access may be accessed while the e200z4204n3 core is running, and will not interfere with processor execution. Accesses to other resources such as the CPUSCR require the e200z4204n3 core to be placed in debug mode to avoid synchronization hazards. Debug firmware may ensure that it is safe to access these resources by determining the state of the e200z4204n3 core prior to access. Note that a scan operation to update the CPUSCR is required prior to exiting debug mode if debug mode has been entered.

Some cases of write accesses other than accesses to the OnCE Command and Control registers, or the EDM bit of DBCR0 require **m_clk** to be running for proper operation. The OnCE control register provides a means of signaling this need to a system level clock control module via the OCR_{WKUP} control bit.

In addition, since the CPU may cause multiple bits of certain registers to change state, reads of certain registers while the CPU is running (DBSR, etc.) may not have consistent bit settings unless read twice with the same value indicated. In order to guarantee that the contents are consistent, the CPU should be placed into debug mode, or multiple reads should be performed until consistent values have been obtained on consecutive reads.

The following table provides a list of access requirements for OnCE registers.

Table 65-27. OnCE Register Access Requirements

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 $_{EDM}$ = 1 for write access	Requires m_clk active for Write Access	Requires CPU to be halted for Read Access	Requires CPU to be halted for Write Access	
Enable_OnCE	N	N	N	N	—	
Bypass	N	N	N	N	N	
CPUSCR	Y	Y	Y	Y	Y	
DAC1–4	Y	Y	Y	N	*[1]	
DBCR0	Y	Y	Y	N	*[1]	*EDBCR0$_{EDM}$ access only requires **jd_en_once** asserted
DBCR1–8	Y	Y	Y	N	*[1]	
DEVENT	Y	Y	Y	N	*[1]	
EDBRAC0 (DBERC0)	Y	N	Y	N	*[1]	
DBSR	Y	Y	Y	N[2]	*[1]	
EDBCR0	Y	N	N	N	N	
EDBSR0	Y	N	Y	N	N	
EDBSRMSK0	Y	N	N	N	N	
IAC1–8	Y	Y	Y	N	*[1]	
JTAG ID	N	N	—	N	—	Read-only
OCR	Y	N	N	N	N	
OSR	Y	N	—	N	—	Read-only, accessed by scanning out IR while **jd_en_once** is asserted
Cache Debug Access Control (CDACNTL)	Y	N	Y	N	N	CPU gives lowest priority to a Cache access request when it is not debug halted
Cache Debug Access Data (CDADATA)	Y	N	Y	N	N	CPU gives lowest priority to a Cache access request when it is not debug halted
Nexus3-Access	Y	N	N	N	N	
PMR-Access	Y	N	N	N	N	
PMR Registers	Y	Y	Y	N	N	
External GPRs	Y	N	N	N	N	

Table continues on the next page...

Table 65-27. OnCE Register Access Requirements (continued)

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 EDM = 1 for write access	Requires m_clk active for Write Access	Requires CPU to be halted for Read Access	Requires CPU to be halted for Write Access	
LSRL Select	Y	N	?	?	?	System Test logic implementation determines LSRL functionality

1. Writes to these registers while the CPU is running may have unpredictable results due to the pipelined nature of operation, and the fact that updates are not synchronized to a particular clock, instruction, or bus cycle boundary, therefore it is strongly recommended to ensure the processor is first placed into debug mode before updates to these registers are performed.
2. Reads of these registers while the CPU is running may not give data that is self-consistent due to synchronization across clock domains.

65.5.8 Methods of Entering Debug Mode

The OnCE Status Register indicates that the CPU has entered the debug mode via the DEBUG status bit. The following sections describe how Debug Mode is entered assuming the OnCE circuitry has been enabled. OnCE operation is enabled by the assertion of the **jd_en_once** input See OnCE Enable (jd_en_once).

65.5.8.1 External Debug Request During RESET

Holding the **jd_de_b** signal asserted during the assertion of **p_reset_b,** and continuing to hold it asserted following the negation of **p_reset_b** causes the e200z4204n3 core to enter Debug Mode. After receiving an acknowledge via the OnCE Status Register DEBUG bit, the external command controller should negate the **jd_de_b** signal before sending the first command. Note that in this case the e200z4204n3 core does not execute an instruction before entering Debug Mode, although the first instruction to be executed will be fetched prior to entering Debug Mode in order to properly initialize the CPUSCR.

65.5.8.2 Debug Request During RESET

Asserting a debug request by setting the DR bit in the OCR during the assertion of **p_reset_b** and then negating **p_reset_b** causes the chip to enter debug mode. In this case the CPU will fetch the first instruction of the reset exception handler in order to properly initialize the CPUSCR, but does not execute an instruction before entering debug mode.

65.5.8.3 Debug Request During Normal Activity

Asserting a debug request by setting the DR bit in the OCR during normal chip activity causes the chip to finish the execution of the current instruction and then enter the debug mode. Note that in this case the chip completes the execution of the current instruction and stops after the newly fetched instruction enters the CPU instruction register. This process is the same for any newly fetched instruction including instructions fetched by the interrupt processing, or those that will be aborted by the interrupt processing.

65.5.8.4 Debug Request During Waiting, Halted or Stopped State

Asserting a debug request by setting the DR bit in the OCR when the chip is in the Waiting state (**p_waiting** asserted), Halted state (**p_halted** asserted) or Stopped state (**p_stopped** asserted) causes the CPU to exit the state and enter the debug mode once the CPU clock **m_clk** has been restored. Note that in this case, the CPU will negate the **p_waiting, p_halted** and **p_stopped** outputs. Once the debug session has ended, the CPU will return to the state it was in prior to entering debug mode.

To signal the chip-level clock generator to re-enable **m_clk**, the **p_wakeup** output will be asserted whenever the debug block is asserting a debug request to the CPU due to OCR_{DR} being set, or **jd_de_b** assertion, and will remain set from then until the debug session ends (**jd_debug_b** goes from asserted to negated). In addition, the status of the **jd_mclk_on** input (after synchronization to the **j_tclk** clock domain) may be sampled along with other status bits from the **j_tdo** outputs during the Shift_IR TAP controller state. This status may be used if necessary by external debug firmware to ensure proper scan sequences occur to registers in the **m_clk** clock domain.

65.5.8.5 Software Request During Normal Activity

Upon executing a '**bkpt**' pseudo-instruction (for e200z4204n3, defined to be an all 0's instruction opcode) when the OCR register's (FDB) bit is set (debug mode enable control bit is true), and $EDBCR0_{EDM}$=1, the CPU enters the debug mode after the instruction following the '**bkpt**' pseudo-instruction has entered the instruction register.

65.5.8.6 Debug Notify Halt Instructions

The **e_dnh** and **se_dnh** instructions allow software to transition the core from a running state to a debug halted state if enabled by $EDBCR0_{DNH_EN}$, and provide the external debugger with bits reserved in the instruction itself to pass additional information. Entry into debug mode is ***not*** conditioned on $EDBCR0_{EDM}$, allowing for debug of software debug handlers as well as other software. For e200z4204n3, when the CPU enters a debug halted state due to a **e_dnh** or **se_dnh** instruction, the instruction will be stored in the CPUSCR[IR] portion, and the CPUSCR[PC] value will point to the instruction. The external debugger should update the CPUSCR prior to exiting the debug halted state to point past the **e_dnh** or **se_dnh** instruction.

65.5.9 CPU Status and Control Scan Chain Register (CPUSCR)

A number of on-chip registers store the CPU pipeline status and are configured in a single scan chain for access by the OnCE controller. The CPUSCR register contains these processor resources, which are used to restore the pipeline and resume normal chip activity upon return from the debug mode, as well as a mechanism for the emulator software to access processor and memory contents. The following figure shows the block diagram of the pipeline information registers contained in the CPUSCR. Once debug mode has been entered, it is required to scan in and update this register prior to exiting debug mode.

NOTE

Note that due to the length of this register, parallel JTAG access capability is not provided.

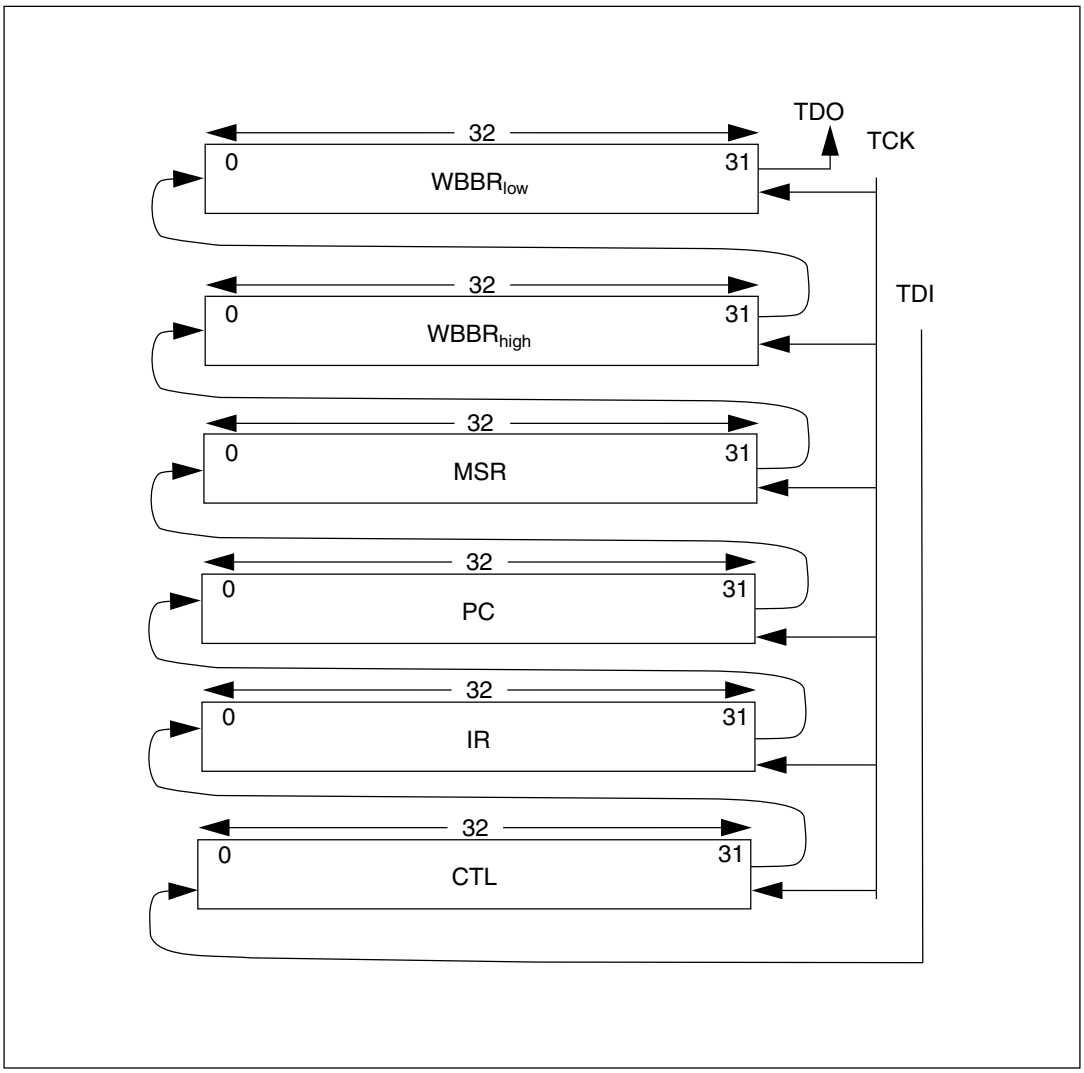

Figure 65-25. CPU Scan Chain Register (CPUSCR)

65.5.9.1 Instruction Register (IR)

The Instruction Register (IR) provides a mechanism for controlling the debug session by serving as a means for forcing in selected instructions, and then causing them to be executed in a controlled manner by the debug control block. The opcode of the next instruction to be executed when entering debug mode is contained in this register when the scan-out of this chain begins. This value should be saved for later restoration if continuation of the normal instruction stream is desired.

On scan-in, in preparation for exiting debug mode, this register is filled with an instruction opcode selected by debug control software. By selecting appropriate instructions and controlling the execution of those instructions, the results of execution may be used to examine or change memory locations and processor registers. The debug

control module external to the processor core will control execution by providing a single-step capability. Once the debug session is complete and normal processing is to be resumed, this register may be loaded with the value originally scanned out.

65.5.9.2 Control State Register (CTL)

The Control State Register (CTL) is a 32-bit register that stores the value of certain internal CPU state variables before the debug mode is entered. This register is affected by the operations performed during the debug session and should normally be restored by the external command controller when returning to normal mode. In addition to saved internal state variables, two of the bits are used by emulation firmware to control the debug process. In certain circumstances, emulation firmware must modify the content of this register as well as the PC and IR values in the CPUSCR before exiting debug mode. These cases are described below.

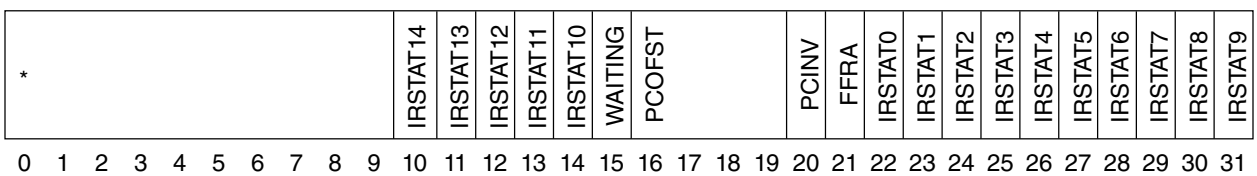

Figure 65-26. Control State Register (CTL)

WAITING — WAITING State Status

This bit indicates whether the CPU was in the waiting state prior to entering debug mode. If set, the CPU was in the waiting state. Upon exiting a debug session, the value of this bit in the restored CPUSCR will determine whether the CPU re-enters the waiting state on a go+exit.

0- CPU was not in the waiting state when debug mode was entered

1- CPU was in the waiting state when debug mode was entered

PCOFST — PC Offset Field

This field indicates whether the value in the PC portion of the CPUSCR must be adjusted prior to exiting debug mode. Due to the pipelined nature of the CPU, the PC value must be backed-up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored into the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction instead of the original IR value, other wise the original value of IR should be restored. (But see PCINV which overrides this field)

0000 - No correction required.

0001 - Subtract 0x04 from PC.

0010 - Subtract 0x08 from PC.

0011 - Subtract 0x0C from PC.

0100 - Subtract 0x10 from PC.

0101 - Subtract 0x14 from PC.

all other encodings are reserved

* — Internal State Bits

Table continues on the next page...

These control bits represent internal processor state and should be restored to their original value after a debug session is completed, i.e when a OnCE command is issued with the GO and EX bits set and not ignored. When performing instruction execution during a debug session. See OnCE Debug Output (jd_debug_b), which is not part of the normal program execution flow, these bits should be set to a 0.

PCINV — PC and IR Invalid Status Bit

This status bit indicates that the values in the IR and PC portions of the CPUSCR are invalid. Exiting debug mode with the saved values in the PC and IR will have unpredictable results. Debug firmware should initialize the PC and IR values in the CPUSCR with desired values prior to exiting debug mode if this bit was set when debug mode was initially entered.

0= No error condition exists.

1= Error condition exists. PC and IR are corrupted.

FFRA— Feed Forward RA Operand Bit

This control bit causes the content of the $WBBR_{lo}$ to be used as the RA operand value (RS for logical, mtspr, mtdcr, cntlzw, and shift operations, RX for VLE se_ instructions, RT for e_{logical_op}2i type instructions, RB for evaddiw, evsubifw, and the value to use as the PC for calculating the LR update value for branch with link type instructions) of the first instruction to be executed following an update of the CPUSCR.

This allows the debug firmware to update processor registers — initialize the $WBBR_{lo}$ with the desired value, set the FFRA bit, and execute a ori Rx,Rx,0 instruction to the desired register.

Note: not all instructions support using the FFRA control. FFRA is mainly intended for use with the ori instruction to allow the debugger to write to a GPR. Support for other instructions is implementation-dependent.

0= No action.

1= Content of $WBBR_{lo}$ used as operand value

IRStat0 — IR Status Bit 0

This control bit indicates a TEA status for the IR.

0= No TEA occurred on the fetch of this instruction.

1= TEA occurred on the fetch of this instruction.

IRStat1 — IR Status Bit 1

This control bit is reserved.

IRStat2 — IR Status Bit 2

This control bit indicates an Instruction Address Compare 1 event status for the IR.

0= No Instruction Address Compare event 1 occurred on the fetch of this instruction.

1= An Instruction Address Compare event 1 occurred on the fetch of this instruction.

IRStat3 — IR Status Bit 3

This control bit indicates an Instruction Address Compare 2 event status for the IR.

0= No Instruction Address Compare 2 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 2 event occurred on the fetch of this instruction.

IRStat4 — IR Status Bit 4

This control bit indicates an Instruction Address Compare 3 event status for the IR.

0= No Instruction Address Compare event 3 occurred on the fetch of this instruction.

1= An Instruction Address Compare event 3 occurred on the fetch of this instruction.

IRStat5 — IR Status Bit 5

This control bit indicates an Instruction Address Compare 4 event status for the IR.

Table continues on the next page...

0= No Instruction Address Compare 4 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 4 event occurred on the fetch of this instruction.

IRStat6 — IR Status Bit 6

This control bit indicates a Parity Error status for the IR.

0= No Parity Error occurred on the fetch of this instruction.

1= Parity Error occurred on the fetch of this instruction from the I-Cache.

IRStat7 — IR Status Bit 7

This control bit indicates a Precise External Termination Error status for the IR.

0= No Precise External Termination Error occurred on the fetch of this instruction.

1= A Precise External Termination Error occurred on the fetch of this instruction.

IRStat8 — IR Status Bit 8

This control bit indicates the PowerISA VLE status for the IR.

0= IR contains a BookE instruction. (unused encoding)

1= IR contains a PowerISA VLE instruction, aligned in the Most Significant Portion of IR if 16-bit.

- this bit should not be modified by the debugger, otherwise the resulting operation is boundedly undefined. It should always indicate VLE (=1).

IRStat9 — IR Status Bit 9

This control bit is reserved.

IRStat10 — IR Status Bit 10

This control bit indicates an Instruction Address Compare 5 event status for the IR.

0= No Instruction Address Compare 5 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 5 event occurred on the fetch of this instruction.

IRStat11 — IR Status Bit 11

This control bit indicates an Instruction Address Compare 6 event status for the IR.

0= No Instruction Address Compare 6 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 6 event occurred on the fetch of this instruction.

IRStat12 — IR Status Bit 12

This control bit indicates an Instruction Address Compare 7 event status for the IR.

0= No Instruction Address Compare 7 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 7 event occurred on the fetch of this instruction.

IRStat13 — IR Status Bit 13

This control bit indicates an Instruction Address Compare 8 event status for the IR.

0= No Instruction Address Compare 8 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 8 event occurred on the fetch of this instruction.

IRStat14 — IR Status Bit 14

This control bit is reserved.

Emulation firmware should modify the content of the CTL, PC, and IR values in the CPUSCR during execution of debug related instructions as well as just prior to exiting debug with a go+exit command. During the debug session, the CTL register should be

written with the FFRA bit set as appropriate, and all other bit set to '0', and the IR set to the value of the desired instruction to be executed. IRStat8 will be used to determine the type of instruction present in the IR.

Just prior to exiting debug mode with a go+exit, the PCINV status bit which was originally present when debug mode was first entered should be tested, and if set, the PC and IR initialized for performing whatever recovery sequence is appropriate for a faulted exception vector fetch. If the PCINV bit is cleared, then the PCOFST bits should be examined to determine whether the PC value must be adjusted. Due to the pipelined nature of the CPU, the PC value must be backed-up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored in to the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction (such as **ori r0,r0,0**) instead of the original IR value, otherwise the original value of IR should be restored. Note that when a correction is made to the PC value, it will generally point to the last completed instruction, although that instruction will not be re-executed. The nop instruction is executed instead, and instruction fetch and execution will resume at location PC+4. IRStat8 will be used to determine the type of instruction present in the IR, thus should be cleared in this case. Note that debug events which may occur on the nop (ICMP) will be generated if enabled.

For the CTL register, the internal state bits should be restored to their original value. The IRStatus bits should be set to '0's if the PC was adjusted. If no PC adjustment was performed, emulation firmware should determine whether other IRStat flags should be set to '0' to avoid re-entry into debug mode for an instruction breakpoint request. Upon exiting debug mode with go+exit, if one of these bits is set, debug mode will be re-entered prior to any further instruction execution.

65.5.9.3 Program Counter Register (PC)

The PC is a 32-bit register that stores the value of the program counter which was present when the chip entered the debug mode. It is affected by the operations performed during the debug mode and must be restored by the external command controller when the CPU returns to normal mode. PC normally points to the instruction contained in the IR portion of CPUSCR. If debug firmware wishes to redirect program flow to an arbitrary location, the PC and IR should be initialized to correspond to the first instruction to be executed upon resumption of normal processing. Alternatively, the IR may be set to a nop and the PC set to point to the location prior to the location at which it is desired to redirect flow to. On exiting debug mode, the nop will be executed, and instruction fetch and execution will resume at PC+4.

65.5.9.4 Write-Back Bus Register ($WBBR_{low}$, $WBBR_{high}$)

WBBR is used as a means of passing operand information between the CPU and the external command controller. Whenever the external command controller needs to read the contents of a register or memory location, it will force the chip to execute an instruction that brings that information to WBBR. $WBBR_{low}$ holds the 32-bit result of most instructions including load data returned for a load or load with update instruction. $WBBR_{high}$ holds the updated effective address calculated by a load with update instruction. It is undefined for other instructions.

As an example, to read the 32 bits of processor register **r1**, an **ori r1,r1,0** instruction is executed, and the result value of the instruction will be latched into $WBBR_{low}$. The contents of $WBBR_{low}$ can then be delivered serially to the external command controller. To update a processor resource, this register is initialized with a data value to be written, and an **ori** instruction is executed which uses this value as a substitute data value. The Control State register FFRA bit forces the value of the $WBBR_{low}$ to be substituted for the normal RS source value of the **ori** instruction, thus allowing updates to processor registers to be performed. (Refer to Control State Register (CTL) for more detail on the CTL_{FFRA} bit.)

$WBBR_{low}$ and $WBBR_{high}$ are generally undefined on instructions which do not writeback a result, and due to control issues are not defined on **lmw** or branch instructions as well.

65.5.9.5 Machine State Register (MSR)

The MSR is a 32-bit register used to read/write the Machine State Register. Whenever the external command controller needs to save or modify the contents of the Machine State Register, this register is used.This register is affected by the operations performed during the debug mode and must be restored by the external command controller when returning to normal mode.

65.5.9.6 Exiting Debug Mode and Interrupt Blocking

When exiting debug mode with a Go+Exit, "asynchronous" interrupts are blocked until the first instruction to be executed begins execution. This includes External and Critical input, NMI, and machine check interrupts. Asynchronous debug interrupts are not blocked however, and the CPU will re-enter debug mode without executing an instruction

following Go+Exit, although it may fetch an instruction and discard it. Exceptions due to an illegal instruction or error flags set within the CPUSCR CTL register are not blocked, since they apply to the instruction in the CPUSCR IR.

65.5.10 Reserved Registers (Reserved)

The Reserved Registers are used to control various test control logic. These registers are not intended for customer use. To preclude device and/or system damage, these registers should not be accessed.

65.6 Watchpoint Support

e200z4204n3 supports the generation and signalling of watchpoints when operating in internal debug mode ($DBCR0_{IDM}$=1) or in external debug mode ($EDBCR0_{EDM}$=1). Watchpoints are indicated with a dedicated set of interface signals. The **jd_watchpt[0:31]** output signals are used to indicate that a watchpoint has occurred. Certain watchpoints however (DEVENT-based, DTC-based, and Performance Monitor watchpoints) are not qualified with $EDBCR0_{EDM}$ or $DBCR0_{IDM}$.

Each debug address compare function (IAC1–8, DAC1–4), as well as other event types are capable of triggering a watchpoint output. The DBCRx control fields are used to configure watchpoints, regardless of whether events are enabled in DBCR0. Watchpoints may occur whenever an associated event would have been posted in the Debug Status Register if enabled. No explicit enable bits are provided for watchpoints; they are always enabled by definition, although the data address compare watchpoints may be controlled for read and write accesses via configuration fields in DBCR4, 7, and 9. During a debug session, debug events (other than PMI, DEVT1 and DEVT2) with a corresponding DBSR bit are blocked from asserting a watchpoint. The Performance Monitor, DEVNT-based and DTC-based watchpoints are not blocked during a debug session. If not desired, for address-based events the base address values for these events may be programmed to an unused system address. MSR_{DE} has no effect on watchpoint generation.

External logic may monitor the assertion of these signals for debugging or triggering purposes. Watchpoints are signaled in the clock cycle following the occurrence of the actual event. The Nexus3 module also monitors assertion of a portion of these output signals (**jd_watchpt[0:31]**) for various development control purposes. (See the "Watchpoint Trace Messaging" section in the Core (e200z4204n3) Nexus 3 Module chapter.)

Note that these signals are **m_clk** domain signals, not **j_tclk** domain signals.

The following table shows the **jd_watchpt[0:31]** output signal assignments to various debug events.

Table 65-28. Watchpoint Output Signal Assignments

Signal Name	Type	Description
jd_watchpt[0]	IAC1	Instruction Address Compare 1 watchpoint Asserted whenever an IAC1 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[1]	IAC2	Instruction Address Compare 2 watchpoint Asserted whenever an IAC2 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[2]	IAC3	Instruction Address Compare 3 watchpoint Asserted whenever an IAC3 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[3]	IAC4	Instruction Address Compare 4 watchpoint Asserted whenever an IAC4 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[4]	DAC1	Data Address Compare 1 watchpoint Asserted whenever a DAC1 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC1CFG}$ settings
jd_watchpt[5]	DAC2	Data Address Compare 2 watchpoint Asserted whenever a DAC2 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC2CFG}$ settings
jd_watchpt[6]	DAC3	Data Address Compare 3 watchpoint Asserted whenever a DAC3 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC3CFG}$ settings
jd_watchpt[7]	DAC4	Data Address Compare 4 watchpoint Asserted whenever a DAC4 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC4CFG}$ settings
jd_watchpt[8]	IAC5	Instruction Address Compare 5 watchpoint Asserted whenever an IAC5 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[9]	IAC6	Instruction Address Compare 6 watchpoint Asserted whenever an IAC6 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[10]	DEVT1	Debug Event Input 1 watchpoint Asserted whenever a DEVT1 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[11]	DEVT2	Debug Event Input 2 watchpoint Asserted whenever a DEVT2 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[12]	DEVNT0	Debug Event Output 0 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[12]
jd_watchpt[13]	DEVNT1	Debug Event Output 1 watchpoint

Table continues on the next page...

Table 65-28. Watchpoint Output Signal Assignments (continued)

Signal Name	Type	Description
		Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[13]
jd_watchpt[14]	IAC7	Instruction Address Compare 7 watchpoint Asserted whenever an IAC7 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[15]	IAC8	Instruction Address Compare 8 watchpoint Asserted whenever an IAC8 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[16]	IRPT	Interrupt watchpoint Asserted whenever an IRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[17]	RET	Return watchpoint Asserted whenever a RET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[18]	CIRPT	Critical Interrupt watchpoint Asserted whenever a CIRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[19]	CRET	Critical Return watchpoint Asserted whenever a CRET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[20]	DEVNT2	Debug Event Output 2 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[20]
jd_watchpt[21]	DEVNT3	Debug Event Output 3 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[21]
jd_watchpt[22]	PMEVENT	Performance Monitor Event input watchpoint Asserted whenever **p_pm_event** transitions from a '0' to a '1' while **m_clk** is running
jd_watchpt[23]	PMC0	Performance Monitor Counter 0 watchpoint Asserted whenever PMC0 triggers an event based on $PMLCa0_{PMP}$
jd_watchpt[24]	PMC1	Performance Monitor Counter 1 watchpoint Asserted whenever PMC1 triggers an event based on $PMLCa1_{PMP}$
jd_watchpt[25]	PMC2	Performance Monitor Counter 2 watchpoint Asserted whenever PMC2 triggers an event based on $PMLCa2_{PMP}$
jd_watchpt[26]	PMC3	Performance Monitor Counter 3 watchpoint Asserted whenever PMC3 triggers an event based on $PMLCa3_{PMP}$
jd_watchpt[27]	—	Reserved
jd_watchpt[28]	TRAP	TRAP watchpoint Asserted whenever an TRAP debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[29]	DTC1	Data Trace Control Range 1 watchpoint

Table continues on the next page...

Table 65-28. Watchpoint Output Signal Assignments (continued)

Signal Name	Type	Description
		Asserted whenever an access meets the conditions for DTC Range 1
jd_watchpt[30]	DTC2	Data Trace Control Range 2 watchpoint Asserted whenever an access meets the conditions for DTC Range 2
jd_watchpt[31]	DTC3	Data Trace Control Range 3 watchpoint Asserted whenever an access meets the conditions for DTC Range 3

65.7 Cache Array Access During Debug

The cache arrays may be read and written during debug mode via the CDACNTL and CDADATA debug registers.

65.8 Basic Steps for Enabling, Using, and Exiting External Debug Mode

The following steps show one possible scenario for a debugger wishing to use the external debug facilities. *This simplified flow is intended to illustrate basic operations, but does not cover all potential methods in depth.*

Enabling External Debug Mode and initializing Debug registers

- The debugger should ensure that the **jd_en_once** control signal is asserted in order to enable OnCE operation
- Select the OCR and write a value to it in which OCR_{DR}, OCR_{WKUP}, are set to '1'. The tap controller must step through the proper states as outlined earlier. This step will place the CPU in a debug state in which it is halted and awaiting single-step commands or a release to normal mode
- Scan out the value of the OSR to determine that the CPU clock is running and the CPU has entered the Debug state. This can be done in conjunction with a Read of the CPUSCR. The OSR is shifted out during the Shift_IR state. The CPUSCR will be shifted out during the Shift_DR state. The debugger should save the scanned-out value of CPUSCR for later restoration.
- Select the DBCR0 register and update it with the $EDBCR0_{EDM}$ bit set

- Clear the DBSR status bits
- Write appropriate values to the DBCR0–8, IAC, and DAC registers. Note that the initial write to DBCR0 will only affect the EDM bit, so the remaining portion of the register must now be initialized, keeping the EDM bit set

At this point the system is ready to commence debug operations. Depending on the desired operation, different steps must occur.

- Optionally, ensure that the values entered into the MSR portion of the CPUSCR during the following steps cause interrupt to be disabled (clearing MSR_{EE} and MSR_{CE}). This will ensure that external interrupt sources do not cause single-step errors.

To single-step the CPU:

- debugger scans in either a new or a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Noexit OnCE Command value.
- The debugger scans out the OSR with "no-register selected", Go cleared, and determines that the PCU has re-entered the Debug state and that no ERR condition occurred

To return the CPU to normal operation (without disabling external debug mode)

- The OCR_{DR} control bit should be cleared, leaving the OCR_{WKUP} bit set
- The debugger restores the CPUSCR with a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared

To exit External Debug Mode

- The debugger should place the CPU in the debug state via the OCR_{DR} with OCR_{WKUP} asserted, scanning out and saving the CPUSCR
- The debugger should write the DBCR0–8 registers as needed, likely clearing every enable except the $EDBCR0_{EDM}$ bit
- The debugger should write the DBSR to a cleared state
- The debugger should re-write the DBCR0 with all bits including EDM cleared

- The debugger should clear the OCR_{DR} bit
- The debugger restores the CPUSCR with the previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared

Note

These steps are meant by way of examples, and are not meant to be an exact template for debugger operation.

Chapter 66
Z2 Nexus 3 Module

66.1 Introduction

The e200z210n3Nexus 3 module provides real-time development capabilities for corresponding core processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

A portion of the pin interface (the JTAG port) is also shared with the OnCE / Nexus 1 unit. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port in these processors.

66.1.1 General description

This chapter defines the auxiliary pin functions, transfer protocols and standard development features of a Class 3 device in compliance with the IEEE-ISTO 5001 standard. The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering, and Processor Overrun Control.

66.1.2 Terms and definitions

The following table contains a set of terms and definitions associated with the Nexus 3 module.

Table 66-1. Terms and definitions

Term	Description
IEEE-ISTO 5001	Consortium & standard for real-time embedded system design. World wide Web documentation at http://www.ieee-isto.org/Nexus5001
Auxiliary Port	Refers to Nexus auxiliary port. Used as auxiliary port to the IEEE 1149.1 JTAG interface.
Branch Trace Messaging (BTM)	Visibility of addresses for taken branches and exceptions, and the number of sequential instructions executed between each taken branch.
Data Read Message (DRM)	External visibility of data reads to memory-mapped resources.
Data Write Message (DWM)	External visibility of data writes to memory-mapped resources.
Data Trace Messaging (DTM)	External visibility of how data flows through the embedded system. This may include DRM and/or DWM.
Data Acquisition Messaging (DQM)	Data Acquisition Messaging (DQM) allows code to be instrumented to export customized information to the Nexus Auxiliary Output Port.
JTAG Compliant	Device complying to IEEE 1149.1 JTAG standard
JTAG IR & DR Sequence	JTAG Instruction Register (IR) scan to load an opcode value for selecting a development register. The JTAG IR corresponds to the OnCE command register (OCMD). The selected development register is then accessed via a JTAG Data Register (DR) scan.
Nexus1	The (OnCE) debug module. This module integrated with each processor provides all static (core halted) debug functionality. This module is compliant with Class1 of the IEEE-ISTO 5001 standard.
Ownership Trace Message (OTM)	Visibility of process/function that is currently executing.
Public Messages	Messages on the auxiliary pins for accomplishing common visibility and controllability requirements
SoC	"System-on-a-Chip". SoC signifies all of the modules on a single die. This generally includes one or more processors with associated peripherals, interfaces & memory modules.
Standard	The phrase "according to the standard" is used to indicate according to the IEEE-ISTO 5001 standard.
Transfer Code (TCODE)	Message header that identifies the number and/or size of packets to be transferred, and how to interpret each of the packets.
Watchpoint	A Data or Instruction Breakpoint or other debug event that does not cause the processor to halt. Instead, a pin is used to signal that the condition occurred. A Watchpoint Message may also be generated.

66.1.3 Feature list

The Nexus 3 module is compliant with Class 3 of the IEEE-ISTO 5001 standard, with additional Class 4 features available. The following features are implemented:

- Program Trace via Branch Trace Messaging (BTM). Branch trace messaging displays program flow discontinuities (direct and indirect branches, exceptions, etc.), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced.
- Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to selected internal memory resources.
- Ownership Trace via Ownership Trace Messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated. An Ownership Trace Message is transmitted when a new process/task is activated, allowing the development tool to trace ownership flow.
- Run-time access to embedded processor memory map via the JTAG port. This allows for enhanced download/upload capabilities.
- Watchpoint Messaging via the auxiliary pins
- Watchpoint Trigger enable of Program and/or Data Trace Messaging
- Auxiliary interface for higher data input
    - Configurable (min/max) Message Data Out pins (**nex_mdo[n:0]**)
    - One (1) or two (2) Message Start/End Out pins (**nex_mseo_b[1:0]**)
    - One (1) Read/Write Ready pin (**nex_rdy_b**) pin
    - One (1) Read/Write Error pin (**nex_err_b**) pin
    - One (1) Watchpoint Event output pin (**evto_b**)
    - One (1) Event In pin (**nex_evti_b**)
    - One (1) MCKO (Message Clock Out) pin
- Registers for Program Trace, Data Trace, Ownership Trace and Watchpoint Trigger
- All features controllable and configurable via the JTAG port
- Conditional software control of the module via SoC signaling input (**nex_sfwcntl_en**)
- Indicates to the FCCU whether it becomes active during functional mode.

Note

For multi-Nexus implementations, the configuration of the Message Data Out pins is controlled by the Port Control Register (at the SoC level). For single Nexus implementations (not normally implemented on an SoC), this configuration is controlled by Development Control Register 1 (DC1) within the Nexus 3 module.

In either implementation, Full Port Mode (FPM - maximum number of MDO pins) or Reduced Port Mode (RPM - minimum number of MDO pins) are supported. This setting should not be changed while the system is running.

Note

The configuration of the Message Start/End Out pins (1 or 2) is determined at the SOC integration level. This option will be hard-wired based on SOC bandwidth requirements.

66.1.4 Functional block diagram

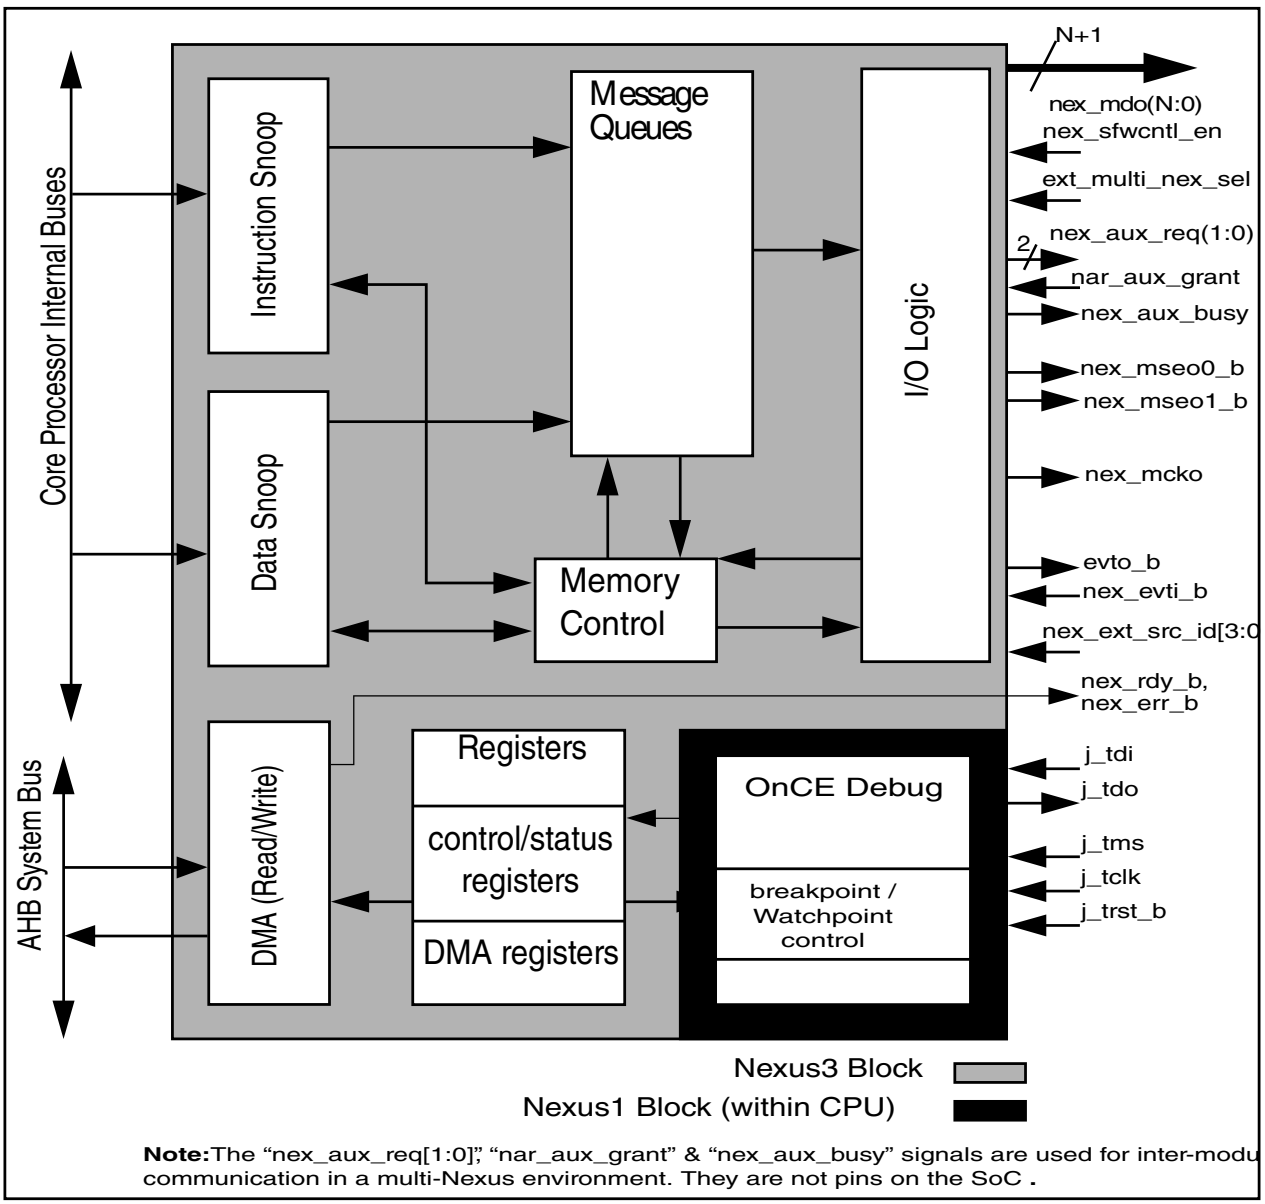

Figure 66-1. Nexus 3 functional block diagram

66.2 Enabling Nexus 3 operation

The Nexus module is enabled by loading a single instruction (*NEXUS3-ACCESS*) into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus3 module, the OCMD value is 0b0001111100. The Nexus 3 module may alternately be enabled if the nex_evti_b input signal is asserted at the time that j_trst_b is initially negated, or is asserted during the Test-Logic-Reset TAP state. Once enabled, the module will be ready to accept control input via the JTAG/OnCE pins.

Enabling the Nexus 3 module automatically enables the generation of Debug Status Messages.

The Nexus 3 module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. This state can be reached by the assertion of the **j_trst_b** pin or by cycling through the state machine using the **j_tms** pin. The Nexus module will also be disabled if a Power-on-Reset (POR) event occurs. If the Nexus 3 module is disabled, no trace output will be provided, and the module will disable (drive inactive) auxiliary port output pins (**nex_mdo[n:0]**, **nex_mseo[1:0]**, **nex_mcko**). Nexus registers will not be available for reads or writes.

In order to support software control of the Nexus 3 module when no external development tool is present, the Nexus 3 module is not forced to be disabled when the JTAG state remains in the Test-Logic-Reset state. Software is allowed to control the Nexus 3 module when the input signal **nex_sfwcntl_en** is asserted by the SoC. This signal is intended to provide a mechanism for allowing software to use the Nexus 3 module to fill on-chip trace buffers or other visibility mechanisms. It is up to the SoC to determine whether a top-level Nexus 3 controller has been enabled by a hardware debugger, or whether appropriate security mechanisms have granted the capability for software to use these resources, and to drive the appropriate value to the **nex_sfwcntl_en** input. Software can enable the module by a write to any of the module's DCRs when **nex_sfwcntl_en** is asserted.

Reset of the Nexus 3 module is accomplished by a transition on **j_trst_b**, on initial entry into the Test_Logic_Reset state from another state, or if a Power-on-Reset (POR) event occurs. The module is not reset by the CPU's **p_reset_b** signal, even when software has control of the module.

66.2.1 Interaction with Low Power Modes

The Nexus 3 module will continue to operate in the Waiting and Halted states, as long as **nex_clk** remains active. In the Stopped state, **nex_clk** is gated off internally to the Nexus 3 logic, therefore watchpoint or hardware triggering recognition, message generation, and Nexus 3 read-write access to memory is suspended. The Nexus 3 logic will wait to enter the Stopped state until the message FIFOs are empty and any in-progress Nexus R/W transfer has completed. If a block transfer has been requested, the remainder of the block transfer is not completed, and the RWCS AC bit is cleared, and the ERR bit is set. Once the Stopped state has been entered, no further messages are queued and no triggering conditions are monitored. Also, Nexus R/W accesses are no longer available. Upon exiting the Stopped state, normal functions will resume assuming **nex_clk** is active.

66.3 TCODEs supported

The Nexus 3 pins allow for flexible transfer operations via Public Messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2003 standard defines a set of public messages and allocates additional TCODEs for vendor-specific features outside the scope of the public messages. The Nexus 3 block supports the TCODEs shown in Table 66-2.

Table 66-2. Supported TCODEs

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Debug Status	6	6	TCODE	fixed	TCODE number = 0
	4	4	SRC	fixed	source processor identifier
	8	8	STATUS	fixed	Development Status Register (DS[31:24])
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Ownership Trace Message	6	6	TCODE	fixed	TCODE number = 2
	4	4	SRC	fixed	source processor identifier
	1	32	PROCESS	variable	Task/Process ID tag
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Program Trace - Direct Branch Message	6	6	TCODE	fixed	TCODE number = 3
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Program Trace - Indirect Branch Message	6	6	TCODE	fixed	TCODE number = 4
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/ exceptions
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Data Trace - Data Write Message	6	6	TCODE	fixed	TCODE number = 5
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 66-7)
	1	32	U-ADDR	variable	unique portion of the data write address
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)

Table continues on the next page...

Table 66-2. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Data Trace - Data Read Message	6	6	TCODE	fixed	TCODE number = 6
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 66-7)
	1	32	U-ADDR	variable	unique portion of the data read address

Resource Full Message	6	6	TCODE	fixed	TCODE number = 27
	4	4	SRC	fixed	source processor identifier
	4	4	RCODE	fixed	resource code (Refer to Table 66-5) - indicates which resource is the cause of this message
	1	32	RDATA	variable	branch / predicate instruction history (See Section Resource Full Messages.)
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Program Trace - Indirect Branch History Message	6	6	TCODE	fixed	TCODE number = 28 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/ exceptions

Table continues on the next page...

Table 66-2. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
	1	32	HIST	variable	branch / predicate instruction history (see Branch Trace Messaging types)
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Program Trace - Indirect Branch History Message w/ Sync	6	6	TCODE	fixed	TCODE number = 29 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	1	32	HIST	variable	branch / predicate instruction history (See Branch Trace Messaging types.)
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Program Trace - Program Correlation Message	6	6	TCODE	fixed	TCODE number = 33
	4	4	SRC	fixed	source processor identifier
	4	4	EVCODE	fixed	event correlated w/ program flow (Refer to Table 66-6)
	2	2	CDF	fixed	# fields of information in CDATA. 00 - reserved, 01 - one field (CDATA1) (reserved), 10 - two fields (CDATA1 + CDATA2), 11 - three fields (reserved)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	CDATA1	variable	correlation data field 1 - [branch / predicate instruction history] (See Program Correlation Messages.)
	0	32	CDATA2	variable	correlation data field 2- PID info (See Program Correlation Messages.)
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)

Note

Program Trace can be implemented using either Branch History/Predicate Instruction Messages, or traditional Direct/ Indirect Branch Messages. The user can select between the two types of Program Trace. The advantages for each are discussed in Branch Trace Messaging types. If the Branch History method is selected, the shaded TCODES above will not be messaged out.

Table 66-3 shows the error code encodings used when reporting an error via the Nexus 3 Error Message.

Table 66-3. Error Code (ECODE) Encoding (TCODE = 8)

Error Code	Description
xxxxxxx1	Watchpoint Trace Message(s) Lost
xxxxxx1x	Data Trace Message(s) Lost
xxxxx1xx	Program Trace Message(s) Lost
xxxx1xxx	Ownership Trace Message(s) Lost
xxx1xxxx	Status Message(s) Lost (Debug Status messages, etc.)
xx1xxxxx	Data Acquisition Message(s) Lost
x1xxxxxx	Reserved
1xxxxxxx	Reserved

Table 66-4 shows the error type encodings used when reporting an error via the Nexus 3 Error Message.

Table 66-4. Error Type (ETYPE) Encoding (TCODE = 8)

Error Type	Description
0000	Message Queue Overrun caused one or more messages to be lost
0001	Contention with higher priority messages caused one or more messages to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus Register unimplemented)
0110 - 1111	Reserved

Table 66-5 shows the encodings used for resource codes for certain messages.

Table 66-5. Resource Code (RCODE) values (TCODE = 27)

Resource Code	Description
0000	Program Trace Instruction counter reached 255 and was reset.
0001	Program Trace, Branch / Predicate Instruction History full. This type of packet is terminated by a stop bit set to 1 after the last history bit.

Table 66-6 shows the event code encodings used for certain messages.

Table 66-6. Event Code (EVCODE) Encoding (TCODE = 33)

Event Code	Description
0000	Entry into Debug Mode
0001	Entry into Low Power Mode (CPU only)
0010-0011	Reserved for future functionality
0100	Disabling Program Trace

Table continues on the next page...

Table 66-6. Event Code (EVCODE) Encoding (TCODE = 33) (continued)

Event Code	Description
0101	Process ID value is established in PID0/NPIDR via **mtspr PID0/NPIDR**
0110-1000	Reserved for future functionality
1001	Begin masking of program trace messages due to MSR_{PMM}=0 and $DC4_{PTMARK}$=1
1010	Branch and link occurrence (direct branch function call)
1011-1111	Reserved for future functionality

Table 66-7 shows the data trace size encodings used for certain messages.

Table 66-7. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14)

DTM Size Encoding	Transfer Size
0000	0 - no data
0001	Byte
0010	Halfword (2 bytes)
0011	Three bytes
0100	Word (4 bytes)
0101	Five bytes
0110	Six bytes
0111	Seven bytes
1000	Doubleword (8 bytes)
1001-1111	Reserved

66.4 Nexus 3 Programmer's model

This section describes the Nexus 3 programmer's model. Nexus 3 registers are accessed using the JTAG/OnCE port in compliance with IEEE 1149.1, or by software via DCRs. See Nexus 3 Register Access via JTAG/OnCE and Nexus 3 Register Access via Software for details on Nexus 3 register access.

Note

Nexus 3 registers and output signals are numbered using bit 0 as the least significant bit. This bit ordering is consistent with the ordering defined by the IEEE-ISTO 5001 standard.

The following table details the register map for the Nexus 3 module.

Table 66-8. Nexus 3 register map

Nexus Register	Nexus Access Opcode	Read/ Write	Read Address	Write Address	DCR #[1]
Client Select Control (CSC)[2]	0x1	R	0x02	-	
Port Configuration Register (PCR)[3]	PCR_INDEX[2]	R/W	-	-

Reserved	0x39 -> 0x3F	-	0x72->0x7E	0x73->7F	

1. Software access via the **mfdcr** and **mtdcr** instructions use these values for the DCR number. Software writes to these registers via **mtdcr** when **nex_sfwcntl_en** is negated are ignored.
2. The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level SoC Nexus controller in a multi-Nexus implementation, not in the Nexus 3 module. The SoC's CSC Register is readable through Nexus, but the PCR is shown for reference only here.

3. The "PCR_INDEX" is a parameter determined by the SoC.

66.4.1 Client Select Control (CSC) register

The CSC Register determines which Nexus client is under development. This register is present at the top-level SOC Nexus 3 controller to select one of multiple on-chip Nexus 3 units.

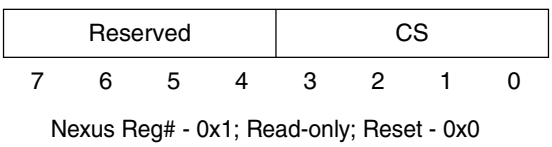

Figure 66-2. Client Select Control (CSC) register

Table 66-9. CSC field descriptions

Bits	Description
CSC[7:4]	Reserved for future Nexus Clients (read as 0)
CSC[3:0]	Client Select Control 0xx - Nexus client (SoC level)

66.4.2 Port Configuration Register (PCR) - reference only

The Port Configuration Register (PCR) controls the basic port functions for all Nexus modules in a multi-Nexus environment. This includes clock control and auxiliary port width. All bits in this register are writable only once after system reset.

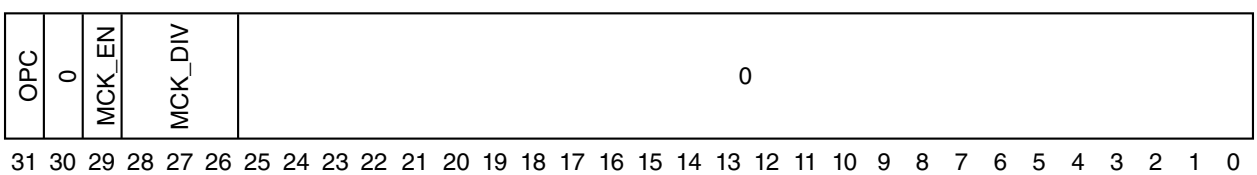

Figure 66-3. Port Configuration Register

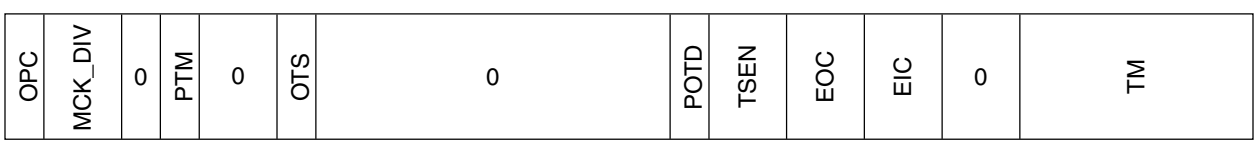
Table 66-10. PCR field descriptions

Bit	Name	Description
31	OPC	Output Port Mode Control (SoC Level) 0 Reduced Port Mode configuration (min# **nex_mdo[n:0]** pins defined by SOC) 1 Full Port Mode configuration (max# **nex_mdo[n:0]** pins defined by SOC)
30	—	Reserved for future functionality

Table continues on the next page...

Table 66-10. PCR field descriptions (continued)



Bit	Name	Description
29	MCK_EN	MCKO Clock Enable (SoC Level) 0 **nex_mcko** is disabled 1 **nex_mcko** is enabled
28:26	MCK_DIV	MCKO Clock Divide Ratio (see note below) (SoC Level) 000 **nex_mcko** is 1x processor clock freq. 001 **nex_mcko** is 1/2x processor clock freq. 010 Reserved (default to 1/2x processor clock freq.) 011 **nex_mcko** is 1/4x processor clock freq. 100 Reserved (default to 1/2x processor clock freq.) 101 Reserved (default to 1/2x processor clock freq.) 110 Reserved (default to 1/2x processor clock freq.) 111 **nex_mcko** is 1/8x processor clock freq.
25:0	—	Reserved for future functionality

Note

The CSC and PCR Registers exist in a separate module at the SoC level in a multi-Nexus environment. If the core Nexus 3 module is the only Nexus module, these registers are not implemented and the Nexus 3 defined Development Control Register 1 (DC1) is used to control the SoC-level Nexus port functionality.

66.4.3 Nexus Development Control Register 1 (DC1)

Nexus Development Control Register 1 is used to control the basic development features of the Nexus 3 module. Development Control Register 1 is shown in Figure 66-4 and its fields are described in Table 66-11.

Nexus Reg# - 0x2; DCR - 368; Read/Write; Reset - 0x0

5:0	TM	Trace Mode[1] 000000 All Trace Disabled XXXXX1 Ownership Trace enabled XXXX1X Data Trace enabled XXX1XX Program Trace enabled XX1XXX Watchpoint Trace enabled X1XXXX Reserved 1XXXXX Data Acquisition Trace enabled

1. This field may be updated by hardware in response to watchpoint triggering if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers for more information on watchpoint triggering.

Note

The Output Port Mode Control bit (OPC) and MCKO Clock Divide Ratio bits (MCK_DIV) MUST ONLY be modified during system reset or debug mode to insure correct output port and output clock functionality. It is also recommended that all other bits of the DC1 also only be modified in one of these two modes.

66.4.4 Nexus Development Control Registers 2 & 3 (DC2, DC3)

Nexus Development Control Registers 2 and 3 are used to control output signaling on the Nexus 3 module. A table of watchpoints can be found in the Core (e200z210n3) Core Debug Support chapter.

Development Control Register 2 is shown in Figure 66-5 and its fields are described in Table 66-12.

0	0	0	0	EWC

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

66.4.5 Nexus Development Control Register 4 (DC4)

Nexus Development Control Register 4 is used to control mark selection for Program and Data Trace Messaging, as well as masking of events that initiate Program Correlation Messages on the Nexus 3 module.

Development Control Register 4 is shown in Figure 66-7 and its fields are described in Table 66-14.

Nexus Reg# - 0x5; DCR - 371; Read/Write; Reset - 0x0

66.4.6 Development Status Register (DS)

The Development Status Register is used to report system debug status. When Debug Mode is entered or exited, or an SoC- or core-defined Low Power Mode is entered (see note below), a Debug Status Message is transmitted with DS[31:24]. The external tool can read this register at any time.

Nexus Reg# - 0x4; DCR - 409; Read-only; Reset - 0x0

66.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers

The Watchpoint Trigger Registers allows the watchpoints defined within the Nexus1 logic to trigger actions. These watchpoints can control Program and/or Data Trace enable and disable. The control bits can be used to produce a related "window" for triggering Trace Messages. Watchpoint trigger register WT is used to control triggering by a single selected watchpoint. The Program Trace Start Trigger Control (PTSTC), Program Trace End Trigger Control (PTETC), Data Trace Start Trigger Control (DTSTC), and Data Trace End Trigger Control (DTETC) are used for extended trigger controls for the respective function. If multiple watchpoints are desired for triggering, or a watchpoint beyond watchpoint #13 is required, then one or more of the extended watchpoint trigger registers may be used. A field encoding of 4'b1111 in one of the WT register fields enables the corresponding extended trigger register. For all other WT field encodings, the corresponding extended trigger register is disabled and the contents are ignored. Note that direct writes to enable program trace and/or data trace in DC1 will override these controls, and trace will remain enabled until another direct write to DC1 to disable program and/or data trace occurs.

When a start trigger is detected, the designated trace features become enabled, and the corresponding enable bits of the DC1 register are set. Whenever a stop trigger is detected, the designated trace features become disabled, and the corresponding enable bits of the DC1 register are cleared. If the same trigger condition is used for both start and stop triggering, then the designated trace features will toggle between being enabled and disabled at each occurrence of the trigger condition. Similarly, if start and stop triggers for a trace feature occur simultaneously, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take

precedence over any trace feature enable state that is derived from watchpoint triggering. A table of watchpoints can be found in the Core (e200z210n3) Core Debug Support chapter.

Figure 66-16. Nexus Overrun Control Register Fields

66.4.10 Data Trace Control Register (DTC) register

The Data Trace Control Register controls whether DTM Messages are restricted to reads, writes, or both for a user programmable address range. In addition, control is provided to restrict data trace message generation to only those load or store accesses that are not stack-related, in order to minimize required data trace message bandwidth.

There are four Data Trace channels controlled by the DTC for the Nexus 3 module. Channels can be programmed to trace data accesses or instruction accesses, but not independently.

Nexus Reg# - 0xD; DCR - 376; Read/Write; Reset - 0x0

Figure 66-17. Data Trace Control Register

Data Trace End Address																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Nexus Reg# - 0x15; DCR - 408; Read/Write; Reset - 0x0

Figure 66-25. Data Trace End Address 4 (DTEA4) register

Table 66-23 illustrates the range that will be selected for Data Trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 66-23. Data trace - address range options

Programmed values	Range Control Bit Value	Range Selected	
DTSA < DTEA	0	DTSA ->	<- DTEA
DTSA < DTEA	1	<- DTSA	DTEA ->
DTSA > DTEA	N/A	Invalid Range - no trace	
DTSA = DTEA	N/A	Invalid Range - no trace	

Note

DTSA must be less than DTEA in order to guarantee correct Data Write/Read Traces. Data Trace ranges are *inclusive* of the DTSA and DTEA addresses for Range Control settings indicating "within range," and are *exclusive* of the DTSA and DTEA addresses for Range Control settings indicating "outside of range."

Accesses that meet the range and access type qualifiers will cause assertion of a watchpoint output for Ranges 1, 2, and 3. There are three dedicated watchpoint outputs, one for each DTSA/DTEA sets 1, 2, and 3. Range 4 does not provide a watchpoint output. Note that when DTC_{DI}=1, all instruction fetches and prefetches (including discarded prefetches) are monitored, and thus these range watchpoints differ from the IACx watchpoint outputs, which are not asserted for instructions that are not executed (i.e. when the instruction prefetch is discarded).

66.4.13 Read/Write Access Control/Status (RWCS) register

The Read Write Access Control/Status Register provides control for Read/Write Access. Read/Write access provides DMA-like access to memory-mapped resources on the AHB System bus either while the processor is halted, or during runtime. Control is provided over access type, size, count, and certain bus attributes.

Note that the internal CPU interfaces to the caches and local memory are not accessible or utilized by this mechanism. Since the external interface is used, base address port settings are used to access local memory, and not the settings of local memory control register base address values.

The RWCS Register also provides Read/Write Access Status information per Table 66-25.

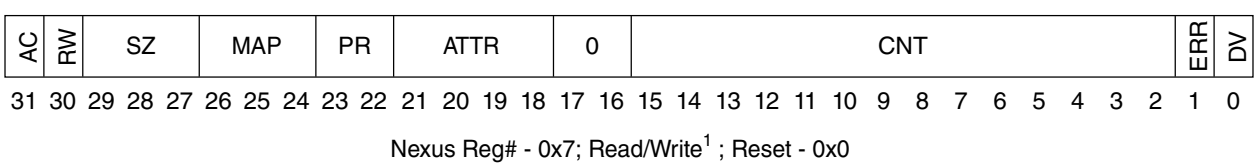

Figure 66-26. Read/Write Access Control/Status (RWCS) register

NOTES:

[1]ERR and DV are read-only

Table 66-24. RWCS field description

Bits	Name	Description
RWCS[31]	AC	Access Control 0 End access/ Access has completed 1 Start access
RWCS[30]	RW	Read/Write Select 0 Read access 1 Write access
RWCS[29:27]	SZ	Word Size 000 8-bit (byte) 001 16-bit (half-word) 010 32-bit (word) 011 64-bit (doubleword, requires two passes through RWD) 100 - 111 Reserved (default to word)
RWCS[26:24]	MAP	MAP Select 000 Primary memory map 001-111 Reserved
RWCS[23:22]	PR[1]	Read/Write Access Priority 00 Reserved (default to highest priority) 01 Reserved (default to highest priority) 10 Reserved (default to highest priority) 11 Highest access priority
RWCS[21:18]	ATTR	Access Attributes 0xxx Reserved 1xxx Reserved x0xx **p_d_hprot[4]** driven to 0 for accesses x1xx **p_d_hprot[4]** driven to 1 for accesses xx0x **p_d_hprot[3]** driven to 0 for accesses xx1x **p_d_hprot[3]** driven to 1 for accesses xxx0 **p_d_hprot[2]** driven to 0 for accesses xxx1 **p_d_hprot[2]** driven to 1 for accesses
RWCS[17:16]	—	RES - Reserved for future functionality
RWCS[15:2]	CNT	Access Control Count hhhh Number of accesses of word size SZ
RWCS[1]	ERR[2]	Read/Write Access Error (see Table 66-25)
RWCS[0]	DV[2]	Read/Write Access Data Valid (see Table 66-25)

1. The priority functionality is not currently implemented.
2. ERR and DV are read-only.

Table 66-25. Read/Write Access Status Bit Encoding

Read Action	Write Action	ERR	DV
Read Access has not completed	Write Access completed without error	0	0
Read Access error has occurred	Write Access error has occurred	1	0
Read Access completed without error	Write Access has not completed	0	1
Not Allowed	Not allowed	1	1

66.4.14 Read/Write Access Data (RWD) register

The Read/Write Access Data (RWD) register provides the data to/from system bus memory-mapped locations when initiating a read or a write access.

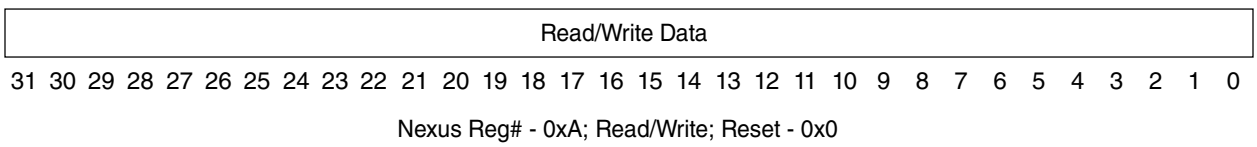

Figure 66-27. Read/Write Access Data (RWD) register

Read/Write accesses to the AHB require that the debug firmware properly retrieve/place the data in the RWD. Table 66-26 shows the proper placement of data into the RWD. Note that doubleword transfers require two passes through RWD.

Table 66-26. RWD data placement for ransfers

Transfer Size and byte offset	RWA(2:0)	RWCS[SZ]	RWD			
			31:24	23:16	15:8	7:0
Byte	x x x	0 0 0	-	-	-	X
Half	x x 0	0 0 1	-	-	X	X
Word	x 0 0	0 1 0	X	X	X	X
Doubleword	0 0 0	0 1 1				
first RWD pass (low order data)			X	X	X	X
second RWD pass (high order data)			X	X	X	X

Table Notes:

"X" indicates byte lanes with valid data

"-" indicates byte lanes that will contain unused data.

Table 66-27 shows the mapping of RWD bytes to byte lanes of the AHB read and write data buses.

Table 66-27. RWD byte lane mapping

Transfer Size and byte offset	RWA(2:0)	RWD			
		31:24	23:16	15:8	7:0
Byte @000	0 0 0	-	-	-	AHB[7:0]
Byte @001	0 0 1	-	-	-	AHB[15:8]
Byte @010	0 1 0	-	-	-	AHB[23:16]
Byte @011	0 1 1	-	-	-	AHB[31:24]
Byte @100	1 0 0	-	-	-	AHB[39:32]
Byte @101	1 0 1	-	-	-	AHB[47:40]
Byte @110	1 1 0	-	-	-	AHB[55:48]
Byte @111	1 1 1	-	-	-	AHB[63:56]
Half @000	0 0 0	-	-	AHB[15:8]	AHB[7:0]
Half @010	0 1 0	-	-	AHB[31:24]	AHB[23:16]
Half @100	1 0 0	-	-	AHB[47:40]	AHB[39:32]
Half @110	1 1 0	-	-	AHB[63:56]	AHB[55:48]
Word @000	0 0 0	AHB[31:24]	AHB[23:16]	AHB[15:8]	AHB[7:0]
Word @100	1 0 0	AHB[63:56]	AHB[55:48]	AHB[47:40]	AHB[39:32]
Doubleword @000	0 0 0				
first RWD pass		AHB[31:24]	AHB[23:16]	AHB[15:8]	AHB[7:0]
second RWD pass		AHB[63:56]	AHB[55:48]	AHB[47:40]	AHB[39:32]

Table Notes:

"-" indicates byte lanes that will contain unused data.

66.4.15 Read/Write Access Address (RWA)

The Read/Write Access Address Register provides the system bus address to be accessed when initiating a read or a write access.

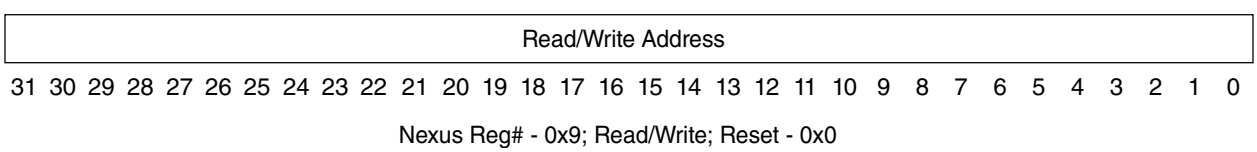

Figure 66-28. Read/Write Access Address (RWA) register

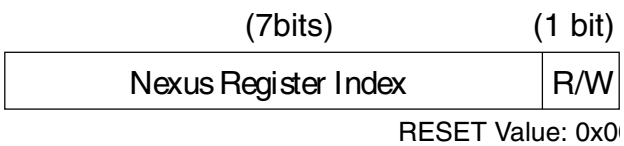

66.5 Nexus 3 Register Access via JTAG/OnCE

Access to Nexus 3 register resources is enabled by loading a single instruction ("*NEXUS3-ACCESS*") into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus 3 block, the OCMD value is 0b0001111100.

Once the NEXUS3-ACCESS instruction has been loaded, the JTAG/OnCE port allows tool/target communications with all Nexus 3 registers according to the register map in Table 66-8.

Reading/writing of a Nexus 3 register then requires two (2) passes through the Data-Scan (DR) path of the JTAG state machine. (See IEEE 1149.1 (JTAG) RD/WR sequences.)

1. The first pass through the DR selects the Nexus 3 register to be accessed by providing an index (see Table 66-8), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the following format:

Nexus Register Index	Selected from values in Table 66-8
Read/Write (R/W):	0 - Read 1 - Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a. During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the "Capture-DR" state.
   b. During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the "Update-DR" state.

66.6 Nexus 3 Register Access via Software

Access to most Nexus 3 register resources by software is supported by mapping the Nexus 3 registers to privileged DCRs (device control registers) that are accessible via the **mfdcr** and **mtdcr** instructions. It is intended that these access only occur when no

possible conflicts with hardware-based accesses are possible. A conflict between hardware and software accesses will produce undefined results. Table 66-8 shows the mappings of Nexus 3 registers to DCR numbers. Software writes to Nexus 3 register resources are blocked when the **nex_sfwcntl_en** input signal is negated, without signaling an exception. Note that the Nexus 3 Read/Write Access functionality is not available to software, since software can use load and store instructions to access memory.

66.7 Nexus message fields

Nexus messages are composed of fields. Each field contains a distinct piece of information within a message, and each message contains multiple fields. Messages are transferred in packets over the Auxiliary Output protocol. A packet is a collection of fields. A packet may contain any number of fixed length fields, but may contain at most one variable length field. The variable length field must be the last field in a packet. The following sub-sections describe a subset of the message field types.

66.7.1 TCODE Field

The TCODE field is a 6-bit fixed length field that identifies the type of message and its format. The field encodings are assigned by IEEE-ISTO 5001.

66.7.2 Source ID Field (SRC)

Each Nexus module in a device is identified by a unique Client Source Identification Number. The number assigned to each Nexus module is determined by the SoC integrator, and is provided on the **nex3_ext_src_id[0:3]** input signals. Multi-threaded processors may assign additional source ID information to indicate which thread a message is associated with. The Nexus 3 module implements a 4-bit fixed length Source ID field consisting of a Client Source ID.

66.7.3 Relative Address Field (U-ADDR)

The non-sync forms of the Program and Data Trace messages include addresses that are relative to the address that was transmitted in the previous Program or Data Trace message, respectively. The relative address format is compliant with IEEE-ISTO 5001 and is designed to reduce the number of bits transmitted for address fields.

The relative address is generated by XORing the new address with the previous, and then using only the results up to the most significant '1'. To recreate the original address, the relative address is XORed with the previously decoded address.

The relative address of a Program Trace message is calculated with respect to the previous Program Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Program Trace messages.

The relative address of a Data Trace message is calculated with respect to the previous Data Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Data Trace messages.

Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

Previous Address (A1) =0x0003FC01, New Address (A2) = 0x0003F365

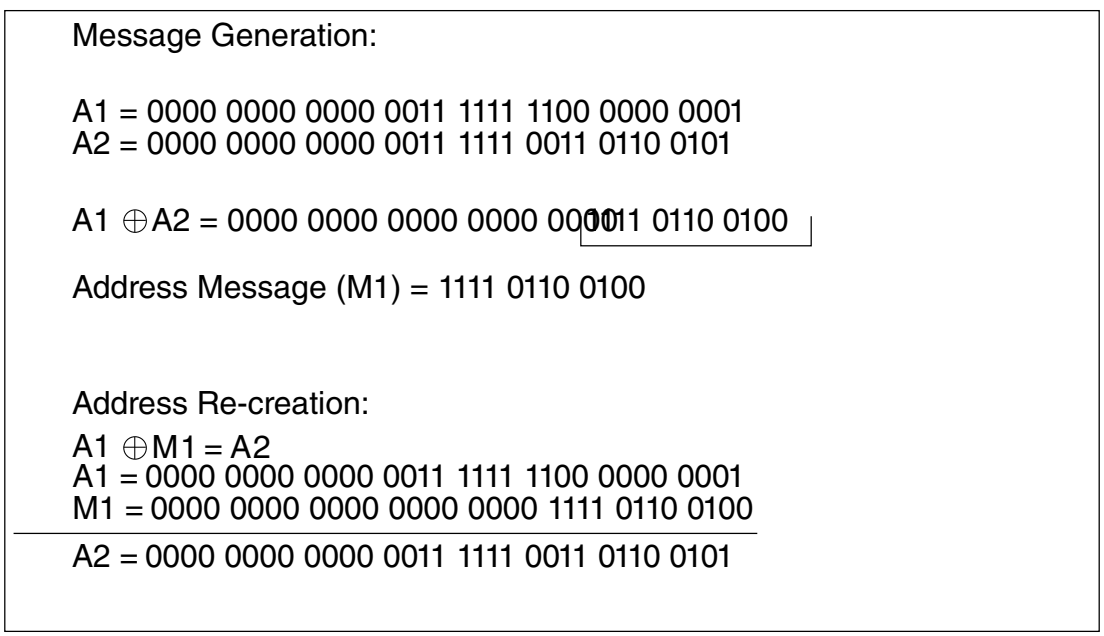

Figure 66-29. Relative address generation and recreation

66.7.4 Full Address Field (F-ADDR)

Program Trace synchronization messages provide the full address associated with the trace event (leading zeroes may be truncated) with the intent of providing a reference point for development tools to operate from when reconstructing relative addresses. Synchronization messages are generated at significant mode switches and are also generated periodically to ensure that development tools are guaranteed to have a reference address given a sufficiently large sample of trace messages. Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

66.7.5 Timestamp field (TSTAMP)

Timestamps may be optionally applied to messages. Enabling of timestamping is controlled by the nex_tsen input signal. The timestamping mode (timestamp frequency of occurrence) is controlled by the value of nex_tsmode[0:1] and the timestamp value is based on the nex_timebase[0:29] inputs. These signals are first synchronized to the nex_clk clock domain, and for nex_timebase[0:29], a gray-code to binary value conversion is performed. The timestamp value is applied to messages as they exit the message queues. Leading zeros in the timestamp value are removed. The table shows the nex_tsmode[0:1] encodings used for the timestamp mode.

Table 66-28. nex_tsmode[0:1] timestamp mode encoding

nex_tsmode[0:1]	Timestamp Mode
00	Timestamp applied to every message
01	Timestamp applied to every 4th message
10	Timestamp applied to every 16th message
11	Timestamp applied to every 64th message

66.8 Nexus Message Queues

The Nexus 3 module implements internal message queues capable of storing up to three messages per cycle into a small initial queue, which then fills a larger queue at up to two messages per cycle. Messages that enter the queues are transmitted in the order in which they are received.

If more than three messages attempt to enter the queue in the same cycle, the highest priority messages are stored and the remaining message(s) will be dropped due to a collision. Collision events are expected to be rare.

The Overrun Control register (OVCR) controls the Nexus behavior as the message queue fills. The Nexus block may be programmed to:

- Allow the queue to overflow, drain the contents, queue an overrun error message and resume tracing.
- Stall the processor when the queue utilization reaches the selected threshold.
- Suppress selected message types when the queue utilization reaches the selected threshold.

66.8.1 Message Queue Overrun

In this mode, the message queue will stop accepting messages when an overrun condition is detected. The contents of the queues will be allowed to drain until empty. Incoming messages are discarded until the queue is emptied. Once empty, an overrun error message is enqueued that contains information about the types of messages that were discarded due to the overrun condition.

66.8.2 CPU Stall

In this mode, processor instruction issue is stalled when the queue utilization reaches the selected threshold. The processor is stalled long enough to drop one threshold level below the level that triggered the stall. For example, if stalling the processor is triggered at 1/4 full, the stall will stay in effect until the queue utilization drops to empty. There may be significant skid from the time that the stall request is made until the processor is able to stop completing instructions. This skid should be taken into consideration when programming the threshold. Refer to Nexus Overrun Control Register (OVCR) for complete programming options.

66.8.3 Message Suppression

In this mode, the message queue will disable selected message types when the queue utilization reaches the selected threshold. This allows lower bandwidth tracing to continue and possibly avoid an overrun condition. If an overrun condition occurs despite this message suppression, the queue will respond according to the behavior described in

Message Queue Overrun. Suppressed message types are reported in the error message if they occur after overrun in addition to other discarded message types. Once triggered, message suppression will remain in effect until queue utilization drops to the threshold below the level selected to trigger suppression.

66.8.4 Nexus Message Priority

Nexus messages may be lost due to contention with other message types under the following circumstances:

- More than three messages are generated in the same cycle

Table 66-29 lists the various message types and their relative priority from highest to lowest.

Up to three message requests can be queued into the message buffer in a given cycle. If more than three message requests exist in a given cycle, the three highest priority message classes are queued into the message buffer. The remaining messages that did not successfully queue into the message buffer in that cycle will generate subsequent responses, as detailed in Table 66-29.

The CPU is capable of completing two instructions per cycle. If multiple trace messages need to be queued at the same time, they will be queued with the following priority: Instruction 0 (oldest instruction) (WPM ->DQM -> PCM_{PIDMSG} -> OTM -> BTM -> DTM)-> Instruction1 (newer instruction) (WPM -> DQM -> OTM -> BTM -> DTM). As many as three messages may be simultaneously queued. Note that for the cycle following a dropped PTM, non-periodic OTM, or DQM message, only two other messages may be queued in addition to the dropped Error Message.

Watchpoint Messages from instructions that complete at the same time or events that occur during the same cycle will be combined.

Table 66-29. Message Type Priority and Message Dropped Responses

Message Type	Message	Priority	Message Dropped Response
Error	Error	0 (highest)	N/A[1]
WP (Watchpoint Trace)	WPM (Watchpoint Message)	1	N/A[1]
DQ (Data Acquisition)	DQM (Data Acquisition Message)	2	DQM Error Message
Program Trace (PID MSG)	PCM - PID/NPIDR update (Program Correlation Message)	2	OTM Error Message

Table continues on the next page...

Table 66-29. Message Type Priority and Message Dropped Responses (continued)

Message Type	Message	Priority	Message Dropped Response
OT (Ownership)	OTM - PID/NPIDR update (Ownership Trace Message)	2	OTM Error Message[2]
Program Trace	BTM (Branch Trace Message)	2	BTM Error Message, Sync upgrade next BTM
	Sync (Program Sync Message)	3	Sync upgrade next BTM
	RFM (Resource Full for Instruction counter or history buffer)	4	BTM Error Message Sync upgrade next BTM
	DS (Debug Status Message)	5	Sync upgrade next BTM
	PCM (Program Correlation Message)	6	BTM Error Message Sync upgrade next BTM
DT (Data Trace)	DTM (Data Trace Message)	7	Sync upgrade next DTM
OT (Ownership)	OTM - Periodic update (Ownership Trace Message)	8 (lowest)	none

1. Error and Watchpoint messages are not dropped due to collisions, due to their priority.
2. Message will always be dropped if program trace is enabled, and program correlation messages for PID messages are not masked (Event Code = 0101). No error message is sent for this case since the PID value is contained in the higher priority message.

66.8.5 Data Acquisition Message Priority Loss Response

If a Data Acquisition Message (DQM) loses arbitration due to contention with higher priority messages, an error message will be generated to indicate that a DQM has been lost due to contention.

66.8.6 Ownership Trace Message Priority Loss Response

If an Ownership Trace message (OTM) due to software updates to the Process ID state loses arbitration due to contention with higher priority messages other than a program correlation message with EVCODE = 0101 (PID update), an error message will be generated to indicate that a OTM has been lost due to contention. If the pending OTM is a periodic update, the event is dropped without generating an error message.

66.8.7 Program Trace Message Priority Loss Response

If a Program Trace message (PTM) loses arbitration due to contention with higher priority messages, and the discarded PTM is a Program Correlation message, a Resource Full message for instruction count or history buffer, or a Branch Trace message, then an Error message is generated to indicate that branch trace information has been lost, and the next Branch Trace message will be upgraded to a sync-type message.

If the discarded PTM is a Program Correlation message with PID information (EVCODE=0101), the Error message will indicate a dropped OTM and a dropped Program Trace (Error code = xxxx11xx).

66.8.8 Program Trace Sync Message Priority Loss Response

If a Program Trace Sync message (SYNC) loses arbitration due to contention with higher priority messages, the Sync event is discarded, and the next Branch Trace message will be upgraded to a sync-type message.

66.8.9 Data Trace Message Priority Loss Response

If a Data Trace message (DTM) loses arbitration due to contention with higher priority messages, the DTM event is discarded, and the next DTM will be upgraded to a sync-type message.

66.9 Debug Status messages

Debug Status Messages report low power mode and debug status. Debug Status messages are enabled when Nexus 3 is enabled. Entering/exiting Debug Mode as well as entering, exiting, or changing Low Power Mode(s) will trigger a Debug Status message, indicating the value of the most significant byte in the Development Status register. Debug status information is sent out in the following format:

(8 bits)	(4 bits)	(6 bits)
DS[31:24]	Src. Proc.	TCODE (000000)

Fixed length = 18 bits

Figure 66-30. Debug Status message format

66.10 Error messages

Error messages are enabled whenever the debug logic is enabled. There are two conditions that will produce an error message, each receiving a separate error type designation:

- A message is discarded due to contention with other (higher priority) message types. These errors will have an Error Type value of 1.
- The message queue overruns. After the queue is drained, an error message is enqueued with an error code that indicates what types of messages were discarded during the interim. These errors will have an Error Type value of 0.

Note

The OVCR Register can be used in order to alleviate potential overrun situations.

Error information is messaged out in the following format (also see Table 66-3 and Table 66-4):

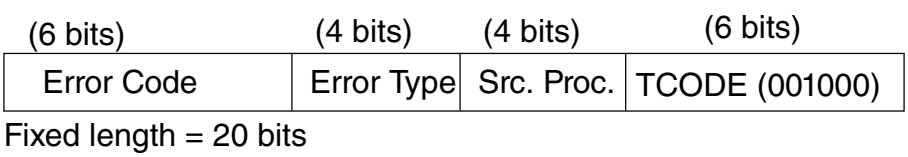

Figure 66-31. Error message format

66.11 Ownership trace

This section details the ownership trace features of the Nexus 3 module.

66.11.1 Overview

Ownership trace provides a macroscopic view, such as task flow reconstruction, when debugging software written in a high level (or object-oriented) language. It offers the highest level of abstraction for tracking operating system software execution. This is especially useful when the developer is not interested in debugging at lower levels.

66.11.2 Ownership Trace Messaging (OTM)

Ownership trace information is messaged via the auxiliary port using an Ownership Trace Message (OTM). Core (e200z210n3) processors contain a *Power ISA 2.06* defined "Process ID" register within the CPU. It is updated by the operating system software to provide task/process ID information. The contents of this register are replicated on the pins of the processor and connected to Nexus. The Process ID (PID) register value can be accessed using the **mfspr/mtspr** instructions.

Note

The CPU includes a Process ID register (PID0), thus the Nexus UBA functionality is not implemented.

In addition, to decouple trace information from the PID0 register and to provide a full independent 32-bit process ID for debug use, the Nexus PID Register (NPIDR) may be used instead of PID0 to provide OTM process ID information. It is updated by the operating system software to provide task/process ID information. The Nexus Process ID (NPIDR) register value can be accessed using the **mfspr/mtspr** instructions. This register is accessible in user or supervisor mode.

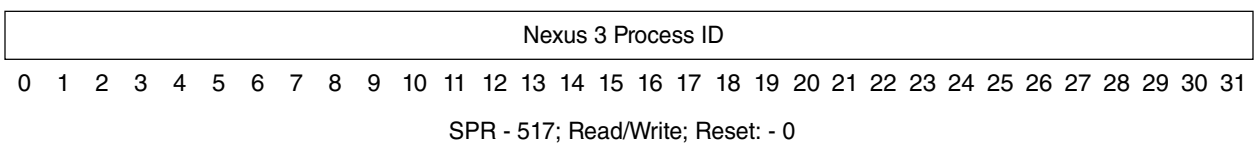

Figure 66-32. Nexus 3 Process ID Register (NPIDR)

Note

OS updates to NPIDR should be performed in addition to normal PID0 updates when a process switch occurs, in order to properly generate OTM messages with new process ID information when NPIDR is selected for OTM use.

The process ID source (PID0 or NPIDR) is selected by the setting of the $DC1_{OTS}$ control bit.

There are two conditions that will cause an Ownership Trace Message when Ownership Trace is enabled:

- When the PID0 register is written to by the processor and $DC1_{OTS}$ indicates PID0 should be used, or when the NPIDR register is written to by the processor and $DC1_{OTS}$ indicates NPIDR should be used, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow. However, if Program Trace is enabled, and program correlation messages for

PID updates are not masked (Event Code = 0101), then an OTM will not be generated for an update to the selected process ID register, since the program correlation message will provide this process ID update information.

- Periodically, at least once every 256 messages, the most recent state of the selected process ID register is messaged out. The resulting Ownership Trace message will indicate in the PID Index sub-field that PID0/NPIDR status is being reported and the most recent value of the PID0/NPIDR register will be conveyed in the Process ID value sub-field. These periodic Ownership Trace message events can be disabled by setting $DC1_{POTD}$.

Ownership trace information is messaged out in the following format:

(1-32 bits)	(4 bits)	(4 bits)	(6 bits)
Process ID	PID Index (0000)	Src. Proc.	TCODE (000010)

Variable length = 15-46 bits

Figure 66-33. Ownership Trace Message format

66.12 Program trace

This section details the program trace mechanism supported by Nexus3 for the e200z210n3 processor. Program trace is implemented via Branch Trace Messaging (BTM) as per the **IEEE-ISTO 5001** standard definition. Branch Trace Messaging for Core (e200z210n3) processors is accomplished by snooping the internal address bus, attribute signals, and CPU Status (**p_mode[0:3]**, **p_pstat_pipe{0,1}[0:5]**).

66.12.1 Branch Trace Messaging types

Traditional Branch Trace Messaging facilitates program trace by providing the following types of information:

- Messaging for taken direct branches includes how many sequential instructions were executed since the last taken branch or exception, including the taken direct branch. Branch instructions are included in the count of sequential instructions.
- Messaging for taken indirect branches and exceptions includes how many sequential instructions were executed since the last taken branch or exception and the unique portion of the branch target address or exception vector address. Branch instructions are included in the count of sequential instructions. For taken indirect branches that trigger generation of a message, the branch is also included in the count.

Branch History Messaging facilitates program trace by providing the following information.

- Messaging for taken indirect branches and exceptions includes a) how many sequential instructions (I-CNT) were executed since the last predicate instruction, taken/not taken direct branch, taken/not-taken indirect branch, or exception, b) the unique portion of the branch target address or exception vector address, and c) a branch/predicate instruction history field. Each bit in the history field represents a direct branch or predicated instruction where a value of one (1) indicates taken, and a value of zero (0) indicates not taken. Not-taken indirect branches will generate a history bit with a value of zero (0). Instructions that generate history bits are not included in instruction counts. For taken indirect branches that trigger generation of this message type, the branch is included in the count, but not in the history field.

66.12.1.1 Indirect Branch Message instructions

Table 66-30 shows the types of instructions and events that cause Indirect Branch Messages or Branch History Messages to be encoded.

Table 66-30. Indirect Branch Message sources

Source of Indirect Branch Message	Instructions / Detail
Taken branch relative to a register value	**bcctr, bcctrl, bclr, bclrl, se_bctr, se_bctrl, se_blr, se_blrl**
System Call / Trap exceptions taken	**se_sc, tw**
Return from interrupts / exceptions	**se_rfi, se_rfci, se_rfdi**
Exit from reset with Program Trace Enabled	**Indirect branch with Sync, target address is initial instruction, count = 1**

66.12.1.2 Direct Branch Message Instructions

Table 66-31 shows the types of instructions that will cause Direct Branch Messages or will toggle a bit in the instruction history buffer to be messaged out in a Resource Full Message or Branch History Message.

Table 66-31. Direct Branch Message sources

Source of Direct Branch Message	Instructions
Taken direct branch instructions Instruction Synchronize	**b, ba, bl, bla, bc, bca, bcl, bcla, se_b. se_bc, se_bl, e_b, e_bc, e_bl, e_bcl, se_isync**

66.12.1.3 BTM using Branch History Messages

Traditional BTM Messaging can accurately track the number of sequential instructions between branches, but cannot accurately indicate which instructions were conditionally executed, and which were not.

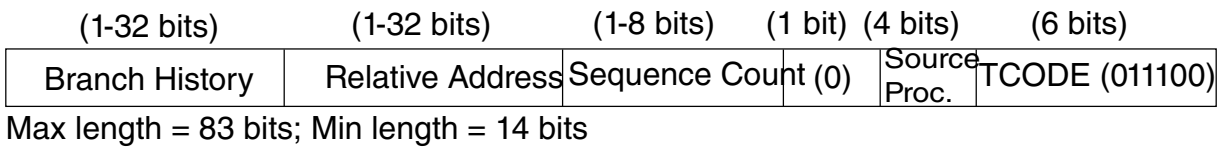
Branch History Messaging solves this problem by providing a predicated instruction history field in each Indirect Branch Message. Each bit in the history represents a predicated instruction or direct branch, or a not-taken indirect branch. A value of one (1) indicates the conditional instruction was executed or the direct branch was taken. A value of zero (0) indicates the conditional instruction was not executed or the branch was not taken.

Branch History Messages solve predicated instruction tracking and save bandwidth since only indirect branches cause messages to be queued.

66.12.1.4 BTM using Traditional Program Trace Messages

Based on the PTM bit in the DC1 Register, Program Tracing can utilize either Branch History Messages (PTM = 1) or traditional Direct/Indirect Branch Messages (PTM = 0).

Branch History will save bandwidth and keep consistency between methods of Program Trace, yet may lose temporal order between BTM messages and other types of messages. Since direct branches are not messaged, but are instead included in the history field of the Indirect Branch History Message, other types of messages may enter the FIFO between Branch History Messages. The development tool cannot determine the ordering of "events" that occurred with respect to direct branches simply by the order in which messages are sent out.



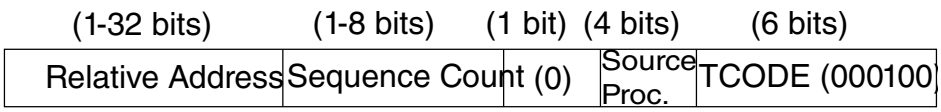
Traditional BTM messages maintain their temporal ordering because each event that can cause a message to be queued will enter the FIFO in the order it occurred and will be messaged out maintaining that order.

66.12.2 BTM Message For mats

The Nexus 3 block supports three types of traditional BTM Messages - Direct, Indirect, and Synchronization Messages. It supports two types of branch history BTM Messages - Indirect Branch History, and Indirect Branch History with Synchronization Messages.

66.12.2.1 Indirect branch messages (history)

Indirect branches include all taken branches whose destination is determined at run time, interrupts, and exceptions. If $DC1_{PTM}$ is set to '1', indirect branch information is messaged out in the following format:



Max length = 83 bits; Min length = 14 bits

Figure 66-34. Indirect branch message (history) format

66.12.2.2 Indirect branch messages (traditional)

If $DC1_{PTM}$ is cleared to '0', indirect branch information is messaged out in the following format:

Max length = 51 bits; Min length = 13 bits

Figure 66-35. Indirect branch message format

66.12.2.3 Direct branch messages (traditional)

Direct branches (conditional or unconditional) are all taken branches whose destination is fixed in the instruction opcode. Direct branch information is messaged out in the following format:

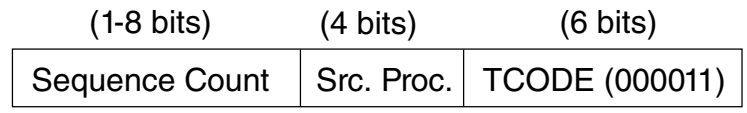


Figure 66-36. Direct Branch message format

Note

When $DC1_{PTM}$ is set, Direct Branch Messages will not be transmitted. Instead, each direct branch, not-taken indirect branch, or predicated instruction will be recorded in the history buffer.

66.12.3 Program Trace Message Fields

The following subsections describe specific fields used for Program Trace messages.

66.12.3.1 Sequential Instruction Count Field (ICNT)

Most of the program trace messages include an instruction count field. For traditional Branch messages, ICNT represents the number of sequential instructions including non-taken branches since the last Direct/Indirect Branch messages. Branch instructions that trigger message generation are included in the ICNT.

For Branch History messages, ICNT represents the number of instructions executed since the last taken/non-taken direct branch, predicate instruction, last taken/not-taken indirect branch, or exception. Branch instructions that trigger message generation are included in the ICNT. Instructions that generate history bits are not included in the ICNT.

The sequential instruction counter overflows after its value reaches 255 and is reset to 0. In addition, the next BTM Message (corresponding to the 256th or later instruction) will be converted to a w/sync type message.

The instruction counter is reset every time the instruction count is transmitted in a message or whenever there is a branch/predicate history event, as well as on exiting from debug mode.

66.12.3.2 Branch/Predicate Instruction History (HIST)

If $DC1_{PTM}$ is set, BTM messaging will use the Branch History format. The branch history (HIST) field in these messages provides a history of branch execution used for reconstructing the program flow. The branch/predicate history buffer stores information about branch and predicate instruction execution. The buffer is implemented as a left-shifting register. The buffer is preloaded with a one (1), which acts as a stop bit (the most significant 1 in the history field is a termination bit for the field). The pre-loaded bit itself is not part of the history, but is transmitted with the packet.

A value of one (1) is shifted into the history buffer for each taken direct branch (program counter relative branch) or predicate instruction whose condition evaluates to true. A value of zero (0) is shifted into the history buffer for each not-taken branch (including indirect branch instructions) or predicate instruction whose condition evaluates to false.

This history buffer information is transmitted as part of an Indirect Branch with History message, as part of a Program Correlation message, or as part of a Resource Full message if the history buffer becomes full. The history buffer is reset every time the history information is transmitted in a message, as well as on exiting from debug mode.

Table 66-32. Branch/Predicate history events

Branch/Predicate History Event	History Bit(s)	Relevant Instructions
Not taken register indirect branches	0	**bcctr, bcctrl, bclr, bclrl**
Not taken direct branches	0	**b, ba, bc, bca, bla, bcla, bl, bcl**
Taken direct branches	1	**b, ba, bc, bca, bla, bcla, bl, bcl**[1]

1. If the EVCODE for direct branch function calls is not masked in DC4, taken **bl** and **bcl** instructions will generate Program Correlation Messages and will not be logged in the history buffer.1

66.12.3.3 Execution Mode Indication

In order for a development tool to properly interpret instruction count and history information, it must be aware of the execution mode context of that information. VLE instructions will be interpreted differently from non-VLE instructions.

Program trace messages provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

66.12.4 Resource Full Messages

The Resource Full Message is used in conjunction with Branch Trace and Branch History Messages. The Resource Full Message is generated when either the internal branch/ predicate history buffer is full, or if the BTM Instruction sequence counter (I-CNT) overflows. If synchronization is needed at the time this message is generated, the synchronization is delayed until the next Branch Trace Message that is not a Resource Full Message.

For history buffer overflow, the Resource Full Message transmits a Resource Code (RCODE) of 0b0001 and the current contents of the history buffer, including the stop bit, are transmitted in the Resource Data (RDATA) field. This history information can be concatenated by the development tool with the branch/predicate history information from subsequent messages to obtain the complete branch/predicate history between indirect changes of flow.

For instruction counter overflow, the Resource Full Message transmits an RCODE of 0b0000 and a value of 0xFF is transmitted in the RDATA field, indicating that 255 sequential instructions have been executed since the last change of flow, or, if program trace is in history mode, since the last instruction that recorded history information.

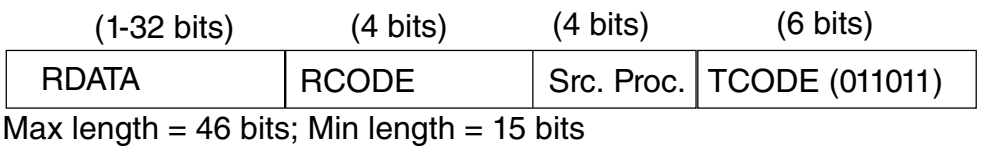

Figure 66-37. Resource Full Message format

The following table shows the RCODE encodings and RDATA information used for Resource Full Messages.

Table 66-33. RCODE encoding

RCODE	Description	RDATA field
0000	Program Trace Instruction counter reached 255 and was reset.	0xFF
0001	Program Trace, Branch / Predicate Instruction History full.	Branch HIstory. This type of packet is terminated by a stop bit set to 1 after the last history bit.

66.12.5 Program Correlation Messages

Program Correlation Messages (PCMs) are used to correlate events to the program flow that may or may not be associated with the instruction stream. The following events will result in a PCM when program trace is enabled:

- When the CPU enters debug mode, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to debug mode entry.
- When the CPU first enters a low power mode in which instructions are no longer executed, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to low power mode entry.
- Whenever program trace is disabled by any means, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to disabling program trace.
- When a "Branch and Link" instruction executes (direct branch function call — **bl/bcl/bla/bcla**-type instructions)
- When program trace becomes masked due to MSR_{PMM}='0' and $DC4_{PTMARK}$='1'.
- When a write to the process ID register selected by $DC1_{OTS}$ (PID0 or NPIDR) is made via a **mtspr** PID0 or **mtspr** NPIDR.

Refer to Table 66-6 for the event codes that are supported in this implementation. Event code masking is available via the EVCDM field of the DC4 register to allow for control over generation of Program Correlation messages for each event type.

Program Correlation is messaged out in the following formats:

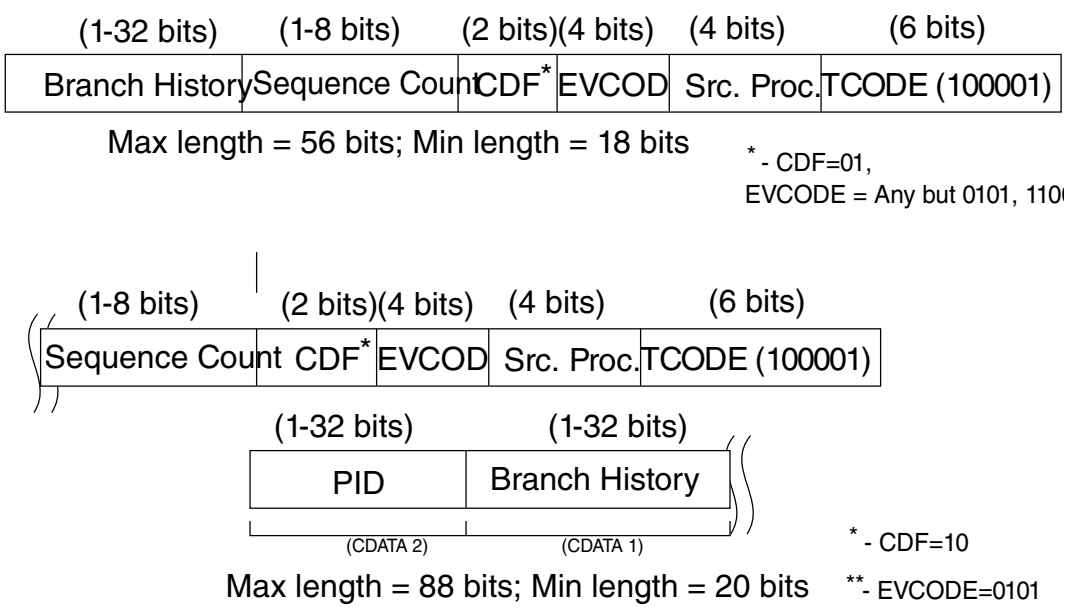

Figure 66-38. Program Correlation message formats

If timestamping is enalbed, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

66.12.5.1 Program Correlation message generation for PID updates

When a (potentially) new value is established in the selected process ID register via a **mtspr** PID0/NPIDR, a Program Correlation message is generated containing the information regarding the new process ID value. This PCM also contains the current history and instruction count. The message is provided so that address translation information can be processed by the development tool in the proper program flow. The **mtspr** PID0/NPIDR is included in the instruction count information. Note that Ownership Trace Messages (other than the periodic OTM) are redundant with the information provided, and may be disabled to avoid unnecessary message bandwidth or collisions.

66.12.6 Program Trace Overflow Error messages

An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied.

66.12.7 Program Trace Synchronization messages

By default, program trace messages will perform XOR compression on the branch target address to produce the address field for the message. This compression is consistent with the specification in IEEE-ISTO 5001.

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see Table 66-34):

- Initial Program Trace message after exit from system reset or whenever program trace is enabled.
- Upon exiting from a CPU Low Power state.
- Upon exiting from Debug Mode.

- Upon occurrence of queue overrun (can be caused by any trace message) or suppression, provided Program Trace is enabled.
- Upon assertion of the Event In (**nex_evti_b**) pin if the EIC bits within the DC1 Register have enabled this feature.
- When program trace becomes unmasked due to $MSR_{PMM} \rightarrow$ '1' with $DC4_{PTMARK}$='1'.

Note that the ICNT information for these messages is driven to zero, thus will not always be meaningful for some of these cases.

The format for Program Trace Synchronization messages is as follows:

(1-32 bits)	(1-8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Seq. Count (0)	(0)	Source Proc.	TCODE (001001)

Max length = 51 bits; Min length = 13 bits

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

Exception conditions that result in Program Trace Synchronization are summarized in Table 66-34.

Table 66-34. Program Trace exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. Upon exiting system reset (**p_reset_b**), if Program Trace is already enabled, a Program Trace Sync Message is sent.
Program Trace Enabled	The first Program Trace Message (after Program Trace has been enabled or re-enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode, a Program Trace Sync Message is sent.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next BTM message in the queue will be a Program Trace Sync Message.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Program Trace Sync Message if Program Trace is enabled and the EIC bits of the DC1 Register have enabled this feature.

Note that for cases where program trace sync messages are generated due to program trace being enabled, the address contained in the sync message may either be the address of the instruction that caused program trace to be enabled, or may be the address of the first instruction of an exception handler that is executed in response to unsuccessful completion of that instruction.

66.12.8 Program Trace Direct/Indirect Branch with Sync messages

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization or a Direct/Indirect Branch with Sync message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see Table 66-34):

- Upon direct/indirect branch after a Program Sync Message was lost due to a collision while attempting to enter the message queue.
- Upon direct/indirect branch after the sequential instruction counter has expired indicating 255 instructions have occurred since the last change of flow.
- When the periodic program trace counter has expired indicating 255 *without-sync* Program Trace messages have occurred since the last *with-sync* message occurred.

Note that the ICNT and History information for the first message will not always be meaningful, since the temporary masking of program trace may result in ambiguous values. Subsequent w/sync messages will not have this issue.

The format for Program Trace Direct/Indirect Branch with Sync Messages is as follows:

(1-32 bits)	(1-8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Sequence Count	(0)	Source Proc.	TCODE (001011 or 001100)

Max length = 51 bits; Min length = 13 bits

Figure 66-39. Direct/Indirect Branch with Sync message format

The format for Program Trace Indirect Branch History with Sync. messages is as follows:

(1-32 bits)	(1-32 bits)	(1-8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Full Target Address	Sequence Count	(0)	Source Proc.	TCODE (011101)

Max length = 83 bits; Min length = 14 bits

Figure 66-40. Indirect Branch History w/ Sync. message format

Exception conditions that result in Program Trace Synchronization using a w/Sync message type are summarized in Table 66-35.

Table 66-35. Program Trace Exception Summary for w/Sync BTM messages

Exception Condition	Exception Handling
Periodic Program Trace Sync.	A forced synchronization occurs periodically after 255 non-sync Program Trace Messages have been queued. A Direct/Indirect Branch w/ Sync. Message is queued. The periodic program trace message counter then resets.
Sequential Instruction Count Overflow	After the sequential instruction counter reaches its maximum count (up to 255 sequential instructions may be executed), a forced synchronization occurs. The sequential counter then resets. A Program Trace Direct/Indirect Branch w/ Sync.Message is queued upon execution of the next branch. A Resource Full Message is Queued on the overflow event. If a branch instruction is the 255th instruction to occur, and causes a Program Trace message to be queued, then no Resource Full Message is queued, and the w/Sync message will be queued for the *next* Program Trace Direct/Indirect Branch Message.
Collision Priority	All Messages have the following priority: Instruction 0 (WPM -> DQM -> PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A BTM Message from Instruction1 that attempts to enter the queue at the same time as three higher priority messages from either instruction will be lost. An Error Message will be sent indicating the BTM was lost. The following direct/indirect branch will queue a Direct/Indirect Branch w/ Sync. Message. The count value within this message will reflect the number of sequential instructions executed after the last successful BTM Message was generated. This count will include the branch that did not generate a message due to the collision.

66.12.9 Enabling Program Trace

Program Trace Messaging can be enabled in one of three ways:

- Setting the TM field of the DC1 Register to enable Program Trace
- Using the PTS field of the WT Register to enable Program Trace on Watchpoint hits (watchpoints are configured within the CPU)
- Filtering of Program Trace messages may be performed using the MSR_{PMM} bit and the setting of $DC4_{PTMARK}$

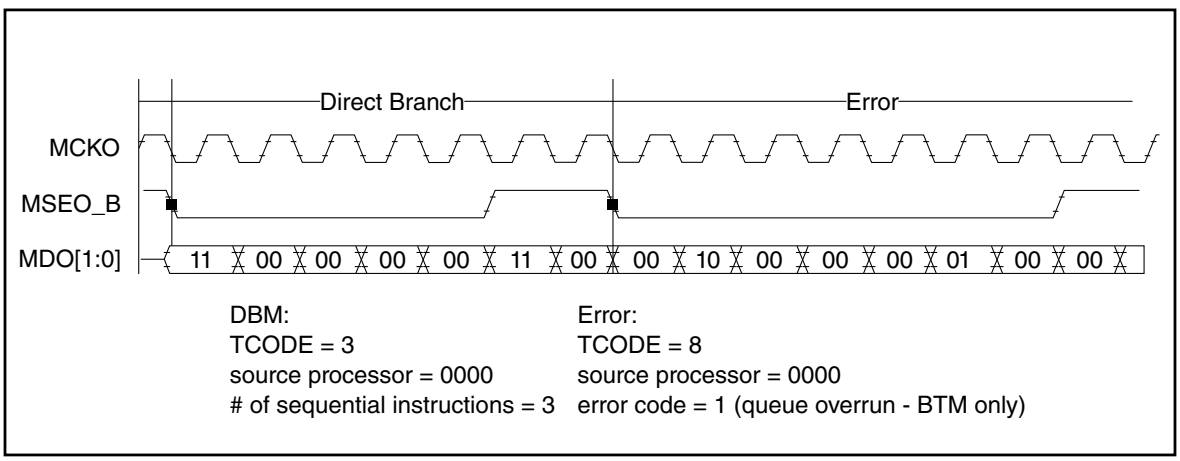

Figure 66-43. Program Trace - Direct Branch (traditional) & Error messages

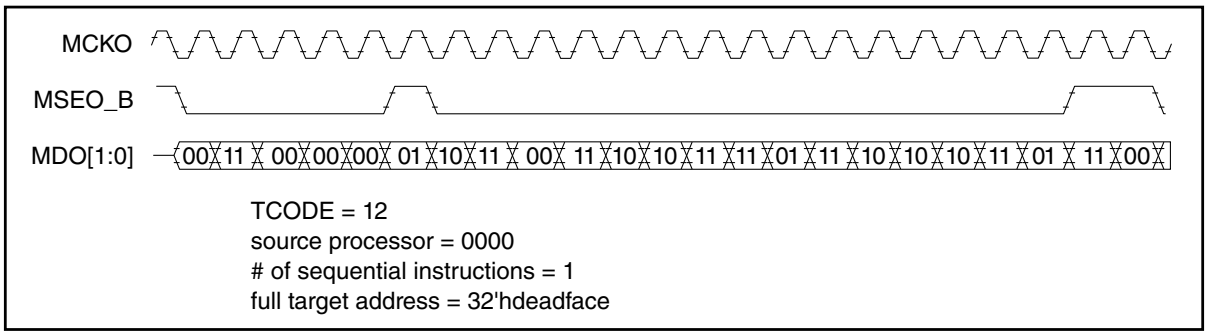

Figure 66-44. Program Trace - Indirect Branch w/ Sync. message

66.13 Data Trace

This section deals with the Data Trace mechanism supported by the Nexus 3 module. Data Trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the **IEEE-ISTO 5001** standard.

66.13.1 Data Trace Messaging (DTM)

Data Trace Messaging is accomplished by snooping the internal address and data buses, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The Nexus 3 module traces all data access that meet the selected range and attributes.

Note

Data Trace is only performed on the internal data buses. This allows for data visibility for Core (e200z210n3) processors that incorporate a data cache. Only CPU initiated accesses will be traced. No DMA accesses to the AHB system bus will be traced.

Data Trace Messaging can be enabled in one of the following ways:

- Setting the TM field of the DC1 Register to enable Data Trace.
- Using the DTS field of the WT Register to enable Data Trace on Watchpoint hits (watchpoints are configured within the Nexus1 module).

66.13.2 DTM Message formats

The Nexus 3 block supports five types of DTM Messages — Data Write, Data Read, Data Write Synchronization, Data Read Synchronization and Error Messages.

66.13.2.1 Data Write messages

The Data Write message contains the data write value and the address of the write access, relative to the previous Data Trace Message. Data Write message information is messaged out in the following format:

(1-64 bits)	(1-32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000101)

Max length = 111 bits; Min length = 17 bits

Figure 66-45. Data Write message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

66.13.2.2 Data Read messages

The Data Read message contains the data read value and the address of the read access, relative to the previous Data Trace message. Data Read message information is messaged out in the following format:

(1-64 bits)	(1-32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000110)

Max length = 111 bits; Min length = 17 bits

Figure 66-46. Data Read fessage format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

Note

* Core (e200z210n3)-based CPUs are capable of generating two (2) reads or writes per clock cycle in cases where multiple registers are accessed with a single instruction (lmw/stmw). These will have a double word pair size encoding (**p_tsiz** =

0b000). In these cases, the Nexus 3 module will send one (1) Data Trace Message with the two 32-bit data values as one combined 64-bit value for each message.

For Core (e200z210n3)-based CPUs, the doubleword encoding (**p_tsiz** = 0b000) may also indicate a doubleword access and will be sent out as a single Data Trace Message with a single 64-bit data value.

The debug/development tool will need to distinguish the two cases based on the family of processor.

66.13.2.3 Data Trace Synchronization messages

A Data Trace Write/Read with Sync. message is messaged via the auxiliary port (provided Data Trace is enabled) for the following conditions (see Table 66-36):

- Initial Data Trace Message after exit from system reset or whenever Data Trace is enabled.
- Upon returning from a CPU Low Power state.
- Upon returning from Debug Mode.
- After occurrence of queue overrun (can be caused by any trace message) or suppression, provided Data Trace is enabled.
- After the periodic data trace counter has expired indicating 255 *without-sync* Data Trace messages have occurred since the last *with-sync* message occurred.
- Upon assertion of the Event In (**nex_evti_b**) pin, the first Data Trace Message will be a synchronization message if the EIC bits of the DC1 Register have enabled this feature.
- Upon Data Trace Write/Read after the previous DTM message was lost due to an attempted access to a secure memory location (for SOC's w/ security).
- Upon Data Trace Write/Read after the previous DTM message was lost due to a collision entering the FIFO between the DTM message and any two of the following: Watchpoint message, Ownership Trace message, or Program Trace message.

Data Trace Synchronization Messages provide the full address (without leading zeros) and insure that development tools fully synchronize with Data Trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the Data Trace address is transmitted. The format for Data Trace Write/Read with Sync. Messages is as follows:

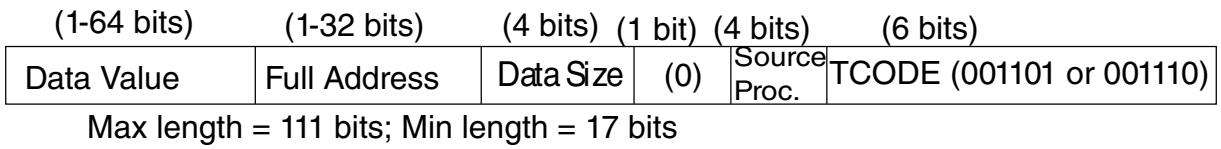

Figure 66-47. Data Write/Read with Sync. message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

Exception conditions that result in Data Trace Synchronization are summarized in Table 66-36.

Table 66-36. Data Trace Exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. If Data Trace is enabled, the first Data Trace Message is a Data Write/Read w/ Sync. Message.
Data Trace Enabled	The first Data Trace Message (after Data Trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode the next Data Trace Message will be converted to a Data Write/Read with Sync. Message.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue will be a Data Write/Read w/ Sync. Message.
Periodic Data Trace Sync.	A forced synchronization occurs periodically after 255 Data Trace Messages have been queued. A Data Write/Read w/ Sync. Message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Data Trace Write/Read w/ Sync. Message upon the next data write/read (if Data Trace is enabled and the EIC bits of the DC1 Register have enabled this feature).
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A DTM Message that attempts to enter the queue at the same time as three other higher priority messages will be lost. A subsequent read/write will queue a Data Trace Read/Write w/ Sync. Message.

66.13.3 DTM Operation

66.13.3.1 Data Trace windowing

Data Write/Read Messages are enabled via the RWT field in the Data Trace Control Register (DTC) for each DTM channel. Data Trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC field in the DTC register. All CPU initiated read/write accesses that fall inside or outside these address ranges, as programmed, are candidates to be traced.

66.13.3.2 Data Access / Instruction Access Data Tracing

The Nexus3 module is capable of tracing either instruction access data or data access data and can be configured for either type of data trace by setting the DI1 field within the Data Trace Control Register. This setting applies to all DTM channels.

66.13.3.3 Data Trace filtering

Data Trace filtering is available base on the settings of MSR_{PMM} and $DC4_{DTMARK}$.

66.13.3.4 Bus Cycle special cases

Table 66-37. Bus Cycle Special Cases

Special Case	Action
Bus cycle aborted	Cycle ignored
Bus cycle with data error ($\overline{TEA}$), [1]	Data Trace Message discarded
Bus cycle completed without error[1]	Cycle captured & transmitted
AHB bus cycle initiated by Nexus 3	Cycle ignored
Bus cycle is an instruction fetch	Cycle selectively ignored based on DTC_{DI} setting
Bus cycle accesses misaligned data (across 64-bit boundary) - both 1st & 2nd transactions within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction within data trace range; 2nd transaction out of data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction within data trace range; 2nd transaction (regardless of within range or not) receives a bus error	Data Trace Message discarded
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction out of data trace range; 2nd transaction within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)

Table continues on the next page...

Table 66-37. Bus Cycle Special Cases (continued)

Special Case	Action
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction out of data trace range; 2nd transaction within range, receives a bus error	Data Trace Message discarded

1. Buffering of stores in the CPU store buffer may generate a DTM prior to the actual memory access, regardless of an error termination condition from memory.

Note

For misaligned accesses (crossing 64-bit boundary), the access is broken into two accesses by the CPU. If either access is within the data trace range, a single DTM will be sent with a size encoding indicating the size of the original access (i.e. word), and the address indicating the original misaligned accesses, unless the misaligned access wraps into the doubleword at address 0. In this case, since the two portions of the misaligned access are not contiguous, two DTMs will be sent, one for each portion. The size encodings and the addresses of the DTMs will indicate the accessed bytes of data. The data trace port handles these cases in the same manner. (See the Data Trace Port section in the Core (e200z210n3) Core Debug Support chapter.)

Note

A store to the store buffer within the data trace range may initiate a DTM message prior to completion of the actual memory access.

66.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration)

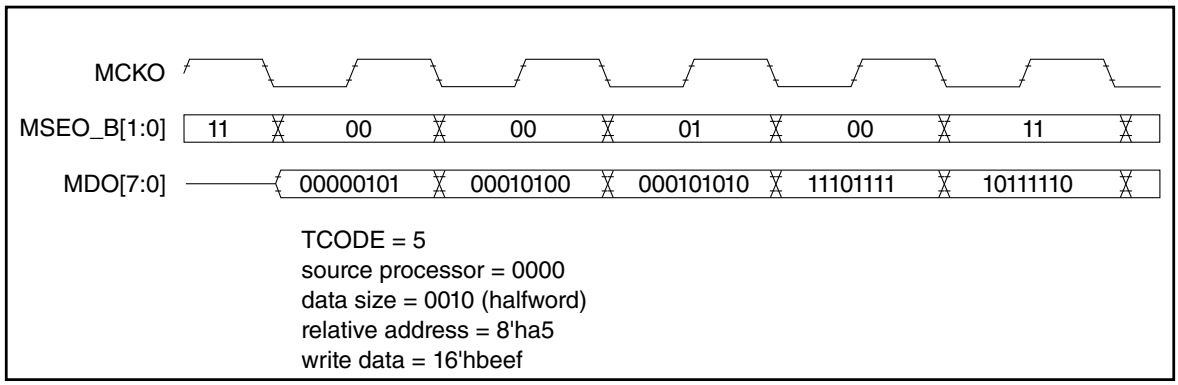

Figure 66-48. Data Trace - Data Write Message

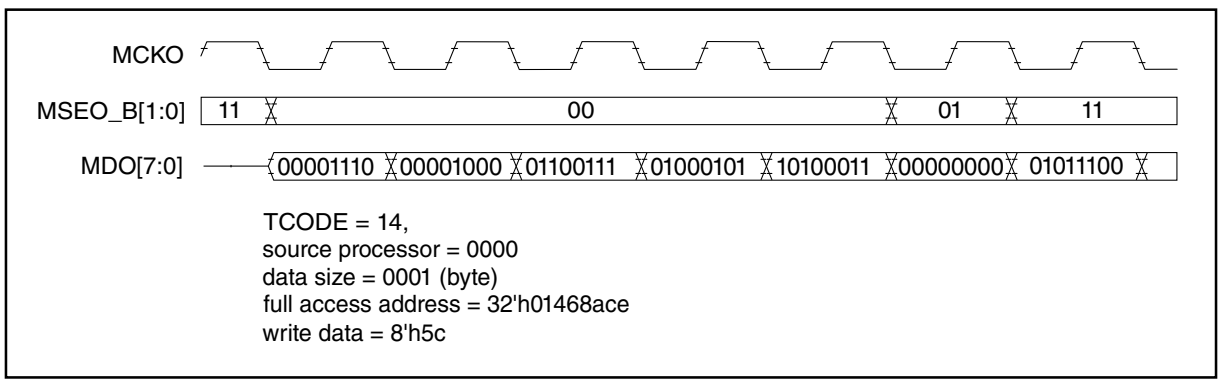

Figure 66-49. Data Trace — Data Read w/ Sync message

66.14 Data Acquisition messaging

This section details the Data Acquisition mechanisms supported by the Nexus 3 module. Data Acquisition Trace is implemented using Data Acquisition Trace Messages in accordance with IEEE-ISTO 5001 definitions. The control mechanism to export the data is different from the recommendations of the standard, however.

Data Acquisition Trace provides a convenient and flexible mechanism for the debugger to observe the architectural state of the machine through software instrumentation.

66.14.1 Data Acquisition ID Tag field

The DQTAG Tag field (DQTAG) is an 8-bit value specifying control or attribute information for the data included in the Data Acquisition message. DQTAG is sampled from $DEVENT_{DQTAG}$ when a write to DDAM is performed via **mtspr** operations. The usage of the DQTAG is left to the discretion of the development tool to be used in whatever manner is deemed appropriate for the application.

66.14.2 Data Acquisition Data field

The Data Acquisition Data field (DQDATA) is the data captured from the DDAM write operation via **mtspr** operations. Leading zeros are omitted from the message.

66.14.3 Data Acquisition Trace event

For DQM, a dedicated SPR has been allocated (DDAM). It is expected that the general use case is to instrument the software and use **mtspr** operations to generate Data Acquisition messages.

There is no explicit error response for failed accesses as a result of contention between an internal and external debugger. Software may be blocked or given ownership of DDAM and the DQTAG field of the DEVENT register via control in EDBRAC0 while in External Debug Mode. Hardware always has access to these registers. Refer to the "External Debug Resource Allocation Control Register (EDBRAC0)" section in the Core (e200z210n3) Core Debug Support chapter for more detail on EDBRAC0.

Reads from the Data Acquisition channel do not generate a Data Acquisition event and will return zeroes for the read data.

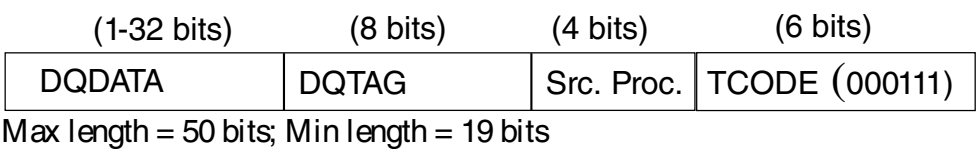

Figure 66-50. Data Acquisition message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

66.15 Watchpoint Trace messaging

Enabling Watchpoint messaging is done by setting the Watchpoint Trace Enable bit in the DC1 Register. Setting the individual Watchpoint sources is supported through the Nexus1 module and the Performance Monitor unit. The Nexus1 module is capable of setting multiple types of watchpoints. Please refer to the Core (e200z210n3) Core Debug Support chapter for details on watchpoint initialization.

When watchpoints occur due to one or more asserted watchpoint event signals and Watchpoint Trace Messaging is enabled, a Watchpoint Trace message will be sent to the message queue to be messaged out. This message includes the watchpoint number indicating which watchpoint(s) caused the message. If more than one enabled watchpoint occurs in a single cycle, only one Watchpoint Trace message is generated and multiple bits of the watchpoint hit field will be set. The settings of the $WMSK_{WEM}$ field control which watchpoints are enabled to generate watchpoint trace messages.

The occurrence of any of the defined watchpoints can also be programmed to assert the Event Out (**evto_b**) pin for one (1) period of the output clock (**nex_mcko**) based on settings in the DC2 and DC3 registers. See Table 66-40 for details on **evto_b**.

Watchpoint information is messaged out in the following format:

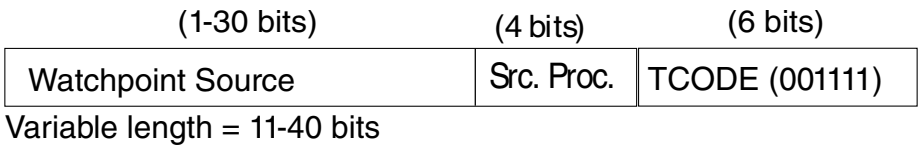

Figure 66-51. Watchpoint message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

The Watchpoint Source message field will contain a '1' for each asserted watchpoint. Leading zeros are truncated.

Table 66-38. Watchpoint Source Encoding

Watchpoint Source (1-30 bits)	Watchpoint Description
000000000000000000000000000000 - No Watchpoints enabled for Watchpoint Trace Messaging	
XXXXXXXXXXXXXXXXXXXXXXXXXXXXX1 - Watchpoint #0 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXXXXXX1X - Watchpoint #1 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXXXXX1XX - Watchpoint #2 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXXXX1XXX - Watchpoint #3 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXXX1XXXX - Watchpoint #4 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXX1XXXXX - Watchpoint #5 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXX1XXXXXX - Watchpoint #6 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXX1XXXXXXX - Watchpoint #7 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXX1XXXXXXXX - Watchpoint #8 enabled for WTM	
XXXXXXXXXXXXXXXXXXXX1XXXXXXXXX - Watchpoint #9 enabled for WTM	
XXXXXXXXXXXXXXXXXXX1XXXXXXXXXX - Watchpoint #10 enabled for WTM	
XXXXXXXXXXXXXXXXXX1XXXXXXXXXXX - Watchpoint #11 enabled for WTM	
XXXXXXXXXXXXXXXXX1XXXXXXXXXXXX - Watchpoint #12 enabled for WTM	
XXXXXXXXXXXXXXXX1XXXXXXXXXXXXX - Watchpoint #13 enabled for WTM	

Table 66-38. Watchpoint Source Encoding

Watchpoint Source (1-30 bits)	Watchpoint Description
XXXXXXXXXXXXXXX1XXXXXXXXXXXXXXX	Watchpoint #14 enabled for WTM
XXXXXXXXXXXXXX1XXXXXXXXXXXXXXXX	Watchpoint #15 enabled for WTM
XXXXXXXXXXXXX1XXXXXXXXXXXXXXXXX	Watchpoint #16 enabled for WTM
XXXXXXXXXXXX1XXXXXXXXXXXXXXXXXX	Watchpoint #17 enabled for WTM
XXXXXXXXXXX1XXXXXXXXXXXXXXXXXXX	Watchpoint #18 enabled for WTM
XXXXXXXXXX1XXXXXXXXXXXXXXXXXXXX	Watchpoint #19 enabled for WTM
XXXXXXXXX1XXXXXXXXXXXXXXXXXXXXX	Watchpoint #20 enabled for WTM
XXXXXXXX1XXXXXXXXXXXXXXXXXXXXXX	Watchpoint #21 enabled for WTM
XXXXXXX1XXXXXXXXXXXXXXXXXXXXXXX	Watchpoint #22 enabled for WTM
XXXXXX1XXXXXXXXXXXXXXXXXXXXXXXX	Watchpoint #23 enabled for WTM
XXXXX1XXXXXXXXXXXXXXXXXXXXXXXXX	Watchpoint #24 enabled for WTM
XXXX1XXXXXXXXXXXXXXXXXXXXXXXXXX	Watchpoint #25 enabled for WTM
XXX1XXXXXXXXXXXXXXXXXXXXXXXXXXX	Watchpoint #26 enabled for WTM
XX1XXXXXXXXXXXXXXXXXXXXXXXXXXXX	Watchpoint #27 enabled for WTM
X1XXXXXXXXXXXXXXXXXXXXXXXXXXXXX	Watchpoint #28 enabled for WTM
1XXXXXXXXXXXXXXXXXXXXXXXXXXXXXX	Watchpoint #29 enabled for WTM

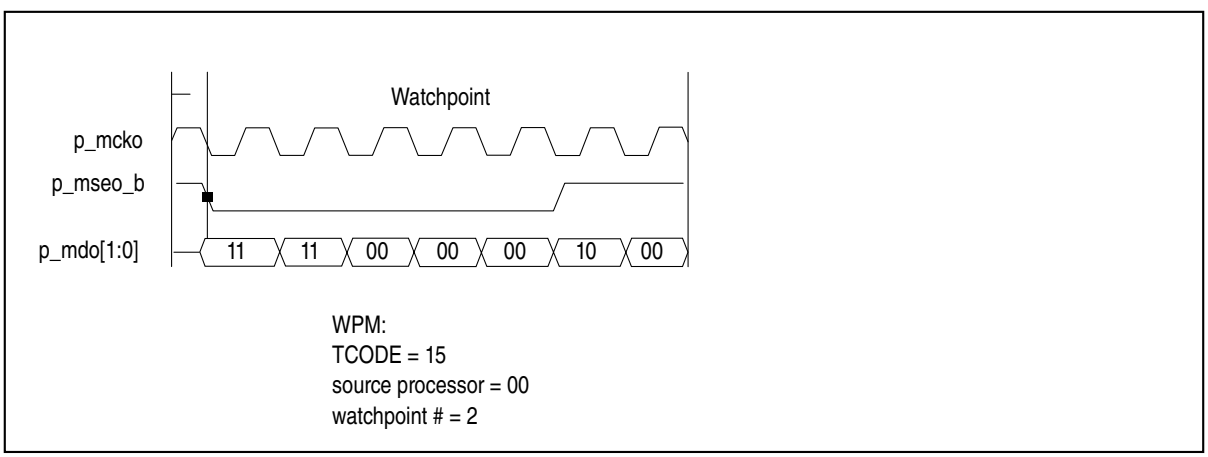

Figure 66-52. Watchpoint Message & Watchpoint Error message

66.16 Nexus 3 Read/Write access to memory-mapped resources

The Read/Write access feature allows access to memory-mapped resources via the JTAG/OnCE port. The Read/Write mechanism supports single as well as block reads and writes to AHB resources.

The Nexus 3 module is capable of accessing resources on the system bus (AHB). Memory-mapped registers and other non-cached memory can be accessed via the standard memory map settings.

All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). Nexus 3 read/write accesses are run as privileged data non-cacheable accesses by default, and drive the **p_d_hprot[5:0]** bus access attributes to 6'b000011 accordingly. The $RWCS_{ATTR}$ field is provided to allow a portion of these default values to be modified when performing read or write accesses using the Nexus 3 Read/Write access mechanism.

Using the Read/Write Access Registers (RWCS/RWA/RWD), memory mapped AHB resources can be accessed through Nexus 3. The following subsections describe the steps required to access memory-mapped resources.

Note

Read/Write Access can only access memory mapped resources when system reset is de-asserted and clocks are running.

Misaligned accesses are NOT supported in the Nexus 3 module.

Uncorrectable ECC errors on Nexus 3 read access will result in the RWD register being updated with the raw data received.

66.16.1 Single write access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Write Address → 32h'xxxxxxxx (write address)
2. Initialize the Read/Write Access Control/Status (RWCS) register through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure the bits as follows:

- Access Control (AC) → 1b'1 (to indicate start access)
- Map Select (MAP) → 3b'000 (primary memory map)
- Access Priority (PR) → 2b'11 (highest priority)
- Read/Write (RW) → 1b'1 (write access)
- Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
- Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note

Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. Initialize the Read/Write Access Data (RWD) register through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Write Data → 32h'xxxxxxxx (write data)
4. The Nexus block will then arbitrate for the AHB system bus and transfer the data value from the data buffer RWD register to the memory mapped address in the Read/Write Access Address (RWA) register. The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed, Nexus clears the AC and DV bits in the RWCS register. If the access has completed without error, (ERR=1'b0), Nexus asserts the **nex_rdy_b** pin (see Table 66-40 for details) and clears the ERR bit in the RWCS register. Otherwise, if the access completes with an error, the **nex_err_b** pin will be asserted and the ERR bit will be set to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once the DV bit has been cleared, this indicates that the device is ready for the next access, or that an error has occurred.

Note

Only the **nex_ahb_start**,**nex_err_b**, and **nex_rdy_b** pins, as well as the AC, DV, and ERR bits within the RWCS, provide Read/Write Access status to the external development tool.

66.16.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in Single write access to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The Nexus block then arbitrates for the AHB system bus and transfers the first data value from the RWD register to the memory-mapped address in the Read/Write Access Address (RWA) register. The nex_ahb_start output is asserted during the first clock of the address phase of the transfer. When the transfer has completed without error, the address from the RWA register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, and the **nex_rdy_b** pin is asserted. If the access has completed without error, Nexus clears the ERR and DV bits in the RWCS register. Otherwise, the ERR bit is set and the DV bit is cleared to indicate an error has occurred, the **nex_err_b** pin is asserted, the block transfer is aborted, and the AC bit in the RWCS register is cleared. Clearing the DV bit indicates that the device is ready for the next access in the block transfer, or that an error has occurred.
3. If the AC bit has not been cleared due to an error, repeat Step 3 in Single write access until the internal CNT value is zero (0). When this occurs, the AC bit within the RWCS register is cleared to indicate the end of the block write access.

Note

The actual RWA register value as well as the CNT field within the RWCS register are not changed when executing a block write access. The original values can be read by the external development tool at any time.

66.16.3 Single read access

1. Initialize the Read/Write Access Address (RWA)register through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Read Address → 32h'xxxxxxxx (read address)
2. Initialize the Read/Write Access Control/Status (RWCS) register through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure the bits as follows:
   - Access Control (AC) → 1b'1 (to indicate start access)
   - Map Select (MAP) → 3b'000 (primary memory map)

- Access Priority (PR) → 2b'11 (highest priority)
- Read/Write (RW) → 1b'0 (read access)
- Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
- Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note

An Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD register. The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS register and asserts the **nex_rdy_b** pin (see Table 66-40 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set, and the DV bit will be cleared to indicate an error has occurred. The **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit is cleared in either case.
4. The data can then be read from the Read/Write Access Data register (RWD) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE.

Note

Only the **nex_ahb_start**, **nex_err_b**, and **nex_rdy_b** pins as well as the AC, DV, and ERR bits within the RWCS register provide Read/Write Access status to the external development tool.

66.16.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in Single read access to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD register. The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access

has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS register and asserts the **nex_rdy_b** pin (see Table 66-40 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.

3. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, Nexus clears the ERR bit and sets the DV bit in the RWCS register, and asserts the **nex_rdy_b** pin (see Table 66-40 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the AC bit is cleared and the block transfer is aborted, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. Once DV has been set, this indicates that the device is ready for the next access in the block transfer, or if ERR is set (AC will be cleared), the block transfer has been aborted.
4. The data can then be read from the RWD register through the access method outlined in Nexus 3 Register Access via JTAG/OnCE.
5. If AC has not been cleared due to an error, repeat Steps 3 and 4 in Single read access until the CNT value is zero (0). When this occurs, the AC bit within the RWCS register is cleared to indicate the end of the block read access.

Note

The data values must be shifted out 32 bits at a time LSB first (i.e. doubleword read = two word reads from the RWD).

Note

The actual RWA value as well as the CNT field within the RWCS register are not changed when executing a block read access. The original values can be read by the external development tool at any time.

66.16.5 Error handling

The Nexus 3 module handles various error conditions as follows:

66.16.5.1 AHB Read/Write error

All address and data errors that occur on read/write accesses to the AHB system bus will return a transfer error encoding on the **p_hresp[1:0]** signals. If this occurs:

1. The access is terminated without retrying (AC bit is cleared)
2. The ERR bit in the RWCS Register is set
3. The Error Message is sent (TCODE = 8) indicating Read/Write error

66.16.5.2 Access termination

The following cases are defined for sequences of the Read/Write protocol that differ from those described in the above sections.

1. If the AC bit in the RWCS Register is set to start Read/Write accesses and invalid values are loaded into the RWD and/or RWA, then an AHB access error may occur. This is handled as described above.
2. If a block access is in progress (all cycles not completed), and the RWCS Register is written, then the original block access is terminated at the boundary of the nearest completed access.
    a. If the RWCS is written with the AC bit set, the next Read/Write access will begin and the RWD can be written to/ read from.
    b. If the RWCS is written with the AC bit cleared, the Read/Write access is terminated at the nearest completed access. This method can be used to break (early terminate) block accesses.

66.16.6 Read/Write access error message

The Read/Write Access Error Message is sent out when an AHB system bus access error (read or write) has occurred.

Error information is messaged out in the following format:

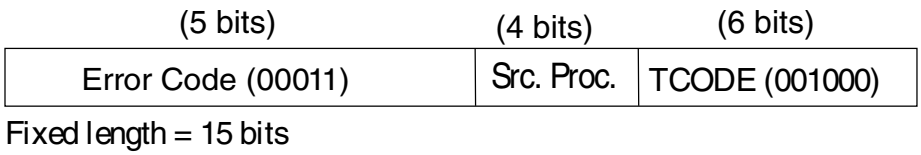

Figure 66-53. Error message format1

66.17 Nexus 3 pin interface

This section details information regarding the Nexus 3 pins and pin protocol.

The Nexus 3 pin interface provides the function of transmitting messages from the messages queues to the external tools. It is also responsible for handshaking with the message queues.

66.17.1 Pins implemented

The Nexus 3 module implements an auxiliary port consisting of one (1) **nex_evti_b** and one (1) **nex_mseo_b** or two (2) **nex_mseo_b[1:0]**. It also implements a configurable number of **nex_mdo[n:0]** pins, (1) **nex_rdy_b** pin, (1) **nex_err_b** pin, (1) **evto_b** pin, and one (1) clock output pin (**nex_mcko**), as well as additional configuration pins described in Table 66-40. The output pins are synchronized to the Nexus 3 output clock (**nex_mcko**).

All Nexus 3 input functionality may be controlled through the JTAG/OnCE port in compliance with IEEE 1149.1 (see Nexus 3 Register Access via JTAG/OnCE for details). The JTAG pins are incorporated as I/O to the processor, and are further described in the "JTAG/OnCE Pins" section of the Core (e200z210n3) Core Debug Support chapter.

Table 66-39. JTAG Pins for Nexus 3

JTAG Pins	Input/ Output	Description of JTAG Pins (included in Nexus 1)
j_tdo	O	The Test Data Output (**j_tdo**) pin is the serial output for test instructions and data. **j_tdo** is three-stateable and is actively driven in the "Shift-IR" and "Shift-DR" controller states. **j_tdo** changes on the falling edge of **j_tclk**.
j_tdi	I	The Test Data Input (**j_tdi**) pin receives serial test instruction and data. TDI is sampled on the rising edge of **j_tclk**.
j_tms	I	The Test Mode Select (**j_tms**) input pin is used to sequence the OnCE controller state machine. **j_tms** is sampled on the rising edge of **j_tclk**.
j_tclk	I	The Test Clock (**j_tclk**) input pin is used to synchronize the test logic, and control register access through the JTAG/OnCE port.
j_trst_b	I	The Test Reset (**j_trst_b**) input pin is used to asynchronously initialize the JTAG/OnCE controller.

The auxiliary pins are used to send and receive messages and are described in Table 66-40.

Table 66-40. Nexus 3 Auxiliary pins

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_mcko	O	Message Clock Out (**nex_mcko**) is a free running output clock to development tools for timing of **nex_mdo[n:0]** & **nex_mseo_b[1:0]** pin functions. **nex_mcko** is programmable through the DC1 Register.
nex_mdo[n:0]	O	Message Data Out (**nex_mdo[n:0]**) are output pins used for OTM, BTM, and DTM. External latching of **nex_mdo[n:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**).
nex_mseo_b[1:0]	O	Message Start/End Out (**nex_mseo_b[1:0]**) are output pins that indicate when a message on the **nex_mdo[n:0]** pins has started, when a variable length packet has ended, and when the message has ended. External latching of **nex_mseo_b[1:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**). One or two pin MSEO functionality is determined at integration time per SOC implementation.
nex_ahb_start	O	AHB Start (**nex_ahb_start**) is an output pin used to indicate to the external tool or SoC that the Nexus block is requesting the next Read/Write Access on the system bus. If Nexus is enabled, this signal is asserted upon an acknowledged request to start an AHB system bus transfer (Nexus read or write) and is pulsed asserted for one **nex_clk** clock period, corresponding to the first clock of the address phase of the transfer. Upon exit from system reset or if Nexus is disabled, **nex_ahb_start** remains de-asserted.
nex_rdy_b	O	Ready (**nex_rdy_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access. If Nexus is enabled, this signal is asserted upon successful (without error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the "Capture_DR" state. Upon exit from system reset or if Nexus is disabled, **nex_rdy_b** remains deasserted.
nex_err_b	O	Error (**nex_err_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access and an error has occurred on the previous access. If Nexus is enabled, this signal is asserted upon unsuccessful (with error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the "Capture_DR" state. Upon exit from system reset or if Nexus is disabled, **nex_err_b** remains deasserted.
evto_b	O	Event Out (**evto_b**) is an output that, when asserted, indicates one of two events has occurred based on the EOC bits in the DC1 Register. **evto_b** is held asserted for one (1) cycle of **nex_mcko**: 1. One (or more) watchpoints has occurred (from Nexus1) & EOC = 2'b00 2. Debug mode was entered (jd_debug_b asserted from Nexus1) & EOC = 2'b01
nex_evti_b	I	Event In (**nex_evti_b**) is an input that, when asserted, will initiate one of two events based on the EIC bits in the DC1 Register (if the Nexus module is enabled at reset): 1. Program Trace & Data Trace synchronization messages (provided Program Trace & Data Trace are enabled & EIC = 2'b00). 2. Debug request to Nexus1 module (provided EIC = 2'b01 and this feature is implemented).
nex_ext_src_id[0:3]	I	**nex_ext_src_id[0:3]** is used to provide the SRC field value used in each message. These pins are tied to a predetermined value at SoC integration time.

Table continues on the next page...

Table 66-40. Nexus 3 Auxiliary pins (continued)

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_sfwcntl_en]	I	**nex_sfwcntl_en** is used to allow software to control the module resources via the DCR register mappings. SoC logic should drive this signal appropriately in a semi-static manner based on the presence of an external hardware debugger and appropriate security precautions.

The Nexus auxiliary port arbitration pins are used when the Nexus 3 module is implemented in a multi-Nexus SoC that shares a single auxiliary output port. The arbitration is controlled by an SoC level Nexus Aurora Router (NAR). Refer to Auxiliary port arbitration for detail on Nexus port arbitration.

Table 66-41. Nexus port arbitration signals

Nexus port arbitration pins	Input/ Output	Description of arbitration pins
nex_aux_req[1:0]	O	Nexus Auxiliary Request (**nex_aux_req[1:0]**) output signals indicate to an SoC level Nexus arbiter a request for access to the shared Nexus auxiliary port in a multi-Nexus implementation. The priority encodings are determined by how many messages are currently in the message queues (See Table 66-43.)
nex_aux_busy	O	Nexus Auxiliary Busy (**nex_aux_busy**) is an output signal to an SoC level Nexus arbiter indicating that the Nexus 3 module is currently transmitting its message after being granted the Nexus auxiliary port.
nar_aux_grant	I	Nexus Auxiliary Grant **(nar_aux_grant)** is an input from the SoC level NAR that the auxiliary port has been granted to the Nexus 3 module to transmit its message.
ext_multi_nex_sel	I	Multi-Nexus Select (**ext_multi_nex_sel**) is a static signal indicating that the Nexus 3 module is implemented within a multi-Nexus environment. If set, port control and arbitration is controlled by the SoC level arbitration module (NAR).

66.17.2 Pin protocol

The protocol for the processor transmitting messages via the auxiliary pins is accomplished with the MSEO pin function outlined in Table 66-42. Both single and dual pin cases are shown.

nex_mseo_b[1:0] is used to signal the end of variable-length packets, and not fixed length packets. **nex_mseo_b[1:0]** is sampled on the rising edge of the Nexus 3 clock (**nex_mcko**).

Single pin MSEO is not supported on the .

Table 66-42. MSEO pin(s) protocol

nex_mseo_b function	Single nex_mseo_b data (serial)	Dual nex_mseo_b[1:0] data
Start of message	1-1-0	11-00
End of message	0-1-1-(more 1's)	00 (or 01)-11-(more 1's)
End of variable length packet	0-1-0	00-01
Message transmission	0's	00's
Idle (no message)	1's	11's

Figure 66-54 illustrates the state diagram for single pin MSEO transfers.

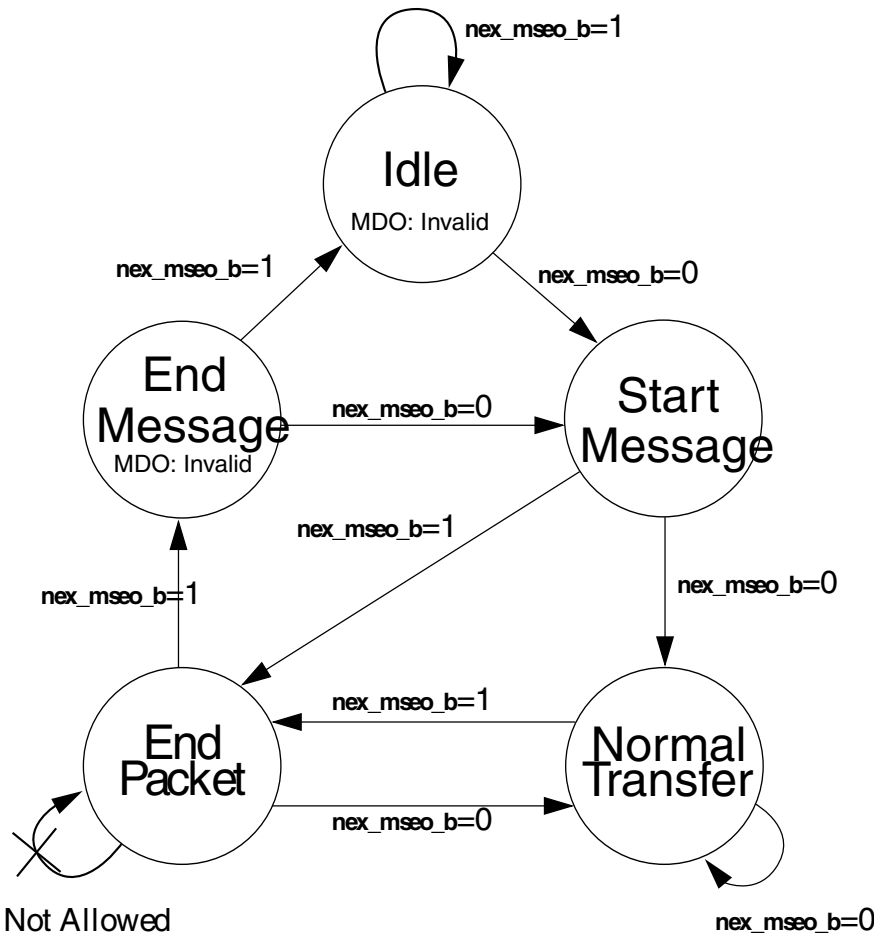

Figure 66-54. Single pin MSEO transfers

Note that the "End Message" state does not contain valid data on the **nex_mdo[n:0]** pins. Also, It is not possible to have two consecutive "End Packet" messages. This implies the minimum packet size for a variable length packet is 2x the number of **nex_mdo[n:0]** pins. This ensures that a false end of message state is not entered by emitting two consecutive '1's on the **nex_mseo_b** pin before the actual end of message.

Figure 66-55 illustrates the state diagram for dual pin MSEO transfers.

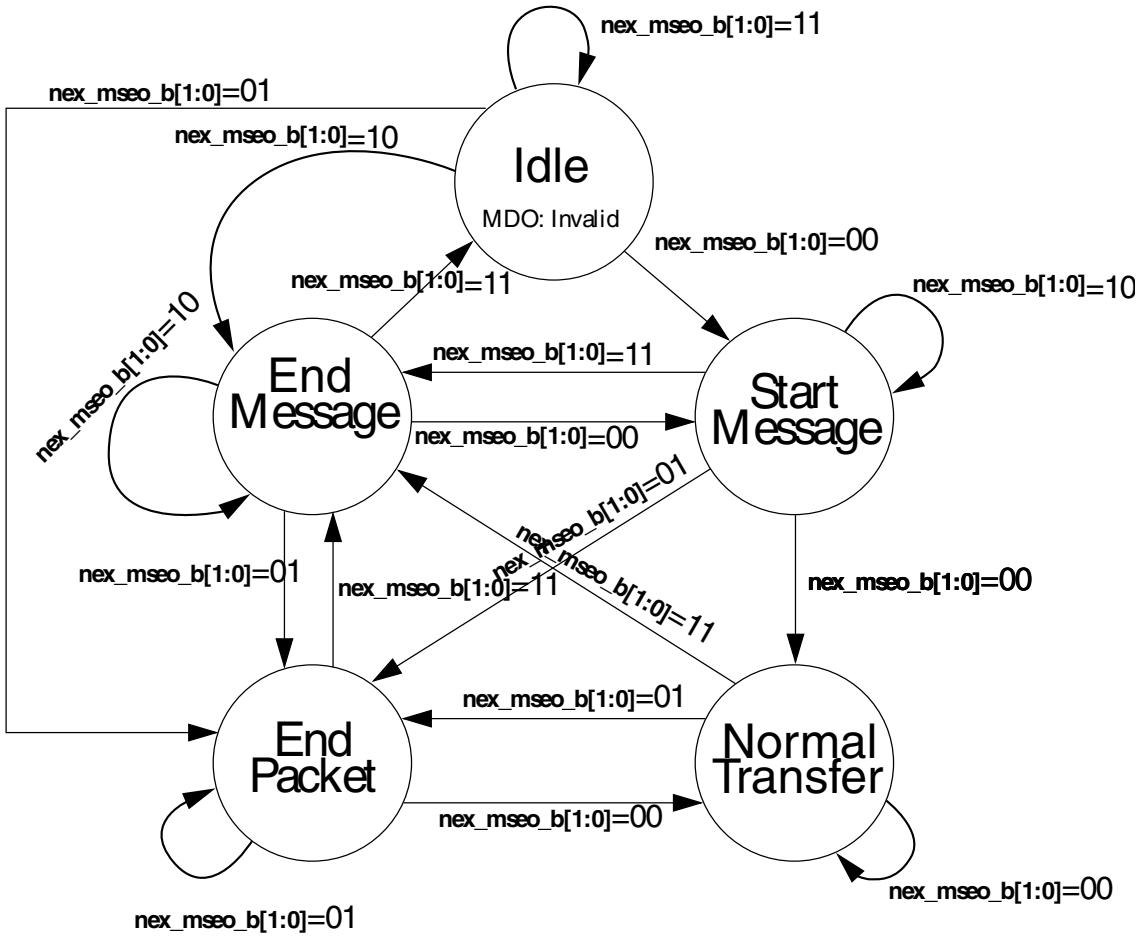

Figure 66-55. Dual pin MSEO transfers

The dual pin MSEO option is more robust that the single pin option. Termination of the current message may immediately be followed by the start of the next message on the consecutive clocks. An extra clock to end the message is not necessary as with the one MSEO pin option. The dual pin option also allows for consecutive "End Packet" states. This can be an advantage when small, variable sized packets are transferred.

Note

The "End Message" state may also indicate the end of a variable-length packet as well as the end of the message when using the dual pin option.

66.18 Rules for output messages

Class 3 compliant embedded processors must provide messages via the auxiliary port in a consistent manner as described below:

- A variable-sized packet within a message must end on a port boundary.
- A variable-sized packet may start within a port boundary only when following a fixed length packet. (If two variable-sized packets end and start on the same clock, it is impossible to know which bit is from the last packet and which bit is from the next packet.)
- Whenever a variable-length packet is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest-order bit so that it can end on a port boundary.

  For example, if the **nex_mdo[n:0]** port is 2 bits wide, and the unique portion of an indirect address TCODE is 5 bits, then the remaining 1 bit of **nex_mdo[n:0]** must be packed with a 0.

66.19 Auxiliary port arbitration

In a multi-Nexus environment, the Nexus 3 module must arbitrate for the shared Nexus port at the SoC level.The request scheme is implemented as a 2-bit request with various levels of priority. The priority levels are defined in Table 66-43 below. The Nexus 3 module will receive a 1-bit grant signal (**nar_aux_grant**) from the SoC level arbiter. When a grant is received, the Nexus 3 module will begin transmitting its message following the protocol outlined in Pin protocol. The Nexus 3 module will maintain control of the port, by asserting the **nex_aux_busy** signal, until the $\overline{\text{MSEO}}$ state machine reaches the "End Message" state.

Table 66-43. MDO Request Encodings

Request level	MDO request encoding (nex_aux_req[1:0])	Condition of queue
No Request	00	No message to send
Low Priority	01	Message queue less than 1/2 full
—	10	Reserved
High Priority	11	Message queue 1/2 full or more

66.20 Examples

The following are examples of Program Trace and Data Trace Messages.

Table 66-44 illustrates an example Indirect Branch Message with 2 MDO / 1MSEO configuration. Table 66-45 illustrates the same example with an 8 MDO / 2 MSEO configuration.

Note that T0 and S0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Ix = Number of instructions (variable)
- Ax = Unique portion of the address (variable)

Note that during clock 13, the **nex_mdo[n:0]** pins are ignored in the single MSEO case.

Table 66-44. Indirect Branch Message Example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I0	MAP	0	Normal Transfer
7	I2	I1	0	Normal Transfer
8	I4	I3	1	End Packet
9	A1	A0	0	Normal Transfer
10	A3	A2	0	Normal Transfer
11	A5	A4	0	Normal Transfer
12	A7	A6	1	End Packet
13	0	0	1	End Message
14	T1	T0	0	Start Message

Table 66-45. Indirect branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	I4	I3	I2	I1	I0	M A	S3	S2	0	1	End Packet

Table continues on the next page...

Table 66-45. Indirect branch message example (8 MDO / 2 MSEO) (continued)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
						P					
3	A7	A6	A5	A4	A3	A2	A1	A0	1	1	End Packet/End Message
4	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 66-46 and Table 66-47 illustrate examples of Direct Branch Messages: one with 2 MDO / 1 MSEO, and one with 8 MDO / 2 MSEO.

Note that T0 and I0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- Ix = Number of Instructions (variable)

Table 66-46. Direct branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I1	I0	1	End Packet
7	0	0	1	End Message

Table 66-47. Direct branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)

66.21 Electrical characteristics

For all electrical characteristics related to core processor and Nexus 3 operation, please refer to the Data Sheet.

66.22 IEEE 1149.1 (JTAG) RD/WR sequences

This section contains example JTAG/OnCE sequences used to access resources.

66.22.1 JTAG sequence for accessing internal Nexus registers

Table 66-50. Accessing internal Nexus 3 registers via JTAG/OnCE

Step #	TMS Pin	Description
1	1	IDLE -> SELECT-DR_SCAN
2	0	SELECT-DR_SCAN -> CAPTURE-DR (Nexus Command Register value loaded in shifter)
3	0	CAPTURE-DR -> SHIFT-DR
4	0	(7) TCK clocks issued to shift in direction (rd/wr) bit and first 6 bits of Nexus reg. addr.
5	1	SHIFT-DR -> EXIT1-DR (7th bit of Nexus reg. shifted in)
6	1	EXIT1-DR -> UPDATE-DR (Nexus shifter is transferred to Nexus Command Register)
7	1	UPDATE-DR -> SELECT-DR_SCAN
8	0	SELECT-DR_SCAN -> CAPTURE-DR (Register value is transferred to Nexus shifter)
9	0	CAPTURE-DR -> SHIFT-DR
10	0	(31) TCK clocks issued to transfer register value to TDO pin while shifting in TDI value
11	1	SHIFT-DR -> EXIT1-DR (MSB of value is shifted in/out of shifter)
12	1	EXIT1-DR -> UPDATE -DR (if access is write, shifter is transferred to register)
13	0	UPDATE-DR -> RUN-TEST/IDLE (transfer complete - Nexus controller to Reg. Select state)

66.22.2 JTAG sequence for read access of memory-mapped resources

Table 66-51. Accessing memory-mapped resources (reads)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Address Register (RWA)
2	37	Write RWA (initialize starting read address — data input on TDI)
3	13	Nexus Command = write to Read/Write Control/Status Register (RWCS)
4	37	Write RWCS (initialize read access mode and CNT value — data input on TDI)
5	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
6	13	Nexus Command = read Read/Write Access Data Register (RWD)
7	37	Read RWD (data output on TDO)
8	—	If CNT > 0, go back to Step #5

66.22.3 JTAG sequence for write access of memory-mapped resources

Table 66-52. Accessing memory-mapped resources (writes)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Control/Status Register (RWCS)
2	37	Write RWCS (initialize write access mode and CNT value - data input on TDI)
3	13	Nexus Command = write to Read/Write Address Register (RWA)
4	37	Write RWA (initialize starting write address - data input on TDI)
5	13	Nexus Command = read Read/Write Access Data Register (RWD)
6	37	Write RWD (data output on TDO)
7	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b**pin
8	—	If CNT > 0, go back to Step #5

Chapter 67
Z4 Nexus 3 Module

67.1 Introduction

The e200z4204n3 Nexus3 module provides real-time development capabilities for corresponding core processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

A portion of the pin interface (the JTAG port) is also shared with the OnCE / Nexus 1 unit. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port in these processors.

67.1.1 General Description

This chapter defines the auxiliary pin functions, transfer protocols and standard development features of a Class 3 device in compliance with the IEEE-ISTO 5001 standard. The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering, and Processor Overrun Control.

67.1.2 Terms and Definitions

The following table contains a set of terms and definitions associated with the Nexus 3 module.

Table 67-1. Terms and Definitions

Term	Description
IEEE-ISTO 5001	Consortium & standard for real-time embedded system design. World wide Web documentation at http://www.ieee-isto.org/Nexus5001
Auxiliary Port	Refers to Nexus auxiliary port. Used as auxiliary port to the IEEE 1149.1 JTAG interface.
Branch Trace Messaging (BTM)	Visibility of addresses for taken branches and exceptions, and the number of sequential instructions executed between each taken branch.
Data Read Message (DRM)	External visibility of data reads to memory-mapped resources.
Data Write Message (DWM)	External visibility of data writes to memory-mapped resources.
Data Trace Messaging (DTM)	External visibility of how data flows through the embedded system. This may include DRM and/or DWM.
Data Acquisition Messaging (DQM)	Data Acquisition Messaging (DQM) allows code to be instrumented to export customized information to the Nexus Auxiliary Output Port.
JTAG Compliant	Device complying to IEEE 1149.1 JTAG standard
JTAG IR & DR Sequence	JTAG Instruction Register (IR) scan to load an opcode value for selecting a development register. The JTAG IR corresponds to the OnCE command register (OCMD). The selected development register is then accessed via a JTAG Data Register (DR) scan.
Nexus1	The (OnCE) debug module. This module integrated with each processor provides all static (core halted) debug functionality. This module is compliant with Class1 of the IEEE-ISTO 5001 standard.
Ownership Trace Message (OTM)	Visibility of process/function that is currently executing.
Public Messages	Messages on the auxiliary pins for accomplishing common visibility and controllability requirements
SoC	"System-on-a-Chip". SoC signifies all of the modules on a single die. This generally includes one or more processors with associated peripherals, interfaces & memory modules.
Standard	The phrase "according to the standard" is used to indicate according to the IEEE-ISTO 5001 standard.
Transfer Code (TCODE)	Message header that identifies the number and/or size of packets to be transferred, and how to interpret each of the packets.
Watchpoint	A Data or Instruction Breakpoint or other debug event that does not cause the processor to halt. Instead, a pin is used to signal that the condition occurred. A Watchpoint Message may also be generated.

67.1.3 Feature List

The Nexus 3 module is compliant with Class 3 of the IEEE-ISTO 5001 standard, with additional Class 4 features available. The following features are implemented:

- Program Trace via Branch Trace Messaging (BTM). Branch trace messaging displays program flow discontinuities (direct and indirect branches, exceptions, etc.), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced.
- Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to selected internal memory resources.
- Ownership Trace via Ownership Trace Messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated. An Ownership Trace Message is transmitted when a new process/task is activated, allowing the development tool to trace ownership flow.
- Run-time access to embedded processor memory map via the JTAG port. This allows for enhanced download/upload capabilities.
- Watchpoint Messaging via the auxiliary pins
- Watchpoint Trigger enable of Program and/or Data Trace Messaging
- Auxiliary interface for higher data input
  - Configurable (min/max) Message Data Out pins (**nex_mdo[n:0]**)
  - One or two Message Start/End Out pins (**nex_mseo_b[1:0]**)
  - One Read/Write Error pin (**nex_err_b**) pin
  - One Watchpoint Event output pin (**nex_evto_b**)
  - One Event In pin (**nex_evti_b**)
  - One MCKO (Message Clock Out) pin
- Registers for Program Trace, Data Trace, Ownership Trace and Watchpoint Trigger.
- All features controllable and configurable via the JTAG port
- Conditional software control of the module via device signaling input (**nex_sfwcntl_en**)

Note

For multi-Nexus implementations, the configuration of the Message Data Out pins is controlled by the Port Control Register (at the device level). For single Nexus

implementations (not normally implemented on an SoC), this configuration is controlled by Development Control Register 1 (DC1) within the Nexus 3 module.

In either implementation, Full Port Mode (FPM - maximum number of MDO pins) or Reduced Port Mode (RPM - minimum number of MDO pins) are supported. This setting should not be changed while the system is running.

Note

The configuration of the Message Start/End Out pins (1 or 2) is determined at the device integration level. This option will be hard-wired based on device bandwidth requirements.

67.1.4 Functional Block Diagram

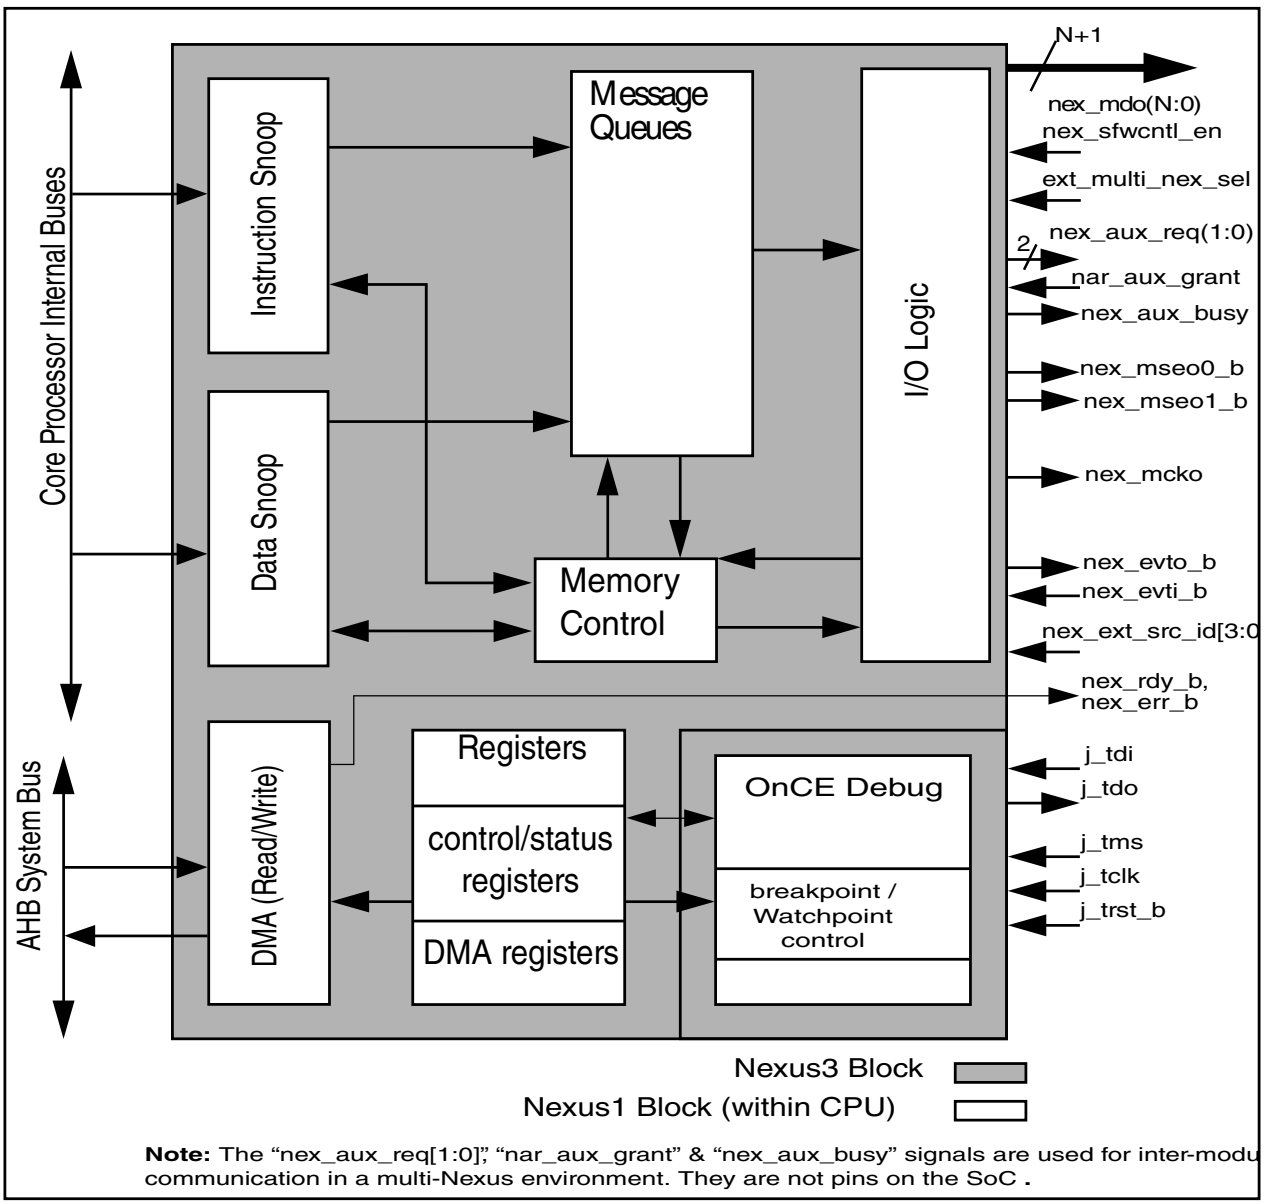

Figure 67-1. Nexus 3 Functional Block Diagram

67.2 Enabling Nexus 3 Operation

The Nexus module is enabled by loading a single instruction (*NEXUS3-ACCESS*) into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus3 module, the OCMD value is 0b0001111100. The Nexus 3 module may alternately be enabled if the nex_evti_b input signal is asserted at the time that j_trst_b is initially negated, or is asserted during the Test-Logic-Reset TAP state. Once enabled, the module will be ready to accept control input via the JTAG/OnCE pins.

Enabling the Nexus 3 module automatically enables the generation of Debug Status Messages.

The Nexus 3 module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. This state can be reached by the assertion of the **j_trst_b** pin or by cycling through the state machine using the **j_tms** pin. The Nexus module will also be disabled if a Power-on-Reset (POR) event occurs. If the Nexus 3 module is disabled, no trace output will be provided, and the module will disable (drive inactive) auxiliary port output pins (**nex_mdo[n:0]**, **nex_mseo[1:0]**, **nex_mcko**). Nexus registers will not be available for reads or writes.

In order to support software control of the Nexus 3 module when no external development tool is present, the Nexus 3 module is not forced to be disabled when the JTAG state remains in the Test-Logic-Reset state. Software is allowed to control the Nexus 3 module when the input signal **nex_sfwcntl_en** is asserted by the SoC. This signal is intended to provide a mechanism for allowing software to use the Nexus 3 module to fill on-chip trace buffers or other visibility mechanisms. It is up to the SoC to determine whether a top-level Nexus 3 controller has been enabled by a hardware debugger, or whether appropriate security mechanisms have granted the capability for software to use these resources, and to drive the appropriate value to the **nex_sfwcntl_en** input. Software can enable the module by a write to any of the module's DCRs when **nex_sfwcntl_en** is asserted.

Reset of the Nexus 3 module is accomplished by a transition on **j_trst_b**, on initial entry into the Test_Logic_Reset state from another state, or if a Power-on-Reset (POR) event occurs. The module is not reset by the CPU's **p_reset_b** signal, even when software has control of the module.

67.2.1 Interaction with Low Power Modes

The Nexus 3 module will continue to operate in the Waiting and Halted states, as long as **nex_clk** remains active. In the Stopped state, **nex_clk** is gated off internally to the Nexus 3 logic, therefore watchpoint or hardware triggering recognition, message generation, and Nexus 3 read-write access to memory is suspended. The Nexus 3 logic will wait to enter the Stopped state until the message FIFOs are empty and any in-progress Nexus R/W transfer has completed. If a block transfer has been requested, the remainder of the block transfer is not completed, and the RWCS AC bit is cleared, and the ERR bit is set. Once the Stopped state has been entered, no further messages are queued and no triggering conditions are monitored. Also, Nexus R/W accesses are no longer available. Upon exiting the Stopped state, normal functions will resume assuming **nex_clk** is active.

67.3 TCODEs supported

The Nexus 3 pins allow for flexible transfer operations via Public Messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001 2003 standard defines a set of public messages and allocates additional TCODEs for vendor-specific features outside the scope of the public messages. The Nexus 3 block supports the TCODEs shown in Table 67-2.

Table 67-2. Supported TCODEs

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Debug Status	6	6	TCODE	fixed	TCODE number = 0
	4	4	SRC	fixed	source processor identifier
	8	8	STATUS	fixed	Development Status Register (DS[31:24])
Ownership Trace Message	6	6	TCODE	fixed	TCODE number = 2
	4	4	SRC	fixed	source processor identifier
	1	32	PROCESS	variable	Task/Process ID tag
Program Trace - Direct Branch Message	6	6	TCODE	fixed	TCODE number = 3
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
Program Trace - Indirect Branch Message	6	6	TCODE	fixed	TCODE number = 4
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/ exceptions
Data Trace - Data Write Message	6	6	TCODE	fixed	TCODE number = 5
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 67-7)
	1	32	U-ADDR	variable	unique portion of the data write address
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
Data Trace - Data Read Message	6	6	TCODE	fixed	TCODE number = 6
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 67-7)

Table continues on the next page...

Table 67-2. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
	1	32	U-ADDR	variable	unique portion of the data read address
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
Data Acquisition Message	6	6	TCODE	fixed	TCODE number = 7
	4	4	SRC	fixed	source processor identifier
	8	8	DQTAG	fixed	identification tag taken from $DEVENT_{DQTAG}$ register field
	1	32	DQDATA	variable	exported data taken from DDAM register
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	source processor identifier
	4	4	ETYPE	fixed	error type
	8	8	ECODE	fixed	error code
Program Trace - Synchronization Message	6	6	TCODE	fixed	TCODE number = 9
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow. Cleared for most sync conditions.
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
Program Trace - Direct Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 11
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
Program Trace - Indirect Branch Message w/Sync	6	6	TCODE	fixed	TCODE number = 12
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
Data Trace - Data Write Message w/ Sync	6	6	TCODE	fixed	TCODE number = 13
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 67-7)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
Data Trace -	6	6	TCODE	fixed	TCODE number = 14
	4	4	SRC	fixed	source processor identifier

Table continues on the next page...

Table 67-2. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Data Read Message w/ Sync	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 67-7)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	source processor identifier
	1	32	WPHIT	variable	Field indicating watchpoint source(s) (leading zeros truncated)
Resource Full Message	6	6	TCODE	fixed	TCODE number = 27
	4	4	SRC	fixed	source processor identifier
	4	4	RCODE	fixed	resource code (Refer to Table 67-5) - indicates which resource is the cause of this message
	1	32	RDATA	variable	branch / predicate instruction history (See Section Resource Full Messages.)
Program Trace - Indirect Branch History Message	6	6	TCODE	fixed	TCODE number = 28 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/ exceptions
	1	32	HIST	variable	branch / predicate instruction history (see Branch Trace Messaging types)
Program Trace - Indirect Branch History Message w/ Sync	6	6	TCODE	fixed	TCODE number = 29 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	1	32	HIST	variable	branch / predicate instruction history (See Branch Trace Messaging types.)
Program Trace - Program Correlation Message	6	6	TCODE	fixed	TCODE number = 33
	4	4	SRC	fixed	source processor identifier
	4	4	EVCODE	fixed	event correlated w/ program flow (Refer to Table 67-6)
	2	2	CDF	fixed	# fields of information in CDATA. 00 - reserved, 01 - one field (CDATA1) (reserved), 10 - two fields (CDATA1 + CDATA2), 11 - three fields (reserved)

Table continues on the next page...

Table 67-2. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	CDATA1	variable	correlation data field 1 - [branch / predicate instruction history] (See Program Correlation Messages.)
	0	32	CDATA2	variable	correlation data field 2- PID info (See Program Correlation Messages.)

Note

Program Trace can be implemented using either Branch History/Predicate Instruction Messages, or traditional Direct/ Indirect Branch Messages. The user can select between the two types of Program Trace. The advantages for each are discussed in Branch Trace Messaging types. If the Branch History method is selected, the shaded TCODES above will not be messaged out.

Table 67-3 shows the error code encodings used when reporting an error via the Nexus 3 Error Message.

Table 67-3. Error Code (ECODE) Encoding (TCODE = 8)

Error Code	Description
xxxxxxx1	Watchpoint Trace Message(s) Lost
xxxxxx1x	Data Trace Message(s) Lost
xxxxx1xx	Program Trace Message(s) Lost
xxxx1xxx	Ownership Trace Message(s) Lost
xxx1xxxx	Status Message(s) Lost (Debug Status messages, etc.)
xx1xxxxx	Data Acquisition Message(s) Lost
x1xxxxxx	Reserved
1xxxxxxx	Reserved

Table 67-4 shows the error type encodings used when reporting an error via the Nexus 3 Error Message.

Table 67-4. Error Type (ETYPE) Encoding (TCODE = 8)

Error Type	Description
0000	Message Queue Overrun caused one or more messages to be lost

Table continues on the next page...

Table 67-4. Error Type (ETYPE) Encoding (TCODE = 8) (continued)

Error Type	Description
0001	Contention with higher priority messages caused one or more messages to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus Register unimplemented)
0110 - 1111	Reserved

Table 67-5 shows the encodings used for resource codes for certain messages.

Table 67-5. Resource Code (RCODE) values (TCODE = 27)

Resource Code	Description
0000	Program Trace Instruction counter reached 255 and was reset.
0001	Program Trace, Branch / Predicate Instruction History full. This type of packet is terminated by a stop bit set to 1 after the last history bit.

Table 67-6 shows the event code encodings used for certain messages.

Table 67-6. Event Code (EVCODE) Encoding (TCODE = 33)

Event Code	Description
0000	Entry into Debug Mode
0001	Entry into Low Power Mode (CPU only)
0010-0011	Reserved for future functionality
0100	Disabling Program Trace
0101	Process ID value is established in PID0/NPIDR via **mtspr PID0/NPIDR**
0110-1000	Reserved for future functionality
1001	Begin masking of program trace messages due to MSR_{PMM}=0 and $DC4_{PTMARK}$=1
1010	Branch and link occurrence (direct branch function call)
1011-1111	Reserved for future functionality

Table 67-7 shows the data trace size encodings used for certain messages.

Table 67-7. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14)

DTM Size Encoding	Transfer Size
0000	0 - no data
0001	Byte
0010	Halfword (2 bytes)
0011	Three bytes
0100	Word (4 bytes)

Table continues on the next page...

Table 67-7. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14) (continued)

DTM Size Encoding	Transfer Size
0101	Five bytes
0110	Six bytes
0111	Seven bytes
1000	Doubleword (8 bytes)
1001-1111	Reserved

67.4 Nexus 3 Programmer's Model

This section describes the Nexus 3 programmers model. Nexus 3 registers are accessed using the JTAG/OnCE port in compliance with IEEE 1149.1, or by software via DCRs. See Nexus 3 Register Access via JTAG/OnCE and Nexus 3 Register Access via Software for details on Nexus 3 register access.

Note

Nexus 3 registers and output signals are numbered using bit 0 as the least significant bit. This bit ordering is consistent with the ordering defined by the IEEE-ISTO 5001 standard.

The following table details the register map for the Nexus 3 module.

Table 67-8. Nexus 3 Register Map

Nexus Register	Nexus Access Opcode	Read/ Write	Read Address	Write Address	DCR #[1]
Client Select Control (CSC)[2]	0x1	R	0x02	-	
Port Configuration Register (PCR)[3]	PCR_INDEX[2]	R/W	-	-

Reserved	0x39 -> 0x3F	-	0x72->0x7E	0x73->7F	

1. Software access via the **mfdcr** and **mtdcr** instructions use these values for the DCR number. Software writes to these registers via **mtdcr** when **nex_sfwcntl_en** is negated are ignored.
2. The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level SoC Nexus controller in a multi-Nexus implementation, not in the Nexus 3 module. The SoC's CSC Register is readable through Nexus, but the PCR is shown for reference only here.
3. The "PCR_INDEX" is a parameter determined by the SoC.

67.4.1 Client Select Control (CSC) register

The CSC Register determines which Nexus client is under development. This register is present at the top-level SOC Nexus 3 controller to select one of multiple on-chip Nexus 3 units.

Nexus Reg# - 0x1; Read-only; Reset - 0x0

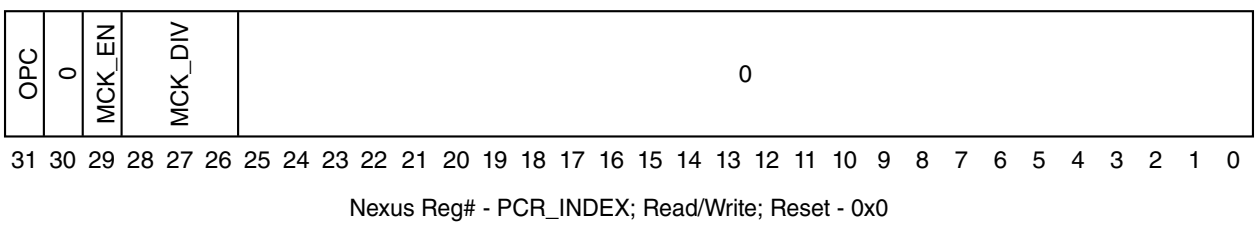

Figure 67-2. Client Select Control (CSC) register

Table 67-9. CSC field descriptions

Bits	Description
CSC[7:4]	Reserved for future Nexus Clients (read as 0)
CSC[3:0]	Client Select Control 0xx - Nexus client (SoC level)

67.4.2 Port Configuration Register (PCR) - reference only

The Port Configuration Register (PCR) controls the basic port functions for all Nexus modules in a multi-Nexus environment. This includes clock control and auxiliary port width. All bits in this register are writable only once after system reset.

Nexus Reg# - PCR_INDEX; Read/Write; Reset - 0x0

Figure 67-3. Port Configuration Register

Table 67-10. PCR field descriptions

Bit	Name	Description
31	OPC	Output Port Mode Control (SoC Level) 0 Reduced Port Mode configuration (min# **nex_mdo[n:0]** pins defined by SOC) 1 Full Port Mode configuration (max# **nex_mdo[n:0]** pins defined by SOC)

29	MCK_EN	MCKO Clock Enable (SoC Level) 0 **nex_mcko** is disabled 1 **nex_mcko** is enabled
28:26	MCK_DIV	MCKO Clock Divide Ratio (see note below) (SoC Level) 000 **nex_mcko** is 1x processor clock freq. 001 **nex_mcko** is 1/2x processor clock freq. 010 Reserved (default to 1/2x processor clock freq.) 011 **nex_mcko** is 1/4x processor clock freq. 100 Reserved (default to 1/2x processor clock freq.) 101 Reserved (default to 1/2x processor clock freq.) 110 Reserved (default to 1/2x processor clock freq.) 111 **nex_mcko** is 1/8x processor clock freq.
25:0	—	Reserved for future functionality

Note

The CSC and PCR Registers exist in a separate module at the SoC level in a multi-Nexus environment. If the core Nexus 3 module is the only Nexus module, these registers are not implemented and the Nexus 3 defined Development Control Register 1 (DC1) is used to control the SoC-level Nexus port functionality.

67.4.3 Nexus Development Control Register 1 (DC1)

Nexus Development Control Register 1 is used to control the basic development features of the Nexus 3 module. Development Control Register 1 is shown in the following figure and its fields are described in the following table.

Nexus Reg# - 0x2; DCR - 368; Read/Write; Reset - 0x0

Figure 67-4. Development Control Register 1

Table 67-11. DC1 field descriptions

Bits	Name	Description
31	OPC	Output Port Mode Control 0 Reduced Port Mode configuration (min# **nex_mdo[n:0]** pins defined 1 Full Port Mode configuration (max# **nex_mdo[n:0]** pins defined

7:6	—	Reserved for future functionality
5:0	TM	Trace Mode This field may be updated by hardware in response to watchpoint triggering if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers for more information on watchpoint triggering. 000000 All Trace Disabled XXXXX1 Ownership Trace enabled XXXX1X Data Trace enabled XXX1XX Program Trace enabled XX1XXX Watchpoint Trace enabled X1XXXX Reserved 1XXXXX Data Acquisition Trace enabled

Note

The Output Port Mode Control bit (OPC) and MCKO Clock Divide Ratio bits (MCK_DIV) MUST ONLY be modified during system reset or debug mode to insure correct output port and output clock functionality. It is also recommended that all other bits of the DC1 also only be modified in one of these two modes.

67.4.4 Nexus Development Control Registers 2 and 3 (DC2, DC3)

Nexus Development Control Registers 2 and 3 are used to control output signaling on the Nexus 3 module. A table of watchpoints can be found in the Z4 Core Core Debug Support chapter.

Development Control Register 2 is shown in Figure 67-5 and its fields are described in Table 67-12.

67.4.5 Nexus Development Control Register 4 (DC4)

Nexus Development Control Register 4 is used to control mark selection for Program and Data Trace Messaging, as well as masking of events that initiate Program Correlation Messages on the Nexus 3 module.

Development Control Register 4 is shown in Figure 67-7 and its fields are described in Table 67-14.

Nexus Reg# - 0x5; DCR - 371; Read/Write; Reset - 0x0

67.4.6 Development Status Register (DS)

The Development Status Register is used to report system debug status. When Debug Mode is entered or exited, or an SoC- or core-defined Low Power Mode is entered (see note below), a Debug Status Message is transmitted with DS[31:24]. The external tool can read this register at any time.

Nexus Reg# - 0x4; DCR - 409; Read-only; Reset - 0x0

Figure 67-8. Development Status Register

Table 67-15. DS field description

25:0	—	Reserved for future functionality (read as 0)

67.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers

The Watchpoint Trigger Registers allows the watchpoints defined within the Nexus1 logic to trigger actions. These watchpoints can control Program and/or Data Trace enable and disable. The control bits can be used to produce a related "window" for triggering Trace Messages. Watchpoint trigger register WT is used to control triggering by a single selected watchpoint. The Program Trace Start Trigger Control (PTSTC), Program Trace End Trigger Control (PTETC), Data Trace Start Trigger Control (DTSTC), and Data

Trace End Trigger Control (DTETC) are used for extended trigger controls for the respective function. If multiple watchpoints are desired for triggering, or a watchpoint beyond watchpoint #13 is required, then one or more of the extended watchpoint trigger registers may be used. A field encoding of 4'b1111 in one of the WT register fields enables the corresponding extended trigger register. For all other WT field encodings, the corresponding extended trigger register is disabled and the contents are ignored. Note that direct writes to enable program trace and/or data trace in DC1 will override these controls, and trace will remain enabled until another direct write to DC1 to disable program and/or data trace occurs.

When a start trigger is detected, the designated trace features become enabled, and the corresponding enable bits of the DC1 register are set. Whenever a stop trigger is detected, the designated trace features become disabled, and the corresponding enable bits of the DC1 register are cleared. If the same trigger condition is used for both start and stop triggering, then the designated trace features will toggle between being enabled and disabled at each occurrence of the trigger condition. Similarly, if start and stop triggers for a trace feature occur simultaneously, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature enable state that is derived from watchpoint triggering. A table of watchpoints can be found in the Z4 Core Core Debug Support chapter.

Nexus Reg# - 0xB; DCR - 375; Read/Write; Reset - 0x0

67.4.9 Nexus Overrun Control Register (OVCR)

The Nexus Overrun Control register controls Nexus behavior as the internal message queues fill up. Response options include suppressing selected message types, or stalling processor instruction execution.

0	SPTHOLD	0	SPEN	0	STTHOLD	0	STEN

67.4.10 Data Trace Control Register (DTC) register

The Data Trace Control Register controls whether DTM Messages are restricted to reads, writes, or both for a user programmable address range. In addition, control is provided to restrict data trace message generation to only those load or store accesses that are not stack-related, in order to minimize required data trace message bandwidth.

There are four Data Trace channels controlled by the DTC for the Nexus 3 module. Channels can be programmed to trace data accesses or instruction accesses, but not independently.

Nexus Reg# - 0xD; DCR - 376; Read/Write; Reset - 0x0

Figure 67-17. Data Trace Control Register

The following table details the Data Trace Control register fields.

Table 67-22. DTC field descriptions

Bits	Name	Description
31:30	RWT1	Read/Write Trace 1 00 No trace enabled X1 Enable Data Read Trace 1X Enable Data Write Trace
29:28	RWT2	Read/Write Trace 2 00 No trace enabled X1 Enable Data Read Trace 1X Enable Data Write Trace
27:26	RWT3	Read/Write Trace 3 00 No trace enabled X1 Enable Data Read Trace 1X Enable Data Write Trace

Figure 67-25. Data Trace End Address 4 (DTEA4) register

Table 67-23 illustrates the range that will be selected for Data Trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 67-23. Data trace - address range options

Programmed values	Range Control Bit Value	Range Selected	
DTSA < DTEA	0	DTSA ->	<- DTEA
DTSA < DTEA	1	<- DTSA	DTEA ->
DTSA > DTEA	N/A	Invalid Range - no trace	
DTSA = DTEA	N/A	Invalid Range - no trace	

Note

DTSA must be less than DTEA in order to guarantee correct Data Write/Read Traces. Data Trace ranges are *inclusive* of the DTSA and DTEA addresses for Range Control settings indicating "within range," and are *exclusive* of the DTSA and DTEA addresses for Range Control settings indicating "outside of range."

Accesses that meet the range and access type qualifiers will cause assertion of a watchpoint output for Ranges 1, 2, and 3. There are three dedicated watchpoint outputs, one for each DTSA/DTEA sets 1, 2, and 3. Range 4 does not provide a watchpoint output. Note that when DTC_{DI}=1, all instruction fetches and prefetches (including discarded prefetches) are monitored, and thus these range watchpoints differ from the IACx watchpoint outputs, which are not asserted for instructions that are not executed (i.e. when the instruction prefetch is discarded).

67.4.13 Read/Write Access Control/Status (RWCS) register

The Read Write Access Control/Status Register provides control for Read/Write Access. Read/Write access provides DMA-like access to memory-mapped resources on the AHB System bus either while the processor is halted, or during runtime. Control is provided over access type, size, count, and certain bus attributes.

Note that the internal CPU interfaces to the caches and local memory are not accessible or utilized by this mechanism. Since the external interface is used, base address port settings are used to access local memory, and not the settings of local memory control register base address values.

The RWCS Register also provides Read/Write Access Status information per Table 67-25.

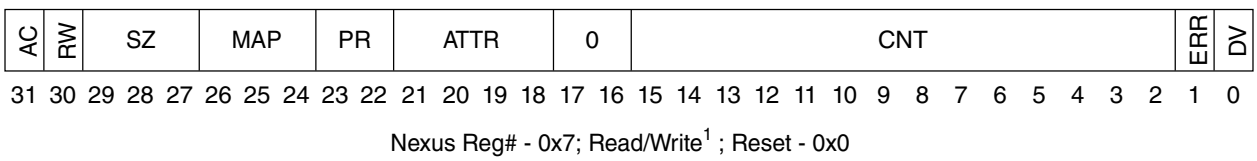

Figure 67-26. Read/Write Access Control/Status (RWCS) register

NOTES:

ERR and DV are read-only.

Table 67-24. RWCS field description

Bits	Name	Description

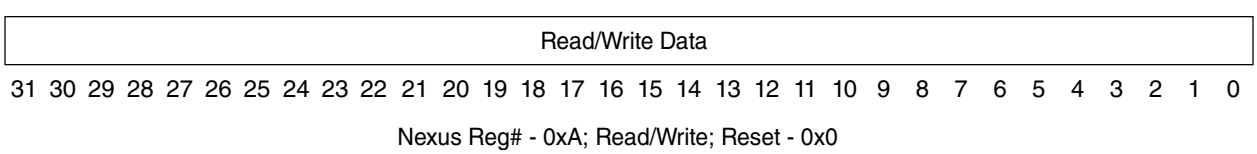
RWCS[0]	DV[2]	Read/Write Access Data Valid (see Table 67-25)



1. The priority functionality is not currently implemented.
2. ERR and DV are read-only.

Table 67-25. Read/Write Access Status Bit Encoding

Read Action	Write Action	ERR	DV
Read Access has not completed	Write Access completed without error	0	0
Read Access error has occurred	Write Access error has occurred	1	0
Read Access completed without error	Write Access has not completed	0	1
Not Allowed	Not allowed	1	1

67.4.14 Read/Write Access Data (RWD) register

The Read/Write Access Data (RWD) register provides the data to/from system bus memory-mapped locations when initiating a read or a write access.

Nexus Reg# - 0xA; Read/Write; Reset - 0x0

Figure 67-27. Read/Write Access Data (RWD) register

Read/Write accesses to the AHB require that the debug firmware properly retrieve/place the data in the RWD. Table 67-26 shows the proper placement of data into the RWD. Note that doubleword transfers require two passes through RWD.

Table 67-26. RWD data placement for ransfers

Transfer Size and byte offset	RWA(2:0)	RWCS[SZ]	RWD			
			31:24	23:16	15:8	7:0
Byte	x x x	0 0 0	-	-	-	X
Half	x x 0	0 0 1	-	-	X	X
Word	x 0 0	0 1 0	X	X	X	X
Doubleword	0 0 0	0 1 1				
first RWD pass (low order data)			X	X	X	X
second RWD pass (high order data)			X	X	X	X

Table Notes:

"X" indicates byte lanes with valid data

"-" indicates byte lanes that will contain unused data.

Table 67-27 shows the mapping of RWD bytes to byte lanes of the AHB read and write data buses.

Table 67-27. RWD byte lane mapping

Transfer Size and byte offset	RWA(2:0)	RWD			
		31:24	23:16	15:8	7:0
Byte @000	0 0 0	-	-	-	AHB[7:0]
Byte @001	0 0 1	-	-	-	AHB[15:8]

Word @100	1 0 0	AHB[63:56]	AHB[55:48]	AHB[47:40]	AHB[39:32]
Doubleword @000	0 0 0				
first RWD pass		AHB[31:24]	AHB[23:16]	AHB[15:8]	AHB[7:0]
second RWD pass		AHB[63:56]	AHB[55:48]	AHB[47:40]	AHB[39:32]

Table Notes:

"-" indicates byte lanes that will contain unused data.

67.4.15 Read/Write Access Address (RWA)

The Read/Write Access Address Register provides the system bus address to be accessed when initiating a read or a write access.

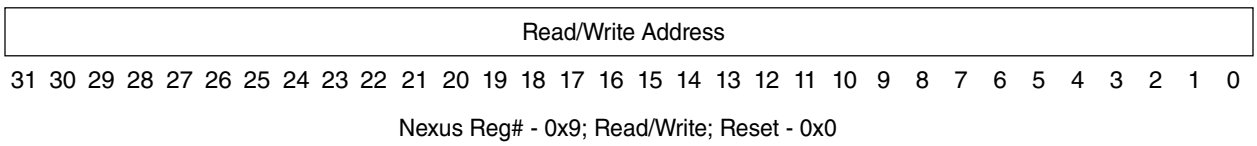

Figure 67-28. Read/Write Access Address (RWA) register

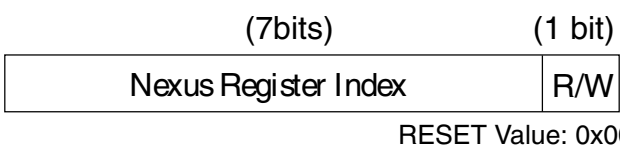

67.5 Nexus 3 Register Access via JTAG/OnCE

Access to Nexus 3 register resources is enabled by loading a single instruction ("*NEXUS3-ACCESS*") into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus 3 block, the OCMD value is 0b0001111100.

Once the NEXUS3-ACCESS instruction has been loaded, the JTAG/OnCE port allows tool/target communications with all Nexus 3 registers according to the register map in Table 67-8.

Reading/writing of a Nexus 3 register then requires two (2) passes through the Data-Scan (DR) path of the JTAG state machine. (See IEEE 1149.1 (JTAG) RD/WR sequences.)

1. The first pass through the DR selects the Nexus 3 register to be accessed by providing an index (see Table 67-8), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the following format:

Nexus Register Index	Selected from values in Table 67-8
Read/Write (R/W):	0 - Read 1 - Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
    a. During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the "Capture-DR" state.
    b. During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the "Update-DR" state.

67.6 Nexus 3 Register Access via Software

Access to most Nexus 3 register resources by software is supported by mapping the Nexus 3 registers to privileged DCRs (device control registers) that are accessible via the **mfdcr** and **mtdcr** instructions. It is intended that these access only occur when no possible conflicts with hardware-based accesses are possible. A conflict between hardware and software accesses will produce undefined results. Table 67-8 shows the mappings of Nexus 3 registers to DCR numbers. Software writes to Nexus 3 register resources are blocked when the **nex_sfwcntl_en** input signal is negated, without signaling an exception. Note that the Nexus 3 Read/Write Access functionality is not available to software, since software can use load and store instructions to access memory.

67.7 Nexus Message Fields

Nexus messages are comprised of fields. Each field contains a distinct piece of information within a message, and each message contains multiple fields. Messages are transferred in packets over the Auxiliary Output protocol. A packet is a collection of fields. A packet may contain any number of fixed length fields, but may contain at most one variable length field. The variable length field must be the last field in a packet. The following sub-sections describe a subset of the message field types.

67.7.1 TCODE Field

The TCODE field is a 6-bit fixed length field that identifies the type of message and its format. The field encodings are assigned by IEEE-ISTO 5001.

67.7.2 Source ID Field (SRC)

Each Nexus module in a device is identified by a unique Client Source Identification Number. The number assigned to each Nexus module is determined by the SoC integrator, and is provided on the **nex3_ext_src_id[0:3]** input signals. Multi-threaded processors may assign additional source ID information to indicate which thread a message is associated with. The Nexus 3 module implements a 4-bit fixed length Source ID field consisting of a Client Source ID.

67.7.3 Relative Address Field (U-ADDR)

The non-sync forms of the Program and Data Trace messages include addresses that are relative to the address that was transmitted in the previous Program or Data Trace message, respectively. The relative address format is compliant with IEEE-ISTO 5001 and is designed to reduce the number of bits transmitted for address fields.

The relative address is generated by XORing the new address with the previous, and then using only the results up to the most significant '1'. To recreate the original address, the relative address is XORed with the previously decoded address.

The relative address of a Program Trace message is calculated with respect to the previous Program Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Program Trace messages.

The relative address of a Data Trace message is calculated with respect to the previous Data Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Data Trace messages.

Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

Previous Address (A1) =0x0003FC01, New Address (A2) = 0x0003F365

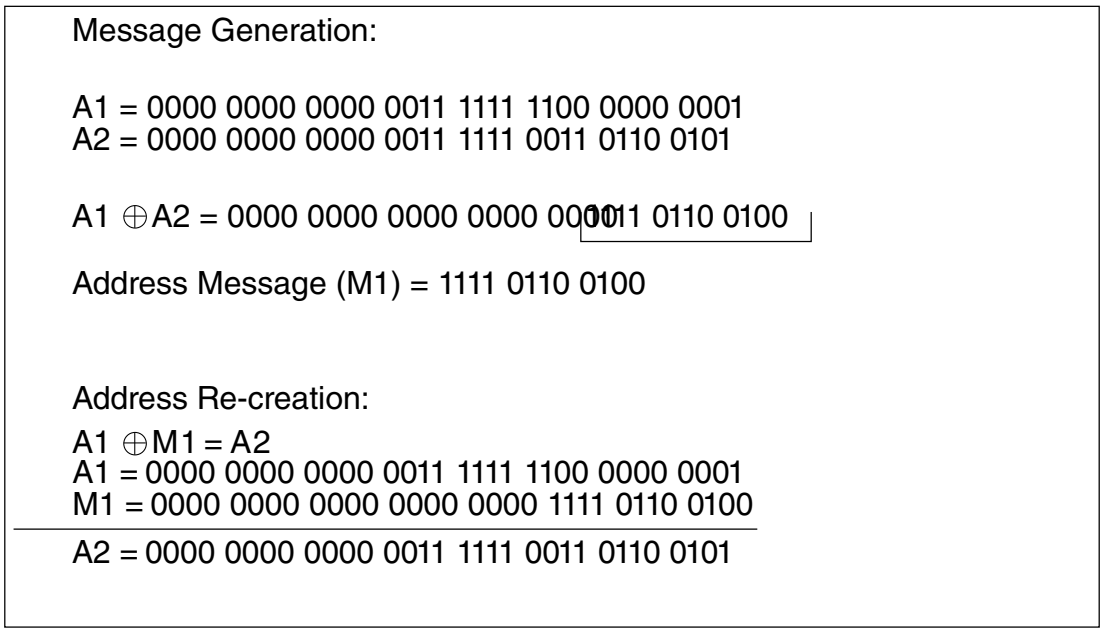

Figure 67-29. Relative address generation and recreation

67.7.4 Full Address Field (F-ADDR)

Program Trace synchronization messages provide the full address associated with the trace event (leading zeroes may be truncated) with the intent of providing a reference point for development tools to operate from when reconstructing relative addresses. Synchronization messages are generated at significant mode switches and are also generated periodically to ensure that development tools are guaranteed to have a reference address given a sufficiently large sample of trace messages. Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

67.8 Nexus Message Queues

The Nexus 3 module implements internal message queues capable of storing up to three messages per cycle into a small initial queue, which then fills a larger queue at up to two messages per cycle. Messages that enter the queues are transmitted in the order in which they are received.

If more than three messages attempt to enter the queue in the same cycle, the highest priority messages are stored and the remaining message(s) will be dropped due to a collision. Collision events are expected to be rare.

The Overrun Control register (OVCR) controls the Nexus behavior as the message queue fills. The Nexus block may be programmed to:

- Allow the queue to overflow, drain the contents, queue an overrun error message and resume tracing.
- Stall the processor when the queue utilization reaches the selected threshold.
- Suppress selected message types when the queue utilization reaches the selected threshold.

67.8.1 Message Queue Overrun

In this mode, the message queue will stop accepting messages when an overrun condition is detected. The contents of the queues will be allowed to drain until empty. Incoming messages are discarded until the queue is emptied. Once empty, an overrun error message is enqueued that contains information about the types of messages that were discarded due to the overrun condition.

67.8.2 CPU Stall

In this mode, processor instruction issue is stalled when the queue utilization reaches the selected threshold. The processor is stalled long enough to drop one threshold level below the level that triggered the stall. For example, if stalling the processor is triggered at 1/4 full, the stall will stay in effect until the queue utilization drops to empty. There may be significant skid from the time that the stall request is made until the processor is able to stop completing instructions. This skid should be taken into consideration when programming the threshold. Refer to Nexus Overrun Control Register (OVCR) for complete programming options.

67.8.3 Message Suppression

In this mode, the message queue will disable selected message types when the queue utilization reaches the selected threshold. This allows lower bandwidth tracing to continue and possibly avoid an overrun condition. If an overrun condition occurs despite this message suppression, the queue will respond according to the behavior described in

Message Queue Overrun. Suppressed message types are reported in the error message if they occur after overrun in addition to other discarded message types. Once triggered, message suppression will remain in effect until queue utilization drops to the threshold below the level selected to trigger suppression.

67.8.4 Nexus Message Priority

Nexus messages may be lost due to contention with other message types under the following circumstances:

- More than three messages are generated in the same cycle

Table 67-28 lists the various message types and their relative priority from highest to lowest.

Up to three message requests can be queued into the message buffer in a given cycle. If more than three message requests exist in a given cycle, the three highest priority message classes are queued into the message buffer. The remaining messages that did not successfully queue into the message buffer in that cycle will generate subsequent responses, as detailed in Table 67-28.

The CPU is capable of completing two instructions per cycle. If multiple trace messages need to be queued at the same time, they will be queued with the following priority: Instruction 0 (oldest instruction) (WPM ->DQM -> PCM_{PIDMSG} -> OTM -> BTM -> DTM)-> Instruction1 (newer instruction) (WPM -> DQM -> OTM -> BTM -> DTM). As many as three messages may be simultaneously queued. Note that for the cycle following a dropped PTM, non-periodic OTM, or DQM message, only two other messages may be queued in addition to the dropped Error Message.

Watchpoint Messages from instructions that complete at the same time or events that occur during the same cycle will be combined.

Table 67-28. Message Type Priority and Message Dropped Responses

Message Type	Message	Priority	Message Dropped Response
Error	Error	0 (highest)	N/A[1]
WP (Watchpoint Trace)	WPM (Watchpoint Message)	1	N/A[1]
DQ (Data Acquisition)	DQM (Data Acquisition Message)	2	DQM Error Message
Program Trace (PID MSG)	PCM - PID/NPIDR update (Program Correlation Message)	2	OTM Error Message

Table continues on the next page...

Table 67-28. Message Type Priority and Message Dropped Responses (continued)

Message Type	Message	Priority	Message Dropped Response
OT (Ownership)	OTM - PID/NPIDR update (Ownership Trace Message)	2	OTM Error Message[2]
Program Trace	BTM (Branch Trace Message)	2	BTM Error Message, Sync upgrade next BTM
	Sync (Program Sync Message)	3	Sync upgrade next BTM
	RFM (Resource Full for Instruction counter or history buffer)	4	BTM Error Message Sync upgrade next BTM
	DS (Debug Status Message)	5	Sync upgrade next BTM
	PCM (Program Correlation Message)	6	BTM Error Message Sync upgrade next BTM
DT (Data Trace)	DTM (Data Trace Message)	7	Sync upgrade next DTM
OT (Ownership)	OTM - Periodic update (Ownership Trace Message)	8 (lowest)	none

1. Error and Watchpoint messages are not dropped due to collisions, due to their priority.
2. Message will always be dropped if program trace is enabled, and program correlation messages for PID messages are not masked (Event Code = 0101). No error message is sent for this case since the PID value is contained in the higher priority message.

67.8.5 Data Acquisition Message Priority Loss Response

If a Data Acquisition Message (DQM) loses arbitration due to contention with higher priority messages, an error message will be generated to indicate that a DQM has been lost due to contention.

67.8.6 Ownership Trace Message Priority Loss Response

If an Ownership Trace message (OTM) due to software updates to the Process ID state loses arbitration due to contention with higher priority messages other than a program correlation message with EVCODE = 0101 (PID update), an error message will be generated to indicate that a OTM has been lost due to contention. If the pending OTM is a periodic update, the event is dropped without generating an error message.

67.8.7 Program Trace Message Priority Loss Response

If a Program Trace message (PTM) loses arbitration due to contention with higher priority messages, and the discarded PTM is a Program Correlation message, a Resource Full message for instruction count or history buffer, or a Branch Trace message, then an Error message is generated to indicate that branch trace information has been lost, and the next Branch Trace message will be upgraded to a sync-type message.

If the discarded PTM is a Program Correlation message with PID information (EVCODE=0101), the Error message will indicate a dropped OTM and a dropped Program Trace (Error code = xxxx11xx).

67.8.8 Program Trace Sync Message Priority Loss Response

If a Program Trace Sync message (SYNC) loses arbitration due to contention with higher priority messages, the Sync event is discarded, and the next Branch Trace message will be upgraded to a sync-type message.

67.8.9 Data Trace Message Priority Loss Response

If a Data Trace message (DTM) loses arbitration due to contention with higher priority messages, the DTM event is discarded, and the next DTM will be upgraded to a sync-type message.

67.9 Debug Status messages

Debug Status Messages report low power mode and debug status. Debug Status messages are enabled when Nexus 3 is enabled. Entering/exiting Debug Mode as well as entering, exiting, or changing Low Power Mode(s) will trigger a Debug Status message, indicating the value of the most significant byte in the Development Status register. Debug status information is sent out in the following format:

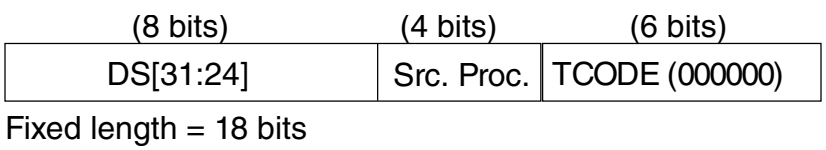

Figure 67-30. Debug Status message format

67.10 Error messages

Error messages are enabled whenever the debug logic is enabled. There are two conditions that will produce an error message, each receiving a separate error type designation:

- A message is discarded due to contention with other (higher priority) message types. These errors will have an Error Type value of 1.
- The message queue overruns. After the queue is drained, an error message is enqueued with an error code that indicates what types of messages were discarded during the interim. These errors will have an Error Type value of 0.

Note

The OVCR Register can be used in order to alleviate potential overrun situations.

Error information is messaged out in the following format (also see Table 67-3 and Table 67-4):

(6 bits)	(4 bits)	(4 bits)	(6 bits)
Error Code	Error Type	Src. Proc.	TCODE (001000)

Fixed length = 20 bits

Figure 67-31. Error message format

67.11 Ownership trace

This section details the ownership trace features of the Nexus 3 module.

67.11.1 Overview

Ownership trace provides a macroscopic view, such as task flow reconstruction, when debugging software written in a high level (or object-oriented) language. It offers the highest level of abstraction for tracking operating system software execution. This is especially useful when the developer is not interested in debugging at lower levels.

67.11.2 Ownership Trace Messaging (OTM)

Ownership trace information is messaged via the auxiliary port using an Ownership Trace Message (OTM). Z4 Core processors contain a *PowerISA 2.06* defined "Process ID" register within the CPU. It is updated by the operating system software to provide task/process ID information. The contents of this register are replicated on the pins of the processor and connected to Nexus. The Process ID (PID) register value can be accessed using the **mfspr/mtspr** instructions.

Note

The CPU includes a Process ID register (PID0), thus the Nexus UBA functionality is not implemented.

In addition, to decouple trace information from the PID0 register and to provide a full independent 32-bit process ID for debug use, the Nexus PID Register (NPIDR) may be used instead of PID0 to provide OTM process ID information. It is updated by the operating system software to provide task/process ID information. The Nexus Process ID (NPIDR) register value can be accessed using the **mfspr/mtspr** instructions. This register is accessible in user or supervisor mode.

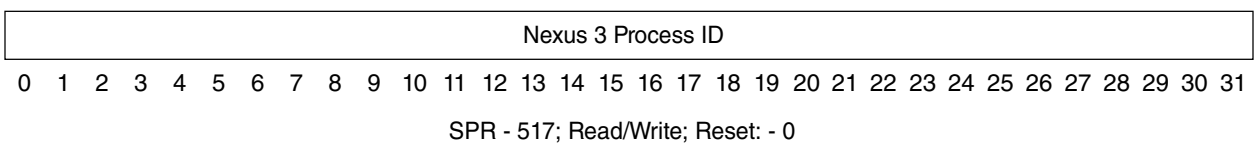

Figure 67-32. Nexus 3 Process ID Register (NPIDR)

Note

OS updates to NPIDR should be performed in addition to normal PID0 updates when a process switch occurs, in order to properly generate OTM messages with new process ID information when NPIDR is selected for OTM use.

The process ID source (PID0 or NPIDR) is selected by the setting of the $DC1_{OTS}$ control bit.

There are two conditions that will cause an Ownership Trace Message when Ownership Trace is enabled:

- When the PID0 register is written to by the processor and $DC1_{OTS}$ indicates PID0 should be used, or when the NPIDR register is written to by the processor and $DC1_{OTS}$ indicates NPIDR should be used, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow. However, if Program Trace is enabled, and program correlation messages for

PID updates are not masked (Event Code = 0101), then an OTM will not be generated for an update to the selected process ID register, since the program correlation message will provide this process ID update information.

- Periodically, at least once every 256 messages, the most recent state of the selected process ID register is messaged out. The resulting Ownership Trace message will indicate in the PID Index sub-field that PID0/NPIDR status is being reported and the most recent value of the PID0/NPIDR register will be conveyed in the Process ID value sub-field. These periodic Ownership Trace message events can be disabled by setting $DC1_{POTD}$.

Ownership trace information is messaged out in the following format:

(1-32 bits)	(4 bits)	(4 bits)	(6 bits)
Process ID	PID Index (0000)	Src. Proc.	TCODE (000010)

Variable length = 15-46 bits

Figure 67-33. Ownership Trace Message format

67.12 Program trace

This section details the program trace mechanism supported by Nexus3 for the z4 processor. Program trace is implemented via Branch Trace Messaging (BTM) as per the **IEEE-ISTO 5001** standard definition. Branch Trace Messaging for z4 processors is accomplished by snooping the internal address bus (between the CPU and Cache), attribute signals, and CPU Status (**p_mode[0:3]**, **p_pstat_pipe{0,1}[0:5]**).

67.12.1 Branch Trace Messaging types

Traditional Branch Trace Messaging facilitates program trace by providing the following types of information:

- Messaging for taken direct branches includes how many sequential instructions were executed since the last taken branch or exception, including the taken direct branch. Branch instructions are included in the count of sequential instructions.
- Messaging for taken indirect branches and exceptions includes how many sequential instructions were executed since the last taken branch or exception and the unique portion of the branch target address or exception vector address. Branch instructions are included in the count of sequential instructions. For taken indirect branches that trigger generation of a message, the branch is also included in the count.

Branch History Messaging facilitates program trace by providing the following information.

- Messaging for taken indirect branches and exceptions includes a) how many sequential instructions (I-CNT) were executed since the last predicate instruction, taken/not taken direct branch, taken/not-taken indirect branch, or exception, b) the unique portion of the branch target address or exception vector address, and c) a branch/predicate instruction history field. Each bit in the history field represents a direct branch or predicated instruction where a value of one (1) indicates taken, and a value of zero (0) indicates not taken. Not-taken indirect branches will generate a history bit with a value of zero (0). Instructions that generate history bits are not included in instruction counts. For taken indirect branches that trigger generation of this message type, the branch is included in the count, but not in the history field.

67.12.1.1 Indirect Branch Message instructions

Table 67-29 shows the types of instructions and events that cause Indirect Branch Messages or Branch History Messages to be encoded.

Table 67-29. Indirect Branch Message sources

Source of Indirect Branch Message	Instructions / Detail
Taken branch relative to a register value	**bcctr, bcctrl, bclr, bclrl, se_bctr, se_bctrl, se_blr, se_blrl**
System Call / Trap exceptions taken	**se_sc, tw**
Return from interrupts / exceptions	**se_rfi, se_rfci, se_rfdi**
Exit from reset with Program Trace Enabled	**Indirect branch with Sync, target address is initial instruction, count = 1**

67.12.1.2 Direct Branch Message Instructions

Table 67-30 shows the types of instructions that will cause Direct Branch Messages or will toggle a bit in the instruction history buffer to be messaged out in a Resource Full Message or Branch History Message.

Table 67-30. Direct Branch Message sources

Source of Direct Branch Message	Instructions
Taken direct branch instructions Instruction Synchronize	**b, ba, bl, bla, bc, bca, bcl, bcla, se_b. se_bc, se_bl, e_b, e_bc, e_bl, e_bcl, se_isync**

67.12.1.3 BTM using Branch History Messages

Traditional BTM Messaging can accurately track the number of sequential instructions between branches, but cannot accurately indicate which instructions were conditionally executed, and which were not.

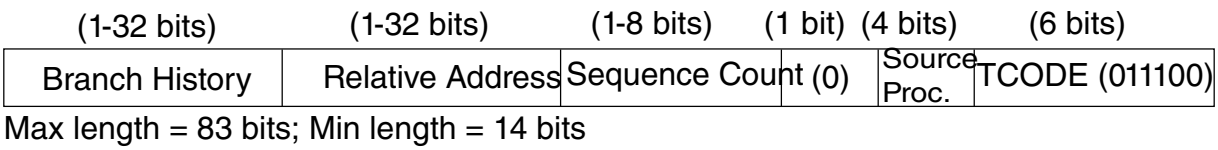
Branch History Messaging solves this problem by providing a predicated instruction history field in each Indirect Branch Message. Each bit in the history represents a predicated instruction or direct branch, or a not-taken indirect branch. A value of one (1) indicates the conditional instruction was executed or the direct branch was taken. A value of zero (0) indicates the conditional instruction was not executed or the branch was not taken.

Branch History Messages solve predicated instruction tracking and save bandwidth since only indirect branches cause messages to be queued.

67.12.1.4 BTM using Traditional Program Trace Messages

Based on the PTM bit in the DC1 Register, Program Tracing can utilize either Branch History Messages (PTM = 1) or traditional Direct/Indirect Branch Messages (PTM = 0).

Branch History will save bandwidth and keep consistency between methods of Program Trace, yet may lose temporal order between BTM messages and other types of messages. Since direct branches are not messaged, but are instead included in the history field of the Indirect Branch History Message, other types of messages may enter the FIFO between Branch History Messages. The development tool cannot determine the ordering of "events" that occurred with respect to direct branches simply by the order in which messages are sent out.



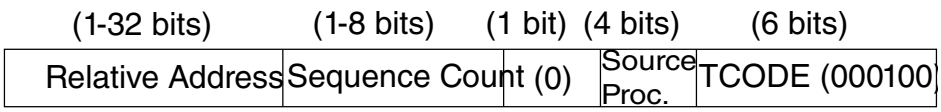
Traditional BTM messages maintain their temporal ordering because each event that can cause a message to be queued will enter the FIFO in the order it occurred and will be messaged out maintaining that order.

67.12.2 BTM Message For mats

The Nexus 3 block supports three types of traditional BTM Messages - Direct, Indirect, and Synchronization Messages. It supports two types of branch history BTM Messages - Indirect Branch History, and Indirect Branch History with Synchronization Messages.

67.12.2.1 Indirect branch messages (history)

Indirect branches include all taken branches whose destination is determined at run time, interrupts, and exceptions. If $DC1_{PTM}$ is set to '1', indirect branch information is messaged out in the following format:



Max length = 83 bits; Min length = 14 bits

Figure 67-34. Indirect branch message (history) format

67.12.2.2 Indirect branch messages (traditional)

If $DC1_{PTM}$ is cleared to '0', indirect branch information is messaged out in the following format:

Max length = 51 bits; Min length = 13 bits

Figure 67-35. Indirect branch message format

67.12.2.3 Direct branch messages (traditional)

Direct branches (conditional or unconditional) are all taken branches whose destination is fixed in the instruction opcode. Direct branch information is messaged out in the following format:

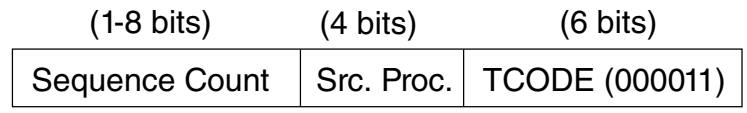


Figure 67-36. Direct Branch message format

Note

When $DC1_{PTM}$ is set, Direct Branch Messages will not be transmitted. Instead, each direct branch, not-taken indirect branch, or predicated instruction will be recorded in the history buffer.

67.12.3 Program Trace Message Fields

The following subsections describe specific fields used for Program Trace messages.

67.12.3.1 Sequential Instruction Count Field (ICNT)

Most of the program trace messages include an instruction count field. For traditional Branch messages, ICNT represents the number of sequential instructions including non-taken branches since the last Direct/Indirect Branch messages. Branch instructions that trigger message generation are included in the ICNT.

For Branch History messages, ICNT represents the number of instructions executed since the last taken/non-taken direct branch, predicate instruction, last taken/not-taken indirect branch, or exception. Branch instructions that trigger message generation are included in the ICNT. Instructions that generate history bits are not included in the ICNT.

The sequential instruction counter overflows after its value reaches 255 and is reset to 0. In addition, the next BTM Message (corresponding to the 256th or later instruction) will be converted to a w/sync type message.

The instruction counter is reset every time the instruction count is transmitted in a message or whenever there is a branch/predicate history event, as well as on exiting from debug mode.

67.12.3.2 Branch/Predicate Instruction History (HIST)

If $DC1_{PTM}$ is set, BTM messaging will use the Branch History format. The branch history (HIST) field in these messages provides a history of branch execution used for reconstructing the program flow. The branch/predicate history buffer stores information about branch and predicate instruction execution. The buffer is implemented as a left-shifting register. The buffer is preloaded with a one (1), which acts as a stop bit (the most significant 1 in the history field is a termination bit for the field). The pre-loaded bit itself is not part of the history, but is transmitted with the packet.

A value of one (1) is shifted into the history buffer for each taken direct branch (program counter relative branch) or predicate instruction whose condition evaluates to true. A value of zero (0) is shifted into the history buffer for each not-taken branch (including indirect branch instructions) or predicate instruction whose condition evaluates to false.

This history buffer information is transmitted as part of an Indirect Branch with History message, as part of a Program Correlation message, or as part of a Resource Full message if the history buffer becomes full. The history buffer is reset every time the history information is transmitted in a message, as well as on exiting from debug mode.

Table 67-31. Branch/Predicate history events

Branch/Predicate History Event	History Bit(s)	Relevant Instructions
Not taken register indirect branches	0	**bcctr, bcctrl, bclr, bclrl**
Not taken direct branches	0	**b, ba, bc, bca, bla, bcla, bl, bcl**
Taken direct branches	1	**b, ba, bc, bca, bla, bcla, bl, bcl**[1]

1. If the EVCODE for direct branch function calls is not masked in DC4, taken **bl** and **bcl** instructions will generate Program Correlation Messages and will not be logged in the history buffer.1

67.12.3.3 Execution Mode Indication

In order for a development tool to properly interpret instruction count and history information, it must be aware of the execution mode context of that information. VLE instructions will be interpreted differently from non-VLE instructions.

Program trace messages provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

67.12.4 Resource Full Messages

The Resource Full Message is used in conjunction with Branch Trace and Branch History Messages. The Resource Full Message is generated when either the internal branch/ predicate history buffer is full, or if the BTM Instruction sequence counter (I-CNT) overflows. If synchronization is needed at the time this message is generated, the synchronization is delayed until the next Branch Trace Message that is not a Resource Full Message.

For history buffer overflow, the Resource Full Message transmits a Resource Code (RCODE) of 0b0001 and the current contents of the history buffer, including the stop bit, are transmitted in the Resource Data (RDATA) field. This history information can be concatenated by the development tool with the branch/predicate history information from subsequent messages to obtain the complete branch/predicate history between indirect changes of flow.

For instruction counter overflow, the Resource Full Message transmits an RCODE of 0b0000 and a value of 0xFF is transmitted in the RDATA field, indicating that 255 sequential instructions have been executed since the last change of flow, or, if program trace is in history mode, since the last instruction that recorded history information.

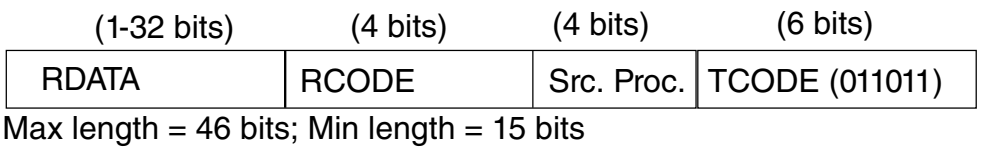

Figure 67-37. Resource Full Message format

The following table shows the RCODE encodings and RDATA information used for Resource Full Messages.

Table 67-32. RCODE encoding

RCODE	Description	RDATA field
0000	Program Trace Instruction counter reached 255 and was reset.	0xFF
0001	Program Trace, Branch / Predicate Instruction History full.	Branch HIstory. This type of packet is terminated by a stop bit set to 1 after the last history bit.

67.12.5 Program Correlation Messages

Program Correlation Messages (PCMs) are used to correlate events to the program flow that may or may not be associated with the instruction stream. The following events will result in a PCM when program trace is enabled:

- When the CPU enters debug mode, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to debug mode entry.
- When the CPU first enters a low power mode in which instructions are no longer executed, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to low power mode entry.
- Whenever program trace is disabled by any means, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to disabling program trace.
- When a "Branch and Link" instruction executes (direct branch function call — **bl/bcl/bla/bcla**-type instructions)
- When program trace becomes masked due to MSR_{PMM}='0' and $DC4_{PTMARK}$='1'.
- When a write to the process ID register selected by $DC1_{OTS}$ (PID0 or NPIDR) is made via a **mtspr** PID0 or **mtspr** NPIDR.

Refer to Table 67-6 for the event codes that are supported in this implementation. Event code masking is available via the EVCDM field of the DC4 register to allow for control over generation of Program Correlation messages for each event type.

Program Correlation is messaged out in the following formats:

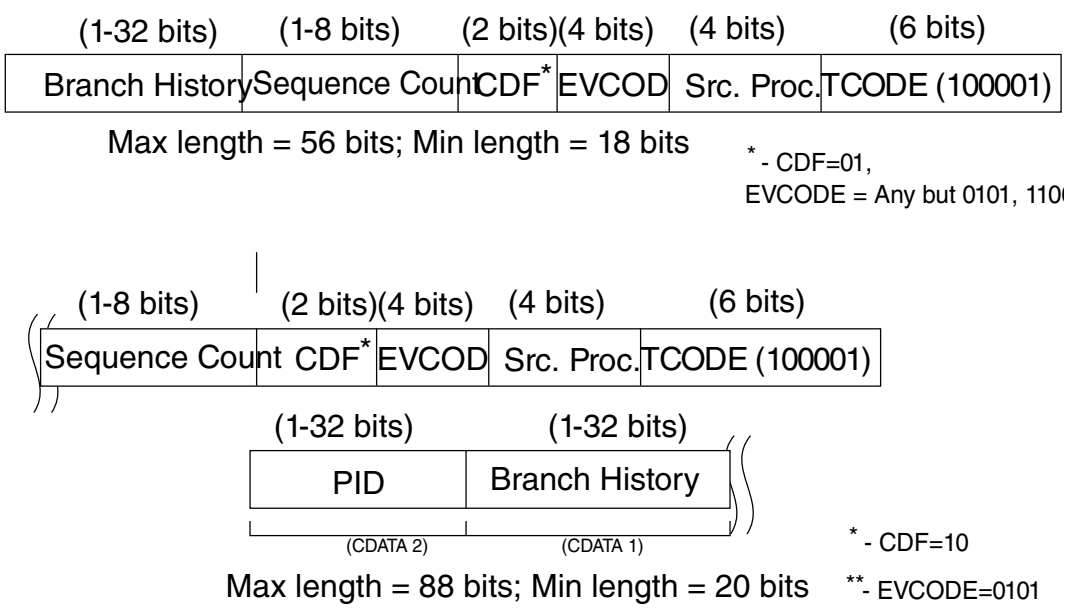

Figure 67-38. Program Correlation message formats

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

67.12.5.1 Program Correlation message generation for PID updates

When a (potentially) new value is established in the selected process ID register via a **mtspr** PID0/NPIDR, a Program Correlation message is generated containing the information regarding the new process ID value. This PCM also contains the current history and instruction count. The message is provided so that address translation information can be processed by the development tool in the proper program flow. The **mtspr** PID0/NPIDR is included in the instruction count information. Note that Ownership Trace Messages (other than the periodic OTM) are redundant with the information provided, and may be disabled to avoid unnecessary message bandwidth or collisions.

67.12.6 Program Trace Overflow Error messages

An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied.

67.12.7 Program Trace Synchronization messages

By default, program trace messages will perform XOR compression on the branch target address to produce the address field for the message. This compression is consistent with the specification in IEEE-ISTO 5001.

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see Table 67-33):

- Initial Program Trace message after exit from system reset or whenever program trace is enabled.
- Upon exiting from a CPU Low Power state.
- Upon exiting from Debug Mode.

- Upon occurrence of queue overrun (can be caused by any trace message), provided Program Trace is enabled.
- Upon assertion of the Event In (**nex_evti_b**) pin if the EIC bits within the DC1 Register have enabled this feature.
- When program trace becomes unmasked due to $MSR_{PMM} \rightarrow$ '1' with $DC4_{PTMARK}$='1'.

Note that the ICNT information for these messages is driven to zero, thus will not always be meaningful for some of these cases.

The format for Program Trace Synchronization messages is as follows:

(1-32 bits)	(1-8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Seq. Count (0)	(0)	Source Proc.	TCODE (001001)

Max length = 51 bits; Min length = 13 bits

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

Exception conditions that result in Program Trace Synchronization are summarized in Table 67-33.

Table 67-33. Program Trace exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. Upon exiting system reset (**p_reset_b**), if Program Trace is already enabled, a Program Trace Sync Message is sent.
Program Trace Enabled	The first Program Trace Message (after Program Trace has been enabled or re-enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode, a Program Trace Sync Message is sent.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next BTM message in the queue will be a Program Trace Sync Message.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Program Trace Sync Message if Program Trace is enabled and the EIC bits of the DC1 Register have enabled this feature.

Note that for cases where program trace sync messages are generated due to program trace being enabled, the address contained in the sync message may either be the address of the instruction that caused program trace to be enabled, or may be the address of the first instruction of an exception handler that is executed in response to unsuccessful completion of that instruction.

67.12.8 Program Trace Direct/Indirect Branch with Sync messages

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization or a Direct/Indirect Branch with Sync message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see Table 67-33):

- Upon direct/indirect branch after a Program Sync Message was lost due to a collision while attempting to enter the message queue.
- Upon direct/indirect branch after the sequential instruction counter has expired indicating 255 instructions have occurred since the last change of flow.
- When the periodic program trace counter has expired indicating 255 *without-sync* Program Trace messages have occurred since the last *with-sync* message occurred.

Note that the ICNT and History information for the first message will not always be meaningful, since the temporary masking of program trace may result in ambiguous values. Subsequent w/sync messages will not have this issue.

The format for Program Trace Direct/Indirect Branch with Sync Messages is as follows:

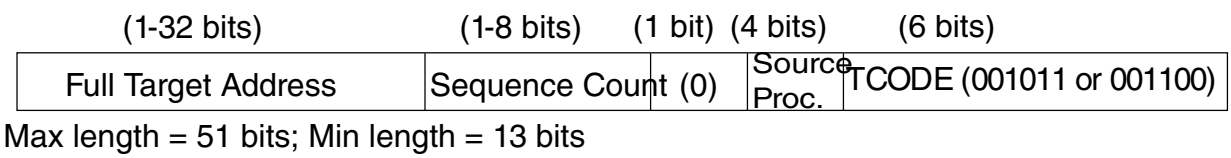

Figure 67-39. Direct/Indirect Branch with Sync message format

The format for Program Trace Indirect Branch History with Sync. messages is as follows:

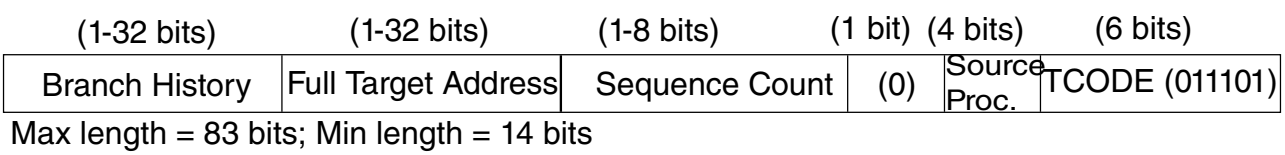

Figure 67-40. Indirect Branch History w/ Sync. message format

Exception conditions that result in Program Trace Synchronization using a w/Sync message type are summarized in Table 67-34.

Table 67-34. Program Trace Exception Summary for w/Sync BTM messages

Exception Condition	Exception Handling
Periodic Program Trace Sync.	A forced synchronization occurs periodically after 255 non-sync Program Trace Messages have been queued. A Direct/Indirect Branch w/ Sync. Message is queued. The periodic program trace message counter then resets.
Sequential Instruction Count Overflow	After the sequential instruction counter reaches its maximum count (up to 255 sequential instructions may be executed), a forced synchronization occurs. The sequential counter then resets. A Program Trace Direct/Indirect Branch w/ Sync.Message is queued upon execution of the next branch. A Resource Full Message is Queued on the overflow event. If a branch instruction is the 255th instruction to occur, and causes a Program Trace message to be queued, then no Resource Full Message is queued, and the w/Sync message will be queued for the *next* Program Trace Direct/Indirect Branch Message.
Collision Priority	All Messages have the following priority: Instruction 0 (WPM -> DQM -> PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A BTM Message from Instruction1 that attempts to enter the queue at the same time as three higher priority messages from either instruction will be lost. An Error Message will be sent indicating the BTM was lost. The following direct/indirect branch will queue a Direct/Indirect Branch w/ Sync. Message. The count value within this message will reflect the number of sequential instructions executed after the last successful BTM Message was generated. This count will include the branch that did not generate a message due to the collision.

67.12.9 Enabling Program Trace

Program Trace Messaging can be enabled in one of three ways:

- Setting the TM field of the DC1 Register to enable Program Trace
- Using the PTS field of the WT Register to enable Program Trace on Watchpoint hits (watchpoints are configured within the CPU)
- Filtering of Program Trace messages may be performed using the MSR_{PMM} bit and the setting of $DC4_{PTMARK}$

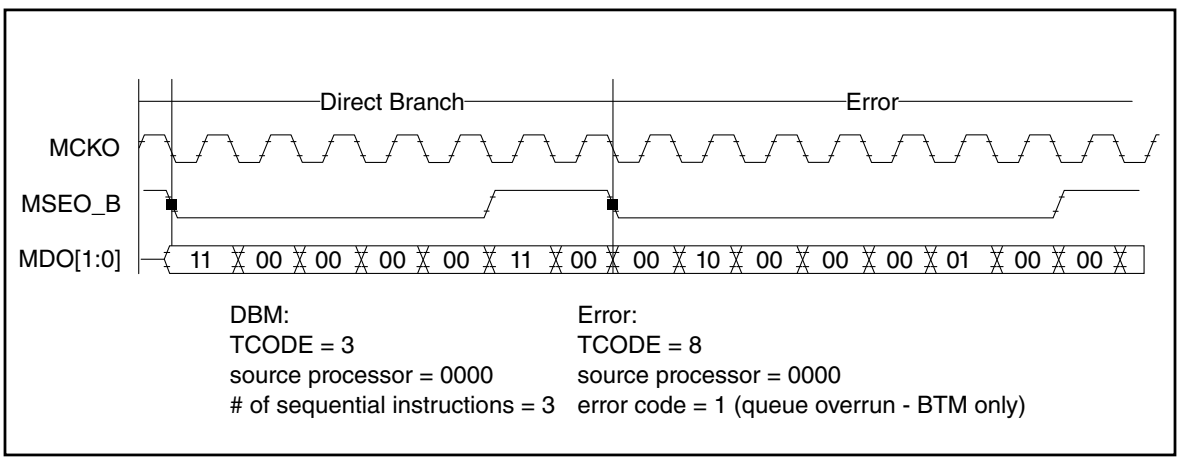

Figure 67-43. Program Trace - Direct Branch (traditional) & Error messages

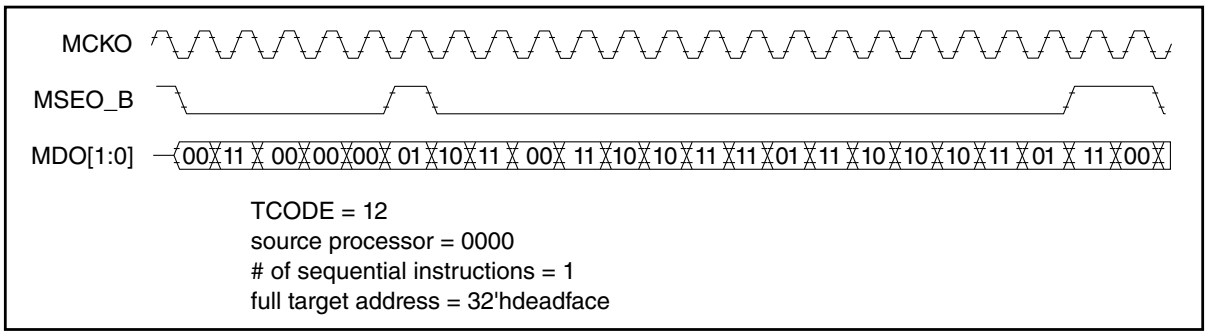

Figure 67-44. Program Trace - Indirect Branch w/ Sync. message

67.13 Data Trace

This section deals with the Data Trace mechanism supported by the Nexus 3 module. Data Trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the **IEEE-ISTO 5001** standard.

67.13.1 Data Trace Messaging (DTM)

Data Trace Messaging is accomplished by snooping the internal address and data buses, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The Nexus 3 module traces all data access that meet the selected range and attributes.

Note

Data Trace is only performed on the internal data buses. This allows for data visibility for Z4 Core processors that incorporate a data cache. Only CPU initiated accesses will be traced. No DMA accesses to the AHB system bus will be traced.

Data Trace Messaging can be enabled in one of three ways.

- Setting the TM field of the DC1 Register to enable Data Trace.
- Using the DTS field of the WT Register to enable Data Trace on Watchpoint hits (watchpoints are configured within the Nexus1 module).

67.13.2 DTM Message formats

The Nexus 3 block supports five types of DTM Messages — Data Write, Data Read, Data Write Synchronization, Data Read Synchronization and Error Messages.

67.13.2.1 Data Write messages

The Data Write message contains the data write value and the address of the write access, relative to the previous Data Trace Message. Data Write message information is messaged out in the following format:

(1-64 bits)	(1-32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000101)

Max length = 111 bits; Min length = 17 bits

Figure 67-45. Data Write message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

67.13.2.2 Data Read messages

The Data Read message contains the data read value and the address of the read access, relative to the previous Data Trace message. Data Read message information is messaged out in the following format:

(1-64 bits)	(1-32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000110)

Max length = 111 bits; Min length = 17 bits

Figure 67-46. Data Read fessage format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

Note

Z4 based CPUs are capable of generating two (2) reads or writes per clock cycle in cases where multiple registers are accessed with a single instruction (lmw/stmw). These will have a double word pair size encoding (**p_tsiz** = 0b000). In these

cases, the nexus3 module will send one (1) Data Trace Message with the two 32-bit data values as one combined 64-bit value for each message.

For Z4 based CPUs, the doubleword encoding (**p_tsiz** = 0b000) may also indicate a doubleword access and will be sent out as a single Data Trace Message with a single 64-bit data value.

The debug/development tool will need to distinguish the two cases based on the family of processor.

67.13.2.3 Data Trace Synchronization messages

A Data Trace Write/Read with Sync. message is messaged via the auxiliary port (provided Data Trace is enabled) for the following conditions (see Table 67-35):

- Initial Data Trace Message after exit from system reset or whenever Data Trace is enabled.
- Upon returning from a CPU Low Power state.
- Upon returning from Debug Mode.
- After occurrence of queue overrun (can be caused by any trace message), provided Data Trace is enabled.
- After the periodic data trace counter has expired indicating 255 *without-sync* Data Trace messages have occurred since the last *with-sync* message occurred.
- Upon assertion of the Event In (**nex_evti_b**) pin, the first Data Trace Message will be a synchronization message if the EIC bits of the DC1 Register have enabled this feature.
- Upon Data Trace Write/Read after the previous DTM message was lost due to an attempted access to a secure memory location (for SOC's w/ security).
- Upon Data Trace Write/Read after the previous DTM message was lost due to a collision entering the FIFO between the DTM message and any two of the following: Watchpoint message, Ownership Trace message, or Program Trace message.

Data Trace Synchronization Messages provide the full address (without leading zeros) and insure that development tools fully synchronize with Data Trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the Data Trace address is transmitted. The format for Data Trace Write/Read with Sync. Messages is as follows:

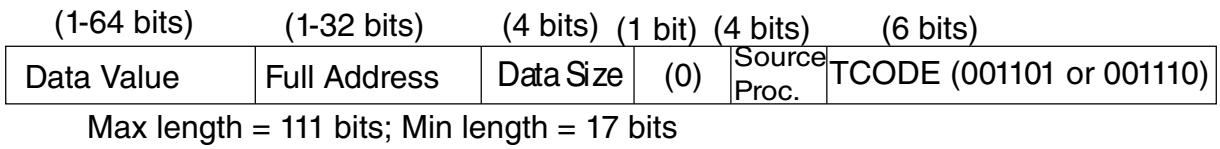

Figure 67-47. Data Write/Read with Sync. message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

Exception conditions that result in Data Trace Synchronization are summarized in Table 67-35.

Table 67-35. Data Trace Exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. If Data Trace is enabled, the first Data Trace Message is a Data Write/Read w/ Sync. Message.
Data Trace Enabled	The first Data Trace Message (after Data Trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode the next Data Trace Message will be converted to a Data Write/Read with Sync. Message.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue will be a Data Write/Read w/ Sync. Message.
Periodic Data Trace Sync.	A forced synchronization occurs periodically after 255 Data Trace Messages have been queued. A Data Write/Read w/ Sync. Message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Data Trace Write/Read w/ Sync. Message upon the next data write/read (if Data Trace is enabled and the EIC bits of the DC1 Register have enabled this feature).
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A DTM Message that attempts to enter the queue at the same time as three other higher priority messages will be lost. A subsequent read/write will queue a Data Trace Read/Write w/ Sync. Message.

67.13.3 DTM Operation

67.13.3.1 Data Trace windowing

Data Write/Read Messages are enabled via the RWT field in the Data Trace Control Register (DTC) for each DTM channel. Data Trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC field in the DTC register. All CPU initiated read/write accesses that fall inside or outside these address ranges, as programmed, are candidates to be traced.

67.13.3.2 Data Access / Instruction Access Data Tracing

The Nexus3 module is capable of tracing either instruction access data or data access data and can be configured for either type of data trace by setting the DI1 field within the Data Trace Control Register. This setting applies to all DTM channels.

67.13.3.3 Data Trace filtering

Data Trace filtering is available base on the settings of MSR_{PMM} and $DC4_{DTMARK}$.

67.13.3.4 Bus Cycle special cases

Table 67-36. Bus Cycle Special Cases

Special Case	Action
Bus cycle aborted	Cycle ignored
Bus cycle with data error ($\overline{TEA}$), [1]	Data Trace Message discarded
Bus cycle completed without error[1]	Cycle captured & transmitted
AHB bus cycle initiated by Nexus 3	Cycle ignored
Bus cycle is an instruction fetch	Cycle selectively ignored based on DTC_{DI} setting
Bus cycle accesses misaligned data (across 64-bit boundary) - both 1st & 2nd transactions within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction within data trace range; 2nd transaction out of data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction within data trace range; 2nd transaction (regardless of within range or not) receives a bus error	Data Trace Message discarded
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction out of data trace range; 2nd transaction within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)

Table continues on the next page...

Table 67-36. Bus Cycle Special Cases (continued)

Special Case	Action
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction out of data trace range; 2nd transaction within range, receives a bus error	Data Trace Message discarded

1. Buffering of stores in the CPU store buffer may generate a DTM prior to the actual memory access, regardless of an error termination condition from memory.

Note

For misaligned accesses (crossing 64-bit boundary), the access is broken into two accesses by the CPU. If either access is within the data trace range, a single DTM will be sent with a size encoding indicating the size of the original access (i.e. word), and the address indicating the original misaligned accesses, unless the misaligned access wraps into the doubleword at address 0. In this case, since the two portions of the misaligned access are not contiguous, two DTMs will be sent, one for each portion. The size encodings and the addresses of the DTMs will indicate the accessed bytes of data. The data trace port handles these cases in the same manner. (See the Data Trace Port section in the Z4 Core Debug Support chapter.)

Note

A store to the cache's store buffer within the data trace range may initiate a DTM message prior to completion of the actual memory access.

67.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration)

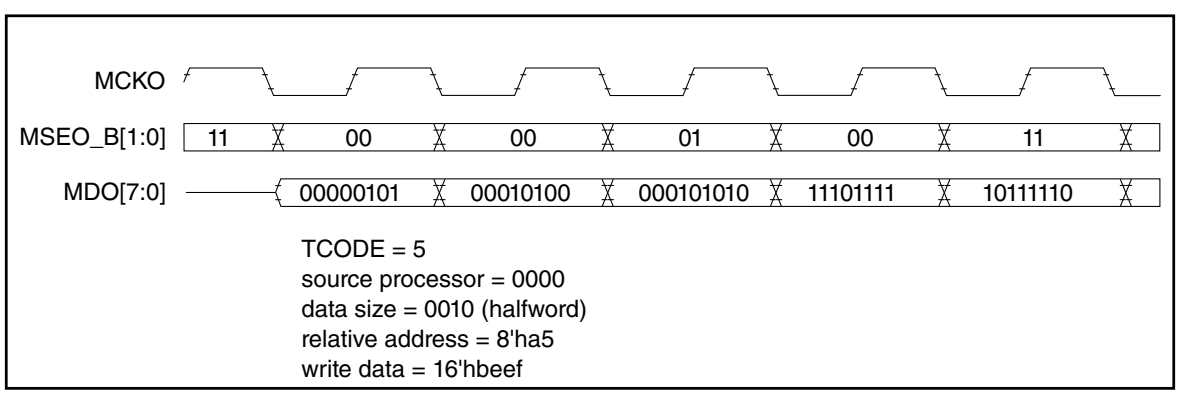

Figure 67-48. Data Trace - Data Write Message

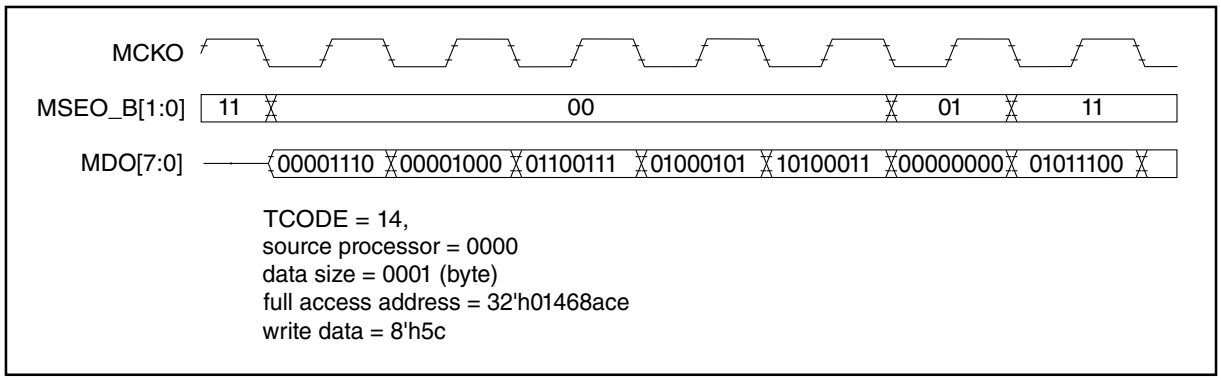

Figure 67-49. Data Trace — Data Read w/ Sync message

67.14 Data Acquisition messaging

This section details the Data Acquisition mechanisms supported by the Nexus 3 module. Data Acquisition Trace is implemented using Data Acquisition Trace Messages in accordance with IEEE-ISTO 5001 definitions. The control mechanism to export the data is different from the recommendations of the standard, however.

Data Acquisition Trace provides a convenient and flexible mechanism for the debugger to observe the architectural state of the machine through software instrumentation.

67.14.1 Data Acquisition ID Tag field

The DQTAG Tag field (DQTAG) is an 8-bit value specifying control or attribute information for the data included in the Data Acquisition message. DQTAG is sampled from $DEVENT_{DQTAG}$ when a write to DDAM is performed via **mtspr** operations. The usage of the DQTAG is left to the discretion of the development tool to be used in whatever manner is deemed appropriate for the application.

67.14.2 Data Acquisition Data field

The Data Acquisition Data field (DQDATA) is the data captured from the DDAM write operation via **mtspr** operations. Leading zeros are omitted from the message.

67.14.3 Data Acquisition Trace event

For DQM, a dedicated SPR has been allocated (DDAM). It is expected that the general use case is to instrument the software and use **mtspr** operations to generate Data Acquisition messages.

There is no explicit error response for failed accesses as a result of contention between an internal and external debugger. Software may be blocked or given ownership of DDAM and the DQTAG field of the DEVENT register via control in EDBRAC0 while in External Debug Mode. Hardware always has access to these registers. Refer to the "External Debug Resource Allocation Control Register (EDBRAC0)" section in the Z4 Core Debug Support chapter for more detail on EDBRAC0.

Reads from the Data Acquisition channel do not generate a Data Acquisition event and will return zeroes for the read data.

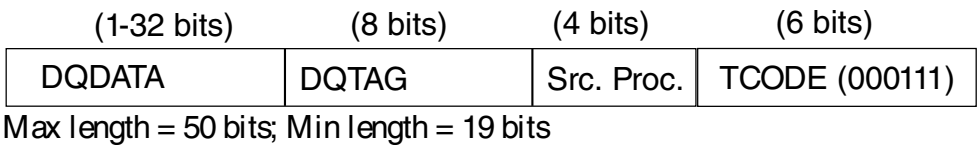

Figure 67-50. Data Acquisition message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

67.15 Watchpoint Trace messaging

Enabling Watchpoint messaging is done by setting the Watchpoint Trace Enable bit in the DC1 Register. Setting the individual Watchpoint sources is supported through the Nexus1 module and the Performance Monitor unit. The Nexus1 module is capable of setting multiple types of watchpoints. Please refer to the Z4 Core Core Debug Support chapter for details on watchpoint initialization.

When watchpoints occur due to one or more asserted watchpoint event signals and Watchpoint Trace Messaging is enabled, a Watchpoint Trace message will be sent to the message queue to be messaged out. This message includes the watchpoint number indicating which watchpoint(s) caused the message. If more than one enabled watchpoint occurs in a single cycle, only one Watchpoint Trace message is generated and multiple bits of the watchpoint hit field will be set. The settings of the $WMSK_{WEM}$ field control which watchpoints are enabled to generate watchpoint trace messages.

The occurrence of any of the defined watchpoints can also be programmed to assert the Event Out (**nex_evto_b**) pin for one (1) period of the output clock (**nex_mcko**) based on settings in the DC2 and DC3 registers. See Table 67-39 for details on **nex_evto_b**.

Watchpoint information is messaged out in the following format:

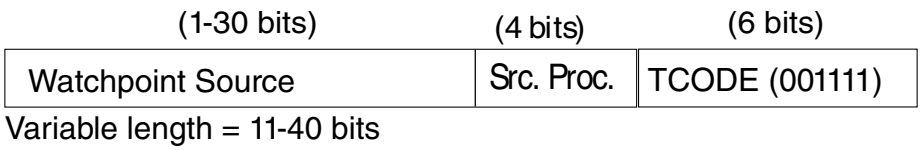

Figure 67-51. Watchpoint message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

The Watchpoint Source message field will contain a '1' for each asserted watchpoint. Leading zeros are truncated.

Table 67-37. Watchpoint Source Encoding

Watchpoint Source (1-30 bits)	Watchpoint Description
000000000000000000000000000000	No Watchpoints enabled for Watchpoint Trace Messaging
XXXXXXXXXXXXXXXXXXXXXXXXXXXXX1	Watchpoint #0 enabled for WTM
XXXXXXXXXXXXXXXXXXXXXXXXXXXX1X	Watchpoint #1 enabled for WTM
XXXXXXXXXXXXXXXXXXXXXXXXXXX1XX	Watchpoint #2 enabled for WTM
XXXXXXXXXXXXXXXXXXXXXXXXXX1XXX	Watchpoint #3 enabled for WTM
XXXXXXXXXXXXXXXXXXXXXXXXX1XXXX	Watchpoint #4 enabled for WTM
XXXXXXXXXXXXXXXXXXXXXXXX1XXXXX	Watchpoint #5 enabled for WTM
XXXXXXXXXXXXXXXXXXXXXXX1XXXXXX	Watchpoint #6 enabled for WTM
XXXXXXXXXXXXXXXXXXXXXX1XXXXXXX	Watchpoint #7 enabled for WTM
XXXXXXXXXXXXXXXXXXXXX1XXXXXXXX	Watchpoint #8 enabled for WTM
XXXXXXXXXXXXXXXXXXXX1XXXXXXXXX	Watchpoint #9 enabled for WTM
XXXXXXXXXXXXXXXXXXX1XXXXXXXXXX	Watchpoint #10 enabled for WTM
XXXXXXXXXXXXXXXXXX1XXXXXXXXXXX	Watchpoint #11 enabled for WTM
XXXXXXXXXXXXXXXXX1XXXXXXXXXXXX	Watchpoint #12 enabled for WTM
XXXXXXXXXXXXXXXX1XXXXXXXXXXXXX	Watchpoint #13 enabled for WTM
XXXXXXXXXXXXXXX1XXXXXXXXXXXXXX	Watchpoint #14 enabled for WTM
XXXXXXXXXXXXXX1XXXXXXXXXXXXXXX	Watchpoint #15 enabled for WTM
XXXXXXXXXXXXX1XXXXXXXXXXXXXXXX	Watchpoint #16 enabled for WTM
XXXXXXXXXXXX1XXXXXXXXXXXXXXXXX	Watchpoint #17 enabled for WTM
XXXXXXXXXXX1XXXXXXXXXXXXXXXXXX	Watchpoint #18 enabled for WTM
XXXXXXXXXX1XXXXXXXXXXXXXXXXXXX	Watchpoint #19 enabled for WTM
XXXXXXXXX1XXXXXXXXXXXXXXXXXXXX	Watchpoint #20 enabled for WTM
XXXXXXXX1XXXXXXXXXXXXXXXXXXXXX	Watchpoint #21 enabled for WTM

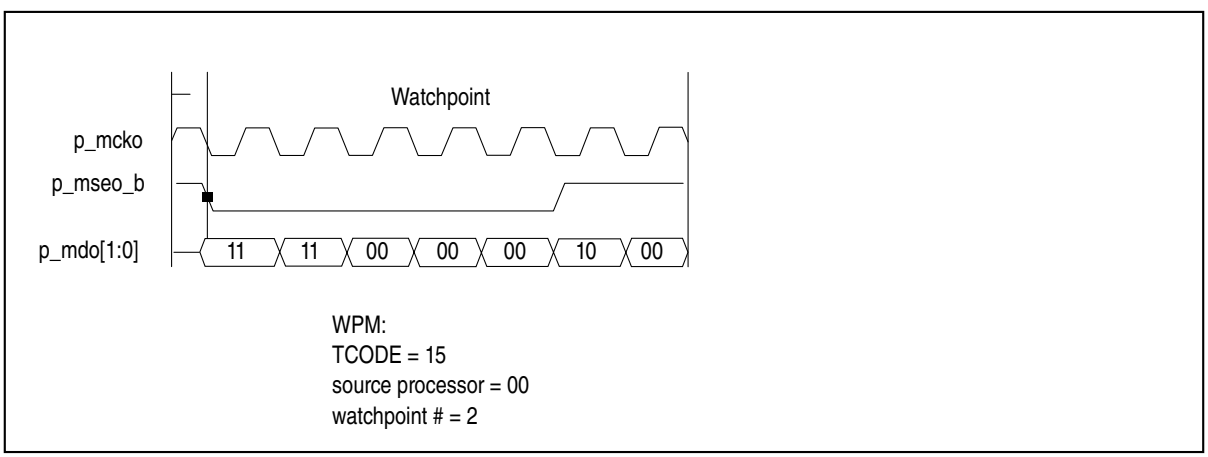

Figure 67-52. Watchpoint Message & Watchpoint Error message

67.16 Nexus 3 Read/Write access to memory-mapped resources

The Read/Write access feature allows access to memory-mapped resources via the JTAG/ OnCE port. The Read/Write mechanism supports single as well as block reads and writes to AHB resources.

The Nexus 3 module is capable of accessing resources on the system bus (AHB). Memory-mapped registers and other non-cached memory can be accessed via the standard memory map settings.

All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). Nexus 3 read/write accesses are run as privileged data non-cacheable accesses by default, and drive the **p_d_hprot[5:0]** bus access attributes to 6'b000011 accordingly. The $RWCS_{ATTR}$ field is provided to allow a portion of these default values to be modified when performing read or write accesses using the Nexus 3 Read/Write access mechanism.

Using the Read/Write Access Registers (RWCS/RWA/RWD), memory mapped AHB resources can be accessed through Nexus 3. The following subsections describe the steps required to access memory-mapped resources.

Note

Read/Write Access can only access memory mapped resources when system reset is de-asserted and clocks are running.

Misaligned accesses are NOT supported in the Nexus 3 module.

Uncorrectable ECC errors on Nexus 3 read access will result in the RWD register being updated with the raw data received.

67.16.1 Single write access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Write Address → 32h'xxxxxxxx (write address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure the bits as follows:
   - Access Control (AC) → 1b'1 (to indicate start access)
   - Map Select (MAP) → 3b'000 (primary memory map)
   - Access Priority (PR) → 2b'11 (highest priority)
   - Read/Write (RW) → 1b'1 (write access)
   - Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   - Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note

Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. Initialize the Read/Write Access Data Register (RWD) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Write Data → 32h'xxxxxxxx (write data)
4. The Nexus block will then arbitrate for the AHB system bus and transfer the data value from the data buffer RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed, Nexus clears the AC and DV bits in the RWCS Register. If the access has completed without error, (ERR=1'b0), Nexus asserts the **nex_rdy_b** pin (see Table 67-39 for details) and clears the ERR bit in the RWCS Register. Otherwise, if the access completes with an error, the **nex_err_b** pin will be asserted and the ERR bit will be set to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once DV has been cleared, this indicates that the device is ready for the next access, or that an error has occurred.

Note

Only the **nex_ahb_start, nex_rdy_b,** and **nex_err_b** pins as well as the AC, DV, and ERR bits within the RWCS provide Read/Write Access status to the external development tool.

67.16.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in Single write access to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and transfer the first data value from the RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, and

the **nex_rdy_b** pin is asserted. If the access has completed without error, Nexus clears the ERR and DV bits in the RWCS Register, otherwise the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the **nex_err_b** pin is asserted, the block transfer is aborted, and the AC bit in the RWCS register is cleared. Once DV has been cleared, this indicates that the device is ready for the next access in the block transfer, or an error has occurred.

3. If AC has not been cleared due to an error, repeat Step 3 in Single write access until the internal CNT value is zero (0). When this occurs, the AC bit within the RWCS will be cleared to indicate the end of the block write access.

Note

The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block write access. The original values can be read by the external development tool at any time.

67.16.3 Single read access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Read Address → 32h'xxxxxxxx (read address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure the bits as follows:
   - Access Control (AC) → 1b'1 (to indicate start access)
   - Map Select (MAP) → 3b'000 (primary memory map)
   - Access Priority (PR) → 2b'11 (highest priority)
   - Read/Write (RW) → 1b'0 (read access)
   - Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   - Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note

Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and asserts the **nex_rdy_b** pin (see Table 67-39 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE.

Note

Only the **nex_ahb_start, nex_rdy_b,** and **nex_err_b** pins as well as the AC, DV and ERR bits within the RWCS provide Read/Write Access status to the external development tool.

67.16.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in Single read access to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and asserts the **nex_rdy_b** pin (see Table 67-39 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.
3. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, Nexus clears the ERR bit and sets the DV bit in the

RWCS Register, and asserts the **nex_rdy_b** pin (see Table 67-39 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the AC bit is cleared and the block transfer is aborted, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. Once DV has been set, this indicates that the device is ready for the next access in the block transfer, or if ERR is set (AC will be cleared), the block transfer has been aborted.

4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE.
5. If AC has not been cleared due to an error, repeat Steps 3 and 4 in Single read access until the CNT value is zero (0). When this occurs, the AC bit within the RWCS is cleared to indicate the end of the block read access.

Note

The data values must be shifted out 32 bits at a time LSB first (i.e. doubleword read = two word reads from the RWD).

Note

The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block read access. The original values can be read by the external development tool at any time.

67.16.5 Error handling

The Nexus 3 module handles various error conditions as follows:

67.16.5.1 AHB Read/Write error

All address and data errors that occur on read/write accesses to the AHB system bus will return a transfer error encoding on the **p_hresp[1:0]** signals. If this occurs:

1. The access is terminated without retrying (AC bit is cleared)
2. The ERR bit in the RWCS Register is set

3. The Error Message is sent (TCODE = 8) indicating Read/Write error

67.16.5.2 Access termination

The following cases are defined for sequences of the Read/Write protocol that differ from those described in the above sections.

1. If the AC bit in the RWCS Register is set to start Read/Write accesses and invalid values are loaded into the RWD and/or RWA, then an AHB access error may occur. This is handled as described above.
2. If a block access is in progress (all cycles not completed), and the RWCS Register is written, then the original block access is terminated at the boundary of the nearest completed access.
   a. If the RWCS is written with the AC bit set, the next Read/Write access will begin and the RWD can be written to/ read from.
   b. If the RWCS is written with the AC bit cleared, the Read/Write access is terminated at the nearest completed access. This method can be used to break (early terminate) block accesses.

67.16.6 Read/Write access error message

The Read/Write Access Error Message is sent out when an AHB system bus access error (read or write) has occurred.

Error information is messaged out in the following format:

(5 bits)	(4 bits)	(6 bits)
Error Code (00011)	Src. Proc.	TCODE (001000)

Fixed length = 15 bits

Figure 67-53. Error message format1

67.17 Nexus 3 pin interface

This section details information regarding the Nexus 3 pins and pin protocol.

The Nexus 3 pin interface provides the function of transmitting messages from the messages queues to the external tools. It is also responsible for handshaking with the message queues.

67.17.1 Pins implemented

The Nexus 3 module implements an auxiliary port consisting of one (1) **nex_evti_b** and one (1) **nex_mseo_b** or two (2) **nex_mseo_b[1:0]**. It also implements a configurable number of **nex_mdo[n:0]** pins, (1) **nex_err_b** pin, (1) **nex_evto_b** pin, and one (1) clock output pin (**nex_mcko**), as well as additional configuration pins described in Table 67-39. The output pins are synchronized to the Nexus 3 output clock (**nex_mcko**).

All Nexus 3 input functionality may be controlled through the JTAG/OnCE port in compliance with IEEE 1149.1 (see Nexus 3 Register Access via JTAG/OnCE for details). The JTAG pins are incorporated as I/O to the processor, and are further described in the "JTAG/OnCE Pins" section of the Z4 Core Core Debug Support chapter.

Table 67-38. JTAG Pins for Nexus 3

JTAG Pins	Input/ Output	Description of JTAG Pins (included in Nexus 1)
j_tdo	O	The Test Data Output (**j_tdo**) pin is the serial output for test instructions and data. **j_tdo** is three-stateable and is actively driven in the "Shift-IR" and "Shift-DR" controller states. **j_tdo** changes on the falling edge of **j_tclk**.
j_tdi	I	The Test Data Input (**j_tdi**) pin receives serial test instruction and data. TDI is sampled on the rising edge of **j_tclk**.
j_tms	I	The Test Mode Select (**j_tms**) input pin is used to sequence the OnCE controller state machine. **j_tms** is sampled on the rising edge of **j_tclk**.
j_tclk	I	The Test Clock (**j_tclk**) input pin is used to synchronize the test logic, and control register access through the JTAG/OnCE port.
j_trst_b	I	The Test Reset (**j_trst_b**) input pin is used to asynchronously initialize the JTAG/OnCE controller.

The auxiliary pins are used to send and receive messages and are described in Table 67-39.

Table 67-39. Nexus 3 Auxiliary pins

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_mcko	O	Message Clock Out (**nex_mcko**) is a free running output clock to development tools for timing of **nex_mdo[n:0]** & **nex_mseo_b[1:0]** pin functions. **nex_mcko** is programmable through the DC1 Register.
nex_mdo[n:0]	O	Message Data Out (**nex_mdo[n:0]**) are output pins used for OTM, BTM, and DTM. External latching of **nex_mdo[n:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**).

Table continues on the next page...

Table 67-39. Nexus 3 Auxiliary pins (continued)

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_mseo_b[1:0]	O	Message Start/End Out (**nex_mseo_b[1:0]**) are output pins that indicate when a message on the **nex_mdo[n:0]** pins has started, when a variable length packet has ended, and when the message has ended. External latching of **nex_mseo_b[1:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**). One or two pin MSEO functionality is determined at integration time per SOC implementation.
nex_err_b	O	Error (**nex_err_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access and an error has occurred on the previous access. If Nexus is enabled, this signal is asserted upon unsuccessful (with error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the "Capture_DR" state. Upon exit from system reset or if Nexus is disabled, **nex_err_b** remains deasserted.
nex_evto_b	O	Event Out (**nex_evto_b**) is an output that, when asserted, indicates one of two events has occurred based on the EOC bits in the DC1 Register. **nex_evto_b** is held asserted for one (1) cycle of **nex_mcko**: 1. One (or more) watchpoints has occurred (from Nexus1) & EOC = 2'b00 2. Debug mode was entered (jd_debug_b asserted from Nexus1) & EOC = 2'b01
nex_evti_b	I	Event In (**nex_evti_b**) is an input that, when asserted, will initiate one of two events based on the EIC bits in the DC1 Register (if the Nexus module is enabled at reset): 1. Program Trace & Data Trace synchronization messages (provided Program Trace & Data Trace are enabled & EIC = 2'b00). 2. Debug request to Nexus1 module (provided EIC = 2'b01 and this feature is implemented).
nex_ext_src_id[0:3]	I	**nex_ext_src_id[0:3]** is used to provide the SRC field value used in each message. These pins are tied to a predetermined value at SoC integration time.
nex_sfwcntl_en]	I	**nex_sfwcntl_en** is used to allow software to control the module resources via the DCR register mappings. SoC logic should drive this signal appropriately in a semi-static manner based on the presence of an external hardware debugger and appropriate security precautions.

The Nexus auxiliary port arbitration pins are used when the Nexus 3 module is implemented in a multi-Nexus SoC that shares a single auxiliary output port. The arbitration is controlled by an SoC level Nexus Aurora Router (NAR). Refer to Auxiliary port arbitration for detail on Nexus port arbitration.

Table 67-40. Nexus port arbitration signals

Nexus port arbitration pins	Input/ Output	Description of arbitration pins
nex_aux_req[1:0]	O	Nexus Auxiliary Request (**nex_aux_req[1:0]**) output signals indicate to an SoC level Nexus arbiter a request for access to the shared Nexus auxiliary port in a multi-Nexus implementation. The priority encodings are determined by how many messages are currently in the message queues (See Table 67-42.)
nex_aux_busy	O	Nexus Auxiliary Busy (**nex_aux_busy**) is an output signal to an SoC level Nexus arbiter indicating that the Nexus 3 module is currently transmitting its message after being granted the Nexus auxiliary port.

Table continues on the next page...

Table 67-40. Nexus port arbitration signals (continued)

Nexus port arbitration pins	Input/ Output	Description of arbitration pins
nar_aux_grant	I	Nexus Auxiliary Grant **(nar_aux_grant)** is an input from the SoC level NAR that the auxiliary port has been granted to the Nexus 3 module to transmit its message.
ext_multi_nex_sel	I	Multi-Nexus Select (**ext_multi_nex_sel**) is a static signal indicating that the Nexus 3 module is implemented within a multi-Nexus environment. If set, port control and arbitration is controlled by the SoC level arbitration module (NAR).

67.17.2 Pin protocol

The protocol for the processor transmitting messages via the auxiliary pins is accomplished with the MSEO pin function outlined in Table 67-41. Both single and dual pin cases are shown.

nex_mseo_b[1:0] is used to signal the end of variable-length packets, and not fixed length packets. **nex_mseo_b[1:0]** is sampled on the rising edge of the Nexus 3 clock (**nex_mcko**).

Single pin MSEO is not supported on the device.

Table 67-41. MSEO pin(s) protocol

nex_mseo_b function	Single nex_mseo_b data (serial)	Dual nex_mseo_b[1:0] data
Start of message	1-1-0	11-00
End of message	0-1-1-(more 1's)	00 (or 01)-11-(more 1's)
End of variable length packet	0-1-0	00-01
Message transmission	0's	00's
Idle (no message)	1's	11's

Figure 67-54 illustrates the state diagram for single pin MSEO transfers.

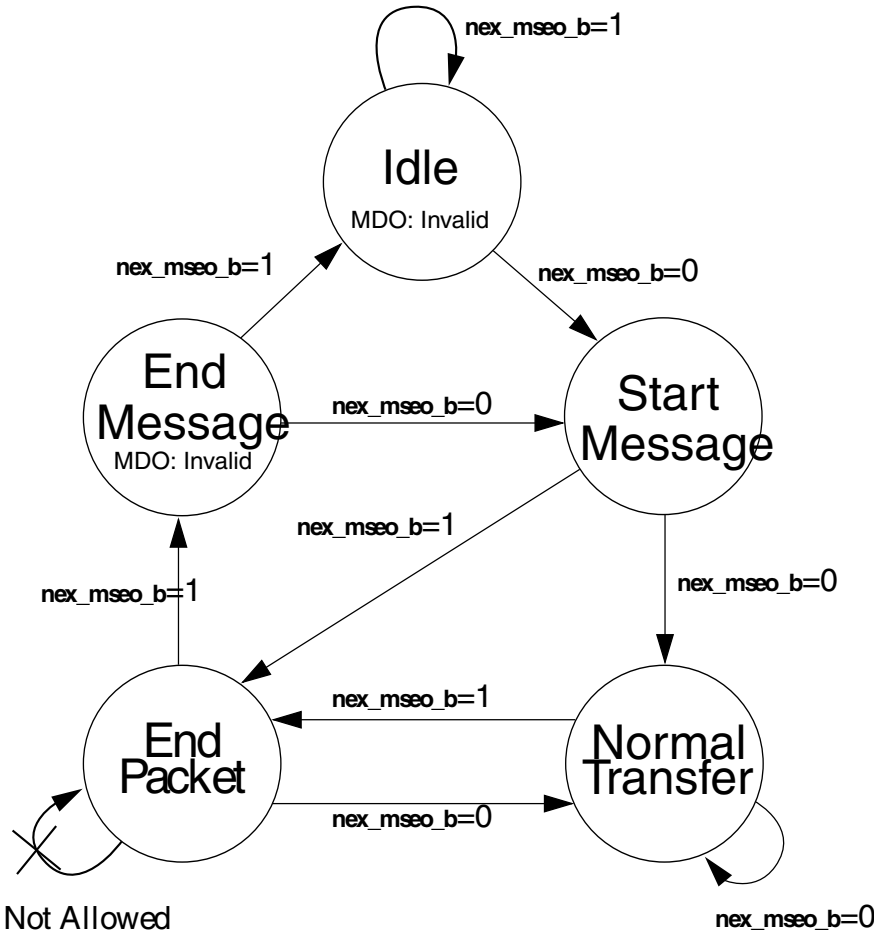

Figure 67-54. Single pin MSEO transfers

Note that the "End Message" state does not contain valid data on the **nex_mdo[n:0]** pins. Also, It is not possible to have two consecutive "End Packet" messages. This implies the minimum packet size for a variable length packet is 2x the number of **nex_mdo[n:0]** pins. This ensures that a false end of message state is not entered by emitting two consecutive '1's on the **nex_mseo_b** pin before the actual end of message.

Figure 67-55 illustrates the state diagram for dual pin MSEO transfers.

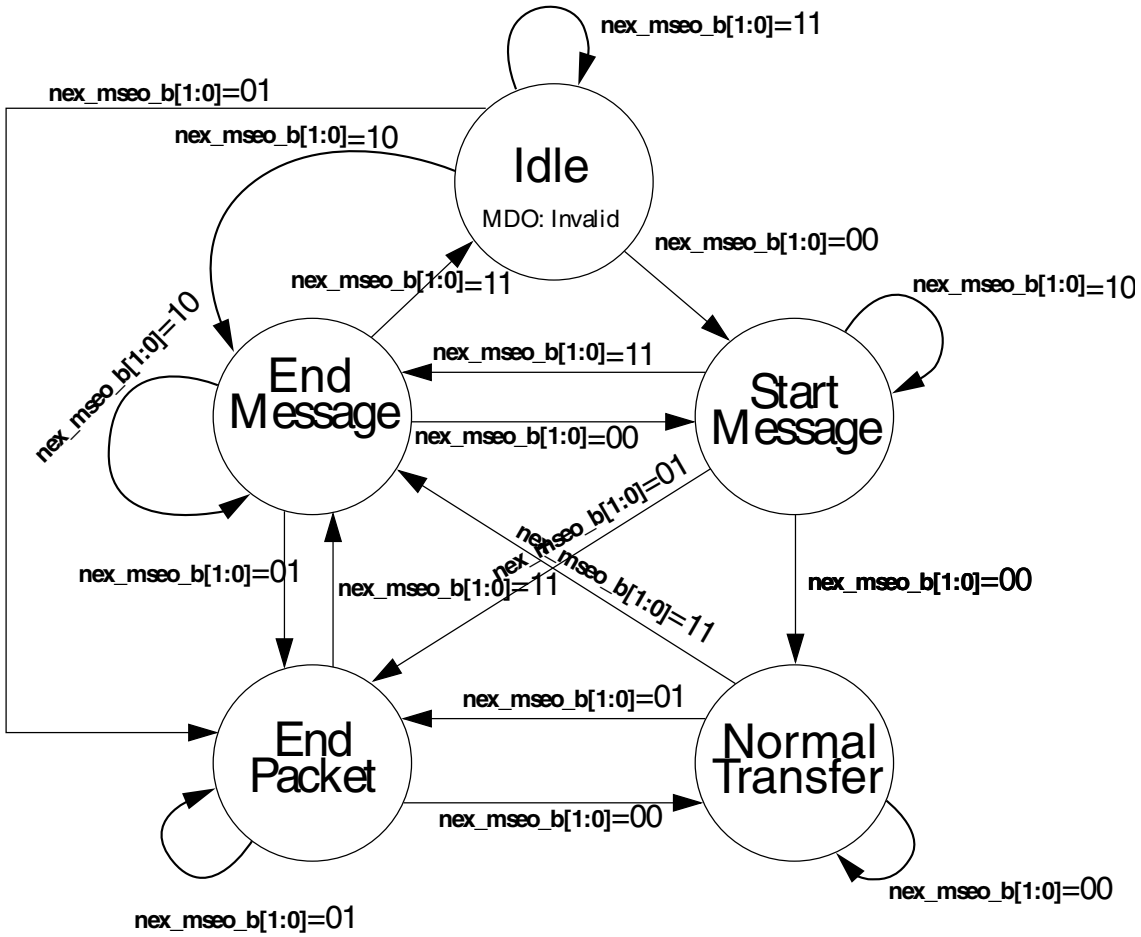

Figure 67-55. Dual pin MSEO transfers

The dual pin MSEO option is more robust that the single pin option. Termination of the current message may immediately be followed by the start of the next message on the consecutive clocks. An extra clock to end the message is not necessary as with the one MSEO pin option. The dual pin option also allows for consecutive "End Packet" states. This can be an advantage when small, variable sized packets are transferred.

Note

The "End Message" state may also indicate the end of a variable-length packet as well as the end of the message when using the dual pin option.

67.18 Rules for output messages

Class 3 compliant embedded processors must provide messages via the auxiliary port in a consistent manner as described below:

- A variable-sized packet within a message must end on a port boundary.
- A variable-sized packet may start within a port boundary only when following a fixed length packet. (If two variable-sized packets end and start on the same clock, it is impossible to know which bit is from the last packet and which bit is from the next packet.)
- Whenever a variable-length packet is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest-order bit so that it can end on a port boundary.

  For example, if the **nex_mdo[n:0]** port is 2 bits wide, and the unique portion of an indirect address TCODE is 5 bits, then the remaining 1 bit of **nex_mdo[n:0]** must be packed with a 0.

67.19 Auxiliary port arbitration

In a multi-Nexus environment, the Nexus 3 module must arbitrate for the shared Nexus port at the SoC level.The request scheme is implemented as a 2-bit request with various levels of priority. The priority levels are defined in Table 67-42 below. The Nexus 3 module will receive a 1-bit grant signal (**nar_aux_grant**) from the SoC level arbiter. When a grant is received, the Nexus 3 module will begin transmitting its message following the protocol outlined in Pin protocol. The Nexus 3 module will maintain control of the port, by asserting the **nex_aux_busy** signal, until the $\overline{\text{MSEO}}$ state machine reaches the "End Message" state.

Table 67-42. MDO Request Encodings

Request level	MDO request encoding (nex_aux_req[1:0])	Condition of queue
No Request	00	No message to send
Low Priority	01	Message queue less than 1/2 full
—	10	Reserved
High Priority	11	Message queue 1/2 full or more

67.20 Examples

The following are examples of Program Trace and Data Trace Messages.

Table 67-43 illustrates an example Indirect Branch Message with 2 MDO / 1MSEO configuration. Table 67-44 illustrates the same example with an 8 MDO / 2 MSEO configuration.

Note that T0 and S0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Ix = Number of instructions (variable)
- Ax = Unique portion of the address (variable)

Note that during clock 13, the **nex_mdo[n:0]** pins are ignored in the single MSEO case.

Table 67-43. Indirect Branch Message Example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I0	MAP	0	Normal Transfer
7	I2	I1	0	Normal Transfer
8	I4	I3	1	End Packet
9	A1	A0	0	Normal Transfer
10	A3	A2	0	Normal Transfer
11	A5	A4	0	Normal Transfer
12	A7	A6	1	End Packet
13	0	0	1	End Message
14	T1	T0	0	Start Message

Table 67-44. Indirect branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	I4	I3	I2	I1	I0	M A	S3	S2	0	1	End Packet

Table continues on the next page...

Table 67-44. Indirect branch message example (8 MDO / 2 MSEO) (continued)

67.21 Electrical characteristics

For all electrical characteristics related to core processor and Nexus 3 operation, please refer to the device Data Sheet.

67.22 IEEE 1149.1 (JTAG) RD/WR sequences

This section contains example JTAG/OnCE sequences used to access resources.

67.22.1 JTAG sequence for accessing internal Nexus registers

Table 67-49. Accessing internal Nexus 3 registers via JTAG/OnCE

Step #	TMS Pin	Description
1	1	IDLE -> SELECT-DR_SCAN
2	0	SELECT-DR_SCAN -> CAPTURE-DR (Nexus Command Register value loaded in shifter)
3	0	CAPTURE-DR -> SHIFT-DR
4	0	(7) TCK clocks issued to shift in direction (rd/wr) bit and first 6 bits of Nexus reg. addr.
5	1	SHIFT-DR -> EXIT1-DR (7th bit of Nexus reg. shifted in)
6	1	EXIT1-DR -> UPDATE-DR (Nexus shifter is transferred to Nexus Command Register)
7	1	UPDATE-DR -> SELECT-DR_SCAN
8	0	SELECT-DR_SCAN -> CAPTURE-DR (Register value is transferred to Nexus shifter)
9	0	CAPTURE-DR -> SHIFT-DR
10	0	(31) TCK clocks issued to transfer register value to TDO pin while shifting in TDI value
11	1	SHIFT-DR -> EXIT1-DR (MSB of value is shifted in/out of shifter)
12	1	EXIT1-DR -> UPDATE -DR (if access is write, shifter is transferred to register)
13	0	UPDATE-DR -> RUN-TEST/IDLE (transfer complete - Nexus controller to Reg. Select state)

67.22.2 JTAG sequence for read access of memory-mapped resources

Table 67-50. Accessing memory-mapped resources (reads)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Address Register (RWA)
2	37	Write RWA (initialize starting read address — data input on TDI)
3	13	Nexus Command = write to Read/Write Control/Status Register (RWCS)
4	37	Write RWCS (initialize read access mode and CNT value — data input on TDI)
5	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
6	13	Nexus Command = read Read/Write Access Data Register (RWD)
7	37	Read RWD (data output on TDO)
8	—	If CNT > 0, go back to Step #5

67.22.3 JTAG sequence for write access of memory-mapped resources

Table 67-51. Accessing memory-mapped resources (writes)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Control/Status Register (RWCS)
2	37	Write RWCS (initialize write access mode and CNT value - data input on TDI)
3	13	Nexus Command = write to Read/Write Address Register (RWA)
4	37	Write RWA (initialize starting write address - data input on TDI)
5	13	Nexus Command = read Read/Write Access Data Register (RWD)
6	37	Write RWD (data output on TDO)
7	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
8	—	If CNT > 0, go back to Step #5

Chapter 68
Enhanced Direct Memory Access (eDMA)

68.1 Introduction

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 32 channels

68.1.1 eDMA system block diagram

Figure 68-1 illustrates the components of the eDMA system, including the eDMA module ("engine").

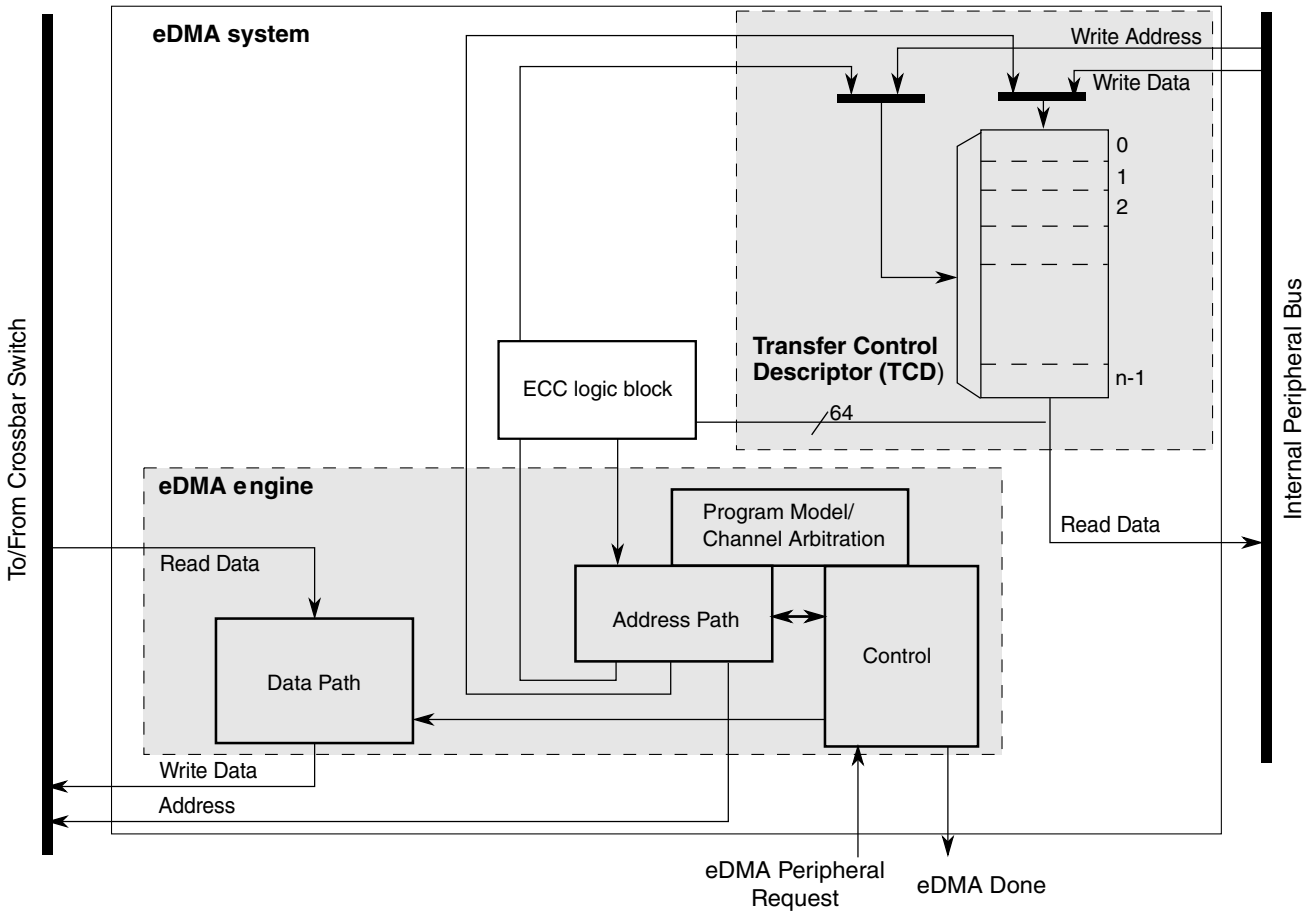

Figure 68-1. eDMA system block diagram

68.1.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer-control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 68-1. eDMA engine submodules

Submodule	Function
Address path	This block implements registered versions of two channel transfer control descriptors, channel x and channel y, and manages all master bus-address calculations. All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by DCHPRI*n*[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution. When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes

Table continues on the next page...

Table 68-1. eDMA engine submodules (continued)

Submodule	Function
	the new values for the TCD*n*_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCD*n*_CITER field, and a possible fetch of the next TCD*n* from memory as part of a scatter/gather operation.
Data path	This block implements the bus master read/write datapath. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output. The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the 1st stage of the bus pipeline (address phase), while the data path module implements the 2nd stage of the pipeline (data phase).
Program model/channel arbitration	This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
Control	This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/ destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write.

The transfer-control descriptor local memory is further partitioned into:

Table 68-2. Transfer control descriptor memory

Submodule	Description
Memory controller	This logic implements the required dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus. As noted earlier, in the event of simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
Memory array	TCD storage for each channel's transfer profile.

68.1.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for enhanced addressing modes

- 32-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage to support 16- and 32-byte transfers
  - Connections to the crossbar switch for bus mastering the data movement
- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests
  - One interrupt per channel, which can be asserted at completion of major iteration count
  - Programmable error terminations per channel and logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing
- Support for complex data structures
- Error detection and error correction

In the discussion of this module, *n* is used to reference the channel number.

68.2 Modes of operation

The eDMA operates in the following modes:

Table 68-3. Modes of operation

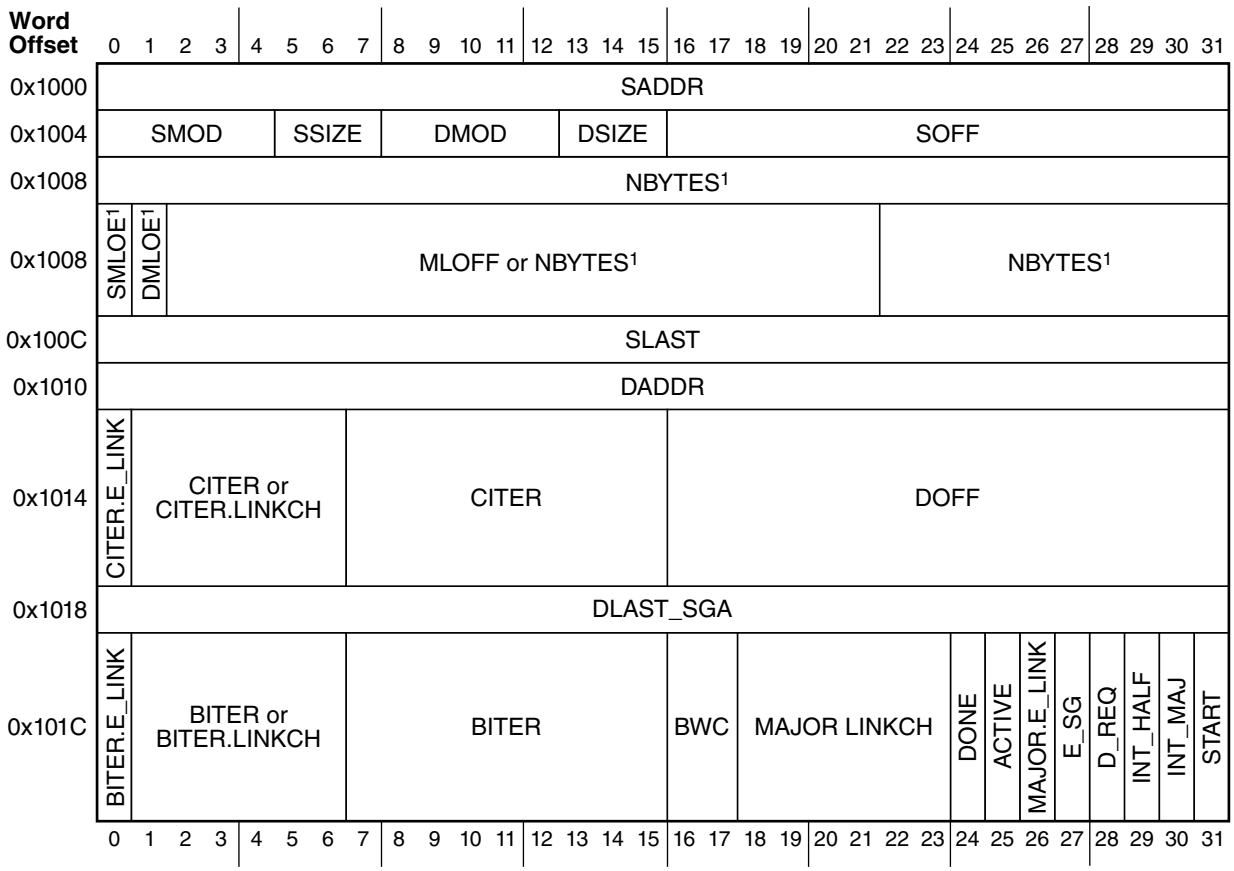
Mode	Description
Normal	In Normal mode, the eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with the eDMA. A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the transfer control descriptor (TCD). The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.
Debug	DMA operation is configurable in Debug mode via the control register: • If CR[EDBG] is cleared, the DMA continues to operate. • If CR[EDBG] is set, the eDMA stops transferring data. If Debug mode is entered while a channel is active, the eDMA continues operation until the channel retires.

68.3 Memory map/register definition

The eDMA's programming model is partitioned into two regions:

- The first region defines a number of registers providing control functions
- The second region corresponds to the local transfer control descriptor (TCD) memory

68.3.1 TCD memory



Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0, channel 1, ... channel 31. Each TCD*n* definition is presented as 11 registers of 16 or 32 bits.

68.3.2 TCD initialization

The initialization of the TCD memory is performed by the eDMA controller after reset. The initialization runs for 256 eDMA clock cycles. All fields in the TCD memory are initialized to 0. All application read or write accesses to the TCD are delayed until the initialization is finished. Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

68.3.3 TCD structure

DMA Basics: TCD Structure
- One DMA engine has a number of channels to react to DMA requests
- Each channel has its own TCD

[1] The fields implemented in Word 2 depend on whether EDMA_CR[EMLM] bit is set to 0 or 1.

68.3.4 Reserved memory and bit fields

- Reading reserved bits in a register returns the value of zero.
- Writes to reserved bits in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

DMA memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

68.3.5 Control Register (DMA_CR)

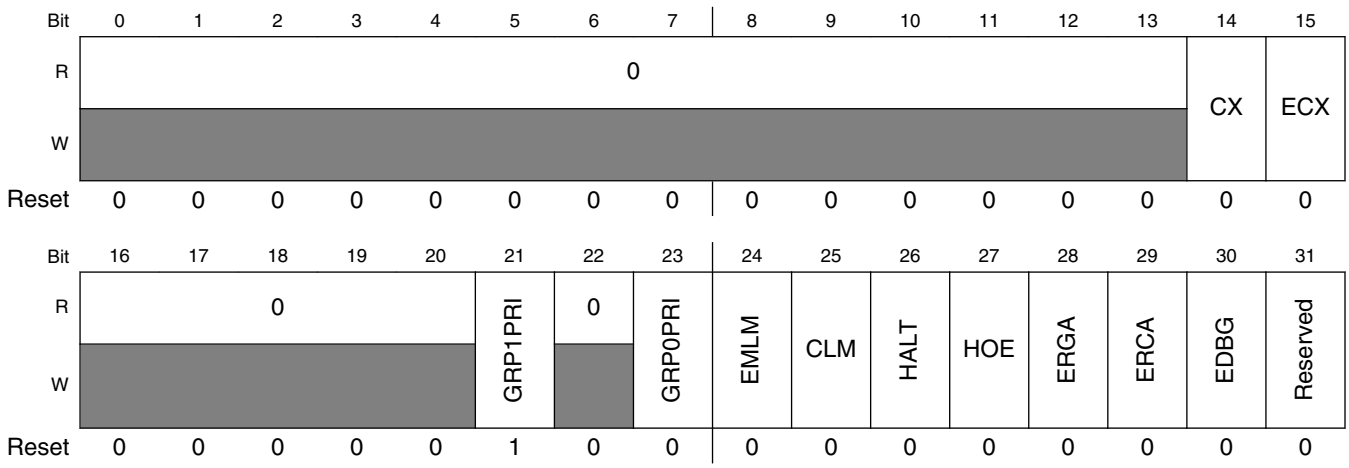
The CR defines the basic operating configuration of the DMA. The DMA arbitrates channel service requests in two groups of 16 channels each:

- Group 1 contains channels 31-16
- Group 0 contains channels 15-0

Arbitration within a group can be configured to use either a fixed-priority or a round-robin scheme. For fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The channel priority registers assign the priorities; see the DCHPRIn registers. For round-robin arbitration, the channel priorities are ignored and channels within each group are cycled through (from high to low channel number) without regard to priority.

NOTE

For correct operation, writes to the CR register must be performed only when the DMA channels are inactive; that is, when TCDn_CSR[ACTIVE] bits are cleared.



The group priorities operate in a similar fashion. In group fixed priority arbitration mode, channel service requests in the highest priority group are executed first, where priority level 1 is the highest and priority level 0 is the lowest. The group priorities are assigned in the GRPnPRI fields of the DMA Control Register (CR). All group priorities must have unique values prior to any channel service requests occurring; otherwise, a configuration error will be reported. For group round robin arbitration, the group priorities are ignored and the groups are cycled through (from high to low group number) without regard to priority.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. When minor loop offsets are enabled, the minor loop offset (MLOFF) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both prior to the addresses being written back into the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (EMLM is 1), TCDn word2 is redefined. A portion of TCDn word2 is used to specify multiple fields: a source enable bit (SMLOE) to specify the minor loop offset should be applied to the source address (TCDn_SADDR) upon minor loop completion, a destination enable bit (DMLOE) to specify the minor loop offset should be applied to the destination address (TCDn_DADDR) upon minor loop completion, and the sign extended minor loop offset value (MLOFF). The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. When both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

When minor loop mapping is disabled (EMLM is 0), all 32 bits of TCDn word2 are assigned to the NBYTES field.

Address: 0h base + 0h offset = 0h

DMA_CR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 CX	Cancel Transfer 0 Normal operation 1 Cancel the remaining data transfer. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The CX bit clears itself after the cancel has been honored. This cancel retires the channel normally as if the minor loop was completed.
15 ECX	Error Cancel Transfer 0 Normal operation 1 Cancel the remaining data transfer in the same fashion as the CX bit. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The ECX bit clears itself after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition, thus updating the Error Status register (DMAx_ES) and generating an optional error interrupt.
16–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 GRP1PRI	Channel Group 1 Priority Group 1 priority level when fixed priority group arbitration is enabled.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 GRP0PRI	Channel Group 0 Priority Group 0 priority level when fixed priority group arbitration is enabled.
24 EMLM	Enable Minor Loop Mapping 0 Disabled. TCDn.word2 is defined as a 32-bit NBYTES field. 1 Enabled. TCDn.word2 is redefined to include individual enable fields, an offset field, and the NBYTES field. The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field is reduced when either offset is enabled.

Table continues on the next page...

DMA_CR field descriptions (continued)

Field	Description
25 CLM	Continuous Link Mode **NOTE:** Do not use continuous link mode with a channel linking to itself if there is only one minor loop iteration per service request, e.g., if the channel's NBYTES value is the same as either the source or destination size. The same data transfer profile can be achieved by simply increasing the NBYTES value, which provides more efficient, faster processing. 0 A minor loop channel link made to itself goes through channel arbitration before being activated again. 1 A minor loop channel link made to itself does not go through channel arbitration before being activated again. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop.
26 HALT	Halt DMA Operations 0 Normal operation 1 Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared.
27 HOE	Halt On Error 0 Normal operation 1 Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared.
28 ERGA	Enable Round Robin Group Arbitration 0 Fixed priority arbitration is used for selection among the groups. 1 Round robin arbitration is used for selection among the groups.
29 ERCA	Enable Round Robin Channel Arbitration 0 Fixed priority arbitration is used for channel selection within each group. 1 Round robin arbitration is used for channel selection within each group.
30 EDBG	Enable Debug 0 When in debug mode, the DMA continues to operate. 1 When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the system exits debug mode or the EDBG bit is cleared.
31 Reserved	This field is reserved. Reserved

68.3.6 Error Status Register (DMA_ES)

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- A configuration error, that is:
  - An illegal setting in the transfer-control descriptor, or
  - An illegal priority register setting in fixed-arbitration
- An error termination to a bus master read or write cycle

- The UCE bit shows an uncorrectable error occurred while the device has ECC protection on the TCD SRAM
- A cancel transfer with error bit that will be set when a transfer is canceled via the corresponding cancel transfer control bit

See Fault reporting and handling for more details.

DMA_ES field descriptions

Field	Description
0 VLD	Logical OR of all ERR status bits 0 No ERR bits are set. 1 At least one ERR bit is set indicating a valid error exists that has not been cleared.
1–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 UCE	Uncorrectable ECC error during channel execution. The UCE bit is set when an uncorrectable ECC error occurs on an access generated by the DMA only. If a CPU access to the TCD causes an uncorrectable ECC error, that access will receive a bus error response. **NOTE:** When the eDMA sees a RAM error on an IPS access (when the user is accessing a TCD), the error is reported as a bus abort. When the dma_engine (the execution engine is accessing a TCD) receives a RAM error, it is recorded in the Error Status register, DMA_ES[UCE], along with the channel number. 0 No uncorrectable ECC error 1 The last recorded error was an uncorrectable TCD RAM error
15 ECX	Transfer Canceled 0 No canceled transfers 1 The last recorded entry was a canceled transfer by the error cancel transfer input
16 GPE	Group Priority Error 0 No group priority error 1 The last recorded error was a configuration error among the group priorities. All group priorities are not unique.

Table continues on the next page...

DMA_ES field descriptions (continued)

Field	Description
17 CPE	Channel Priority Error 0 No channel priority error 1 The last recorded error was a configuration error in the channel priorities within a group. Channel priorities within a group are not unique.
18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error, excluding GPE and CPE errors, or last recorded error canceled transfer.
24 SAE	Source Address Error 0 No source address configuration error. 1 The last recorded error was a configuration error detected in the TCDn_SADDR field. TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE].
25 SOE	Source Offset Error 0 No source offset configuration error 1 The last recorded error was a configuration error detected in the TCDn_SOFF field. TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE].
26 DAE	Destination Address Error 0 No destination address configuration error 1 The last recorded error was a configuration error detected in the TCDn_DADDR field. TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE].
27 DOE	Destination Offset Error 0 No destination offset configuration error 1 The last recorded error was a configuration error detected in the TCDn_DOFF field. TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE].
28 NCE	NBYTES/CITER Configuration Error 0 No NBYTES/CITER configuration error 1 The last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields. • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE], or • TCDn_CITER[CITER] is equal to zero, or • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK]
29 SGE	Scatter/Gather Configuration Error 0 No scatter/gather configuration error 1 The last recorded error was a configuration error detected in the TCDn_DLASTSGA field. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. TCDn_DLASTSGA is not on a 32 byte boundary.
30 SBE	Source Bus Error 0 No source bus error 1 The last recorded error was a bus error on a source read

68.3.7 Enable Request Register (DMA_ERQ)

The ERQ register provides a bit map for the 32 channels to enable the request signal for each channel. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ registers. These registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to the ERQ.

DMA request input signals and this enable request flag must be asserted before a channel's hardware service request is accepted. The state of the DMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.

Address: 0h base + Ch offset = Ch

68.3.9 Set Enable Request Register (DMA_SERQ)

The SERQ provides a simple memory-mapped mechanism to set a given bit in the ERQ to enable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be set. Setting the SAER bit provides a global set function, forcing the entire contents of ERQ to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7
Read	0	0				0		
Write	NOP	SAER	0			SERQ		
Reset	0	0	0	0	0	0	0	0

DMA_SERQ field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 SAER	Set All Enable Requests 0 Set only the ERQ bit specified in the SERQ field 1 Set all bits in ERQ
2 Reserved	This field is reserved.
3–7 SERQ	Set Enable Request Sets the corresponding bit in ERQ.

68.3.10 Clear Enable Request Register (DMA_CERQ)

The CERQ provides a simple memory-mapped mechanism to clear a given bit in the ERQ to disable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be cleared. Setting the CAER bit provides a global clear function, forcing the entire contents of the ERQ to be cleared, disabling all DMA request inputs. If NOP is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 19h offset = 19h

Bit	0	1	2	3	4	5	6	7
Read	0	0				0		
Write	NOP	CAER	0			CERQ		
Reset	0	0	0	0	0	0	0	0

DMA_CERQ field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 CAER	Clear All Enable Requests 0 Clear only the ERQ bit specified in the CERQ field 1 Clear all bits in ERQ
2 Reserved	This field is reserved.
3–7 CERQ	Clear Enable Request Clears the corresponding bit in ERQ.

68.3.11 Set Enable Error Interrupt Register (DMA_SEEI)

The SEEI provides a simple memory-mapped mechanism to set a given bit in the EEI to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be set. Setting the SAEE bit provides a global set function, forcing the entire EEI contents to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Ah offset = 1Ah

Bit	0	1	2	3	4	5	6	7
Read	0	0				0		
Write	NOP	SAEE	0			SEEI		
Reset	0	0	0	0	0	0	0	0

DMA_SEEI field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 SAEE	Sets All Enable Error Interrupts 0 Set only the EEI bit specified in the SEEI field. 1 Sets all bits in EEI
2 Reserved	This field is reserved.
3–7 SEEI	Set Enable Error Interrupt Sets the corresponding bit in EEI

68.3.12 Clear Enable Error Interrupt Register (DMA_CEEI)

The CEEI provides a simple memory-mapped mechanism to clear a given bit in the EEI to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be cleared. Setting the CAEE bit provides a global clear function, forcing the EEI contents to be cleared, disabling all DMA request inputs. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Bh offset = 1Bh

Bit	0	1	2	3	4	5	6	7
Read	0	0				0		
Write	NOP	CAEE	0			CEEI		
Reset	0	0	0	0	0	0	0	0

DMA_CEEI field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 CAEE	Clear All Enable Error Interrupts 0 Clear only the EEI bit specified in the CEEI field 1 Clear all bits in EEI
2 Reserved	This field is reserved.
3–7 CEEI	Clear Enable Error Interrupt Clears the corresponding bit in EEI

68.3.13 Clear Interrupt Request Register (DMA_CINT)

The CINT provides a simple, memory-mapped mechanism to clear a given bit in the INT to disable the interrupt request for a given channel. The given value on a register write causes the corresponding bit in the INT to be cleared. Setting the CAIR bit provides a global clear function, forcing the entire contents of the INT to be cleared, disabling all DMA interrupt requests. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7
Read	0	0				0		
Write	NOP	CAIR	0			CINT		
Reset	0	0	0	0	0	0	0	0

DMA_CINT field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 CAIR	Clear All Interrupt Requests 0 Clear only the INT bit specified in the CINT field 1 Clear all bits in INT
2 Reserved	This field is reserved.
3–7 CINT	Clear Interrupt Request Clears the corresponding bit in INT

68.3.14 Clear Error Register (DMA_CERR)

The CERR provides a simple memory-mapped mechanism to clear a given bit in the ERR to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the ERR to be cleared. Setting the CAEI bit provides a global clear function, forcing the ERR contents to be cleared, clearing all channel error indicators. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Dh offset = 1Dh

Bit	0	1	2	3	4	5	6	7
Read	0	0		0				
Write	NOP	CAEI	0	CERR				
Reset	0	0	0	0	0	0	0	0

DMA_CERR field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 CAEI	Clear All Error Indicators 0 Clear only the ERR bit specified in the CERR field 1 Clear all bits in ERR
2 Reserved	This field is reserved.
3–7 CERR	Clear Error Indicator Clears the corresponding bit in ERR

68.3.15 Set START Bit Register (DMA_SSRT)

The SSRT provides a simple memory-mapped mechanism to set the START bit in the TCD of the given channel. The data value on a register write causes the START bit in the corresponding transfer control descriptor to be set. Setting the SAST bit provides a global set function, forcing all START bits to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Eh offset = 1Eh

Bit	0	1	2	3	4	5	6	7
Read	0	0				0		
Write	NOP	SAST	0			SSRT		
Reset	0	0	0	0	0	0	0	0

DMA_SSRT field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 SAST	Set All START Bits (activates all channels) 0 Set only the TCDn_CSR[START] bit specified in the SSRT field 1 Set all bits in TCDn_CSR[START]
2 Reserved	This field is reserved.
3–7 SSRT	Set START Bit Sets the corresponding bit in TCDn_CSR[START]

68.3.16 Clear DONE Status Bit Register (DMA_CDNE)

The CDNE provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding transfer control descriptor to be cleared. Setting the CADN bit provides a global clear function, forcing all DONE bits to be cleared. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Fh offset = 1Fh

Bit	0	1	2	3	4	5	6	7
Read	0	0		0				
Write	NOP	CADN	0	CDNE				
Reset	0	0	0	0	0	0	0	0

DMA_CDNE field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 CADN	Clears All DONE Bits 0 Clears only the TCDn_CSR[DONE] bit specified in the CDNE field 1 Clears all bits in TCDn_CSR[DONE]
2 Reserved	This field is reserved.
3–7 CDNE	Clear DONE Bit Clears the corresponding bit in TCDn_CSR[DONE]

68.3.17 Interrupt Request Register (DMA_INT)

The INT register provides a bit map for the 32 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt on data transfer completion. The outputs of this register are directly routed to the interrupt controller. During the interrupt-service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT register in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT register. On writes to INT, a 1 in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no affect on the corresponding channel's current interrupt status. The CINT register is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT register.

Address: 0h base + 24h offset = 24h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

68.3.18 Error Register (DMA_ERR)

The ERR provides a bit map for the 32 channels, signaling the presence of an error for each channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI, then logically summed across groups of 16 and 32 channels to form several group error interrupt requests, which are then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. Typically, a write to the CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected.

The contents of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEI. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a one in any bit position clears the corresponding channel's error status. A zero in any bit position has no affect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be cleared.

68.3.19 Hardware Request Status Register (DMA_HRS)

The HRS register provides a bit map for the DMA channels, signaling the presence of a hardware request for each channel. The hardware request status bits reflect the current state of the register and qualified (via the ERQ fields) DMA request signals as seen by the DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

NOTE

These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQ bits.

68.3.20 Channel n Priority Register (DMA_DCHPRI*n*)

When fixed-priority channel arbitration is enabled (CR[ERCA] = 0), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, etc. Software must program the channel priorities with unique values; otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15. When read, the GRPPRI bits of the DCHPRIn register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not affected by writes to the DCHPRIn registers. The group priority is assigned in the DMA control register.

Address: 0h base + 100h offset + (1d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7
Read	ECP	DPA	GRPPRI		CHPRI			
Write								
Reset	0	0	*	*	*	*	*	*

* Notes:
- CHPRI field: See bit field description.
- GRPPRI field: See bit field description.

DMA_DCHPRI*n* field descriptions

Field	Description
0 ECP	Enable Channel Preemption. 0 Channel n cannot be suspended by a higher priority channel's service request. 1 Channel n can be temporarily suspended by the service request of a higher priority channel.

Table continues on the next page...

DMA_DCHPRI*n* field descriptions (continued)

Field	Description
1 DPA	Disable Preempt Ability. 0 Channel n can suspend a lower priority channel. 1 Channel n cannot suspend any channel, regardless of channel priority.
2–3 GRPPRI	Channel n Current Group Priority Group priority assigned to this channel group when fixed-priority arbitration is enabled. This field is read-only; writes are ignored. **NOTE:** Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, that is, DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] equals 0b1111.
4–7 CHPRI	Channel n Arbitration Priority Channel priority when fixed-priority arbitration is enabled **NOTE:** Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, that is, DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] = 0b01111.

68.3.21 Channel n Master ID Register (DMA_DCHMID*n*)

The DMA master ID replication registers allow the DMA to use the same protection level and system bus ID of the master programming the DMA's TCD. When enabled, the DMA uses the master ID and protection level stored in the DCHMID register instead of the DMA's default values. When a master, for example, a core, programs a TCD, its master ID and protection level are captured when the TCDn.CSR control attributes are written. Although the scatter/gather operation can change the contents of TCDn_CSR, that operation does not affect the DCHMID *n* registers.

Address: 0h base + 140h offset + (1d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7
Read	EMI	PAL	0		MID			
Write								
Reset	0	0	0	0	0	0	0	0

DMA_DCHMID*n* field descriptions

Field	Description
0 EMI	Enable Master ID replication **NOTE:** If Master ID replication is disabled, the privileged protection level (supervisor mode) for DMA transfers is used.

Table continues on the next page...

DMA_DCHMID*n* field descriptions (continued)

Field	Description
	0 Master ID replication is disabled 1 Master ID replication is enabled
1 PAL	Privileged Access Level **NOTE:** The protection level captured in this register reflects the level used when writing the channel's control attributes; lower byte of TCDn.CSR. 0 User protection level for DMA transfers 1 Privileged protection level for DMA transfers
2–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 MID	Master ID DMA's master ID when channel n is active and master ID replication is enabled. **NOTE:** The master ID captured in this register reflects the ID used when writing the channel's control attributes; lower byte of TCDn.CSR.

68.3.22 TCD Source Address (DMA_TCD*n*_SADDR)

Address: 0h base + 1000h offset + (32d × i), where i=0d to 31d

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMA_TCD*n*_ATTR field descriptions

Field	Description
0–4 SMOD	Source Address Modulo 0 Source address modulo feature is disabled ≠0 This value defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range.
5–7 SSIZE	Source data transfer size **NOTE:** Using a Reserved value causes a configuration error. 000 8-bit 001 16-bit 010 32-bit 011 64-bit 100 Reserved 101 32-byte burst (4 beats of 64 bits) 110 Reserved 111 Reserved
8–12 DMOD	Destination Address Modulo See the SMOD definition
13–15 DSIZE	Destination data transfer size See the SSIZE definition

68.3.24 TCD Signed Source Address Offset (DMA_TCD*n*_SOFF)

Address: 0h base + 1006h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	SOFF															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMA_TCD*n*_SOFF field descriptions

Field	Description
0–15 SOFF	Source address signed offset Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.

68.3.25 TCD Minor Byte Count (Minor Loop Mapping Disabled) (DMA_TCD*n*_NBYTES_MLNO)

This register, or one of the next two registers (TCD_NBYTES_MLOFFNO, TCD_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is disabled (CR[EMLM] = 0)

If minor loop mapping is enabled, see the TCD_NBYTES_MLOFFNO and TCD_NBYTES_MLOFFYES register descriptions for the definition of TCD word 2.

Address: 0h base + 1008h offset + (32d × i), where i=0d to 31d

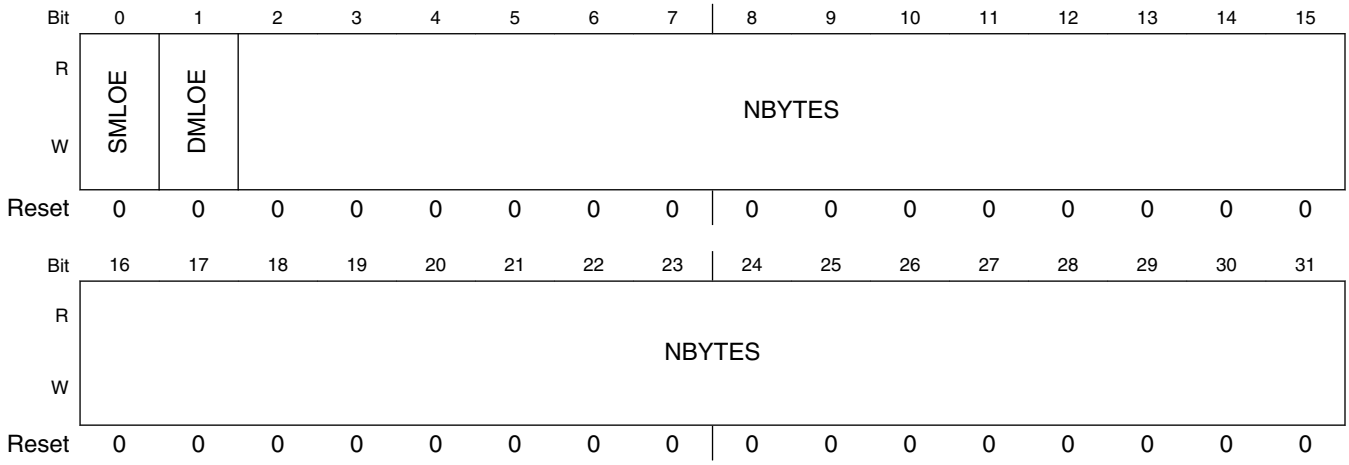
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMA_TCD*n*_NBYTES_MLNO field descriptions

Field	Description
0–31 NBYTES	Minor Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. **NOTE:** An NBYTES value of 0x0000_0000 is interpreted as a 4 GB transfer.

68.3.26 TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled) (DMA_TCD*n*_NBYTES_MLOFFNO)



One of three registers (this register, TCD_NBYTES_MLNO, or TCD_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- SMLOE = 0 and DMLOE = 0

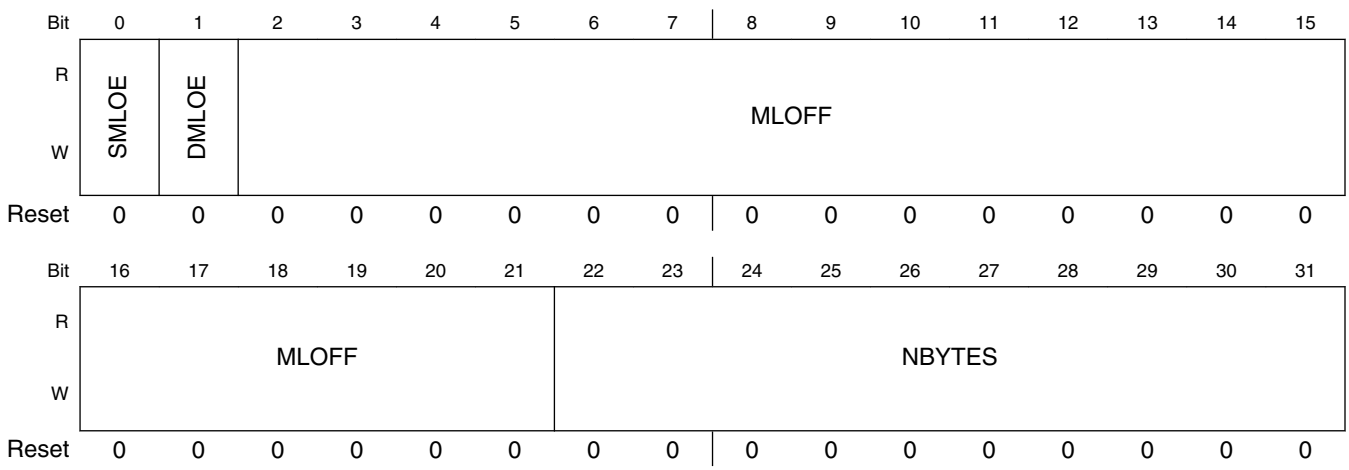
If minor loop mapping is enabled and SMLOE or DMLOE is set, then refer to the TCD_NBYTES_MLOFFYES register description. If minor loop mapping is disabled, then refer to the TCD_NBYTES_MLNO register description.

Address: 0h base + 1008h offset + (32d × i), where i=0d to 31d

DMA_TCD*n*_NBYTES_MLOFFNO field descriptions

Field	Description
0 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 The minor loop offset is not applied to the SADDR 1 The minor loop offset is applied to the SADDR
1 DMLOE	Destination Minor Loop Offset enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 The minor loop offset is not applied to the DADDR 1 The minor loop offset is applied to the DADDR
2–31 NBYTES	Minor Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

68.3.27 TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled) (DMA_TCD*n*_NBYTES_MLOFFYES)



One of three registers (this register, TCD_NBYTES_MLNO, or TCD_NBYTES_MLOFFNO), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- Minor loop offset is enabled (SMLOE or DMLOE = 1)

If minor loop mapping is enabled and SMLOE and DMLOE are cleared, then refer to the TCD_NBYTES_MLOFFNO register description. If minor loop mapping is disabled, then refer to the TCD_NBYTES_MLNO register description.

Address: 0h base + 1008h offset + (32d × i), where i=0d to 31d

DMA_TCD*n*_NBYTES_MLOFFYES field descriptions

Field	Description
0 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 The minor loop offset is not applied to the SADDR 1 The minor loop offset is applied to the SADDR
1 DMLOE	Destination Minor Loop Offset enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 The minor loop offset is not applied to the DADDR 1 The minor loop offset is applied to the DADDR

Table continues on the next page...

DMA_TCD*n*_NBYTES_MLOFFYES field descriptions (continued)

Field	Description
2–21 MLOFF	If SMLOE or DMLOE is set, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
22–31 NBYTES	Minor Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

68.3.28 TCD Last Source Address Adjustment (DMA_TCD*n*_SLAST)

Address: 0h base + 100Ch offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	SLAST																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMA_TCD*n*_SLAST field descriptions

Field	Description
0–31 SLAST	Last Source Address Adjustment Adjustment value added to the source address at the completion of the major iteration count. This value can be applied to restore the source address to the initial value, or adjust the address to reference the next data structure. This register uses two's complement notation; the overflow bit is discarded.

68.3.29 TCD Destination Address (DMA_TCD*n*_DADDR)

Address: 0h base + 1010h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DMA_TCD*n*_DADDR field descriptions

Field	Description
0–31 DADDR	Destination Address Memory address pointing to the destination data.

68.3.30 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD*n*_CITER_ELINKYES)

If TCDn_CITER[ELINK] is set, the TCDn_CITER register is defined as follows.

Address: 0h base + 1014h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7
Read Write	ELINK	0	LINKCH					CITER
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read Write	CITER							
Reset	0	0	0	0	0	0	0	0

DMA_TCD*n*_CITER_ELINKYES field descriptions

Field	Description
0 ELINK	Enable channel-to-channel linking on minor-loop complete As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** This bit must be equal to the BITER[ELINK] bit; otherwise, a configuration error is reported. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
1 Reserved	This field is reserved.
2–6 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by this field by setting that channel's TCDn_CSR[START] bit.
7–15 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE:** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE:** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

68.3.31 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCD*n*_CITER_ELINKNO)

If TCDn_CITER[ELINK] is cleared, the TCDn_CITER register is defined as follows.

Address: 0h base + 1014h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7
Read Write	ELINK	CITER

DMA_TCD*n*_DLASTSGA field descriptions

Field	Description
0–31 DLASTSGA	Destination last address adjustment or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0) then: • Adjustment value added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo-32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo-32-byte, otherwise a configuration error is reported.

68.3.34 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD*n*_BITER_ELINKYES)

If the TCDn_BITER[ELINK] bit is set, the TCDn_BITER register is defined as follows.

Address: 0h base + 101Ch offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7
Read	ELINK	0	LINKCH					BITER
Write

Write								
Reset	0	0	0	0	0	0	0	0

DMA_TCD*n*_BITER_ELINKYES field descriptions

Field	Description
0 ELINK	Enables channel-to-channel linking on minor loop complete As the channel completes the minor loop, this flag enables the linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
1 Reserved	This field is reserved.
2–6 LINKCH	Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] bit. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field.
7–15 BITER	Starting major iteration count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

68.3.35 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCD*n*_BITER_ELINKNO)

If the TCDn_BITER[ELINK] bit is cleared, the TCDn_BITER register is defined as follows.

Address: 0h base + 101Ch offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7
Read Write	ELINK	BITER						
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read Write	BITER							
Reset	0	0	0	0	0	0	0	0

DMA_TCD*n*_BITER_ELINKNO field descriptions

Field	Description
0 ELINK	Enables channel-to-channel linking on minor loop complete As the channel completes the minor loop, this flag enables the linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
1–15 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

68.3.36 TCD Control and Status (DMA_TCD*n*_CSR)

Address: 0h base + 101Eh offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7
Read	BWC			MAJORLINKCH				
Write			0					
Reset	0	0	0	0	0	0	0	0

Write								
Reset	0	0	0	0	0	0	0	0

DMA_TCD*n*_CSR field descriptions

Field	Description
0–1 BWC	Bandwidth Control Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch. **NOTE:** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00 No eDMA engine stalls. 01 Enable eDMA master high-priority elevation (HPE) mode. No eDMA engine stalls. 10 eDMA engine stalls for 4 cycles after each R/W. 11 eDMA engine stalls for 8 cycles after each R/W.
2 Reserved	This field is reserved.
3–7 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: • No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise: • After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] bit.
8 DONE	Channel Done This flag indicates the eDMA has completed the major loop. The eDMA engine sets it as the CITER count reaches zero. The software clears it, or the hardware when the channel is activated. **NOTE:** This bit must be cleared to write the MAJORELINK or ESG bits.
9 ACTIVE	Channel Active

Table continues on the next page...

DMA_TCD*n*_CSR field descriptions (continued)

Field	Description
	This flag signals the channel is currently in execution. It is set when channel service begins, and is cleared by the eDMA as the minor loop completes or when any error condition is detected.
10 MAJORELINK	Enable channel-to-channel linking on major loop complete As the channel completes the major loop, this flag enables the linking to another channel, defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. **NOTE:** To support the dynamic linking coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set. 0 The channel-to-channel linking is disabled. 1 The channel-to-channel linking is enabled.
11 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLASTSGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as the transfer control descriptor into the local memory. **NOTE:** To support the dynamic scatter/gather coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set. 0 The current channel's TCD is normal format. 1 The current channel's TCD specifies a scatter gather format. The DLASTSGA field provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution.
12 DREQ	Disable Request If this flag is set, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches zero. 0 The channel's ERQ bit is not affected. 1 The channel's ERQ bit is cleared when the major loop is complete.
13 INTHALF	Enable an interrupt when major counter is half complete. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT register when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER >> 1)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE:** If BITER = 1, do not use INTHALF. Use INTMAJOR instead. 0 The half-point interrupt is disabled. 1 The half-point interrupt is enabled.
14 INTMAJOR	Enable an interrupt when major iteration count completes. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches zero. 0 The end-of-major loop interrupt is disabled. 1 The end-of-major loop interrupt is enabled.
15 START	Channel Start

Table continues on the next page...

DMA_TCD*n*_CSR field descriptions (continued)

Field	Description
	If this flag is set, the channel is requesting service. The eDMA hardware automatically clears this flag after the channel begins execution. 0 The channel is not explicitly started. 1 The channel is explicitly started via a software initiated service request.

68.4 Functional description

The operation of the eDMA is described in the following subsections.

68.4.1 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

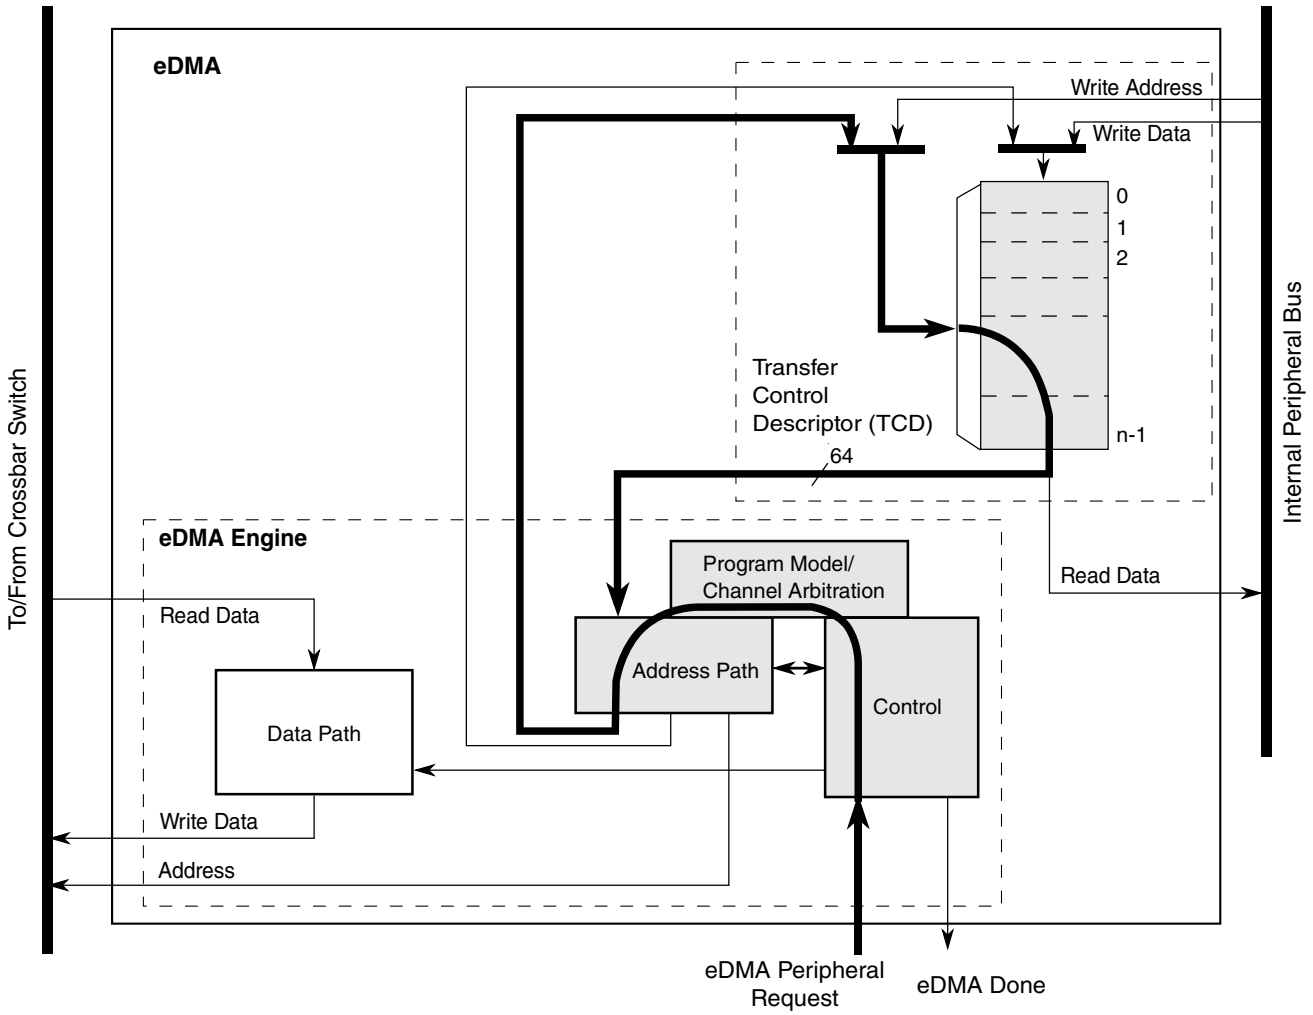

Figure 68-2. eDMA operation, part 1

This example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, the channel arbitration performs, using the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the required descriptor read from the local memory and loaded into the eDMA engine address path channel x or y registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path channel x or y registers.

The following diagram illustrates the second part of the basic data flow:

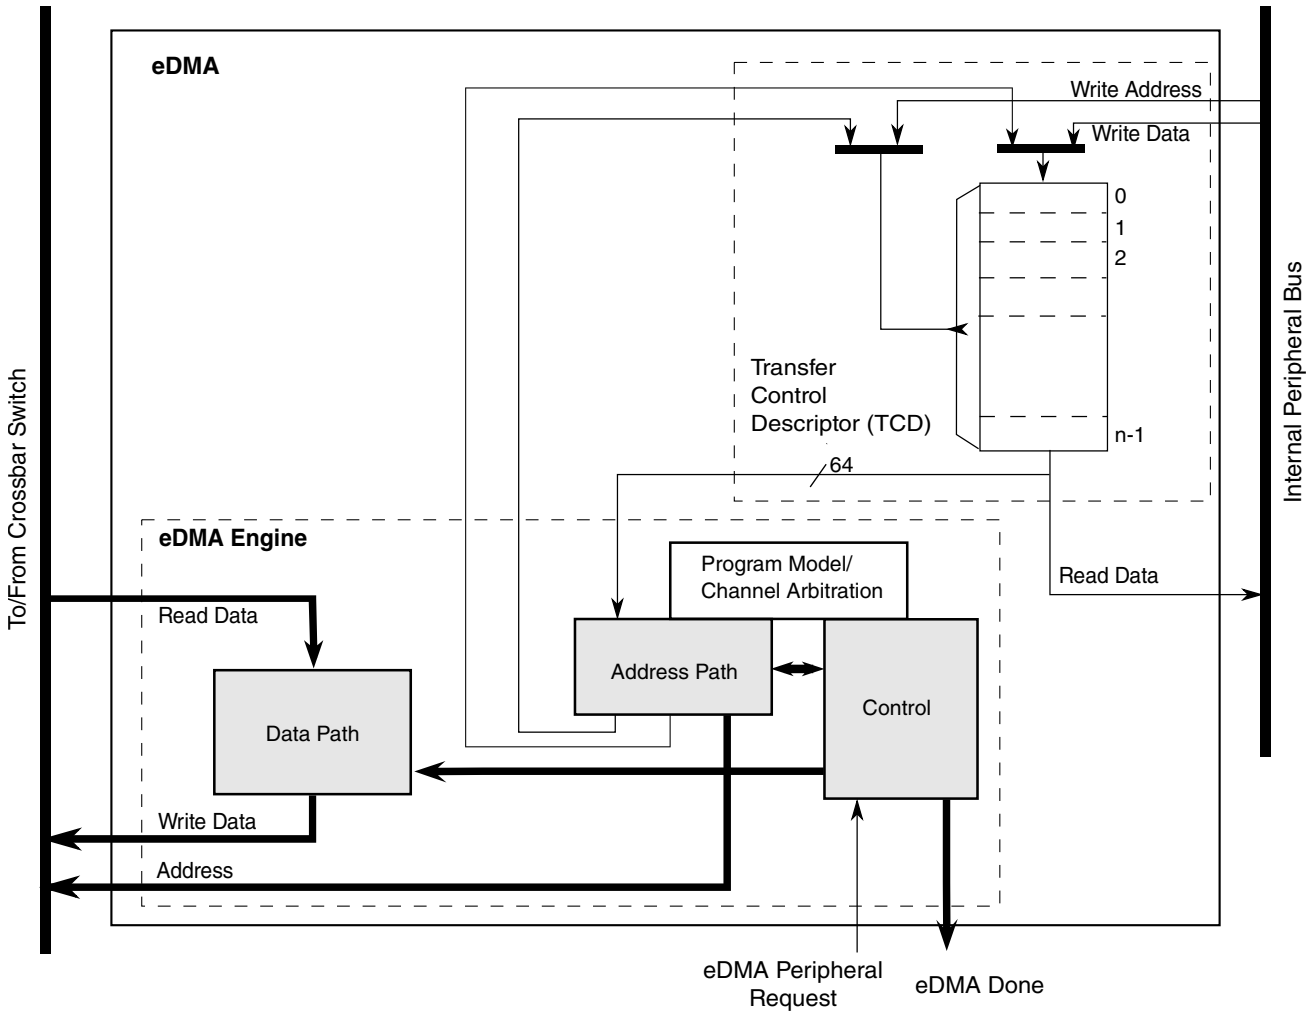

Figure 68-3. eDMA operation, part 2

The modules associated with the data transfer (address path, data path, and control) sequence through the required source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

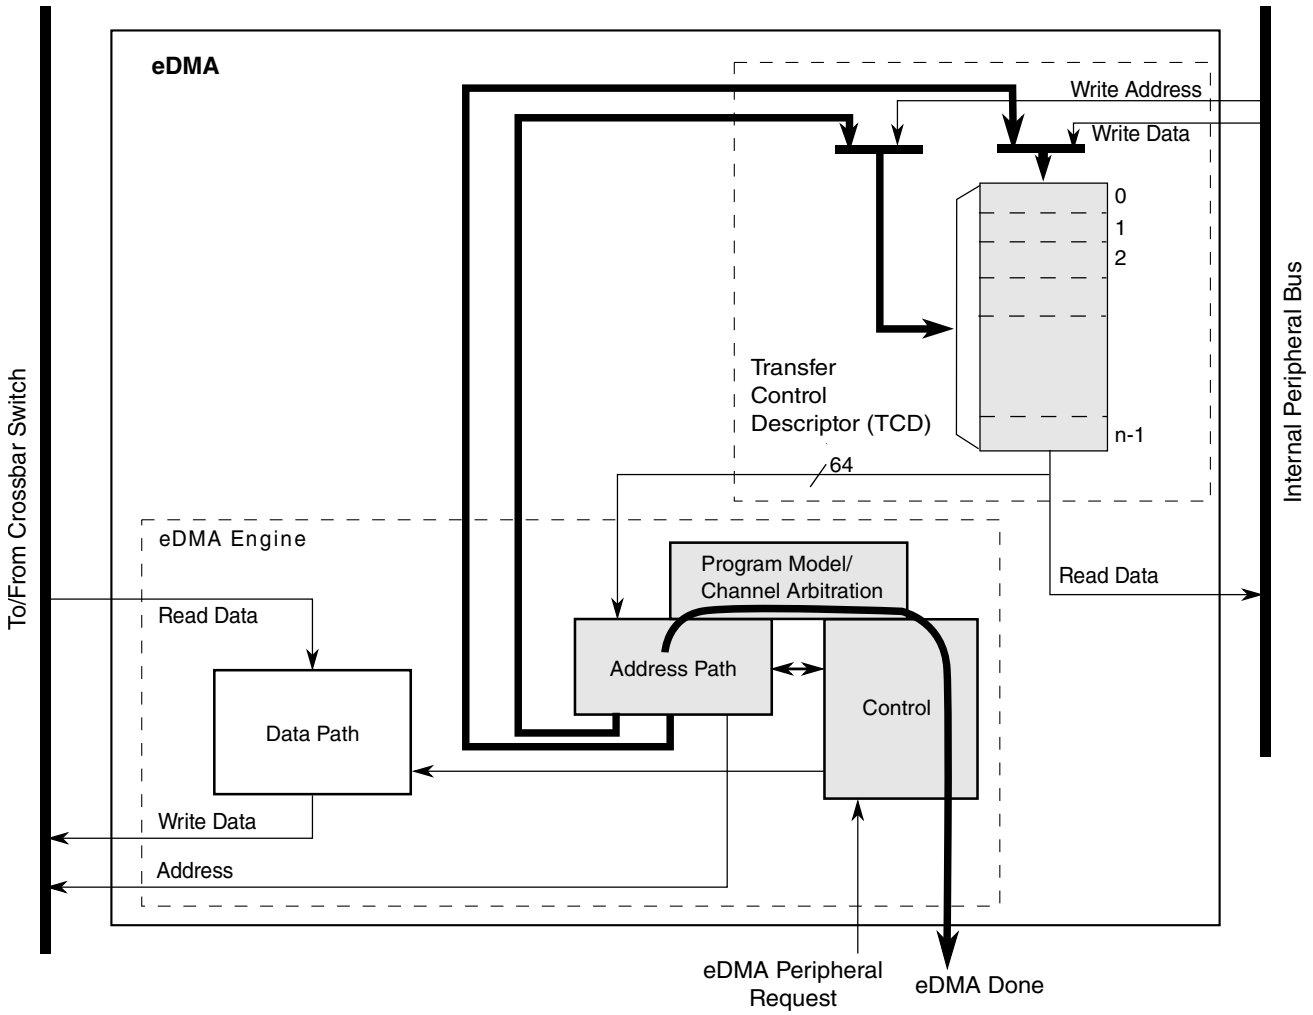

Figure 68-4. eDMA operation, part 3

68.4.2 Fault reporting and handling

Channel errors are reported in the Error Status register (DMAx_ES) and can be caused by:

- A configuration error, which is an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed-Arbitration mode
- An uncorrectable ECC error, or
- An error termination to a bus master read or write cycle

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes are detailed below:

- The addresses and offsets must be aligned on 0-modulo-transfer-size boundaries.

- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size respectively.
- In fixed arbitration mode, a configuration error is caused by any two channel priorities being equal. All channel priority levels must be unique when fixed arbitration mode is enabled.

NOTE

When two channels have the same priority, a channel priority error exists and will be reported in the Error Status register. However, the channel number will not be reported in the Error Status register. When all of the channel priorities within a group are not unique, the channel number selected by arbitration is undetermined.

To aid in Channel Priority Error (CPE) debug, set the Halt On Error bit in the DMA's Control Register. If all of the channel priorities within a group are not unique, the DMA will be halted after the CPE error is recorded. The DMA will remain halted and will not process any channel service requests. Once all of the channel priorities are set to unique numbers, the DMA may be enabled again by clearing the Halt bit.

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[E_LINK] bit does not equal the TCDn_BITER[E_LINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error

occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

If an uncorrectable ECC error occurs during a peripheral bus access, the access is terminated with a bus error. The occurrence of an uncorrectable ECC error during an eDMA engine read causes the eDMA engine to stop the active channel immediately. The ECC error and channel number are recorded in the eDMA's Error Status register.

A transfer may be cancelled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the Error Status register (DMAx_ES) is updated with the cancelled channel number and ECX is set. The TCD of a cancelled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD because the aforementioned fields no longer represent the original parameters. When a transfer is cancelled by the error cancel transfer mechanism, the channel number is loaded into DMA_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

NOTE

The cancel transfer request allows the user to stop a large data transfer in the event the full data transfer is no longer needed. The cancel transfer bit does not abort the channel. It simply stops the transferring of data and then retires the channel through its normal shutdown sequence. The application software must handle the context of the cancel. If an interrupt is desired (or not), then the interrupt should be enabled (or disabled) before the cancel request. The application software must clean up the transfer control descriptor since the full transfer did not occur.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the Error Status register (DMAx_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request,

are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

68.4.3 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the DCHPRIn[ECP] bit. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel has completed all its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected.

A channel's ability to preempt another channel can be disabled by setting DCHPRIn[DPA]. When a channel's preempt ability is disabled, that channel cannot suspend a lower priority channel's data transfer, regardless of the lower priority channel's ECP setting. This allows for a pool of low priority, large data-moving channels to be defined. These low priority channels can be configured to not preempt each other, thus preventing a low priority channel from consuming the preempt slot normally available to a true, high priority channel.

68.5 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

68.5.1 eDMA initialization

To initialize the eDMA:

1. Write to the CR if a configuration other than the default is desired.

2. Write the channel priority levels to the DCHPRI*n* registers if a configuration other than the default is desired.
3. Enable error interrupts in the EEI register if so desired.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the ERQ register.
6. Request channel service via either:
   - Software: setting the TCD*n*_CSR[START]
   - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in the following table, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, as defined by TCD*n*_SADDR, to the destination, as defined by TCD*n*_DADDR, continue until the number of bytes specified by TCD*n*_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing executes, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 68-4. TCD Control and Status fields

TCD*n*_CSR field name	Description
START	Control bit to start channel explicitly when using a software initiated DMA service (Automatically cleared by hardware)
ACTIVE	Status bit indicating the channel is currently in execution
DONE	Status bit indicating major loop completion (cleared by software when using a software initiated DMA service)
D_REQ	Control bit to disable DMA request at end of major loop completion when using a hardware initiated DMA service
BWC	Control bits for throttling bandwidth control of a channel
E_SG	Control bit to enable scatter-gather feature
INT_HALF	Control bit to enable interrupt when major loop is half complete
INT_MAJ	Control bit to enable interrupt when major loop completes

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

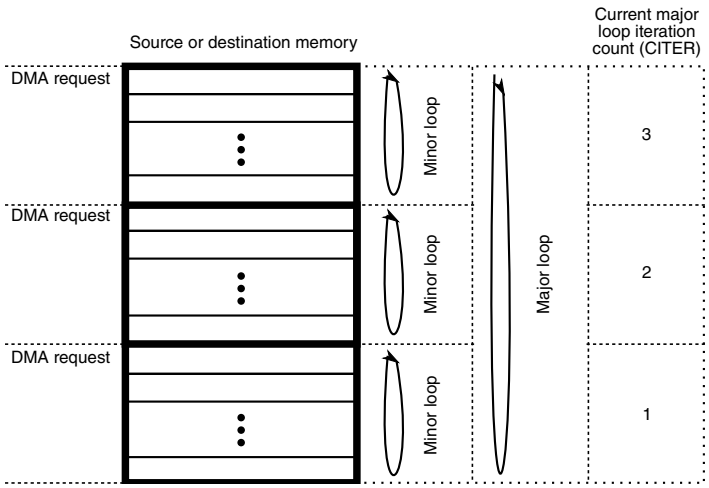

Figure 68-5. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings interrelate.

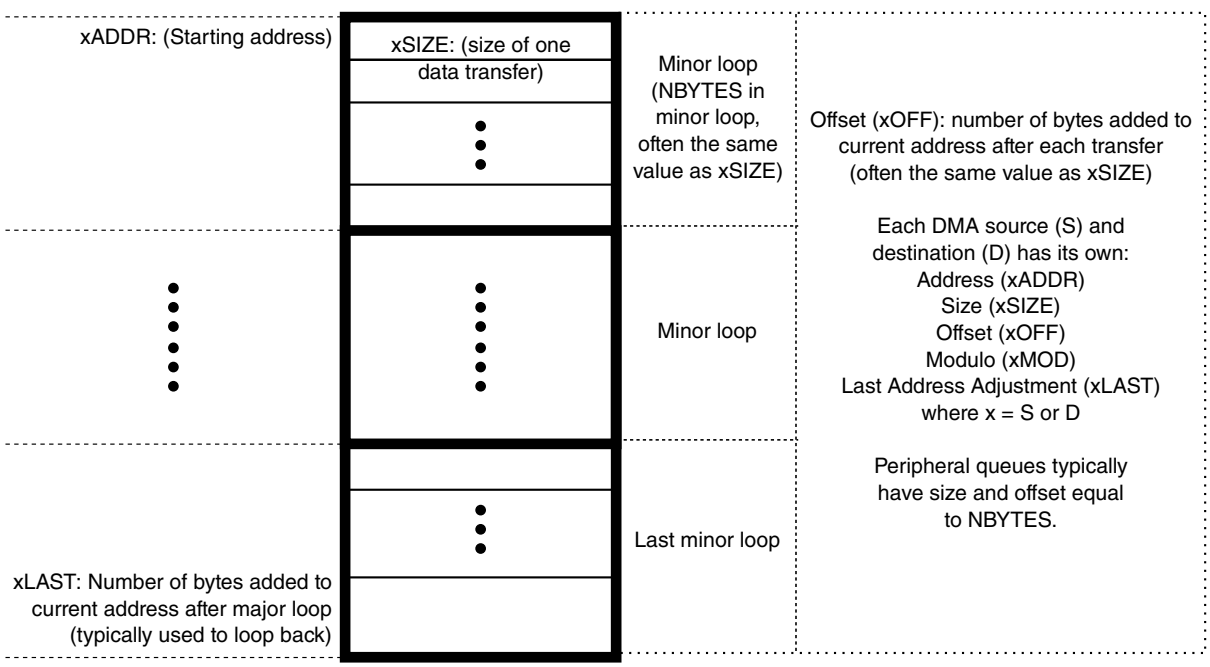

Figure 68-6. Memory array terms

68.5.2 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per channel basis with the exception of channel priority error (ES[CPE]).

For all error types other than group or channel priority errors, the channel number causing the error is recorded in the Error Status register (DMAx_ES). If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

Channel priority errors are identified within a group once that group has been selected as the active group. For example:

1. The eDMA is configured for fixed group and fixed channel arbitration modes.
2. Group 1 is the highest priority and all channels are unique in that group.
3. Group 0 is the next highest priority and has two channels with the same priority level.
4. If Group 1 has any service requests, those requests will be executed.
5. After all of Group 1 requests have completed, Group 0 will be the next active group.
6. If Group 0 has a service request, then an undefined channel in Group 0 will be selected and a channel priority error will occur.
7. This repeats until the all of Group 0 requests have been removed or a higher priority Group 1 request comes in.

In this sequence, for item 2, the eDMA acknowledge lines will assert only if the selected channel is requesting service via the eDMA peripheral request signal. If interrupts are enabled for all channels, the user will get an error interrupt, but the channel number for the ERR register and the error interrupt request line may be wrong because they reflect the selected channel. A group priority error is global and any request in any group will cause a group priority error.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest channel/group priority with an active request is selected, but the lowest numbered channel with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting is associated with the selected channel.

68.5.3 Arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

68.5.3.1 Fixed group arbitration, Fixed channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so that the channels within one group use "fixed" priorities, and that group is assigned the highest "fixed" priority of all groups, that group can take all the bandwidth of the eDMA controller. That is, no other groups will be serviced if there is always at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly. Preemption is available in this scenario only.

68.5.3.2 Fixed group arbitration, Round-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This scenario could cause the same bandwidth consumption problem as indicated in Fixed group arbitration, Fixed channel arbitration, but all the channels in the highest priority group will be serviced. Service latency will be short on the highest priority group, but could potentially be very much longer as the group priority decreases.

68.5.4 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

68.5.4.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the TCD*n*_CSR[DONE] bit is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA= -16
TCDn_CSR[INT_MAJ] = 1
TCDn_CSR[START] = 1 (Should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] bit requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
    a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
    b. Write 32-bits to location 0x2000 → first iteration of the minor loop.
    c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.

d. Write 32-bits to location 0x2004 → second iteration of the minor loop.

e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.

f. Write 32-bits to location 0x2008 → third iteration of the minor loop.

g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.

h. Write 32-bits to location 0x200C → last iteration of the minor loop → major loop complete.

6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[*n*] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

68.5.4.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware, that is, eDMA peripheral, request for channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source to destination transfers are executed as follows:

   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.

b. Write 32-bits to location 0x2000 → first iteration of the minor loop.

c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.

d. Write 32-bits to location 0x2004 → second iteration of the minor loop.

e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.

f. Write 32-bits to location 0x2008 → third iteration of the minor loop.

g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.

h. Write 32-bits to location 0x200C → last iteration of the minor loop.

6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0.
8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware, that is, eDMA peripheral, requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads: channel TCD data from local memory to internal register file.
13. The source to destination transfers are executed as follows:

a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.

b. Write 32-bits to location 0x2010 → first iteration of the minor loop.

c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.

d. Write 32-bits to location 0x2014 → second iteration of the minor loop.

e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.

f. Write 32-bits to location 0x2018 → third iteration of the minor loop.

g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.

h. Write 32-bits to location 0x201C → last iteration of the minor loop → major loop complete.

14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2 (TCD*n*_BITER).

15. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[n] = 1.

16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

68.5.4.3 Using the modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567*x*) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes and the MOD field is set to 4, allowing for a 2^4 byte (16-byte) size queue.

Table 68-5. Modulo example

Transfer Number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

68.5.5 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

68.5.5.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software initiated service requests. The first is to read the TCD*n*_CITER field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test the TCD*n*_CSR[START] bit and the TCD*n*_CSR[ACTIVE] bit. The minor-loop-complete condition is indicated by both bits reading zero after the TCD*n*_CSR[START] was set. Polling the TCD*n*_CSR[ACTIVE] bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute the following sequence for a software activated channel:

Stage	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	1	0	0	Channel service request via software
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

The best method to test for minor-loop completion when using hardware, that is, peripheral, initiated service requests is to read the TCD*n*_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute the following sequence for a hardware-activated channel:

Stage	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	0	0	0	Channel service request via hardware (peripheral request asserted)
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

For both activation types, the major-loop-complete status is explicitly indicated via the TCD*n*_CSR[DONE] bit.

The TCD*n*_CSR[START] bit is cleared automatically when the channel begins execution regardless of how the channel activates.

68.5.5.2 Reading the transfer descriptors of active channels

The eDMA reads back the true TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_NBYTES values if read while a channel executes. The true values of the SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses, SADDR and DADDR, and NBYTES, which decrement to zero as the transfer progresses, can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

68.5.5.3 Checking channel preemption status

Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in fixed group, fixed channel arbitration mode, the determination of the actively running relative priority outstanding requests become undefined. Channel and/or group priorities are treated as equal, that is, constantly rotating, when Round-Robin Arbitration mode is selected.

The TCD*n*_CSR[ACTIVE] bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two TCD*n*_CSR[ACTIVE] bits are set simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

68.5.6 Channel Linking

Channel linking (or chaining) is a mechanism where one channel sets the TCD*n*_CSR[START] bit of another channel (or itself), therefore initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCD*n*_CITER[E_LINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[E_LINK] = 1
TCDn_CITER[LINKCH] = 0xC
```

```
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_E_LINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] bit
2. Minor loop done → set TCD12_CSR[START] bit
3. Minor loop done → set TCD12_CSR[START] bit
4. Minor loop done, major loop done→ set TCD7_CSR[START] bit

When minor loop linking is enabled (TCD*n*_CITER[E_LINK] = 1), the TCD*n*_CITER[CITER] field uses a nine bit vector to form the current iteration count. When minor loop linking is disabled (TCD*n*_CITER[E_LINK] = 0), the TCD*n*_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCD*n*_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

Note

The TCD*n*_CITER[E_LINK] bit and the TCD*n*_BITER[E_LINK] bit must equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, i.e, use another channel's TCD, at the end of a loop.

Table 68-6. Channel Linking Parameters

Desired Link Behavior	TCD Control Field Name	Description
Link at end of Minor Loop	CITER[E_LINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	CITER[LINKCH]	Link channel number when linking at end of minor loop (current iteration)
Link at end of Major Loop	CSR[MAJOR_E_LINK]	Enable channel-to-channel linking on major loop completion
	CSR[MAJOR_LINKCH]	Link channel number when linking at end of major loop

68.5.7 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

68.5.7.1 Dynamically changing the channel priority

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to Round-Robin Channel Arbitration mode, change the channel priorities, then switch back to Fixed Arbitration mode,
2. Disable all the channels, change the channel priorities, then enable the appropriate channels.

68.5.7.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCD.major.e_link bit during channel execution (see the diagram in TCD structure). This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCD.major.e_link bit at the same time the eDMA engine is retiring the channel. The TCD.major.e_link would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The following coherency model is recommended when executing a dynamic channel link request.

1. Write 1 to the TCD.major.e_link bit.
2. Read back the TCD.major.e_link bit.
3. Test the TCD.major.e_link request status:
   - If TCD.major.e_link = 1, the dynamic link attempt was successful.
   - If TCD.major.e_link = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCD.major.e_link bit to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

NOTE

The user must clear the TCD.done bit before writing the TCD.major.e_link bit. The TCD.done bit is cleared

automatically by the eDMA engine after a channel begins execution.

68.5.7.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources.When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in eDMA programmer's model, thus replacing the current descriptor.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic scatter/gather operation by enabling the TCD.e_sg bit at the same time the eDMA engine is retiring the channel. The TCD.e_sg would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the major.linkch field and the e_sg bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD.major.e_link and TCD.e_sg bits to zero on any writes to a channel's TCD.word7 if that channel's TCD.done bit is set indicating the major loop is complete.

NOTE

The user must clear the TCD.done bit before writing the TCD.major.e_link or TCD.e_sg bits. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

68.5.7.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCD.major.e_link bit is zero, the TCD.major.linkch field is not used by the eDMA. In this case, the TCD.major.linkch bits may be used for other purposes. This method uses the TCD.major.linkch field as a TCD indentification (ID).

1. When the descriptors are built, write a unique TCD ID in the TCD.major.linkch field for each TCD associated with a channel using dynamic scatter/gather.
2. Write 1b to the TCD.d_req bit.

   Should a dynamic scatter/gather attempt fail, setting the TCD.d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offest value.

3. Write the TCD.dlast_sga field with the scatter/gather address.
4. Write 1b to the TCD.e_sg bit.
5. Read back the 16 bit TCD control/status field.
6. Test the TCD.e_sg request status and TCD.major.linkch value:

   If e_sg = 1b, the dynamic link attempt was successful.

   If e_sg = 0b and the major.linkch (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring).

   If e_sg = 0b and the major.linkch (ID) changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

68.5.7.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCD.dlast_sga field as a TCD indentification (ID).

1. Write 1b to the TCD.d_req bit.

   Should a dynamic scatter/gather attempt fail, setting the d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offest value.

2. Write theTCD.dlast_sga field with the scatter/gather address.
3. Write 1b to the TCD.e_sg bit.
4. Read back the TCD.e_sg bit.

5. Test the TCD.e_sg request status:

   If e_sg = 1b, the dynamic link attempt was successful.

   If e_sg = 0b, read the 32 bit TCD dlast_sga field.

   If e_sg = 0b and the dlast_sga did not change, the attempted dynamic link did not succeed (the channel was already retiring).

   If e_sg = 0b and the dlast_sga changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

Direct Memory Access Multiplexer

69.1 Chip-specific DMA MUX information

69.1.1 DMA MUX configuration

This device includes two DMA request MUXes that allows up to 32 DMA request signals to be mapped to the first 16 DMA channels [DMA_CH0 - DMA_CH15] for DMACHMUX_0 and the last 16 DMA channels [DMA_CH16 - DMA_CH31] for DMACHMUX_1. There is one DMA Mux module for each 16 channels of DMA as one DMACHMUX is has a configuration of 64 inputs to 16 muxed outputs.

The tables below shows the DMACHMUX_0 and DMACHMUX_1 channel mapping.

Table 69-1. DMA request sources

69.2 Introduction

69.2.1 Overview

The Direct Memory Access Multiplexer (DMAMUX) routes DMA sources, called slots, to any of the 16 DMA channels. This process is illustrated in the following figure.

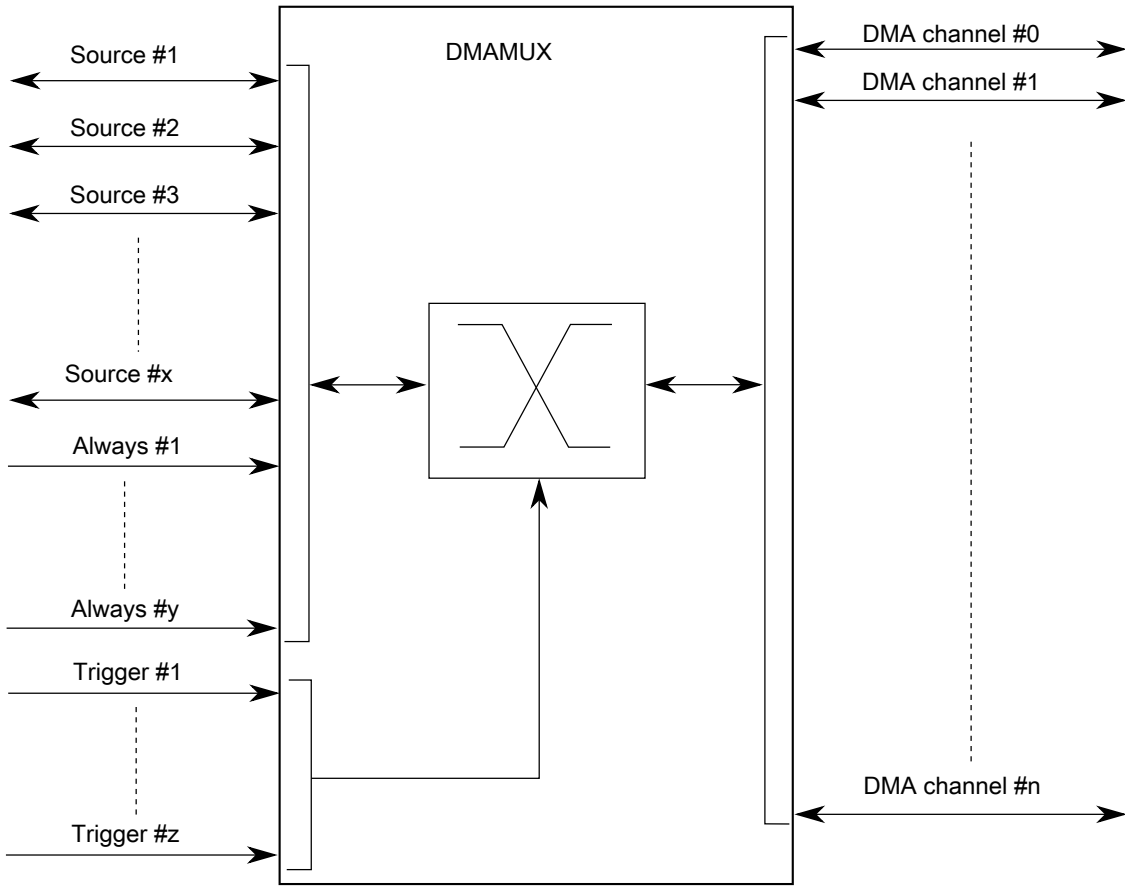

Figure 69-1. DMAMUX block diagram

69.2.2 Features

The DMAMUX module provides these features:

- Up to 61 peripheral slots and up to two always-on slots can be routed to 16 channels.
- 16 independently selectable DMA channel routers.
  - The first two channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of the possible peripheral DMA slots or to one of the always-on slots.

69.2.3 Modes of operation

The following operating modes are available:

- Disabled mode

In this mode, the DMA channel is disabled. Because disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA channel MUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place, for example, changing the period of a DMA trigger.

- Normal mode

  In this mode, a DMA source is routed directly to the specified DMA channel. The operation of the DMAMUX in this mode is completely transparent to the system.

- Periodic Trigger mode

  In this mode, a DMA source may only request a DMA transfer, such as when a transmit buffer becomes empty or a receive buffer becomes full, periodically.

  Configuration of the period is done in the registers of the periodic interrupt timer (PIT). This mode is available only for channels 0–1.

69.3 External signal description

The DMAMUX has no external pins.

69.4 Memory map/register definition

This section provides a detailed description of all memory-mapped registers in the DMAMUX.

DMAMUX memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Channel Configuration register (DMAMUX_CHCFG0)	8	R/W	00h	69.4.1/2966
1	Channel Configuration register (DMAMUX_CHCFG1)	8	R/W	00h	69.4.1/2966
2	Channel Configuration register (DMAMUX_CHCFG2)	8	R/W	00h	69.4.1/2966
3	Channel Configuration register (DMAMUX_CHCFG3)	8	R/W	00h	69.4.1/2966
4	Channel Configuration register (DMAMUX_CHCFG4)	8	R/W	00h	69.4.1/2966
5	Channel Configuration register (DMAMUX_CHCFG5)	8	R/W	00h	69.4.1/2966
6	Channel Configuration register (DMAMUX_CHCFG6)	8	R/W	00h	69.4.1/2966
7	Channel Configuration register (DMAMUX_CHCFG7)	8	R/W	00h	69.4.1/2966
8	Channel Configuration register (DMAMUX_CHCFG8)	8	R/W	00h	69.4.1/2966

Table continues on the next page...

DMAMUX memory map (continued)

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
9	Channel Configuration register (DMAMUX_CHCFG9)	8	R/W	00h	69.4.1/2966
A	Channel Configuration register (DMAMUX_CHCFG10)	8	R/W	00h	69.4.1/2966
B	Channel Configuration register (DMAMUX_CHCFG11)	8	R/W	00h	69.4.1/2966

D	Channel Configuration register (DMAMUX_CHCFG13)	8	R/W	00h	69.4.1/2966
E	Channel Configuration register (DMAMUX_CHCFG14)	8	R/W	00h	69.4.1/2966
F	Channel Configuration register (DMAMUX_CHCFG15)	8	R/W	00h	69.4.1/2966

69.4.1 Channel Configuration register (DMAMUX_CHCFG*n*)

Each of the DMA channels can be independently enabled/disabled and associated with one of the DMA slots (peripheral slots or always-on slots) in the system.

NOTE

Setting multiple CHCFG registers with the same source value will result in unpredictable behavior. This is true, even if a channel is disabled (ENBL==0).

Before changing the trigger or source settings, a DMA channel must be disabled via CHCFGn[ENBL].

Address: 0h base + 0h offset + (1d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7
Read Write	ENBL	TRIG	SOURCE					
Reset	0	0	0	0	0	0	0	0

DMAMUX_CHCFG*n* field descriptions

Field	Description
0 ENBL	DMA Channel Enable Enables the DMA channel. 0 DMA channel is disabled. This mode is primarily used during configuration of the DMAMux. The DMA has separate channel enables/disables, which should be used to disable or reconfigure a DMA channel. 1 DMA channel is enabled
1 TRIG	DMA Channel Trigger Enable Enables the periodic trigger capability for the triggered DMA channel.

Table continues on the next page...

DMAMUX_CHCFG*n* field descriptions (continued)

Field	Description
	0 Triggering is disabled. If triggering is disabled and ENBL is set, the DMA Channel will simply route the specified source to the DMA channel. (Normal mode) 1 Triggering is enabled. If triggering is enabled and ENBL is set, the DMAMUX is in Periodic Trigger mode.
2–7 SOURCE	DMA Channel Source (Slot) Specifies which DMA source, if any, is routed to a particular DMA channel. See the chip-specific DMAMUX information for details about the peripherals and their slot numbers.

69.5 Functional description

The primary purpose of the DMAMUX is to provide flexibility in the system's use of the available DMA channels.

As such, configuration of the DMAMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in Enabling and configuring sources is followed, the configuration of the DMAMUX may be changed during the normal operation of the system.

Functionally, the DMAMUX channels may be divided into two classes:

- Channels that implement the normal routing functionality plus periodic triggering capability
- Channels that implement only the normal routing functionality

69.5.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first 2 channels of the DMAMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames, or packets at fixed intervals without the need for processor intervention.

The trigger is generated by the periodic interrupt timer (PIT); as such, the configuration of the periodic triggering interval is done via configuration registers in the PIT. See the section on periodic interrupt timer for more information on this topic.

Note

Because of the dynamic nature of the system (due to DMA channel priorities, bus arbitration, interrupt service routine lengths, etc.), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

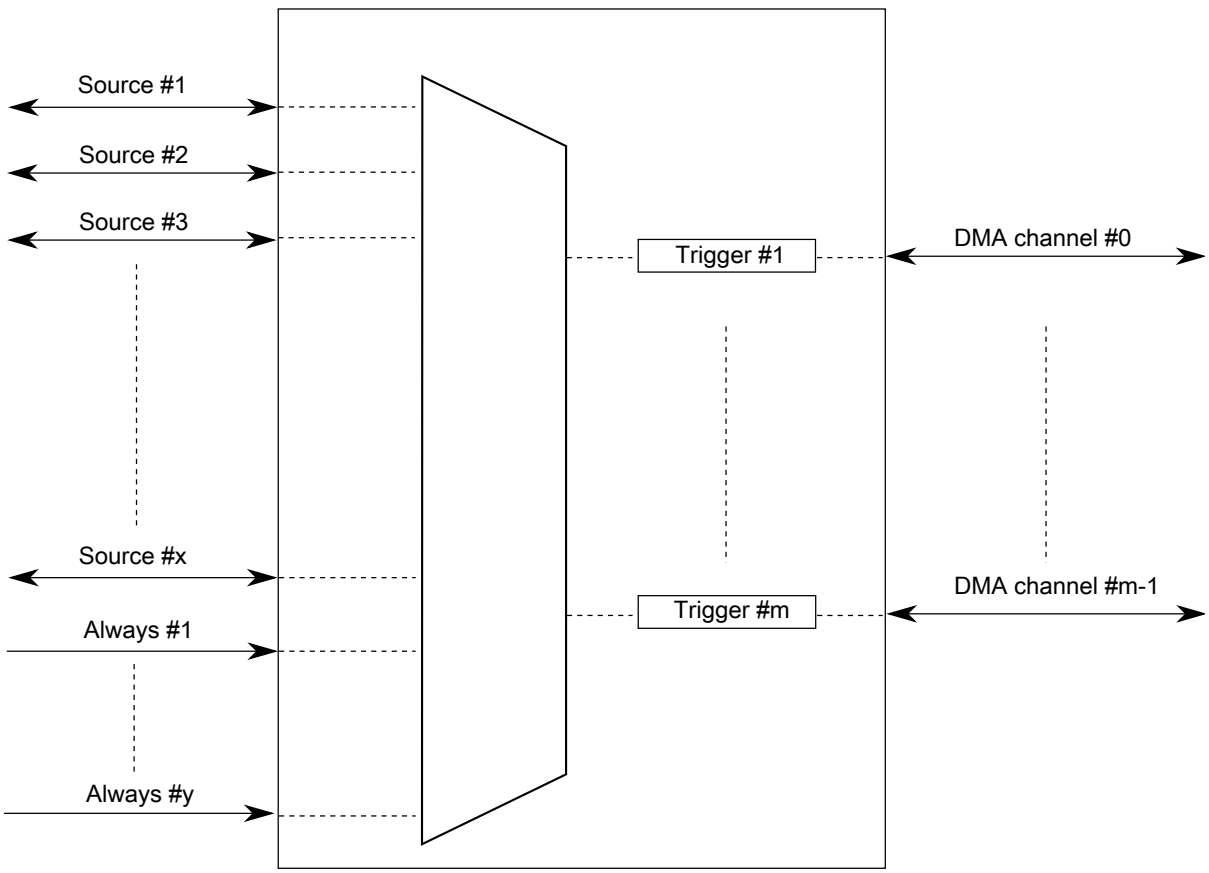

Figure 69-2. DMAMUX triggered channels

The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the peripheral to the DMA until a trigger event has been seen. This is illustrated in the following figure.

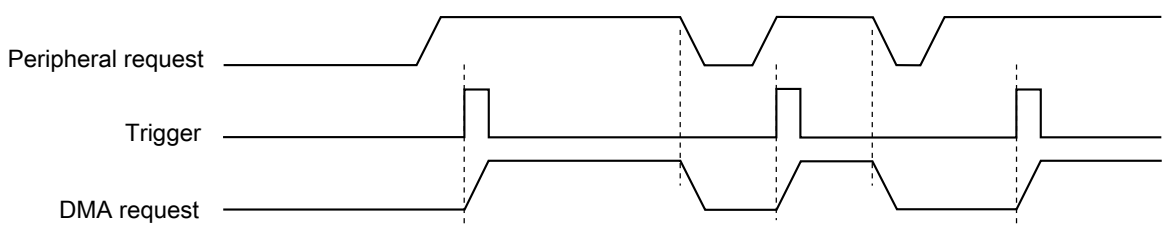

Figure 69-3. DMAMUX channel triggering: normal operation

After the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral reasserts its request and the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, then that trigger will be ignored. This situation is illustrated in the following figure.

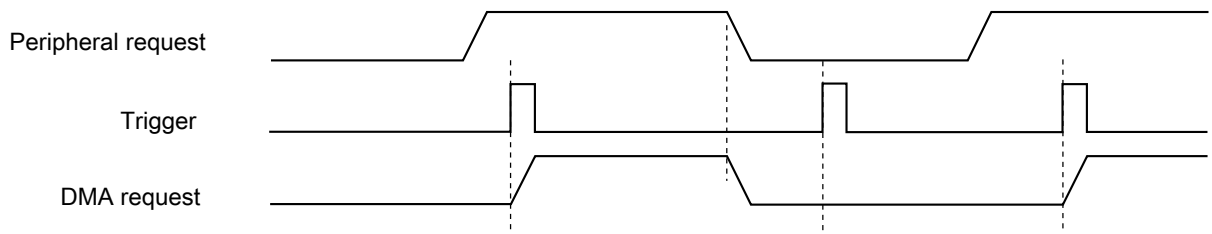

Figure 69-4. DMAMUX channel triggering: ignored trigger

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations:

- Periodically polling external devices on a particular bus

  As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. After it has been set up, the SPI will request DMA transfers, presumably from memory, as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5 µs (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.

- Using the GPIO ports to drive or sample waveforms

  By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

A more detailed description of the capability of each trigger, including resolution, range of values, and so on, may be found in the periodic interrupt timer section.

69.5.2 DMA channels with no triggering capability

The other channels of the DMAMUX provide the normal routing functionality as described in Modes of operation.

69.5.3 Always-enabled DMA sources

In addition to the peripherals that can be used as DMA sources, there are two additional DMA sources that are always enabled. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the sources that are always enabled provide no such "throttling" of the data transfers. These sources are most useful in the following cases:

- Performing DMA transfers to/from GPIO—Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Performing DMA transfers from memory to memory—Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Performing DMA transfers from memory to the external bus, or vice-versa—Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation—Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, an always-enabled DMA source can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require that a new start event be sent. This can either be a new software activation, or a transfer request from the DMA channel MUX. The options for doing this are:

- Transfer all data in a single minor loop.

  By configuring the DMA to transfer all of the data in a single minor loop (that is, major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will impose on the system. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use explicit software reactivation.

  In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel by writing to the DMA registers *after every minor loop*. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use an always-enabled DMA source.

In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMA channel MUX does the channel reactivation. For this option, the DMA channel should be enabled and pointing to an "always enabled" source. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

69.6 Initialization/application information

This section provides instructions for initializing the DMA channel MUX.

69.6.1 Reset

The reset state of each individual bit is shown in Memory map/register definition. In summary, after reset, all channels are disabled and must be explicitly enabled before use.

69.6.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 2 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with periodic triggering capability:

1. Write 0x00 to CHCFG1.

2. Configure channel 1 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC5 to CHCFG1.

The following code example illustrates steps 1 and 4 above:

```
void DMAMUX_Init(uint8_t DMA_CH, uint8_t DMAMUX_SOURCE)
{
    DMAMUX_0.CHCFG[DMA_CH].B.SOURCE = DMAMUX_SOURCE;
    DMAMUX_0.CHCFG[DMA_CH].B.ENBL   = 1;
    DMAMUX_0.CHCFG[DMA_CH].B.TRIG   = 1;
}
```

To enable a source, without periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 2 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is set while CHCFG[TRIG] is cleared.

NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with no periodic triggering capability:

1. Write 0x00 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Write 0x85 to CHCFG1.

The following code example illustrates steps 1 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
```

```
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);

In File main.c:
#include "registers.h"
:
:
*CHCFG1 = 0x00;
*CHCFG1 = 0x85;
```

To disable a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module-specific configuration may be necessary. See the appropriate section for more details.

To switch the source of a DMA channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

To switch DMA channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn't have triggering capability.
2. Write 0x00 to CHCFG8.
3. Write 0x87 to CHCFG8. (In this example, setting CHCFG[TRIG] would have no effect due to the assumption that channel 8 does not support the periodic triggering functionality.)

The following code example illustrates steps 2 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);
```

```
In File main.c:
#include "registers.h"
:
:
*CHCFG8 = 0x00;
*CHCFG8 = 0x87;
```

Chapter 70
PRAMC

70.1 Chip-specific PRAMC information

70.1.1 Register reset value

Reset value of PRAMC_PRCR1 register is device specific as shown in the following table

Table 70-1. Register reset value

Register	Register Value
PRAMC_PRCR1	0x0000_0200

70.2 Introduction

This section provides an overview of the Platform RAM Controller. The RAM controller acts as an interface between the system bus (AHB-Lite 2.v6) and the integrated system RAM. It converts the protocols between the system bus and the dedicated RAM array interface.

The RAM controller supports two 64-bit AHB interfaces and a 64-bit RAM array interface. The primary AHB port provides a connection to the platform crossbar for direct RAM access from the various crossbar masters. The backdoor AHB port provides a connection from the flash controller to facilitate calibration overlay access. Shown below in Figure 70-1 is a simplified block diagram depicting the position of the RAM controller within a typical platform architecture.

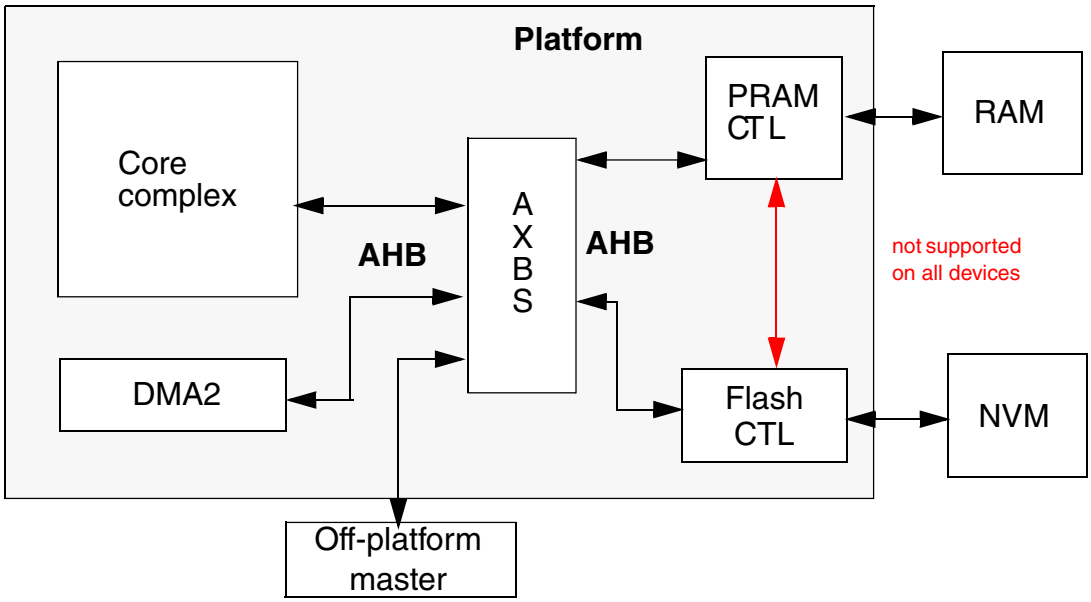

Figure 70-1. Simplified platform block diagram

The following list summarizes the key features of the RAM controller:

- System bus supports 64-bit data + 8-bit ECC AHB interfaces
- Array interface supports a 64-bit data + 8-bit ECC interface
- Late-write support via 64-bit data + 8-bit ECC storage buffer to support single-cycle write accesses
- Configurable read access timing (zero or one wait-state programmable) allowing use in large range of frequency targets
- Read-modify-write operation to support array write size less than a doubleword

The address path of the RAM controller contains a mux that chooses among the addresses presented on the system bus for a read request, either the address from the temporary holding register or the address from the late-write buffer. The temporary holding register contains the address which was presented during the AHB address phase of the write request. The request is stalled from being presented to the RAM by one cycle in order to present simultaneously the address and associated write data, which is not valid until the AHB dataphase. The late-write buffer holds write requests which are delayed to facilitate single-cycle response on the system bus.

The read datapath contains a mux that chooses the source of the read data to be presented on the system bus on a read request. In the event that a read request matches the contents of the late-write buffer, a RAM access is not required and the late-write buffer contents are selected onto the read databus. Otherwise, the read data is a result of a RAM access. Along with the read and write data, the corresponding ECC codewords traverse the entire datapath of the RAM controller, including the late-write storage buffer, to support end-to-end ECC (e2eECC) coverage.

The write datapath contains the mux that chooses the source of the write data as well as the control logic for generating read-modify-write operations on writes that are less than 64 bits in size. A write operation can be performed to empty the contents of the late-write buffer. In the case of back-to-back writes, the write may be forced to bypass the late-write buffer and instead be stored directly, precisely in the RAM.

70.3 SRAM controller memory map and register definition

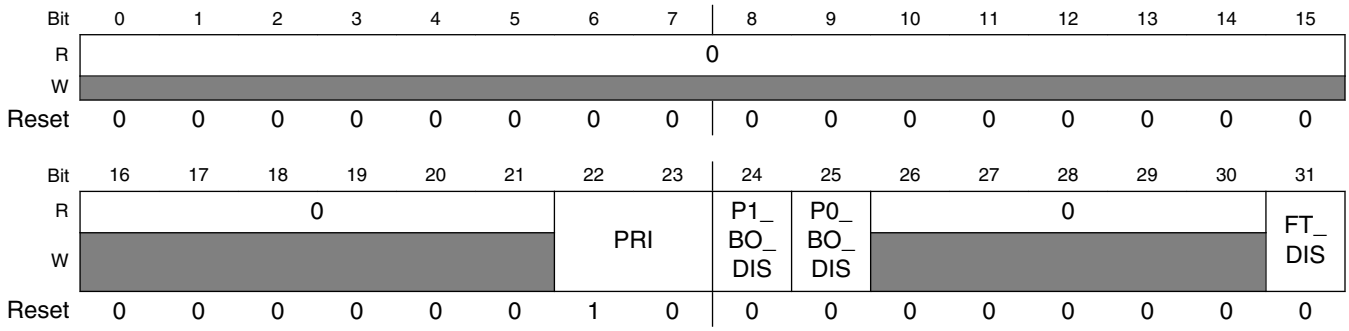
The RAM controller module provides an IPS programming model mapped to a standard on-platform peripheral slot. The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses generate an IPS error termination.

NOTE

Attempted updates to the PRAMC programming model while a PRAMC operation is in progress will result in non-deterministic behavior. Software must be architected to avoid this scenario by ensuring that PRAMC configuration changes are made only during system boot or when only one master is enabled. In multi-core devices, update the PRAMC configuration only when one core is active and no other masters, e.g., DMA or communications modules, are enabled. Move any instruction execution or memory references outside the system RAM while updating the PRAMC configuration, e.g., to the core local memory space.

PRAMC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Platform RAM Configuration Register 1 (PRAMC_PRCR1)	32	R/W	0000_0200h	70.3.1/2977



70.3.1 Platform RAM Configuration Register 1 (PRAMC_PRCR1)

The Platform RAM Configuration Register 1 (PRCR1) is used to specify operation of the RAM controller.

NOTE

This register is accessible only in supervisor mode. Accesses in user mode return a transfer error.

Address: 0h base + 0h offset = 0h

PRAMC_PRCR1 field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 PRI	AHB port arbitration mode. Use this register to select the AHB port arbitration mode. 00 Round Robin arbitration is selected. 01 Port p0 has priority over port p1. 10 Port p1 has priority over port p0. 11 Reserved.
24 P1_BO_DIS	Port p1 read burst optimization disable. **NOTE:** The number of cycles taken for a RAM access can vary ±1 clock cycle depending on the RAM speed relative to the PRAMC controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller, a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency, a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to the PRAMC controller clock frequency. 0 64-bit WRP4 read bursts are optimized such that the controller returns a 2-1-1-1 response when PRCR1[FT_DIS]=1 1 64-bit WRP4 read bursts are not optimized; the controller returns a 2-2-2-2 response when PRCR1[FT_DIS]=1
25 P0_BO_DIS	Port p0 read burst optimization disable. **NOTE:** The number of cycles taken for a RAM access can vary ±1 clock cycle depending on the RAM speed relative to the PRAMC controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller, a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency, a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to the PRAMC controller clock frequency. 0 64-bit WRP4 read bursts are optimized such that the controller returns a 2-1-1-1 response when PRCR1[FT_DIS]=1 1 64-bit WRP4 read bursts are not optimized; the controller returns a 2-2-2-2 response when PRCR1[FT_DIS]=1
26–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PRAMC_PRCR1 field descriptions (continued)

Field	Description
31 FT_DIS	Flow through disabled. This field defines the AHB response on reads. The state of this field has no impact on the response latency on writes. This bit is cleared by hardware reset. **NOTE:** Do not change the FT_DIS bit value while accessing system RAM. Relocate code programming the FT_DIS bit to another memory area, e.g., local core memory. 0 RAM read data is passed directly to the system bus, incurring no additional latency 1 RAM read data is registered prior to returning on the system bus, incurring 1 extra cycle of latency

70.4 Functional description

This section describes the functions of the RAM controller.

70.4.1 Read and Write operations

The RAM controller processes read and write requests to on-chip RAM and provides a register interface for access to performance tuning functions.

NOTE

The RAM controller register interface is accessible only in supervisor mode. Accesses in user mode return a transfer error.

70.4.1.1 Reads

Read transfers, of any size, can be configured to complete with a zero or one additional wait state response on the system bus.

70.4.1.2 Optional read wait-state

The RAM controller can be optionally programmed to register RAM read data prior to returning it on the system bus. Setting the PRCRx[FT_DIS] field inserts a register in the read data path for use when operating the controller at high frequencies. The state of PRCRx[FT_DIS] field has no effect on writes.

A random, initial access will take 2 clock cycles (2T) to complete if PRCRx[FT_DIS]=0, and a WRAP4 burst will have an access time of 2-2-2-2. A random, initial access will take 3 clock cycles (3T) to complete if PRCRx[FT_DIS]=1, and a WRAP4 burst will have an access time of 3-2-2-2.

NOTE

The number of cycles taken for a RAM access can vary ±1 clock cycle depending on the RAM speed relative to the PRAMC controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller, a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency, a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to the PRAMC controller clock frequency.

70.4.2 Writes

This section discusses various write operations of the RAM controller.

70.4.2.1 64-bit writes

Aligned 64-bit writes execute in a single AHB data phase cycle, allowing for zero wait states on back-to-back writes of these sizes. If, during the data phase of a write, a read is requested on the AHB, the write is registered in the late-write buffer, allowing the read to take place without a wait state. The valid buffered or late-write data is stored on the next available array address phase.

Back to back 64-bit writes execute slightly differently whereby the first write bypasses the late-write buffer. Rather, the write data is stored directly to the array in the same cycle in which it is valid on the AHB.

70.4.2.2 Less than 64-bit writes

Writes of size less than 64 bits incur a read-modify-write action as a consequence of the ECC coding scheme's 64-bit granularity. In the case of a read-modify-write action, the RAM controller performs SEC/DED on the read data. The write data is merged into the appropriate byte lanes along with the potentially corrected read data. A new codeword is generated based on the newly formed doubleword. The newly formed doubleword and its

associated checkbits are subsequently written to the RAM. Figure 70-2 provides details on the read-modify-write datapath. For details on the ECC coding scheme, refer to Reliability considerations.

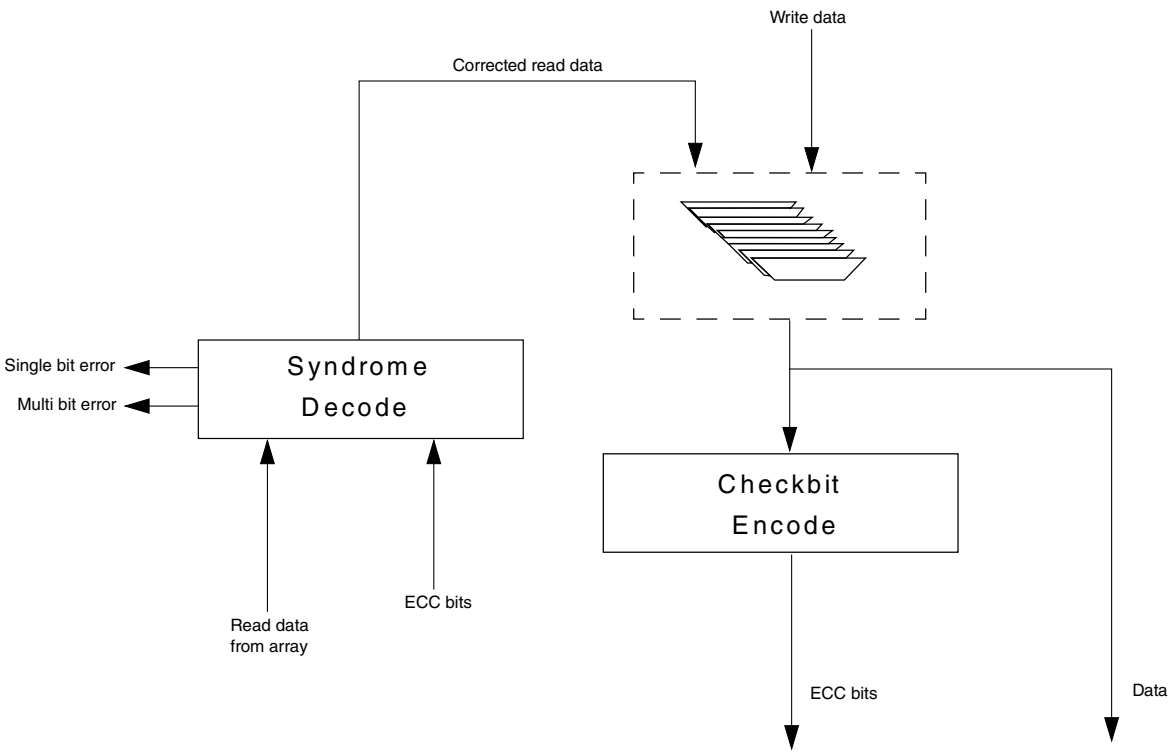


Figure 70-2. Read-modify-write datapath

On a read-modify-write operation, the array read data is registered after it is decoded and before it is merged with the AHB write data. Therefore, writes of size less than 64 bits require the insertion of one wait state before the data phase can be completed.

70.4.2.3 Unaligned writes

The RAM controller is compliant with the AMBA-AHB2.v6 Extensions specification with regard to byte strobes. The size of the transfer is sufficient to cover all bytes being written and covers more bytes in the case of an unaligned transfer. The address of the transfer is rounded down to the nearest boundary of the size of the transaction.

NOTE

Unaligned writes always generate read-modify-write operations in the RAM controller in order to preserve the validity of the ECC codeword.

70.5 Initialization/application information

It is essential that each memory address be written to a known value before it is read, to initialize the ECC. This includes reads generated from the read-modify-write operation which occurs when a write transfer of less than 64 bits or an unaligned write is requested. Without writing an address to a known value first, a read from this address will most likely generate an uncorrectable ECC event.

One possibility for initializing PRAMC memory space is to use a stored 64-bit word instruction such as Store Multiple Word (e_stmw) in Power Architecture VLE.

70.6 Reliability considerations

This section discusses reliability considerations of the RAM controller.

70.6.1 Hsiao ECC algorithm

The e2eECC scheme implements a single-error correction, double-error detection (SECDED) code using the so-called Hsiao odd-weight column criteria. These codes are named for M.Y. Hsiao, an IBM researcher who published extensively in the early 1970s on SECDED codes better suited for implementation in protecting (mainframe) computer memories than traditional Hamming codes.

The Hsiao codes are Hamming distance 4 implementations which provide the SECDED capabilities. The minimum odd-weight constraints defined by Hsiao are relatively simple in the resulting implementation of the parity check H matrix which defines the association between the data (and address) bits and the checkbits. They are:

1. There are no all-zeroes columns.
2. Every column is distinct.
3. Every column contains an odd number of ones, and hence is "odd weight".

In defining the H-matrix for this family of devices, these requirements from Hsiao were applied. Additionally, there are a variety of ECC codeword requirements associated with specific functional requirements associated with the system RAM that further dictated the specific column definitions. In any case, the resulting ECC is organized based on 64 data bits plus 29 address bits (the upper bits of the 32-bit address field minus the 3 bits which select the byte within the 64-bit (8-byte) data field.

The basic H-matrix for this (101, 93) code (93 is the total number of data bits, 101 is the total number of data bits (93) plus 8 checkbits) is shown in the following table. A '*' in the table indicates the corresponding data or address bit is XOR'ed to form the final checkbit value on the left. For 64-bit data writes, the table sections corresponding to D[63:32], D[31:0], and A[31:3] are logically summed (output of each table section is XOR'ed) together to the final value driven on the hwchkbit[7:0] outputs. Note that this table uses *the AHB bit numbering convention where bit[0] is the least significant bit*.

Table 70-2. RAM controller basic H-matrix definition

		XOR sum	Data Bit[1]																																					
			Byte 7								Byte 6								Byte 5								Byte 4							
			63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32

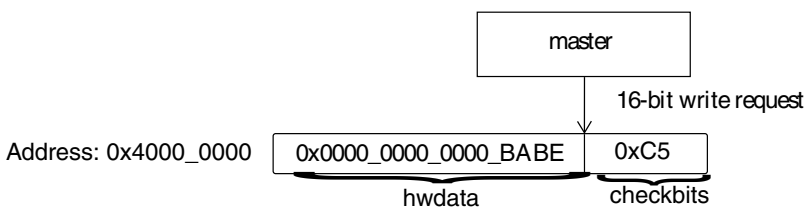
	5			*	*	*			*	*			*	*		*		*		*	*			*	*	*		*	*	*	*				
	4		*	*	*		*	*		*		*	*	*	*		*					*	*		*	*	*		*	*					
	3		*		*		*	*	*		*		*	*	*			*		*		*	*		*		*	*	*		*				
	2		*	*			*		*	*	*	*				*	*	*	*	*	*	*		*	*		*		*		*				
	1		*		*	*		*	*		*	*		*	*		*		*	*	*		*	*	*					*	*				
	0		*		*	*	*			*	*		*		*	*	*		*		*	*	*			*		*	*		*				

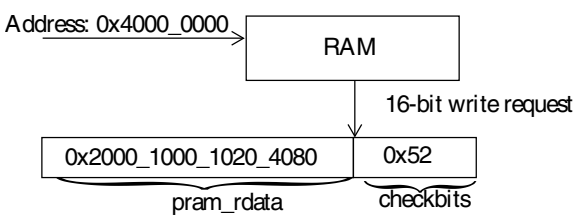
1. Bit numbering is AHB convention: bit 0 is LSB. D[7:0] corresponds to byte at address 0. D[63:56] corresponds to byte at address 7.



2. Bit numbering is AHB convention: bit 0 is LSB. D[7:0] corresponds to byte at address 0. D[63:56] corresponds to byte at address 7.

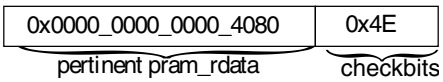
70.6.1.1 e2eECC considerations on less-than-64-bit write transactions

Recall writes of size less than 64-bit incur a read-modify-write action as a consequence of the ECC coding scheme 64-bit granularity. In the case of a read-modify-write action, the RAM controller performs SEC/DED on the read data. The RAM controller uses the following checkbit manipulation technique to ensure any faults in the PRAMC control logic associated with performing the read-modify-write action will ultimately be detectable by e2eECC:



- On an 8-, 16-, or 32-bit write request, the write data is presented by the master on the AHB bus in the correct byte lanes, with the non-pertinent byte lanes zeroed out, and the associated checkbit is based on this "zero-padded" write data.

  Consider the following example whereby the master presents a 16-bit write request at address 0x40000000:



- The RAM controller detects that the request is a less-than-64-bit write request and initiates a read to address 0x40000000. An ECC check and potential single-bit correction is performed on the data returned from the RAM. In addition, the ECC event is reported to the Memory Error Management Unit (MEMU).

  If a non-correctable ECC event is detected, the AHB request is terminated with error on the system bus. In addition, the ECC event is reported to the MEMU.

- The RAM controller isolates the pertinent byte lanes of the read data by zero-padding the non-pertinent byte lanes and calculating the checkbit contribution associated with the read data in the byte lanes to be updated as a result of the write request.

- Merge the non-pertinent read data bytes with the write data in the appropriate byte lanes. Take the checkbit value that was stored in the RAM and remove the checkbit contribution associated with the read data in the byte lanes to be updated. Then introduce the checkbits associated with the write data. The result is ultimately a checkbit value associated with the complete 64-bit data to be written to the array.

This technique calculates the ultimate checkbit value on a read-modify-write transaction through a series of data manipulations, taking care to avoid discarding the original checkbits provided by the requesting master, such that faults in the crossbar (XBAR) and RAM controller datapath and control logic are covered by e2eECC.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The RAM controller performs EDC after ECC check on all read-modify-write transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the FCCU module.

70.6.2 Transaction monitor

The integrity of the address and data on a system RAM transaction is covered by e2eECC check performed by the requesting master. Fault detection coverage of the address path and control within the RAM controller is handled by a transaction monitor which verifies the integrity of the transactions between the RAM controller and the RAM array. The transaction monitor verifies RAM transactions initiated to service the following types of transactions:

- Direct system bus read or write request
- Read followed by write to fulfill a read-modify write transaction
- Write transaction to empty the late-write buffer

The function of the transaction monitor relies on a feedback path between the RAM controller and RAM array, wherein the RAM provides latched address and control feedback outputs as an indication of received inputs when a RAM access is initiated.

This feedback information is used by the RAM controller transaction monitor to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the RAM controller or the transmission path between the RAM controller and RAM array, the event is forwarded to the Fault Collection and Control Unit (FCCU).

Since writes to the RAM can be buffered, the transaction monitor also tracks the contents of the late-write buffer. When the late-write buffer is emptied, outputs from the RAM are evaluated against the expected contents of the late-write buffer as tracked by the transaction monitor.

As a countermeasure against false misses to the late-write buffer on reads, the transaction monitor also verifies the expected source of data returned on a read as supplied either from the RAM or from the late-write buffer.

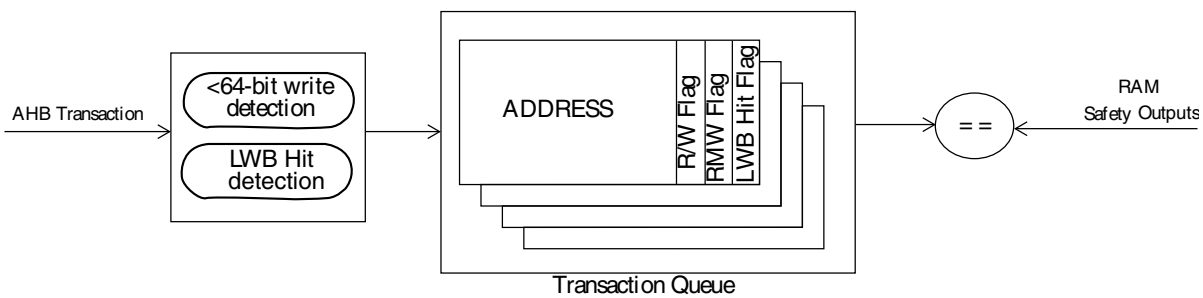


Figure 70-3. RAM controller transaction monitor block diagram

Chapter 71
Flash memory controller

71.1 Chip-specific Flash memory controller information

71.1.1 Master IDs

The registers in the following table contain fields that map to platform bus masters:

Register	Field
Platform Flash Access Protection Register (PFLASH_PFAPR)	M*n*AP
Platform Flash Configuration Register 3 (PFLASH_PFCR3)	P2_M*n*PFE

The "M*n*" portion of each of the field names refers to a bus master by its *logical* master ID. For example, the PFCR1[P0_M15PFE] field refers to the bus master with logic ID 15.

See Table 20-1 for a list of valid bus masters and their logical IDs.

NOTE

The fields associated with bus masters are mapped according to the bus master's logical master ID value, not the AXBS crossbar (XBAR) port number.

71.2 Introduction

The flash memory controller has these functions:

- It acts as an interface between the system bus (AHB-Lite 2.v6) and the flash memory array.
- It serves as the interface to on-chip System RAM that can be used as overlay RAM.

The flash memory controller supports three 64-bit AHB buses and a 256-bit read data interface from each flash memory array. Each AHB port contains a 4-entry, 2-way set-associative mini-cache as well as an associated controller that prefetches sequential lines of data from the flash arrays into the mini-cache. This buffer mechanism serves to deliver flash read data with zero-wait state response on lines that reside in the cache. AHB requests that miss the cache generate the needed flash array access and are forwarded to the AHB upon completion. Each mini-cache entry is 256 bits in size, matching the flash array page size and providing 256 bytes of total buffered storage. Along with the read and write data, the corresponding ECC codewords traverse the entire datapath of the flash memory controller, including the mini-cache, to support end-to-end ECC (e2eECC) coverage.

71.3 Features

The following list summarizes the key features of the flash memory controller:

- Three 64-bit AHB interface (p0, p1, p2) allowing simultaneous access to dedicated prefetch mini-cache per slave port.
- 256-bit read data bus + 64-bit write data bus
- Configurable read buffering and line prefetching support via 4-entry, 2-way set-associative mini-cache plus prefetch controller per AHB port to provide single-cycle "buffer hit" read response.
- Configurable access control based on read/write and AHB master ID attributes.
- Configurable access timing (wait-state programmable) allowing use in a wide range of frequency targets.
- Optional address pipelining capability to maximize throughput.
- Support for reporting of single- and multi-bit flash ECC events on a 64-bit doubleword boundary.
- Configurable overlay remapping of logical flash accesses to on-chip system RAM, on-chip flash memory

71.4 Block diagrams

Figure 71-1 illustrates the connections of the flash memory controller and flash memory array within the chip.

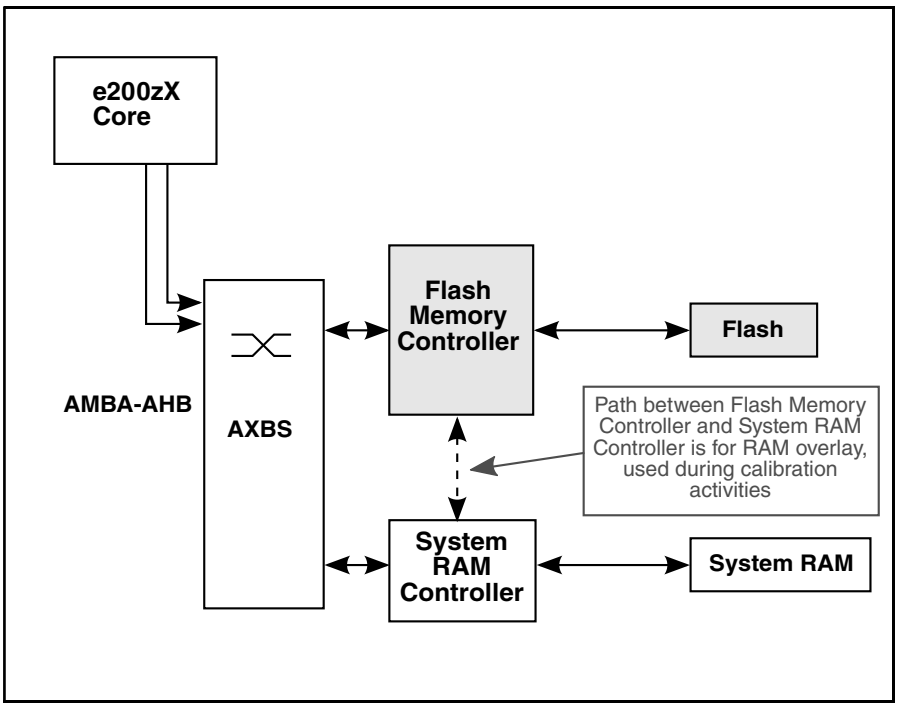

Figure 71-1. Platform-centric simple block diagram with flash memory controller

71.5 Flash memory controller memory map

The flash memory controller module provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot. The programming model consists of flash memory access configuration and overlay remapping configuration.

The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses or in user mode generates an IPS error termination. The flash controller allows access to the programming model by all system bus masters.

The programming model can only be accessed in supervisor mode.

A write to any flash memory controller register, when executed concurrently with a flash memory access, will result in non-deterministic behavior and may include lockup of the flash memory controller. There is no idle indicator for the flash controller, so software must be architected to prevent any possible conflicts. The following recommendations will help.

- For multi-core devices, start only one core and execute initialization code to completion before starting the remaining cores.

- If flash must be reconfigured during application code execution, temporarily move all required code and data to system RAM before any writes to flash memory controller registers.
- If application software functionality includes invalidating a port read buffer, the recommended method for invalidating a port read buffer is:
  a. Unlock the buffer's enable field by setting the PFLASH_PFCR3[BFEN_LK] field to '0'
  b. Disable the buffer by setting it's associated enable field (PFLASH_PFCR1[Pn_BFEN]) to '0'
  c. If needed, enable the buffer by setting it's associated enable field (PFLASH_PFCR1[Pn_BFEN]) to '1'

The above method requires updating flash memory controller registers, so software must ensure that no flash accesses are issued concurrently with any of the steps. In cases where that cannot be guaranteed, there is a workaround but its use is not generally recommended because it relies on a hardware side effect instead of the flash memory controller's built-in functions intended for invalidating port read buffers. The workaround is to issue an interlock write without an accompanying program or erase operation—an interlock write, without an accompanying program or erase, does not change any flash content.

NOTE

1. If this workaround is implemented in application code, note that an interlock write invalidates only the buffers associated with the system bus port on which the interlock write was issued.
2. See the flash memory chapter for the steps to issue an interlock write.
3. See the flash memory controller's chip-specific information for any restrictions on the interlock write data size.

PFLASH_PFCR1 field descriptions (continued)

Field	Description
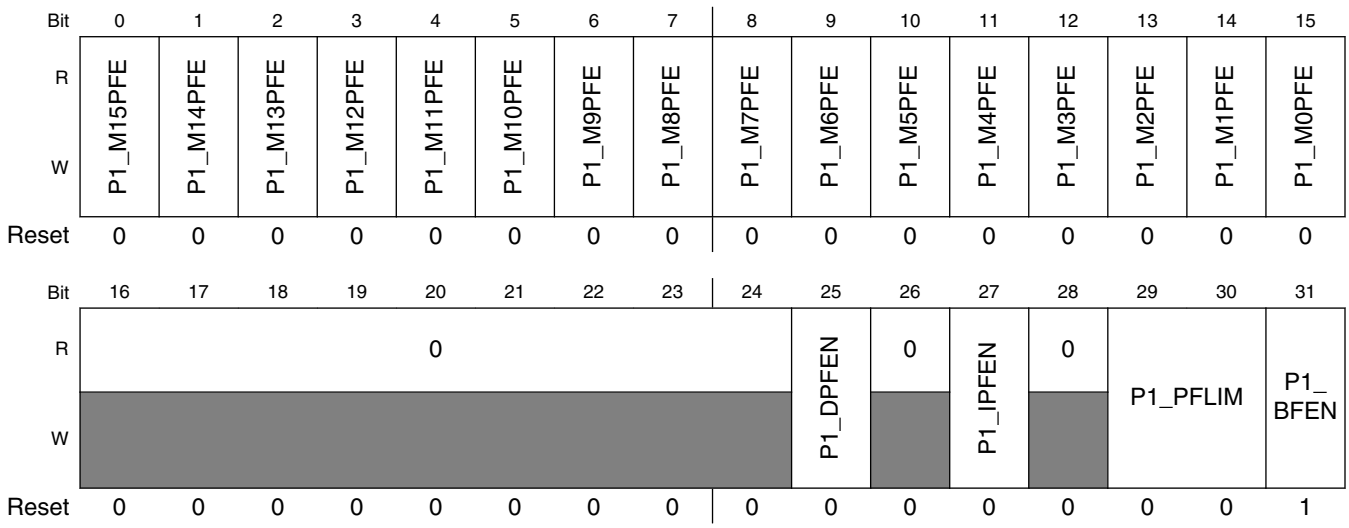
12 P0_M3PFE	Port0 Master 3 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 3. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
13 P0_M2PFE	Port0 Master 2 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 2. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
14 P0_M1PFE	Port0 Master 1 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 1. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
15 P0_M0PFE	Port0 Master 0 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 0. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
16–18 APC	Address Pipeline Control. This field controls the number of cycles that a subsequent flash read from the opposite AHB port can be initiated prior to the previous read data being valid. This field applies to the configuration of Port0 and Port1. For valid RWSC and APC combinations please refer to the device data sheet. **NOTE:** 1. A value of '1' in the most significant bit causes the flash controller to function in retrograde/ legacy mode, in which there is no pipelining between the sampling of flash read data and the presentation of the next address for flash lookup. 2. Flash operation is not guaranteed for RWSC/APC combinations other than those specified in the data sheet. 000 Pipelined access to the flash disabled. 001 A pipelined access can be initiated 1 cycle before the previous data is valid 010 A pipelined access can be initiated 2 cycles before the previous data is valid 011 A pipelined access can be initiated 3 cycles before the previous data is valid 1xx Pipelined access to the flash is disabled and one wait state is inserted before a subsequent access can be initiated
19–23 RWSC	Read Wait State Control. This field controls the number of wait-states to be added to the best-case flash array access time for reads. The best-case flash array access time for reads is one cycle. This field must be set to a value corresponding to the operating frequency of the flash memory controller and the actual read access time of the flash memory controller. For valid RWSC and APC combinations please refer to the device data sheet. **NOTE:** 1. Higher operating frequencies require non-zero settings for this field for proper flash operation. 2. Flash operation is not guaranteed for RWSC/APC combinations other than those specified in the device data sheet. This field applies to the configuration of Port0, Port1, and Port2. 00000 No additional wait-states are added 00001 One additional wait-state is added ... 11111 Thirty-one additional wait-states are added

Table continues on the next page...

PFLASH_PFCR1 field descriptions (continued)

Field	Description
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 P0_DPFEN	Port0 Data Prefetch Enable. This field enables or disables prefetching initiated by a data read access. 0 No prefetching is triggered by a data read access 1 Prefetching may be triggered by any data read access
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 P0_IPFEN	Port0 Instruction Prefetch Enable. This bit enables or disables prefetching initiated by an instruction read access. 0 No prefetching is triggered by an instruction read access 1 Prefetching may be triggered by any instruction read access
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 P0_PFLIM	Port0 PFlash Prefetch Limit. This field controls the prefetch algorithm used by the prefetch controller. This field defines a limit on the maximum number of sequential prefetches which will be attempted between buffer misses. In all situations when enabled, only a single prefetch is initiated on each buffer miss or hit. 00 No prefetching or buffering is performed. 01 The referenced line is prefetched on a buffer miss, that is, prefetch on miss. 10 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit. 11 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit.
31 P0_BFEN	Port0 PFlash Line Read Buffers Enable. This bit enables or disables line read buffer hits. It is also used to invalidate the buffers. This bit can only be updated while PFCR3[BAF_DIS]=0. After execution of the boot code, as indicated by PFCR3[BAF_DIS]=1, this bit becomes read-only until the next hardware reset. 0 The line read buffers are disabled from satisfying read requests, and all buffer valid bits are cleared. 1 The line read buffers are enabled to satisfy read requests on hits. Buffer valid bits may be set when the buffers are successfully filled.



71.5.2 Platform Flash Configuration Register 2 (PFLASH_PFCR2)

The PFlash Configuration Register 2 (PFCR2) controls the operation of Port1 of the PFLASH_C55FM flash memory controller.

NOTE

See the chip-specific platform flash controller information for details about the masters.

Address: 0h base + 4h offset = 4h

31 P1_BFEN	Port1 PFlash Line Read Buffers Enable. This bit enables or disables line read buffer hits. It is also used to invalidate the buffers. This bit can only be updated while PFCR3[BAF_DIS]=0. After execution of the boot code, as indicated by PFCR3[BAF_DIS] = 1, this bit becomes read-only until the next hardware reset. 0 The line read buffers are disabled from satisfying read requests, and all buffer valid bits are cleared. 1 The line read buffers are enabled to satisfy read requests on hits. Buffer valid bits may be set when the buffers are successfully filled.

71.5.3 Platform Flash Configuration Register 3 (PFLASH_PFCR3)

Address: 0h base + 8h offset = 8h

PFLASH_PFCR3 field descriptions

Field	Description
0–1 P0_WCFG	Port0 Way Configuration. This field controls the configuration of the line buffers for a given set across two ways in the controller cache. The indexed set can be organized as a "pool" of available resources, or with a fixed partition between instruction and data buffers.

Table continues on the next page...

PFLASH_PFCR3 field descriptions (continued)

Field	Description
	In all cases, when a buffer miss occurs, the flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 Both buffers in an indexed set are available for any flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved 10 The buffers in an indexed set are partitioned into two groups with way 0 allocated for instruction fetches and way 1 for data accesses. 11 Reserved
2–3 P1_WCFG	Port1 Way Configuration. This field controls the configuration of the line buffers for a given set across two ways in the controller cache. The indexed set can be organized as a "pool" of available resources, or with a fixed partition between instruction and data buffers. In all cases, when a buffer miss occurs, the flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 Both buffers are available for any flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved 10 The buffers are partitioned into two groups with way 0 allocated for instruction fetches and way 1 for data accesses. 11 Reserved
4–5 P2_WCFG	Port2 Line Buffer Configuration. This field controls the configuration of the line buffers for a given set across both ways in the controller cache. The indexed set can be organized as a “pool” of available resources, or with a fixed partition between instruction and data buffers. In all cases, when a buffer miss occurs, the flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. 6–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 Reserved	This field is reserved.
12–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PFLASH_PFCR3 field descriptions (continued)

Field	Description
15 BAF_DIS	BAF Disable. This field controls executable access to the BAF (Boot Assist Flash) region of the flash. Once this field is set, attempted instruction accesses targeting the BAF region are aborted and terminated with a system bus error. The affect of this field applies to system bus transfers through both, Port0 and Port1. Data-type accesses to the BAF region are not affected by this field. Once this field is set, it becomes a read-only field and can only be cleared by hardware reset. Once this field is set, any subsequent write attempts to modify this field are ignored with an error-free data transfer termination. This field is initialized by hardware reset. 0 Executable access to the BAF flash region is allowed. 1 Executable access to the BAF flash region is prohibited.
16–19 ARBM	Arbitration Mode. This 4-bit field controls the arbitration of concurrent flash access requests from the three AHB ports of the flash memory controller. In both fixed priority or round-robin modes, write requests are prioritized higher than read requests, and read requests are prioritized higher than speculative prefetch requests whenever multiple ports issue concurrent requests. This field is initialized by hardware reset. **NOTE:** Specifying a reserved value in this field causes it to default to round-robin arbitration. 0000 Fixed priority arbitration with AHB p0>p1>p2 0001 Fixed priority arbitration with AHB p0>p2>p1 0010 Fixed priority arbitration with AHB p2>p0>p1 0011 Fixed priority arbitration with AHB p2>p1>p0 0100 Fixed priority arbitration with AHB p1>p0>p2 0101 Fixed priority arbitration with AHB p1>p2>p0 0110 Reserved 0111 Reserved 1000 Reserved 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Round-robin arbitration
20–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

71.5.4 Platform Flash Access Protection Register (PFLASH_PFAPR)

The PFlash Access Protection Register (PFAPR) is used to control read and write accesses to the flash array.

NOTE

See the chip-specific platform flash controller information for details about the actual masters available on the device.

Field	Description
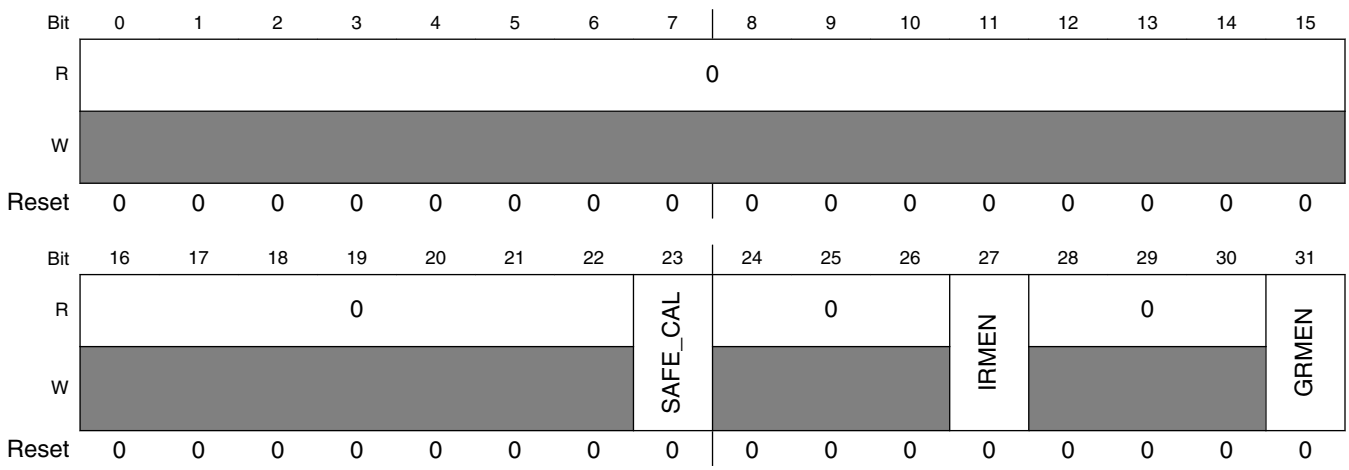
24–25 M12AP	Master 12 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
26–27 M13AP	Master 13 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
28–29 M14AP	Master 14 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
30–31 M15AP	Master 15 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master

71.5.5 Platform Flash Remap Control Register (PFLASH_PFCRCR)

The PFCRCR is used to globally enable/disable the calibration remap function.



CAUTION

Overlay remap functions, when used with line read buffers enabled (PFLASH_PFCRx[BFy_EN] field(s)='1') have a potential to cause data coherency issues, i.e., prefetched data in a line read buffer can become out-of-sync with data contained at the associated flash address range. To prevent this issue, always clear the flash controller line read buffers prior to enabling any remap region.

To clear the flash controller line read buffers, issue an interlock write command to a valid flash memory address. There will not be an actual flash program operation performed, but the flash controller mini-cache will be cleared as a side effect of executing the command. The interlock write must be issued from a core having appropriate access to flash. The sequence is as follows:

1. Set the C55FMC_MCR[PGM] field to '1'
2. Issue a 64-bit write to a valid flash address on a 64-bit boundary, i.e., the least significant 5 bits of the address are '0'
3. Clear C55FMC_MCR[PGM]

Address: 0h base + 10h offset = 10h

PFLASH_PFCRCR field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 SAFE_CAL	Safe Calibration. This bit facilitates the use of safety-critical calibration data. When this bit is enabled, the flash memory controller is configured to perform redundancy checking on the calibration remap function and reduce the total number of potential calibration regions from 16 to 8. This field is initialized by hardware reset. 1 Established calibration overlay regions are considered safety-critical. 0 Established calibration overlay regions are not considered safety-critical.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 IRMEN	Instruction Remap. This bit enables calibration remapping evaluation on instruction fetches. When PFCRCR[GRMEN] is disabled, this bit is ignored. This field is initialized by hardware reset.

Table continues on the next page...

PFLASH_PFCRCR field descriptions (continued)

Field	Description
	0 Calibration remap evaluation is performed on any incoming data fetch requests only. 1 Calibration remap evaluation is performed on all incoming flash access requests - data and instruction fetches.
28–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 GRMEN	Global Remap Enable. This bit globally enables or disables the calibration remapping evaluation on system flash accesses. This field is initialized by hardware reset. 0 Calibration remap evaluation is not performed on any incoming system flash access requests. 1 Calibration remap evaluation is performed on all incoming system flash access requests.

71.5.6 Platform Flash Remap Descriptor Enable Register (PFLASH_PFCRDE)

The PFlash Calibration Remap Descriptor Enable Register (PFCRDE) is used to enable or disable up to 16 calibration remap descriptors. Note there is also a global remap enable (PFCRCR[GRMEN]) that also must be asserted in conjunction with the individual CRDnEN flags to enable a given remap descriptor.

PFLASH_PFCR4 field descriptions (continued)

Field	Description
11 P2_M4PFE	Port2 Master 4 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 4. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
12 P2_M3PFE	Port2 Master 3 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 3. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
13 P2_M2PFE	Port2 Master 2 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 2. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
14 P2_M1PFE	Port2 Master 1 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 1. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
15 P2_M0PFE	Port2 Master 0 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 0. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
16–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 P2_DPFEN	Port2 Data Prefetch Enable. This field enables or disables prefetching initiated by a data read access. 0 No prefetching is triggered by a data read access 1 Prefetching may be triggered by any data read access
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 P2_IPFEN	Port2 Instruction Prefetch Enable. This bit enables or disables prefetching initiated by an instruction read access. 0 No prefetching is triggered by an instruction read access 1 Prefetching may be triggered by any instruction read access
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 P2_PFLIM	Port2 PFlash Prefetch Limit. This field controls the prefetch algorithm used by the prefetch controller. This field defines a limit on the maximum number of sequential prefetches which will be attempted between buffer misses. In all situations when enabled, only a single prefetch is initiated on each buffer miss or hit. 00 No prefetching or buffering is performed. 01 The referenced line is prefetched on a buffer miss, that is, prefetch on miss. 10 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit. 11 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit
31 P2_BFEN	PFlash Line Read Buffers Enable. This bit enables or disables line read buffer hits. It is also used to invalidate the buffers. This bit can only be updated while PFCR3[BAF_DIS]=0. After execution of the boot code, as indicated by PFCR3[BAF_DIS] = 1, this bit becomes read-only until the next hardware reset.

Table continues on the next page...

PFLASH_PFCR4 field descriptions (continued)

Field	Description
	0 The line read buffers are disabled from satisfying read requests, and all buffer valid bits are cleared. 1 The line read buffers are enabled to satisfy read requests on hits. Buffer valid bits may be set when the buffers are successfully filled.

71.5.8 Platform Flash Calibration Region Descriptor n Word0 (PFLASH_PFCRD*n*_Word0)

Each 96-bit (12-byte) region descriptor specifies an overlay region where a flash access can be remapped during calibration and debug. The calibration remap descriptors are organized sequentially as 128-bit (16-byte) structures in the Platform Flash Controller's programming model. Each of the three 32-bit words that define a single calibration region are detailed in the subsequent sections; the fourth word is unused.

The first word of the flash memory controller overlay region descriptor defines the 0-modulo-size logical start (byte) address of the calibration remap region. It is software's responsibility to guarantee the low-order bits of the address, as defined by the remap descriptor size, are zeroed to enable the remap descriptor hit logic to function correctly.

The hardware performs basic checks on the validity of the logical start address when this word is written; if a non-supported logical start address is defined, the register write is terminated with an error and the register left unchanged and the valid bit cleared. Successful writes to this word also clear the calibration remap descriptor's valid bit.

Address: 0h base + 100h offset + (16d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PFLASH_PFCRD*n*_Word0 field descriptions

Field	Description
0–27 LSTARTADDR	Logical Start Address. This field defines the most significant bits of the 0-modulo-size logical start address of the overlay remap region. It corresponds to the logical system address which maps to the flash memory space. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid.
28–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

71.5.9 Platform Flash Calibration Region Descriptor n Word1 (PFLASH_PFCRD*n*_Word1)

The second word of the flash memory controller calibration region descriptor defines the 0-modulo-size byte physical start (byte) address of the calibration remap region.

The contents of this word define the targeted destination overlay memory. It is software's responsibility to guarantee the low-order bits of the address, as defined by the remap descriptor size, are zeroed to enable the remap descriptor hit logic to function correctly.

Attempted writes to this register with illegal values, as defined by the sizes and locations of the overlay memories, are terminated with an error and clear the valid bit. Successful writes to this word also clear the calibration remap descriptor's valid bit.

Address: 0h base + 104h offset + (16d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

71.6 Functional description

The flash memory controller interfaces between:

- The AHB system bus ports
- Flash memory array
- System RAM

For accesses targeting the flash array, the flash memory controller generates read and write enables, block selects, array address, write size and write data as inputs to the flash array. The flash memory controller captures read data from the flash array and drives it onto the AHB system bus. Up to four pages of data (256-bit page size) may be buffered in each of two ways of the flash memory controller mini-cache. Lines may be prefetched in advance of being requested, allowing single-cycle (zero AHB wait-states) read data responses on buffer hits.

Several prefetch control algorithms are available for controlling line read buffer fills. Prefetch triggering may be restricted to instruction accesses only, data accesses only, or may be unrestricted. Prefetch triggering may also be controlled on a per-master basis.

Buffers may also be selectively enabled or disabled for allocation by instruction and data prefetch.

Access protections may be applied on a per-master basis for both reads and writes to support security and privilege mechanisms.

71.6.1 Basic interface protocol

Read accesses are terminated under control of the appropriate wait state settings. Thus, the access time of the operation is determined by the setting of the PFCR1[RWSC] field. Access timing can be varied to account for the operating conditions of the SoC (frequency, voltage, temp) by appropriately setting the PFCR1[RWSC] field.

71.6.2 Access protections

On-chip Flash memory accesses are subject to restrictions based on chip security implementation and/or requirements based on functional restrictions of the flash memory, e.g., a read access to a flash block while it is currently being written is not allowed. When a prohibited access is attempted, a system bus error termination results.

The flash memory controller may invoke a system bus error termination in the following scenarios:

- Attempted access by an AHB master whose corresponding read access control or write access control settings do not allow the access, thus causing a protection violation. See Platform Flash Access Protection Register (PFLASH_PFAPR) for more detail. In this case the flash memory controller does not initiate the requested flash array access.
- Attempted instruction fetch by an AHB master to the BAF flash region when the PFCR3[BAF_DISABLE] field in Platform Flash Configuration Register 3 (PFCR3) is set. The assertion of PFCR3[BAF_DISABLE] indicates that code stored in the BAF region should not be executed. See Platform Flash Configuration Register 3 (PFLASH_PFCR3) for more detail. In this case, the flash memory controller does not initiate a flash array access.
- Attempted access by an AHB master to a flash region where the corresponding censorship control is asserted.
- The flash returns an error response on an attempted access to a partition that is unavailable. (see Flash error response operation or Embedded Flash Memory).
- Attempted access by an AHB master to a reserved region in the flash memory map.

The flash array may also signal an error response to terminate a requested access due to improper sequencing during program/erase operations, improper sequencing during array integrity testing. When an error response is received the flash memory controller does not

update or validate a page read buffer. An error response may be signaled on a read or interlock write operation. For more information on the specifics related to signaling of flash errors, including flash ECC events, array integrity testing and read-while-write events, refer to the flash memory chapter.

71.6.2.1 Censorship

The flash space is defined by regions:

- Code flash (instruction and constant data)
- Data flash (data for EEPROM emulation)
- Secure code flash (instruction for security module)
- Secure data flash (data for security module)
- UTEST flash
- Security flash blocks

Each section can be independently censored, and the flash memory controller provides independent censorship control inputs for each region on a read vs. write basis.

71.6.2.2 PFAPR - Platform Flash Access Protection Register (PFAPR)

The flash memory controller provides programmable, configurable access protections for both read and write cycles on a per-master basis via the PFlash Access Protection Register (PFAPR). It allows restriction of read and write requests on a per-master basis. This functionality is described in Platform Flash Access Protection Register (PFLASH_PFAPR). Detection of a protection violation results in an error response from the flash memory controller on the AHB transfer.

71.6.2.3 BAF execution disable

The flash memory controller provides a mechanism to disable instruction execution of the BAF (Boot Assist Flash) code. Setting the BAF Disable field (BAF_DIS) in the PFlash Configuration Register 3 (PFCR3) prevents execution of the BAF instructions. When this field is set, all incoming requests from the system bus on Port0, Port1, or Port2 are evaluated. If the flash memory controller detects an attempted instruction fetch access to the BAF region of the flash, the flash memory controller aborts the access and returns a system bus error. Data accesses to the BAF region are not affected by the state of PFCR3[BAF_DIS].

71.6.3 Security module exclusive control

During "Production at OEM" lifecycle state and beyond, the HSM can establish the secure flash blocks to be exclusive to the HSM and route program or erasing of secure flash blocks to the alternate programming interface.

The secure flash space is independently controlled for each of the following regions:

- 64 KB secure code flash blockA at address range 0x0061_0000 - 0x0061_FFFF
- 64 KB secure code flash blockB at address range 0x0062_0000 - 0x0062_FFFF
- Two 16 KB secure data flash blocks at address range 0x00F8_0000 - 0x00F8_7FFF

The HSM provides flags to individually control the HSM-exclusivity for each of the secure flash regions. When a given secure flash block is marked as exclusive to the HSM, the HSM is the only system bus master granted access to that block and access attempts by non-HSM masters are terminated with error. Once HSM-exclusivity is established for a given secure flash block, the HSM is guaranteed access to that block, regardless of the state of the censorship controls. Secure flash exclusivity applies to read and write accesses.

71.6.4 Security Module Alternate Programming Interface

The secure flash space is independently controlled for each of the following regions:

- 64 KB secure code flash block2 at address range 0x0061_0000 - 0x0061_FFFF
- 64 KB secure code flash block3 at address range 0x0062_0000 - 0x0062_FFFF
- Two 16 KB secure data flash blocks at address range 0x00F8_0000 - 0x00F8_7FFF

The HSM provides flags to individually control the routing interlock write for each of the four secure flash regions to either the main program/erase interface or the alternate program/erase interface. When a given secure flash block is assigned to the alternate program interface, the flash controller appropriately routes incoming interlock write requests within the given secure flash block address range to the flash's alternate program interface. Alternate program control can be controlled independent of HSM exclusivity for a given secure flash block

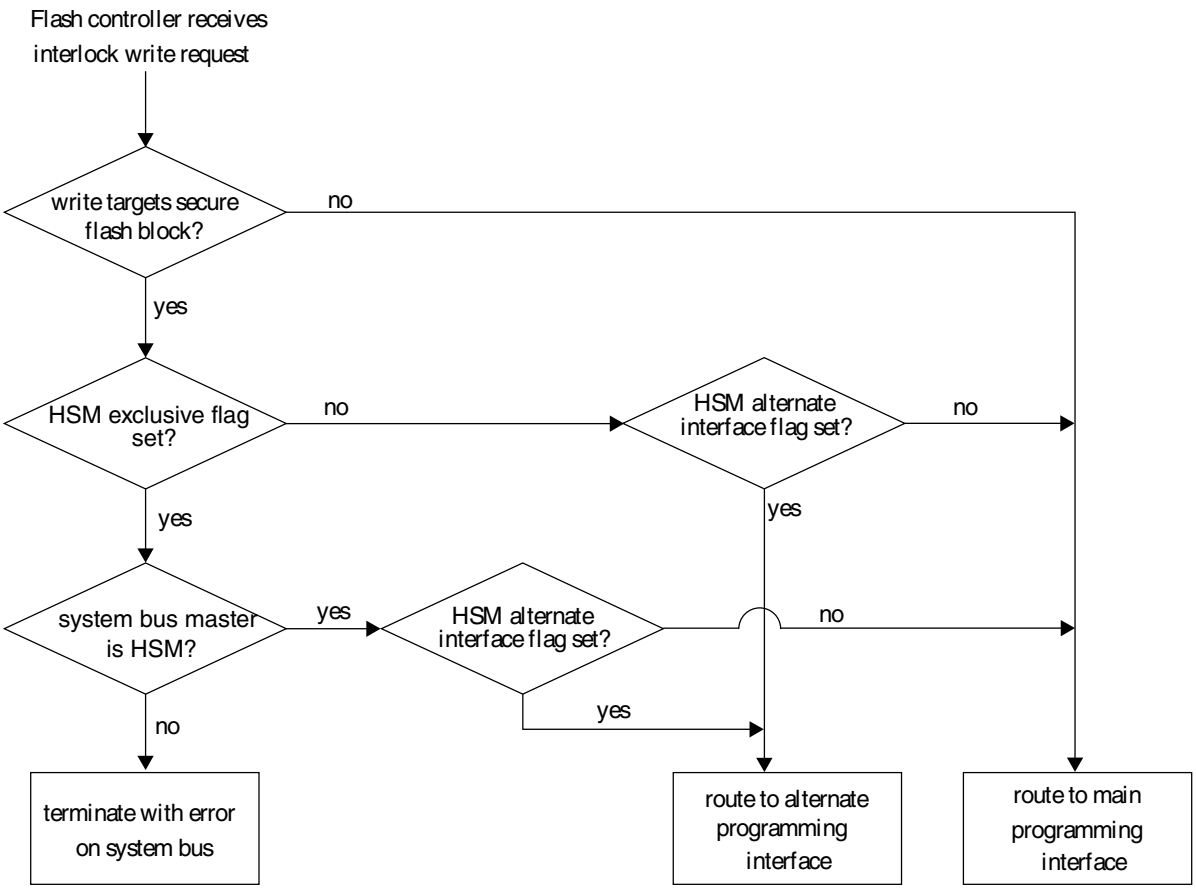

Figure 71-2. Interlock Write Alternate Programming Interface Routing Flowchart

71.6.5 Access pipelining

Accesses to the flash array may be pipelined by driving a subsequent access address and control signals while waiting for the current access to complete. Pipelined access requests are always run to completion and are not aborted by the flash memory controller. Flash access pipelining allows for improved performance by reducing the access latency seen by the AHB master. Access pipelining may be applied only to read cycles targeting the flash array. Address pipelining is enabled by setting the PFCR1[APC] field.

Access pipelining is only supported for normal flash access and is not supported for calibration overlay RAM fetches. On calibration reads, the setting of PFCR1[APC] is ignored.

NOTE

Not all combinations of PFCR1[APC] (Address Pipeline Control) and PFCR1[RWSC] (Read Wait State Control) settings are recommended or supported. Please refer to the device data sheet for guidance.

71.6.6 Line read buffers and prefetch operation

The AHB ports of the flash memory controller each contain a two-way set-associative mini cache, where each way contains four page buffers which are used to hold data read from the flash arrays. Each 256-bit buffer operates independently, and is filled using a single array access. The buffers are used for both prefetch and normal demand fetches.

Prefetch triggering is controllable on a per-master and access-type basis (see Platform Flash Configuration Register 1 (PFLASH_PFCR1)). Bus masters may be enabled or disabled from triggering prefetches, and triggering may be further restricted based on whether a read access is for instruction or data. A read access by the flash memory controller may trigger a prefetch to the next sequential line of array data on the cycle following the request. The access address is incremented by 32-bytes, and a subsequent flash access is initiated. A flash array prefetch is initiated if the data is not already resident in a line read buffer. Prefetched data is always loaded into the least-recently-used buffer.

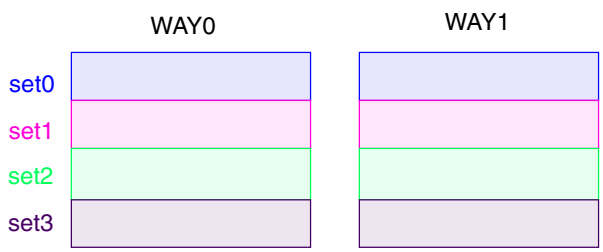

Figure 71-3. Flash memory controller 4-entry, 2-way mini-cache organization

Once the candidate line buffer has been selected, the flash array is accessed and read data loaded into the buffer. If the buffer load was in response to a miss, the buffer which was loaded is immediately marked as most-recently-used. If the buffer load was in response to a speculative fetch to the next-sequential line address after a buffer hit, *the recently-used status is not changed*. Rather, it is marked as most-recently-used only after a subsequent buffer hit.

This policy maximizes performance based on reference patterns of flash accesses and allows for prefetched data to remain valid when non-prefetch enabled bus masters are granted flash access.

Several algorithms are available for prefetch control which trade off performance for power. They are described in Platform Flash Configuration Register 1 (PFLASH_PFCR1). More aggressive prefetching may increase power due to the number of potentially discarded prefetches, but may increase performance by lowering average read latency.

For prefetching to occur, all of the following must apply:

1. PFCR{1,2,4}[P{0,1,2}_BFEN] must be set to '1',
2. PFCR{1,2,4}[P{0,1,2}_PFLIM] must be non-zero, and
3. Either PFCR{1,2,4}[P{0,1,2}_IPFEN] or PFCR{1,2,4}[P{0,1,2}_DPFEN] must be asserted.

Refer to Platform Flash Configuration Register 1 (PFLASH_PFCR1) for a description of these controls.

71.6.7 Instruction/Data prefetch triggering

Port0 prefetch triggering may be enabled for instruction reads via the PFCR1[IPFEN] control field, while Port0 prefetching for data reads is enabled via the PFCR1[DPFEN] control field. Additionally, the PFCR1[PFLIM] must also be set to enable prefetching on Port0. Refer to Platform Flash Configuration Register 1 (PFLASH_PFCR1) for a description of these controls. Prefetches are never triggered by write cycles.

Port1 prefetch triggering may be enabled for instruction reads via the PFCR2[IPFEN] control field, while Port1 prefetching for data reads is enabled via the PFCR2[DPFEN] control field. Additionally, the PFCR2[PFLIM] must also be set to enable prefetching on Port1. Refer to Platform Flash Configuration Register 2 (PFLASH_PFCR2) for a description of these controls. Prefetches are never triggered by write cycles.

Port2 prefetch triggering may be enabled for instruction reads via the PFCR4[IPFEN] control field, while Port2 prefetching for data reads is enabled via the PFCR4[DPFEN] control field. Additionally, the PFCR4[PFLIM] must also be set to enable prefetching on Port2. Refer to the Platform Flash Configuration Register 4 (PFCR4) section for a description of these controls. Prefetches are never triggered by write cycles.

71.6.8 Per-Master prefetch triggering

Prefetch triggering may be controlled for individual bus masters. Refer to Platform Flash Configuration Register 1 (PFLASH_PFCR1) for a description of these controls.

71.6.9 Buffer allocation

Allocation of the line read buffers is controlled via the PFCR3 control register, specifically the line buffer configuration ({P0,P1,P2}_WCFG) field. Refer to Platform Flash Configuration Register 3 (PFLASH_PFCR3). The buffers can be organized as a

"pool" of available resources (with both ways within a given set) or with a fixed partition between ways allocated to instruction or data accesses. For the fixed partitions, way 0 is allocated for instruction fetches and way 1 for data accesses.

71.6.10 PFlash calibration remap support

The flash memory controller supports calibration development by providing a remapping function to route flash accesses to on-chip System RAM that can be used as overlay RAM.

Additionally, support is provided to reroute flash accesses to other on-chip flash memory addresses.

The overlay function supports the following features:

- Can be mapped over internal flash memory
  - Allows calibration of constant data without requirement for additional external RAMs and calibration memory interfaces
- Protected with error detection and correction mechanism
- Accesses to all overlay RAMs can achieve the same timing as accesses to internal flash
  - Timing for calibration accesses to overlay RAM is only guaranteed if RWSC is set sufficiently high to cover the intrinsic burst access incurred when fetching a full page of calibration data
- Support for up to 32 distinct calibration remap regions.
- Protection against accidental enable and reconfiguration of calibration remap function :
  - Two stage mechanism to enable remap, using both global and individual calibration region descriptor enable bits
  - Optional configuration of calibration region descriptors as redundant pairs, allowing detection of accidental region reconfiguration.
- Support for overlay remapping to unique calibration regions on a per-master basis.

The calibration remap function supports the following overlay targets:

- A portion of the system RAM can be used for overlay.
- Addresses within any non-dedicated block of on-chip flash memory. Secure flash, UTEST flash, and BAF cannot be used as overlay targets.

71.6.10.1 PFlash calibration remap to RAM

The overlay RAM is selected based on the translated physical address.

The translated physical address defines the destination memory. Table 71-1 shows the base addresses for the calibration data memories as defined by the system memory map.

Table 71-1. Calibration data memory base addresses

Calibration Memory	Base Address	Possible Access Sources
Flash Arrays	0x0{8,9,A}--_----	P0, P1
System RAM	0x40{0,1}-_----	P0, P1

The system RAM connection from the calibration remap logic is implemented via a private 64-bit connection to the platform RAM controller.

Accesses to the flash arrays always use the logical, non-remapped system address. Calibration data store references to the system RAM always use the physical, non-remapped system address. Conversely, calibration data load references can be accessed using a translated physical address or, if provided by the requesting master, the physical, non-remapped system address.

The read data interface of system RAM is 64 bits wide , whereas the flash read data interface is 256 bits wide. As a result, a remapped calibration load access initiates a four-beat burst sequence to mimic the throughput of a single flash access. There is a direct relationship between the operating frequency range and the required number of wait states to correctly sample flash read data. By contrast, a remapped calibration load access has a fixed, intrinsic 4-beat latency. Therefore, in order for an initial, random calibration load access to mimic the flash access time, PFCR1[RWSC] read wait state setting must be programmed to a value which sufficiently covers the intrinsic access time to complete a four-beat burst sequence from the slowest available overlay target at the specified device operating frequency. Expressed mathematically:

$$(\mathrm{RWSC}+2) \geq \left(\frac{\mathrm{IntrinsicFlashAccessTime}}{\mathrm{OperatingFrequencyClockPeriod}}+2\right) \geq (\mathrm{OverlayRAMTransferBurstLatency})$$

Equation 45. Access time

Notice the overall latency on a random, initial flash access that does not hit in the prefetch mini-buffer incurs an additional cycle latency beyond the intrinsic flash access time. This cycle accounts for pipeline stalls incurred by the flash controller state machine. The formula above is based on specified intrinsic flash access times of the C55FMC array at 150 °C. Calibration data that is loaded in the flash controller's mini-cache is returned with single-cycle latency.

The memory-mapped calibration remap (region) descriptor (CRD*n*) registers define the required address translation. Each calibration remap descriptor includes the logical base address, the translated physical base address and a region size (plus other control bits). The calibration remap evaluation is initiated when the flash controller is presented with a

flash access request from any system bus master to a location in the mirrored flash address space. Conversely, references using the associated non-mirrored flash system address are not evaluated for calibration remapping.

The address translation mechanism requires the logical and physical base addresses of the region be aligned on 0-modulo-size boundaries.

The region size is decoded to create the appropriate address bit enables which are then applied to the registered logical flash address. An equality comparator then compares the adjusted logical flash address against the logical address from the calibration remap descriptor to determine the region "hit". The hit determination is further qualified based on the bus master number that initiated the flash access. At the same time, the logical flash address and the physical address defined in the calibration remap descriptor are merged to form the translated address to be used in the event of a calibration region hit. Aside from the individual instantiations of the calibration remap descriptors, this logic examines all the descriptor hit indicators to select the appropriate translated address.

In the absence of a region "hit" data is returned from the flash at the provided logical address.

It should be noted in the event of *overlapping remap regions*, the calibration remap descriptor with the largest number is used for the address translation, that is, if a logical flash address hits in multiple descriptors, say CRDx and CRDy, the translated address from CRDy is used, given y > x.

In general, the calibration remap logic operates only on flash *data* accesses. However, flash instruction references can optionally remapped while in debug modes of operation to support the use of software breakpoints when PFCRC[IRMEN] is set.

71.6.10.2 PFlash calibration remap to flash memory

Calibration remapping of a flash access to another on-chip flash address uses the same mechanism and controls as remapping to RAM addresses. The following should be noted:

- UTEST flash, BAF, and secure flash blocks cannot be remapped nor can accesses to other flash blocks be rerouted to addresses in UTEST flash, BAF, or secure flash
- All other flash blocks can be overlaid using the *mirrored* address range[1].

1. A *mirror* address for an address within a flash block is calculated by setting bit 27 (where the least significant bit of the address field is numbered 0).

71.6.11 Reliability considerations

This section summarizes mechanism to enhance the reliability of flash by correcting and detecting faults.

71.6.11.1 e2eECC End-to-End ECC

71.6.11.1.1 e2eECC and flash accesses

There are multiple complications associated with the use of the standard e2eECC algorithm with flash memory. The basic issues involve: the default state of a flash block that is erased (all ones) and the fact that programming an erased flash involves changing the state of memory bit from a logical 1 to a logical 0. These factors require that the system level e2eECC must be modified on references to the flash memory in three ways.

First, the all-ones codeword, since it reflects the state of an erased flash location, is treated as a valid error free encoding; in particular, it is required that the checkbits associated with the all all-ones value and the all zeroes data value are required to be the same with a checkbit value of 0xFF. Second, since an erased flash block generates an all-ones data for all locations, the address field cannot be included in the ECC code used by the flash. The flash array implements special address re-encoding logic based on the decoded array address to protect against address faults. Third, there are additional ECC implications associated with the flash memory and its support for EEPROM emulation. Lastly, there are ECC implications associated with the storage and retrieval of overlaid calibration data.

In summary, the basic operation of an NVM bit cell impacts the e2eECC algorithm used in the flash memory in multiple ways. The required ECC adjustments are handled by the platform flash controller before data is written to the flash array(s) or applied to read data accessed from the array(s). These adjustments are two-fold. Consider a flash write during a programming event:

1. Remove the address field from the ECC codeword by XOR'ing the address calculation of the H-matrix from the checkbits.
2. Invert the resulting 8-bit ECC checkbit vector. This step is required to support the all-ones erased state.

On a flash read operation, a similar but "reversed" set of steps are performed as the data is driven into the system bus interconnect:

1. Invert the 8-bit ECC checkbit vector read from the flash.
2. Factor the address field into the ECC checkbits by XOR'ing the address calculation of the H-matrix.

Consider the following flash ECC example. Let the flash block containing address 0x00345678 be erased. The following is the sequence of operations:

1. Read address 0x00345678. Flash array returns fl_rdata = 0xFFFFFFFF_FFFFFFFF, fl_cdata = 0xFF. The flash memory controller calculates the addr_chkbit = 0xC4 using the H-matrix; it inverts the fl_cdata vector to 0x00 and factors in the addr_chkbit = 0xC4 to produce the following valid e2eECC codeword:

   addr = 0x00345678, rdata = 0xFFFFFFFF_FFFFFFFF, rchkbit = 0xC4 (0x00 ^ 0xC4)

2. Program address 0x00345678 with data = 0xBABEFACE_DEADBEEF. The initiating bus master calculates the e2eECC codeword as:

   addr = 0x00345678, wdata = 0xBABEFACE_DEADBEEF, wchkbit = 0xE3

   Before performing the interlock write to the flash array, the flash memory controller adjusts the chkbit value as fl_wchkbit = 0xD8 (0xE3 ^ 0xff ^ 0xC4) by toggling the original write checkbits and then factoring in the addr_ecc. Accordingly, the codeword stored in the flash array is:

   fl_data = 0xBABEFACE_DEADBEEF, fl_checkbit = 0xD8

3. Read address 0x00345678. The flash array returns the stored codeword, fl_rdata = 0xBABEFACE_DEADBEEF, fl_rchkbit = 0xD8. The flash memory controller inverts the checkbit vector and factors in the address checkbits (0xD8 ^ 0xFF ^ 0xC4) to produce:

   addr = 0x00345678, rdata = 0xBABEFACE_DEADBEEF, rchkbit = 0xE3

   This read codeword matches the original e2eECC codeword generated by the write.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The flash memory controller performs EDC after ECC check on all flash transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the device fault collection module.

71.6.11.2 Flash address generation check

Fault detection coverage of the address and data are handled by ECC performed within the flash and e2eECC performed at the master. Fault detection coverage of the address path and control within the flash memory controller rely on a feedback path between the flash controller and flash. Recall on a requested access to flash, the flash memory controller must decode the system AHB bus signals to generate the corresponding flash

interface signals to invoke a flash lookup. In addition to providing the requested read data, the flash also provides output sidebands reflecting the encoded address and block selects used to perform the actual row lookup.

This sideband information is used by the flash memory controller to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the flash memory controller or the transmission path between the flash memory controller and flash array, the event is forwarded to the device fault collection module and the corresponding buffer is invalidated.

71.6.11.2.1 Overlay RAM feedback check

The integrity of the address and data on an overlay RAM transaction is covered by e2eECC check performed by the requesting master. Fault detection coverage of the address path and control within the flash memory controller is handled by a transaction monitor which verifies the integrity of the transactions between the flash memory controller and the on-chip overlay RAM. The function of the transaction monitor relies on a feedback path between the flash memory controller and the on-chip overlay RAM, wherein the RAM provides latched address and control feedback outputs as an indication of received inputs when a RAM access is initiated. This feedback information is used by the flash memory controller transaction monitor to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the flash memory controller or the transmission path between the flash memory controller and on-chip overlay RAM array, the event is forwarded to the Fault Collection and Control Unit (FCCU).

71.6.11.2.2 Reliability considerations on overlay accesses

Because calibration write accesses are always presented with the physical, non-remapped system address, the write data checkbits presented by the master are calculated based on the physical overlay RAM system address. On a subsequent overlay read, the ECC checkbits must be manipulated to replace the physical overlay RAM address contribution with the logical flash address contribution. This is required to satisfy the e2eECC check at the originating master.

In addition, the flash memory controller can be configured to treat calibration RAM space as a safety-critical component. By programming PFCRCR[SAFE_CAL]=1, the flash memory controller treats the set of available calibration region descriptors as a replicated pair, with each set containing half the total number of available calibration region descriptors.

If there are 32 calibration region descriptors, CRD0 – CRD31, and PFCRCR[SAFE_CAL]=1, the flash memory controller treats CRD0 – CRD15 and CRD16 – 32 as replicated sets of 16 calibration region descriptors, where:

- CRD0 and CRD16 are configured identically
- CRD1 and CRD17 are configured identically
- CRD2 and CRD18 are configured identically
- ...
- and CRD15 and CRD31 are configured identically

Expressed more generally, the contents of CRD[*n*] must be identical to the contents of CRD[(N/2) + *n*], where N is the total number of region descriptors and $0 \le n \le (N/2) - 1$.

Note

It is the user's responsibility to establish redundant calibration region descriptors by programming the associated pairs of CRDs.

Incoming flash read requests are compared simultaneously against the calibration regions defined in CRD0 to CRD[(N/2) – 1] and the calibration regions defined in CRD[N/2] to CRD[N – 1]. Due to the enabled redundancy, the parallel overlay remap hardware structures should evaluate to symmetric results. If a mismatch is detected, the event is reported to the FCCU and calibration remapping is not performed. Instead, data is returned from the flash.

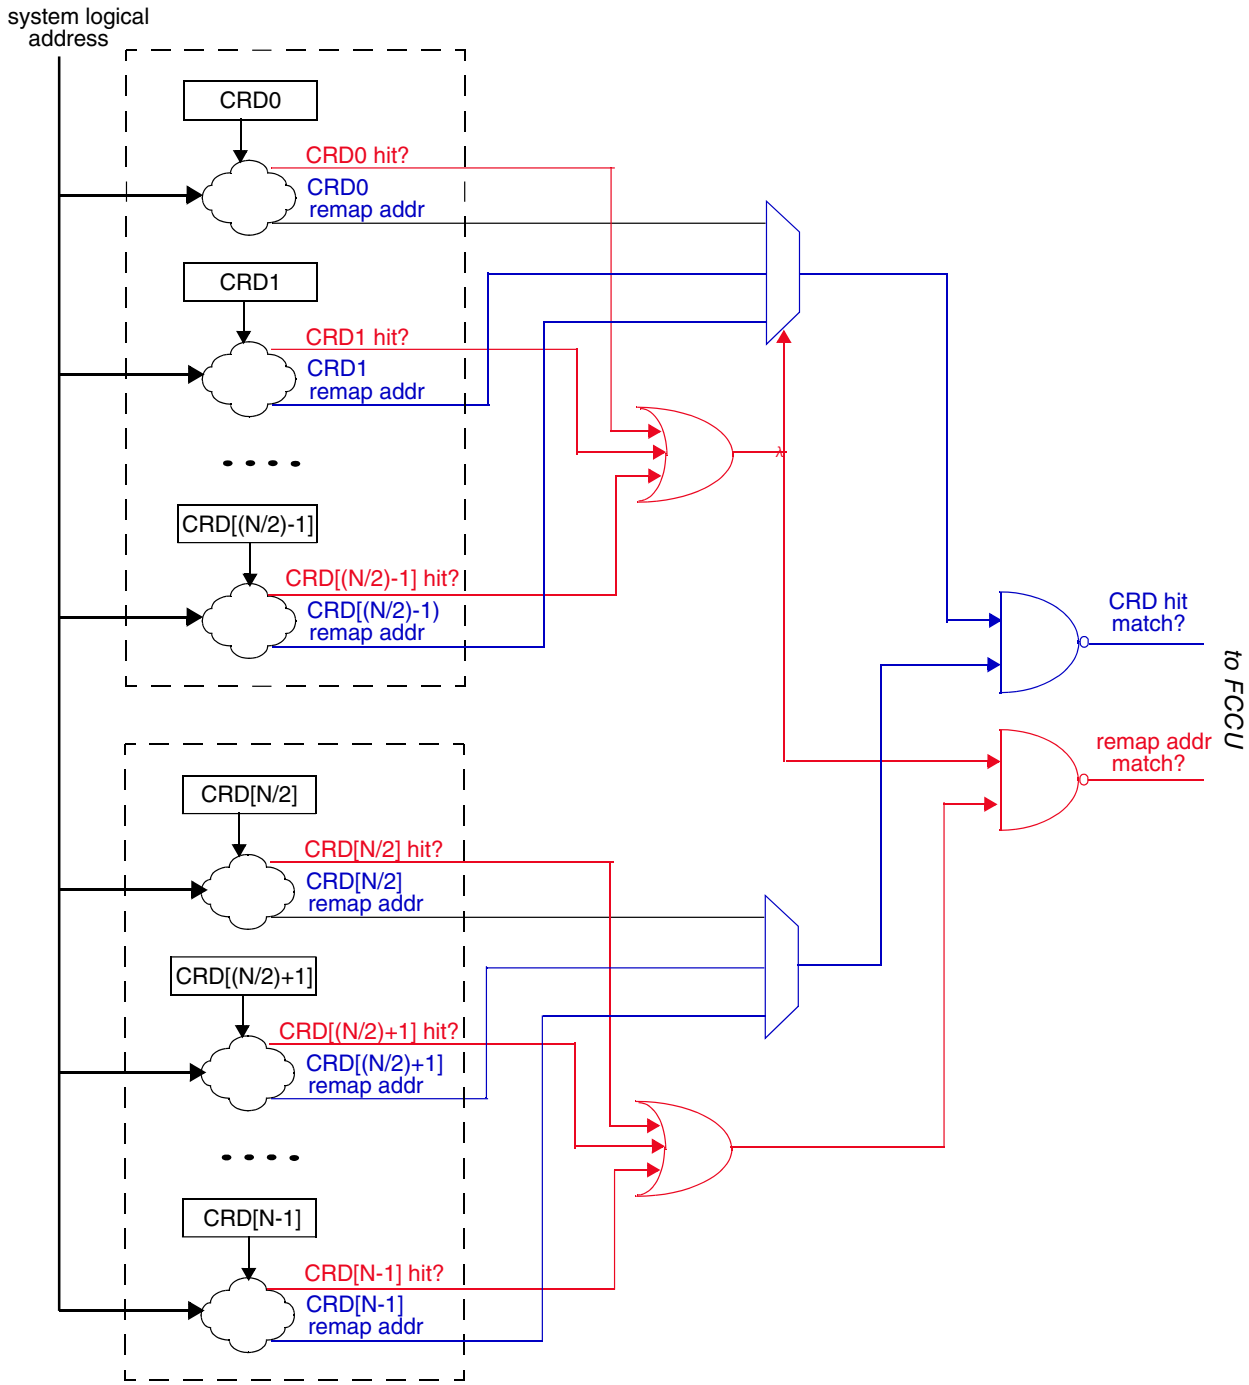

Figure 71-4. Safety-critical calibration remap datapath with redundancy

71.6.12 ECC on data flash accesses

For single-bit correction events, the corrected data and checkbits are returned to the requesting master, and the single-bit correction event is reported to the MEMU.

In the event of a non-correctable error detection, a fixed, illegal opcode value (1555_1555h) is returned to the requesting master along with the associated ECC checkbits as determined by the requesting address and the non-correctable error event is reported to the MEMU.

NOTE

EEPROM should be avoided for storage of executable code.

71.6.13 Array integrity considerations

During an array integrity sequence, the flash memory array ignores any incoming read requests. When a flash array integrity check is in progress, the flash memory controller terminates all flash access requests with an error. More specifically, it aborts the incoming flash access requests and terminates the system bus transfer with an error.

Chapter 72
Embedded Flash Memory

72.1 Chip-specific Embedded Flash memory information

72.1.1 Embedded Flash Memory configuration

This section describes the configuration of this module specific to the MPC5746C.

72.1.2 Register bit mapping

The C55FMC_LOCKn registers have the same bit-to-block mapping as the C55FMC_SELn registers.

72.1.7 Embedded Flash Memory register reset value

All register reset values for the FMC registers that are device specific are shown below. All other registers reset values are shown in the Embedded Flash Memory chapter

Module Configuration Register (FMC_MCR) register resets to 0000_0600h.

Extended Module Configuration Register (FMC_MCRE) register resets to 0B01_0C51h.

Over-Program Protection 0 register (FMC_OPP0) register resets to 0000_0000h.

Over-Program Protection 1 register (FMC_OPP1) register resets to 0000_0000h.

Over-Program Protection 2 register (FMC_OPP2) register resets to 0000_0000h.

Over-Program Protection 3 register (FMC_OPP3) register resets to 0000_0000h.

NOTE

Do not access the reserved area of the C55FMC memory map.

72.2 Introduction

The primary function of the embedded flash memory is to serve as electrically programmable and erasable non-volatile memory (NVM) that may be used for instruction or data storage.

The following figure shows the top-level diagram and functional organization of the flash memory unit.

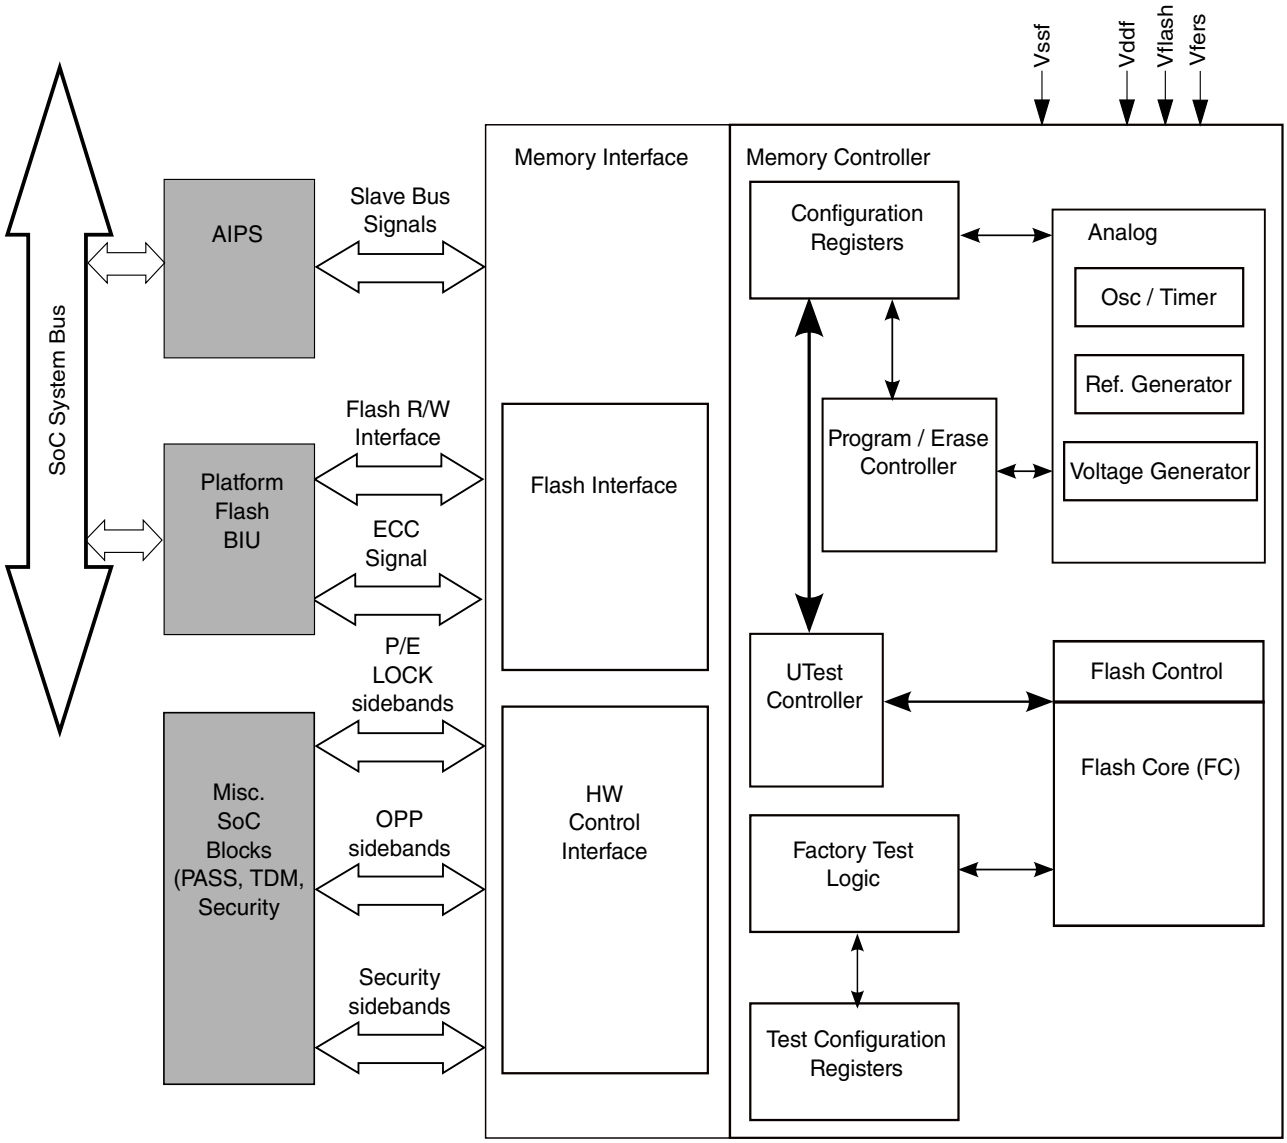

Figure 72-1. c55fmc block diagram

72.2.1 Overview

The embedded flash memory is addressable by word (32 bits) or double word (64 bits) for program operation, and page (256 bits) for read operation. Multiple word or double-word writes may be done to the flash memory to fill up the program page buffer (256 bits), enabling page programming (256 bits, requiring 4 double-word writes) and quad-page programming (1024 bits, requiring 16 double-word writes). Flash memory reads always return 256 bits, although read page buffering may be performed by the Bus Interface Unit (BIU).

For more details on the embedded flash memory architecture and features, see Functional Description.

72.2.2 Features

The embedded flash memory includes these distinct features:

- Test information stored in a dedicated nonvolatile block (referred to as the UTest block)
- OTP space made available in the UTest block
- Read page size of 256 bits (8 words)
- ECC with single-bit correction, double-bit detection (all 1's valid)
- Quad Page programming (64-bit granularity)
- Software programmable block program/erase restriction control
- Erasing of selected block(s)
- Independent programming of the UTest NVM block
- Embedded hardware program and erase algorithms
- Support for reading while writing when the accesses are to different partitions
- Erase suspend, program suspend, and erase-suspended program
- UTest mode (user-accessible test modes) including Array Integrity and Margin Read
- Triple Voted Flops for flash functions requiring high reliability, e.g., internal trimming, redundancy, and mode control

72.2.3 Modes of operation

Following is a brief description of the embedded flash memory operating modes.

- *User mode* is the default operating mode of the embedded flash memory. In this mode, it is possible to read and write registers, read and interlock write the memory array, program the memory array, and erase the memory array. In this mode program and erase operations are initiated by doing array and register writes, and are controlled by an internal state machine.
- *Low power mode* turns off all DC current sources within the embedded flash memory on the Vflash domain, and enables VDDF to be power gated. The embedded flash memory is not accessible for read, write, program, or erase when in low power mode.
- *UTest mode* is a tiered test mode strategy in which a portion of the factory test modes are made available. This mode is protected but accessible.

72.3 UTest NVM block

The UTest NVM block may be enabled by the BIU. When the UTest NVM space is enabled, all operations are mapped to the UTest NVM block. User-mode programming of the UTest NVM block is enabled only when MCR[PEAS] is high. The UTest NVM block is an OTP block (assuming Test Mode Disable Seal is written) - thus erase is not allowed.

The UTest NVM block supports RWW, and is grouped with the blocks in partition 0.

The UTest NVM block may be locked against program by using the lock registers.

Programming of the UTest NVM space has restrictions that are similar to those of the main space in terms of how ECC is calculated. Only one program operation is allowed per 64-bit ECC segment.

The UTest NVM block contains specified data that is needed for embedded flash memory or SoC features.

72.4 Test mode disable seal

Also included in the UTest NVM block is a mechanism to disable factory entry into Test mode. Extreme care must be taken when using this feature, as blocks that are selected to be protected in this method will not be able to have possible failures analyzed by factory failure analysts. Once sealed, the UTest block becomes OTP (Erase Locked, and Over Program Protection enabled). The UTest Block also is not accessible in Test mode.

Protection of this sort prevents all high-voltage operations to the flash executed by the internal state-machine, as well as reads through this state machine, and reads through the Array Integrity state machine when using Test mode interfaces.

UTest operations Margin Read and Array Integrity are also protected by preventing MISR updates on blocks selected for protection, although reads will still be done and single bit corrections and double bit detections will be logged. Protection through other interfaces is protected by normal User mode protection mechanisms, and are device-specific.

The method to disable factory entry into Test mode is to first program the Test Mode Disable Seal location to be 0x2D3C_4B5A. Once the next reset is asserted, Test mode will be disabled.

It is possible to create a password to enable factory entry into test mode. This can be programmed into the Test Mode Disable Override Passcode. The passcode may not be 0x0000_0000, 0xFFFF_FFFF, or 0x5555_5555. These are all invalid passcodes and will not be accepted to override. If it is desired by the customer that override never be possible, one of the three invalid passcodes should be put into this location. Passcode may be entered to authenticate entry (if enabled) by doing a 32-bit register write to register address 0x90. The UTest NVM block is always protected even if the Test Mode Disable Seal password is written. UTest operations Margin Read and Array Integrity are always protected even if the Test Mode Disable Seal password is written.

Only blocks selected in the Test Mode Disable Block Select field(s) are controlled by the Test Mode Disable feature. Thus it is possible for customers to selectively pick blocks that have this type of protection, and will not be eligible for factory failure analysis. Bits programmed to 0 in the Test Mode Disable Block Select field(s) will designate blocks that are controlled by the Test Mode Disable feature. If either Test Mode Disable Block Select - 0 or Test Mode Disable Block Select - 1 have a 0 programmed, that block will be protected. In order to provide two opportunities to select blocks for the Test Mode Disable, two regions are available, Test Mode Disable Block Select - 0 and Test Mode Disable Block Select - 1. The bit of these two regions are logically ANDed, to define which blocks are effectively selected for the Test Mode Disable feature. The Block Select field is organized as follows, and aligns with how blocks are defined in the LOCK registers.

Table 72-1. Test mode disable block select

Block	Bits used to select blocks
Low Block Disable	Data[13:0]
Unused	Data[15:14]
Mid Block Disable	Data[31:16]
High Block Disable	Data[47:32]
256K Block Disable	Data[95:48]

72.5 Memory map and register definition

The embedded flash memory map consists of a flash memory array (which includes main array space and UTest NVM space) and a region of registers associated with the programming model that enable flash memory array operation and modification.

The address space consists of 16 KB, 32 KB, 64 KB, and 256 KB blocks.

C55FMC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

72.5.1 Module Configuration Register (C55FMC_MCR)

NOTE

1. A number of Module Configuration Register (MCR) bits are locked against write by other bits. These locks are discussed in relationship to each bit in this section. Simultaneously writing bits which lock each other out is also discussed in Functional Description.
2. See Functional Description for information about simultaneous MCR writes, and priority levels.

Address: 0h base + 0h offset = 0h

C55FMC_MCR field descriptions

Field	Description
0 RVE	Read Voltage Error RVE provides information on previous reads monitoring the read pump voltage. If the read voltage is detected to be out of range, this bit is set to indicate that previous reads requested may have been

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
	corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without voltage issues 1 A previous read may have been corrupted due to read voltage being out of range
1 RRE	Read Reference Error RRE provides information on previous reads monitoring the read reference. If the read reference is detected to be out of range, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without reference issues 1 A previous read may have been corrupted due to read reference being out of range
2 AEE	Address Encode Error AEE provides information on previous reads monitoring the address encode feature. On every read request to the flash, the incoming address is compared to an encoded address (row, column, and block) coming back from the memory array using the read data sense amplifier timing. If these two values do not match (zero selected, multiple selected, wrong selected), or the timing is incorrect, an address encode error will be recorded. If an address encode mismatch is detected, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without address encode mismatches 1 A previous read may be corrupted based on address encode mismatch
3 EEE	ECC after ECC Error EEE provides information on previous reads monitoring the ECC after ECC feature. On every read request to the flash, ECC is recalculated serially, and if there is a mismatch between the ECC calculations (taking into account corrections or detections) a late error will be reported. If an ECC after ECC mismatch is detected, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without ECC after ECC mismatches 1 A previous read may be corrupted based on ECC calculation errors
4–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 EER	ECC Event Error This bit provides information on previous reads. If a double bit detection occurred, the EER bit is set to a '1'. This bit must then be cleared, or a reset must occur before it returns to a 0 state. This bit may not be set by software. In the event of a single bit detection and correction, this bit is not set. If EER is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of EER) are correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring normally. 1 An ECC Error occurred during a previous read.
17 RWE	Read-While-Write Event Error This bit provides information on previous read-while-write (RWW) reads. If an RWW error occurs, this bit is set to 1. The bit must then be cleared, or a reset must occur before it returns to a 0 state. This bit may not be written to a 1. If RWE is not set, or remains 0, this indicates that all previous RWW reads (from the last

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
	reset, or clearing of RWE) are correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring normally. 1 A read-while-write error occurred during a previous read.
18 SBC	Single Bit Correction SBC provides information on previous reads, if the SBCE is set. If a single bit correction occurred, the SBC bit is set to a 1. This bit must then be cleared, or a reset must occur before this bit returns to a 0 state. If SBC is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of SBC) did not require a correction. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without corrections. 1 A Single Bit Correction occurred during a previous read.
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 PEAS	Program Access Space PEAS indicates which space is valid for program or erase operations — either main array space or UTest NVM space. It should be noted that if the flash is sealed, and the Test Mode Disable Seal is programmed, erase is not allowed on the UTest NVM space. PEAS = 0 indicates the main address space is active for all program or erase operations. PEAS = 1 indicates the UTest NVM address space is active for program or erase (if applicable) operations. The value in PEAS is captured and held when the UTest NVM block is enabled with the first interlock write done for program operations(and erase operations if the flash is unsealed). The value of PEAS is retained between sampling events (in other words, subsequent first interlock writes). The value in PEAS may be changed during erase-suspended program, and reverts back to its original state once the erase-suspended program is completed. PEAS is read only. 0 UTest NVM address space is disabled for program/erase and main address space enabled. 1 UTest NVM address space is enabled for program/erase and main address space disabled.
21 DONE	State Machine Status DONE indicates whether the embedded flash memory is performing a high voltage operation. DONE is set to a 1 on termination of the embedded flash memory reset. DONE is read only. DONE is set to a 1 at the end of program and erase high voltage sequences. **NOTE:** This bit transitions from a 0 to 1 during reset and remains at 1 after reset. 0 Flash memory is executing a high voltage operation. 1 Flash memory is not executing a high voltage operation.
22 PEG	Program/Erase Good The PEG bit indicates the completion status of the last flash memory program or erase sequence for which high voltage operations were initiated. The value of PEG is updated automatically during the program and erase high voltage operations. Aborting a program/erase high voltage operation causes PEG to be cleared, indicating the sequence failed. PEG is set to a 1 when the embedded flash memory is reset. PEG is read only. The value of PEG is valid only when PGM = 1 or ERS = 1 and after DONE transitions from 0 to 1 due to an abort or the completion of a program/erase operation. PEG is valid until PGM/ERS makes a 1 to 0 transition or EHV makes a 0 to 1 transition. The value in PEG is not valid after a 0 to 1 transition of DONE caused by PSUS or ESUS being set to logic 1. If PGM and ERS are both 1 when DONE makes a qualifying 0 to 1 transition the value of PEG indicates the completion status of the PGM sequence. This happens in an erase-suspended program operation.

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
	PEG will be 0 if an Erase-Suspended Program is attempted to a block that has been selected for Erase. PEG will also be 0 in the event of an error in the interlock write for program only. An error in the interlock write occurs when the ECC value provided to the flash memory does not match the ECC calculated within the flash memory. In the event of this, high voltage will not be applied to the array, and PEG will indicate a failed program. **NOTE:** 1. If program or erase operations are attempted on blocks that are locked, the response from embedded flash memory is PEG = 1, indicating that the operation was successful, and the contents of the block are properly protected from the program or erase operation. PEG = 1 is also true if an abort occurs during an HV request to a locked block. 2. If a program operation is attempted to a location marked as OTP, the response from the embedded flash memory is PEG = 0, indicating that the operation was not allowed, and the value interlocked was not programmed, since the desired doubleword was already programmed with a previous program operation. 0 Program or erase operation failed. 1 Program or erase operation successful.
23 PECIE	Program/Erase Complete Interrupt Enable PECIE provides a mechanism to trigger an interrupt request upon the assertion of the DONE flag due to a high voltage event (program or erase) finishing (normal, abort, suspend). If PECIE is written while not in a high voltage event, the interrupt will not immediately trigger, but will trigger after the next high voltage event is completed. 0 An interrupt request will not be generated when the DONE flag is set. 1 An interrupt request will be generated when the DONE flag is set.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 PGM	Program PGM is used to set up embedded flash memory for a program operation. A 0 to 1 transition of PGM initiates a program sequence. A 1 to 0 transition of PGM ends the program sequence. PGM can be set only under one of the following conditions: • User mode read (ERS is low and UTE is low) • Erase suspend (ERS and ESUS are 1) with EHV low PGM can be cleared only when PSUS and EHV are low and DONE is high. PGM is cleared on reset. 0 Flash memory is not executing a program sequence. 1 Flash memory is executing a program sequence.
28 PSUS	Program Suspend PSUS is used to indicate the embedded flash memory is in program suspend or in the process of entering a suspend state. The embedded flash memory is in program suspend when PSUS = 1 and DONE = 1. PSUS can be set high only when PGM and EHV are high. A 0 to 1 transition of PSUS starts the sequence which sets DONE and places the embedded flash memory in program suspend. The embedded flash memory enters suspend within Tpsus of this transition. PSUS can be cleared only when DONE and EHV are high. A 1 to 0 transition of PSUS with EHV = 1 starts the sequence which clears DONE and returns the embedded flash memory to program. The embedded flash memory cannot exit program suspend and clear DONE while EHV is low. PSUS is cleared on reset. 0 Program sequence is not suspended. 1 Program sequence is suspended.

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
29 ERS	Erase ERS is used to set up embedded flash memory for an erase operation. A 0 to 1 transition of ERS initiates an erase sequence. A 1 to 0 transition of ERS ends the erase sequence. ERS can only be set in user mode read (PGM is low and UTE is low). ERS can be cleared only when ESUS and EHV are low and DONE is high. ERS is cleared on reset. 0 Flash memory is not executing an erase sequence. 1 Flash memory is executing an erase sequence.
30 ESUS	Erase Suspend ESUS is used to indicate that the embedded flash memory is in erase suspend or in the process of entering a suspend state. The embedded flash memory is in erase suspend when ESUS = 1 and DONE = 1. ESUS can be set high only when ERS and EHV are high and PGM is low. A 0 to 1 transition of ESUS starts the sequence which sets DONE and places the flash memory in erase suspend. The embedded flash memory enters suspend within Tesus of this transition. ESUS can be cleared only when DONE and EHV are high and PGM is low. A 1 to 0 transition of ESUS with EHV = 1 starts the sequence which clears DONE and returns the embedded flash memory to erase. The embedded flash memory cannot exit erase suspend and clear DONE while EHV is low. ESUS is cleared on reset. 0 Erase sequence is not suspended. 1 Erase sequence is suspended.
31 EHV	Enable High Voltage The EHV bit enables the embedded flash memory for a high voltage program/erase operation. EHV is cleared on reset. EHV must be set after an interlock write to start a program/erase sequence. EHV may be set, initiating a program/erase, after an interlock under one of the following conditions: • Erase (ERS = 1, ESUS = 0) • Program (ERS = 0, ESUS = 0, PGM = 1, PSUS = 0) • Erase-suspended program (ERS = 1, ESUS = 1, PGM = 1, PSUS = 0) If a program operation is to be initiated while an erase is suspended, EHV must be cleared while in erase suspend before setting PGM. In normal operation, a 1 to 0 transition of EHV with DONE high, PSUS low, and ESUS low terminates the current program/erase high-voltage operation. In an erase-suspended program operation, a 1 to 0 transition of EHV with DONE high, ESUS high, PGM high, ERS high, and PSUS low terminates the program that is the current high voltage operation. When an operation is aborted, there is a 1 to 0 transition of EHV with DONE low and the suspend bit for the current program/erase sequence low. An abort causes the value of PEG to be cleared, indicating a failed program/erase; address locations being operated on by the aborted operation contain indeterminate data after an abort. EHV may not be written to a 1 after an abort is requested (EHV being cleared) and before DONE transitions high. A suspended operation cannot be aborted. EHV may be written during suspend. EHV must be high for the embedded flash memory to exit suspend. EHV may not be written after a suspend bit is set high and before DONE transitions high. EHV may not be set low after the current suspend bit is set low and before DONE transitions low. **NOTE:** Aborting a high voltage operation leaves FC addresses in an indeterminate data state. This may be recovered by executing an erase on the affected blocks. 0 Flash memory is not enabled to perform a high voltage operation. 1 Flash memory is enabled to perform a high voltage operation.

72.5.2 Extended Module Configuration Register (C55FMC_MCRE)

NOTE

The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

- The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

C55FMC_MCRE field descriptions

Field	Description
0 HT	High Temperature Enabled. HT provides configuration information of the module. If the flash is tuned for high temperature operation (165 °C) at reduced performance (slower read at 165 °C and less and slower program and erase at 150 °C or less), and limited features at this temperature (no margin reads), the HT status bit will be a 1. Default is 150 °C as maximum operating temperature, and the HT status bit will be a 0. HT is read only. 0 150 °C maximum operating temperature. **NOTE:** 165 °C operating temperature maximum is not supported on this device. 1 Reserved
1–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 n256K	Number of 256 KB blocks. The value of this field is dependent upon the size of the embedded flash memory. This field is read only. 00000 Zero 256 KB blocks. 00001 Two 256 KB blocks (512 KB total). 00010 Four 256 KB blocks (1 MB total). 00011 Six 256 KB blocks (1.5 MB total). 00100 Eight 256 KB blocks (2 MB total).

72.5.3 Lock 0 register (C55FMC_LOCK0)

The Lock 0 (LOCK0) register provides a means to protect blocks from being modified.

Address: 0h base + 10h offset = 10h

C55FMC_LOCK0 field descriptions

Field	Description
0 TSLOCK	UTest NVM Lock. This bit is used to lock the UTest NVM block from programs (erase protection not needed since UTest NVM is OTP and not erasable). A value of 1 in the TSLOCK register signifies that the UTest NVM block is locked for program. A value of 0 in the TSLOCK register signifies that the UTest NVM block is available to receive program pulses. The TSLOCK register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, TSLOCK register is not writable if a high voltage operation is suspended.

Table continues on the next page...

C55FMC_LOCK0 field descriptions (continued)

Field	Description
	0 UTest NVM block is available to be programmed. 1 UTest NVM block is locked and cannot be programmed.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 LOWLOCK	Low Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the Low Blocks starts at LOWLOCK[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. Low Blocks exist in partitions 0 and 1. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high voltage operation is suspended. The default value of the LOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations. 1 Block is locked and unavailable for program and erase operations
16–31 MIDLOCK	Mid Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the Mid Blocks starts at MIDLOCK[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. Mid Blocks exist in partitions 2 and 3. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high-voltage operation is suspended. The default value of the LOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations. 1 Block is locked and unavailable for program and erase operations

72.5.4 Lock 1 register (C55FMC_LOCK1)

The Lock 1 (LOCK1) register provides a means to protect blocks from being modified.

Address: 0h base + 14h offset = 14h

C55FMC_LOCK2 field descriptions

Field	Description
0–31 A256KLOCK	256 KB Block Lock 256KLOCK has the same characteristics as LOWLOCK. Please see that description for more information. The block numbering for the 256 KB blocks starts with 256KLOCK[0] and continues until all blocks are accounted. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the 256 KB blocks starts with 256KLOCK[0] and continues until all blocks are accounted. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high-voltage operation is suspended. The default value of the LOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations. 1 Block is locked and unavailable for program and erase operations

72.5.6 Lock 3 register (C55FMC_LOCK3)

The Lock 3 (LOCK3) register provides a means to protect blocks from being modified.

Address: 0h base + 1Ch offset = 1Ch

C55FMC_LOCK3 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 A256KLOCK	256 KB Block Lock 256KLOCK has the same characteristics as LOWLOCK. Please see that description for more information. The block numbering for the 256 KB blocks starts with 256KLOCK[0] and continues until all blocks are accounted. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the 256 KB blocks starts with 256KLOCK[0] and continues until all blocks are accounted.

Table continues on the next page...

C55FMC_LOCK3 field descriptions (continued)

Field	Description
	The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high-voltage operation is suspended. The default value of the LOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations. 1 Block is locked and unavailable for program and erase operations

72.5.7 Select 0 register (C55FMC_SEL0)

The Select 0 (SEL0) register provides a means to select blocks to be operated on during erase.

Address: 0h base + 38h offset = 38h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

C55FMC_SEL0 field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 LOWSEL	LOW Block Select. A value of 1 in the select register signifies that the block is selected for erase. A value of 0 in the select register signifies that the block is not selected. The reset value for the select registers is 0, or unselected. The block numbering for the Low Blocks starts at LOWSEL[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. Low Blocks exist in partitions 0 and 1. The blocks must be selected (or unselected) before doing an erase interlock write as part of the erase sequence. The select register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation, or if a high-voltage operation is suspended. LOWSEL is also not writeable during UTest operations, when AIE is high. In the event that blocks are not present (due to configuration or total memory size), the corresponding select bits default to unselected, and are not writable. The reset value is always 0, and register writes have no effect. 0 The block is not selected 1 The block is selected for erase

Table continues on the next page...

C55FMC_SEL0 field descriptions (continued)

Field	Description
16–31 MIDSEL	Mid Block Select. A value of 1 in the select register signifies that the block is selected for erase. A value of 0 in the select register signifies that the block is not selected. The reset value for the select registers is 0, or unselected. The block numbering for the Mid Blocks starts at MIDLSEL[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. Mid Blocks exist in partitions 2 and 3. The blocks must be selected (or unselected) before doing an erase interlock write as part of the erase sequence. The select register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation, or if a high-voltage operation is suspended. MIDSEL is also not writeable during UTest operations, when AIE is high. In the event that blocks are not present (due to configuration or total memory size), the corresponding select bits default to unselected, and are not writable. The reset value is always 0, and register writes have no effect. 0 The block is not selected 1 The block is selected for erase

72.5.8 Select 1 register (C55FMC_SEL1)

The Select 1 (SEL1) register provides a means to select blocks to be operated on during erase.

Address: 0h base + 3Ch offset = 3Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

C55FMC_SEL1 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 HIGHSEL	High Block Select. A value of 1 in the select register signifies that the block is selected for erase. A value of 0 in the select register signifies that the block is not selected. The reset value for the select registers is 0, or unselected. The block numbering for the High Blocks starts at HIGHSEL[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. HIGH Blocks exist in partitions 4 and 5.

Table continues on the next page...

C55FMC_SEL1 field descriptions (continued)

Field	Description
	The blocks must be selected (or unselected) before doing an erase interlock write as part of the erase sequence. The select register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation, or if a high-voltage operation is suspended. HIGHSEL is also not writeable during UTest operations, when AIE is high. In the event that blocks are not present (due to configuration or total memory size), the corresponding select bits default to unselected, and are not writable. The reset value is always 0, and register writes have no effect. 0 The block is not selected for erase 1 The block is selected for erase

72.5.9 Select 2 register (C55FMC_SEL2)

The Select 2 (SEL2) register provides a means to select blocks to be operated on during erase.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

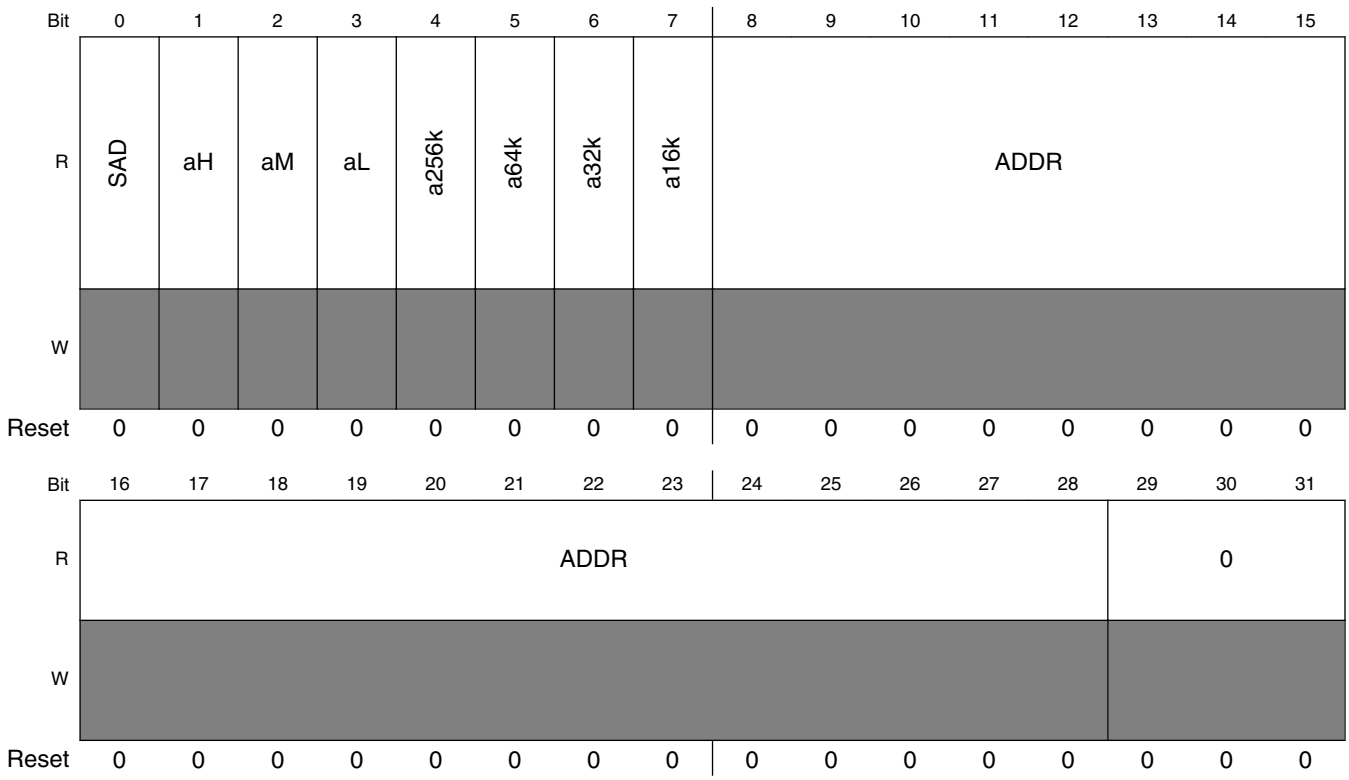
C55FMC_SEL2 field descriptions

Field	Description
0–31 A256KSEL	256 KB Block Select. A value of 1 in the select register signifies that the block is selected for erase. A value of 0 in the select register signifies that the block is not selected. The reset value for the select registers is 0, or unselected. The block numbering for the 256 KB blocks starts with 256KSEL[0] and continues until all blocks are accounted. The blocks must be selected (or unselected) before doing an erase interlock write as part of the erase sequence. The select register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation, or if a high-voltage operation is suspended. 256KSEL is also not writeable during UTest operations, when AIE is high. In the event that blocks are not present (due to configuration or total memory size), the corresponding select bits default to unselected, and are not writable. The reset value is always 0, and register writes have no effect. 0 The block is not selected 1 The block is selected for erase

72.5.10 Select 3 register (C55FMC_SEL3)

The Select 3 (SEL3) register provides a means to select blocks to be operated on during erase.

Address: 0h base + 44h offset = 44h



C55FMC_SEL3 field descriptions

Field	Description
0–15 Reserved	This field is reserved. Reserved, reset to 0.
16–31 A256KSEL	256 KB Block Select. A value of 1 in the select register signifies that the block is selected for erase. A value of 0 in the select register signifies that the block is not selected. The reset value for the select registers is 0, or unselected. The block numbering for the 256 KB blocks starts with 256KSEL[0] and continues until all blocks are accounted. The blocks must be selected (or unselected) before doing an erase interlock write as part of the erase sequence. The select register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation, or if a high-voltage operation is suspended. 256KSEL is also not writeable during UTest operations, when AIE is high. In the event that blocks are not present (due to configuration or total memory size), the corresponding select bits default to unselected, and are not writable. The reset value is always 0, and register writes have no effect. 1 The block is selected for erase. 0 The block is not selected.

72.5.11 Address register (C55FMC_ADR)

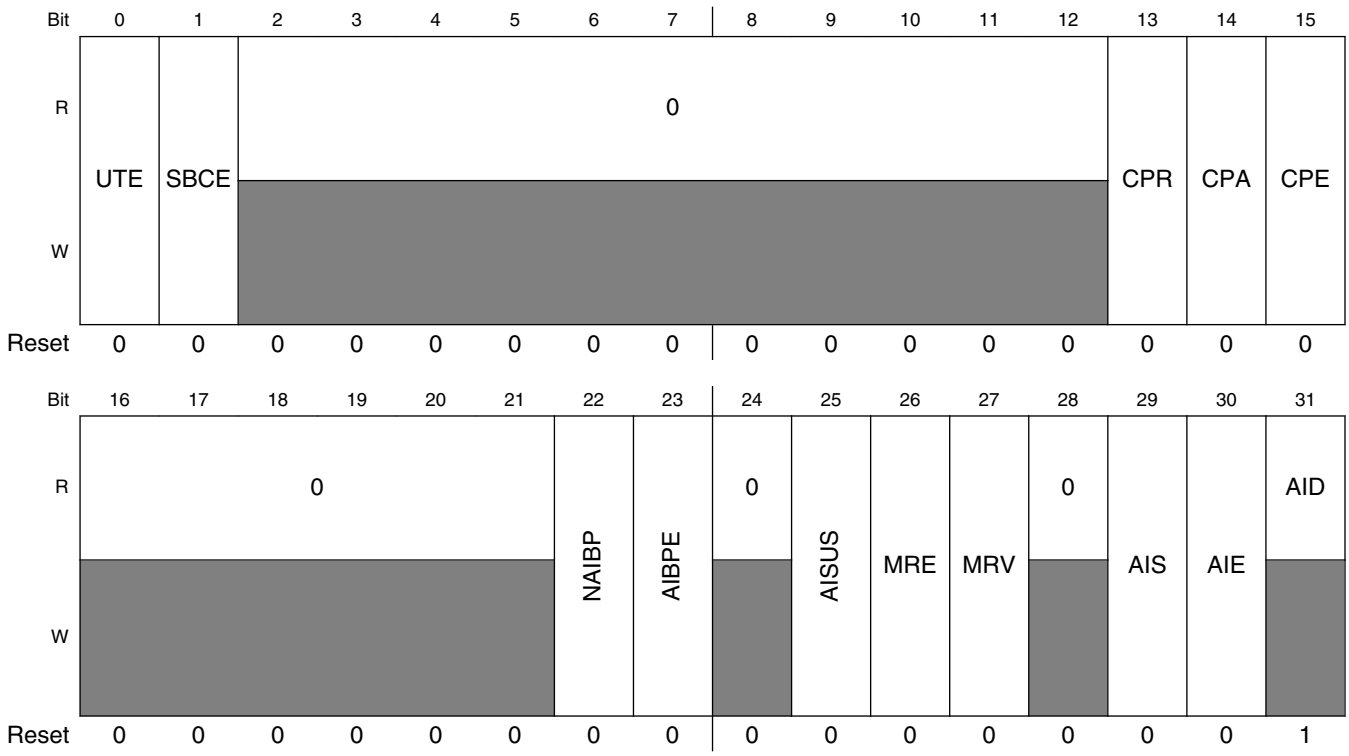
The Address register (ADR) provides the first failing address in the event of a failure (ECC or PGM/Erase state machine), as well as single bit correction information.

Address: 0h base + 50h offset = 50h

C55FMC_ADR field descriptions

Field	Description
0 SAD	UTest NVM Address. The SAD bit qualifies the address captured during an ECC Event Error, Single Bit Correction, or State Machine operation. SAD has the same characteristics as ADDR related to capturing of addresses. The SAD field is not writable. 0 Address captured is from main array Space. 1 Address captured is from UTest NVM array space.
1 aH	Address High region. The aH bit qualifies the address field (ADDR) to the region of a16K, a32K and a64k. If aH is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from high address region. 1 Address captured or to be accessed is from high address region.
2 aM	Address Mid region. The aM bit qualifies the address field (ADDR) to the region of a16K, a32K and a64k. If aM is set, then the ADDR field maps to that region. See ADDR description for more information.

Table continues on the next page...



C55FMC_ADR field descriptions (continued)

Field	Description
	0 Address captured or to be accessed is not from mid address region. 1 Address captured or to be accessed is from mid address region.
3 aL	Address Low region. The aL bit qualifies the address field (ADDR) to the region of a16K, a32K and a64k. If aL is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from low address region. 1 Address captured or to be accessed is from low address region.
4 a256k	Address 256 KB region. The a256k bit qualifies the address field (ADDR) to the region. If a256k is set, then the ADDR field maps to that region. See ADDR description for more information. The a256k register is writable. 0 Address captured or to be accessed is not from 256 KB region. 1 Address captured or to be accessed is from 256 KB region.
5 a64k	Address 64 KB region. The a64k bit qualifies the address field (ADDR) to the region. If a64k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 64 KB region. 1 Address captured or to be accessed is from 64 KB region.
6 a32k	Address 32 KB region. The a32k bit qualifies the address field (ADDR) to the region. If a32k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 32 KB region. 1 Address captured or to be accessed is from 32 KB region.
7 a16k	Address 16 KB region. The a16k bit qualifies the address field (ADDR) to the region. If a16k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 16 KB region. 1 Address captured or to be accessed is from 16 KB region.
8–28 ADDR	Address. The ADR provides the first failing address in the event of ECC event error (EER set), Single Bit Correction (SBC set), as well as providing the address of a failure that may have occurred in a state machine operation (PEG cleared). ECC event errors take priority over Single Bit Corrections, which take priority over state machine errors. This is especially valuable in the event of an RWW operation, where the read senses an ECC error or Single Bit correction, and the state machine fails simultaneously. The failing address for ECC event error is held until EER is cleared. The failing address for Single Bit Correction is held until an ECC event error, or until SBC is cleared. State machine address is held until an ECC event error or Single Bit Correction event occurs, or until the next state machine event (PEG cleared) occurs. This address is always a doubleword address that selects 64 bits. ADDR[23:3] is an offset from a base address of 0x0 for each block size region. The aH, aM, aL, a16k, a32k, a64k, and a256k qualify the block size region the ADDR field.
29–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

72.5.12 UTest 0 register (C55FMC_UT0)

The User Test 0 (UT0) register provides a means to control UTest. UTest mode gives the ability to perform test features on the flash memory. This register is only writable when the flash memory is put into UTest mode by writing a passcode.

Address: 0h base + 54h offset = 54h

C55FMC_UT0 field descriptions

Field	Description
0 UTE	U-Test Enable. This status bit gives indication when U-Test is enabled. All bits in UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 are locked when this bit is 0. This bit is not writeable to a 1, but may be cleared. The reset value is 0. The method to set this bit is to provide a password, and if the password matches, the UTE bit is set to reflect the status of enabled, and is enabled until it is cleared by a register write. The UTE password will only be accepted if PGM = 0 and ERS = 0 (program and erase are not being requested). UTE can only be cleared if AID = 1, MRE and AIE = 0. While clearing UTE, writes to set AIE or MRE will be ignored. For UTE, the password 0xF9F9_9999 must be written to the UT0 register. 0 All bits in the UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 registers are locked 1 Bits in the UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 registers are unlocked
1 SBCE	Single Bit Correction Enable. SBCE enables Single Bit Correction results to be observed in SBC. ECC corrections that occur when SBCE is cleared will not be logged.

Table continues on the next page...

C55FMC_UT0 field descriptions (continued)

Field	Description
	0 Single Bit Corrections observation is disabled. 1 Single Bit Correction observation is enabled.
2–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 CPR	Customer Programmable Read Voltage and Reference Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a Read Voltage and Reference Error detection will be noted. This bit may not be set while CPE and CPA are set. If CPE or CPA are high, this bit will be locked. If attempts are made to write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable Read Voltage and Reference Detection Error is not enabled 1 Customer Programmable Read Voltage and Reference Detection Error is enabled
14 CPA	Customer Programmable Address Encode Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a Address Encode Error detection will be noted. This bit may not be set while CPE and CPR are set. If CPE or CPR are high, this bit will be locked. If attempts are made to write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable Address Encode Detection Error is not enabled 1 Customer Programmable Address Encode Detection Error is enabled
15 CPE	Customer Programmable EDC after ECC Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a EDC after ECC Error detection will be noted. This bit may not be set while CPR and CPA are set. If CPR or CPA are high, this bit will be locked. If attempts are made o write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable EDC after ECC Detection Error is not enabled 1 Customer Programmable EDC after ECC Detection Error is enabled
16–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 NAIBP	Next Array Integrity Break Point. If AIBPE is set, NAIBP will be set once a single bit correction (if enabled) or double bit detection is noted during the Array Integrity test. NAIBP is not writable to 1, but may be cleared to 0. Clearing NAIBP to 0, will enable the Array Integrity operation to be re-started after a breakpoint is encountered. If the Array Integrity operation completes without encountering another correction or detection, AID will be set with NAIBP remaining 0. 1 Array Integrity state machine is at a break point. 0 Array Integrity state machine is not currently at a break point.
23 AIBPE	Array Integrity Break Point Enable. If you want to enable breakpoints during an array integrity test, AIBPE may be set. See NAIBP description for more information about array integrity breakpoints. 1 Array Integrity breakpoints are enabled during Array Integrity Checks. 0 Array Integrity breakpoints are not enabled.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 AISUS	Array Integrity Suspend. AISUS enables a suspend of an Array Integrity Operation. Array Integrity may be suspend by Setting AISUS, and resumed by clearing AISUS. AISUS is writeable only when AID is low. AISUS is clearable only when AID is high. Attempting to write AISUS and AIE on the same clock cycle will result in only AIE getting written.

Table continues on the next page...

C55FMC_UT0 field descriptions (continued)

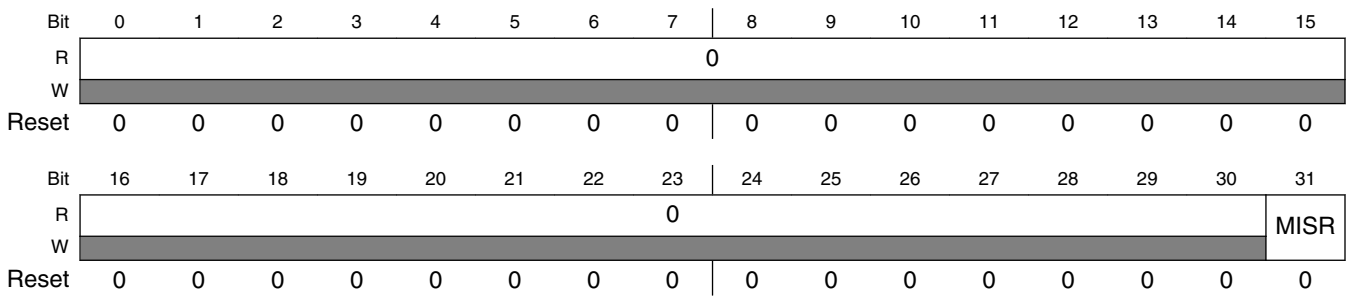
Field	Description
	1 Array integrity sequence is suspended. 0 Array integrity sequence not suspended.
26 MRE	Margin Read Enable. MRE combined with MRV enables user margin reads to be done. Normal user reads are not affected by MRE, although user reads while the margin read operation is ongoing are not supported. MRE is not writable if AID is low, or if AISUS is high, or if NAIBP is high. 1 Margin reads are enabled. 0 Margin reads are not enabled.
27 MRV	Margin Read Value. MRV selects the margin level that is being checked. Margin can be checked to an erased level (MRV=1) or to a programmed level (MRV=0). In order for this value to be valid, MRE must also be set. MRV is not writable if AID is low, or if AISUS is high, or if NAIBP is high. 1 One's margin reads are requested. 0 Zero's margin reads are requested.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 AIS	Array Integrity Sequence. AIS determines the address sequence to be used during array integrity checks. The default sequence (AIS = 0) is meant to replicate sequences that normal user code follows, and thoroughly checks the read propagation paths. This sequence is proprietary. The alternative sequence (AIS = 1) is logically sequential. It should be noted that the time to run a sequential sequence is shorter than the time to run the proprietary sequence. AIS is not writeable if AIE is high. **NOTE:** Only sequential addressing is supported for margin read checks. 1 Array integrity sequence is sequential. 0 Array integrity sequence is proprietary sequence.
30 AIE	Array Integrity Enable. AIE set to one starts the array integrity check done on all selected blocks. The address sequence is determined by AIS, and the MISR (UM0 through UM9) can be checked after the operation is complete, to determine if a correct signature has been obtained. Once an array integrity operation is requested (AIE=1), it may be terminated by clearing AIE if the operation has finished (AID = 1) or aborted by clearing AIE if the operation is ongoing (AID = 0). AIE is not simultaneously writable to a 1 as UTE is being cleared to a 0. 0 Array integrity checks are not enabled. 1 Array integrity checks are enabled.
31 AID	Array Integrity Done. AID is cleared upon an array integrity check being enabled (to signify the operation is ongoing). Once completed, AID is set to indicate that the array integrity check is complete. At this time the MISR (UMR registers) can be checked. AID may also assert if breakpoints are enabled (AIBPE is set), an abort is requested or a suspend is requested. AID cannot be written, and is status only. 0 Array integrity check is ongoing. 1 Array integrity check is done.

72.5.13 UMISR register (C55FMC_UM*n*)

The Multiple Input Signature registers provide a means to evaluate array integrity.

Address: 0h base + 58h offset + (4d × i), where i=0d to 8d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	MISR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



C55FMC_UM*n* field descriptions

Field	Description
0–31 MISR	MISR[31:0]. The MISR registers accumulate a signature from an array integrity event. The MISR captures all data fields, as well as ECC fields, and the ECC error signal. Data (read and ECC) captured in the MISR is after the ECC logic, and represents corrected data (if required). The MISR can be seeded to any value by writing the MISR registers. **NOTE:** Writing the MISR register during an array integrity operation (including suspend or breakpoint) although possible, is not recommended. A write of the MISR registers at this point may alter the final signature in an unpredictable way. The MISR register provides a means to calculate a MISR during array integrity operations. The MISR can be represented by the following polynomial: $x^{289} + x^{7} + x^{6} + x^{5} + x^{4} + x^{2} + 1$ The MISR is calculated by taking the previous MISR value and then "exclusive ORing" the new data. In addition the most significant bit (in this case it is MISR[288]), is then "exclusive ORed" into input of MISR[7], MISR[6], MISR[5], MISR[4], MISR[2] and MISR[0]. The result of the "exclusive OR" is shifted left on each read. The MISR register is used in array integrity operations. If during address sequencing, reads extend into an invalid address location (in other words, greater than the maximum address for a given array size) then reads are still executed to the array, but the results from the array read are not deterministic. In this instance, the MISR registers is not recalculated, and the previous value is retained.

72.5.14 UMISR register (C55FMC_UM9)

The Multiple Input Signature registers provide a means to evaluate array integrity.

Address: 0h base + 7Ch offset = 7Ch

C55FMC_UM9 field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 MISR	MISR[288]. The MISR registers accumulate a signature from an array integrity event. The MISR captures all data fields, as well as ECC fields, and the ECC error signal. Data (read and ECC) captured in the MISR is after the ECC logic, and represents corrected data (if required). The MISR can be seeded to any value by writing the MISR registers. **NOTE:** Writing the MISR register during an array integrity operation (including suspend or breakpoint) although possible, is not recommended. A write of the MISR registers at this point may alter the final signature in an unpredictable way. The MISR register provides a means to calculate a MISR during array integrity operations. The MISR can be represented by the following polynomial: $x^{289} + x^{7} + x^{6} + x^{5} + x^{4} + x^{2} + 1$ The MISR is calculated by taking the previous MISR value and then "exclusive ORing" the new data. In addition the most significant bit (in this case it is MISR[288]), is then "exclusive ORed" into input of MISR[7], MISR[6], MISR[5], MISR[4], MISR[2] and MISR[0]. The result of the "exclusive OR" is shifted left on each read. The MISR register is used in array integrity operations. If during address sequencing, reads extend into an invalid address location (in other words, greater than the maximum address for a given array size) then reads are still executed to the array, but the results from the array read are not deterministic. In this instance, the MISR registers is not recalculated, and the previous value is retained

72.5.15 Over-Program Protection 0 register (C55FMC_OPP0)

The Over-Program Protection 0 (OPP0) register provides a means to protect blocks from being over-programmed. This register shows the over-program protection status.

NOTE

The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

Address: 0h base + 80h offset = 80h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:

- MIDOPP field: The reset value of the MIDOPP field is set at the factory and varies among devices. See the chip-specific C55FMC information for details.
- LOWOPP field: The reset value of the LOWOPP field is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

C55FMC_OPP0 field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 LOWOPP	Low Block Over-Program Protection[13:0]. A value of 1 in a bit of the over-program protection register signifies that the corresponding block is protected from over-programming. A value of 0 in the OPP register signifies that the corresponding block is available to be over-programmed. The block numbering for the Low Blocks starts at LOWOPP[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. The LOWOPP register is not writable, and is status only. The default value of the LOWOPP bits is not OPP. In the event that blocks are not present (due to configuration or total memory size), the OPP bits default not OPP, and will remain 0. 1 The corresponding block is protected from over-programming. 0 The corresponding block is available to be over-programmed.
16–31 MIDOPP	Mid Block Over-Program Protection[15:0]. A value of 1 in a bit of the over-program protection register signifies that the corresponding block is protected from over-programming. A value of 0 in the OPP register signifies that the corresponding block is available to be over-programmed. The block numbering for the Mid Blocks starts at MIDOPP[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted.

Table continues on the next page...

C55FMC_OPP0 field descriptions (continued)

Field	Description
	The MIDOPP register is not writable, and is status only. The default value of the MIDOPP bits is not OPP. In the event that blocks are not present (due to configuration or total memory size), the OPP bits default not OPP, and will remain 0. 1 The corresponding block is protected from over-programming. 0 The corresponding block is available to be over-programmed.

72.5.16 Over-Program Protection 1 register (C55FMC_OPP1)

The Over-Program Protection 1 (OPP1) register provides a means to protect blocks from being over programmed. This register shows the over-program protection status.

NOTE

The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

Address: 0h base + 84h offset = 84h

C55FMC_OPP1 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 HIGHOPP	High Block Over-Program Protection[15:0]. A value of 1 in a bit of the over-program protection register signifies that the corresponding block is protected from over-programming. A value of 0 in the OPP register signifies that the corresponding block is available to be over-programmed. The block numbering for the High Blocks starts at HIGHOPP[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. The HIGHOPP register is not writable, and is status only. The default value of the HIGHOPP bits is not OPP. In the event that blocks are not present (due to configuration or total memory size), the OPP bits default not OPP, and will remain 0. 1 The corresponding block is protected from over-programming. 0 The corresponding block is available to be over-programmed.

72.5.17 Over-Program Protection 2 register (C55FMC_OPP2)

The Over-Program Protection 2 (OPP2) register provides a means to protect blocks from being over programmed. This register shows the over-program protection status.

NOTE

The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

72.6 Functional Description

The embedded flash memory consists of address spaces in four groupings:

- Low address space
- Mid address space
- High address space
- 256 KB address space

The main address space is divided into partitions. Each address space mentioned above consists of a partition pair. Partitions are used to determine locations for valid read-while-write (RWW) operations. While the embedded flash memory is performing a write (program or erase) to a given partition, it can simultaneously perform a read from any other partition. For program operations, only the address specified by an interlock write determines the partition being written (block locking and block select registers do not determine the RWW partitions being written). For erase operations, only blocks that are selected and unlocked determine the RWW partitions being written.

The main address space is also divided into blocks to implement independent erase and program protection. The UTest NVM block also exists as a block, and has independent program protection. The UTest NVM block is included to support systems that require nonvolatile memory (NVM) for security or to store system initialization information.

A number of MCR bits are protected against write when another bit, or set of bits, is in a specific state. These write locks are covered on a bit-by-bit basis in Module Configuration Register (C55FMC_MCR). The write locks do not consider the effects of trying to write two or more bits simultaneously. The embedded flash memory does not allow bits to be written simultaneously which put the device into an illegal state. This is implemented through a priority mechanism among the bits. The bit changing priorities are detailed in the following table.

Table 72-2. MCR bit set/clear priority levels

Priority level	MCR Bit(s)
1	ERS
2	PGM
3	EHV
4	ESUS, PSUS

If two or more MCR bits are written simultaneously only the bit with the lowest priority number is accepted for modification. Setting two bits with the same priority number is prevented by existing write locks or do not put the flash memory in an illegal state.

For example, setting ERS and PGM simultaneously results in only ERS being set. Attempting to clear EHV while setting PSUS results in EHV being cleared, while PSUS is unaffected.

Each read of the embedded flash memory retrieves a page, or eight consecutive words (256 bits), of information. The address for each word retrieved within a page differs from the other addresses in the page only by address bits [4:2]. The flash memory page read architecture easily supports both cache and burst mode at the BIU level for high-speed read applications.

The embedded flash memory supports fault tolerance through error correction code (ECC) and error detection. ECC implemented within the embedded flash memory corrects single-bit failures and detects double-bit failures.

A software mechanism is provided to independently lock and unlock each block.

Program and erase of the embedded flash memory requires multiple system clock cycles to complete. The program and erase sequence may be suspended or aborted.

The embedded flash memory may reside in various modes. The modes that are available include:

- User mode
- Low Power mode
- UTest mode

Each of these modes is discussed in detail in the following sections.

72.6.1 User Mode

In user mode the embedded flash memory may be read and written (register writes and interlock writes), programmed or erased. The following sub-sections define all actions that may be performed in user mode.

72.6.1.1 Read and write

The default state of the embedded flash memory is read. The main and UTest NVM address space can be read only in the read state. The MCR is always available for read, except when the embedded flash memory is in low power mode. The embedded flash memory enters the read state on reset. The embedded flash memory is in the read state under four sets of conditions:

- The read state is active when the embedded flash memory is enabled (User Mode Read).
- The read state is active when MCR[PGM] or MCR[ERS] are high and high-voltage operation is ongoing (read-while-write).

NOTE

Reads done to the partition(s) being operated on (either erased or programmed) result in an error and the MCR[RWE] bit is set.

- The read state is active when MCR[PGM] and MCR[PSUS] are high (program suspend).
- The read state is active when MCR[ERS] and MCR[ESUS] are high and MCR[PGM] is low (erase suspend).

In embedded flash memory, flash core reads return 256 bits (1 page). Register reads return 32 bits of data.

NOTE

Flash core reads are done through the BIU. In many cases the BIU does read page buffering to allow sequential reads to be done with higher performance. This could provide a data coherency issue that must be handled with software. Data coherency may be an issue after a program or erase operation, as well as UTest NVM block operations.

In user mode, registers may be written. Array may be written to do interlock writes.

Register reads to unmapped register address space return all zeroes.

Register writes to unmapped register address space have no effect.

Interlock writes that are attempted during a high-voltage operation (MCR[EHV] = 1 or MCR[DONE] =0) will result in the interlock write being ignored, and address and data will not be updated.

NOTE

Care must be taken when doing 32-bit interlock writes. Performing two 32-bit interlock writes to the same word location is not supported. In addition, mixing 32-bit interlock writes with 64-bit interlock writes to the same double-word location is not supported. If these combinations are done, and a program operation is executed, the result will be MCR[PEG] = 0. See the Module Configuration Register (MCR) section for more information.

72.6.1.2 Program

A flash memory program sequence operates on any page within the flash core. Within a page, up to eight words may be altered in a single program operation. Also, up to four pages can be altered in a single program operation. Whenever the array is programmed, the ECC bits also get programmed. ECC is handled on a 64-bit boundary. Thus, if only one word in any given 64-bit ECC segment is programmed, the adjoining word (in that segment) should not be programmed, since ECC calculation has already completed for that 64-bit segment. Attempts to program the adjoining word will probably result in an operation failure. It is recommended that all programming operations be from 64 bits to 1024 bits, and be 64-bit aligned. The programming operation should completely fill selected ECC segments within the page. Only one program is allowed per 64-bit ECC segment between erases.

Warning

In rare cases over-programming of a 64-bit ECC segment may be done (EEPROM emulation).

Programming changes the value stored in an array bit from logic 1 to logic 0 only. Programming cannot change a stored logic 0 to a logic 1.

NOTE

If a logic 0 is attempted to be over-programmed by a logic 1, the resulting operation will fail (MCR[PEG] = 0), and the 0's that are interlocked will be merged (ORed) with 0's that are already present in the 64-bit ECC segment, unless the block is designated as an Over-Program Protected block.

Addresses in locked/disabled blocks cannot be programmed. Values may be programmed in any or all of eight words, within a page, with a single program sequence. Page-bound words have addresses which differ only in address bits [4:2]. Up to four pages can be programmed at once on a quad-page boundary, which differ only in address bits [6:5]. The program operation consists of the following sequence of events:

1. Change the value in the MCR[PGM] bit from a 0 to a 1.

   NOTE

   Ensure the block that contains the address to be programmed is unlocked.

2. Write the first address to be programmed with the program data. The embedded flash memory latches address bits [22:7] and SoC-specific UTest NVM enable at this time. The embedded flash memory latches data written as well. This write is referred to as

a program data interlock write. An interlock write may be done as a 64-bit transaction or a 32-bit transaction. Refer to the Flash Memory Controller chapter for information on the size of writes that are allowed.

3. If more than one word or doubleword is to be programmed, write each additional address in the page with data to be programmed. This is referred to as a program data write. The embedded flash memory ignores address bits [22:7] and SoC-specific UTest NVM enable for program data writes. All unwritten data words default to 0xFFFF_FFFF.
4. Write a logic 1 to the MCR[EHV] bit to start the internal program sequence or skip to step 9 to terminate.
5. Wait until the MCR[DONE] bit goes high.

NOTE

Since MCR[DONE] clears with MCR[EHV] being set, it may not be possible for software to read MCR[DONE] as a 0 prior to this step, depending on the operation selected.

6. Confirm MCR[PEG] = 1.
7. Write a logic 0 to the MCR[EHV] bit.
8. If more addresses are to be programmed, return to step 2.
9. Write a logic 0 to the MCR[PGM] bit to terminate the program sequence.

The first write after a program is initiated determines the quad-page address to be programmed. Program may be initiated with the 0 to 1 transition of the MCR[PGM] bit or by clearing the MCR[EHV] bit at the end of a previous program. This first write is referred to as an interlock write. The interlock write determines if the UTest NVM or normal array space is to be programmed by sampling SoC-specific UTest NVM enable and causing MCR[PEAS] to be set/cleared.

In the case of an erase-suspended program, the values in MCR[PEAS] may be modified via the program interlock write, enabling erase-suspended programs to and from UTest NVM space.

An interlock write must be performed before setting MCR[EHV]. A program sequence may be terminated by clearing MCR[PGM] prior to setting MCR[EHV].

After the interlock write, additional writes affect the data to be programmed at the word location determined by address bits [4:2], as well as the page location within a 1024-bit segment (determined by address bits [6:5]). Unwritten locations default to a data value of 0xFFFF_FFFF. If multiple writes are done to the same location, the data for the last write is used in programming.

While DONE is low, EHV is high, and PSUS is low, then EHV may be cleared, resulting in a program abort. A program abort forces the embedded flash memory to step 8 of the program sequence. An aborted program results in PEG being set low, indicating a failed operation. The data space being operated on before the abort contains indeterminate data. A program sequence may not be aborted while in program suspend.

Warning

Aborting a program operation leaves the flash core addresses being programmed in an indeterminate data state. This may be recovered by executing an erase on the affected blocks.

72.6.1.2.1 Program software locking

A software mechanism is provided to independently lock/unlock blocks against program and erase.

Software locking is done through the LOCK0, LOCK1, LOCK2, and LOCK3 registers. These may be written through register writes, and may be read through register reads.

72.6.1.2.2 Program hardware locking

Hardware locking which only affects the program operation is also available for UTest, 16 KB, 32 KB, 64 KB, and 256 KB blocks.

72.6.1.2.3 Program suspend/resume

The program sequence may be suspended to allow read access to the flash core. It is not possible to erase during a program suspend, or to program during a program suspend. These operations are prevented by register locking described in the Module Configuration Register (MCR) section. Read-while-write operation may also be used to read the array during a program sequence, providing the read is to a different partition.

A program suspend can be initiated by changing the value of the MCR[PSUS] bit from a 0 to a 1. MCR[PSUS] can be set high at any time when MCR[PGM] and MCR[EHV] are high. A 0 to 1 transition of MCR[PSUS] causes the embedded flash memory to start the sequence to enter program suspend, which is a read state. MCR[DONE] must become a logic level 1 before the embedded flash memory is suspended. At this time flash core reads may be attempted. Once suspended, the flash core may only be read. During suspend, all reads to flash core locations targeted for program, and blocks targeted for erase, return indeterminate data.

The program sequence is resumed by writing a logic 0 to MCR[PSUS]. MCR[EHV] must be set to a 1 before clearing MCR[PSUS] to resume operation. When the operation resumes, the embedded flash memory continues the program sequence from one of a set of predefined points. This may extend the time required for the program operation.

NOTE

Repeated suspends at a high frequency may result in the operation not completing normally. Although suspend frequency is not limited, enabling at least 20 µs between suspend resume and future suspend requests improve the opportunity for the flash to complete the operation successfully.

72.6.1.2.4 Over-program protection enable

One-time programming can be enabled on a block basis. In an over-program protection enabled block, any doubleword which has already been programmed cannot be programmed again. The over-program protection enable does not affect erase operation. Attempts to over-program will result in MCR[PEG] being cleared. If any doubleword within the quad-page has an over-program protection violation, MCR[PEG] will be cleared, and no doublewords will be programmed.

One-time programming can be enabled for 16 KB, 32 KB, 64 KB, or 256 KB blocks.

Over-program protection is enabled by sideband signals, and if enabled, the program operation will be modified to check for programmed bits prior to doing a high-voltage program event.

72.6.1.2.5 Successful program address

To enable the SoC to create logic to authenticate operations with a program (such as in a diary operation), the flash module provides the last successful address programmed as a sideband signal. This value will be held until the next successful program. A successful program is defined as a program operation of data that is not all 1's to an unlocked block, and the operation results in MCR[PEG] returning a 1. If any doubleword within the pages being programmed is interlocked with all 1's, the sideband signal will not be updated. An address of all 1's, and each of the block size selects selected, is the default (and invalid) address after reset.

72.6.1.3 Erase

Erase changes the value stored in all bits of the selected block(s) to logic 1. An erase sequence operates on any combination of blocks in the main address space. The erase sequence is fully automated within the flash memory. Blocks to be erased must be selected prior to initiating the erase sequence. Locked/disabled blocks cannot be erased. If multiple blocks are selected for erase during an erase sequence, the blocks are erased sequentially starting with the lowest numbered block and terminating with the highest (low first, mid second, high last, 16 KB first, 32 KB second, 64 KB third, last blocks are 256 KB). The erase sequence consists of the following events:

1. Change the value in the MCR[ERS] bit from 0 to 1.
2. Select the block or blocks to be erased by writing ones to the appropriate registers in SEL0, SEL1, SEL2, or SEL3 registers.

NOTE

Lock and Select are independent. If a block is selected and locked, no erase occurs.

3. Write to any address in flash memory. This is referred to as an erase interlock write. An erase interlock write to UTest NVM space is not allowed if sealed (since erase is not allowed in the UTest NVM space when sealed).
4. Write a logic 1 to the MCR[EHV] bit to start an internal erase sequence or skip to step 9 to terminate.
5. Wait until the MCR[DONE] bit goes high.

NOTE

Since MCR[DONE] clears with MCR[EHV] being set, it may not be possible for software to read MCR[DONE] as a 0 prior to this step, depending on the operation selected.

6. Confirm MCR[PEG] = 1.
7. Write a logic 0 to the MCR[EHV] bit.
8. If more blocks are to be erased, return to step 2.
9. Write a logic 0 to the MCR[ERS] bit to terminate the erase.

After setting ERS, one write, referred to as an interlock write, must be performed before EHV can be set to a 1. Data words written during erase sequence interlock writes are ignored. The erase sequence may be terminated by clearing ERS before setting EHV.

An erase operation may be aborted by clearing EHV, assuming DONE is low, EHV is high, and ESUS is low. An erase abort forces the embedded flash memory to step eight of the erase sequence. An aborted erase results in PEG being set low, indicating a failed operation. The block(s) being operated on before the abort contain indeterminate data. An erase sequence may not be aborted while in erase suspend.

72.6.1.3.1 Erase software locking

Software Locking affect erase operation. For details on this see Program software locking.

72.6.1.3.2 Erase hardware locking

Hardware locking which only affects the erase operation is also available for UTest, 16 KB, 32 KB, 64 KB, and 256 KB blocks.

72.6.1.3.3 Erase suspend/resume

The erase sequence may be suspended to allow read access to the flash core. The erase sequence may also be suspended to program (Erase-Suspended Program) the flash core. A program started during erase suspend can in turn be suspended. Only one erase suspend and one program suspend are allowed at a time during an operation. It is not possible to erase during an erase suspend, or program during a program suspend. During suspend, all reads to flash core locations targeted for program and blocks targeted for erase return indeterminate data.

Read-while-write operation may also be used to read the array during an erase sequence, provided the read is to a partition not selected for erase.

An erase suspend can be initiated by changing the value of the MCR[ESUS] bit from a 0 to a 1. MCR[ESUS] can be set to a 1 at any time when MCR[ERS] and MCR[EHV] are high and MCR[PGM] is low. A 0 to 1 transition of MCR[ESUS] causes the embedded flash memory to start the sequence which places it in erase suspend. MCR[DONE] must become a logic level 1 before the embedded flash memory is suspended and further actions are attempted. Once suspended, the array may be read or a program sequence may be initiated (erase-suspended program). Before initiating a program sequence, MCR[EHV] must first be cleared. If a program sequence is initiated, the values of SoC-specific UTest NVM enable is recaptured. Once the erase-suspended program is completed, the value of PEAS is returned to its erase value. Flash core reads that occur while MCR[ESUS] = 1 from the block(s) being erased will return indeterminate data.

The erase sequence is resumed by writing a logic 0 to MCR[ESUS]. MCR[EHV] must be set to a 1 and MCR[PGM] must be cleared (in the event of an erase-suspended program) before MCR[ESUS] can be cleared to resume the operation. The embedded flash memory continues the erase sequence from one of a set of predefined points. This may extend the time required for the erase operation.

NOTE

1. In an erase-suspended program, programming flash core locations in blocks which were being operated on will respond by completing the operation with a fail code (MCR[PEG] = 0). Programming voltages will not be applied to the memory array in this case.
2. Repeated suspends at a high frequency may result in the operation not completing normally. Although suspend frequency is not limited, enabling at least 5ms between suspend resume and future suspend requests improve the opportunity for the flash to complete the operation successfully.

72.6.2 Low Power mode

In Low Power mode, the embedded flash memory enables VDDF power gating, and disables circuits on the VFLASH domain. No reads from or writes to the embedded flash memory are possible when in Low Power mode.

Prior to entering Low Power Mode, it is required that all program, erase, and UTest operations be stopped prior to entering the mode. If Low Power mode is entered while an operation is suspended, entering Low Power mode will have the same effect as a reset during suspend.

When in Low Power mode, register access is prevented. Flash core accesses are also prevented until power mode is exited. Flash core reads and writes may occur after power mode is exited.

The embedded flash memory returns to a post-reset state in all cases.

72.6.3 UTest mode

UTest mode is a mode into which customers can put the embedded flash memory so as to do specific tests that check the integrity of the embedded flash memory.

72.6.3.1 Array integrity self check

The Array Integrity (AI) operation is a flash-specific self-test feature in which a MISR signature value is generated from data read from selected flash blocks. After the operation is complete, customer code compares the resulting MISR signature to the expected value to determine if an incorrect read or ECC detection occurred.

Array integrity operations are fully contained within the flash module. Results of Array integrity operations are not reported beyond the boundary of the flash module.

During array integrity test, user mode array reads are ignored to ensure the array integrity operation is not corrupted. User mode array reads may be executed if suspended or at a breakpoint.

AI read operations are executed using a predefined address sequence selected via the UT0[AIS] register field value. The data to be read is customer-specific, e.g., user program code that has been programmed into the flash memory. Any random or nonrandom code is valid. The expected MISR signature is calculated based on the specific data to be read.

Note that array integrity MISR signature calculations are performed after ECC detection and correction so correctable ECC events do not cause the MISR signature to deviate from the expected value.

Array integrity processing requires the flash memory controller's PFLASH_PFCR1[RWSC] and PFLASH_PFCR1[APC] register fields to be set to values that are valid for the system frequency being used. Only the valid/recommended RWSC and APC values for a given frequency, as stated in the device data sheet, are supported.

The Array integrity check consists of the following sequence:

1. Enable UTest mode by setting the UT0[UTE] bit to 1.
2. Select one or more blocks for an array integrity check by writing 1's to the appropriate bits in the SEL0 – SEL3 registers. Blocks selected for AI test do not need to be unlocked.

   Flash blocks that have not been selected are still read as part of the array integrity sequence to enable full transition coverage. Reads on unselected blocks are not captured in the MISR. Selecting fewer blocks may not result in a faster array integrity execution time, depending on the combinations of blocks selected and the sequence.

   Blocks protected with the Test Mode Disable Seal are still read as part of the array integrity sequence. The resulting read on sealed blocks is not captured in the MISR, but the Single Bit Correction, Double Bit Detection and breakpoints are still honored.

NOTE

It is not possible to do array integrity operations on the UTest NVM block.

3. If desired, set the UT0[AIS] bit to 1 for sequential addressing only.

   For normal integrity checks of the flash memory, sequential addressing is recommended. If it is required to more fully check the read path (in a diagnostic mode), it is recommended that UT0[AIS] be left at 0, to use the address sequence that checks the read path more fully, and examine read transitions. This sequence takes more time.

4. Seed the MISR registers (UM0 — UM9) with desired values.
5. If breakpoints are desired, set UT0[AIBPE] to 1, and ensure that MCR[EER] and MCR[SBC] are cleared. If it is desired to break on single-bit correction, the UT0[SBCE] must be set.
6. Initiate AI by setting the UT0[AIE] bit to 1.

   The array integrity operation may be aborted prior to UT0[AID] going high. This may be done by clearing the UT0[AIE] bit and continuing to the next step. It should be noted that in the event of an aborted array integrity check the MISR registers contain a signature for the portion of the operation that was completed prior to the abort, and are not deterministic. Prior to doing another array integrity operation, the UM0 – UM9 registers may need to be initialized to the desired seed value by doing register writes.

   The array integrity operation may be suspended prior to UT0[AID] going high. UT0[AISUS] may be set to request an array integrity suspend. After the UT0[AISUS] bit is set, the user should wait for UT0[AID] bit to go high, which indicates the flash has entered the suspend state, and normal reads to the flash may be done. After the UT0[AID] bit goes high, the UT0[AISUS] bit may be cleared to resume the array integrity sequence.

7. Wait until the UT0[AID] bit goes high, indicating that array integrity test is complete.
8. If breakpoints are enabled, check the UT0[NAIBP] bit. If set to 1, the MCR[EER], MCR[SBC], and ADDR registers may be checked to determine the cause of the break and the address of the break. Prior to resuming the operation, clear the MCR[SBC] or MCR[EER] bits, then resume the operation by clearing the UT0[NAIBP] bit. Continue to wait until the UT0[AID] bit goes high. If breakpoints are not enabled, or if the UT0[NAIBP] bit is low when the UT0[AID] bit goes high, the operation is complete. Continue to the next step.
9. Read values in the MISR registers (UM0 — UM9) to ensure correct signature.

NOTE

Array integrity reads may be done to unselected (or non-present) locations. Reads done to these locations do not update the MISR, and do not update the MCR[EER] and MCR[SBC] error bits.

10. Write a logic 0 to the UT0[AIE] bit to complete array integrity test.

72.6.3.2 User margin read

User Margin Read is a flash-specific self-test feature that enables reads to be done at a Program margin or Erase margin level.

Margin reads are performed with an internal read reference voltage that has been adjusted, i.e., "margined" toward the threshold voltage being checked. The read reference voltage is either margined toward a 0 (programmed bit) or margined towards a 1 (erased bit), depending on the margin read operation selected.

User margin read is done using the array integrity interface, and has all the associated features of the array integrity interface (MISR and Breakpoints). User margin read is a self-timed event, and is independent of system clocks or wait states selected.

Margin read operations are fully contained within the flash module. Results of margin read operations are not reported beyond the boundary of the flash module.

During margin read operations, user mode array reads are ignored to ensure the operation is not corrupted. User mode array reads may be executed if suspended or at a breakpoint.

ECC corrections and detections are noted during the user margin read test. Note that margin read MISR signature calculations are performed *after* ECC detection and correction so correctable ECC events do not cause the MISR signature to deviate from the expected value.

The data to be read is customer-specific, e.g., user program code that has been programmed into the flash memory. Any random or non-random code is valid. The expected MISR signature is calculated based on the specific data to be read. After the operation is completed the margin read results can be checked by reading the MCR[EER] and MCR[SBC] bits to determine if zero, one, or two bits are being detected by the margin read, and comparing the generated MISR signature to the expected value.

The use model for margin read is in the event of a user-detected single bit correction (through user reads). A margin read may be done to check for a possible second bit falling within the selected margin levels.

The procedure for doing margin reads is:

1. Enable UTest mode by setting the UT0[UTE] bit to 1.
2. Select one or more blocks for margin read check by writing 1's to the appropriate bits in SEL0 – SEL3 registers. Blocks selected for margin read do not need to be unlocked.

   Flash blocks that have not been selected are still read as part of the margin read sequence to enable full transition coverage. Reads on unselected blocks are not captured in the MISR. Selecting fewer blocks does not result in a faster margin read execution time.

   Blocks protected with the Test Mode Disable Seal are still read as part of the margin read sequence. The resulting read on sealed blocks is not captured in the MISR, but the Single Bit Correction, Double Bit Detection and breakpoints are still honored.

   NOTE

   It is not possible to do margin read operations on the UTest NVM block.

3. Set the UT0[AIS] bit to 1 for sequential addressing only.

   NOTE

   Only sequential addressing is supported for margin read checks.

4. Seed the MISR registers (UM0 — UM9) with desired values.
5. If breakpoints are desired, set UT0[AIBPE] to 1, and ensure that MCR[EER] and MCR[SBC] are cleared. If it is desired to break on single-bit correction, the UT0[SBCE] bit must be set to 1.
6. Initiate margin read by setting the UT0[MRE] bit to 1.
7. Select either one's margin or zero's margin by setting the UT0[MRV] bit to the appropriate value.
8. Set the UT0[AIE] bit.

   During margin read operations, with UT0[AID] low, it is not recommended to attempt write operations to the MCR[SBC] and MCR[EER] bits. It is recommended that these bits only be written during suspend, breakpoints, or at completion of the Margin Read operation.

9. Wait until the UT0[AID] bit goes high, indicating that margin read test is complete.

   If breakpoints were enabled or a suspend was requested during margin read, the operation may be at a breakpoint or a suspend state. See Step 8 in section Array integrity self check for more information.

10. Read values in the MISR registers (UM0 — UM9) to ensure correct signature.

NOTE

Margin reads may be done to unselected (or non-present) locations. Reads done to these locations do not update the MISR, and do not update the MCR[EER] and MCR[SBC] error bits.

11. Write a logic 0 to the UT0[AIE] bit.

72.7 Initialization information

A reset is the highest priority operation for the embedded flash memory and terminates all other operations.

The embedded flash memory uses reset to initialize register and status bits to their default reset values. If the embedded flash memory is executing a program or erase operation (PGM or ERS = 1) and a reset is issued, the operation is aborted and the embedded flash memory disables the high-voltage logic without damage to the high-voltage circuits. Reset aborts all operations and forces the embedded flash memory into user mode ready to receive accesses.

After reset is requested, MCR[DONE] goes low, and remains low during reset and reset recovery. At the end of reset recovery, MCR[DONE] transitions from a 0 to a 1.

After reset is completed, register reads may be done, although it should be noted that registers that require updating from UTest NVM information, or other inputs, may not read updated values until MCR[DONE] transitions high.

During reset recovery, register writes are not allowed until the MCR[DONE] bit transitions high to indicate reset recovery is completed.

Warning

Resetting during a program or erase operation leaves the flash core blocks being programmed or erased in an indeterminate data state. This may be recovered by executing an erase on the affected blocks.

Chapter 73
Memory Error Management Unit (MEMU)

73.1 Chip-specific MEMU information

73.1.1 MEMU configuration

This section describes the configuration of MEMU_0 and MEMU_1 specific to the MPC5746C.

73.1.2 MEMU system connections

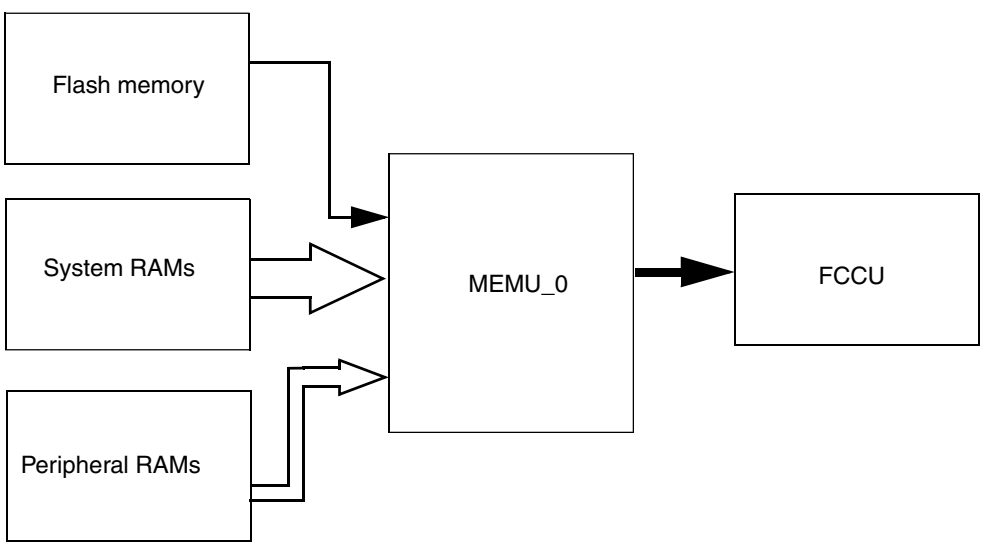

Figure 73-1. MEMU_0 system connections

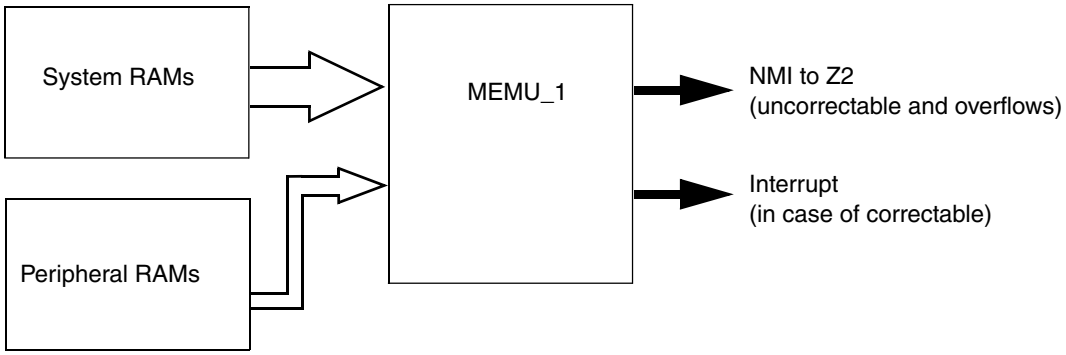

Figure 73-2. MEMU_1 system connections

73.1.3 MEMU error sources

This chip includes two instances of MEMU as follows:

- MEMU_0 (for error sources in the full power domain)
- MEMU_1 (for error sources in the LPU domain)

The following tables shows the MEMU error sources for each instance configured on this chip.

Table 73-1. MEMU_0 error sources

Instance	Value
Number of system RAM unique error sources	10
Number of peripheral RAM unique error sources	5
Number of flash memory unique error sources	3

Table 73-2. MEMU_1 error sources

Instance	Value
Number of system RAM unique error sources	4
Number of peripheral RAM unique error sources	2
Number of flash memory unique error sources	0

73.1.4 Reporting table implementation

MEMU establishes the following categories of error reporting:

- Flash memory error reporting

- System RAM error reporting (any RAM that is CPU accessible falls into this category)
- Peripheral RAM error reporting (any RAM that is not CPU accessible falls into this category)

Each category of error reporting has two tables associated with it, these are:

- Correctable error reporting table
- Uncorrectable error reporting table

Each entry in a reporting table corresponds to a unique error event. The number of entries supported by each table depends upon the error source.

The table below describes the number of entries in each reporting table for the different error sources.

Table 73-3. Number of entries in each reporting table for MEMU_0

Error source	Number of entries in correctable error reporting table	Number of entries in un-correctable error reporting table
Flash memory	20	1
Peripheral RAM	2	1
System RAM	10	1

Table 73-4. Number of entries in each reporting table for MEMU_1

Error source	Number of entries in correctable error reporting table	Number of entries in un-correctable error reporting table
Flash memory	0	0
Peripheral RAM	1	1
System RAM	3	1

73.1.5 Concurrent overflow register (OFLW) implementation for MEMU_0

Errors are reported to the MEMU from these categories:

- Flash memory
- System RAM
- Peripheral RAM

In an overflow condition, it is possible to identify the unique error source that caused the overflow. Corresponding error sources for the OFLW register details the corresponding error source to the respective bit-field in the Concurrent Overflow registers.

Positions not explicitly listed in the tables below are reserved.

Table 73-5. Corresponding error sources for system RAM OFLW0 register

Bit number	Error source	Clock relationship with respect to MEMU
0	z4 Instruction Cache	Asynchronous
1	z4 Data Cache	Asynchronous
2	z4 Instruction AHB	Asynchronous
3	z4 Data AHB	Asynchronous
4	Reserved	-
5	Reserved	-
6	Reserved	-
7	Reserved	-
8	DMA AHB	Synchronous
9	HSM AHB	Synchronous
10	Ethernet AHB	Synchronous
11	Flexray AHB	Synchronous
12	Reserved	-
13	Reserved	-
14	Reserved	-
15	Reserved	-
16	PRAM_1 AHB	Asynchronous
17	Reserved	-
18	PRAM_1 DMC	Asynchronous
19	Reserved	-

NOTE

This table shows that the master's AHB could be a source of an uncorrectable RAM error. Thus, if any master AHB from this table accesses a flash-memory location with an uncorrectable ECC error, the MEMU will report both the flash-memory error and a RAM uncorrectable error.

Table 73-6. Corresponding error sources for peripheral RAM OFLW0 register

Bit number	Error source	Clock relationship with respect to MEMU
0	PBRIDGE B	Synchronous
1	DMA TCD	Synchronous

Table continues on the next page...

Table 73-6. Corresponding error sources for peripheral RAM OFLW0 register (continued)

Bit number	Error source	Clock relationship with respect to MEMU
2	HSM instruction cache	Synchronous
3	HSM PRAM	Synchronous
4	PBRIDGE B DMC	Synchronous

Table 73-7. Corresponding error sources for flash memory OFLW0 register

Bit number	Error source	Clock relationship with respect to MEMU
0	PFLASH_0	Asynchronous
1	PFLASH_1	Asynchronous
2	PFLASH_2	Asynchronous

73.1.6 Concurrent overflow register (OFLW) implementation for MEMU_1

Errors are reported to the MEMU from these categories:

- System RAM
- Peripheral RAM

In an overflow condition, it is possible to identify the unique error source that caused the overflow. Corresponding error sources for the OFLW register details the corresponding error source to the respective bit-field in the Concurrent Overflow registers.

Positions not explicitly listed in the tables below are reserved.

Table 73-8. Corresponding error sources for system RAM OFLW0 register

Bit number	Error source	Clock relationship with respect to MEMU
0	z2 Instruction AHB	Synchronous
1	z2 Data AHB	Synchronous
2	PRAM_0 AHB	Asynchronous
3	PRAM_0 DMC	Asynchronous

Table 73-9. Corresponding error sources for peripheral RAM OFLW0 register

Bit number	Error source	Clock relationship with respect to MEMU
0	PBRIDGE A	Synchronous
1	PBRIDGE A DMC	Synchronous

73.1.7 MEMU_0 registers

The following table shows the address offsets and implementation of the MEMU_0 registers in this chip.

Table 73-10. MEMU_0 registers

Offset	Register
0x0000	Control register (CTRL)
0x0004	Error flag register (ERR_FLAG)
0x000C	Debug register (DEBUG)
0x0020	System RAM correctable error reporting table status register (SYS_RAM_CERR_STS0)
0x0024	System RAM correctable error reporting table address register (SYS_RAM_CERR_ADDR0)
0x0028	System RAM correctable error reporting table status register (SYS_RAM_CERR_STS1)
0x002C	System RAM correctable error reporting table address register (SYS_RAM_CERR_ADDR1)
0x0030	System RAM correctable error reporting table status register (SYS_RAM_CERR_STS2)
0x0034	System RAM correctable error reporting table address register (SYS_RAM_CERR_ADDR2)
0x0038	System RAM correctable error reporting table status register (SYS_RAM_CERR_STS3)
0x003C	System RAM correctable error reporting table address register (SYS_RAM_CERR_ADDR3)
0x0040	System RAM correctable error reporting table status register (SYS_RAM_CERR_STS4)
0x0044	System RAM correctable error reporting table address register (SYS_RAM_CERR_ADDR4)
0x0048	System RAM correctable error reporting table status register (SYS_RAM_CERR_STS5)
0x004C	System RAM correctable error reporting table address register (SYS_RAM_CERR_ADDR5)
0x0050	System RAM correctable error reporting table status register (SYS_RAM_CERR_STS6)
0x0054	System RAM correctable error reporting table address register (SYS_RAM_CERR_ADDR6)

0x0C8C	Flash memory correctable error reporting table address register (FLASH_CERR_ADDR13)
0x0C90	Flash memory correctable error reporting table status register (FLASH_CERR_STS14)
0x0C94	Flash memory correctable error reporting table address register (FLASH_CERR_ADDR14)
0x0C98	Flash memory correctable error reporting table status register (FLASH_CERR_STS15)
0x0C9C	Flash memory correctable error reporting table address register (FLASH_CERR_ADDR15)
0x0CA0	Flash memory correctable error reporting table status register (FLASH_CERR_STS16)

Table continues on the next page...

Table 73-10. MEMU_0 registers (continued)

Offset	Register
0x0CA4	Flash memory correctable error reporting table address register (FLASH_CERR_ADDR16)
0x0CA8	Flash memory correctable error reporting table status register (FLASH_CERR_STS17)
0x0CAC	Flash memory correctable error reporting table address register (FLASH_CERR_ADDR17)
0x0CB0	Flash memory correctable error reporting table status register (FLASH_CERR_STS18)
0x0CB4	Flash memory correctable error reporting table address register (FLASH_CERR_ADDR18)
0x0CB8	Flash memory correctable error reporting table status register (FLASH_CERR_STS19)
0x0CBC	Flash memory correctable error reporting table address register (FLASH_CERR_ADDR19)
0x0CC0	Flash memory uncorrectable error reporting table status register (FLASH_UNCERR_STS)
0x0CC4	Flash memory uncorrectable error reporting table address register (FLASH_UNCERR_ADDR)
0x0CC8	Flash memory concurrent overflow register (FLASH_OFLW0)

73.1.8 MEMU_1 registers

The following table shows the address offsets and implementation of the MEMU_1 registers in this chip.

Table 73-11. MEMU_1 registers

Offset	Register
0x0000	Control register (CTRL)
0x0004	Error flag register (ERR_FLAG)
0x000C	Debug register (DEBUG)
0x0020	System RAM correctable error reporting table status register (SYS_RAM_CERR_STS0)
0x0024	System RAM correctable error reporting table address register (SYS_RAM_CERR_ADDR0)
0x0028	System RAM correctable error reporting table status register (SYS_RAM_CERR_STS1)
0x002C	System RAM correctable error reporting table address register (SYS_RAM_CERR_ADDR1)
0x0030	System RAM correctable error reporting table status register (SYS_RAM_CERR_STS2)
0x0034	System RAM correctable error reporting table address register (SYS_RAM_CERR_ADDR2)
0x0038	System RAM uncorrectable error reporting table status register (SYS_RAM_UNCERR_STS)
0x003C	System RAM uncorrectable error reporting table address register (SYS_RAM_UNCERR_ADDR)
0x0040	System RAM concurrent overflow register (SYS_RAM_OFLW0)
0x0620	Peripheral RAM correctable error reporting table status register (PERIPH_RAM_CERR_STS0)
0x0624	Peripheral RAM correctable error reporting table address register (PERIPH_RAM_CERR_ADDR0)
0x0628	Peripheral RAM uncorrectable error reporting table status register (PERIPH_RAM_UNCERR_STS)
0x062C	Peripheral RAM uncorrectable error reporting table address register (PERIPH_RAM_UNCERR_ADDR)
0x0630	Peripheral RAM concurrent overflow register (PERIPH_RAM_OFLW0)

NOTE

Reserved locations with offset values as 0xC20, 0xC24, 0xC28, 0xC2C, and 0xC30 would not give error on access.

73.2 Introduction

The MEMU is responsible for collection and reporting of error events associated with ECC (Error Correction Code) logic used on:

- System RAM
- Peripheral RAM
- Flash memory

When any of the following events occur the MEMU receives an error signal which causes an event to be recorded and corresponding error flags to be set and reported to FCCU (Fault Collection and Control Unit).

- Correctable Error: It comprises the following:
  - Single Bit error in the data part that is detected via ECC for:
    - System RAM
    - Peripheral RAM
    - Flash memory
  - Single Bit error in the data part that is detected via MBIST on any RAM.
- Uncorrectable Error: It comprises the following:
  - Multiple bit error that is detected via ECC for:
    - System RAM
    - Peripheral RAM
    - Flash memory
  - Multiple bit error that is detected via MBIST on any SRAM. Based on MBIST implementation, the MBIST might report several correctable errors in the same word instead of an uncorrectable one. It is the task of the software after MBIST to aggregate these reports and detect the uncorrectable error.
  - Addressing errors and unused data bit errors detected by ECC logic.

The MEMU system connections are chip-specific; see the chip-specific MEMU information.

When multiple errors are indicated from various sources at same instant, an Overflow can be indicated by the MEMU to the FCCU. Overflow can also be indicated if the reporting table entries are full and a new unique error is reported by the system.

MEMU processes the errors based on whether they are correctable or uncorrectable (from either ECC or MBIST logic), independent of the source generating these errors.

The MEMU has multiple instances of the basic reporting block; one each for:

- System RAM ECC and MBIST
- Peripheral RAM ECC
- Flash memory ECC

Each instance has two reporting tables. Correctable errors are reported in one table, and the uncorrectable errors are reported in the other.

See Design overview for the reporting block details.

73.3 Features

The MEMU has the following features:

- Supports up to 128 error sources per the following reporting blocks (the number of error sources are chip-specific; see the chip-specific MEMU information):
  - System RAM ECC and MBIST
  - Peripheral RAM ECC
  - Flash memory ECC
- Support for error reporting from the following category of error sources (both for ECC and MBIST):
  - System RAM
  - Peripheral RAM
  - Flash memory
- Unique reported errors are logged into the module's reporting table which is accessible to CPU via memory mapped CPU register programming interface.
- MEMU handles overflow during error assertion and reports status accordingly.
- Unique errors are stored in correctable and non correctable section of the reporting table and corresponding indication is generated to the FCCU.
- CPU can program the known errors into the reporting table to avoid their re-reporting by MEMU.
- CPU can clear the reporting table errors.
- The reporting table for uncorrectable errors supports only 1 entry.

73.4 Block diagram

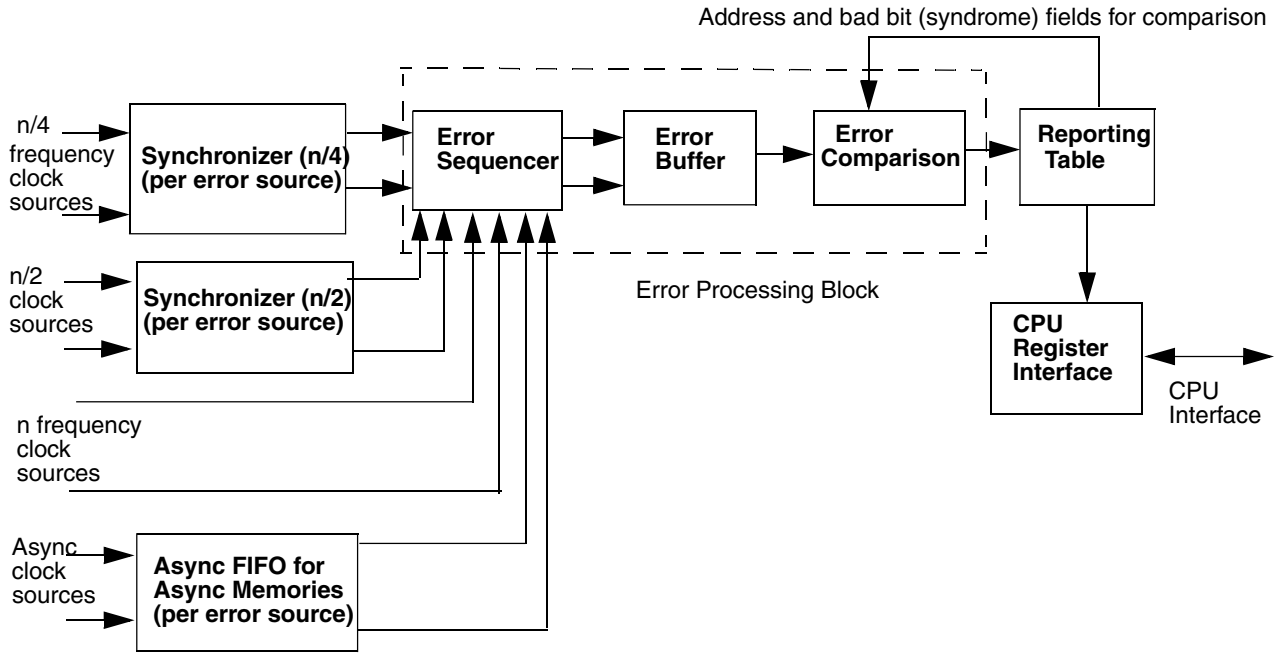

Figure 73-3. MEMU block diagram

73.5 Design overview

The MEMU should be enabled on power-on reset. The user software can write known error addresses into the reporting table to prevent reporting of those errors addresses to FCCU should they later be accessed in operation. All writes into the reporting table by the CPU that assert the Valid Bit (of the respective reporting table entry) will be indicated as a new error detected and will be reported to the FCCU. This feature can also be used as self-checking option of the MEMU and the MEMU-FCCU connection.

The MEMU design does not limit any particular sequence or errors. See Handling overflows (Multiple error reporting), for details on overflow behaviors.

The basic algorithm flow/architecture for error reporting in the MEMU is summarized below:

1. Synchronizer block

   For asynchronous inputs, a FIFO-based structure (per asynchronous channel) is implemented. All the error inputs (correctable error reported, uncorrectable error reported, error address and bad bits/syndrome) are concatenated and stored in the

FIFO. While storing the entry in the FIFO, a duplicity check is performed with the previously stored entry (the entry which was stored in the last cycle). If both the entries are duplicate the new entry is deleted and the pointers are rolled back to the old value, otherwise the new entry is stored. Whenever there is an overflow (FULL condition) in the Asynchronous FIFO, it is denoted by setting the Error Buffer Overflow or the EBO flag to the FCCU and the corresponding bit in the Concurrent Overflow Register is set.

For synchronous inputs, inputs are sampled whenever the corresponding clock synchronizing signal is asserted for a particular channel.

2. Error Processing block

This block is used to process the incoming errors coming from the device.

- Error Sequencer is used for sequencing the errors so that these are processed one per clock. In case of more than one errors detected by the sequencer logic, one is sent for the processing (error comparison block), the other is stored in the error buffer and the rest are marked as overflows in the Concurrent overflow register.
- All the sequences of incoming errors are supported. However, in case of multiple errors being asserted in back to back clock cycles, MEMU will process the errors being forwarded by the sequencer logic and register the rest of the errors as Concurrent Overflows in the Concurrent Overflow Register.

  For example, the MEMU processes a 0-2-2 sequence like this:

  1. The MEMU sends the first error directly to the processing.
  2. The MEMU stores the second error in the error buffer.
  3. The MEMU performs a uniqueness check, comparing the third error with the existing entry in the error buffer for uniqueness.

  If the errors are unique, the MEMU:

  - Classifies the fourth error as an overflow
  - Sets the corresponding EBO flag in Error flag register (MEMU_ERR_FLAG)

  If the errors are not unique, the MEMU:

  - Drops the third error
  - Stores the fourth error in the error buffer
  - Does not set any EBO flag in Error flag register (MEMU_ERR_FLAG)

- While storing the error in the error buffer, uniqueness is determined by comparing the error address, correctable or uncorrectable error type and the bad bit/syndrome (depending on ECC or MBIST logic) of the incoming error with

the one stored in buffer. If the error buffer is full, and the incoming error to be stored in the error buffer is not yet in the error table, Error Buffer Overflow (EBO) is registered and the corresponding bit in the Concurrent Overflow Register is set., else the incoming error is dropped.

- While doing the error buffer uniqueness check, the type of error i.e Correctable Error (CE) or Uncorrectable Error UCE) is also compared, hence even if the Error Address and the Bad bit/syndrome fields (Depending on whether the incoming error is generated from ECC or MBIST logic) of the incoming error matches with the error buffer, if the type of errors (CE and UCE) differ they are treated as unique
- Determine the type and uniqueness of errors in the error comparison block and store them in the correct reporting table (correctable or uncorrectable)
- Generate signals to assert the necessary flags. Be aware that it takes several MEMU clock cycles (<=5 unless the error gets temporarily stored in the error buffer due to a collision) for an error report to cause a signal to be sent to the FCCU.

3. Reporting table

   This is a pre-defined table in the MEMU to store the details for the device. For the reporting table if the entry is unique it is stored in the reporting table. If the entry is not unique it is not stored and discarded.

   The MEMU asserts proper flags when error is stored in the reporting table or an overflow is asserted. Flags are also asserted when the software writes the VLD bit to the reporting table.

   The CPU can clear the flags signaling errors or overflows to the FCCU directly by writing 1 at the corresponding valid bit of the status register (i.e. ..._CERR_STS or ..._UNCERR_STS). The clearing of flags is totally independent from the status of VLD bits in the reporting table.

   The reporting table sizes are chip-specific; see the chip-specific MEMU information.

4. Register block

   The CPU register programming interface provides the memory-mapped registers necessary for the CPU to access the reporting table and other control and status registers for the modules. Flags to FCCU will be asserted on write by CPU to the valid bit or by MEMU itself if a unique error is stored. However, in the situation when both MEMU and the CPU are accessing the same Register location, a wait cycle will be signaled to the CPU and the CPU command will be completed in the next clock cycle.

The software, in principle, is not supposed to write VLD to 1 if it is already 1.

The CPU register interface provides the decoding of the peripheral signals to allow access to the reporting table and other registers in module.

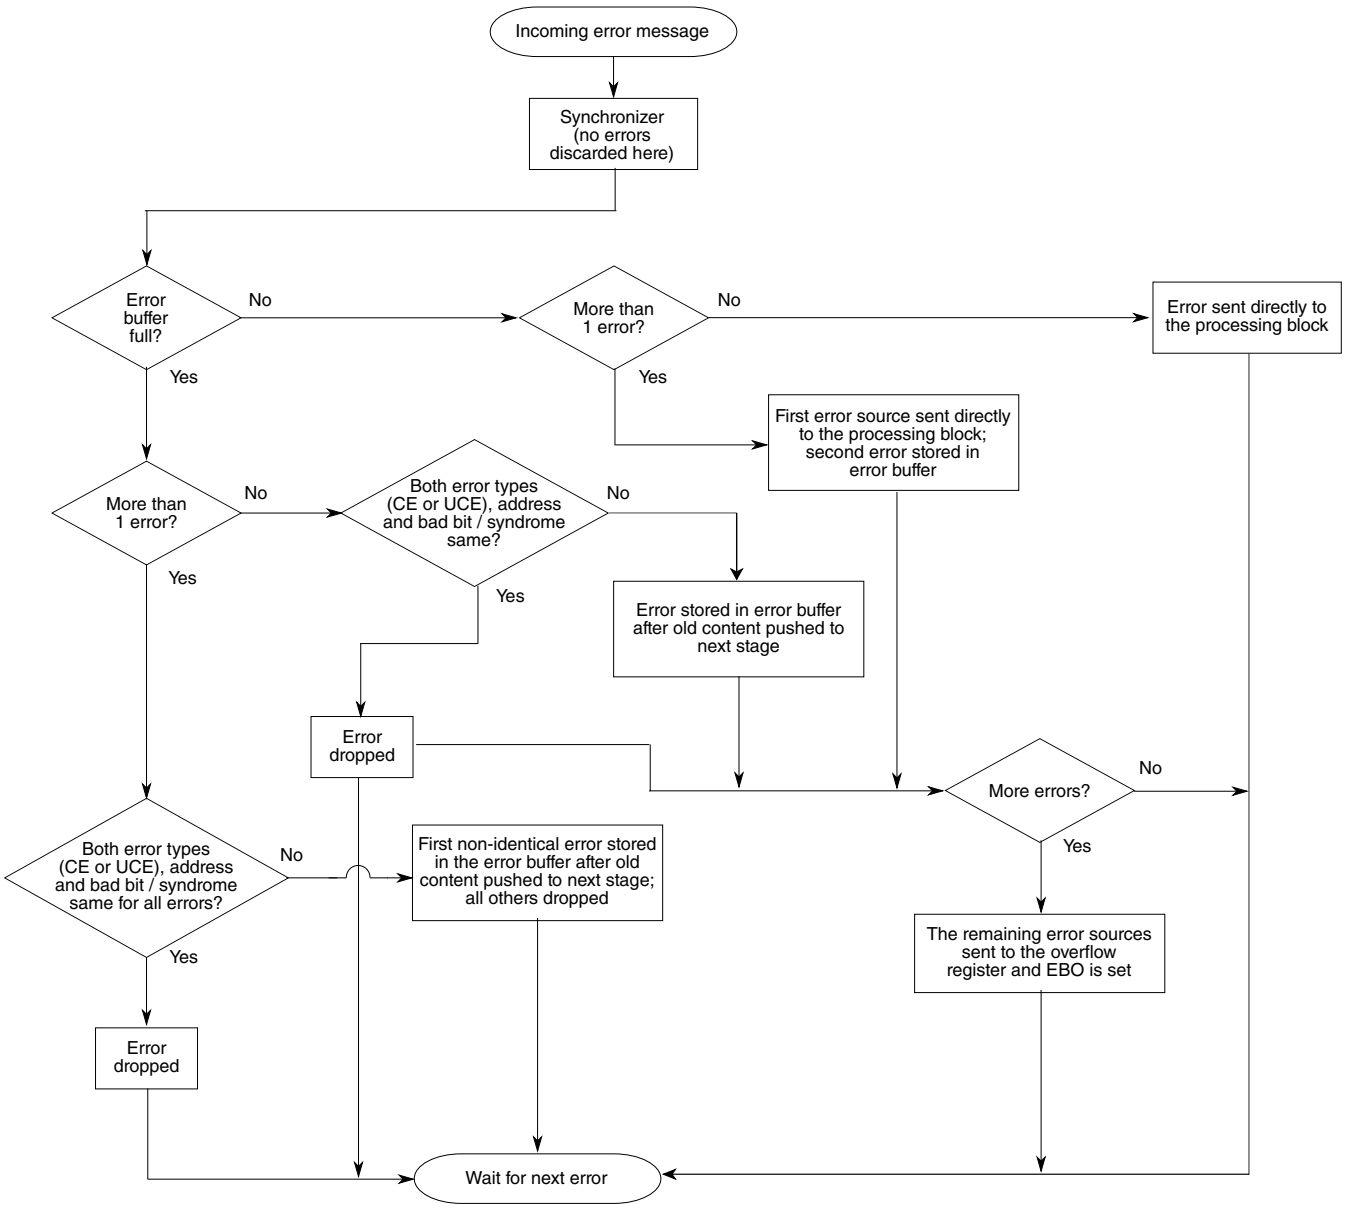

Figure 73-4. MEMU error buffer uniqueness check flow chart

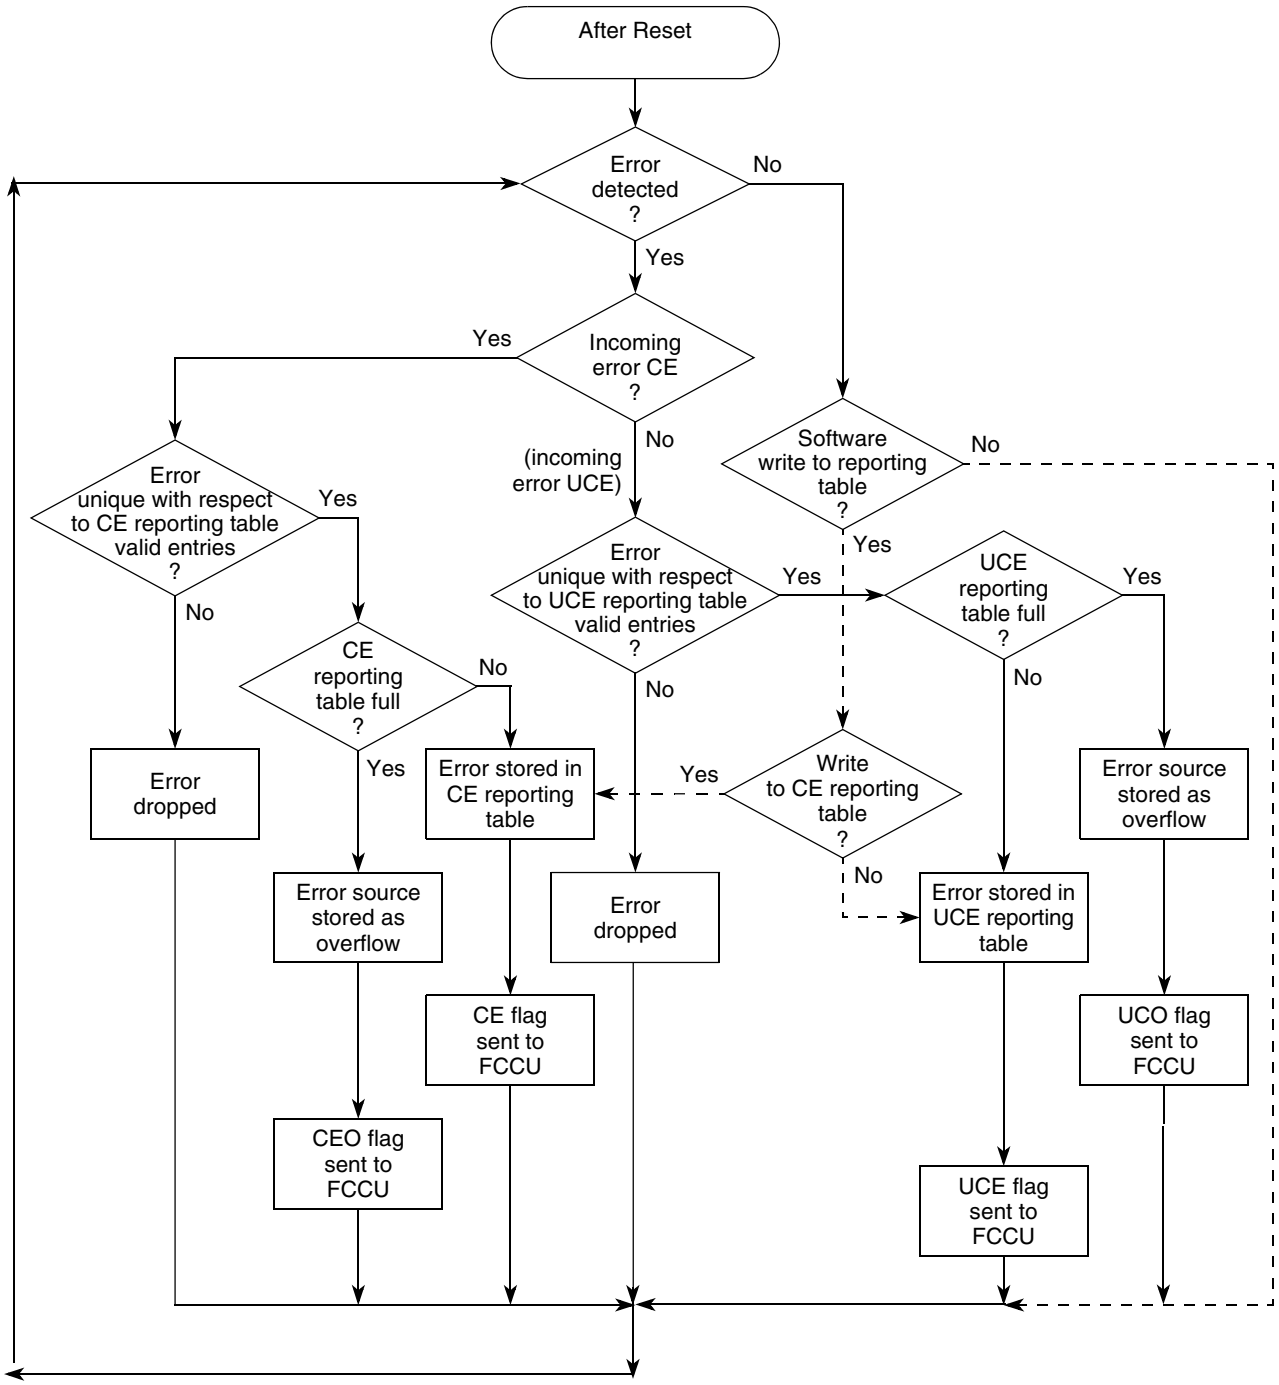

Figure 73-5. MEMU reporting table uniqueness check flow chart

73.6 External signal description

MEMU has no external signals.

73.7 Memory map and register definition

This section describes the registers on this module.

73.7.1 Overview

The memory map comprises 32-bit aligned registers that can be accessed via 8-bit,16-bit, or 32-bit accesses. Write access to reserved address locations will generate a transfer error. Read data from reserved locations will also generate a transfer error and the read data bus will return all 0's.

NOTE

The module does not check for correctness of the programmed values in registers. Software must ensure that the correct values are being written.

NOTE

The memory map in this section shows all the possible registers on this module and the associated offsets (which vary depending on the number of registers actually implemented). The actual availability, number and addresses of registers, and number of reported errors in the reporting table are chip-specific; see the Device Configuration chapter that describes how modules are configured and connected.

MEMU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Control register (MEMU_CTRL)	32	R/W	0000_0000h	73.7.2/3106
4	Error flag register (MEMU_ERR_FLAG)	32	w1c	0000_0000h	73.7.3/3106
C	Debug register (MEMU_DEBUG)	32	R/W	0000_0000h	73.7.4/3110
20	System RAM correctable error reporting table status register (MEMU_SYS_RAM_CERR_STS0)	32	R/W	0000_0000h	73.7.5/3112
24	System RAM correctable error reporting table address register (MEMU_SYS_RAM_CERR_ADDR0)	32	R/W	0000_0000h	73.7.6/3113
28	System RAM correctable error reporting table status register (MEMU_SYS_RAM_CERR_STS1)	32	R/W	0000_0000h	73.7.5/3112
2C	System RAM correctable error reporting table address register (MEMU_SYS_RAM_CERR_ADDR1)	32	R/W	0000_0000h	73.7.6/3113
30	System RAM correctable error reporting table status register (MEMU_SYS_RAM_CERR_STS2)	32	R/W	0000_0000h	73.7.5/3112

Table continues on the next page...

MEMU memory map (continued)

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
CC4	Flash memory uncorrectable error reporting table address register (MEMU_FLASH_UNCERR_ADDR)	32	R/W	0000_0000h	73.7.18/ 3120
CC8	Flash memory concurrent overflow register (MEMU_FLASH_OFLW0)	32	w1c	0000_0000h	73.7.19/ 3120

73.7.2 Control register (MEMU_CTRL)

Access: User read/write

Address: 0h base + 0h offset = 0h

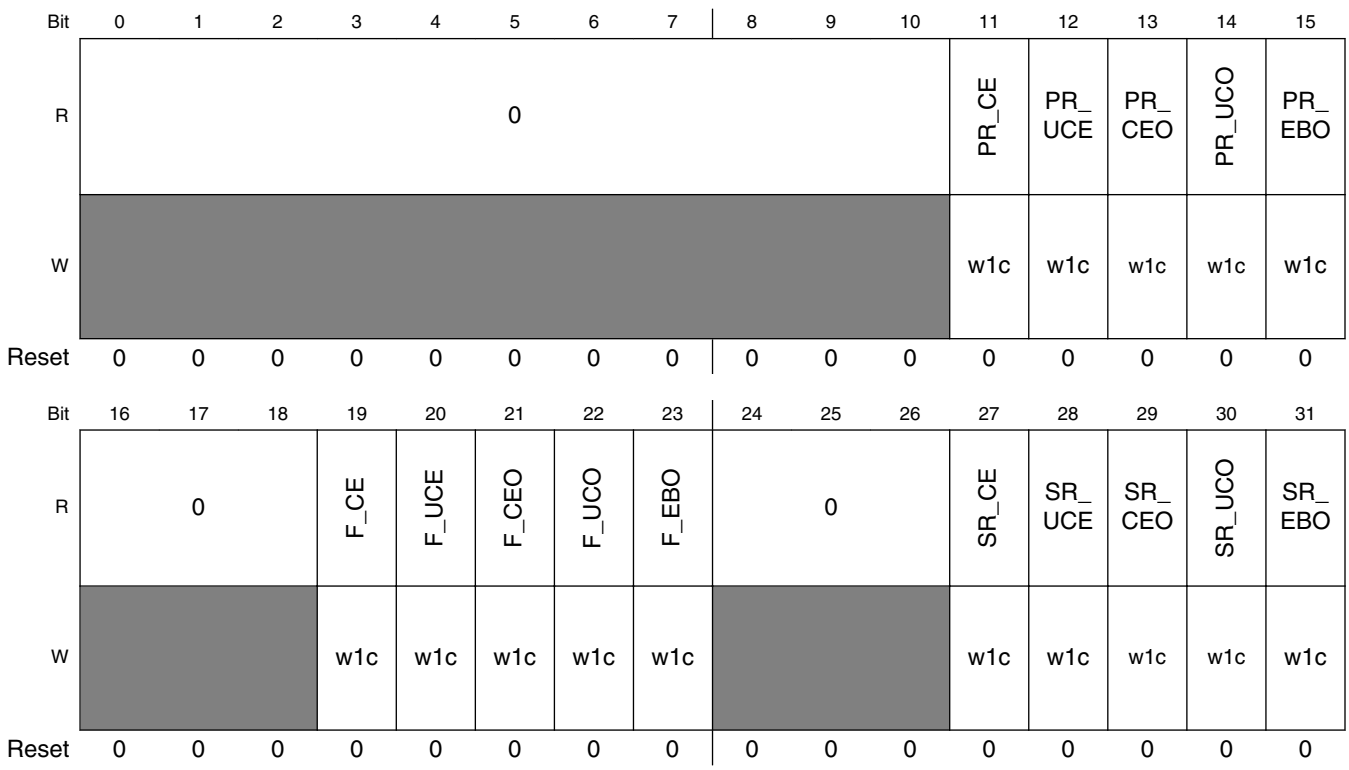
MEMU_CTRL field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SWR	Software Reset bit. Setting this will clear status flags and overflow register. However, the reporting table registers are not cleared. This bit will auto clear on next clock cycle. 0 No reset. 1 Reset asserted.
17–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

73.7.3 Error flag register (MEMU_ERR_FLAG)

Bits in the ERR_FLAG register indicate:

- A new entry in an error reporting table has been made (indicated by PR_CE, PR_UCE, F_CE, F_UCE, SR_CE, and SR_UCE)



- An overflow condition has been encountered when attempting to make a new entry in an error reporting table (indicated by SR_UCO, SR_CEO, F_UCO,F_CEO, PR_UCO, and PR_CEO)
- An overflow condition has been encountered in the internal error processing buffer of a MEMU reporting block.

Individual flags can be cleared by writing a '1'. This also resets the corresponding error indication to FCCU. Flags will not automatically reset if entries are removed from the reporting table. They have to be explicitly cleared by SW.

Bits SR_UCO, SR_CEO, F_UCO, F_CEO, PR_UCO, and PR_CEO are asserted when an overflow in the uncorrectable error reporting table is detected.

Access: User read/write

Address: 0h base + 4h offset = 4h

MEMU_ERR_FLAG field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 PR_CE	Peripheral RAM ECC Correctable Error detect flag. Indicates that a new and unique Peripheral RAM ECC correctable error is detected. Asserted when a new entry is inserted into the correctable error reporting table (either by CPU or module).

Table continues on the next page...

MEMU_ERR_FLAG field descriptions (continued)

Field	Description
	0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
12 PR_UCE	Peripheral RAM ECC Uncorrectable Error Detect flag. Asserted when a new Peripheral RAM ECC uncorrectable error was detected or a new entry is inserted into the uncorrectable error reporting table (either by CPU or module). 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
13 PR_CEO	Peripheral RAM ECC Correctable error Overflow flag. Asserted when the Peripheral RAM ECC correctable error reporting table is full and a new entry is attempted to be made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
14 PR_UCO	Peripheral RAM ECC Uncorrectable error Overflow flag. Asserted when the Peripheral RAM ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
15 PR_EBO	Peripheral RAM ECC Error buffer Overflow flag. Asserted when the internal error processing buffer of Peripheral RAM ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to 1 if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 F_CE	Flash ECC Correctable Error Detect flag. Indicates that a new and unique Flash ECC correctable error was detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
20 F_UCE	Flash ECC Uncorrectable Error Detect flag. Asserted when: • a new Flash ECC uncorrectable error was detected. • a new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
21 F_CEO	Flash ECC Correctable Error Overflow flag. Asserted when the Flash ECC correctable error reporting table is full and a new entry is made to this table.

Table continues on the next page...

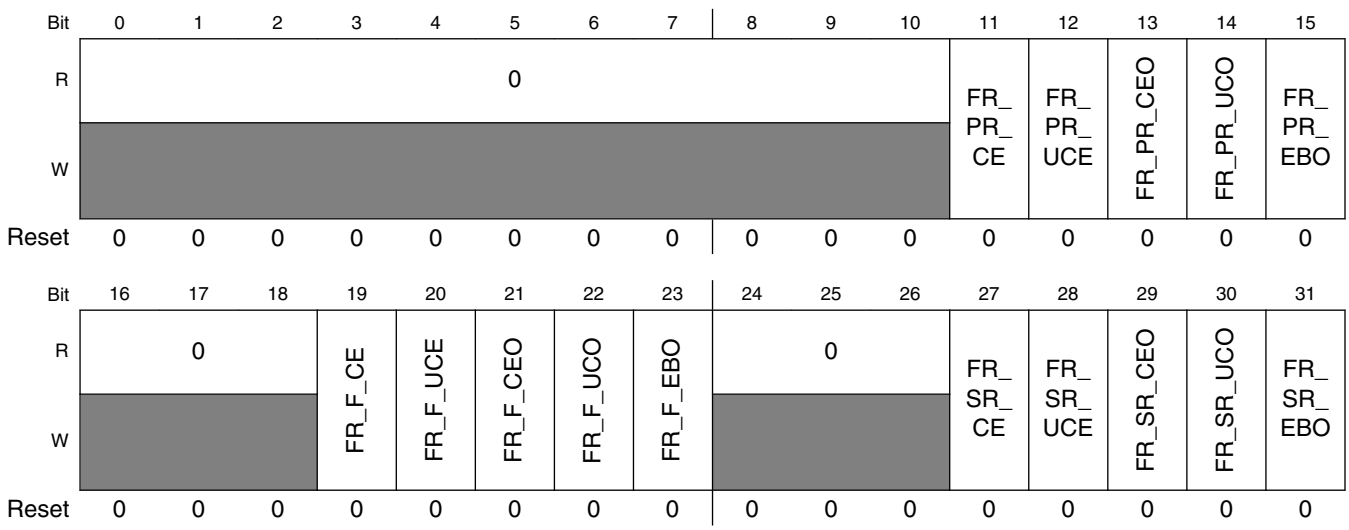
MEMU_ERR_FLAG field descriptions (continued)

Field	Description
	0 No Overflow. 1 Overflow in the correctable error reporting table detected.
22 F_UCO	Flash ECC Uncorrectable Error Overflow flag. Asserted when the Flash ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
23 F_EBO	Flash ECC Error buffer Overflow. Flag Asserted when the internal error processing buffer of Flash ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for MEMU to process them all. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to 1 if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 SR_CE	System RAM ECCand MBIST Correctable Error detect flag. Indicates that a new and unique System RAM ECCand MBISTcorrectable error is detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
28 SR_UCE	System RAM ECCand MBIST Uncorrectable Error Detect flag. Asserted when: • A new System RAM ECCand MBIST uncorrectable error is detected • A new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
29 SR_CEO	System RAM ECCand MBIST Correctable error Overflow flag. Asserted when the System RAM ECCand MBIST correctable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
30 SR_UCO	System RAM ECCand MBIST Uncorrectable error Overflow flag. Asserted when the System RAM ECCand MBIST uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
31 SR_EBO	System RAM ECCand MBIST Error buffer Overflow.

Table continues on the next page...

MEMU_ERR_FLAG field descriptions (continued)

Field	Description
	Flag asserted when the internal error processing buffer of System RAM ECCand MBIST MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to 1 if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.



73.7.4 Debug register (MEMU_DEBUG)

This register is used to check the connections between MEMU & FCCU.

The error output of the MEMU towards FCCU shall stay set if forced until reset by SW via the MEMU in the normal way.

Access: User read/write

Address: 0h base + Ch offset = Ch

MEMU_DEBUG field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 FR_PR_CE	Force Peripheral RAM Correctable Error detect flag. 0 Forcing is disabled. 1 Forces PR_CE flag going towards FCCU to 1.

Table continues on the next page...

MEMU_DEBUG field descriptions (continued)

Field	Description
12 FR_PR_UCE	Force Peripheral RAM Uncorrectable Error detect flag. 0 Forcing is disabled. 1 Forces PR_UCE flag going towards FCCU to 1.
13 FR_PR_CEO	Force Peripheral RAM Correctable Error overflow flag 0 Forcing is disabled. 1 Forces PR_CEO flag going towards FCCU to 1.
14 FR_PR_UCO	Forces Peripheral RAM Uncorrectable Error overflow flag. 0 Forcing is disabled. 1 Forces PR_UCO flag going towards FCCU to 1.
15 FR_PR_EBO	Forces Peripheral RAM Error Buffer Overflow Flag. 0 Forcing is disabled. 1 Forces PR_EBO flag going towards FCCU to 1.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 FR_F_CE	Forces Flash Correctable Error detect flag 0 Forcing is disabled. 1 Forces F_CE flag going towards FCCU to 1.
20 FR_F_UCE	Forces Flash Uncorrectable Error detect flag 0 Forcing is disabled. 1 Forces F_UCE flag going towards FCCU to 1.
21 FR_F_CEO	Forces Flash Correctable Error overflow flag 0 Forcing is disabled. 1 Forces F_CEO flag going towards FCCU to 1.
22 FR_F_UCO	Forces Flash Uncorrectable Error overflow flag 0 Forcing is disabled. 1 Forces F_UCO flag going towards FCCU to 1.
23 FR_F_EBO	Forces Flash Error buffer Overflow flag 0 Forcing is disabled. 1 Forces F_EBO flag going towards FCCU to 1.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 FR_SR_CE	Forces System RAM Correctable Error detect flag 0 Forcing is disabled. 1 Forces SR_CE flag going towards FCCU to 1.
28 FR_SR_UCE	Forces System RAM Uncorrectable Error detect flag 0 Forcing is disabled. 1 Forces SR_UCE flag going towards FCCU to 1.

Table continues on the next page...

MEMU_DEBUG field descriptions (continued)

Field	Description
29 FR_SR_CEO	Forces System RAM Correctable Error overflow flag 0 Forcing is disabled. 1 Forces SR_CEO flag going towards FCCU to 1.
30 FR_SR_UCO	Forces System RAM Uncorrectable Error overflow flag 0 Forcing is disabled. 1 Forces SR_UCO flag going towards FCCU to 1.
31 FR_SR_EBO	Forces System RAM Error buffer Overflow Flag 0 Forcing is disabled. 1 Forces SR_EBO flag going towards FCCU to 1.

73.7.5 System RAM correctable error reporting table status register (MEMU_SYS_RAM_CERR_STS*n*)

Access: User read/write

NOTE

The reporting table is not cleared on software reset.

Address: 0h base + 20h offset + (8d × i), where i=0d to 9d

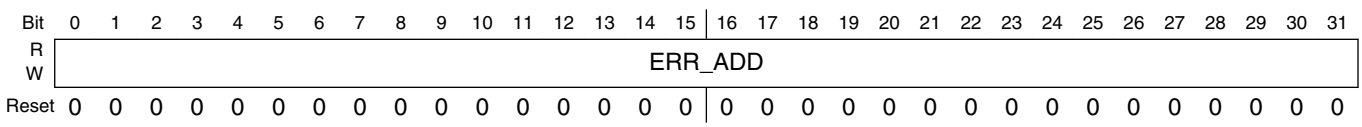
Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	VLD	0														
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0								BAD_BIT							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MEMU_SYS_RAM_CERR_STS*n* field descriptions

Field	Description
0 VLD	Valid bit. This indicates that the entry in reporting table is valid. Assertion of this bit causes the correctable error detect flag to be asserted. 0 Entry in table is invalid. 1 Entry in table is valid.
1–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 BAD_BIT	Bad bit field. Indicates the bit position in RAM where the error is detected. This is also known as the syndrome. For non-BIST type of errors, this field is not used and reads as 0xFF.

Table continues on the next page...



MEMU_SYS_RAM_CERR_STS*n* field descriptions (continued)

Field	Description
	Any value other than 0xFF - Position of the bit in RAM where error is found. 0xFF - Invalid Bad Bit. This field should not be used when processing errors.

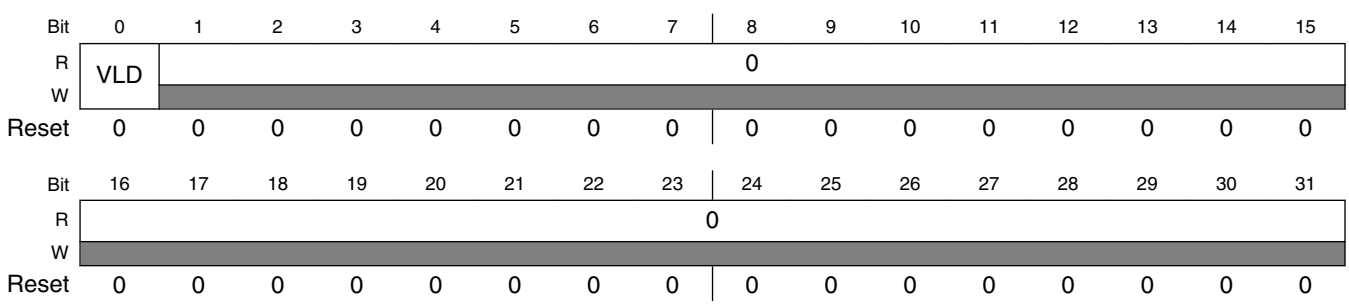
73.7.6 System RAM correctable error reporting table address register (MEMU_SYS_RAM_CERR_ADDR*n*)

Access: User read/write

Address: 0h base + 24h offset + (8d × i), where i=0d to 9d

MEMU_SYS_RAM_CERR_ADDR*n* field descriptions

Field	Description
0–31 ERR_ADD	Error address field Indicates the address on which the error was detected.



73.7.7 System RAM uncorrectable error reporting table status register (MEMU_SYS_RAM_UNCERR_STS)

Access: User read/write

NOTE

The reporting table is not cleared on software reset.

Address: 0h base + 70h offset = 70h

MEMU_SYS_RAM_UNCERR_STS field descriptions

Field	Description
0 VLD	Valid bit. This indicates that the entry in reporting table is valid. Assertion of this bit causes the uncorrectable error detect flag to be asserted. 0 Entry in table is invalid. 1 Entry in table is valid.
1–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

73.7.8 System RAM uncorrectable error reporting table address register (MEMU_SYS_RAM_UNCERR_ADDR)

Access: User read/write

NOTE

The reporting table is not cleared on software reset.

Address: 0h base + 74h offset = 74h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

MEMU_PERIPH_RAM_CERR_STS*n* field descriptions

Field	Description
0 VLD	Valid bit. This indicates that the entry in reporting table is valid. Assertion of this bit causes the correctable error detect flag to be asserted. 0 Entry in table is invalid. 1 Entry in table is valid.
1–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 BAD_BIT	Bad bit field. Indicates the bit position in RAM where the error is detected. This is also known as the syndrome. For non-BIST type of errors, this field is not used and reads as 0xFF. Any value other than 0xFF - Position of the bit in RAM where error is found. 0xFF - Invalid Bad Bit. This field should not be used when processing errors.

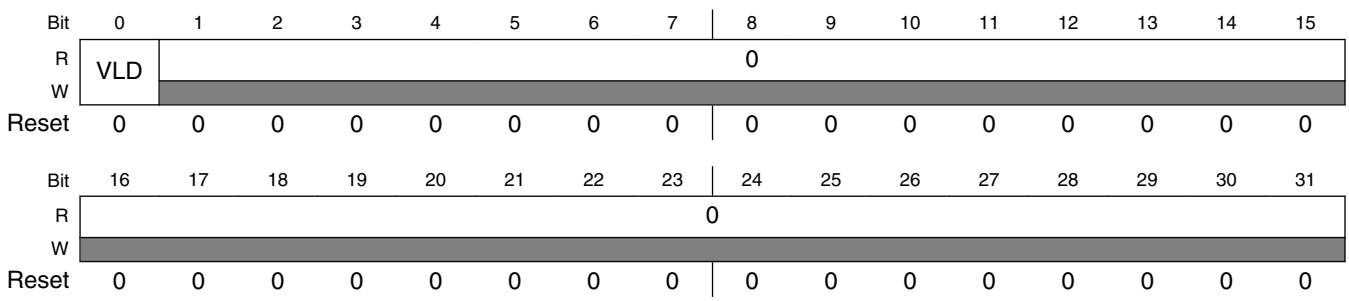
73.7.11 Peripheral RAM correctable error reporting table address register (MEMU_PERIPH_RAM_CERR_ADDR*n*)

Access: User read/write

Address: 0h base + 624h offset + (8d × i), where i=0d to 1d

MEMU_PERIPH_RAM_CERR_ADDR*n* field descriptions

Field	Description
0–31 ERR_ADD	Error address field Indicates the address on which the error was detected.



73.7.12 Peripheral RAM uncorrectable error reporting table status register (MEMU_PERIPH_RAM_UNCERR_STS)

Access: User read/write

NOTE

The reporting table is not cleared on software reset.

Address: 0h base + 630h offset = 630h

MEMU_PERIPH_RAM_UNCERR_STS field descriptions

Field	Description
0 VLD	Valid bit. This indicates that the entry in reporting table is valid. Assertion of this bit causes the uncorrectable error detect flag to be asserted.

MEMU_FLASH_OFLW*n* field descriptions

Field	Description
0–31 OFLW	Overflow Bit. Each bit corresponds to an error source and is asserted when any of the conditions mentioned in Handling overflows (Multiple error reporting) occurs.

73.8 Functional description

In this section, the term “bad bit” and “syndrome” are equivalent, and are used to indicate the position of the bit in error.

73.8.1 Initializing MEMU

MEMU is always enabled and can be configured by user software for known errors which the system/application has collected over a period of time. The MEMU logic will not update the reporting table corresponding to the programmed values which have the VLD bit SET.

The user software can write into the reporting table and must make VLD bit ='1' for the programmed entry to be valid. Any write by the CPU that asserts the VLD bit will cause a corresponding flag to FCCU.

The software can program the table with known error addresses by setting the valid bit and storing the corresponding error address. The sequence of programming to prevent a collision of reporting table entries written by the HW and the SW is as follows:

1. Check that the VLD bit is not set,
2. Write an invalid address/bad bit information,
3. Set VLD bit,
4. Check that the address still has an invalid value,
5. Write address/bad bit information to desired address.

If the FCCU is programmed to cause an IRQ on new MEMU table entries, steps 3 to 5 should be executed with interrupts disabled to prevent any error handling SW to read the invalid address written in step 2). Note that in the case the software is in between the 3rd and the 5th step, and the MEMU writes an error with the same address that Software wants to program, both the errors will be stored in the reporting table (i.e. duplicate entries).

73.8.2 Reading the reporting table

The software at any time can read the reporting table via the software programming interface. It should read the entries with the valid bit set and take necessary action. To invalidate any entry, the valid bit must be cleared. Reading an entry which does not have the VLD bit set will return invalid data.

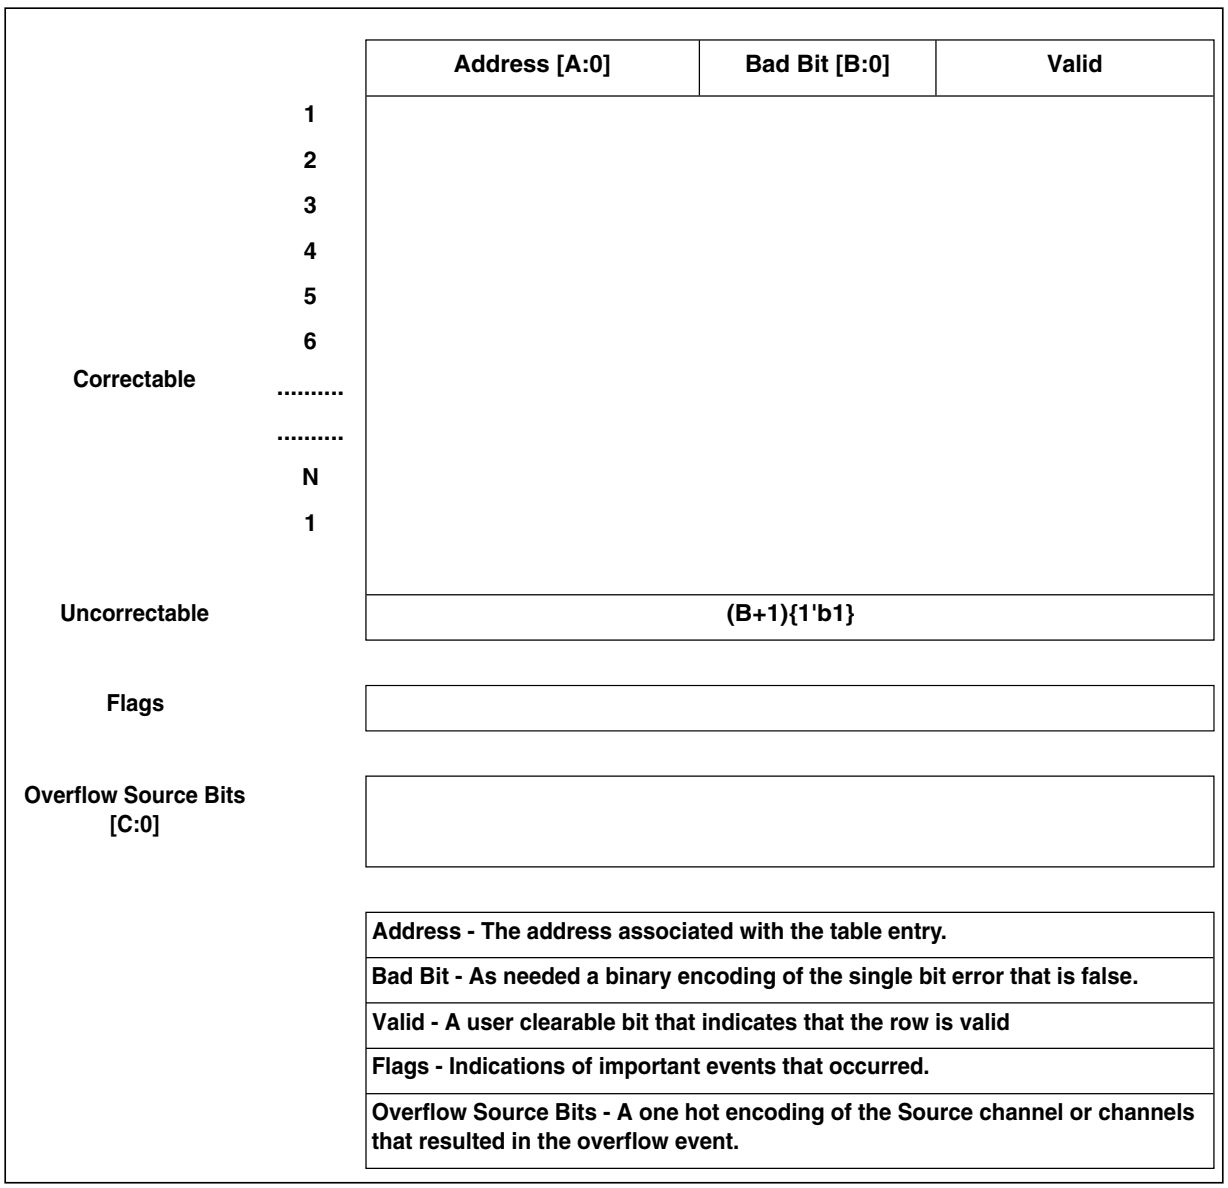

Figure 73-6. Generic representation of the reporting table of one MEMU reporting block

73.8.3 Handling overflows (Multiple error reporting)

When a bit in the overflow registers (either error buffer or reporting table though the overflow registers are same) is asserted it can indicate the occurrence of one of the following conditions:

1. Error buffer overflow–More than two memories reporting an error at the same instant or the input ASYNC FIFOs reach the FULL level (overflow)
    - More than 2 errors detected at same time. This would lead to overflow in the error buffer. MEMU can process only one error at a time while storing the other in the error buffer. So this would be indicated as an overflow. The uniqueness check in the input buffer does not "guarantee" that an ECC-supervised memory with only one error will not be marked as overflow source. If that one error occurs together with two (or more) additional errors at the same cycle it can get flagged as an overflow.
2. Correctable/Uncorrectable Error Overflow–Overflow in correctable and uncorrectable reporting table occurs only when a unique entry is to be stored but the tables are already full (all entries have valid bit set).
    - An ECC error which matches the address of an MBIST error is dropped (same as if it matched the address of an ECC error). In case, where a MBIST error comes with ECC error already in the table, both the address and bad bits are compared to determine uniqueness.
3. The Overflows will be stored in the bit-wise order i.e., if the error bit 31 reports an error, the bit 31 of the overflow register will be set to '1'.

Chapter 74
Fault Collection and Control Unit (FCCU)

74.1 Chip-specific FCCU information

74.1.1 FCCU configuration

This section describes the configuration of FCCU specific to the MPC5746C.

NOTE

To observed the toggling of the Eout signal as per protocol in fault state for FCCU, the SMC field of the MSCR register correspond to EOUT pads should be set.

NOTE

FCCU alarm will configure pads for tri-state unless SIUL2_MSCR[SMC] is enabled even though MCU is not in SAFE mode.

74.1.2 FCCU register reset values

All reset values for the FCCU registers that are device specific are shown in the following table. All other register reset values are shown in the FCCU memory map section.

Table 74-1. FCCU register reset values

Register	Register Value
Control Register (FCCU_CTRL)	0x0000_00C0
Configuration Register (FCCU_CFG)	See FCCU_CFG register bit value sources (N and C) by event.
NCF Configuration Register (FCCU_NCF_CFG0)	0xFFFF_FFFF
NCF Configuration Register (FCCU_NCF_CFG1)	0xFFFF_FFFF

Table continues on the next page...

Table 74-1. FCCU register reset values (continued)

Register	Register Value
NCF Configuration Register (FCCU_NCF_CFG2)	0x0000_00FF
NCFS Configuration Register (FCCU_NCFS_CFG0)	0x0008_2000
NCFS Configuration Register (FCCU_NCFS_CFG1)	0x0000_0000
NCFS Configuration Register (FCCU_NCFS_CFG2)	0x0000_0008
NCFS Configuration Register (FCCU_NCFS_CFG3)	0x0000_0000
NCFS Configuration Register (FCCU_NCFS_CFG4)	0x0000_0000
NCFS Configuration Register (FCCU_NCFS_CFG5)	0x0000_0000
NCF Enable Register (FCCU_NCF_E0)	0x0000_0240
NCF Enable Register (FCCU_NCF_E1)	0x0000_0002
NCF Enable Register (FCCU_NCF_E2)	0x0000_0000
NCF Time-out Enable Register (FCCU_NCF_TOE0)	0x0000_0000
NCF Time-out Enable Register (FCCU_NCF_TOE1)	0x0000_0000
NCF Time-out Enable Register (FCCU_NCF_TOE2)	0x0000_0000
MCS Register (FCCU_MCS)	0x0000_8083

74.1.3 FCCU_CFG register event bit values by source (N and C)

For each bit in the Configuration (FCCU_CFG) register, this table specifies the values of *N* and *C* for this chip. For information on how to interpret and use these values, see FCCU_CFG register bit value sources (N and C) by event.

Bit	N (chip-specific or user-specified value provided by the bit's associated NVMCFG signal)	C (chip-specific value provided by the bit's associated constant inside the module)

74.1.4 Fault inputs

The following table shows the source of the fault signals and the type of fault input to which these signals are connected at the FCCU. NCF is used to identify a non-critical fault input at the FCCU.

Table 74-2. FCCU non-critical fault mapping

Non Critical Fault	Source	NCF_CFG (HW Rec/ SW Rec)	NCF_POL (Polarity of fault)	NCFS_CFG (Fault Reaction (Long/ Short Reset/ None))	NCF_EN (Enable fault source whether to go from state N to A or F)	NCF_TOEN (Time out EN or DIS by default)	Set/Clear available	Description
Register		**FCCU_NCF_CGF[0:3]**		**FCCU_NCFS_CFG[0:7]**	**FCCU_NCF_E[0:3]**	**FCCU_NCF_TOE[0:3]**		
NCF[0]	Flash	SW	HIGH	None	-	DIS	Yes	Flash reset error: Sideband signal from flash to indicate that flash encountered faults during its reset reads. This is caused by ECC double bit detection as well as the coherency checks done on the test row reads.
NCF[1]	Flash	SW	HIGH	None	-	DIS	Yes	Flash Low power error: A signal to indicate that a request for Flash entry into Low Power mode was rejected. This occurs if a LP request is sent if a High Voltage or Utest operations are ongoing.
NCF[2][1]	Flash	SW	HIGH	None	-	DIS	Yes	Flash read voltage error: A fault signal indication from flash, it tells that previous reads were affected by a read voltage loss of regulation.
NCF[3][1]	Flash	SW	HIGH	None	-	DIS	Yes	Flash reference current error:

Table continues on the next page...

Table 74-2. FCCU non-critical fault mapping (continued)

Non Critical Fault	Source	NCF_CFG (HW Rec/ SW Rec)	NCF_POL (Polarity of fault)	NCFS_CFG (Fault Reaction (Long/ Short Reset/ None))	NCF_EN (Enable fault source whether to go from state N to A or F)	NCF_TOEN (Time out EN or DIS by default)	Set/Clear available	Description
NCF[57]	MEMU_1	SW	HIGH	None	-	DIS		System RAM uncorrectable ECC error
NCF[58]	MEMU_1	SW	HIGH	None	-	DIS		System RAM error overflow
NCF[59]	MEMU_1	SW	HIGH	None	-	DIS		Peripheral RAM correctable ECC error
NCF[60]	MEMU_1	SW	HIGH	None	-	DIS		Peripheral RAM uncorrectable ECC error
NCF[61]	MEMU_1	SW	HIGH	None	-	DIS		Peripheral RAM error overflow
NCF[62]	MBIST Error	SW	HIGH	None	-	DIS		MBIST Error PRAM_0
NCF[63]	MBIST Error	SW	HIGH	None	-	DIS		MBIST Error PRAM_0, PRAM_1
NCF[64]	MBIST Error	SW	HIGH	None	-	DIS		MBIST ERROR z4 (DTAG, DCACHE)
NCF[65]	MBIST Error	SW	HIGH	None	-	DIS		MBIST ERROR z4 (ITAG, ICACHE)
NCF[66]	MBIST Error	SW	HIGH	None	-	DIS		MBIST ERROR HSM (TAG, DCACHE, RAM)
NCF[67]	MBIST Error	SW	HIGH	None	-	DIS		MBIST ERROR CAN
NCF[68]	MBIST Error	SW	HIGH	None	-	DIS		MBIST ERROR Non-Core masters (except HSM)
NCF[69]	ADC1 CF	SW	HIGH	None	-	DIS		ADC1 Internal Selftest critical fault
NCF[70]	ADC1 NCF	SW	HIGH	None	-	DIS		ADC1 Internal Selftest non-critical fault
NCF[71]					-			Reserved

1. These faults may get set during chip level debug mode and needs to be ignored.
2. The FCCU alarms indicate a fault in the PRAMC internal address decode that causes an errant hit/miss evaluation of the PRAMC store buffer.
3. This source should be configured to generate reset when the respective clocks are used as system clocks.

74.1.5 Error signal flow diagram

* This condition must be satisfied only when FCCU is configured for Bistable fault-output mode (FCCU_CFG[FOM]).

Figure 74-1. Error signal flow

74.2 Introduction

The Fault Collection and Control Unit (FCCU) offers a hardware channel to collect faults and to place the device into a safe state when a failure in the device is detected. No CPU intervention is requested for collection and control operation.

The FCCU offers a systematic approach to fault collection and control. The distinctive features of the module are:

- Redundant collection of fault information from safety relevant modules on the device
- Collection of test results
- Configurable fault control
- Configurable internal reactions for each NCF:
  - No reaction
  - IRQ
  - Short functional reset
  - Long functional reset
  - NMI
- External reactions via configurable output pins
- Watchdog timer for the reconfiguration phase
- Lockable configuration
- Nonvolatile memory interface (NVMCFG signals) for configuration loading
- One of the fault-output (EOUT) signals is high to indicate operational (OK) state (in bi-stable operation mode). The above is not true in case the error out protocol is configured to be a toggling protocol, for example, dual rail and time switching.
- After power on, the EOUT signals have high impedance.[1] They show operational state only after configuration by software.
- In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_min, even if SW tries to release it before (for the case of error pin configured in Bi-stable mode only).

1. Actual value depends on device specific setting at pad level.

- The overall fault detection, processing and indication time is less than 10 ms.
- The actual maximum time is 5 CLKSAFE cycles**.**

The FCCU is operative with the default configuration. Internal (short or long functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable. The default configuration can be modified only in the CONFIG state. FCCU is designed to function when CLKSYS is faster than the CLKSAFE clocks.

74.2.1 Acronyms and abbreviations

Term	Description
CF	Critical fault
CPU	Central processing unit
EOUT	Error out
FSM	Finite state machine
INTC	Interrupt controller
intf	Interface
IRQ	Interrupt request
MC_ME	Mode entry module
NCF	Noncritical fault
NMI	Nonmaskable interrupt
NVM	Nonvolatile memory
SoC	System-on-chip
STCU	Self-test control unit
SW	Software
WKPU	Wake-up unit

74.3 Main features

- Management of noncritical faults
- HW or SW fault recovery management
- Fault detection and collection
- Fault injection (fake faults)

- External reaction (fault state): EOUT signaling. Error indication via the pin(s) is controlled by the FCCU.
- Internal chip reactions (alarm state): interrupt request
- Internal chip reactions (fault state):
  - long functional reset request pulse
  - short functional reset request pulse
  - NMI
- Bi-Stable, Dual-Rail and Time Switching output protocols on EOUT
- Internal (to the FCCU) watchdog timer for the reconfiguration phase
- Configuration lock
- Nonvolatile memory interface (NVMCFG signals) for configuration loading

74.4 Block diagram

The following figure is a top-level diagram of the FCCU module.

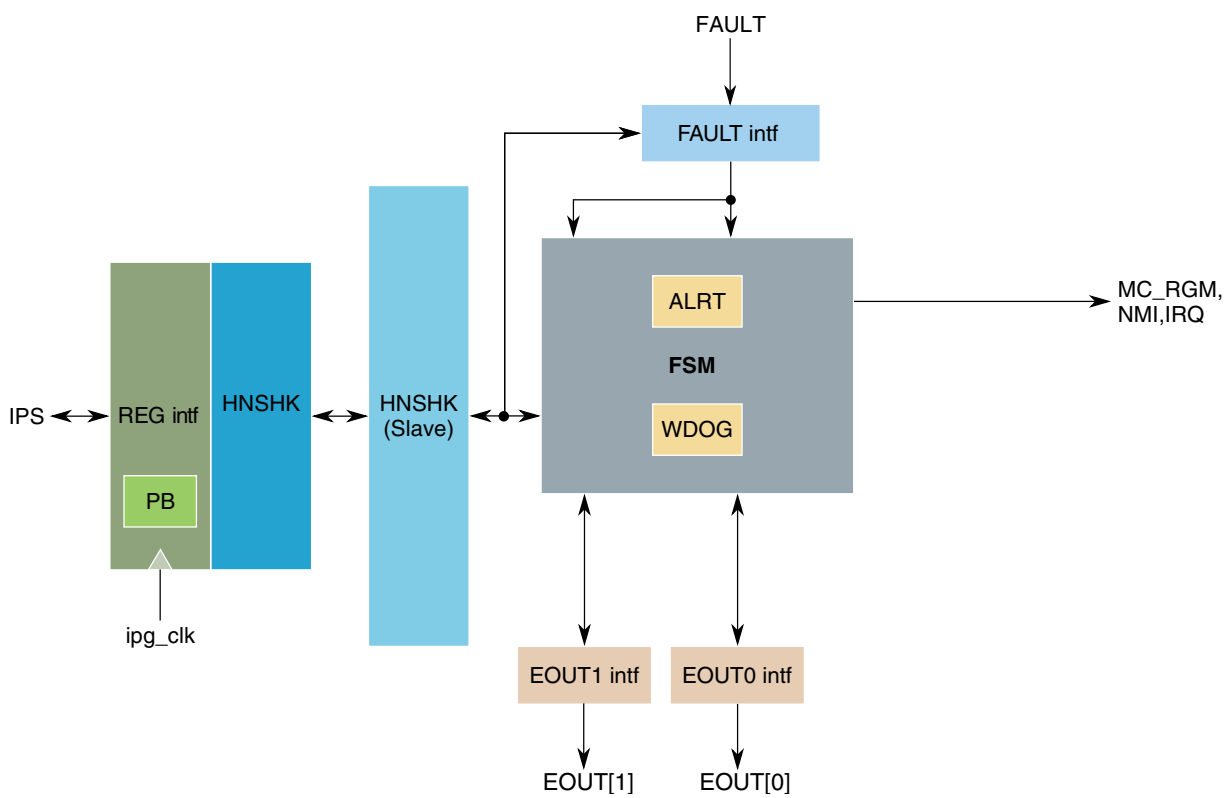

Figure 74-2. FCCU block diagram

This table describes the FCCU submodules.

Table 74-3. FCCU submodules

Submodule	Description
REG intf	Includes the register file, the IPS bus interface, the IRQ interface and the parity block (PB) for the configuration registers
HNSHK blocks (master and slave blocks)	Includes the FSM's ability to support the handshake between the REG interface and the FSM unit due to the usage of 2 asynchronous clocks (IPS system clock and RC oscillator clock)
FSM unit	Implements the main functions of the FCCU. The FSM also includes the: • Watchdog timer (WDG) • Alarm timer (ALRT)
FAULT intf	Implements the interface for the fault conditioning and management
EOUTx units	Implement the output stage to manage the EOUT interfaces

74.5 Signal description

74.5.1 Signals

This table describes the signals on the boundary of FCCU.

Signal	Direction	Function	Active level	Clock
Clock and reset				
CLKSYS	Input	System Clock—Supplies the primary clock.	Rising edge	—
CLKSAFE0	Input	Safe Clock 0—Supplies one of two 16 MHz clocks for use by various redundant submodules. This clock and CLKSAFE1 are often referred to as the same clock (CLKSAFE).	Rising edge	—
CLKSAFE1	Input	Safe Clock 1—Supplies one of two 16 MHz clocks for use by various redundant submodules. This clock and CLKSAFE0 are often referred to as the same clock (CLKSAFE).	Rising edge	—
EOUT interface				
EIN[1:0]	Input	Error Input—Provide the mechanism for FCCU to capture the states that off-chip logic drives on the associated EOUT[1:0] signals. (On the chip, the EOUT signals are connected to their corresponding EIN signals.) FCCU captures the states in the EIN1 and EIN0 fields.	—	Asynchronous

Table continues on the next page...

Signal	Direction	Function	Active level	Clock
EOUT[1:0]	Output	Error Output—Indicate FCCU's condition (Faulty, Nonfaulty, or Configuration) to off-chip logic.	Programmable	CLKSAFE0, CLKSAFE1
WKPU interface				
NMIWKPU	Input	WKPU Nonmaskable Interrupt Request—Receives nonmaskable interrupt requests from the WKPU module.	Low	CLKSYS
WAKEWKPU	Output	Wake WKPU—Wakes the WKPU module to bring the chip out of dormant state when FCCU enters Fault state as the result of a noncritical fault for which NMI is enabled as the reaction (FCCU_NMI_ENa[NMIENx]).	High	CLKSAFE0, CLKSAFE1
Interrupt interface				
NMIOUT	Output	Nonmaskable Interrupt Output—Sends a nonmaskable interrupt request to the processor core or cores when FCCU enters Fault state as the result of a noncritical fault for which NMI is enabled as the reaction (FCCU_NMI_ENa[NMIENx]).	Low	CLKSYS
NVM interface				
NVMCFG[21:0]	Input	Nonvolatile Memory Configuration—Provide the values of certain bits in the Configuration (FCCU_CFG) register when certain events occur. See Configuration (FCCU_CFG). Some or all of these signals may be driven by bits in a data record in nonvolatile (flash) memory or may be tied high (1) or low (0). See FCCU_CFG register bit value sources (N and C) by event.	Static value	—
SSCMDONE	Input	SSCM Done—After an FCCU reset, indicates that the SSCM module is now driving any NVMCFG signals that are associated with a data record stored in nonvolatile (flash) memory.	High	CLKSYS

74.6 Put FCCU in Configuration or Normal state

74.6.1 Introduction

You put FCCU in Configuration state to change its configuration. You put FCCU in Normal state to save changes to the configuration.

74.6.2 About changing states

When changing states, keep the following in mind:

- To put FCCU in Configuration state, FCCU must be in Normal state.
- After FCCU is reset, the configuration is temporarily locked. You must temporarily unlock the configuration before you can put FCCU in Configuration state.
- When FCCU is in Configuration state, FCCU doesn't actually save the changes you make to the configuration. To save changes to the configuration, you must manually put FCCU in Normal state. If FCCU automatically leaves Configuration state and enters Normal state because the configuration-timer interval (TO) expires (called a Configuration-state timeout), FCCU changes the value of the Configuration (FCCU_CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. For information on the Configuration-state timeout value, see FCCU_CFG register bit value sources (N and C) by event. For a list of configuration registers, see Configuration registers.

74.6.3 Put FCCU in Configuration state

1. Temporarily unlock the configuration (see Temporarily unlock the configuration).
2. To determine FCCU's state, run the OP3 operation (see Run an operation).
3. Check the operation status (OPS).
   - If the operation status is Successful, go to step 4.
   - If the operation status is Aborted, go to step 2.
4. Check the FCCU status (STATUS).
   - If the FCCU status is Configuration, FCCU is in Configuration state. Stop.
   - If the FCCU status is Normal, go to step 5.
   - If the FCCU status is Alarm or Fault, go to step 7.
5. To put FCCU in Configuration state, run the OP1 operation (see Run an operation).
6. Check the operation status (OPS).
   - If the operation status is Successful, FCCU is in Configuration state. Stop.
   - If the operation status is Aborted, the configuration is probably permanently locked. Go to step 9.
7. Recover all faults.
8. Go to step 2.
9. Reset FCCU.

74.6.4 Put FCCU in Normal state

1. To determine FCCU's state, run the OP3 operation (see Run an operation).
2. Check the operation status (OPS).
   - If the operation status is Successful, go to step 3.
   - If the operation status is Aborted, go to step 1.
3. Check the FCCU status (STATUS).
   - If the FCCU status is Normal, FCCU is in Normal state. Go to step 8.
   - If the FCCU status is Configuration, go to step 4.
   - If the FCCU status is Alarm or Fault, go to step 6.
4. To put FCCU in Normal state, run the OP2 operation (see Run an operation).
5. Check the operation status (OPS).
   - If the operation status is Successful, FCCU is in Normal state. Go to step 8.
   - If the operation status is Aborted, go to step 4.
6. Recover all faults.
7. Go to step 1.
8. If you want to prevent changes to the configuration, lock it:
   - To require a key to unlock the configuration, temporarily lock the configuration (see Temporarily lock the configuration).
   - To require a reset of FCCU to unlock the configuration, permanently lock the configuration (see Permanently lock the configuration).

74.7 Run operations

74.7.1 Introduction

You run operations to perform actions such as putting FCCU in Configuration state or reading a timer. For a complete list of operations you can run, see OPR.

74.7.2 About running operations

When running operations, keep the following in mind:

- FCCU ignores any operations initiated while the operation status is In Progress.
- Certain operations must be unlocked before you can initiate them. After you initiate them, they are again locked.

74.7.3 Run an operation

1. Check the operation status (OPS).
2. If the operation status is In Progress, go to step 1.
3. If the operation must be unlocked before you can initiate it, unlock the operation (CTRLK) using a 32-bit write.

NOTE

The Control Key (FCCU_CTRLK) register used in this step and the Control (FCCU_CTRL) register used in the next step must be written with consecutive instructions. Do not use read-modify-write instructions, such as bit-field instructions, to modify these registers.

4. Initiate the operation (OPR) using a 32-bit write.
5. Check the operation status (OPS).
6. If the operation status is In Progress, go to step 5.

The operation status is now Idle (OP15 only), Aborted, or Successful.

74.8 Lock and unlock the configuration

74.8.1 Introduction

After you configure FCCU, you can lock its configuration to prevent accidental changes.

74.8.2 About locking the configuration

When locking the configuration, keep the following in mind:

- If you attempt to lock the configuration while FCCU is in Configuration state, FCCU doesn't actually lock the configuration until FCCU leaves Configuration state—that is, either you put FCCU in Normal state, or FCCU puts FCCU in Normal state because the configuration-timer interval (TO) expires.
- After you permanently lock the configuration, you must reset FCCU before you can put FCCU in Configuration state.

74.8.3 Temporarily lock the configuration

1. From Supervisor mode, write a lock value to TRANSKEY.
2. Put FCCU in Normal state if it's in Configuration state (see Put FCCU in Normal state).

74.8.4 Temporarily unlock the configuration

- From Supervisor mode, write the unlock value to TRANSKEY.

74.8.5 Permanently lock the configuration

1. From Supervisor mode, write the lock value to PERMNTKEY.
2. Put FCCU in Normal state if it's in Configuration state (see Put FCCU in Normal state).

The configuration is permanently locked until FCCU is reset.

74.9 Functional description

74.9.1 Definitions

In general, the following definitions are applicable for the fault management:

- HW recoverable fault: the fault indication is an edge-triggered and level-sensitive signal that remains asserted until the fault cause is deasserted. That is, if logical 0 on the fault signal indicates fault, then the status flags are valid as long as the fault line stays at 0. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched external to the FCCU in the module where the fault occurred. The FCCU state transitions are consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.
- SW recoverable fault: the fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error source/s by FCCU management SW, in case it is known that the fault is recoverable by itself when the fault condition gets corrected.

These type of chip resets reset the FCCU:
- Power-on
- Destructive
- Long functional, when initiated by the assertion of the chip reset pin (RESET_B)

These types of chip resets don't reset the FCCU:
- Long functional, when initiated by anything other than the assertion of the chip reset pin (RESET_B)
- Short functional reset

For more information on each type of reset, see the MC_RGM and reset chapters.

74.9.2 FSM description

FCCU functionality is depicted by the finite state machine (FSM) state diagram.

Basically four states are identified with the following meaning:

- Configuration: Used only to modify the configuration of FCCU from its default. A subset of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, timeout, noncritical fault masking) can be accessed in write mode only in Configuration state.

  Configuration state is accessible only in Normal state and if the configuration is not locked. The permanent configuration lock can be disabled by a reset which also resets the FCCU., The transient lock register is unlocked by writing BCh into it. FCCU gets transiently locked again if an invalid key is written into FCCU_TRANS_LOCK register (that is, other than BCh). Key to lock FCCU permanently is FFh, written in the FCCU_PERMNT_LOCK register.

  After the release of reset the state of the transient lock will be locked. The state of the permanent lock will be unlocked.

  The locking feature only restricts the FSM movement into Configuration state. Once the user enters Configuration state and then tries to lock the configuration, the locking of configuration will be effective after FCCU moves to Normal state, it will not be effective in the current Configuration state.

  The Configuration to Normal state transition can be executed by SW or automatically following a timeout condition of the watchdog. In case the timeout information and the SW request to mode change to Normal appears at the same time, watchdog

timeout has the priority and hence the Configuration registers (those that are writable only in Configuration state) are reset to their default values. The movement to Normal is made.

The incoming faults, occurring during the configuration phase (Configuration state) are latched in order to process them when FCCU is moved into Normal state, according to the new configuration.

All pending faults that occur during Configuration state result in both of the following:

- Highest-priority state transition
- Interrupt generation (NMI or alarm IRQ)

If the state transition occurs, it gives the reset reaction corresponding to the worst case based on all the faults (pending or nonpending faults) that occurred during Configuration state.

- Normal: This is FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Following state transitions occur on one of the following events:
  - unmasked noncritical faults with the timeout disabled → FCCU moves to Fault state
  - unmasked noncritical faults with the timeout enabled → FCCU moves to Alarm state
  - masked noncritical faults → FCCU stays in Normal state
- Alarm: FCCU moves into Alarm state when an unmasked noncritical fault occurs and the timeout is enabled. The transition to Alarm state goes along with an interrupt alarm, if enabled. By definition, this fault may be recovered within a programmable timeout period, before it generates a transition to Fault state. The timeout is reinitialized if FCCU enters Normal state. The timeout restarts following the recovery from Fault state.
- Fault: FCCU moves into Fault state when one of the following condition occurs:
  - timeout related to a noncritical fault when FCCU is in Alarm state
  - unmasked noncritical faults with the timeout disabled

The transition from Normal/Alarm to Fault state goes along with the generation of:

- NMI interrupt (optional)

- EOUT signaling (optional)
- SW option: Soft reaction (Short functional reset request pulse if configured)
- SW option: Hard reaction (Long functional reset request pulse if configured)

After moving to Fault state, if there is either a previous pending fault or a new fault for which NMI is enabled, NMI generation takes place.

Multiple faults can occur at the same time. Consider the case where there is a fault for which Alarm state is enabled and IRQ is programmed along with a fault for which Alarm state is disabled. In that case, the FSM moves to Fault state, but with the generation of alarm IRQ for the fault which has IRQ enabled.

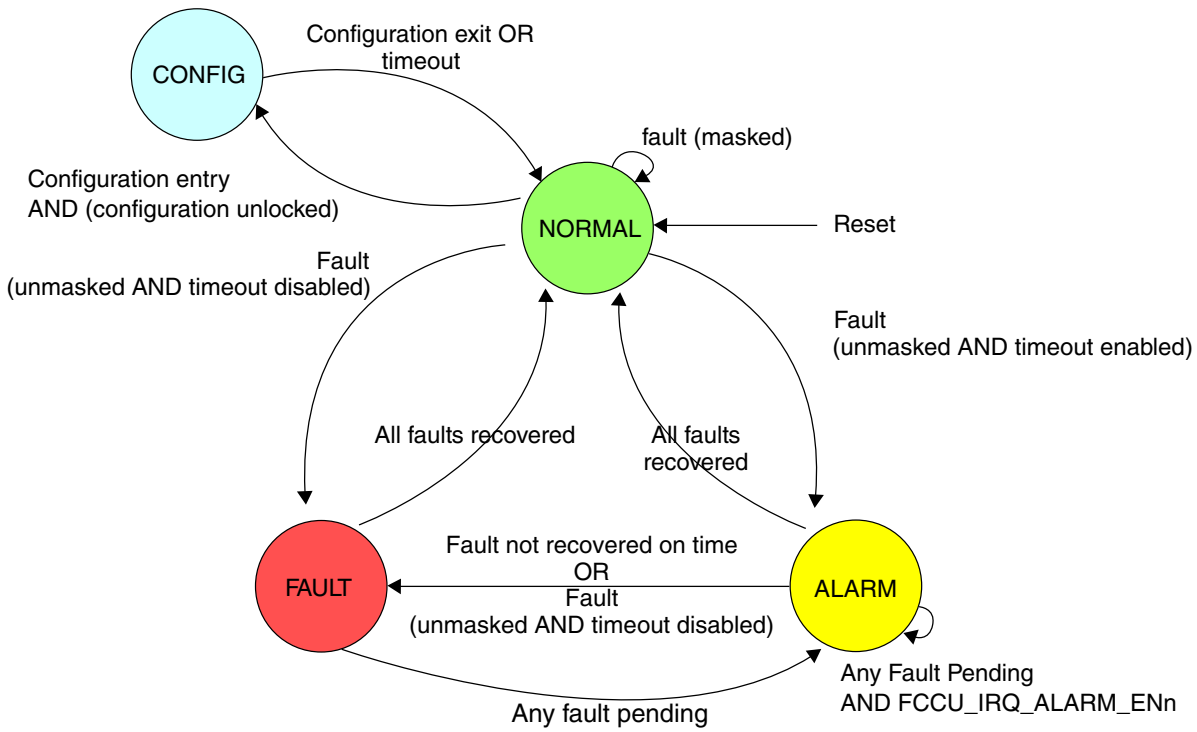

Figure 74-3. FCCU state diagram

74.9.3 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (noncritical) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a noncritical fault (unmasked and with time-out disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the noncritical faults (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU will remain in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the noncritical faults (including the faults that have been collected after the entry in the FAULT/ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU will move to the ALARM state (if any noncritical fault is still pending and the time-out is not elapsed).

In general, no fault nesting is supported except for the noncritical faults that cause an ALARM to FAULT state transition. In this case the NCF timer is stopped until the FAULT state is recovered. If FCCU is in ALARM state and another fault comes, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

74.9.4 Fault recovery

The following timing diagrams describe the main use cases of the FCCU in terms of fault events and related recovery.

A typical sequence related to a noncritical FAULT management (ALARM state), see Figure 74-4 and Figure 74-5, is as follows:

- Noncritical fault assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - alarm interrupt request (if enabled)
  - time-out running
- system state: RUN
- alarm interrupt management: FAULT recovery (by SW)
  - FCCU state transition ALARM → NORMAL

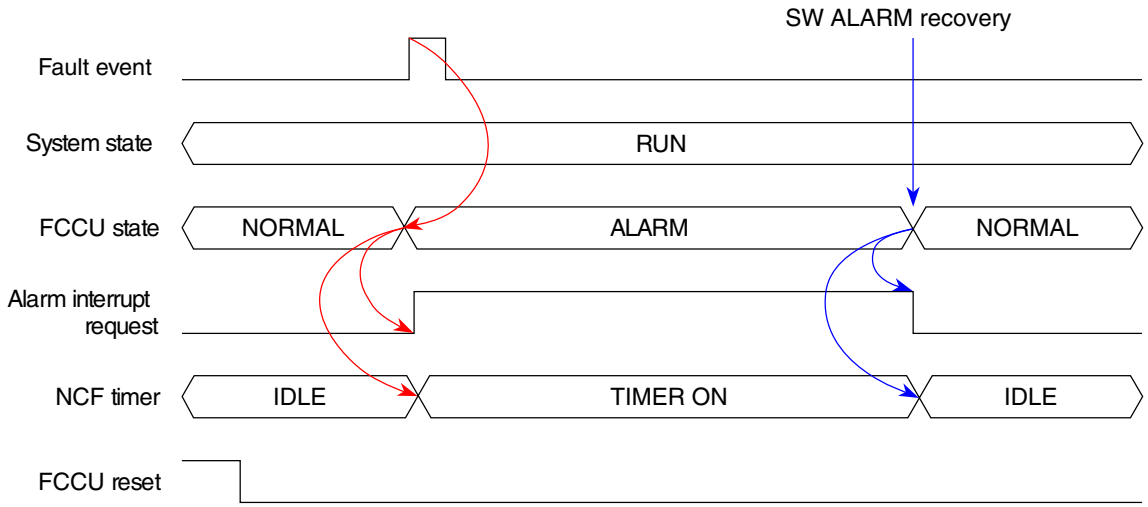

Figure 74-4. Noncritical FAULT (ALARM state) recovery (a)

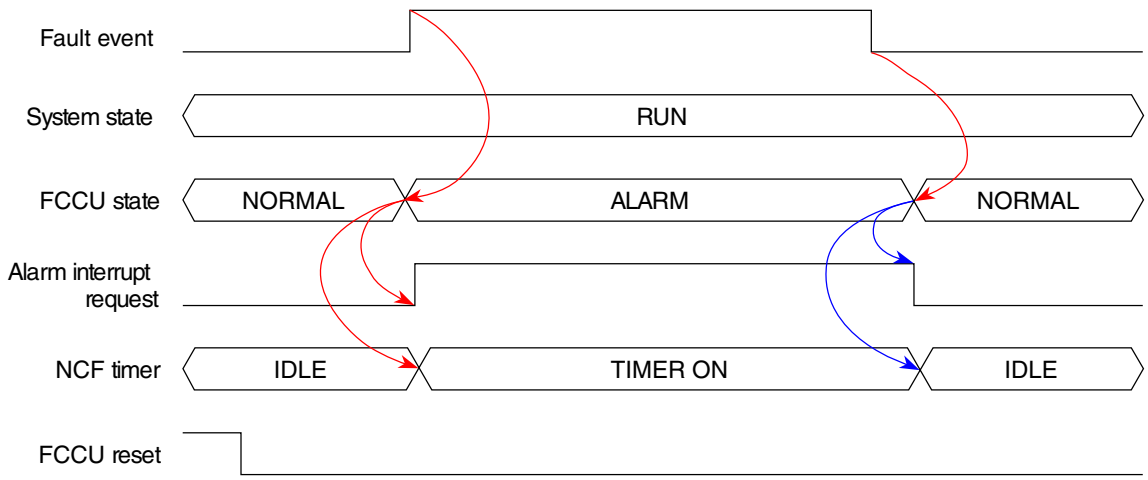

Figure 74-5. Noncritical FAULT (ALARM state) recovery (b)

A typical sequence related to a noncritical FAULT management (ALARM → FAULT state), see Figure 74-6, is as follows:

- Noncritical fault assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - alarm interrupt request (if enabled)
  - time-out running
- FCCU state transition (following the time-out trigger): ALARM → FAULT
  - NMI assertion (if enabled)
- system state transition: RUN → SAFE
- NMI interrupt management (if enabled)

- FAULT recovery (by SW): FCCU state transition FAULT → NORMAL
- system state transition: SAFE → RUN

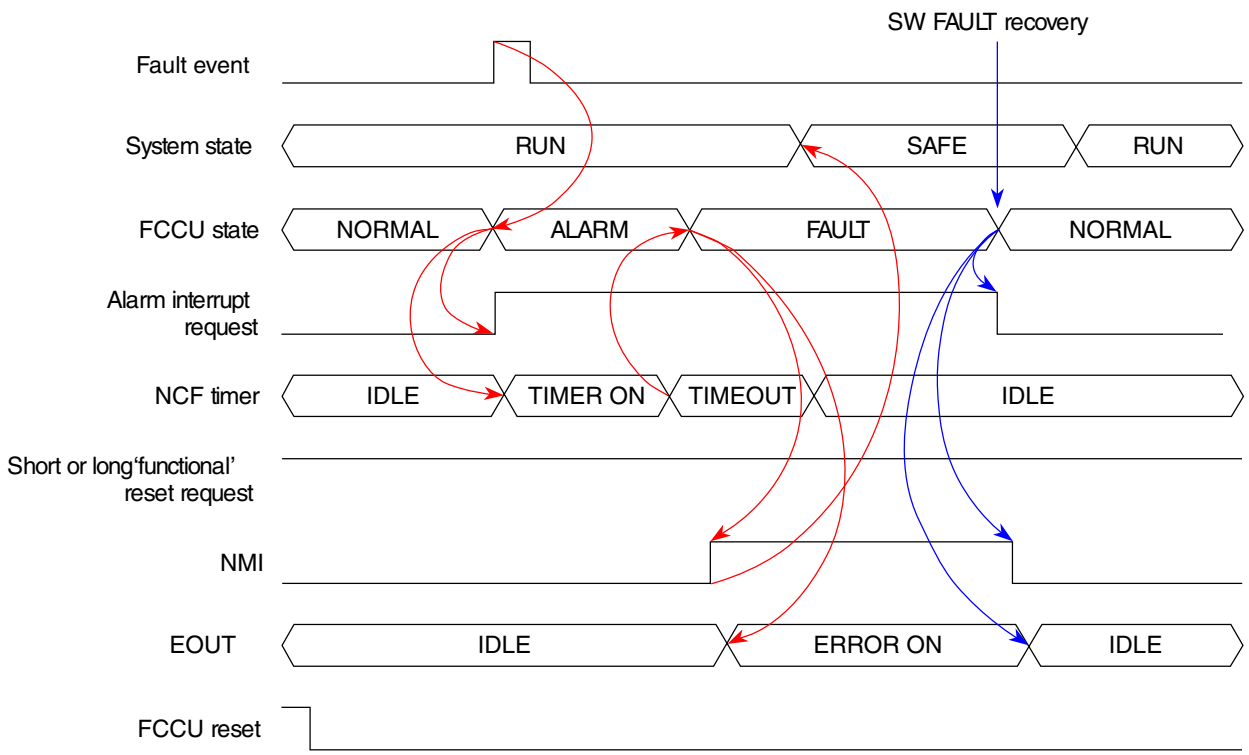

Figure 74-6. FAULT (ALARM → FAULT state) recovery

74.9.5 NMI/WKPU interface

NMIOUT is connected to all processor cores on the chip but is masked when any one of the following is true:

- An FCCU asynchronous reset is in progress.
- The chip is in RESET mode.
- The chip has automatically entered DRUN mode from RESET mode and software has not yet requested another mode change.

This figure shows the logical scheme.

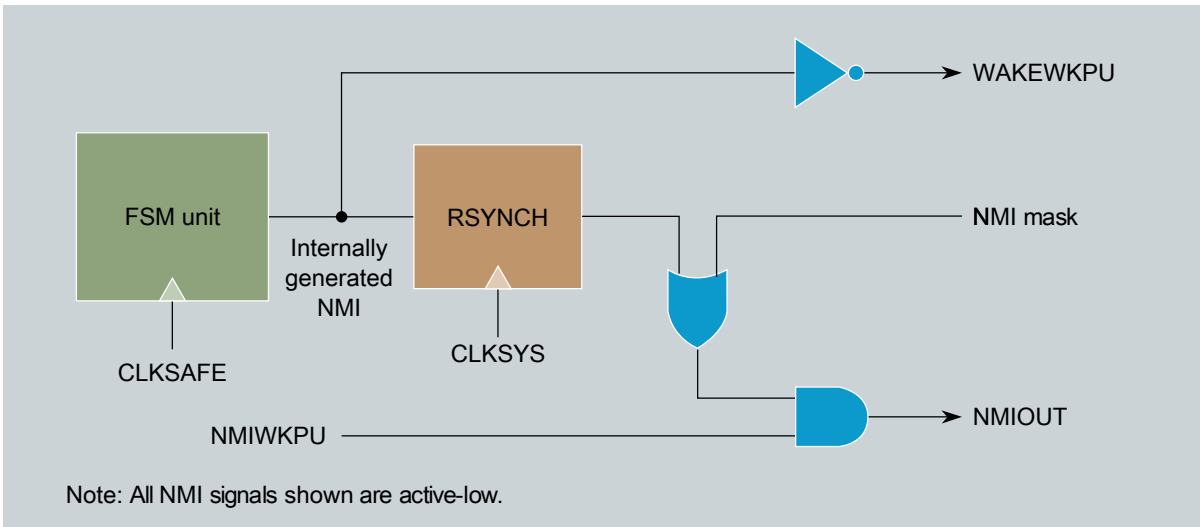

Figure 74-7. NMI/WKPU scheme

74.9.6 STCU interface

The STCU interface includes:

- A set of signals resulting from the self-checking procedure connected externally at the FCCU.

  The STCU fault signals are processed by the FCCU when the SoC is re-booted following the self-testing procedure. The STCU includes a status register that stores the self-testing results (flags).

- a mask that inhibits the EOUT dummy signaling until the STCU self-checking procedure has been completed.

During the self-testing procedure, depending on the STCU results, three cases are applicable:

1. STCU completes the self-testing procedure successfully. The SoC reboots and the FCCU is responsible for fault collection and indication.
2. STCU completes the self-testing procedure with low severity failures. The FCCU records the fault condition but does not, by default, trigger a reset cycle.
3. STCU completes the self-testing procedure with serious failures. The FCCU triggers a reset cycle in response to this fault input from the STCU. Because the fault condition survives reset, new reset cycles are subsequently triggered until the reset escalation feature takes control, freezing the chip in the reset state until a POR. This feature is optionally programmable using MC_RGM.

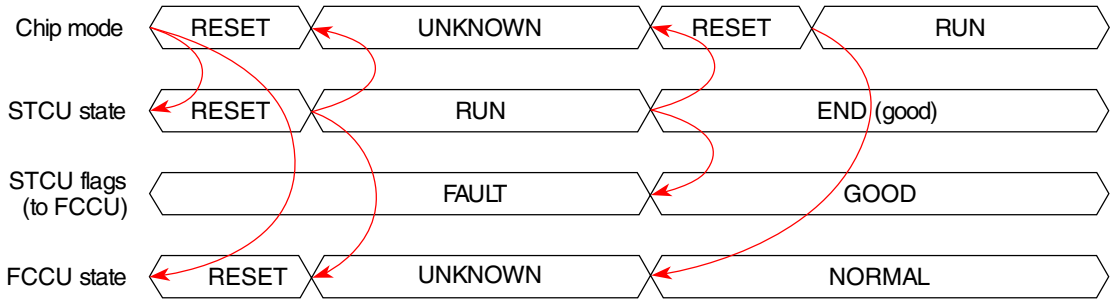

Figure 74-8. STCU-FCCU (case 1)

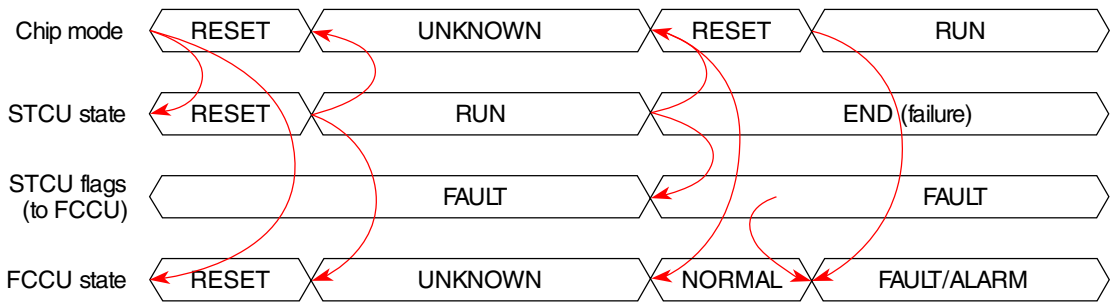

Figure 74-9. STCU-FCCU (case 2)

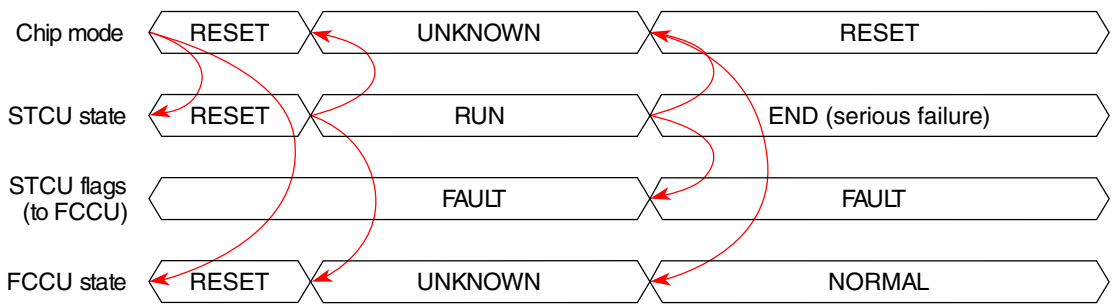

Figure 74-10. STCU-FCCU (case 3)

74.9.7 Nonvolatile memory interface

FCCU includes a nonvolatile memory interface (NVMCFG signals) that provides the values of certain bits in the Configuration (FCCU_CFG) register when certain events occur. See Configuration (FCCU_CFG). Whether any of these signals are actually connected to nonvolatile (flash) memory is chip-specific. Some or all of these signals may be driven by bits in a data record in nonvolatile (flash) memory or may be tied high (1) or low (0). See FCCU_CFG register bit value sources (N and C) by event.

The timing diagram related to the NVM interface is given in Figure 74-11.

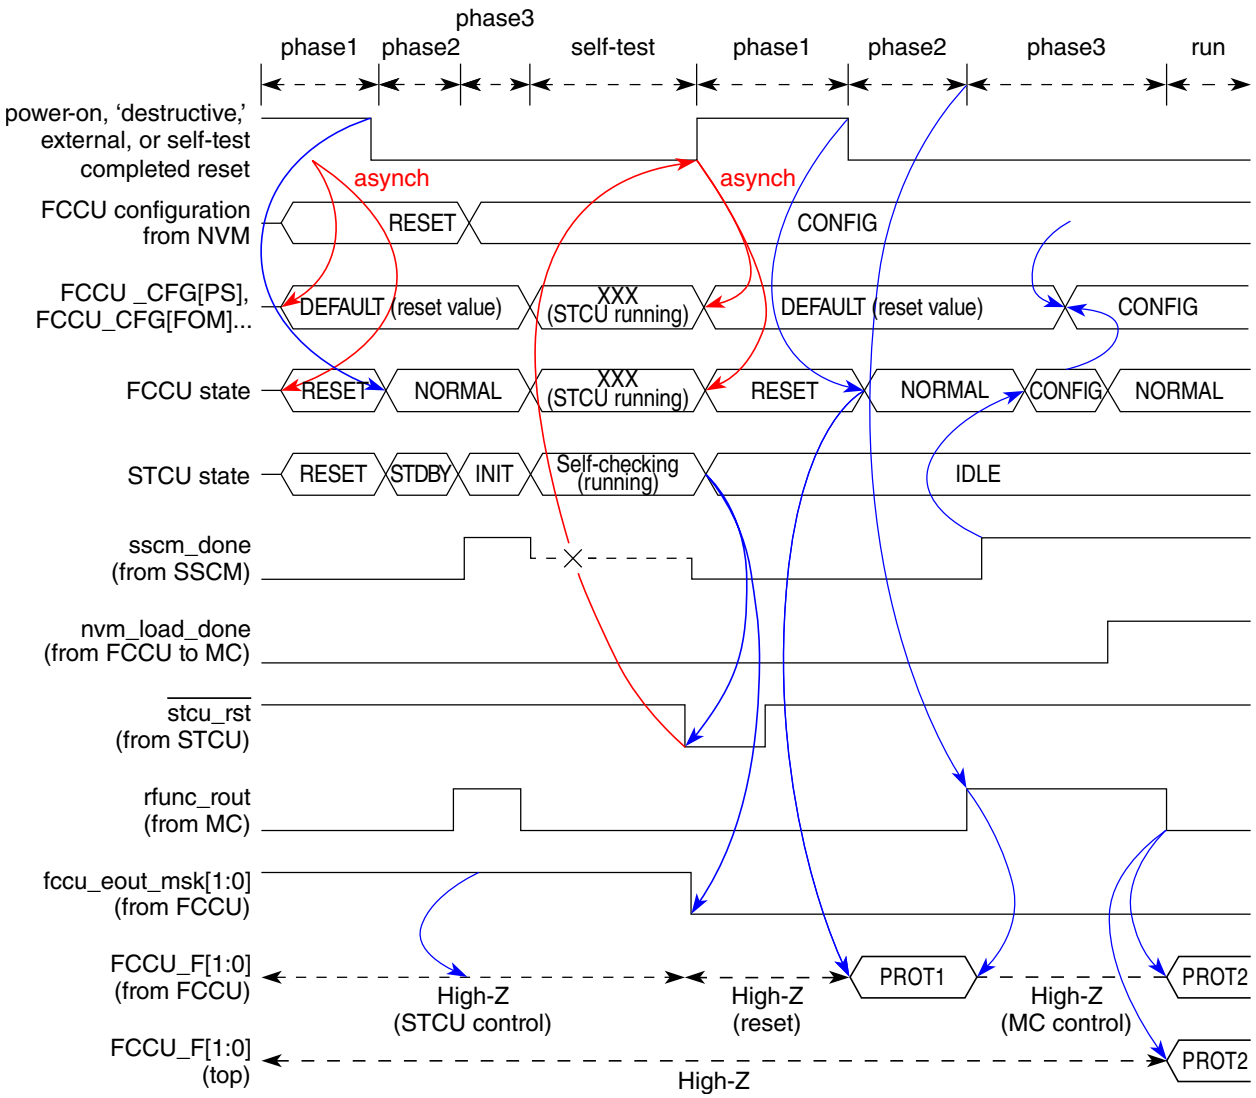

Figure 74-11. NVM interface

74.9.8 EOUT interface

74.9.8.1 Introduction

You use the EOUT[1:0] signals to indicate FCCU's condition to off-chip logic. For information on the availability and names of these FCCU signals on the boundary of this chip, see the chip-specific FCCU information.

74.9.8.2 The FCCU conditions

There are three FCCU conditions:

Condition	Description
Faulty	The fault-output (EOUT) timer is running (see How the fault-output (EOUT) timer works).
Nonfaulty	All of the following are true: • The fault-output (EOUT) timer is not running. • FCCU is in Alarm or Normal state.
Configuration	All of the following are true: • The fault-output (EOUT) timer is not running. • FCCU is in Configuration state.

74.9.8.3 How the fault-output (EOUT) timer works

FCCU starts the fault-output (EOUT) timer when all of the following are true:

- The fault-output (EOUT) signals are not programmed to be always low (FCCU_SET_CLEAR).
- The fault-output (EOUT) timer isn't already running.
- FCCU enters Fault state as the result of a fault.

When the fault-output (EOUT) timer is already running and a new fault occurs:

- When FCCU is in Configuration state: FCCU doesn't restart the fault-output (EOUT) timer.
- When FCCU is in Normal state or Alarm state:
  - And Alarm state is enabled for the fault (noncritical): FCCU enters (or remains in) Alarm state but doesn't restart the fault-output (EOUT) timer.
  - And Alarm state is disabled for the fault (noncritical): FCCU enters Fault state and restarts the fault-output (EOUT) timer.
- When FCCU is in Fault state: FCCU restarts the fault-output (EOUT) timer.

FCCU stops and reinitializes the fault-output (EOUT) timer when all of the following are true:

- If the EOUT signals are in Bistable fault-output mode (FOM), T_min has expired.
- All faults that caused FCCU to enter or remain in Fault state since FCCU started the fault-output (EOUT) timer have been cleared, causing FCCU to return to Normal state.

74.9.8.4 Prepare the EOUT signals to indicate FCCU's condition

Make sure all of the following are true:

- The EOUT signals are active (FCCU_SET_AFTER_RESET).
- The EOUT signals are controlled by FCCU's finite state machine (FCCU_SET_CLEAR).

74.9.8.5 More about the EOUT interface

Because SIUL2 does not control the pad-buffer enable for an Alternate function, FCCU provides a mechanism to drive the pads for EOUT[1:0] in Open-Drain (OD) mode (FCCU_CFG[OD]) so that a pad is in a high-impedance state when FCCU drives a logic 1 and is low when FCCU drives a logic 0.

Different fault-output modes (protocols) for the fault-output (EOUT) interface are supported (FCCU_CFG[FOM]):

- Dual-Rail
- Time-Switching
- Bistable
- Test

You can further configure the fault-output modes using the following attributes:

Attribute	Field	Setting used in the example diagrams and tables that follow
Switching mode	FCCU_CFG[SM]	Slow
Polarity selection	FCCU_CFG[PS]	For the faulty indication, EOUT1 is high, and EOUT0 is low.
Derived prescaler	FCCU_CFG[FOPE], FCCU_CFG[FOP]	0

The external monitor of the EOUT protocol should oversample the EOUT signals in order to synchronize periodically the external clock (used by the monitor) and CLKSAFE (which detects the edge transition of the EOUT protocol) in Dual-Rail or Time-Switching fault-output mode.

In case of a failure event or on software request for EOUT indication, the signal(s) are set to the faulty state for a minimum time T_min, even if software tries to release it before. If software configures the error pins to OK(1), and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and the error signals indicate NOK,

such as an incoming fault is not masked when software has set the error signal to high. During the T_min by a non-software fault, the FCCU FSM moves independently of this signal state (low), and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself in, and it is not possible to set the signals to OK by software moving FCCU to Configuration state, as long as this timer is running. No software intervention is needed to bring the signal from the low state.

Software can bring the pin back to OK state by clearing the faults and waiting for the T_min interval to expire, after which the FCCU automatically enters Normal state and the error signal indicates OK.

In case another failure event happens within T_min after a first one, the T_min counter is restarted.

NOTE

The transition from Fault to Configuration state is not possible but is shown to display the behavior in all four states—reset, normal, error, and configuration.

NOTE

FCCU remains in Normal state when a fault is disabled; therefore, *NA* (not applicable) appears in the following table.

NOTE

The following table is valid only when the EOUT signals are active (FCCU_SET_AFTER_RESET).

Table 74-4. FCCU error pin behavior on state transitions

Fault signaling state	Transition from Normal to Fault state			Normal+Configuration states			Transition from Normal to Alarm state		
	with Fault disabled | enabled						with Fault disabled | enabled		
	Internal error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad
Disabled	NA | OK	NA | 1	NA | OK	OK	1	OK	NA | OK	NA | 1	NA | OK
Enabled	NA | NOK	NA | 1	NA | NOK	OK	1	OK	NA | OK	NA | 1	NA | OK

NOTE

The first time FCCU is in Configuration state, the EOUT pads are in a high-impedance state; thereafter, their states reflect the programmed EOUT protocol.

74.9.8.6 Dual-rail protocol

Dual-rail encoding is an alternate method for encoding bits. In contrast with classical encoding, where each signal carries a single-bit value, dual-rail encoded circuits use two wires to carry each bit. The encoding scheme is given in Table 74-5 and the related timing diagram is given in Figure 74-12 and Figure 74-13.

Table 74-5. Dual-rail encoding

Logical state	Dual-rail encoding (output pins EOUT[1:0])	Note
non-faulty	10	toggling
non-faulty	01	
faulty	00	toggling
faulty	11	
reset	Hi impedence[1]	no toggling
configuration	same as NORMAL	toggling

1. Final value depends on the SoC setting at pad level.

In the RESET phase the output pins are set as "high impedance".

Note

Figure 74-12 and Figure 74-13 are formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

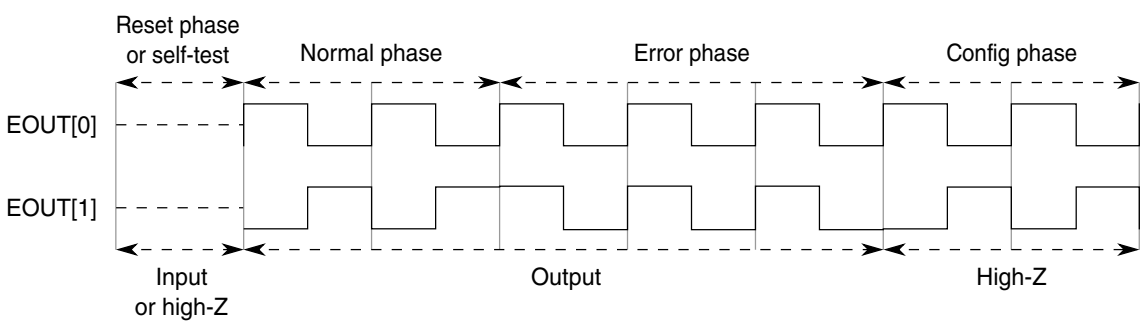

Figure 74-12. Dual-rail protocol (slow switching mode)

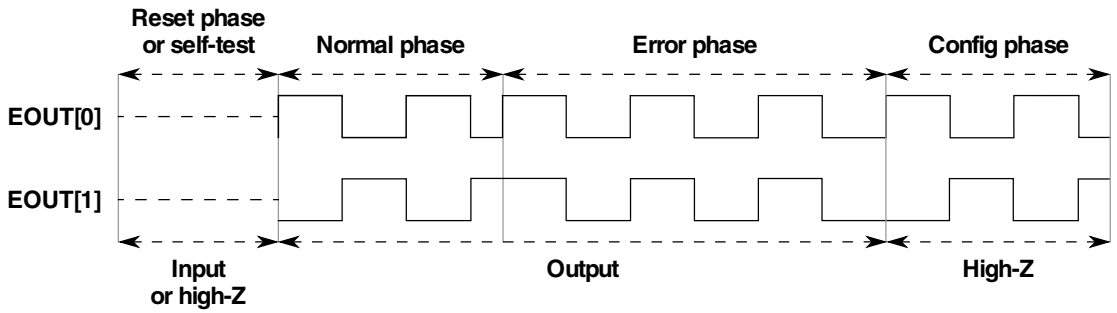

Figure 74-13. Dual-rail protocol (fast switching mode)

74.9.8.7 Time-switching protocol

The encoding scheme is given in Table 74-6 and the related timing diagram is given in Figure 74-14.

Table 74-6. Time-switching encoding

Logical state	Time-switching encoding (output pins EOUT[1:0])	Note
non-faulty	10	toggling
non-faulty	01	
faulty	10	no toggling
reset	high-Z[1]	no toggling
configuration	same as NORMAL	toggling

1. Final value depends on device specific settings at pad level.

As long as FCCU is in NORMAL or ALARM state, outputs will show "non-faulty" signal. Output pins #0, #1 will toggle between 01 and 10 with frequency specified by the CFG[FOP].

In the FAULT state, the output pin EOUT[0] is set as low.

In Time Switching mode the second output (EOUT[1]) is the inverted signal of first output (EOUT[0]).

In the RESET phase the output pins are set as "high impedance".[2]

Note

Figure 74-14 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

2. Actual value depends on device specific settings at pad level.

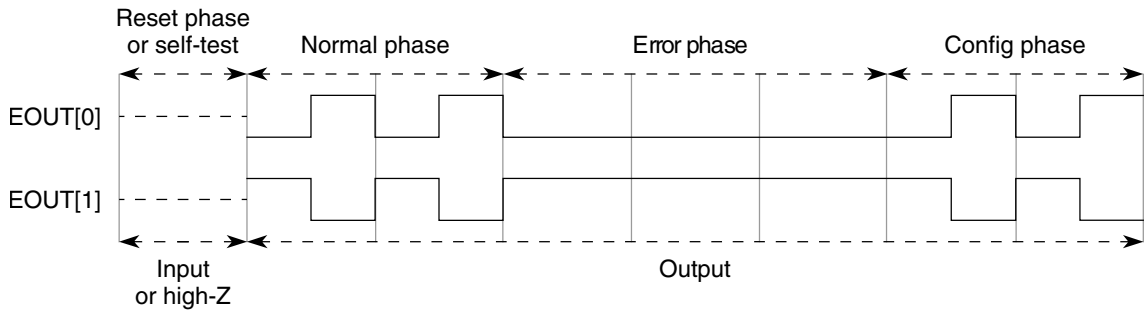

Figure 74-14. Time-switching protocol

74.9.8.8 Bi-stable protocol

The encoding scheme is given in Table 74-7 and the related timing diagram is given in Figure 74-15.

Table 74-7. Bi-stable encoding

Logical state	Bi-stable encoding (output pins EOUT[1:0])	Note
non-faulty	01	no toggling
faulty	10	no toggling
reset	high-Z[1]	no toggling
configuration	same as NORMAL	no toggling

1. Final value depends on device specific settings at pad level.

In the FAULT state, the faulty logical state is indicated. In NORMAL or ALARM state, "no-faulty" state is indicated. In Bi-stable mode the second output (EOUT[1]) is the inverted signal of first output (EOUT[0]).

In the RESET phase the output pins are set as "high impedance".[3]

Note

Figure 74-15 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

3. Actual value depends on device specific settings at pad level.

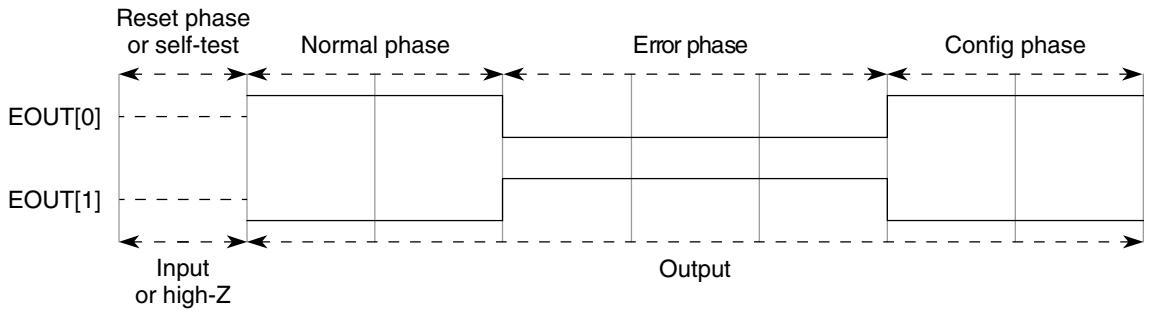

Figure 74-15. Bi-stable protocol

74.9.8.9 Option 1, Option 2

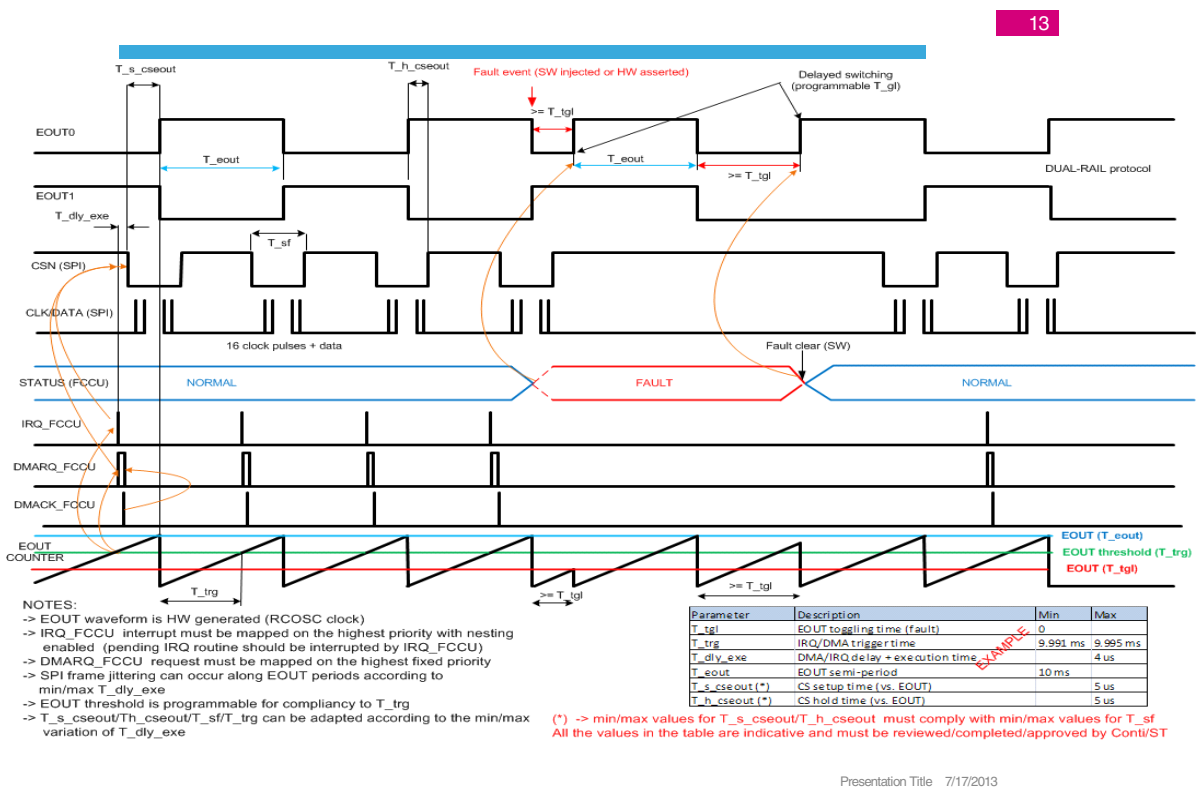

Figure 74-16. Option1 , Option 2

The internal counter used to generate the EOUT waveforms is used to control a IRQ or DMA trigger event. This event shall appear only when the FCCU is not in FAULT mode as showin in the above figure.

NOTE

While switching fom Non-Fault to Fault state or vice versa, Delay equal to T_Tgl will only be visible if EOUT COUNTER is less than T_Tgl.

74.9.8.10 Option 3

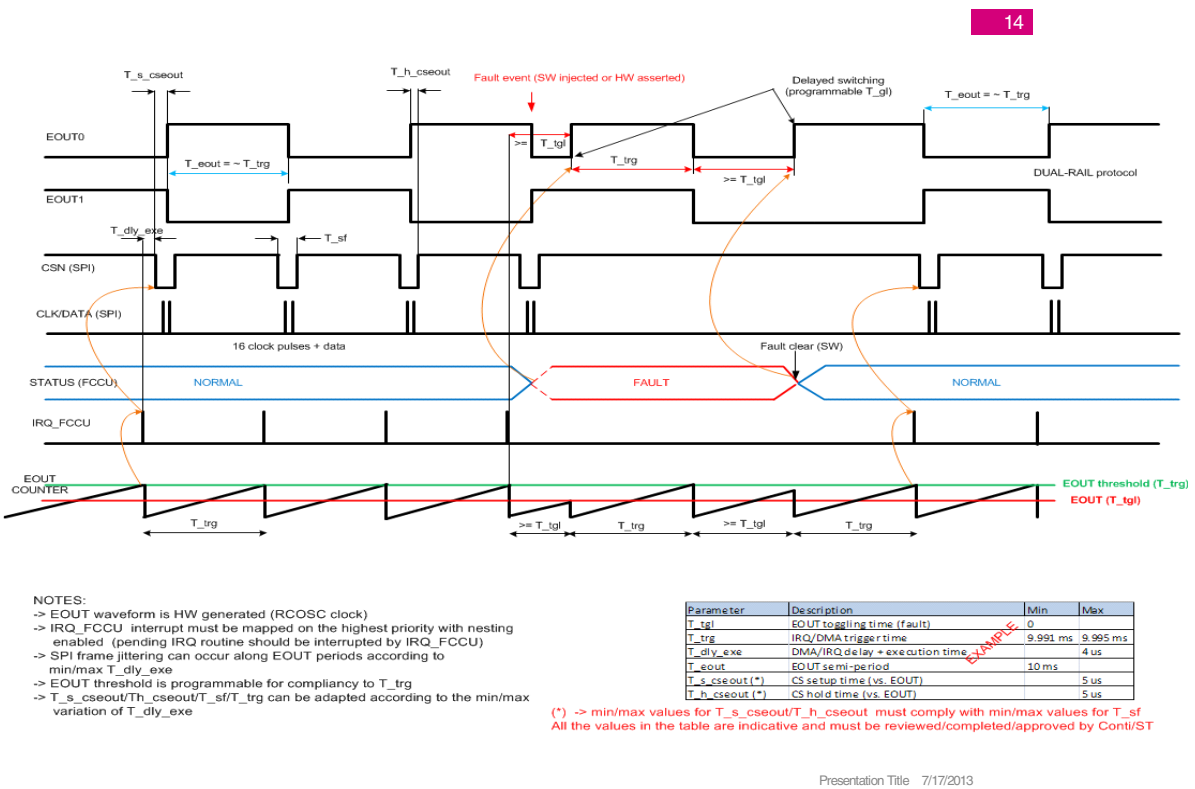

Figure 74-17. Option3

When FCCU_CFG. FOME = 11, the EOUT pin state is controlled by the application SW as far as the FCCU is in NORMAL or ALARM state. As soon as a the FCCU enters the FAULT state, both the EOUT pins are forced by the HW to the same level, which can be 0-0 or 1-1 depending on the polarity configuration. As far as the FCCU is in FAULT

state, the SW has no control over the EOUT pins. Once the fault condition is recovered, the FCCU returns to the NORMAL state and the SW can take back the control of the EOUT pins. Figure 24 shows how this is accomplished. As far as the FCCU is not in FAULT mode, the IRQ interrupts are asserted when the FCCU internal timer reaches the programmed threshold. If needed, it is responsibility of the SW to toggle the EOUT pins within the ISR. The EOUT pin toggling period depends on the IRQ assertion frequency (controlled by the HW) plus the interrupt service time and SW execution. This period will be stable and close to the IRQ programmed period as far as the interrupt service routine can be serviced in a deterministic time frame and executed at the highest priority. During the ISR, additional operations can be done: the figure shows an example of a DSPI frame sent before every EOUT toggling, but with the DSPI CS being kept asserted for some time after the EOUT has toggled. When the FCCU enters into the FAULT state, no IRQ interrupt is fired anymore and the EOUT pins are controlled by the HW. During this time frame, the EOUT pin toggling is exactly matching the programmed period.

74.9.9 Error signal flow

See the chip-specific FCCU information for the diagram of the signal flow.

74.10 Register descriptions

The FCCU registers are listed in the table below. Any address offset not explicitly mentioned in this table is reserved.

The FCCU supports word (32-bit), half-word (16-bit), and byte (8-bit) read and write accesses.

Follow these register-access guidelines:

- Don’t read from or write to any addresses that are not shown in the following table. Doing so may result in a transfer error.
- Don’t write to any of the configuration registers unless FCCU is in Configuration state. Doing so results in a transfer error.
- Don’t write to FCCU_TRANS_LOCK or FCCU_PERMNT_LOCK unless your code runs in Supervisor mode. Doing so results in a transfer error.

All the registers accessible in write mode only in CONFIG state are referred as configuration registers. These configuration registers return to the default value after configuration watchdog timer expires. These are the registers protected by FCCU_TRANS_LOCK and FCCU_PERMNT_LOCK registers. The configuration register setting has effect only when the FCCU state exits from the CONFIG state.

For each possible NCF failure source, a different reaction—including no reaction—is configurable through the use of NMI, IRQ, and long/short reset selection registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

The FCCU is not reset by short or long functional resets.

74.10.1 Control (FCCU_CTRL)

Initiates and indicates the status of operations, indicates that FCCU successfully loaded configuration data from the NVMCFG signals, controls glitch-filter settings, and enables Debug mode.

Address: 0h base + 0h offset = 0h

FCCU_CTRL field descriptions

Field	Description
0 FILTER_ BYPASS	Filter bypass 0 glitch filter not bypassed 1 glitch filter bypassed
1–2 FILTER_WIDTH	Filter width 00 filters glitches up to 50 µs 01 filters glitches up to 75 µs 10 filters glitches up to 100 µs 11 filters glitches up to 100 µs

Table continues on the next page...

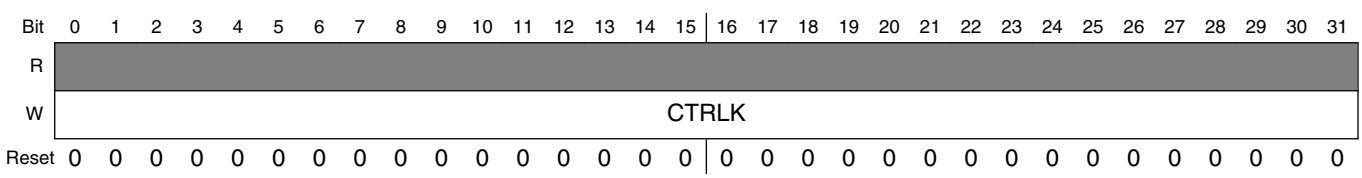
FCCU_CTRL field descriptions (continued)

Field	Description
3–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 DEBUG	Debug Mode Enable Specifies whether Debug mode is enabled. If so, FCCU enters Debug mode when the Debug signal is asserted. When FCCU enters Debug mode, it halts operation and remains in the state it was in before it entered Debug mode. 0 Disabled 1 Enabled
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–25 OPS	Operation status. This bit can be read and cleared (via OP15 operation) by the software. 00 Idle 01 In progress 10 Aborted 11 Successful
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 OPR	Operation Run Initiates operations that perform actions such as putting FCCU in Configuration state or reading a timer. For information on how to run operations, see Run operations. FCCU ignores any write to this field while the operation status (OPS) is In Progress. After completion of an operation, FCCU sets this field to OP0. The following events result in an operation status (OPS) of Aborted: • Writing to a Noncritical Fault Status (FCCU_NCF_S*n*) register (which automatically initiates the OP12 operation) without first successfully unlocking the register (NCFK) • Initiating an OP1 operation when FCCU is not in Normal state or the configuration is locked • Initiating an OP1, OP2, or OP31 operation without first unlocking the operation (CTRLK) 00000 OP0—No operation 00001 OP1—Applies only when the configuration is unlocked, when FCCU is in Normal state, and immediately after you unlock the operation (CTRLK). Put FCCU in Configuration state. 00010 OP2—Applies only immediately after you unlock the operation (CTRLK). Put FCCU in Normal state. 00011 OP3—Capture FCCU's state and the states of the EOUT signals in the Status (FCCU_STAT) register. 00100 OP4—Read the FCCU frozen status flags (NA Freeze Status (FCCU_N2AF_STATUS)). 00101 OP5—Read the FCCU frozen status flags (AF Freeze Status (FCCU_A2FF_STATUS)). 00110 OP6—Read the FCCU frozen status flags (NF Freeze Status (FCCU_N2FF_STATUS)). 00111 OP7—Read the FCCU frozen status flags (FA Freeze Status (FCCU_F2A_STATUS)). 01000 Reserved 01001 Reserved 01010 OP10—Read the Noncritical Fault Status (FCCU_NCF_S*n*) register. 01011 Reserved

Table continues on the next page...

FCCU_CTRL field descriptions (continued)

Field	Description
	01100 OP12—Do not initiate this operation; it is automatically initiated by FCCU. A Noncritical Fault Status (FCCU_NCF_S*n*) register status clear operation is in progress. 01101 OP13—Clear the freeze status registers (see the freeze registers). 01110 OP14—Do not initiate this operation; it is automatically initiated by FCCU. A Configuration-state timeout is in progress. For more information, see Configuration registers. 01111 OP15—Set the operation status (OPS) to Idle. 10000 Reserved 10001 OP17—Read the Alarm-state timer (XTMR). 10010 Reserved 10011 OP19—Read the Configuration-state timer (XTMR). 10100 OP20—Read the Error Pin low counter value (XTMR). 10101–11110 Forbidden. Writing any of these values returns an operation status (OPS) of Aborted with no side effect. 11111 OP31—Applies only immediately after you unlock the operation (CTRLK). Load configuration data from the NVMCFG signals to certain fields in the Configuration (FCCU_CFG) register, but without resetting FCCU (for testing and debugging). See FCCU_CFG register bit value sources (N and C) by event. The operation status (OPS) for this operation is always Successful.



74.10.2 Control Key (FCCU_CTRLK)

Writable only with a 32-bit write. Unlocks locked operations so you can initiate them (OPR). For information on how to unlock locked operations before you initiate them, see Run an operation.

NOTE

Reading from this register always returns the value 0000_0000h.

Address: 0h base + 4h offset = 4h

FCCU_CTRLK field descriptions

Field	Description
0–31 CTRLK	Locked-Operation Control Key Unlocks locked operations so you can initiate them (OPR). For information on how to unlock locked operations before you initiate them, see Run an operation.

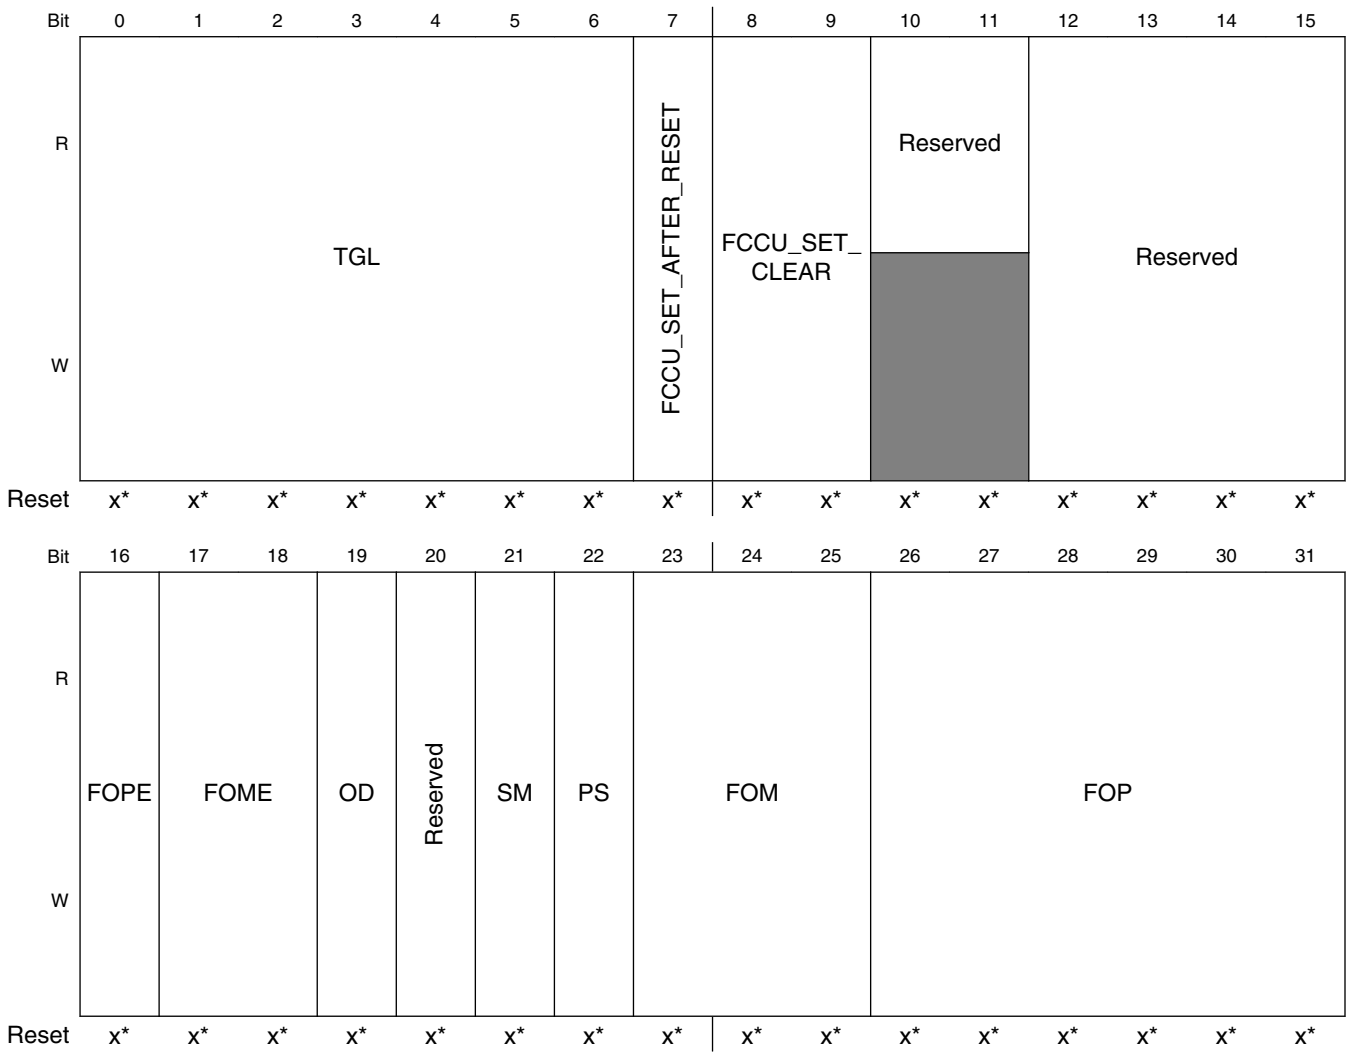
FCCU_CTRLK field descriptions (continued)

Field	Description
	NOTE: You must initiate an operation in the instruction that immediately follows the instruction that unlocks it; otherwise, the operation is again locked. 9137_56AFh: Unlock OP1. 825A_132Bh: Unlock OP2. 29AF_8752h: Unlock OP31. Any other value: Do nothing.

74.10.3 Configuration (FCCU_CFG)

Writable only when FCCU is in Configuration state. Specifies the global configuration for FCCU.

The values of the bits in this register are affected by writes as well as any of the following events:



- The chip resets FCCU.
- FCCU automatically leaves Configuration state and enters Normal state because the configuration-timer interval (TO) expires. This is called a Configuration-state timeout.
- You run an OP31 operation.

For information on the sources of bit values for these events, see FCCU_CFG register bit value sources (N and C) by event.

NOTE

If you specify a new value for any of the fields in this register that affect the EOUT signals while the fault-output (EOUT) timer is running (FCCU is indicating a fault on the EOUT signals), FCCU doesn't use the new settings you specified until after the fault-output (EOUT) timer expires (FCCU stops indicating a fault on the EOUT signals).

Address: 0h base + 8h offset = 8h

* Notes:

- For information on this register's reset value, see FCCU_CFG register bit value sources (N and C) by event.x = Undefined at reset.

FCCU_CFG field descriptions

Field	Description
0–6 TGL	EOUT Toggling Time Active only if CFG[SM] specifies slow switching. This value is the minimum duration of the EOUT pulse during Fault -> Normal/Alarm and Normal/Alarm -> Fault state transitions. For more information, see the FOME field description for the setting 11b. Min = 1 µs, Max = 128 µs, resolution = 1 µs
7 FCCU_SET_AFTER_RESET	Fault-Output (EOUT) Activate For fault-output (EOUT) signaling, controls whether the EOUT signals are active.

Table continues on the next page...

FCCU_CFG field descriptions (continued)

Field	Description
	0 Inactive (the EOUT signals are in a high-impedance state) 1 Active (the EOUT signals indicate FCCU's condition)
8–9 FCCU_SET_CLEAR	Fault-Output (EOUT) Control Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Controls whether the fault-output (EOUT) signals are controlled by FCCU's finite state machine (FSM). 00 Controlled by the FSM 01 Always low 10 Controlled by the FSM 11 High until a fault occurs on a channel, regardless of whether that fault is disabled; thereafter, controlled by the FSM. Note: FCCU ignores an attempt to write this value if the fault-output (EOUT) timer is already running.
10–11 Reserved	This field is reserved.
12–15 Reserved	This field is reserved. Always write the reset value to this field.
16 FOPE	Fault-Output (EOUT) Prescaler Extension For fault-output (EOUT) signaling, specifies the most significant bit of the derived prescaler that controls the signaling frequency. For more information, see the description of the FOP field.
17–18 FOME	Fault Output Mode Extension 00 Current behavior (default) 01 Option #1: HW interrupt trigger(IRQ_EOUT) asserted by the FCCU when EOUT reaches T_Trig value when in NORMAL/ALARM state. (EOUT counter saturation is shown in Option 1, Option 2). 10 Option #2: DMA request (DMARQ_EOUT) asserted by the FCCU when EOUT reaches T_Trig value (EOUT counter saturation as shown in Option 1, Option 2) when in NORMAL/ALARM state. 11 Option #3 only if CFG[FOM] is 000b: EOUT protocol is SW controlled in NORMAL/ALARM state and HW controlled in FAULT state (dual rail, in phase toggling with programmable delay) following a HW interrupt trigger (IRQ_EOUT) asserted by the FCCU when EOUT reaches T_Trig value (EOUT counter saturation as shown in Option 3 section) when in NORMAL/ALARM state in order to generate the EOUT protocol via SW. An alternative option is to use an external eTMR. EOUT dual-rail protocol: • NORMAL/ALARM: for example, 10 ms toggling in opposite phase • FAULT: for example, 10 ms toggling in phase starting after a programmable delay T_tgl, slow switching mode (SM is 0) • FAULT: fast switching mode (SM is 1) in phase (no periodic toggling). For details, please refer to Option 1, Option 2 section. For details, please refer to Option 3 section. If option #3 is disabled when CFG[FOM] is 000b, the result is dual-rail mode (current behavior).
19 OD	Open-Drain Mechanism to select between Push-pull and Open drain(OD) mode for the error indicating pin(s) 0 Push-pull 1 Open-drain
20 Reserved	This field is reserved. Always write the reset value to this field.
21 SM	Fault-Output (EOUT) Switching Mode

Table continues on the next page...

FCCU_CFG field descriptions (continued)

Field	Description
	For fault-output (EOUT) signaling, controls how quickly the signals switch between faulty and nonfaulty indication. Applies only to Dual-Rail and Time-Switching fault-output modes. 0 Slow: No EOUT frequency violation during the FCCU state transition (Normal to Fault or vice versa, and Configuration to Normal). The indication transition occurs after a maximum delay equal to the duration of the semiperiod of the EOUT frequency. 1 Fast: The indication transition (Normal to Fault or vice versa, and Configuration to Normal) occurs immediately. A pulse with the minimum duration corresponding to the CLKSAFE period can occur in this mode. It implies a frequency violation of the EOUT protocol.
22 PS	Fault-Output (EOUT) Polarity Selection For fault-output (EOUT) signaling, controls the polarity of the signals for fault-output-mode indications that hold the signals low or high (versus toggling them or placing them in a high-impedance state). Applies only to Time-Switching fault-output mode (for faulty and configuration indications) and Bistable fault-output mode (for all indications). 0 For the faulty indication, EOUT1 is high, and EOUT0 is low. 1 For the faulty indication, EOUT1 is low, and EOUT0 is high.
23–25 FOM	Fault-Output (EOUT) Mode For fault-output (EOUT) signaling, controls the protocol of the signaling. **NOTE:** In the test modes, a simple double-stage resynchronization stage is used to resynchronize the EOUT input/outputs with CLKSAFE. 000 Dual-Rail (default state) [EOUT[1:0]= outputs] 001 Time-Switching [EOUT[1:0]= output to be used] 010 Bistable 011 Reserved 100 Reserved 101 Test 0 (controlled by the FCCU_EINOUT register; EOUT1 is an output; EOUT0 is an input) 110 Test 1 (controlled by the FCCU_EINOUT register; EOUT1 and EOUT0 are both outputs) 111 Test 2 (controlled by the FCCU_EINOUT register; EOUT1 is an input; EOUT0 is an output)
26–31 FOP	Fault-Output (EOUT) Prescaler For fault-output (EOUT) signaling, specifies the least significant bits of the derived prescaler that controls the signaling frequency. The derived prescaler is the concatenation of FOPE and FOP and is represented by *{FOPE, FOP}*. The following equation defines the signaling frequency in terms of the CLKSAFE frequency ($CLKSAFE_{freq}$) and the derived prescaler: $EOUT_{freq} = CLKSAFE_{freq} / ((\{FOPE, FOP\} + 1) \times 2 \times 2048)$ The following example values and meanings are for the derived (7-bit) prescaler, not FOP alone. The meanings show the derived prescaler followed by the corresponding value by which the input clock frequency is then divided. 0000000: 0; divide by 2 × 2048 (4096) 0000001: 1; divide by 4 × 2048 (8192) 0000010: 2; divide by 6 × 2048 (12,288) … 0001000: 8; divide by 18 × 2048 (36,864)

Table continues on the next page...

FCCU_CFG field descriptions (continued)

Field	Description
	… 1111101: 125; divide by 252 × 2048 (516,096) 1111110: 126; divide by 254 × 2048 (520,192) 1111111: 127; divide by 256 × 2048 (524,288)

74.10.4 Noncritical Fault Configuration (FCCU_NCF_CFG*n*)

Contains the configuration of noncritical faults in terms of fault-recovery management. The configuration depends on the type of signaling of a fault event. Hardware-recoverable faults should be configured only if a previous latching stage captures and holds the physical fault; otherwise, the fault can be lost. All other faults should be configured as software faults.

NOTE

These registers are writable only when FCCU is in Configuration state.

Noncritical Fault Configuration (FCCU_NCF_CFG*n*) register (value of n)	Offset	NCFCx fields (value of x)

* Notes:

- The reset value is chip-specific. See the chip-specific FCCU information.x = Undefined at reset.

FCCU_NCF_CFG*n* field descriptions

Field	Description
0–31 NCFCx	Noncritical Fault Configuration. Defines the fault recovery mode. Hardware-recoverable faults are self-recovered (status flag clearing and related) if the root cause (input fault) has been removed. Software-recoverable faults are recovered (status flag clearing) by software clearing of the related status flag.

FCCU_NCF_CFG*n* field descriptions (continued)

Field	Description
	For the mapping of the NCFCx fields among registers, see the earlier table in this register description. 0 Hardware-recoverable fault 1 Software-recoverable fault

74.10.5 Noncritical Fault State Configuration (FCCU_NCFS_CFG*n*)

The FCCU_NCFS_CFGx registers contain the configuration of each noncritical fault in terms of fault reaction (short or long functional reset request pulse) when it is the root cause for the FAULT state transition.

NOTE

These registers are writable only when the FCCU is in the CONFIG state.

Table 74-8 shows FCCU configuration register channels.

Table 74-8. FCCU NCFS configuration register channels

Address offset	Register name	Channel range (x)
4Ch	FCCU_NCFS_CFG0	NCFSCx[15:0]

74.10.6 Noncritical Fault Status (FCCU_NCF_S*n*)

The FCCU_NCF_Sx register contains the latched fault indication collected from the noncritical fault sources. Faults are latched also in the CONFIG state and independently from the enabling or reactions programmed for the NCF.

No reactions are executed until the FCCU moves in the NORMAL state.

FCCU reacts and moves from the NORMAL state into the ALARM state only if the respective enable bit for a fault is set in the FCCU_NCF_Ex register and the respective enable bit for the timeout is set in the FCCU_TOEx register.

FCCU reacts and moves from the NORMAL or ALARM state into the FAULT state if the respective enable bit for a fault is set in the FCCU_NCF_Ex register and the respective enable bit for the timeout is disabled in the FCCU_TOEx register.

FCCU reacts and moves from the ALARM state into the FAULT state if the timeout (FCCU_TO register) is elapsed before recovering from the fault.

The timeout is stopped only when the FCCU returns in the NORMAL state.

The FCCU_NCF_Sx register is encoded respectively into the N2FF_STATUS or A2FF_STATUS register to freeze the entry condition in the FAULT state. The status bits of the FCCU_NCF_Sx register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the proper key into the FCCU_NCFK register.
2. Clear the status (flag) bit NCFSx => the opcode OP12 is automatically set into the FCCU_CTRL.OPR field.
3. Wait for the completion of the operation (FCCU_CTRL.OPS field).
4. Read the FCCU_NCF_Sx register in order to verify the effective deletion and in case of failure to repeat the sequence.

As result of the above sequence, in addition the FAULT interface provides support to clear the external fake FAULT root .

NOTE

There should not be any other operation in between the above steps.

The FCCU moves from the FAULT or ALARM state into the NORMAL state if all the source faults that caused the transition into the FAULT state have been removed (HW recoverable fault) or cleared via SW (SW recoverable fault). In case of nested faults that are not all recovered, the FCCU will remain in the FAULT or ALARM state.

The SW application executes the FCCU_NCF_Sx read operation by the following sequence:

1. Set the OP10 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU_NCF_Sx register.

In case of re-configuration of the FCCU (CONFIG state), before to return in NORMAL state the pending status bits into the FCCU_NCF_Sx must be cleared in order to avoid a false transition in ALARM/FAULT state.

The following faults are ignored:

- to write a wrong key into the FCCU_NCFK register
- to attempt to clear a HW recoverable fault

Noncritical Fault Status (FCCU_NCF_S*n*) register (value of n)	Offset	NCFSx fields (value of x)

FCCU_NCF_S*n* field descriptions

Field	Description
0–31 NCFSx	Noncritical fault status. The status bits related to the noncritical fault configured as HW recoverable faults are read-only and the flag is self cleared when the fault source is removed. For the mapping of the NCFSx fields among registers, see the earlier table in this register description. 0 No "noncritical" fault latched 1 "Noncritical" fault latched

74.10.7 Noncritical Fault Key (FCCU_NCFK)

The FCCU_NCFK register implements the key access to clear the status flags of the FCCU_NCF_Sx register.

The status bits of the FCCU_NCF_Sx register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the key into the FCCU_NCFK register.
2. Clear the status (flag) bit NCFSx .

The key must be written for each FCCU_NCF_Sx clear operation.

The FCCU_NCFK register is not readable; a 0000_0000h value is always returned in case of read operation.

Address: 0h base + 90h offset = 90h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FCCU_NCFK field descriptions

Field	Description
0–31 NCFK	Noncritical fault key = AB34_98FEh

74.10.8 Noncritical Fault Enable (FCCU_NCF_E*n*)

The FCCU_NCF_En registers enable the fault sources to allow a transition from the NORMAL into the FAULT or ALARM state. In case of fault masking, the respective status bit into the FCCU_NCF_Sn register is set (for debugging purposes), only the reaction is masked.

NOTE

These registers are writable only when the FCCU is in the CONFIG state.

NOTE

Any enabled fault should be programmed to result in a defined action. For example, set up an ALARM IRQ action by

programming the IRQ Alarm Enable Register (FCCU_IRQ_ALARM_ENn).

Noncritical Fault Enable (FCCU_NCF_E*n*) register (value of n)	Offset	NCFEx fields (value of x)	
		Most significant (leftmost) bit	Least significant (rightmost) bit

FCCU_NCF_E*n* field descriptions

Field	Description
0–31 NCFEx	Noncritical fault enable For the mapping of the NCFEx fields among registers, see the earlier table in this register description. 0 No actions following the respective noncritical fault assertion 1 FCCU moves to ALARM or FAULT state

74.10.9 Noncritical Fault Timeout Enable (FCCU_NCF_TOE*n*)

The FCCU_NCF_TOEx registers enable a transition from the NORMAL state into the ALARM state if the respective noncritical fault is enabled (NCFEx and NCFTOEx are set). In case the respective timeout is disabled (NCFTOEx is cleared) and the noncritical fault is enabled (NCFEx is set) the FCCU moves into the FAULT state if the related noncritical fault is asserted. The timer (preset with the timeout value defined by FCCU_TO register) is started when the FCCU moves into the ALARM state. If the fault is not recovered within the timeout the FCCU moves from the ALARM state to the FAULT state.

NOTE

These registers are writable only when the FCCU is in the CONFIG state.

Noncritical Fault Timeout Enable (FCCU_NCF_TOE*n*) register (value of n)	Offset	NCFTOEx fields (value of x)

FCCU_NCF_TOE*n* field descriptions

Field	Description
0–31 NCFTOEx	Fault timeout enable For the mapping of the NCFTOEx fields among registers, see the earlier table in this register description. 0 FCCU moves into the FAULT state if the respective fault is enabled 1 FCCU moves into the ALARM state if the respective fault is enabled

74.10.10 Noncritical Fault Timeout (FCCU_NCF_TO)

Defines the preset value of the timer for the recovery of enabled noncritical faults. Once FCCU enters Alarm state, following the assertion of a noncritical fault that is enabled (NCFEa and NCFTOEa are set), the timer starts the countdown.

If the fault is not recovered within the timeout period, the FCCU moves from the Alarm state to the Fault state.

NOTE

This register is writable only when FCCU is in Configuration state.

Address: 0h base + B4h offset = B4h

FCCU_CFG_TO field descriptions

Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 TO	Configuration-State Timer Interval Controls the maximum amount of time (T_max) that FCCU can be in Configuration state according to this equation: T_max = $T_{16MHz} \times 2^{(TO + 10)}$ If you put FCCU in Configuration state and this timer interval expires (called a Configuration-state timeout), then FCCU: • Automatically leaves Configuration state and enters Normal state. • Changes the value of the Configuration (FCCU_CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. For information on the Configuration (FCCU_CFG) register's Configuration-state-timeout value, see FCCU_CFG register bit value sources (N and C) by event. For a list of configuration registers, see Configuration registers. 000: 64 µs ... 111: 8192 µs

74.10.12 IO Control (FCCU_EINOUT)

The FCCU_EINOUT register allows the following operations typically in NORMAL state:

- to control the EOUT[1] output level when the FCCU is configured in "Test1" or "Test0" fault output mode (FCCU_CFG.FOM)
- to control the EOUT[0] output level when the FCCU is configured in "Test1" or "Test2" fault output mode (FCCU_CFG.FOM)
- to observe the EOUT[1:0] signals in input mode

Table 74-9 shows Bi-stable encoding.

Table 74-9. Bi-stable encoding

Mode = FCCU_CFG.FOM	EOUT[0]	EOUT[1]
Test1	output	output
Test2	output	input
Test0	input	output

NOTE

Due to the resynchronization stage of the EOUT interface, there is a latency of a few CLKSAFE cycles following a write/read operation of the FCCU_EINOUT register.

Table 74-10. EOUTX bit encoding

Register		Signals		Description
EINOUT.EOUT0	EINOUT.EOUT0	FCCU_EOUT1	FCCU_EOUT0

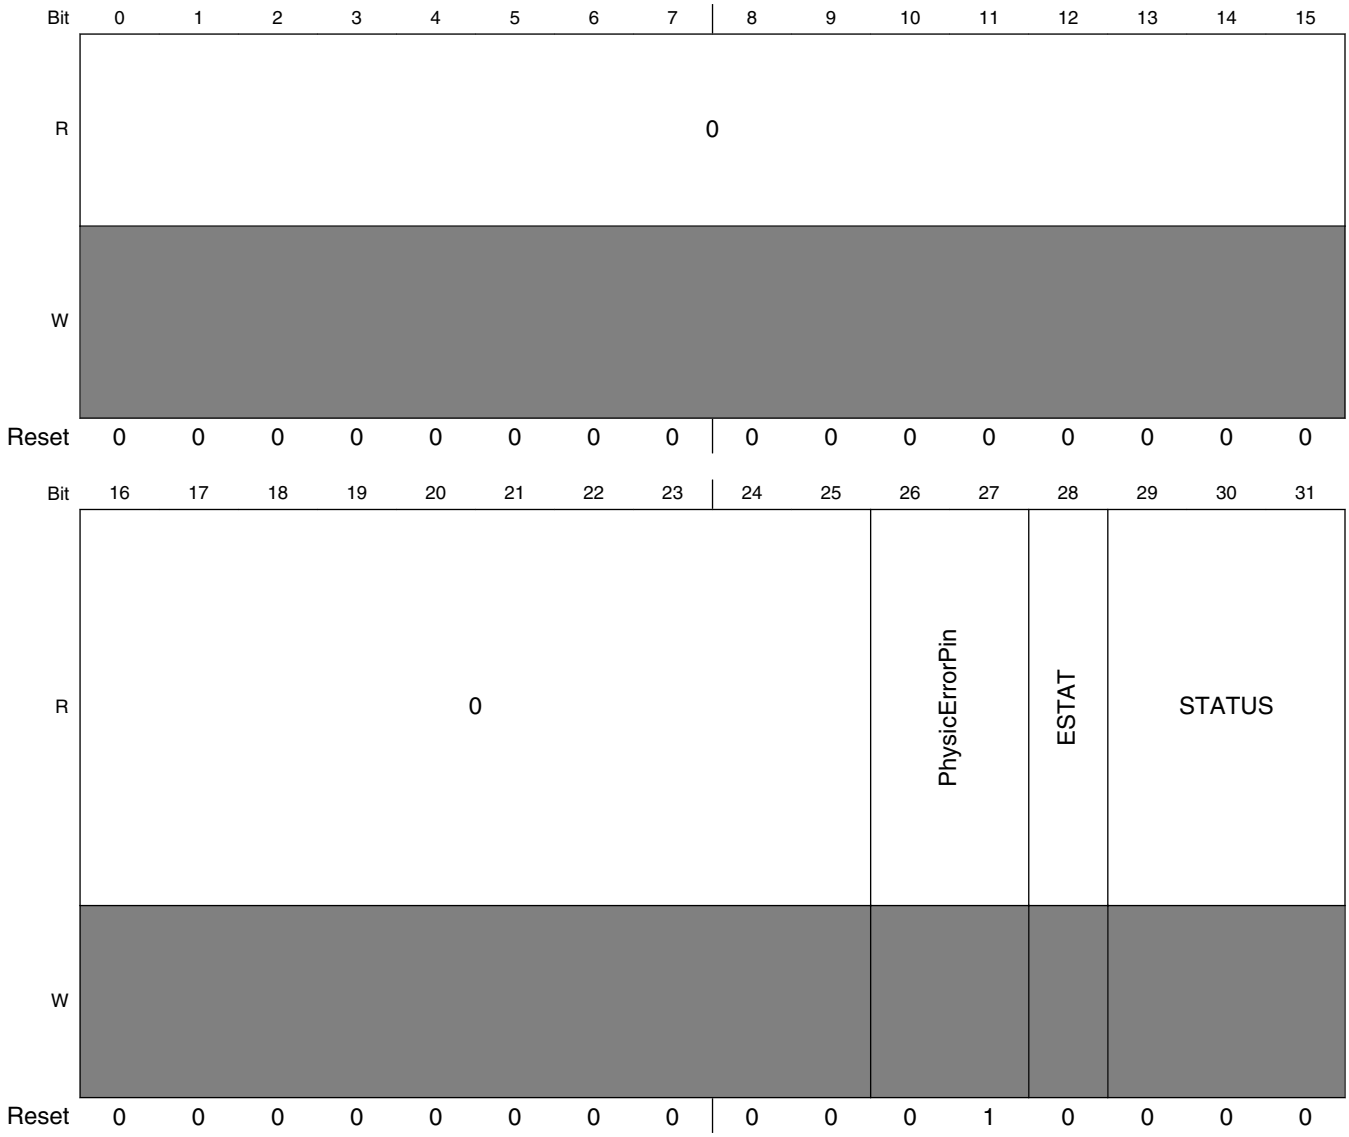
FCCU_EINOUT field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 EIN1	Error Input 1 Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Indicates the state of the EIN1 signal. 0 Low 1 High
27 EIN0	Error Input 0 Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Indicates the state of the EIN0 signal. 0 Low 1 High
28–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 EOUTX	EOUT protocol is SW controlled in NORMAL/ALARM state and HW controlled in FAULT state (dual rail, in phase toggling with programmable delay) a HW interrupt trigger (IRQ_EOUT) asserted by the FCCU (EOUT counter saturation) when in NORMAL/ALARM state in order to generate the EOUT protocol via SW. As alternative an external eTMR can be optionally used. EOUT dual rail protocol: NORMAL/ALARM : e.g. 10 ms toggling in opposite phase FAULT : e.g. 10 ms toggling in phase starting after a programmable delay T_tgl, slow switching mode (SM=0) FAULT : fast switching mode (SM =1) in phase (no periodic toggling). For details, please refer to Option 3 See Table 74-10. **NOTE:** When the configuration watchdog timer expires, FCCU changes the value of this field to its reset value.



74.10.13 Status (FCCU_STAT)

The FCCU_STAT register includes the FCCU status for debugging/test purposes. The FCCU finite state machine operates by the RC oscillator clock asynchronous with the system clock. The FCCU status read operation requires a safe mechanism operated by a HW/SW synchronization sequence. The SW application executes a FCCU status read operation by the following sequence:

1. Set the OP3 operation into the FCCU_CTRL.OPR field.

2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU status (FCCU_STAT register).

Address: 0h base + C0h offset = C0h

FCCU_STAT field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–27 PhysicErrorPin	Fault Output (EOUT) States Applies only after successfully running an OP3 operation (OPR) and only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Indicates the states that FCCU is driving on the EOUT signals. 00 EOUT1 is low; EOUT0 is low. 01 EOUT1 is low; EOUT0 is high.

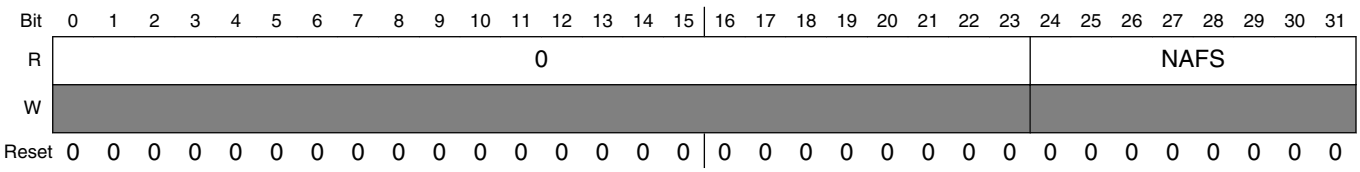
Table continues on the next page...

FCCU_STAT field descriptions (continued)

Field	Description
	10 EOUT1 is high; EOUT0 is low. 11 EOUT1 is high; EOUT0 is high.
28 ESTAT	Fault State Applies only after successfully running an OP3 operation (OPR). Indicates whether FCCU is in Fault state. 0 Not in Fault state (in Normal, Alarm, or Configuration state) 1 In Fault state
29–31 STATUS	FCCU State Applies only after successfully running an OP3 operation (OPR). Indicates FCCU's state. 000 Normal 001 Configuration 010 Alarm 011 Fault 100 Reserved 101 Reserved 110 Reserved 111 Reserved

74.10.14 NA Freeze Status (FCCU_N2AF_STATUS)

The N2AF_STATUS register contains a unique code to identify the "noncritical fault" source (fccu_ncf[x]) that caused the state transition from the NORMAL state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.



The SW application executes the N2AF_STATUS read operation by the following sequence:

1. Set the OP4 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the N2AF_STATUS register.

The SW application executes the N2AF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

Address: 0h base + C4h offset = C4h

FCCU_N2AF_STATUS field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 NAFS	Normal to Alarm Frozen Status 00000000 No transition from NORMAL to ALARM state 00000001 NORMAL to ALARM state transition cause => fccu_ncf[0] fault 00000010 NORMAL to ALARM state transition cause => fccu_ncf[1] fault 00000011 NORMAL to ALARM state transition cause => fccu_ncf[2] fault ... 10000000 NORMAL to ALARM state transition cause => fccu_ncf[127]/ fault 11111111 NORMAL to ALARM state transition cause => multiple fccu_ncf[]/ faults

74.10.15 AF Freeze Status (FCCU_A2FF_STATUS)

The A2FF_STATUS register contains a unique code to identify the timeout trigger (noncritical fault) that caused the state transition from the ALARM state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the A2FF_STATUS read operation by the following sequence:

1. Set the OP5 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the A2FF_STATUS register.

The SW application executes the FCCU_AFFS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).

All the freeze registers are cleared by this operation.

74.10.17 FA Freeze Status (FCCU_F2A_STATUS)

The F2AF_STATUS register contains a unique code to identify the source of the noncritical fault (fccu_ncf[x]) that caused the state transition from the FAULT state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the F2AF_STATUS read operation by the following sequence:

1. Set the OP7 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the F2AF_STATUS register.

The SW application executes the F2AF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

74.10.18 Noncritical Fault Fake (FCCU_NCFF)

The FCCU_NCFF register contains a unique code to set a noncritical fault in mutually exclusive mode by the external FAULT interface (signal setting). It allows the SW emulation of the noncritical faults, by the injection of the fault directly in the FAULT root, in order to verify the entire path and reaction. The reaction following a fake noncritical fault cannot be masked. The FCCU_NCFF is a write-only register with a set of codes corresponding to each noncritical fault injection.

Address: 0h base + DCh offset = DCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

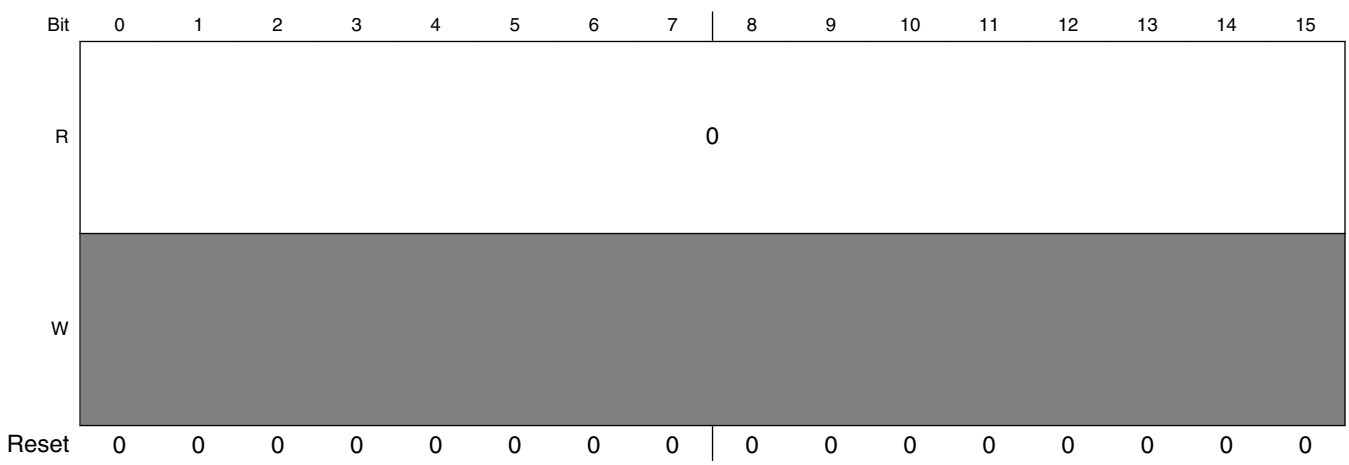
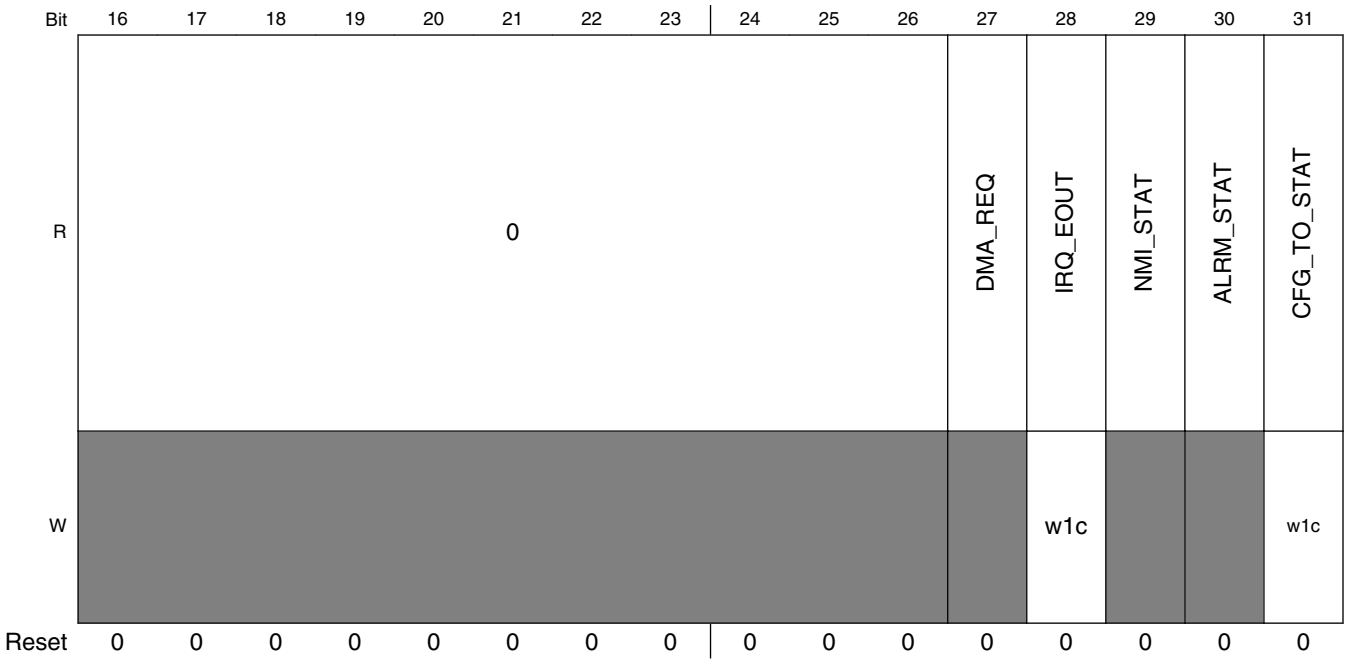
FCCU_NCFF field descriptions

Field	Description
0–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 FNCFC	FNCFC/ : Fake noncritical fault code **NOTE:** Only writing to this register, fake fault injection occurs, writing 00 and default value being zero give different results. 00h: Fake noncriticalfault injection at noncriticalfault source 0 01h: Fake noncriticalfault injection at noncriticalfault source 1 02h: Fake noncriticalfault injection at noncriticalfault source 2 ... 7Fh: Fake noncriticalfault injection at noncriticalfault source 127

74.10.19 IRQ Status (FCCU_IRQ_STAT)



The FCCU_IRQ_STAT register provides the FCCU interrupt status related to the following events:



- Configuration timeout error
- Alarm interrupt
- NMI interrupt

The configuration timeout interrupt is asserted if the CFG_TO_STAT bit of the FCCU_IRQ_STAT register is set and the CFG_TO_IEN bit of the FCCU_IRQ_EN register is also set. It is cleared when a 1 is written to the CFG_TO_STAT bit.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the FCCU_IRQ_STAT trace the status of the related interrupt lines.

Address: 0h base + E0h offset = E0h

FCCU_IRQ_STAT field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 DMA_REQ	Status bit asserted when EOUT counter = T_TRG in NORMAL/ALARM mode (DMA_REQ assertion). For details, please refer to Option 1, Option 2 section. Cleared on DMA_ACK assertion. **NOTE:** For more information: In the CFG register, see the FOME field description for the setting 10b. **NOTE:** SPI frame is DMA controlled following a DMA request (DMARQ_EOUT) asserted by the FCCU (EOUT counter saturation) when in NORMAL/ALARM state. An interrupt by SPI/DMA engine is asserted in order to update the data packet for the next watchdog refresh SPI controlled only via DMA in time division mode..
28 IRQ_EOUT	Interrupt status bit asserted when EOUT counter = T_TRG in NORMAL/ALARM mode. Usable to assert an interrupt (if FCCU_IRQ_EN[IRQ_EOUT_EN] = 1) and to control via SW the EOUTx pins in NORMAL/ALARM mode. **NOTE:** For more information: In the CFG register, see the FOME field description for the settings 01b and 11b. **NOTE:** SPI frame is SW controlled following a HW interrupt trigger (IRQ_EOUT) asserted by the FCCU (EOUT counter saturation) when in NORMAL/ALARM state.. For details, please refer to Option1 , Option 2 section. **NOTE:** EOUT protocol is SW controlled in NORMAL/ALARM state and HW controlled in FAULT state (dual rail, in phase toggling with programmable delay) a HW interrupt trigger (IRQ_EOUT) asserted by the FCCU (EOUT counter saturation) when in NORMAL/ALARM state in order to generate the EOUT protocol via SW. As alternative an external eTMR can be optionally used. EOUT dual rail protocol: NORMAL/ALARM : e.g. 10 ms toggling in opposite phase FAULT : e.g. 10 ms toggling in phase starting after a programmable delay T_tgl, slow switching mode (SM=0) FAULT : fast switching mode (SM =1) in phase (no periodic toggling). For details, please refer to Option 3 section.

74.10.20 IRQ Enable (FCCU_IRQ_EN)

The FCCU_IRQ_EN register defines the FCCU interrupt enable register related to the following event:

- Configuration timeout error

The configuration timeout interrupt is asserted if the CFG_TO_STAT bit of the FCCU_IRQ_STAT register is set and the CFG_TO_IEN bit of the FCCU_IRQ_EN register is also set.

Address: 0h base + E4h offset = E4h

31 CFG_TO_IEN	Configuration Timeout Interrupt Enable 0 Configuration timeout interrupt disabled 1 Configuration timeout interrupt enabled

74.10.21 XTMR (FCCU_XTMR)

The FCCU_XTMR register contains the read values of the Alarm or Watchdog Timer. These timers are clocked by CLKSAFE.

ETMR is the EOUT pin in logic 0 counter. After EOUT has been set to low (by SW or by a real fault), it goes high at the end of the T_min period from the last fault trigger.

The SW application executes the timer read operation by the following sequence:

1. Set any of the following operations into the FCCU_CTRL.OPR field:
   - OP17
   - OP19
   - OP20
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU_XTMR register.

Table 74-11 shows Timer state/value.

Table 74-11. Timer state/value

TIMER	CONFIG state	NORMAL state	ALARM state	FAULT state
ALARM	00000000h	Initial value	Running	Idle/End of count
CFG	Running	0001FFFFh	0001FFFFh	0001FFFFh

FCCU_TRANS_LOCK field descriptions

Field	Description
0–22 Reserved	This field is reserved.
23–31 TRANSKEY	Transient Configuration Lock Writable only by code running in Supervisor mode. Temporarily locks and unlocks the configuration. Locking the configuration prevents FCCU from entering Configuration state. BCh: Unlock. Any other value: Lock.

74.10.24 Permanent Configuration Lock (FCCU_PERMNT_LOCK)

Writable only by code running in Supervisor mode. Permanently locks the configuration, which prevents FCCU from entering Configuration state until FCCU is reset.

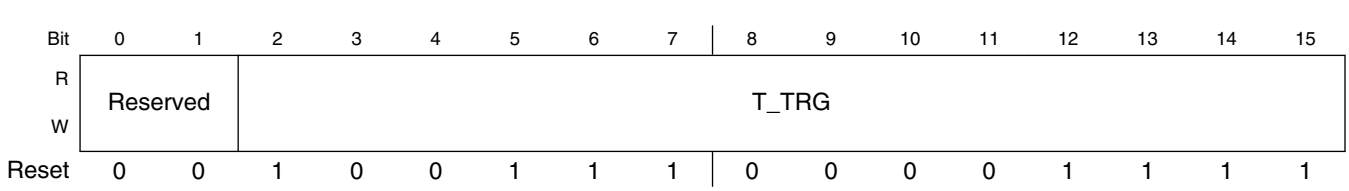
Address: 0h base + F4h offset = F4h

FCCU_PERMNT_LOCK field descriptions

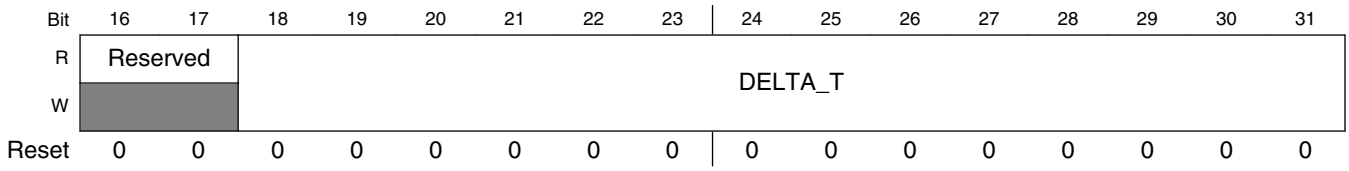
Field	Description
0–22 Reserved	This field is reserved.
23–31 PERMNTKEY	Permanent Configuration Lock Writable only by code running in Supervisor mode. Permanently locks the configuration, which prevents FCCU from entering Configuration state until FCCU is reset. FFh: Lock. Any other value: Do nothing.

74.10.25 Delta T (FCCU_DELTA_T)

The FCCU_DELTA_T register is used for programming the value of delta_T constant, in microseconds.



NOTE



This register can be written only when the FCCU is in CONFIG state.

NOTE

Reserved bits should always be written as all 0's.

Address: 0h base + F8h offset = F8h

FCCU_DELTA_T field descriptions

Field	Description
0–1 Reserved	This field is reserved.
2–15 T_TRG	IRQDMA trigger time In FAULT mode, if CFG[SM] is 0, the EOUT semi-period is T_TRG + 1 [µs]. In NORMAL/ALARM mode, if T_TRG > 0, T_TRG is the IRQ_EOUTDMA_REQ interrupt time base. Min = 2 µs, Max = 16.385 µs, Resolution = 1 µs **NOTE:** EOUT protocol is SW controlled in NORMAL/ALARM state and HW controlled in FAULT state (dual rail, in phase toggling with programmable delay) a HW interrupt trigger (IRQ_EOUT) asserted by the FCCU (EOUT counter saturation) when in NORMAL/ALARM state in order to generate the EOUT protocol via SW. As alternative an external eTMR can be optionally used. EOUT dual rail protocol: NORMAL/ALARM : e.g. 10 ms toggling in opposite phase FAULT : e.g. 10 ms toggling in phase starting after a programmable delay T_tgl, slow switching mode (SM=0) FAULT : fast switching mode (SM =1) in phase (no periodic toggling). For details, please refer to Option 3 section.
16–17 Reserved	This field is reserved.
18–31 DELTA_T	Bistable Minimum Fault-Output (EOUT) Faulty Interval Applies only to Bistable fault-output mode (FOM). Controls the minimum amount of time (T_min) that the fault-output (EOUT) timer runs according to this equation: T_min = 250 µs + DELTA_T The following values and meanings are for DELTA_T: 00_0000_0000_0000: 0 µs 00_0000_0000_0001: 1 µs … 11_1111_1111_1110: 16,382 µs 11_1111_1111_1111: 16,383 µs **NOTE:** The durations shown for the DELTA_T values are for CLKSAFE clock signals running at exactly 16 MHz. However, the CLKSAFE signals are sourced from an internal chip clock signal (for example, IRC)—or an integer division of it (see the chip-specific FCCU information)—that has a trimmed frequency variation. Therefore, the DELTA_T durations may vary. See your chip's data sheet for the trimmed frequency variation (for example, δF_{var}).

74.10.26 IRQ Alarm Enable (FCCU_IRQ_ALARM_EN*n*)

These registers enable the corresponding IRQ alarm.

IRQ Alarm Enable (FCCU_IRQ_ALARM_EN*n*) register (value of n)	Offset	IRQENx fields (value of x)	
		Most significant (leftmost) bit	Least significant (rightmost) bit
0	0FCh	31	0
1	100h	63	32
2	104h	95	64

NOTE

These registers can be written only when the FCCU is in CONFIG state.

Address: 0h base + FCh offset + (4d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FCCU_IRQ_ALARM_EN*n* field descriptions

Field	Description
0–31 IRQENx	IRQ alarm enable For the mapping of the IRQENx fields among registers, see the earlier table in this register description. 0 Alarm is disabled for error source x. 1 Alarm is enabled for error source x.

74.10.27 NMI Enable (FCCU_NMI_EN*n*)

These registers enable the NMI.

Table 74-12 shows FCCU NMI enable register channels.

Table 74-12. FCCU NMI enable register channels

Address offset	Register name	Channel range (x) (bit location [0:31])
10Ch	FCCU_NMI_EN0	NMIENE[31:0]
110h	FCCU_NMI_EN1	NMIENE[63:32]
114h	FCCU_NMI_EN2	NMIENE[95:64]

NOTE

These registers can be written only when the FCCU is in CONFIG state.

Address: 0h base + 10Ch offset + (4d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	NMIENx																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FCCU_NMI_EN*n* field descriptions

Field	Description
0–31 NMIENx	NMI enable See Table 74-12 for register offset to channel number relationship. 0 NMI is disabled for error (NCF) source x. 1 NMI is enabled for error (NCF) source x.

74.10.28 Bistable Fault-Output (EOUT) Mode Signaling Enable (FCCU_EOUT_SIG_EN*n*)

Writable only when FCCU is in Configuration state. Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). When FCCU is configured for Bistable fault-output mode (FOM), controls whether fault-output (EOUT) signaling is enabled for the associated noncritical fault channel (x). (For other fault-output modes, fault-output signaling is always enabled, regardless of the value of this field.)

When FCCU is configured for a fault-output mode other than Bistable, controls whether FCCU asserts the FIF signal when a fault occurs on the associated noncritical fault channel (x). (When FCCU is configured for Bistable fault-output mode, FCCU always asserts the FIF signal when a fault occurs on the channel, regardless of the value of this field.)

Bistable Fault-Output (EOUT) Mode Signaling Enable (FCCU_EOUT_SIG_EN*n*) register (value of n)	Offset	EOUTENx fields (value of x)	
		Most significant (leftmost) bit	Least significant (rightmost) bit
0	11Ch	31	0
1	120h	63	32
2	124h	95	64

Address: 0h base + 11Ch offset + (4d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	EOUTENx

FCCU_EOUT_SIG_EN*n* field descriptions

Field	Description
0–31 EOUTENx	Bistable Fault-Output (EOUT) Mode Signaling Enable x Writable only when FCCU is in Configuration state. Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). When FCCU is configured for Bistable fault-output mode (FOM), controls whether fault-output (EOUT) signaling is enabled for the associated noncritical fault channel (x). (For other fault-output modes, fault-output signaling is always enabled, regardless of the value of this field.) When FCCU is configured for a fault-output mode other than Bistable, controls whether FCCU asserts the FIF signal when a fault occurs on the associated noncritical fault channel (x). (When FCCU is configured for Bistable fault-output mode, FCCU always asserts the FIF signal when a fault occurs on the channel, regardless of the value of this field.) For the mapping of the EOUTENx fields among registers, see the earlier table in this register description. 0 Disabled 1 Enabled

74.10.29 Configuration registers

74.10.29.1 Definition

Configuration registers are registers that:

- Let you configure FCCU's Alarm-state timer interval, fault channels, and fault-output (EOUT) signals.
- You can write to only when the configuration is not locked (see Lock and unlock the configuration) and FCCU is in Configuration state (see Put FCCU in Configuration or Normal state).
- Save the values you write to them while FCCU is in Configuration state only after you manually put FCCU in Normal state. If FCCU automatically leaves Configuration state and enters Normal state because the configuration-timer interval (TO) expires (called a Configuration-state timeout), FCCU changes the value of the FCCU_CFG register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. For information on the Configuration-state timeout value, see FCCU_CFG register bit value sources (N and C) by event.

74.10.29.2 The configuration registers

The following registers are the configuration registers, listed in offset order from lowest to highest:

- Configuration (FCCU_CFG)
- Noncritical Fault Configuration (FCCU_NCF_CFG*n*)

- Noncritical Fault State Configuration (FCCU_NCFS_CFG*n*)
- Noncritical Fault Enable (FCCU_NCF_E*n*)
- Noncritical Fault Timeout Enable (FCCU_NCF_TOE*n*)
- Noncritical Fault Timeout (FCCU_NCF_TO)
- Delta T (FCCU_DELTA_T)
- IRQ Alarm Enable (FCCU_IRQ_ALARM_EN*n*)
- NMI Enable (FCCU_NMI_EN*n*)
- Bistable Fault-Output (EOUT) Mode Signaling Enable (FCCU_EOUT_SIG_EN*n*)

74.10.30 FCCU_CFG register bit value sources (N and C) by event

Certain events affect the bit values of the Configuration (FCCU_CFG) register; when one of these events occurs, the bit value is either unaffected, or FCCU changes it to one of the following:

- N: a chip-specific (or, for some chips, user-specified) value provided by the bit's associated NVMCFG signal
- C: a chip-specific value provided by the bit's associated constant inside the module

For each bit in the Configuration (FCCU_CFG) register, this table shows the associated NVMCFG signal, if any, and indicates the source of the bit value for the events that affect it. For specific values of *N* and *C* for each bit, see the chip-specific FCCU information.

Bit	NVMCFG signal	FCCU reset	Configuration-state timeout	OP31 operation
0	21	N	C	N
1	20	N	C	N
2	19	N	C	N
3	18	N	C	N
4	17	N	C	N
5	16	N	C	N
6	15	N	C	N
7	—	C	C	(Unaffected)
8	—	C	C	(Unaffected)

29	2	N	C	N
30	1	N	C	N
31	0	N	C	N

74.11 Use cases and limitations

74.11.1 Configuration guidelines

Follow these guidelines to configure FCCU:

- If you want FCCU to react to a fault on a noncritical fault channel:
  - Enable the channel (NCFEx).
  - Enable at least one type of Fault-state reaction for the channel: chip reset (NCFSCx), fault-output (EOUT) signaling (EOUTENx), or nonmaskable interrupt (NMIENx).
  - If you enable chip reset as the type of Fault-state reaction for the channel (NCFSCx), enable either Alarm state (NCFTOEx) or at least one other type of Fault-state reaction for the channel: fault-output (EOUT) signaling (EOUTENx) or nonmaskable interrupt (NMIENx).
  - If you enable Alarm state for the channel (NCFTOEx), enable the Alarm-state reaction (IRQENx).

NOTE

If you enable a noncritical fault channel but disable all reactions for that channel, FCCU changes state if necessary but doesn't perform any reaction because reactions are disabled. If you enable reactions for a noncritical fault channel but disable that channel, and FCCU is in Normal state when a fault occurs on the channel, FCCU doesn't enter Alarm or Fault state and therefore doesn't perform any reaction.

74.11.2 Recommendations to configure FCCU

1. After a power on, 'destructive', or long external reset, where both system and FCCU are reset, the following steps could be followed to configure FCCU:
   a. Check and clear any pending fault status
   b. Verify FCCU is in NORMAL state, else repeat step(a) above
   c. Configure FCCU
2. After a short external or any 'functional' reset of the system, arising out of a reset request from FCCU or other sources, the following steps could be followed to reconfigure FCCU:
   a. If active, wait for the Error out T_min to expire
   b. Check and clear fault status
   c. Error pin moves to "non faulty" state, once fault status is cleared and T_min expires
   d. Verify FCCU is in NORMAL state, else repeat step(a) above
   e. Read and verify value in FCCU_NCF_Ex
   f. Reconfigure FCCU, if necessary

Chapter 75
Self-Test Control Unit (STCU2)

75.1 Chip-specific STCU2 information

75.1.1 STCU configuration

The Self-Test Control Unit (STCU2) controls the execution of the built-in self-test of the MPC5746C.

The built-in self-test supports in the application:

- Memory (RAM/ROM) Built-In Self-Test (MBIST) at startup and shutdown.

The following table summarizes the three self-test modes.

Table 75-1. STCU2 self-test modes

Self-test mode	Description	Availability
Normal self-test mode	MBIST for all memories with a checkerboard/inverted checkerboard algorithm	In startup mode and shutdown mode
Long self-test mode	MBIST for all memories with the reduced RAM and ROM algorithm	Only during shutdown mode
Diagnostic mode	MBIST for all memories with the full RAM and ROM algorithm	Only during shutdown mode

In application mode, the STCU2 initiates self-test execution:

- after Power-on Reset (POR)
- after external reset (if triggered as long-functional reset)
- after destructive reset
- when initiated by software

The STCU2 communicates any fault information to the Fault Control and Collection Unit (FCCU) and to the Reset Generation Module (MC_RGM).

The startup self-test is implemented by NXP. The user can choose either to run normal self-test execution during startup of the device or to bypass the startup self-test execution by programming the appropriate records in the UTEST flash memory.

The shutdown self-test sequence is user programmable and must be started by the user application on demand. This self-test can be executed at less critical times in the application. After the self-test is executed during shutdown, a long functional reset is initiated, and the self-test results are accessible.

The STCU2 includes the SSCM DCF bus to load the self-test parameters from flash memory—consisting of both the test flash memory, which is programmed by NXP, and the UTEST flash, which is user-programmable—during the startup self-test phase.

NOTE

Ensure Flash is in IDLE state (i.e. no Program/Erase) prior to starting Self Test operation.

75.1.2 Supported BIST sequence

NXP has validated and therefore supports only particular STCU2 built-in self-test (BIST) sequences for this chip. For descriptions of the supported BIST sequences for this chip, see the engineering bulletin titled MPC5746C STCU BIST Configuration (document EB820).

75.1.3 Device specific STCU Registers

The STCU2 module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/half-word/word (free byte enables or other operations) on each register
- Any write operation on Security Key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other access to STCU2 registers)
- Any write operation performed on a register when the Security keys have not been applied
- Any write operation performed on read-only registers

Write operations to fields marked as reserved do not generate the transfer error.

75.1.4 STCU register reset values

All reset values for the STCU registers that are device specific are shown in the following table. All other register reset values are shown in the STCU Register description.

NOTE

These are the reset values when startup self-test is not configured by DCF's otherwise these will change as per the DCF configurations of startup self-test.

Table 75-2. STCU register reset values

Register	Register Value
STCU2 Configuration Register (STCU2_CFG)	0x7F00_0000
STCU2 Watchdog Register Granularity (STCU2_WDG)	0x0000_FFFF
STCU2 Error FM Register (STCU2_ERR_FM)	0x0000_0000
STCU2 MBIST Unrecoverable FM Low Register (STCU2_MBUFML)	0x0000_0000
STCU2 MBIST Unrecoverable FM Medium Register (STCU2_MBUFMM)	0x0000_0000
STCU2 MBIST Unrecoverable FM High Register (STCU2_MBUFMH)	0x0000_0000
STCU2 MBIST Control Register (STCU2_MB_CTRLn)	0x0000_0000

75.1.5 Partition overview

MBIST

The MBIST for the memories on the device is set to separate operations as then the triple SRAM can be started individually. This leads to the flexibility to operate an MBIST on one RAM where as the device is in operation on the other RAM of the device.

An individual MBIST (on a per memory basis) start is beneficial to maintain lower power consumption while MBIST is running in a lower power budget. Each system RAM support a separate MBIST. This allows a separate MBIST execution on the three System RAMs The STCU2 controller handles all memories in the device. Results of the MBIST is reported on the STCU2 to the FCCU.

MBIST Partitions

The following table describes the mapping between the MBIST number, as the STCU2 captures it, and the appropriate memory in the design.

75.1.6 STCU On-Line and Off-Line Self-Test sequence preparation

This is the typical mode of using the STCU2 module during the application run. For more details, see Online self test sequence

Before you initiate the execution of an STCU on-line self-test, you must complete the prerequisite procedure. PLL clock needs to be locked at 40 MHz for running On-Line self test sequence in PLL clock. For running self-test sequence on IRC, no additional configuration is required.

75.1.7 AUTOLOCK_VALUE for register write access and DCF_COMPLETION value for DCF write completion

Register write-access watchdog timer refers to two clock-cycle values related to the STCU2's write-access watchdog. The following table provides these values on this chip.

Clock-cycle value	Number of STCU2 clock cycles
AUTOLOCK_VALUE	1024
DCF_COMPLETION	16

75.1.8 Wait time for writing to the online registers

When writing to the online registers, the user must wait for the expiration of the offline key. The time the user should wait is (IPS_CLK)*4096 clock periods. If the IPS_CLK is 66.5 Mhz then the user must wait (1/66.5)*4096 = 61.6 µs.

75.1.9 On-Line reset generation (only MBIST)

The On-Line execution of the MBIST does not generate any reset from STCU2 at the end of the execution. This is because the software application has to manage all the possible consequences related to the write operations performed by the MBIST execution other

than preventing any read/write operation during the Self-Test execution. If necessary, the software must also restore the memory content (only for RAMs) at the end of the Self-Test execution.

NOTE

During online self-test execution, it is possible that a functional reset event does not cause HW abort. In such scenarios, STCU watchdog timeout will generate reset.

NOTE

A functional reset must be generated for proper operation of the chip after online MBIST self-test.

75.2 Introduction

Self Test Control Unit (STCU2) is a comprehensive programmable hardware module that controls the self test sequence applied both during the Off-Line and/or On-Line conditions. It is able to manage by hardware the device's SRAM/ROM Built-In Self Test (MBIST) blocks. The STCU2 includes the SSCM DCF bus to load the Self-test parameters (MBIST scheduling activity, Unrecoverable/Recoverable faults management, PLL management, and so on) from flash memory during the Off-Line Self-Test phase. This interface is able only to write the configuration parameters and start the Self-Test execution once after the STCU2 global reset has been applied. The register access by software is granted by an IPS interface with the purpose to check the results of the Off-Line Self-Test but also to load/check the execution of the On-Line Self-Test.

The STCU2 includes:

- A programmable Watchdog timer (WDG) to check the Self-Test operations (MBIST) have been completed within the assigned time slot or the STCU2 RUN or BYPASS bits have been programmed before Watchdog time-out
- The PLL direct control during the Off-Line Self-Test sequence
- Two sets of Result registers to collect the MBIST result during Off/On-Line Self-Test separately

To increase the security capability of this module, a different Security Key sequence is also required during Off/On-Line Self-Test in order to unlock the write access to the STCU2 registers. The STCU2 also implements two power-saving mechanisms to switch off:

- The global STCU2 clock after Self-Test sequence is completed
- The register ITF clock when the WDG time-out is detected after a Double Security Key sequence is applied during the application run (available only when IPS write access is enabled otherwise the clock is off).

75.3 Main features

- Double registers interface (SSCM DCF with priority over IPS)
- SSCM DCF write one time register interface
- IPS read and write (depends on SSCM enable parameters and STCU2_CFG.WRP bit) register interface
- Programmable scheduler for MBIST execution
- MBIST concurrent/sequential execution
- On-Line hardware Self-Test sequence abort capability
- Programmable Internal clock prescaler to reduce Internal and MBIST TCK clocks
- Programmable PLL direct control during Off-Line Self-test sequence
- PLL Lock signal monitoring during Off/On-Line Self Test
- Programmable WDG Timer for Self-Check MBIST Time Execution
- Hard Coded WDG time-out to flag off-line initialization faults
- Hard Coded WDG time-out to Auto-lock STCU2 write access after Double-Key sequence
- SRAM/ROM MBIST Off-Line status flags
- STCU2 internal errors Off-Line status flag
- SRAM/ROM MBIST On-Line status flags
- STCU2 internal errors On-Line Status flag
- On-Line hardware abort status flag
- SRAM/ROM MBIST Off/On-Line programmable failure severity - unrecoverable fault/recoverable fault (UF/RF)
- STCU2 internal errors Off-On/Line programmable failure severity - unrecoverable fault/recoverable fault (UF/RF)

- STCU2 errors (UF/RF) lines for FCCU signaling
- Redundant UF/RF generation logic to improve reliability
- FCCU UF/RF faults injection mechanism
- Self-Test Bypass capability
- Global write register's protection mechanism based on Double Security Key
- STCU2 Global Auto Power-saving when Self-Test is completed, bypass mode is selected or WDT time-out is detected
- STCU2 ITF/WDG clock wake-up mechanism when software application writes Double Security Key sequence (available when STCU2_CFG.WRP bit is active)
- STCU2 ITF/WDG Auto Power-saving when Hard Coded WDG time-out is detected after software application writes Double Security Key sequence (available when STCU2_CFG.WRP bit is active)

75.4 Block diagram

The top level diagram of the STCU2 module is given in Figure 75-1.

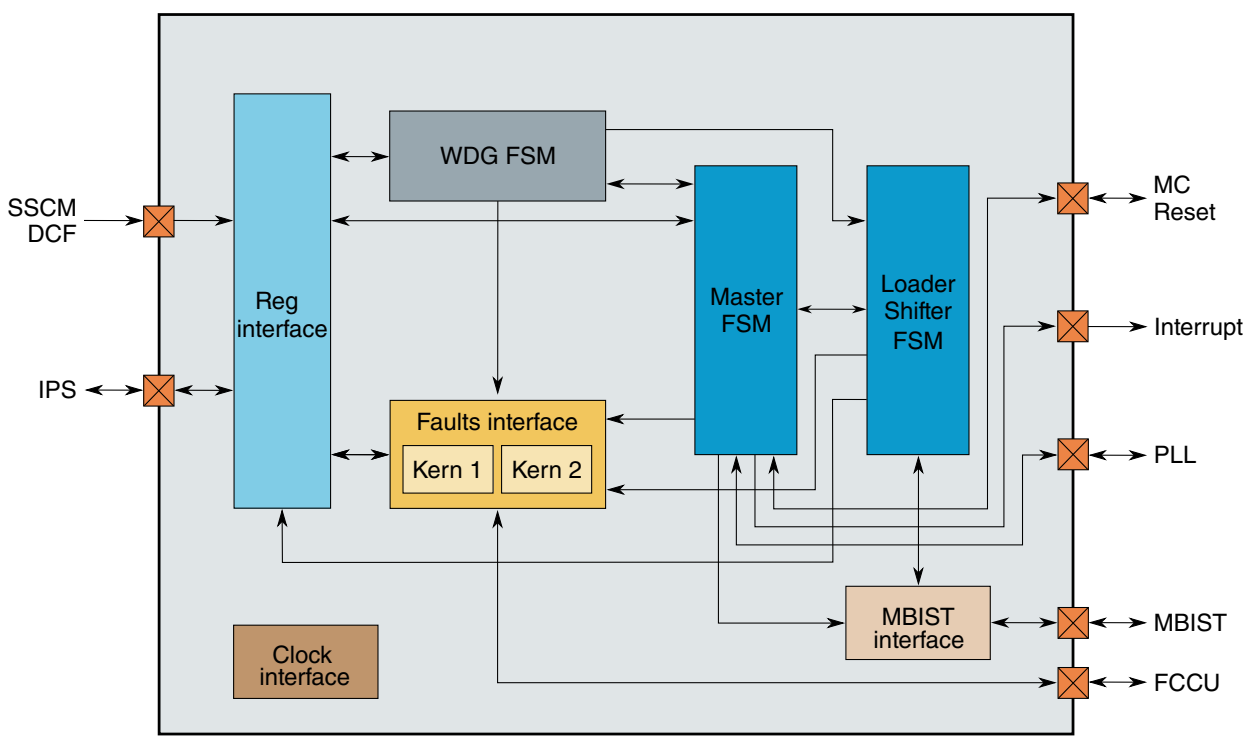

Figure 75-1. STCU2 block diagram

The STCU2 module includes the following sub-modules:

- ***Reg interface***: This module includes the registers, the security key logic, the IPS and SSCM DCF bus interface
- ***Fault interface***: This module collects the fault conditions related to MBIST execution and STCU2 internal failures and, depending on the UF/RF configuration of each one of them, sets the global STCU2 UF or RF flag. It also manages the UF/RF fault lines and the Set/Clear injection mechanism provided by the FCCU. To improve the intrinsic reliability of this critical logic, the generation logic is duplicated.
- ***Clock Interface***: This module manages the internal and the MBIST TCK clock prescaler, the internal Clock Gating Power Saving and the wake-up clock feature.
- ***WDG FSM***: This module includes two different Watchdogs. The first one is Hard Coded and is used to Auto Lock the STCU2 access forcing a reset condition on the Double Security Key registers while the second one has a double functionality. After a reset event initializes the STCU2, it is used as Hard Coded Watchdog time-out while during MBIST run it is used as programmable Watchdog timer to check the MBIST have been completed in the assigned MBIST time slot.
- ***STCU2 Master FSM***: This module includes the main FSM of the STCU2 used to coordinate and schedule all the operations performed during the Self-Test Sequence.
- ***STCU2 Load Shifter FSM***: This module includes the common shifter register and the related state machine used to program the MBIST registers and read back the data to be checked at the end of each Test operation.
- ***MBIST interface***: This module includes the interface between the MBIST controller and STCU2 controllers.

75.5 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus read operations (contiguous byte enables) are supported:

- Word (32 bits) data read operations to any registers
- Low and high half-words (16 bits, data[31:16] or data[15:0]) data read operations to any registers
- Byte(8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data read operations to any registers
- Any other operation (free byte enables or other operations) has to be avoided.

The same operations are also supported in write mode only in the following scenario:

- The Self-Test sequence parameters are loaded before Off-Line Self-test is executed
- The IPS access on a specific register is allowed by software only when the bit STCU2_CFG.WRP is cleared
- In all the other conditions the write operations are not supported and all the STCU2 registers can be only read. Only exceptions are the following read/write bits: STCU2_CFG.WRP, STCU2_ERR_STAT.UFSF and STCU2_ERR_STAT.RFSF. See related register description for additional details

The STCU2 module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register
- Any write operation on Double Security Key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other access to STCU2 registers)
- Any write operation performed on a register when the Double Security keys have not been applied
- Any write operation performed on registers when the STCU2_CFG.WRP bit is set and the access is performed through software (IPS interface)
- Any write operation performed through software (IPS interface) on Read/On-Line_Write/Off-Line registers
- Any write operation performed off-line on registers in which writing operation is allowed only in the On-Line Self-Test phase when STCU2_CFG[WRP] = 1
- Any write operation performed on Read Only registers

The registers of the STCU2 module are accessible (read/write) in each access mode: user, supervisor or test.

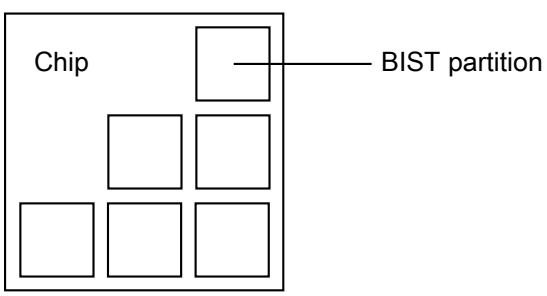
In case there are write operations on bits marked as reserved, the transfer error is not generated.

NOTE

See the chip-specific STCU2 information for the wait time necessary to write to the online registers.

75.6 BISTs and BIST partitions

75.6.1 Definition: BIST



A *built-in self-test (BIST)* is a test that the chip can execute to verify the functional integrity of a part of itself. The chip uses STCU2 and other on-chip hardware to execute a BIST.

75.6.2 Definition: BIST partition

A *built-in self-test (BIST) partition* is a part of a chip for which a BIST has been defined. The hardware that is included in a given BIST partition is chip-specific. For a list of the hardware included in each of the BIST partitions on this chip, see the chip-specific STCU2 information.

75.6.3 Example: BIST partitions on a chip

This is an example of a chip with six built-in self-test (BIST) partitions:

75.6.4 Types of BIST partitions

The STCU2 module on this chip supports the following type or types of built-in self-test (BIST) partitions:

BIST partition type	Description
Memory BIST (MBIST) partition	An SRAM or ROM block

75.7 BIST sequences

75.7.1 Definition: BIST sequence

A *built-in self-test (BIST) sequence* is a programmable series of one or more phases, each of which executes one or more individual BISTs.

75.7.2 Example: Single-phase BIST sequence

This is an example of a single-phase BIST sequence in which STCU2 executes only one BIST:

Phase	BIST executed
0	MBIST 16

75.7.3 Example: Multiphase BIST sequence

This is an example of a multiphase BIST sequence in which STCU2 executes more than one BIST in parallel in some phases:

Phase	BISTs executed
0	MBISTs 7, 38
1	MBIST 23
2	MBISTs 6, 16, 29, 23

75.7.4 Types of BIST sequences

The STCU2 module on this chip supports these types of built-in self-test (BIST) sequences:

BIST sequence type	Description
Online BIST sequence	A BIST sequence that STCU2 executes during runtime at the request of software. Application software configures and initiates execution of the BIST sequence by loading values into STCU2 registers.

Table continues on the next page...

BIST sequence type	Description
	Use this type of BIST sequence when you want to test the chip hardware but need to minimize the system startup time. Also use it for failure diagnostics and quality control within a manufacturing environment. You can choose the most appropriate point during runtime at which to execute this type of BIST sequence.
Offline BIST sequence	A BIST sequence that STCU2 automatically executes during reset, either when power is first applied to the chip or when the chip resets STCU2. The chip's SSCM module configures and initiates execution of the BIST sequence by loading values into STCU2 registers from Device Configuration Format (DCF) records that are stored in the chip's UTEST flash memory. Use this type of BIST sequence when you want to test the chip hardware before runtime. The location of the DCF record area is chip-specific. The size of the DCF record area is sequence-specific. For the location of the DCF record area, see the chip-specific STCU2 information.

75.7.5 Supported BIST sequences

NXP has validated and therefore supports only specific built-in self-test (BIST) sequences for this chip. For a list of the supported BIST sequences, see the chip-specific STCU2 information.

75.7.6 Definition: Default offline BIST sequence

The *default offline built-in self-test (BIST) sequence* is the offline BIST sequence whose configuration NXP has programmed into the chip's Device Configuration Format (DCF) records that are stored in the chip's UTEST flash memory.

If you choose to use the default offline BIST sequence, or if it's the only one supported by NXP, there is no need to create additional DCF records for the offline BIST sequence.

75.8 Functional description

75.8.1 FSM description

The module has three state machines that work together: Master State Machine, Loader/Shifter State Machine, and the Watchdog State Machine. Basically the Master State Machine is the core unit of the STCU2 module. It coordinates all the Self Test operations and the other State Machines. The Loader/Shifter State Machine is used to program the MBIST parameters and to retrieve the related results depending on the parameters stored into the STCU2 registers and under the control of the Master State Machine. The Watchdog State Machine evaluates all the schedule time for MBIST and the time-out in case of wrong STCU2 programming.

75.8.2 Reset management

Assertion of the STCU2 reset input signal initializes the STCU2 module status, forcing the Off-Line Self-Test condition and cleaning up all the registers and state machine of the module.

The reset signals generated by the STCU2 module at the end of the Self-Test execution phase depends on the Self-Test conditions.

75.8.2.1 Off-Line reset generation

At the end of the Off-Line Self-Test execution the STCU2 raises the global functional reset.

75.8.2.2 On-Line reset generation

See the chip-specific STCU2 information for details about On-Line reset generation.

75.8.3 Built-in self-test scheduling

The STCU2 module has been designed to be very flexible allowing to program the parallel/serial execution of the MBIST depending on the power/timing/coverage constraints. The limitation in the programming flexibility is described in Design implementation information.

The mechanism used to provide this flexibility is a linked list where the starting pointer is the bitfield STCU2_CFG.PTR. The first MBIST is mapped to the address 10h, the second to 11h and so on. The additional pointers are in the bitfield STCU2_MB_CTRL[Y].PTR

for MBIST (where Y is the selected MBIST) and have to be filled depending on the selected sequence of run. The additional bitfield STCU2_MB_CTRL.CSM provide the flexibility to run concurrently or sequentially the chosen set of the MBIST or to close the linked list setting the NIL pointer. For more details, see and STCU2 MBIST Control Register (STCU2_MB_CTRL*n*).

75.8.4 ABORT management

The STCU2 module provides On-Line Self-Test execution abort. When the abort is detected, the On-Line Self-Test operation stops running and the status of the currently running MBIST is saved into the related registers to provide intermediate results that might be useful in case of debug or in case of concurrent run.

75.8.4.1 Hardware ABORT management

The STCU2 enters the hardware abort condition as a consequence of a Functional reset which causes Self-Test execution to abort .

When hardware abort is detected the bit ABORTHW of the STCU2_ERR_STAT register is set. This flag allows the software to diagnose what has happened during the On-Line Self-Test execution run.

75.8.5 PLL interface

The STCU2 module is able to directly control the PLL during the Off-Line Self-Test operations depending on the status of the STCU2_RUN[MBPLLEN].

When STCU2_RUN[RUN] is set to start the Off-Line Self-test operations, the STCU2 takes control of the PLL and changes the PLL clock configurations parameters according to the values programmed into the STCU2_PLL_CFG register.

When the STCU2_RUN[MBPLLEN] is active and the MBIST is currently selected, the STCU2 waits for the PLL lock signal. As soon as the lock happens, the STCU2 forces the clock to switch to the PLL output clock. This allows the MBIST to proceed at the PLL output frequency. At the end of the MBIST run the clock source is reverted to the original one.

75.8.6 FCCU interface

The FCCU interface is the hardware flag mechanism towards the system, to indicate the occurrence of an Unrecoverable fault and/or a Recoverable fault failure during the Self Test sequence.

To diagnose physical defects on the two fault signals, a fault injection mechanism is also provided. In this case, the FCCU interface allows the user application to check the integrity of the UF and RF connection lines between the STCU2 and the FCCU. Refer to the description of FCCU fault injection mechanism to understand how the UF/RF set/clear mechanism works.

75.8.7 Watchdogs

The STCU2 implements three different watchdogs to ensure that operations are finished in time.

75.8.7.1 Initialization watchdog timer

The STCU2 has two initialization operating modes: program the self-test sequence and run it (Safety mode) or bypass completely the self-test sequence setting the bit STCU2_CFG.BYP. In case there are faults during the initialization phase preventing the selection of one of these two operating modes, a hard-coded watchdog time-out flags the wrong behavior.

75.8.7.2 Built-in self-test watchdog timer

The MBIST execution time has to be configured as described in STCU2 Watchdog Granularity (STCU2_WDG), to account for the overall execution time of the Self-Test sequence. In case the selected MBISTs are not yet completed during the Off-line Self-Test assigned time, the current or MBISTs execution is interrupted and a failure is flagged into STCU2_ERR_STAT.WDTO and STCU2_MBEL/M/H registers while in case of On-Line Self-Test into STCU2_ERR_STAT.WDTOSW and STCU2_MBELSW/MSW/HSW.

In case of multiple sequential run in the same On-Line/Off-Line session and the time-out happens in the middle of a sequential run, the next sequential run will be skipped and the execution ends with the current updated status of the registers reported above.

In all the cases, the STCU2 reset generation is managed in one of the modes described in Reset management.

75.8.7.3 Register write-access watchdog timer

As explained in the STCU2_SKC register description:

- A key mechanism protects STCU2 registers during the self-test configuration phase (both online/offline) by preventing any unwanted access.
- A hardware watchdog timer locks register-write access after a number of STCU2 clock cycles. To refresh the hardware watchdog timer before it times out, write only security key 2 to STCU2_SKC.

AUTOLOCK_VALUE is the number of STCU2 clock cycles after which the hardware watchdog timer locks register-write access. See the chip-specific STCU2 information for the value of AUTOLOCK_VALUE.

NOTE

For write completion, each DCF record requires a number of STCU2 clock cycles equal to DCF_COMPLETION. The maximum number of DCF records that can be executed before the watchdog timer must be refreshed is AUTOLOCK_VALUE divided by DCF_COMPLETION. See the chip-specific STCU2 information for the value of DCF_COMPLETION.

The hardware watchdog timer is particularly useful in case STCU2_CFG[WRP] is 0 during the software self-test configuration. In this case, the software application might enable write access to the STCU2 registers.

75.8.8 SSCM interface

The SSCM interface is used to program the STCU2's configuration parameters without the CPU intervention after a reset trigger event initializes the STCU2. This bus interface has the priority over the IPS.

75.9 Register description

During Offline SELFTEST, once the STCU2 registers are configured they cannot be overridden.

During Online SELFTEST, once the STCU2 registers are configured they cannot be overridden via IPS till the selftest is complete.

The STCU2 registers are listed in this section.

STCU2 memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	STCU2 Run Register (STCU2_RUN)	32	R/W	0000_0000h	75.9.1/3223

75.9.1 STCU2 Run Register (STCU2_RUN)

The STCU2_RUN register defines the RUN bit to start the off-line self testing procedure.

The R/W fields in this register are readable at any time. However, you can write to these fields only when Off-line Self-Test phase is still active.

Address: 0h base + 0h offset = 0h

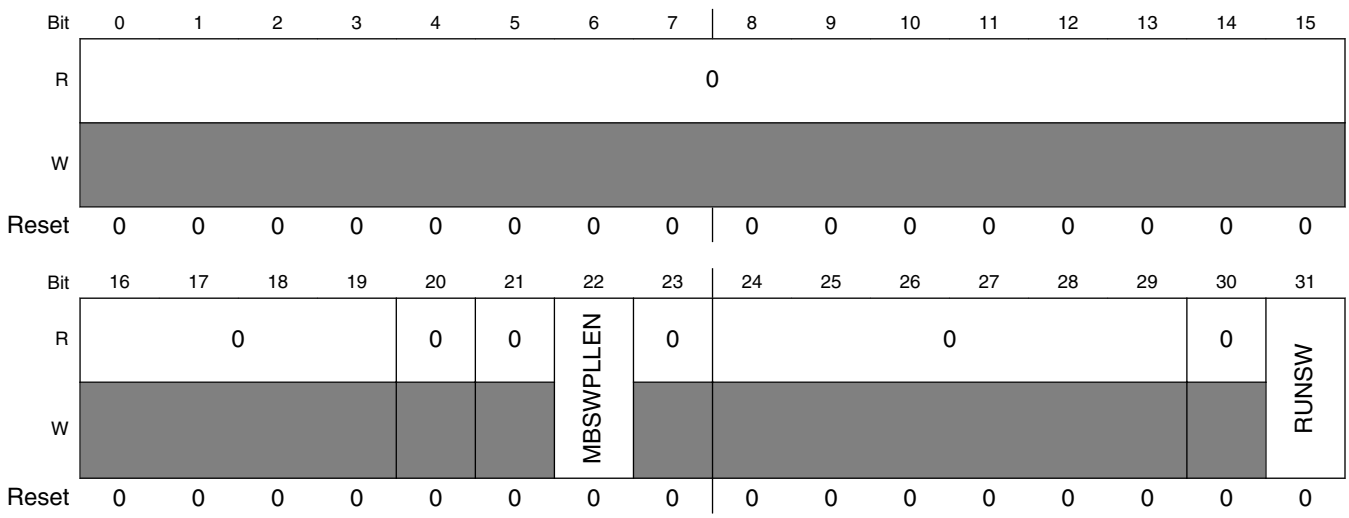
STCU2_RUN field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 BYP	Bypass mode 0 Off-Line Self-Test is active. In case the RUN bit into the STCU2_RUN register is not set before the Hard-Coded WDG Time-out, the WDTO error is generated into the STCU2_ERR_STAT register. 1 Off-Line Self-Test is completely bypassed and the access to STCU2 is locked until the STCU2_SKC register is written according to the request access mode.
22 MBPLLEN	Off-Line MBIST with PLL Enabled 0 Off-Line MBIST is executed without using the on-chip PLL. 1 Off-Line MBIST is executed enabling the on-chip PLL control interface selecting the parameters defined into STCU2_PLL_CFG register.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

STCU2_RUN field descriptions (continued)

Field	Description
24–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 RUN	RUN: RUN The RUN bit is automatically cleared by the STCU2 when the off-line self testing procedure has been completed. 0 Idle 1 Off-Line Self testing procedure is running



75.9.2 STCU2 Run Software Register (STCU2_RUNSW)

The STCU2_RUNSW register defines the RUN bit to start the on-line self testing procedure.

The R/W fields in this register are readable at any time. However, you can write to these fields only when both of the following conditions are true:

- STCU2_CFG[WRP] = 0
- On-line Self-Test phase is active. The On-Line condition starts when the Off-Line is over. In this condition, system is alive and the SW can program the STCU2

Address: 0h base + 4h offset = 4h

STCU2_RUNSW field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

STCU2_RUNSW field descriptions (continued)

Field	Description
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 MBSWPLLEN	On-Line MBIST with PLL Enabled 0 On-Line MBIST is executed without using the on-chip PLL. 1 On-Line MBIST is executed using the PLL configuration provided by software. STCU2 does not take the PLL control but monitors the PLL lock signal to check if PLL is working correctly.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 RUNSW	RUNSW The RUNSW bit is automatically cleared by the STCU2 when the on-line self testing procedure has been completed. 0 Idle 1 On-line self testing procedure is running

75.9.3 STCU2 SK Code Register (STCU2_SKC)

The STCU2_SKC register implements the security key code mechanism needed to access in write mode to the other STCU2 registers. In order to unlock the STCU2 access after:

- The STCU2 asynchronous reset
- The end of the STCU2 run

the software (IPS bus)or the SSCM interfaces have to apply the following sequence:

- write the key1 into the STCU2_SKC register
- write the key2 into the STCU2_SKC register

Depending on the off/on-line test step, the two keys will be different. Byte write operation is not allowed since the full key has to be recognized as one unit.

It should be noted that after the Self-Test sequence has been completed or the Bypass feature has been enabled (setting the bit BYP into the STCU2_CFG), the SSCM interface is no longer available.

In case of invalid access or sequence (Key1/2 have to be applied consecutively), a transfer error on the IPS or SSCM busis asserted depending on the selected source. The STCU2 write access is locked and to unlock the access the sequence has to be applied again.

In case the STCU2 register access lasts more cycles than the one defined into the Hard-coded WDG time-out, the STCU2 write access is locked and the WDG and Register ITF clocks are switched off. Also in this case, in order to enable again the write access to the STCU2 and the WDG and Register ITF clocks, it is required to apply again the sequence.

In case it is required to extend the STCU2 register access cycles before the Hard-coded WDG time-out expires, only the Key2 has to be applied. The effect of this write operation is to re-initialize the WDG time-out counter. In such a condition, Key1 has not to be applied otherwise a transfer error on the IPS bus is asserted depending on the selected source. The STCU2 write access is locked and to unlock the access the sequence has to be applied again.

The STCU2_SKC register is not readable. The value 00000000h is always returned in case of read operation.

Address: 0h base + 8h offset = 8h

75.9.4 STCU2 Configuration Register (STCU2_CFG)

NOTE

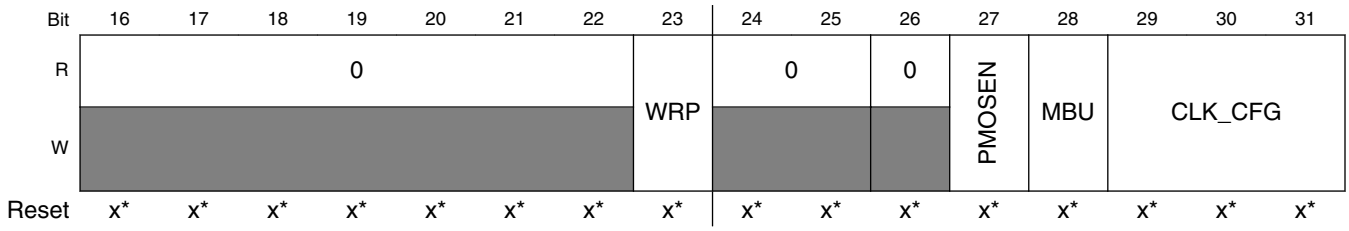
The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_CFG register includes the global configuration of the STCU2 and can be updated both in the Off/On-Line Test steps.

The access to this register is described in the following figure. It further depends on the state of the WRP bit as follows:

- When WRP = 0: The register can be written during the on-line Self-Test case without restrictions
- When WRP = 1:
  - The only bit that can be written without any restriction is WRP.
  - In case there are software operations that write all the register's bits, a transfer error is raised only if the value of the selected byte written differs from the current status of the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate this single bit clean capability.

MBIST can be run in three different test types according to how the STCU2_CFG register bits 27 and 28 are set.



The following table describes the test algorithm and coverage of the different test types.

Table 75-4. MBIST algorithm and coverage according to test type

MBIST Type	STCU2_CFG[PMOSEN]	STCU2_CFG[MBU]	MBIST Algorithm	Internal Nodes/ Circuits Additionally Covered by Test	Use Case	Test Cycle
Full Test	1	0	Test memory using all built in algorithms. Open PMOS algorithm included	Address Decoder and Bitcell as well as resistive defects in the address decoder	Used by MCU production test. Recommended to use in the field for MBIST online self-test.	About 3 to 4x more than Auto Test
Reduced Test	0	0	Test memory using all built in algorithms except the open PMOS algorithm.	Address Decoder and Bitcell	Recommended to use in the field for MBIST online self-test if the Full Test takes too long.	About 10% less than Full Test
Auto Test	x	1	A smaller set of algorithms which target latent defect mechanisms.	Latent defects such as NBTI of the PMOS transistors in the bitcells	Recommended to use for MBIST offline self-test as an optimum balance of test time vs. fault coverage.	About 3 to 4x faster than Full Test

Address: 0h base + Ch offset = Ch

STCU2_CFG field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–7 PTR	MBIST pointer PTR defines the logical pointer to the first MBIST to be scheduled when the self testing procedure is enabled. PTR is the entry pointer to a linked list of BIST descriptors. You can always read this field. In the off-line Self-Test phase, you can always write to this field. In the on-line Self-Test phase, you can write to this field only when WRP = 0. 10h to (10h + MBIST -1): pointer to MBIST 7Fh: pointer to NIL. No BIST execution.
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 WRP	Write Protection 0: Specific STCU2 registers can be written through IPS bus interface after Off-Line Self-Test sequence has been completed 1: Specific STCU2 registers cannot be written though IPS also after Off-Line Self-Test sequence has been completed preventing in such a way any user application write operation
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 PMOSEN	MBIST PMOS Test Enable When MBU is 1 then "Auto test" MBIST test type will be selected regardless of the setting of this field. 0 When MBU is 0 then selects the "Reduced test" MBIST test type. 1 When MBU is 0 then selects the "Full test" MBIST test type.
28 MBU	MBIST MBU Test Enabled 0 Either "Full test" or "Reduced test" MBIST test type will be selected according to the PMOSEN value. 1 Selects "Auto test" MBIST test type regardless of the PMOSEN value.
29–31 CLK_CFG	Logic, Memory BIST and STCU2 core CLK Clock configuration CLK_CFG defines the ratio between the sys_clk and the TCK used to program the MBIST and the STCU2 core clock. The punch-out mechanism is used to generate the derived clocks. The allowed configurations are the following:

Table continues on the next page...

STCU2_CFG field descriptions (continued)

Field	Description
	000: sys_clk 001: sys_clk/2 010: sys_clk/3 ... 101: sys_clk/6 110: sys_clk/7 111: sys_clk/8 You can always read this field. In the off-line Self-Test phase, you can always write to this field. In the on-line Self-Test phase, you can write to this field only when WRP = 0.

75.9.5 STCU2 Watchdog Granularity (STCU2_WDG)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_WDG register defines the time limit for MBIST execution, providing a protection mechanism in case of deadlock or endless conditions during the self test procedure.

When the offline self test sequence is not run and the STCU2_CFG[BYP] field is not set, bits 15..0 define the time-out before the STCU2_ERR[WDTO] field is set and the STCU2 core clock is switched off.

In case offline/online self test sequence is run, the STCU2_WDG value defines the time-out of the execution run.

The register fields are always readable. You can write to these fields when either of the following conditions is true:

- Offline self test phase is active
- Online self test phase is active and CFG[WRP] = 0

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

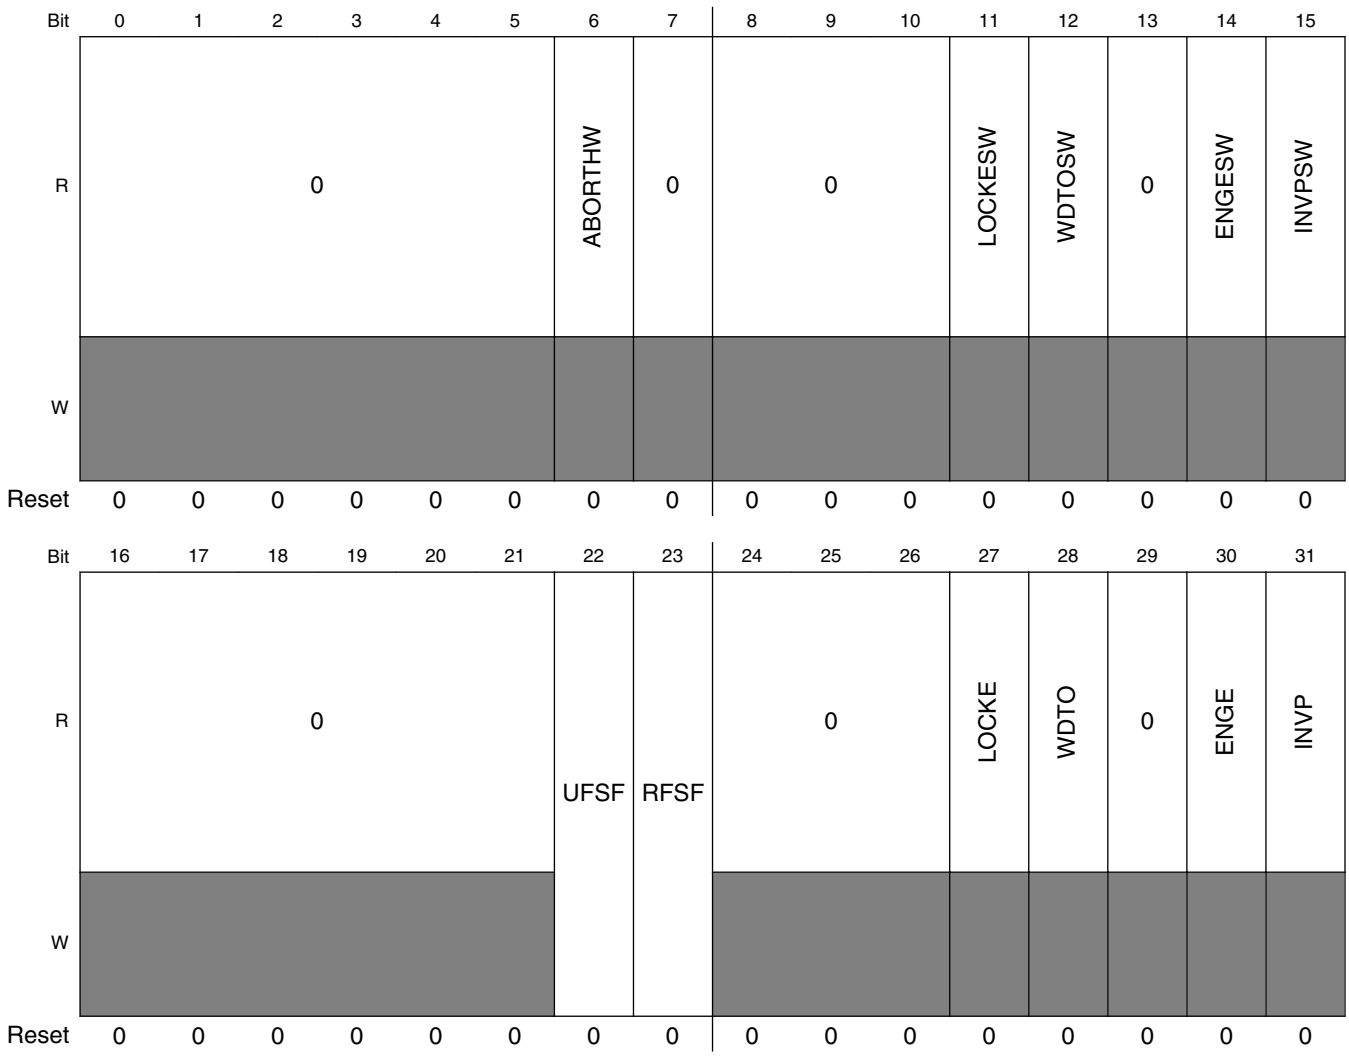
* Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

STCU2_WDG field descriptions

Field	Description
0–31 WDGEOC	Watchdog End of Count Timer This value defines the time limit for offline and online self test execution to ensure correct operation within the allowed time. **NOTE:** If this register is programmed while STCU2_RUN[RUN]=1, the new STCU2_WDG value, programmed after STCU2_RUN, does not take effect. The allowed values are: 0000 0000h: 1 × 16 STCU2 Core clock cycles 0000 0001h: 2 × 16 STCU2 Core clock cycles 0000 0002h: 3 × 16 STCU2 Core clock cycles ... FFFF FFFDh: 4294967294 × 16 STCU2 Core clock cycles FFFF FFFEh: 4294967295 × 16 STCU2 Core clock cycles FFFF FFFFh: 4294967296 × 16 STCU2 Core clock cycles

75.9.6 STCU2 Error Register (STCU2_ERR_STAT)



The STCU2_ERR_STAT register includes the status flags related to the STCU2 internal fault conditions occurred during the configuration or the On/Off-Line self testing execution.

The UFSF and RFSF can be set/cleared using the FCCU dedicated channels.

The access to this register is described in the following figure and as follows:

- If you select the byte write capability to write only the UFSF and RFSF, then there is no restriction in writing these bits.
- If your software performs the write operations on other bits besides UFSF/RFSF, then a transfer error is generated only if the value you are writing to the other bits differs from their value currently stored in the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate the UFSF/RFSF single bit set/clean capability.

Address: 0h base + 24h offset = 24h

STCU2_ERR_STAT field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 ABORTHW	On-line hardware abort flag You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 No hardware abort was requested during the On-Life Self-Test sequence 1 A hardware abort was detected during the On-Life Self-Test sequence
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 LOCKESW	On-Line LOCK Error

Table continues on the next page...

STCU2_ERR_STAT field descriptions (continued)

Field	Description
	You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 In case PLL is enabled, it is correctly locked during the Self-Test sequence 1 When the PLL is enabled, this flag highlight that there has been an unexpected PLL unlock event during the On-Line Self-Test sequence execution. The On-Line Self-test run is stopped and the status of the current running MBISTs is saved into the related registers.
12 WDTOSW	On-Line Watchdog time-out You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 MBIST time slot have been completed within the assigned watchdog time. 1 MBIST time slot haven't been completed within the assigned watchdog time or there are internal mismatches among End of Execution signals. The conditions that flag the failures are the following: • MBIST BEND status flags that at least one of the selected MBIST run is not finished
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 ENGESW	On-Line Engine Error You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 Valid Engine execution 1 Invalid Engine execution. The following conditions set this bit: • STCU2 state machines (Watchdog, Master and Loader/Shifter) selects an unused code • Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned • Serial bend status of the selected MBIST and the global BEND flag are not aligned
15 INVPSW	On-Line Invalid Pointer You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: • Initial MBIST pointer is out of range • Error in the MBIST linking (execution generates an infinite loop)
16–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 UFSF	Unrecoverable Faults Status Flag This flag reports the global status of the UF. This field can be set or cleared using the FCCU dedicated channel, and can also be set or cleared by software. 0 No errors that trigger the Unrecoverable Faults condition 1 There are errors that trigger the Unrecoverable Faults condition
23 RFSF	Recoverable Faults Status Flag This flag reports the global status of the RF. This field can be set or cleared using the FCCU dedicated channel, and can also be set or cleared by software. 0 No errors that trigger the Recoverable Faults condition 1 There are errors that trigger the Recoverable Faults condition

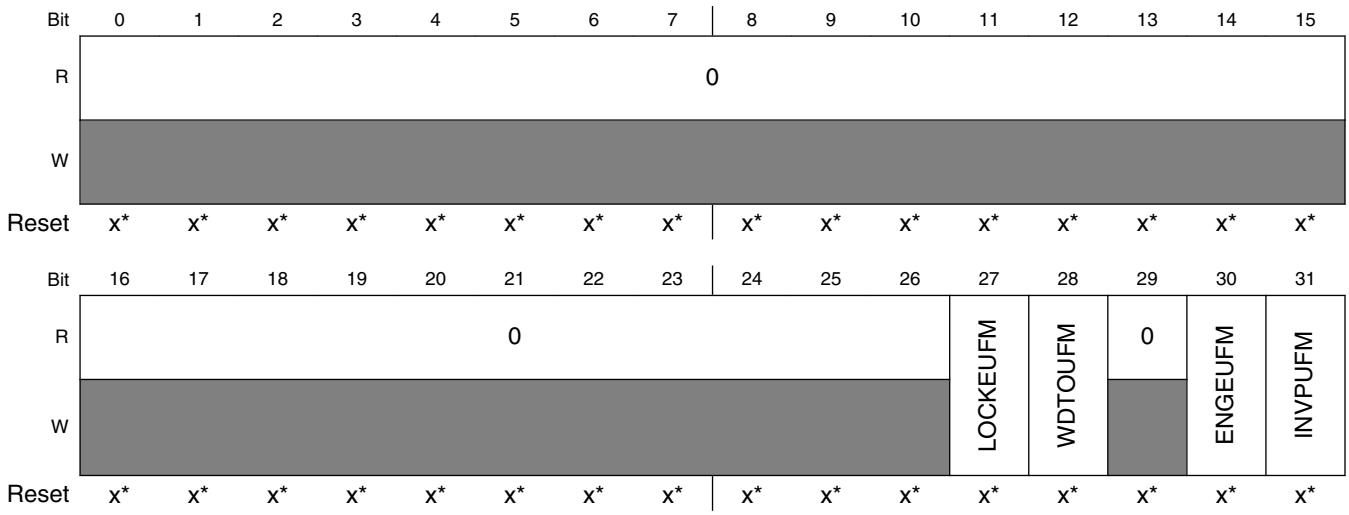
Table continues on the next page...

STCU2_ERR_STAT field descriptions (continued)

Field	Description
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 LOCKE	Off-Line LOCK Error 0 The PLL is correctly locked during the Self-Test sequence 1 When the PLL is enabled, this flag highlights that there has been an unexpected PLL unlock event during the Off-Line Self-Test sequence execution. The Off-Line Self-test run is stopped and the status of the current running MBISTs is saved into the related registers. The LOCK signal is monitored during the the MBIST run when STCU2_RUN[MBPLLEN] = 1.
28 WDTO	Off-Line Watchdog time-out 0 MBIST time slot have been completed within the assigned watchdog time. 1 MBIST time slot haven't been completed within the assigned watchdog time or there are internal mismatches among End of Execution signals. The conditions that flag the failures are the following: • The STCU2_RUN[RUN] bit or the STCU2_RUN[BYP] bit is not set before the Watchdog reaches the End of Count • MBIST BEND status flags that at least one of the selected MBIST run is not finished
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 ENGE	Off-Line Engine Error 0 Valid Engine execution 1 Invalid Engine execution. The following conditions set this bit: • STCU2 state machines (Watchdog, Master and Loader/Shifter) selects an unused code • Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned • Serial bend status of the selected MBIST and the global BEND flag are not aligned
31 INVP	Off-Line Invalid pointer 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: • Initial MBIST pointer is out of range • Error in the MBIST linking (execution generates an infinite loop)

75.9.7 STCU2 Error FM Register (STCU2_ERR_FM)

NOTE



The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_ERR_FM register defines the fault mapping of the STCU2 faults described into the register STCU2_ERR_STAT in terms of Unrecoverable or Recoverable Fault. All sources of internal faults can be routed to UF and RF.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 28h offset = 28h

* Notes:

- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.x = Undefined at reset.

STCU2_ERR_FM field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 LOCKEUFM	PLL LOCK Unrecoverable Fault Mapping 0 Recoverable Fault Mapping 1 Unrecoverable Fault Mapping
28 WDTOUFM	Watchdog time-out Unrecoverable Fault Mapping 0 Recoverable Fault Mapping 1 Unrecoverable Fault Mapping

75.9.22 STCU2 MBIST Unrecoverable FM High Register (STCU2_MBUFMH)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_MBUFMH register defines the fault mapping, in terms of Unrecoverable or Recoverable fault, of the MBIST in the range NMCUT = 64-95.

The size of the register depends on the number of BISTed RAMs/ROMs.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 7Ch offset = 7Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

75.9.23 STCU2 MBIST Control Register (STCU2_MB_CTRL*n*)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_MB_CTRL register defines the control setting of MBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

The offset of this register is a function of NMCUT .

Address: 0h base + 600h offset + (4d × i), where i=0d to 44d

STCU2_MB_CTRL*n* field descriptions

Field	Description
0 CSM	Concurrent/sequential mode 0 Sequential mode 1 Concurrent mode
1–7 PTR	Next MBIST pointer PTR defines the logical pointer to the next MBIST to be scheduled. The next MBIST is scheduled concurrently to the current one if the CSM bit is set to 1; otherwise it is scheduled sequentially to the completion of the current MBIST execution. In case of NIL pointer the CSM bit must be set Sequential (0) to define this is the end of the list. The self-testing procedure is stopped when the current MBIST has been completed.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

75.10 Use cases and limitations

The STCU2 module is designed to give high flexibility during the on/off-line test. In the following are reported the programming operations that have to be performed to correctly use the functionality of this module considering the three typical usage cases:

- the Off-line Self Test Sequence after a reset trigger event
- the bypass mode of the Self Test Sequence after a reset trigger event
- the On-line Self-test Sequence

75.10.1 Offline self-test sequence

This is the typical mode of using the STCU2 module after reset trigger event is applied to STCU2. The SSCM DCF bus is used to retrieve the STCU2 schedule and MBIST execution parameters stored into the NVM memory.The target is to cover the amount of physical defects in the digital logic and in the System RAMs/ROMs according to the System specifications. The sequence is the following:

- Unlock the Off-Line STCU2 access writing the Key1/Key2 sequence into the STCU2_SKC register
- Program the MBIST fault reaction conditions (UF/RF) setting, depending on the number of memories, the STCU2_MBUFML/M/H registers
- Program the STCU2 internal fault reaction conditions (UF/RF) setting the STCU2_ERR_FM register
- Program the STCU2_MB_CTRL registers of each NMCUT to be executed
- Program the STCU2_WDG register to define the time budget assigned for the MBIST execution

- Program the STCU2_CFG register to define: the core and MBIST TCK clock prescaling factor setting the CLK_CFG bits, the PMOSEN or MBU in order to define the algorithm to be used during MBIST run, and finally set the pointer to the first NMCUT to be executed
- In case the PLL usage has been enabled, program the STCU2_PLL_CFG value in order to set the required system frequency
- Program the RUN bit into the STCU2_RUN register to enable the Off-Line Self-Test execution and the MBPLLEN bits to enable the PLL during MBIST execution according to STCU2_PLL_CFG register content
- Start the Off-Line Self-Test and, depending on PLL management and MBIST execution order, when PLL LOCK is high.
- Wait the WDGEOC run time execution specified into the STCU2_WDG register.
- The STCU2 switches off the core clock at the end of the Self-Test run and releases the PLL control in case this feature has been enabled.
- The STCU2 resets the STCU2_RUN[RUN] bit and the device exits from boot sequence. In case there are failures, the STCU2 flags these failures toward the FCCU.
- The software application reads the STCU2_MBSL/M/H flag registers, depending on the number of memories, to check the failed RAMs/ROMs Memory BIST when UF or RF is/are detected.
- The software application reads the STCU2_MBEL/M/H flag registers, depending on the number of memories, to check if the RAMs/ROMs Memory BIST is still on-going when UF or RF is/are detected.
- The software application reads the bits INV, ENGE, WDTO, LOCKE of the STCU2_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UF or RF is/are detected.

NOTE

The software application reads operations on the STCU2 register after off-line self test execution has been successfully performed are just an additional reliability layer added to improve the already implemented Auto Self-Test feature included into STCU2.

75.10.2 Online self test sequence

The online self test sequence is the most commonly used STCU2 application mode. The IPS interface is used to program the STCU2 registers and to schedule MBIST execution. Since online MBIST operations clean-up the content of RAM (MBIST) tested, activation of this mode must be approached with caution. The suggested sequence is the following:

1. Ensure the RUN_CFG field value in all implemented MC_ME_PCTL*n* registers forces the associated peripheral to a frozen, clock gated state.
2. Write the Key1/Key2 sequence to the SKC register to unlock online STCU2 access.
3. Ensure CFG[WRP]=0 to enable IPS bus access to the online self test registers.
4. If required, program the following registers to select the MBIST and STCU2 internal fault reaction: MBUFML/M/H and ERR_FM.

NOTE

The MBIST and STCU2 internal fault reaction should have been already programmed during the offline self test sequence and so there should be no need to program again. However, in case they have not been programmed or there is the need of changing them for any reason, they can be overwritten.

5. Overwrite/Program the MB_CTRL registers of each NMCUT to be executed.
6. Overwrite/Program the WDG register to define the time budget assigned for the MBIST execution
7. Overwrite/Program the CFG register to define: the core and MBIST TCK clock prescaling factor setting the CLK_CFG bits, the PMOSEN or MBU in order to define the algorithm to be used during MBIST run, and finally set the pointer to the first NMCUT to be executed.
8. Program the RUNSW[RUNSW] field to enable online self test execution; the MBSWPLLEN bits to enable the PLL lock signal monitor during MBIST execution
9. Start the online self test and depending on PLL management and MBIST execution order, also when PLL LOCK is high.
10. Wait the WDGEOC run time execution specified into the WDG register
11. The STCU2 switch-off the core clock at the end of the self test run
12. The STCU2 resets the RUNSW[RUNSW] field. In both the reset cases and in case of fault/s, the STCU2 flags the failure toward the FCCU.
13. The software application reads the MBSLSW/MSW/HSW flag registers, depending on the number of memories, to check the failed RAMs/ROMs Memory BIST when UF or RF is/are detected.
14. The software application reads the MBELSW/MSW/HSW flag registers, depending on the number of memories, to check if the RAMs/ROMs Memory BIST is still on-going when UF or RF is/are detected.

15. The software application reads the bit INVPSW, ENGESW, WDTOSW, LOCKESW of the ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UF or RF is/are detected.

NOTE

1. A reset is necessary after running any kind of online self test.
2. The software application read operations on the STCU2 register after successful online self test execution are an additional reliability layer to improve the auto-self-test feature included in the STCU2.
3. Flash memory must be in the idle state when BIST execution is started. Program and erase functionality must not be enabled when entering BIST execution.

75.10.3 Bypass USER Mode

In this case, the USER application parameters stored in FLASH and read by SSCM are written in order to skip the Self-Test procedure after a reset trigger event is applied. It might be useful in case the device is not configured for applications requiring improved reliability. The sequence is the following:

1. Unlock the STCU2 access writing the Off-Line Key1/Key2 sequence into the STCU2_SKC register
2. Set the BYP bit in the STCU2_RUN register

After BYP bit is set, the core clock is switched off, the Self-Test sequence is not applied and the system can wake up and start the user application.

75.10.4 Design implementation information

The following list reports the limitations related to the current implementation:

- Every NMCUT BIST can be run once during the online or offline self-test procedure.
- Because software has full control of the system while applications are running during the online self-test, STCU2 is not allowed to take control of the PLL but can just monitor the lock signal to flag wrong unlock events.

Chapter 76
Cyclic Redundancy Check (CRC) Unit

76.1 Introduction

The Cyclic Redundancy Check (CRC) computing unit is dedicated to the computation of CRC, off-loading the CPU. Each context has a separate CRC computation engine in order to allow the concurrent computation of the CRC of multiple data streams. The CRC computation is performed at speed without wait-state insertion. Bit-swap and bit-inversion operations can be applied on the final CRC signature. Each context can be configured with one of three hard-wired polynomials, normally used for most of the standard communication protocols. The data stream supports multiple data width (byte/halfword/word) formats.

76.2 Main features

- Single context is supported
- Zero-wait states during the CRC computation (pipeline scheme)
- Four hard-wired polynomials (two CRC-8, CRC-32 ITU-T V.42, and CRC-16-CCITT)
- Support for byte, halfword, or word width of the input data stream

76.2.1 Standard features

- Peripheral bus interface
- CRC-8 VDA CAN
- CRC-16-CCITT

- CRC-32 ITU-T V.42 (see note below)
- CRC-8-H2F Autosar polynomial

NOTE

Although the CRC-32 ITU-T V.42 polynomial is used for CRC generation, the generation algorithm differs (MISR) from the one used by the IEEE 802.3 standard.

76.3 Block diagram

The top level diagram of the CRC module is given in the following figure. Refer to Main features for number of contexts in this module.

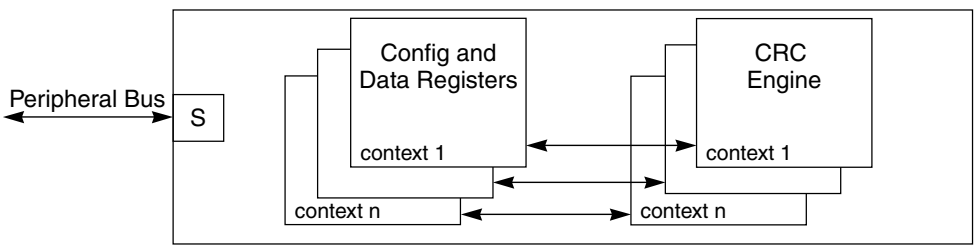

Figure 76-1. CRC top level diagram

76.4 External signal description

The CRC module does not generate any external signals.

76.4.1 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration and data streaming (CRC computation) purposes via CPU or DMA. The following bus operations (contiguous byte enables) are supported:

- Word (32 bits) data write/read operations to any registers
- Low and high halfword (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers

- Byte (8 bits, data[31:24], data[23:16], data[15:8], or data[7:0]) data write/read operations to any registers
- Any other operation (free byte enables or other operations) must be avoided.

The CRC module generates a transfer error in the following cases:

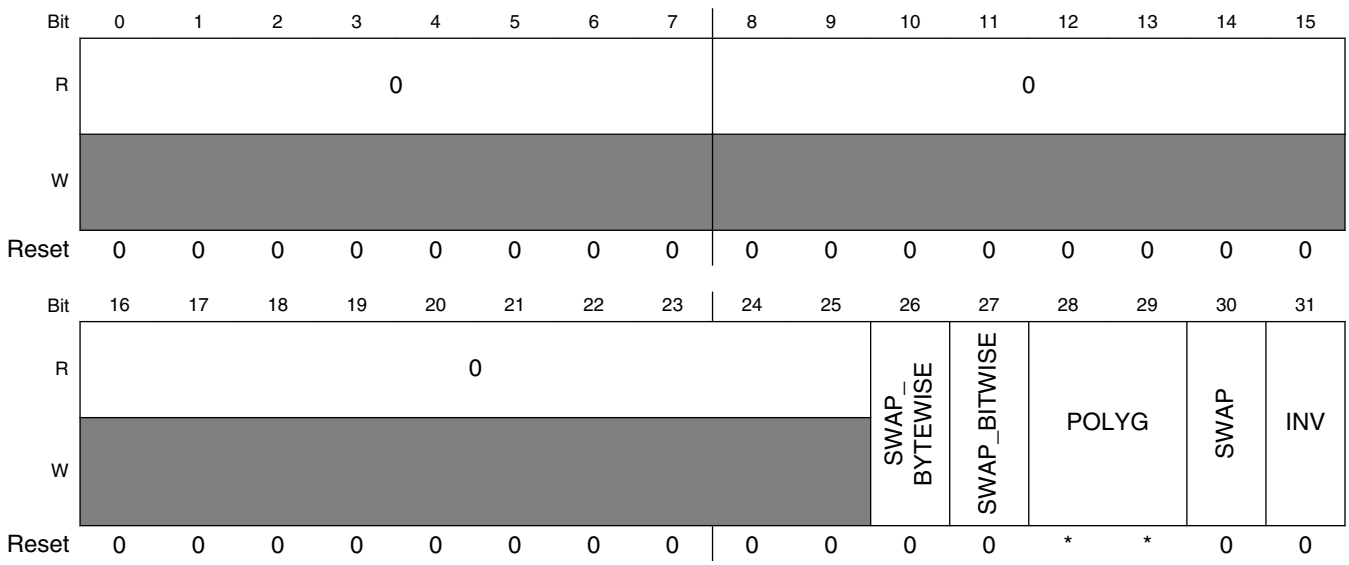
- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register

The registers of the CRC module are read/write accessible in each access mode:
- user
- supervisor

The following summarizes bus operation performance:

- Zero wait states (single bus cycle) for each write/read operation to the CRC_CFG and CRC_INP registers
- Zero wait states (single bus cycle) for each write operation to the CRC_ CSTAT register
- Double wait states (3 bus cycles) for each read operation to the CRC_ CSTAT or CRC_OUTP registers immediately following (next clock cycle) a write operation to the CRC_CSTAT, CRC_INP, or CRC_CFG registers belonging to the same context; in all the other cases, no wait states are inserted

76.5 CRC memory map and registers



CRC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Configuration Register (CRC_CFG)	32	R/W	See section	76.5.1/3276
4	Input Register (CRC_INP)	32	R/W	0000_0000h	76.5.2/3277
8	Current Status Register (CRC_CSTAT)	32	R/W	FFFF_FFFFh	76.5.3/3278
C	Output Register (CRC_OUTP)	32	R	FFFF_FFFFh	76.5.4/3278

76.5.1 Configuration Register (CRC_CFG)

Access: User read/write.

Address: 0h base + 0h offset = 0h

* Notes:

- POLYG field: Reset value is a function of n in CRC_CFGn. When n%2 = 0, reset value = 01b. When n%2 = 1,reset value = 00b. So CRC_CFG1 POLYG reset value = 00b (Since 1%2=1).

CRC_OUTP field descriptions

Field	Description
0–31 OUTP	Final CRC signature This register includes the final signature corresponding to the CRC_CSTAT register value eventually swapped and inverted. In the case of the CRC-CCITT polynomial, only the 16 least-significant bits are significant. The 16 MSB bits are set to 0 during the computation. In the case of the CRC-8 polynomial, only the 8 least-significant bits are significant. The 24 most-significant bits are set to 0 during the computation.

76.6 Functional description

The CRC module supports the CRC computation for each context. Each context has its own complete set of registers, including the CRC engine. The data flow of each context can be interleaved. The data stream can be structured as a sequence of bytes, halfwords, or words. The input data sequence is provided, eventually mixing the data formats (byte, halfword, and word), writing to the input data register (CRC_INP).

The data stream is generally executed by *n* concurrent DMA data transfers (mem2mem) where *n* is less or equal to the number of contexts.

The standard generator polynomials are given in Equation 46 on page 3279, Equation 47 on page 3279, and Equation 48 on page 3279 for the CRC computation of each context. Two separate registers are available: CRC_INP for writing data and CRC_CSTAT for retrieving the (accumulated up to now) CRC.

$$x^8 + x^4 + x^3 + x^2 + 1$$

Equation 46. CRC8 VDA CAN

$$x^{16} + x^{12} + x^5 + 1$$

Equation 47. CRC-CCITT (x.25 protocol)

$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

Equation 48. CRC-32 (ITU-T V.42 protocol)

$$x^5 + x^3 + x^2 + x + 1$$

Equation 49. CRC-8-H2F (Autosar 4.0 protocol)

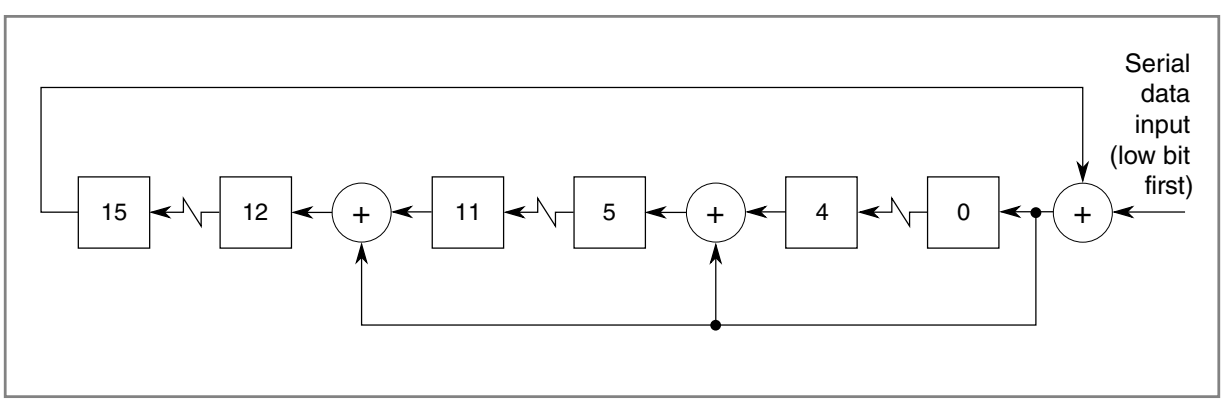

Figure 76-2. CRC-CCITT engine concept scheme

The initial seed value of the CRC can be programmed by initializing the CRC_CSTAT register. A diagram illustrating serial data loading of the CRC engine is shown in Figure 76-2 for the CRC-CCITT. Note that, conceptually, the least-significant, or "right-most," bit shown in Input Register (CRC_INP), is fed first into the engine. The actual implementation executes the CRC computation in a single clock cycle (parallel data loading). A pipeline scheme has been adopted to decouple the IPS bus interface from the CRC engine in order to allow the computation of the CRC at speed (zero wait states).

If the CRC signature is used for encapsulation in the data frame of a communication protocol (for example, SPI, etc.), a bit swap (high bit for low bit or low bit for high bit) and/or bit inversion of the final CRC signature can be applied to CRC_OUTP before transmitting the CRC.

Use of the CRC module is summarized in the flow chart given in Figure 76-3.

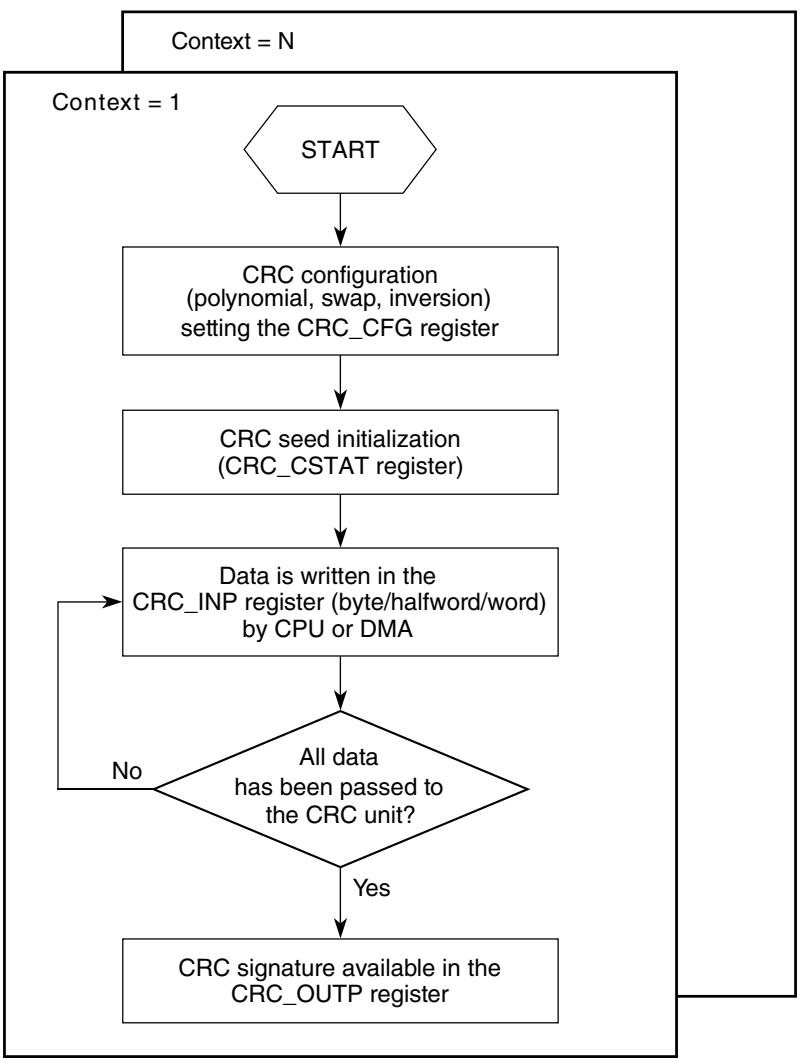

Figure 76-3. CRC computation flow

76.7 Use cases

76.7.1 Programming example

The number of contexts depends on the application. The overall number of contexts for the CRC peripheral depends on the number of peripherals that concurrently require intervention by the CRC module. Two main use cases are considered:

- Calculation of the CRC of the configuration registers during the process safety time
- Calculation of the CRC on the incoming/outcoming frames for the communication protocols (not protected with CRC by definition of the protocol itself) used as a safety-relevant peripheral

The signature of the configuration registers is computed correctly only if these registers do not contain any status bit.

Assuming that the DMA engine has *n* channels (greater than or equal to the number of contexts) configurable for the following types of data transfer—mem2mem, periph2mem, mem2periph—the following sequence, as shown in the following figure, is applied to manage the transmission data flow:

1. DMA/CRC module configuration (context x, channel x) by CPU
2. Payload transfer from the MEM to the CRC module (CRC_INP register) after MSB-to-LSB change (input mirroring) to calculate the CRC signature (phase1) by DMA (mem2mem data transfer, channel x)
3. CRC signature copy from the CRC module (CRC_OUTP register) to the MEM (phase 2) by CPU
4. Data block (payload + CRC) transfer from the MEM to the PERIPH module (for example, SPI Tx FIFO) (phase 3) by DMA (mem2periph data transfer, channel x)

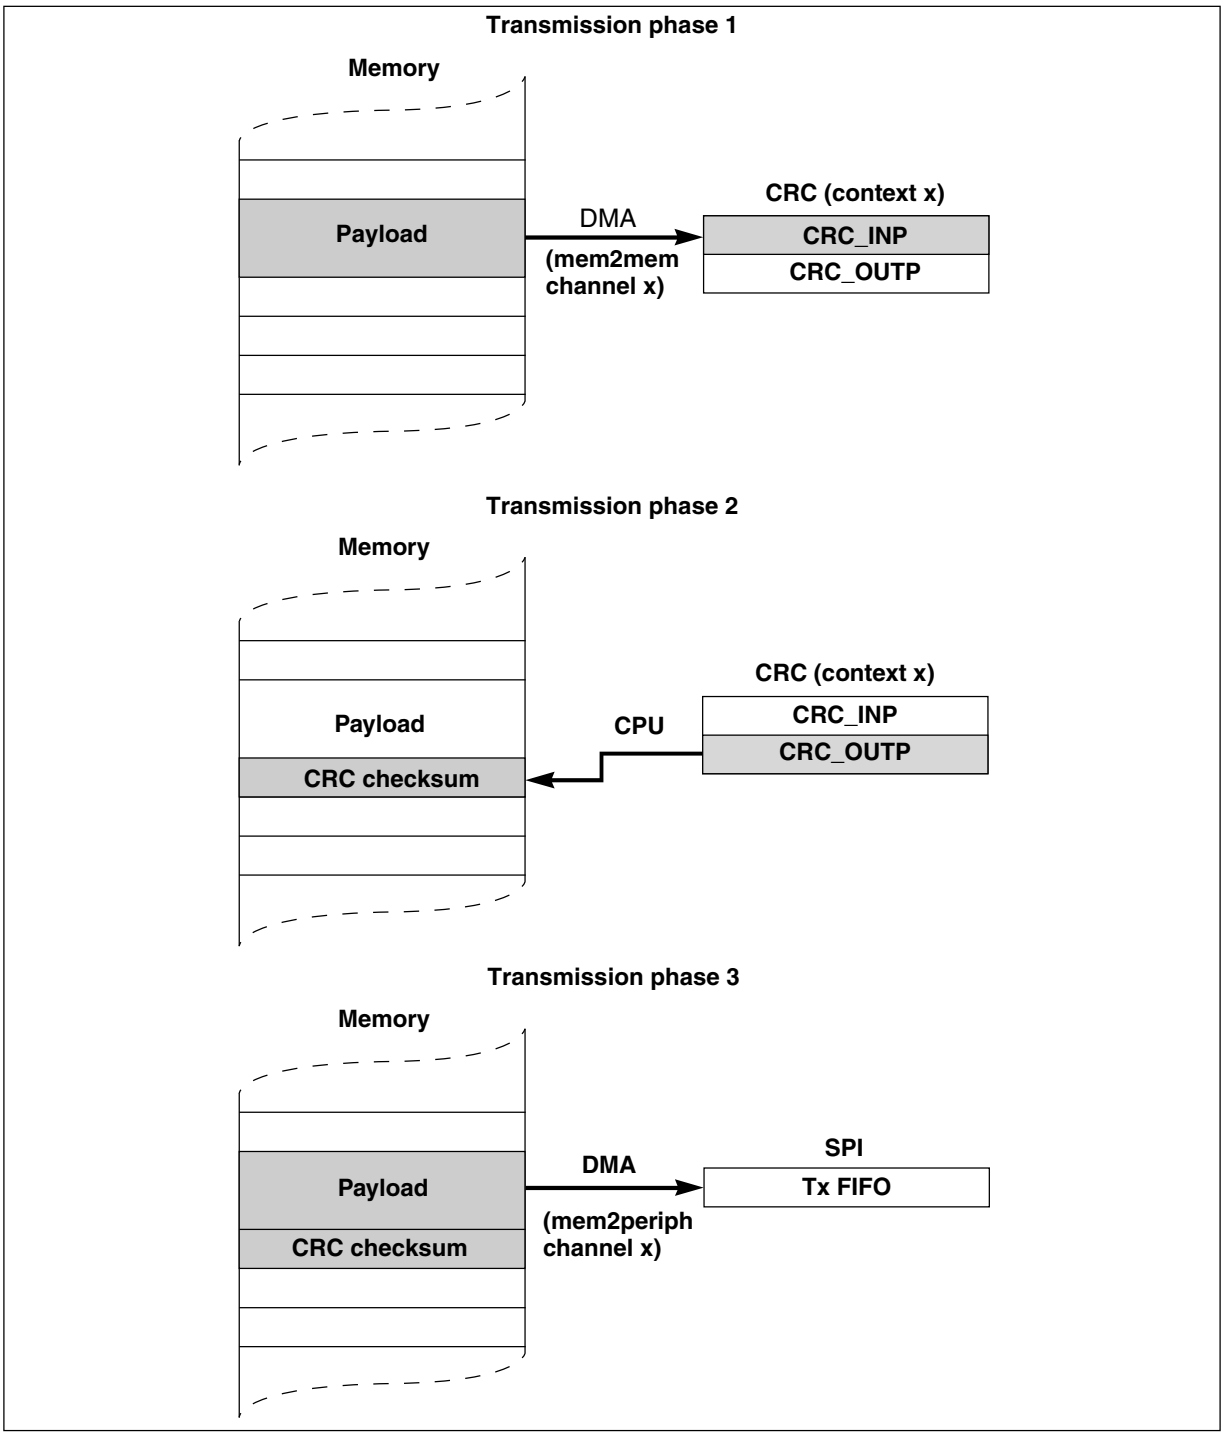

Figure 76-4. DMA-CRC transmission sequence

76.7.2 Register programming

- INV and/or SWAP (affecting the output only) can be applied to CRC-8, CRC-16, and CRC-32. Both can be applied together.

- SWAP_BITWISE (affecting the input only) can be applied for all polynomials if required by an application.
- SWAP_BYTEWISE (affecting the input only) can be applied for CRC-16 and CRC-32 polynomials only.
- SWAP_BITWISE has priority over SWAP_BYTEWISE when both are applied together.
- When generating CRC-32 for the ITU-T V.42 standard the user needs to set SWAP_BYTEWISE together with INV and SWAP.
- When generating CRC-16 the user needs to set SWAP_BITWISE bit.

Chapter 77
Register Protection

77.1 Chip-specific Register Protection information

77.1.1 Register protection configuration

Some modules on this device include a built-in register protection mechanism that can be used to override the normal write permissions associated with individual registers in the module. This mechanism is software controlled and can be dynamically reconfigured at runtime or made effective until device reset. For a detailed explanation, see the Register protection chapter.

Table 77-1. Related information

Topic	Related module
System memory map	All
SIUL registers	SIUL
PMC Digital Interface (PMCDIG) registers	PMCDIG
Mode Entry (MC_ME) module registers	MC_ME
PLL Digital Interface (PLLDIG) registers	PLLDIG
Clock Monitor Unit (CMU) registers	CMU
Fast Oscillator Digital Interface (FXOSC) registers	FXOSC
Slow External Oscillator (SXOSC) registers	SXOSC
Memory Error Management Unit (MEMU_0 and MEMU_1) registers	MEMU
Clock Generation Module (MC_CGM) registers	MC_CGM
Reset Generation Module (MC_RGM) registers	MC_RGM
LPU controller (LPU_CTL) registers	LPU_CTL

NOTE

This following restriction applies to the CGM memory mapped registers (FIRC, FXOSC , SIRC, SXOSC and CMU) which are usable in LPU mode:

1. Access to these registers should be unlocked via Register Protection configuration in RUN/DRUN modes before LPU modes entry to allow access to modify these registers OR.
2. If Access to these registers are locked via Register Protection configuration in RUN/DRUN modes before LPU modes entry, then don't access these registers in LPU modes as it would generate exception.

77.1.2 Clock Monitor Unit (CMU) protected registers

The following table lists the Clock Monitor Unit (CMU) module registers that can be protected.

Table 77-2. Protected CMU registers

Register	Register size (bits)	Offset from module base address	Protected size (bits)
CMU_CSR	32	0h	8 (Byte 3)
CMU_HFREFR	32	8h	16 (Bytes 2 and 3)
CMU_LFREFR	32	Ch	16 (Bytes 2 and 3)

77.2 Overview

The Register Protection (REG_PROT) module offers a mechanism to protect defined memory-mapped address locations in a module under protection from being written. The address locations that can be protected are module-specific.

The protection module is located between the module under protection and the peripheral bridge (PBRIDGE/AIPS-Lite). This is shown in the following figure.

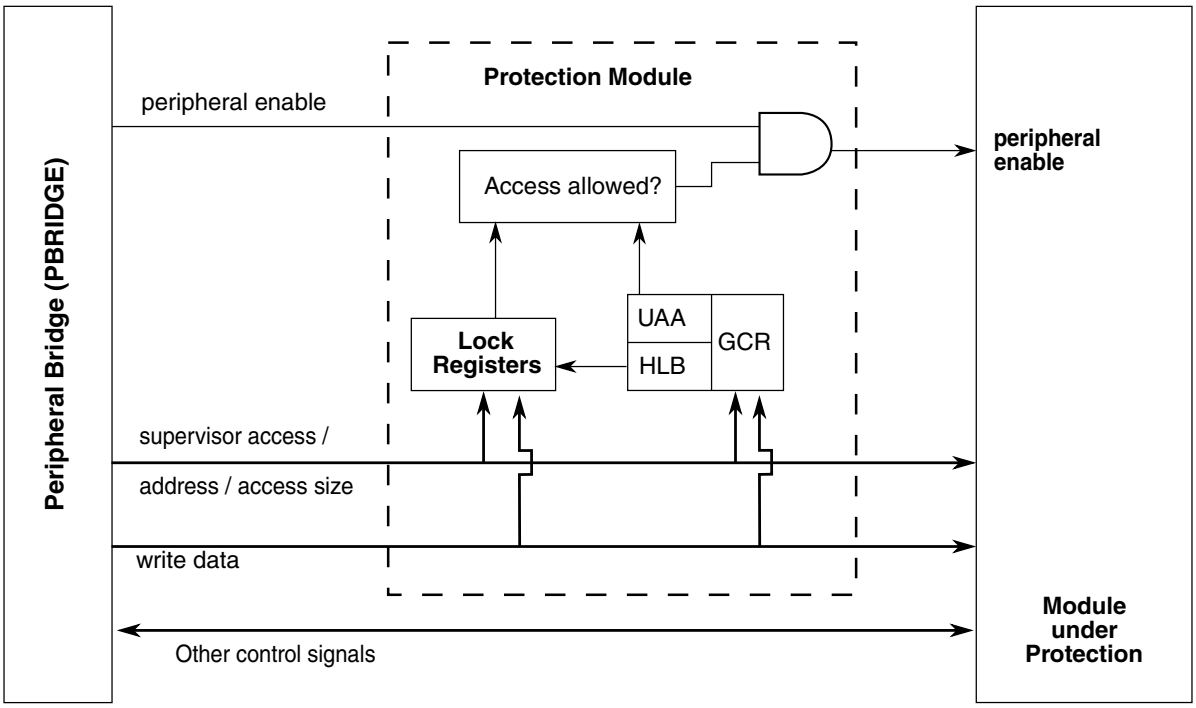

Figure 77-1. REG_PROT Block Diagram

77.3 Features

Register Protection includes these distinctive features:

- Restrict write accesses for the module under protection to supervisor mode only
- Lock registers for first 6 KB of memory-mapped address space
- Write to address mirror automatically sets corresponding lock bit
- Once configured lock bits can be protected from changes

77.4 Modes of operation

The Register Protection module is operable when the module under protection is operable.

77.5 External signal description

There are no external signals.

77.6 Memory map and register definition

This section provides a detailed description of the memory map of a module with register protection. The original 16 KB module memory space is divided into five areas as shown in the following figure.

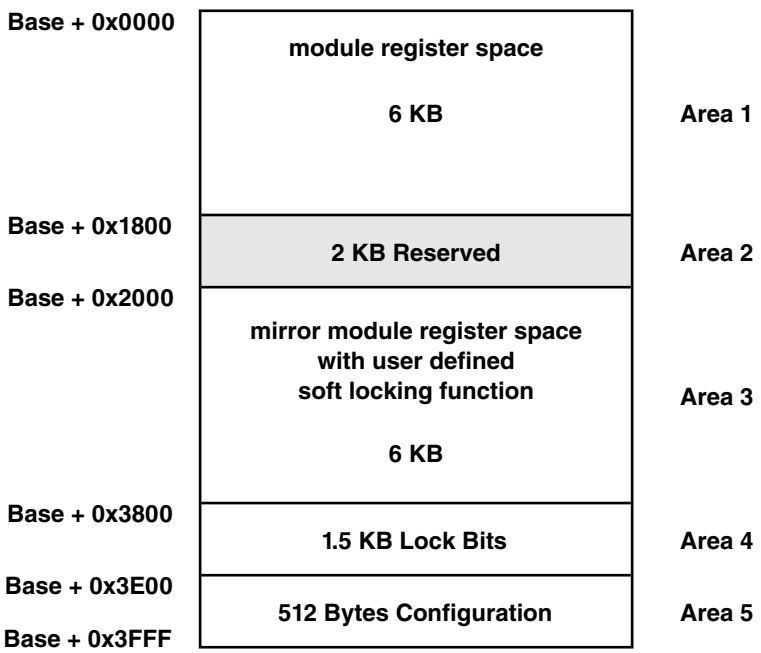

Figure 77-2. REG_PROT Memory Diagram

- Area 1 is 6 KB and holds the normal functional module registers and is transparent for all read/write operations.
- Area 2 is 2 KB starting at offset 0x1800 is a reserved area, which shall not be accessed.
- Area 3 is 6 KB, starting at offset 0x2000 and is a mirror of area 1. A read/write access to an offset 0x2000+X will read/write the register at offset X. However a write access to offset 0x2000+X will additionally set the optional Soft Lock Bits for this offset X in the same cycle as the register at offset X is written. This provides for an automatic write and lock operation. Not all registers in area 1 need to have protection defined by associated Soft Lock Bits. For unprotected registers at offset Y, accesses to offset 0x2000+Y will be identical to accesses at offset Y.

- Area 4 is 1.5 KB and holds the Soft Lock Bits, one bit per byte in area 1. The four Soft Lock Bits associated with one module register word are arranged at byte boundaries in the memory map. The Soft Lock Bit registers can be directly written using a bit mask.
- Area 5 is 512 bytes large and holds the configuration bits of the protection mode. There is one configuration hard lock bit per module that prevents all further modifications to the Soft Lock Bits and can only be cleared by a system reset once set. The other bits, if set, will allow user access to the protected module.

If any locked byte is accessed with a write transaction, a transfer error will be issued to the system and the write transaction will not be executed. This is true even if not all accessed bytes are locked.

Accessing unimplemented 32-bit registers in Areas 4 and 5 will result in a transfer error.

77.6.1 Memory map

Following is the memory map for a module which is protected via a REG_PROT module.

Table 77-13. Generic Protected Module Memory Map

Offset	Use
0x0000	Module Register 0 (MR0)
0x0001	Module Register 1 (MR1)
0x0002	Module Register 2 (MR2)
0x0003 - 0x17FF	Module Register 3 (MR3) - Module Register 6143(MR6143)
0x1800 - 0x1FFF	Reserved
0x2000	Module Register 0 (MR0) + Set Soft Lock Bit 0 (LMR0)
0x2001	Module Register 1 (MR1) + Set Soft Lock Bit 1 (LMR1)
0x2002 - 0x37FF	Module Register 2 (MR2) + Set Soft Lock Bit 2 (LMR2) - Module Register 6143 (MR6143) + Set Soft Lock Bit 6143 (LMR6143)
0x3800	Soft Lock Bit Register 0 (SLBR0): Soft Lock Bits 0-3
0x3801	Soft Lock Bit Register 1 (SLBR1): Soft Lock Bits 4-7
0x3802 - 0x3DFF	Soft Lock Bit Register 2 (SLBR2): Soft Lock Bits 8-11 -Soft Lock Bit Register 1535 (SLBR1535): Soft Lock Bits 6140-6143
0x3E00 - 0x3FFB	Reserved
0x3FFC	Global Configuration Register (GCR)

Note

Reserved registers in area #1 will be handled as specified in the protected module's documentation.

77.6.2 Register descriptions

This section describes in address order all the REG_PROT registers. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

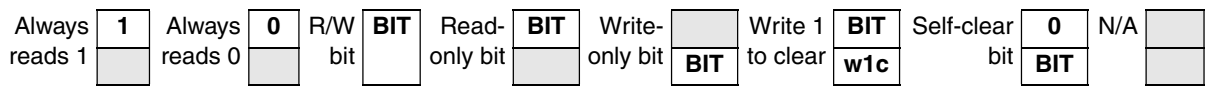

Figure 77-3. Register description

77.6.2.1 Module Registers (MR0-6143)

This is the lower 6 KB module memory space which holds all the functional registers of the module that is protected by the REG_PROT module.

77.6.2.2 Module register and set soft lock bit (LMR0-6143)

This is memory area #3 that provides mirrored access to the MR0-6143 registers with the side effect of setting Soft Lock Bits in case of a write access to a MR that is defined as protectable by the locking mechanism. Each MR is protectable by one associated bit in a SLBRn.SLBm, according to the mapping described in the Soft Lock Bit Register section.

77.7 Memory map and registers

REG_PROT memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3800	Soft Lock Bit Register n (REG_PROT_SLBRn)	8	R/W	00h	77.7.1/3296
3FFC	Global Configuration Register (REG_PROT_GCR)	32	R/W	0000_0000h	77.7.2/3298

77.7.1 Soft Lock Bit Register *n* (REG_PROT_SLBRn)

The Soft Lock Bit Registers hold the Soft Lock Bits for the protected registers in memory area #1, which is the normal register address space of the protected module. Each SLB register has a four Soft Lock Bits (SLB0-SLB3), each of which controls write access to a byte in memory area #1. Each Soft Lock Bit also has a corresponding Write Enable bit in the same register that controls whether the Soft Lock Bit can be written. The following table shows the mapping between the Soft Lock Bits to the bytes in memory area #1.

Table 77-14. Soft Lock Bits vs. Protected Address

Soft Lock Bit	Protected address
SLBR0.SLB0	MR0
SLBR0.SLB1	MR1
SLBR0.SLB2	MR2
SLBR0.SLB3	MR3
SLBR1.SLB0	MR4
SLBR1.SLB1	MR5
SLBR1.SLB2	MR6
SLBR1.SLB3	MR7
SLBR2.SLB0	MR8
...	...

NOTE

- As many as 1536 Soft Lock Bit Registers (SLBRn) may be implemented, depending on the number of protected module register bytes.
- Access in User Mode is read-only; in Supervisor Mode access is read/write.

Address: 0h base + 3800h offset = 3800h

Bit	0	1	2	3	4	5	6	7
Read	0	0	0	0	SLB0	SLB1	SLB2	SLB3
Write	WE0	WE1	WE2	WE3				
Reset	0	0	0	0	0	0	0	0

REG_PROT_SLBRn field descriptions

Field	Description

3 WE3	Write Enable Bits for Soft Lock Bits (SLB) WE3 enables writing to SLB3 1 Value is written to SLB 0 SLB is not modified
4 SLB0	Soft Lock Bits for one MRn register SLB0 can block accesses to MR[n *4 + 0] 1 Associated MRn byte is locked against write accesses 0 Associated MRn byte is unprotected and writable
5 SLB1	Soft Lock Bits for one MRn register SLB1 can block accesses to MR[n *4 + 1] 1 Associated MRn byte is locked against write accesses 0 Associated MRn byte is unprotected and writable
6 SLB2	Soft Lock Bits for one MRn register SLB2 can block accesses to MR[n *4 + 2] 1 Associated MRn byte is locked against write accesses 0 Associated MRn byte is unprotected and writable
7 SLB3	Soft Lock Bits for one MRn register SLB3 can block accesses to MR[n *4 + 3] 1 Associated MRn byte is locked against write accesses 0 Associated MRn byte is unprotected and writable

77.7.2 Global Configuration Register (REG_PROT_GCR)

Address: 0h base + 3FFCh offset = 3FFCh

REG_PROT_GCR field descriptions

Field	Description
0 HLB	Hard Lock Bit This register cannot be cleared once it is set by software. It can only be cleared by a system reset. **NOTE:** Access in User Mode is read/write if UAA is set to 1 otherwise it is read-only; in Supervisor Mode access is read/write. 1 All SLB bits are write protected and can not be modified. 0 All SLB bits are accessible and can be modified.
1–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 UAA	User Access Allowed. Controls the User and Supervisor mode access to registers of the module under protection, as well as the REG_PROT_GCR and REG_PROT_SLBR*n*. 1 The registers in the module under protection can be accessed in the mode defined for the module registers without any additional restrictions. 0 The registers in the module under protection can be written in supervisor mode only. All write accesses in non-supervisor mode are not executed and a transfer error is issued. This access restriction is in addition to any access restrictions imposed by the protected IP module.
9–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

77.8 Functional description

The following sections describe the functional characteristics of the Register Protection module.

77.8.1 General

This module provides a generic register (address) write-protection mechanism. The protection size can be:

- 32-bit (address == multiples of 4)
- 16-bit (address == multiples of 2)
- 8-bit (address == multiples of 1)

Which addresses are protected and the protection size depends on the SoC and/or module.

For all addresses (peripheral registers) that are protected there are SLBRn.SLBm bits that specify whether the address is locked. When an address is locked it can only be read but not written in any mode (supervisor/normal). If an address is unprotected the corresponding SLBRn.SLBm bit is always 0b0 no matter what software is writing to.

77.8.2 Change lock settings

To change the setting whether an address is locked or unlocked the corresponding SLBRn.SLBm bit needs to be changed. This can be done using the following methods:

- Modify the SLBRn.SLBm directly by writing to area #4
- Set the SLBRn.SLBm bit(s) by writing to the mirror module space (area #3)

Both methods are explained in the following sections.

77.8.2.1 Change lock settings directly via Area #4

In memory area #4 the lock bits are located. They can be modified by writing to them. Each SLBRn.SLBm bit has a mask bit SLBRn.WEm which protects it from being modified. This masking makes clear-modify-write operations unnecessary.

The following figure shows two modification examples. In the left example there is a write access to the SLBRn register specifying a mask value which allows modification of all SLBRn.SLBm bits. The example on the right specifies a mask which only allows modification of the bits SLBRn.SLB[3:1].

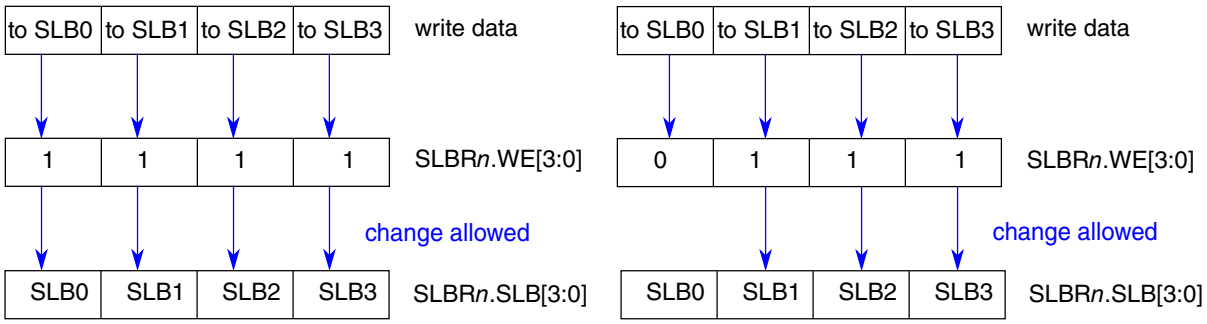

Figure 77-4. Change lock settings directly via Area #4

The previous figure shows four registers that can be protected 8-bit wise. The following figures show registers with 16- and 32-bit protection respectively:

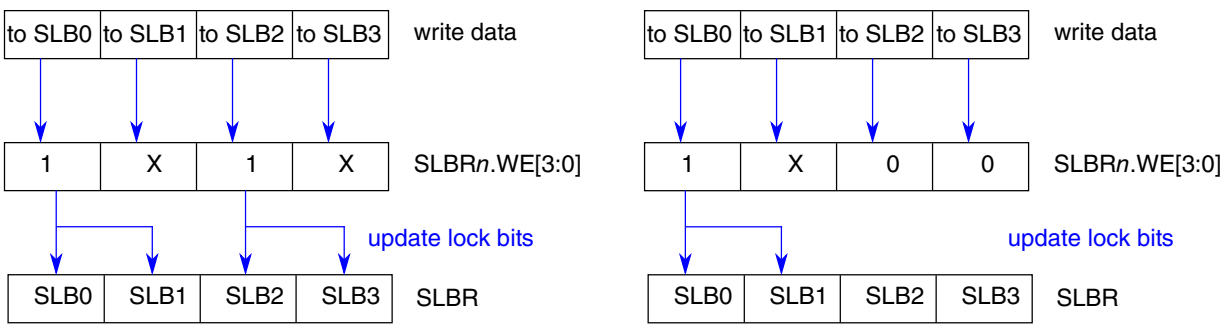

Figure 77-5. Change lock settings for 16-bit protected addresses

On the right side of the previous figure it is shown that the data written to SLBRn.SLB[0] is automatically written to SLBRn.SLB[1] also. This is done as the address reflected by SLBRn.SLB[0] is protected 16-bit wise. Note that in this case the write enable SLBRn.WE[0] must be set while SLBRn.WE[1] does not matter. As the enable bits SLBRn.WE[3:2] are cleared the lock bits SLBRn.SLB[3:2] remain unchanged.

In the example on the left side of the previous figure the data written to SLBRn.SLB[0] is mirrored to SLBRn.SLB[1] and the data written to SLBRn.SLB[2] is mirrored to SLBRn.SLB[3] as for both registers the write enables are set.

The next figure shows a 32-bit wise protected register. When SLBRn.WE[0] is set the data written to SLBRn.SLB[0] is automatically written to SLBRn.SLB[3:1] also. Otherwise SLBRn.SLB[3:0] remains unchanged.

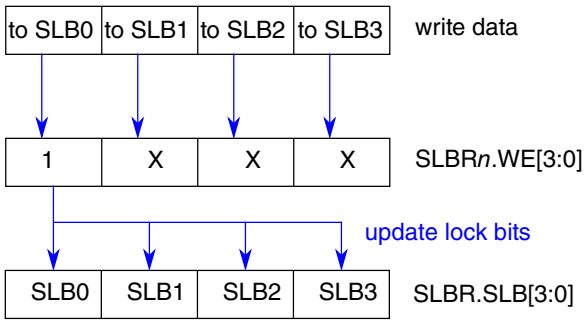

Figure 77-6. Change lock settings for 32-bit protected addresses

The following figure shows a mixed protection size configuration:

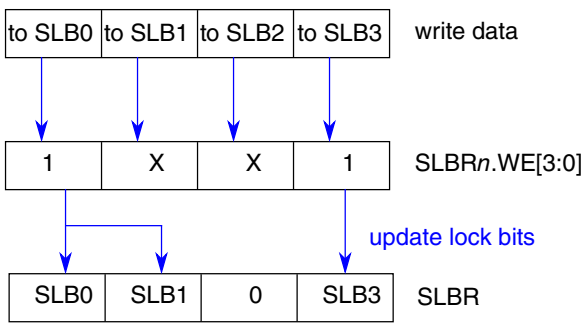

Figure 77-7. Change lock settings for mixed protection

The data written to SLBRn.SLB[0] is mirrored to SLBRn.SLB[1] as the corresponding register is 16-bit protected. The data written to SLBRn.SLB[2] is blocked as the corresponding register is unprotected. The data written to SLBRn.SLB[3] is written to SLBRn.SLB[3].

77.8.2.2 Enable locking via mirror module space (Area #3)

It is possible to enable locking for a register after writing to it. To do so the mirrored module address space must be used. For example:

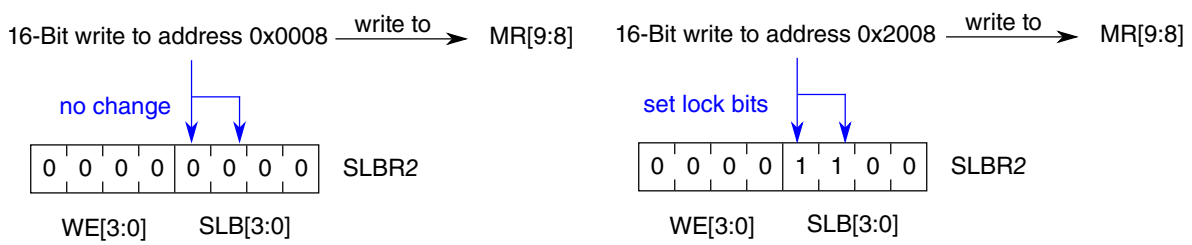

Figure 77-8. Enable Locking Via Mirror Module Space (Area #3)

When writing to address 0x0008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits remain unchanged (see the left part of Figure 77-5).

When writing to address 0x2008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits SLBR2.SLB[1:0] are set while the lock bits SLBR2.SLB[3:2] remain unchanged (right part of Figure 77-5).

The following figure shows an example where some addresses are protected and some are not:

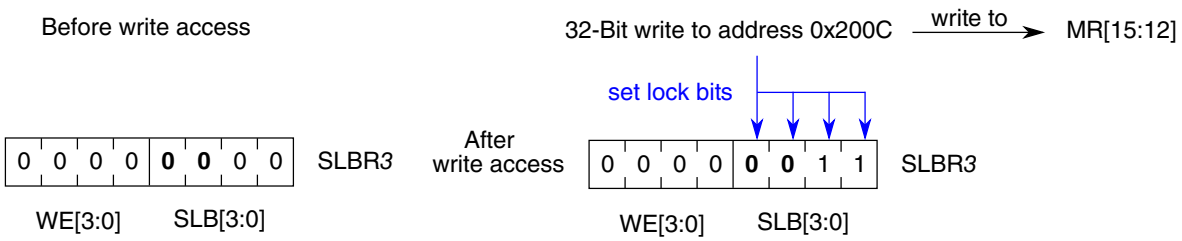

Figure 77-9. Enable locking for protected and unprotected addresses

In the previous figure addresses 0x0C and 0x0D are unprotected. Therefore their corresponding lock bits SLBR3.SLB[1:0] are always 0b0 (shown in bold). When doing a 32-bit write access to address 0x200C only lock bits SLBR3.SLB[3:2] are set while bits SLBR3.SLB[1:0] stay 0b0.

Note

Lock bits can only be set via writes to the mirror module space. Reads from the mirror module space will not change the lock bits.

77.8.2.3 Write protection for locking bits

Changing the locking bits through any of the procedures mentioned in Change lock settings directly via Area #4 and Enable locking via mirror module space (Area #3) is only possible as long as the bit GCR.HLB is cleared. Once this bit is set the locking bits can no longer be modified until there is a system reset.

77.8.3 Access errors

The protection module generates transfer errors under several circumstances. For the area definition refer to Figure 77-2

1. If accessing area #1 or area #3, the protection module will pass on any access error from the underlying Module under Protection.
2. If user mode is not allowed, user writes to all areas will assert a transfer error and the writes will be blocked.

3. If accessing the reserved area #2, a transfer error will be asserted.
4. If accessing unimplemented 32-bit registers in area #4 and area #5 a transfer error will be asserted.
5. If writing to a register in area #1 and area #3 with Soft Lock Bit set for any of the affected bytes a transfer error is asserted and the write will be blocked. Also the complete write operation to non-protected bytes in this word is ignored.
6. If writing to a Soft Lock Register in area #4 with the Hard Lock Bit being set a transfer error is asserted.
7. Any write operation in any access mode to area #3 while Hard Lock Bit GCR.HLB is set

Chapter 78
Password and Device Security Module (PASS)

78.1 Chip-specific PASS information

78.1.1 Password and Device Security Module (PASS) configuration

The PASS module is used to implement password-based read and write protection for flash blocks. Up to four levels of password protection can be implemented for each flash block.

NOTE

The registers discussed in this section are initialized via DCF records, so the reset values depend on user settings.

CAUTION

Do not access address offset 0x00D0 . This is for internal use only.

Each password group defined in the DCF records has a set of four LOCK*n* registers association with it—PASS_LOCK*n*_PG*n*. The bits of these registers are associated with specific flash blocks. The mapping is shown in the following sections.

78.1.1.1 PASS_LOCK0_PGn register bit mapping

Table 78-1. Debug Interface Enable Truth Table (continued)

Input Conditions				Outcome
Lifecycle	**Censorship**	**Debug Enable (LOCK3[DBL] bit)**	**JTAG Password**	**Debug Interface Enable**
	Censored	Unlocked (DBL=0)	Don't Care	Enabled
		Locked (DBL=1)	Matched	Enabled
			Not Matched	Blocked
Failure Analysis	Don't Care	Don't Care	Don't Care	Enabled

NOTE

User should keep external reset asserted to make the core enter debug mode from first instruction after JTAG Password Challenge.

78.1.1.6 Flash Test Mode protection

In Failure Analysis Lifecycle, Flash Test Mode entry is protected by combination of below two inputs.

1. DCF_FTMP (See)
2. TEST MODE ENABLE_DCF_CLIENT

Table 78-2. Flash Test Mode protection

DCF_FTMP	TEST MODE ENABLE DCF CLIENT	Flash TEST MODE ACCESS
0	Don't care	YES (NO Test mode enable PASSWORD REQUIRED)
1	0	Test Mode not enabled.
1	1	YES (Test mode enable PASSWORD REQUIRED)

78.2 Introduction

78.2.1 Overview

The Password and device security (PASS) module shown in the following figure, receives password challenges and determines their validity. It also maintains the device security and access states.

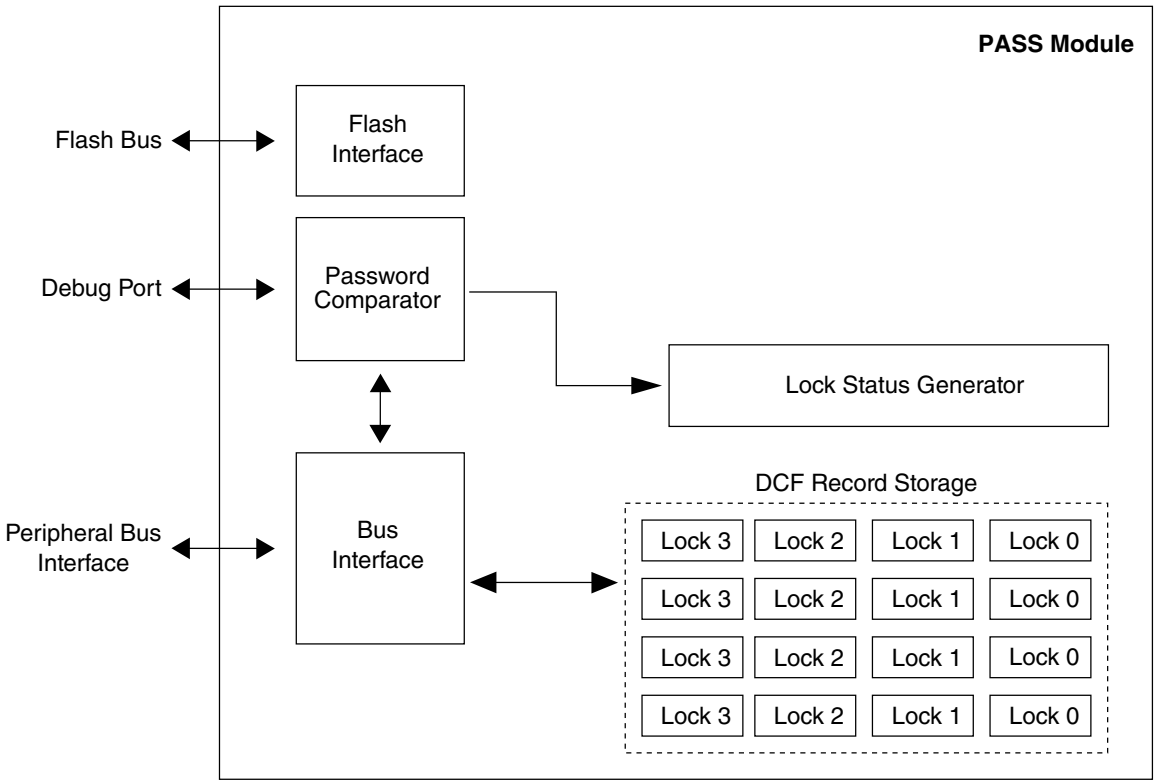

Figure 78-1. PASS module block diagram

78.2.2 Features

The PASS includes these distinctive features:

- Life Cycle status
- Password comparison
- JTAG password comparison
- Test mode enable Configuration and Password Comparison
- Flash read, write, and erase control

78.2.3 Modes of operation

The PASS operates identically in all system modes.

78.3 Memory map and register definition

This section provides a detailed description of all memory-mapped registers and DCF clients in the PASS.

Where a DCF client is listed, the reset value of that register may automatically be pre-loaded during reset based on the data stored in DCF Records in flash UTEST region.

The following table shows the memory map for the PASS. Note that all addresses are offsets; the absolute address for registers may be calculated by adding the specified offset to the base address of the PASS. The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section of the Reference Manual.

NOTE

Non-implemented registers generate bus aborts if enabled.

The following registers are available in the PASS. The shaded bits are reserved for future use. For future compatibility, only write '0' to these bits; they always read '0'.

PASS memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Life Cycle Status Register (PASS_LCSTAT)	32	R	See section	78.3.1/3313

78.3.1 Life Cycle Status Register (PASS_LCSTAT)

The Life Cycle Status Register reflects the production status and DCF Censorship client status of the device. It is possible to mature the device (move the device life cycle forward), but never to revert the life cycle to an earlier state.

The reset value of the LCSTAT register LIFE field derives from an external life cycle management module (like SSCM). It is a 3-bit life cycle. This register simply displays the life cycle input from external blocks.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	CNS	JUN	TME	0												
W																
Reset	*	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0													LIFE		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	*	*	*

* Notes:
- LIFE field: Reset value is the Life Cycle of the device, and is unaffected by reset.
- CNS field: Reset value depends on the Censorship DCF client

PASS_LCSTAT field descriptions

Field	Description
0 CNS	This field indicates whether the DCF Censorship client has been written with a DCF record to 0x55AA or if the DCF Censorship client contains any other value than 0x55AA. The bit can be set (or cleared) via DCF Record in UTest Flash. **NOTE:** If no DCF record has been written to affect the value of the CNS bit, its reset value will be 1. 1 DCF Censorship Client value is anything other than 0x55AA. 0 DCF Censorship client value is 0x55AA.
1 JUN	This field indicates whether the device has been temporarily uncensored. Successful transmission of the JTAG password sets this bit to '1', otherwise it will be 0. (In life cycle FA, the JUN bit will always be 0.) Unsuccessful transmission clears this bit.
2 TME	Test Mode enable. This field indicates whether the test mode DCF Client is set to enable test mode in FA. 0 Test mode cannot be enabled 1 Test mode can be enabled with test mode password
3–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 LIFE	The life cycle setting is manipulated externally (SSCM). Pass displays a 3-bit input life cycle 000 Failure Analysis 001 Reserved 010 OEM Production 011 Customer Delivery 100 Reserved 101 Reserved 110 MCU Production 111 In Field

78.3.2 Challenge Selector Register (PASS_CHSEL)

This register determines which password group is challenged via the Challenge Input Register.

When the Master Only (MO) bit of the PASS_LOCK3_PGn register is set, only the master that unlocked access to the passgroup settings will be able to access these registers. The CMST field of the Challenge Status Register will reflect the locking master. When the Master Only (MO) bit of the PASS_LOCK3_PGn register is not set, the passgroup settings can be accessed by any master.

When a master writes this register, its ID sets the CMST field of the Challenge Status register.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PASS_CHSEL field descriptions

Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 GRP	Password Group to unlock 00 Password Group 0 01 Password Group 1 10 Password Group 2 11 Password Group 3

78.3.3 Challenge Status Register (PASS_CSTAT)

This register provides status information for the password challenge.

Only the master shown in this register can access the CINn registers - access by other masters result in a comparison fail regardless of the values written.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PASS_CSTAT field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 CMST	ID of the master which has last written the CHSEL register

78.3.4 Challenge Input Register (PASS_CIN*n*)

This register is used to provide the Challenge word *n* for a password group as selected by the Challenge Selector Register.

After programming the Challenge Selector Register, the password challenge needs to be written with eight 32-bit writes from CIN0 to CIN7 in that order. The most significant 32 bits of the password challenge must be written to CIN0. Once CIN7 is written, the password is compared. The write access only completes after the comparison has been executed. In case of a successful password comparison, the PASS module stores the ID of the master which has written CIN0 to CIN7 in the PASS_LOCK3_PGn register of the selected password group, as well as clears the PGL bit of that register.

All accesses to these registers need to be made by the bus master that wrote the CHSEL register previously. If another master writes any of the CIN registers before the original master has written CIN7, the comparison fails.

Address: 0h base + 20h offset + (4d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PASS_CIN*n* field descriptions

Field	Description
0–31 PW32	32 bits of the 256-bit password challenge. Only 32-bit writes may be used.

78.3.5 Password Group *n* - Lock 0 Status Register (PASS_LOCK0_PG*n*)

Each Password Group has one Lock 0 Status register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked the register becomes writable. For additional details of the LOCK bits, refer to the Flash memory description.

The LOCK bits do not come into effect before the life cycle has matured to *OEM Production* or older.

LOCK0_PG*n* register functions are as shown in this section.

NOTE

Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during functional reset. The default value before any DCF record is written is '1', indicating that a block is locked.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes to this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

Warning

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is OEM Production or older, the Flash blocks are always unlocked, regardless of the values in the password groups.

Address: 0h base + 100h offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*

* Notes:

- MIDLOCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to ‘1’.

- LOWLOCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to ‘1’.
- ATSL field: If no DCF records have been written to change the ATSL bit state, the bit will reset to ‘1’.
- TSLOCK field: If no DCF records have been written to change the TS bit state, the bit will reset to ‘1’.

PASS_LOCK0_PG*n* field descriptions

Field	Description
0 TSLOCK	UTest NVM Lock. This bit is used to lock the UTest NVM block from programs (erase protection not needed since UTest NVM is OTP and not erasable).
1 ATSL	Alternate Interface UTest NVM Lock. This bit is used to lock the UTest NVM block from programs on the alternate interface (erase protection not needed since UTest NVM is OTP and not erasable).
2–15 LOWLOCK	Low Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.
16–31 MIDLOCK	Mid Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

78.3.6 Password Group *n* - Lock 1 Status Register (PASS_LOCK1_PG*n*)

Each Password Group has one Lock 1 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable . For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the life cycle matures to OEM Production or older.

LOCK1_PG*n* register functions are as shown in this section.

NOTE

Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during functional reset . The default value before any DCF record is written is '1', which indicates a block is locked. If no DCF records have been written to change the lock state, the bits will reset to '1'.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group to prevent permanent and irreversible locking of Flash blocks.

CAUTION

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF

Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is older than OEM Production, the Flash blocks are always unlocked, regardless of the values in the password groups.

Address: 0h base + 104h offset + (16d × i), where i=0d to 3d

* Notes:
- HIGHLOCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to ‘1’.

PASS_LOCK1_PG*n* field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 HIGHLOCK	High Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

78.3.7 Password Group *n* - Lock 2 Status Register (PASS_LOCK2_PG*n*)

Each Password Group has one Lock 2 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable . For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the life cycle is matured to OEM Production or older.

NOTE

Lock registers can only be accessed with 32-bit operations.

LOCK2_PG*n* register functions are as shown in this section.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during functional reset. The default value before any DCF record is written is '1', which indicates a block is locked.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

Warning

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is older than OEM Production, the Flash blocks are always unlocked, regardless of the values in the password groups.

Address: 0h base + 108h offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:

- L_256LCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit resets to '1'.

PASS_LOCK2_PG*n* field descriptions

Field	Description
0–31 L_256LCK	Lower 256KByte Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

78.3.8 Password Group *n* - Lock 3 Status Register (PASS_LOCK3_PG*n*)

Each Password Group has one Lock 3 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable.

The LOCK bits do not come into effect before the life cycle matures to OEM Production or older.

LOCK3_PGn register functions are as shown in this section.

NOTE

Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during functional reset. The default value before any DCF record is written is '1', which indicates a block is locked.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

Warning

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is older than OEM Production, the Flash blocks are always unlocked, regardless of the values in the password groups.

Once a censored device enters the Failure Analysis life cycle, read protection is active regardless whether the system is in debug mode or not. It is still possible to unlock Flash regions with the correct passwords, however. Flash Utest region controlled by LOCK3[0] is read unlocked in Failure Analysis life cycle.

NOTE

Do not toggle DBL and RLx bits with the same write command. Use one instruction to program the DBL bit and a separate instruction to toggle the RLx bits.

Address: 0h base + 10Ch offset + (16d × i), where i=0d to 3d

* Notes:

- U_256LCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to '1'.
- RL0 field: If no DCF records have been written to change the RL0 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- RL1 field: If no DCF records have been written to change the RL1 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- RL2 field: If no DCF records have been written to change the RL2 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- RL3 field: If no DCF records have been written to change the RL3 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- RL4 field: If no DCF records have been written to change the RL4 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- MO field: If no DCF records have been written to change the MO bit lock state, the bit will reset to ‘1’.
- DBL field: If no DCF records have been written to change the DBL bit lock state, the bit will reset to ‘1’.
- PGL field: Reset value depends on life cycle. If life cycle is Customer Delivery or earlier, the value will be 0, otherwise 1.

PASS_LOCK3_PG*n* field descriptions

Field	Description
0 PGL	Password Group Lock. This bit may be set in software to lock the password group, when the device is older than Customer Delivery. Before that the value of the bit is always 0. This bit is only updatable from SW path. It cannot be updated from DCF load from Flash. This bit can be cleared by writing a valid password to the Password Challenge Input Registers. 0 Password group registers are unlocked. All four registers in the Password group may be read and written without restriction. 1 Password group registers are locked. Writes to the password group registers have no effect. Read accesses work normally. (If life cycle is Customer Delivery or earlier, this bit has no effect and the registers are always unlocked.)

Table continues on the next page...

PASS_LOCK3_PG*n* field descriptions (continued)

Field	Description
1 DBL	Debug Interface Lock. The default value of this bit would be '1' if not updated from flash. 0 Debug interface is unlocked. Accessed to all JTAG clients is allowed (Except HSM) 1 Debug interface is locked. Only access to JTAG password challenge register is possible. Access to all other JTAG clients is blocked
2 MO	Master Only. 0 All masters can modify the passgroup settings if PGL is cleared 1 Only the Master which unlocked the passgroup can change the passgroup settings
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 MSTR	Master Access. Only the Master with this matching master ID can change the passgroup settings. This field is loaded with the ID of the master which unlocked the passgroup once the correct password is provided.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 RL4	Read Lock Regison 4 lock bit. The default value of this bit would be '1' if not updated from flash. 0 Region 4 is not protected. 1 Region 4 is protected.
12 RL3	Region 3 is protected. The default value of this bit would be '1' if not updated from flash. 0 Region 3 is not protected. 1 Region 3 is protected.
13 RL2	Region 2 is protected. The default value of this bit would be '1' if not updated from flash. 0 Region 2 is not protected. 1 Region 2 is protected.
14 RL1	Region 1 is protected. The default value of this bit would be '1' if not updated from flash. 0 Region 1 is not protected. 1 Region 1 is protected.
15 RL0	Region 0 is protected. The default value of this bit would be '1' if not updated from flash. 0 Region 0 is not protected. 1 Region 0 is protected.
16–31 U_256LCK	Upper 256 KB Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

78.4 DCF clients

The following table shows the DCF clients for the PASS.

Where a DCF client is listed, the reset value of that register may automatically be pre-loaded during reset based on the data stored in DCF Records in Flash UTEST region.

The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section of the Reference Manual or in DCF sheet attached to this document.

Table 78-3. PASS DCF clients

Offset	Register	Access	Reset Value	DCF Client Address (ADDR[14:0])	Section
Censorship					
None	Censorship	None	0x0000_0000	0x00B0	Censorship
Test mode enable					
None	Test mode enable	None	0x0000_0001	0x00E0	Test mode enable DCF Client

78.4.1 Censorship

Censorship is a DCF client that is *not* accessible by software. It is automatically pre-loaded during reset with data stored in DCF Record format in the Flash UTEST region.

78.4.2 Test mode enable DCF Client

This DCF client is used to configure the password protected Test mode enable feature. See Test mode enable for details.

The Test mode DCF Client is not directly readable in software, but the state of the Test mode bit can be read in the LCSTAT register (Life Cycle Status Register (PASS_LCSTAT)).

DCF Client Address: 0x00E0 Test Mode Enable — Access:DCF Record Read Once Only

78.5 Functional description

The primary purpose of the PASS is to provide fine-grained access control to the Flash and debugger interface. It utilizes the DCF mechanism, as described in the SSCM section.

78.5.1 Censorship

Censorship is the overall control that enables and disables two independent security features: Debug Interface access and flash memory read protection.

The Debug Interface access is controlled by the CNS and LIFE bits of the LCSTAT register (Life Cycle Status Register (PASS_LCSTAT)) according to the Debug Interface Access truth table. The flash memory read protection is also controlled by the CNS and LIFE bits of the LCSTAT register according to the Flash memory read protection truth table.

The CNS bit is set or cleared by executing a DCF record that writes to the Censorship DCF client (See Censorship). The LIFE bits of the LCSTAT register are controlled by the SSCM using user programmed values from specific locations in the UTEST flash.

78.5.2 Debug Interface Access

The debug interface is fully enabled in Customer Delivery life cycle. But from OEM Production life cycle, it can be blocked using censorship and unlocked by either entering a 256 bits password via JTAG or by software clearing the DBL bit the PASS_LOCK3 registers (See Password Group *n* - Lock 3 Status Register (PASS_LOCK3_PG*n*)). Both these debug enabling options are further conditioned by life cycle.

The debug interface enable truth table for this chip is shown in the device specific PASS section of this chapter.

78.5.2.1 JTAG Password Challenge

To enable the Debug Interface Access, the JTAG password challenge register in the JTAGC, can be written by an external tool. If that password matches the JTAG password stored in UTEST flash, Debug Interface Access is enabled. The password matching is done only after the chip has come out of reset PHASE3. The Debug Interface Access stays enabled until the next destructive reset.

78.5.3 Flash Memory Read Protection

Flash Memory Read Protection is a security feature that can selectively make regions of the flash memory unreadable. Any attempt to read a region of flash that is read protected results in the read access terminating with a transfer error. This is consistent for all bus masters including debug bus masters.

The assertion of flash memory region read protection is controlled by Life Cycle, Censorship and whether the Debug Interface access is enabled or blocked. The Flash memory read protection truth table describes the combination of conditions that drive Flash Memory Read Protection.

The intention of the feature is to protect the contents of the flash from being read. The flash memory is readable in normal operation, allowing the application to run, but becomes read protected when a Debug tool is attached and enabled (JTAG password or LOCK3[DBL] bit).

The flash memory is also read protected when the life cycle status is Failure Analysis. This life cycle is used for a module field failure, where the device is returned for failure analysis. This protection prevents the contents of the flash memory from being read.

The flash memory is divided into a number of Regions (3 to 5 depending on the device). The assignment of the regions is defined in the device reference manual.

Table 78-5. Flash Memory Read Protection Truth Table

INPUTS				OUTPUTS

	Censored	Don't Care	Locked (1)	Readable	Read Blocked
			Unlocked (0)	Readable	Readable

78.5.4 Flash Memory Write and Erase Protection

This section describes write and erase permissions for flash memory. From Power ON to SSCM Done, all regions of flash memory are in locked state. After Power ON, SSCM scans flash memory for valid DCF records. These DCF records carry program and erase protection settings for flash memory regions. SSCM module finds the settings and load them into PASS configuration via the DCF path. Once SSCM Done is asserted, the new configuration loaded by SSCM into PASS come into force and unlocks different regions of flash for program and erase.

To enable write and erase access of a particular region of flash memory, add corresponding DCF records in the flash memory once chip comes out of reset (i.e. SSCM Done). User can also change the settings by providing valid password to the PASS module, and by modifying the settings of following registers bits fields:

- PASS_LOCK0_PGn[MIDLOCK]
- PASS_LOCK0_PGn[LOWLOCK]
- PASS_LOCK1_PGn[HIGHLOCK]
- PASS_LOCK2_PGn[L_256LCK]
- PASS_LOCK3_PGn[U_256LCK]

See chip-specific PASS information for mapping of the above mentioned bits fields.

In the PASS module there is no individual access protection for Write or Erase access types, but Write and Erase accesses summated.

78.5.5 Test mode enable

Test mode can be used for testing different features of Flash and internal blocks. These features can be used in Failure analysis life cycle. Following are the guidelines for customers:

- During customer assembly, customer programmes DCF Record in UTEST to write test mode DCF client with 1.
- During customer assembly, the customer programmes the test mode enable Password into Flash
- The customer maintains a system for retrieving these passwords for the life of the module
- If the part is returned to JDP for FA, the customer must provide the test mode enable password that was originally programmed into the device.
- If the password is lost or irretrievable, the customer must accept that FA cannot be done.

NOTE

Usage of this case causes restrictions on failure analysis.

78.5.6 Test mode enable password

The Test mode enable password is a password entered by the manufacturer via JTAG interface, during device FA, to gain access to Flash Test Mode. Flash Test Mode is required to perform Vt Distribution analysis and other tests on an MCU. This password is only functional during FA life cycle. During other life cycles, Flash Test Mode is either available; completely blocked; or requires the Retest Password. Flash blocks that are assigned as sealed during production are locked against any form of Flash test, including reading, erasing and Vt Distribution analysis.

78.5.6.1 Test mode enable password generation

The Test mode enable password is created by the customer during their module assembly process. It must be programmed into UTEST Flash while in Customer Delivery life cycle.

When an MCU is returned to manufacturer for FA, it must be in FA life cycle and the password must also be provided to the manufacturer to allow access to Flash Test Mode. Therefore the customer should develop a process for managing Test mode enable passwords for the life of the module.

78.5.6.2 Test mode enable password storage

The test mode enable password is 224 bits (28 bytes) wide and is to be stored in UTEST Flash at a fixed location. See the device reference manual for the address of the test mode password.

The password region of UTEST Flash is readable only when in Customer Delivery life cycle. In any life cycle after this (including FA life cycle), this region is read protected.

78.5.6.3 Test mode enable password Challenge entry

The Test mode enable password challenge in entered by an external tool to the password register in JTAGC

As the Test mode enable password is 224 bits; and the JTAGC password register is 256, only the least significant 224 bits of the register are used.

78.5.6.4 Test mode enable password compare

The Test mode password challenged, is compared against the password stored in UTEST Flash. Only the least significant 224 bits are compared as the most significant 32 bits of the Flash page contain different data not related to Test mode enable.

If the password matches, Flash Test Mode access is allowed until the next POR reset.

There are no passwords that the hardware will detect as illegal. All 0 and all 1 are valid passwords.

78.6 Initialization/application information

78.6.1 Reset

The reset state of each individual bit is shown within the Register Description section. However, many bits receive their values based on DCF records stored in the UTEST Flash memory block.

78.6.2 Setting lock bits in a password group

There is no restriction on setting and clearing lock registers in the UTEST Flash, apart from the available space for DCF records. It is possible to set and clear them multiple times.

Table 78-6. CS/ADDR Values for Lock Registers

Register	DCF Command Word
PW Group 0	
Lock0	0xxxxx[1] _0100
Lock1	0xxxxx[1] _0104

0x14	0xFFFF_FFFF	
…	…	

Chapter 79
Tamper Detect Module (TDM)

79.1 Chip-specific TDM information

79.1.1 Tamper Detection Module (TDM) configuration

The Tamper Detection Module provides a type of flash memory write protection mechanism that forces software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. An additional feature is provided to enable customers to override the protection mechanism for any TDR so that no record is required to be written before a block within the TDR can be erased.

Additionally, the TDM provides a mechanism for configuring individual flash memory blocks as One Time Programmable (OTP), i.e., write once, blocks.

The following sections provide details on the TDM configuration registers and DCF clients.

NOTE

The TDM configuration registers detailed in this section are DCF clients. In general, DCF clients can only be written once —their intended values must be carefully selected beforehand.

79.1.2 Diary Base Address (DBA) DCF client

DBA DCF client holds the base address of the diary, which is the region of flash that contains records corresponding to erase operations.

79.1.3 Tamper Region Override (TO) DCF client

Tamper detection can be overridden by writing to enable bits (one per region) in the Tamper Region Override (TO) DCF client. The mapping is shown below.

DCF Client Address: 0x0001 Access: DCF write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	TOE5	TOE4	TOE3	TOE2	TOE1	TOE0
W																																
Default	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The mapping of the Tamper Region Override Enable (TOEn) DCF client is as follows:

Table 79-1. TOEn field mapping

Field	TDR
TOE0	0
TOE1	1
TOE2	2
TOE3	3
TOE4	4
TOE5	5

79.1.4 OTPEN*n* DCF clients

Configuring individual flash blocks as OTP blocks is accomplished by setting the appropriate values in the TDM_OTPENn DCF clients. Each mapped bit is associated with a specific flash block. A “1” bit value indicates a block is OTP.

The mappings are shown in the attached TDR and OTP LOCK Register excel .

79.1.5 TDRx_LOCKn DCF clients

Configuration of the 6 tamper regions is accomplished by setting field values in LOCK DCF clients (4 for each TDR).

Each set of 4 LOCKn DCF clients acts as a map of the MCU's flash memory blocks. A "1" in a LOCKn bit indicates that software must write a record before the corresponding block can be modified. The mapping of TDM_LOCKn DCF client bits to flash blocks is identical to the OTPENn mapping as shown in the sections above.

Any available flash block can be mapped to any tamper protection region.

79.1.6 TDM register reset value

All register reset values for the TDM registers that are device specific are shown below. All other registers reset values are shown in the TDM Memory chapter.

TDR Status Register (TDM_TDRSR) resets to 0x0000_ 003Fh.

79.2 Overview

The Tamper Detection Module provides a type of flash memory erase protection mechanism that requires software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. The mechanism does not *prohibit* an erase operation on any block within a TDR—it requires a record to be written before the operation can execute. Collectively, the records are referred to as a "diary". At minimum, the diary serves as an erase counter. Because the diary record content is customer-defined, the diary can also serve as a history.

Up to 6 TDRs can be defined via DCF records.

The following figure shows the block diagram of the TDM and its interface to other system components.

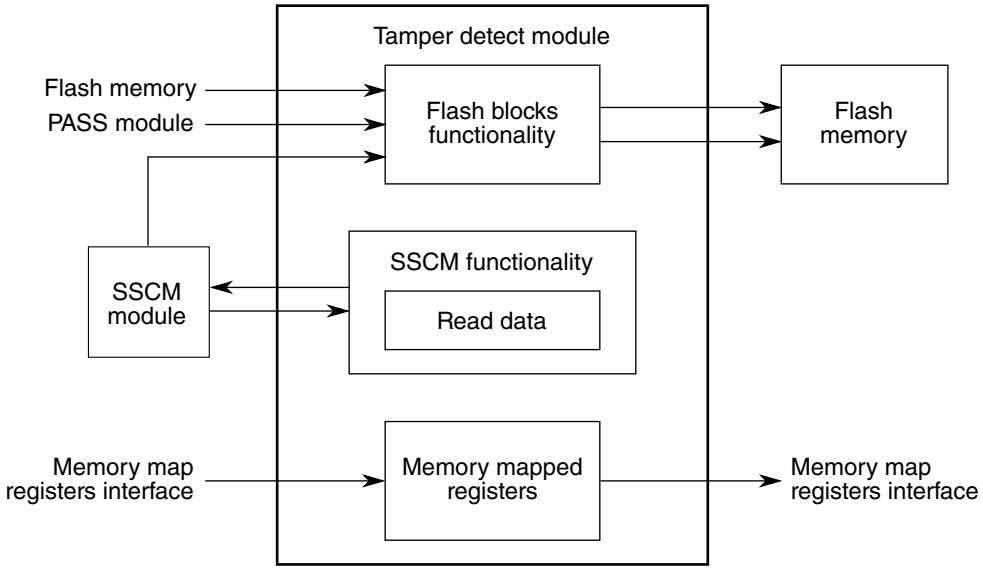

Figure 79-1. Tamper Detection Module block diagram

Security information is passed to the TDM by the SSCM module via the DCF bus. Among the data are:

- OTP (One Time Programmable) settings for each of the flash blocks
- Base address for the diary in the flash
- Block assignments for the TDRs
- Tamper region override information
- Software tamper region disable

The TDM module controls the flash blocks for erase operations and sets them as OTP.

The two flash buses are used to control the flash blocks for erase operation and set them as OTP. OTP means that flash erase of the entire block is disabled and the only words that are already erased can be programmed. Over-programming is not possible.

NOTE

The pass module provides the control for erase operation for each flash block as well as for each region of flash memory, and the PASS settings have priority over the settings of TDM.

The flash block indicates to the TDM the address of the programmed word. This address is internally decoded and provides a means to verify whether the block is part of any TDRs. The memory map registers interface provides a means to the user to read information of the TDM registers.

79.3 Features

The Tamper Detection Module supports these distinctive features:

- Erase counter (diary) for each TDR to record up to 256 write attempts on the flash blocks
  - The diary is divided into 6 parts (TDRs), each consisting of 256 64-bit records.
  - The diary block should be assigned as OTP region in flash.
  - The diary area can store any type of relevant information.
- Tamper Detection Region Block Assignment
  - Any flash block can be assigned to any TDR and be controlled.
- 32-bit Erase Lock DCF clients for each flash memory TDR defined.
- 32-bit OTP Enable DCF clients to disable the erase operation for an entire flash block
- Override TDR via DCF records[1]
  - Allows block assigned to a TDR to be unlocked for erase even if the TDR is locked for this operation.
- Memory mapped registers interface for reading via software of specific registers.

79.4 External signal description

There are no external signals driving or being driven by the TDM.

79.5 DCF clients

TDM-related DCF records perform the following functions:

- Establish a permanent diary base address
- Define Tamper Detect Regions (TDRs) to monitor on-chip flash memory program/ erase activity
- Permanently disable one or more Tamper Regions
- Configure flash memory as One Time Programmable (OTP) on a per-block basis

The following table gives an overview on the TDM DCF clients implemented.

1. The Tamper Region Override DCF record is a "write one only" DCF record. If an override is applied to a TDR it is permanent and cannot be reversed.

Table 79-2. DCF clients

DCF Client Name	Description	Strategy
Diary Base Address	Stores the base address of the tamper detection diary	write once, write 1 to 0 only
Tamper Region Override	Stores information of which TDR is to be overridden	write 0 to 1 only
Software Tamper Region Override Disable	Stores information to disable the software mechanism to override the TDR	write once, write 0 to 1 only
OTPEN[nb] (OTP Enable)	Stores information of which flash blocks is to be assigned as OTP (One Time Programmable) - nb means one register for each Lock register of the flash memory	write 0 to 1 only
TDR[n]_LOCK[m] Region Assignment	Stores information of which flash block is assigned to a TDR. • n specifies a TDR • m specifies the flash blocks as per the LOCK registers of the flash memory.	write once, write 0 to 1 only

79.5.1 Diary Base Address (DBA) DCF client

This DCF client holds base address information of the diary. The following diagram depicts this client.

CAUTION

This write-once DCF client can be written only one time. After one DCF record has written to this client, all subsequent writes are ignored.

DCF Client Address: 0x0000 Access: DCF write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table 79-3. Diary Base Address (DBA) DCF client field description

Field	Description
0–31 DBA	Diary Base Address. This field holds the base address of the diary. This information is then used to verify if the diary being programmed matches any TDR region. **NOTE:** Diary Base Address must be on a 4 KB boundary.

79.5.2 Tamper Region Override (TO) DCF client

This DCF client holds override information for each TDR. The following figure shows the diagram for this register.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the override of a TDR permanent.

DCF Client Address: 0x0001 Access: DCF write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table 79-4. Tamper Region Override (TO) DCF client field descriptions

Field	Description
0–25 Reserved	This field is reserved and should be written with all zeroes when programming the TOE fields.
26–31 TOE5 to TOE0	TDR Override Enable. Each TOE*n* field, where *n* represents the TDRs, holds information of the Override Enable status for each TDR. 0 Normal operation. Blocks assigned to this TDR can NOT be erased until the diary is written. 1 Diary override. The blocks assigned to this TDR can be erased WITHOUT writing to the diary.

79.5.3 Software Tamper Region Override Disable (STO_DIS) DCF client

This DCF client holds information to disable the software mechanism to override the tamper detect regions.

CAUTION

This write-once DCF client can be written only one time. After one DCF record has written to this client, all subsequent writes are ignored.

DCF Client Address: 0x0002 Access: DCF write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table 79-5. Software Tamper Region Override Disable (STO_DIS) DCF client field descriptions

Field	Description
0–25 Reserved	This field is reserved and should be written with all zeroes when programming the STO_DIS fields.
26–31 STO_DIS5 to STO_DIS0	Software TDR Override Disable TDR*n*. Each STO_DIS*n* field, where *n* represents the TDR number, holds information to disable the software mechanism to override TDR*n*. 0 Software tamper detect override mechanism supported 1 Software tamper detect override mechanism disabled. Any attempt to override TDR*n* by loading a service key value in STO_KEY*n* register is ignored.

79.5.4 One Time Programmable Enable (OTPEN0) DCF client

This DCF client holds OTP information for particular blocks of flash memory. This DCF client mirrors the LOCK0 register of the flash memory. The following diagram depicts this client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the OTP assignment of a flash memory block irreversible.

DCF Client Address: 0x0008 Access: DCF write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table 79-6. One Time Programmable Enable (OTPEN0) DCF client

Field	Description
0–3 Reserved	This field is reserved and should be written with all zeroes when writing to this client.
4–15 LOWOTPEN	Low Block OTP Enable. This field affects flash memory blocks in Low address space. See the chip-specific information for the mapping between field bits and flash blocks. The same mapping also applies to control similar functions in the flash memory module. 0 Corresponding flash blocks are not assigned as OTP 1 Corresponding flash blocks are assigned as OTP
16–31 MIDOTPEN	Mid Block OTP Enable. This field affects flash memory blocks in Mid address space. See the chip-specific information for the mapping between field bits and flash blocks. The same mapping also applies to control similar functions in the flash memory module. 0 Corresponding flash blocks are not assigned as OTP 1 Corresponding flash blocks are assigned as OTP

79.5.5 One Time Programmable Enable (OTPEN1) DCF client

This DCF client holds OTP information for particular blocks of flash memory. This DCF client mirrors the LOCK1 register of the flash memory. The following diagram depicts the client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the OTP assignment of a flash memory block irreversible.

DCF Client Address: 0x0009 Access: DCF write

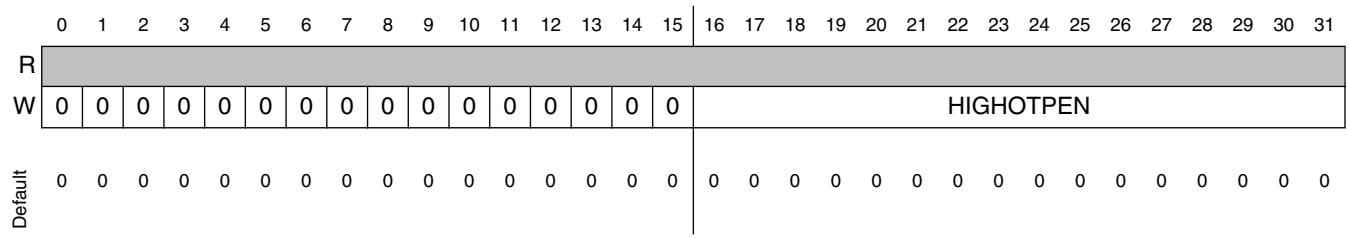

Table 79-7. One Time Programmable Enable (OTPEN1) DCF client field descriptions

Field	Description
0–15 Reserved	This field is reserved and should be written with zeroes when writing to this client.
16–31 HIGHOTPEN	High Block OTP Enable. This field affects flash memory blocks in High address space. See the chip-specific information for the mapping between field bits and flash blocks. The same mapping also applies to control similar functions in the flash memory module. 0 Corresponding flash blocks are not assigned as OTP 1 Corresponding flash blocks are assigned as OTP

79.5.6 One Time Programmable Enable (OTPEN2) DCF client

This DCF client holds OTP information for particular blocks of flash memory. This DCF client mirrors the LOCK2 register of the flash memory. The following diagram depicts the client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the OTP assignment of a flash memory block irreversible.

DCF Client Address: 0x000A Access: DCF write

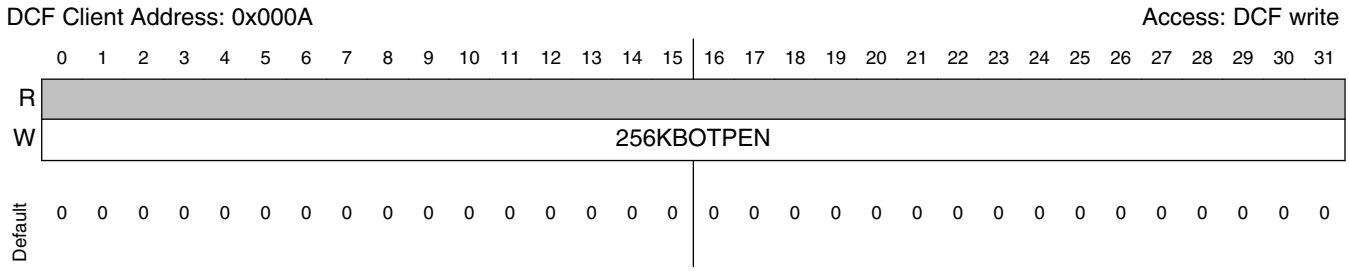

Table 79-8. One Time Programmable Enable (OTPEN2) DCF client field descriptions

Field	Description
0–31 256KBOTPEN	256 KB Block OTP Enable. This field affects flash memory blocks in 256KB address space. See the chip-specific information for the mapping between field bits and flash blocks. The same mapping also applies to control similar functions in the flash memory module. 0 Corresponding flash blocks are not assigned as OTP 1 Corresponding flash blocks are assigned as OTP

79.5.7 One Time Programmable Enable (OTPEN3) DCF client

This DCF client holds OTP information for particular blocks of flash memory. This DCF client mirrors the LOCK3 register of the flash memory. The following diagram depicts the client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the OTP assignment of a flash memory block irreversible.

DCF Client Address: 0x000B — Access: DCF write

The same mapping also applies to control similar functions in the flash memory module. 0 Corresponding flash blocks are not assigned as OTP 1 Corresponding flash blocks are assigned as OTP

79.5.8 Tamper Region Assignment DCF client (TDRn_LOCK0)

This DCF client holds the assignment information of flash memory blocks to a specific TDR. Each flash memory block can be assigned to any TDR (*n* varies from 0 to 5). This DCF client holds the assignment information for only those blocks specified in the LOCK0 register in the flash memory. For that reason, the layout of this DCF client mirrors the LOCK0 register in the flash memory. The following diagram depicts the TDRn_LOCK0 DCF client.

CAUTION

This write-once DCF client can be written only one time. After one DCF record has written to this client, all subsequent writes are ignored.

DCF Client Address: 0x0014 + ((n x 4) + 0) Access: DCF write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

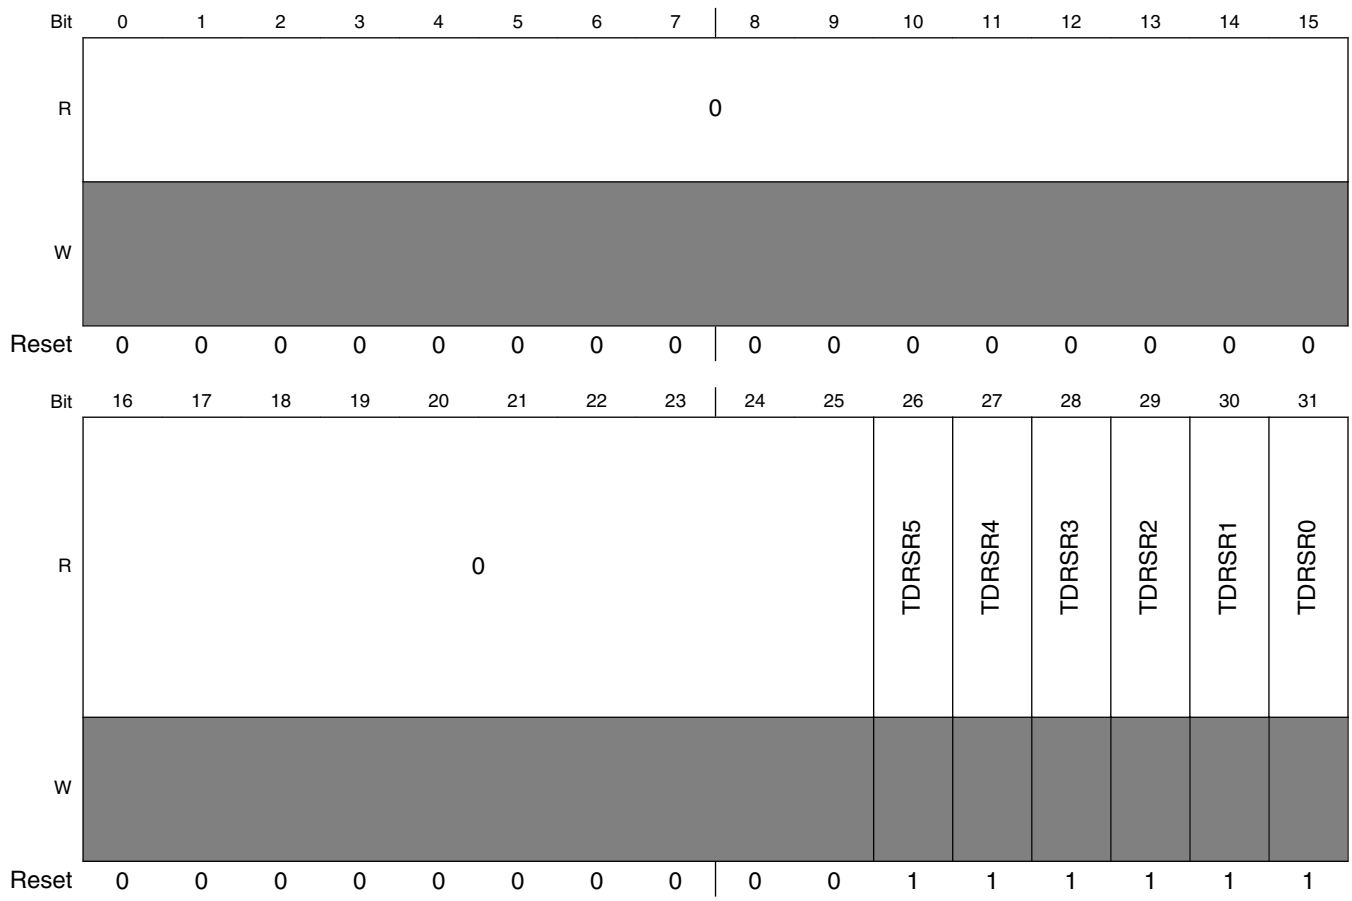
79.6.1 TDR Status Register (TDM_TDRSR)

This register contains the current status, i.e., locked or unlocked, of each tamper region, i.e., TDR.

- If a tamper region is locked, the blocks assigned to that tamper region cannot be erased.
- If a region is unlocked, the blocks within the tamper region can be erased.

The register contains a status bit for each TDR. Status is determined as follows:



1. The default status for each TDR is ‘1’, which indicates that the erase operation is disabled for all flash blocks associated with the TDR.

2. The status bit for a TDR is set to ‘0’ (indicating that the erase operation for all flash blocks associated with the TDR is enabled) if either a successful programming operation to the TDR diary region has been performed or the TDR Override bit for that TDR is set.

NOTE

- TDRSR is a read-only register and writes have no effect on it. Write operations result in a transfer error.
- If the reset value for this register is determined by a DCF record, it will be noted in the chip-specific information at the beginning of this chapter. Otherwise, the reset value is as shown.

Address: 0h base + 0h offset = 0h

TDM_TDRSR field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 TDRSR5	Represents the status of TDR 5 in conjunction with the Diary Override Enable status.

Table continues on the next page...

TDM_TDRSR field descriptions (continued)

Field	Description
	0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
27 TDRSR4	Represents the status of TDR 4 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
28 TDRSR3	Represents the status of TDR 3 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
29 TDRSR2	Represents the status of TDR 2 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
30 TDRSR1	Represents the status of TDR 1 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
31 TDRSR0	Represents the status of TDR 0 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.

79.6.2 Last Flash Programmed Address Register (TDM_LFPAR)

This register holds information of the address of the last successful programming operation provided from the flash memory to the TDM. Writes to this register are ignored and will generate a transfer error.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:
- The reset value of this register is set via DCF record.x = Undefined at reset.

TDM_DBA field descriptions

Field	Description
0–31 DBA	Diary Base Address. These bits represent the address of the diary location in the flash. **NOTE:** The diary base address is established via the DBA DCF record. The reset value of this register is determined by that record.

79.6.4 Software Tamper Override Key Region (TDM_STO_KEY*n*)

The STO_KEYn register holds the service key for overriding the Tamper Detect Region n, where n denotes the Tamper Detect Region number.

Caution

1. The STO_KEYn registers can only be written once.
2. The associated DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored.

Address: 0h base + 10h offset + (4d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	STO_KEY

TDM_STO_KEY*n* field descriptions

Field	Description
0–31 STO_KEY	Software Tamper Override Key Diary n. This field holds the service key value for overriding Tamper Detect Region n. By loading STO_KEYn with the correct signature of 0x55AA5A5A, Tamper Detect Region n is overridden, and the flash blocks assigned to Tamper Detect Region n are open for erase. This field has no effect when STO_DISn field of STO_DIS DCF client is set. **Caution:** The STO_KEYn registers can only be written once.

79.7 Functional description

The primary purpose of the TDM is to provide a Tamper Detection mechanism by enabling an Erase Counter (or diary) for regions within the flash. These regions are called Tamper Detection Regions. The following sections cover the entire functionality of this module.

79.7.1 Flash erase counter and tamper detection

A flash region block or part of it is assigned for implementing the diary. The base address for the diary is defined by a DCF Record.

The diary is divided into 6 parts where each part consists of 256 × 64-bit records, to record up to 256 write attempts on the flash blocks assigned to each Tamper Detection Region. For correct operation, the diary should reside in a flash block that is assigned as OTP.

Each flash block can be assigned to any of the TDRs. Related to each TDR is a group of 4 × 32-bit internal hardware registers that are initialized by DCF records that define the tamper region. These registers mirror exactly the LOCK registers bits from the flash module.

Each TDR*n*_LOCK*m* register is loaded at boot time by the SSCM, which defines if the associated flash block is Locked for Erase in a particular TDR:

- ’1’ means the flash block is locked for erase
- ’0’ means the flash block is not locked for erase

Before performing an erase in one of the blocks locked for erase and associated to a TDR, a program operation has to be performed on the diary part for that TDR. As the diary should be OTP, successive writes are allowed on unprogrammed double words only. This ensures that diary records can only increase and that data recorded in the diary is not modifiable by software.

At the end of a successful double-word program operation, the flash module indicates to the TDM the address of the programmed double word. The TDM determines whether the programmed data was written to the correct TDR diary location and then unlocks the blocks for erase operation for the corresponding TDR. The TDM ensures that this erase operation on unlocked blocks is allowed until the completion of the erase sequence or until next desctructive reset.

When attempting to update the TDM diary and erase flash blocks, set MCR[PECIE] in the Embedded Flash Memory registers to enable interrupt notification for program and erase operations. Then clear MCR[PECIE] to service the interrupt after each program or erase operation. This sequence must be executed before attempting to update the TDM diary, and then again before attempting to erase the unlocked flash blocks.

NOTE

All blocks associated to a TDR where an erase operation is allowed can be erased all together.

The data programmed in the diary location is flexible, and may include count information or other important customer information.

NOTE

There is no restriction on the type or format of data that can be programmed in the diary, so software must verify whether the diary is full. If a TDR's diary area is full, the tamper detect mechanism can be disabled for that TDR by creating a Tamper Region Override (TO) DCF record with the TDR's corresponding TDR Override Enable (TOE) bit set to '1'. This

allows erase operations to be performed to the TDR without any diary entry.

The setting from “override tamper region lock” DCF record (Diary) has priority over the settings in the TDRn_LOCK0 – 3 registers. In other words, if a TDR is unlocked for erase by the override tamper region lock, the TDR*n*_LOCK*m* bits have no effect on the TDR that has been overridden, but the tamper detection remains active for all TDRs not having the override bit set.

Moreover, if a block is locked by the PASS_LOCK*x*_PG*n* registers or by TDR*n*_LOCK*m*, the block is locked for erase.

NOTE

The settings in the Tamper Region Override Register have priority over the TDR*n*_LOCK*m* registers. The PASS module also has priority over the settings done in the TDM. For instance, if blocks in a TDR are unlocked for erase operation via the TDM, but the same blocks are programmed to be locked for erase operation in PASS, the blocks end up being locked for erase operation.

Attempts to erase the flash without first writing the diary will be ignored by the flash. The contents in the flash block will remain unchanged and MCR[PEG] will be asserted, indicating the operation was successful and the contents of the block are properly protected from the erase operation.

79.7.2 Assigning blocks to Tamper Detect Regions (TDR)

Each TDR is defined by a group of 4 x 32-bit DCF records and clients, with each containing bits that map to specific blocks in a flash region. These mappings mirror exactly the LOCK registers bits from the flash module. Hence, the block assignment registers are named as TDR*n*_LOCK*m* where *n* is the number of a tamper region, that is, 0- 5 and *m* varies from 0-3 as flash contains four Lock registers.

In these DCF records:

- ’1’ means that the corresponding flash block is assigned to this TDR
- ’0’ means that the corresponding flash block is not assigned to this TDR (Default)

DCF clients are not visible to software. They can not be read nor written. They can only be initialized by DCF record within the UTest flash block during reset. The value of these registers can be evaluated by reading all the UTest DCF records and searching for records that correspond to these clients.

NOTE

No flash block should be assigned to more than one TDR. Each block should correspond to a single TDR. For example, if a single block is assigned to TDR0 and TDR1, then even if the Diary is programmed for both TDR0 and TDR1, this flash block will never be unlocked for erase operation.

79.7.3 Diary

The diary is a region of the flash memory where records of block erases for each TDR are stored. The format and size of the records are not fixed. The only requirements are that each diary has a maximum size of 2 KB, and the minimum size of any programming operation is 8 bytes to honor OTP restrictions. Therefore, each diary can hold a maximum of 256 64-bit entries.

A flash region block or part of it must be assigned for implementing the diary. The base address for the diary is determined by a value written in a DCF record. The diary can be placed within any flash block in flash array, and history records in it can be read by any core and from the HSM.

NOTE

To maintain the security of the TDR, the block where the diary is placed must be assigned as OTP within the OTP registers.

The base address of the diary is implemented using a DCF Client. The DCF client is only writable once and the default bit state is 1.

The DCF clients can not be read nor written by software. They can only be initialized by DCF record from within UTEST block during reset. The value of these registers can be evaluated by reading all the UTEST DCF records and searching for records that write these DCF clients.

79.7.4 Specifying the diary base address

The diary is a region of flash memory where records of block erases for each TDR are stored. The format and size of these records is defined by the customer. The only hardware constraints are that each diary has a maximum size of 2 KB and the minimum size of any programming operation is 8 bytes. Therefore, each diary region limits the erases of the assigned blocks to 256 erases.

The diary can be placed within any flash block in the flash array. To maintain the security of the TDR, the block where the diary is placed, must be assigned as OTP within the OTP registers, while in customer delivery or OEM production life cycle states.

The base address of the diary is implemented with a 20-bit DCF client that can be initialized by the SSCM during reset. The DCF client is writable once and the default bit state is ‘1’.

The base address register is not visible to software. It cannot be read nor written. It can only be initialized by DCF record within UTest flash during reset. The value of this register can be evaluated by reading all the UTest flash DCF Records and searching for record that writes this register.

Each TDR is assigned a 2 KB section of the diary. With 6 TDRs, 12 KB of diary space is required.

The diary base address must be at a 4 KB boundary. Therefore the least significant 12 bits of the base address must all be ‘0’.

The Base address of the diary is represented by:

Diary_Base_Address = 0bxxxx_xxxx_xxxx_xxxx_xxxx_0000_0000_0000

The base address of each TDR is shown below:

- TDR0 = Diary_Base_Address + 0b00_0000_0000_0000
- TDR1 = Diary_Base_Address + 0b00_1000_0000_0000
- TDR2 = Diary_Base_Address + 0b01_0000_0000_0000
- TDR3 = Diary_Base_Address + 0b01_1000_0000_0000
- TDR4 = Diary_Base_Address + 0b10_0000_0000_0000
- TDR5 = Diary_Base_Address + 0b10_1000_0000_0000
- End of the diary = Diary_Base_Address + 0b11_0000_0000_0000

79.7.5 TDR lock status

The status of whether a TDR is locked for erase is maintained by the TDM. This is accomplished by implementing a register with as many bits as the number of TDRs. The default state of these bits is 1, which is defined as "TDR Erase Blocked". See TDR Status Register (TDM_TDRSR) for further details about this register.

When the flash memory module has completed a programming operation, the address of the location programmed is output from the flash module. The TDM in turn compares that address to determine if it falls within the range of any TDR diary regions. If it is within any TDR, the corresponding status bit is set to 0 meaning "TDR Erase Enabled".

These status bits are all reset to 1 when the flash module signals an erase complete by asserting the PEC (Program Erase Complete) signal.

The state of the 6 status bits can be read through the TDRSR. See TDR Status Register (TDM_TDRSR). The address of the last successful programming operation provided from the flash memory to the TDM can be read through the LFPAR. See Last Flash Programmed Address Register (TDM_LFPAR).

79.7.6 TDR override

Before a block protected by a tamper detect region can be erased, a record must be written to the associated diary. Software must search through the diary to find the end of the records, where the next available diary location that can be written. After a maximum of 256 records are programmed to the diary, a TDR diary is full. Full means that at least 1 bit has been programmed to ‘0’ in each 64 bit double word within the 2 KB diary.

If software determines that a particular TDR diary is full it may override the diary to allow erasing to continue or it may choose to stop further erases and to flag an error.

Diary Override bits are implemented with a DCF client consisting of 6 bits, one for each TDR. See the device configuration information at the beginning of this chapter for TDM DCF client details.

The Diary Override bits are by default set to ‘0’; which means the diary must be written before an erase can occur. The DCF client can be written many times but the bits can only be written to ‘1’. Writes to ‘0’ are ignored. In this way, by default, all Tamper Detect Regions are active. The Tamper detect region diaries can be individually overridden by writing a DCF record that sets that corresponding bit to ‘1’. In this mode, the TDR status bit is permanently set to 0 to allow flash erase.

The application can also override the diary by loading a service key to the STO_KEY*n* program-visible register, where n denotes the tamper detect region. By loading the value 0x55AA5A5A into STO_KEYn register, the corresponding tamper detect region is overridden. This software override mechanism is disabled if the STO_DISn field of the STO_DIS DCF Client is set.

79.7.7 One time programmable (OTP)

79.7.7.1 Overview

Any flash block within the flash array can be assigned, at any time, to be OTP. Once a flash block is assigned OTP, it cannot be changed back.

OTP means that flash erase of the entire block is disabled and only 64-bit double words that are already erased (that is, flash content is 0xFFFF_FFFF_FFFF_FFFF) can be programmed. Over-programming is not possible.

Flash blocks are assigned as OTP by writing a DCF record. The block will become OTP after the next functional reset.

Chapter 80
Flash Memory Programming and Configuration

80.1 Introduction

This chapter provides basic guidance on activities related to configuring and programming the embedded flash memory in the MPC5746C microcontroller.

Multiple layers of protection are available to prevent unintended updates to flash contents and unauthorized reads and writes to flash contents. The protection mechanisms range from simple write-protect bits for individual flash blocks to four levels of 256-bit password read and/or write protection and configuration of flash memory blocks as One Time Programmable (OTP).

Additionally, the MPC5746C microcontroller includes a tamper detection feature, debug port enable/disable, and the ability to disable the ability for the device to be put into factory test mode.

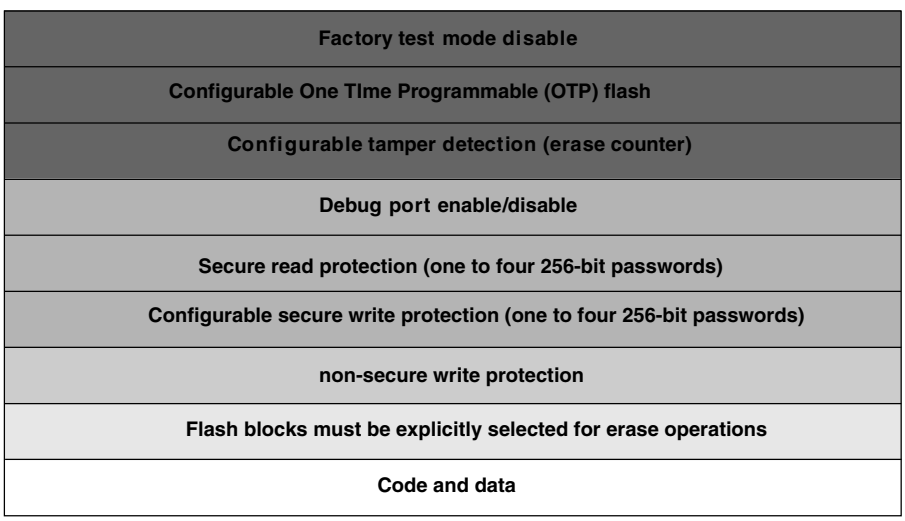

Figure 80-1. Flash memory protection layers

At the lowest layer of protection, all flash erase operations require the explicit selection of one or more blocks of flash memory before the operation is performed. When executed, the operation is only performed on the selected block(s).

The next layer is the chip's ability to lock individual flash blocks against unintended programming and erase operations. This level of protection does not offer any password protection and is intended to provide protection against *accidental* changes to code and data.

The first layer of *secure* protection is the microcontroller's ability to support up to four levels of 256-bit password-secured *write* protection for individual flash blocks.

Similarly, up to four levels of password-secured *read* protection can be implemented. Unlike the password-secured write protection, which is implemented on a per-block basis, password-secured read protection applies to five pre-defined (at the factory) groups of flash blocks. The read protection applied to a group applies to each block within the group. In contrast, secure write protection is defined at the individual block level.

Secure password protection can also be implemented for the debug port.

The MPC5746C microcontroller also includes a tamper detection feature. In its most basic implementation, tamper detection acts as an erase counter. If tamper detection is implemented, a DCF record in the tamper detection *diary* must be written by software before a protected flash block can be erased. Multiple tamper detection regions can be defined by the customer, with each region containing one or more blocks. A block can be included in more than one tamper detection region if desired.

Another protection feature related to tamper detection is the ability to configure any flash block as one-time programmable (OTP).

Finally, the microcontroller includes a feature that allows the customer to disable the ability to place the device in factory test mode.

The remainder of the chapter provides details regarding these protection mechanisms and gives a brief overview of security configuration planning.

Note

Most of the topics in this chapter build on information presented in previous topics. To get a clear overview of how the flash protection features work and relate to each other, please read the chapter in sequence from beginning to end.

Access protection configuration is applied on a per-block basis (except read protection and tamper detection applied to groups of flash memory blocks), i.e., a custom level of access protection can be provided for each flash memory block. This is accomplished

through the use of registers containing bits that are mapped to individual flash blocks. Understanding the mapping is key to understanding the implementation and use of the MPC5746C microcontroller's flash protection features.

Depending on the type of protection to be applied, different sets of registers (or even DCF records) are used, but the mapping scheme is consistent. This mapping scheme is first presented in Selection of flash memory blocks for erase. It is important to understand the topic before proceeding to other sections.

80.2 Selection of flash memory blocks for erase

The registers used for selecting flash blocks for erase operations are the flash control registers named LOCK0, LOCK1, and LOCK2. There is also a LOCK3 register, but no flash blocks are mapped to it.

The LOCK0–2 registers are 32-bit registers containing fields associated with specific address spaces: low, mid, high, and 256 KB. Each non-reserved bit in the fields is mapped to a specific flash block.

For example, Figure 80-2 shows the Select 0 (SEL0) register for the flash module. This register provides a way of selecting blocks in the low and mid address spaces for erase operations.

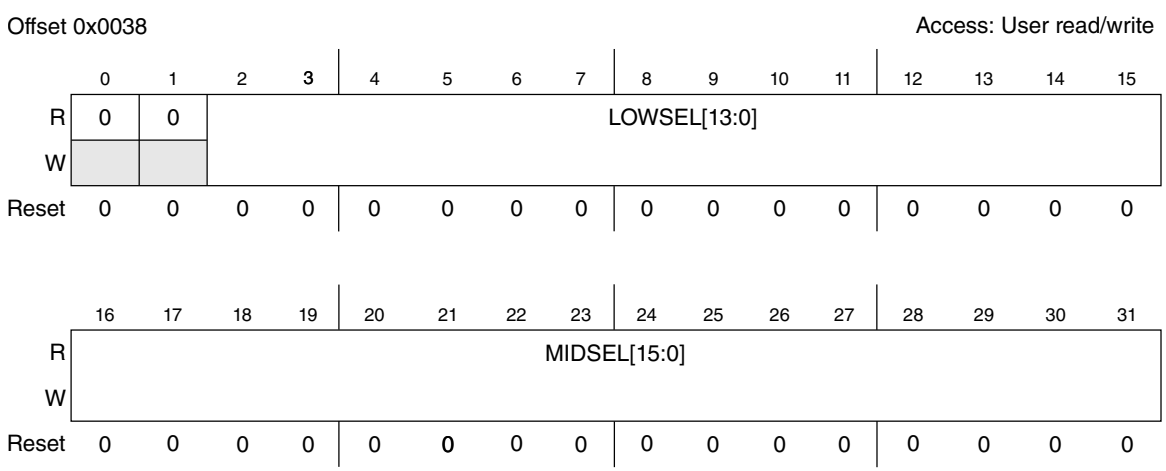

Figure 80-2. SEL0 flash control register

Table 80-1 shows an example of a mapping of SEL0 register's LOWSEL and MIDSEL field bits to individual flash blocks[1]. In this case, not all bits of the LOWSEL and MIDSEL fields are mapped—only LOWSEL bits 0–9 (register bits 15–6,[2]) and

1. The table lists the LOWLOCK register field but the structure is identical to the LOWSEL field in Figure 80-2.
2. Register bits in Power Architecture-based microcontrollers are numbered with the most significant bit as 0. This is not necessarily the case with register field bit numbering. The field bit numbering shown in the figure has the least significant bit numbered as 0.

MIDSEL bits 0–7 are mapped. Before any mapped block can be erased, it must be selected by writing a '1' to its corresponding bit in one of the SEL*n* registers. See the Embedded Flash Memory configuration for the complete mapping.

Note

Values written to the SEL registers do not persist through device reset. As indicated by the reset values shown in Figure 80-2, all bits are reset to '0'. As a result, after a device reset all blocks mapped to the register are, by default, not selected for erase.

Table 80-1. Flash address space and flash lock bit mapping

Start Address	End Address	Size	Partition	LOCKn Register[1]	LOCKn Register Field bit	LOCKn DCF Record DATA bit[2]	Read Lock Group[3]	Test Mode Disable Block Select Bit	Description

0x01080000	0x010BFFFF	256	6	LOCK2	256KLOCK[2]	2	1	53	256KB Code Flash block2
0x01040000	0x0107FFFF	256	6	LOCK2	256KLOCK[1]	1	1	54	256KB Code Flash block1
0x01000000	0x0103FFFF	256	6	LOCK2	256KLOCK[0]	0	1	55	256KB Code Flash block0

1. There are multiple sets of LOCKn registers, i.e., the flash module's LOCK0–-3 registers and PASS module's PASS_LOCK0–3_PG0–3, but all use the same mapping of register bits to flash blocks. The same mapping applies the the flash module's SEL0–3 registers.
2. The DCF record DATA bit refers to the DATA[31:0] field contained in DCF records created during OEM configuration activities. The DCF records related to flash blocks are used to implement password-secured write protection, passwordsecured read protection, tamper detection, and debug port enable/disable as a permanent part of the device configuration.
3. The Read Lock group pertains to protecting code and data blocks from being read by debuggers. This type of protection is implemented using DCF records and the PASS_LOCK3_PG0–3 registers.
4. One time programmable.
5. The Boot Assist Flash (BAF) is one time programmable and the majority of it is programmed in the factory. The BAF handles the initial start up of the device.

Example: 80.2.1 Selecting blocks for erase

Selecting blocks for erase

Referring to Table 80-1, writing the value 0x0030_0000 to the SEL0 register (Figure 80-2) selects the following blocks for erase:

Start Address	End Address	Size (KB)	Partition	LOCK*n* Register	LOCK*n* Register Field Bit	LOCK*n* DCF Record DATA Bit	Read Lock group	Test Mode Disable Block Select Bit	Description
0x00FD0000	0x00FD7FFF	32	1	LOCK0	LOWLOCK[4]	20	1	3	32KB Code Flash block
0x00FD8000	0x00FDFFFF	32	1	LOCK0	LOWLOCK[5]	21	1	2	32KB Code Flash block

80.3 Non-secure write protection

Non-secure write protection refers to the chip's ability to lock individual flash blocks against programming and erase operations. This level of protection is intended to provide protection against *accidental* changes to code and data. Although similar in function, this is *not* associated with the built-in register protection (REG_PROT) feature included with many of the chip's modules. The non-secure write protection feature detailed here applies only to embedded flash memory.

Implementing non-secure write protection is almost identical to selecting specific flash blocks for an erase operation—the only difference is the register used. To provide non-secure write protection for a block, write a '1' to the corresponding mapped bit found in one of the LOCK0–2 flash control registers.

Note

As indicated by the reset values shown in Figure 80-3, after reset all blocks mapped to the register are, by default locked against programming and erase. Values written to the LOCK and SEL registers do not persist through device reset.

The same bit mapping that applies to the SEL0–3 registers also applies to the LOCK0–3 registers.

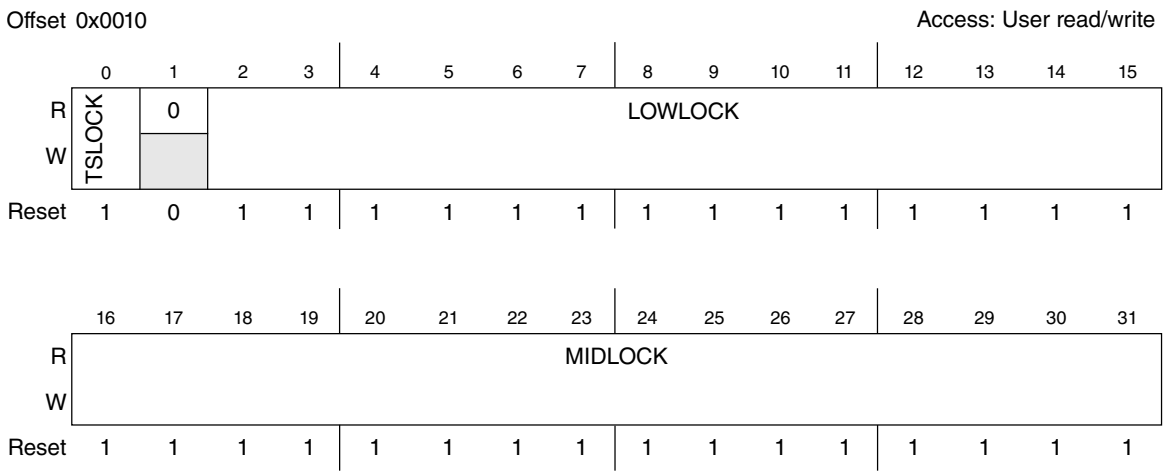

Figure 80-3. LOCK0 flash control register

Example: 80.3.1 Selecting

Selecting

Referring to Table 80-2, writing the value 0x0030_0000 (same value used in Selecting blocks for erase) to the LOCK0 register (Figure 80-3) locks the following blocks (same blocks selected in Selecting blocks for erase) so they cannot be programmed or erased, even if selected for erase:

Start Address	End Address	Size (KB)	Partition	LOCK*n* Register	LOCK*n* Register Field Bit	LOCK*n* DCF Record DATA Bit	Read Lock group	Test Mode Disable Block Select Bit	Description
0x00FD0000	0x00FD7FFF	32	1	LOCK0	LOWLOCK[4]	20	1	3	32KB Code Flash block
0x00FD8000	0x00FDFFFF	32	1	LOCK0	LOWLOCK[5]	21	1	2	32KB Code Flash block

As long as the LOCK0[LOWLOCK] bits are unchanged, the above blocks cannot be modified unless the protection is overridden (discussed in Secure write protection). All other blocks mapped to bits in the LOCK0 *can* be programmed because their corresponding bits have been set to '0'.

80.4 Secure write protection

Secure write protection refers to the chip's ability to implement up to four levels of 256-bit password-secured *write* protection for individual flash blocks. Use of this feature is optional but the default behavior of the MPC5746C microcontroller is to apply secure write protection. If there is a need to *not* write-protect specific blocks, that needs to be configured by creating the appropriate DCF records.

Note that the *secure* write protection settings override the non-secure write protection detailed in Non-secure write protection.

Implementing a custom secure write protection scheme requires creating DCF records that define the level of write protection to be applied to each flash block. The DCF records use a bit mapping scheme identical to the mapping in the flash module's SEL*n* and LOCK*n* registers. The write protection scheme becomes a permanent part of the device but blocks can be temporarily unlocked. Depending on the specific implementation, temporarily unlocking the write protection requires matching up to four 256-bit passwords.

The easiest way to understand the secure write protection functionality is to examine the role played by the PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* registers.

The PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* registers are four identical sets of registers contained in the PASS module—they distinguished by the PG*n* suffix. The PG*n* (Password Group *n*) suffix indicates the password required to unlock that set of registers. Password 0 unlocks PASS_LOCK0_PG0, PASS_LOCK1_PG0, PASS_LOCK2_PG0, and PASS_LOCK3_PG0. Similarly, the registers suffixed with PG1 are unlocked by matching password 1, and so on.

The PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* register sets have two functions related to secure write protection:

- Reading the registers provides the secure write lock status for each flash block.
- Changing the value of a mapped bit in a register changes the secure write protect status of the corresponding flash block.

Each set of registers contains the same mapping of bits to flash blocks as the flash module's SEL*n* and LOCK*n* registers. In any of the four PASS_LOCK*x*_PG*n* register sets, if a mapped bit is set to '1', locking a flash block, that value can only be changed by successfully supplying the password value for that set of registers to gain write access to the register, and setting the bit to '0'. If the same bit is set to '1' in more than one

PASS_LOCK*x*_PG*n* register set, each must be unlocked using the corresponding password and the bit must be set to '0' before the flash block is available for programming or erase.

Figure 80-4 shows how the registers interact. Note that secure write protection is only affected by the settings in PASS_LOCK0_PG*n*–PASS_LOCK2_PG*n*. The PASS_LOCK3_PG*n* registers have additional security functions, discussed in later topics.

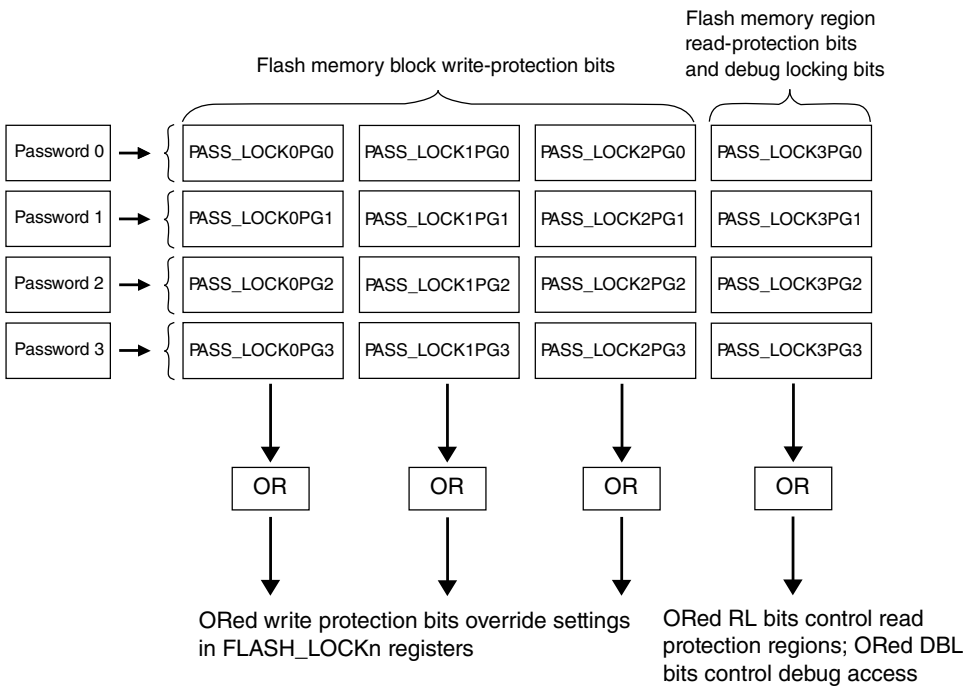

Figure 80-4. Secure write protection

The next sections discuss implementing secure write protection and overriding secure write protection.

80.4.1 Implementing secure write protection

Implementing secure write protection is a one-time task performed either at the factory or by the customer during chip configuration activities. It normally requires creating a DCF record for each of the PASS_LOCK0_PG*n*–PASS_LOCK2_PG*n* registers[3]. The DCF records have a structure that includes the same mapping of bits to flash memory blocks as

3. The default behavior for secure write protection in the case where passwords are created but no secure write protection DCF records are created, is for all blocks to have four levels of password-secured write protection. To vary the protection among all blocks, a DCF record for each password group must be created.

the flash module's SEL*n* and LOCK*n* registers. The values assigned become the permanent register reset values for the PASS_LOCK0_PG*n*–PASS_LOCK2_PG*n* registers.

See Device Configuration Format (DCF) Records for complete details on DCF records. This section summarizes the contents of a DCF record as required to implement secure write protection.

Even though the mapping of bits to flash memory blocks is identical to the mapping used for selecting flash blocks for erase of non-secure write locking, there are two significant differences:

1. Configuring flash blocks for secure write protection is done only during device configuration to customer specifications, either at the factory or by the customer during OEM production activities. The selection becomes a permanent part of the device configuration.
2. Configuration of blocks for secure write protection is done by writing *DCF records*, which is why the selection becomes a permanent part of the device.

CAUTION

Careful planning is required before writing DCF records. They are created in a write-once area of flash. Multiple instances of any DCF record can be created, but in some cases only the record created first is used and with others only the most-recently written record is used. Be sure to understand the characteristics of a DCF record before creating it.

The DCF records required for implementing a secure write protection scheme are detailed in the PASS section of DCF client list table in the attached DCF_clients.xlsx. Table entries provide the CS and Address value combinations that correspond to PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* registers.

The format of a secure write protection record is summarized here for convenience.

DCF records appear as contiguous double-word (64-bit) entries programmed in a reserved area of OTP UTEST flash memory. The structure of a DCF Record is shown in Figure 80-5.

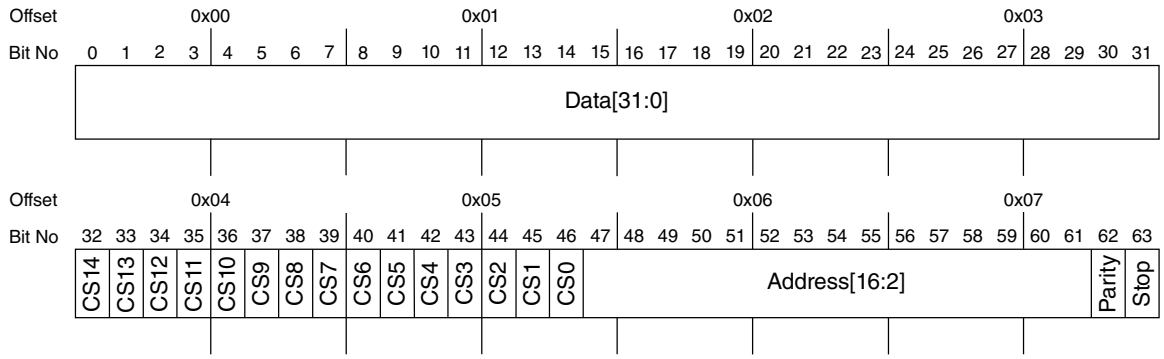

Figure 80-5. DCF record structure

Note

1. The values in the PASS_LOCK*x*PG*n* registers override the settings in the flash module's LOCK0–3 registers.
2. Values written to the PASS_LOCK*x*PG*n* registers do not persist through device reset. The reset value is determined by DCF record or, if no relevant DCF record has been created, each mapped bit has a reset value of '1', which causes the associated flash block to be locked against programming or erase.
3. The PASS_LOCK*x*PG*n* bits take effect when the life cycle is matured to "OEM Production" or older.

Example: 80.4.1.1 Implementing secure write protection

Implementing secure write protection

Implementation of secure write protection is done during initial flash setup as follows:

1. Four 256-bit passwords (passwords 0–3) must be stored in a protected OTP area of device flash called UTEST flash. Each password secures a set of registers in the PASS module (PASS_LOCK0_PG*n* –PASS_LOCK3_PG*n*) that have the same mapping of register bits to flash blocks as the flash module's SEL0–3 registers and LOCK0–3 registers.
2. DCF records must be created to define which flash memory blocks are to be locked and which blocks are not locked.

The records defined in step 2, determine the reset values of the PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* registers and therefore the write protection settings that take effect each time the microcontroller is reset.

Assume four passwords have been previously implemented and the following blocks are to be locked in the password 0 group:

Start Address	End Address	Size (KB)	Partition	LOCK*n* Register	LOCK*n* Register Field Bit	LOCK*n* DCF Record DATA Bit	Read Lock group	Test Mode Disable Block Select Bit	Description
0x00FD0000	0x00FD7FFF	32	1	LOCK0	LOWLOCK[4]	20	1	3	32KB Code Flash block
0x00FD8000	0x00FDFFFF	32	1	LOCK0	LOWLOCK[5]	21	1	2	32KB Code Flash block

From the PASS section of the attached DCF_clients.xlsx:

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0000_1000	000_0000_0100_0000	LOCK0_PG0

Referring to Figure 80-5, the values for the DCF record are:

- Data[31:0] is 0x0030_0000 (bits 0–31) (same value used in previous examples)
- CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
- Address[16:2] is 0b000_0000_0100_0000 (bits 47–61)
- Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
- Preferred Stop value is 0 (see footnotes in Figure 80-6.

The following DCF record provides secure write protection for the blocks in Table 80-1 by setting the reset values PASS_LOCK0_PG0 to the appropriate value to lock the blocks.

Bit No	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit No	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47	48	49	50	51	52	53	54	55	56	57	58	59	60	61	62	63
	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	x^1	x^2

Figure 80-6. Sample DCF record for secure write protection

The remaining blocks mapped to the PASS_LOCK0_PG*n* registers do *not* have secure write protection provided by the password 0 register set because the DATA field of DCF record has only the bits mapped to flash blocks 4 and 5 set to '1'.

CAUTION

The above example is intended to highlight the need to carefully understand how DCF records work. The protected blocks are secured by password 0 but by default they are also secured by passwords 1, 2, and 3. In contrast the blocks *not* secured by password 0 in this example *are* secured by passwords 1, 2, and 3.

See the PASS section of DCF client list table in the attached DCF_clients.xlsx.

80.4.2 Overriding secure write protection

The "PG*n*" (Password Group *n*) suffix on each the register names indicates the password each set of registers is associated with. For example, password 0, is used to unlock PASS_LOCK0_PG0, PASS_LOCK1_PG0, PASS_LOCK2_PG0, and PASS_LOCK3_PG0. The bits in the first three registers (PASS_LOCK0_PG0, PASS_LOCK1_PG0, and PASS_LOCK2_PG0) are mapped exactly the same as the bits in the flash module's SEL0–2 registers and LOCK0–2 registers.

Like the SEL0 and LOCK0 registers, the PASS_LOCK0_PG*n* registers all contain bits mapped to the low and mid address spaces, and the mapping scheme is the same. A mapped bit set to '1' in any of the registers causes the corresponding block to be locked against program or erase. A mapped bit set to '0' in any of the registers makes the corresponding block available for programming or erase.

If a bit is set to '1', locking a flash block, that value can only be changed by successfully supplying the password value for that set of registers to gain write access, and setting the bit to '0'. If the same bit is set to '1' in more than one of the PASS_LOCK*x*PG*n* register sets, each must be unlocked using the corresponding password and the bit must be set to '0' before the flash block is available for programming or erase.

Figure 80-7 shows the PASS_LOCK0_PG*n* register. As you can see, it has the same structure as the flash module's LOCK0 register. In addition to the main difference of being among a group of four parallel sets of locking registers, the other difference between the PASS_LOCK*x*_PG*n* registers and the flash LOCK*n* registers is how the reset values are determined.

By default, all mapped bits are set to '1', locking their corresponding flash blocks from programming and erase. The reset value is user-configurable, though, by writing a DCF record. This is discussed in a later section.

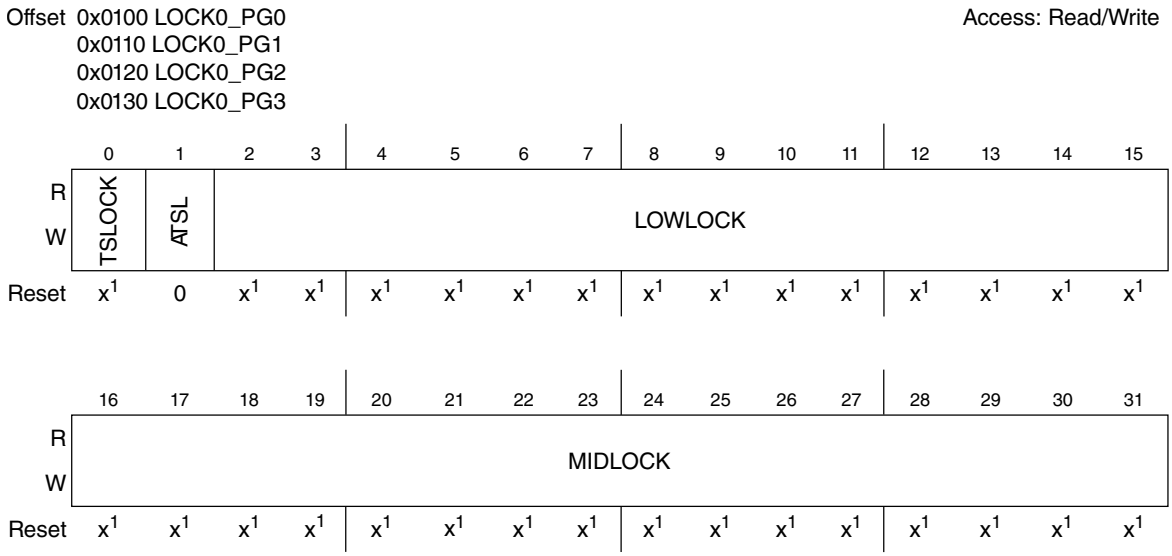

Figure 80-7. LOCK0_PG*n* register

Note

1. The values in the PASS_LOCK*x*PG*n* registers override the settings in the flash module's LOCK0–3 registers.
2. Values written to the PASS_LOCK*x*PG*n* registers do not persist through device reset. The reset value is determined by DCF record or, if no relevant DCF record has been created, each mapped bit has a reset value of '1', which causes the associated flash block to be locked against programming or erase. The purpose of the registers is to indicate secure write protection status and to provide a way to temporarily override secure write protection.
3. The PASS_LOCK*x*PG*n* bits take effect after the life cycle is matured to "OEM Production" or older.

Example: 80.4.2.1 Overriding secure write protection

Overriding secure write protection

Assume four passwords have been created but no DCF records have been written to set the reset values of the PASS_LOCK*x*_PG*n* registers, so the reset value for each mapped bit defaults to '1', causing all mapped blocks to have four levels of 256-bit password-secured write protection.

Since the settings in the PASS_LOCK*x*_PG*n* registers override the settings in the flash module's LOCK0–3 registers, the settings in those registers are irrelevant. Each of the four sets of the PASS module's LOCK registers must be unlocked by supplying the correct password for each set and then the appropriate bits must be set to '0' to make the desired flash blocks available for program or erase.

1. First write 0b00 to the PASS_CHSEL[GRP] register field to indicate registers controlled by password 0 are to be unlocked.
2. Write the 256-bit value for password 0 to the set of eight 32-bit password challenge input registers (PASS_CIN*n*) beginning with PASS_CIN0. The password must be written as a sequence of eight 32-bit writes, with the most significant bits of the password written to PASS CIN0.
3. Write 0xFFCF_FFFF to the PASS_LOCK0_PG0 register and verify a successful write.
4. Repeat the above steps for passwords 1–3.

Just as in previous examples, the result is the following blocks are available for program and erase operations but at a much higher level of security.

Start Address	End Address	Size (KB)	Partition	LOCK*n* Register	LOCK*n* Register Field Bit	LOCK*n* DCF Record DATA Bit	Read Lock group	Test Mode Disable Block Select Bit	Description
0x00FD0000	0x00FD7FFF	32	1	LOCK0	LOWLOCK[4]	20	1	3	32KB Code Flash block
0x00FD8000	0x00FDFFFF	32	1	LOCK0	LOWLOCK[5]	21	1	2	32KB Code Flash block

80.5 Secure read protection

Read Protection is ability of the flash controller to block read accesses to the flash memory from all bus masters. This includes the blocking of:

- Instruction fetches and load instructions from the CPU
- Debug reads from an outside tool
- DMA reads
- All other types of bus master reads

When secure read protection is active, the affected flash blocks are readable by any bus master until a debugger is attached to the JTAG port and debug is enabled. If a debugger is attached and debug is enabled while an application is running, the next access to a flash read protected region terminates with a bus error.

Most instances of flash memory read protection in the MPC5746C microcontroller are *not* configurable by the customer. An example of this is the 256-bit passwords stored in UTEST flash memory. Password-based read protection *is* customer-configurable[4] and is similar to the password-based write protection mechanism detailed in Secure write protection.

There are two significant differences between password-based read protection and password-based write protection in the MPC5746C microcontroller.

1. Read protection can only be applied to pre-defined groups of flash memory blocks. These groups, called "Read Lock groups", cannot be re-defined, meaning the blocks assigned to those groups are permanently assigned and cannot be assigned to other groups and no new groups can be created.
2. Read protection is applicable if the device is censored (Please refer PASS_LCSTAT[CNS] and PASS_LCSTAT[JUN] bit fields for details). This protection is only active either when a debugger is attached to the JTAG port and debug is enabled; or the lifecycle has been advanced to "Failure Analysis".

Another difference is that only the PASS_LOCK3_PG*n* register for each password group is used:

- PASS_LOCK3_PG0
- PASS_LOCK3_PG1
- PASS_LOCK3_PG2
- PASS_LOCK3_PG3

4. Secure read protection is user-configurable in that the default lock/unlock state for each mapped block at reset is controlled by user-created DCF records, giving the user the ability to determine the number of levels of password protection implemented. The read protection is applied to groups of blocks instead of individual blocks and the groups are not user-definable.

The next sections discuss implementing secure read protection and overriding secure write protection.

80.5.1 Implementing secure read protection

Implementation of secure read protection is done during initial flash setup as follows:

1. Four 256-bit passwords (passwords 0–3) are stored in a protected OTP area of device flash named UTEST flash. Each password secures a set of registers in the PASS module (PASS_LOCK0_PG*n* –PASS_LOCK3_PG*n*) that have the same mapping of register bits to flash blocks as the flash module's SEL0–3 registers and LOCK0–3 registers. These are the same passwords used by secure write protection and other secure functions. The passwords are only created once.
2. DCF records must be created to define which flash memory blocks are to be locked. Those records determine the reset values of the PASS_LOCK3_PG*n* registers.

   Like the other PASS_LOCK*x*_PG*n* registers, the PASS_LOCK3_PG*n* registers have two functions.

   - Reading the registers provides a lock status for each Read Locking group.
   - Changing the value of a mapped bit in a register changes the read protect status of the corresponding Read Locking group.

The layout of the PASS_LOCK3_PG*n* registers is shown in Figure 80-8. The fields relevant to implementing secure read protection are RL4–RL0.

Offset 0x010C LOCK3_PG0
0x011C LOCK3_PG1

0x01180000	0x011BFFFF	256	6	LOCK2	256KLOCK[6]	6	49	256KB Code Flash block6
0x01140000	0x0117FFFF	256	6	LOCK2	256KLOCK[5]	5	50	256KB Code Flash block5
0x01100000	0x0113FFFF	256	6	LOCK2	256KLOCK[4]	4	51	256KB Code Flash block4
0x010C0000	0x010FFFFF	256	6	LOCK2	256KLOCK[3]	3	52	256KB Code Flash block3
0x01080000	0x010BFFFF	256	6	LOCK2	256KLOCK[2]	2	53	256KB Code Flash block2
0x01040000	0x0107FFFF	256	6	LOCK2	256KLOCK[1]	1	54	256KB Code Flash block1
0x01000000	0x0103FFFF	256	6	LOCK2	256KLOCK[0]	0	55	256KB Code Flash block0

1. There are multiple sets of LOCKn registers, i.e., the flash module's LOCK0–-3 registers and PASS module's PASS_LOCK0–3_PG0–3, but all use the same mapping of register bits to flash blocks. The same mapping applies the the flash module's SEL0–3 registers.
2. The DCF record DATA bit refers to the DATA[31:0] field contained in DCF records created during OEM configuration activities. The DCF records related to flash blocks are used to implement password-secured write protection, passwordsecured read protection, tamper detection, and debug port enable/disable as a permanent part of the device configuration.
3. One time programmable.
4. The Boot Assist Flash (BAF) is one time programmable and the majority of it is programmed in the factory. The BAF handles the initial start up of the device.

To provide two level of password protection for only Read Lock group 3 and leave all other groups unlocked, the RL3 bit can be set in any two of the four PASS_LOCK3_PG*n* registers. For this example, we will choose password groups 0 and 1.

We need to create DCF records that define the reset values for all RL*n* bits as 0, with the exception of PASS_LOCK3_PG0 and PASS_LOCK3_PG1. The information required is from the PASS section of the attached DCF_clients.xlsx.

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0000_1000	000_0000_0100_0011	LOCK3_PG0
000_0000_0000_1000	000_0000_0100_0111	LOCK3_PG1
000_0000_0000_1000	000_0000_0100_1011	LOCK3_PG2
000_0000_0000_1000	000_0000_0100_1111	LOCK3_PG3

Referring to Figure 80-5, the values for the DCF record are:

- For LOCK3_PG0
  - Data[31:0] is 0x0008_0000 (bits 0–31)
  - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
  - Address[16:2] is 0b000_0000_0100_0011 (bits 47–61)
  - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
  - Preferred Stop value is 0.
- For LOCK3_PG1
  - Data[31:0] is 0x0008_0000 (bits 0–31)
  - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
  - Address[16:2] is 0b000_0000_0100_0111 (bits 47–61)
  - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
  - Preferred Stop value is 0.
- For LOCK3_PG2
  - Data[31:0] is 0x0000_0000 (bits 0–31)
  - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
  - Address[16:2] is 0b000_0000_0100_1011 (bits 47–61)
  - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
  - Preferred Stop value is 0.
- For LOCK3_PG3
  - Data[31:0] is 0x0000_0000 (bits 0–31)
  - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
  - Address[16:2] is 0b000_0000_0100_1111 (bits 47–61)

- Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
- Preferred Stop value is 0.

80.5.2 Overriding secure read protection

As noted previously, the PASS_LOCK3_PG*n* registers (see Figure 80-8) contain five read protection fields, RL0–RL4, that correspond to pre-defined Read Lock groups. To temporarily unlock a Read Lock group, the appropriate PASS_LOCK3_PG*n*[RL*n*] bits must be set to 0.

Like the register bits controlling secure write protection, the reset value of bits controlling secure read protection is determined by DCF record or, in the absence of a relevant DCF record, each bit resets to '1', causing the blocks associated with each read group to be read locked.

Example: 80.5.2.1 Overriding secure read protection

Overriding secure read protection

Building on Implementing secure read protection, where Read Lock group 3 was protected by passwords 0 and 1, temporarily overriding secure read protection for that group is accomplished by first unlocking the PASS_LOCK3_PG0 and PASS_LOCK3_PG1 registers and then setting the RL3 bit to '0' in both.

1. First write 0b00 to the PASS_CHSEL[GRP] register field to indicate registers controlled by password 0 are to be unlocked.
2. Write the 256-bit value for password 0 to the set of eight 32-bit password challenge input registers (PASS_CIN*n*) beginning with PASS_CIN0. The password must be written as a sequence of eight 32-bit writes, with the most significant bits of the password written to PASS CIN0.
3. Write a 0 to PASS_LOCK3_PG0[RL3] bit and verify a successful write.
4. Repeat the above steps for password 1.

The result of a successful sequence is that the blocks associated with the unlocked read lock group can be read by a debugger.

80.6 Debug port enable/disable

The mechanism for temporarily enabling the MPC5746C debug port after it has been locked by its life cycle state is similar to the flash memory read protection mechanism detailed in Secure read protection. The difference is that the PASS_LOCK3_PG*n*[DBL] field is used instead of the RL0–RL4 fields.

80.7 Tamper detection

The Tamper Detection Module (TDM) provides a type of flash memory write protection mechanism that forces software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. An additional feature is provided to enable customers to override the protection mechanism for any TDR so that no record is required to be written before a block within the TDR can be erased.

This section provides details on the mapping between DCF record bits and individual flash memory blocks to be selected for tamper detection.

See Tamper Detection Module (TDM) for details on tamper detection, including the DCF clients and two additional memory-mapped registers.

There are two significant differences between selecting blocks for tamper detection and selecting blocks for other activities, e.g., a flash erase operation:

1. Selection of blocks for tamper detection protection is done only during device configuration to customer specifications, either at the factory or by the customer during OEM production activities. The selection becomes a permanent part of the device configuration.
2. The selection of blocks for tamper detection is done by writing *DCF records*, which is why the selection becomes a permanent part of the device.

The Tamper Detect section of DCF client list table in the attached DCF_Clients.xlsx. gives the CS and Address value combinations that correspond to groups of LOCK0–LOCK3 registers, similar to the flash module's LOCK0–LOCK3 registers.

The mapping of individual flash blocks to TDM DCF record data field bits is shown in Tamper Detection Module (TDM) configuration

80.7.1 Implementing tamper detection

Implementing tamper detection requires:

1. Creating the tamper detect diary
2. Assigning blocks to Tamper Detection Regions (TDRs)

The tasks are detailed in the following sections

80.7.2 Creating the tamper detect diary

Tamper detection in the MPC5746C microcontroller is user-defined. The basic functionality provided is an erase counter, or diary, for 6 user-defined regions, called "tamper detect regions", or TDRs, within the flash memory. Each TDR is defined using a set of DCF records that is similar in function and layout to the flash module's SEL*n* and LOCK*n* registers, which contain bits matched to specific flash blocks.

For a program or erase operation to be performed on a block included in a TDR, a record must be written to a "diary" that tracks flash modification operations. The format and size of records is customer-defined. The only hardware constraints are that each diary has a maximum size of 2 KB and the minimum size of any programming operation is 8 bytes.

Note

The limiting factor for tamper detection records is the diary size. The total diary size is given by the number of TDRs (6 for MPC5746C) multiplied by 2 KB, the portion of the diary allotted to records associated with each TDR.

Since the minimum flash programming operation size is 8 bytes, the maximum number of tamper detect records for a given TDR is 256 8-byte entries.

The diary can be placed within any flash block in the flash array but to maintain the security of the TDR, there are two constraints:

- The block where the diary is placed must be assigned as OTP within the OTP registers (covered in the next section)
- The diary base address must be on a 4 KB boundary, therefore the least significant 12 bits of the base address must all be '0'

Warning

The tamper detect diary base address DCF record is a "write once" record. All subsequent tamper detect diary base address DCF records created are ignored.

Example: 80.7.2.1 Creating the tamper detect diary

Creating the tamper detect diary

If the total space required for a diary is 12 KB (as in the case of 6 TDRs), any flash block can be used because the smallest flash blocks in the MPC5746C microcontroller are 16 KB. Since the diary base address must be on a 4 KB, boundary, though, if the diary base address is within a 16 KB flash block, it can only be assigned to the base address of the block or the address given by the base address plus 4 KB.

If the base address of the 16 KB block is 0x00F90000, the base address of the diary is given by:

0b0000_0000_1111_1001_0000_0000_0000_0000 (16 KB base address)
or
0b0000_0000_1111_1001_0001_0000_0000_0000 (16 KB base address + 4 KB)

The base address of each TDR's section of the diary is:

- TDR0 = Diary_Base_Address + 0b00_0000_0000_0000
- TDR1 = Diary_Base_Address + 0b00_1000_0000_0000
- TDR2 = Diary_Base_Address + 0b01_0000_0000_0000
- TDR3 = Diary_Base_Address + 0b01_1000_0000_0000
- TDR4 = Diary_Base_Address + 0b10_0000_0000_0000
- TDR5 = Diary_Base_Address + 0b10_1000_0000_0000
- End of the diary = Diary_Base_Address + 0b11_0000_0000_0000

We need to create one DCF record that defines the base address for the diary. The information required is from the Tamper Detect section of the attached DCF_Clients.xlsx sheet.

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0001_0000	000_0000_0000_0000	Diary Base Address

Referring to Figure 80-5, the values for the DCF record are:

- Diary Base Address
  - Data[31:0] is 0x00F90000 (the base address)
  - CS[14:0] is 0b000_0000_0001_0000 (bits 32–46)
  - Address[16:2] is 0b000_0000_0000_0000 (bits 47–61)
  - Parity value is irrelevant because it is not used in Tamper Detect DCF records (bit 62)
  - Preferred Stop value is 0.

See the Tamper Detect section of DCF client list table refer to the attached DCF_Clients.xlxs sheet for details.

Note

User software must check whether the diary is full. If the diary area for a TDR is full, user software must program a DCF record to override blocking of erase from TDR, disabling tamper detect, so that erases can be done to that TDR without any diary entry. This is detailed in Overriding tamper detection.

80.7.3 Assigning blocks to Tamper Detection Regions (TDRs)

Tamper detection regions are defined by creating TDR*x*_LOCK*n* DCF records. For example, in a microcontroller with six tamper detection regions, the following records define the TDRs:

- TDR0_LOCK0, TDR0_LOCK1, TDR0_LOCK2, TDR0_LOCK3
- TDR1_LOCK0, TDR1_LOCK1, TDR1_LOCK2, TDR1_LOCK3
- TDR2_LOCK0, TDR2_LOCK1, TDR2_LOCK2, TDR2_LOCK3
- TDR3_LOCK0, TDR3_LOCK1, TDR3_LOCK2, TDR3_LOCK3
- TDR4_LOCK0, TDR4_LOCK1, TDR4_LOCK2, TDR4_LOCK3
- TDR5_LOCK0, TDR5_LOCK1, TDR5_LOCK2, TDR5_LOCK3

Each set of TDR*x*LOCK*n* DCF records mapped in exactly the same way as the flash module's SEL*n* and LOCK*n* registers (see the detailed flash block map in the flash section of the Device Configuration chapter for the mapping).

In the TDR*x*LOCK*n* DCF records:

- A bit set to '1' means the corresponding flash block is assigned to this TDR
- A bit set to '0' means the corresponding flash block is NOT assigned to this TDR

The default state (no TDRs defined) is defined as 'Block NOT assigned to the TDR'.

80.7.4 Overriding tamper detection

When a TDR's diary section is full, a Tamper Override (TO) record must be created before a block assigned to the TDR can be programmed or erased.

The details of the data section of the DCF record used to override tamper detection is shown in Figure 80-9.

warning

Bits in this DCF record is writable from 0 to 1only. Attempted writes of bits from 1 to 0 are ignored.

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
W	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
W	0	0	0	0	0	0	0	0	0	0	TOE5	TOE4	TOE3	TOE2	TOE1	TOE0

Figure 80-9. Data portion of Tamper Region Override (TO) DCF record

Example: 80.7.4.1 Implementing secure write protection

Implementing secure write protection

Assume the diary Tamper Detection Region 3 is full

We need to create one DCF record that defines that overrides tamper detection for the tamper detection region whose diary is full. The information required is from the Tamper Detect section of the attached DCF_Clients.xlsx sheet.

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0001_0000	000_0000_0000_0001	Tamper Region Override

Referring to Figure 80-5, the values for the DCF record are:

- Data[31:0] is 0x0000_0008 (TOE3)
- CS[14:0] is 0b000_0000_0001_0000 (bits 32–46)
- Address[16:2] is 0b000_0000_0000_0001 (bits 47–61)
- Parity value is irrelevant because it is not used in Tamper Detect DCF records (bit 62)
- Preferred Stop value is 0.

See the Tamper Detect section of DCF client list table of the attached DCF_Clients.xlsx sheet for details.

80.8 Implementing OTP

Any flash block within the flash array can be assigned, at any time, to be OTP. OTP means that flash erase of the entire block is disabled and only 64-bit double words that are already erased (i.e., flash content is 0xFFFF_FFFF_FFFF_FFFF) can be programmed. Over-programming is not possible.

Flash blocks are assigned as OTP by writing a DCF record. The block becomes OTP after the next reset.

warning

After a flash block is configured as OTP, it cannot be changed back.

This capability resides within the Tamper Detection Module (TDM). The records are detailed in the attached DCF_Clients.xlsx sheet. See the entries for the OTP_EN0, OTP_EN1, OTP_EN2, and OTP_EN3 DCF records in the Tamper Detect section of the table.

80.9 Implementing test mode disable

The MPC5746C flash memory module includes a mechanism to disable manufacturer entry into test mode. Extreme care must be taken when using this feature, as blocks that are selected to be protected in this method are able to have possible failures analyzed by manufacturer's failure analysts.

Test mode disable prevents all high voltage operations to the flash executed by the internal state-machine, as well as reads through the state machine, and reads through the Array Integrity state machine when using test mode interfaces.

Optionally, the customer can create a password to enable manufacturer entry into test mode.

80.9.1 Unconditional test mode disable seal

Warning

This process is not reversible. After completing these steps the MPC5746C microcontroller is permanently prevented from entering test mode for factory analysis.

The steps for unconditionally disabling test mode are the same steps required for implementing passcode-protected entry into test mode with one exception—the passcode specified must not be one of the following three *invalid* passcodes:

- 0x0000_0000
- 0xFFFF_FFFF
- 0x5555_5555

To unconditionally disable test mode entry:

1. Select individual flash blocks to be protected by programming the appropriate values into the Test Mode Disable Block Select Group A and Test Mode Disable Block Select Group B areas shown in the UTEST flash memory map.
2. Program one of the three *invalid* passcodes shown above into the Test Mode Override Passcode area shown in the UTEST flash memory map.
3. Program the value 0x2D3C_4B5A into the Test Mode Disable Seal location specified in the UTEST flash memory map.

After the next reset is asserted, Test Mode is permanently disabled.

Note

1. Blocks selected for test mode disable can be selected in either or both Test Mode Disable Block Select Groups (A and B) because those fields are logically ORed to determine the blocks to be protected.

2. The lifecycle state must be programmed to 'Production at OEM' or later for the disable seal to be in effect.

80.9.2 Passcode-protected test mode disable seal

The steps for implementing passcode-protected entry into test mode are the same required for unconditionally disabling test mode with the exception that —the passcode specified must NOT be one of the following three *invalid* passcodes:

- 0x0000_0000
- 0xFFFF_FFFF
- 0x5555_5555

To implement passcode-protected test mode entry:

1. Select individual flash blocks to be protected by programming the appropriate values into the Test Mode Disable Block Select Group A and Test Mode Disable Block Select Group B areas shown in the UTEST flash memory map.
2. Program a valid passcode into the Test Mode Override Passcode area shown in the UTEST flash memory map.
3. Program the value 0x2D3C_4B5A into the Test Mode Disable Seal location specified in the UTEST flash memory map.

After the next reset is asserted, Test Mode is permanently passcode protected.

Note

1. Blocks selected for test mode disable can be selected in either or both Test Mode Disable Block Select Groups (A and B) because those fields are logically ORed to determine the blocks to be protected.
2. The lifecycle state must be programmed to 'Production at OEM' or later for the disable seal to be in effect.

80.9.3 Selecting flash memory blocks for test mode disable seal

Selecting flash memory blocks for test mode disable seal protection is similar to selecting blocks for tamper detection in that it involves writing to non-register flash locations. In the case of the test mode disable seal function, there are two areas of UTEST flash memory that have identical mapping to flash memory blocks. When the test mode disable seal takes effect, the mapped bits are logically ORed to determine the blocks to be protected.

CAUTION

1. The mapping of bits to blocks for this function is different from the mapping used for other functions. See the table in the device configuration chapter for the map.
2. Selecting a block for test mode disable requires a '0' in the mapped bit—not a '1' as with other functions.

The mapping of individual flash blocks to Test Mode Disable Block Select bits is shown in Table 80-3.

Table 80-3. Mapping of Test Mode Disable Block Select bitsto flash blocks

Start Address	End Address	Byte offset[1]	Test Mode Disable Block Select Bit	Description
0x00610000	0x0061FFFF	0	0	64KB HSM code block 2
0x00FE0000	0x00FEFFFF	0	1	64KB code block

1. The byte offset is from the start address of either the Test Mode Disable Block Select Group A (0x00400010) or the start address of the Test Mode Disable Block Select Group B (0x00400030) area of UTEST flash.

80.10 Security configuration planning

At minimum, designing the flash security framework consists of selecting the security features to be implemented and determining the scope of implementation for each selected feature.

In devices containing a Hardware Security Module (HSM), significant planning must go into the implementation of HSM functions. The HSM is an independent software platform within the microcontroller. It is intended to be used to implement advanced security functions that are defined by customer software.

Note

Details of advanced security features, including the advanced security architecture and the Hardware Security Module (HSM) are contained in the *MPC5746C Microcontroller Security Reference Manual*. Distribution of the document is restricted to qualified customers.

The basic security features available in the MPC5746C microcontroller include:

- Secure write protection
- Secure read protection
- Debug port enable/disable
- One-time-programmable (OTP) flash memory block assignment
- Factory test mode disable

80.10.1 Hardware Security Module (HSM)

Details of the HSM are included in the *MPC5746C Microcontroller Security Reference Manual*. It is mentioned here because the flash memory module includes blocks that can be configured for exclusive access by the HSM. If the HSM is to be used in an application it is advisable to protect HSM code by configuring it for exclusive access by the HSM. The blocks configurable for exclusive access by the HSM appear in Table 3-2 in NVM memory map. They are labeled as HSM code flash or HSM data flash blocks. They are not configured for HSM-exclusive access by default, though—they are available to act as secure flash areas but must be explicitly configured for that purpose. See the *MPC5746C Microcontroller Security Reference Manual* for details.

80.10.2 Creating password groups

Most basic security features in the MPC5746C microcontroller are password-based. Therefore, one of the early tasks that must be performed is the creation of four 256-bit passwords. They are programmed by the customer into the locations identified in the UTEST memory map (Table 3-3) in Memory Map.

The UTEST memory map fields to be written are:

- PASS Password Group 0
- PASS Password Group 1
- PASS Password Group 2
- PASS Password Group 3

Warning

The password fields are in OTP UTEST flash, so they can only be written once.

80.10.3 Planning secure write protection

Up to four levels of password-secured write protection can be assigned to any block. Note that by default, all blocks of user flash are write protected, so this could be more accurately viewed as planning which blocks of user flash will *not* have four levels of password-secured write protection. The write protection desired will depend on the usage of the flash blocks. Before creating DCF records to implement secure write protection, please thoroughly review the implementation steps detailed in Implementing secure write protection and in the attached DCF_Clients.xlsx sheet.

80.10.4 Planning secure read protection

Up to four levels of password-secured write protection can be assigned to flash blocks in pre-defined Read Locking groups. Note that by default, all blocks of user flash are read protected, so this could be more accurately viewed as planning which blocks of user flash will *not* have four levels of password-secured read protection. The read protection desired will depend on the usage of the flash blocks. Before creating DCF records to implement secure read protection, please thoroughly review the implementation steps detailed in Implementing secure read protection and in the attached DCF_Clients.xlsx shee.

80.10.5 Planning debug port enable/disable

Please see Debug port enable/disable and in the attached DCF_Clients.xlsx sheet.

80.10.6 Planning OTP flash memory block assignment

Any block of user flash can be configured as OTP. The need to configure blocks as OTP will depend on the data or code to be stored in the block. It is important to note that configuring a flash block as OTP is not reversible.

Before creating DCF records to implemented OTP flash blocks, please thoroughly review the implementation steps detailed in Implementing OTP and in the attached DCF_Clients.xlsx shee.

80.10.7 Planning factory test mode disable

Please see Implementing test mode disable and in the attached DCF_Clients.xlsx shee.

Appendix A
Release Notes

A.1 General changes

This section covers the changes, not covered below in their respective sections.

• Added *MPC5746C_Module_Reset_Status* spreadsheet in RM as attachment and a reference to this spreadsheet also listed in Module Status During Reset Process section
• Removed the redundant note "For the chip-specific implementation details of this module's instances, see the chip configuration information" from various places in RM.

• In Chapter Z2 Core description :
  • Added section End-to-End ECC Support
  • Added section End-to-End ECC fault injection by software
  • Added section End-to-End ECC Control Register 0 (E2ECTL0)
  • Added section End-to-End ECC control and configuration
  • In Table 62-7, added row for Critical Input
  • Added section Critical Input Interrupt (offset 0x00)

• In Chapter PRAMC :
  • Added P1_BO_DIS
  • Added PRI
  • Added P0_BO_DIS
  • Updated list item below Figure 70-1 : *System bus supports 64-bit data + 8-bit ECC AHB interfaces*
  • In Initialization/application information, added paragraph text *One possibility for initializing PRAMC memory space is to use a stored 64-bit word instruction such as Store Multiple Word (e_stmw) in Power Architecture VLE.*

• In Chapter Tamper Detect Module (TDM) :
  • Added Software Tamper Override Key Region (TDM_STO_KEY*n*)
  • In TDR override, added paragraph
  • In DCF clients, removed the list item *Permanently disable ability for software to permanently override one or more TDRs*
  • Updated Table 79-2
  • Added section Software Tamper Region Override Disable (STO_DIS) DCF client
  • In Tamper Region Override (TO) DCF client, updated Caution

• In Chapter IEEE 1149.7 Compact JTAG Test Access Port Controller (CJTAG) :
  • In 1149.7 TAP signals, deleted references to nTRST. It is not implemented on this chip.
  • In SP Format, deleted the list item pertaining to SScan. SScan is not implemented on this chip.
  • In Overview, deleted content pertaining to SScan. SScan is not implemented on this chip.
  • In EPU (Extended Protocol Unit) Operation, deleted the "Scan Selection Directive (SSD)" section. SSD is not implemented on this chip.

• In Chapter System Memory Protection Unit (SMPU) :
  • Updated Application information
  • Updated Region Descriptor n, Word 2 (SMPU_RD_*n*W2) name and register description

- Removed "Region Descriptor n, Word 2 Format 1 (SMPU_RD_nW2_F1)" register
- Updated Region Descriptor n, Word 3 (SMPU_RGD*n*_WRD3) description
- Updated SMPU_RGDn_WRD3[FMT], SMPU_RGDn_WRD3[ACCSET3], SMPU_RGDn_WRD3[ACCSET2] and SMPU_RGDn_WRD3[ACCSET1] as Reserved

- In Chapter Wakeup Unit (WKPU) :
  - Removed "Wakeup/Interrupt Pulldown Enable Register (WKPU_WIPDER)" register

- In Chapter Configurable Enhanced Modular IO Subsystem (eMIOS) :
  - Updated MODE
  - Updated Single Action Input Capture (SAIC) Mode
  - Removed eMIOS_OUDIS[OU23_OU0] and added OU31_OU0
  - Removed "QDEC" references from this chapter
  - Removed Notes from eMIOS_C*n*[EDPOL] bit description

- In Chapter Periodic Interrupt Timer (PIT-RTI) :
  - In Interrupts, replaced "a low-power mode" with "STOP mode", in paragraph text
  - Updated Introduction, Features with Stop mode details
  - Added Example configuration for the lifetime timer
  - Added PIT Lower Lifetime Timer Register (PIT_LTMR64L) and PIT Upper Lifetime Timer Register (PIT_LTMR64H)

- In Chapter Software Watchdog Timer (SWT) :
  - In SWT Control Register (SWT_CR), deleted the earlier reset value of this register and added a footnote
  - In SWT Control Register (SWT_CR), also added a Note in description that states "The reset value of this register is implementation specific. See the chip-specific SWT information."

- In Chapter Password and Device Security Module (PASS) :
  - Updated JTAG Password Challenge
  - Added new section Flash Memory Write and Erase Protection
  - Removed "External signal description" section

- In Chapter PLL Digital Interface (PLLDIG) :
  - Removed PLL Calibration Register 1 (PLLDIG_PLLCAL1) register

- In Chapter Enhanced Direct Memory Access (eDMA) :
  - Removed Wait row from Table 68-3
  - Updated description at Value "01" of BWC

- In Chapter Peripheral Bridge :
  - Updated Access support
  - Updated MPRA and MPRB

- In Chapter FlexCAN :
  - Added DMA and updates throughout the chapter for DMA functionality
  - The number of message buffers was changed from 64 to 96 and appropriate changes were made throughout the chapter
  - The FlexCAN module was changed to use the ISO CAN FD protocol and appropriate changes were made throughout the chapter
  - Added PREXCEN and added EDFLTDIS bits in CAN_CTRL2 register
  - Updated ERJW bit-width and description in CAN_CBT register
  - Updated FRJW bit-width and description in CAN_FDCBT register

- In Chapter Synchronous Audio Interface (SAI) :
  - I2S_TCSR[STOPE] bit is now Reserved
  - I2S_RCSR[STOPE] bit is now Reserved

- In Chapter Fault Collection and Control Unit (FCCU) :
  - Updated last paragraph in Introduction section
  - Updated description of XTMR bit
  - In FCCU_CTRL[OPR] bit, updated the field value description at value "10100"
  - Updated description in XTMR (FCCU_XTMR)

- In Chapter Decorated Storage Memory Controller (DSMC) :
  - Removed section "DSMC block diagram"
  - Removed section "DSMC timing diagram"

- In Chapter Crossbar Switch (AXBS) :

• Added "HLP" bit in AXBS_CRS*n* register • Updated reset value of "PCTL" bit in AXBS_CRS*n* register
• In Chapter Ethernet MAC (ENET) : • Deleted Note from ENET_ATCR[RESTART] bit • Deleted Note from ENET_ATCR[CAPTURE] bit • Removed section "Timer Synchronization for Multi-Port Implementations" and its reference from chapter • Updated ENET_MRBR1[R_BUF_SIZE], ENET_MRBR2[R_BUF_SIZE] and ENET_MRBR[R_BUF_SIZE] bit-width from 7 bits to 10 bits • Added TPWC bit • Updated bit field value description of TMODE bit at "1110" and "1111" values • Added Note in TCC bit description
• In Chapter Deserial Serial Peripheral Interface (DSPI) : • Added Multiple Transfer Operation (MTO) section • Added Parallel Chaining section • Added Serial Chaining section • Added "MTOE" and "MTOCNT" bits in DSI Configuration Register 0 (DSPI_DSICR0) • Updated Slave Mode section • Updated PCS4/$\overline{\text{MTRIG}}$—Peripheral Chip Select 4/Master Trigger section • Updated HT—Hardware Trigger section • Updated Features section • Updated Module signal descriptions section • Updated Deserial Serial Interface (DSI) Configuration section • Updated Change In Data Control section • Added Timed Serial Bus (TSB) section • Added MSC Dual Receiver Support with PCS Switch Over section • Updates throughout the chapter pertaining to TSB mode support • Added Interleaved TSB (ITSB) Mode section and its sub-sections • Updates throughout the chapter pertaining to ITSB mode support
• In Chapter Nexus Crossbar Multi-Master Client (NXMC) : • Removed "Peripheral interface" section and its sub sections • Removed ICTM feature and instances from this chapter • Updated Watchpoint trigger register (WT) • Updated Development control register 2 (DC2) • Updated Development control register 1 (DC1) • Added HSM master filtering and information pertaining to HSM
• In Chapter Fast OSC Digital Interface (FXOSC) : • Updated paragraph text in Oscillator startup delay • Updated Oscillator bypass mode section
• In Chapter Boot Assist Flash (BAF) : • Added information pertaining to NO_ECHO throughout the chapter
• In Chapter Self-Test Control Unit (STCU2) : • Content updated throughout the chapter

A.2 Introduction changes

• Updated Table 2-2 thoroughly • Added Table 2-3, Table 2-4 and Table 2-5 • In Table 2-6 : • In Communications row: Updated number of message buffers to 128 for FlexCAN • Updated Analog row for ADC • Updated Boot support row • Updated Safety row for MEMU instances

A.3 Memory Map changes

- In Table 3-5 :
  - Updated row corresponding to start address "0xFFF74000" and end address "0xFFF77FFF" as "Reserved".
  - In row with start address "0xFFF34000", added "TDM" region and updated Peripheral Bridge slot number as "OPACR50"
  - Replaced the BAR region row with Reserved in address range "0xFFFFC000 to 0xFFFFFFFF"
  - Several editorial updates in this table

- In Table 3-1, the row with "0x00F8C000 to 0x00FAFFFF" address is now split into 2 separate entries:
  - 0x00F8C000 - 0x00F8FFFF : 16 KB : Small HSM Code Block
  - 0x00F90000 - 0x00FAFFFF : 128 KB : Small and Medium NVM Blocks
- In Table 3-6 "Off Platform Bridge B":
  - Removed the first 6 entries for Reserved
  - Added a row in place of it, "0xF9000000 : 0xFBC17FFF : 44 MB : Reserved
- Updated MC_CGM mapped peripherals memory map section and table

A.4 Signal description changes

- In MSCR assignments, updated paragraph text from "*As an example, PAD18/PB[2] has SRE, ODE, SMC, IBE, HYS, WPS, WPUE, SSS and OBE are implemented with the reset value 0000_0000*" to "*As an example, PAD18/PB[2] has SRE, ODE, SMC, IBE, HYS, PUS, PUE, SSS and OBE are implemented with the reset value 0000_0000*".
- Added a Note : "Implemented SIUL2 Multiplexed Single Configuration Register..... and so on"
- In Table 4-1, added row for GPIO[197]

A.5 Security overview changes

- No substantial content changes

A.6 Platform overview changes

- New Chapter added in RM.

A.7 Power management overview changes

- In Accelerated Low Power Exit, updated "Required Software Configurations".

- In Introduction, added "MC_ME" and "LPU_CTL" modules to the list of Power Management infrastructure.
- In Features section, updated first bullet
- Updated Figure 7-2
- Added SRAM Configuration section

• Updated Table 7-4 • Updated Voltage monitoring section • Removed "*External regulator and low power modes*" section • Added Applications and Low Power Modes section
• Topics PORST in EXTERNAL REGULATION and External regulator contol are updated completely.

A.8 LPU changes

• In Module Disable (LPU_MDIS), description added a note "During transition from RUNx mode ..... clock cycles during RUNx to LPU transition."
• In LPU Mode Control Register (LPU_MCTL), description added a note "Software should always .....request is initiated."
• In Reset, added a note "If the application software is..... be flagged at RGM_FES[F_Z2_DBG]." • Updated Figure 8-1

A.9 Clocking changes

• Updated Figure 9-14.
• Updated Figure 9-21. • Added a note "If FXOSC failure happens, ... clock source again" in Loss of PLL lock/FXOSC clock. • Added a sentence "It is not recommended..... system clock" in FXOSC monitor
• In PLLDIG initialization information, point 1 subpoint c, changed "PLLFM[MODEN] = 1" to "PLLFM[SSCGBYP] = 0". • In Figure 9-13, updated 0101 to "LPU sys clk" and 0110 to "Z2 core clk". • In Figure 9-13, added a footnote "FXOSC_ANA_CLK is a output of analog ..... frequency as FXOSC". • In PLL Monitor, updated sentence from "There is an option to generate an interrupt when the flag bit is set" to "This will lead to FCCU_NCF[32] fault being set when the flag bit is set". • In FlexRay clocking added a sentence, "Control host interface (CHI) clock of FlexRay is sourced from FS80 group" and updated Figure 9-4

• In Peripheral Clock Restrictions added a bullet point "Flexray PE clock always need 80 Mhz..... flexray data rates".
• In Linear DFS Configuration
  ◦ Added footnote in "Case 2: Linear DFS" row for "FlexRay" in Table 9-2.
  ◦ Updated "Suggested configuration sequence for Linear DFS".

• In SWT clocking removed Note "*If SWT is configured in STOP/STANDBY/LPU modes, SIRC should be kept ON in target modes (RUNx/DRUN) also, to exit properly*". • In SWT clocking added Note "*SIRC should always be kept ON (in DRUN/RUNx modes) if at least one SWT is enabled to allow proper mode transitions*".
• Updated Figure 9-7 • Editorial updates in ENET clocking section • Updated Table 9-6 and also added new rows
• Updated "FXOSC_ANA_CLK" in Figure 9-16.
• Updated table header for Table 9-7.
• In ENET clocking updated timer clock from "40MHz" to "50MHz".

A.10 Embedded memories changes

• In SRAM Controller (PRAMC), added list items for "SRAM address spaces" for PRAMC_0 and PRAMC_1.

• PRAMC_0 valid control register bits :
  • Removed note: "This register includes reserved bits with R/W access. Values written to bits 22:25 have no effect on device function."
  • Removed R/W reserved field (bits 22-25)
  • Added PRI field (bits 22-23)
  • Added P1_BO_DIS field (bit 24)
  • Added P0_BO_DIS field (bit 25)
• PRAMC_1 valid control register bits :
  • Removed note: "This register includes reserved bits with R/W access. Values written to bits 22:25 have no effect on device function."
  • Removed R/W reserved field (bits 22-25)
  • Increased size of ROZ reserved field from 22 to 25 bits (bits 0-24)
  • Added P0_BO_DIS field (bit 25)
  • In register definitions figure, changed "PRAMC_n_PRCR1" to "PRAMC_1_PRCR1"

A.11 DCF Records changes

• In DCF records sequence :
  • Removed a paragraph, "The stop bit is never set by the factory,....."
  • Updated Table 11-4

• In Safety features of DCF clients updated sentence "Depending on its role in the device a client may be equipped with a safety feature or a combination of safety features".
• Removed *UTEST miscellaneous register [UTEST_MISC]* section from RM. Refer to attached DCF_Clients spreadsheet for all the details. • In Introduction, in third paragraph, updated the reference to attached DCF_Clients spreadsheet for details.
• Added new section External Regulation Exit Trim Wait (PMCDIG_ERETW)

A.12 Debug overview changes

• JTAG ID section, updated and optimized for clarity.
• Added section TCK clock relation with NPC clock.
• Deleted note "LPM handshake for STOP mode entry/exit has a restriction that .....STANDBY and LPU STANDBY modes." from NPC Handshake module

A.13 Reset and boot overview changes

• In Table 13-4, added a new row for SWT0. • Updated Self-Test Control Unit (STCU).

- Added new section Software Watchdog Timeout (SWT0).
- In Table 13-16, added a new row for SWT0.
- In Table 13-2, added a new Reserved row at Reset Source 11

A.14 Functional Safety changes

- Added new Chapter.

A.15 SIUL2 changes

- In SIUL2 MCU ID Register #1 (SIUL2_MIDR1) :
  - Updated PARTNUM description
  - Updated PKG description
  - Updated footnote on "PKG" field
  - Added footnotes to "MINOR_MASK" and "MAJOR_MASK" fields
- In SIUL2 MCU ID Register #2 (SIUL2_MIDR2) :
  - Updated FLASH_SIZE_1 description
  - Updated FLASH_SIZE_2 description
  - Updated PARTNUM description

A.16 Crossbar switch changes

A.16.1 Crossbar switch configuration changes

- In CRS register reset values added Note.

A.16.2 Crossbar switch module changes

- Initialization/application information :
  - Minor edit
  - Added note about configuration: other masters must be idle.
  - Added note about preventing reconfiguration.

A.17 AIPS changes

A.17.1 Peripheral Bridge configuration changes

- In Table 17-1 and Table 17-2, updated AIPS reset values.

A.17.2 AIPS module changes

- Corrected misspellings in Memory map/register definition.

- Peripheral Access Control Register (AIPS_PACR*n*) : Added note to register description regarding the PACR0 reset value.
- In register descriptions for Peripheral Access Control Register (AIPS_PACR*n*) and Off-Platform Peripheral Access Control Register (AIPS_OPACR*n*) : reworded for grammar and clarity, added paragraph about not accessing unimplemented PACR/OPACR registers, and added sentence in OPCAR register description about seeing the device's memory map for details.

A.18 DSMC module changes

- No substantial content changes

A.19 IAHBG changes

A.19.1 IAHB Gasket configuration changes

- No substantial content changes

A.19.2 IAHBG module changes

- No substantial content changes

A.20 SMPU changes

A.20.1 SMPU configuration changes

- In System Memory Protection Unit (SMPU) configuration, updated term "data storage buffer" to "store buffer" and added a paragraph at the end "HDBCR0 is the hardware debug cache control register..... reference manual for details."

A.20.2 SMPU module changes

- Application information
  - Correction: Previously, the "Modifying a region descriptor" bulleted list item at the beginning of the section stated, "Writing to Word 3 re-enables the region descriptor valid bit." Writing to RGD*n*_Word5 re-enables the region descriptor valid bit.

- In Application information section's bulleted list item "Modifying a region descriptor," clarified how to re-enable region descriptor by revising second sentence:
  - From: "Writing to RGD*n*_Word5 re-enables the region descriptor valid bit."
  - To: "Writing 1 to RGD*n*_WRD5[VLD] re-enables the region descriptor."
- In Application information section's bulleted list item "Removing a region descriptor," changed register name from RGD*n*_Word5 to RGD*n*_WRD5

A.21 SEMA42 module changes

- No substantial content changes

A.22 PCM changes

- In Bus Bridge Configuration Register 0 (PCM_IAHB_BE0) :
  - Updated register reset value to "0707_0700h"
  - Updated bit access of Reserved bits at Bit 5, Bit 13 and Bit 21 to R/W from ROZ
  - Bit[16:20], access changed to ROZ
  - Bit[29:31], access changed to R/W from ROZ

A.23 INTC changes

A.23.1 INTC configuration changes

• In Table 23-1 : Updated source description for "LPU_CTL" at Vector number 250 to "LPU_ICR[NEM] | LPU_ICR[MRIG]" from "o_interrupt".
• In Table 23-1, updated "Source Module" and "Source description" column from rows 295 to 329.
• Added note "Interrupts are not serviced during selftest" in INTC interrupt sources. • Added Interrupts handling during mode transitions section

A.23.2 INTC module changes

• No substantial content changes

A.24 WKPU changes

A.24.1 WKPU configuration changes

• In Interrupts added a note "Software must enable ..... mode of the device.".
• Updated Table 24-3 • In Pull control of wakeup pads , added a new paragraph "*The pull up/down voltage level for unconnected wakeup/ interrupt input is VDD_HV_A supply level.*"
• Added sentence "Recommended WKPU Configuration....." in Pull control of wakeup pads • Added NMI on standby exit section

A.24.2 WKPU module changes

• Added Wakeup/Interrupt Pull Enable Register (WKPU_WIPER).

A.25 PLLDIG changes

• In PLL Calibration Register 3 (PLLDIG_PLLCAL3)
  • Updated field width of MFDEN from 16 to 15 bits (bits 3..17).
  • Updated Reserved field width from 2 to 3 bits (bits 0..2).

• In Frequency modulation

• Removed equation 'Modulation depth' and corresponding text.

• Editorial updates.
• In Frequency modulation
  • Updated the first equation in the NOTE, "(PLLFM[STEPSIZE] × PLLFM[STEPNO])..."
  • Updated equation for PLLFM[STEPNO].

A.26 SIRC changes

• No substantial content changes

A.27 FIRC changes

• No substantial content changes

A.28 SXOSC changes

• No substantial content changes

A.29 FXOSC changes

• FXOSC Control Register (FXOSC_CTL)
  • Added note to register description, "The FXOSC_CTL is only writable in supervisor mode."
  • Updated note "After reset, writing the..." so "XOSC_CTL" is now "FXOSC_CTL".

• FXOSC Control Register (FXOSC_CTL)   • Updated FXOSC_CTL[I_OSC] field access to W1C.

A.30 CMU changes

• CMU Interrupt Status Register (CMU_ISR)
  • Added note to the CMU_ISR[FLLI] field description.
  • Added note to the Reserved field description at bit location 28.

• CMU Measurement Duration Register (CMU_MDR)   • Added note to MD field description, "Only values that do not cause..."
• Added a note in CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)
• CMU Interrupt Status Register (CMU_ISR)   • Updated Note in OLRI field description.
• CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)

- Added the note "For correct synchronization of CMU_LFREFR write..." to the register description.
- CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)
  - Updated the note "For correct synchronization of CMU_HFREFR write..." to the register description.

- CLKMN1 supervisor
  - Updated NOTE "An example of determining the $HFREF_{Actual}$...".

- CMU Control Status Register (CMU_CSR)
  - Added note to CSR[SFM] field description, "MSR[MD] must be written before enabling...".

A.31 MC_CGM changes

- In Auxiliary Clock 3 Select Status Register (MC_CGM_AC3_SS) bit[7] is set to "Reserved" with RO access.
- Updated .

- In Progressive System Clock Switching, added a paragraph "It is recommended to .....SAFE mode or RESET event".

- Removed "Auxiliary Clock 3 Select Control Register (MC_CGM_AC3_SC)"
- Removed "MC_CGM Auxiliary Clock 3 Generation Overview" figure
- "This register is reset only on a POR reset", this sentence is added in the following registers:
  - Auxiliary Clock 2 Select Control Register (MC_CGM_AC2_SC)
  - Auxiliary Clock 5 Select Control Register (MC_CGM_AC5_SC)
  - Auxiliary Clock 6 Select Control Register (MC_CGM_AC6_SC)
  - Auxiliary Clock 8 Select Control Register (MC_CGM_AC8_SC)
  - Auxiliary Clock 2 Select Status Register (MC_CGM_AC2_SS)
  - Auxiliary Clock 3 Select Status Register (MC_CGM_AC3_SS)
  - Auxiliary Clock 5 Select Status Register (MC_CGM_AC5_SS)
  - Auxiliary Clock 6 Select Status Register (MC_CGM_AC6_SS)
  - Auxiliary Clock 8 Select Status Register (MC_CGM_AC8_SS)
  - Auxiliary Clock 9 Select Status Register (MC_CGM_AC9_SS)
  - Clockout 1 Select Register (MC_CGM_CLKOUT1_SC)
  - PCS Switch Duration Register (MC_CGM_PCS_SDUR)
  - PCS Divider Change Register 1 (MC_CGM_PCS_DIVC1)
  - PCS Divider Change Register 2 (MC_CGM_PCS_DIVC2)
  - PCS Divider End Register 1 (MC_CGM_PCS_DIVE1)
  - PCS Divider Start Register 1 (MC_CGM_PCS_DIVS1)
  - PCS Divider End Register 2 (MC_CGM_PCS_DIVE2)
  - PCS Divider Start Register 2 (MC_CGM_PCS_DIVS2)
  - Auxiliary Clock 9 Select Control Register (MC_CGM_AC9_SC)
  - System Clock Select Status Register (MC_CGM_SC_SS)
- "This register is reset only on POR reset, while .... corresponding to programmed value", this sentence is added in the following registers:
  - Aux Clock 6 Divider Configuration 0 for CLKOUT_0 (MC_CGM_AC6_DC0)
  - CLKOUT1_DC Configuration Register (MC_CGM_CLKOUT1_DC)
  - System Clock Divider 0 Configuration Register (MC_CGM_SC_DC0)
  - System Clock Divider 1 Configuration Register (MC_CGM_SC_DC1)
  - System Clock Divider 2 Configuration Register (MC_CGM_SC_DC2)
  - System Clock Divider 3 Configuration Register (MC_CGM_SC_DC3)
  - System Clock Divider 4 Configuration Register (MC_CGM_SC_DC4)
  - System Clock Divider 5 Configuration Register (MC_CGM_SC_DC5)
  - System Clock Divider 6 Configuration Register (MC_CGM_SC_DC6)
- "This register is reset only on a PHASE3 reset", this sentence is added in the following registers:
  - Divider Update Abort Register (MC_CGM_DIV_UPD_ABRTD)
  - System Clock Divider Ratio Change Register (MC_CGM_SC_DIV_RC)
  - Divider Update Type Register (MC_CGM_DIV_UPD_TYPE)
  - Divider Update Trigger Register (MC_CGM_DIV_UPD_TRIG)
  - Divider Update Status Register (MC_CGM_DIV_UPD_STAT)

A.32 Input Glitch Filter Changes

A.32.1 IGF module changes

- No substantial content changes

A.33 HFIF Changes

A.33.1 HFIF chapter changes

- No substantial content changes

A.34 ADC changes

A.34.1 ADC configuration changes

- Added new section: ADC's stop-stop ack protocol

A.34.2 ADC module changes

- Added subsection Conversion time for BCTU interface to section Conversion time.

- Updated Reserved field access from RW to ROZ (bit 16) in Interrupt Mask Register (ADC_IMR) .
- Updated the access of Reserved fields to ROZ in Conversion Timing Register 0 (ADC_CTR0) .

- Editorial changes

- Main Status register (ADC_MSR)
  - Added the sentence "MSR[CHADDR] is only valid..." to the MSR[CHADDR] field description.

- BCTU Control mode
  - Removed the paragraph "If another BCTU trigger is received..."

- In DMA functionality
  - Updated content throughout.

- Calibration, BIST Control and status Register (ADC_CALBISTREG)
  - Updated NOTE in the NR_SMPL field description.

- Updated reset values for the following registers:
  - Conversion Timing Register 0 (ADC_CTR0)

- Conversion Timing Register 1 (ADC_CTR1)
- Conversion Timing Register 2 (ADC_CTR2)

A.35 CMP changes

A.35.1 CMP configuration changes

- No substantial content changes

A.35.2 CMP module changes

- No substantial content changes

A.36 BCTU changes

A.36.1 BCTU configuration changes

- Added new section: BCTU's stop-stop ack protocol

A.36.2 BCTU module changes

- In Introduction and BCTU overview :
  - Updated number of trigger signals information.
  - Updated number of ADC modules information.
- In Introduction and BCTU Interacting with other peripherals removed information related to eTPU.
- Removed BCTU_SFTRGR3 register.

- In Trigger priority and multiplexing , updated Figure "Priority stages architecture" to show correct number of ADCs.

A.37 eMIOS changes

A.37.1 eMIOS configuration changes

- Updated Figure 37-1 : Marked the Red bus as Counter_bus_F.

A.37.2 eMIOS module changes

• No substantial content changes

A.38 MC_PCU changes

• No substantial content changes

A.39 PMCDIG changes

• In PMCDIG_MCR[LP_ST_CHG_IN_PRGRS] register, added a sentence, "This bit should always be set to '0' before a low power mode transition request is initiated".
• In SGSR register, added a note, "Bits 24-30 will remain set and will not get cleared if respective supply is below voltage monitor threshold. Please refer device data sheet for voltage monitor threshold levels.".

A.40 MC_ME changes

• Updated bitfield description of S_MRIG bit in Invalid Mode Transition Status Register (MC_ME_IMTS)
• In Use Case 1: Software Tasks with Different Clock Requirements, added a note "All ME_PCTLx controlled ..... register configuration."
• In Mode Control Register (MC_ME_MCTL), added a note "Software should always.....request is initiated".
• In Example 1: Minimal Code to Bring Up a PLL, updated code.

• In Memory Map and Register Definition, added a note "All registers are read only in user mode".
• In S_FXOSC bit of Global Status Register (MC_ME_GS) added a note "S_XOSC alone should not be relied on..... is 1 and OLRI flag = 0".
• In Mode Enable Register (MC_ME_ME) updated modes in the description. RESET changed to RESET_FUNC and RESET_DEST is added.
• In STOP0 Mode added notes:
  • If waking up from stop..... clearing module interrupt.
  • All interrupts that are ..... which causes a hang.
  • A potential system hang scenario ..... finished before stop mode change.
• In Protection of Mode Configuration Registers added three bulet points, "If the FIRC_CLK is selected....."

• Updated Figure 40-5
• Updated reset value of Global Status Register (MC_ME_GS) to 0x0C13_0010h.

A.41 GPR changes

• Updated reset value of GPR Status Register (GPR_STAT) to 0x0000_0002. • Access changed to RO (Read only) for bit 30 of GPR Status Register (GPR_STAT)
• Bit descriptions and bitfield value description are updated for CMP2_STDBY, CMP1_STDBY, CMP0_STDBY of GPR Control Register (GPR_CTL)
• In GPR Control Register (GPR_CTL), GPR_CTL[GPR_HSM_RAM_FAST_INIT_BYPASS] is placed at GPR_CTL[0].

A.42 DSPI changes

A.42.1 DSPI configuration changes

• Added new section: DSPI's stop-stop ack protocol
• Added TSB mode information in Table 42-1 and Table 42-2.

A.42.2 SPI configuration changes

• Added TSB information in Table 42-3

A.42.3 DSPI module changes

• In Status Register (DSPI_SR) - Changed TXRXS bitfield access from W1C to RO.

• Deleted note from SOUT—Serial Output.
• Clarified Memory Map/Register Definition introductory text by changing second sentence:
  • From: "Write access to the POPR and RXFRn also results in a transfer error."
  • To: "Any Write access to the POPR and RXFRn also results in a transfer error."

• Updated PUSH TX FIFO Register In Master Mode (DSPI_PUSHR) description.
• In section, PCS0/$\overline{SS}$—Peripheral Chip Select/Slave Select : Added note.
• In section, Memory Map/Register Definition : Added note
• Updated section, Receive FIFO Drain Interrupt or DMA Request with, "Configure the DMA to drain only one FIFO location per transfer". • Updated notes in Command FIFO Fill Interrupt or DMA Request and Transmit FIFO Fill Interrupt or DMA Request • Updated bit field descriptions for SR[TFFF, RFDF] • Updated bit field descriptions for SR[CMDFFF] • Updated notes in Command FIFO Fill Interrupt or DMA Request and Transmit FIFO Fill Interrupt or DMA Request • Updated bit field descriptions for SR[TFFF, RFDF] • Updated bit field descriptions for SR[CMDFFF]
• In Status Register (DSPI_SR), edited field description of:

• CMDFFF • RFDF • TFFF
• In Memory Map/Register Definition Note, edited text and reorganized items as a list
• In Status Register (DSPI_SR), edited field description of: • CMDFFF_DIRS

A.43 ENET changes

A.43.1 ENET configuration changes

• Added new section: ENET's stop-stop ack protocol • Added new section: Recieve Parser Match Array Table Depth

A.43.2 ENET module changes

• In Ethernet Control Register (ENET_ECR), 20-bit Reserved field was divided into two fields and their corresponding description's were added.
• Frame parser : Added “Initialize the entire parser memory to zero before creating entries in parser entry table.” to section. • Ethernet interfaces : Removed "ECR[SPEED]" column from table. • Adjustable Timer Control Register (ENET_ATCR) : • Added note to register description regarding when fields can be written. • Changed access of reserved bits 19 and 21 from ROZ to RW. Changed field descriptions of these bits. • Ethernet Control Register (ENET_ECR) : Reworded descriptions, but not meaning, of reserved fields.
• Frame parser : In "Receive parser flowchart" figure, changed "Freescale Semiconductor" to "NXP B.V." • Legacy buffer descriptors : Changed first paragraph from "To support the Ethernet controller on previous Freescale devices, legacy FEC buffer descriptors are available. To enable legacy support, clear ENET*n*_ECR[1588EN]." to "To support the Ethernet controller on previous chips, legacy FEC buffer descriptors are available. To enable legacy support, write 0 to ENET*n*_ECR[1588EN]."

A.44 FlexCAN changes

A.44.1 FlexCAN configuration changes

• Added new section: External time tick
• Added new section: FlexCAN's stop-stop ack protocol

A.44.2 FlexCAN module changes

• Modified description of CRCERR and STFERR. Changed "in either a non-FD message or in the slow rate part of a FD message" to "in a non-FD message or else in an FD message's arbitration or data phase." • Modified description of BIT1ERR and BIT0ERR. Changed "Arbitration Phase" to "arbitration or data phase."
• Added FlexCAN message buffer memory map.
• In the introduction section of Memory map/register definition, added text explaining that there is a separate message buffer memory map section, and added a link to that section.
• Table in CAN_CTRL2[RFFN] field description was modified to show that "Remaining Available Mailboxes" end value is 95.
• Removed reference to Doze mode in CAN_MCR[PNET_EN] field description. • Removed reference to Doze mode in Modes of operation.
• In Protocol timing, in bullet point about Time Segment 1 changed "4 to 16 time quanta" to "2 to 16 time quanta" and changed "1 to 39 time quanta" to "2 to 39 time quanta." • In Figure 44-6, changed "4...16" to "2...16" for Time Segment 1. • In Figure 44-7, changed "4...96" to "2...96" for Time Segment 1 in top image. Removed references to triple sampling in bottom image.
• In Transmission abort mechanism, added line to abort procedure summary list about reconfiguring EDL, BRS, and ESI fields in MB.
• Editorial cleanup throughout chapter.
• Modified description of Rx Individual Mask Registers (CAN_RXIMR*n*) to note option of using RXIMR memory region as general access memory. • Modified Bus interface to explain how to use RXIMR memory region as general access memory.

A.45 I2C changes

A.45.1 IIC configuration changes

• Added new section: I2C configurations

A.45.2 I2C changes

• Moved information from Clock rate and IBFD settings into two new subsections, Timing definitions and Divider and hold values, and revised this information. • In I2C Bus Frequency Divider Register (I2C_IBFD), revised the IBC field description to match the changes in Clock rate and IBFD settings. • In START condition and STOP condition, added "See Clock rate and IBFD settings and I2C Bus Frequency Divider Register (I2C_IBFD) for the associated timing requirements."
• Editorial changes.

A.46 LinFlexD changes

A.46.1 LinFlexD configuration changes

• Added new section: LinflexD's stop-stop ack protocol

A.46.2 LINFlexD module changes

• In section: Memory map and register description: Updated list item: 'If not specified ... '
• In section: Memory map and register description: Removed: "If generic slave = 0 ... cannot be programmed." from LINCR2[IOPE]
• In section: Memory map and register description: Updated the access of bits 27 and 28 from RW to ROZ in register LINSR • In section: Memory map and register description: Updated the bitfield description of bit TDFL_TFC from 'Bit 15 is reserved ... ' to 'Bit 16 is reserved ... '
• In section: Memory map and register description: Updated the access and description of bit: 25 of LINCR1 register to RW. • Updated the description of LINSR[LINS] for Init mode.
• Minor editorial updates throughout
• Changed 'Adsorb' to 'Absorb' in UART – TX mode and UART – RX mode
• In section: Memory map and register description: Updated the note 'For LIN mode, in case a bit error ...' present in bitfield DTF

A.47 FlexRay changes

A.47.1 FlexRay configuration changes

• No substantial content changes

A.47.2 FlexRay module changes

• Redefined StopWatch Count Register (FR_STPWR) as StopWatch Count High Register (STPWHR) and StopWatch Count Low Register (STPWLR).
• Updated bitfield description of FID_EF.
• Updated slot related conditions in Slot Status Counter Registers

A.48 SAI changes

A.48.1 SAI configuration changes

• Added new section: SAI's stop-stop ack protocol

A.48.2 I2S/SAI changes

• No substantial content changes

A.49 PIT-RTI changes

A.49.1 PIT-RTI configuration changes

• Updated paragraph text in Input Output section • In PIT_14 row, added FlexCAN_0 in Table 49-1 • In PIT_15 row, added FlexCAN_4 in Table 49-1
• Added new section: PIT-RTI's stop-stop ack protocol

A.49.2 PIT module changes

• No substantial content changes

A.50 SWT changes

A.50.1 SWT configuration changes

• In SWT register reset value, updated reference to reset value of SWT_0 Control register (SWT_0_CR).
• Updated SWT register reset value : added SWT_HSM_TO and SWT_HSM_CR register reset values. • Added new section: Service mode watchpoint input.

A.50.2 SWT module changes

- In description of each MAP*n* field in SWT Control Register (SWT_CR)
  - Added new paragraph beginning with this sentence: "The number of this field corresponds to the logical ID of the bus master."
  - Changed last paragraph:
    - from: "Not all MAPn fields are implemented. See the device configuration section for master ports that are implemented on the crossbar switch."
    - to: "For the masters with the logical IDs to which the MAP*n* fields correspond, see the chip-specific information for the Crossbar Switch."

- In "Memory Map and Registers"
  - In introductory text, incorporated minor edits and reorganized some paragraph text as list
  - Incorporated minor edits in each register description
- In SWT Control Register (SWT_CR) description of ITR field
  - In Note, changed "reset requests" to "reset requests and interrupt requests"
- In SWT Control Register (SWT_CR) description of RIA field
  - Added a Note: "For a description of how this chip implements SWT reset requests resulting from SWT invalid accesses, see the chip-specific SWT information."
  - Edited description of field value 1
- In Window mode edited and reorganized entire section

A.51 RTC-API changes

A.51.1 RTC-API configuration changes

- Added Seamless RTC operation across functional and destructive resets
- Added new section: RTC-API's stop-stop ack protocol

A.51.2 RTC-API module changes

- In RTC Compare Value register (RTC_RTCVAL) register description added sentence "The minimum value of RTCVAL should be 4".

- Throughout this chapter: Removed low-power related information
- In Features, removed bullet item: *Operates in all modes of operation*
- Removed following sections:
  - Test Mode
  - Detailed signal description
- Removed *as the ipg_debug is detected active* from FRZEN description
- Replaced *assertion of trigger_en_out signal* with *trigger* in TRIG_EN description
- Updated ANLCMP description
- In Functional Mode, removed phrase *and the input isolation is disabled*
- In RTC :
  - Removed *ipg_clk*
  - Replaced *wakeup_signal* with *wakeup*
  - Replaced *trigger_en_out signal* with *trigger signal to Analog Comparator*

A.52 STM changes

A.52.1 STM configuration changes

- No substantial content changes

A.52.2 STM module changes

- No substantial content changes

A.53 MC_RGM changes

- In 'Functional' Event Status Register (MC_RGM_FES), bitfieldvalue description of "1" in F_JTAG_FUNC bit is changed to "A JTAG Functional Reset event has occurred. For Example, the EXTEST, HIGHZ, and CLAMP instructions cause a JTAG 'functional' reset event to occur, which sets this field to 1"

- Editorial change: In 'Functional' Bidirectional Reset Enable Register (MC_RGM_FBRE) updated sentence *from* "This register is reset only on power-onThis register is reset only on power-on and any ‘destructive’ reset" *to* "This register is reset only on power-on and any ‘destructive’ reset".
- In Table 53-1, updated "What gets Reset" column for external and functional resets.

- Updated Figure 53-1

- In RGM_memoryMap added notes "Reserved fields ..... reset values only." and "The following registers are reset to their default values.....".
- In External Reset bullet point added "a ‘functional’ reset event configured.... reset"

- In 'Functional' Bidirectional Reset Enable Register (MC_RGM_FBRE) :
  - Updated register reset value to 0x0003_7FBC.
  - Updated bit descriptions and access for various bits.

A.54 SSCM changes

A.54.1 SSCM configuration changes

- No substantial content changes

A.54.2 SSCM module changes

• "Freescale production" is changed to "MCU Production" in following topics:
  • In bitfield value description of 110 in LC.
  • Life Cycle.
  • Table 54-13
• In Figure 54-3 updated "Freescale production" to "MCU Production".

• In Memory map and register definition added a note "Reserved IPS register access is prohibited"

A.55 BAF changes

A.55.1 BAF configuration changes

• MPC5746C cores/BAF CPU*n* :
  • Edited first sentence for clarity
  • Added space between device name and "core" in table column heading

• Added section BAF NMI event handling. • In Table 55-8, removed rows for "SC_SS" and "SWT_0_CR".

A.55.2 BAF module changes

• Flow of control :   • Added footnote to Figure 55-1 : "SWT0 is disabled after serial boot regardless of the configuration specified in the UTEST_MISC[SWT0_WDG_DIS] register field."
• Introduction :   • In second paragraph, "...services the watchdog and CSE..." changed to "...services the watchdog and HSM..."
• BAF NMI Event Handling :   • Topic has been moved to the BAF configuration section

• DATA32 – 32-bit data DCF client :
  • Phrase, "masks the least significant 2-bits to ‘0’", removed from sentence, "BAF takes the memory address provided by the ADDR client, masks the least significant 2-bits to ‘0’ (Only 32-bit aligned writes are supported) and writes this 32-bit data to the address."
• DATA16 – 16-bit data DCF client :
  • Phrase, "masks the least significant 2-bits to ‘0’", removed from sentence, "BAF takes the memory address provided by the ADDR client, masks the least significant bits to ‘0’ (Only 16-bit aligned writes are supported) and writes least significant 16-bit data to the address."

• Serial boot mode protocol :
  • Removed following statement: "If exiting from Standby mode, any core can be used to start execution"
• Flow of control :
  • Figure updated: In final decision block, "Low Power Exit Status" changed to "Low Power Standby Exit Status"

• Serial boot mode protocol :   • Note added: "Serial boot is not allowed from standby mode exit."
• Optionally perform serial boot :   • In first paragraph, changed "JDP/FSL Production" to "MCU Production".

- Boot modes :
  - In second bulleted item, changed "JDP/FSL Production" to "MCU Production".
- Flow of control :
  - In Figure 55-1, changed "Lifecycle == JDP/FSL_Production" to "Lifecycle == MCU_Production"

- Introduction :
  - Added two paragraphs describing initial task of checking for DCF record ECC errors and clearing ECC errors latched during SSCM processing.
- Flow of control :
  - In Figure 55-1, added processing block and decision block at beginning of flow for clearing errors latching during SSCM processing and checking for uncorrectable ECC error when reading DCF records starting address.

- Device initialization :
  - In item beginning with, "BAF checks for multiple cores in execution, changed second sentence from, "...then device is put in SAFE mode and made to wait for an external event", to, "...then the device is put in SAFE mode and executes a wait instruction in a loop".
  - In the item beginning with, "BAF sets up the exception vector table...", first sentence changed to, "...which may occur if there are any uncorrectable ECC errors in the BAF execution path (was, "...which may occur if there are any uncorrectable ECC errors.")
  - In the item beginning with, "BAF sets up the exception vector table...", changed, "If an ECC error occurs during reading of DMEM, the BAF will still issue a destructive reset.", to, "If the machine check exception occurs due to any other reason during BAF execution, the BAF will still issue a destructive reset."

A.56 NXMC changes

A.56.1 NXMC configuration changes

- No substantial content changes

A.56.2 NXMC module changes

- For Development control register 2 (DC2) Seperated bit field 0 from [23:0] and added 'Read/Write – default values must not be changed for normal operation' in description.
- For Development control register 2 (DC2) added 'This is read/write field, so default value must not be changed changed for normal operation' for EWC field value description.
- For Development control register 1 (DC1) added 'Read/Write – default values must not be changed for normal operation' for field 31-29 in description.

A.57 JTAG changes

A.57.1 JTAGC configuration changes

- In JTAGC Control 1 register : TMNXMC[12:13] bit is marked as Reserved.

A.57.2 JTAGC module changes

- No substantial content changes

- In Table 57-2 of External signal description :
  - Moved content from Pull column to Reset State column and removed Pull column
  - Updated "Up" to "Weak pullup"

A.58 JDC changes

- In Use case example :
  - Added new step #5 (between previous steps #4 and 5) "Check if a Flash program/erase operation is in progress. If a Flash program/erase operation is in progress, wait for it to complete".
  - Renumbered subsequent steps.

A.59 CJTAG changes

- No substantial content changes

A.60 NPC changes

A.60.1 NPC configuration changes

- Added sections:
  - EVTO sharing - Pulse time
  - Trace messages for transactions with error responses
  - Trace loss during resets
  - EVTI_IN pin

A.60.2 NPC module changes

- Minor editorial change in IEEE 1149.1-2001 (JTAG) TAP.

A.61 Core Complex Overview changes

- No substantial content changes

A.62 Z2 Core description module changes

A.62.1 Core description module changes

- No substantial content changes

A.63 Z4 Core description module changes

- No substantial content changes

A.64 Z2 Core debug support module changes

A.64.1 Core Debug Support changes

- No substantial content changes

A.65 Z4 Core Debug Support changes

- No substantial content changes

A.66 Z2 Nexus 3 module changes

A.66.1 Core Nexus Module changes

- In sections Program Trace Synchronization messages and Data Trace Synchronization messages, in the fourth bullet for both sections, added phrase "or suppression".

A.67 Z4 Nexus 3 module changes

A.67.1 Z4 Core Nexus Module changes

- No substantial content changes

A.68 eDMA module changes

- Error Status Register (DMA_ES) : In bullet about uncorrectable TCD SRAM errors, specified name of bit.
- eDMA initialization : In bullet beginning with "Enable any hardware service requests..." replaced "ERQH and ERQL registers" with "ERQ register."
- Error Status Register (DMA_ES) : In description, replaced "See the Error Reporting and Handling section" with "See Fault reporting and handling.

A.69 DMACHMUX changes

A.69.1 DMACHMUX configuration changes

- No substantial content changes

A.69.2 DMAMUX module changes

- No substantial content changes

A.70 PRAMC changes

A.70.1 PRAMC configuration changes

- No substantial content changes

A.70.2 PRAMC module changes

- No substantial content changes

A.71 Flash memory controller changes

A.71.1 Flash memory controller configuration changes

- Added new section : Master IDs

A.71.2 Flash memory controller module changes

- Flash memory controller memory map :
  - Revised content describing possible non-deterministic behavior caused by updating flash memory controller programming model concurrently with a flash write operation. Added description of workaround enabling software to invalidate port read buffers without updating programming model.

- For clarity, removed "This bit is cleared by hardware reset" or "This field is cleared by hardware reset" from descriptions of P*n*_M*m*PFE, P*n*_DPFEN, P*n*_IPFEN, and P*n*_PFLIM in:
  - Platform Flash Configuration Register 1 (PFLASH_PFCR1)
  - Platform Flash Configuration Register 2 (PFLASH_PFCR2)
  - Platform Flash Configuration Register 4 (PFLASH_PFCR4)

  These bitfields can also be cleared by writing 0.

- Flash memory controller memory map :
  - Typo fixed: "If application software functionality includes invalidating a port read buffer, t recommended method..." changed to, "If application software functionality includes invalidating a port read buffer, the recommended method..."

- ECC on data flash accesses :
  - Correction: ECC errors are reported to the MEMU (previously stated errors were suppressed from being reported).
  - Content significantly rearranged.

A.72 Embedded Flash Memory changes

A.72.1 Embedded Flash Memory configuration changes

- Start and end address is updated in the following register bit mapping:
  - C55FMC_LOCK0 and C55FMC_SEL0 register bit mapping
  - C55FMC_LOCK1 and C55FMC_SEL1 register bit mapping
  - C55FMC_LOCK2 and C55FMC_SEL2 register bit mapping
- Added note "Do not access the reserved area of the C55FMC memory map" in Embedded Flash Memory register reset value

A.72.2 c55fmc module changes

- No substantial content changes

A.73 MEMU changes

A.73.1 MEMU configuration changes

- In Table 73-5, Table 73-6, Table 73-7, Table 73-8, and Table 73-9, added a column "Clock relationship with respect to MEMU".
- In Concurrent overflow register (OFLW) implementation for MEMU_0, updated note: *from* "As per this table the ..... the FLASH Error." *to* "This table shows that..... error and a RAM uncorrectable error.".

A.73.2 MEMU changes

- In System RAM uncorrectable error reporting table address register (MEMU_SYS_RAM_UNCERR_ADDR), in the ERR_ADD field description, deleted "This field must be read-only when its corresponding valid bit (SYS_RAM_UNCERR_STS[VLD]) = 0."
- In Peripheral RAM uncorrectable error reporting table address register (MEMU_PERIPH_RAM_UNCERR_ADDR), in the ERR_ADD field description, deleted "This field must be read-only when its corresponding valid bit (PERIPH_RAM_UNCERR_STS[VLD]) = 0."
- In Flash memory uncorrectable error reporting table address register (MEMU_FLASH_UNCERR_ADDR), in the ERR_ADD field description, deleted "This field must be read-only when its corresponding valid bit (FLASH_UNCERR_STS[VLD]) = 0."
- In Design overview, added an example of how MEMU processes a 0-2-2 sequence.

A.74 FCCU changes

A.74.1 FCCU configuration changes

• Added topic FCCU_CFG register event bit values by source (N and C) • Updated reset value of FCCU_CFG register in Table 74-1

• In Table 74-2 :
  • Updated details in rows for NCF[0], NCF[1], NCF[2] and NCF[3].
  • Updated description column for NCF[5], NCF[8], NCF[10], NCF[11], NCF[69] and NCF[70].
  • Added footnote "*These faults may get set during chip level debug mode and needs to be ignored*", to NCF[2], NCF[3], NCF[25], NCF[26], NCF[34], NCF[36], NCF[37], NCF[38], NCF[39], NCF[40], NCF[42], NCF[43], NCF[44], NCF[51], NCF[53] and NCF[55].

A.74.2 FCCU module changes

• In the Mode Controller Status (FCCU_MCS) register description, changed the footnote for the register reset value from *The MC_ME module changes the value of the register immediately after the chip leaves RESET mode.* to *The reset value is chip-specific. See the chip-specific FCCU information. (The MC_ME module changes the value of the register immediately after the chip leaves RESET mode.)*.
• In the NA Freeze Status (FCCU_N2AF_STATUS) register description, in the NAFS field description, deleted this note: *This field can be read and written but writing 1 has no effect.* • In the AF Freeze Status (FCCU_A2FF_STATUS) register description, changed the access types of the AF_SRC and AFFS fields from read-write to read-only. In the AF_SRC and AFFS field descriptions, deleted this note: *This field can be read and written but writing 1 has no effect.* • In the NF Freeze Status (FCCU_N2FF_STATUS) register description, changed the access types of the NF_SRC and NFFS fields from read-write to read-only. In the NF_SRC and NFFS field descriptions, deleted this note: *This field can be read and written but writing 1 has no effect.* • In the FA Freeze Status (FCCU_F2A_STATUS) register description, in the FAFS field description, deleted this note: *This field can be read and written but writing 1 has no effect.*
• In the Noncritical Fault State Configuration (FCCU_NCFS_CFG*n*) and NMI Enable (FCCU_NMI_EN*n*) register descriptions, removed the following inaccurate note: *Do not configure the same channel for both a RESET reaction in the FCCU_NCFS_CFGn register and an NMI reaction in the FCCU_NMI_ENn register at the same time.*
• In Use cases and limitations, rewrote Configuration guidelines (formerly titled "Misconfigurations") to improve the accuracy and clarity of the material by putting it in terms of guidelines you must follow. Added guidelines about what you must do if you enable chip reset as the type of Fault-state reaction for a noncritical fault channel and if you enable Alarm state for the channel.
• In Fault recovery, added the word *noncritical* before the word *FAULT*.
• In the PhysicErrorPin field description, added the spelled-out name of the field, Fault Output (EOUT) States. Replaced *PhysicErrorPin : Physical Error Pin's state. PhysicErrorPin[0] corresponds to error pin 0 and PhysicErrorPin[1] corresponds to error pin 1. For each of these, the bit values have the following meanings: 0: Error Pin is at logical 0; 1: Error Pin is at logical 1* with *Applies only after successfully running an OP3 operation (OPR) and only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Indicates the states that FCCU is driving on the EOUT signals.* Deleted *During Fault state, a static or toggling value is observed based on selected protocol.* Replaced the list of two values and meanings with a list of four values and meanings.
• In the Mode Controller Status (FCCU_MCS) register description, changed the general description from *and whether FCCU was in Fault state when FCCU captured each mode* to *and whether FCCU was in Fault state and NMIOUT was asserted (as the result of a noncritical fault) when FCCU captured each mode*. In the FS0 field description (and similarly in the FS1, FS2, and FS3 field descriptions), changed *Indicates whether FCCU was in Fault state when*

FCCU captured MCS0 to *Indicates whether FCCU was in Fault state and NMIOUT was asserted (as the result of a noncritical fault) when FCCU captured MCS0*; changed the meaning for the value 0 from *A state other than Fault state* to *Not in Fault state or NMIOUT not asserted*; changed the meaning for the value 1 from *Fault state* to *In Fault state and NMIOUT asserted*.

- In the Permanent Configuration Lock (FCCU_PERMNT_LOCK) register description, changed the register name from *Permanent Lock* to *Permanent Configuration Lock*; in the general description, changed *The FCCU_PERMNT_LOCK register is used for locking configuration permanently by writing FFh. This register is available only in supervisor mode. The permanent lock can only be removed by applying a reset (not necessarily power on reset). This register is write only.* to *Writable only by code running in Supervisor mode. Permanently locks the configuration, which prevents FCCU from entering Configuration state until FCCU is reset.*; changed the access type of the reserved field from Read-Only Zero to Reserved, Unimplemented. In the PERMNTKEY field description, changed *Transition Locking Key value* to *Permanent Configuration Lock—Writable only by code running in Supervisor mode. Permanently locks the configuration, which prevents FCCU from entering Configuration state until FCCU is reset.*; changed the meaning for the value FFh from *Configuration Locked* to *Lock.*; changed the meaning for the value *Any other value* from *No Change* to *Do nothing.*
- In the Transient Configuration Lock (FCCU_TRANS_LOCK) register description, changed the register name from *Transient Lock* to *Transient Configuration Lock*; in the general description, changed *The FCCU_TRANS register is used for unlocking configuration by writing BCh. This register is available only in supervisor mode. This register is write only.* to *Writable only by code running in Supervisor mode. Temporarily locks and unlocks the configuration. Locking the configuration prevents FCCU from entering Configuration state.*; changed the access type of the reserved field from Read-Only Zero to Reserved, Unimplemented. In the TRANSKEY field description, changed *Transition Unlocking Key value* to *Transient Configuration Lock—Writable only by code running in Supervisor mode. Temporarily locks and unlocks the configuration. Locking the configuration prevents FCCU from entering Configuration state.*; changed the meaning for the value BCh from *Configuration Unlocked* to *Unlock.*; changed the meaning for the value *Any other value* from *FCCU gets transiently locked again.* to *Lock.*

- Because the fault-output (EOUT) signaling frequency is programmable (FOP), not fixed at 61 Hz:
  - In EOUT interface, deleted *With a CLKSAFE frequency of 16 MHz, this drives a signal of 61 Hz on EOUT.*
  - In Dual-rail protocol, deleted *As long as FCCU is in NORMAL or ALARM state, output will show "non-faulty" signal. Output pins EOUT[0:1] will toggle between 01 and 10 with a given frequency of 61 Hz.* Note that, although deleted here, the information regarding the "nonfaulty" indication on the EOUT signals during Normal and Alarm states remains true and is documented elsewhere.

- In the Configuration (FCCU_CFG) register description, in the FCCU_SET_CLEAR field description, added the field name, Fault-Output (EOUT) Control; rewrote the function description and value meanings.

- In the FCCU_SET_AFTER_RESET field description, added the spelled-out name of the field, Fault-Output (EOUT) Activate; rewrote the general description; rewrote the meanings for both values.

- In the Delta T (FCCU_DELTA_T) register description, in the DELTA_T field description, added the spelled-out name of the field, Bistable Minimum Fault-Output (EOUT) Faulty Interval; added the following sentence: *Applies only to Bistable fault-output mode (FOM)*; changed *EOUT fault-indication timer* to *fault-output (EOUT) timer*; moved the information that is after the equation to EOUT interface because it's general and not only applicable to DELTA_T.
- Inserted the following new sections in EOUT interface prior to Dual-rail protocol :
  - Introduction. Moved the first paragraph from the previous EOUT interface section into this section. In the moved information, replaced *The FCCU provides up to two bidirectional signals (EOUT[1:0]) as a failure indication to the external world.* with *You use the EOUT[1:0] signals to indicate FCCU's condition to off-chip logic.*
  - The FCCU conditions. Added new content.
  - How the fault-output (EOUT) timer works. Moved general information from the DELTA_T field description to this section. In the moved information, changed *EOUT fault-indication timer* to *fault-output (EOUT) timer*. In the first paragraph of the moved information, added the following new list item to the beginning of the list: *The fault-output (EOUT) signals are not programmed to be always low (FCCU_SET_CLEAR)*. In the third paragraph of the moved information, changed the first list item from *T_min has expired* to *If the EOUT signals are in Bistable fault-output mode (FOM), T_min has expired*. In the second paragraph, deleted *or not applicable*.
  - Prepare the EOUT signals to indicate FCCU's condition. Added new content.
  - More about the EOUT interface. In one of the notes, changed *after software has enabled the EOUT signals (FCCU_CFG[FCCU_SET_AFTER_RESET]* to *when the EOUT signals are active (FCCU_SET_AFTER_RESET)*.
- Revised the Bistable Fault-Output (EOUT) Mode Signaling Enable (FCCU_EOUT_SIG_EN*n*) register description for clarity.

- In Signals, rewrote the description of the EOUT[1:0] signal function for accuracy and clarity.
- In the figure in Block diagram, changed the double-headed arrow between *EOUT1 intf* and *EOUT[1]* to a single-headed arrow that indicates that EOUT[1] is an output only.

• In the Status (FCCU_STAT) register description, rewrote the ESTAT and STATUS field descriptions for clarity.
• In the IO Control (FCCU_EINOUT) register description, for the EIN1 and EIN0 fields, changed the reset value to indeterminate (x) and rewrote the field descriptions for clarity. • In Signals, added a table row for the EIN[1:0] signals.

• Added the following sections to clarify how to perform certain procedures:
  • Put FCCU in Configuration or Normal state
  • Run operations
  • Lock and unlock the configuration

• In Acronyms and abbreviations, added a row for *NVM*.
In Introduction : • Replaced the list item that begins with *The FCCU's configuration is lockable* with *Lockable configuration*. • Added the list item *Nonvolatile memory interface (NVMCFG signals) for configuration loading*.
• In Main features, added the list item *Nonvolatile memory interface (NVMCFG signals) for configuration loading*.
• In the Control Key (FCCU_CTRLK) register description, rewrote the description of the register's function and the description of the CTRLK field's function so it includes the OP31 operation.
• Added FCCU_CFG register bit value sources (N and C) by event.
• Added Configuration registers.
• In Signals, added table rows for the NVMCFG[21:0] and SSCMDONE signals.
• In the Configuration-State Timer Interval (FCCU_CFG_TO) register description, changed its name to *Configuration-State Timer Interval*, and rewrote the description of the register's function and the description of the TO field's function.
• In the Configuration (FCCU_CFG) register description, rewrote the description of the register's function and rewrote the footnote on the register diagram.

• In the Control (FCCU_CTRL) register description:
  • Rewrote the description of the register's function.
  • Rewrote the description of the OPR field.

• Added Nonvolatile memory interface.
• In Introduction, changed *They show operational state only on software request* to *They show operational state only after configuration by software*.
• In More about the EOUT interface, deleted this paragraph: *These resets influence the state of the failure indication pins…Other resets should not influence the state of the failure indication pins*.
• In the Delta T (FCCU_DELTA_T) register description, rewrote the note in the DELTA_T field description to clarify that the variance of the DELTA_T durations is chip-specific.
• In More about the EOUT interface, changed *NA (not applicable) appears in the following table* to *NA (not applicable) appears in the following table*.
• In the Bistable Fault-Output (EOUT) Mode Signaling Enable (FCCU_EOUT_SIG_EN*n*) register description, rewrote the register's function description and the EOUTENx field's function description.
• In NMI/WKPU interface, changed *another mode* to *another mode change*.

• Throughout the chapter, changed *non-critical* to *noncritical*.
• In each of the following register descriptions, changed the format of the table in the register function summary and reworded the sentence in the field function summary that refers to the table:
  • Noncritical Fault Configuration (FCCU_NCF_CFG*n*)
  • Noncritical Fault Status (FCCU_NCF_S*n*)
  • Noncritical Fault Enable (FCCU_NCF_E*n*)
  • Noncritical Fault Timeout Enable (FCCU_NCF_TOE*n*)
  • IRQ Alarm Enable (FCCU_IRQ_ALARM_EN*n*)
  • Bistable Fault-Output (EOUT) Mode Signaling Enable (FCCU_EOUT_SIG_EN*n*) (no sentence rewording)

• In Introduction, changed *One of the error out pins is high* to *One of the fault-output (EOUT) signals is high*.

A.75 STCU2 changes

A.75.1 STCU2 configuration changes

• In On-Line reset generation (only MBIST) added a Note "During online selftest execution, ... will generate reset."
• Added Supported BIST sequence section. • Updated section AUTOLOCK_VALUE for register write access and DCF_COMPLETION value for DCF write completion.
• Added note "A functional reset must be generated for proper functioning of the chip after online MBIST self-test" to On-Line reset generation (only MBIST)

A.75.2 STCU2 module changes

• In the STCU2 Run Software Register (STCU2_RUNSW) register description, changed the access type of bit 20 from read-write to read-only zero.

• In the Register write-access watchdog timer section:
  • Revised the first paragraph and reorganized part of its content into a list.
  • In the second list item, added a sentence: "To refresh the hardware watchdog timer before it times out, write only security key 2 to STCU2_SKC."
  • In the Note:
  • Replaced "8 STCU2 clock cycles" with "a number of STCU2 clock cycles equal to DCF_COMPLETION."
  • Replaced "AUTOLOCK Value divided by 8" with "AUTOLOCK_VALUE divided by DCF_COMPLETION."
  • For DCF_COMPLETION, added a reference to the chip-specific STCU2 information.
  • Removed a sentence: "To refresh the hardware watchdog timer, the user must write key 2 into the STCU2_SKC register."
  • Edited the last paragraph.

• In the second-to-last paragraph of the STCU2 SK Code Register (STCU2_SKC) register description, changed *a transfer error on the IPS or SSCM bus* to *a transfer error on the IPS bus*.

• Added the following sections to clarify terminology:
  • BISTs and BIST partitions
  • BIST sequences

• In the STCU2 Run Software Register (STCU2_RUNSW) register description, fixed bit 21 in the diagram.
• In the register description, fixed bit 31 in the diagram.

• STCU2 Watchdog Granularity (STCU2_WDG) :
  • Throughout: Edited for clarity
  • Note added to WDG[WDGEOC] field description: "If this register is programmed while STCU2_RUN[RUN]=1, the new STCU2_WDG value, programmed after STCU2_RUN, does not take effect."

• Offline self-test sequence :   • Removed: "Optionally, also the STCU2_LB_PRPGL/H can be programmed in order to load a specific seed."
• In the STCU2 Off-Line MBIST Status Medium Register (STCU2_MBSM) register description, in the note in each of the field descriptions, changed *STCU2_MBEL* to *STCU2_MBEM*.

• Online self test sequence :
  • New step added: "Ensure the RUN_CFG field value in all implemented MC_ME_PCTL*n* registers forces the associated peripheral to a frozen, clock gated state."
  • Numerous editorial changes

• Steps changed to a numbered sequence instead of a bulleted list • STCU2 Register names referenced in this section are no longer prefixed with "STCU2_".
• In the STCU2 Configuration Register (STCU2_CFG) register description, changed *FSL production* to *MCU production*.

A.76 CRC module changes

• In Input Register (CRC_INP), added a Note.
• Replaced "Ethernet" instances with "ITU-T V.42" standard throughout the chapter • In Standard features, updated the Note
• In Configuration Register (CRC_CFG), updated reset value footnote for POLYG field.

A.77 REG PROT changes

A.77.1 REG_PROT configuration changes

• In section, Mode Entry (MC_ME) protected registers, table: Protected MC_ME registers: • Removed information pertaining to ME_PCTL81

A.77.2 REG_PROT module changes

• In Global Configuration Register (REG_PROT_GCR)
  • Removed Note "Access in....read/write" from register description.
  • Modified Note for HLB bit as "Access in....access is read/write." and its description.
  • Added description to UAA bit as "Controls the User and....REG_PROT_SLBR*n*."

A.78 PASS changes

A.78.1 PASS configuration changes

• Removed the attachment *PASS_Lock_register_details* spreadsheet from RM and updated all the relevant details in this document by adding the following sections:
  • PASS_LOCK0_PGn register bit mapping
  • PASS_LOCK1_PGn register bit mapping
  • PASS_LOCK2_PGn register bit mapping
  • PASS_LOCK3_PGn register bit mapping
  • Debug Interface Access
  • Flash Test Mode protection

- In PASS_LOCK3_PGn register bit mapping FSL_PROD changed to MCU_PROD.

A.78.2 PASS module changes

- In register: Life Cycle Status Register (PASS_LCSTAT) :
  - Removed reset value and added footnote 'Reset value is the Life Cycle ... ' to bit 'LIFE'.
- In register bit field: LIFE :
  - Changed 'Freescale Production' to 'MCU Production'
- In section Test mode enable password,Test mode enable password generation
  - Changed 'FSL' to 'Manufacturer'
- Editorial change: Added cross ref in Censorship

A.79 TDM changes

A.79.1 TDM configuration changes

- No substantial content changes

A.79.2 TDM module changes

- In section Flash erase counter and tamper detection
  - Removed text "Alternatively,...the diary length for that TDR." from second note in this section.

A.80 Flash Memory Programming and Configuration changes

- Added new Chapter
