To prevent Clock Domain Crossing issues, inputs from SDR0–1 or ASDR0–1 should not change while they are being sampled into the Protocol Domain. This is ensured in the following manner for the ASDR0 inputs. The initial write performed on ASDR0 register will cause the 32-bit ASDR0 input to be latched into a temporary register which is then locked (further latching is prevented) until this data gets synchronized into the Protocol Domain. Once synchronized, the lock is removed and the next ASDR0 write will again trigger this process. If there was a write performed on ASDR0 while the lock was asserted, this will be taken into consideration as soon as the previous synchronization process completes and lock gets de-asserted. In case,multiple writes were performed on ASDR0 when lock was asserted, only the latest value will be considered for synchronization once the lock gets de-asserted. This process is true for ASDR1 register as well.

The entire process explained above is also true for the SDR0 and SDR1 inputs, the only difference being that SDR0–1 inputs are delayed internally by a single Bus clock (register interface clock) to detect a change in the parallel input pins.

Once the synchronization process for a particular De-serial input begins, it takes up to 5 Bus clock (register interface clock) periods and 5 Protocol clock periods before the synchronization process for the next De-serial input can begin. Hence the writes performed on ASDR0–1 and SDR0–1 are constrained with this timing.

The DSPI_PISR0-3 registers (DSPI_PISR0-7 registers if DSICR1[DSI64E] is enabled) allow to change relative position of the Parallel input pins in the transmitted frame. Each transmitted frame bit can be selected from 16 adjacent Parallel Inputs by writing IPSn fields. The IPSn field is treated as 4 bit integer number, representing numbers from -8 to 7. The Parallel Input pin number, selected by IPSn field is defined by the difference between the IPSn field number (n) and the IPSn field value. If the operation result is negative the number 32 should be added. If the result is higher than 32, 32 should be subtracted from the result. (When DSICR1[DSI64E] is enabled, if the above operation result is negative, the number 64 should be added. If the result is higher than 64, 64 should be subtracted from the result).

For example, IPS0, set to minus 1 (binary 1111), preselects Parallel Input 1 to 0 position in the transmitted frame. (This preselects parallel input to 0 position in the transmitted frame when DSICR1[DSI64E] is set). Following examples are true when DSICR1[DSI64E] is disabled.

IPS6, set to 3 (binary 0011), preselects Parallel Input 3 to be bit number 6 in the transmitted frame. The value minus 2 (1110) preselects Parallel Input 8.

IPS31, set to minus 8 (binary 1000), preselects Parallel Input 7 to be bit number 31 in the transmitted frame.

Note

The Parallel Input pin state, to be transmitted, should be selected by TXSS or DSPI_SSR0–1 register and the frame size should be higher than the bit position in the preselected frame.

DSPI_SSR0–1 register provides additional way to create the frame for transmission. Each bit from this register is OR'd with the TXSS bit and controls individual transmitted bit source. This way, the transmitted frame can have any combination of the DSPI_SDR0–1 and DSPI_ASDR0–1 bits. This feature allows control SPI based devices, requiring control and data fields in the frame. Control field may come from DSPI_ASDR0–1 register, set by the device's CPU, while data field can be generated by device peripheral modules, like PWM timers.

A copy of the last DSI frame shifted out of the Shift Register is stored in the DSPI DSI Transmit Comparison Registers (DSPI_COMPR0–1). This register provides added visibility for debugging and it serves as a reference for transfer initiation control. The following figure shows the DSI Serialization logic.

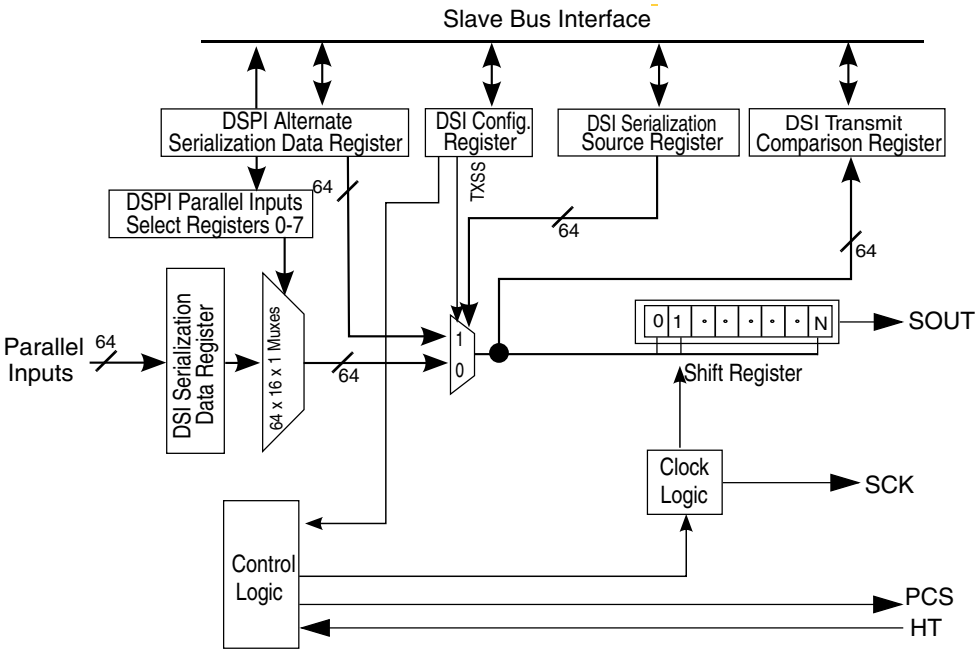

Figure 42-4. DSI Serialization Diagram

42.5.3.4 DSI Deserialization

When all bits in a DSI frame have been shifted in, the frame is copied to the DSPI DSI Deserialization Data Register (DSPI_DDR0/1). This register presents the deserialized data as Parallel Output signal values. DSPI_DDR0/1 is memory mapped to allow host software to read the deserialized data directly.

The received data is bit-wise compared to the value of the DSI Deserialized Data Polarity Interrupt Register (DSPI_DPIR0/1), bit-wise AND'ed with DSI Deserialized Interrupt Mask Register (DSPI_DIMR0/1) and the results OR'ed to produce DDIF flag in the DSPI_SR register; which in turn can cause DDI interrupt request or DMA request based on RSER[DDIF_RE] and RSER[DDIF_DIRS] bits and/or stop DSI frame transmissions if DSICR0[DMS] bit is set.

The following figure shows the DSI Deserialization logic.

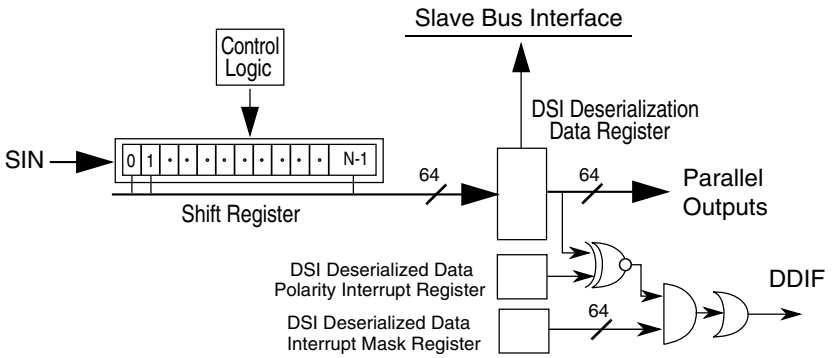

Figure 42-5. DSI Deserialization Diagram

42.5.3.5 DSI Transfer Initiation Control

Data transfers for a DSPI in DSI configuration are initiated by a condition. The transfer initiation conditions are selected by the TRRE and CID bits in the DSPI_DSICR0.

NOTE

By default, the TRRE and CID bits are programmed using DSICR0[TRRE] and DSICR0[CID]. When TRIG[ENABLE] is set, the TRRE and CID bits are given by TRIG[TRRE] and TRIG[CID] respectively and the bits DSICR0[TRRE], DSICR0[CID] have no effect.

The following table lists the transfer initiation conditions.

Table 42-8. DSI Data Transfer Initiation Control

TRRE	CID	ASDR_WT	Transfer Initiation Control
0	0	0	Continuous
0	0	1	ASDR Write
0	1	0	Change in Data
0	1	1	Change in Data or ASDR Write
1	0	0	Triggered
1	0	1	Triggered or ASDR Write
1	1	0	Triggered or Change in Data
1	1	1	Triggered or Change in Data or ASDR Write

42.5.3.5.1 Continuous Control

For Continuous Control a new DSI frame shifts out when the previous transfer cycle has completed and the Delay after Transfer (t_{DT}) has elapsed. This has no effect when DSPI is in Slave Mode.

42.5.3.5.2 ASDR Write Control

For ASDR Write Control, a DSI frame shifts out whenever a write operation to ASDR0 is detected. For ASDR_WT to have any affect, TRIG[ASDR_WT] bit must be set. Note that ASDR0 write operations will not generate ASDR write triggers when the module is in STOPPED state, including when MCR[HALT] is asserted.

NOTE

If a DSI frame > 32 bits needs to be transmitted, the user must update ASDR1 before updating ASDR0.

42.5.3.5.3 Change In Data Control

The $\overline{\text{MTRIG}}$ output signal is asserted every time a change in data is detected.

For change in data control a transfer is initiated when the data to be serialized has changed since the transfer of the last DSI frame. A copy of the previously transferred DSI data is stored in DSPI_COMPR0/1. When the data selected for the transfer from the DSPI_SDR0/1 and DSPI_ASDR0/1 registers is different from the data in DSPI_COMPR0/1 a new DSI frame is transmitted. The $\overline{\text{MTRIG}}$ output signal is asserted every time a change in data is detected.

NOTE

It is not advisable to configure a DSPI slave with the combination DSICR0[DCONT] = 1, DSICR0[CID] = 1 ; since the following statement then holds true.

Once slave select is asserted, there is a very small window (of up to t module clocks) after every SOF (Start of Frame) during which if a write on ASDR/SDR registers occur, the next frame to be transmitted would be loaded into the shift register. However, it is not feasible that such a write be initiated and completed within this short span of time; hence the data transmitted by DSPI slave would lag by one data frame.

42.5.3.5.4 Change In Data or ASDR Write Control

For Change in Data or ASDR Write Control, initiation of a transfer is controlled by the detection of a change in data to be serialized or whenever a write operation to ASDR0 is detected.

NOTE

For any DSI transfer initiation combination where TRIG[ASDR_WT] and DSICR0[HT] are both enabled, it is possible that the ASDR0 write operation causes a Change of DSI Data. This special condition results in transmission of a single DSI frame even though 2 separate triggers were generated.

42.5.3.5.5 Triggered Control

For Triggered Control initiation of a transfer is controlled by the Hardware Trigger signal (HT). The TPOL bit in the DSPI_DSICR0 selects the active edge of HT. For HT to have any affect, DSICR0[TRRE] bit must be set. Note that HT will not have any effect when the module is in STOPPED state, including when MCR[HALT] is asserted.

42.5.3.5.6 Triggered or ASDR Write Control

For Triggered or ASDR Write Control, initiation of a transfer is controlled by the HT signal or whenever a write operation to ASDR0 is detected.

42.5.3.5.7 Triggered or Change In Data Control

For Triggered or Change in Data Control, initiation of a transfer is controlled by the HT signal or by the detection of a change in data to be serialized.

42.5.3.5.8 Triggered or Change In Data or ASDR Write Control

For Triggered or Change in Data or ASDR Write Control, initiation of a transfer is controlled by the HT signal or by the detection of a change in data to be serialized or whenever a write operation to ASDR0 is detected.

42.5.3.6 Multiple Transfer Operation (MTO)

In DSI Configuration the MTO feature allows for multiple DSPIs within a device to be chained together in a parallel or serial configuration. The parallel chaining allows multiple DSPIs internal to a device and multiple SPI devices external to the device to

share SCK and PCS signals thereby saving the device pins. The serial chaining allows bits from multiple DSPIs to be concatenated into a single DSI frame. MTO is enabled by setting the MTOE bit in the DSPI_DSICR0.

In parallel and serial chaining there is one bus master and multiple bus slaves. The bus master initiates and controls the transfers, but the DSPI slaves generate trigger signals for the bus DSPI master when an internal condition in the slave warrants a transfer. The DSPI slaves also propagate triggers from other slaves to the master. When a DSPI slave detects a trigger signal on its HT input, the slave generates a trigger signal on the $\overline{\text{MTRIG}}$ output.

Serial and parallel chaining require multiplexing of signals external to the DSPI.

Note

TSB operation is not available in MTO mode. DSICR0[TSBC] and DSICR0[MTOE] bits should not be set simultaneously.

Note

DSI64 mode is not available in MTO mode. DSICR1[DSI64] and DSICR0[MTOE] bits must not be set simultaneously.

42.5.3.6.1 Parallel Chaining

Parallel chaining allows multiple DSPIs internal to a device and multiple SPI/DSI devices external to a device to share common SCK and PCS signals thereby saving pins. Two pins are saved per pair of DSPI/SPI. The following figure shows an example of how the blocks can be connected in a device.

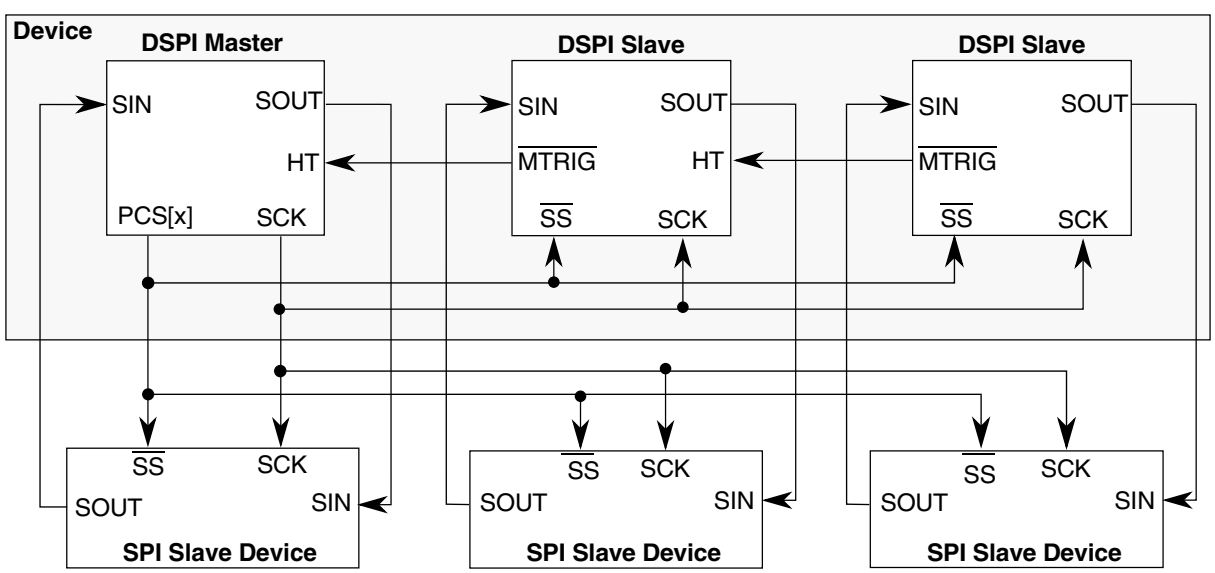

Figure 42-6. Example of Parallel Chaining of DSPIs

The DSPI master controls and initiates all transfer, but the DSPI slaves have a trigger output signal $\overline{\text{MTRIG}}$ that indicates to the master DSPI to start a transfer. When the DSPI slave has a change in its data to be serialized, it generates a pulse on the $\overline{\text{MTRIG}}$ signal to the master DSPI, which initiates the transfer. When a DSPI slave has its HT signal asserted it also generates a pulse on its $\overline{\text{MTRIG}}$ signal thereby propagating trigger signals from other DSPI slaves to the DSPI master.

To enable $\overline{\text{MTRIG}}$ signals generation the MTO has to be enabled for the DSPI slaves. The chained DSPI modules also should be in DSI configuration. The DSPI_DSICR0[MTOCNT] field must be written with the same number of bits to be transferred for each slave DSPI. The MTOCNT value must also match the FMSZ field of the DSPI_CTAR1 in the DSPI slaves and selected DSPI_CTAR register for the master DSPI module.

42.5.3.6.2 Serial Chaining

The serial chaining allows transfers of DSI frames of up to a total of 64 bits, using transfers of smaller DSI frames concatenated together by multiple DSPIs. The following figure shows an example of how the blocks can be connected in a device.

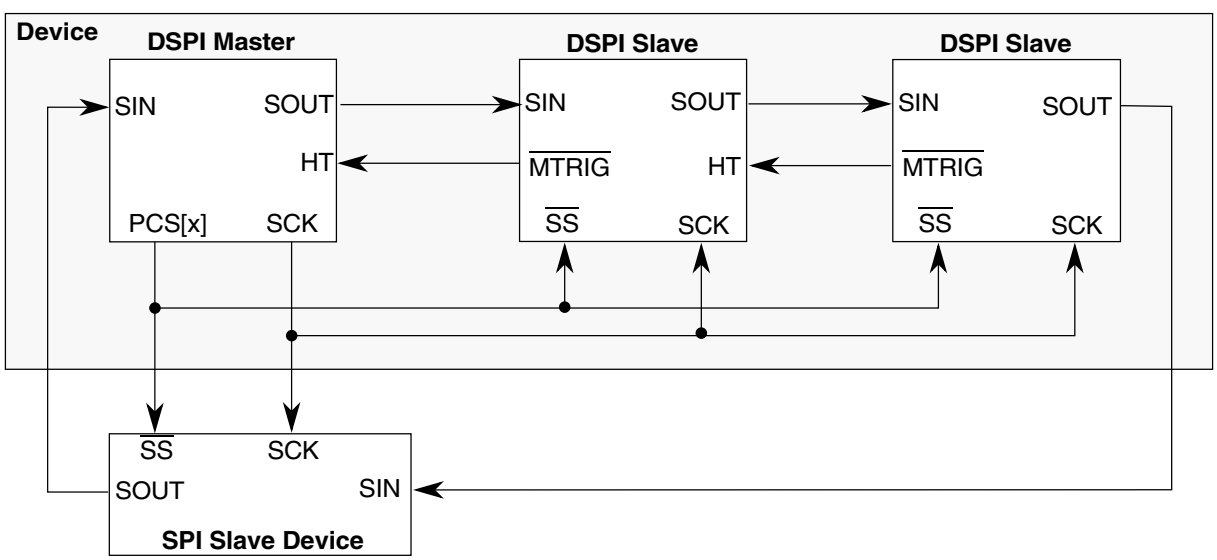

Figure 42-7. Example of Serial Chaining of DSPIs

The SOUT of the DSPI master is connected to the SIN of the first DSPI slave. The SOUT of the first DSPI slave is connected to the SIN input of the second slave and so on. The SOUT of the last DSPI slave is connected to the SIN of the external SPI slave. The SOUT of the external SPI slave is connected to the SIN of the DSPI master.

The DSPI master controls and initiates all transfers, but the slave DSPIs use the trigger output signal $\overline{\text{MTRIG}}$ to indicate to the DSPI master that a trigger condition has occurred. When a DSPI slave has a change in data to be serialized it asserts the $\overline{\text{MTRIG}}$ signal to

the DSPI master which initiates the transfer. When a DSPI slave has its HT signal asserted it will assert its $\overline{\text{MTRIG}}$ signal thereby propagating trigger signals from other DSPI slaves to the DSPI master.

The DSPI_DSICR0[MTOE] bit must be set in master and all slave devices. The DSPI_DSICR0[MTOCNT] field for the master and all slave devices must be written with the same value. The value must equal the sum of all FMSZ fields in the selected DSPI_CTAR registers for the DSPI master and all DSPI slaves. For example if one 16-bit DSI frame is created by concatenating eight bits from the DSPI master, and four bits from each of the DSPI slaves in the above figure, the DSPI master frame size must be set to eight in the FMSZ field, and the DSPI slaves frame size must be set to four. The largest DSI frame supported by the MTOCNT field is 64 bits. Any number of DSPIs can be connected together to concatenate DSI frames, as long as each DSPI transfers a minimum of 4 bits and a maximum of 32 bits and the total size of the concatenated frame is less than 65 bits long.

42.5.4 Combined Serial Interface (CSI) Configuration

The CSI Configuration of the DSPI is used to support SPI and DSI functions on a frame by frame basis. CSI Configuration allows interleaving of DSI data frames from the parallel input signals with SPI data frames from the TX FIFO. The data returned from the bus slave is either used to drive the Parallel Output signals or it is stored in the RX FIFO. The CSI Configuration allows serialized data and configuration or diagnostic data to be transferred to a slave device using only one serial link. The DSPI is in CSI Configuration when the DCONF field in the DSPI_MCR is 0b10. The following figure shows an example of how a DSPI can be used with a deserializing peripheral that supports SPI control for control and diagnostic frames.

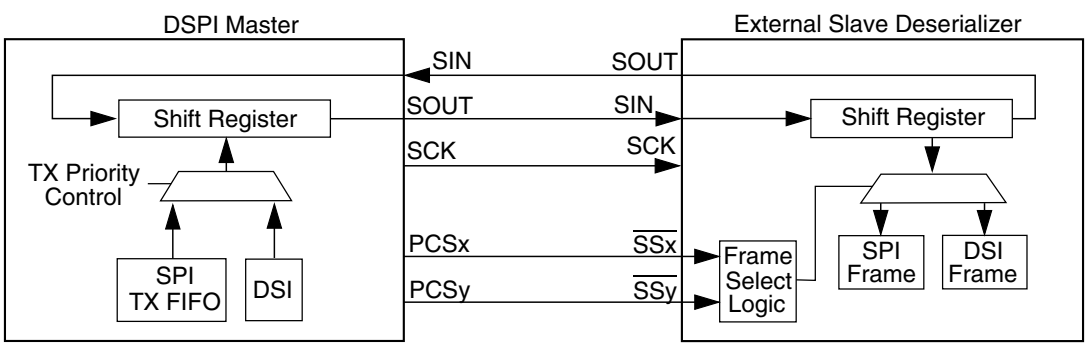

Figure 42-8. Example of System using DSPI in CSI Configuration

In CSI Configuration the DSPI transfers DSI data based on DSI Transfer Initiation Control .

When DSICR1[CSI_PRTY] is set to zero and there are SPI commands in the TX FIFO, the SPI frames have priority over the DSI frames. When the TX FIFO or CMD FIFO is empty, DSI transfer resumes.

When DSICR1[CSI_PRTY] bit is set, the DSI frames have priority over SPI frames. Thus, only when the DSI frame initiation requests have been catered to, will the SPI frames be transmitted, if available.

NOTE

The following combination is not a legal scenario and should be avoided - DSICR1[CSI_PRTY] = 1, DSICR1[TRRE] = 0 and DSICR1[CID] = 0, since such a configuration prevents SPI frames from ever getting transmitted.

Two peripheral chip select signals indicate whether DSI data or SPI data is transmitted. The user must configure the DSPI so that the two CTAR registers associated with DSI data and SPI data assert different peripheral chip select signals denoted in the figure as PCSx and PCSy. The CSI Configuration is only supported in master mode.

Data returned from the external slave while a DSI frame is transferred is placed on the Parallel Output signals. Data returned from the external slave while a SPI frame is transferred is moved to the RX FIFO. The TX FIFO, CMD FIFO and RX FIFO are fully functional in CSI mode.

42.5.4.1 CSI Serialization

Serialization in the CSI configuration is similar to serialization in DSI Configuration. The transfer attributes for SPI frames are determined by the DSPI_CTAR register selected by the CTAS field in the SPI command halfword. The transfer attributes for the DSI frames are determined by the DSPI_CTAR register selected by the DSICTAS field in the DSPI_DSICR0.

The Parallel Inputs signal states are latched into the DSPI DSI Serialization Data Register (DSPI_SDR0/1) and serialized based on the transfer initiation control settings in the DSPI_DSICR0.When SPI frames are written to the TX FIFO (and when CMD FIFO is not empty) they have priority over DSI data from the DSPI_SDR and are transferred at the next frame boundary.A copy of the most recently transferred DSI frame is stored in DSPI_COMPR0/1. The Transfer Priority Logic selects the source of the serialized data and asserts the appropriate PCS signal.

Separate frame completion interrupts are available to indicate frame transmission completion from SPI and DSI frames.

42.5.4.2 CSI Deserialization

The deserialized frames in CSI Configuration go into the DSPI_DDR0/1 or the RX FIFO based on the transfer priority logic.When DSI frames are transferred the returned frames are deserialized and latched into the DSPI_DDR0/1. When SPI frames are transferred the returned frames are deserialized and written to the RX FIFO.

42.5.5 Module baud rate and clock delay generation

The SCK frequency and the delay values for serial transfer are generated by dividing the protocol clock frequency by a prescaler and a scaler with the option for doubling the baud rate. The following figure shows conceptually how the SCK signal is generated.

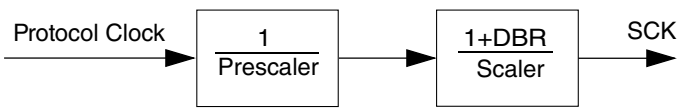

Figure 42-9. Communications clock prescalers and scalers

42.5.5.1 Baud rate generator

The baud rate is the frequency of the SCK. The protocol clock is divided by a prescaler (PBR) and scaler (BR) to produce SCK with the possibility of halving the scaler division. The DBR, PBR, and BR fields in the CTARs select the frequency of SCK by the formula in the BR field description. The following table shows an example of how to compute the baud rate.

Table 42-9. Baud rate computation example

f_P	PBR	Prescaler	BR	Scaler	DBR	Baud rate
100 MHz	0b00	2	0b0000	2	0	25 Mb/s
20 MHz	0b00	2	0b0000	2	1	10 Mb/s

NOTE

The clock frequencies mentioned in the preceding table are given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

42.5.5.2 PCS to SCK Delay (t_{CSC})

The PCS to SCK delay is the length of time from assertion of the PCS signal to the first SCK edge. See Figure 42-11 for an illustration of the PCS to SCK delay. The PCSSCK and CSSCK fields in the CTAR*x* registers select the PCS to SCK delay by the formula in the CSSCK field description. The following table shows an example of how to compute the PCS to SCK delay.

Table 42-10. PCS to SCK delay computation example

f_{SYS}	PCSSCK	Prescaler	CSSCK	Scaler	PCS to SCK Delay
100 MHz	0b01	3	0b0100	32	0.96 µs

PCSCSK and CSSCK fields have no effect in TSB configuration.

NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

42.5.5.3 After SCK Delay (t_{ASC})

The After SCK Delay is the length of time between the last edge of SCK and the negation of PCS. See Figure 42-11 and Figure 42-12 for illustrations of the After SCK delay. The PASC and ASC fields in the CTAR*x* registers select the After SCK Delay by the formula in the ASC field description. The following table shows an example of how to compute the After SCK delay.

Table 42-11. After SCK Delay computation example

f_P	PASC	Prescaler	ASC	Scaler	After SCK Delay
100 MHz	0b01	3	0b0100	32	0.96 µs

PCASC and ASC fields have no effect in TSB configuration.

NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

42.5.5.4 Delay after Transfer (t_{DT})

The Delay after Transfer is the minimum time between negation of the PCS signal for a frame and the assertion of the PCS signal for the next frame. See Figure 42-11 for an illustration of the Delay after Transfer. The PDT and DT fields in the CTAR*x* registers select the Delay after Transfer by the formula in the DT field description. The following table shows an example of how to compute the Delay after Transfer.

Table 42-12. Delay after Transfer computation example

f_P	PDT	Prescaler	DT	Scaler	Delay after Transfer
100 MHz	0b01	3	0b1110	32768	0.98 ms

NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

When in Non-Continuous Clock mode the t_{DT} delay is configured according to the equation specified in the CTAR[DT] field description. When in Continuous Clock mode and TSB is not enabled, the delay is fixed at 1 SCK period.

In TSB mode the Delay after Transfer is equal to a number formed by concatenation of PDT and DT fields plus 1 of the SCK clock periods. See detailed information on Timed Serial Bus (TSB)".

42.5.5.5 Peripheral Chip Select Strobe Enable ($\overline{\text{PCSS}}$)

The $\overline{\text{PCSS}}$ signal provides a delay to allow the PCS signals to settle after a transition occurs thereby avoiding glitches. When the Module is in Master mode and the PCSSE bit is set in the MCR, $\overline{\text{PCSS}}$ provides a signal for an external demultiplexer to decode peripheral chip selects other than PCS5 into glitch-free PCS signals. The following figure shows the timing of the $\overline{\text{PCSS}}$ signal relative to PCS signals.

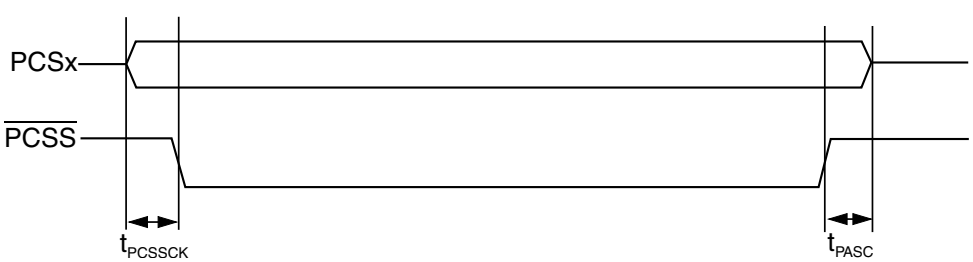

Figure 42-10. Peripheral Chip Select Strobe timing

The delay between the assertion of the PCS signals and the assertion of $\overline{\text{PCSS}}$ is selected by the PCSSCK field in the CTAR based on the following formula:

$$t_{\text{PCSSCK}} = \frac{1}{f_{\text{P}}} \times \text{PCSSCK}$$

At the end of the transfer, the delay between $\overline{\text{PCSS}}$ negation and PCS negation is selected by the PASC field in the CTAR based on the following formula:

$$t_{\text{PASC}} = \frac{1}{f_{\text{P}}} \times \text{PASC}$$

The following table shows an example of how to compute the t_{pcssck} delay.

Table 42-13. Peripheral Chip Select Strobe Assert computation example

f_P	PCSSCK	Prescaler	Delay before Transfer
100 MHz	0b11	7	70.0 ns

The following table shows an example of how to compute the t_{pasc} delay.

Table 42-14. Peripheral Chip Select Strobe Negate computation example

f_P	PASC	Prescaler	Delay after Transfer
100 MHz	0b11	7	70.0 ns

The $\overline{\text{PCSS}}$ signal is not supported when Continuous Serial Communication SCK or TSB mode is enabled.

NOTE

The clock frequency mentioned in the preceding tables is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

42.5.6 Transfer formats

The SPI serial communication is controlled by the Serial Communications Clock (SCK) signal and the PCS signals. The SCK signal provided by the master device synchronizes shifting and sampling of the data on the SIN and SOUT pins. The PCS signals serve as enable signals for the slave devices.

In Master mode, the CPOL and CPHA bits in the Clock and Transfer Attributes Registers (CTARn) select the polarity and phase of the serial clock, SCK.

- CPOL - Selects the idle state polarity of the SCK
- CPHA - Selects if the data on SOUT is valid before or on the first SCK edge

Even though the bus slave does not control the SCK signal, in Slave mode the values of CPOL and CPHA must be identical to the master device settings to ensure proper transmission. In SPI Slave mode, only CTAR0 is used. In DSI slave mode, only CTAR1 is used.

The module supports four different transfer formats:

- Classic SPI with CPHA=0
- Classic SPI with CPHA=1
- Modified Transfer Format with CPHA = 0
- Modified Transfer Format with CPHA = 1

A modified transfer format is supported to allow for high-speed communication with peripherals that require longer setup times. The module can sample the incoming data later than halfway through the cycle to give the peripheral more setup time. The MTFE bit in the MCR selects between Classic SPI Format and Modified Transfer Format.

In the interface configurations, the module provides the option of keeping the PCS signals asserted between frames. See Continuous Selection Format for details.

42.5.6.1 Classic SPI Transfer Format (CPHA = 0)

The transfer format shown in following figure is used to communicate with peripheral SPI slave devices where the first data bit is available on the first clock edge. In this format, the master and slave sample their SIN pins on the odd-numbered SCK edges and change the data on their SOUT pins on the even-numbered SCK edges.

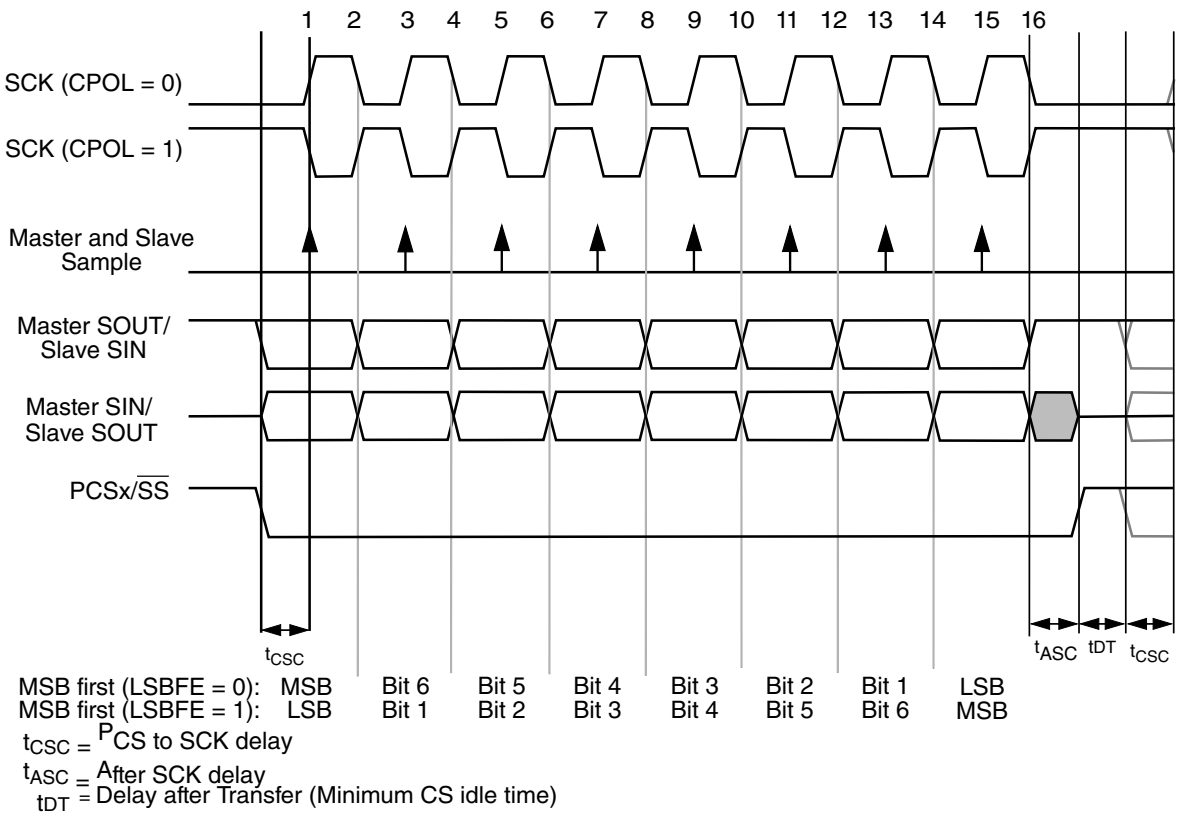

Figure 42-11. Module transfer timing diagram (MTFE=0, CPHA=0, FMSZ=8)

The master initiates the transfer by placing its first data bit on the SOUT pin and asserting the appropriate peripheral chip select signals to the slave device. The slave responds by placing its first data bit on its SOUT pin. After the t_{CSC} delay elapses, the master outputs the first edge of SCK. The master and slave devices use this edge to sample the first input data bit on their serial data input signals. At the second edge of the SCK, the master and slave devices place their second data bit on their serial data output signals. For the rest of the frame the master and the slave sample their SIN pins on the odd-numbered clock edges and changes the data on their SOUT pins on the even-numbered clock edges. After the last clock edge occurs, a delay of t_{ASC} is inserted before the master negates the PCS signals. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

42.5.6.2 Classic SPI Transfer Format (CPHA = 1)

This transfer format shown in the following figure is used to communicate with peripheral SPI slave devices that require the first SCK edge before the first data bit becomes available on the slave SOUT pin. In this format, the master and slave devices change the data on their SOUT pins on the odd-numbered SCK edges and sample the data on their SIN pins on the even-numbered SCK edges.

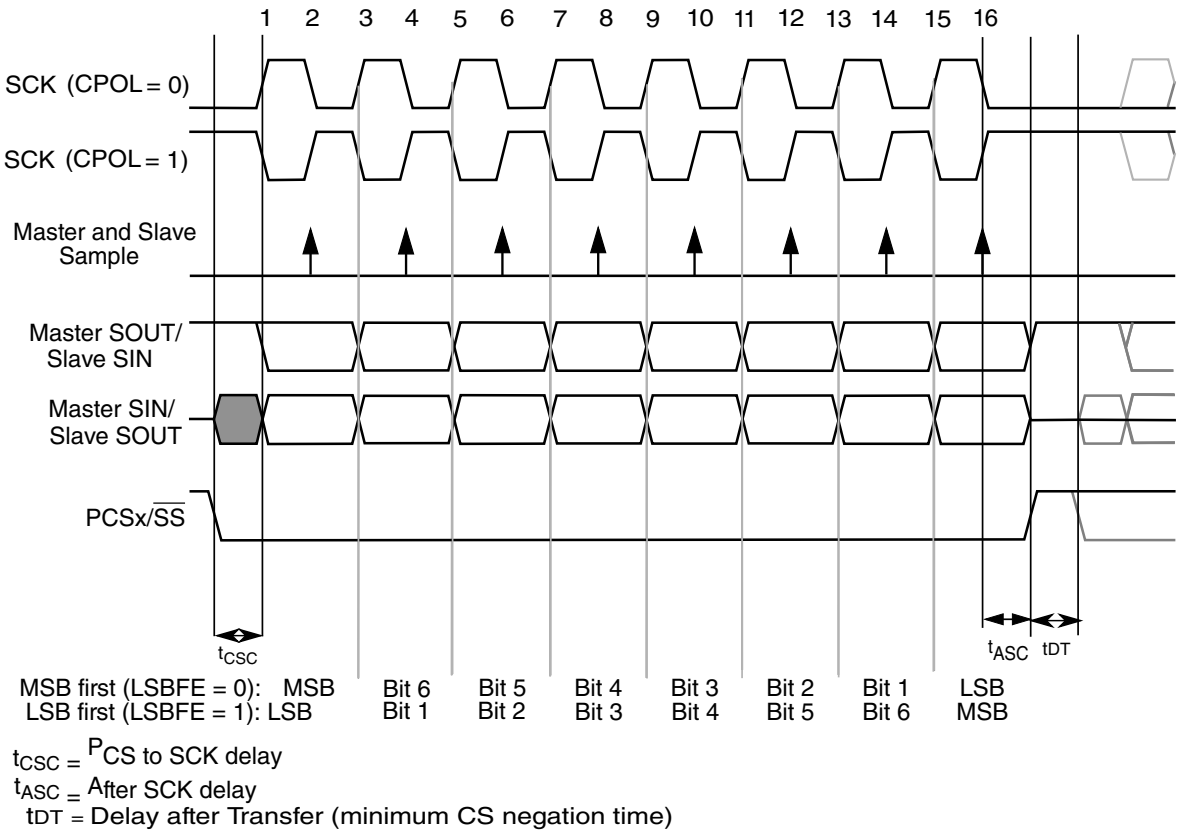

Figure 42-12. Module transfer timing diagram (MTFE=0, CPHA=1, FMSZ=8)

The master initiates the transfer by asserting the PCS signal to the slave. After the t_{CSC} delay has elapsed, the master generates the first SCK edge and at the same time places valid data on the master SOUT pin. The slave responds to the first SCK edge by placing its first data bit on its slave SOUT pin.

At the second edge of the SCK the master and slave sample their SIN pins. For the rest of the frame the master and the slave change the data on their SOUT pins on the odd-numbered clock edges and sample their SIN pins on the even-numbered clock edges. After the last clock edge occurs, a delay of t_{ASC} is inserted before the master negates the PCS signal. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

42.5.6.3 Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 0)

In this Modified Transfer Format both the master and the slave sample later in the SCK period than in Classic SPI mode to allow the logic to tolerate more delays in device pads and board traces. These delays become a more significant fraction of the SCK period as the SCK period decreases with increasing baud rates.

The master and the slave place data on the SOUT pins at the assertion of the PCS signal. After the PCS to SCK delay has elapsed the first SCK edge is generated. The slave samples the master SOUT signal on every odd numbered SCK edge. The DSPI in the slave mode when the MTFE bit is set also places new data on the slave SOUT on every odd numbered clock edge. Regular external slave, configured with CPHA=0 format drives its SOUT output at every even numbered SCK clock edge.

The DSPI master places its second data bit on the SOUT line one protocol clock after odd numbered SCK edge if the protocol clock frequency to SCK frequency ratio is higher than three. If this ratio is below four the master changes SOUT at odd numbered SCK edge. The point where the master samples the SIN is selected by the DSPI_MCR[SMPL_PT] field. The master sample point can be delayed by one or two protocol clock cycles. The SMPL_PT field should be set to 0 if the protocol to SCK frequency ratio is less than 4. However if this ratio is less than 4, the actual sample point is delayed by one protocol clock cycle automatically by the design.

The following timing diagrams illustrate the DSPI operation with MTFE=1. Timing delays shown are:

- T_{csc} - PCS to SCK assertion delay
- T_{acs} - After SCK PCS negation delay
- T_{su_ms} - master SIN setup time
- T_{hd_ms} - master SIN hold time
- T_{vd_sl} - slave data output valid time, time between slave data output SCK driving edge and data becomes valid.
- T_{su_sl} - data setup time on slave data input
- T_{hd_sl} - data hold time on slave data input
- T_{sys} - protocol clock period.

The following figure shows the modified transfer format for CPHA = 0 and Fsys/Fsck = 4. Only the condition where CPOL = 0 is illustrated. Solid triangles show the data sampling clock edges. The two possible slave behavior are shown.

- Signal, marked "SOUT of Ext Slave", presents regular SPI slave serial output.
- Signal, marked "SOUT of DSPI Slave", presents DSPI in the slave mode with MTFE bit set.

Other MTFE = 1 diagrams show DSPI SIN input as being driven by a regular external SPI slave, configured according DSPI master CPHA programming.

Note

In the following diagrams, f_{sys} represents the protocol clock frequency from which the Baud frequency f_{sck} is derived.

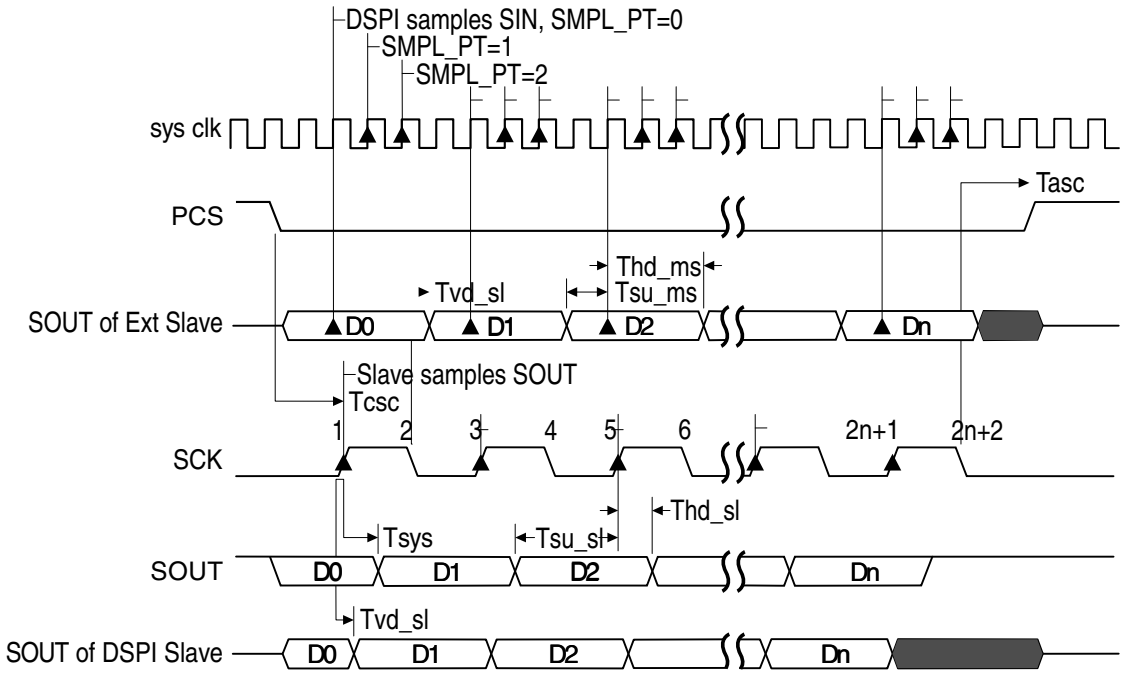

Figure 42-13. DSPI Modified Transfer Format (MTFE=1, CPHA=0, $f_{sck} = f_{sys}/4$)

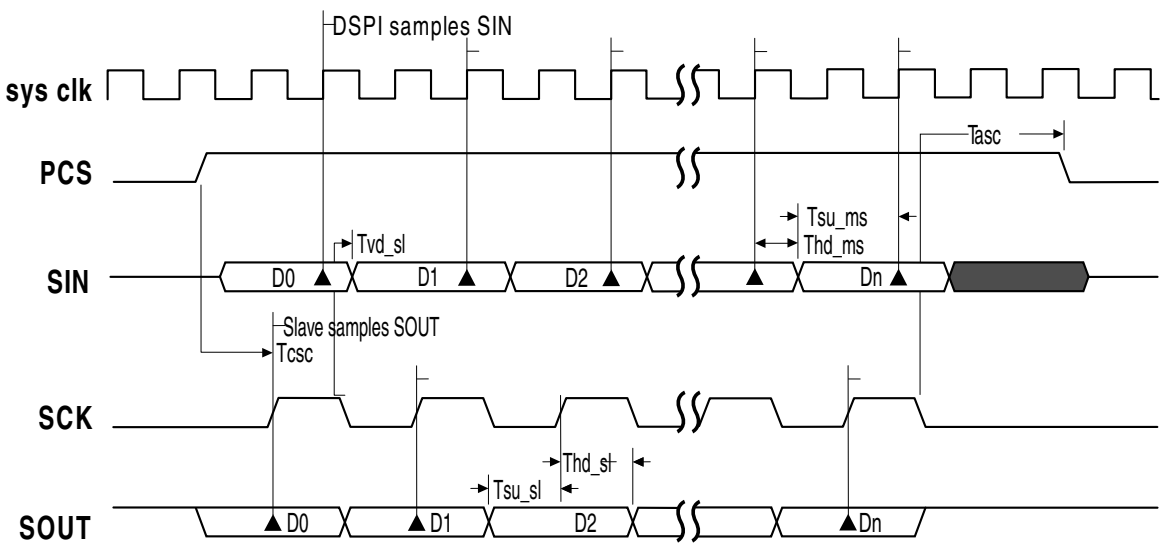

Figure 42-14. DSPI Modified Transfer Format (MTFE=1, CPHA=0, $f_{sck} = f_{sys}/2$)

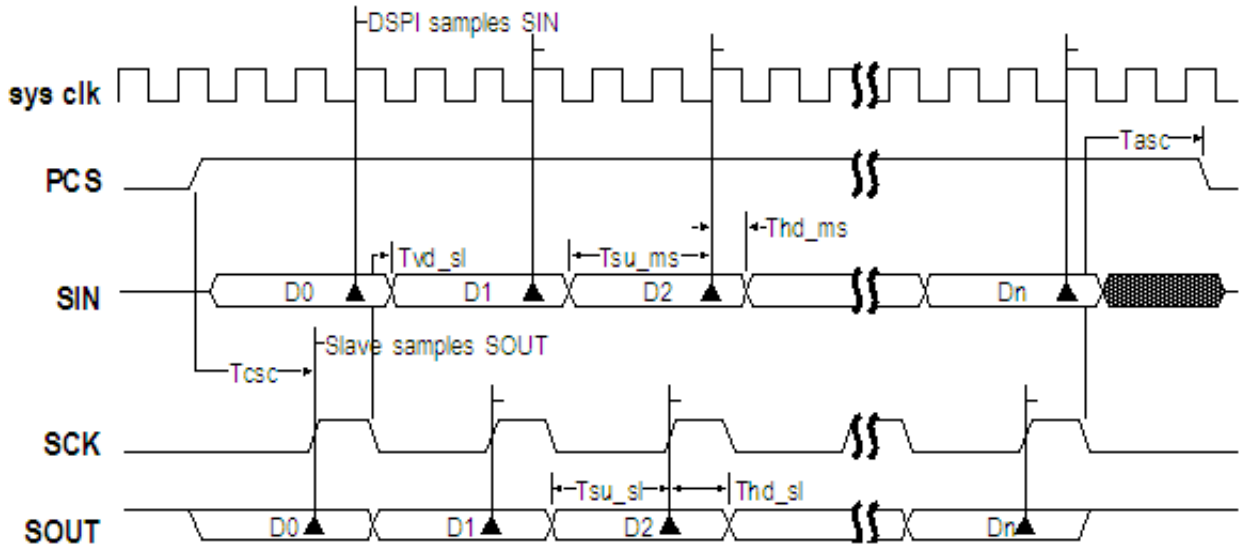

Figure 42-15. DSPI Modified Transfer Format (MTFE=1, CPHA=0, $f_{sck} = f_{sys}/3$)

42.5.6.4 Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 1)

The following figures show the Modified Transfer Format for CPHA = 1. Only the condition, where CPOL = 0 is shown. At the start of a transfer the DSPI asserts the PCS signal to the slave device. After the PCS to SCK delay has elapsed the master and the slave put data on their SOUT pins at the first edge of SCK . The slave samples the master SOUT signal on the even numbered edges of SCK. The master samples the slave SOUT signal on the odd numbered SCK edges starting with the third SCK edge. The slave samples the last bit on the last edge of the SCK. The master samples the last slave SOUT bit one half SCK cycle after the last edge of SCK. No clock edge will be visible on the master SCK pin during the sampling of the last bit. **The SCK to PCS delay and the After SCK delay must be greater or equal to half of the SCK period.**

NOTE

When MTFE=1 with continuous SCK enabled (MCR [CONT_SCKE] =1) in master mode, configure CTAR[LSBFE]=0 for correct operations while receiving unequal length frames. If PUSHR[CONT] is also set for back to back frame transfer, also configure the frame size of the first frame as less than or equal to the frame size of the next frame. In this scenario, make sure that for all received frames, the bits are read equal to their respective frame sizes and any extra bits during POP operation are masked.

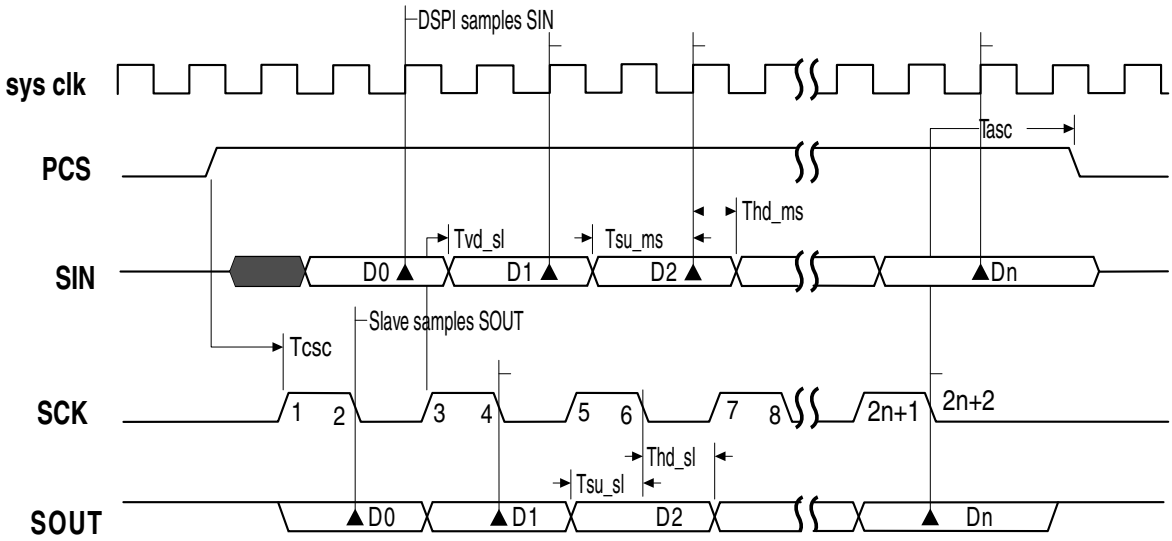

Figure 42-16. DSPI Modified Transfer Format (MTFE=1, CPHA=1, $f_{sck} = f_{sys}/2$)

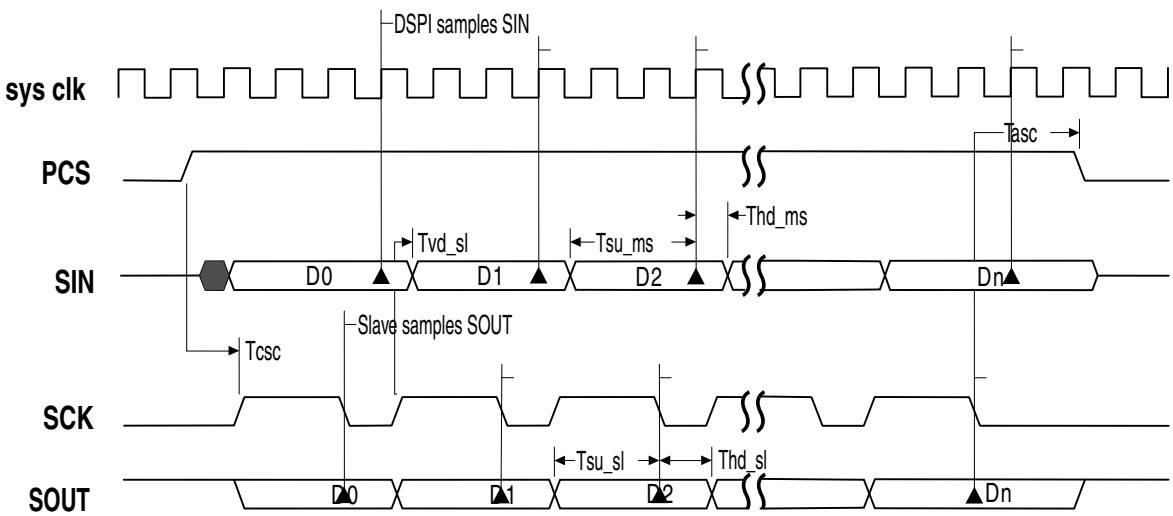

Figure 42-17. DSPI Modified Transfer Format (MTFE=1, CPHA=1, $f_{sck} = f_{sys}/3$)

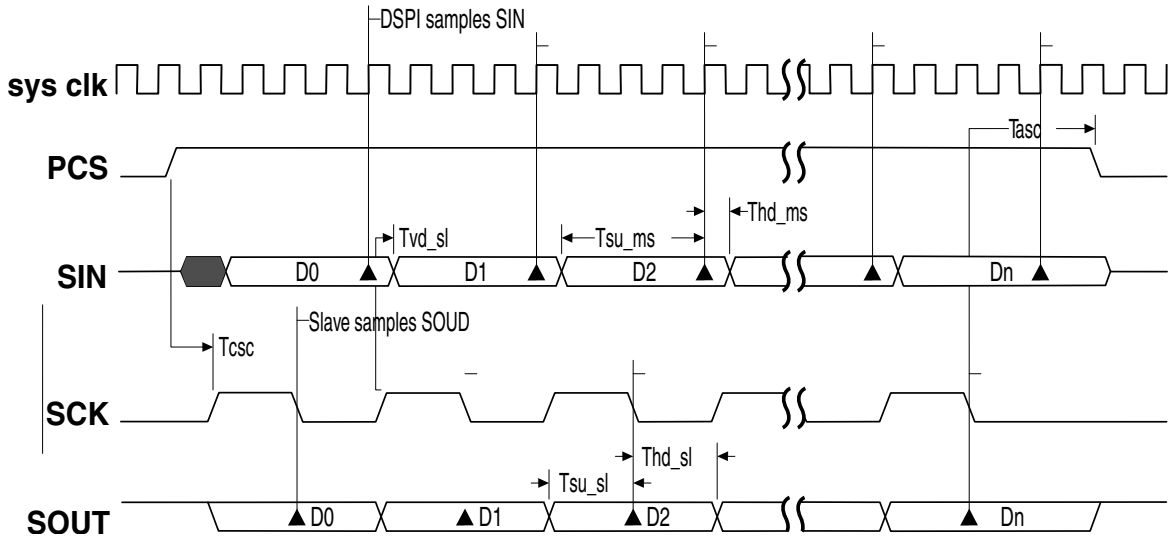

Figure 42-18. DSPI Modified Transfer Format (MTFE=1, CPHA=1, $f_{sck} = f_{sys}/4$)

42.5.6.5 Continuous Selection Format

Some peripherals must be deselected between every transfer. Other peripherals must remain selected between several sequential serial transfers. The Continuous Selection Format provides the flexibility to handle both the following cases. The Continuous Selection Format is enabled for the SPI configuration by setting the CONT bit in the SPI command. Continuous Selection is enabled for the DSI Configuration by setting the DCONT bit in the DSICR0.The behavior of the PCS signals in the two configurations is identical so only SPI configuration will be described.

When the CONT bit = 0, the module drives the asserted Chip Select signals to their idle states in between frames. The idle states of the Chip Select signals are selected by the PCSISn bits in the MCR. The following timing diagram is for two four-bit transfers with CPHA = 1 and CONT = 0.

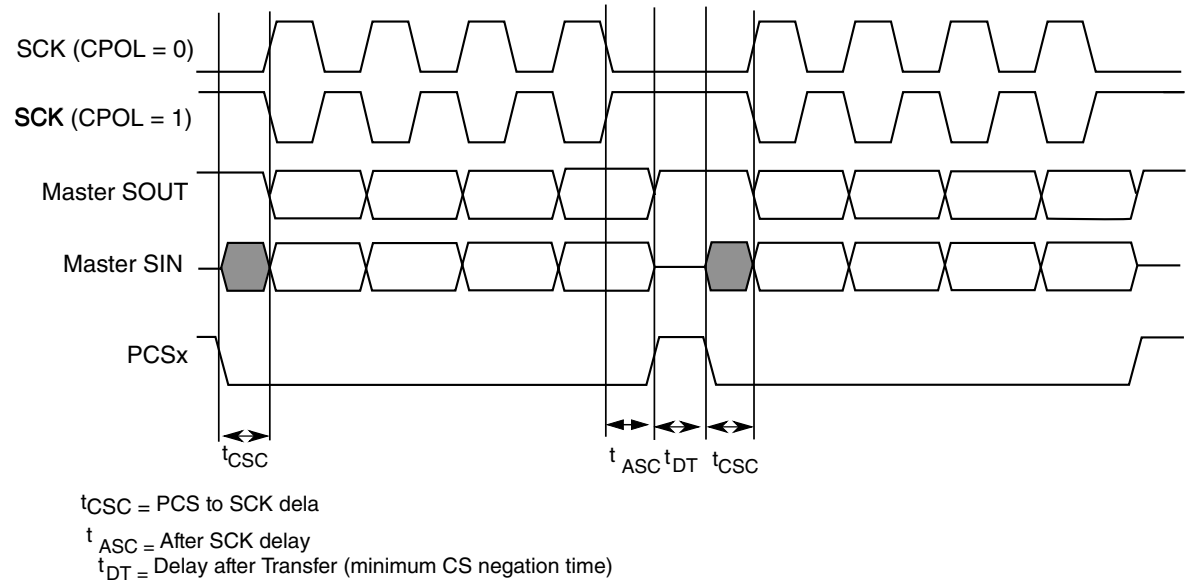

Figure 42-19. Example of non-continuous format (CPHA=1, CONT=0)

When the CONT bit = 1, the PCS signal remains asserted for the duration of the two transfers. The Delay between Transfers (t_{DT}) is not inserted between the transfers. The following figure shows the timing diagram for two four-bit transfers with CPHA = 1 and CONT = 1.

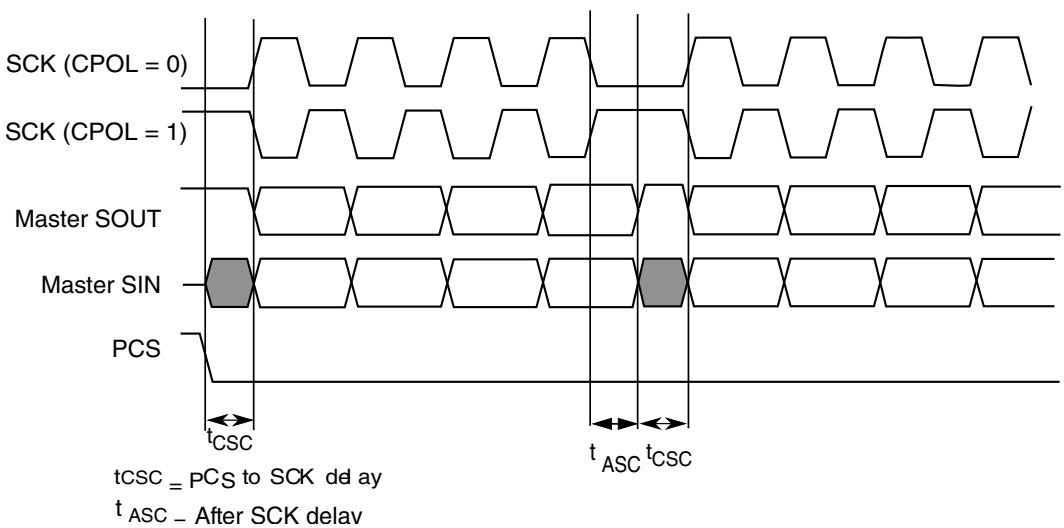

Figure 42-20. Example of continuous transfer (CPHA=1, CONT=1)

When using the module with continuous selection follow these rules:

- All transmit commands must have the same PCSn bits programming.
- The CTARs, selected by transmit commands, must be programmed with the same transfer attributes. Only FMSZ field can be programmed differently in these CTARs.

- When transmitting multiple frames in this mode, the user software must ensure that the last frame has the PUSHR[CONT] bit deasserted in Master mode and the user software must provide sufficient frames in the TX_FIFO to be sent out in Slave mode and the master deasserts the PCSn at end of transmission of the last frame.
- PUSHR[CONT] and DSICR0[DCONT] must be deasserted before asserting MCR[HALT] in master mode. This will make sure that the PCSn signals are deasserted. Asserting MCR[HALT] during continuous transfer will cause the PCSn signals to remain asserted and hence Slave Device cannot transition from Running to Stopped state.

NOTE

User must fill the TX FIFO with the number of entries that will be concatenated together under one PCS assertion for both master and slave before the TX FIFO becomes empty.

When operating in Slave mode, ensure that when the last entry in the TX FIFO is completely transmitted, that is, the corresponding TCF flag is asserted and TXFIFO is empty, the slave is deselected for any further serial communication; otherwise, an underflow error occurs.

42.5.6.6 Fast Continuous Selection Format

The Fast Continuous Selection Format functions similar to Continuous Selection Format except that the inter command delays, t_{ASC} and t_{CSC}, can be masked out and are not inserted by the hardware.

NOTE

The Fast Continuous Selection Format is available in the SPI configuration only and when Continuous Serial Communication Clock mode is disabled. Masking of delays is not allowed in DSI and CSI configurations or if the transfer is non-continuous.

The Fast Continuous Selection Format is enabled by writing ‘1’ into FCPCS bit of the MCR register. When this bit is asserted, MASC and MCSC bits of the PUSHR register perform the function of mask bits for the transmit frame. These bits individually mask the t_{ASC} and t_{CSC} delays as programmed by the user software. A normal Continuous Selection Format has these two delays for each frame that is transmitted with the CONT

bit asserted. In order to avoid these delays and to speed up the transfer process, the software can simply mask these delays while programming the command in the PUSHR register.

While masking the delays, the software must follow the following masking rules, else correct operation is not guaranteed.

- MASC bit masks the “After SCK” delay for the current frame.
- MCSC bit masks the “PCS to SCK” delay for the next frame.
- “After SCK” (t_{ASC}) delay must not be masked when the current frame is the last frame in the continuous selection format.
- The “PCS to SCK” delay for the first frame in the continuous selection format cannot be masked.
- Masking of only t_{ASC} is not allowed. If t_{ASC} is masked then t_{CSC} must be masked too.
- Masking of both t_{ASC} and t_{CSC} delays is allowed. In this case, the delay between two frames is equal to half the baud rate set by the user software.
- Masking of only t_{CSC} is allowed. In this case, the delay between two frames is equal to the t_{ASC} time and thus the user software must ensure that the t_{ASC} time is greater than the baud rate.
- The user software must not mask these delays if the continuous selection format is not used and MCR[FCPCS] is asserted.
- Rules applicable to the Continuous Selection Format are applicable here too.

The following figure shows the timing for a Fast Continuous Selection Format transfer. Here seven frames are transferred with both t_{ASC} and t_{CSC} delays masked except for the last frame that terminated the transfer. The last frame has t_{ASC} delay at its end.

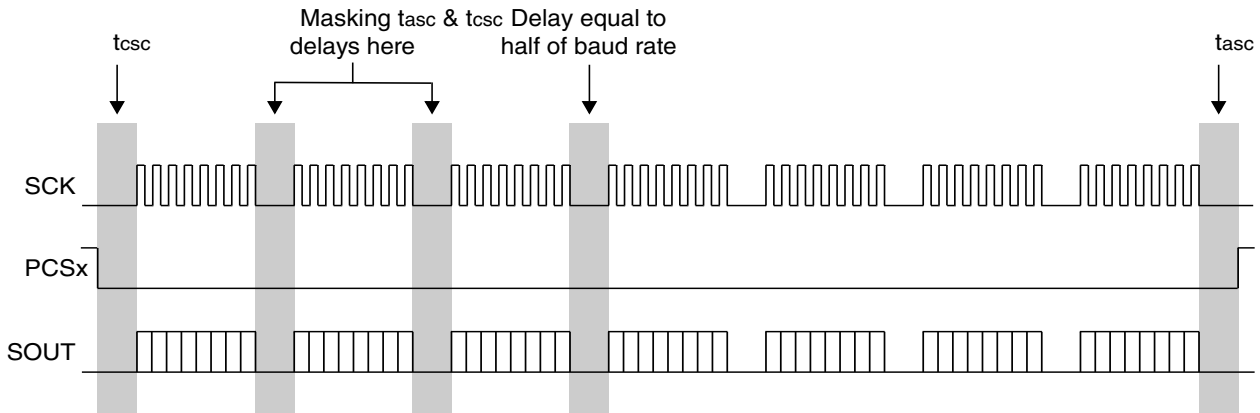

Figure 42-21. Example of Fast Continuous Selection Format

In case any chip select is to be changed, then the fast continuous selection format should be terminated and then the chips selects should change and appropriate delays must be introduced.

42.5.7 Continuous Serial Communications Clock

The module provides the option of generating a Continuous SCK signal for slave peripherals that require a continuous clock.

Continuous SCK is enabled by setting the CONT_SCKE bit in the MCR. Enabling this bit generates the Continuous SCK only if MCR[HALT] bit is low. Continuous SCK is valid in all configurations.

Continuous SCK is only supported for CPHA=1. Clearing CPHA is ignored if the CONT_SCKE bit is set. Continuous SCK is supported for Modified Transfer Format.

Clock and transfer attributes for the Continuous SCK mode are set according to the following rules:

- When the module is in SPI configuration, CTAR0 is used initially. At the start of each SPI frame transfer, the CTAR specified by the CTAS for the frame is used.
- When the module is in DSI configuration, the CTAR specified by the DSICTAS field is used at all times.
- When the module is in CSI configuration, the CTAR selected by the DSICTAS field is used initially.

- At the start of a SPI frame transfer, the CTAR specified by the CTAS value for the frame is used.
- At the start of a DSI frame transfer, the CTAR specified by the DSICTAS field is used.

- In all configurations, the currently selected CTAR remains in use until the start of a frame with a different CTAR specified, or the Continuous SCK mode is terminated.

It is recommended to keep the baud rate the same while using the Continuous SCK. Switching clock polarity between frames while using Continuous SCK can cause errors in the transfer. Continuous SCK operation is not guaranteed if the module is put into the External Stop mode or Module Disable mode.

Enabling Continuous SCK disables the PCS to SCK delay and the Delay after Transfer (t_{DT}) is fixed to one SCK cycle. When TSB configuration is enabled the t_{DT} is programmable from 1 to 64 SCK cycles. The following figure is the timing diagram for Continuous SCK format with Continuous Selection disabled.

NOTE

In Continuous SCK mode, for the SPI transfer CTAR0 should always be used, and the TX FIFO must be cleared using the MCR[CLR_TXF] field before initiating transfer.

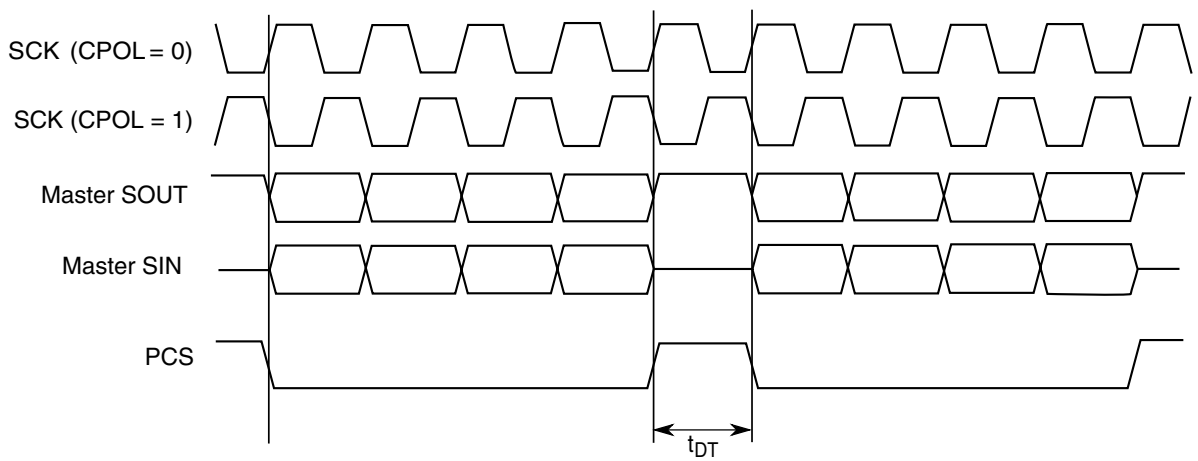

Figure 42-22. Continuous SCK Timing Diagram (CONT=0)

If the CONT bit in the TX FIFO entry is set or the DCONT in DSICR0 is set, PCS remains asserted between the transfers. Under certain conditions, SCK can continue with PCS asserted, but with no data being shifted out of SOUT, that is, SOUT pulled high. This can cause the slave to receive incorrect data. Those conditions include:

- Continuous SCK with CONT bit set, but no data in the TX FIFO.

- Continuous SCK with CONT bit set and entering Stopped state (refer to Start and Stop of module transfers).
- Continuous SCK with CONT bit set and entering Stop mode or Module Disable mode.

The following figure shows timing diagram for Continuous SCK format with Continuous Selection enabled.

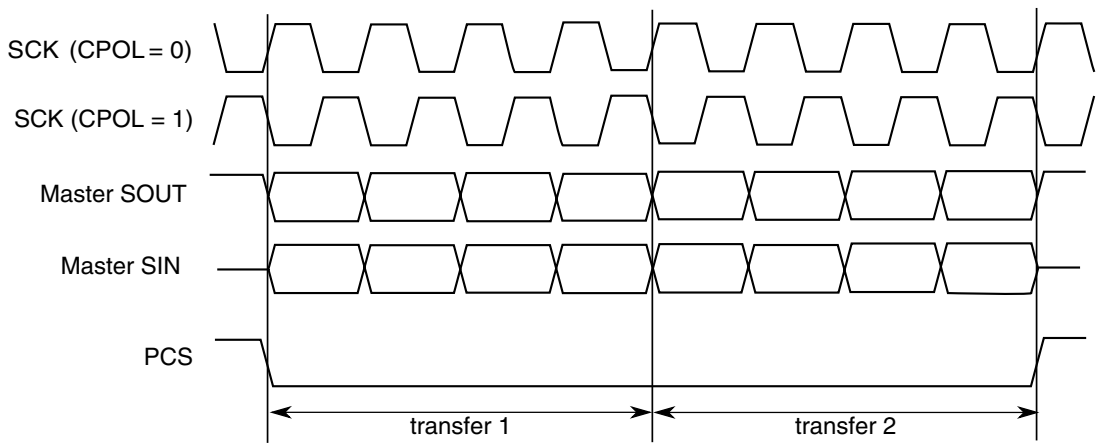

Figure 42-23. Continuous SCK timing diagram (CONT=1)

42.5.8 Slave Mode Operation Constraints

Slave mode logic shift register is buffered. This allows data streaming operation, when the module is permanently selected and data is shifted in with a constant rate.

The transmit data is transferred at second SCK clock edge of the each frame to the shift register if the $\overline{SS}$ signal is asserted and any time when transmit data is ready and $\overline{SS}$ signal is negated.

Received data is transferred to the receive buffer at last SCK edge of each frame, defined by frame size programmed to the CTAR0/1 register. Then the data from the buffer is transferred to the RXFIFO or DDR register.

If the $\overline{SS}$ negates before that last SCK edge, the data from shift register is lost.

42.5.9 Timed Serial Bus (TSB)

The DSPI can be programmed in Timed Serial Bus configuration by setting the TSBC bit in the DSPI_DSICR0 register. See DSPI DSI Configuration Register 0 (DSPI_DSICR0) for details.

TSB configuration provides the Micro Second Channel (MSC) downstream channel support.

The MSC upstream channel is not supported by the DSPI, but can be supported by any available Serial Communication Controller (SCI or UART) in the SoC.

The DSI Continuous Frame Selection Format is not supported by the TSB Mode (DSICR0[DCONT] bit cannot not be asserted).

To work in TSB mode the DSPI must be in master mode and in DSI (DCONF = 0b01) or CSI (DCONF = 0b10) configuration. Both Continuous and Non Continuous Serial Communication Clock (controlled by the DSPI_MCR[CONT_SCKE] bit) are supported in the TSB mode.

The following figure shows the signals used in the TSB interface.

In the TSB configuration the DSPI is able to send from 4 to 66 bits MSC data frames (4 to 64 serialized data bits and up to 2 Data Selection zero bits). The serialized data bits source can be either:

- the DSPI DSI Alternate Serialization Data Register (DSPI_ASDR0/1), written by the host software,
- Parallel Input pin states latched into the DSPI DSI Serialization Data Register (DSPI_SDR0/1).

DSPI_DSICR0 TXSS bit or DSPI_SSR0–1 register bits define the source of the data.

The Least Significant Bits of the DSPI_ASDR0 or DSPI_SDR0 registers are selected to be serialized if the data frame is set to less than 32 bits.

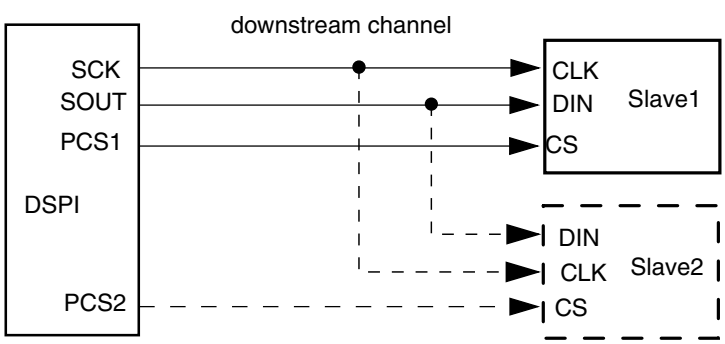

Figure 42-24. DSPI usage in the TSB Configuration

The PCS signals are driven together with SOUT. The t_{CSC} and t_{ASC} delays are not available. Delay after Transfer (DT) is set in SCK clock periods as a binary number formed by concatenation of the DSPI_CTARn PDT and DT fields plus one, allowing to set DT from 1 to 64 serial clock periods. DT field provides least significant bits and PDT field provides most significant bits of the Delay after Transfer.

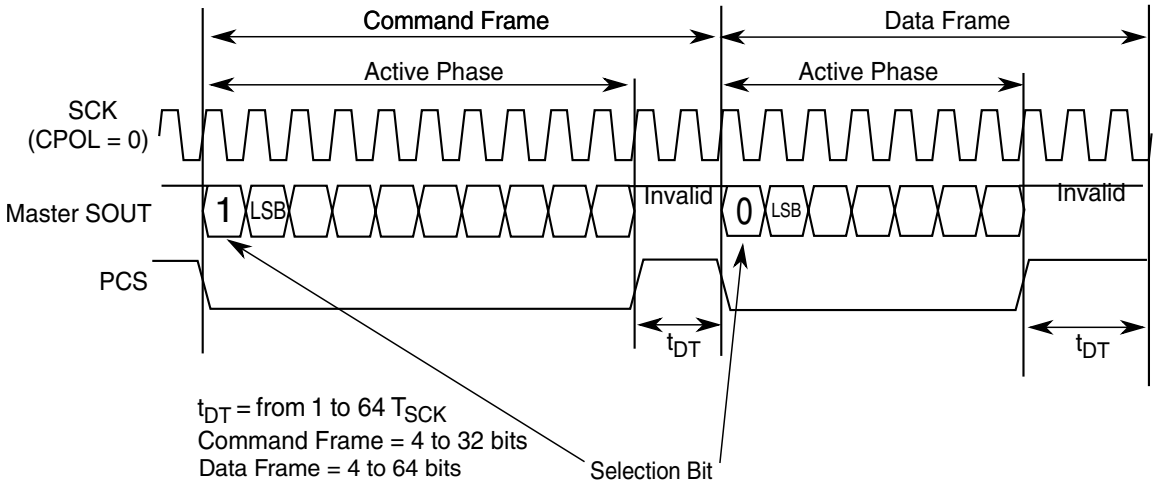

Figure 42-25. TSB Downstream Frames

Above figure shows the two types of MSC downstream frames - command frame, and data frame.

The first transmitted bit, called the selection bit, determines the frame type:

- The selection bit "0" indicates a data frame
- The selection bit "1" indicates a command frame

Data frame may contain up to 2 selection bits to support two external slave devices, (so called dual receiver configuration) or no selection bits at all.

The command frame can be written by software, through SPI TX FIFO, using one or two FIFO entries with help of the CONT bit or MCR[XSPI]. The data frame consists of up to 64 bits from the SDR0–1 or ASDR0–1 registers and up to two selection bits (0). Number of data bits in the data frame is defined by the DSCICR1[TSBCNT] field.

The selection bit of the MSC command frames (1) can be implemented by software.

The selection bits in the data frames are enabled by DSPI_DSICR1 DSE0 and DSE1 bits. Each DSEn bit set increases the data frame size by one bit.

To comply with MSC specification, set DSPI_CTARn[LSBFE] to transmit least significant bit first.

Regardless the LSBFE bit setting, the Data Frame Selection Bits, if enabled, are always transmitted first, before corresponded data sub frames.

42.5.9.1 MSC Dual Receiver Support with PCS Switch Over

When in TSB mode it is possible to switch the set of PCS signals that are driven during the first part of the frame to a different set of PCS signals during the second part of the frame. The bit, at which this switch over occurs, is defined by FMSZ field of the DSPI_CTARn register, selected by DSICTAS field of the DSICR0 register. If DSICR1[DSI64E] is enabled, then the bit at which the PCS switch occurs, is defined by the concatenation of {DSICR0[FMSZ4], CTAR[FMSZ]} fields.

Number of the bits, not including the Data Selection Bit, in the first part of the frame is equal to value of the FMSZ field plus one. (This value changes to {FMSZ4,FMSZ} plus one, when DSICR1[DSI64E] is enabled). During this part of the frame the PCS signal levels are controlled by DSPI_DSICR0 DPCSn bits, after that by DSPI_DSICR1 DPCS1_n bits.

The PCS switch over occurs at driving edge of the SCK clock output.

The second Data Selection Bit is inserted after the PCS switch over if enabled.

Data Frame with PCS switch over is shown in the following figure.

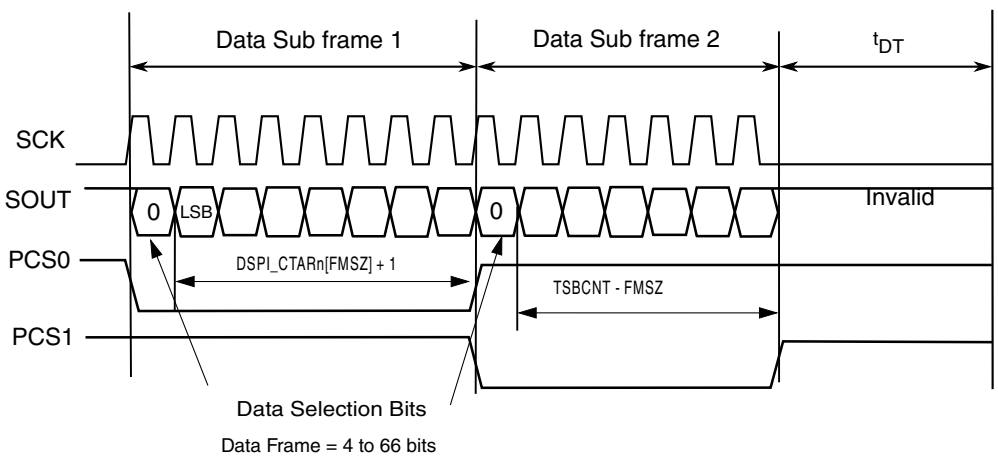

Figure 42-26. TSB Data Frame Format for MSC Dual Receiver Operation

42.5.10 Interleaved TSB (ITSB) Mode

This mode is similar to the TSB mode in some aspects except for the differences mentioned in the table below. The major difference is that the ITSB mode is highly generic in its approach to be compliant with the Downstream operation of the

Microsecond Channel Protocol. It includes a triggered time-slot based system with user configurable options for the frames to be transmitted in each time slot. (The time period between any two triggers is known as a time-slot).

The DSPI can be programmed to the ITSB Mode by asserting DSICR0[TSBC], DSICR0[ITSB]. To work in ITSB Mode, the DSPI must be in Master Mode and MCR[DCONF] must be set to CSI mode. (DCONF = 0b10). Both continuous and non-continuous clock serial communication clock (MCR[CONT_SCKE] are supported in this mode.

There are three types of frames which can be transmitted in a time slot i.e. Data Frame, Command Frame and Passive (Idle) frame. Similar to the TSB Mode, SPI frames are used for MSC Command frames, while DSI frames are used for MSC Data frames. A Passive Frame is an Idle frame in which no chip selects are asserted and no data is transmitted. The frame transmission is broadly governed by the following rules:

- Transmission of frames is done on trigger pulses that can be generated internal to the DSPI. The internal trigger is periodic with a period of 4. Thus there are 4 time-slots which appear periodically in the ITSB mode. The frame rules to be followed during each of the 4 time-slots can be programmed via TS_CONF[TSn] fields. The length of each time slot can be programmed via TSL[TSx_LEN] fields. The minimum length of a time slot is governed by the following formulae :
  - Minimum Length for Time slot X = Frame size of the frame to be transmitted in Time slot X + no. of selection bits, if any + 2 (Inherent time(Delay) changed by baud rate(Fp/n)).
  - The above constraint is only true for Data and Command frames. Passive frames do not have a minimum trigger length constraint. The user software shall configure the trigger lengths and trigger source.
- If the previously transmitted frame was a Command (SPI) frame or the TX_FIFO (or CMD FIFO) is empty, the non-passive frame transmitted on a subsequent trigger will not be a command frame.
- If the previously transmitted frame was not a Command (SPI) frame and the TX_FIFO (and CMD FIFO) have sufficient data to allow a SPI frame transmission, the frame transmitted on subsequent trigger can be a Command (SPI) frame.
- A Dual Receiver Frame (DRF) is a single Data (DSI) Frame which is split and transmitted to two different receivers (via occurrence of PCS switchover at the split) - the former part being called DRF1 and the latter part as DRF2 (Dual Receiver Frames 1 & 2). Using TS_CONF[TSn] fields, a time-slot can be programmed to transmit a sole DRF1 or a DRF2 frame. A sole DRF1 frame followed by any other frame is a valid scenario. A DRF2 frame programmed for a time slot is only valid if

the immediate previous time-slot was DRF1 - an invalid DRF2 frame, if programmed results in the transmission of a Passive frame (PF).

This mode does not change the way DSI and SPI frame transmissions are done except that ITSB mode interleaves the source (SPI or DSI) with a configurable set of rules based on triggered time-slot system. All features of SPI and DSI mode can be used except for the Continuous Frame Selection format (PUSHR[CONT] and DSICR0[DCONT] bits should not be asserted).

MCR[MTFE] should be set to 0 during ITSB Mode of operation, since MicroSecond Channel upstream operation is not supported.

The following table lists the differences between the TSB and ITSB modes:

Table 42-15. Differences between TSB and ITSB modes

TSB Mode	ITSB Mode
Priority available to frames from SPI. Back to back SPI frames are sent out.	No priority. Messages are interleaved such that there are no back-to-back SPI frames
Selection Bit inserted for DSI frames only. Selection bit for SPI frames is inserted by software.	Selection bit for both DSI and SPI frames inserted automatically. Encoding of selection bit same as TSB mode (0 = DSI; 1 = SPI).
Occasionally triggered transmission (that is trigger is received via hardware trigger input).	Triggered time-slot based transmission (that is frames are transmitted continuously on every trigger).
Gap between frames is configurable. Time between frames is t_{DT} which is configurable from 1 to 64 baud rate clock cycles.	Gap between frames is configurable and can be introduced in any of the two ways - By programming a Passive Frame or by increasing the length of a time-slot. Time t_{DT} is not used in this mode as it can be made part of the trigger period (as passive time).

In both TSB & ITSB mode, separate frame completion interrupts will be available to indicate frame transmission completion from SPI & DSI frames. MSC dual receiver support with PCS switchover is also supported in ITSB mode. See MSC Dual Receiver Support with PCS Switch Over for more details.

The ITSB mode is suitable to implement the Downstream Channel for the MSC Bus because of the above features.

42.5.10.1 Configuring DSPI for ITSB mode

The following steps give the recommended way to initialize the DSPI for the ITSB mode of operation:

- The DSPI should be put in HALT mode (by asserting the MCR[HALT] bit) before programming the registers.

- Set the DSICR0[TSBC] and DSICR0[ITSB] bits. The DSICR0[TRRE] and DSICR0[CID] bits should be cleared. DSICR0[DCONT] and PUSHR[CONT] should not be used in ITSB mode. The bit MCR[MTFE] should be cleared as Upstream operation is not supported in ITSB Mode. If DSICR0[ITSB] bit is set without setting DSICR0[TSBC], then the DSPI operates in the Normal Mode depending on MCR[DCONF] bit.
- Configure the Time Slot Length's via TSL register and the frame rules for each time slot via TS_CONF register.
- Based on trigger source requirements, set the values in the DSICR0[TRG] bit.
- Enable frame completion interrupts for either any frame completion (TCF) or separate frame complete (DSITCF and SPITCF) as required by application.
- When remainder configuration of DSPI is complete, clear the MCR[HALT] bit to allow DSPI to start operations.

Once configured and DSPI is brought out of HALT, the ITSB mode shall start sequencing the frames from either DSI or SPI as per the rules mentioned in Interleaved TSB (ITSB) Mode.

42.5.10.2 Variable Length Time Slots

In the Interleaved TSB Mode, the TSL[TSx_LEN] registers are used to configure the time slot length's as required by the application. There are up to 4 time slots named TS0, TS1, TS2 and TS3 respectively, which repeat periodically. To achieve a periodicity less than 4, any time slot length can be programmed as 0 (which eliminates this time slot). The following figures illustrate this concept.

In the figure below, the fields TSL[TSx_LEN] are programmed to be non-zero for x = 0,1,2,3. Hence, the time slots repeat after every 4 trigger pulses as shown.

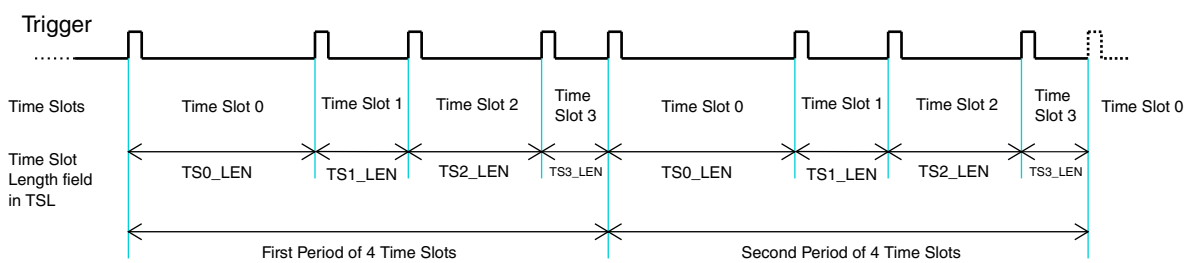

Figure 42-27. Periodic Time Slots with period = 4

In the figure below, the fields TSL[TSx_LEN] are programmed to be non-zero for x = 0,1,2, while TSL[TS3_LEN] = 0. Hence, the time slots repeat after every 3 trigger pulses as shown.

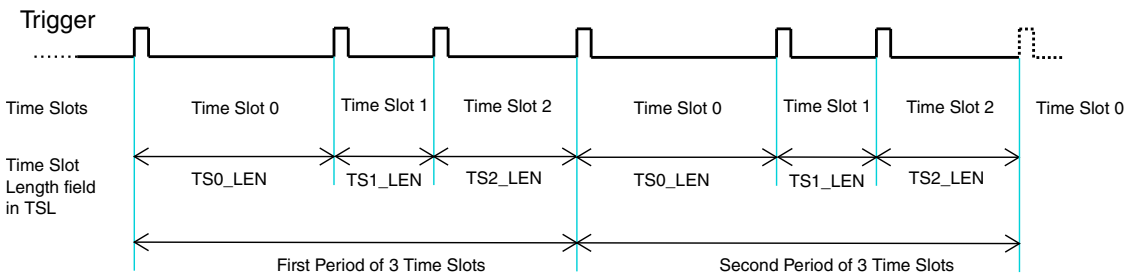

Figure 42-28. Periodic Time Slots with period = 3

The following figure shows time slots with periodicity of 1. Here the fields TSL[TSx_LEN] are programmed to zero for x = 1,2 and 3 while TSL[TS0_LEN] is non-zero. Hence, the time slots repeat after every trigger as shown.

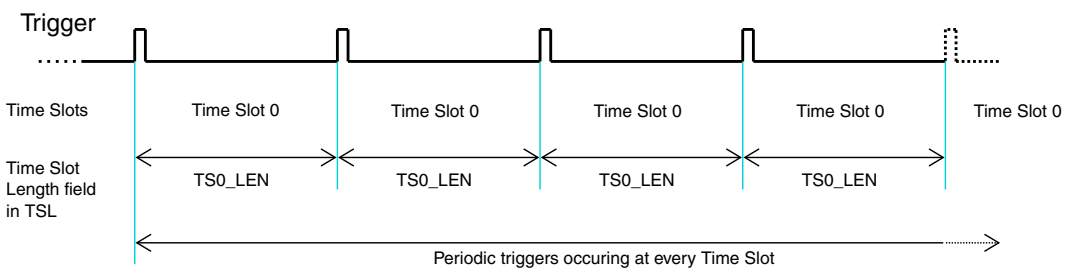

Figure 42-29. Periodic Time Slots with period = 1

Similarly, any TSL[TSx_LEN] can be made 0 to vary periodicity of time slots, but it is an illegal scenario to have all TSL[TSx_LEN] fields as 0.

NOTE

If external triggering mechanism is enabled (DSICR[TRG] is set), then it must be ensured that the minimum distance between two trigger pulses is at least 5P, where P is the protocol clock period.

When internal triggering mechanism is enabled (DSICR[TRG] is zero), the minimum value which can be programmed in the field TSL[TSx_LEN] is given by L = F + 1 + m; where F is the frame size of the frame programmed to be transmitted for the time slot TSx. The variable 'm' equals 1 when maximum baud rate is programmed (i.e. SCK = protocol clock frequency/ 2) and 0 otherwise.

42.5.10.3 Using ITSB mode for MSC Downstream Channel

MSC Downstream Channel uses three types of frames: command frames, data frames and passive frames. The Downstream operation of these frames require:

- Data frames can be sent back to back.
- Back to back command frames are not a legal scenario.
- Passive frames are used when no activity is desired for any time slot. In a passive frame, chip selects are de-asserted, and no SCK or data is transmitted. For this reason Command Frames cannot be separated by Passive frames as it would still be an illegal scenario.
- In dual MSC ASIC, some bits of the data frame goes to first ASIC and remainder bits to second ASIC. The first part is referred to as DRF1 (Dual Receiver Frame 1) and the second part as DRF2 (Dual Receiver Frame 2).
- A DRF2 programmed for a time slot is only valid if the immediately preceding time slot was DRF1. If DRF2 is valid, it would be transmitted seamlessly after DRF1 without waiting for the trigger pulse for the time slot of DRF2. For that reason, the TSL[TSx_LEN] for DRF1 must be programmed to the minimum possible value. If DRF2 is not valid, a Passive Frame is transmitted instead.

The ITSB mode can help implement the MSC Downstream Channel by allowing the command frames to be sent via the SPI interface and data frames to be sent via the DSI interface. Once the DSPI has been configured to work in ITSB mode (See Configuring DSPI for ITSB mode), the user software can program the DSI and SPI sides to send data and command frames respectively. The programming of frames for transmission via DSI or SPI is same as explained in Combined Serial Interface (CSI) Configuration.

The following figure shows a sample MSC Downstream transmission for the ITSB mode with the following configuration:

- All TSL[LEN] are programmed to be non-zero. Note that the length between triggers are not drawn to scale in the figure. The lengths of all 4 time slots shown are unequal.
- Data and Command selection bits are enabled, i.e. DSICR1[DSE0] and DSICR1[CSE] are set.
- TS_CONF[TS0] = CMD_SRDF
- TS_CONF[TS1] = CMD_SRDF
- TS_CONF[TS2] = CMD_PF

- TS_CONF[TS3] = CMD_SRDF
- PCS0 is used for Data Frames while PCS1 is used for Command Frames. Both chip select's are active low.

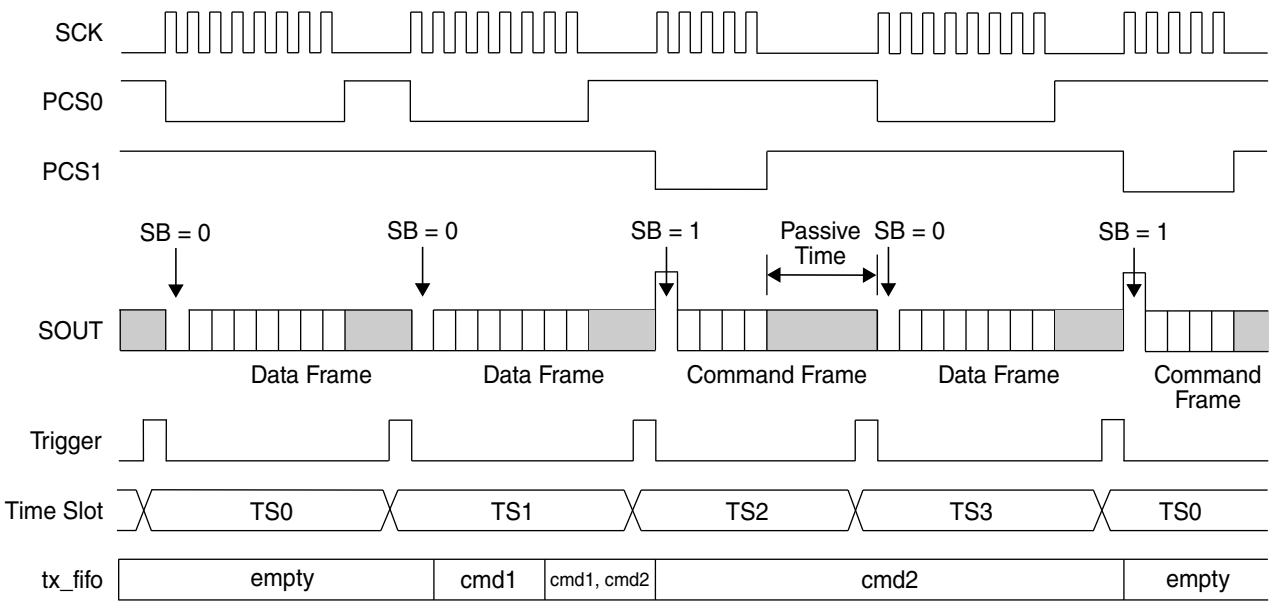

Figure 42-30. Sample MSC Downstream transmission using ITSB mode

Brief description of operation includes:

- At the first trigger, TS0 is initiated. The frame rule for TS0 is configured as CMD_SRDF (Command if valid, else Single Receiver Data Frame). Since there is no data present in the TXFIFO, a valid command frame is not available to be transmitted. Hence a single receiver data frame is transmitted instead.
- The second trigger initiates TS1. Again a single receiver data frame is transmitted since the frame rule for TS1 is programmed to CMD_SRDF and a command frame is not valid as there is no data present in the TXFIFO when TS1 is initiated.
- During TS1, two frames are pushed into the TX_FIFO.
- At third trigger, TS2 is initiated , the frame rule for which is programmed to CMD_PF (Command if valid. else Passive Frame). A Command frame is transmitted as the TX_FIFO is not empty.
    - Since the frame size of the command frame is less than the trigger length for TS2, no transmission happens till next trigger. This is marked as the “Passive Time”. Such passive time exists in all frames after frame transmission completes and until next trigger pulse is detected.

- For TS3, the frame rule programmed is CMD_SRDF. Since the previous transmission was a command frame, a single receiver data frame is transmitted during TS3.
- The time slot TS0 repeats, and this time a command frame is transmitted during TS0 since the Command Frame is eligible to be transmitted.
- At sixth trigger (not shown), TS1 occurs and the process continues.

The figure below shows another sample MSC Downstream transmission for the ITSB mode with the following configuration:

- All TSL[LEN] are programmed to be non-zero. Note that the length between triggers are not drawn to scale in the figure. The lengths of all 4 time slots shown are unequal.
- Data and Command selection bits are enabled, i.e. DSICR1[DSE0] and DSICR1[CSE] are set.
- TS_CONF[TS0] = CMD_DRF1
- TS_CONF[TS1] = DRF2
- TS_CONF[TS2] = CMD_DRF1
- TS_CONF[TS3] = CMD_DRF2
- PCS0 is used for DRF1 while PCS1 is used for DRF2 or Command Frames. Both chip select's are active low.

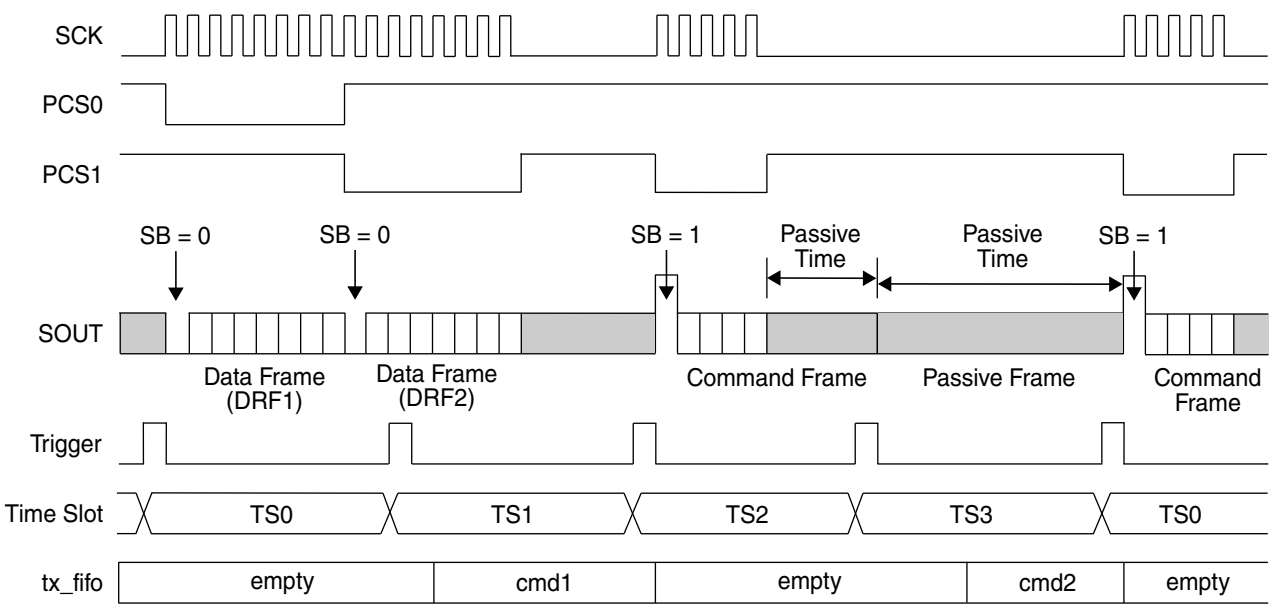

Figure 42-31. Sample MSC Downstream transmission using ITSB mode

Brief description of operation includes:

- At the first trigger, TS0 is initiated. The frame rule for TS0 is configured as CMD_DRF1 (Command if valid, else Dual Receiver Frame 1). Since there is no data present in the TXFIFO, a valid command frame is not available to be transmitted. Hence DRF1 is selected for transmission. Now it is checked if the next trigger is DRF2 which is true and hence DRF1 and DRF2 are transmitted back-to-back seamlessly with the PCS switch-over occurring in between. Note that this happens independent of the next trigger. If the next trigger were configured to CMD_DRF2 instead, then at the current trigger, the validity of CMD is checked to confirm the presence of DRF2 for next trigger. If presence of DRF2 is confirmed for next trigger, it is transmitted along with DRF1 seamlessly as shown here, otherwise only DRF1 would be transmitted in the current trigger and the CMD frame would be transmitted in the next trigger.
- During TS1, one frame is pushed into the TX_FIFO.
- Since DRF2 is transmitted immediately after DRF1, the occurrence second trigger does not cause any operation. Hence it must be ensured by the user that Trigger Length of TS0 must be programmed to minimum possible value - during which DRF1 can be successfully transmitted. This ensures that trigger for TS1 occurs sometime after the switch-over and not after DRF2 has been transmitted.
- The third trigger initiates TS2, the frame rule for which is configured as CMD_DRF1. A Command frame is transmitted as the data required to transmit a command frame is available (TX_FIFO and CMD_FIFO is not empty) and the previous transmitted frame was not a command frame.
- The fourth trigger initiates TS3, the frame rule for which is configured as CMD_DRF2. Since a CMD frame isn't available and DRF2 is not valid (since DRF1 wasn't transmitted in the previous trigger), a passive frame is transmitted instead.
- The time slot TS0 repeats, and this time a command frame is transmitted during TS0 since the Command Frame is eligible to be transmitted.
- At sixth trigger (not shown), TS1 occurs and the process continues.

NOTE

For a command/data frame to be transmitted on a trigger, they should be available some time before the occurrence of the trigger. A DSI frame must be updated/present "X" time units before the occurrence of the trigger for the time slot in which this data is to be transmitted. This is true for all DSI frames and also implies that when DRF1 and DRF2 are positioned to be

transmitted seamlessly, both DRF1 and DRF2 frames must be available 'X' time units before occurrence of trigger pulse for the time slot of DRF1 itself.

Similarly, a command frame must be available "Y" time units before the occurrence of the trigger for the time slot in which this data is to be transmitted.

Here X = 2R + 1P and Y = 1R + 3P; where R = register clock period, P = protocol clock period.

42.5.11 Parity Generation and Check

The module can generate and check parity in the serial frame. The parity bit replaces the last transmitted bit in the frame. The parity is calculated for all transmitted data bits in frame, not including the last data bit that would be transmitted. The parity generation/ control is done on frame basis. The registers field setting frame size defines the total number of bits in the frame, including the parity bit. Thus, to transmit/receive the same number of data bits with parity check, increase the frame size by one versus the same data size frame without the parity check.

Parity can be selected as odd or even. Parity Errors in the received frame set Parity Error flags in the Status register. The Parity Error Interrupt Requests are generated if enabled. The module can be programmed to stop frame transmission in case of a frame reception with parity error.

42.5.11.1 Parity for SPI Frames

When the module is in the master mode the parity generation is controlled by PE and PP bits of the CMD FIFO entries (PUSHR). Setting the PE bit enables parity generation for transmitted SPI frames and parity check for received frames. PP bit defines polarity of the parity bit.

When continuous PCS selection is used to transmit SPI data, two parity generation scenarios are available:

- Generate/check parity for the whole frame
- Generate/check parity for each sub-frame separately.

To generate/check parity for the whole frame set PE bit only in the last command/TX FIFO entry, forming this frame (with the PUSHR register).

To generate/check parity for each sub-frame set PE bit in each command/TX FIFO entry, forming this frame.

If the parity error occurs for received SPI frame, the SR[SPEF] bit is set. If MCR[PES] bit is set, the module stops SPI frames transmission. To resume SPI operation clear the SR[SPEF] or the MCR[PES] bits.

In slave mode the parity is controlled by the PE and PP bits of the CTAR0 register similar to the master mode parity generation without continuous PCS selection.

42.5.11.2 Parity for DSI Frames

When DSPI is in Master Mode, parity generation is controlled by PE and PP bits of the DSPI_DSICR0 register similar to the SPI frames. The parity is calculated and checked for each DSI frame. DSPI_DSICR0[DCONT] bit has no effect on parity generation. In slave mode the parity is controlled by the PE and PP bits of the CTAR1 register.

If the parity error occurs for received DSI frame, the DSPI_SR[DPEF] bit is set. If DSPI_DSICR0[PES] bit is set, the DSPI stops DSI frames transmission. To resume DSI operation clear the DSPI_SR[DPEF] or the DSPI_DSICR0[PES] bits.

42.5.12 Interrupts/DMA requests

The module has several conditions that can generate only interrupt requests and two conditions that can generate interrupt or DMA requests. The following table lists these conditions.

Table 42-16. Interrupt and DMA request conditions

Condition	Flag	Interrupt	DMA
End of Queue (EOQ)	EOQF	Yes	-
TX FIFO Fill	TFFF	Yes	Yes
CMD FIFO Fill	CMDFFF	Yes	Yes
TX FIFO Invalid Write	TFIWF	Yes	-
Transfer Complete	TCF	Yes	-
CMD Transfer Complete	CMDTCF	Yes	-
SPI Transfer Complete	SPITCF	Yes	-
DSI Transfer Complete	DSITCF	Yes	-
TX FIFO Underflow	TFUF	Yes	-
RX FIFO Drain	RFDF	Yes	Yes
RX FIFO Overflow	RFOF	Yes	-
SPI Parity Error	SPEF	Yes	-

Table continues on the next page...

Table 42-16. Interrupt and DMA request conditions (continued)

Condition	Flag	Interrupt	DMA
DSI Parity Error	DPEF	Yes	-
DSI Deserialized Data Match	DDIF	Yes	Yes

Each condition has a flag bit in the module Status Register (SR) and a Request Enable bit in the DMA/Interrupt Request Select and Enable Register (RSER). Certain flags (as shown in above table) generate interrupt requests or DMA requests depending on configuration of RSER register.

The module also provides a global interrupt request line, which is asserted when any of individual interrupt requests lines is asserted.

42.5.12.1 End Of Queue interrupt request

The End Of Queue (EOQ) interrupt request indicates that the end of a transmit queue is reached. The module generates the interrupt request when EOQ interrupt requests are enabled (RSER[EOQF_RE]) and the EOQ bit in the executing SPI command is 1.

When Extended SPI mode is enabled (MCR[XSPI]) and the EOQ bit in the executing SPI command is 1, the module generates the EOQ interrupt request when the last bit of the last data frame in the command cycle has been transmitted.

When Extended SPI mode is disabled (MCR[XSPI]), the module generates the interrupt request when the last bit of the SPI frame with EOQ bit set is transmitted.

42.5.12.2 Transmit FIFO Fill Interrupt or DMA Request

The Transmit FIFO Fill Request indicates that the TX FIFO is not full. The Transmit FIFO Fill Request is generated when the number of entries in the TX FIFO is less than the maximum number of possible entries, and the TFFF_RE bit in the RSER is set. The TFFF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

NOTE

TFFF flag clears automatically when DMA is used to fill TX FIFO. Configure the DMA to fill only one FIFO location per transfer.

To clear TFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill TX FIFO:

1. Wait until TFFF = 1.
2. Write data to PUSHR using CPU.
3. Clear TFFF by writing a 1 to its location. If TX FIFO is not full, this flag will not clear.

42.5.12.3 Command FIFO Fill Interrupt or DMA Request

The Command FIFO Fill Request indicates that the CMD FIFO is not full. The Command FIFO Fill Request is generated when the number of entries in the CMD FIFO is less than the maximum number of possible entries, and the CMDFFF_RE bit in the RSER is set. The CMDFFF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

This Request is useful when MCR[XSPI] is enabled, since TX FIFO and CMD FIFO can be filled independantly. If MCR[XSPI] is disabled, then 'TX FIFO Fill Interrupt or DMA Request' will suffice to fill both FIFO's since both FIFO's must be filled simultaneously.

NOTE

CMDFFF flag clears automatically when DMA is used to fill CMD FIFO. Configure the DMA to fill only one FIFO location per transfer.

To clear CMDFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill CMDFIFO:

1. Wait until CMDFFF = 1
2. Write data to PUSHR using CPU.
3. Clear CMDFFF by writing a 1 to its location. If CMD FIFO is not full, this flag will not clear.

42.5.12.4 Transmit FIFO Invalid Write Interrupt Request

The Transmit FIFO Invalid Write Request is valid only when MCR[XSPI] is enabled. This Request indicates that Data exists in the TX FIFO while the CMD FIFO is empty. Since no Command Fields are associated with the Data present in TX FIFO, this data is considered invalid until a Command Entry becomes available. The Transmit FIFO Invalid Write Request is generated for the above condition when TFIWF_RE bit is set in the RSER.

42.5.12.5 Transfer Complete Interrupt Request

The Transfer Complete Request indicates the end of the transfer of a serial frame. The Transfer Complete Request is generated at the end of each frame transfer when the TCF_RE bit is set in the RSER.

42.5.12.6 Command Transfer Complete Interrupt Request

The Command Transfer Complete Request indicates the end of transfer of the last SPI frame in a Command Cycle. The Transfer Complete Request is generated for the above condition when the CMDTCF_RE bit is set in the RSER.

42.5.12.7 SPI Transfer Complete Interrupt Request

The SPI Transfer Complete Request indicates the end of transfer of an SPI frame in any Transmission Mode which uses DSPI in CSI Mode. The SPI Transfer Complete Request is generated when SR[SPITCF] flag asserts and SPITCF_RE bit is set in the RSER.

42.5.12.8 DSI Transfer Complete Interrupt Request

The DSI Transfer Complete Request indicates the end of transfer of a DSI frame in any Transmission Mode which uses DSPI in CSI Mode. The DSI Transfer Complete Request is generated when SR[DSITCF] flag asserts and DSITCF_RE bit is set in the RSER.

42.5.12.9 Transmit FIFO Underflow Interrupt Request

The Transmit FIFO Underflow Request indicates that an underflow condition in the TX FIFO has occurred. The transmit underflow condition is detected only for the module operating in Slave mode and SPI configuration. The TFUF bit is set when the TX FIFO of the module is empty, and a transfer is initiated from an external SPI master. If the TFUF bit is set while the TFUF_RE bit in the RSER is set, an interrupt request is generated.

42.5.12.10 Receive FIFO Drain Interrupt or DMA Request

The Receive FIFO Drain Request indicates that the RX FIFO is not empty. The Receive FIFO Drain Request is generated when the number of entries in the RX FIFO is not zero, and the RFDF_RE bit in the RSER is set. The RFDF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated. Configure the DMA to drain only one FIFO location per transfer.

42.5.12.11 Receive FIFO Overflow Interrupt Request

The Receive FIFO Overflow Request indicates that an overflow condition in the RX FIFO has occurred. A Receive FIFO Overflow request is generated when RX FIFO and shift register are full and a transfer is initiated. The RFOF_RE bit in the RSER must be set for the interrupt request to be generated.

Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

42.5.12.12 SPI Frame Parity Error Interrupt Request

The SPI Frame Parity Error Flag indicates that a SPI frame with parity error had been received. The SPEF_RE bit in the RSER must be set for the interrupt request to be generated.

42.5.12.13 DSI Frame Parity Error Interrupt Request

The DSI Frame Parity Error Flag indicates that a DSI frame with parity error has been received. The DPEF_RE bit in the DSPI_RSER must be set for the interrupt request to be generated.

42.5.12.14 Deserialized Data Match Interrupt or DMA Request

The Deserialized Data Match Flag (DDIF) indicates that a DSI frame matches DSPI_DPIR0–1 data, masked with DSPI_DIMR0–1, had been received. The DDIF_RE bit in the DSPI_RSER must be set for the request to be generated. The DDIF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

42.5.13 Power saving features

The module supports following power-saving strategies:

- External Stop mode
- Module Disable mode – Clock gating of non-memory mapped logic

42.5.13.1 Stop mode (External Stop mode)

This module supports the Stop mode protocol. When a request is made to enter External Stop mode, the module acknowledges the request . If a serial transfer is in progress, then this module waits until it reaches the frame boundary before it is ready to have its clocks shut off . While the clocks are shut off, this module's memory-mapped logic is not accessible. This also puts the module in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. The states of the interrupt and DMA request signals cannot be changed while in External Stop mode.

42.5.13.2 Module Disable mode

Module Disable mode is a block-specific mode that the module can enter to save power. Host CPU can initiate the Module Disable mode by setting the MDIS bit in the MCR. The Module Disable mode can also be initiated by hardware.

When the MDIS bit is set, the module negates the Clock Enable signal at the next frame boundary. Once the Clock Enable signal is negated, it is said to have entered Module Disable Mode. This also puts the module in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. If implemented, the Clock Enable signal can stop the clock to the non-memory mapped logic. When Clock Enable is negated, the module is in a dormant state, but the memory mapped registers are still accessible. Certain read or write operations have a different effect when the module is in the Module Disable mode. Reading the RX FIFO Pop Register does not change the state of the RX FIFO. Similarly, writing to the PUSHR Register does not change the state of the TX FIFO or CMD FIFO. Clearing either of the FIFOs has no effect in the Module Disable mode. Changes to the DIS_TXF and DIS_RXF fields of the MCR have no effect in the Module Disable mode. In the Module Disable mode, all status bits and register flags in the module return the correct values when read, but writing to them has no effect. Writing to the TCR during Module Disable mode has no effect. Interrupt and DMA request signals cannot be cleared while in the Module Disable mode.

42.6 Initialization/application information

This section describes how to initialize the module.

42.6.1 How to manage queues

The queues are not part of the module, but it includes features in support of queue management. Queues are primarily supported in SPI configuration.

1. When module executes last command word from a queue, the EOQ bit in the command word is set to indicate it that this is the last entry in the queue.
2. At the end of the transfer, corresponding to the command word with EOQ set is sampled, the EOQ flag (EOQF) in the SR is set.
3. The setting of the EOQF flag disables serial transmission and reception of data, putting the module in the Stopped state. The TXRXS bit is cleared to indicate the Stopped state.
4. The DMA can continue to fill TX FIFO until it is full or step 5 occurs.
5. Disable DMA transfers by disabling the DMA enable request for the DMA channel assigned to TX FIFO (and CMD FIFO) and RX FIFO. This is done by clearing the corresponding DMA enable request bits in the DMA Controller.
6. Ensure all received data in RX FIFO has been transferred to memory receive queue by reading the RXCNT in SR or by checking RFDF in the SR after each read operation of the POPR.
7. Modify DMA descriptor of TX and RX channels for new queues
8. Flush TX FIFO (and CMD FIFO) by writing a 1 to the CLR_TXF bit in the MCR. Flush RX FIFO by writing a '1' to the CLR_RXF bit in the MCR.
9. Clear transfer count either by setting CTCNT bit in the command word of the first entry in the new queue or via CPU writing directly to SPI_TCNT field in the TCR.
10. Enable DMA channel by enabling the DMA enable request for the DMA channel assigned to the module TX FIFO, (and CMD FIFO) and RX FIFO by setting the corresponding DMA set enable request bit.
11. Enable serial transmission and serial reception of data by clearing the EOQF bit.

42.6.2 Switching Master and Slave mode

When changing modes in the module, follow the steps below to guarantee proper operation.

1. Halt it by setting MCR[HALT].
2. Clear the transmit and receive FIFOs by writing a 1 to the CLR_TXF and CLR_RXF bits in MCR.
3. Set the appropriate mode in MCR[MSTR] and enable it by clearing MCR[HALT].

42.6.3 Initializing Module in Master/Slave Modes

Once the appropriate mode in MCR[MSTR] is configured, the module is enabled by clearing MCR[HALT]. It should be ensured that module Slave is enabled before enabling it's Master. This ensures the Slave is ready to be communicated with, before Master initializes communication.

42.6.4 Baud rate settings

The following table shows the baud rate that is generated based on the combination of the baud rate prescaler PBR and the baud rate scaler BR in the CTARs. The values calculated assume a 100 MHz protocol frequency and the double baud rate DBR bit is cleared.

Table 42-17. Baud rate values (bps)

		Baud rate divider prescaler values			
		2	3	5	7
Baud Rate Scaler Values	2	25.0M	16.7M	10.0M	7.14M
	4	12.5M	8.33M	5.00M	3.57M
	6	8.33M	5.56M	3.33M	2.38M
	8	6.25M	4.17M	2.50M	1.79M
	16	3.12M	2.08M	1.25M	893k
	32	1.56M	1.04M	625k	446k
	64	781k	521k	312k	223k
	128	391k	260k	156k	112k
	256	195k	130k	78.1k	55.8k
	512	97.7k	65.1k	39.1k	27.9k

Table continues on the next page...

Table 42-17. Baud rate values (bps) (continued)

		Baud rate divider prescaler values			
		2	3	5	7
	1024	48.8k	32.6k	19.5k	14.0k
	2048	24.4k	16.3k	9.77k	6.98k
	4096	12.2k	8.14k	4.88k	3.49k
	8192	6.10k	4.07k	2.44k	1.74k
	16384	3.05k	2.04k	1.22k	872
	32768	1.53k	1.02k	610	436

42.6.5 Delay settings

The following table shows the values for the Delay after Transfer (t_{DT}) and CS to SCK Delay (T_{CSC}) that can be generated based on the prescaler values and the scaler values set in the CTARs. The values calculated assume a 100 MHz protocol frequency.

NOTE

The clock frequency mentioned above is given as an example in this chapter. See the clocking chapter for the frequency used to drive this module in the device.

This table does not apply for TSB Continuous mode.

Table 42-18. Delay values

		Delay prescaler values			
		1	3	5	7
Delay scaler values	2	20.0 ns	60.0 ns	100.0 ns	140.0 ns
	4	40.0 ns	120.0 ns	200.0 ns	280.0 ns
	8	80.0 ns	240.0 ns	400.0 ns	560.0 ns
	16	160.0 ns	480.0 ns	800.0 ns	1.1 µs
	32	320.0 ns	960.0 ns	1.6 µs	2.2 µs
	64	640.0 ns	1.9 µs	3.2 µs	4.5 µs
	128	1.3 µs	3.8 µs	6.4 µs	9.0 µs
	256	2.6 µs	7.7 µs	12.8 µs	17.9 µs
	512	5.1 µs	15.4 µs	25.6 µs	35.8 µs
	1024	10.2 µs	30.7 µs	51.2 µs	71.7 µs
	2048	20.5 µs	61.4 µs	102.4 µs	143.4 µs
	4096	41.0 µs	122.9 µs	204.8 µs	286.7 µs
	8192	81.9 µs	245.8 µs	409.6 µs	573.4 µs
	16384	163.8 µs	491.5 µs	819.2 µs	1.1 ms

Table continues on the next page...

Table 42-18. Delay values (continued)

		Delay prescaler values			
		1	3	5	7
	32768	327.7 µs	983.0 µs	1.6 ms	2.3 ms
	65536	655.4 µs	2.0 ms	3.3 ms	4.6 ms

42.6.6 Calculation of FIFO pointer addresses

Complete visibility of the FIFO contents is available through the FIFO registers, and valid entries can be identified through a memory-mapped pointer and counter for each FIFO. The pointer to the first-in entry in each FIFO is memory mapped. For the TX FIFO the first-in pointer is the Transmit Next Pointer (TXNXTPTR). For the CMD FIFO the first-in pointer is the Command Next Pointer (CMDNXTPTR). For the RX FIFO the first-in pointer is the Pop Next Pointer (POPNXTPTR). The following figure illustrates the concept of first-in and last-in FIFO entries along with the FIFO Counter. The TX FIFO is chosen for the illustration, but the concepts carry over. See Transmit First In First Out (TX FIFO) buffering mechanism, Command First In First Out (CMD FIFO) Buffering Mechanism and Receive First In First Out (RX FIFO) buffering mechanism for details on the FIFO operation.

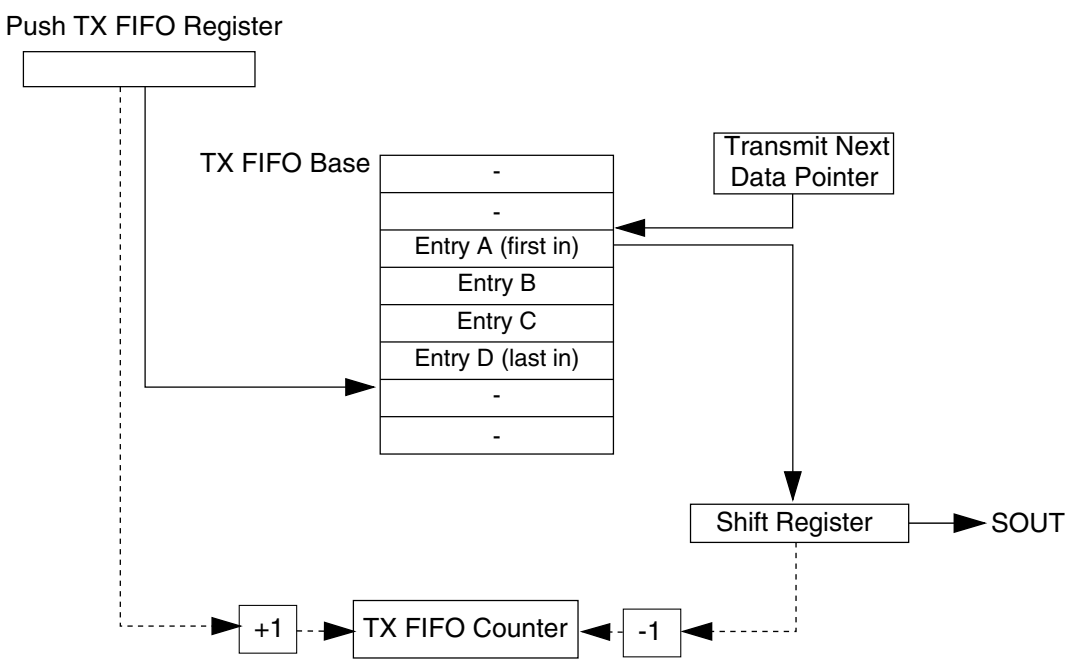

Figure 42-32. TX FIFO pointers and counter

42.6.6.1 Address Calculation for the First-in Entry and Last-in Entry in the TX FIFO

The memory address of the first-in entry in the TX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{TXFIFOBase} + (4 \times \text{TXNXTPTR})$$

The memory address of the last-in entry in the TX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{TXFIFOBase} + 4 \times (\text{TXCTR} + \text{TXNXTPTR} - 1) \bmod (\text{TXFIFOdepth})$$

TX FIFO Base - Base address of TX FIFO
TXCTR - TX FIFO Counter
TXNXTPTR - Transmit Next Pointer
TX FIFO Depth - Transmit FIFO depth, implementation specific

42.6.6.2 Address Calculation for the First-in Entry and Last-in Entry in the CMD FIFO

The memory address of the first-in entry in the CMD FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{TXFIFOBase} + (4 \times \text{TXNXTPTR})$$

The memory address of the last-in entry in the CMD FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{TXFIFOBase} + 4 \times (\text{TXCTR} + \text{TXNXTPTR} - 1) \bmod (\text{TXFIFOdepth})$$

CMD FIFO Base - Base address of CMD FIFO
CMDCTR - CMD FIFO Counter
CMDNXTPTR - Command Next Pointer
CMD FIFO Depth - Command FIFO depth, implementation specific

42.6.6.3 Address Calculation for the First-in Entry and Last-in Entry in the RX FIFO

The memory address of the first-in entry in the RX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{RX FIFOBase} + \left(4 \times \text{POPNXTPTR}\right)$$

The memory address of the last-in entry in the RX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{RX FIFO Base} + 4 \times \left(\text{RXCTR} + \text{POPNXTPTR} - 1\right) \text{mod} \left(\text{RXFIFOdepth}\right)$$

RX FIFO Base - Base address of RX FIFO
RXCTR - RX FIFO counter
POPNXTPTR - Pop Next Pointer
RX FIFO Depth - Receive FIFO depth, implementation specific

Chapter 43
Ethernet MAC (ENET)

43.1 Chip-specific ENET information

43.1.1 ENET Configuration

NOTE

It is only possible to use ENET0 and ENET1 simultaneously when both are configured for MII_Lite

ENET byte swapping control

The endianess of the ENET AHB interface is controlled via the GPR register bits in the device.

Refer -GPR Control Register (GPR_CTL) and -GPR Status Register (GPR_STAT) for details.

43.1.2 ENET Interrupt mapping

The following tables lists the ENET interrupt mapping implemented in this device.

Table 43-1. ENET0 Interrupt mapping

ENET0 Interrupt Group0	MAC 0 Periodic Timer Overflow
	MAC 0 Time Stamp Available
	MAC 0 Wakeup Request (sync)
	MAC 0 Payload Receive Error
	MAC 0 Transmit FIFO Underrun
	MAC 0 Collision Retry Limit
	MAC 0 Late Collision
	MAC 0 Ethernet Bus Error

Table continues on the next page...

Table 43-1. ENET0 Interrupt mapping (continued)

	MAC 0 MII Data Transfer Done
	MAC 0 Graceful Stop
	MAC 0 Babbling Transmit Error
	MAC 0 Babbling Receive Error
ENET0 Interrupt Group1	RX_FLUSH0
	MAC 0 Receive Buffer Done
	MAC 0 Receive Frame Done
ENET0 Interrupt Group2	MAC 0 Transmit Buffer Done
	MAC 0 Transmit Frame Done
ENET0 Interrupt Group3	MAC 0 Frame rejected due to Match/Inverse Match
	MAC 0 Frame rejected due to Parser Error
ENET0 Interrupt Group4	MAC 0 1588 Timer Interrupt - synchronous
ENET0 Interrupt Group5	RX_FLUSH1
	Receive Buffer_1 Done
	Receive Frame_1 Done
ENET0 Interrupt Group6	Transmit Buffer_1 Done
	Transmit Frame_1 Done
ENET0 Interrupt Group7	RX_FLUSH2
	Receive Buffer_2 Done
	Receive Frame_2 Done
ENET0 Interrupt Group8	Transmit Buffer_2 Done
	Transmit Frame_2 Done

43.1.3 ENET's stop-stop ack protocol

1. An acknowledgment to stop request is sent only when the MAC is disabled or in the idle state.
2. If the stop request is asserted to the ENET, only magic packet detection can wakeup the module.

43.1.4 Recieve Parser Match Array Table Depth

The depth of Physical table for Match Array table, which is the maximum value that can be programmed in ENET_RXPCTL[MAXINDEX] register field is 64.

43.2 Introduction

The MAC-NET core, in conjunction with a 10/100-Mbit/s MAC, implements layer 3 network acceleration functions. These functions are designed to accelerate the processing of various common networking protocols, such as IP, TCP, UDP, and ICMP, providing wire speed services to client applications.

43.3 Overview

The core implements a dual-speed 10/100-Mbit/s Ethernet MAC compliant with the IEEE802.3-2002 standard. The MAC layer provides compatibility with half- or full-duplex 10/100-Mbit/s Ethernet LANs.

The MAC operation is fully programmable and can be used in Network Interface Card (NIC), bridging, or switching applications. The core implements the remote network monitoring (RMON) counters according to IETF RFC 2819.

The core also implements a hardware acceleration block to optimize the performance of network controllers providing TCP/IP, UDP, and ICMP protocol services. The acceleration block performs critical functions in hardware, which are typically implemented with large software overhead.

The core implements programmable embedded FIFOs that can provide buffering on the receive path for lossless flow control.

Advanced power management features are available with magic packet detection and programmable power-down modes.

A unified DMA (uDMA), internal to the ENET module, optimizes data transfer between the ENET core and the SoC, and supports an enhanced buffer descriptor programming model to support IEEE 1588 functionality.

The programmable Ethernet MAC with IEEE 1588 integrates a standard IEEE 802.3 Ethernet MAC with a time-stamping module. The IEEE 1588 standard provides accurate clock synchronization for distributed control nodes for industrial automation applications.

43.3.1 Features

The MAC-NET core includes the following features.

43.3.1.1 Ethernet MAC features

- Implements the full 802.3 specification with preamble/SFD generation, frame padding generation, CRC generation and checking
- Supports zero-length preamble
- Dynamically configurable to support 10/100-Mbit/s operation
- Supports 10/100 Mbit/s full-duplex and configurable half-duplex operation
- Compliant with the AMD magic packet detection with interrupt for node remote power management
- Seamless interface to commercial ethernet PHY devices via one of the following:
  - a 4-bit Media Independent Interface (MII) operating at 2.5/25 MHz.
  - a 4-bit non-standard MII-Lite (MII without the CRS and COL signals) operating at 2.5/25 MHz.
  - a 2-bit Reduced MII (RMII) operating at 50 MHz.
- Simple 64-Bit FIFO user-application interface
- CRC-32 checking at full speed with optional forwarding of the frame check sequence (FCS) field to the client
- CRC-32 generation and append on transmit or forwarding of user application provided FCS selectable on a per-frame basis
- In full-duplex mode:
  - Implements automated pause frame (802.3 x31A) generation and termination, providing flow control without user application intervention
  - Pause quanta used to form pause frames — dynamically programmable
  - Pause frame generation additionally controllable by user application offering flexible traffic flow control
  - Optional forwarding of received pause frames to the user application
  - Implements standard flow-control mechanism
- In half-duplex mode: provides full collision support, including jamming, backoff, and automatic retransmission
- Supports VLAN-tagged frames according to IEEE 802.1Q
- Programmable MAC address: Insertion on transmit; discards frames with mismatching destination address on receive (except broadcast and pause frames)
- Programmable promiscuous mode support to omit MAC destination address checking on receive
- Multicast and unicast address filtering on receive based on 64-entry hash table, reducing higher layer processing load
- Programmable frame maximum length providing support for any standard or proprietary frame length

- Statistics indicators for frame traffic and errors (alignment, CRC, length) and pause frames providing for IEEE 802.3 basic and mandatory management information database (MIB) package and remote network monitoring (RFC 2819)
- Simple handshake user application FIFO interface with fully programmable depth and threshold levels
- Provides separate status word for each received frame on the user interface providing information such as frame length, frame type, VLAN tag, and error information
- Multiple internal loopback options
- MDIO master interface for PHY device configuration and management supports two programmable MDIO base addresses, and standard (IEEE 802.3 Clause 22) and extended (Clause 45) MDIO frame formats
- Supports legacy FEC buffer descriptors
- Interrupt coalescing reduces the number of interrupts generated by the MAC, reducing CPU loading
- Traffic-shaping bandwidth distribution supports credit-based and round-robin-based policies. Either policy can be combined with time-based shaping.
- AVB (Audio Video Bridging, IEEE 802.1Qav) features:
  - Credit-based bandwidth distribution policy can be combined with time-based shaping
  - AVB endpoint talker and listener support
  - Support for arbitration between different priority traffic (for example, AVB class A, AVB class B, and non-AVB)
- Receive frame parser enables flexible Ethernet frame pattern matching in order to finally accept or reject a frame.

43.3.1.2 IP protocol performance optimization features

- Operates on TCP/IP and UDP/IP and ICMP/IP protocol data or IP header only
- Enables wire-speed processing
- Supports IPv4 and IPv6
- Transparent passing of frames of other types and protocols
- Supports VLAN tagged frames according to IEEE 802.1q with transparent forwarding of VLAN tag and control field
- Automatic IP-header and payload (protocol specific) checksum calculation and verification on receive
- Automatic IP-header and payload (protocol specific) checksum generation and automatic insertion on transmit configurable on a per-frame basis

- Supports IP and TCP, UDP, ICMP data for checksum generation and checking
- Supports full header options for IPv4 and TCP protocol headers
- Provides IPv6 support to datagrams with base header only — datagrams with extension headers are passed transparently unmodifed/unchecked
- Provides statistics information for received IP and protocol errors
- Configurable automatic discard of erroneous frames
- Configurable automatic host-to-network (RX) and network-to-host (TX) byte order conversion for IP and TCP/UDP/ICMP headers within the frame
- Configurable padding remove for short IP datagrams on receive
- Configurable Ethernet payload alignment to allow for 32-bit word-aligned header and payload processing
- Programmable store-and-forward operation with clock and rate decoupling FIFOs

43.3.1.3 IEEE 1588 features

- Supports all IEEE 1588 frames.
- Allows reference clock to be chosen independently of network speed.
- Software-programmable precise time-stamping of ingress and egress frames
- Timer monitoring capabilities for system calibration and timing accuracy management
- Precise time-stamping of external events with programmable interrupt generation
- Programmable event and interrupt generation for external system control
- Supports hardware- and software-controllable timer synchronization.
- Provides a 4-channel IEEE 1588 timer. Each channel supports input capture and output compare using the 1588 counter.

43.3.2 Block diagram

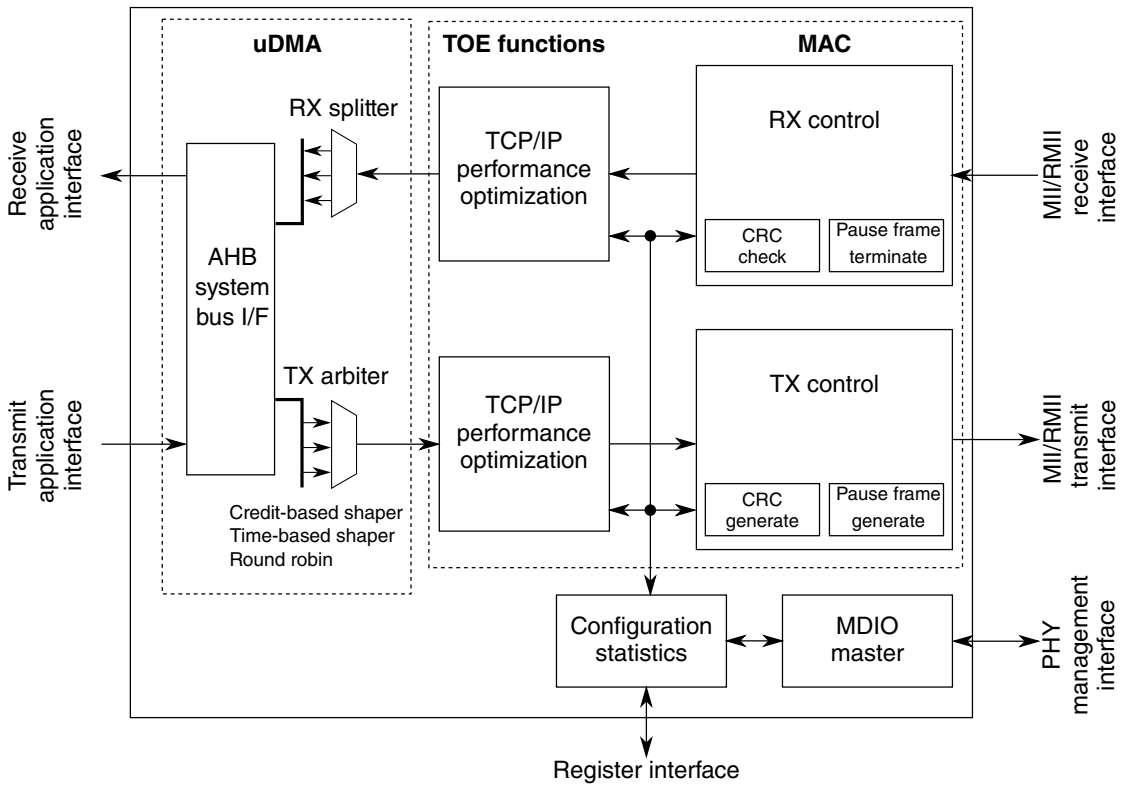

Figure 43-1. Ethernet MAC-NET core block diagram

43.4 External signal description

NOTE

The MII column pertains only to devices that support MII.

MII	RMII	Description	I/O
MII_COL	—	Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full-duplex mode.	I
MII_CRS	—	Carrier sense. When asserted, indicates transmit or receive medium is not idle. In RMII mode, this signal is present on the RMII_CRS_DV pin.	I

Table continues on the next page...

MII	RMII	Description	I/O
MII_MDC	RMII_MDC	Output clock provides a timing reference to the PHY for data transfers on the MDIO signal.	O
MII_MDIO	RMII_MDIO	Transfers control information between the external PHY and the media-access controller. Data is synchronous to MDC. This signal is an input after reset.	I/O
MII_RXCLK	—	In MII mode, provides a timing reference for RXDV, RXD[3:0], and RXER.	I
MII_RXDV	RMII_CRS_DV	Asserting this input indicates the PHY has valid nibbles present on the MII. RXDV must remain asserted from the first recovered nibble of the frame through to the last nibble. Asserting RXDV must start no later than the SFD and exclude any EOF. In RMII mode, this pin also generates the CRS signal.	I
MII_RXD[3:0]	RMII_RXD[1:0]	Contains the Ethernet input data transferred from the PHY to the media-access controller when RXDV is asserted.	I
MII_RXER	RMII_RXER	When asserted with RXDV, indicates the PHY detects an error in the current frame.	I
MII_TXCLK	—	Input clock, which provides a timing reference for TXEN, TXD[3:0], and TXER.	I
MII_TXD[3:0]	RMII_TXD[1:0]	Serial output Ethernet data. Only valid during TXEN assertion.	O
MII_TXEN	RMII_TXEN	Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is deasserted before the first TXCLK following the final nibble of the frame.	O
MII_TXER	—	When asserted for one or more clock cycles while TXEN is also asserted, PHY sends one or more illegal symbols.	O

Table continues on the next page...

MII	RMII	Description	I/O
—	RMII_REF_CLK	In RMII mode, this signal is the reference clock for receive, transmit, and the control interface.	I
1588_TMR*n*	1588_TMR*n*	Capture/Compare block input/output event bus. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCR*n* register for inspection by software. When configured for compare, the corresponding signal 1588_TMR*n* is asserted for 1 to 32 cycles when the timer reaches the compare value programmed in ENET_TCCR*n*. An interrupt can be triggered if ENET_TCSR*n*[TIE] is set. A DMA request can be triggered if ENET_TCSR*n*[TDRE] is set.	I/O
ENET_1588_CLKIN	ENET_1588_CLKIN	Alternate IEEE 1588 Ethernet clock input; Clock period should be an integer number of nanoseconds	I

43.5 Memory map/register definition

ENET registers must be read or written with 32-bit accesses. Non-32 bit accesses will terminate with an error.

Reserved bits should be written with 0 and ignored on read. Unused registers read zero and a write has no effect.

This table shows Ethernet registers organization.

Table 43-2. Register map summary

Offset Address	Section	Description
0x0000 – 0x01FF	Configuration	Core control and status registers
0x0200 – 0x03FF	Statistics counters	MIB and Remote Network Monitoring (RFC 2819) registers
0x0400 – 0x0430	1588 control	1588 adjustable timer (TSM) and 1588 frame control
0x0580 – 0x05FF	Receive Parser	Receive parser configuration

43.5.1 Interrupt Event Register (ENET_EIR)

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.

NOTE

TxBD[INT] and RxBD[INT] must be set to 1 to allow setting the corresponding EIR register flags in enhanced mode, ENET_ECR[EN1588] = 1. Legacy mode does not require these flags to be enabled.

Address: 0h base + 4h offset = 4h

ENET_EIR field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 BABR	Babbling Receive Error Indicates a frame was received with length in excess of RCR[MAX_FL] bytes.
2 BABT	Babbling Transmit Error Indicates the transmitted frame length exceeds RCR[MAX_FL] bytes. Usually this condition is caused when a frame that is too long is placed into the transmit data buffer(s). Truncation does not occur.
3 GRA	Graceful Stop Complete This interrupt is asserted after the transmitter is put into a pause state after completion of the frame currently being transmitted. See Graceful Transmit Stop (GTS) for conditions that lead to graceful stop. **NOTE:** The GRA interrupt is asserted only when the TX transitions into the stopped state. If this bit is cleared by writing 1 and the TX is still stopped, the bit is not set again.
4 TXF	Transmit Frame Interrupt Indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated.
5 TXB	Transmit Buffer Interrupt Indicates a transmit buffer descriptor has been updated.
6 RXF	Receive Frame Interrupt Indicates a frame has been received and the last corresponding buffer descriptor has been updated.
7 RXB	Receive Buffer Interrupt Indicates a receive buffer descriptor is not the last in the frame has been updated.
8 MII	MII Interrupt. Indicates that the MII has completed the data transfer requested.
9 EBERR	Ethernet Bus Error Indicates a system bus error occurred when a uDMA transaction is underway. When this bit is set, ECR[ETHEREN] is cleared, halting frame processing by the MAC. When this occurs, software must ensure proper actions, possibly resetting the system, to resume normal operation.

Table continues on the next page...

ENET_EIR field descriptions (continued)

Field	Description
10 LC	Late Collision Indicates a collision occurred beyond the collision window (slot time) in half-duplex mode. The frame truncates with a bad CRC and the remainder of the frame is discarded.
11 RL	Collision Retry Limit Indicates a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. This error can only occur in half-duplex mode.
12 UN	Transmit FIFO Underrun Indicates the transmit FIFO became empty before the complete frame was transmitted. A bad CRC is appended to the frame fragment and the remainder of the frame is discarded.
13 PLR	Payload Receive Error Indicates a frame was received with a payload length error. See Frame Length/Type Verification: Payload Length Check for more information.
14 WAKEUP	Node Wakeup Request Indication Read-only status bit to indicate that a magic packet has been detected. Will act only if ECR[MAGICEN] is set.
15 TS_AVAIL	Transmit Timestamp Available Indicates that the timestamp of the last transmitted timing frame is available in the ATSTMP register.
16 TS_TIMER	Timestamp Timer The adjustable timer reached the period event. A period event interrupt can be generated if ATCR[PEREN] is set and the timer wraps according to the periodic setting in the ATPER register. Set the timer period value before setting ATCR[PEREN].
17 RXFLUSH_2	RX DMA Ring 2 flush indication. This ring's RX frame has been flushed due to either RDAR2[RDAR] or RxBD[E] being clear and only if QOS[RXFLUSH_2] is enabled.
18 RXFLUSH_1	RX DMA Ring 1 flush indication. This ring's RX frame has been flushed due to either RDAR1[RDAR] or RxBD[E] being clear and only if QOS[RXFLUSH_1] is enabled.
19 RXFLUSH_0	RX DMA Ring 0 flush indication. . This ring's RX frame has been flushed due to either RDAR[RDAR] or RxBD[E] being clear and only if QOS[RXFLUSH_0] is enabled.
20 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
21 PARSERR	Receive parser error or all entries of the match table checked without any match.
22 PARSRF	Receive frame rejected due to the match with the table entry with MCONFIG[RF] = 1.
23 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
24 TXF2	Transmit frame interrupt, class 2 This bit indicates that a frame has been transmitted and the last corresponding buffer descriptor has been updated (ring/class 2).
25 TXB2	Transmit buffer interrupt, class 2 This field indicates that a transmit buffer descriptor has been updated (ring/class 2).

Table continues on the next page...

ENET_EIR field descriptions (continued)

Field	Description
26 RXF2	Receive frame interrupt, class 2 This field indicates that a frame has been received and the last corresponding buffer descriptor has been updated (ring/class 2).
27 RXB2	Receive buffer interrupt, class 2 This field indicates that a receive buffer descriptor, that not the last in the frame, has been updated (ring/class 2).
28 TXF1	Transmit frame interrupt, class 1 This bit indicates that a frame has been transmitted and the last corresponding buffer descriptor has been updated (ring/class 1).
29 TXB1	Transmit buffer interrupt, class 1 This field indicates that a transmit buffer descriptor has been updated (ring/class 1).
30 RXF1	Receive frame interrupt, class 1 This field indicates that a frame has been received and the last corresponding buffer descriptor has been updated (ring/class 1).
31 RXB1	Receive buffer interrupt, class 1 This field indicates that a receive buffer descriptor, that not the last in the frame, has been updated (ring/class 1).

43.5.2 Interrupt Mask Register (ENET_EIMR)

EIMR controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR field (write 1 to clear) or a 0 is written to the EIMR field.

ENET_EIMR field descriptions

Field	Description
0 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
1 BABR	BABR Interrupt Mask Corresponds to interrupt source EIR[BABR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR BABR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
2 BABT	BABT Interrupt Mask Corresponds to interrupt source EIR[BABT] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR BABT field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
3 GRA	GRA Interrupt Mask Corresponds to interrupt source EIR[GRA] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR GRA field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
4 TXF	TXF Interrupt Mask Corresponds to interrupt source EIR[TXF] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
5 TXB	TXB Interrupt Mask Corresponds to interrupt source EIR[TXB] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
6 RXF	RXF Interrupt Mask Corresponds to interrupt source EIR[RXF] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.

Table continues on the next page...

ENET_EIMR field descriptions (continued)

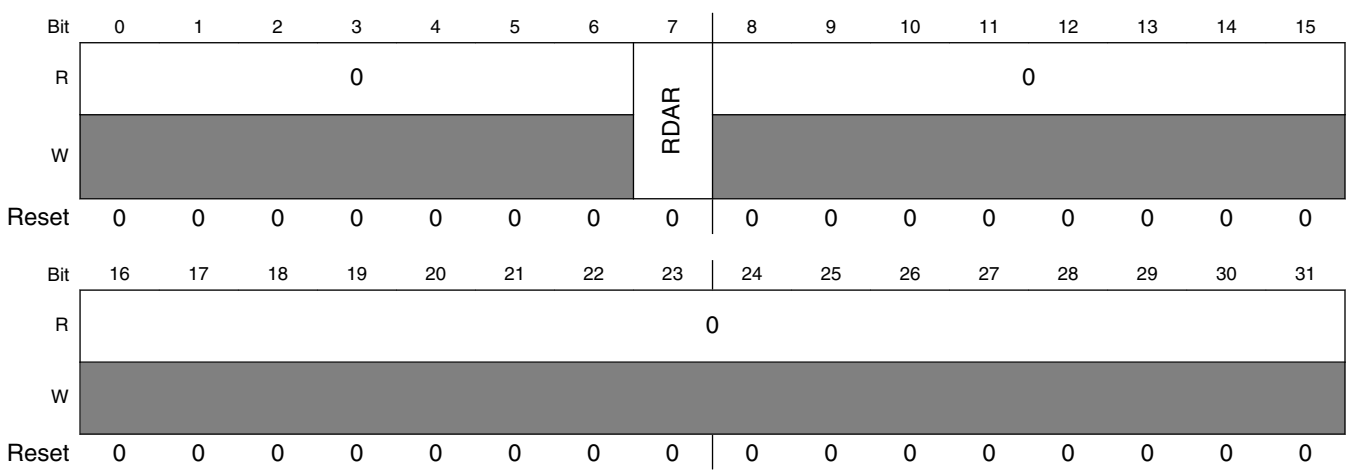
Field	Description
7 RXB	RXB Interrupt Mask Corresponds to interrupt source EIR[RXB] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RXB field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
8 MII	MII Interrupt Mask Corresponds to interrupt source EIR[MII] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR MII field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
9 EBERR	EBERR Interrupt Mask Corresponds to interrupt source EIR[EBERR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR EBERR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
10 LC	LC Interrupt Mask Corresponds to interrupt source EIR[LC] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR LC field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
11 RL	RL Interrupt Mask Corresponds to interrupt source EIR[RL] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
12 UN	UN Interrupt Mask Corresponds to interrupt source EIR[UN] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR UN field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
13 PLR	PLR Interrupt Mask Corresponds to interrupt source EIR[PLR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR PLR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
14 WAKEUP	WAKEUP Interrupt Mask Corresponds to interrupt source EIR[WAKEUP] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR WAKEUP field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
15 TS_AVAIL	TS_AVAIL Interrupt Mask Corresponds to interrupt source EIR[TS_AVAIL] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting

Table continues on the next page...

ENET_EIMR field descriptions (continued)

Field	Description
	source. The corresponding EIR TS_AVAIL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
16 TS_TIMER	TS_TIMER Interrupt Mask Corresponds to interrupt source EIR[TS_TIMER] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_TIMER field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
17 RXFLUSH_2	Corresponds to interrupt source EIR[RXFLUSH_2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXFLUSH_2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
18 RXFLUSH_1	Corresponds to interrupt source EIR[RXFLUSH_1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXFLUSH_1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
19 RXFLUSH_0	Corresponds to interrupt source EIR[RXFLUSH_0] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXFLUSH_0] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
20 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
21 PARSERR	Interrupt mask bit corresponding to EIR[PARSERR]. This field determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[PARSERR] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
22 PARSRF	Interrupt mask bit corresponding to EIR[PARSRF]. This field determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[PARSRF] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
23 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
24 TXF2	Transmit frame interrupt, class 2 Corresponds to interrupt source EIR[TXF2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[TXF2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
25 TXB2	Transmit buffer interrupt, class 2 Corresponds to interrupt source EIR[TXB2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[TXB2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
26 RXF2	Receive frame interrupt, class 2 Corresponds to interrupt source EIR[RXF2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXF2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
27 RXB2	Receive buffer interrupt, class 2

Table continues on the next page...



ENET_EIMR field descriptions (continued)

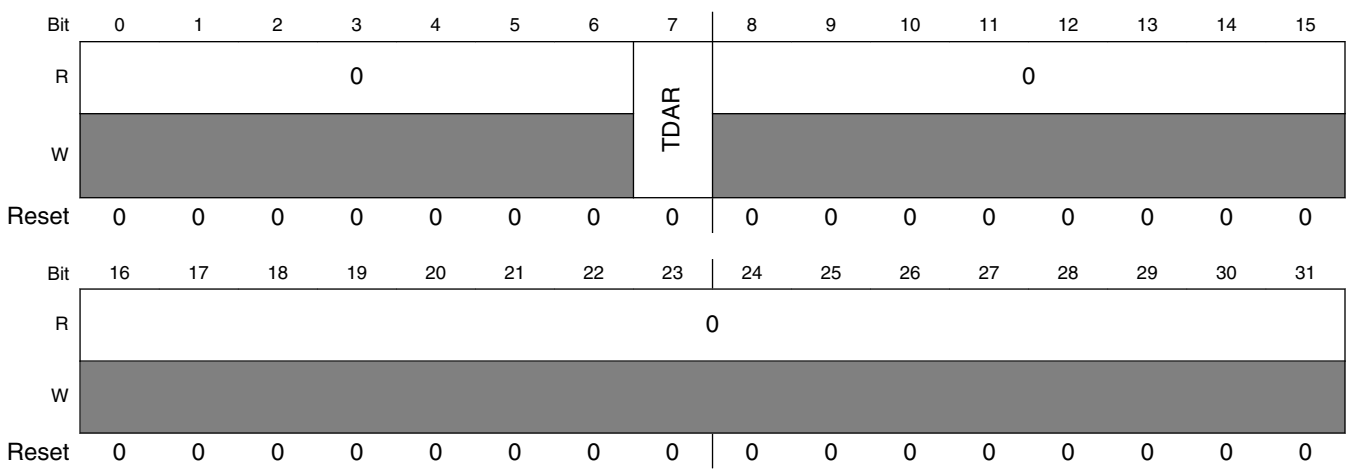
Field	Description
	Corresponds to interrupt source EIR[RXB2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXB2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
28 TXF1	Transmit frame interrupt, class 1 Corresponds to interrupt source EIR[TXF1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[TXF1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
29 TXB1	Transmit buffer interrupt, class 1 Corresponds to interrupt source EIR[TXB1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[TXB1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
30 RXF1	Receive frame interrupt, class 1 Corresponds to interrupt source EIR[RXF1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXF1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
31 RXB1	Receive buffer interrupt, class 1 Corresponds to interrupt source EIR[RXB1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXB1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.

43.5.3 Receive Descriptor Active Register - Ring 0 (ENET_RDAR)

RDAR is a command register, written by the user, to indicate that the receive descriptor ring 0 has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

Address: 0h base + 10h offset = 10h

ENET_RDAR field descriptions



Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 RDAR	Receive Descriptor Active Always set to 1 when this register is written, regardless of the value written. This field is cleared by the MAC device when no additional empty descriptors remain in the receive ring. It is also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

43.5.4 Transmit Descriptor Active Register - Ring 0 (ENET_TDAR)

The TDAR is a command register that the user writes to indicate that the transmit descriptor ring 0 has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

The TDAR register is cleared at reset, when ECR[ETHEREN] transitions from set to cleared, or when ECR[RESET] is set.

Address: 0h base + 14h offset = 14h

ENET_TDAR field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TDAR	Transmit Descriptor Active Always set to 1 when this register is written, regardless of the value written. This bit is cleared by the MAC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.

Table continues on the next page...

ENET_TDAR field descriptions (continued)

Field	Description
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

43.5.5 Ethernet Control Register (ENET_ECR)

ECR is a read/write user register, though hardware may also alter fields in this register. It controls many of the high level features of the Ethernet MAC, including legacy FEC support through the EN1588 field.

Address: 0h base + 24h offset = 24h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	Reserved														Reserved	
Reset	0	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved				SVLANDBL	VLANUSE2ND	SVLANEN	DBSWP	Reserved	DBGEN	0	EN1588	SLEEP	MAGICEN	ETHEREN	RESET
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_ECR field descriptions

Field	Description
0–13 Reserved	This field is reserved. Always write 01110000000000b to this field.
14–19 Reserved	This field is reserved. Always write 0 to this field.
20 SVLANDBL	S-VLAN double tag If enabled, S-VLAN detection requires a double-tagged frame to define a frame as being a VLAN frame. The following rules apply: • If the first tag is the S-VLAN type, it must be followed by a second tag with the C-VLAN type to declare the frame as VLAN frame. • If the first tag is the S-VLAN type but no 2nd tag follows, it is not considered a VLAN frame but instead treated as an untagged frame. • If the first tag is the C-VLAN type, it is considered a VLAN frame as normal. **NOTE:** VLANUSE2ND can be used to determine from which tag the data should be extracted. This applies only if SVLAN_EN = 1, ignored otherwise.

Table continues on the next page...

ENET_ECR field descriptions (continued)

Field	Description
21 VLANUSE2ND	VLAN use second tag 0 Always extract data from the first VLAN tag if it exists. 1 When a double-tagged frame is detected, the data of the second tag is extracted for further processing. A double-tagged frame is defined as: • The first tag can be a C-VLAN or a S-VLAN (if SVLAN_ENA = 1) • The second tag must be a C-VLAN
22 SVLANEN	S-VLAN enable Enable additional detection of S-VLAN tag according to IEEE802.1Q. 0 Only the EtherType 0x8100 will be considered for VLAN detection. 1 The EtherType 0x88a8 will be considered in addition to 0x8100 (C-VLAN) to identify a VLAN frame in receive. When a VLAN frame is identified, the two bytes following the VLAN type are extracted and used by the classification match comparators, RCMRn.
23 DBSWP	Descriptor Byte Swapping Enable Swaps the byte locations of the buffer descriptors. **NOTE:** This field resets to 0 and must not be changed. 0 The buffer descriptor bytes are not swapped to support big-endian devices. 1 The buffer descriptor bytes are swapped to support little-endian devices.
24 Reserved	This field is reserved. Always write 0 to this field.
25 DBGEN	Debug Enable Enables the MAC to enter hardware freeze mode when the device enters debug mode. 0 MAC continues operation in debug mode. 1 MAC enters hardware freeze mode when the processor is in debug mode.
26 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
27 EN1588	EN1588 Enable Enables enhanced functionality of the MAC. 0 Legacy FEC buffer descriptors and functions enabled. 1 Enhanced frame time-stamping functions enabled.
28 SLEEP	Sleep Mode Enable 0 Normal operating mode. 1 Sleep mode.
29 MAGICEN	Magic Packet Detection Enable Enables/disables magic packet detection. **NOTE:** MAGICEN is relevant only if the SLEEP field is set. If MAGICEN is set, changing the SLEEP field enables/disables sleep mode and magic packet detection. 0 Magic detection logic disabled. 1 The MAC core detects magic packets and asserts EIR[WAKEUP] when a frame is detected.

Table continues on the next page...

ENET_ECR field descriptions (continued)

Field	Description
30 ETHEREN	Ethernet Enable Enables/disables the Ethernet MAC. When the MAC is disabled, the buffer descriptors for an aborted transmit frame are not updated. The uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers. Hardware clears this field under the following conditions: • RESET is set by software • An error condition causes the EBERR field to set. **NOTE:** • ETHEREN must be set at the very last step during ENET configuration/setup/initialization, only *after* all other ENET-related registers have been configured. • If ETHEREN is cleared to 0 by software then next time ETHEREN is set, the EIR interrupts must cleared to 0 due to previous pending interrupts. 0 Reception immediately stops and transmission stops after a bad CRC is appended to any currently transmitted frame. 1 MAC is enabled, and reception and transmission are possible.
31 RESET	Ethernet MAC Reset When this field is set, it clears the ETHEREN field.

43.5.6 MII Management Frame Register (ENET_MMFR)

Writing to MMFR triggers a management frame transaction to the PHY device unless MSCR is programmed to zero.

If MSCR is changed from zero to non-zero during a write to MMFR, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the EIR[MII] interrupt indication to avoid writing to the MMFR register while frame generation is in progress.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ENET_MMFR field descriptions

Field	Description
0–1 ST	Start Of Frame Delimiter See Table 43-41 (Clause 22) or Table 43-43 (Clause 45) for correct value.

Table continues on the next page...

ENET_MMFR field descriptions (continued)

Field	Description
2–3 OP	Operation Code See Table 43-41 (Clause 22) or Table 43-43 (Clause 45) for correct value.
4–8 PA	PHY Address See Table 43-41 (Clause 22) or Table 43-43 (Clause 45) for correct value.
9–13 RA	Register Address See Table 43-41 (Clause 22) or Table 43-43 (Clause 45) for correct value.
14–15 TA	Turn Around This field must be programmed to 10 to generate a valid MII management frame.
16–31 DATA	Management Frame Data This is the field for data to be written to or read from the PHY register.

43.5.7 MII Speed Control Register (ENET_MSCR)

MSCR provides control of the MII clock (MDC pin) frequency and allows a preamble drop on the MII management frame.

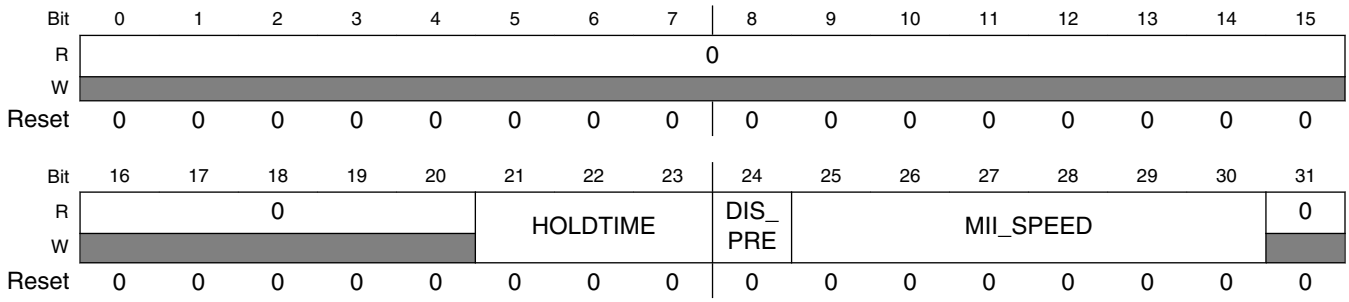
The MII_SPEED field must be programmed with a value to provide an MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be cleared to turn off MDC. The MDC signal generated has a 50% duty cycle except when MII_SPEED changes during operation. This change takes effect following a rising or falling edge of MDC.

For example, if the internal module clock (i.e., IPS bus clock) is 25 MHz, programming MII_SPEED to 0x4 results in an MDC as given in the following equation:

MII clock frequency = 25 MHz / ((4 + 1) x 2) = 2.5 MHz

The following table shows the optimum values for MII_SPEED as a function of IPS bus clock frequency.

Table 43-3. Programming Examples for MSCR



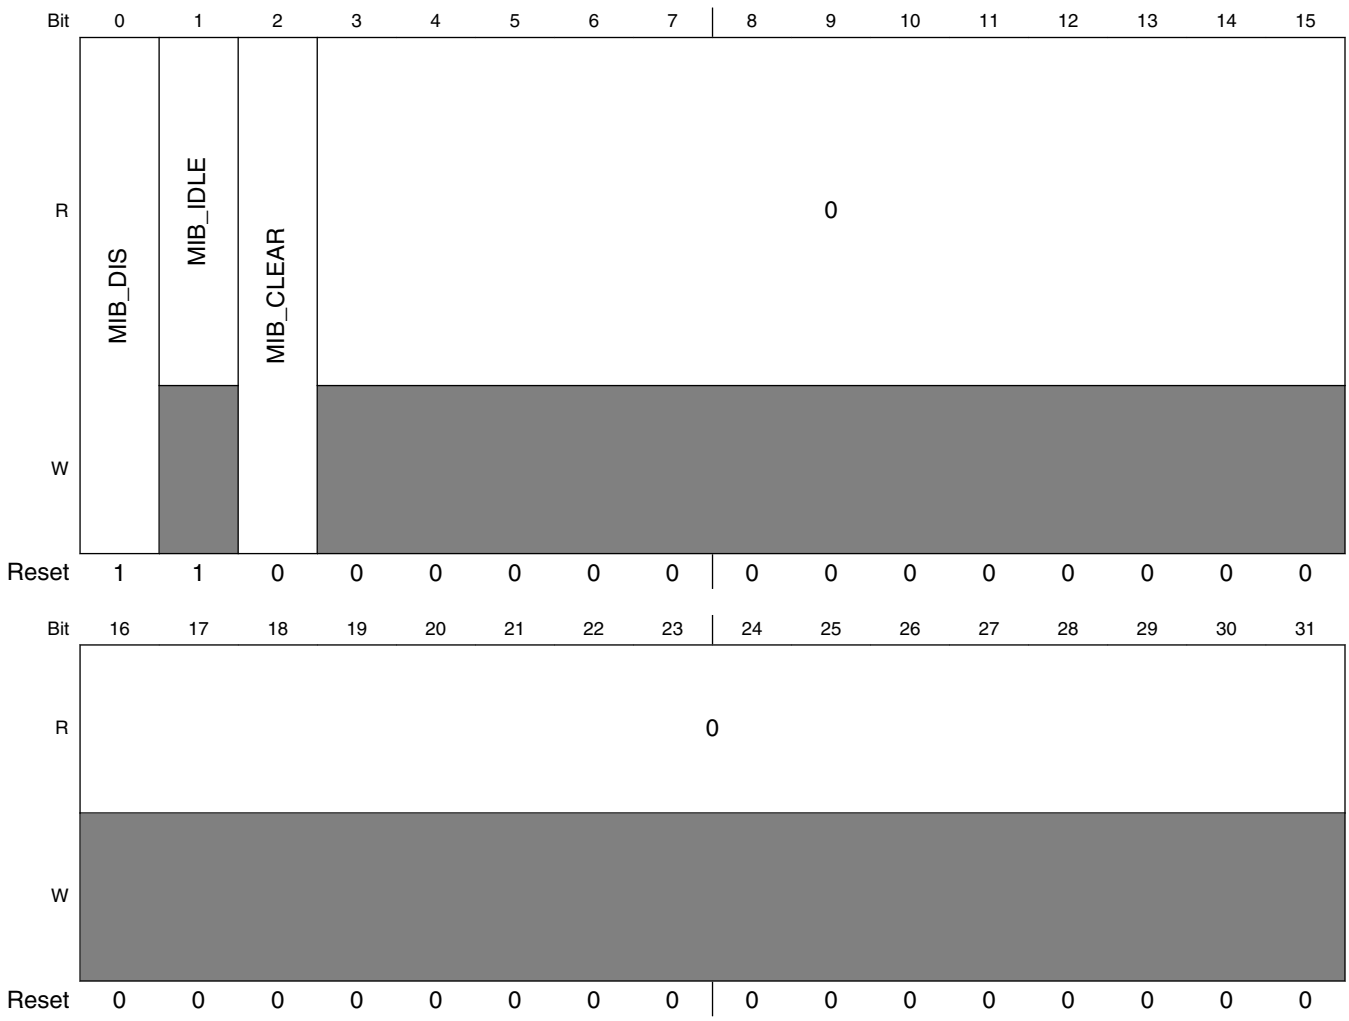
Internal module clock frequency	MSCR [MII_SPEED]	MDC frequency
25 MHz	0x4	2.50 MHz
33 MHz	0x6	2.36 MHz
40 MHz	0x7	2.50 MHz
50 MHz	0x9	2.50 MHz

Table continues on the next page...

Table 43-3. Programming Examples for MSCR (continued)

Internal module clock frequency	MSCR [MII_SPEED]	MDC frequency
66 MHz	0xD	2.36 MHz

Address: 0h base + 44h offset = 44h



ENET_MSCR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–23 HOLDTIME	Hold time On MDIO Output IEEE802.3 clause 22 defines a minimum of 10 ns for the hold time on the MDIO output. Depending on the host bus frequency, the setting may need to be increased. 000 1 internal module clock cycle 001 2 internal module clock cycles 010 3 internal module clock cycles 111 8 internal module clock cycles
24 DIS_PRE	Disable Preamble Enables/disables prepending a preamble to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY devices do not require it. 0 Preamble enabled. 1 Preamble (32 ones) is not prepended to the MII management frame.
25–30 MII_SPEED	MII Speed Controls the frequency of the MII management interface clock (MDC) relative to the internal module clock. A value of 0 in this field turns off MDC and leaves it in low voltage state. Any non-zero value results in the MDC frequency of: 1/((MII_SPEED + 1) x 2) of the internal module clock frequency
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

43.5.8 MIB Control Register (ENET_MIBC)

MIBC is a read/write register controlling and observing the state of the MIB block. Access this register to disable the MIB block operation or clear the MIB counters. The MIB_DIS field resets to 1.

Address: 0h base + 64h offset = 64h

ENET_MIBC field descriptions

Field	Description
0 MIB_DIS	Disable MIB Logic If this control field is set, 0 MIB logic is enabled. 1 MIB logic is disabled. The MIB logic halts and does not update any MIB counters.

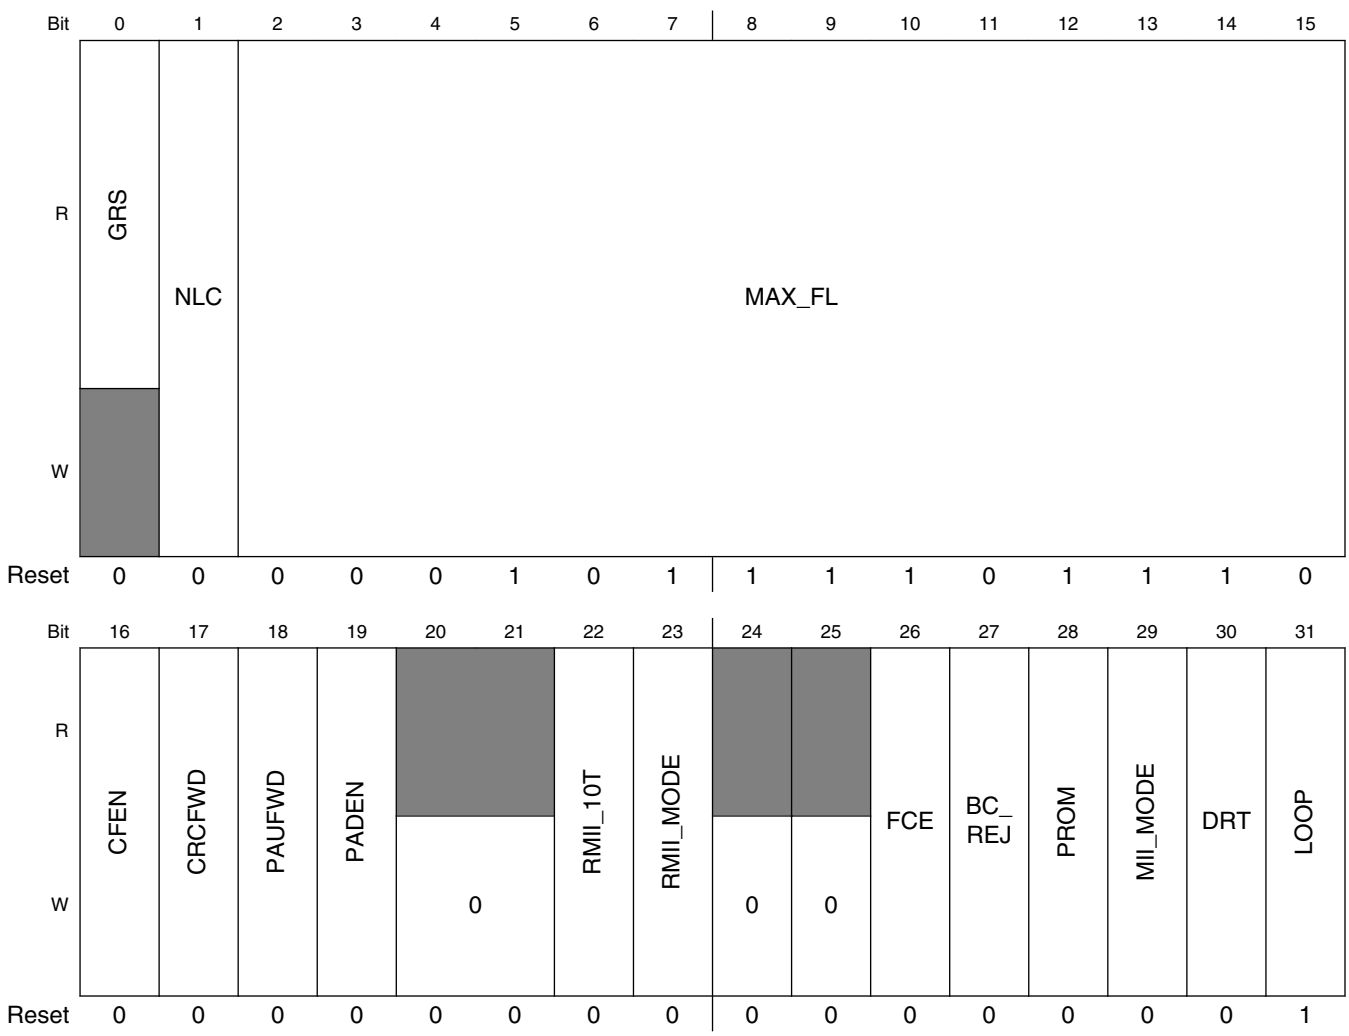


Table continues on the next page...

ENET_MIBC field descriptions (continued)

Field	Description
1 MIB_IDLE	MIB Idle 0 The MIB block is updating MIB counters. 1 The MIB block is not currently updating any MIB counters.
2 MIB_CLEAR	MIB Clear **NOTE:** This field is not self-clearing. To clear the MIB counters set and then clear this field. 0 See note above. 1 All statistics counters are reset to 0.
3–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

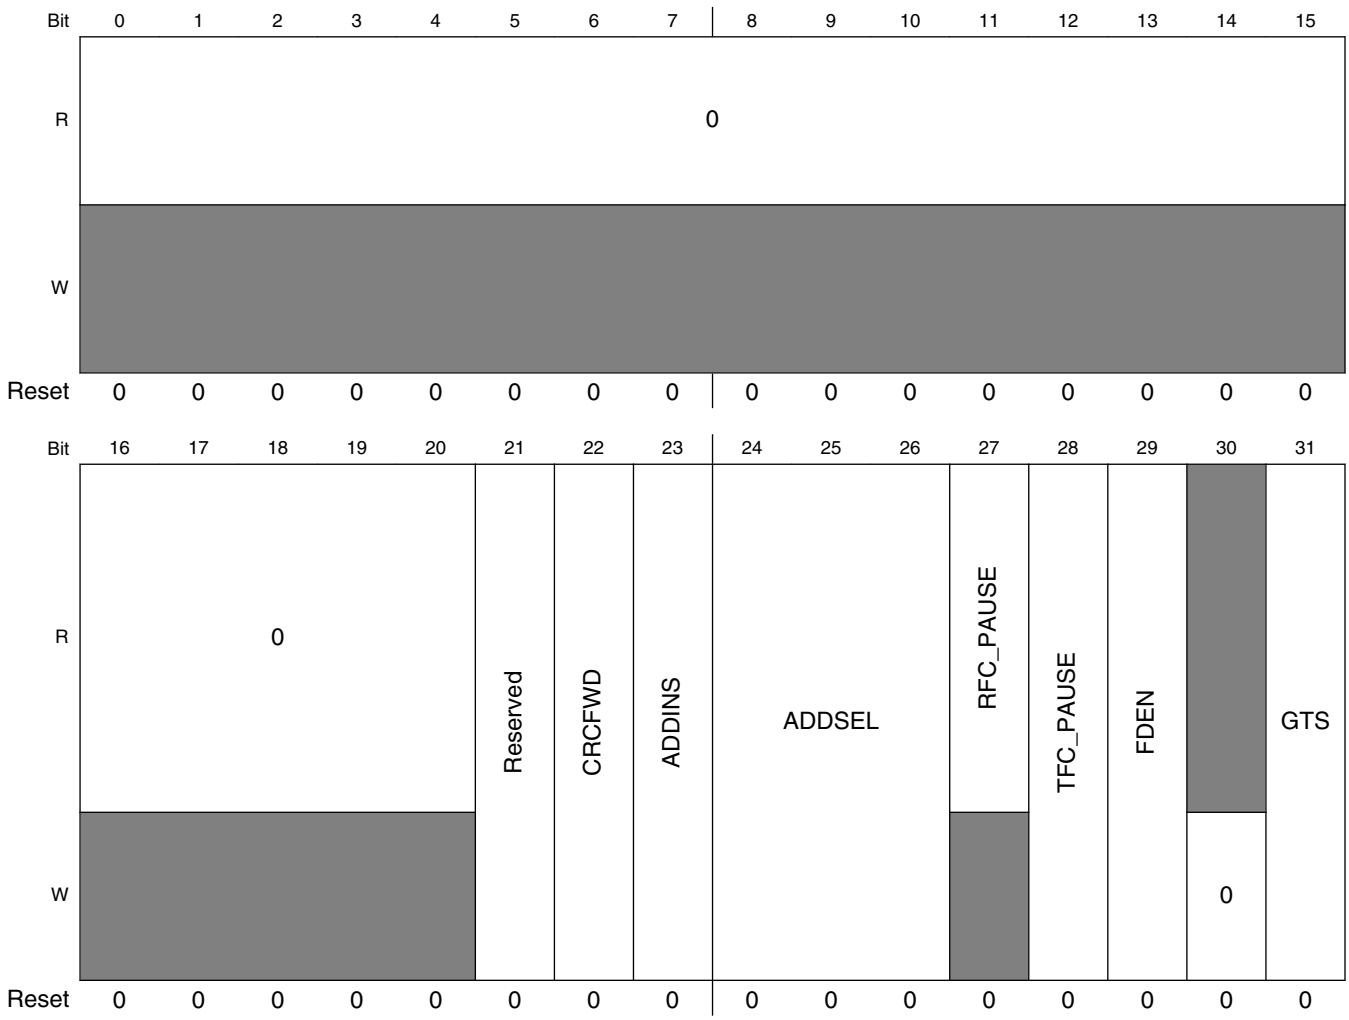
43.5.9 Receive Control Register (ENET_RCR)

Address: 0h base + 84h offset = 84h

ENET_RCR field descriptions

Field	Description
0 GRS	Graceful Receive Stopped Read-only status indicating that the MAC receive datapath is stopped.
1 NLC	Payload Length Check Disable Enables/disables a payload length check. 0 The payload length check is disabled. 1 The core checks the frame's payload length with the frame length/type field. Errors are indicated in the EIR[PLC] field.
2–15 MAX_FL	Maximum Frame Length Resets to decimal 1518. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL cause the BABT interrupt to occur. Receive frames longer than MAX_FL cause the BABR interrupt to occur and set the LG field in the end of frame receive buffer descriptor. The recommended default value to be programmed is 1518 or 1522 if VLAN tags are supported.
16 CFEN	MAC Control Frame Enable Enables/disables the MAC control frame. 0 MAC control frames with any opcode other than 0x0001 (pause frame) are accepted and forwarded to the client interface. 1 MAC control frames with any opcode other than 0x0001 (pause frame) are silently discarded.
17 CRCFWD	Terminate/Forward Received CRC Specifies whether the CRC field of received frames is transmitted or stripped. **NOTE:** If padding function is enabled (PADEN = 1), CRCFWD is ignored and the CRC field is checked and always terminated and removed. 0 The CRC field of received frames is transmitted to the user application. 1 The CRC field is stripped from the frame.
18 PAUFWD	Terminate/Forward Pause Frames Specifies whether pause frames are terminated or forwarded. 0 Pause frames are terminated and discarded in the MAC. 1 Pause frames are forwarded to the user application.
19 PADEN	Enable Frame Padding Remove On Receive Specifies whether the MAC removes padding from received frames. 0 No padding is removed on receive by the MAC. 1 Padding is removed from received frames.
20–21 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
22 RMII_10T	Enables 10-Mbit/s mode of the RMII . 0 100-Mbit/s operation. 1 10-Mbit/s operation.

Table continues on the next page...



ENET_RCR field descriptions (continued)

Field	Description
23 RMII_MODE	RMII Mode Enable Specifies whether the MAC is configured for MII mode or RMII operation . 0 MAC configured for MII mode. 1 MAC configured for RMII operation.
24 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
25 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
26 FCE	Flow Control Enable If set, the receiver detects PAUSE frames. Upon PAUSE frame detection, the transmitter stops transmitting data frames for a given duration.
27 BC_REJ	Broadcast Frame Reject If set, frames with destination address (DA) equal to 0xFFFF_FFFF_FFFF are rejected unless the PROM field is set. If BC_REJ and PROM are set, frames with broadcast DA are accepted and the MISS (M) is set in the receive buffer descriptor.
28 PROM	Promiscuous Mode All frames are accepted regardless of address matching. 0 Disabled. 1 Enabled.
29 MII_MODE	Media Independent Interface Mode This field must always be set. 0 Reserved. 1 MII or RMII mode, as indicated by the RMII_MODE field.
30 DRT	Disable Receive On Transmit 0 Receive path operates independently of transmit (i.e., full-duplex mode). Can also be used to monitor transmit activity in half-duplex mode. 1 Disable reception of frames while transmitting. (Normally used for half-duplex mode.)
31 LOOP	Internal Loopback This is an MII internal loopback, therefore MII_MODE must be written to 1 and RMII_MODE must be written to 0. 0 Loopback disabled. 1 Transmitted frames are looped back internal to the device and transmit MII output signals are not asserted. DRT must be cleared.

43.5.10 Transmit Control Register (ENET_TCR)

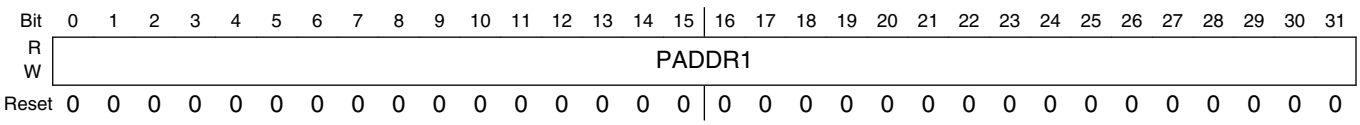
TCR is read/write and configures the transmit block. This register is cleared at system reset. FDEN can only be modified when ECR[ETHEREN] is cleared.

Address: 0h base + C4h offset = C4h

ENET_TCR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 Reserved	This field is reserved. This field is read/write and must be set to 0.
22 CRCFWD	Forward Frame From Application With CRC

Table continues on the next page...



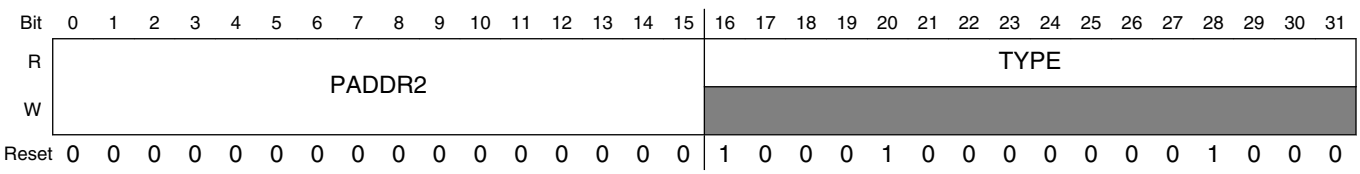
ENET_TCR field descriptions (continued)

Field	Description
	0 TxBD[TC] controls whether the frame has a CRC from the application. 1 The transmitter does not append any CRC to transmitted frames, as it is expecting a frame with CRC from the application.
23 ADDINS	Set MAC Address On Transmit 0 The source MAC address is not modified by the MAC. 1 The MAC overwrites the source MAC address with the programmed MAC address according to ADDSEL.
24–26 ADDSEL	Source MAC Address Select On Transmit If ADDINS is set, indicates the MAC address that overwrites the source MAC address. 000 Node MAC address programmed on PADDR1/2 registers. 100 Reserved. 101 Reserved. 110 Reserved.
27 RFC_PAUSE	Receive Frame Control Pause This status field is set when a full-duplex flow control pause frame is received and the transmitter pauses for the duration defined in this pause frame. This field automatically clears when the pause duration is complete.
28 TFC_PAUSE	Transmit Frame Control Pause Pauses frame transmission. When this field is set, EIR[GRA] is set. With transmission of data frames stopped, the MAC transmits a MAC control PAUSE frame. Next, the MAC clears TFC_PAUSE and resumes transmitting data frames. If the transmitter pauses due to user assertion of GTS or reception of a PAUSE frame, the MAC may continue transmitting a MAC control PAUSE frame. 0 No PAUSE frame transmitted. 1 The MAC stops transmission of data frames after the current transmission is complete.
29 FDEN	Full-Duplex Enable If this field is set, frames transmit independent of carrier sense and collision inputs. Only modify this bit when ECR[ETHEREN] is cleared.
30 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
31 GTS	Graceful Transmit Stop When this field is set, MAC stops transmission after any frame currently transmitted is complete and EIR[GRA] is set. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this, clear ECR[ETHEREN] following the GRA interrupt.

43.5.11 Physical Address Lower Register (ENET_PALR)

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the six-byte source address field when transmitting PAUSE frames.

Address: 0h base + E4h offset = E4h



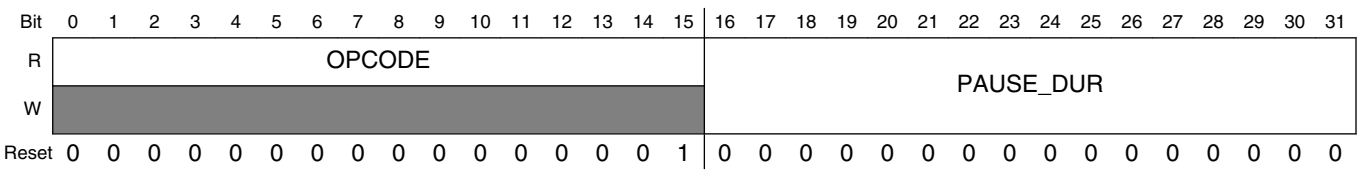
ENET_PALR field descriptions

Field	Description
0–31 PADDR1	Pause Address Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8), and 3 (bits 7:0) of the 6-byte individual address are used for exact match and the source address field in PAUSE frames.

43.5.12 Physical Address Upper Register (ENET_PAUR)

PAUR contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 4 and 5 of the six-byte source address field when transmitting PAUSE frames. Bits 15:0 of PAUR contain a constant type field (0x8808) for transmission of PAUSE frames.

Address: 0h base + E8h offset = E8h



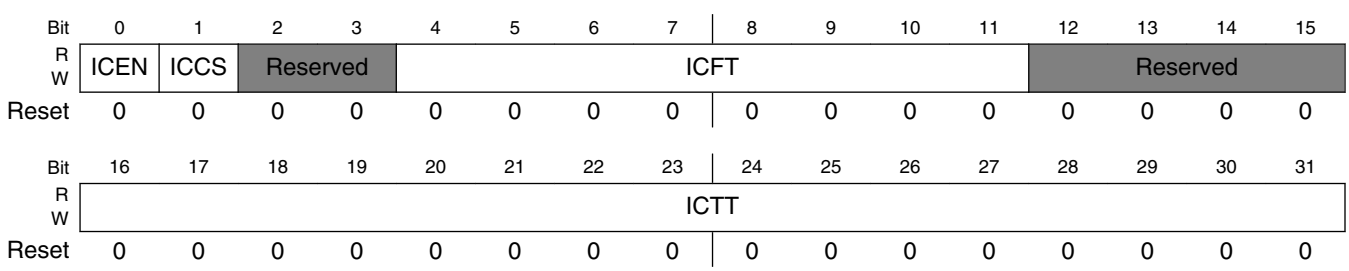
ENET_PAUR field descriptions

Field	Description
0–15 PADDR2	Bytes 4 (bits 31:24) and 5 (bits 23:16) of the 6-byte individual address used for exact match, and the source address field in PAUSE frames.
16–31 TYPE	Type Field In PAUSE Frames These fields have a constant value of 0x8808.

43.5.13 Opcode/Pause Duration Register (ENET_OPD)

OPD is read/write accessible. This register contains the 16-bit opcode and 16-bit pause duration fields used in transmission of a PAUSE frame. The opcode field is a constant value, 0x0001. When another node detects a PAUSE frame, that node pauses transmission for the duration specified in the pause duration field. The lower 16 bits of this register are not reset and you must initialize it.

Address: 0h base + ECh offset = ECh



ENET_OPD field descriptions

Field	Description
0–15 OPCODE	Opcode Field In PAUSE Frames These fields have a constant value of 0x0001.
16–31 PAUSE_DUR	Pause Duration Pause duration field used in PAUSE frames.

43.5.14 Transmit Interrupt Coalescing Register (ENET_TXIC*n*)

See Interrupt coalescence for more information.

Address: 0h base + F0h offset + (4d × i), where i=0d to 2d

ENET_TXIC*n* field descriptions

Field	Description
0 ICEN	Interrupt Coalescing Enable

Table continues on the next page...

ENET_TXIC*n* field descriptions (continued)

Field	Description
	0 Disable Interrupt coalescing. 1 Enable Interrupt coalescing.
1 ICCS	Interrupt Coalescing Timer Clock Source Select 0 Use MII/GMII TX clocks. 1 Use ENET system clock.
2–3 Reserved	This field must be set to 0. This field is reserved.
4–11 ICFT	Interrupt coalescing frame count threshold This value determines the number of frames needed to be transmitted for raising an interrupt. Frame counter restarts after reaching this threshold value or after the expiring of the coalescing timer. Must be greater than zero to avoid unpredictable behavior.
12–15 Reserved	This field must be set to 0. This field is reserved.
16–31 ICTT	Interrupt coalescing timer threshold Interrupt coalescing timer threshold in units of 64 clock periods. This value determines the maximum amount of time after transmitting a frame before raising an interrupt. The threshold timer is disabled after expiring or number of frame transmission defined by ICFT and starts again upon transmission of the next first frame. Must be greater than zero to avoid unpredictable behavior.

43.5.15 Receive Interrupt Coalescing Register (ENET_RXIC*n*)

See Interrupt coalescence for more information.

Address: 0h base + 100h offset + (4d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	ICEN	ICCS	Reserved		ICFT								Reserved			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R W	ICTT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_RXIC*n* field descriptions

Field	Description
0 ICEN	Interrupt Coalescing Enable 0 Disable Interrupt coalescing. 1 Enable Interrupt coalescing.

Table continues on the next page...

ENET_RXIC*n* field descriptions (continued)

Field	Description
1 ICCS	Interrupt Coalescing Timer Clock Source Select 0 Use MII/GMII TX clocks. 1 Use ENET system clock.
2–3 Reserved	This field must be set to 0. This field is reserved.
4–11 ICFT	Interrupt coalescing frame count threshold This value determines the number of frames needed to be received for raising an interrupt. Frame counter restarts after reaching this threshold value or after the expiring of the coalescing timer. Must be greater than zero to avoid unpredictable behavior.
12–15 Reserved	This field must be set to 0. This field is reserved.
16–31 ICTT	Interrupt coalescing timer threshold Interrupt coalescing timer threshold in units of 64 clock periods. This value determines the maximum amount of time after receiving a frame before raising an interrupt. The threshold timer is disabled after expiring or number of frame reception defined by ICFT and starts again upon reception of the next first frame. Must be greater than zero to avoid unpredictable behavior.

43.5.16 Descriptor Individual Upper Address Register (ENET_IAUR)

IAUR contains the upper 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the destination address (DA) field of receive frames with an individual DA. This register is not reset and you must initialize it.

Address: 0h base + 118h offset = 118h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	IADDR1																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_IAUR field descriptions

Field	Description
0–31 IADDR1	Contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR1 contains hash index bit 63. Bit 0 of IADDR1 contains hash index bit 32.

43.5.17 Descriptor Individual Lower Address Register (ENET_IALR)

IALR contains the lower 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the DA field of receive frames with an individual DA. This register is not reset and you must initialize it.

Address: 0h base + 11Ch offset = 11Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	IADDR2

ENET_IALR field descriptions

Field	Description
0–31 IADDR2	Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR2 contains hash index bit 31. Bit 0 of IADDR2 contains hash index bit 0.

43.5.18 Descriptor Group Upper Address Register (ENET_GAUR)

GAUR contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. You must initialize this register.

Address: 0h base + 120h offset = 120h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	GADDR1																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_GAUR field descriptions

Field	Description
0–31 GADDR1	Contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR1 contains hash index bit 63. Bit 0 of GADDR1 contains hash index bit 32.

43.5.19 Descriptor Group Lower Address Register (ENET_GALR)

GALR contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. You must initialize this register.

Address: 0h base + 124h offset = 124h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

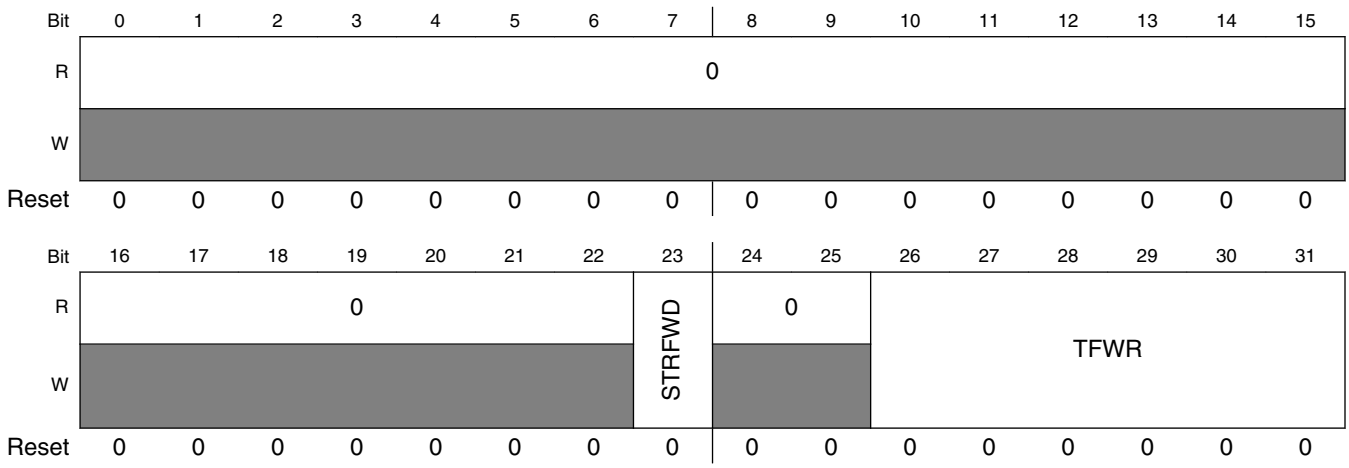
ENET_GALR field descriptions

Field	Description
0–31 GADDR2	Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0.

43.5.20 Transmit FIFO Watermark Register (ENET_TFWR)



If TFWR[STRFWD] is cleared, TFWR[TFWR] controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement, for example, worst-case bus access latency by the transmit data uDMA channel.

When the FIFO level reaches the value the TFWR field and when the STR_FWD is set to ‘0’, the MAC transmit control logic starts frame transmission even before the end-of-frame is available in the FIFO (cut-through operation).

If a complete frame has a size smaller than the threshold programmed with TFWR, the MAC also transmits the Frame to the line.

To enable store and forward on the Transmit path, set STR_FWD to ‘1’. In this case, the MAC starts to transmit data only when a complete frame is stored in the Transmit FIFO.

Address: 0h base + 144h offset = 144h

ENET_TFWR field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 STRFWD	Store And Forward Enable 0 Reset. The transmission start threshold is programmed in TFWR[TFWR]. 1 Enabled.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 TFWR	Transmit FIFO Write If TFWR[STRFWD] is cleared, this field indicates the number of bytes, in steps of 64 bytes, written to the transmit FIFO before transmission of a frame begins. **NOTE:** If a frame with less than the threshold is written, it is still sent independently of this threshold setting. The threshold is relevant only if the frame is larger than the threshold given. 000000 64 bytes written. 000001 64 bytes written. 000010 128 bytes written. 000011 192 bytes written. ... ... 011111 1984 bytes written.

43.5.21 Receive Descriptor Ring 1 Start Register (ENET_RDSR1)

RDSR1 points to the beginning of circular receive buffer descriptor queue 1 in external memory. This pointer must be 64-bit aligned (bits 29–31 must be zero); however, for optimal performance the pointer should be 512-bit aligned, that is, evenly divisible by 64.

NOTE

This register must be initialized prior to operation.

Address: 0h base + 160h offset = 160h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

ENET_TDSR1 field descriptions

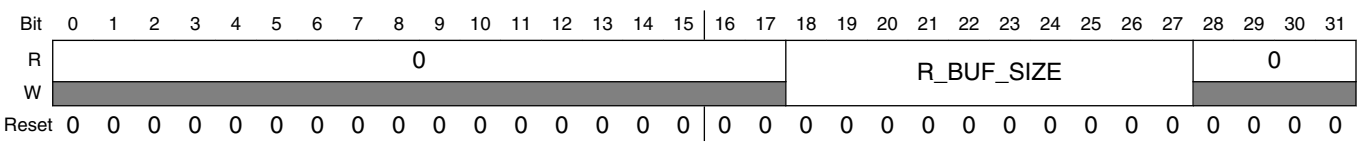
Field	Description
0–28 X_DES_START	Pointer to the beginning of transmit buffer descriptor queue 1.

Table continues on the next page...

ENET_TDSR1 field descriptions (continued)

Field	Description
29 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

43.5.23 Maximum Receive Buffer Size Register - Ring 1 (ENET_MRBR1)



MRBR1 is a user-programmable register that dictates the maximum size of all ring-1 receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer.

- To allow one maximum size frame per buffer, MRBR1 must be set to RCR[MAX_FL] or larger.
- R_BUF_SIZE is concatentated with the four least-significant bits of this register and are used as the maximum receive buffer size.
- To properly align the buffer, MRBR1 must be evenly divisible by 64. To ensure this, set the lower two bits of R_BUF_ZIZE to zero. The lower four bits are already set to zero by the device.
- To minimize bus usage (descriptor fetches), set MRBR1 greater than or equal to 256 bytes.

NOTE

This register must be initialized before operation.

Address: 0h base + 168h offset = 168h

ENET_MRBR1 field descriptions

Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–27 R_BUF_SIZE	Receive buffer size in bytes. This value, concatenated with the four least-significant bits of this register (which are always zero), is the effective maximum receive buffer size.
28–31 Reserved	This field, which is always zero, is the four least-significant bits of the maximum receive buffer size. This field is reserved. This read-only field is reserved and always has the value 0.

43.5.24 Receive Descriptor Ring 2 Start Register (ENET_RDSR2)

RDSR points to the beginning of circular receive buffer descriptor queue 2 in external memory. This pointer must be 64-bit aligned (bits 29–31 must be zero); however, for optimal performance the pointer should be 512-bit aligned, that is, evenly divisible by 64.

NOTE

This register must be initialized prior to operation

Address: 0h base + 16Ch offset = 16Ch

ENET_RDSR2 field descriptions

Field	Description
0–28 R_DES_START	Pointer to the beginning of receive buffer descriptor queue 2.
29 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

43.5.25 Transmit Buffer Descriptor Ring 2 Start Register (ENET_TDSR2)

TDSR2 provides a pointer to the beginning of circular transmit buffer descriptor queue 2 in external memory. This pointer must be 64-bit aligned (bits 29–31 must be zero); however, for optimal performance the pointer should be 512-bit aligned, that is, evenly divisible by 64.

NOTE

This register must be initialized prior to operation

Address: 0h base + 170h offset = 170h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	X_DES_START															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	X_DES_START														0	
W														0		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_TDSR2 field descriptions

Field	Description
0–28 X_DES_START	Pointer to the beginning of transmit buffer descriptor queue 2.
29 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

43.5.26 Maximum Receive Buffer Size Register - Ring 2 (ENET_MRBR2)

MRBR2 is a user-programmable register that dictates the maximum size of all ring-2 receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer.

- To allow one maximum size frame per buffer, MRBR2 must be set to RCR[MAX_FL] or larger.
- R_BUF_SIZE is concatentated with the four least-significant bits of this register and are used as the maximum receive buffer size.
- To properly align the buffer, MRBR2 must be evenly divisible by 64. To ensure this, set the lower two bits of R_BUF_SIZE to zero. The lower four bits are already set to zero by the device.
- To minimize bus usage (descriptor fetches), set MRBR2 greater than or equal to 256 bytes.

NOTE

This register must be initialized prior to operation

Address: 0h base + 174h offset = 174h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

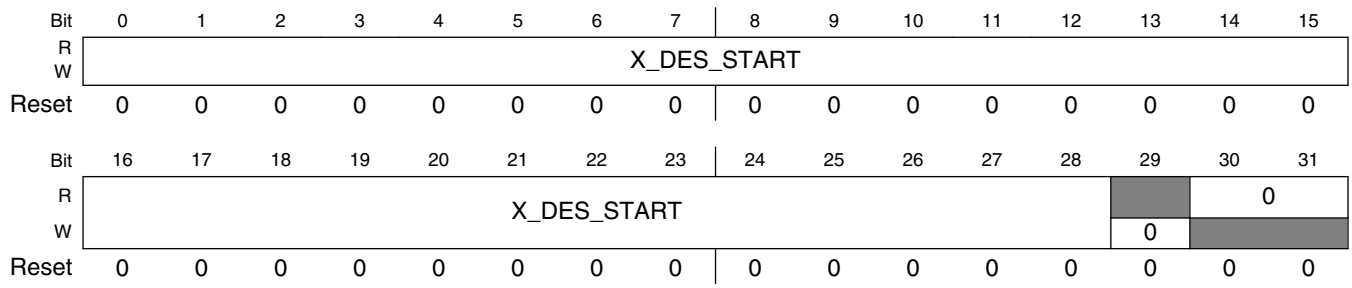
R	R_DES_START														0	
W														0		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_RDSR field descriptions

Field	Description
0–28 R_DES_START	Pointer to the beginning of the receive buffer descriptor queue. 0
29 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.



43.5.28 Transmit Buffer Descriptor Ring 0 Start Register (ENET_TDSR)

TDSR provides a pointer to the beginning of the circular transmit buffer descriptor queue 0 in external memory. This pointer must be 64-bit aligned (bits 29–31 must be zero); however, for optimal performance the pointer should be 512-bit aligned, that is, evenly divisible by 64.

NOTE

This register must be initialized prior to operation.

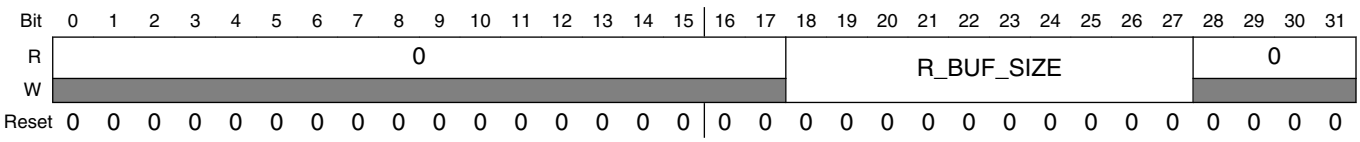
Address: 0h base + 184h offset = 184h

ENET_TDSR field descriptions

Field	Description
0–28 X_DES_START	Pointer to the beginning of the transmit buffer descriptor queue.
29 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

43.5.29 Maximum Receive Buffer Size Register - Ring 0 (ENET_MRBR)

The MRBR is a user-programmable register that dictates the maximum size of all ring-0 receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer.



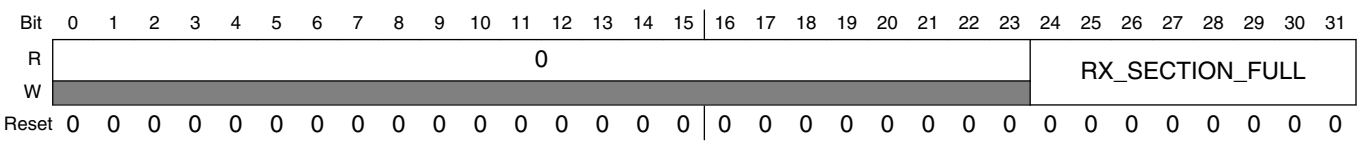
- R_BUF_SIZE is concatentated with the four least-significant bits of this register and are used as the maximum receive buffer size.
- To allow one maximum size frame per buffer, MRBR must be set to RCR[MAX_FL] or larger.

- To properly align the buffer, MRBR must be evenly divisible by 64. To ensure this, set the lower two bits of R_BUF_SIZE to zero. The lower four bits of this register are already set to zero by the device.
- To minimize bus usage (descriptor fetches), set MRBR greater than or equal to 256 bytes.

NOTE

This register must be initialized before operation.

Address: 0h base + 188h offset = 188h

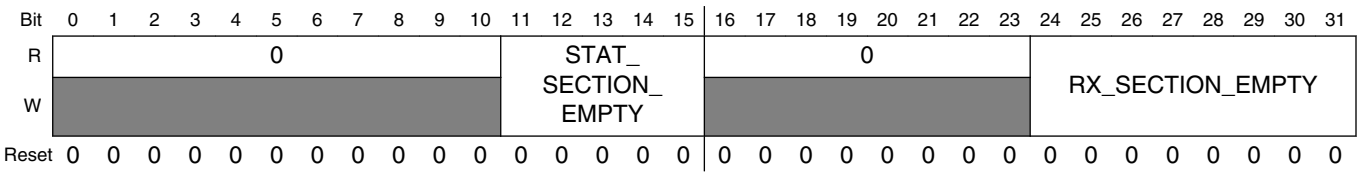


ENET_MRBR field descriptions

Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–27 R_BUF_SIZE	Receive buffer size in bytes. This value, concatenated with the four least-significant bits of this register (which are always zero), is the effective maximum receive buffer size.
28–31 Reserved	This field, which is always zero, is the four least-significant bits of the maximum receive buffer size. This field is reserved. This read-only field is reserved and always has the value 0.

43.5.30 Receive FIFO Section Full Threshold (ENET_RSFL)

Address: 0h base + 190h offset = 190h

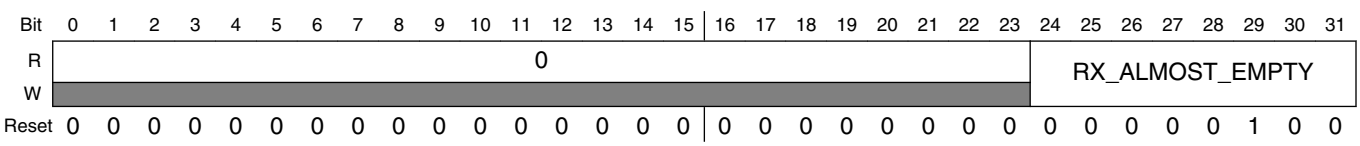


ENET_RSFL field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 RX_SECTION_ FULL	Value Of Receive FIFO Section Full Threshold Value, in 64-bit words, of the receive FIFO section full threshold. Clear this field to enable store and forward on the RX FIFO. When programming a value greater than 0 (cut-through operation), it must be greater than RAEM[RX_ALMOST_EMPTY]. When the FIFO level reaches the value in this field, data is available in the Receive FIFO (cut-through operation).

43.5.31 Receive FIFO Section Empty Threshold (ENET_RSEM)

Address: 0h base + 194h offset = 194h



ENET_RSEM field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 STAT_ SECTION_ EMPTY	RX Status FIFO Section Empty Threshold Defines number of frames in the receive FIFO, independent of its size, that can be accepted. If the limit is reached, reception will continue normally, however a pause frame will be triggered to indicate a possible congestion to the remote device to avoid FIFO overflow. A value of 0 disables automatic pause frame generation
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 RX_SECTION_ EMPTY	Value Of The Receive FIFO Section Empty Threshold Value, in 64-bit words, of the receive FIFO section empty threshold. When the FIFO has reached this level, a pause frame will be issued. A value of 0 disables automatic pause frame generation. When the FIFO level goes below the value programmed in this field, an XON pause frame is issued to indicate the FIFO congestion is cleared to the remote Ethernet client. **NOTE:** The section-empty threshold indications from both FIFOs are OR'ed to cause XOFF pause frame generation.

43.5.32 Receive FIFO Almost Empty Threshold (ENET_RAEM)

Address: 0h base + 198h offset = 198h

ENET_RAEM field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

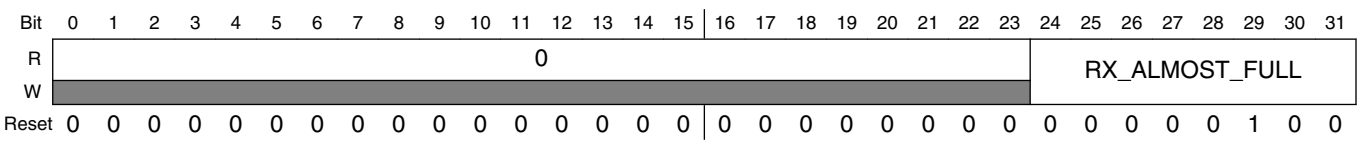


Table continues on the next page...

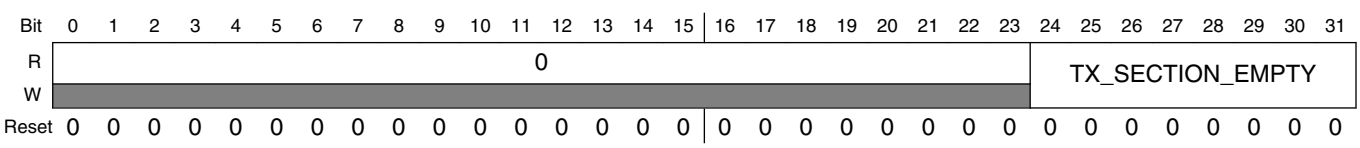
ENET_RAEM field descriptions (continued)

Field	Description
24–31 RX_ALMOST_ EMPTY	Value Of The Receive FIFO Almost Empty Threshold Value, in 64-bit words, of the receive FIFO almost empty threshold. When the FIFO level reaches the value programmed in this field and the end-of-frame has not been received for the frame yet, the core receive read control stops FIFO read (and subsequently stops transferring data to the MAC client application). It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO. A minimum value of 4 should be set.

43.5.33 Receive FIFO Almost Full Threshold (ENET_RAFL)

Address: 0h base + 19Ch offset = 19Ch



ENET_RAFL field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 RX_ALMOST_ FULL	Value Of The Receive FIFO Almost Full Threshold Value, in 64-bit words, of the receive FIFO almost full threshold. When the FIFO level comes close to the maximum, so that there is no more space for at least RX_ALMOST_FULL number of words, the MAC stops writing data in the FIFO and truncates the received frame to avoid FIFO overflow. The corresponding error status will be set when the frame is delivered to the application. A minimum value of 4 should be set.

43.5.34 Transmit FIFO Section Empty Threshold (ENET_TSEM)

Address: 0h base + 1A0h offset = 1A0h

ENET_TSEM field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ENET_TSEM field descriptions (continued)

Field	Description
24–31 TX_SECTION_ EMPTY	Value Of The Transmit FIFO Section Empty Threshold Value, in 64-bit words, of the transmit FIFO section empty threshold. See Transmit FIFO for more information.

43.5.35 Transmit FIFO Almost Empty Threshold (ENET_TAEM)

Address: 0h base + 1A4h offset = 1A4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ENET_TAEM field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 TX_ALMOST_ EMPTY	Value of Transmit FIFO Almost Empty Threshold Value, in 64-bit words, of the transmit FIFO almost empty threshold. When the FIFO level reaches the value programmed in this field, and no end-of-frame is available for the frame, the MAC transmit logic, to avoid FIFO underflow, stops reading the FIFO and transmits a frame with an MII error indication. See Transmit FIFO for more information. A minimum value of 4 should be set.

43.5.36 Transmit FIFO Almost Full Threshold (ENET_TAFL)

Address: 0h base + 1A8h offset = 1A8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																								TX_ALMOST_FULL							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

ENET_TAFL field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 TX_ALMOST_ FULL	Value Of The Transmit FIFO Almost Full Threshold

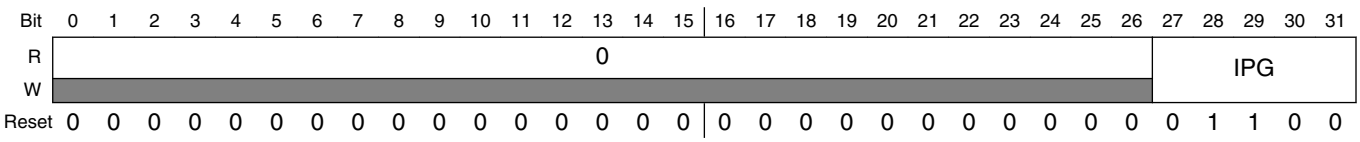

Table continues on the next page...

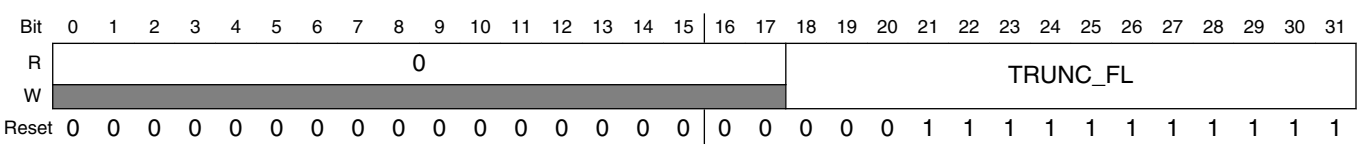
ENET_TAFL field descriptions (continued)

Field	Description
	Value, in 64-bit words, of the transmit FIFO almost full threshold. A minimum value of six is required . A recommended value of at least 8 should be set allowing a latency of two clock cycles to the application. If more latency is required the value can be increased as necessary (latency = TAFL - 5). When the FIFO level comes close to the maximum, so that there is no more space for at least TX_ALMOST_FULL number of words, the pin ff_tx_rdy is deasserted. If the application does not react on this signal, the FIFO write control logic, to avoid FIFO overflow, truncates the current frame and sets the error status. As a result, the frame will be transmitted with an GMII/MII error indication. See Transmit FIFO for more information. **NOTE:** A FIFO overflow is a fatal error and requires a global reset on the transmit datapath or at least deassertion of ETHEREN.

43.5.37 Transmit Inter-Packet Gap (ENET_TIPG)

Address: 0h base + 1ACh offset = 1ACh



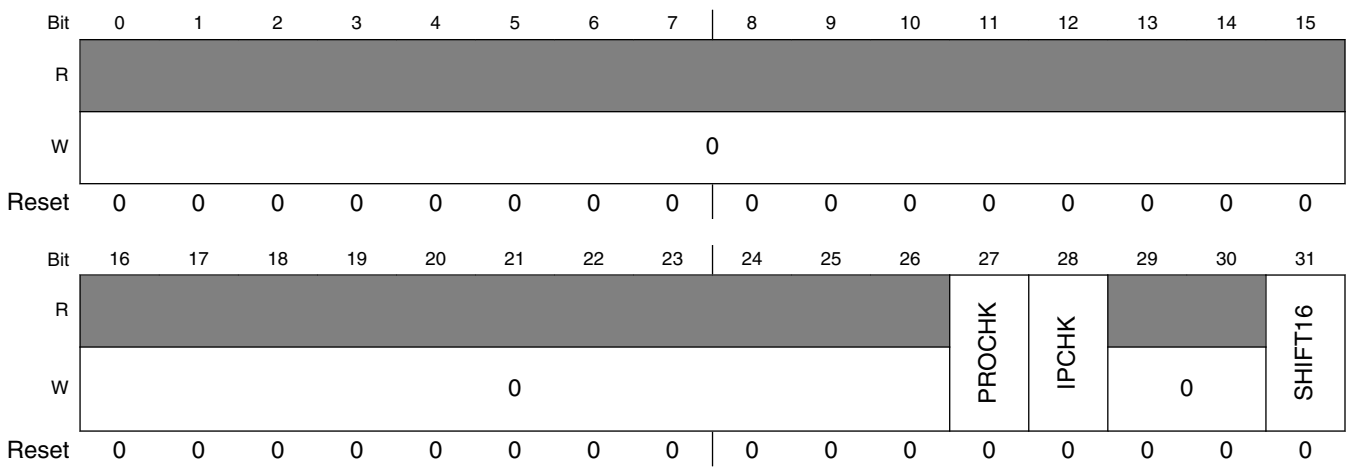
ENET_TIPG field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 IPG	Transmit Inter-Packet Gap Indicates the IPG, in bytes, between transmitted frames. Valid values range from 8 to 26. If the written value is less than 8 or greater than 26, the internal (effective) IPG is 12. **NOTE:** The IPG value read will be the value that was written, even if it is out of range.

43.5.38 Frame Truncation Length (ENET_FTRL)

Address: 0h base + 1B0h offset = 1B0h

ENET_FTRL field descriptions



Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–31 TRUNC_FL	Frame Truncation Length Indicates the value a receive frame is truncated, if it is greater than this value. Must be greater than or equal to RCR[MAX_FL]. **NOTE:** Truncation happens at TRUNC_FL. However, when truncation occurs, the application (FIFO) may receive less data, guaranteeing that it never receives more than the set limit.

43.5.39 Transmit Accelerator Function Configuration (ENET_TACC)

TACC controls accelerator actions when sending frames. The register can be changed before or after each frame, but it must remain unmodified during frame writes into the transmit FIFO.

The TFWR[STRFWD] field must be set to use the checksum feature.

Address: 0h base + 1C0h offset = 1C0h

ENET_TACC field descriptions

Field	Description
0–26 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
27 PROCHK	Enables insertion of protocol checksum. 0 Checksum not inserted. 1 If an IP frame with a known protocol is transmitted, the checksum is inserted automatically into the frame. The checksum field must be cleared. The other frames are not modified.
28 IPCHK	Enables insertion of IP header checksum.

Table continues on the next page...

ENET_TACC field descriptions (continued)

Field	Description
	0 Checksum is not inserted. 1 If an IP frame is transmitted, the checksum is inserted automatically. The IP header checksum field must be cleared. If a non-IP frame is transmitted the frame is not modified.
29–30 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
31 SHIFT16	TX FIFO Shift-16 0 Disabled. 1 Indicates to the transmit data FIFO that the written frames contain two additional octets before the frame data. This means the actual frame begins at bit 16 of the first word written into the FIFO. This function allows putting the frame payload on a 32-bit boundary in memory, as the 14-byte Ethernet header is extended to a 16-byte header.

43.5.40 Receive Accelerator Function Configuration (ENET_RACC)

Address: 0h base + 1C4h offset = 1C4h

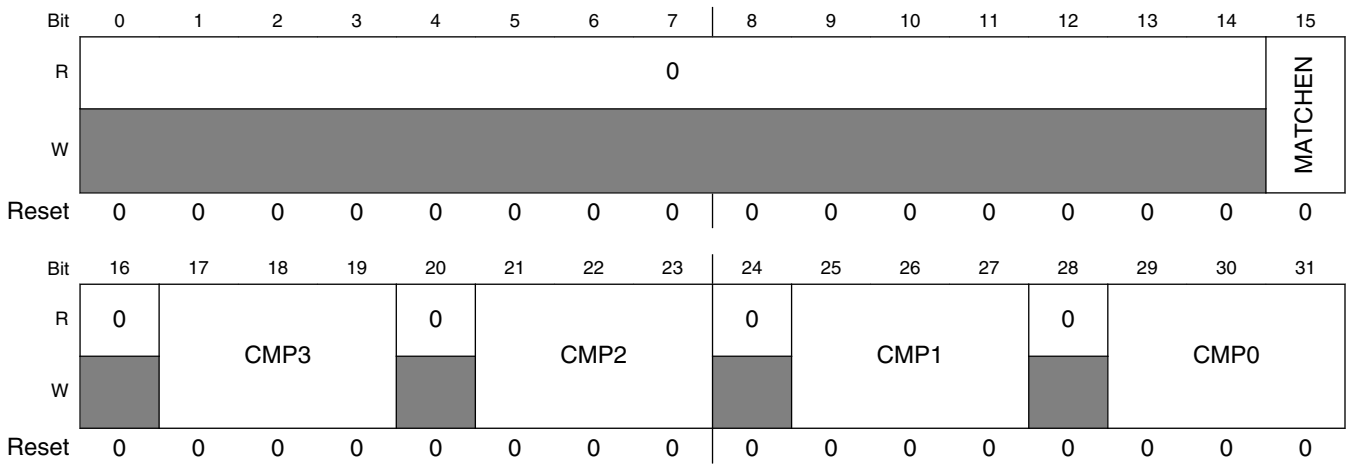
Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R																
W	0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R									SHIFT16	LINEDIS				PRODIS	IPDIS	PADREM
W	0										0					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_RACC field descriptions

Field	Description
0–23 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
24 SHIFT16	RX FIFO Shift-16 When this field is set, the actual frame data starts at bit 16 of the first word read from the RX FIFO aligning the Ethernet payload on a 32-bit boundary. **NOTE:** This function only affects the FIFO storage and has no influence on the statistics, which use the actual length of the frame received. 0 Disabled. 1 Instructs the MAC to write two additional bytes in front of each frame received into the RX FIFO.

Table continues on the next page...



ENET_RACC field descriptions (continued)

Field	Description
25 LINEDIS	Enable Discard Of Frames With MAC Layer Errors 0 Frames with errors are not discarded. 1 Any frame received with a CRC, length, or PHY error is automatically discarded and not forwarded to the user application interface.
26–28 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
29 PRODIS	Enable Discard Of Frames With Wrong Protocol Checksum 0 Frames with wrong checksum are not discarded. 1 If a TCP/IP, UDP/IP, or ICMP/IP frame is received that has a wrong TCP, UDP, or ICMP checksum, the frame is discarded. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).
30 IPDIS	Enable Discard Of Frames With Wrong IPv4 Header Checksum 0 Frames with wrong IPv4 header checksum are not discarded. 1 If an IPv4 frame is received with a mismatching header checksum, the frame is discarded. IPv6 has no header checksum and is not affected by this setting. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).
31 PADREM	Enable Padding Removal For Short IP Frames 0 Padding not removed. 1 Any bytes following the IP payload section of the frame are removed from the frame.

43.5.41 Receive Classification Match Register for Class n (ENET_RCMR*n*)

This match register allows specifying up to four priorities, which are tested (OR'ed) simultaneously. The match detection uses the extracted VLAN field according to the rules for VLAN detection configured through the ECR register. If both match registers, RCMR1 and RCMR2, report a match at the same time, only the class 1 match is indicated as the final result.

Address: 0h base + 1C8h offset + (4d × i), where i=0d to 1d

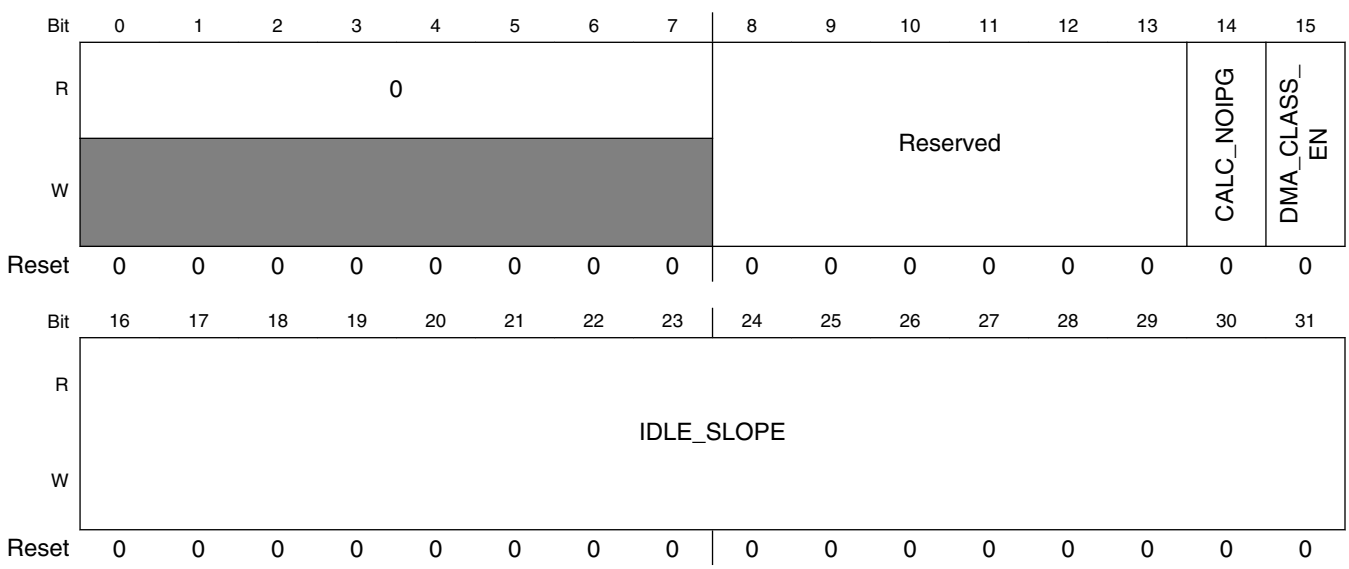
ENET_RCMR*n* field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 MATCHEN	Match Enable **NOTE:** A comparison is done only on incoming VLAN frames. If no VLAN frame is received no match will occur. If both match registers have overlapping compare values and hence can match both on the same frame, only class 1 will be indicated and the class 2 match is ignored. 0 Disabled (default): no compares will occur and the classification indicator for this class will never assert. 1 The register contents are valid and a comparison with all compare values is done when a VLAN frame is received.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–19 CMP3	Compare 3 Fourth value to compare against. If unused it must be set to the same value as CMP0.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ENET_RCMR*n* field descriptions (continued)

Field	Description
21–23 CMP2	Compare 2 Third value to compare against. If unused it must be set to the same value as CMP0.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–27 CMP1	Compare 1 Second value to compare against. If unused it must be set to the same value as CMP0.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 CMP0	Compare 0 A three-bit value that will be compared with the frame's VLAN priority field (if a VLAN frame is received). All four compare values, CMP0..3, will be used in parallel. If any of the values match, a match for the class is reported (if MATCHEN is 1). **NOTE:** To implement a single priority match, all four compare values must be set to the same value.



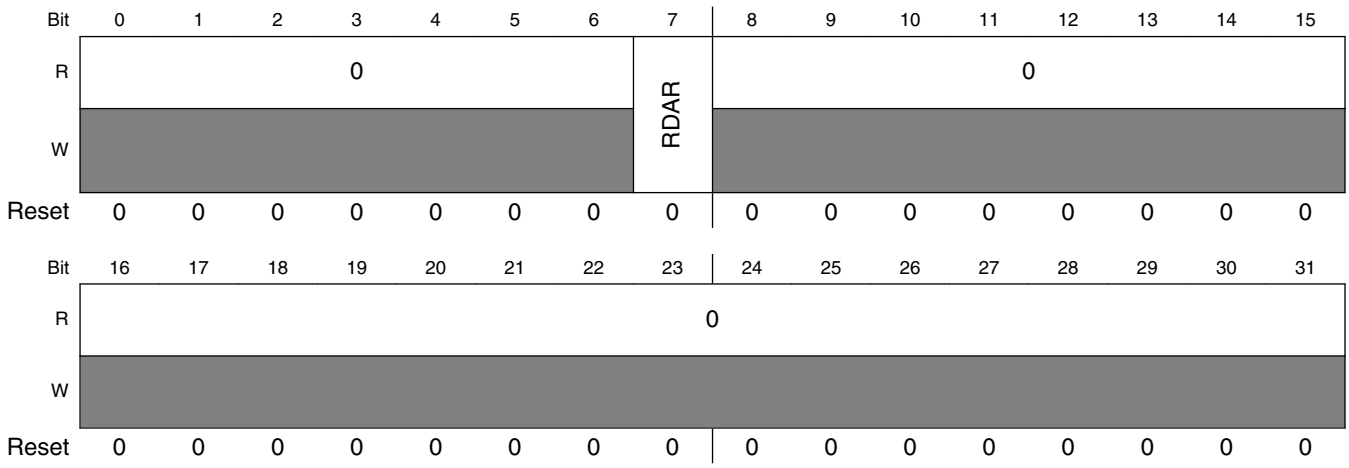
43.5.42 DMA Class Based Configuration (ENET_DMA*n*CFG)

The DMA class based configuration registers are used to configure the DMA controller interface to support the additional class 1 (buffer descriptor ring 1) and class 2 (buffer descriptor ring 2) traffic and define configuration options such as bandwidth allocation as needed.

NOTE

The registers are cleared when ECR[ETHEREN] becomes 0.

Address: 0h base + 1D8h offset + (4d × i), where i=0d to 1d



ENET_DMA*n*CFG field descriptions

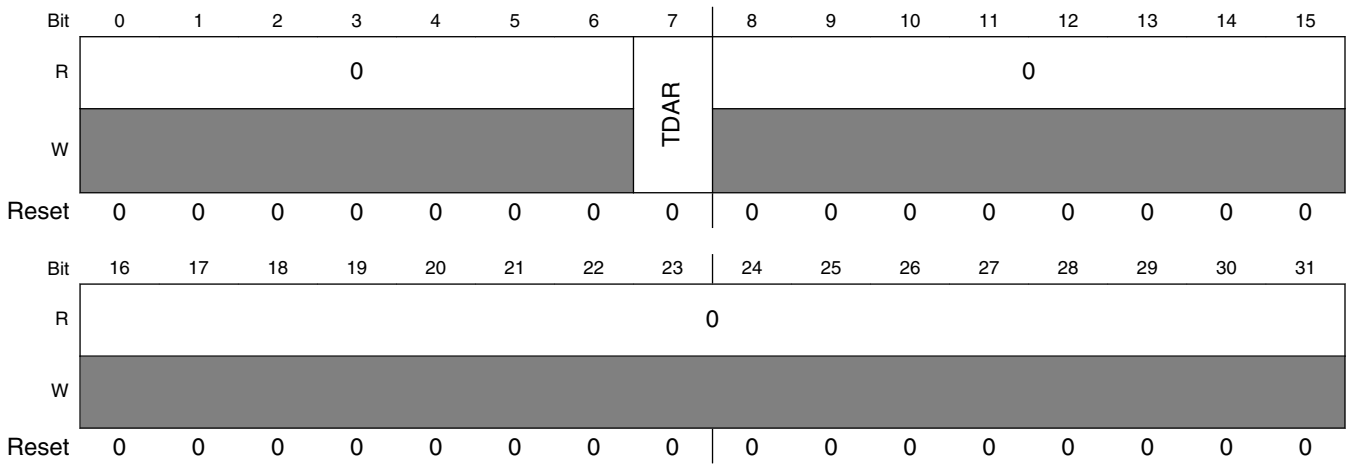
Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–13 Reserved	This field is reserved. **NOTE:** Write only zeroes to this field.
14 CALC_NOIPG	Calculate no IPG Disable inclusion of IPG bytes for bandwidth calculations. 0 The traffic shaper function should consider 12 octets of IPG in addition to the frame data transferred for a frame when doing bandwidth calculations. This is the default. 1 Addition of 12 bytes for the IPG should be omitted when calculating the bandwidth (for traffic shaping, when writing a frame into the transmit FIFO, the shaper will usually consider 12 bytes of IPG for every frame as part of the bandwidth allocated by the frame. This addition can be suppressed, meaning short frames will become more bandwidth than large frames due to the relation of data to IPG overhead).
15 DMA_CLASS_EN	DMA class enable 0 The DMA controller's channel for the class is not used. **NOTE:** Disabling the DMA controller of a class also requires disabling the class match comparator for the class (see registers RCMRn). When class 1 and class 2 queues are disabled then their frames will be placed in queue 0. 1 Enable the DMA controller to support the corresponding descriptor ring for this class of traffic.
16–31 IDLE_SLOPE	Idle slope 16-bit value to define the per class idle slope setting used by the credit based shaper defining allocated bandwidth for the class. This value is used to calculate the BW (bandwidth) fraction, given by the equation, BW fraction = 1/(1+512/IDLE_SLOPE). Idle slope is restricted to certain values. For values less than 128, idle slope = 2^n, where n = 0, 1, 2, ...6. For values equal to or greater than 128, idle slope = 128×m, where m = 1, 2, 3, ...12. Example 1. BW fraction = 0.20 = 1/(1+(512/128)); therefore idleslope = 128. Example 2. BW fraction = 0.33 = 1/(1+(512/256)); therefore idleslope = 256. Example 3. BW fraction = 0.75 = 1/(1+(512/1536)); therefore idleslope = 1536. **NOTE:** For AVB applications, the BW fraction of class 1 and class 2 combined must not exceed .75.

43.5.43 Receive Descriptor Active Register - Ring 1 (ENET_RDAR1)

RDAR1 is a command register, written by the user, to indicate that the receive descriptor ring 1 has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

Address: 0h base + 1E0h offset = 1E0h

ENET_RDAR1 field descriptions



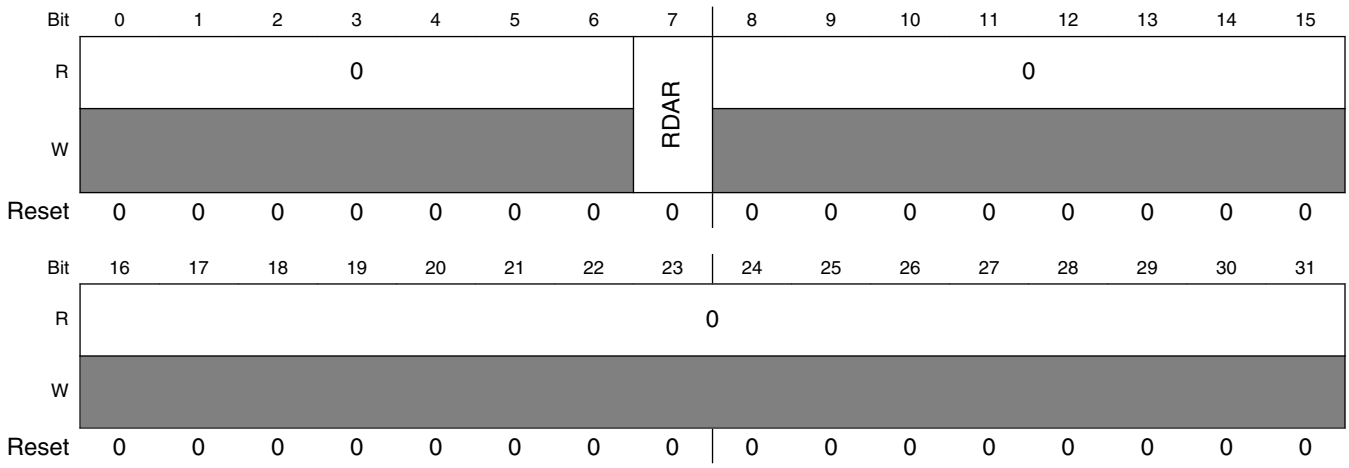
Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 RDAR	Receive Descriptor Active Always set to 1 when this register is written, regardless of the value written. This field is cleared by the MAC device when no additional empty descriptors remain in the receive ring. It is also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

43.5.44 Transmit Descriptor Active Register - Ring 1 (ENET_TDAR1)

TDAR1 is a command register that the user writes to indicate that transmit descriptor ring 1 has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

The TDAR register is cleared at reset, when ECR[ETHEREN] transitions from set to cleared, or when ECR[RESET] is set.

Address: 0h base + 1E4h offset = 1E4h



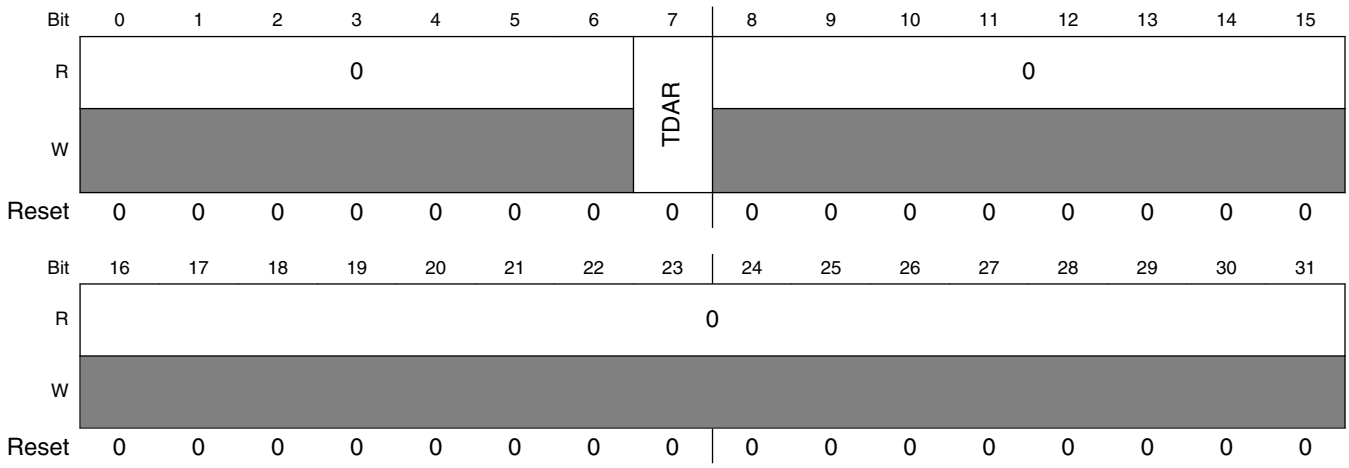
ENET_TDAR1 field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TDAR	Transmit Descriptor Active Always set to 1 when this register is written, regardless of the value written. This bit is cleared by the MAC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

43.5.45 Receive Descriptor Active Register - Ring 2 (ENET_RDAR2)

RDAR2 is a command register, written by the user, to indicate that the receive descriptor ring 2 has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

Address: 0h base + 1E8h offset = 1E8h



ENET_RDAR2 field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 RDAR	Receive Descriptor Active Always set to 1 when this register is written, regardless of the value written. This field is cleared by the MAC device when no additional empty descriptors remain in the receive ring. It is also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

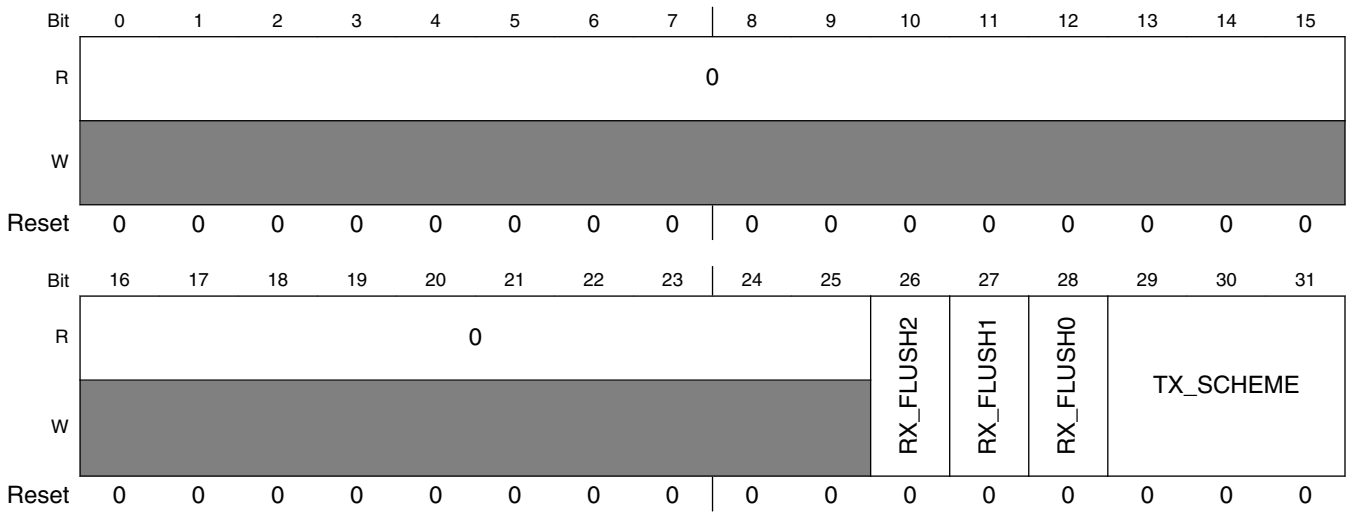
43.5.46 Transmit Descriptor Active Register - Ring 2 (ENET_TDAR2)

TDAR2 is a command register that the user writes to indicate that transmit descriptor ring 2 has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

Address: 0h base + 1ECh offset = 1ECh

ENET_TDAR2 field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TDAR	Transmit Descriptor Active Always set to 1 when this register is written, regardless of the value written. This bit is cleared by the MAC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.



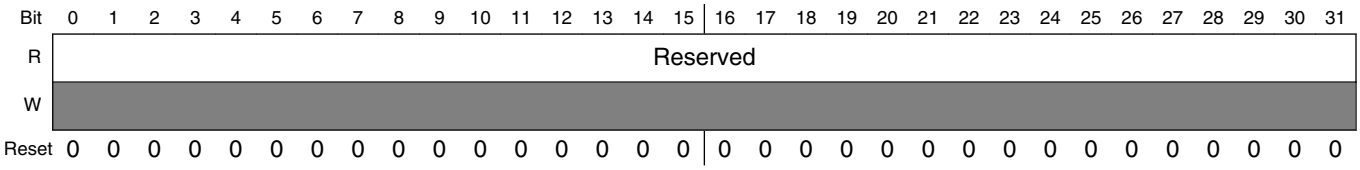
43.5.47 QOS Scheme (ENET_QOS)

This register sets the QOS scheme.

NOTE

When both class 1 and class 2 are disabled, RX flushing for these rings must also be disabled.

Address: 0h base + 1F0h offset = 1F0h

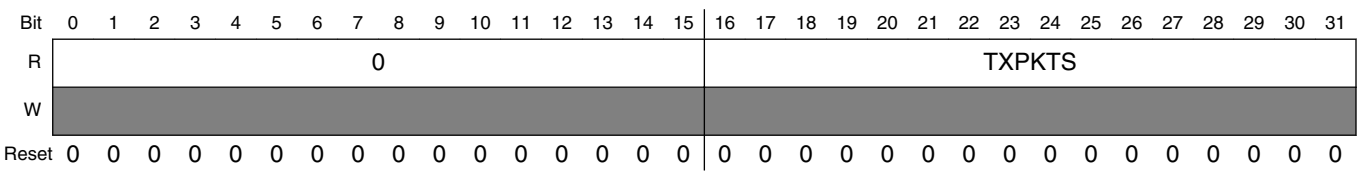


ENET_QOS field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 RX_FLUSH2	RX Flush Ring 2 Enable or disable RX Flush for ring 2. See Receive flushing. 0 Disable 1 Enable
27 RX_FLUSH1	RX Flush Ring 1 Enable or disable RX Flush for ring 1. See Receive flushing. 0 Disable 1 Enable
28 RX_FLUSH0	RX Flush Ring 0 Enable or disable RX Flush for ring 0. See Receive flushing. 0 Disable 1 Enable
29–31 TX_SCHEME	TX scheme configuration Configuration information for DMA to select transmitter queue selection/arbitration scheme. 000 Credit-based scheme 001 Round-robin scheme 010-111 Reserved

43.5.48 Reserved Statistic Register (ENET_RMON_T_DROP)

Address: 0h base + 200h offset = 200h



ENET_RMON_T_DROP field descriptions

Field	Description
0–31 Reserved	This read-only field always has the value 0. This field is reserved.

43.5.49 Tx Packet Count Statistic Register (ENET_RMON_T_PACKETS)

Address: 0h base + 204h offset = 204h

ENET_RMON_T_PACKETS field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TXPKTS	Packet count Transmit packet count

43.5.50 Tx Broadcast Packets Statistic Register (ENET_RMON_T_BC_PKT)

RMON Tx Broadcast Packets

Address: 0h base + 208h offset = 208h

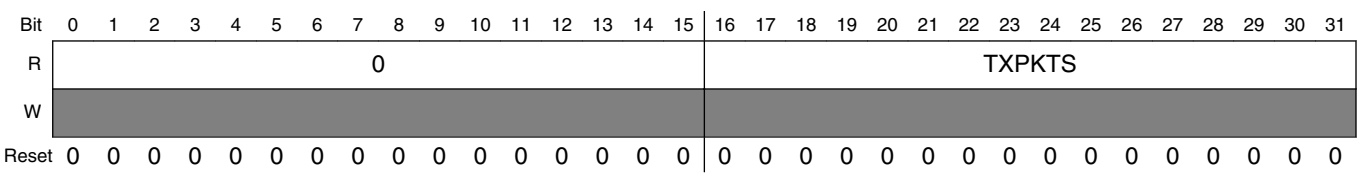
ENET_RMON_T_P256TO511 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TXPKTS	Number of 256- to 511-byte transmit packets

43.5.62 Tx 512- to 1023-byte Packets Statistic Register (ENET_RMON_T_P512TO1023)

.

Address: 0h base + 238h offset = 238h

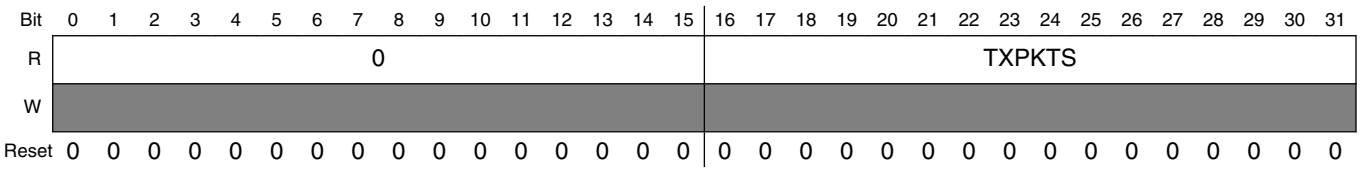


ENET_RMON_T_P512TO1023 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TXPKTS	Number of 512- to 1023-byte transmit packets

43.5.63 Tx 1024- to 2047-byte Packets Statistic Register (ENET_RMON_T_P1024TO2047)

Address: 0h base + 23Ch offset = 23Ch

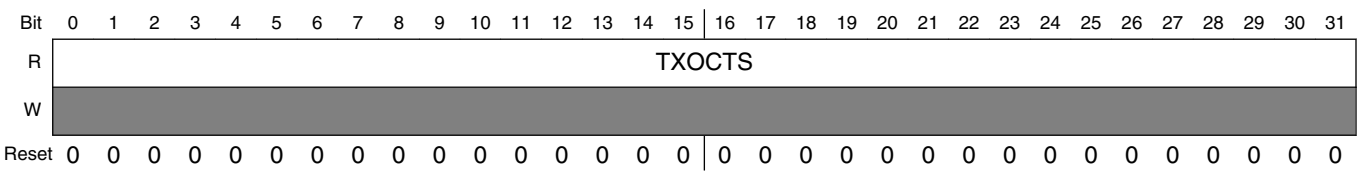


ENET_RMON_T_P1024TO2047 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TXPKTS	Number of 1024- to 2047-byte transmit packets

43.5.64 Tx Packets Greater Than 2048 Bytes Statistic Register (ENET_RMON_T_P_GTE2048)

Address: 0h base + 240h offset = 240h

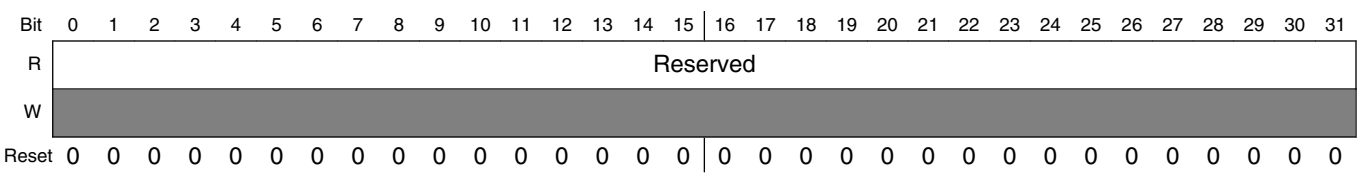


ENET_RMON_T_P_GTE2048 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TXPKTS	Number of transmit packets greater than 2048 bytes

43.5.65 Tx Octets Statistic Register (ENET_RMON_T_OCTETS)

Address: 0h base + 244h offset = 244h

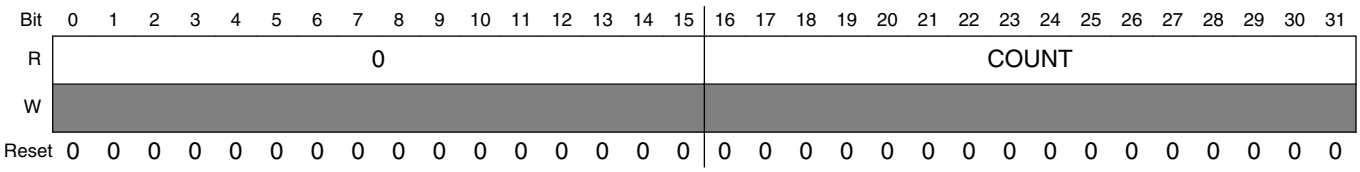


ENET_RMON_T_OCTETS field descriptions

Field	Description
0–31 TXOCTS	Number of transmit octets

43.5.66 Reserved Statistic Register (ENET_IEEE_T_DROP)

Address: 0h base + 248h offset = 248h

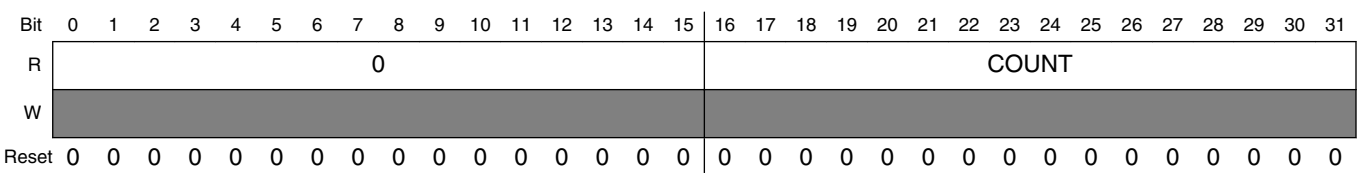


ENET_IEEE_T_DROP field descriptions

Field	Description
0–31 Reserved	This read-only field always has the value 0. This field is reserved.

43.5.67 Frames Transmitted OK Statistic Register (ENET_IEEE_T_FRAME_OK)

Address: 0h base + 24Ch offset = 24Ch



ENET_IEEE_T_FRAME_OK field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted OK **NOTE:** Does not increment for the broadcast frames when broadcast reject is enabled and promiscuous mode is disabled within the receive control register (RCR).

43.5.68 Frames Transmitted with Single Collision Statistic Register (ENET_IEEE_T_1COL)

Address: 0h base + 250h offset = 250h

ENET_IEEE_T_1COL field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted with one collision

43.5.69 Frames Transmitted with Multiple Collisions Statistic Register (ENET_IEEE_T_MCOL)

Address: 0h base + 254h offset = 254h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ENET_IEEE_R_OCTETS_OK field descriptions

Field	Description
0–31 COUNT	Number of octets for frames received without error **NOTE:** Counts total octets (includes header and FCS fields). Does not increment for the broadcast frames when broadcast reject is enabled and promiscuous mode is disabled within the receive control register (RCR).

43.5.102 Adjustable Timer Control Register (ENET_ATCR)

ATCR command fields can trigger the corresponding events directly. It is not necessary to preserve any of the configuration fields when a command field is set in the register, that is, no read-modify-write is required.

NOTE

The CAPTURE and RESTART fields and bits 19 and 21 must be 0 in order to write to the other fields in this register.

Address: 0h base + 400h offset = 400h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0		SLAVE	Reserved	CAPTURE	Reserved	RESTART		PINPER			PEREN	OFFRST	OFFEN		EN
W								0		0	1				0	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_ATCR field descriptions

Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 SLAVE	Enable Timer Slave Mode 0 The timer is active and all configuration fields in this register are relevant. 1 The internal timer is disabled and the externally provided timer value is used. All other fields, except CAPTURE, in this register have no effect. CAPTURE can still be used to capture the current timer value.
19 Reserved	This field is reserved. Always write 0 to this field.
20 CAPTURE	Capture Timer Value When this field is set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes. 0 No effect. 1 The current time is captured and can be read from the ATVR register.
21 Reserved	This field is reserved. Always write 0 to this field.
22 RESTART	Reset Timer Resets the timer to zero. This has no effect on the counter enable. If the counter is enabled when this field is set, the timer is reset to zero and starts counting from there. When set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes.
23 Reserved	This field is reserved.
24 PINPER	Enables event signal output assertion on period event. **NOTE:** Not all devices contain the event signal output. See the chip configuration details.

Table continues on the next page...

ENET_ATCR field descriptions (continued)

Field	Description
	0 Disable. 1 Enable.
25 Reserved	This field is reserved.
26 Reserved	This field is reserved. **NOTE:** This field must be written always with one.
27 PEREN	Enable Periodical Event 0 Disable. 1 A period event interrupt can be generated (EIR[TS_TIMER]) and the event signal output is asserted when the timer wraps around according to the periodic setting ATPER. The timer period value must be set before setting this bit. **NOTE:** Not all devices contain the event signal output. See the chip configuration details.
28 OFFRST	Reset Timer On Offset Event 0 The timer is not affected and no action occurs, besides clearing OFFEN, when the offset is reached. 1 If OFFEN is set, the timer resets to zero when the offset setting is reached. The offset event does not cause a timer interrupt.
29 OFFEN	Enable One-Shot Offset Event 0 Disable. 1 The timer can be reset to zero when the given offset time is reached (offset event). The field is cleared when the offset event is reached, so no further event occurs until the field is set again. The timer offset value must be set before setting this field.
30 Reserved	This field is reserved.
31 EN	Enable Timer 0 The timer stops at the current value. 1 The timer starts incrementing.

43.5.103 Timer Value Register (ENET_ATVR)

Address: 0h base + 404h offset = 404h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ATIME

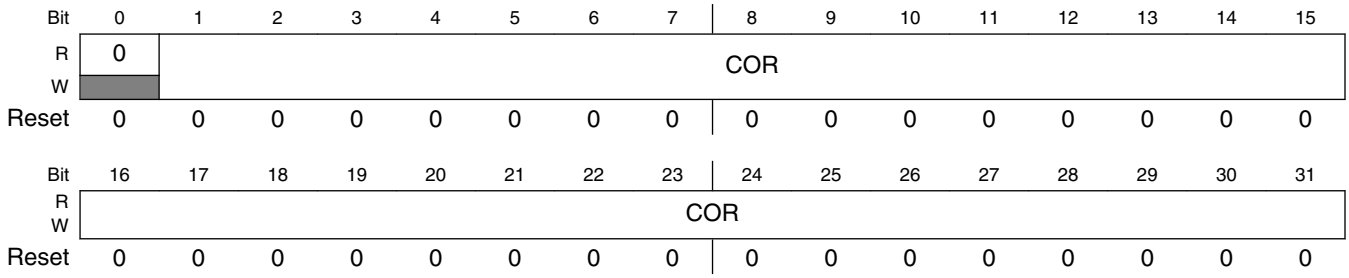
ENET_ATOFF field descriptions

Field	Description
0–31 OFFSET	Offset value for one-shot event generation. When the timer reaches the value, an event can be generated to reset the counter. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds.

43.5.105 Timer Period Register (ENET_ATPER)

Address: 0h base + 40Ch offset = 40Ch



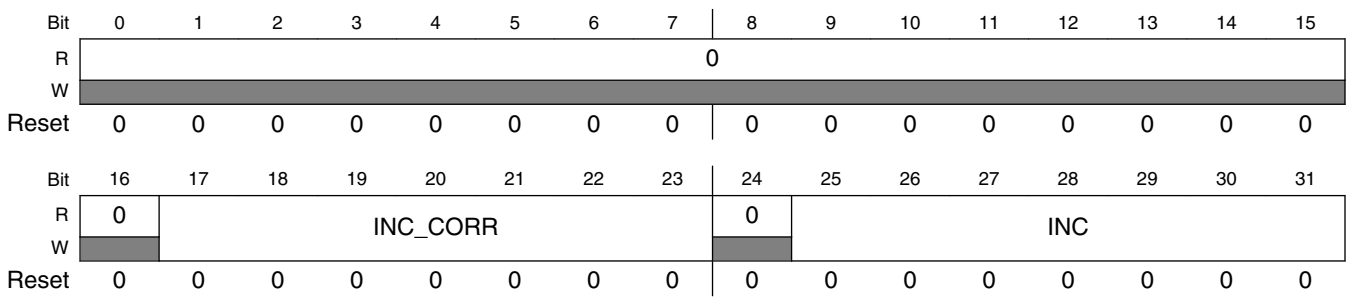
Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	PERIOD																															
Reset	0	0	1	1	1	0	1	1	1	0	0	1	1	0	1	0	1	1	0	0	1	0	1	0	0	0	0	0	0	0	0	0

ENET_ATPER field descriptions

Field	Description
0–31 PERIOD	Value for generating periodic events. Each instance the timer reaches this value, the period event occurs and the timer restarts. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds. The value should be initialized to 1,000,000,000 (1×10^9) to represent a timer wrap around of one second. The increment value set in ATINC should be set to the true nanoseconds of the period of clock ts_clk, hence implementing a true 1 second counter. **NOTE:** The value of PERIOD has the following constraint: 2^{32} – ENET_ATINC[INC_COR] – 3×ENET_ATINC[INC] ≥ PERIOD > 0.

43.5.106 Timer Correction Register (ENET_ATCOR)

Address: 0h base + 410h offset = 410h



ENET_ATCOR field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–31 COR	Correction Counter Wrap-Around Value Defines after how many timer clock cycles (ts_clk) the correction counter should be reset and trigger a correction increment on the timer. The amount of correction is defined in ATINC[INC_CORR]. A value of 0 disables the correction counter and no corrections occur. **NOTE:** This value is given in clock cycles, not in nanoseconds as all other values.

43.5.107 Time-Stamping Clock Period Register (ENET_ATINC)

Address: 0h base + 414h offset = 414h

ENET_ATINC field descriptions

Field	Description
0–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–23 INC_CORR	Correction Increment Value This value is added every time the correction timer expires (every clock cycle given in ATCOR). A value less than INC slows down the timer. A value greater than INC speeds up the timer.

Table continues on the next page...

ENET_ATINC field descriptions (continued)

Field	Description
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 INC	Clock Period Of The Timestamping Clock (ts_clk) In Nanoseconds The timer increments by this amount each clock cycle. For example, set to 10 for 100 MHz, 8 for 125 MHz, 5 for 200 MHz. **NOTE:** For highest precision, use a value that is an integer fraction of the period set in ATPER.

43.5.108 Timestamp of Last Transmitted Frame (ENET_ATSTMP)

Address: 0h base + 418h offset = 418h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ENET_MDATA field descriptions

Field	Description
0–31 MATCHDATA	Match Data Data to be used for pattern matching when corresponding MMASK bit is set to 1.

43.5.110 Match Entry Mask Register (ENET_MMASK)

See Frame parser for more information.

Address: 0h base + 584h offset = 584h

Bit	0–15	16–31
R W	MATCHMASK	
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

ENET_MMASK field descriptions

Field	Description
0–31 MATCHMASK	Match Mask Mask used in conjunction with MDATA register to control which bits in MDATA to compare. If MMASK[*n*] is set to 1, then MDATA[*n*] will be used for comparison. If MMASK[*n*] is 0, then MDATA[*n*] will not be compared.

43.5.111 Match Entry Rules Configuration Register (ENET_MCONFIG)

See Frame parser for more information.

Address: 0h base + 588h offset = 588h

Bit	0	1	2	3–7	8–15
R W	AF	RF	IM	0	OK_INDEX
Reset	0	0	0	0 0 0 0 0	0 0 0 0 0 0 0 0

Bit	16–23	24–29	30	31
R W	0	FRMOFF	0	
Reset	0 0 0 0 0 0 0 0	0 0 0 0 0 0	0	0

ENET_MCONFIG field descriptions

Field	Description
0 AF	Accept Frame If okay, put frame into queue defined by the OK_INDEX. Meaning of okay is defined by the IM field. **NOTE:** If both the AF and RF fields are set to 1, AF will take precedence and RF will be ignored.
1 RF	Reject Frame

Table continues on the next page...

ENET_MCONFIG field descriptions (continued)

Field	Description
	If okay, reject/drop frame. The meaning of okay is defined by the IM field. **NOTE:** If both the AF and RF fields are set to 1, AF will take precedence and RF will be ignored.
2 IM	Invert Match When set to 1, okay means not matched. When cleared to 0, okay means match with entry.
3–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 OK_INDEX	When AF = 0 and RF = 0, this value shows the next entry of the matching table to be used for comparison instead of using the next entry sequentially. This value should be less than the total number of valid entries defined by RXPCTL[MAX_INDEX]. The minimum value can be 0. When AF = 1, this value is used as the queue index where the frame should be received. The least-significant two bits of this field are used as the queue index. Maximum value of the queue index is 2.
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–29 FRMOFF	Frame Offset Points to the word, from the start of the frame, to be compared for matching. This value must be less than or equal to MAXFRMOFF or else a parser programming error will occur, resulting in ENET_EIR[PARSERR] being asserted and the frame being discarded.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

43.5.112 Match Entry Read/Write Command Register (ENET_MENTRYRW)

See Frame parser for more information.

Table continues on the next page...

ENET_MENTRYRW field descriptions (continued)

Field	Description
22 RD	Entry Read Command When set to 1, the current entry values of the Match Entry table are read and available within the match entry registers, MATCH_DATA, MATCH_MASK, and MCONFIG. This field is automatically cleared when the read operation is completed. Match entry registers are valid and ready for reading only when this field is cleared to 0 after a read operation. **NOTE:** If both the WR and RD fields are set to 1, the write operation will take precedence and the read operation will be ignored.
23 WR	Entry write command When set to 1, the current values of the match entry registers (MATCH_DATA, MATCH_MASK, and MCONFIG) are written to the Match Entry table. This field is automatically cleared when the write operation is complete. **NOTE:** If both the WR and RD fields are set to 1, the write operation will take precedence and the read operation will be ignored.
24–31 ENTRYADD	Entry Address Address location of the Match Entry table on which read or write operations will be done. The Match Entry table contains ENET_RXPCTL[MAXINDEX] entries of 96-bit words. Therefore valid ENTRYADD values range from a minimum of 0 to a maximum of ENET_RXPCTL[MAXINDEX]-1. For example, if ENET_RXPCTL[MAXINDEX] = 64, then ENTRYADD may range from 0 to 63, inclusive.

43.5.113 Receive Parser Control Register (ENET_RXPCTL)

See Frame parser for more information.

Address: 0h base + 590h offset = 590h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R								ACPTEERR	ENDERRQ							
W	0

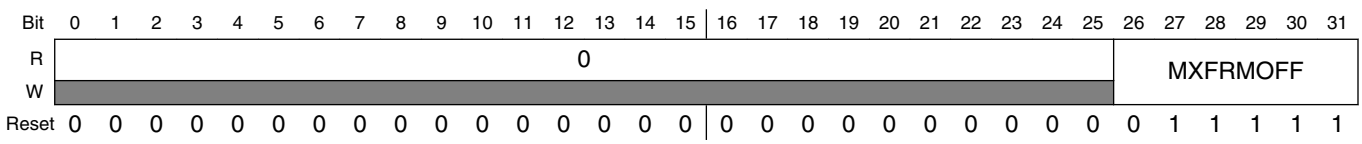
R	MAXINDEX											PRSRSCLR			INVBYTORD	ENPARSER
W									0				0			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_RXPCTL field descriptions

Field	Description
0–6 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
7 ACPTEERR	Accept End Error Accept the current frame when parsing is not completed for the current frame and parsing for the next frame has started. The corresponding accept statistics counter for the queue defined by ENDERRQ will be incremented. **NOTE:** RXPARST[PRSENDERR] assertion is independent of this field.
8–15 ENDERRQ	End Error Queue Queue number for the accepted frames that encounters the RXPARST[PRSENDERR]. Only one bit should be set. 00000001 Place the frame in Queue 0 00000010 Place the frame in Queue 1 00000100 Place the frame in Queue 2
16–23 MAXINDEX	Maximum Index Number of valid entries in the Match Array table. This value must be less than or equal to the depth of the physical table and greater than or equal to 1. If this value is cleared to 0, parser is disabled. **NOTE:** The depth of the Match Array table is chip-specific. See the ENET chip-specific information for this value.
24–26 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
27 PRSRSCLR	Clear Parser Statistics Counter The field is automatically cleared to 0 after resetting the parser statistics register. Returns 0 on read.
28–29 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
30 INVBYTORD	Inverse Frame Byte Order When set to 1: • The byte order within a frame word is changed before comparison. • The least-significant byte is compared with most-significant byte of the parser table entry data word. • And most-significant byte of the frame word is compared with least-significant byte of the table entry data word.
31 ENPARSER	Enable Receive Parser **NOTE:** When enabled, at least one entry within the Match Array Table should be valid. See MAXINDEX field for more details. 0 Parser is disabled. 1 Parser is enabled.



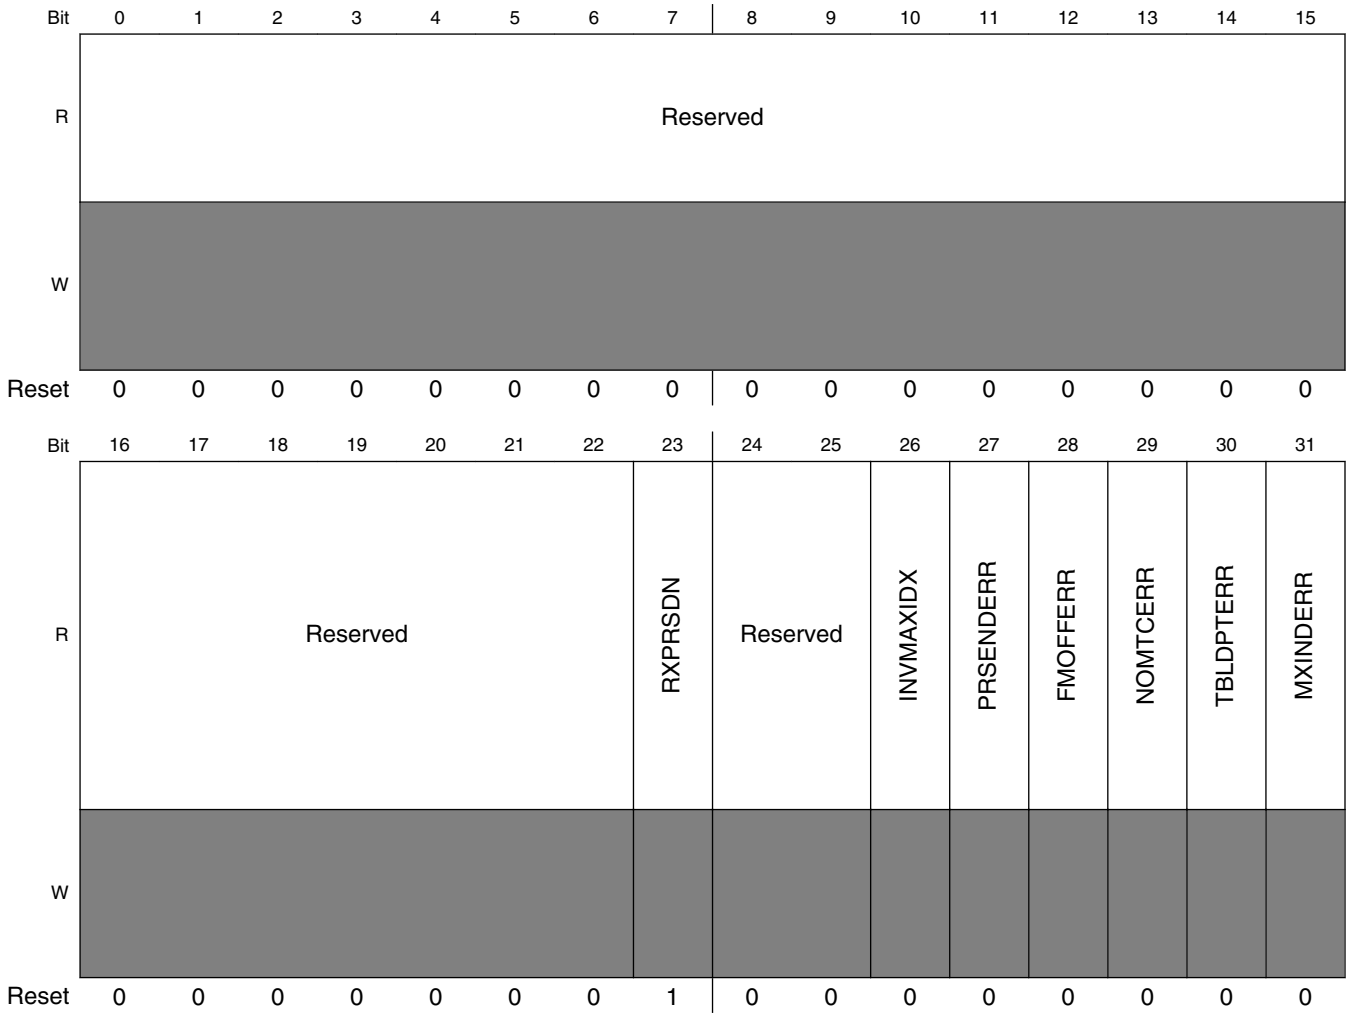
43.5.114 Maximum Frame Offset (ENET_MAXFRMOFF)

Maximum value of the 32-bit word index position of the frame to be inspected. Maximum value is 63. With a value of 31 (default) it is possible to inspect any byte position from 0 to 127.

NOTE

MCONFIG[FRMOFF] should be always less than or equal to this value, otherwise parser state machine will generate parser programming error, assert EIR[PARS_ERR], and frame will be discarded.

Address: 0h base + 594h offset = 594h



ENET_MAXFRMOFF field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 MXFRMOFF	Max. Frame Offset

43.5.115 Receive Parser Status (ENET_RXPARST)

Address: 0h base + 598h offset = 598h

ENET_RXPARST field descriptions

Field	Description
0–22 Reserved	This field is reserved.
23 RXPRSDN	Receive Parser Done Current status of the receive parser state machine. Asserted to indicate that the parser is in idle state. De-asserted when parser is active and currently parsing a receive frame.
24–25 Reserved	This field is reserved.
26 INVMAXIDX	Invalid Value of MAXINDEX This field is set to 1 when the parser is currently enabled, but the number of valid entries (MAXINDEX) within the table is set to 0 or is larger than the physical table depth.

Table continues on the next page...

ENET_RXPARST field descriptions (continued)

Field	Description
27 PRSENDERR	Parser End Error Frame parsing started for the next frame before end of parsing for the current frame. The frame is accepted or rejected depending on the configuration of RXPCTL[ACPTEERR]. This field is cleared on read or if parser is disabled.
28 FMOFFERR	Maximum Frame Offset Error Frame rejected due to parser error as frame offset is larger than expected maximum frame offset value defined by the MAXFRMOFF register. Latch high bit. Cleared on read or if parser is disabled.
29 NOMTCERR	No Match Error No Match error. Frame rejected due to parser error as no match or invert match found after end of parsing. Latch high bit. Cleared on read or if parser is disabled.
30 TBLDPTERR	Table Depth Error Frame rejected due to parser error as table entry index larger than or equal to parser table physical depth. Latch high bit. Cleared on read or if parser is disabled.
31 MXINDERR	Maximum Index Error Frame rejected due to parser error as table entry index greater than or equal to number of valid entries within the table defined by RXPCTL[MAX_INDEX]. Latch high bit. Cleared on read or if parser is disabled.

43.5.116 Parser Discard Count (ENET_PARSDSCD)

Number of frames rejected by the receive parser due to no matching, inverse matching, or parser programming error.

Address: 0h base + 5A0h offset = 5A0h

29 TF2	Copy Of Timer Flag For Channel 2 0 Timer Flag for Channel 2 is clear 1 Timer Flag for Channel 2 is set
30 TF1	Copy Of Timer Flag For Channel 1 0 Timer Flag for Channel 1 is clear 1 Timer Flag for Channel 1 is set
31 TF0	Copy Of Timer Flag For Channel 0 0 Timer Flag for Channel 0 is clear 1 Timer Flag for Channel 0 is set

43.5.124 Timer Control Status Register (ENET_TCSR*n*)

Address: 0h base + 608h offset + (8d × i), where i=0d to 3d

ENET_TCSR*n* field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–20 TPWC	Timer PulseWidth Control Specifies the pulse width associated with TMODE values of 1110 or 11X1. Updating this field takes a few cycles to register because it is synchronized to the 1588 clock. When changing this field: 1. Always disable the channel and read the TMODE field to verify that the channel is disabled. 2. Set TPWC to the desired value. 3. Reenable the channel. 00000 Pulse width is one 1588-clock cycle. 00001 Pulse width is two 1588-clock cycles. 00010 Pulse width is three 1588-clock cycles. 00011 Pulse width is four 1588-clock cycles. ... ... 11111 Pulse width is 32 1588-clock cycles.
21–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 TF	Timer Flag Sets when input capture or output compare occurs. This flag is double buffered between the module clock and 1588 clock domains. When this field is 1, it can be cleared to 0 by writing 1 to it. 0 Input Capture or Output Compare has not occurred. 1 Input Capture or Output Compare has occurred.
25 TIE	Timer Interrupt Enable 0 Interrupt is disabled 1 Interrupt is enabled
26–29 TMODE	Timer Mode

Table continues on the next page...

ENET_TCSR*n* field descriptions (continued)

Field	Description
	Updating the Timer Mode field takes a few cycles to register because it is synchronized to the 1588 clock. The version of Timer Mode returned on a read is from the 1588 clock domain. When changing Timer Mode, always disable the channel and read this register to verify the channel is disabled first. 0000 Timer Channel is disabled. 0001 Timer Channel is configured for Input Capture on rising edge. 0010 Timer Channel is configured for Input Capture on falling edge. 0011 Timer Channel is configured for Input Capture on both edges. 0100 Timer Channel is configured for Output Compare - software only. 0101 Timer Channel is configured for Output Compare - toggle output on compare. 0110 Timer Channel is configured for Output Compare - clear output on compare. 0111 Timer Channel is configured for Output Compare - set output on compare. 1000 Reserved 1010 Timer Channel is configured for Output Compare - clear output on compare, set output on overflow. 10X1 Timer Channel is configured for Output Compare - set output on compare, clear output on overflow. 110X Reserved 1110 Timer Channel is configured for Output Compare - pulse output low on compare for 1 to 32 1588-clock cycles as specified by TPWC. 1111 Timer Channel is configured for Output Compare - pulse output high on compare for 1 to 32 1588-clock cycles as specified by TPWC.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 TDRE	Timer DMA Request Enable 0 DMA request is disabled 1 DMA request is enabled

43.5.125 Timer Compare Capture Register (ENET_TCCR*n*)

Address: 0h base + 60Ch offset + (8d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	TCC																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_TCCR*n* field descriptions

Field	Description
0–31 TCC	Timer Capture Compare This register is double buffered between the module clock and 1588 clock domains. When configured for compare, the 1588 clock domain updates with the value in the module clock domain whenever the Timer Channel is first enabled and on each subsequent compare. Write to this register with the first compare value before enabling the Timer Channel. When the Timer Channel is enabled, write the second compare value either immediately, or at least before the first compare occurs. After each compare, write the next compare value before the previous compare occurs and before clearing the Timer Flag.

ENET_TCCR*n* field descriptions (continued)

Field	Description
	The compare occurs one 1588 clock cycle after the IEEE 1588 Counter increments past the compare value in the 1588 clock domain. If the compare value is less than the value of the 1588 Counter when the Timer Channel is first enabled, then the compare does not occur until following the next overflow of the 1588 Counter. If the compare value is greater than the IEEE 1588 Counter when the 1588 Counter overflows, or the compare value is less than the value of the IEEE 1588 Counter after the overflow, then the compare occurs one 1588 clock cycle following the overflow. When configured for capture, the value of the IEEE 1588 Counter is captured into the 1588 clock domain and then updated into the module clock domain, provided the Timer Flag is clear. Always read the capture value before clearing the Timer Flag. **NOTE:** TCC must fall within the following range: ENET_ATINC[INC] ≤ TCC ≤ (ENET_ATPER[PERIOD] – ENET_ATINC[INC])

43.6 Functional description

This section provides a complete functional description of the MAC-NET core.

43.6.1 Ethernet MAC frame formats

The IEEE 802.3 standard defines the Ethernet frame format as follows:

- Minimum length of 64 bytes
- Maximum length of 1518 bytes excluding the preamble and the start frame delimiter (SFD) bytes

An Ethernet frame consists of the following fields:

- Seven bytes preamble
- Start frame delimiter (SFD)
- Two address fields
- Length or type field
- Data field
- Frame check sequence (CRC value)

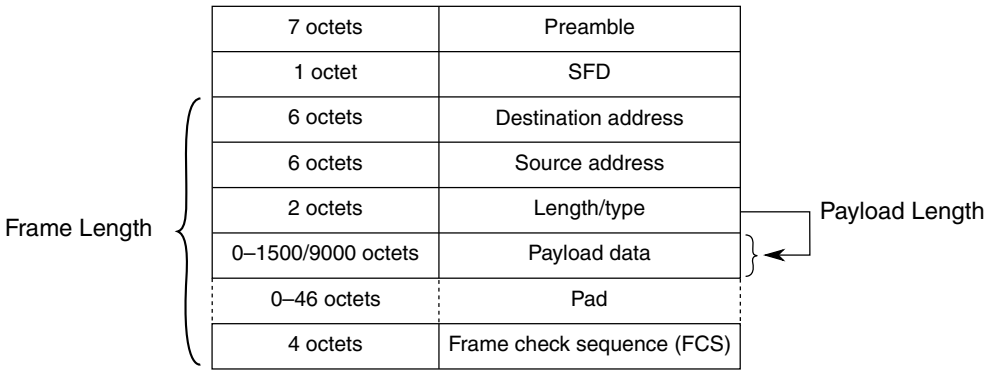

Figure 43-2. MAC frame format overview

Optionally, MAC frames can be VLAN-tagged with an additional four-byte field inserted between the MAC source address and the type/length field. VLAN tagging is defined by the IEEE P802.1q specification. VLAN-tagged frames have a maximum length of 1522 bytes, excluding the preamble and the SFD bytes.

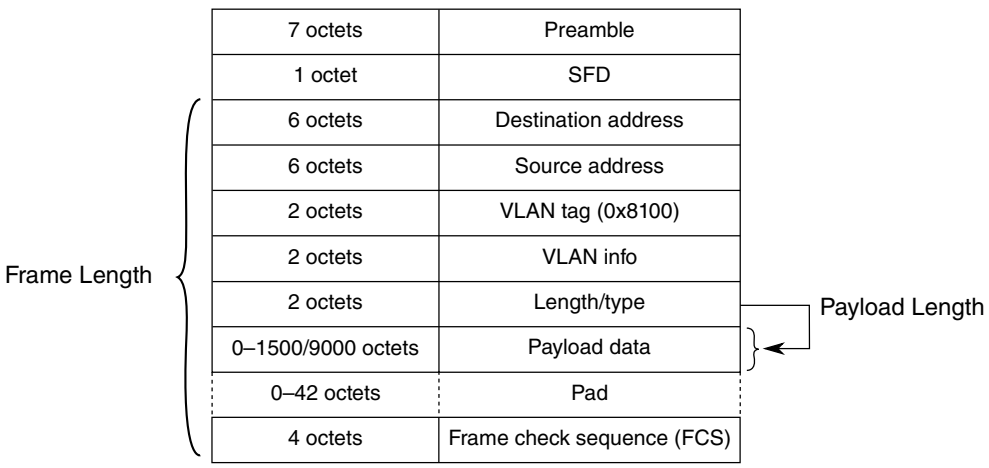

Figure 43-3. VLAN-tagged MAC frame format overview

Table 43-4. MAC frame definition

Term	Description
Frame length	Defines the length, in octets, of the complete frame without preamble and SFD. A frame has a valid length if it contains at least 64 octets and does not exceed the programmed maximum length.
Payload length	The length/type field indicates the length of the frame's payload section. The most significant byte is sent/received first. • If the length/type field is set to a value less than 46, the payload is padded so that the minimum frame length requirement (64 bytes) is met. For VLAN-tagged frames, a value less than 42 indicates a padded frame. • If the length/type field is set to a value larger than the programmed frame maximum length (e.g. 1518) it is interpreted as a type field.
Destination and source address	48-bit MAC addresses. The least significant byte is sent/received first and the first two least significant bits of the MAC address distinguish MAC frames, as detailed in MAC address check.

Note

Although the IEEE specification defines a maximum frame length, the MAC core provides the flexibility to program any value for the frame maximum length.

43.6.1.1 Pause Frames

The receiving device generates a pause frame to indicate a congestion to the emitting device, which should stop sending data.

Pause frames are indicated by the length/type set to 0x8808. The two first bytes of a pause frame following the type, defines a 16-bit opcode field set to 0x0001 always. A 16-bit pause quanta is defined in the frame payload bytes 2 (P1) and 3 (P2) as defined in the following table. The P1 pause quanta byte is the most significant.

Table 43-5. Pause Frame Format (Values in Hex)

1	2	3	4	5	6	7	8	9	10	11	12	13	14
55	55	55	55	55	55	55	D5	01	80	C2	00	00	01
Preamble							SFD	Multicast Destination Address					
15	16	17	18	19	20	21	22	23	24	25	26	27 –68	
00	00	00	00	00	00	88	08	00	01	hi	lo	00	
Source Address						Type		Opcode		P1	P2	pad (42)	
69	70	71	72										
26	6B	AE	0A										
CRC-32													

There is no payload length field found within a pause frame and a pause frame is always padded with 42 bytes (0x00).

If a pause frame with a pause value greater than zero (XOFF condition) is received, the MAC stops transmitting data as soon the current frame transfer is completed. The MAC stops transmitting data for the value defined in pause quanta. One pause quanta fraction refers to 512 bit times.

If a pause frame with a pause value of zero (XON condition) is received, the transmitter is allowed to send data immediately (see Full-duplex flow control operation for details).

43.6.1.2 Magic packets

A magic packet is a unicast, multicast, or broadcast packet, which carries a defined sequence in the payload section.

Magic packets are received and inspected only under specific conditions as described in Magic packet detection.

The defined sequence to decode a magic packet is formed with a synchronization stream which consists of six consecutive 0xFF bytes, and is followed by sequence of sixteen consecutive unicast MAC addresses of the node to be awakened.

This sequence can be located anywhere in the magic packet payload. The magic packet is formed with a standard Ethernet header, optional padding, and CRC.

43.6.2 IP and higher layers frame format

The following sections use the term datagram to describe the protocol specific data unit that is found within the payload section of its container entity.

For example, an IP datagram specifies the payload section of an Ethernet frame. A TCP datagram specifies the payload section within an IP datagram.

43.6.2.1 Ethernet types

IP datagrams are carried in the payload section of an Ethernet frame. The Ethernet frame type/length field discriminates several datagram types.

The following table lists the types of interest:

Table 43-6. Ethernet type value examples

Type	Description
0x8100	VLAN-tagged frame. The actual type is found 4 octets later in the frame.
0x0800	IPv4
0x0806	ARP
0x86DD	IPv6

43.6.2.2 IPv4 datagram format

The following figure shows the IP Version 4 (IPv4) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words. The first byte sent/received is the leftmost byte of the first word (in other words, version/IHL field).

The IP header can contain further options, which are always padded if necessary to guarantee the payload following the header is aligned to a 32-bit boundary.

The IP header is immediately followed by the payload, which can contain further protocol headers (for example, TCP or UDP, as indicated by the protocol field value). The complete IP datagram is transported in the payload section of an Ethernet frame.

Table 43-7. IPv4 header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Version	IHL	TOS		Length			
Fragment ID				Flags	Fragment offset		
TTL		Protocol		Header checksum			
Source address							
Destination address							
Options							

Table 43-8. IPv4 header fields

Field name	Description
Version	4-bit IP version information. 0x4 for IPv4 frames.
IHL	4-bit Internet header length information. Determines number of 32-bit words found within the IP header. If no options are present, the default value is 0x5.
TOS	Type of service/DiffServ field.
Length	Total length of the datagram in bytes, including all octets of header and payload.
Fragment ID, flags, fragment offset	Fields used for IP fragmentation.
TTL	Time-to-live. In effect, is decremented at each router arrival. If zero, datagram must be discarded.
Protocol	Identifier of protocol that follows in the datagram.
Header checksum	Checksum of IP header. For computational purposes, this field's value is zero.
Source address	Source IP address.
Destination address	Destination IP address.

43.6.2.3 IPv6 datagram format

The following figure shows the IP version 6 (IPv6) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words and has a fixed length of ten words (40 bytes). The next header field identifies the type of the header that follows the IPv6 header. It is defined similar to the protocol identifier within IPv4, with new definitions for identifying extension headers. These headers can be inserted between the IPv6 header and the protocol header, which will shift the protocol header accordingly.The accelerator currently only supports IPv6 without extension headers (in other words, the next header specifies TCP, UDP, or IMCP).

The first byte sent/received is the leftmost byte of the first word (in other words, version/ traffic class fields).

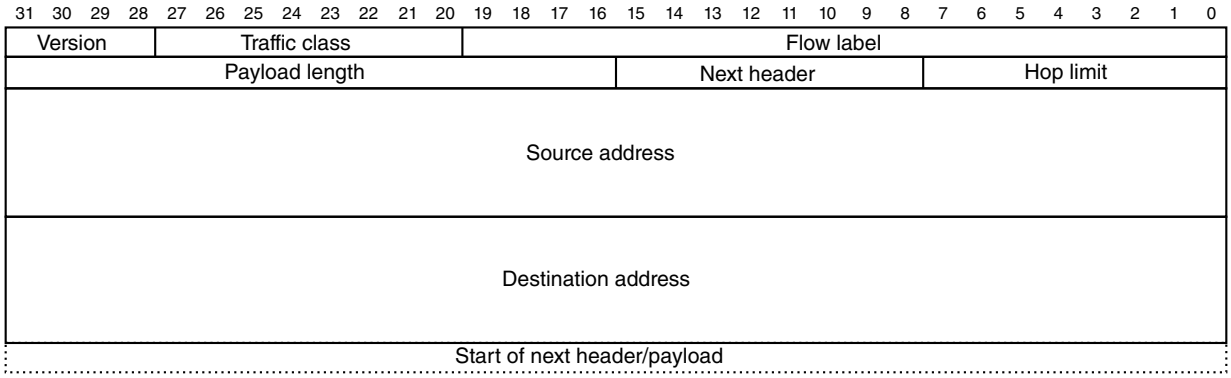

Figure 43-4. IPv6 header format

Table 43-9. IPv6 header fields

Field name	Description
Version	4-bit IP version information. 0x6 for all IPv6 frames.
Traffic class	8-bit field defining the traffic class.
Flow label	20-bit flow label identifying frames of the same flow.
Payload length	16-bit length of the datagram payload in bytes. It includes all octets following the IPv6 header.
Next header	Identifies the header that follows the IPv6 header. This can be the protocol header or any IPv6 defined extension header.
Hop limit	Hop counter, decremented by one by each station that forwards the frame. If hop limit is 0 the frame must be discarded.
Source address	128-bit IPv6 source address.
Destination address	128-bit IPv6 destination address.

43.6.2.4 Internet Control Message Protocol (ICMP) datagram format

An internet control message protocol (ICMP) is found following the IP header, if the protocol identifier is 1. The ICMP datagram has a four-octet header followed by additional message data.

Table 43-10. ICMP header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Type		Code		Checksum			
ICMP message data							

Table 43-11. IP header fields

Field name	Description
Type	8-bit type information
Code	8-bit code that is related to the message type
Checksum	16-bit one's complement checksum over the complete ICMP datagram

43.6.2.5 User Datagram Protocol (UDP) datagram format

A user datagram protocol header is found after the IP header, when the protocol identifier is 17.

The payload of the datagram is after the UDP header. The header byte order follows the conventions given for the IP header above.

Table 43-12. UDP header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source port				Destination port			
Length				Checksum			

Table 43-13. UDP header fields

Field name	Description
Source port	Source application port
Destination port	Destination application port
Length	Length of user data which immediately follows the header, including the UDP header (that is, minimum value is 8)
Checksum	Checksum over the complete datagram and some IP header information

43.6.2.6 TCP datagram format

A TCP header is found following the IP header, when the protocol identifier has a value of 6.

The TCP payload immediately follows the TCP header.

Table 43-14. TCP header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0

Sequence number	Transmit sequence number
Ack. number	Receive sequence number
Offset	Data offset, which is number of 32-bit words within TCP header — if no options selected, defaults to value of 5
Flags	URG, ACK, PSH, RST, SYN, FIN flags
Window	TCP receive window size information
Checksum	Checksum over the complete datagram (TCP header and data) and IP header information
Options	Additional 32-bit words for protocol options

43.6.3 IEEE 1588 message formats

The following sections describe the IEEE 1588 message formats.

43.6.3.1 Transport encapsulation

The precision time protocol (PTP) datagrams are encapsulated in Ethernet frames using the UDP/IP transport mechanism, or optionally, with the newer 1588v2 directly in Ethernet frames (layer 2).

Typically, multicast addresses are used to allow efficient distribution of the synchronization messages.

43.6.3.1.1 UDP/IP

The 1588 messages (v1 and v2) can be transported using UDP/IP multicast messages.

Table 43-16 shows IP multicast groups defined for PTP. The table also shows their respective MAC layer multicast address mapping according to RFC 1112 (last three octets of IP follow the fixed value of 01-00-5E).

Table 43-16. UDP/IP multicast domains

Name	IP Address	MAC Address mapping
DefaultPTPdomain	224.0.1.129	01-00-5E-00-01-81
AlternatePTPdomain1	224.0.1.130	01-00-5E-00-01-82
AlternatePTPdomain2	224.0.1.131	01-00-5E-00-01-83
AlternatePTPdomain3	224.0.1.132	01-00-5E-00-01-84

Table 43-17. UDP port numbers

Message type	UDP port	Note
Event	319	Used for SYNC and DELAY_REQUEST messages
General	320	All other messages (for example, follow-up, delay-response)

43.6.3.1.2 Native Ethernet (PTPv2)

In addition to using UDP/IP frames, IEEE 1588v2 defines a native Ethernet frame format that uses ethertype = 0x88F7. The payload of the Ethernet frame immediately contains the PTP datagram, starting with the PTPv2 header.

Besides others, version 2 adds a peer delay mechanism to allow delay measurements between individual point-to-point links along a path over multiple nodes. The following multicast domains are also defined in PTPv2.

Table 43-18. PTPv2 multicast domains

Name	MAC address
Normal messages	01-1B-19-00-00-00
Peer delay messages	01-80-C2-00-00-0E

43.6.3.2 PTP header

All PTP frames contain a common header that determines the protocol version and the type of message, which defines the remaining content of the message.

All multi-octet fields are transmitted in big-endian order (the most significant byte is transmitted/received first).

The last four bits of versionPTP are at the same position (second byte) for PTPv1 and PTPv2 headers. This allows accurate identification by inspecting the first two bytes of the message.

43.6.3.2.1 PTPv1 header

Table 43-19. Common PTPv1 message header

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	2	versionPTP = 0x0001							
2	2	versionNetwork							
4	16	subdomain							
20	1	messageType							
21	1	sourceCommunicationTechnology							
22	6	sourceUuid							
28	2	sourcePortId							
30	2	sequenceId							
32	1	control							
33	1	0x00							
34	2	flags							
36	4	reserved							

The type of message is encoded in the messageType and control fields as shown in Table 43-20 :

Table 43-20. PTPv1 message type identification

messageType	control	Message Name	Message
0x01	0x0	SYNC	Event message
0x01	0x1	DELAY_REQ	Event message
0x02	0x2	FOLLOW_UP	General message
0x02	0x3	DELAY_RESP	General message
0x02	0x4	MANAGEMENT	General message
other	other	—	Reserved

The field sequenceId is used to non-ambiguously identify a message.

43.6.3.2.2 PTPv2 header

Table 43-21. Common PTPv2 message header

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	1	transportSpecific				messageId			
1	1	reserved				versionPTP = 0x2			
2	2	messageLength							
4	1	domainNumber							
5	1	reserved							
6	2	flags							
8	8	correctionField							
16	4	reserved							
20	10	sourcePortIdentity							
30	2	sequenceId							
32	1	control							
33	1	logMeanMessageInterval							

The type of message is encoded in the field messageId as follows:

Table 43-22. PTPv2 message type identification

messageId	Message name	Message
0x0	SYNC	Event message
0x1	DELAY_REQ	Event message
0x2	PATH_DELAY_REQ	Event message
0x3	PATH_DELAY_RESP	Event message
0x4–0x7	—	Reserved
0x8	FOLLOW_UP	General message
0x9	DELAY_RESP	General message
0xa	PATH_DELAY_FOLLOW_UP	General message
0xb	ANNOUNCE	General message
0xc	SIGNALING	General message
0xd	MANAGEMENT	General message

The PTPv2 flags field contains further details on the type of message, especially if one-step or two-step implementations are used. The one- or two-step implementation is controlled by the TWO_STEP bit in the first octet of the flags field as shown below. Reserved bits are cleared.

Table 43-23. PTPv2 message flags field definitions

Bit	Name	Description
0	ALTERNATE_MASTER	See IEEE 1588 Clause 17.4
1	TWO_STEP	1 Two-step clock 0 One-step clock
2	UNICAST	1 Transport layer address uses a unicast destination address 0 Multicast is used
3	—	Reserved
4	—	Reserved
5	Profile specific	
6	Profile specific	
7	—	Reserved

43.6.4 MAC receive

The MAC receive engine performs the following tasks:

- Check frame framing
- Remove frame preamble and frame SFD field
- Discard frame based on frame destination address field
- Terminate pause frames
- Check frame length
- Remove payload padding if it exists
- Calculate and verify CRC-32
- Write received frames in the core receive FIFO

If the MAC is programmed to operate in half-duplex mode, it will also check if the frame is received with a collision.

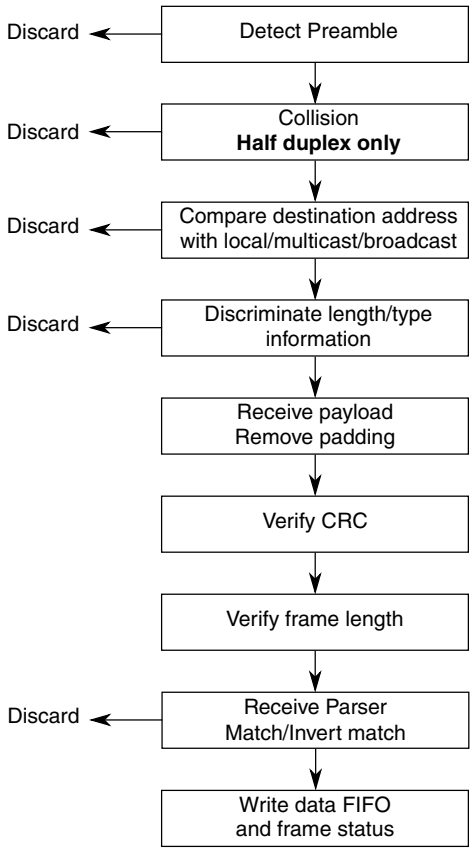

Figure 43-5. MAC receive flow

43.6.4.1 Collision detection in half-duplex mode

If the packet is received with a collision detected during reception of the first 64 bytes, the packet is discarded (if frame size was less than ~14 octets) or transmitted to the user application with an error and RxBD[CE] set.

43.6.4.2 Preamble processing

The IEEE 802.3 standard allows a maximum size of 56 bits (seven bytes) for the preamble, while the MAC core allows any preamble length, including zero length preamble.

The MAC core checks for the start frame delimiter (SFD) byte. If the next byte of the preamble, which is different from 0x55, is not 0xD5, the frame is discarded.

Although the IEEE specification dictates that the inner-packet gap should be at least 96 bits, the MAC core is designed to accept frames separated by only 64 10/100-Mbit/s operation (MII) bits.

The MAC core removes the preamble and SFD bytes.

43.6.4.3 MAC address check

The destination address bit 0 differentiates between multicast and unicast addresses.

- If bit 0 is 0, the MAC address is an individual (unicast) address.
- If bit 0 is 1, the MAC address defines a group (multicast) address.
- If all 48 bits of the MAC address are set, it indicates a broadcast address.

43.6.4.3.1 Unicast address check

If a unicast address is received, the destination MAC address is compared to the node MAC address programmed by the host in the PADDR1/2 registers.

If the destination address matches any of the programmed MAC addresses, the frame is accepted.

If Promiscuous mode is enabled (RCR[PROM] = 1) no address checking is performed and all unicast frames are accepted.

43.6.4.3.2 Multicast and unicast address resolution

The hash table algorithm used in the group and individual hash filtering operates as follows.

- The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits in ENET*n*_GAUR/GALR (group address hash match) or ENET*n*_IAUR/IALR (individual address hash match).
- This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63.
- The msb of the CRC result selects ENET*n*_GAUR (msb = 1) or ENET*n*_GALR (msb = 0).
- The five lsbs of the hash result select the bit within the selected register.
- If the CRC generator selects a bit set in the hash table, the frame is accepted; else, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (or 87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + 1$

If Promiscuous mode is enabled (ENET*n*_RCR[PROM] = 1) all unicast and multicast frames are accepted regardless of ENET*n*_GAUR/GALR and ENET*n*_IAUR/IALR settings.

43.6.4.3.3 Broadcast address reject

All broadcast frames are accepted if BC_REJ is cleared or ENET*n*_RCR[PROM] is set. If PROM is cleared when ENET*n*_RCR[BC_REJ] is set, all broadcast frames are rejected.

Table 43-24. Broadcast address reject programming

PROM	BC_REJ	Broadcast frames
0	0	Accepted
0	1	Rejected
1	0	Accepted
1	1	Accepted

43.6.4.3.4 Miss-bit implementation

For higher layer filtering purposes, RxBD[M] indicates an address miss when the MAC operates in promiscuous mode and accepts a frame that would otherwise be rejected.

If a group/individual hash or exact match does not occur and Promiscuous mode is enabled (RCR[PROM] = 1), the frame is accepted and the M bit is set in the buffer descriptor; otherwise, the frame is rejected.

This means the status bit is set in any of the following conditions during Promiscuous mode:

- A broadcast frame is received when BC_REJ is set

- A unicast is received that does not match either:
  - Node address (PALR[PADDR1] and PAUR[PADDR2])
  - Hash table for unicast (IAUR[IADDR1] and IALR[IADDR2])
- A multicast is received that does not match the GAUR[GADDR1] and GALR[GADDR2] hash table entries

43.6.4.4 Frame length/type verification: payload length check

If the length/type is less than 0x600 and NLC is set, the MAC checks the payload length and reports any error in the frame status word and interrupt bit PLR.

If the length/type is greater than or equal to 0x600, the MAC interprets the field as a type and no payload length check is performed.

The length check is performed on VLAN and stacked VLAN frames. If a padded frame is received, no length check can be performed due to the extended frame payload because padded frames can never have a payload length error.

43.6.4.5 Frame length/type verification: frame length check

When the receive frame length exceeds MAX_FL bytes, the BABR interrupt is generated and the RxBD[LG] bit is set.

The frame is not truncated unless the frame length exceeds the value programmed in ENET*n*_FTRL[TRUNC_FL]. If the frame is truncated, RxBD[TR] is set. In addition, a truncated frame always has the CRC error indication set (RxBD[CR]).

43.6.4.6 VLAN frames processing

VLAN frames have a length/type field set to 0x8100 immediately followed by a 16-Bit VLAN control information field.

VLAN-tagged frames are received as normal frames because the VLAN tag is not interpreted by the MAC function, and are pushed complete with the VLAN tag to the user application. If the length/type field of the VLAN-tagged frame, which is found four octets later in the frame, is less than 42, the padding is removed. In addition, the frame status word (RxBD[NO]) indicates that the current frame is VLAN tagged.

43.6.4.7 Pause frame termination

The receive engine terminates pause frames and does not transfer them to the receive FIFO. The quanta is extracted and sent to the MAC transmit path via a small internal clock rate decoupling asynchronous FIFO.

The quanta is written only if a correct CRC and frame length are detected by the control state machine. If not, the quanta is discarded and the MAC transmit path is not paused.

Good pause frames are ignored if ENET*n*_RCR[FCE] is cleared and are forwarded to the client interface when ENET*n*_RCR[PAUFWD] is set.

43.6.4.8 CRC check

The CRC-32 field is checked and forwarded to the core FIFO interface if ENET*n*_RCR[CRCFWD] is cleared and ENET*n*_RCR[PADEN] is set.

When CRCFWD is set (regardless of PADEN), the CRC-32 field is checked and terminated (not transmitted to the FIFO).

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + 1$

The 32 bits of the CRC value are placed in the frame check sequence (FCS) field with the x^{31} term as right-most bit of the first octet. The CRC bits are thus received in the following order: x^{31}, x^{30},..., x^{1}, x^{0}.

If a CRC error is detected, the frame is marked invalid and RxBD[CR] is set.

43.6.4.9 Frame padding removal

When a frame is received with a payload length field set to less than 46 (42 for VLAN-tagged frames and 38 for frames with stacked VLANs), the zero padding can be removed before the frame is written into the data FIFO depending on the setting of ENET*n*_RCR[PADEN].

Note

If a frame is received with excess padding (in other words, the length field is set as mentioned above, but the frame has more than 64 octets) and padding removal is enabled, then the

padding is removed as normal and no error is reported if the frame is otherwise correct (for example: good CRC, less than maximum length, and no other error).

43.6.4.10 Frame classification (AVB)

To support protocols such as Audio Video Bridging (AVB, IEEE 802.1Qav), normal traffic is separated from time-sensitive traffic immediately at the application interface to allow storing them in different queues for further processing. For every frame received, a classification based on VLAN priority can be performed. When a frame is received, and it contains a VLAN tag, the priority is compared against the values set in the classification match registers (see Receive Classification Match Register for Class n (ENET_RCMR*n*)) and the following figure.

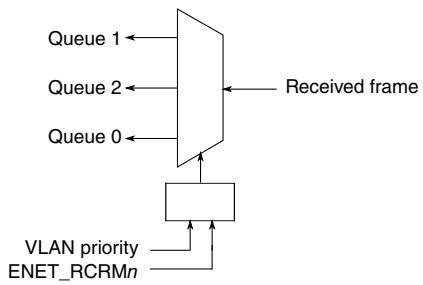

Figure 43-6. AVB frame classification

43.6.4.11 Frame parser

Ethernet frame pattern matching is used on receive frame to finally accept or reject the frame. When a frame is accepted, it is placed into a queue/ring depending on the matching entry configuration.

A matching entry table is implemented with a 96-bit pattern defined for each entry. A 96-bit pattern is separated into three 32-bit registers:

- MDATA: Data to be compared with the incoming frame. Data bits are used with the combination of mask bits.
- MMASK: Data bit within the MDATA will be used for comparison only when corresponding mask bit is set to 1.
- MCONFIG: Rule set for matching the data with incoming frame. See Match Entry Rules Configuration Register (ENET_MCONFIG) for more details.

The number of valid entries within the table can be defined through the RXPCTL register.

Initialize the entire parser memory to zero before creating entries in parser entry table.

Steps to write an entry within the matching entry table:

- Write the match registers MDATA, MMASK, and MCONFIG registers with desired configuration for the entry.
- Write the MENTRYRW register with the ENTRY_ADDRESS field as the table entry location and setting the WR field to 1.
- Wait until MENTRYRW[WR] is automatically cleared to 0 . When WR is cleared, write access is completed and table is ready for next read/write access.

Steps to read an entry from the matching entry table:

- Write the MENTRYRW register with the ENTRY_ADDRESS field as the table entry location and setting the RD field to 1.
- Wait until MENTRYRW[RD] is automatically cleared to 0. When RD is cleared, the 96-bit pattern is available and ready for reading from the registers MDATA, MMASK, and MCONFIG.
- Read the registers MDATA, MMASK, and MCONFIG.

Each pattern within the Match Entry table is compared sequentially starting from entry index0 with the incoming frame for match or invert match when the MCONFIG[AF] or MCONFIG[RF] field for that entry is non-zero. If match or invert match occurs for that entry and MCONFIG[AF] is set, the frame is accepted and placed into the queue defined by the MCONFIG[OK_INDEX] for that entry. The frame is rejected and EIR[PARSRF] is asserted when MCONFIG[RF] is set for that matching or invert-matching entry. See interrupt1 in following flowchart. When both MCONFIG[AF] and MCONFIG[RF] of the match entry is 0, the entry index of the table jumps to the index defined by MCONFIG[OK_INDEX] for the current entry.

When all entries are checked and no match or invert match is found or a parser programming error for that entry is found, EIR[PARSERR] is set to 1. See interrupt2 in the following flowchart.

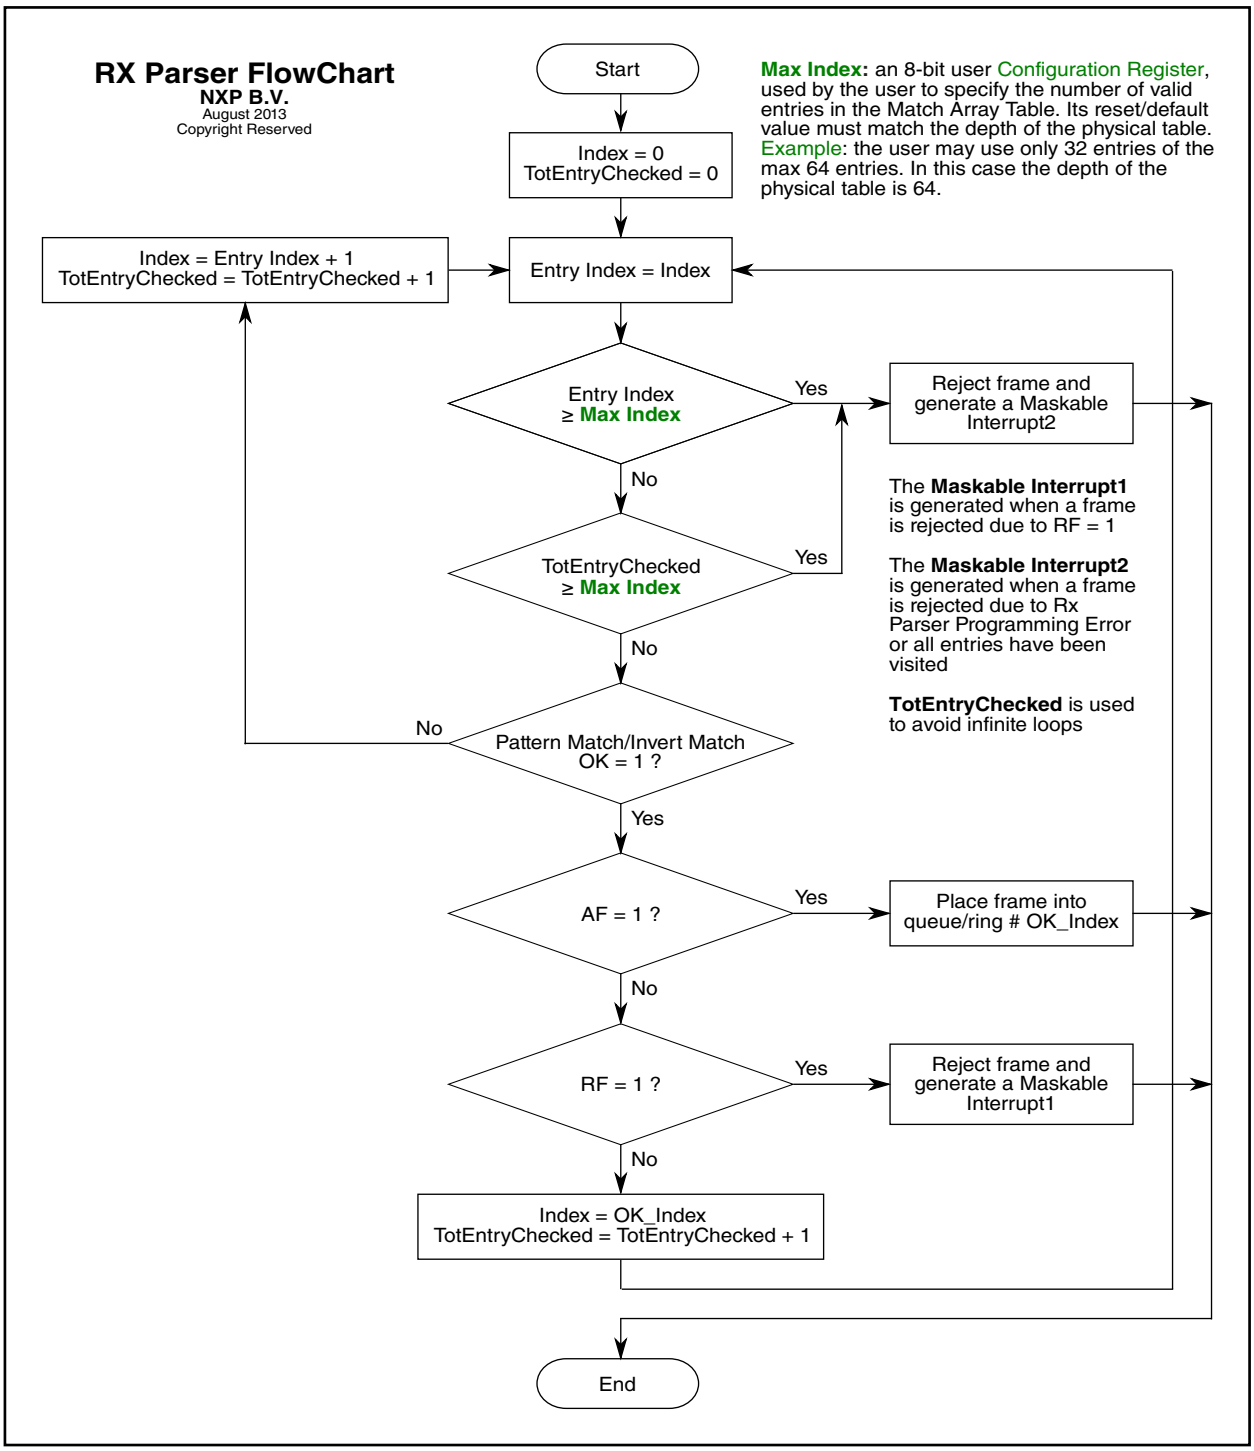

Figure 43-7. Receive parser flowchart

43.6.4.12 Receive flushing

RX flushing prevents frames in the RX FIFO from being blocked. Blocking can occur if the frame at the head of the RX FIFO cannot be forwarded because the ring it is associated with cannot accept it. This situation occurs when either the ring's RxBD[EMPTY] is not set or ENET_RDAR*n* is not set. When RX flushing is enabled, via QOS Scheme (ENET_QOS), the blocking frame will be flushed (discarded).

43.6.5 MAC transmit

Frame transmission starts when the transmit FIFO holds enough data.

After a transfer starts, the MAC transmit function performs the following tasks:

- Generates preamble and SFD field before frame transmission
- Generates XOFF pause frames if the receive FIFO reports a congestion or if ENET*n*_TCR[TFC_PAUSE] is set with ENET*n*_OPD[PAUSE_DUR] set to a non-zero value
- Generates XON pause frames if the receive FIFO congestion condition is cleared or if TFC_PAUSE is set with PAUSE_DUR cleared
- Suspends Ethernet frame transfer (XOFF) if a non-zero pause quanta is received from the MAC receive path
- Adds padding to the frame if required
- Calculates and appends CRC-32 to the transmitted frame
- Sends the frame with correct inter-packet gap (IPG) (deferring)

When the MAC is configured to operate in half-duplex mode, the following additional tasks are performed:

- Collision detection
- Frame retransmit after back-off timer expires

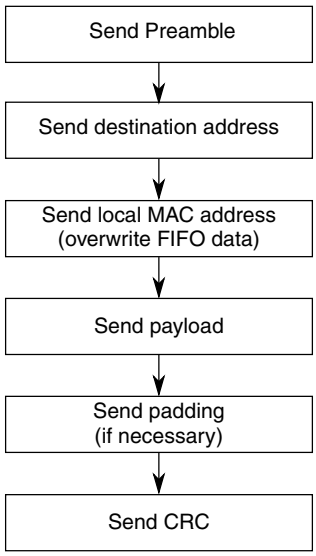

Figure 43-8. Frame transmit overview

43.6.5.1 Frame payload padding

The IEEE specification defines a minimum frame length of 64 bytes.

If the frame sent to the MAC from the user application has a size smaller than 60 bytes, the MAC automatically adds padding bytes (0x00) to comply with the Ethernet minimum frame length specification. Transmit padding is always performed and cannot be disabled.

If the MAC is not allowed to append a CRC (TxBD[TC] = 1), the user application is responsible for providing frames with a minimum length of 64 octets.

43.6.5.2 MAC address insertion

On each frame received from the core transmit FIFO interface, the source MAC address is either:

- Replaced by the address programmed in the PADDR1/2 fields (ENET*n*_TCR[ADDINS] = 1)
- Transparently forwarded to the Ethernet line (ENET*n*_TCR[ADDINS] = 0)

43.6.5.3 CRC-32 generation

The CRC-32 field is optionally generated and appended at the end of a frame.

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + 1$

The 32 bits of the CRC value are placed in the FCS field so that the x^{31} term is the right-most bit of the first octet. The CRC bits are thus transmitted in the following order: x^{31}, x^{30},..., x^{1}, x^{0}.

43.6.5.4 Inter-packet gap (IPG)

In full-duplex mode, after frame transmission and before transmission of a new frame, an IPG (programmed in ENET*n*_TIPG) is maintained. The minimum IPG can be programmed between 8 and 26 byte-times (64 and 208 bit-times).

In half-duplex mode, the core constantly monitors the line. Actual transmission of the data onto the network occurs only if it has been idle for a 96-bit time period, and any back-off time requirements have been satisfied. In accordance with the standard, the core begins to measure the IPG from CRS de-assertion.

43.6.5.5 Collision detection and handling — half-duplex operation only

A collision occurs on a half-duplex network when concurrent transmissions from two or more nodes take place. During transmission, the core monitors the line condition and detects a collision when the PHY device asserts COL.

When the core detects a collision while transmitting, it stops transmission of the data and transmits a 32-bit jam pattern. If the collision is detected during the preamble or the SFD transmission, the jam pattern is transmitted after completing the SFD, which results in a minimum 96-bit fragment. The jam pattern is a fixed pattern that is not compared to the actual frame CRC, and has a very low probability (0.532) of having a jam pattern identical to the CRC.

If a collision occurs before transmission of 64 bytes (including preamble and SFD), the MAC core waits for the backoff period and retransmits the packet data (stored in a 64-byte re-transmit buffer) that has already been sent on the line. The backoff period is generated from a pseudo-random process (truncated binary exponential backoff).

If a collision occurs after transmission of 64 bytes (including preamble and SFD), the MAC discards the remainder of the frame, optionally sets the LC interrupt bit, and sets TxBD[LCE].

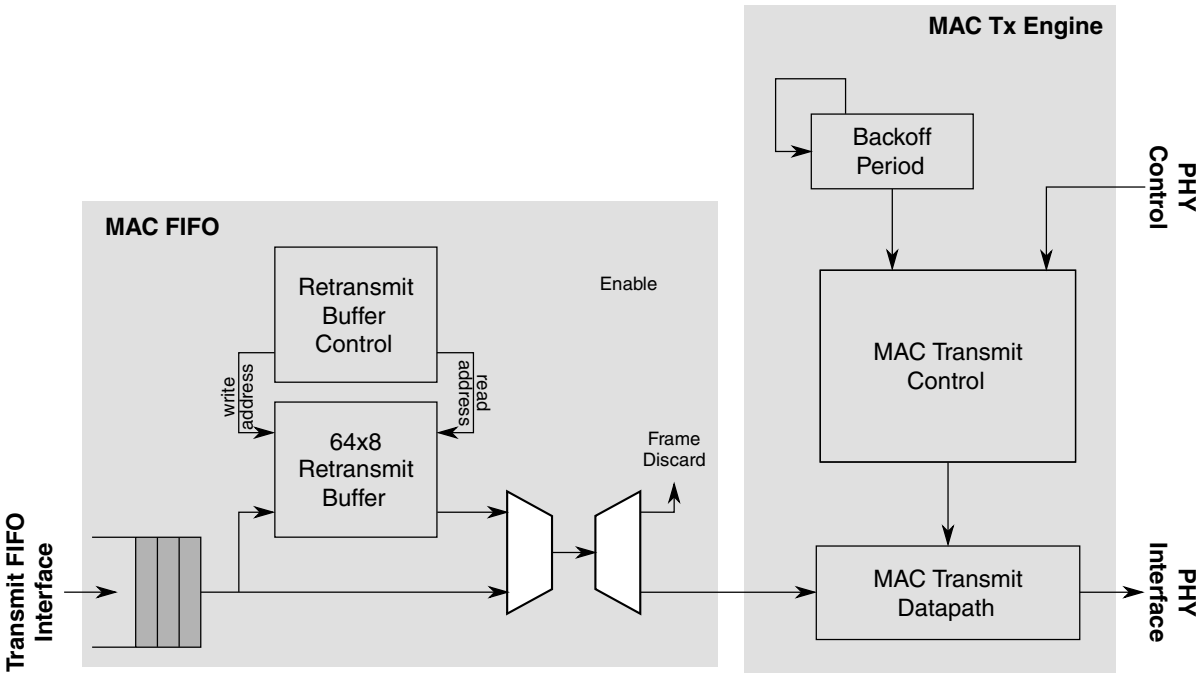

Figure 43-9. Packet re-transmit overview

The backoff time is represented by an integer multiple of slot times. One slot is equal to a 512-bit time period. The number of the delay slot times, before the n^{th} re-transmission attempt, is chosen as a uniformly-distributed random integer in the range:

- $0 < r < 2^k$
- $k = \min(n, N)$; where n is the number of retransmissions and $N = 10$

For example, after the first collision, the backoff period is 0 or 1 slot time. If a collision occurs on the first retransmission, the backoff period is 0, 1, 2, or 3, and so on.

The maximum backoff time (in 512-bit time slots) is limited by N = 10 as specified in the IEEE 802.3 standard.

If a collision occurs after 16 consecutive retransmissions, the core reports an excessive collision condition (ENET*n*_EIR[RL] interrupt field and TxBD[EE]) and discards the current packet from the FIFO.

In networks violating the standard requirements, a collision may occur after transmission of the first 64 bytes. In this case, the core stops the current packet transmission and discards the rest of the packet from the transmit FIFO. The core resumes transmission with the next packet available in the core transmit FIFO.

warning

Ethernet PHYs that support the SQE Test, or "heartbeat,"
feature must disable this feature. When this feature is enabled,

the PHY asserts the collision signal after a frame is transmitted to indicate to the ENET that the PHY's collision logic is working. This may cause data corruption in the next frame from the ENET. This corrupted frame contains up to 21 zero bytes which start somewhere within the MAC destination address field. The ENET, however, will still generate a good FCS (CRC-32) but with corrupted data.

43.6.5.6 Rate limiting / traffic shaping support

The MAC-NET supports two methods to optimize frame traffic for either time-sensitive AVB frames (Class A and Class B) or best-effort non-AVB frames:

- Round-robin scheme
- Credit-based traffic shaping

To ensure that sufficient bandwidth is allocated for the AVB frames, the credit-based shaper must be used. Either method can be combined with a time-based shaper to ensure that a frame is always transmitted in its correct time slot.

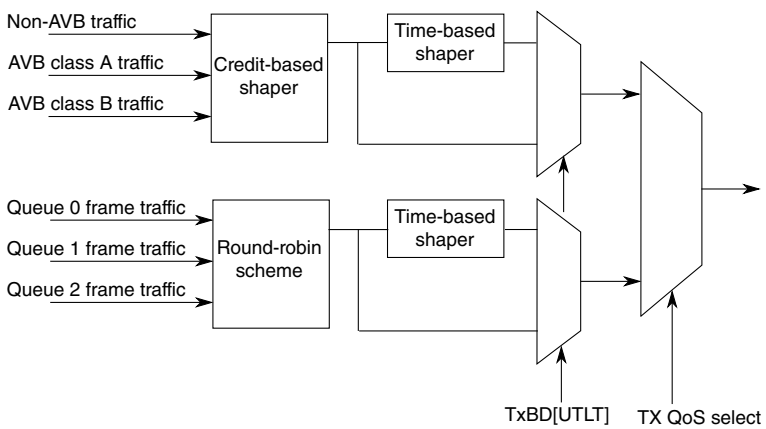

Figure 43-10. Transmit arbitration schemes

43.6.5.6.1 Round-robin policy

In the round-robin QoS scheme, each queue is given an equal opportunity to transmit one frame. For example, if queue *n* has a frame to transmit, the queue transmits its frame. After queue *n* has transmitted its frame, or if queue *n* does not have a frame to transmit, queue *n*+1 is then allowed to transmit its frame, and so on.

43.6.5.6.2 Credit-based shaper

The AVB credit based shaper acts independently, per class, to control the bandwidth distribution between normal traffic and time-sensitive traffic with respect to the total link bandwidth available. As per the IEEE 802.1Q, the maximum bandwidth distribution that can be allocated for the time-sensitive frames is 75%. The following example uses 70% for AVB frames and 30% for non-AVB frames:

Table 43-25. Bandwidth allocation example

AVB Class A	50%
AVB Class B	20%
non-AVB frames	30%
Total	100%

See DMA Class Based Configuration (ENET_DMA*n*CFG) for information on how to allocate bandwidth. The following figure shows how frame traffic is controlled within the MAC-NET core.

43.6.5.6.3 Time-based shaper

The time-based shaper enables the user to specify when a frame can be transmitted. It is always used in combination with either the round-robin scheme or the credit-based shaper. Use of the time-based shaper can ensure that frames are always transmitted in the correct time slot.

43.6.5.6.3.1 Time-based shaper example

Time-based shaping involves the following procedure:

1. Read the current value of the timer. See Timer Value Register (ENET_ATVR) and Adjustable Timer Control Register (ENET_ATCR).
2. Calculate the frame launch time and write this value to the TLT field of the frame's TxBD. See Enhanced transmit buffer descriptor.
3. Instruct the ENET to use the TLT by setting TxBD[UTLT].

The frame will be fetched and transmitted only if TxBD[TLT] is less than the current value of the timer. In other words, the timer must be past, that is, be greater than, the transmit launch time before the frame will be fetched and transmitted.

The transmit launch time must be not be greater than the current value of ENET_ATVR + (0.5 × ENET_ATPER). This means the application can not prepare frames with launch times beyond ENET_ATVR + (0.5 × ENET_ATPER). Because ENET_ATVR wraps, calculate TLT using the equation

$$(ENET_ATVR + (0.5 \times ENET_ATPER)) \bmod ENET_ATPER$$

For example, if ENET_ATPER is set to the recommended value of 1,000,000,000 ns (one second), then the user must not prepare future frames with launch times greater than (500,000,000 + ENET_ATVR).

As a specific example, if the current value of ENET_ATVR is 100,000, then you can prepare the following frames:

1. Frame 1 TxBD[TLT] = 100,000ns + 125,000ns
2. Frame 2 TxBD[TLT] = 100,000ns + 250,000ns
3. And so on

43.6.6 Full-duplex flow control operation

Three conditions are handled by the core's flow control engine:

- Remote device congestion — The remote device connected to the same Ethernet segment as the core reports congestion and requests that the core stop sending data.
- Core FIFO congestion — When the core's receive FIFO reaches a user-programmable threshold (RX section empty), the core sends a pause frame back to the remote device requesting the data transfer to stop.
- Local device congestion — Any device connected to the core can request (typically, via the host processor) the remote device to stop transmitting data.

43.6.6.1 Remote device congestion

When the MAC transmit control gets a valid pause quanta from the receive path and if ENET*n*_RCR[FCE] is set, the MAC transmit logic:

- Completes the transfer of the current frame.
- Stops sending data for the amount of time specified by the pause quanta in 512 bit time increments.
- Sets ENET*n*_TCR[RFC_PAUSE].

Frame transfer resumes when the time specified by the quanta expires and if no new quanta value is received, or if a new pause frame with a quanta value set to 0x0000 is received. The MAC also resets RFC_PAUSE to zero.

If ENET*n*_RCR[FCE] cleared, the MAC ignores received pause frames.

Optionally and independent of ENET*n*_RCR[FCE], pause frames are forwarded to the client interface if PAUFWD is set.

43.6.6.2 Local device/FIFO congestion

The MAC transmit engine generates pause frames when the local receive FIFO is not able to receive more than a pre-defined number of words (FIFO programmable threshold) or when pause frame generation is requested by the local host processor.

- To generate a pause frame, the host processor sets ENET*n*_TCR[TFC_PAUSE]. A single pause frame is generated when the current frame transfer is completed and TFC_PAUSE is automatically cleared. Optionally, an interrupt is generated.
- An XOFF pause frame is generated when the receive FIFO asserts its section empty flag (internal). An XOFF pause frame is generated automatically, when the current frame transfer completes.
- An XON pause frame is generated when the receive FIFO deasserts its section empty flag (internal). An XON pause frame is generated automatically, when the current frame transfer completes.

When an XOFF pause frame is generated, the pause quanta (payload byte P1 and P2) is filled with the value programmed in ENET*n*_OPD[PAUSE_DUR].

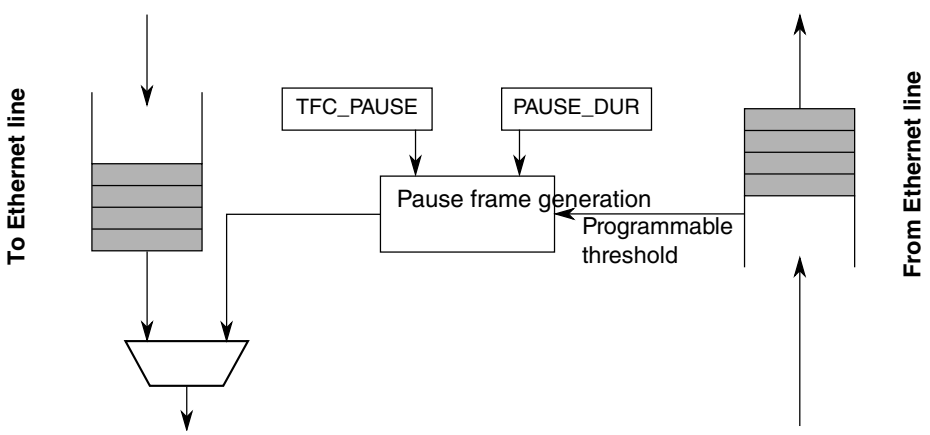

Figure 43-11. Pause frame generation overview

Note

Although the flow control mechanism should prevent any FIFO overflow on the MAC core receive path, the core receive FIFO is protected. When an overflow is detected on the receive FIFO,

the current frame is truncated with an error indication set in the frame status word. The frame should subsequently be discarded by the user application.

43.6.7 Magic packet detection

Magic packet detection wakes a node that is put in power-down mode by the node management agent. Magic packet detection is supported only if the MAC is configured in sleep mode.

43.6.7.1 Sleep mode

To put the MAC in Sleep mode, set ENET*n*_ECR[SLEEP]. At the same time ENET*n*_ECR[MAGICEN] should also be set to enable magic packet detection.

In addition, when the processor is in Stop mode, Sleep mode is entered, without affecting the ENET*n*_ECR register bits.

When the MAC is in Sleep mode:

- The transmit logic is disabled.
- The FIFO receive/transmit functions are disabled.
- The receive logic is kept in Normal mode, but it ignores all traffic from the line except magic packets. They are detected so that a remote agent can wake the node.

43.6.7.2 Magic packet detection

The core is designed to detect magic packets (see Magic packets) with the destination address set to:

- Any multicast address
- The broadcast address
- The unicast address programmed in PADDR1/2

When a magic packet is detected, EIR[WAKEUP] is set and none of the statistic registers are incremented.

43.6.7.3 Wakeup

When a magic packet is detected, indicated by ENET*n*_EIR[WAKEUP], ENET*n*_ECR[SLEEP] should be cleared to resume normal operation of the MAC. Clearing the SLEEP bit automatically masks ENET*n*_ECR[MAGICEN], disabling magic packet detection.

43.6.8 IP accelerator functions

The following sections describe the IP accelerator functions.

43.6.8.1 Checksum calculation

The IP and ICMP, TCP, UDP checksums are calculated with one's complement arithmetic summing up 16-bit values.

- For ICMP, the checksum is calculated over the complete ICMP datagram, in other words without IP header.
- For TCP and UDP, the checksums contain the header and data sections and values from the IP header, which can be seen as a pseudo-header that is not actually present in the data stream.

Table 43-26. IPv4 pseudo-header for checksum calculation

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source address							
Destination address							
Zero		Protocol		TCP/UDP length			

Table 43-27. IPv6 pseudo-header for checksum calculation

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source address							
Destination address							
TCP/UDP length							
Zero						Next header	

The TCP/UDP length value is the length of the TCP or UDP datagram, which is equal to the payload of an IP datagram. It is derived by subtracting the IP header length from the complete IP datagram length that is given in the IP header (IPv4), or directly taken from the IP header (IPv6). The protocol field is the corresponding value from the IP header. The Zero fields are all zeroes.

For IPv6, the complete 128-bit addresses are considered. The next header value identifies the upper layer protocol as either TCP or UDP. It may differ from the next header value of the IPv6 header if extension headers are inserted before the protocol header.

The checksum calculation uses 16-bit words in network byte order: The first byte sent/received is the MSB, and the second byte sent/received is the LSB of the 16-bit value to add to the checksum. If the frame ends on an odd number of bytes, a zero byte is appended for checksum calculation only, and is not actually transmitted.

43.6.8.2 Additional padding processing

According to IEEE 802.3, any Ethernet frame must have a minimum length of 64 octets.

The MAC usually removes padding on receive when a frame with length information is received. Because IP frames have a type value instead of length, the MAC does not remove padding for short IP frames, as it is not aware of the frame contents.

The IP accelerator function can be configured to remove the Ethernet padding bytes that might follow the IP datagram.

On transmit, the MAC automatically adds padding as necessary to fill any frame to a 64-byte length.

43.6.8.3 32-bit Ethernet payload alignment

The data FIFOs allow inserting two additional arbitrary bytes in front of a frame. This extends the 14-byte Ethernet header to a 16-byte header, which leads to alignment of the Ethernet payload, following the Ethernet header, on a 32-bit boundary.

This function can be enabled for transmit and receive independently with the corresponding SHIFT16 bits in the ENET*n*_TACC and ENET*n*_RACC registers.

When enabled, the valid frame data is arranged as shown in Table 43-28.

Table 43-28. 64-bit interface data structure with SHIFT16 enabled

63 56	55 48	47 40	39 32	31 24	23 16	15 8	7 0	

Table continues on the next page...

Table 43-28. 64-bit interface data structure with SHIFT16 enabled (continued)

Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0	Any value	Any value
Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8	Byte 7	Byte 6
...							

43.6.8.3.1 Receive processing

When ENET*n*_RACC[SHIFT16] is set, each frame is received with two additional bytes in front of the frame.

The user application must ignore these first two bytes and find the first byte of the frame in bits 23–16 of the first word from the RX FIFO.

Note

SHIFT16 must be set during initialization and kept set during the complete operation, because it influences the FIFO write behavior.

43.6.8.3.2 Transmit processing

When ENET*n*_TACC[SHIFT16] is set, the first two bytes of the first word written (bits 15–0) are discarded immediately by the FIFO write logic.

The SHIFT16 bit can be enabled/disabled for each frame individually if required, but can be changed only between frames.

43.6.8.4 Received frame discard

Because the receive FIFO must be operated in store and forward mode (ENET*n*_RSFL cleared), received frames can be discarded based on the following errors:

- The MAC function receives the frame with an error:
  - The frame has an invalid payload length
  - Frame length is greater than MAX_FL
  - Frame received with a CRC-32 error
  - Frame truncated due to receive FIFO overflow
  - Frame is corrupted as PHY signaled an error (RX_ERR asserted during reception)

- An IP frame is detected and the IP header checksum is wrong
- An IP frame with a valid IP header and a valid IP header checksum is detected, the protocol is known but the protocol-specific checksum is wrong

If one of the errors occurs and the IP accelerator function is configured to discard frames (ENET*n*_RACC), the frame is automatically discarded. Statistics are maintained normally and are not affected by this discard function.

43.6.8.5 IPv4 fragments

When an IPv4 IP fragment frame is received, only the IP header is inspected and its checksum verified. 32-bit alignment operates the same way on fragments as it does on normal IP frames, as specified above.

The IP fragment frame payload is not inspected for any protocol headers. As such, a protocol header would only exist in the very first fragment. To assist in protocol-specific checksum verification, the one's-complement sum is calculated on the IP payload (all bytes following the IP header) and provided with the frame status word.

The frame fragment status field (RxBD[FRAG]) is set to indicate a fragment reception, and the one's-complement sum of the IP payload is available in RxBD[Payload checksum].

Note

After all fragments have been received and reassembled, the application software can take advantage of the payload checksum delivered with the frame's status word to calculate the protocol-specific checksum of the datagram.

For example, if a TCP payload is delivered by multiple IP fragments, the application software can calculate the pseudo-header checksum value from the first fragment, and add the payload checksums delivered with the status for all fragments to verify the TCP datagram checksum.

43.6.8.6 IPv6 support

The following sections describe the IPv6 support.

43.6.8.6.1 Receive processing

An Ethernet frame of type 0x86DD identifies an IP Version 6 frame (IPv6) frame. If an IPv6 frame is received, the first IP header is inspected (first ten words), which is available in every IPv6 frame.

If the receive SHIFT16 function is enabled, the IP header is aligned on a 32-bit boundary allowing more efficient processing (see 32-bit Ethernet payload alignment).

For TCP and UDP datagrams, the pseudo-header checksum calculation is performed and verified.

To assist in protocol-specific checksum verification, the one's-complement sum is always calculated on the IP payload (all bytes following the IP header) and provided with the frame status word. For example, if extension headers were present, their sums can be subtracted in software from the checksum to isolate the TCP/UDP datagram checksum, if required.

43.6.8.6.2 Transmit processing

For IPv6 transmission, the SHIFT16 function is supported to process 32-bit aligned datagrams.

IPv6 has no IP header checksum; therefore, the IP checksum insertion configuration is ignored.

The protocol checksum is inserted only if the next header of the IP header is a known protocol (TCP, UDP, or ICMP). If a known protocol is detected, the checksum over all bytes following the IP header is calculated and inserted in the correct position.

The pseudo-header checksum calculation is performed for TCP and UDP datagrams accordingly.

43.6.9 Resets and stop controls

The following sections describe the resets and stop controls.

43.6.9.1 Hardware reset

To reset the Ethernet module, set ENET*n*_ECR[RESET].

43.6.9.2 Soft reset

When ENET*n*_ECR[ETHER_EN] is cleared during operation, the following occurs:

- uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.
- A currently ongoing transmit is terminated by asserting TXER to the PHY.
- A currently ongoing transmit FIFO write from the application is terminated by stopping the write to the FIFO, and all further data from the application is ignored. All subsequent writes are ignored until re-enabled.
- A currently ongoing receive FIFO read is terminated. The RxBD has arbitrary values in this case.

43.6.9.3 Hardware freeze

When the processor enters debug mode and ECR[DBGEN] is set, the MAC enters a freeze state where it stops all transmit and receive activities gracefully.

The following happens when the MAC enters hardware freeze:

- A currently ongoing receive transaction on the receive application interface is completed as normal. No further frames are read from the FIFO.
- A currently ongoing transmit transaction on the transmit application interface is completed as normal (in other words, until writing end-of-packet (EOP)).
- A currently ongoing frame receive is completed normally, after which no further frames are accepted from the MII.
- A currently ongoing frame transmit is completed normally, after which no further frames are transmitted.

43.6.9.4 Graceful stop

During a graceful stop, any currently ongoing transactions are completed normally and no further frames are accepted. The MAC can resume from a graceful stop without the need for a reset (for example, clearing ETHER_EN is not required).

The following conditions lead to a graceful stop of the MAC transmit or receive datapaths.

43.6.9.4.1 Graceful transmit stop (GTS)

When gracefully stopped, the MAC is no longer reading frame data from the transmit FIFO and has completed any ongoing transmission.

In any of the following conditions, the transmit datapath stops after an ongoing frame transmission has been completed normally.

- ENET*n*_TCR[GTS] is set by software.
- ENET*n*_TCR[TFC_PAUSE] is set by software requesting a pause frame transmission. The status (and register bit) is cleared after the pause frame has been sent.
- A pause frame was received stopping the transmitter. The stopped situation is terminated when the pause timer expires or a pause frame with zero quanta is received.
- MAC is placed in Sleep mode by software or the processor entering Stop mode (see Sleep mode).
- The MAC is in Hardware Freeze mode.

When the transmitter has reached its stopped state, the following events occur:

- The GRA interrupt is asserted, when transitioned into stopped.
- In Hardware Freeze mode, the GRA interrupt does not wait for the application write completion and asserts when the transmit state machine (in other words, line side of TX FIFO) reaches its stopped state.

43.6.9.4.2 Graceful receive stop (GRS)

When gracefully stopped, the MAC is no longer writing frames into the receive FIFO.

The receive datapath stops after any ongoing frame reception has been completed normally, if any of the following conditions occur:

- MAC is placed in Sleep mode either by the software or the processor is in Stop mode). The MAC continues to receive frames and search for magic packets if enabled (see Magic packet detection). However, no frames are written into the receive FIFO, and therefore are not forwarded to the application.
- The MAC is in Hardware Freeze mode. The MAC does not accept any frames from the MII.

When the receive datapath is stopped, the following events occur:

- If the RX is in the stopped state, RCR[GRS] is set
- The GRA interrupt is asserted when the transmitter and receiver are stopped
- Any ongoing receive transaction to the application (RX FIFO read) continues normally until the frame end of package (EOP) is reached. After this, the following occurs:
  - When Sleep mode is active, all further frames are discarded, flushing the RX FIFO
  - In Hardware Freeze mode, no further frames are delivered to the application and they stay in the receive FIFO.

Note

The assertion of GRS does not wait for an ongoing FIFO read transaction on the application side of the FIFO (FIFO read).

43.6.9.4.3 Graceful stop interrupt (GRA)

The graceful stopped interrupt (GRA) is asserted for the following conditions:

- In Sleep mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- In Hardware Freeze mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- The MAC transmit datapath is stopped for any other condition (GTS, TFC_PAUSE, pause received).

The GRA interrupt is triggered only once when the stopped state is entered. If the interrupt is cleared while the stop condition persists, no further interrupt is triggered.

43.6.10 IEEE 1588 functions

To allow for IEEE 1588 or similar time synchronization protocol implementations, the MAC is combined with a time-stamping module to support precise time-stamping of incoming and outgoing frames. Set ENET*n*_ECR[EN1588] to enable 1588 support.

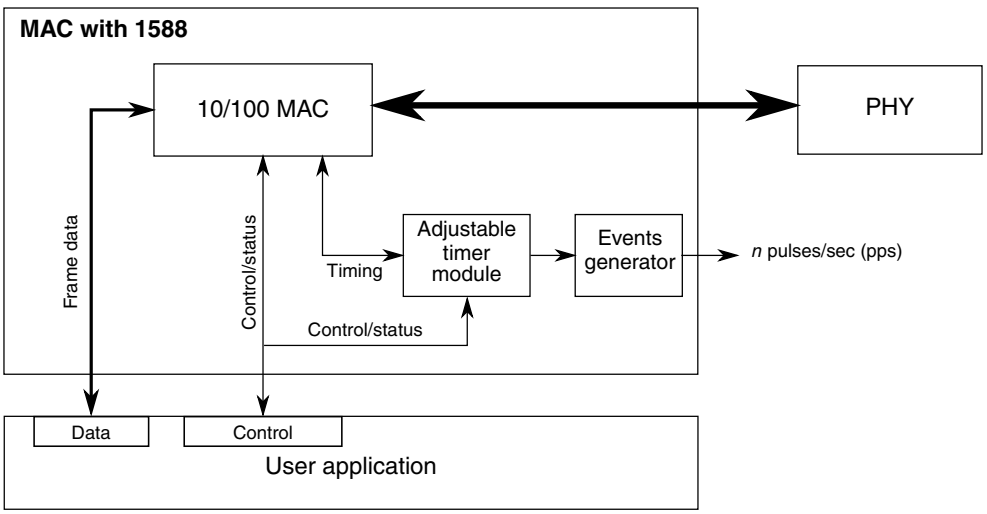

Figure 43-12. IEEE 1588 functions overview

43.6.10.1 Adjustable timer module

The adjustable timer module (TSM) implements the free-running counter (FRC), which generates the timestamps. The FRC operates with the time-stamping clock, which can be set to any value depending on your system requirements.

Through dedicated correction logic, the timer can be adjusted to allow synchronization to a remote master and provide a synchronized timing reference to the local system. The timer can be configured to cause an interrupt after a fixed time period, to allow synchronization of software timers or perform other synchronized system functions.

The timer is typically used to implement a period of one second; hence, its value ranges from 0 to (1×10^9)-1. The period event can trigger an interrupt, and software can maintain the seconds and hours time values as necessary.

43.6.10.1.1 Adjustable timer implementation

The adjustable timer consists of a programmable counter/accumulator and a correction counter. The periods of both counters and their increment rates are freely configurable, allowing very fine tuning of the timer.

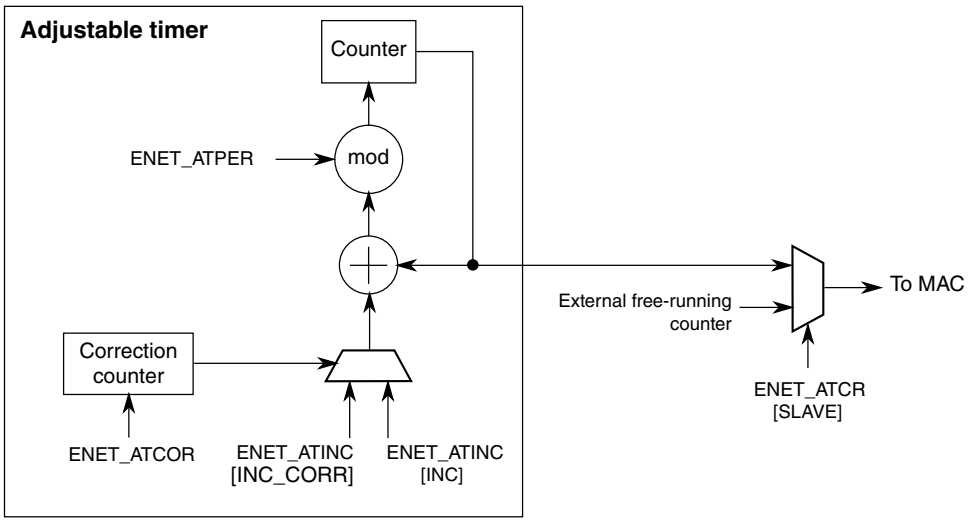

Figure 43-13. Adjustable timer implementation detail

The counter produces the current time. During each time-stamping clock cycle, a constant value is added to the current time as programmed in ENET*n*_ATINC. The value depends on the chosen time-stamping clock frequency. For example, if it operates at 125 MHz, setting the increment to eight represents 8 ns.

The period, configured in ENET*n*_ATPER, defines the modulo when the counter wraps. In a typical implementation, the period is set to 1×10^9 so that the counter wraps every second, and hence all timestamps represent the absolute nanoseconds within the one second period. When the period is reached, the counter wraps to start again respecting the period modulo. This means it does not necessarily start from zero, but instead the counter is loaded with the value (Current + Inc $-(1 \times 10^9)$), assuming the period is set to 1×10^9.

The correction counter operates fully independently, and increments by one with each time-stamping clock cycle. When it reaches the value configured in ENET*n*_ATCOR, it restarts and instructs the timer once to increment by the correction value, instead of the normal value.

The normal and correction increments are configured in ENET*n*_ATINC. To speed up the timer, set the correction increment more than the normal increment value. To slow down the timer, set the correction increment less than the normal increment value.

The correction counter only defines the distance of the corrective actions, not the amount. This allows very fine corrections and low jitter (in the range of 1 ns) independent of the chosen clock frequency.

By enabling slave mode (ENET*n*_ATCR[SLAVE] = 1), the timer is ignored and the current time is externally provided from one of the external modules. See the Chip Configuration details for which clock source is used. This is useful if multiple modules

within the system must operate from a single timer. When slave mode is enabled, you still must set ENET*n*_ATINC[INC] to the value of the master, since it is used for internal comparisons.

43.6.10.2 Transmit timestamping

Only 1588 event frames need to be time-stamped on transmit. The client application (for example, the MAC driver) should detect 1588 event frames and set TxBD[TS] together with the frame.

If TxBD[TS] is set, the MAC records the timestamp for the frame in ENET*n*_ATSTMP. ENET*n*_EIR[TS_AVAIL] is set to indicate that a new timestamp is available.

Software implements a handshaking procedure by setting TxBD[TS] when it transmits the frame for which a timestamp is needed, and then waits for ENET*n*_EIR[TS_AVAIL] to determine when the timestamp is available. The timestamp is then read from ENET*n*_ATSTMP. This is done for all event frames. Other frames do not use TxBD[TS] and, therefore, do not interfere with the timestamp capture.

43.6.10.3 Receive timestamping

When a frame is received, the MAC latches the value of the timer when the frame's start of frame delimiter (SFD) field is detected, and provides the captured timestamp on RxBD[1588 timestamp]. This is done for all received frames.

43.6.10.4 Time synchronization

The adjustable timer module is available to synchronize the local clock of a node to a remote master. It implements a free running 32-bit counter, and also contains an additional correction counter.

The correction counter increases or decreases the rate of the free running counter, enabling very fine granular changes of the timer for synchronization, yet adding only very low jitter when performing corrections.

The application software implements, in a slave scenario, the required control algorithm, setting the correction to compensate for local oscillator drifts and locking the timer to the remote master clock on the network.

The timer and all timestamp-related information should be configured to show the true nanoseconds value of a second (in other words, the timer is configured to have a period of one second). Hence, the values range from 0 to (1×10^9)–1. In this application, the seconds counter is implemented in software using an interrupt function that is executed when the nanoseconds counter wraps at 1×10^9.

43.6.10.5 Input Capture and Output Compare

The Input Capture Output Compare block can be used to provide precise hardware timing for input and output events.

43.6.10.5.1 Input capture

The TCCR*n* capture registers latch the time value when the corresponding external event occurs. An event can be a rising-, falling-, or either-edge of one of the 1588_TMR*n* signals. An event will cause the corresponding TCSR*n*[TF] timer flag to be set, indicating that an input capture has occurred. If the corresponding interrupt is enabled with the TCSR*n*[TIE] field, an interrupt can be generated.

43.6.10.5.2 Output compare

The TCCR*n* compare registers are loaded with the time at which the corresponding event should occur. When the ENET free-running counter value matches the output compare reference value in the TCCR*n* register, the corresponding flag, TCSR*n*[TF], is set, indicating that an output compare has occurred. The corresponding interrupt, if enabled by TCSR*n*[TIE], will be generated.The corresponding 1588_TMR*n* output signal will be asserted according to TCSR*n*[TMODE].

43.6.10.5.3 DMA requests

A DMA request can be enabled by setting TCSR*n*[TDRE]. The corresponding DMA request is generated when the TCSR*n*[TF] timer flag is set. When the DMA has completed, the corresponding TCSRn[TF] flag is cleared.

43.6.11 FIFO thresholds

The core FIFO thresholds are fully programmable to dynamically change the FIFO operation.

For example, store and forward transfer can be enabled by a simple change in the FIFO threshold registers.

The thresholds are defined in 64-bit words.

The receive and transmit FIFOs both have a depth of 256 words.

43.6.11.1 Receive FIFO

Four programmable thresholds are available, which can be set to any value to control the core operation as follows.

Table 43-29. Receive FIFO thresholds definition

Register	Description
ENET*n*_RSFL [RX_SECTION_FULL]	When the FIFO level reaches the ENET*n*_RSFL value, the MAC status signal is asserted to indicate that data is available in the receive FIFO (cut-through operation). Once asserted, if the FIFO empties below the threshold set with ENET*n*_RAEM and if the end-of-frame is not yet stored in the FIFO, the status signal is deasserted again. If a frame has a size smaller than the threshold (in other words, an end-of-frame is available for the frame), the status is also asserted. To enable store and forward on the receive path, clear ENET*n*_RSFL. The MAC status signal is asserted only when a complete frame is stored in the receive FIFO. When programming a non-zero value to ENET*n*_RSFL (cut-through operation) it should be greater than ENET*n*_RAEM.
ENET*n*_RAEM [RX_ALMOST_EMPTY]	When the FIFO level reaches the ENET*n*_RAEM value, and the end-of-frame has not been received, the core receive read control stops the FIFO read (and subsequently stops transferring data to the MAC client application). It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO. Set ENET*n*_RAEM to a minimum of six.
ENET*n*_RAFL [RX_ALMOST_FULL]	When the FIFO level approaches the maximum and there is no more space remaining for at least ENETn_RAFL number of words, the MAC control logic stops writing data in the FIFO and truncates the receive frame to avoid FIFO overflow. The corresponding error status is set when the frame is delivered to the application. Set ENET*n*_RAFL to a minimum of 4.
ENET*n*_RSEM [RX_SECTION_EMPTY]	When the FIFO level reaches the ENET*n*_RSEM value, an indication is sent to the MAC transmit logic, which generates an XOFF pause frame. This indicates FIFO congestion to the remote Ethernet client. When the FIFO level goes below the value programmed in ENET*n*_RSEM, an indication is sent to the MAC transmit logic, which generates an XON pause frame. This indicates the FIFO congestion is cleared to the remote Ethernet client. Clearing ENET*n*_RSEM disables any pause frame generation.

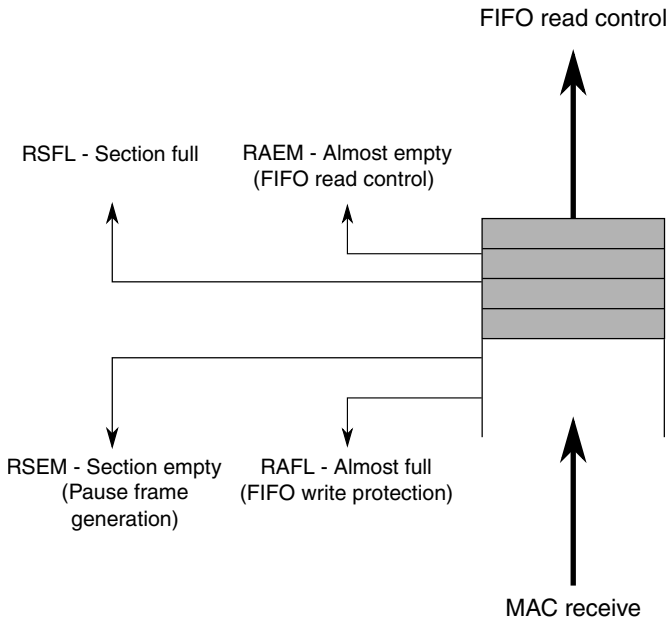

Figure 43-14. Receive FIFO overview

43.6.11.2 Transmit FIFO

Four programmable thresholds are available which control the core operation as described below.

Table 43-30. Transmit FIFO thresholds definition

Register	Description
ENET*n*_TAEM [TX_ALMOST _EMPTY]	When the FIFO level reaches the ENET*n*_TAEM value and no end-of-frame is available for the frame, the MAC transmit logic avoids a FIFO underflow by stopping FIFO reads and transmitting the Ethernet frame with an MII error indication. Set ENET*n*_TAEM to a minimum of 4.
ENET*n*_TAFL [TX_ALMOST _FULL]	When the FIFO level approaches the maximum, so that there is no more space for at least ENET*n*_TAFL number of words, the MAC deasserts its control signal to the application. If the application does not react on this signal, the FIFO write control logic avoids FIFO overflow by truncating the current frame and setting the error status. As a result, the frame is transmitted with an MII error indication. Set ENET*n*_TAFL to a minimum of 4. Larger values allow more latency for the application to react on the MAC control signal deassertion, before the frame is truncated. A typical setting is 8, which offers 3–4 clock cycles of latency to the application to react on the MAC control signal deassertion.
ENET*n*_TSEM [TX_SECTION _EMPTY]	When the FIFO level reaches the ENET*n*_TSEM value, a MAC status signal is deasserted to indicate that the transmit FIFO is getting full. This gives the ENET module an indication to slow or stop its write transaction to avoid a buffer overflow. This is a pure indication function to the application. It has no effect within the MAC. When ENET*n*_TSEM is 0, the signal is never deasserted.
ENET*n*_TFWR	When the FIFO level reaches the ENET*n*_TFWR value and when STRFWD is cleared, the MAC transmit control logic starts frame transmission before the end-of-frame is available in the FIFO (cut-through operation).

Table 43-30. Transmit FIFO thresholds definition

Register	Description
	If a complete frame has a size smaller than the ENET*n*_TFWR threshold, the MAC also transmits the frame to the line. To enable store and forward on the transmit path, set STRFWD. In this case, the MAC starts to transmit data only when a complete frame is stored in the transmit FIFO.

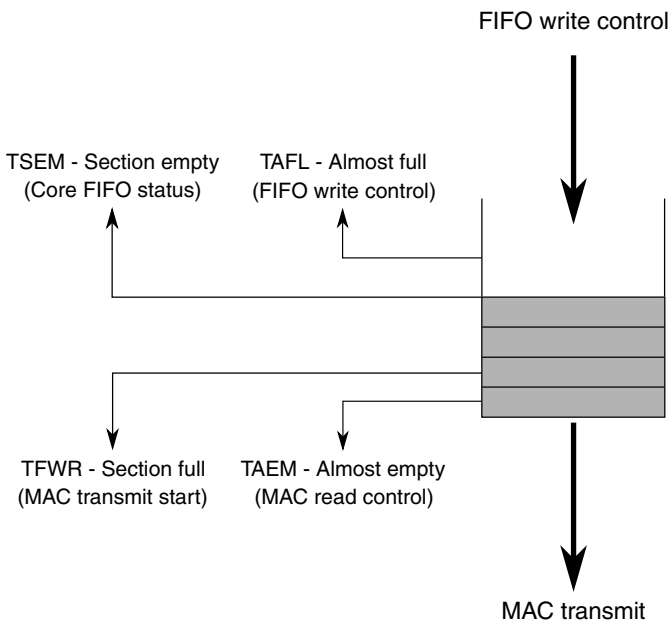

Figure 43-15. Transmit FIFO overview

43.6.12 Loopback options

The core implements external and internal loopback options, which are controlled by the ENET*n*_RCR register fields found here.

The core implements external and internal loopback options, which are controlled by the following ENET*n*_RCR register fields:

Table 43-31. Loopback options

Register field	Description
LOOP	Internal MII loopback. The MAC transmit is returned to the MAC receive. No data is transmitted to the external interfaces. In MII internal loopback, MII_TXCLK and MII_RXCLK must be provided with a clock signal (2.5 MHz for 10 Mbit/s, and 25 MHz for 100 Mbit/s))

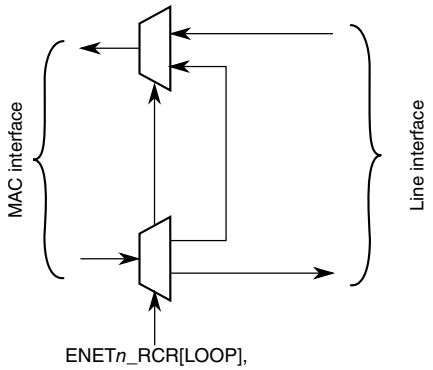

Figure 43-16. Loopback options

43.6.13 Legacy buffer descriptors

To support the Ethernet controller on previous chips, legacy FEC buffer descriptors are available. To enable legacy support, write 0 to ENET*n*_ECR[1588EN].

NOTE

- Legacy buffer descriptors are used in single-ring mode, that is, when DMA*n*CFG[DMA_CLASS_EN] are zero. In multi-ring mode, legacy TxBDs are used only with the round-robin scheme.
- The legacy buffer descriptor tables show the byte order for big-endian chips. DBSWP must be set to 0 after reset to enable big-endian mode.

43.6.13.1 Legacy receive buffer descriptor

The following table shows the legacy FEC receive buffer descriptor. Table 43-35 contains the descriptions for each field.

Table 43-32. Legacy FEC receive buffer descriptor (RxBD)

	Byte 0								Byte 1							
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Offset + 6	Tx Data Buffer Pointer — low halfword															

1. This field is not supported by the uDMA.

43.6.14 Enhanced buffer descriptors

This section provides a description of the enhanced operation of the driver/uDMA via the buffer descriptors.

It is followed by a detailed description of the receive and transmit descriptor fields. To enable the enhanced features, set ENET*n*_ECR[1588EN].

NOTE

The enhanced buffer descriptor tables show the byte order for big-endian chips. DBSWP must be set to 0 after reset to enable big-endian mode.

43.6.14.1 Enhanced receive buffer descriptor

The following table shows the enhanced uDMA receive buffer descriptor. Table 43-35 contains the descriptions for each field.

Table 43-34. Enhanced uDMA receive buffer descriptor (RxBD)

	Byte 0								Byte 1							
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 43-35. Receive buffer descriptor field definitions

Word	Field	Description
Offset + 0	0 E	Empty. Written by the MAC (= 0) and user (= 1). 0 The data buffer associated with this BD is filled with received data, or data reception has aborted due to an error condition. The status and length fields have been updated as required. 1 The data buffer associated with this BD is empty, or reception is currently in progress.
Offset + 0	1 RO1	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 0	2 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location. 1 The next buffer descriptor is found at the location defined in ENET*n*_RDSR.
Offset + 0	3 RO2	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 0	4 L	Last in frame. Written by the uDMA. 0 The buffer is not the last in a frame. 1 The buffer is the last in a frame.
Offset + 0	5–6	Reserved, must be cleared.
Offset + 0	7 M	Miss. Written by the MAC. This field is set by the MAC for frames accepted in promiscuous mode, but flagged as a miss by the internal address recognition. Therefore, while in promiscuous mode, you can use this field to quickly determine whether the frame was destined to this station. This field is valid only if the L and PROM fields are set to 1. 0 The frame was received because of an address recognition hit. 1 The frame was received because of promiscuous mode. The information needed for this field comes from the promiscuous_miss(ff_rx_err_stat[26]) sideband signal.
Offset + 0	8	Set if the DA is broadcast (FFFF_FFFF_FFFF).

Table continues on the next page...

Table 43-35. Receive buffer descriptor field definitions (continued)

Word	Field	Description
	BC	
Offset + 0	9 MC	Set if the DA is multicast and not BC.
Offset + 0	10 LG	Receive frame length violation. Written by the MAC. A frame length greater than RCR[MAX_FL] was recognized. This field is valid only if the L field is set. The receive data is not altered in any way unless the length exceeds TRUNC_FL bytes.
Offset + 0	11 NO	Receive non-octet aligned frame. Written by the MAC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error or a PHY error occurred. This field is valid only if the L field is set. If this field is set, the CR field is not set.
Offset + 0	12	Reserved, must be cleared.
Offset + 0	13 CR	Receive CRC or frame error. Written by the MAC. This frame contains a PHY or CRC error and is an integral number of octets in length. This field is valid only if the L field is set.
Offset + 0	14 OV	Overrun. Written by the MAC. A receive FIFO overrun occurred during frame reception. If this field is set, the other status fields, M, LG, NO, and CR, lose their normal meaning and are zero. This field is valid only if the L field is set.
Offset + 0	15 TR	Set if the receive frame is truncated (frame length >TRUNC_FL). If the TR field is set, the frame must be discarded and the other error fields must be ignored because they may be incorrect.
Offset + 2	0–15 Data Length	Data length. Written by the MAC. Data length is the number of octets written by the MAC into this BD's data buffer if L is cleared (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the MAC once as the BD is closed.
0ffset + 4	0–15 Data buffer pointer high	Receive data buffer pointer, high halfword[1]
Offset + 6	0–15 Data buffer pointer low	Receive data buffer pointer, low halfword
Offset + 8	0 ME	MAC error. This field is written by the uDMA. This field means that the frame stored in the system memory was received with an error (typically, a receive FIFO overflow). This field is only valid when the L field is set.
Offset + 8	1–4	Reserved, must be cleared.
Offset + 8	5 PE	PHY Error. This field is written by the uDMA. Set to "1"when the frame was received with an Error character on the PHY interface. The frame is invalid. This field is valid only when the L field is set.
Offset + 8	6 CE	Collision. This field is written by the uDMA. Set when the frame was received with a collision detected during reception. The frame is invalid and sent to the user application. This field is valid only when the L field is set.
Offset + 8	7 UC	Unicast. This field is written by the uDMA, and means that the frame is unicast. This field is valid regardless of whether the L field is set.
Offset + 8	8 INT	Generate RXB/RXF interrupt. This field is set by the user to indicate that the uDMA is to generate an interrupt on the *dma_int_rxb* / *dma_int_rxfevent*.
Offset + 8	9–15	Reserved, must be cleared.

Table continues on the next page...

Table 43-35. Receive buffer descriptor field definitions (continued)

Word	Field	Description
Offset + A	0–2 VPCP	VLAN priority code point. This field is written by the uDMA to indicate the frame priority level. Valid values are from 0 (best effort) to 7 (highest). This value can be used to prioritize different classes of traffic (e.g., voice, video, data). This field is only valid if the L field is set.
Offset + A	3–9	Reserved, must be cleared.
Offset + A	10 ICE	IP header checksum error. This is an accelerator option. This field is written by the uDMA. Set when either a non-IP frame is received or the IP header checksum was invalid. An IP frame with less than 3 bytes of payload is considered to be an invalid IP frame. This field is only valid if the L field is set.
Offset + A	11 PCR	Protocol checksum error. This is an accelerator option. This field is written by the uDMA. Set when the checksum of the protocol is invalid or an unknown protocol is found and checksumming could not be performed. This field is only valid if the L field is set.
Offset + A	12	Reserved, must be cleared.
Offset + A	13 VLAN	VLAN. This is an accelerator option. This field is written by the uDMA. It means that the frame has a VLAN tag. This field is valid only if the L field is set.
Offset + A	14 IPV6	IPV6 Frame. This field is written by the uDMA. This field indicates that the frame has an IPv6 frame type. If this field is not set it means that an IPv4 or other protocol frame was received. This field is valid only if the L field is set.
Offset + A	15 FRAG	IPv4 Fragment.This is an accelerator option.This field is written by the uDMA. It indicates that the frame is an IPv4 fragment frame. This field is only valid when the L field is set.
Offset + C	0–4 Header length	Header length. This is an accelerator option. This field is written by the uDMA. This field is the sum of 32-bit words found within the IP and its following protocol headers. If an IP datagram with an unknown protocol is found, then the value is the length of the IP header. If no IP frame or an erroneous IP header is found, the value is 0. The following values are minimum values if no header options exist in the respective headers: • ICMP/IP: 6 (5 IP header, 1 ICMP header) • UDP/IP: 7 (5 IP header, 2 UDP header) • TCP/IP: 10 (5 IP header, 5 TCP header) This field is only valid if the L field is set.
Offset + C	5–7	Reserved, must be cleared.
Offset + C	8–15 Protocol type	Protocol type. This is an accelerator option. The 8-bit protocol field found within the IP header of the frame. It is valid only when ICE is cleared. This field is valid only when the L field is set.
Offset + E	0–15 Payload checksum	Internet payload checksum. This is an accelerator option. It is the one's complement sum of the payload section of the IP frame. The sum is calculated over all data following the IP header until the end of the IP payload. This field is valid only when the L field is set.
Offset + 10	0 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).
Offset + 10	1–15	Reserved, must be cleared.
Offset + 12	0–15	Reserved, must be cleared.
Offset + 14	0–15 1588 timestamp	This value is written by the uDMA. It is only valid if the L field is set.
Offset + 16		
Offset + 18	0–15	Reserved, must be cleared.

Table 43-35. Receive buffer descriptor field definitions

Word	Field	Description
– Offset + 1E		

1. The receive buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 64. The buffer must reside in memory external to the MAC. The Ethernet controller never modifies this value.

43.6.14.2 Enhanced transmit buffer descriptor

Table 43-36. Enhanced transmit buffer descriptor (TxBD)

Table 43-37. Enhanced transmit buffer descriptor field definitions

Word	Field	Description
Offset + 0	0 R	Ready. Written by the MAC and user. 0 The data buffer associated with this BD is not ready for transmission. You are free to manipulate this BD or its associated data buffer. The MAC clears this field after the buffer has been transmitted or after an error condition is encountered. 1 The data buffer, prepared for transmission by you, has not been transmitted or currently transmits. You may write no fields of this BD after this field is set.
Offset + 0	1	Transmit software ownership. This field is reserved for software use. This read/write field is not modified by hardware and its value does not affect hardware.

Table continues on the next page...

Table 43-37. Enhanced transmit buffer descriptor field definitions (continued)

Word	Field	Description
	TO1	
Offset + 0	2 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location 1 The next buffer descriptor is found at the location defined in ETDSR.
Offset + 0	3 TO2	Transmit software ownership. This field is reserved for use by software. This read/write field is not modified by hardware and its value does not affect hardware.
Offset + 0	4 L	Last in frame. Written by user. 0 The buffer is not the last in the transmit frame 1 The buffer is the last in the transmit frame
Offset + 0	5 TC	Transmit CRC. Written by user, and valid only when L is set. 0 End transmission immediately after the last data byte 1 Transmit the CRC sequence after the last data byte This field is valid only when the L field is set.
Offset + 0	6 ABC	Append bad CRC. **Note:** This field is not supported by the uDMA and is ignored.
Offset + 0	7–15	Reserved, must be cleared.
Offset + 2	0–15 Data Length	Data length, written by user. Data length is the number of octets the MAC should transmit from this BD's data buffer. It is never modified by the MAC.
Offset + 4	0–15 Data buffer pointer high	Tx data buffer pointer, high halfword. The buffer must reside in memory external to the MAC. This value is never modified by the Ethernet controller. **NOTE:** For optimal performance, make the transmit buffer pointer evenly divisible by 64.
Offset + 6	0–15 Data buffer pointer low	Tx data buffer pointer, low halfword
Offset + 8	0	Reserved, must be cleared.
Offset + 8	1 INT	Generate interrupt flags. This field is written by the user. This field is valid regardless of the L field and must be the same for all EBD for a given frame. The uDMA does not update this value.
Offset + 8	2 TS	Timestamp. This field is written by the user. This indicates that the uDMA is to generate a timestamp frame to the MAC. This field is valid regardless of the L field and must be the same for all EBD for the given frame. The uDMA does not update this value.
Offset + 8	3 PINS	Insert protocol specific checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the protocol checksum and overwrites the corresponding checksum field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + 8	4 IINS	Insert IP header checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the IP header checksum and overwrites the corresponding header field with the calculated value. The checksum field must be cleared by

Table continues on the next page...

Table 43-37. Enhanced transmit buffer descriptor field definitions (continued)

Word	Field	Description
		the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + 8	5-6	Reserved, must be cleared.
Offset + 8	7 UTLT	Use transmit launch time. If set to 1, TLT high and low values are used to determine if the frame can be transmitted. This field must only be set in the *first* BD of a frame. TLT is always used in combination with either the round-robin scheme or the credit-based shaper. TLT can be used with single a BD queue. However, at least one DMA class, DMA*n*CFG[DMA_CLASS_ EN] must be enabled. For example, to use TLT with only queue 0, enable one of the DMA*n*CFG[DMA_CLASS_EN] fields and clear both TDAR1 and TDAR2. Although this enables multi-queue, only the single queue 0 is used.
Offset + 8	8–11 FTYPE	Type of frame to be transmitted. If a credit-based scheme is used, this field must match the BD ring queue. 0x0 – Non-AVB. Corresponds to ENET_TDSR. 0x1 – AVB Class A. Corresponds to ENET_TDSR1. 0x2 – AVB Class B. Corresponds to ENET_TDSR2. All other values are reserved.
Offset + 8	12–15	Reserved, must be cleared.
Offset + A	0 TXE	Transmit error occurred. This field is written by the uDMA. This field indicates that there was a transmit error of some sort reported with the frame. Effectively this field is an OR of the other error fields including UE, EE, FE, LCE, OE, and TSE. This field is valid only when the L field is set.
Offset + A	1	Reserved, must be cleared.
Offset + A	2 UE	Underflow error. This field is written by the uDMA. This field indicates that the MAC reported an underflow error on transmit. This field is valid only when the L field is set.
Offset + A	3 EE	Excess Collision error. This field is written by the uDMA. This field indicates that the MAC reported an excess collision error on transmit. This field is valid only when the L field is set.
Offset + A	4 FE	Frame with error. This field is written by the uDMA. This field indicates that the MAC reported that the uDMA reported an error when providing the packet. This field is valid only when the L field is set.
Offset + A	5 LCE	Late collision error. This field is written by the uDMA. This field indicates that the MAC reported that there was a Late Collision on transmit. This field is valid only when the L field is set.
Offset + A	6 OE	Overflow error. This field is written by the uDMA. This field indicates that the MAC reported that there was a FIFO overflow condition on transmit. This field is only valid when the L field is set.
Offset + A	7 TSE	Timestamp error. This field is written by the uDMA. This field indicates that the MAC reported a different frame type then a timestamp frame. This field is valid only when the L field is set.
Offset + A	8–15	Reserved, must be cleared.
Offset + C	0–15 TLT high	Transmit launch time high. Specifies when frame can by transmitted.

Table continues on the next page...

Table 43-37. Enhanced transmit buffer descriptor field definitions (continued)

Word	Field	Description
Offset + E	0–15 TLT low	Transmit launch time low. Specifies when frame can by transmitted.
Offset + 10	0 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).
Offset + 10	1–15	Reserved, must be cleared.
Offset + 12	0–15	Reserved, must be cleared.
Offset + 14	0–15	This value is written by the uDMA . It is valid only when the L field is set.
Offset + 16	1588 timestamp	
Offset + 18–Offset + 1E	0–15	Reserved, must be cleared.

43.6.15 Client FIFO application interface

The FIFO interface is completely asynchronous from the Ethernet line, and the transmit and receive interface can operate at a different clock rate.

All transfers to/from the user application are handled independently of the core operation, and the core provides a simple interface to user applications based on a two-signal handshake.

43.6.15.1 Data structure description

The data structure defined in the following tables for the FIFO interface must be respected to ensure proper data transmission on the Ethernet line. Byte 0 is sent to and received from the line first.

Table 43-38. FIFO interface data structure

	63 56	55 48	47 40	39 32	31 24	23 16	15 8	7 0
Word 0	Byte 7	Byte 6	Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0
Word 1	Byte 15	Byte 14	Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8
...	...							

The size of a frame on the FIFO interface may not be a modulo of 64-bit.

The user application may not care about the Ethernet frame formats in full detail. It needs to provide and receive an Ethernet frame with the following structure:

- Ethernet MAC destination address

- Ethernet MAC source address
- Optional 802.1q VLAN tag (VLAN type and info field)
- Ethernet length/type field
- Payload

Frames on the FIFO interface do not contain preamble and SFD fields, which are inserted and discarded by the MAC on transmit and receive, respectively.

- On receive, CRC and frame padding can be stripped or passed through transparently.
- On transmit, padding and CRC can be provided by the user application, or appended automatically by the MAC independently for each frame. No size restrictions apply.

Note

On transmit, if ENET*n*_TCR[ADDINS] is set, bytes 6–11 of each frame can be set to any value, since the MAC overwrites the bytes with the MAC address programmed in the ENET*n*_PAUR and ENET*n*_PALR registers.

Table 43-39. FIFO interface frame format

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address
12–13	Length/type field
14–N	Payload data

VLAN-tagged frames are supported on both transmit and receive, and implement additional information (VLAN type and info).

Table 43-40. FIFO interface VLAN frame format

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address
12–15	VLAN tag and info
16–17	Length/type field
18–N	Payload data

Note

The standard defines that the LSB of the MAC address is sent/received first, while for all the other header fields — in other words, length/type, VLAN tag, VLAN info, and pause quanta — the MSB is sent/received first.

43.6.15.2 Data structure examples

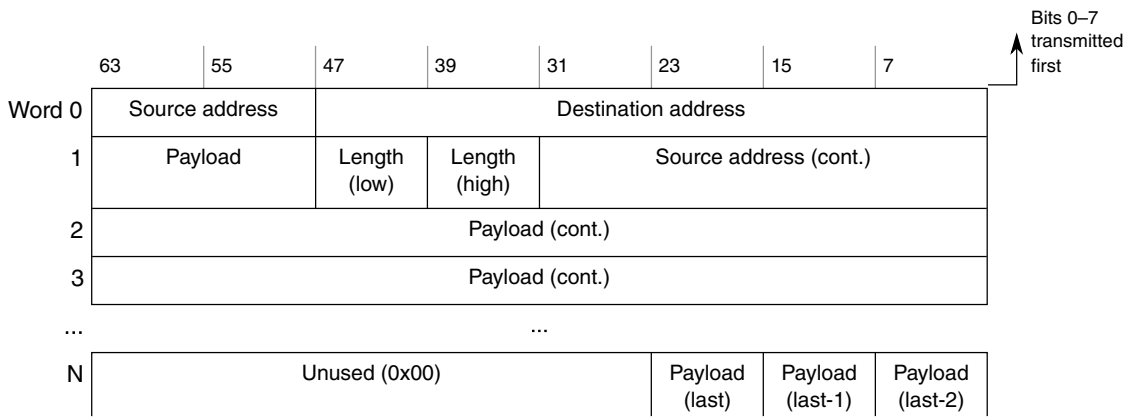

Figure 43-17. Normal Ethernet frame 64-bit mapping example

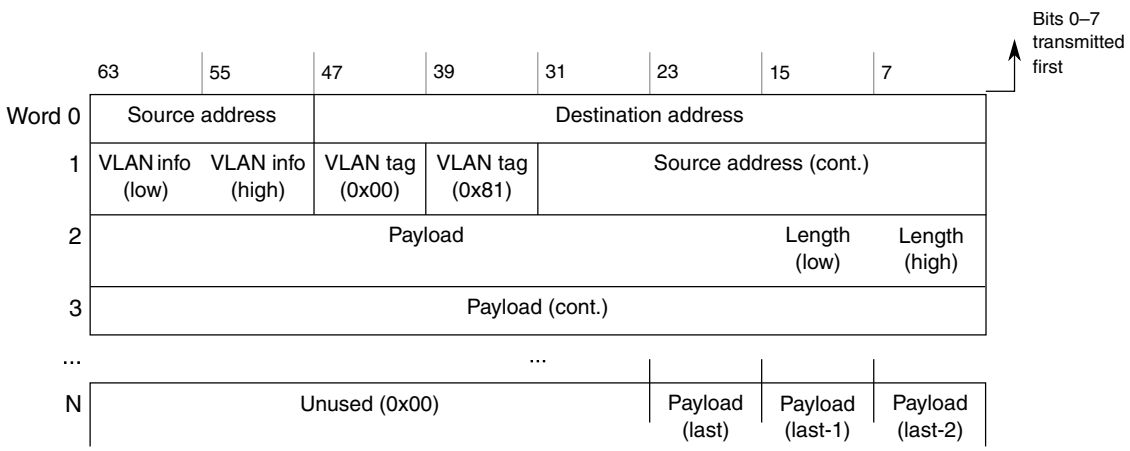

Figure 43-18. VLAN-tagged frame 64-bit mapping example

If CRC forwarding is enabled (CRCFWD = 0), the last four valid octets of the frame contain the FCS field. The non-significant bytes of the last word can have any value.

43.6.15.3 Frame status

A MAC layer status word and an accelerator status word is available in the receive buffer descriptor.

See Enhanced buffer descriptors for details.

The status is available with each frame with the last data of the frame.

If the frame status contains a MAC layer error (for example, CRC or length error), RxBD[ME] is also set with the last data of the frame.

43.6.16 FIFO protection

The following sections describe the FIFO protection mechanisms.

43.6.16.1 Transmit FIFO underflow

During a frame transfer, when the transmit FIFO reaches the almost empty threshold with no end-of-frame indication stored in the FIFO, the MAC logic:

- Stops reading data from the FIFO
- Asserts the MII error signal (MII_TXER) (1 in Figure 43-19) to indicate that the fragment already transferred is not valid
- Deasserts the MII transmit enable signal (MII_TXEN) to terminate the frame transfer (2)

After an underflow, when the application completes the frame transfer (3), the MAC transmit logic discards any new data available in the FIFO until the end of packet is reached (4) and sets the enhanced TxBD[UE] field.

The MAC starts to transfer data on the MII interface when the application sends a new frame with a start of frame indication (5).

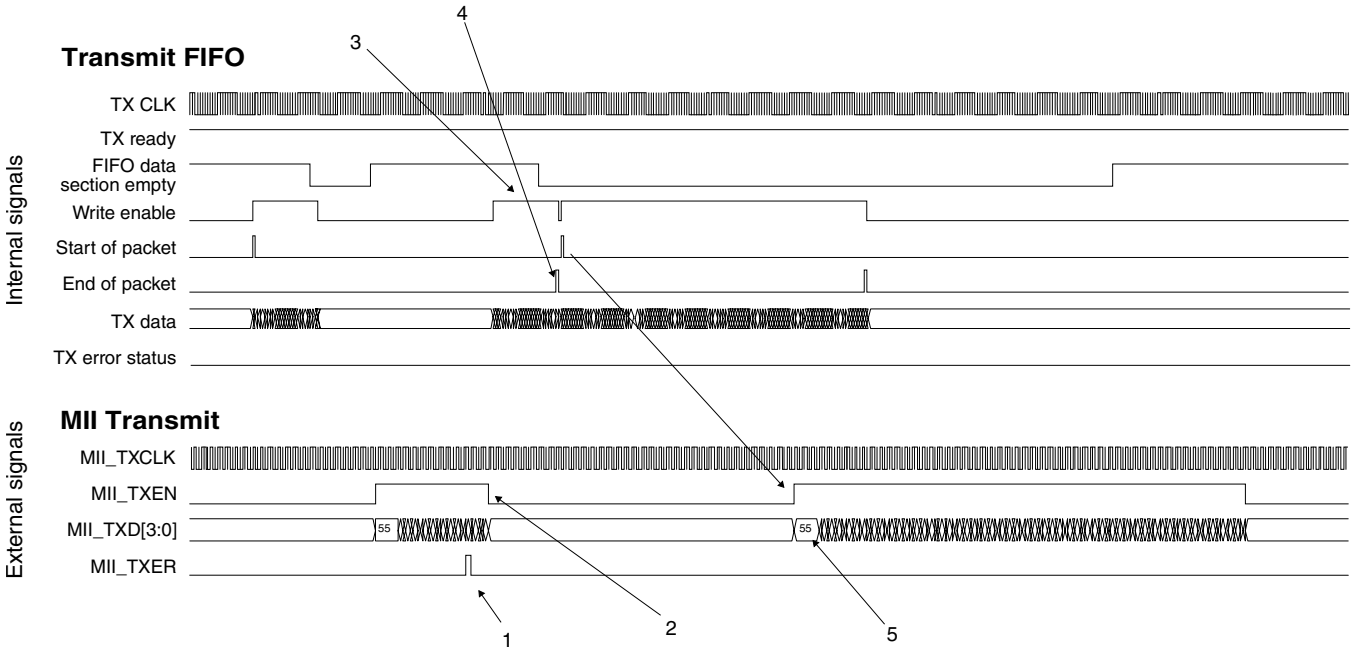

Figure 43-19. Transmit FIFO underflow protection

43.6.16.2 Transmit FIFO overflow

On the transmit path, when the FIFO reaches the programmable almost full threshold, the internal MAC ready signal is deasserted. The application should stop sending new data.

However, if the application keeps sending data, the transmit FIFO overflows, corrupting contents that were previously stored. The core logic sets the enhanced TxBD[OE] field for the next frame transmitted to indicate this overflow occurence.

Note

Overflow is a fatal error and must be addressed by resetting the core or clearing ENET*n*_ECR[ETHER_EN], to clear the FIFOs and prepare for normal operation again.

43.6.16.3 Receive FIFO overflow

During a frame reception, if the client application is not able to receive data (1), the MAC receive control truncates the incoming frame when the FIFO reaches the programmable almost-full threshold to avoid an overflow.

The frame is subsequently received on the FIFO interface with an error indication (enhanced RxBD[ME] field set together with receive end-of-packet) (2) with the truncation error status field set (3).

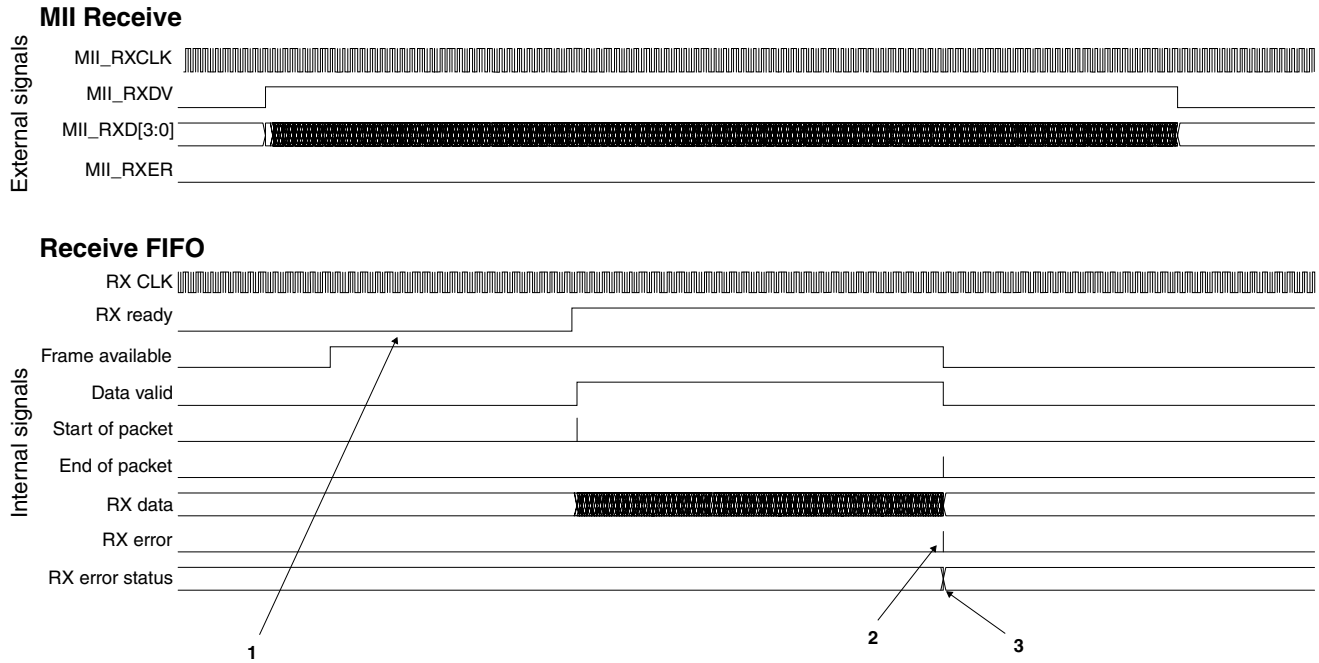

Figure 43-20. Receive FIFO overflow protection

43.6.17 Reference clock

The input clocks to the ENET module must meet the specifications in the following table.

Ethernet speed mode	Ethernet bus clock	Minimum ENET system clock
10 Mbit/s	2.5 MHz	5 MHz
100 Mbit/s	25.0 MHz	50 MHz

43.6.18 PHY management interface

The MDIO interface is a two-wire management interface. The MDIO management interface implements a standardized method to access the PHY device management registers.

The core implements a master MDIO interface, which can be connected to up to 32 PHY devices.

43.6.18.1 MDIO clause 22 frame format

The core MDIO master controller communicates with the slave (PHY device) using frames that are defined in the following table.

A complete frame has a length of 64 bits made up of an optional 32-bit preamble, 14-bit command, 2-bit bus direction change, and 16-bit data. Each bit is transferred on the rising edge of the MDIO clock (MDC signal). The MDIO data signal is tri-stated between frames.

The core PHY management interface supports the standard MDIO specification (IEEE 802.3 Clause 22).

Table 43-41. MDIO clause 22 frame structure

ST	OP	PHYADR	REGADR	TA	DATA

Table 43-42. MDIO frame field descriptions

Field	Description
ST (2 bits)	Start indication field, programmed with ENET*n*_MMFR[ST] and equal to 01 for Standard MDIO (Clause 22).
OP (2 bits)	Opcode defines type of operation. Programmed with ENET*n*_MMFR[OP]. 01 Write operation 10 Read operation
PHYADR (5 bits)	Five-bit PHY device address, programmed with ENET*n*_MMFR[PA]. Up to 32 devices can be addressed.
REGADR (5 bits)	Five-bit register address, programmed with ENET*n*_MMFR[RA]. Each PHY can implement up to 32 registers.
TA (2 bits)	Turnaround time, programmed with ENET*n*_MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.
Data (16 bits)	Data, set by ENET*n*_MMFR[DATA]. Written to or read from the PHY

43.6.18.2 MDIO clause 45 frame format

The extended MDIO frame structure defined in IEEE 802.3 Clause 45 introduces indirect addressing. First, a write transaction to an address register is done, followed by a write or read transaction which will put the 16-bit data in the register or retrieve the register contents respectively. A preamble of 32 bits of logical ones is sent prior to every transaction. The MDIO data signal is tri-stated between frames.

The extended MDIO defines four transactions, which are determined by the two-bit opcode field.

Table 43-43. MDIO clause 45 frame structure

ST	OP	PRTAD	DEVAD	TA	ADDR/DATA

All bits are transmitted from left to right (Preamble bits first) and all fields have their Most-Significant bit sent first (leftmost in above table). The complete frame has a length of 64 bits (32-bit preamble, 14-bit command, 2-bit bus direction change, 16-bit data). Each bit is transferred with the rising edge of the MDIO clock (MDC).

The fields and transactions are summarized in the following tables.

Table 43-44. MDIO clause 45 frame field descriptions

Field	Description
ST	Start indication. Indicates the end of the preamble and start of the frame. This value is 00 for extended MDIO (Clause 45) frames.
OP	Opcode defines if a read or write operation is performed and is programmed with ENET*n*_MMFR[OP]. See Table 43-45 for more information. 00 Address write 01 Write operation 10 Read inc. operation 11 Read operation
PRTAD	The port address specifies a MDIO port. Each Port can have up to 32 devices which each can have a separate set of registers.
DEVAD	Device address. Up to 32 devices can be addressed (within a port).
TA	Turnaround time, programmed with ENET*n*_MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.
ADDR/DATA	16-bit address (for address write) or data, set by ENET*n*_MMFR[DATA], written to or read from the PHY.

Table 43-45. MDIO Clause 45 Transactions

Transaction Type	Description
Address	A write transaction to the internal address register of the device/port. The data section of the frame contains the value to be stored in the device's internal address "pointer" register for further transactions.
Write	Data write to a register. The 16 bit data will be written to the register identified by the device-internal address.
Read	Data is read from the register identified by the device-internal address.
Read inc.	Read with address postincrement. The register identified by the device-internal address is read. After this, the device-internal address is incremented. If the address register is all '1' (0xFFFF) no increment is done (i.e. increment does not wrap around).

43.6.18.3 MDIO clock generation

The MDC clock is generated from the internal bus clock (i.e., IPS bus clock) divided by the value programmed in ENET*n*_MSCR[MII_SPEED].

43.6.18.4 MDIO operation

To perform an MDIO access, set the MDIO command register (ENET*n*_MMFR) according to the description provided in MII Management Frame Register (ENETn_MMFR).

To check when the programmed access completes, read the ENET*n*_EIR[MII] field.

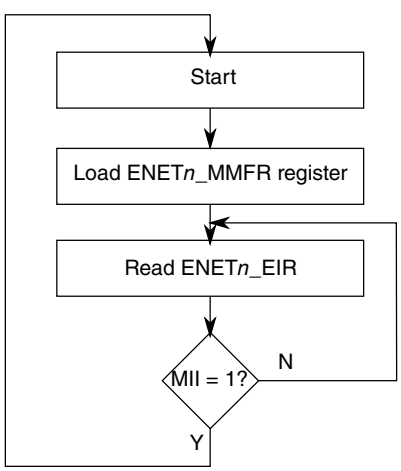

Figure 43-21. MDIO access overview

43.6.19 Ethernet interfaces

The following Ethernet interfaces are implemented:

- Fast Ethernet MII (Media Independent Interface)
- RMII 10/100 using interface converters/gaskets

The following table shows how to configure ENET registers to select each interface.

Mode	RCR[RMII_10T]	RCR[RMII_MODE]
MII - 10 Mbit/s	—	0
MII - 100 Mbit/s	—	0
RMII - 10 Mbit/s	1	1
RMII - 100 Mbit/s	0	1

43.6.19.1 RMII interface

In RMII receive mode, for normal reception following assertion of CRS_DV, RXD[1:0] is 00 until the receiver determines that the receive event has a proper start-of-stream delimiter (SSD).

The preamble appears (RXD[1:0]=01) and the MACs begin capturing data following detection of SFD.

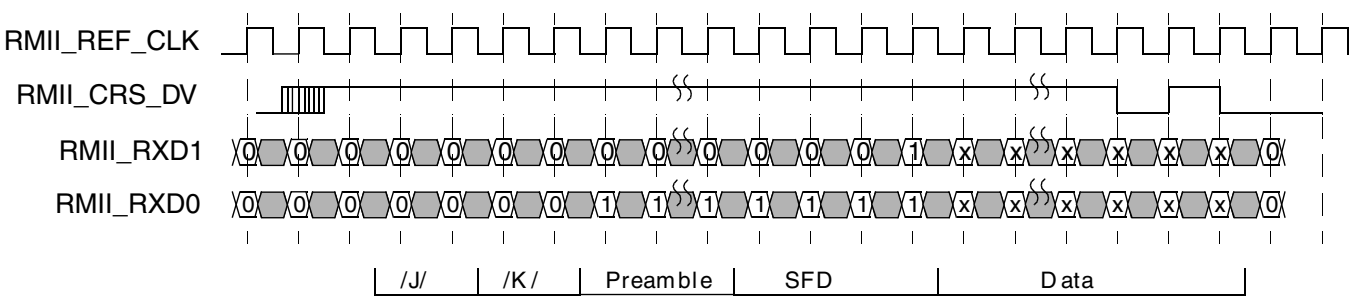

Figure 43-22. RMII receive operation

If a false carrier is detected (bad SSD), then RXD[1:0] is 10 until the end of the receive event. This is a unique pattern since a false carrier can only occur at the beginning of a packet where the preamble is decoded (RXD[1:0] = 01).

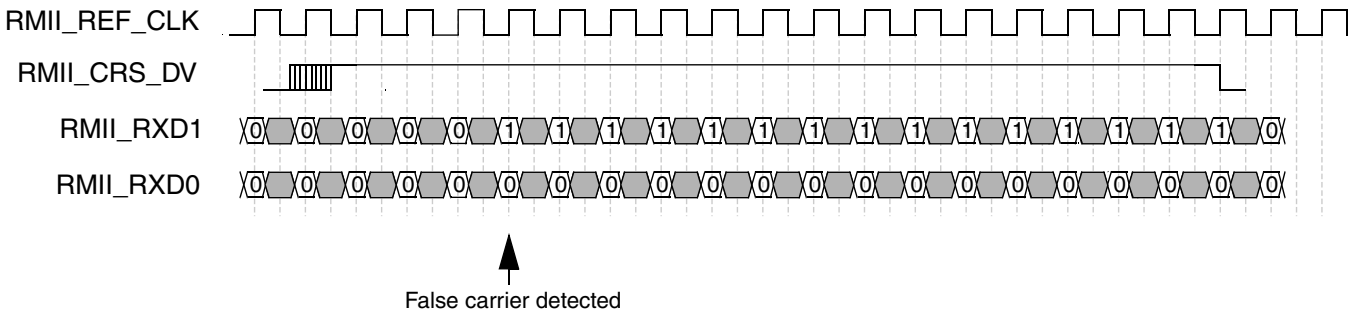

Figure 43-23. RMII receive operation with false carrier

In RMII transmit mode, TXD[1:0] provides valid data for each REF_CLK period while TXEN is asserted.

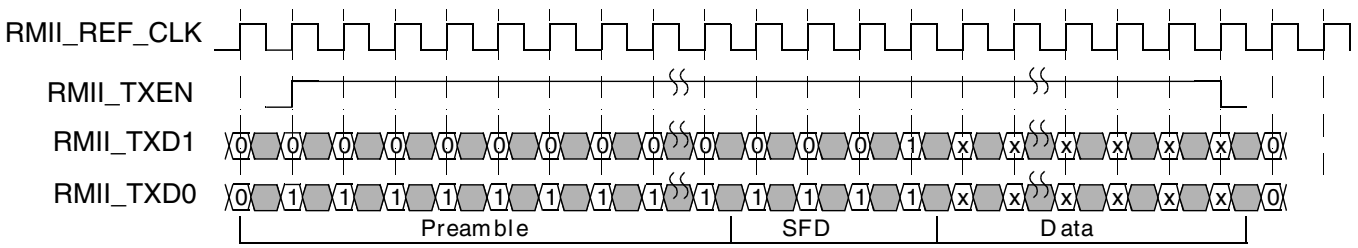

Figure 43-24. RMII transmit operation

43.6.19.2 MII Interface — transmit

On transmit, all data transfers are synchronous to MII_TXCLK rising edge. The MII data enable signal MII_TXEN is asserted to indicate the start of a new frame, and remains asserted until the last byte of the frame is present on the MII_TXD[3:0] bus.

Between frames, MII_TXEN remains deasserted.

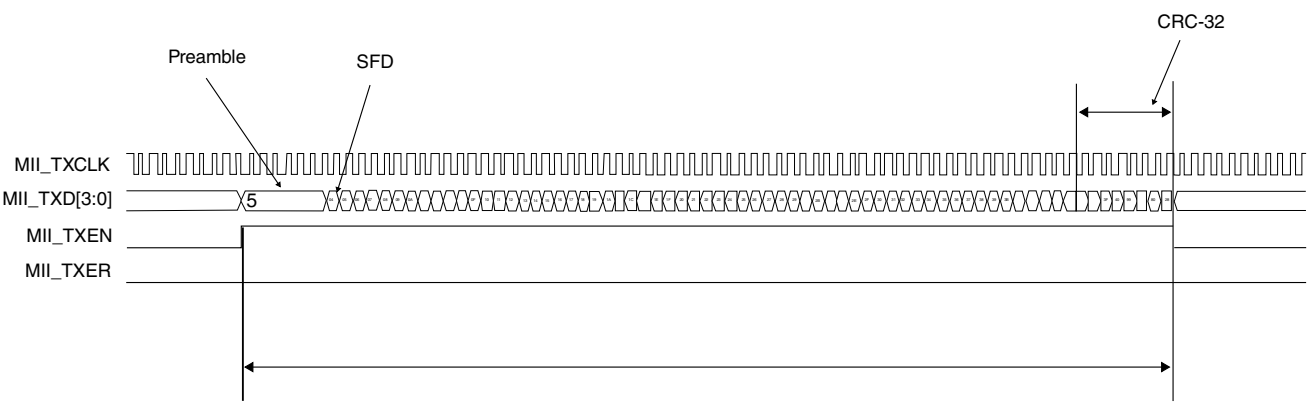

Figure 43-25. MII transmit operation

If a frame is received on the FIFO interface with an error (for example, RxBD[ME] set) the frame is subsequently transmitted with the MII_TXER error signal for one clock cycle at any time during the packet transfer.

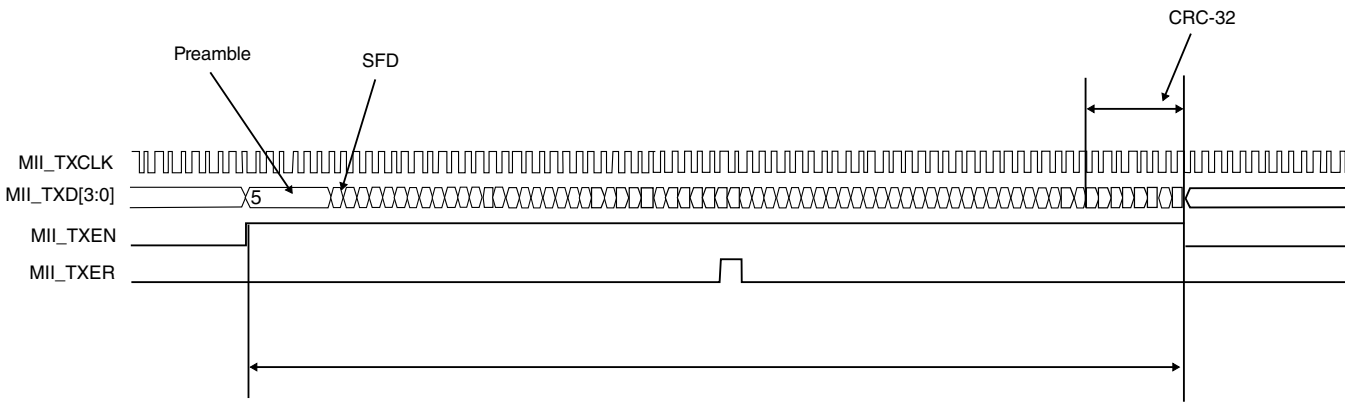

Figure 43-26. MII transmit operation — errored frame

43.6.19.2.1 Transmit with collision — half-duplex

When a collision is detected during a frame transmission (MII_COL asserted), the MAC stops the current transmission, sends a 32-bit jam pattern, and re-transmits the current frame.

(See Collision detection in half-duplex mode for details)

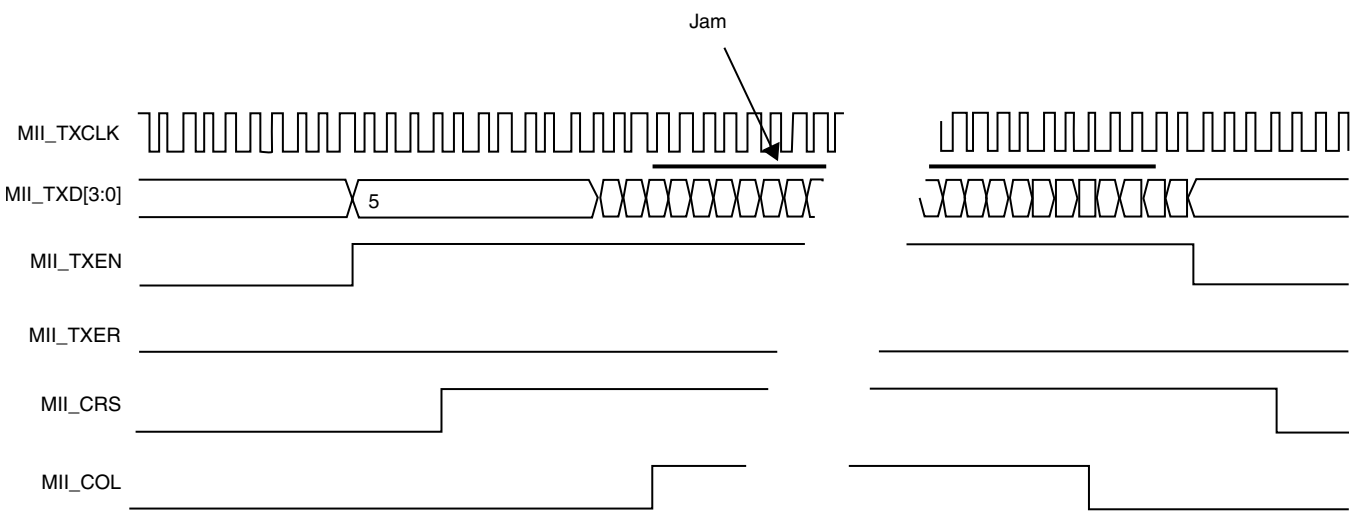

Figure 43-27. MII transmit operation — transmission with collision

43.6.19.3 MII interface — receive

On receive, all signals are sampled on the MII_RXCLK rising edge. The MII data enable signal, MII_RXDV, is asserted by the PHY to indicate the start of a new frame and remains asserted until the last byte of the frame is present on MII_RXD[3:0] bus.

Between frames, MII_RXDV remains deasserted.

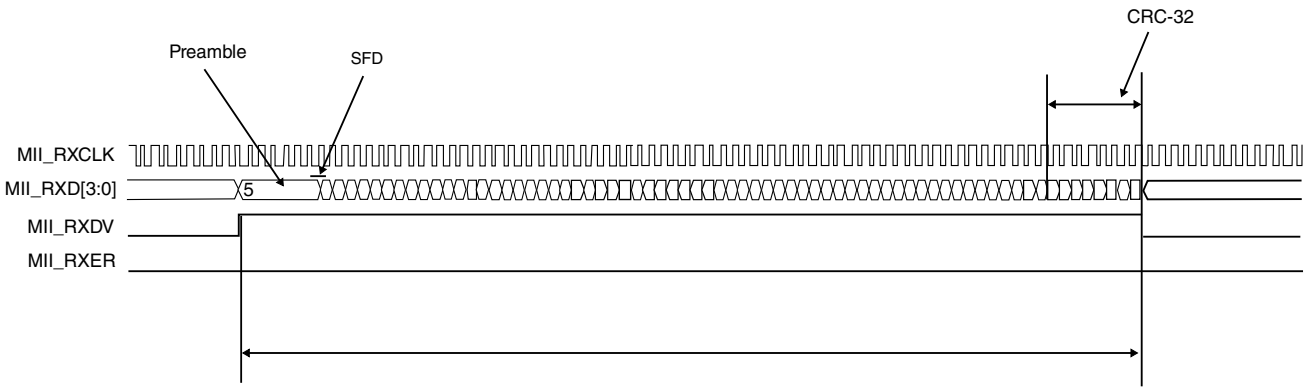

Figure 43-28. MII receive operation

If the PHY detects an error on the frame received from the line, the PHY asserts the MII error signal, MII_RXER, for at least one clock cycle at any time during the packet transfer.

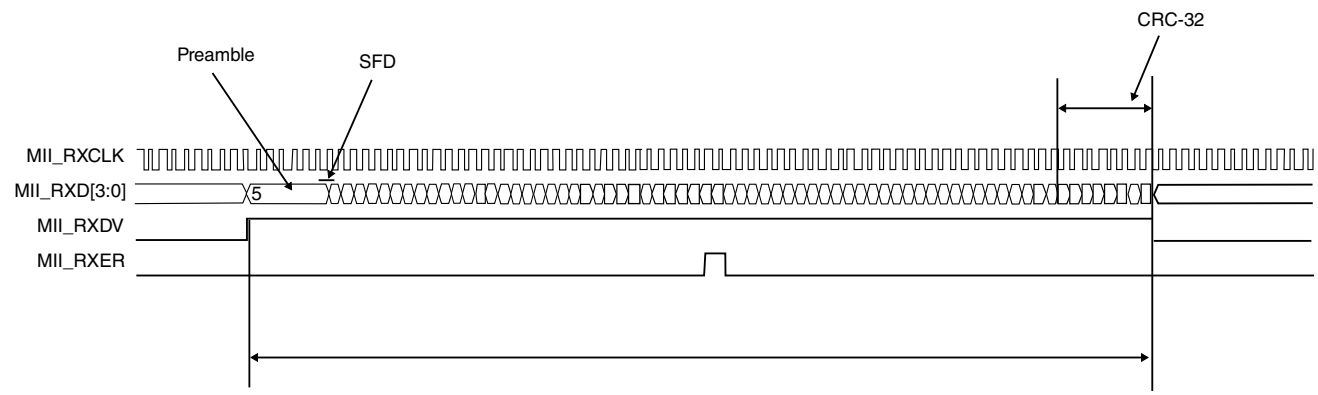

Figure 43-29. MII receive operation — errored frame

A frame received on the MII interface with a PHY error indication is subsequently transferred on the FIFO interface with RxBD[ME] set.

43.6.20 AVB configuration

The following steps give an example of how to initialize the ENET module for AVB.

1. Set up ENET_QOS:
   - Set TX_SCHEME to 000b, credit-based scheme.
   - Set RX_FLUSH0 to 1, enable RX flush for ring 0.
2. Set up TX BD ring and RX BD ring for each queue, 0-2.
   - Program ENET_MRBR, ENET_TDSR, and ENET_RDSR.
   - Program ENET_MRBR1, ENET_TDSR1, and ENET_RDSR1.
   - Program ENET_MRBR2, ENET_TDSR2, and ENET_RDSR2.
   - Program each TX and RX BD ring queue for all classes used in memory.

NOTE

If using credit-based scheme, ensure that enhanced transmit buffer descriptor FTYPE field matches BD ring queue, for example:
- FTYPE = 0h corresponds to ENET_TDSR
- FTYPE = 1h corresponds to ENET_TDSR1
- FTYPE = 2h corresponds to ENET_TDSR2

3. Program ENET_DMA1CFG and ENET_DMA2CFG for class 1 and class 2 corresponding to BD ring queue 1 and 2. DMA_CLASS_EN must be set to one for that class to be enabled. See DMA Class Based Configuration (ENET_DMA*n*CFG) for information on how to program IDLE_SLOPE.
4. Program ENET_RCMR1 and ENET_RCMR2 for class 1 and class 2 matching for receive.

NOTE

Even if a match occurs, if ENET_DMA*n*CFG[DMA_CLASS_EN] is zero for the corresponding class, the RX frame will be automatically forwarded to BD ring queue 0.

5. Program the other ENET registers according to application requirements.
6. Program ENET_RDAR, ENET_RDAR1, ENET_RDAR2, ENET_TDAR, ENET_TDAR1, and ENET_TDAR2 to 0100_0000h according to the classes used.
7. Set ENET_ECR[ETHEREN] to one.

43.6.21 Interrupt coalescence

The purpose of the interrupt coalescing is to reduce the number of interrupts generated by the MAC so as to reduce the CPU loading.

To facilitate this interrupt coalescing for each queue, these registers are available with the same control and configuration fields.

- Transmit Interrupt Coalescing Register (ENET_TXIC*n*) where n=0,1,2 for queue/class 0,1,2.
- Receive Interrupt Coalescing Register (ENET_RXIC*n*) where n=0,1,2 for queue/class 0,1,2.

When coalescing is enabled by asserting the corresponding ICEN field and such interrupt is also enabled by the corresponding interrupt mask of the EIMR register, the MAC generates an interrupt when the threshold number of frames is reached (defined by ICFT) or when the threshold timer expires (defined by ICTT).

When coalescing is disabled by de-asserting ICEN, but interrupt is enabled by the corresponding interrupt mask of the EIMR register, the MAC generates an interrupt as they are received without using coalescing. Interrupt coalescing is done for each transmit and receive queue/class independently.

43.6.21.1 Interrupt coalescence setup

Interrupt coalescence supports both legacy and enhanced BDs. The following guidelines are recommended when setting up interrupt coalescence.

- When the MAC is configured for enhanced (IEEE 1588) mode, that is, enhanced BDs:
  - Set the INT bit in the enhanced received buffer descriptor to one.
  - Set the INT bit in the enhanced transmit buffer descriptor(s) to one.
- Clear the RXB, RXB1, and RXB2 fields in the EIMR register.
- Clear the TXB, TXB1, and TXB2 fields in the EIMR register.

43.6.21.2 Updating the frame count threshold on-the-fly

To update the ICFT field in the RXIC*n* and TXIC*n* registers:

1. Disable interrupt coalescence by clearing the appropriate ICEN field. This will allow the internal interrupt coalescence counter to reset to zero.

NOTE

When disabling interrupt coalescence, if an interrupt event is pending, that is, the interrupt counter is not zero, then an interrupt will occur.

2. Write the new threshold value to the ICFT field.
3. Set ICEN to one.

NOTE

The ICFT field can be updated on-the-fly without disabling the ICEN field. The hardware interrupt will continue and there is a

possibility that an interrupt will occur depending on the state of the hardware counter and the previous ICFT value.

43.6.21.3 Updating the timer threshold on-the-fly

To update the ICTT field in the RXIC*n* and TXIC*n* registers:

1. Disable interrupt coalescence by clearing the appropriate ICEN field. This will allow the internal interrupt coalescence counter to reset to zero.

NOTE

When disabling interrupt coalescence, if an interrupt event is pending, that is, the interrupt counter is not zero, then an interrupt will occur.

2. Write the new timer value to the ICTT field.
3. Set ICEN to one.

Chapter 44
FlexCAN

44.1 Chip-specific FlexCAN information

44.1.1 FlexCAN configuration

This device contains 8 Controller Area Network (CAN) modules: FlexCAN[0:7].

All 8 instances of CAN support FD feature.

FlexCAN_0 includes a new FlexCAN module feature called Pretended Networking mode that addresses the low power requirements of applications. For a CAN node, this mode enables a local approach whereby it can decide when and how it switches into a power saving mode, reducing power consumption and wake-up response time. The Pretended Networking mode is in contrast to partial networking, which would control node clusters within an application.

FlexCAN_0 supports additional filtering (including range) for Pretended Networking. FlexCAN_0 supports Pretended Networking functionality in STOP and LPU_STOP modes.

Each FlexCAN module supports DMA requests from the RxFIFO. Each FlexCAN instantiation supports 96 Message Buffers.

Each FlexCAN module has one external output CAN_Tx (CAN Transmit) and one external input CAN_Rx (CAN Receive).

FLEXCAN_0 supports continuous operation across LPU_RUN mode with FLEXCAN0 CHI running on FXOSC selected via MC_CGM_AC9_SC[SELCTL]. For this, LPU_RUN_CF[CAN0_CONT] needs to be programmed. If CAN0 is operating with this configuration and FXOSC is disabled in between then the Software would not be able to read the CAN0 registers. Hence FXOSC should be kept enabled throughout the CAN0 operation in this configuration.

44.1.1.1 FlexCAN_0 Registers

The Pretended Network Registers are available for FlexCAN_0 instances only.

44.1.1.2 FlexCAN_1 to FlexCAN_7 Registers

The following table shows the address offsets and implementation of the FlexCAN_1 to FlexCAN_7 registers in this chip.

Table 44-1. Register access and reset information

Register	Access type	Affected by hard reset	Affected by soft reset
Module Configuration Register (MCR)	S	Yes	Yes
Control 1 register (CTRL1)	S/U	Yes	No
Free Running Timer register (TIMER)	S/U	Yes	Yes
Rx Mailboxes Global Mask register (RXMGMASK)	S/U	No	No
Rx Buffer 14 Mask register (RX14MASK)	S/U	No	No
Rx Buffer 15 Mask register (RX15MASK)	S/U	No	No
Error Counter Register (ECR)	S/U	Yes	Yes
Error and Status 1 Register (ESR1)	S/U	Yes	Yes
Interrupt Masks 1 register (IMASK1)	S/U	Yes	Yes
Interrupt Flags 1 register (IFLAG1)	S/U	Yes	Yes
Control 2 Register (CTRL2)	S/U	Yes	No
Error and Status 2 Register (ESR2)	S/U	Yes	Yes
CRC Register (CRCR)	S/U	Yes	Yes
Rx FIFO Global Mask register (RXFGMASK)	S/U	No	No
Rx FIFO Information Register (RXFIR)	S/U	No	No
Message buffers	S/U	No	No
Rx Individual Mask Registers	S/U	No	No

44.1.2 Requirements for entering FlexCAN modes: Freeze, Module Disable, Stop

Follow the procedure described in Freeze mode entry to place the FlexCAN module in that mode.

On this chip, the FlexCAN module cannot directly enter:

- Module Disable mode
- Stop mode

To enter these modes, the FlexCAN module must first enter Freeze mode. See the following information about each of the modes.

44.1.2.1 Freeze mode entry

See Freeze mode for details about this mode.

On this chip, the procedure to enter Freeze mode is:

1. Set both CAN_MCR[FRZ] (Freeze Enable) and CAN_MCR[HALT] (Halt) to 1.
2. Check whether CAN_MCR[MDIS] (Module Disable) is set to 1. If it is, clear it to 0.
3. Poll the MCR register until CAN_MCR[FRZACK] (Freeze Mode Acknowledge) is set to 1 or the timeout is reached.

NOTE

The minimum timeout duration must be equivalent to:

a. 730 CAN Nominal bits if CAN_MCR[FDEN] (CAN FD Operation Enable) is set to 1 (CAN bits calculated at arbitration bit rate),
b. 180 CAN bits if CAN_MCR[FDEN] is cleared to 0.

4. If CAN_MCR[FRZACK] is set to 1, no further action is required. Skip steps 5 to 8.
5. If the timeout is reached because CAN_MCR[FRZACK] remains cleared to 0, then set CAN_MCR[SOFTRST] (Soft Reset) to 1.
6. Poll MCR until CAN_MCR[SOFTRST] is cleared to 0.
7. Reconfigure the Module Control Register (CAN_MCR).
8. Reconfigure all the Interrupt Mask Registers (CAN_IMASK*n*).

After these steps are complete, the module is in Freeze mode.

44.1.2.2 Module Disable mode entry

See Module Disable mode for details about this mode.

CAUTION

In the detailed description of this mode, the list of FlexCAN behavior that begins with "If the module is disabled during transmission or reception" does not apply to this chip.

On this chip, the procedure to enter Module Disable mode is:

1. Enter Freeze mode by following the procedure described in Freeze mode entry.
2. Request Module Disable mode by setting CAN_MCR[MDIS] to 1.
3. Poll CAN_MCR until CAN_MCR[LPMACK] is set to 1. The minimum timeout duration for setting CAN_MCR[LPMACK] is 2 CAN Nominal bits.

44.1.2.3 Stop mode entry

See Stop mode for details about this mode.

CAUTION

In the detailed description of this mode, the list of FlexCAN behavior that begins with "If Stop mode is requested during transmission or reception" does not apply to this chip.

On this chip, the procedure to enter Stop mode is:

1. Enter Freeze mode by following the procedure described in Freeze mode entry.
2. Request Stop mode.
3. Poll MCR until CAN_MCR[LPMACK] is set to 1. The minimum timeout duration for setting CAN_MCR[LPMACK] is 2 CAN Nominal bits.

44.1.3 External time tick

The external time tick for the Free Running Timer counter is given by PIT-RTI as per the following table for the multiple instances of FlexCAN.

Table 44-2. External time tick

FlexCAN Instance	PIT Channel
FlexCAN_0, FlexCAN_1, FlexCAN_2, FlexCAN_3	PIT_14
FlexCAN_4, FlexCAN_5, FlexCAN_6, FlexCAN_7	PIT_15

44.1.4 FlexCAN's stop-stop ack protocol

- If FlexCAN is disabled, it acknowledges the stop request immediately.
- If FlexCAN is enabled, it will acknowledge the stop request after all current Tx or Rx process is finished.

Acknowledgement for stop mode request will be asserted within 180 CAN bits from the low-power mode request by the core, and negated within 2 CAN bits after the low-power mode request removal (see Protocol timing). When FlexCAN is in Pretended Networking mode acknowledgement will be negated within 180 CAN bits after the low-power mode request removal.

44.2 Introduction

The FlexCAN module is a communication controller implementing the CAN protocol according to the ISO 11898-1 standard and CAN 2.0 B protocol specifications. A general block diagram is shown in the following figure, which describes the main subblocks implemented in the FlexCAN module, including one associated memory for storing message buffers, Receive Global Mask registers, Receive Individual Mask registers, Receive FIFO filters, and Receive FIFO ID filters. The functions of the submodules are described in subsequent sections.

NOTE

Rx FIFOs cannot be used in FD mode.

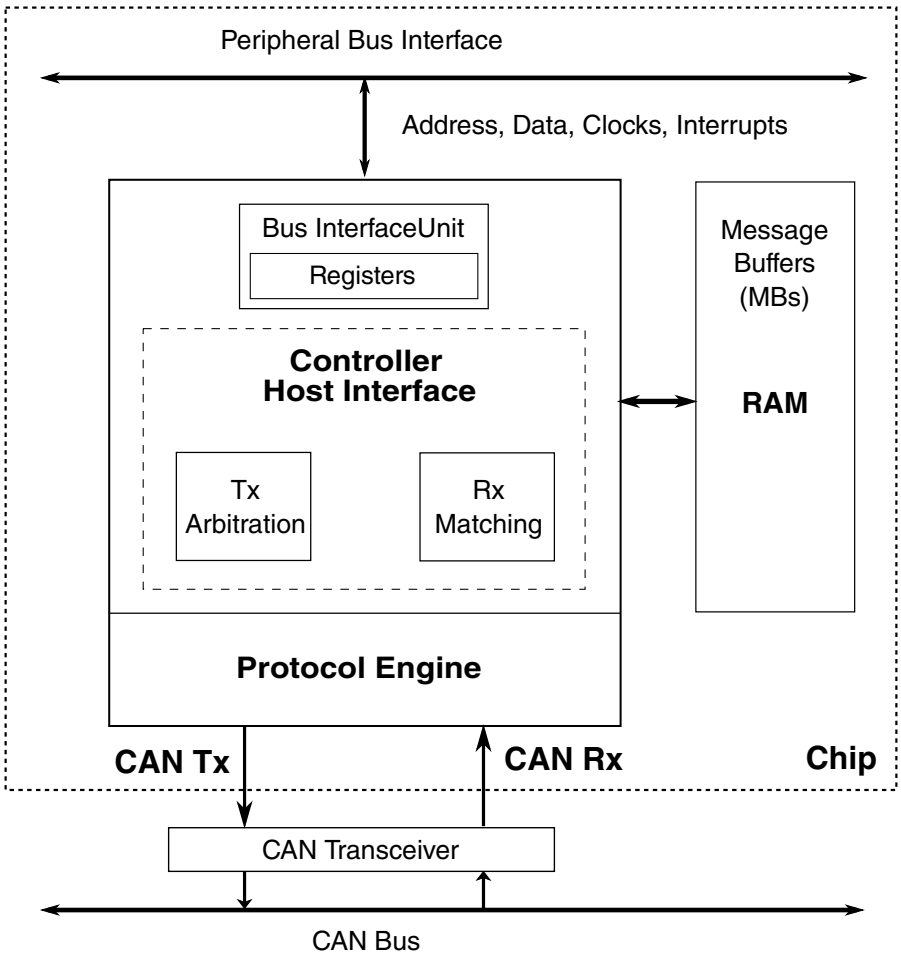

Figure 44-1. FlexCAN block diagram

44.2.1 Overview

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific requirements of this field:

- Real-time processing
- Reliable operation in the EMI environment of a vehicle
- Cost-effectiveness
- Required bandwidth

The FlexCAN module is a full implementation of the CAN protocol specification, the CAN with Flexible Data rate (CAN FD) protocol and the CAN 2.0 version B protocol, which supports both standard and extended message frames and long payloads up to 64 bytes transferred at faster rates up to 8 Mbps. The message buffers are stored in an embedded RAM dedicated to the FlexCAN module. See the chip configuration details for the actual number of message buffers configured in the chip.

The Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- Requesting RAM access for receiving and transmitting message frames
- Validating received messages
- Performing error handling
- Detecting CAN FD messages

The Controller Host Interface (CHI) sub-module handles message buffer selection for reception and transmission, taking care of arbitration and ID matching algorithms for both CAN FD and non-CAN FD message formats.

The Bus Interface Unit (BIU) sub-module controls the access to and from the internal interface bus, in order to establish connection to the CPU and to other blocks. Clocks, address and data buses, interrupt outputs, DMA and test signals are accessed through the BIU.

44.2.2 FlexCAN module features

The FlexCAN module includes these distinctive features:

- Full implementation of the CAN with Flexible Data Rate (CAN FD) protocol specification and CAN protocol specification, Version 2.0 B
    - Standard data frames
    - Extended data frames
    - Zero to sixty four bytes data length
    - Programmable bit rate (see the chip-specific FlexCAN information for the specific maximum rate configuration)
    - Content-related addressing
- Compliant with the ISO 11898-1 standard
- Flexible mailboxes configurable to store 0 to 8, 16, 32 or 64 bytes data length
- Each mailbox configurable as receive or transmit, all supporting standard and extended messages
- Individual Rx Mask registers per mailbox
- Full-featured Rx FIFO with storage capacity for up to six frames and automatic internal pointer handling with DMA support

- Transmission abort capability
- Flexible message buffers (MBs), totaling 96 message buffers of 8 bytes data length each, configurable as Rx or Tx
- Programmable clock source to the CAN Protocol Interface, either peripheral clock or oscillator clock
- RAM not used by reception or transmission structures can be used as general purpose RAM space
- Listen-Only mode capability
- Programmable Loop-Back mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Time stamp based on 16-bit free-running timer, with an optional external time tick
- Global network time, synchronized by a specific message
- Maskable interrupts
- Independence from the transmission medium (an external transceiver is assumed)
- Short latency time due to an arbitration scheme for high-priority messages
- Low power modes, with programmable wake up on bus activity or matching with received frames (Pretended Networking)
- Transceiver Delay Compensation feature when transmitting CAN FD messages at faster data rates
- Remote request frames may be handled automatically or by software
- CAN bit time settings and configuration bits can only be written in Freeze mode
- Tx mailbox status (Lowest priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- SYNCH bit available in Error in Status 1 register to inform that the module is synchronous with CAN bus
- CRC status for transmitted message
- Rx FIFO Global Mask register
- Selectable priority between mailboxes and Rx FIFO during matching process

- Powerful Rx FIFO ID filtering, capable of matching incoming IDs against either 128 extended, 256 standard, or 512 partial (8 bit) IDs, with up to 32 individual masking capability
- 100% backward compatibility with previous FlexCAN version
- Supports Pretended Networking functionality in low power: Stop mode

44.2.3 Modes of operation

The FlexCAN module has these functional modes:

- Normal mode (User or Supervisor):

  In Normal mode, the module operates receiving and/or transmitting message frames, errors are handled normally, and all CAN Protocol functions are enabled. User and Supervisor Modes differ in the access to some restricted control registers.

- Freeze mode:

  Freeze mode is enabled when the FRZ bit in MCR is asserted. If enabled, Freeze mode is entered when MCR[HALT] is set or when Debug mode is requested at chip level and MCR[FRZ_ACK] is asserted by the FlexCAN. In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See Freeze mode for more information.

- Loop-Back mode:

  The module enters this mode when the LPB field in the Control 1 Register is asserted. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic '1'). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

- Listen-Only mode:

  The module enters this mode when the LOM field in the Control 1 Register is asserted. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by

another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

- CAN FD Active mode:

  In this mode, FlexCAN is capable of transmitting and receiving all messages formatted according to the CAN FD Protocol and CAN 2.0 Protocol 2.0 in a interleaved fashion. The CPU can set the FlexCAN into CAN FD Active mode by configuring the MCR[FDEN] bit field in Freeze Mode.

For low-power operation, the FlexCAN module has:

- Module Disable mode:

  This low-power mode is entered when the MDIS bit in the MCR Register is asserted by the CPU and the LPM_ACK is asserted by the FlexCAN. When disabled, the module requests to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Exit from this mode is done by negating the MDIS bit in the MCR register. See Module Disable mode for more information.

- Stop mode:

  This low power mode is entered when Stop mode is requested at chip level and the LPM_ACK bit in the MCR Register is asserted by the FlexCAN. When in Stop Mode, the module puts itself in an inactive state and then informs the CPU that the clocks can be shut down globally. Exit from this mode happens when the Stop mode request is removed, or when activity is detected on the CAN bus and the Self Wake Up mechanism is enabled. See Stop mode for more information.

- Pretended Network Mode:

  This mode can be selected to operate together with Stop mode. Before entering in one of these low power modes the PNET_EN bit in MCR Register must be asserted. Once in low power mode, CHI sub-block clocks are shut down and CAN_PE sub-block is kept clocked, so that the Rx receive process is still active to filter incoming messages (see Receive Process under Pretended Networking Mode) as defined by the configuration registers (see Pretended Networking Control 1 Register (CTRL1_PN)). Upon detecting a wake up event, a Wake Up interrupt is issued to the system. When PNET_EN bit in MCR is asserted, the CPU must disable the Self Wake Up feature by negating SLF_WAK bit in MCR register (see Module Configuration Register (MCR)).

44.3 FlexCAN signal descriptions

The FlexCAN module has two I/O signals connected to the external chip pins. These signals are summarized in the following table and described in more detail in the next subsections.

Table 44-3. FlexCAN signal descriptions

Signal	Description	I/O
CAN Rx	CAN Receive Pin	Input
CAN Tx	CAN Transmit Pin	Output

44.3.1 CAN Rx

This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

44.3.2 CAN Tx

This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

44.4 Memory map/register definition

This section describes the registers and data structures in the FlexCAN module. The base address of the module depends on the particular memory map of the chip.

44.4.1 FlexCAN memory mapping

The memory map for the FlexCAN module is shown in the following table.

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address offset 0x0080.

Each individual register is identified by its complete name and the corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U). Most of the registers can be configured to have either Supervisor or Unrestricted access by programming the SUPV field in the MCR register. These registers are identified as S/U in the Access column of Table 44-4.

Table 44-4. Register access and reset information

Register	Access type	Affected by hard reset	Affected by soft reset
Module Configuration Register (CAN_MCR)	S	Yes	Yes
Control 1 register (CAN_CTRL1)	S/U	Yes	No
Free Running Timer register (CAN_TIMER)	S/U	Yes	Yes
Rx Mailboxes Global Mask register (CAN_RXMGMASK)	S/U	No	No
Rx Buffer 14 Mask register (CAN_RX14MASK)	S/U	No	No
Rx Buffer 15 Mask register (CAN_RX15MASK)	S/U	No	No
Error Counter Register (CAN_ECR)	S/U	Yes	Yes
Error and Status 1 Register (CAN_ESR1)	S/U	Yes	Yes
Interrupt Masks 2 register (CAN_IMASK2)	S/U	Yes	Yes
Interrupt Masks 1 register (CAN_IMASK1)	S/U	Yes	Yes
Interrupt Flags 2 register (CAN_IFLAG2)	S/U	Yes	Yes
Interrupt Flags 1 register (CAN_IFLAG1)	S/U	Yes	Yes
Control 2 Register (CAN_CTRL2)	S/U	Yes	No
Error and Status 2 Register (CAN_ESR2)	S/U	Yes	Yes
CRC Register (CAN_CRCR)	S/U	Yes	Yes
Rx FIFO Global Mask register (CAN_RXFGMASK)	S/U	No	No
Rx FIFO Information Register (CAN_RXFIR)	S/U	No	No
CAN Bit Timing Register (CAN_CBT)	S/U	Yes	No
Interrupt Masks 3 register (CAN_IMASK3)	S/U	Yes	Yes
Interrupt Flags 3 register (CAN_IFLAG3)	S/U	Yes	Yes
Message buffers	S/U	No	No
Rx Individual Mask Registers	S/U	No	No
Pretended Networking Control 1 register (CAN_CTRL1_PN)	S/U	Yes	Yes
Pretended Networking Control 2 register (CAN_CTRL2_PN)	S/U	Yes	Yes
Pretended Networking Wake Up Match register (CAN_WU_MTC)	S/U	Yes	Yes
Pretended Networking ID Filter 1 Register (CAN_FLT_ID1)	S/U	Yes	Yes
Pretended Networking DLC Filter register (CAN_FLT_DLC)	S/U	Yes	Yes
Pretended Networking Payload Low Filter 1 register (CAN_PL1_LO)	S/U	Yes	Yes
Pretended Networking Payload High Filter 1 register (CAN_PL1_HI)	S/U	Yes	Yes
Pretended Networking ID Filter 2 Register / ID Mask register (CAN_FLT_ID2_IDMASK)	S/U	Yes	Yes
Pretended Networking Payload Low Filter 2 Register / Payload Low Mask Register (CAN_PL2_PLMASK_LO)	S/U	Yes	Yes

Table continues on the next page...

Table 44-4. Register access and reset information (continued)

Register	Access type	Affected by hard reset	Affected by soft reset
Pretended Networking Payload High Filter 2 Register / Payload High Mask Register (CAN_PL2_PLMASK_HI)	S/U	Yes	Yes
Pretended Networking Wake Up Message Buffer 0 register (CAN_WMB0)	S/U	Yes	No
Pretended Networking Wake Up Message Buffer 1 register (CAN_WMB1)	S/U	Yes	No
Pretended Networking Wake Up Message Buffer 2 register (CAN_WMB2)	S/U	Yes	No
Pretended Networking Wake Up Message Buffer 3 register (CAN_WMB3)	S/U	Yes	No
CAN FD Control register (CAN_FDCTRL)	S/U	Yes	No
CAN FD Bit Timing register (CAN_FDCBT)	S/U	Yes	No
CAN FD CRC register (CAN_FDCRC)	S/U	Yes	Yes

The FlexCAN module can store CAN messages for transmission and reception using mailboxes and Rx FIFO structures.

The table below shows the FlexCAN memory map.

The address range from offset 0x80 to 0x67F allocates the ninety-six 128-bit Message Buffers (MBs).

The memory maps for the message buffers are in FlexCAN message buffer memory map.

CAN memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Module Configuration Register (CAN_MCR)	32	R/W	See section	44.4.2/1542
4	Control 1 register (CAN_CTRL1)	32	R/W	0000_0000h	44.4.3/1547
8	Free Running Timer (CAN_TIMER)	32	R/W	0000_0000h	44.4.4/1551
10	Rx Mailboxes Global Mask Register (CAN_RXMGMASK)	32	R/W	Undefined	44.4.5/1552
14	Rx 14 Mask register (CAN_RX14MASK)	32	R/W	Undefined	44.4.6/1553

CAN_MCR field descriptions

Field	Description
0 MDIS	Module Disable This bit controls whether FlexCAN is enabled or not. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface sub-modules. This bit is not affected by soft reset.

Table continues on the next page...

CAN_MCR field descriptions (continued)

Field	Description
	0 Enable the FlexCAN module. 1 Disable the FlexCAN module.
1 FRZ	Freeze Enable The FRZ bit specifies the FlexCAN behavior when the HALT bit in the CAN_MCR Register is set or when Debug mode is requested at chip level. When FRZ is asserted, FlexCAN is enabled to enter Freeze mode. Negation of this bit field causes FlexCAN to exit from Freeze mode. 0 Not enabled to enter Freeze mode. 1 Enabled to enter Freeze mode.
2 RFEN	Rx FIFO Enable This bit controls whether the Rx FIFO feature is enabled or not. When RFEN is set, MBs 0 to 5 cannot be used for normal reception and transmission because the corresponding memory region (0x80-0xDC) is used by the FIFO engine as well as additional MBs (up to 32, depending on CAN_CTRL2[RFFN] setting) which are used as Rx FIFO ID Filter Table elements. RFEN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in the table "Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate" (see Arbitration and matching timing). This bit can be written in Freeze mode only because it is blocked by hardware in other modes. **NOTE:** This bit cannot be set when CAN FD operation is enabled (see FDEN bit). 0 Rx FIFO not enabled. 1 Rx FIFO enabled.
3 HALT	Halt FlexCAN Assertion of this bit puts the FlexCAN module into Freeze mode. The CPU should clear it after initializing the Message Buffers and the Control Registers CAN_CTRL1 and CAN_CTRL2. No reception or transmission is performed by FlexCAN before this bit is cleared. Freeze mode cannot be entered while FlexCAN is in a low power mode. 0 No Freeze mode request. 1 Enters Freeze mode if the FRZ bit is asserted.
4 NOTRDY	FlexCAN Not Ready This read-only bit indicates that FlexCAN is either in Disable mode, Stop mode or Freeze mode. It is negated once FlexCAN has exited these modes. This bit is not affected by soft reset. 0 FlexCAN module is either in Normal mode, Listen-Only mode or Loop-Back mode. 1 FlexCAN module is either in Disable mode, Stop mode or Freeze mode.
5 WAKMSK	Wake Up Interrupt Mask This bit enables the Wake Up Interrupt generation under Self Wake Up mechanism. 0 Wake Up Interrupt is disabled. 1 Wake Up Interrupt is enabled.
6 SOFTRST	Soft Reset When this bit is asserted, FlexCAN resets its internal state machines and some of the memory mapped registers.

Table continues on the next page...

CAN_MCR field descriptions (continued)

Field	Description
	The SOFTRST bit can be asserted directly by the CPU when it writes to the MCR Register. Because soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, it may take some time to fully propagate its effect. The SOFTRST bit remains asserted while reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed. Soft reset cannot be applied while clocks are shut down in a low power mode. The module should be first removed from low power mode, and then soft reset can be applied. This bit is not affected by soft reset. 0 No reset request. 1 Resets the registers affected by soft reset.
7 FRZACK	Freeze Mode Acknowledge This read-only bit indicates that FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore the software can poll the FRZACK bit to know when FlexCAN has actually entered Freeze mode. If Freeze Mode request is negated, then this bit is negated after the FlexCAN prescaler is running again. If Freeze mode is requested while FlexCAN is in a low power mode, then the FRZACK bit will be set only when the low-power mode is exited. See Section "Freeze Mode". This bit is not affected by soft reset. **NOTE:** FRZACK will be asserted within 178 CAN bits from the freeze mode request by the CPU, and negated within 2 CAN bits after the freeze mode request removal (see Section "Protocol Timing"). 0 FlexCAN not in Freeze mode, prescaler running. 1 FlexCAN in Freeze mode, prescaler stopped.
8 SUPV	Supervisor Mode This bit configures the FlexCAN to be either in Supervisor or User mode. The registers affected by this bit are marked as S/U in the Access Type column of the module memory map. Reset value of this bit is 1, so the affected registers start with Supervisor access allowance only. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 FlexCAN is in User mode. Affected registers allow both Supervisor and Unrestricted accesses. 1 FlexCAN is in Supervisor mode. Affected registers allow only Supervisor access. Unrestricted access behaves as though the access was done to an unimplemented register location.
9 SLFWAK	Self Wake Up This bit enables the Self Wake Up feature when FlexCAN is in a low-power mode other than Disable mode. When this feature is enabled, the FlexCAN module monitors the bus for wake up event, that is, a recessive-to-dominant transition. If a wake up event is detected during Stop mode, then FlexCAN generates, if enabled to do so, a Wake Up interrupt to the CPU so that it can exit Stop mode globally and FlexCAN can request to resume the clocks. When FlexCAN is in a low-power mode other than Disable mode, this bit cannot be written as it is blocked by hardware. When Pretended Networking mode is set, this feature must be disabled. 0 FlexCAN Self Wake Up feature is disabled. 1 FlexCAN Self Wake Up feature is enabled.
10 WRNEN	Warning Interrupt Enable

Table continues on the next page...

CAN_MCR field descriptions (continued)

Field	Description
	When asserted, this bit enables the generation of the TWRNINT and RWRNINT flags in the Error and Status Register 1 (ESR1). If WRNEN is negated, the TWRNINT and RWRNINT flags will always be zero, independent of the values of the error counters, and no warning interrupt will ever be generated. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0 TWRNINT and RWRNINT bits are zero, independent of the values in the error counters. 1 TWRNINT and RWRNINT bits are set when the respective error counter transitions from less than 96 to greater than or equal to 96.
11 LPMACK	Low-Power Mode Acknowledge This read-only bit indicates that FlexCAN is in a low-power mode (Disable mode, Stop mode). A low-power mode cannot be entered until all current transmission or reception processes have finished, so the CPU can poll the LPMACK bit to know when FlexCAN has actually entered low power mode. This bit is not affected by soft reset. **NOTE:** LPMACK will be asserted within 180 CAN bits from the low-power mode request by the CPU, and negated within 2 CAN bits after the low-power mode request removal (see Section "Protocol Timing"). When FlexCAN is in Pretended Networking mode LPMACK will be negated within 180 CAN bits after the low-power mode request removal. 0 FlexCAN is not in a low-power mode. 1 FlexCAN is in a low-power mode.
12 WAKSRC	Wake Up Source This bit defines whether the integrated low-pass filter is applied to protect the Rx CAN input from spurious wake up. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 FlexCAN uses the unfiltered Rx input to detect recessive to dominant edges on the CAN bus. 1 FlexCAN uses the filtered Rx input to detect recessive to dominant edges on the CAN bus.
13 Reserved	This field is reserved. When writing to this field, always write the reset value.
14 SRXDIS	Self Reception Disable This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the module will not be stored in any MB, regardless if the MB is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due to the frame reception. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Self reception enabled. 1 Self reception disabled.
15 IRMQ	Individual Rx Masking And Queue Enable This bit indicates whether Rx matching process will be based either on individual masking and queue or on masking scheme with CAN_RXMGMASK, CAN_RX14MASK, CAN_RX15MASK and CAN_RXFGMASK. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0 Individual Rx masking and queue feature are disabled. For backward compatibility with legacy applications, the reading of C/S word locks the MB even if it is EMPTY. 1 Individual Rx masking and queue feature are enabled.
16 DMA	DMA Enable

Table continues on the next page...

CAN_MCR field descriptions (continued)

Field	Description
	The DMA Enable bit controls whether the DMA feature is enabled or not. The DMA feature can only be used in Rx FIFO, consequently the bit CAN_MCR[RFEN] must be asserted. When DMA and RFEN are set, the CAN_IFLAG1[BUF5I] generates the DMA request and no RX FIFO interrupt is generated. This bit can be written in Freeze mode only as it is blocked by hardware in other modes. 0 DMA feature for RX FIFO disabled. 1 DMA feature for RX FIFO enabled.
17 PNET_EN	Pretended Networking Enable This bit enables the Pretended Networking functionality. Once in Stop mode, CAN_PE sub-block is kept operational, able to process Rx message filtering as defined by the Pretended Networking configuration registers. See Receive Process under Pretended Networking Mode. This bit can be written in Freeze mode only. 0 Pretended Networking mode is disabled. 1 Pretended Networking mode is enabled.
18 LPRIOEN	Local Priority Enable This bit is provided for backwards compatibility with legacy applications. It controls whether the local priority feature is enabled or not. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11-bit for standard frames and 29-bit for extended frames. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Local Priority disabled. 1 Local Priority enabled.
19 AEN	Abort Enable When asserted, this bit enables the Tx abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. **NOTE:** When CAN_MCR[AEN] is asserted, only the abort mechanism (see Transmission abort mechanism) must be used for updating Mailboxes configured for transmission. **CAUTION:** Writing the Abort code into Rx Mailboxes can cause unpredictable results when the CAN_MCR[AEN] is asserted. 0 Abort disabled. 1 Abort enabled.
20 FDEN	CAN FD operation enable This bit enables the CAN with Flexible Data rate (CAN FD) operation. This bit can be written in Freeze mode only. **NOTE:** The Rx FIFO Enable (RFEN) bit cannot be set if FDEN is asserted. 1 CAN FD is enabled. FlexCAN is able to receive and transmit messages in both CAN FD and CAN 2.0 formats. 0 CAN FD is disabled. FlexCAN is able to receive and transmit messages in CAN 2.0 format.
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 IDAM	ID Acceptance Mode

Table continues on the next page...

CAN_MCR field descriptions (continued)

Field	Description
	This 2-bit field identifies the format of the Rx FIFO ID Filter Table elements. Note that all elements of the table are configured at the same time by this field (they are all the same format). See Section "Rx FIFO Structure". This field can be written only in Freeze mode because it is blocked by hardware in other modes. 00 Format A: One full ID (standard and extended) per ID Filter Table element. 01 Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID Filter Table element. 10 Format C: Four partial 8-bit Standard IDs per ID Filter Table element. 11 Format D: All frames rejected.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 MAXMB	Number Of The Last Message Buffer This 7-bit field defines the number of the last Message Buffers that will take part in the matching and arbitration processes. The reset value (0x0F) is equivalent to a 16 MB configuration. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Number of the last MB = MAXMB **NOTE:** MAXMB must be programmed with a value smaller than or equal to the number of available Message Buffers, as described in FlexCAN Memory Partition for CAN FD. Additionally, the definition of MAXMB value must take into account the region of MBs occupied by Rx FIFO and its ID filters table space defined by RFFN bit in CAN_CTRL2 register. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table "Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate" (see Arbitration and matching timing).

44.4.3 Control 1 register (CAN_CTRL1)

This register is defined for specific FlexCAN control features related to the CAN bus, such as bit-rate, programmable sampling point within an Rx bit, Loop Back mode, Listen-Only mode, Bus Off recovery behavior and interrupt enabling (Bus-Off, Error, Warning). It also determines the Division Factor for the clock prescaler.

The CAN bit timing variables (PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW) can also be configured in CAN_CBT register, which extends the range of all these variables. If CAN_CBT[BTF] is set, PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW fields of CAN_CTRL1 become read only.

NOTE

When the CAN FD feature is enabled, do not use the PRESDIV, RJW, PSEG1, PSEG2, and PROPSEG fields of the CAN_CTRL1 register for CAN bit timing. Instead use the the CAN_CBT register's EPRESDIV, ERJW, EPSEG1, EPSEG2, and EPROPSEG fields.

The contents of this register are not affected by soft reset.

NOTE

The CAN bit variables in CAN_CTRL1 and in CAN_CBT are stored in the same register.

Address: 0h base + 4h offset = 4h

CAN_CTRL1 field descriptions

Field	Description
0–7 PRESDIV	Prescaler Division Factor This 8-bit field defines the ratio between the PE clock frequency and the Serial Clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The Maximum value of this field is 0xFF, that gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. See Section "Protocol Timing". This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (PRESDIV + 1)
8–9 RJW	Resync Jump Width This 2-bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization. One time quantum is equal to the Sclock period. The valid programmable values are 0–3. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = RJW + 1.
10–12 PSEG1	Phase Segment 1 This 3-bit field defines the length of Phase Segment 1 in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (PSEG1 + 1) × Time-Quanta.

Table continues on the next page...

CAN_CTRL1 field descriptions (continued)

Field	Description
13–15 PSEG2	Phase Segment 2 This 3-bit field defines the length of Phase Segment 2 in the bit time. The valid programmable values are 1–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 2 = (PSEG2 + 1) × Time-Quanta.
16 BOFFMSK	Bus Off Interrupt Mask This bit provides a mask for the Bus Off Interrupt BOFFINT in CAN_ESR1 register. 0 Bus Off interrupt disabled. 1 Bus Off interrupt enabled.
17 ERRMSK	Error Interrupt Mask This bit provides a mask for the Error Interrupt ERRINT in the CAN_ESR1 register. 0 Error interrupt disabled. 1 Error interrupt enabled.
18 CLKSRC	CAN Engine Clock Source This bit selects the clock source to the CAN Protocol Engine (PE) to be either the peripheral clock or the oscillator clock. The selected clock is the one fed to the prescaler to generate the Serial Clock (Sclock). In order to guarantee reliable operation, this bit can be written only in Disable mode because it is blocked by hardware in other modes. See Protocol timing". 0 The CAN engine clock source is the oscillator clock. Under this condition, the oscillator clock frequency must be lower than the bus clock. 1 The CAN engine clock source is the peripheral clock.
19 LPB	Loop Back Mode This bit configures FlexCAN to operate in Loop-Back mode. In this mode, FlexCAN performs an internal loop back that can be used for self test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. **NOTE:** In this mode, the CAN_MCR[SRXDIS] cannot be asserted because this will impede the self reception of a transmitted message. **NOTE:** The TDCEN bit in CAN_FDCTRL register must be disabled when LPB is asserted. 0 Loop Back disabled. 1 Loop Back enabled.
20 TWRNMSK	Tx Warning Interrupt Mask This bit provides a mask for the Tx Warning Interrupt associated with the TWRNINT flag in the Error and Status Register 1 (ESR1). This bit is read as zero when CAN_MCR[WRNEN] bit is negated. This bit can be written only if CAN_MCR[WRNEN] bit is asserted.

Table continues on the next page...

CAN_CTRL1 field descriptions (continued)

Field	Description
	0 Tx Warning Interrupt disabled. 1 Tx Warning Interrupt enabled.
21 RWRNMSK	Rx Warning Interrupt Mask This bit provides a mask for the Rx Warning Interrupt associated with the RWRNINT flag in the Error and Status Register 1 (ESR1). This bit is read as zero when CAN_MCR[WRNEN] bit is negated. This bit can be written only if CAN_MCR[WRNEN] bit is asserted. 0 Rx Warning Interrupt disabled. 1 Rx Warning Interrupt enabled.
22 Reserved	This field is reserved.
23 Reserved	This field is reserved.
24 SMP	CAN Bit Sampling This bit defines the sampling mode of CAN bits at the Rx input. It can be written in Freeze mode only because it is blocked by hardware in other modes. **NOTE:** For proper operation, to assert SMP it is necessary to guarantee a minimum value of 2 TQs in CAN_CTRL1[PSEG1] (or CAN_CBT[EPSEG1]).This bit cannot be asserted when CAN FD is enabled (CAN_MCR[FDEN] = 1). 0 Just one sample is used to determine the bit value. 1 Three samples are used to determine the value of the received bit: the regular one (sample point) and 2 preceding samples; a majority rule is used.
25 BOFFREC	Bus Off Recovery This bit defines how FlexCAN recovers from Bus Off state. If this bit is negated, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from Bus Off is disabled and the module remains in Bus Off state until the bit is negated by the user. If the negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then Bus Off recovery happens as if the BOFFREC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FlexCAN will re-synchronize to the bus by waiting for 11 recessive bits before joining the bus. After negation, the BOFFREC bit can be re-asserted again during Bus Off, but it will be effective only the next time the module enters Bus Off. If BOFFREC was negated when the module entered Bus Off, asserting it during Bus Off will not be effective for the current Bus Off recovery. 0 Automatic recovering from Bus Off state enabled. 1 Automatic recovering from Bus Off state disabled.
26 TSYN	Timer Sync This bit enables a mechanism that resets the free-running timer each time a message is received in Message Buffer 0. This feature provides means to synchronize multiple FlexCAN stations with a special “SYNC” message, that is, global network time. If the RFEN bit in CAN_MCR is set (Rx FIFO enabled), the first available Mailbox, according to CAN_CTRL2[RFFN] setting, is used for timer synchronization instead of MB0. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0 Timer Sync feature disabled 1 Timer Sync feature enabled
27 LBUF	Lowest Buffer Transmitted First

Table continues on the next page...

CAN_CTRL1 field descriptions (continued)

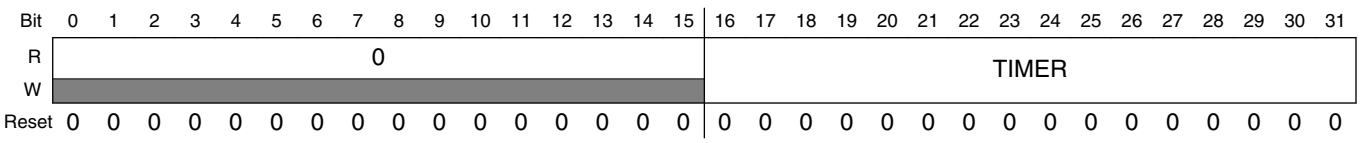
Field	Description
	This bit defines the ordering mechanism for Message Buffer transmission. When asserted, the CAN_MCR[LPRIOEN] bit does not affect the priority arbitration. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0 Buffer with highest priority is transmitted first. 1 Lowest number buffer is transmitted first.
28 LOM	Listen-Only Mode This bit configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters described in CAN_ECR register are frozen and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error without changing the receive error counter (RXERRCNT) in CAN_ECR register, as if it was trying to acknowledge the message. Listen-Only mode is acknowledged by the state of CAN_ESR1[FLTCONF] field indicating Passive Error. There can be some delay between the Listen-Only mode request and acknowledge. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0 Listen-Only mode is deactivated. 1 FlexCAN module operates in Listen-Only mode.
29–31 PROPSEG	Propagation Segment This 3-bit field defines the length of the Propagation Segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation Segment Time = (PROPSEG + 1) × Time-Quanta. Time-Quantum = one Sclock period.

44.4.4 Free Running Timer (CAN_TIMER)

This register represents a 16-bit free running counter that can be read and written by the CPU. The timer starts from 0x0 after Reset, counts linearly to 0xFFFF, and wraps around.

When the TIMER_SRC in CAN_CTRL2 register is asserted, the timer is continuously incremented by an external time tick. The time tick must be synchronous to the Peripheral Clock, with a minimum pulse width of one clock cycle.

When the TIMER_SRC bit in CAN_CTRL2 register is negated, the timer is incremented by the CAN bit clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable, Stop, Pretended Networking and Freeze modes.



The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the Time Stamp entry in a message buffer after a successful reception or transmission of a message.

If bit CAN_CTRL1[TSYN] is asserted, the Timer is reset whenever a message is received in the first available Mailbox, according to CAN_CTRL2[RFFN] setting.

The CPU can write to this register anytime. However, if the write occurs at the same time that the Timer is being reset by a reception in the first Mailbox, then the write value is discarded.

Reading this register affects the Mailbox Unlocking procedure, see Section "Mailbox Lock Mechanism".

Address: 0h base + 8h offset = 8h

CAN_TIMER field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TIMER	Timer Value Contains the free-running counter value.

44.4.5 Rx Mailboxes Global Mask Register (CAN_RXMGMASK)

This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When the CAN_MCR[IRMQ] bit is negated, RXMGMASK is always in effect (the bits in the MG field will mask the Mailbox filter bits).
- When the CAN_MCR[IRMQ] bit is asserted, RXMGMASK has no effect (the bits in the MG field will not mask the Mailbox filter bits).

RXMGMASK is used to mask the filter fields of all Rx MBs, excluding MBs 14-15, which have individual mask registers.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CAN_RXMGMASK field descriptions

Field	Description
0–31 MG	Rx Mailboxes Global Mask Bits These bits mask the Mailbox filter bits. Note that the alignment with the ID word of the Mailbox is not perfect as the two most significant MG bits affect the fields RTR and IDE, which are located in the Control and Status word of the Mailbox. The following table shows in detail which MG bits mask each Mailbox filter field.

SMB[RTR] [1]	CAN_CTRL2[RRS]	CAN_CTRL2[EACEN]	Mailbox filter fields			
			MB[RTR]	MB[IDE]	MB[ID]	Reserved
0	-	0	note [2]	note [3]	MG[28:0]	MG[31:29]
0	-	1	MG[31]	MG[30]	MG[28:0]	MG[29]
1	0	-	-	-	-	MG[31:0]
1	1	0	-	-	MG[28:0]	MG[31:29]
1	1	1	MG[31]	MG[30]	MG[28:0]	MG[29]

1. RTR bit of the Incoming Frame. It is saved into an auxiliary MB called Rx Serial Message Buffer (Rx SMB).
2. If the CTRL2[EACEN] bit is negated, the RTR bit of Mailbox is never compared with the RTR bit of the incoming frame.
3. If the CAN_CTRL2[EACEN] bit is negated, the IDE bit of Mailbox is always compared with the IDE bit of the incoming frame.

0 The corresponding bit in the filter is "don't care."
1 The corresponding bit in the filter is checked.

1. RTR bit of the Incoming Frame. It is saved into an auxiliary MB called Rx Serial Message Buffer (Rx SMB).
2. If the CTRL2[EACEN] bit is negated, the RTR bit of Mailbox is never compared with the RTR bit of the incoming frame.
3. If the CAN_CTRL2[EACEN] bit is negated, the IDE bit of Mailbox is always compared with the IDE bit of the incoming frame.

44.4.6 Rx 14 Mask register (CAN_RX14MASK)

This register is located in RAM.

RX14MASK is provided for legacy application support. When the CAN_MCR[IRMQ] bit is asserted, RX14MASK has no effect.

RX14MASK is used to mask the filter fields of Message Buffer 14.

This register can only be programmed while the module is in Freeze mode as it is blocked by hardware in other modes.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CAN_RX15MASK field descriptions

Field	Description
0–31 RX15M	Rx Buffer 15 Mask Bits

CAN_RX15MASK field descriptions (continued)

Field	Description
	Each mask bit masks the corresponding Mailbox 15 filter field in the same way that RXMGMASK masks other Mailboxes' filters. See the description of the CAN_RXMGMASK register. 0 The corresponding bit in the filter is "don't care." 1 The corresponding bit in the filter is checked.

44.4.8 Error Counter (CAN_ECR)

This register has four 8-bit fields reflecting the value of the FlexCAN error counters:

- Transmit Error Counter (TXERRCNT field)
- Receive Error Counter (RXERRCNT field)
- Transmit Error Counter for errors detected in the Data Phase of CAN FD messages with the BRS bit set (TXERRCNT_FAST field)
- Receive Error Counter for errors detected in the Data Phase of CAN FD messages with the BRS bit set (RXERRCNT_FAST field)

The TXERRCNT and RXERRCNT counters take into account all errors in both CAN FD and non-FD message formats. TXERRCNT_FAST and RXERRCNT_FAST are dedicated to count only the errors occurred in the Data Phase of CAN FD frames with the BRS bit set.

The Fault Confinement State (FLTCONF field in Error and Status Register 1 - CAN_ESR1) is updated based on TXERRCNT and RXERRCNT counters only. TXERRCNT and RXERRCNT counters can be written in Freeze mode only. TXERRCNT_FAST and RXERRCNT_FAST counters are read-only except in Freeze mode where the CPU can write value zero. The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FlexCAN module.

The following are the basic rules for FlexCAN bus state transitions:

- If the value of TXERRCNT or RXERRCNT increases to be greater than or equal to 128, the FLTCONF field in the Error and Status Register is updated to reflect "Error Passive" state.
- If the FlexCAN state is "Error Passive", and either TXERRCNT or RXERRCNT decrements to a value less than or equal to 127 while the other already satisfies this condition, the FLTCONF field in the Error and Status Register is updated to reflect "Error Active" state.

- If the value of TXERRCNT increases to be greater than 255, the FLTCONF field in the Error and Status Register is updated to reflect "Bus Off" state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in "Bus Off' state, then TXERRCNT is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, TXERRCNT is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around while incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, the FLTCONF field in the Error and Status Register is updated to be "Error Active" and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value. The TXERRCNT_FAST counter is frozen during busoff.
- If during system start-up, only one node is operating, then its TXERRCNT increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACKERR bit in the Error and Status Register). After the transition to "Error Passive" state, the TXERRCNT does not increment anymore by acknowledge errors. Therefore the device never goes to the "Bus Off" state.
- If the RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected while being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to resume to "Error Active" state.
- TXERRCNT_FAST and RXERRCNT_FAST error counters values increment and decrement based on errors detected only in the Data Phase of CAN FD frames with the BRS bit set, following the same increment and decrement rules as TXERRCNT and RXERRCNT counters. These counters do not wrap around and get stuck at their maximum value (255). They stop counting and keep their values frozen while FlexCAN is in "Bus Off" state. They are reset when FlexCAN leaves "Bus Off" state and restart counting once FlexCAN resumes to "Error Active" state.
- When FlexCAN is in Pretended Networking mode, the RXERRCNT and RXERRCNT_FAST keep counting errors and error flags are stored. The TXERRCNT and TXERRCNT_FAST preserve their values and do not change, since no transmission occurs under Pretended Networking mode. Error counters and error flags that changed values while in Pretended Networking mode are updated in CAN_ECR and CAN_ESR1 when FlexCAN resumes back to Normal mode. The FAST error flags in CAN_ESR1 register will not be set if FlexCAN is in Pretended Networking mode.

Address: 0h base + 1Ch offset = 1Ch

CAN_ECR field descriptions

Field	Description
0–7 RXERRCNT_ FAST	Receive Error Counter for fast bits Receive Error Counter for errors detected in the Data Phase of received CAN FD messages with the BRS bit set. The RXERRCNT_FAST counter is read-only except in Freeze mode, where the CPU can write a 8-bit zero value only.
8–15 TXERRCNT_ FAST	Transmit Error Counter for fast bits Transmit Error Counter for errors detected in the Data Phase of transmitted CAN FD messages with the BRS bit set. The TXERRCNT_FAST counter is read-only except in Freeze mode, where the CPU can write a 8-bit zero value only.
16–23 RXERRCNT	Receive Error Counter Receive Error Counter for all errors detected in received messages. The RXERRCNT counter is read-only except in Freeze mode, where it can be written by the CPU.
24–31 TXERRCNT	Transmit Error Counter Transmit Error Counter for all errors detected in transmitted messages. The TXERRCNT counter is read-only except in Freeze mode, where it can be written by the CPU.

44.4.9 Error and Status 1 register (CAN_ESR1)

This register reports various error conditions detected in the reception and transmission of a CAN frame, some general status of the device and it is the source of some interrupts to the CPU.

The reported error conditions are BIT1ERR, BIT0ERR, ACKKERR, CRCERR, FRMERR and STFERR, for errors detected in CAN frames of any format, and BIT1ERR_FAST, BIT0ERR_FAST, CRCERR_FAST, FRMERR_FAST and STFERR_FAST for errors detected in the Data Phase of CAN FD frames with the BRS bit set only.

An error detected in a single CAN frame may be reported by one or more error flags. Also, error reporting is cummulative in case more error events happen in the next frames while the CPU does not attempt to read this register.

TXWRN, RXWRN, IDLE, TX, FLTCONF, RX and SYNCH are status bits.

BOFFINT, BOFFDONEINT, ERRINT, ERRINT_FAST, WAKINT, TWRNINT and RWRNINT are interrupt bits. It is recommended the CPU to use the following procedure when servicing interrupt requests generated by these bits:

- Read this register to capture all error condition and status bits. This action clear the respective bits that were set since the last read access.
- Write 1 to clear the interrupt bit that has triggered the interrupt request.
- Write 1 to clear the ERR_OVR bit if it is set.

Starting from all error flags cleared, a first error event sets either the ERRINT or the ERRINT_FAST (provided the corresponding mask bit is asserted). If other error events in subsequent frames happen before the CPU to serve the interrupt request, the ERR_OVR bit is set to indicate that errors from different frames had accumulated.

SYNCH	IDLE	TX	RX	FlexCAN State
0	0	0	0	Not synchronized to CAN bus
1	1	x	x	Idle
1	0	1	0	Transmitting
1	0	0	1	Receiving

CAN_ESR1 field descriptions

Field	Description
0 BIT1ERR_FAST	Bit1 Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates when an inconsistency occurs between the transmitted and the received bit in the Data Phase of CAN FD frames with the BRS bit set. 0 No such occurrence. 1 At least one bit sent as recessive is received as dominant.
1 BIT0ERR_FAST	Bit0 Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates when an inconsistency occurs between the transmitted and the received bit in the Data Phase of CAN FD frames with the BRS bit set. 0 No such occurrence. 1 At least one bit sent as dominant is received as recessive.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 CRCERR_FAST	Cyclic Redundancy Check Error in the CRC field of CAN FD frames with the BRS bit set This bit indicates that a CRC Error has been detected by the receiver node in the CRC field of CAN FD frames with the BRS bit set, that is, the calculated CRC is different from the received. 0 No such occurrence. 1 A CRC error occurred since last read of this register.
4 FRMERR_FAST	Form Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates that a Form Error has been detected by the receiver node in the Data Phase of CAN FD frames with the BRS bit set, that is, a fixed-form bit field contains at least one illegal bit.

Table continues on the next page...

CAN_ESR1 field descriptions (continued)

Field	Description
	0 No such occurrence. 1 A Form Error occurred since last read of this register.
5 STFERR_FAST	Stuffing Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates that a Stuffing Error has been detected in the Data Phase of CAN FD frames with the BRS bit set. 0 No such occurrence. 1 A Stuffing Error occurred since last read of this register.
6–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 ERROVR	Error Overrun bit This bit indicates that an error condition occurred when any error flag is already set. This bit is cleared by writing it to 1. 0 Overrun has not occurred. 1 Overrun has occurred.
11 ERRINT_FAST	Error Interrupt for errors detected in the Data Phase of CAN FD frames with the BRS bit set This bit indicates that at least one of the Error Bits detected in the Data Phase of CAN FD frames with the BRS bit set (BIT1ERR_FAST, BIT0ERR_FAST, CRCERR_FAST, FRMERR_FAST or STFERR_FAST) is set. If the corresponding mask bit CAN_CTRL2[ERRMSK_FAST] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0 No such occurrence. 1 Indicates setting of any Error Bit detected in the Data Phase of CAN FD frames with the BRS bit set.
12 BOFFDONEINT	Bus Off Done Interrupt This bit is set when the Tx Error Counter (TXERRCNT) has finished counting 128 occurrences of 11 consecutive recessive bits on the CAN bus and is ready to leave Bus Off. If the corresponding mask bit in the Control 2 Register (BOFFDONEMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0 No such occurrence. 1 FlexCAN module has completed Bus Off process.
13 SYNCH	CAN Synchronization Status This read-only flag indicates whether the FlexCAN is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the FlexCAN. See the table in the overall CAN_ESR1 register description. 0 FlexCAN is not synchronized to the CAN bus. 1 FlexCAN is synchronized to the CAN bus.
14 TWRNINT	Tx Warning Interrupt Flag If the WRNEN bit in CAN_MCR is asserted, the TWRNINT bit is set when the TXWRN flag transitions from 0 to 1, meaning that the Tx error counter reached 96. If the corresponding mask bit in the Control 1 Register (CAN_CTRL1[TWRNMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when the WRNEN is set again. Writing 0 has no effect. This flag is not generated during Bus Off state. This bit is not updated during Freeze mode.

Table continues on the next page...

CAN_ESR1 field descriptions (continued)

Field	Description
	When FlexCAN returns to Normal mode from Pretended Network mode (see Receive Process under Pretended Networking Mode), this bit is not updated. 0 No such occurrence. 1 The Tx error counter transitioned from less than 96 to greater than or equal to 96.
15 RWRNINT	Rx Warning Interrupt Flag If the WRNEN bit in CAN_MCR is asserted, the RWRNINT bit is set when the RXWRN flag transitions from 0 to 1, meaning that the Rx error counters reached 96. If the corresponding mask bit in the Control 1 Register (CAN_CTRL1[RWRNMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when the WRNEN is set again. Writing 0 has no effect. This bit is not updated during Freeze mode. When FlexCAN returns to Normal mode from Pretended Network mode (see Receive Process under Pretended Networking Mode), this bit is updated to reflect the Rx error counter state. 0 No such occurrence. 1 The Rx error counter transitioned from less than 96 to greater than or equal to 96.
16 BIT1ERR	Bit1 Error This bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. This bit is updated when FlexCAN returns to Normal mode from Pretended Network mode. **NOTE:** This bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits. 0 No such occurrence. 1 At least one bit sent as recessive is received as dominant.
17 BIT0ERR	Bit0 Error This bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. This bit is updated when FlexCAN returns to Normal mode from Pretended Network mode. 0 No such occurrence. 1 At least one bit sent as dominant is received as recessive.
18 ACKERR	Acknowledge Error This bit indicates that an Acknowledge Error has been detected by the transmitter node, that is, a dominant bit has not been detected during the ACK SLOT. This bit is updated when FlexCAN returns to Normal mode from Pretended Network mode. 0 No such occurrence. 1 An ACK error occurred since last read of this register.
19 CRCERR	Cyclic Redundancy Check Error This bit indicates that a CRC Error has been detected by the receiver node either in a non-FD message or in the arbitration or data phase of a frame in CAN FD format, that is, the calculated CRC is different from the received. This bit is updated when FlexCAN returns to Normal mode from Pretended Network mode.

Table continues on the next page...

CAN_ESR1 field descriptions (continued)

Field	Description
	0 No such occurrence. 1 A CRC error occurred since last read of this register.
20 FRMERR	Form Error This bit indicates that a Form Error has been detected in a non-FD message or else in an FD message's arbitration or data phase by the receiver node, that is, a fixed-form bit field contains at least one illegal bit. This bit is updated when FlexCAN returns to Normal mode from Pretended Network mode. 0 No such occurrence. 1 A Form Error occurred since last read of this register.
21 STFERR	Stuffing Error This bit indicates that a Stuffing Error has been detected in a non-FD message or else in an FD message's arbitration or data phase by the receiver node. This bit is updated when FlexCAN returns to Normal mode from Pretended Network mode. 0 No such occurrence. 1 A Stuffing Error occurred since last read of this register.
22 TXWRN	TX Error Warning This bit indicates when repetitive errors are occurring during message transmission and is affected by the value of TXERRCNT in CAN_ECR register only. This bit is not updated during Freeze mode. 0 No such occurrence. 1 TXERRCNT is greater than or equal to 96.
23 RXWRN	Rx Error Warning This bit indicates when repetitive errors are occurring during message reception and is affected by the value of RXERRCNT in CAN_ECR register only. This bit is not updated during Freeze mode. Additionally, it is updated when FlexCAN returns to Normal mode from Pretended Networking mode. 0 No such occurrence. 1 RXERRCNT is greater than or equal to 96.
24 IDLE	This bit indicates when CAN bus is in IDLE state. See the table in the overall CAN_ESR1 register description. 0 No such occurrence. 1 CAN bus is now IDLE.
25 TX	FlexCAN In Transmission This bit indicates if FlexCAN is transmitting a message. See the table in the overall CAN_ESR1 register description. 0 FlexCAN is not transmitting a message. 1 FlexCAN is transmitting a message.
26–27 FLTCONF	Fault Confinement State This 2-bit field indicates the Confinement State of the FlexCAN module.

Table continues on the next page...

CAN_ESR1 field descriptions (continued)

Field	Description
	If the LOM bit in the Control Register 1 is asserted, after some delay that depends on the CAN bit timing the FLTCONF field will indicate “Error Passive”. The very same delay affects the way how FLTCONF reflects an update to CAN_ECR register by the CPU. It may be necessary up to one CAN bit time to get them coherent again. This bit field is affected by soft reset, but if the LOM bit is asserted, its reset value lasts just one CAN bit. After this time, FLTCONF reports "Error Passive". 00 Error Active 01 Error Passive 1x Bus Off
28 RX	FlexCAN In Reception This bit indicates if FlexCAN is receiving a message. See the table in the overall CAN_ESR1 register description. 0 FlexCAN is not receiving a message. 1 FlexCAN is receiving a message.
29 BOFFINT	Bus Off Interrupt This bit is set when FlexCAN enters ‘Bus Off’ state. If the corresponding mask bit in the Control Register 1 (CAN_CTRL1[BOFFMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0 No such occurrence. 1 FlexCAN module entered Bus Off state.
30 ERRINT	Error Interrupt This bit indicates that at least one of the Error Bits (BIT1ERR, BIT0ERR, ACKERR. CRCERR, FRMERR or STFERR) is set. If the corresponding mask bit CAN_CTRL1[ERRMSK] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0 No such occurrence. 1 Indicates setting of any Error Bit in the Error and Status Register.
31 WAKINT	Wake-Up Interrupt This field applies when FlexCAN is in low-power mode under Self Wake Up mechanism: • Stop mode When a recessive-to-dominant transition is detected on the CAN bus and if the CAN_MCR[WAKMSK] bit is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When CAN_MCR[SLFWAK] is negated, this flag is masked. The CPU must clear this flag before disabling the bit. Otherwise it will be set when the SLFWAK is set again. Writing 0 has no effect. 0 No such occurrence. 1 Indicates a recessive to dominant transition was received on the CAN bus.

44.4.10 Interrupt Masks 2 register (CAN_IMASK2)

This register allows any number of a range of the 32 Message Buffer Interrupts to be enabled or disabled for MB63 to MB32. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding CAN_IFLAG2 bit is set.

Address: 0h base + 24h offset = 24h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	BUF63TO32M																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CAN_IMASK2 field descriptions

Field	Description
0–31 BUF63TO32M	Buffer MB $_i$ Mask Each bit enables or disables the corresponding FlexCAN Message Buffer Interrupt for MB63 to MB32. **NOTE:** Setting or clearing a bit in the CAN_IMASK2 Register can assert or negate an interrupt request, if the corresponding IFLAG2 bit is set. 0 The corresponding buffer Interrupt is disabled. 1 The corresponding buffer Interrupt is enabled.

44.4.11 Interrupt Masks 1 register (CAN_IMASK1)

This register allows any number of a range of the 32 Message Buffer Interrupts to be enabled or disabled for MB31 to MB0. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding CAN_IFLAG1 bit is set.

Address: 0h base + 28h offset = 28h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CAN_IMASK1 field descriptions

Field	Description
0–31 BUF31TO0M	Buffer MB $_i$ Mask

CAN_IMASK1 field descriptions (continued)

Field	Description
	Each bit enables or disables the corresponding FlexCAN Message Buffer Interrupt for MB31 to MB0. **NOTE:** Setting or clearing a bit in the CAN_IMASK1 Register can assert or negate an interrupt request, if the corresponding IFLAG1 bit is set. 0 The corresponding buffer Interrupt is disabled. 1 The corresponding buffer Interrupt is enabled.

44.4.12 Interrupt Flags 2 register (CAN_IFLAG2)

This register defines the flags for the 32 Message Buffer interrupts for MB63 to MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the respective CAN_IFLAG2 bit. If the corresponding CAN_IMASK2 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating CAN_MCR[MAXMB] field, CPU must service the CAN_IFLAG2 bits whose MB value is greater than the MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

Address: 0h base + 2Ch offset = 2Ch

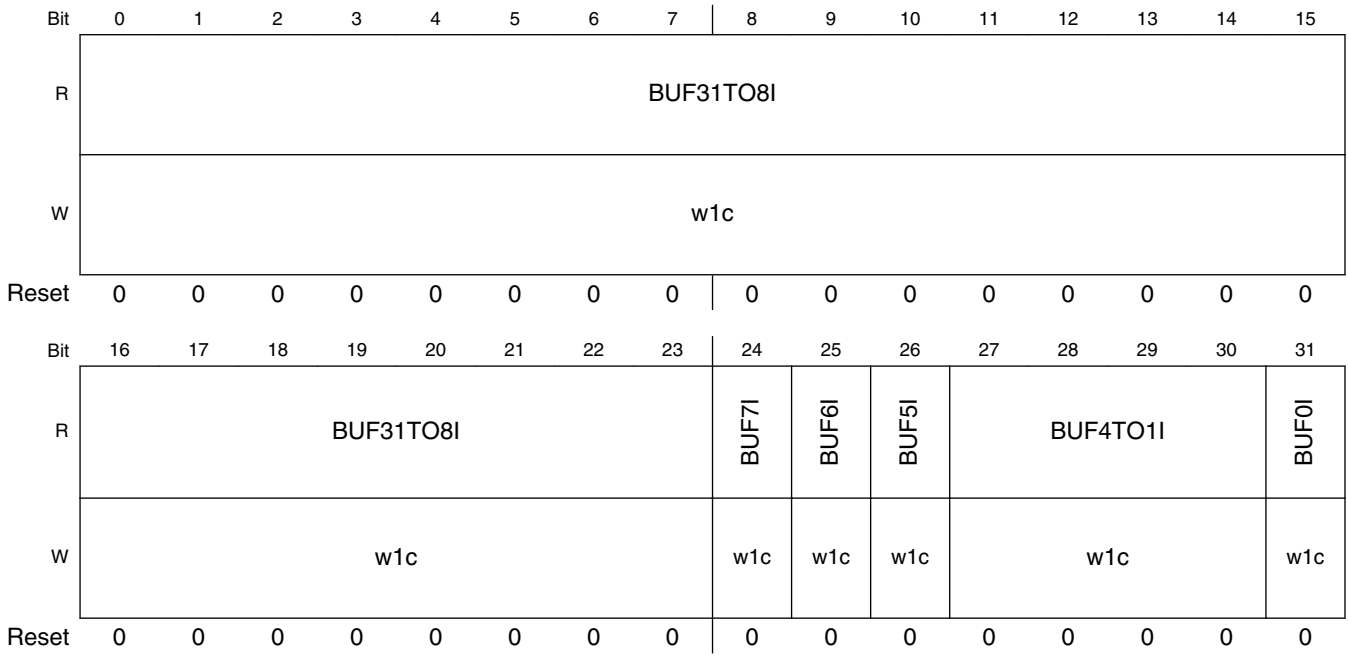
Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	BUF63TO32I																															
W	w1c																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CAN_IFLAG2 field descriptions

Field	Description
0–31 BUF63TO32I	Buffer MB $_i$ Interrupt Each bit flags the corresponding FlexCAN Message Buffer interrupt for MB63 to MB32. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception. 1 The corresponding buffer has successfully completed transmission or reception.

44.4.13 Interrupt Flags 1 register (CAN_IFLAG1)

This register defines the flags for the 32 Message Buffer interrupts for MB31 to MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding CAN_IFLAG1 bit. If the corresponding CAN_IMASK1 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect. There is an exception when DMA for Rx FIFO is enabled, as described below.



The BUF7I to BUF5I flags are also used to represent FIFO interrupts when the Rx FIFO is enabled. When the bit CAN_MCR[RFEN] is set and the bit CAN_MCR[DMA] is negated, the function of the 8 least significant interrupt flags changes: BUF7I, BUF6I and BUF5I indicate operating conditions of the FIFO, BUF0I is used to empty FIFO, and BUF4I to BUF1I bits are reserved.

Before enabling the CAN_MCR[RFEN], the CPU must service the IFLAG bits asserted in the Rx FIFO region; see Section "Rx FIFO". Otherwise, these IFLAG bits will mistakenly show the related MBs now belonging to FIFO as having contents to be serviced. When the CAN_MCR[RFEN] bit is negated, the FIFO flags must be cleared. The same care must be taken when an CAN_CTRL2[RFFN] value is selected extending Rx FIFO filters beyond MB7. For example, when RFFN is 0x8, the MB0-23 range is occupied by Rx FIFO filters and related IFLAG bits must be cleared.

When both the CAN_MCR[RFEN] and CAN_MCR[DMA] bits are asserted (DMA feature for Rx FIFO enabled), the function of the 8 least significant interrupt flags (BUF7I - BUF0I) are changed to support the DMA operation. BUF7I and BUF6I are not used, as well as, BUF4I to BUF1I. BUF5I indicates operating condition of FIFO, and BUF0I is used to empty FIFO. Moreover, BUF5I does not generate a CPU interrupt, but generates a DMA request. IMASK1 bits in Rx FIFO region are not considered when bit CAN_MCR[DMA] is enabled. In addition the CPU must not clear the flag BUF5I when DMA is enabled. Before enabling the bit CAN_MCR[DMA], the CPU must service the IFLAGs asserted in the Rx FIFO region. When the bit CAN_MCR[DMA] is negated, the FIFO must be empty. FIFO must be disabled when FDEN bit in CAN_MCR register is enabled.

Before updating CAN_MCR[MAXMB] field, CPU must service the CAN_IFLAG1 bits whose MB value is greater than the CAN_MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

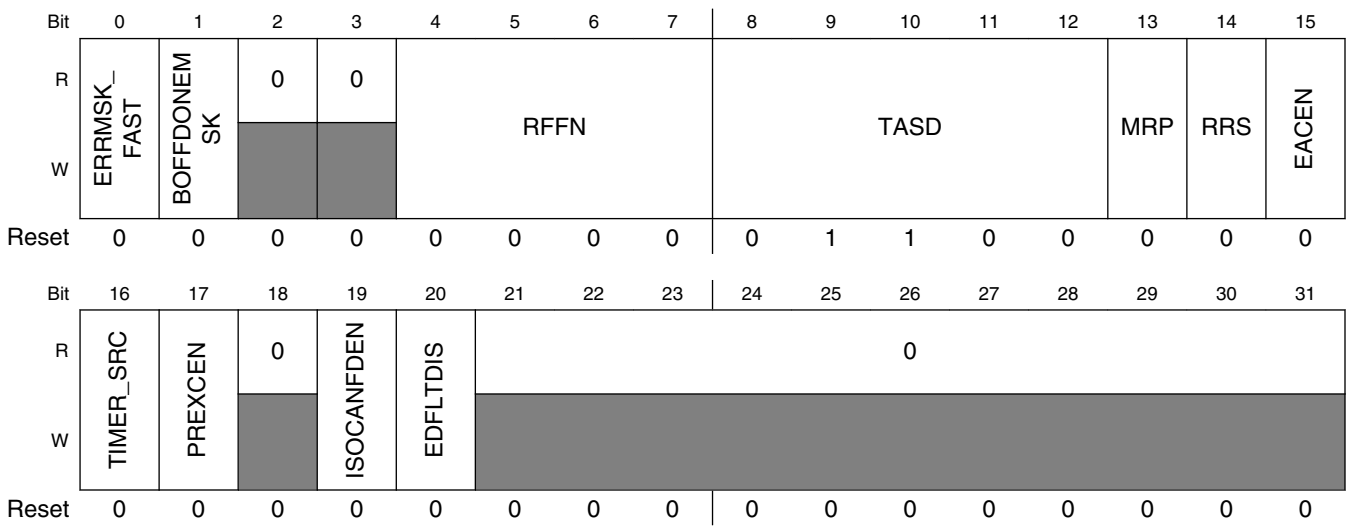
Address: 0h base + 30h offset = 30h

CAN_IFLAG1 field descriptions

Field	Description
0–23 BUF31TO8I	Buffer MB_i Interrupt Each bit flags the corresponding FlexCAN Message Buffer interrupt for MB31 to MB8. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception. 1 The corresponding buffer has successfully completed transmission or reception.
24 BUF7I	Buffer MB7 Interrupt Or "Rx FIFO Overflow" When the RFEN bit in the CAN_MCR register is cleared (Rx FIFO disabled), this bit flags the interrupt for MB7. **NOTE:** This flag is cleared by the FlexCAN whenever the bit CAN_MCR[RFEN] is changed by CPU writes. The BUF7I flag represents "Rx FIFO Overflow" when CAN_MCR[RFEN] is set. In this case, the flag indicates that a message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. 0 No occurrence of MB7 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO overflow when MCR[RFEN]=1 1 MB7 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO overflow when MCR[RFEN]=1
25 BUF6I	Buffer MB6 Interrupt Or "Rx FIFO Warning" When the RFEN bit in the CAN_MCR register is cleared (Rx FIFO disabled), this bit flags the interrupt for MB6. **NOTE:** This flag is cleared by the FlexCAN whenever the bit CAN_MCR[RFEN] is changed by CPU writes.

Table continues on the next page...

CAN_IFLAG1 field descriptions (continued)



Field	Description
	The BUF6I flag represents "Rx FIFO Warning" when CAN_MCR[RFEN] is set. In this case, the flag indicates when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. Note that if the flag is cleared while the number of unread messages is greater than 4, it does not assert again until the number of unread messages within the Rx FIFO is decreased to be equal to or less than 4. 0 No occurrence of MB6 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO almost full when MCR[RFEN]=1 1 MB6 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO almost full when MCR[RFEN]=1
26 BUF5I	Buffer MB5 Interrupt Or "Frames available in Rx FIFO" When the RFEN bit in the MCR is cleared (Rx FIFO disabled), this bit flags the interrupt for MB5. **NOTE:** This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes. When MCR[RFEN] is set (Rx FIFO enabled), the BUF5I flag represents "Frames available in Rx FIFO" and indicates that at least one frame is available to be read from the Rx FIFO. When the MCR[DMA] bit is enabled, this flag generates a DMA request and the CPU must not clear this bit by writing 1 in BUF5I. 0 No occurrence of MB5 completing transmission/reception when MCR[RFEN]=0, or of frame(s) available in the FIFO, when MCR[RFEN]=1 1 MB5 completed transmission/reception when MCR[RFEN]=0, or frame(s) available in the Rx FIFO when MCR[RFEN]=1. It generates a DMA request in case of MCR[RFEN] and MCR[DMA] are enabled.
27–30 BUF4TO1I	Buffer MB $_i$ Interrupt Or "reserved" When the RFEN bit in the CAN_MCR register is cleared (Rx FIFO disabled), these bits flag the interrupts for MB4 to MB1. **NOTE:** These flags are cleared by the FlexCAN whenever the bit CAN_MCR[RFEN] is changed by CPU writes. The BUF4TO1I flags are reserved when CAN_MCR[RFEN] is set. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0. 1 The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.
31 BUF0I	Buffer MB0 Interrupt Or "reserved" When the RFEN bit in the CAN_MCR register is cleared (Rx FIFO disabled), this bit flags the interrupt for MB0. **NOTE:** This flag is cleared by the FlexCAN whenever the bit CAN_MCR[RFEN] is changed by CPU writes. The BUF0I flag is reserved when CAN_MCR[RFEN] is set. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0. 1 The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.

44.4.14 Control 2 register (CAN_CTRL2)

This register complements Control1 Register providing control bits for memory write access in Freeze Mode, for extending FIFO filter quantity, and for adjust the operation of internal FlexCAN processes like matching and arbitration.

The contents of this register are not affected by soft reset.

Address: 0h base + 34h offset = 34h

CAN_CTRL2 field descriptions

Field	Description
0 ERRMSK_FAST	Error Interrupt Mask for errors detected in the Data Phase of fast CAN FD frames This bit provides a mask for the ERRINT_FAST Interrupt in CAN_ESR1 register. 0 ERRINT_FAST Error interrupt disabled. 1 ERRINT_FAST Error interrupt enabled.
1 BOFFDONEMSK	Bus Off Done Interrupt Mask This bit provides a mask for the Bus Off Done Interrupt in CAN_ESR1 register. 0 Bus Off Done interrupt disabled. 1 Bus Off Done interrupt enabled.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 RFFN	Number Of Rx FIFO Filters This 4-bit field defines the number of Rx FIFO filters, as shown in the following table. The maximum selectable number of filters is determined by the chip. This field can only be written in Freeze mode as it is blocked by hardware in other modes. This field must not be programmed with values that make the

Table continues on the next page...

CAN_CTRL2 field descriptions (continued)

Field	Description
	number of Message Buffers occupied by Rx FIFO and ID Filter exceed the number of Mailboxes present, defined by CAN_MCR[MAXMB]. **NOTE:** Each group of eight filters occupies a memory space equivalent to two Message Buffers which means that the more filters are implemented the less Mailboxes will be available. Considering that the Rx FIFO occupies the memory space originally reserved for MB0-5, RFFN should be programmed with a value corresponding to a number of filters not greater than the number of available memory words which can be calculated as follows: (SETUP_MB - 6) × 4 where SETUP_MB is the least between the parameter NUMBER_OF_MB and CAN_MCR[MAXMB]. The number of remaining Mailboxes available will be: (SETUP_MB - 8) - (RFFN × 2) If the Number of Rx FIFO Filters programmed through RFFN exceeds the SETUP_MB value (memory space available) the exceeding ones will not be functional. **NOTE:** • The number of the last remaining available mailboxes is defined by the least value between the NUMBER_OF_MB minus 1 and the CAN_MCR[MAXMB] field. • If Rx Individual Mask Registers are not enabled then all Rx FIFO filters are affected by the Rx FIFO Global Mask.
8–12 TASD	Tx Arbitration Start Delay

CAN_CTRL2 field descriptions (continued)

Field	Description
	This 5-bit field indicates how many CAN bits the Tx arbitration process start point can be delayed from the first bit of CRC field on CAN bus. See Tx Arbitration start delay for more details. This field can be written only in Freeze mode because it is blocked by hardware in other modes.
13 MRP	Mailboxes Reception Priority If this bit is set the matching process starts from the Mailboxes and if no match occurs the matching continues on the Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Matching starts from Rx FIFO and continues on Mailboxes. 1 Matching starts from Mailboxes and continues on Rx FIFO.
14 RRS	Remote Request Storing If this bit is asserted Remote Request Frame is submitted to a matching process and stored in the corresponding Message Buffer in the same fashion of a Data Frame. No automatic Remote Response Frame will be generated. If this bit is negated the Remote Request Frame is submitted to a matching process and an automatic Remote Response Frame is generated if a Message Buffer with CODE=0b1010 is found with the same ID. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Remote Response Frame is generated. 1 Remote Request Frame is stored.
15 EACEN	Entire Frame Arbitration Field Comparison Enable For Rx Mailboxes This bit controls the comparison of IDE and RTR bits within Rx Mailboxes filters with their corresponding bits in the incoming frame by the matching process. This bit does not affect matching for Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Rx Mailbox filter's IDE bit is always compared and RTR is never compared despite mask bits. 1 Enables the comparison of both Rx Mailbox filter's IDE and RTR bit with their corresponding bits within the incoming frame. Mask bits do apply.
16 TIMER_SRC	Timer Source Selects the time tick source used for incrementing the Free Running Timer counter. This bit can be written in Freeze mode only. 0 The Free Running Timer is clocked by the CAN bit clock, which defines the baud rate on the CAN bus. 1 The Free Running Timer is clocked by an external time tick. The period can be either adjusted to be equal to the baud rate on the CAN bus, or a different value as required. See the device specific section for details about the external time tick.
17 PREXCEN	Protocol Exception Enable This bit enables the Protocol Exception feature. This field is writable only in Freeze mode. 0 Protocol Exception is disabled. 1 Protocol Exception is enabled.
18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 ISOCANFDEN	ISO CAN FD Enable

Table continues on the next page...

CAN_CTRL2 field descriptions (continued)

Field	Description
	This field enables the CAN FD protocol according to ISO specification (ISO 11898-1) (see CAN FD ISO compliance). This field is writable only in Freeze mode. 0 FlexCAN operates using the non-ISO CAN FD protocol. 1 FlexCAN operates using the ISO CAN FD protocol (ISO 11898-1).
20 EDFLTDIS	Edge Filter Disable This bit disables the Edge Filter used during the bus integration state. When the Edge Filter is enabled, two consecutive nominal time quanta with dominant bus state are required to detect an edge that causes synchronization. When synchronization occurs, the counting of the sequence of eleven consecutive recessive bits is restarted. The Edge Filter prevents the dominant pulses that are shorter than a nominal bit time (present during the data phase of an FD Frame) from being mistaken for an idle condition. This field is writable only in Freeze mode. 0 Edge Filter is enabled. 1 Edge Filter is disabled.
21–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

44.4.15 Error and Status 2 register (CAN_ESR2)

This register reports some general status information.

Address: 0h base + 38h offset = 38h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0									LPTM						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	VPS	IMB	0												
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CAN_ESR2 field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 LPTM	Lowest Priority Tx Mailbox If CAN_ESR2[VPS] is asserted, this field indicates the lowest number inactive Mailbox (see the CAN_ESR2[IMB] bit description). If there is no inactive Mailbox then the Mailbox indicated depends on CAN_CTRL1[LBUF] bit value. If CAN_CTRL1[LBUF] bit is negated then the Mailbox indicated is the one

Table continues on the next page...

CAN_ESR2 field descriptions (continued)

Field	Description
	that has the greatest arbitration value (see the "Highest priority Mailbox first" section). If CAN_CTRL1[LBUF] bit is asserted then the Mailbox indicated is the highest number active Tx Mailbox. If a Tx Mailbox is being transmitted it is not considered in LPTM calculation. If CAN_ESR2[IMB] is not asserted and a frame is transmitted successfully, LPTM is updated with its Mailbox number.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 VPS	Valid Priority Status This bit indicates whether CAN_ESR2[IMB] and CAN_ESR2[LPTM] contents are currently valid or not. It is asserted upon every complete Tx arbitration process unless the CPU writes to Control and Status word of a Mailbox that has already been scanned, that is, it is behind Tx Arbitration Pointer, during the Tx arbitration process. If there is no inactive Mailbox and only one Tx Mailbox that is being transmitted then VPS is not asserted. This bit is negated upon the start of every Tx arbitration process or upon a write to Control and Status word of any Mailbox. **NOTE:** CAN_ESR2[VPS] is not affected by any CPU write into Control Status (C/S) of a MB that is blocked by abort mechanism. When CAN_MCR[AEN] is asserted, the abort code write in C/S of a MB that is being transmitted (pending abort), or any write attempt into a Tx MB with CAN_IFLAG set is blocked. 0 Contents of IMB and LPTM are invalid. 1 Contents of IMB and LPTM are valid.
18 IMB	Inactive Mailbox If ESR2[VPS] is asserted, this bit indicates whether there is any inactive Mailbox (CODE field is either 0b1000 or 0b0000). This bit is asserted in the following cases: • During arbitration, if an CAN_ESR2[LPTM] is found and it is inactive. • If CAN_ESR2[IMB] is not asserted and a frame is transmitted successfully. This bit is cleared in all start of arbitration (see Section "Arbitration process"). **NOTE:** CAN_ESR2[LPTM] mechanism have the following behavior: if an MB is successfully transmitted and CAN_ESR2[IMB]=0 (no inactive Mailbox), then CAN_ESR2[VPS] and CAN_ESR2[IMB] are asserted and the index related to the MB just transmitted is loaded into CAN_ESR2[LPTM]. 0 If ESR2[VPS] is asserted, the ESR2[LPTM] is not an inactive Mailbox. 1 If ESR2[VPS] is asserted, there is at least one inactive Mailbox. LPTM content is the number of the first one.
19–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

44.4.16 CRC Register (CAN_CRCR)

This register provides information about the CRC of transmitted messages for non FD messages. This register only reports the 15 low order bits of CRC calculations for messages in CAN FD format that require either 17 or 21 bits. For CAN FD format frames, the CAN_FDCRC register must be used. This register is updated at the same time the Tx Interrupt Flag is asserted.

Address: 0h base + 44h offset = 44h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0									MBCRC						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	TXCRC														
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CAN_CRCR field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 MBCRC	CRC Mailbox This field indicates the number of the Mailbox corresponding to the value in CAN_CRCR[TXCRC] field.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–31 TXCRC	Transmitted CRC value This field indicates the CRC value of the last transmitted message for non-FD frames. For FD frames, CRC value is reported in CAN_FDCRC register.

44.4.17 Rx FIFO Global Mask register (CAN_RXFGMASK)

This register is located in RAM.

If Rx FIFO is enabled, RXFGMASK is used to mask the Rx FIFO ID Filter Table elements that do not have a corresponding RXIMR according to CAN_CTRL2[RFFN] field setting.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Address: 0h base + 48h offset = 48h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	FGM

* Notes:
- x = Undefined at reset.

CAN_RXFGMASK field descriptions

Field	Description
0–31 FGM	Rx FIFO Global Mask Bits These bits mask the ID Filter Table elements bits in a perfect alignment. The following table shows how the FGM bits correspond to each IDAF field.

Rx FIFO ID Filter Table Elements Format (CAN_MCR[IDAM])	Identifier Acceptance Filter Fields					
	RTR	IDE	RXIDA	RXIDB [1]	RXIDC [2]	Reserved
A	FGM[31]	FGM[30]	FGM[29:1]	-	-	FGM[0]
B	FGM[31], FGM[15]	FGM[30], FGM[14]	-	FGM[29:16], FGM[13:0]		-
C	-	-		-	FGM[31:24], FGM[23:16], FGM[15:8], FGM[7:0]	

1. If CAN_MCR[IDAM] field is equivalent to the format B only the fourteen most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.
2. If CAN_MCR[IDAM] field is equivalent to the format C only the eight most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.

0 The corresponding bit in the filter is "don't care."
1 The corresponding bit in the filter is checked.

1. If CAN_MCR[IDAM] field is equivalent to the format B only the fourteen most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.
2. If CAN_MCR[IDAM] field is equivalent to the format C only the eight most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.

44.4.18 Rx FIFO Information Register (CAN_RXFIR)

RXFIR provides information on Rx FIFO.

This register is the port through which the CPU accesses the output of the RXFIR FIFO located in RAM. The RXFIR FIFO is written by the FlexCAN whenever a new message is moved into the Rx FIFO as well as its output is updated whenever the output of the Rx FIFO is updated with the next message. See Section "Rx FIFO" for instructions on reading this register.

Address: 0h base + 4Ch offset = 4Ch

Bit	0–22	23–31
R	0	IDHIT
W		
Reset	x*	x*

* Notes:
- x = Undefined at reset.

CAN_RXFIR field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–31 IDHIT	Identifier Acceptance Filter Hit Indicator This field indicates which Identifier Acceptance Filter was hit by the received message that is in the output of the Rx FIFO. If multiple filters match the incoming message ID then the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only while the CAN_IFLAG1[BUF5I] is asserted.

44.4.19 CAN Bit Timing Register (CAN_CBT)

This register is an alternative way to store the CAN bit timing variables described in CAN_CTRL1 register. EPRESDIV, EPROPSEG, EPSEG1, EPSEG2 and ERJW are extended versions of PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW bit fields respectively.

The BTF bit selects the use of the timing variables defined in this register.

The contents of this register are not affected by soft reset.

NOTE

The CAN bit variables in CAN_CTRL1 and in CAN_CBT are stored in the same register.

NOTE

When the CAN FD feature is enabled (CAN_MCR[FDEN] is set), always set CAN_CBT[BTF].

Address: 0h base + 50h offset = 50h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	BTF	EPRESDIV										ERJW				
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R W	EPROPSEG						EPSEG1					EPSEG2				
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CAN_CBT field descriptions

Field	Description
0 BTF	Bit Timing Format Enable Enables the use of extended CAN bit timing fields EPRESDIV, EPROPSEG, EPSEG1, EPSEG2 and ERJW replacing the CAN bit timing variables defined in CAN_CTRL1 register. This field can be written in Freeze mode only. 0 Extended bit time definitions disabled. 1 Extended bit time definitions enabled.
1–10 EPRESDIV	Extended Prescaler Division Factor This 10-bit field defines the ratio between the PE clock frequency and the Serial Clock (Sclock) frequency when CAN_CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CAN_CTRL1[PRESDIV] value range. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (EPRESDIV + 1)
11–15 ERJW	Extended Resync Jump Width This 5-bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization when CAN_CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CAN_CTRL1[RJW] value range. One time quantum is equal to the Sclock period. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = ERJW + 1.
16–21 EPROPSEG	Extended Propagation Segment This 6-bit field defines the length of the Propagation Segment in the bit time when CAN_CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CAN_CTRL1[PROPSEG] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation Segment Time = (EPROPSEG + 1) × Time-Quanta. Time-Quantum = one Sclock period.
22–26 EPSEG1	Extended Phase Segment 1 This 5-bit field defines the length of Phase Segment 1 in the bit time when CAN_CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CAN_CTRL1[PSEG1] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (EPSEG1 + 1) × Time-Quanta. Time-Quantum = one Sclock period.

Table continues on the next page...

CAN_CBT field descriptions (continued)

Field	Description
27–31 EPSEG2	Extended Phase Segment 2 This 5-bit field defines the length of Phase Segment 2 in the bit time when CAN_CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CAN_CTRL1[PSEG2] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (EPSEG2 + 1) × Time-Quanta. Time-Quantum = one Sclock period.

44.4.20 Interrupt Masks 3 Register (CAN_IMASK3)

This register allows any number of a range of the 32 Message Buffer Interrupts to be enabled or disabled for MB95 to MB64. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding CAN_IFLAG3 bit is set.

Address: 0h base + 6Ch offset = 6Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	BUF95TO64M																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CAN_IMASK3 field descriptions

Field	Description
0–31 BUF95TO64M	Buffer MB $_i$ Mask Each bit enables or disables the corresponding FlexCAN Message Buffer Interrupt for MB95 to MB64. When CAN FD is enabled, the MB range is defined in accordance to the MBDSRs bit fields of CAN_FDCTRL register. **NOTE:** Setting or clearing a bit in the CAN_IMASK3 Register can assert or negate an interrupt request, if the corresponding CAN_IFLAG3 bit is set. 0 The corresponding buffer Interrupt is disabled. 1 The corresponding buffer Interrupt is enabled.

44.4.21 Interrupt Flags 3 Register (CAN_IFLAG3)

This register defines the flags for the 32 Message Buffer interrupts for MB95 to MB64. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding CAN_IFLAG3 bit. If the corresponding CAN_IMASK3 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating CAN_MCR[MAXMB] field, CPU must service the CAN_IFLAG3 bits whose MB value is greater than the MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

Address: 0h base + 74h offset = 74h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CAN_IFLAG3 field descriptions

Field	Description
0–31 BUF95TO64	Buffer MB $_i$ Interrupt Each bit flags the corresponding FlexCAN Message Buffer interrupt for MB95 to MB64.When CAN FD is enabled, the MB range is defined in accordance to the MBDSRs bit fields of CAN_FDCTRL register. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception 1 The corresponding buffer has successfully completed transmission or reception

44.4.22 Rx Individual Mask Registers (CAN_RXIMR*n*)

The RX Individual Mask Registers are used to store the acceptance masks for ID filtering in Rx MBs and the Rx FIFO.

When the Rx FIFO is disabled (CAN_MCR[RFEN] bit is negated), an individual mask is provided for each available Rx Mailbox on a one-to-one correspondence. When the Rx FIFO is enabled (CAN_MCR[RFEN] bit is asserted), an individual mask is provided for each Rx FIFO ID Filter Table Element on a one-to-one correspondence depending on the setting of CAN_CTRL2[RFFN] (see Rx FIFO).

CAN_RXIMR0 stores the individual mask associated to either MB0 or ID Filter Table Element 0, CAN_RXIMR1 stores the individual mask associated to either MB1 or ID Filter Table Element 1 and so on.

CAN_RXIMR registers can only be accessed by the CPU while the module is in Freeze mode, otherwise, they are blocked by hardware. These registers are not affected by reset. They are located in RAM and must be explicitly initialized prior to any reception.

It is possible for the RXIMR memory region to be accessed as general purpose memory. See Bus interface for more information.

Address: 0h base + 880h offset + (4d × i), where i=0d to 95d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CAN_RXIMR*n* field descriptions

Field	Description
0–31 MI	Individual Mask Bits Each Individual Mask Bit masks the corresponding bit in both the Mailbox filter and Rx FIFO ID Filter Table element in distinct ways. For Mailbox filters, see the RXMGMASK register description. For Rx FIFO ID Filter Table elements, see the RXFGMASK register description. 0 The corresponding bit in the filter is "don't care." 1 The corresponding bit in the filter is checked.

44.4.23 Pretended Networking Control 1 Register (CAN_CTRL1_PN)

This register contains control bits for Pretended Networking mode filtering selection. Configure this register with the filter criteria to be used to receive wake up messages. It can be written in Freeze mode only, except WTOF_MSK and WUMF_MSK bits.

Address: 0h base + B00h offset = B00h

CAN_CTRL1_PN field descriptions

Field	Description
0–13 Reserved	This field is reserved.
14 WTOF_MSK	Wake Up by Timeout Flag Mask Bit This bit masks the generation of a wake up event originated by a timeout. 0 Timeout wake up event is disabled 1 Timeout wake up event is enabled
15 WUMF_MSK	Wake Up by Match Flag Mask Bit This bit masks the generation of a wake up event originated by a successful filtered Rx message. 0 Wake up match event is disabled 1 Wake up match event is enabled
16–23 NMATCH	Number of Messages Matching the Same Filtering Criteria This 8-bit field defines the number of times a given message must match the predefined filtering criteria for ID and/or PL before generating a wake up event. This quantity can be configured in the 1 to 255 range by using values from 0x01 to 0xFF, respectively. 00000001 Received message must match the predefined filtering criteria for ID and/or PL once before generating a wake up event. 00000010 Received message must match the predefined filtering criteria for ID and/or PL twice before generating a wake up event.

Table continues on the next page...

CAN_CTRL1_PN field descriptions (continued)

Field	Description
	... ... 11111111 Received message must match the predefined filtering criteria for ID and/or PL 255 times before generating a wake up event.
24–25 Reserved	This field is reserved.
26–27 PLFS	Payload Filtering Selection This 2-bit field selects the level of payload filtering to be applied when FlexCAN is under Pretended Networking mode. Filtering does not accept remote messages (RTR=1) when payload filtering is active. 00 Match upon a payload contents against an exact target value 01 Match upon a payload value greater than or equal to a specified target value 10 Match upon a payload value smaller than or equal to a specified target value 11 Match upon a payload value inside a range, greater than or equal to a specified lower limit and smaller than or equal a specified upper limit
28–29 IDFS	ID Filtering Selection This 2-bit field selects the level of ID filtering to be applied when FlexCAN is under Pretended Networking mode. In ID filtering, the IDE and RTR bits are also considered as part of reception filter if IDE_MSK and RTR_MSK bits in the CAN_FLT_ID2_IDMASK register are set. 00 Match upon a ID contents against an exact target value 01 Match upon a ID value greater than or equal to a specified target value 10 Match upon a ID value smaller than or equal to a specified target value 11 Match upon a ID value inside a range, greater than or equal to a specified lower limit and smaller than or equal a specified upper limit
30–31 FCS	Filtering Combination Selection This 2-bit field selects the filtering criteria to be applied when FlexCAN is under Pretended Networking mode. See Receive Process under Pretended Networking Mode for more details. 00 Message ID filtering only 01 Message ID filtering and payload filtering 10 Message ID filtering occurring a specified number of times. 11 Message ID filtering and payload filtering a specified number of times

44.4.24 Pretended Networking Control 2 Register (CAN_CTRL2_PN)

This register contains configuration bits for the timeout value under Pretended Networking mode. It can be written in Freeze mode only.

Address: 0h base + B04h offset = B04h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CAN_CTRL2_PN field descriptions

Field	Description
0–15 Reserved	This field is reserved.
16–31 MATCHTO	Timeout for No Message Matching the Filtering Criteria This 16-bit field defines a timeout value that generates a wake up event if CAN_MCR[PNET_EN] is asserted. If the timeout counter reaches the target value, when FlexCAN is under Pretended Networking mode, then a wake up event is generated. The timeout limit can be configured from 1 to 65535 to control an internal 16-bit up-count timer to produce a trigger upon reaching this configured value. The internal timer is incremented based on periodic time ticks, which period is 64 times the CAN Bit Time unit. When MATCHTO is configured with 0x0000 the timeout is disabled.

44.4.25 Pretended Networking Wake Up Match Register (CAN_WU_MTC)

This read-only register contains wake up information related to the matching processes performed while FlexCAN receives frames under Pretended Networking mode.

Address: 0h base + B08h offset = B08h

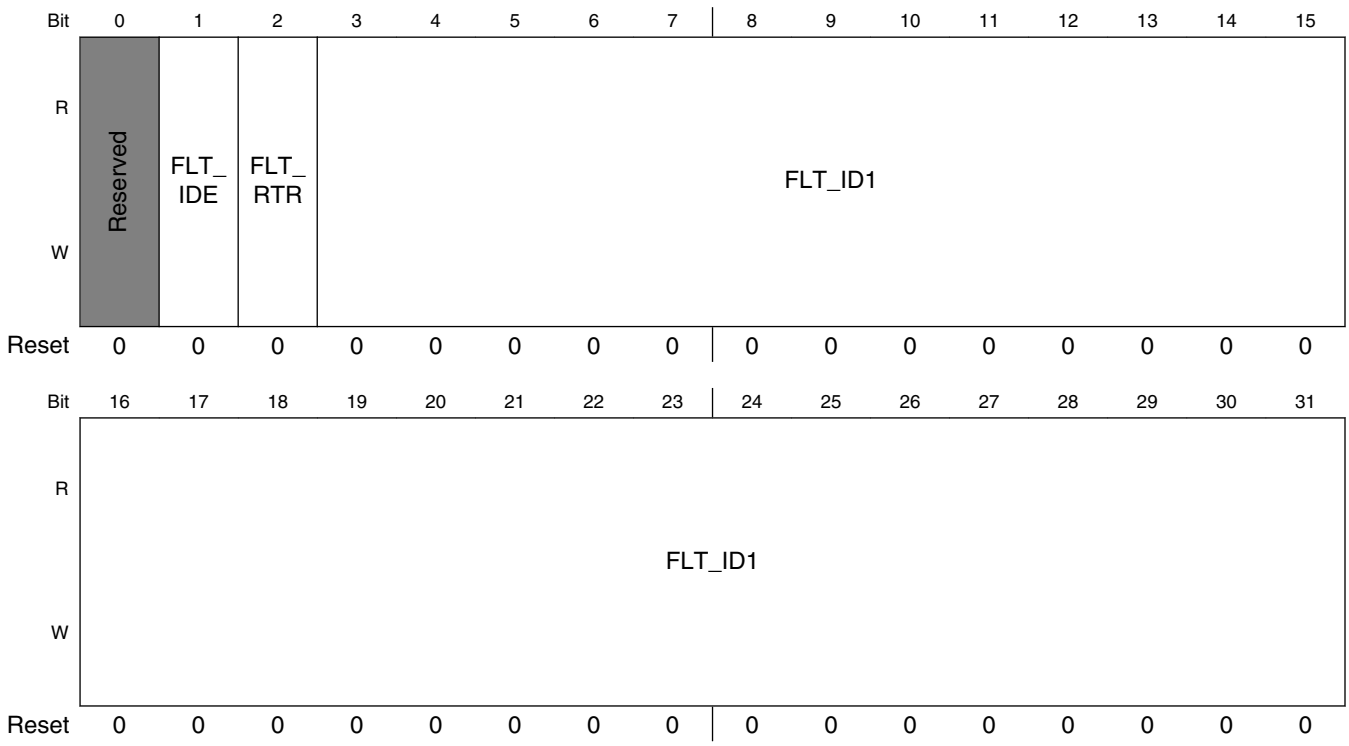
14 WTOF	Wake Up by Timeout Flag Bit

Table continues on the next page...



CAN_WU_MTC field descriptions (continued)

Field	Description
	This bit identifies whether the FlexCAN has detected a timeout event during a time interval defined by CAN_CTRL2_PN[MATCHTO]. This flag generates a wake up event if CAN_CTRL1_PN[WTOF_MSK] is enabled. 0 No wake up by timeout event detected 1 Wake up by timeout event detected
15 WUMF	Wake Up by Match Flag Bit This bit identifies whether the FlexCAN has detected a matching Rx incoming message, which passed the filtering criteria specified in CAN_CTRL1_PN register. This flag generates a wake up event if CAN_CTRL1_PN[WUMF_MSK] is enabled. 0 No wake up by match event detected 1 Wake up by match event detected
16–23 MCOUNTER	Number of Matches while in Pretended Networking This 8-bit field reports the number of times a given message have been matched the predefined filtering criteria for ID and/or PL before a wake up event. This register is reset by FlexCAN when it enters in Pretended Networing mode, and is not affected by soft reset.
24–31 Reserved	This field is reserved.

44.4.26 Pretended Networking ID Filter 1 Register (CAN_FLT_ID1)

This register contains FLT_ID1 target value, as well as, IDE and RTR target values used to filter incoming message ID. The FLT_ID1 is used either for equal to, smaller than, greater than comparisons, or as the lower limit value in a ID range detection. It can be written in Freeze mode only.

Address: 0h base + B0Ch offset = B0Ch

CAN_FLT_ID1 field descriptions

Field	Description
0 Reserved	This field is reserved.
1 FLT_IDE	ID Extended Filter This bit identifies whether the frame format is standard or extended. It is used as part of the ID reception filter. 0 Accept standard frame format 1 Accept extended frame format
2 FLT_RTR	Remote Transmission Request Filter This bit identifies whether the frame is remote or not. It is used as part of the ID reception filter. 0 Reject remote frame (accept data frame) 1 Accept remote frame

Table continues on the next page...

CAN_FLT_ID1 field descriptions (continued)

Field	Description
3–31 FLT_ID1	ID Filter 1 for Pretended Networking filtering This 29-bit field defines either the 29 bits of a extended frame format, considering all bits, or the 11 bits of a standard frame format, considering just the 11 leftmost bits.

44.4.27 Pretended Networking DLC Filter Register (CAN_FLT_DLC)

This register contains the DLC inside range target values (FLT_DLC_LO and FLT_DLC_HI) used to filter incoming message. The DLC range is used only for payload filtering. It can be written in Freeze mode only.

NOTE

When a fixed quantity of data bytes is required, both FLT_DLC_LO and FLT_DLC_HI need to be configured with the same value, otherwise a range of DLC is considered for filtering (see Receive Process under Pretended Networking Mode).

Address: 0h base + B10h offset = B10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Field	Description
0–11 Reserved	This field is reserved.
12–15 FLT_DLC_LO	Lower Limit for Length of Data Bytes Filter This field specifies the lower limit for the number of data bytes considered valid for payload comparison. It is used as part of payload reception filter.
16–27 Reserved	This field is reserved.
28–31 FLT_DLC_HI	Upper Limit for Length of Data Bytes Filter This field specifies the upper limit for the number of data bytes considered valid for payload comparison. It is used as part of payload reception filter.

44.4.28 Pretended Networking Payload Low Filter 1 Register (CAN_PL1_LO)

This register contains Payload Filter 1 low order bits of the target value used to filter incoming message payload. It is used either for “equal to”, “smaller than or equal”, “greater than or equal” comparisons, or as the lower limit value in a payload range detection. It can be written in Freeze mode only.

Address: 0h base + B14h offset = B14h

24–31 Data_byte_7	Payload Filter 1 high order bits for Pretended Networking payload filtering corresponding to the data byte 7.

44.4.30 Pretended Networking ID Filter 2 Register / ID Mask Register (CAN_FLT_ID2_IDMASK)

This register contains FLT_ID2 target value used only as the upper limit value in ID range detection. Also, when exact ID filtering criteria is selected, this register is used to store the ID mask. IDE_MSK and RTR_MSK bits are used in both ID filtering (exact and range) to enable FLT_IDE and FLT_RTR respectively to be used as part of ID reception filter. This register can be written in Freeze mode only.

Address: 0h base + B1Ch offset = B1Ch

CAN_FLT_ID2_IDMASK field descriptions

Field	Description
0 Reserved	This field is reserved.
1 IDE_MSK	ID Extended Mask Bit This bit indicates whether the frame format (standard / extended) is used as part of the ID reception filter. 0 The corresponding bit in the filter is “don’t care” 1 The corresponding bit in the filter is checked
2 RTR_MSK	Remote Transmission Request Mask Bit This bit indicates whether the frame type (data / remote) is part of the ID reception filter. 0 The corresponding bit in the filter is “don’t care” 1 The corresponding bit in the filter is checked
3–31 FLT_ID2_ IDMASK	ID Filter 2 for Pretended Networking Filtering / ID Mask Bits for Pretended Networking ID Filtering This register is used to define either the ID filter value in extended frame format (29 bits), considering the FLT_ID2[28:0], or the ID filter value in standard frame format (11 bits), considering the FLT_ID2[28:18] (other bits in the [17:0] range have no meaning). Used only in range of ID filtering. It can also be used to define either the mask values for the extended frame format (29 bits), considering the IDMASK[28:0], or for the standard frame format (11 bits), considering the IDMASK[28:18] (other bits in the [17:0] range have no meaning). Used only in exact ID filtering.

44.4.31 Pretended Networking Payload Low Filter 2 Register / Payload Low Mask Register (CAN_PL2_PLMASK_LO)

This register has two functions. First, it contains the low order bits for the Payload Filter 2 used only as the upper limit value in a payload range detection. Second, when exact payload filtering criteria is selected, this register is used as payload mask. Otherwise, this register is unused. It can be written in Freeze mode only.

Address: 0h base + B20h offset = B20h

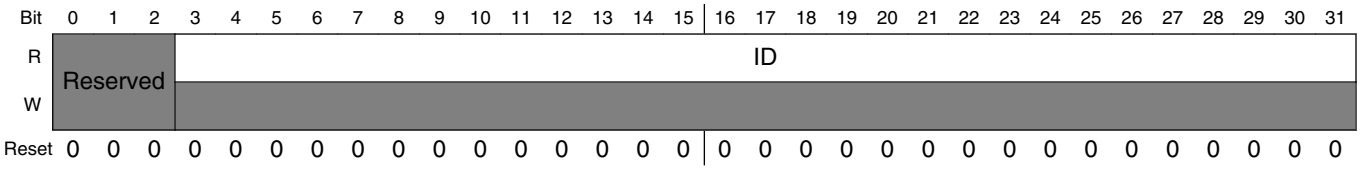
CAN_WMB*n*_CS field descriptions

Field	Description
0–8 Reserved	This field is reserved.
9 SRR	Substitute Remote Request This bit can be received either recessive or dominant.
10 IDE	ID Extended Bit This bit identifies whether the frame format is standard or extended 0 Frame format is standard 1 Frame format is extended
11 RTR	Remote Transmission Request Bit This bit identifies whether the frame is remote or not. 0 Frame is data one (not remote) 1 Frame is a remote one
12–15 DLC	Length of Data in Bytes This 4-bit field is the length (in bytes) of the Rx data received when FlexCAN is in Pretended Networking mode. This 4-bit field is written by the FlexCAN module, copied from the DLC (Data Length Code) field of the received frame. The DLC field indicates which data bytes are valid.
16–31 Reserved	This field is reserved.



44.4.34 Wake Up Message Buffer Register for ID (CAN_WMB*n*_ID)

Each of the four WMBs contains a register to store the ID information of an incoming Rx message.

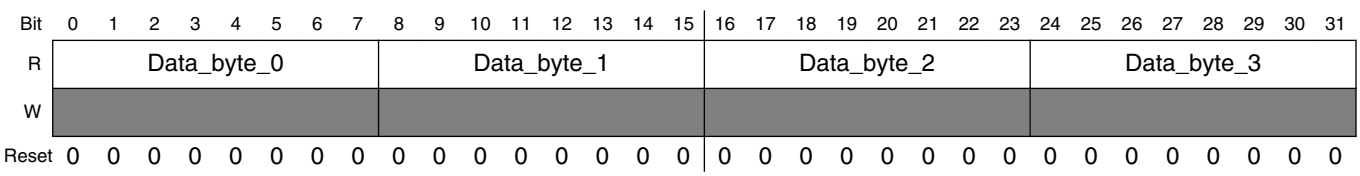
NOTE

The ID registers are located at 0xB44 for WMB0, 0xB54 for WMB1, 0xB64 for WMB2, and 0xB74 for WMB3.

Address: 0h base + B44h offset + (16d × i), where i=0d to 3d

CAN_WMB*n*_ID field descriptions

Field	Description
0–2 Reserved	This field is reserved.
3–31 ID	Received ID under Pretended Networking mode This register stores either the 29 bits of the extended frame format (considering the ID[0:28] field), or the 11 bits of the standard frame format (considering the ID[0:10] field only, the remaining bits in the ID[11:28] range have no meaning).



44.4.35 Wake Up Message Buffer Register for Data 0-3 (CAN_WMB*n*_D03)

Each of the four WMBs contains a register to store the data bytes 0 to 3 of the payload information of an incoming Rx message. This register's content is cleared when the incoming matched message is either a remote frame (RTR=1) or a data frame with DLC=0.

NOTE

The Data 0-3 registers are located at 0xB48 for WMB0, 0xB58 for WMB1, 0xB68 for WMB2, and 0xB78 for WMB3.

Address: 0h base + B48h offset + (16d × i), where i=0d to 3d

CAN_WMB*n*_D03 field descriptions

Field	Description
0–7 Data_byte_0	Received payload corresponding to the data byte 0 under Pretended Networking mode
8–15 Data_byte_1	Received payload corresponding to the data byte 1 under Pretended Networking mode
16–23 Data_byte_2	Received payload corresponding to the data byte 2 under Pretended Networking mode
24–31 Data_byte_3	Received payload corresponding to the data byte 3 under Pretended Networking mode

44.4.36 Wake Up Message Buffer Register Data 4-7 (CAN_WMB*n*_D47)

Each of the four WMBs contains a register to store the data bytes 4 to 7 of the payload information of an incoming Rx message. This register's content is cleared when the incoming matched message is either a remote frame (RTR=1) or a data frame with DLC=0.

NOTE

The Data 4-7 registers are located at 0xB4C for WMB0, 0xB5C for WMB1, 0xB6C for WMB2, and 0xB7C for WMB3.

Address: 0h base + B4Ch offset + (16d × i), where i=0d to 3d

24–31 Data_byte_7	Received payload corresponding to the data byte 7 under Pretended Networking mode

44.4.37 CAN FD Control Register (CAN_FDCTRL)

This register contains control bits for the CAN FD operation. It also defines the data size of Message Buffers allocated in different partitions of RAM (memory blocks) as described in the table below.

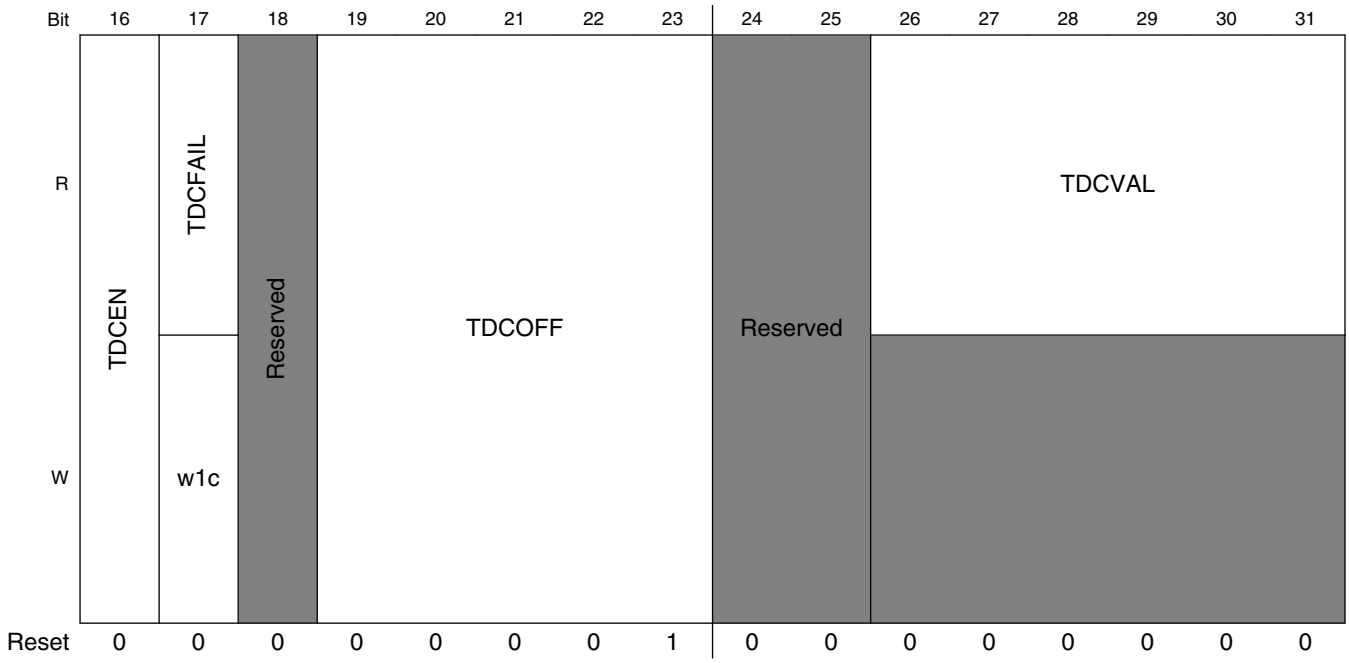
When 8 bytes payload is selected:

- Block R0 allocates MB0 to MB31.
- Block R1 allocates MB32 to MB63.
- Block R2 allocates MB64 to MB95.

When more than 8 bytes payload is selected, the maximum number of MBs in a block is limited as described below:

Table 44-5. Number of Message Buffers

Payload Size	Maximum number of Message Buffers per RAM block
8 bytes	32
16 bytes	21
32 bytes	12
64 bytes	7



NOTE

One memory block fits exactly 32 MBs with 8 bytes payload. For the other options of payload sizes, empty memory may exist between last MB in a block and the beginning of the next block. This empty memory corresponds to less than one MB, and must not be used.

The contents of this register are not affected by soft reset.

Address: 0h base + C00h offset = C00h

CAN_FDCTRL field descriptions

Field	Description
0 FDRATE	Bit Rate Switch Enable This bit enables the effect of the Bit Rate Switch (BRS bit) during the data phase of Tx messages. The CPU can write this bit any time. However, its effect turns active only when the CAN bus is in Wait for Bus Idle, Bus Idle or Bus Off state, or when the current frame under reception or transmission reaches the interframe space. By negating the CAN_FDCTRL[FDRATE] bit, the CPU can force all bits in CAN FD messages to be transmitted in nominal bit rate, despite of the value in the BRS bit of the Tx MBs. 0 Transmit a frame in nominal rate. The BRS bit in the Tx MB has no effect. 1 Transmit a frame with bit rate switching if the BRS bit in the Tx MB is recessive.
1–4 Reserved	This field is reserved.
5–6 Reserved	This field is reserved.
7 Reserved	This field is reserved.
8–9 MBDSR2	Message Buffer Data Size for Region 2 This two bit field selects the data size (8, 16, 32 or 64 bytes) for the region R2 of Message Buffers allocated in RAM. It can be written in Freeze Mode only. 00 Selects 8 bytes per Message Buffer. 01 Selects 16 bytes per Message Buffer. 10 Selects 32 bytes per Message Buffer. 11 Selects 64 bytes per Message Buffer.

Table continues on the next page...

CAN_FDCTRL field descriptions (continued)

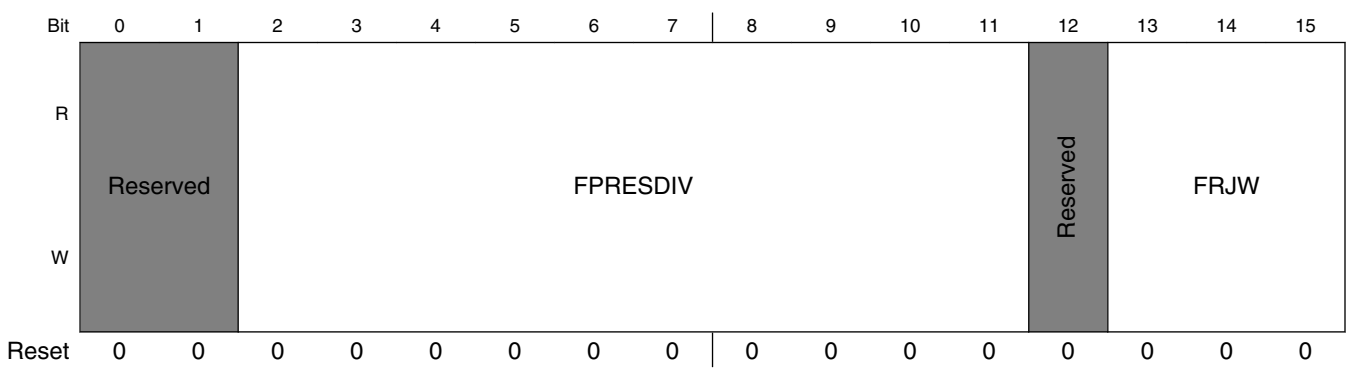
Field	Description
10 Reserved	This field is reserved.
11–12 MBDSR1	Message Buffer Data Size for Region 1 This two bit field selects the data size (8, 16, 32 or 64 bytes) for the region R1 of Message Buffers allocated in RAM. It can be written in Freeze Mode only. 00 Selects 8 bytes per Message Buffer. 01 Selects 16 bytes per Message Buffer. 10 Selects 32 bytes per Message Buffer. 11 Selects 64 bytes per Message Buffer.
13 Reserved	This field is reserved.
14–15 MBDSR0	Message Buffer Data Size for Region 0 This two bit field selects the data size (8, 16, 32 or 64 bytes) for the region R0 of Message Buffers allocated in RAM. It can be written in Freeze Mode only. 00 Selects 8 bytes per Message Buffer. 01 Selects 16 bytes per Message Buffer. 10 Selects 32 bytes per Message Buffer. 11 Selects 64 bytes per Message Buffer.
16 TDCEN	Transceiver Delay Compensation Enable This bit can be used to enable and disable the TDC feature. It can be written in Freeze mode only. **NOTE:** TDC must be disabled when the Loop Back Mode is enabled (see CAN_CTRL1[LPB] register). 0 TDC is disabled 1 TDC is enabled
17 TDCFAIL	Transceiver Delay Compensation Fail This bit indicates when the Transceiver Delay Compensation (TDC) mechanism is out of range, unable to compensate the transceiver's loop delay and successfully compare the delayed received bits to the transmitted ones (see Transceiver Delay Compensation. TDCFAIL sets in the first time FlexCAN detects the out of range condition. The CPU needs to write 1 to clear it. 0 Measured loop delay is in range. 1 Measured loop delay is out of range.
18 Reserved	This field is reserved.
19–23 TDCOFF	Transceiver Delay Compensation Offset This bit field contains the offset value to be added to the measured transceiver's loop delay in order to define the position of the delayed comparison point when bit rate switching is active. See Transceiver Delay Compensation for more details on how the loop delay measurement is performed. TDCOFF can be written in Freeze mode only. Its value can be defined in Protocol Engine (PE) Clock periods (CANCLK, see Protocol timing for more details), and must be selected to be smaller than the CAN bit duration in the data bit rate for proper operation.

Table continues on the next page...

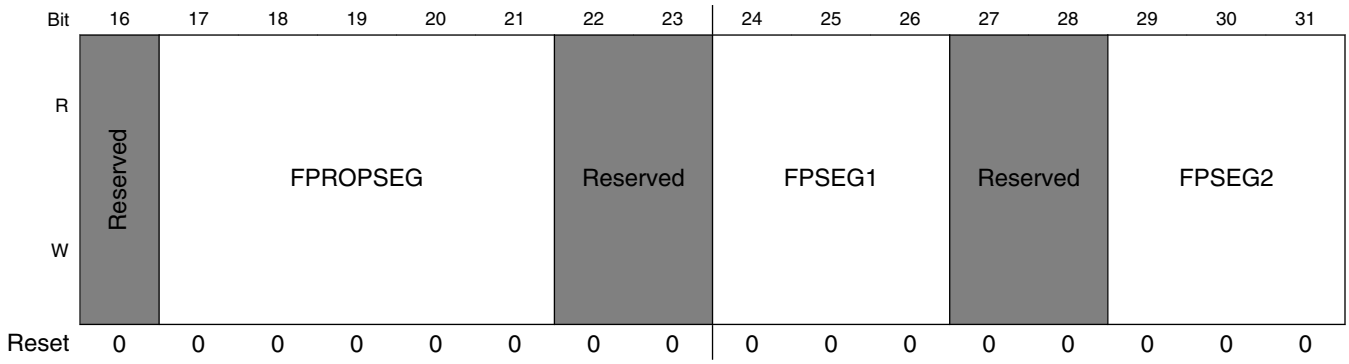
CAN_FDCTRL field descriptions (continued)

Field	Description
	NOTE: It is not recommended to use TDCOFF equal to zero.
24–25 Reserved	This field is reserved.
26–31 TDCVAL	Transceiver Delay Compensation Value This register contains the value of the transceiver loop delay measured from the transmitted EDL to R0 transition edge to the respective received one added to the TDCOFF value specified in the CAN_FDCTRL register. This value is an integer multiple of the Protocol Engine (PE) Clock period (CANCLK). See Protocol timing for more details on how the loop delay measurement is performed.

44.4.38 CAN FD Bit Timing Register (CAN_FDCBT)



This register stores the CAN bit timing variables used in the data phase of CAN FD messages when the CAN_FDCTRL[FDRATE] is set, compatible with CAN FD specification. FPRESDIV, FPROPSEG, FPSEG1, FPSEG2 and FRJW are used to define the time quantum duration, the number of time quanta per CAN bit and the sample point position for the data bit rate portion of a CAN FD message with the BRS bit set.



The contents of this register are not affected by soft reset.

NOTE

The sum of the Fast Propagation Segment (FPROPSEG) and Fast Phase Segment 1 (FPSEG1) must be at least two time quanta.

Address: 0h base + C04h offset = C04h

CAN_FDCBT field descriptions

Field	Description
0–1 Reserved	This field is reserved.
2–11 FPRESDIV	Fast Prescaler Division Factor This 10-bit field defines the ratio between the PE clock frequency and the Serial Clock (Sclock) frequency in the data bit rate portion of a CAN FD message with the BRS bit set. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (FPRESDIV + 1). **NOTE:** To minimize errors when processing FD frames, use the same value for FPRESDIV and PRESDIV (in CAN_CBT or CAN_CTRL1). For more details refer to the first NOTE in section CAN FD frames.
12 Reserved	This field is reserved.
13–15 FRJW	Fast Resync Jump Width This 3-bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization in the data bit rate portion of a CAN FD message with the BRS bit set. One time quantum is equal to the Sclock period. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = FSJW + 1.
16 Reserved	This field is reserved.
17–21 FPROPSEG	Fast Propagation Segment This 5-bit field defines the length of the Propagation Segment in the bit time in the data bit rate portion of a CAN FD message with the BRS bit set. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation Segment Time = FPROPSEG × Time-Quanta. Time-Quantum = one Sclock period.
22–23 Reserved	This field is reserved.
24–26 FPSEG1	Fast Phase Segment 1

Table continues on the next page...

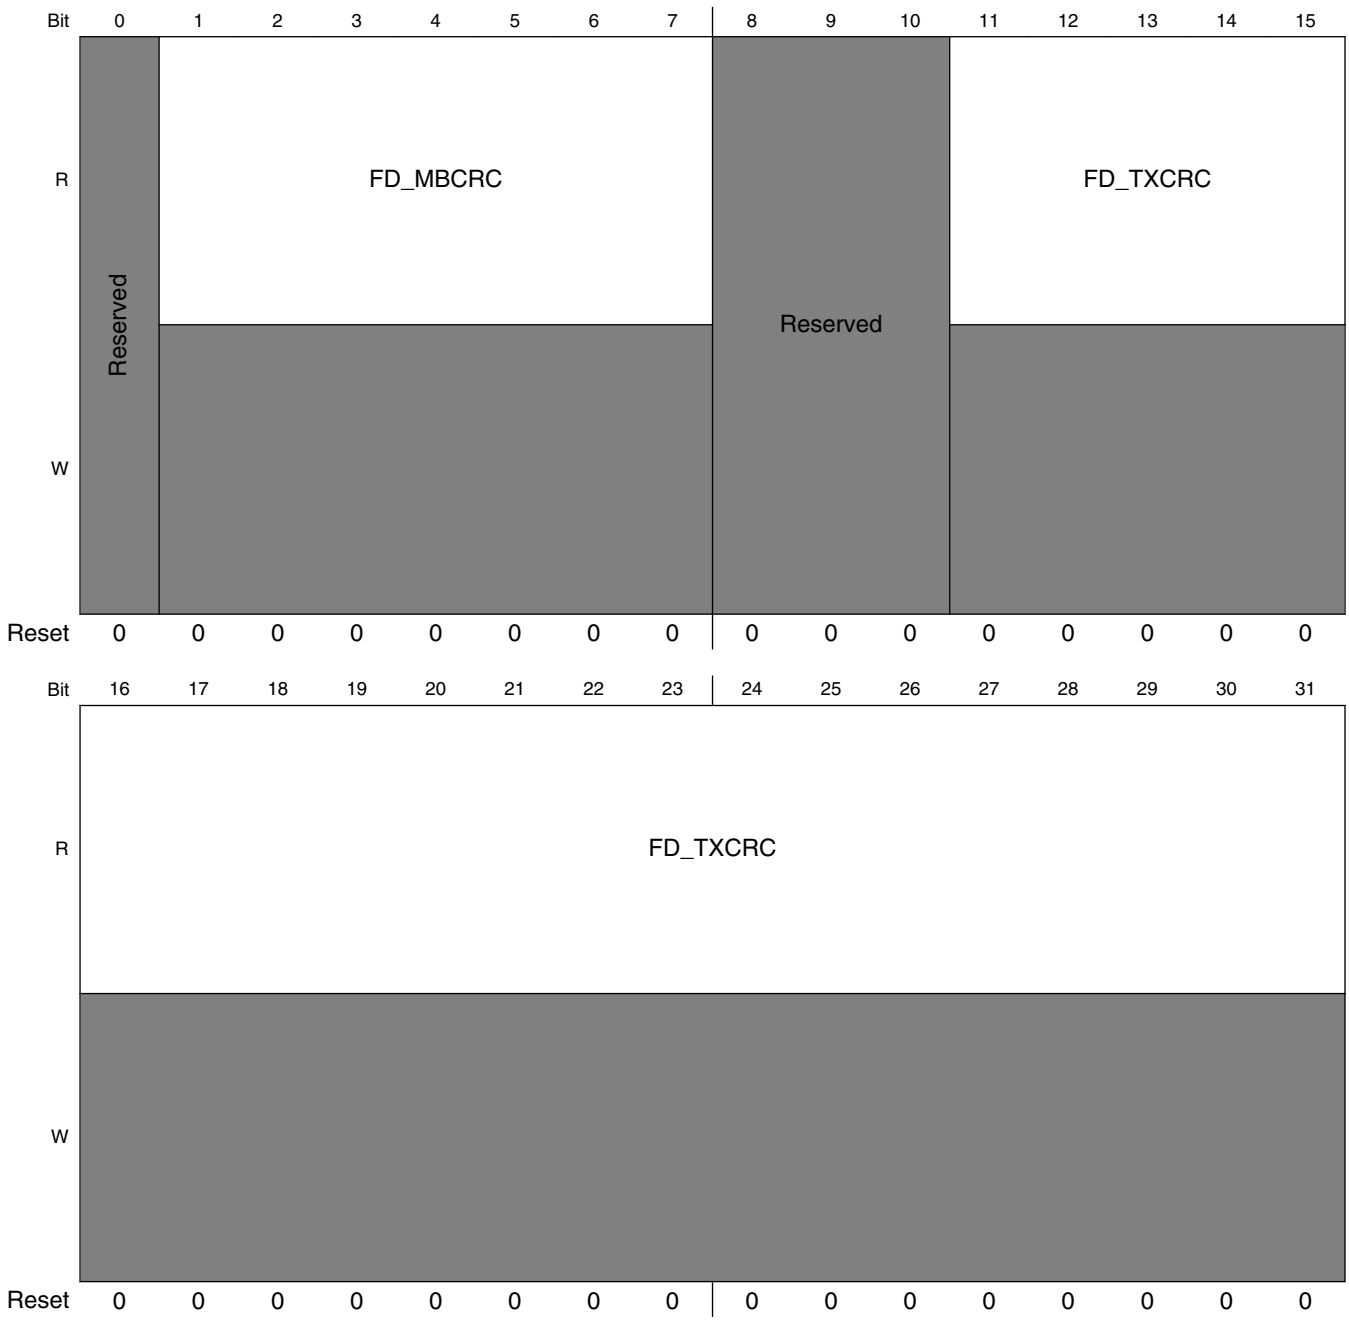
CAN_FDCBT field descriptions (continued)

Field	Description
	This 3-bit field defines the length of Phase Segment 1 in the bit time in the data bit rate portion of a CAN FD message with the BRS bit set. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Segment 1 = (FPSEG1 + 1) × Time-Quanta. Time-Quantum = one Sclock period.
27–28 Reserved	This field is reserved.
29–31 FPSEG2	Fast Phase Segment 2 This 3-bit field defines the length of Phase Segment 2 in the data bit rate portion of a CAN FD message with the BRS bit set. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Segment 2 = (FPSEG2 + 1) × Time-Quanta. Time-Quantum = one Sclock period.

44.4.39 CAN FD CRC Register (CAN_FDCRC)

This register provides information about the CRC of transmitted messages.

FlexCAN uses different CRC polynomials for different frame formats, as shown below.



The CRC_15 polynomial is used for all frames in CAN format. The CRC_17 polynomial is used for frames in CAN FD format with a DATA FIELD up to sixteen bytes. The CRC_21 polynomial is used for frames in CAN FD format with a DATA FIELD longer than sixteen bytes. Each polynomial shown below results in a Hamming Distance of 6. This register is updated at the same time the Tx Interrupt Flag is asserted.

CRC_15 = 0xC599: $(x^{15} + x^{14} + x^{10} + x^8 + x^7 + x^4 + x^3 + 1)$

CRC_17 = 0x3685B: $(x^{17} + x^{16} + x^{14} + x^{13} + x^{11} + x^6 + x^4 + x^3 + x^1 + 1)$

CRC_21 = 0x302899: $(x^{21} + x^{20} + x^{13} + x^{11} + x^7 + x^4 + x^3 + 1)$

Address: 0h base + C08h offset = C08h

CAN_FDCRC field descriptions

Field	Description
0 Reserved	This field is reserved.
1–7 FD_MBCRC	CRC Mailbox Number for FD_TXCRC This field indicates the number of the Mailbox corresponding to the value in FD_TXCRC field, for both FD and non-FD frames. It reports the same information as in MBCRC bit field in CAN_CRCR register.

Table continues on the next page...

CAN_FDCRC field descriptions (continued)

Field	Description
8–10 Reserved	This field is reserved.
11–31 FD_TXCRC	Extended Transmitted CRC value This 21-bit field contains the CRC value calculated over the most recent transmitted message. Different CRC polynomials are used for different frame formats. A 15-bit polynomial, CRC_15, is used for all frames in CAN format. The second 17-bit polynomial, CRC_17, is used for frames in CAN FD format with a data field up to sixteen bytes long. The third 21-bit polynomial, CRC_21, is used for frames in CAN FD format with a data field longer than sixteen bytes. For CRC_15 and CRC_17, the 6 most significant bits and the 4 most significant bits are reported as zeros, respectively. For CRC_15, this register has the same content as CRC Register.

44.4.40 Message buffer structure

The message buffer structure used by the FlexCAN module is represented in the following figure. Both Extended (29-bit identifier) and Standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual MB is formed by 16, 24, 40 or 72 bytes, depending on the quantity of data bytes allocated for the message payload: 8, 16, 32 or 64 data bytes, respectively.

The memory area from 0x80 to 0x67F is used by the mailboxes. When CAN FD is enabled, the exact address for each MB depends on the size of its payload. See FlexCAN Memory Partition for CAN FD for more detailed information.

Table 44-6. Message buffer structure - example with 64 bytes payload

	0	1	2	3	4 7	8	9	10	11	12 13 14 15	16 23	24 31

= Unimplemented or Reserved

EDL - Extended Data Length

This bit distinguishes between CAN format and CAN FD format frames. The EDL bit must not be set for Message Buffers configured to RANSWER with code field 0b1010 (see Table below).

BRS - Bit Rate Switch

This bit defines whether the bit rate is switched inside a CAN FD format frame.

ESI - Error State Indicator

This bit indicates if the transmitting node is error active or error passive.

CODE - Message Buffer Code

This 4-bit field can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in Table 44-7 and Table 44-8. See Functional description for additional information.

Table 44-7. Message buffer code for Rx buffers

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
0b0000: INACTIVE - MB is not active.	INACTIVE	-	-	-	MB does not participate in the matching process.
0b0100: EMPTY - MB is active and empty.	EMPTY	-	FULL	-	When a frame is received successfully (after the Move-in) process), the CODE field is automatically updated to FULL.

Table continues on the next page...

Table 44-7. Message buffer code for Rx buffers (continued)

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
0b0010: FULL - MB is full.	FULL	Yes	FULL	-	The act of reading the C/S word followed by unlocking the MB (SRV) does not make the code return to EMPTY. It remains FULL. If a new frame is moved to the MB after the MB was serviced, the code still remains FULL. See Matching process for matching details related to FULL code.
		No	OVERRUN	-	If the MB is FULL and a new frame is moved to this MB before the CPU services it, the CODE field is automatically updated to OVERRUN. See Matching process for details about overrun behavior.
0b0110: OVERRUN - MB is being overwritten into a full buffer.	OVERRUN	Yes	FULL	-	If the CODE field indicates OVERRUN and CPU has serviced the MB, when a new frame is moved to the MB then the code returns to FULL.
		No	OVERRUN	-	If the CODE field already indicates OVERRUN, and another new frame must be moved, the MB will be overwritten again, and the code will remain OVERRUN. See Matching process for details about overrun behavior.

Table continues on the next page...

Table 44-7. Message buffer code for Rx buffers (continued)

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
0b1010: RANSWER[4] - A frame was configured to recognize a Remote Request Frame and transmit a Response Frame in return.[5]	RANSWER	-	TANSWER(0b1110)	0	A Remote Answer was configured to recognize a remote request frame received. After that an MB is set to transmit a response frame. The code is automatically changed to TANSWER (0b1110). See Matching process for details. If CAN_CTRL2[RRS] is negated, transmit a response frame whenever a remote request frame with the same ID is received.
		-	-	1	This code is ignored during matching and arbitration process. See Matching process for details.
CODE[0]=1: BUSY - FlexCAN is updating the contents of the MB. The CPU must not access the MB.	BUSY[6]	-	FULL	-	Indicates that the MB is being updated. It will be negated automatically and does not interfere with the next CODE.
		-	OVERRUN	-	

1. SRV: Serviced MB. MB was read and unlocked by reading TIMER or other MB.
2. A frame is considered a successful reception after the frame to be moved to MB (move-in process). See Move-in for details.
3. Remote Request Stored bit, see "Control 2 Register (CAN_CTRL2)" for details.
4. Code 0b1010 is not considered Tx and an MB with this code should not be aborted.
5. Code 0b1010 must be used in Message Buffers configured in CAN FD format, having the EDL bit set.
6. Note that for Tx MBs, the BUSY bit should be ignored upon read, except when AEN bit is set in the MCR register. If this bit is asserted, the corresponding MB does not participate in the matching process.

Table 44-8. Message buffer code for Tx buffers

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
0b1000: INACTIVE - MB is not active	INACTIVE	-	-	MB does not participate in arbitration process.
0b1001: ABORT - MB is aborted	ABORT	-	-	MB does not participate in arbitration process.
0b1100: DATA - MB is a Tx Data Frame (MB RTR must be 0)	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the MB automatically returns to the INACTIVE state.
0b1100: REMOTE - MB is a Tx Remote Request Frame (MB RTR must be 1)	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the MB automatically becomes an Rx Empty MB with the same ID.
0b1110: TANSWER - MB is a Tx Response Frame from an incoming Remote Request Frame	TANSWER	-	RANSWER	This is an intermediate code that is automatically written to the MB by the CHI as a result of a match to a remote request frame. The remote response frame will be transmitted unconditionally once, and then the code will automatically return to RANSWER (0b1010). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. See Matching process and Arbitration process for details.

SRR - Substitute Remote Request

Fixed recessive bit, used only in extended format. It must be set to one by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, then it is interpreted as an arbitration loss.

1 = Recessive value is compulsory for transmission in extended format frames

0 = Dominant is not a valid value for transmission in extended format frames

IDE - ID Extended Bit

This field identifies whether the frame format is standard or extended.

1 = Frame format is extended

0 = Frame format is standard

RTR - Remote Transmission Request

This bit affects the behavior of remote frames and is part of the reception filter. See Table 44-7, Table 44-8, and the description of the RRS bit in Control 2 Register (CAN_CTRL2) for additional details.

If FlexCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as an arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FlexCAN module treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

1 = Indicates the current MB may have a remote request frame to be transmitted if MB is Tx. If the MB is Rx then incoming remote request frames may be stored.

0 = Indicates the current MB has a data frame to be transmitted. In Rx MB it may be considered in matching processes.

NOTE

When configuring CAN FD frames, the RTR bit must be negated.

DLC - Length of Data in Bytes

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 0x8 through 0xF of the MB space (see Table 44-6) . In reception, this field is written by the FlexCAN module, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see Table 44-9).

TIME STAMP - Free-Running Counter Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

PRIO - Local priority

This 3-bit field is used only when LPRIO_EN bit is set in CAN_MCR, and it only makes sense for Tx mailboxes. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See Arbitration process.

ID - Frame Identifier

In standard frame format, only the 11 most significant bits (3 to 13) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.

DATA BYTE 0 to 63 - Data Field

Up to sixty four bytes can be used for a data frame, depending on the size of payload selected for the Message Buffers.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC as shown in the table below.

Table 44-9. DATA BYTEs validity

DLC	Valid DATA BYTEs
0	none
1	DATA BYTE 0
2	DATA BYTE 0 to 1
3	DATA BYTE 0 to 2
4	DATA BYTE 0 to 3
5	DATA BYTE 0 to 4
6	DATA BYTE 0 to 5
7	DATA BYTE 0 to 6
8	DATA BYTE 0 to 7
9	DATA BYTE 0 to 11
10	DATA BYTE 0 to 15
11	DATA BYTE 0 to 19
12	DATA BYTE 0 to 23
13	DATA BYTE 0 to 31
14	DATA BYTE 0 to 47
15	DATA BYTE 0 to 63

44.4.41 FlexCAN Memory Partition for CAN FD

When CAN FD is enabled, the FlexCAN RAM can be partitioned in blocks of 512 bytes. Each block can accommodate a number of Message Buffers which depends on the configuration provided by CAN_FDCTRL[MBDSRn] bit fields as shown in table below.

Table 44-10. RAM partition

RAM block	Number of MBs with 8 bytes (default range)	Size control bit field in CAN_FDCTRL register	Number of MBs of different sizes, per block
0	0 to 31	MBDSR0	MBDSR0=00, 32 MBs with 8 bytes payload MBDSR0=01, 21 MBs with 16 bytes payload MBDSR0=10, 12 MBs with 32 bytes payload MBDSR0=11, 7 MBs with 64 bytes payload
1	32 to 63	MBDSR1	MBDSR1=00, 32 MBs with 8 bytes payload MBDSR1=01, 21 MBs with 16 bytes payload MBDSR1=10, 12 MBs with 32 bytes payload MBDSR1=11, 7 MBs with 64 bytes payload
2	64 to 95	MBDSR2	MBDSR2=00, 32 MBs with 8 bytes payload MBDSR2=01, 21 MBs with 16 bytes payload MBDSR2=10, 12 MBs with 32 bytes payload MBDSR2=11, 7 MBs with 64 bytes payload

When payload sizes of 16, 32 or 64 bytes are configured in some or all RAM blocks, the total number of MBs and its respective number order may differ from the default configuration of 8 bytes. For example, suppose Block0 is configured to 8 bytes payload, Block1 to 16 bytes, Block2 to 32 bytes, than the following table indicates how the Message Buffers will be arranged into RAM.

Table 44-11. RAM partition example

RAM block	Payload size	Number of MBs in the RAM block	Message Buffer range
0	CAN_FDCTRL[MBDSR0]=00, 8 bytes payload	32	0 to 31

Table continues on the next page...

Table 44-11. RAM partition example (continued)

RAM block	Payload size	Number of MBs in the RAM block	Message Buffer range
1	CAN_FDCTRL[MBDSR1]=01, 16 bytes payload	21	32 to 52
2	CAN_FDCTRL[MBDSR2]=10, 32 bytes payload	12	53 to 64

44.4.42 FlexCAN message buffer memory map

The FlexCAN memory buffers are allocated in memory according to the tables below.

44.4.43 Rx FIFO structure

When the CAN_MCR[RFEN] bit is set, the memory area from 0x80 to 0xDC (which is normally occupied by MBs 0–5) is used by the reception FIFO engine.

The region 0x80-0x8C contains the output of the FIFO which must be read by the CPU as a message buffer. This output contains the oldest message that has been received but not yet read. The region 0x90-0xDC is reserved for internal use of the FIFO engine.

An additional memory area, which starts at 0xE0 and may extend up to 0x2DC (normally occupied by MBs 6–37) depending on the CAN_CTRL2[RFFN] field setting, contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the FIFO.

Out of reset, the ID filter table flexible memory area defaults to 0xE0 and extends only to 0xFC, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Rx FIFO data structure.

Table 44-16. Rx FIFO structure

	0 3	7 8	9	10	11	12 13 14 15	16 23	24 31
0x80	IDHIT		SRR	IDE	RTR	DLC	TIME STAMP	
0x84		ID standard				ID extended		
0x88	Data byte 0		Data byte 1				Data byte 2	Data byte 3
0x8C	Data byte 4		Data byte 5				Data byte 6	Data byte 7
0x90 to 0xDC	Reserved							
0xE0	ID filter table element 0							
0xE4	ID filter table element 1							
0xE8 to 0x2D4	ID filter table elements 2 to 125							
0x2D8	ID filter table element 126							
0x2DC	ID filter table element 127							

= Unimplemented or reserved

Each ID filter table element occupies an entire 32-bit word and can be compounded by one, two, or four Identifier Acceptance Filters (IDAF) depending on the CAN_MCR[IDAM] field setting. The following figures show the IDAF indexation.

The following table shows the three different formats of the ID table elements. Note that all elements of the table must have the same format. See Rx FIFO for more information.

Table 44-17. ID table structure

	0	1	2 7	8 15	16	17	18 23	24 30	31
A	RTR	IDE	RXIDA (standard = 2–12, extended = 2–30)						
B	RTR	IDE	RXIDB_0 (standard = 2–12, extended = 2–15)		RTR	IDE	RXIDB_1 (standard = 18–28, extended = 18–31)		
C	RXIDC_0 (std/ext = 0–7)			RXIDC_1 (std/ext = 8–15)	RXIDC_2 (std/ext = 16–23)			RXIDC_3 (std/ext = 24–31)	

= Unimplemented or Reserved

RTR — Remote Frame

This bit specifies if Remote Frames are accepted into the FIFO if they match the target ID.

1 = Remote Frames can be accepted and data frames are rejected

0 = Remote Frames are rejected and data frames can be accepted

IDE — Extended Frame

Specifies whether extended or standard frames are accepted into the FIFO if they match the target ID.

1 = Extended frames can be accepted and standard frames are rejected

0 = Extended frames are rejected and standard frames can be accepted

RXIDA — Rx Frame Identifier (Format A)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, only the 11 most significant bits (2 to 12) are used for frame identification. In the extended frame format, all bits are used.

RXIDB_0, RXIDB_1 — Rx Frame Identifier (Format B)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (2 to 12 and 18 to 28) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3 — Rx Frame Identifier (Format C)

Specifies an ID to be used as acceptance criteria for the FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

IDHIT — Identifier Acceptance Filter Hit Indicator

This 9-bit field indicates which Identifier Acceptance Filter was hit by the received message that is in the output of the Rx FIFO. See Rx FIFO for more information.

44.5 Functional description

The FlexCAN module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system is composed by a set of Message Buffers (MB) that store configuration and control data, time stamp, message ID and data (see Message buffer structure). The memory corresponding to the first 38 MBs can be configured to support a FIFO reception scheme with a powerful ID filtering mechanism, capable of checking incoming frames against a table of IDs (up to 128 extended IDs or 256 standard IDs or 512 8-bit ID slices), with individual mask register for up to 32 ID Filter Table elements.

For Classical CAN frames, simultaneous reception through FIFO and mailbox is supported. For CAN FD frames, reception is supported through mailboxes only. For mailbox reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed on its ID field. A masking scheme makes it possible to match the ID programmed on the MB with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

Before proceeding with the functional description, an important concept must be explained. A Message Buffer is said to be "active" at a given time if it can participate in both the Matching and Arbitration processes. An Rx MB with a 0b0000 code is inactive (refer to Table 44-7). Similarly, a Tx MB with a 0b1000 or 0b1001 code is also inactive (refer to Table 44-8).

The FlexCAN module is also able to receive and transmit messages in CAN FD format. The Message Buffers are sized to adequately store the quantity of data bytes selected by the MBDSRn bit fields in CAN_FDCTRL register. The quantity of FD MBs available for a given quantity of data bytes is described CAN_FDCTRL register. See also FlexCAN Memory Partition for CAN FD.

44.5.1 Transmit process

To transmit a CAN frame, the CPU must prepare a Message Buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (0b1001) to the CODE field of the Control and Status word to request an abortion of the transmission. Wait for the corresponding IFLAG bit to be asserted by polling the CAN_IFLAG register or by the interrupt request if enabled by the respective IMASK bit. Then read back the CODE field to check if the transmission was aborted or transmitted (see Transmission abort mechanism). If backwards compatibility is desired (CAN_MCR[AEN] bit is negated), just write the INACTIVE code (0b1000) to the CODE field to inactivate the MB but then the pending frame may be transmitted without notification (see Mailbox inactivation).
3. Write the ID word.
4. Write the data bytes.

5. Write the DLC, Control, and CODE fields of the Control and Status word to activate the MB. When CAN_MCR[FDEN] is set, write also the EDL, BRS and ESI bits.

When the MB is activated, it participates in the arbitration process and is eventually transmitted according to its priority. When the DLC value stored in the MB selected for transmission is larger than the respective MB payload size, FlexCAN adds the necessary number of bytes with constant 0xCC pattern to complete the expected DLC.

At the end of the successful transmission, the value of the Free Running Timer is written into the Time Stamp field, the CODE field in the Control and Status word is updated, both CAN_CRC and CAN_FDCRC Registers are updated, a status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit. The new CODE field after transmission depends on the code that was used to activate the MB (see Table 44-7 and Table 44-8 in Message buffer structure).

When the Abort feature is enabled (CAN_MCR[AEN] is asserted), after the Interrupt Flag is asserted for a Mailbox configured as transmit buffer, the Mailbox is blocked. Therefore the CPU is not able to update it until the Interrupt Flag is negated by CPU. This means that the CPU must clear the corresponding IFLAG bit before starting to prepare this MB for a new transmission or reception.

44.5.2 Arbitration process

The arbitration process scans the Mailboxes searching the Tx one that holds the message to be sent in the next opportunity. This Mailbox is called the *arbitration winner*.

The scan starts from the lowest number Mailbox and runs toward the higher ones.

The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the CAN_CTRL2[TASD] field value.
- During the Error Delimiter field of a CAN frame.
- During the Overload Delimiter field of a CAN frame.
- When the winner is inactivated and the CAN bus has still not reached the first bit of the Intermission field.
- When there is CPU write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the Intermission field.

- When CHI is in Idle state and the CPU writes to the C/S word of any MB.
- When FlexCAN exits Bus Off state.
- Upon leaving Freeze mode or Low Power mode.

If the arbitration process does not manage to evaluate all Mailboxes before the CAN bus has reached the first bit of the Intermission field the temporary arbitration winner is invalidated and the FlexCAN will not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx Mailboxes at the end of the scan according to both CAN_CTRL1[LBUF] and CAN_MCR[LPRIOEN] bits settings.

44.5.2.1 Lowest-number Mailbox first

If CAN_CTRL1[LBUF] bit is asserted the first (lowest number) active Tx Mailbox found is the arbitration winner. CAN_MCR[LPRIOEN] bit has no effect when CAN_CTRL1[LBUF] is asserted.

44.5.2.2 Highest-priority Mailbox first

If CAN_CTRL1[LBUF] bit is negated, then the arbitration process searches the active Tx Mailbox with the highest priority, which means that this Mailbox's frame would have a higher probability to win the arbitration on CAN bus when multiple external nodes compete for the bus at the same time.

The sequence of bits considered for this arbitration is called the *arbitration value* of the Mailbox. The highest-priority Tx Mailbox is the one that has the lowest arbitration value among all Tx Mailboxes.

If two or more Mailboxes have equivalent arbitration values, the Mailbox with the lowest number is the arbitration winner.

The composition of the arbitration value depends on CAN_MCR[LPRIOEN] bit setting.

44.5.2.2.1 Local Priority disabled

If CAN_MCR[LPRIOEN] bit is negated the arbitration value is built in the exact sequence of bits as they would be transmitted in a CAN frame (see the following table) in such a way that the Local Priority is disabled.

Table 44-18. Composition of the arbitration value when Local Priority is disabled

Format	Mailbox Arbitration Value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

44.5.2.2.2 Local Priority enabled

If Local Priority is desired CAN_MCR[LPRIOEN] must be asserted. In this case the Mailbox PRIO field is included at the very left of the arbitration value (see the following table).

Table 44-19. Composition of the arbitration value when Local Priority is enabled

Format	Mailbox Arbitration Value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

As the PRIO field is the most significant part of the arbitration value Mailboxes with low PRIO values have higher priority than Mailboxes with high PRIO values regardless the rest of their arbitration values.

Note that the PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

44.5.2.3 Arbitration process (continued)

After the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called move-out and after it is done, write access to the C/S word of the corresponding MB is blocked (if the AEN bit in CAN_MCR register is asserted). Write access is restored in the following events:

- After the MB is transmitted and the corresponding IFLAG bit is cleared by the CPU
- FlexCAN enters in Freeze mode or Bus Off
- FlexCAN loses the bus arbitration or there is an error during the transmission

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules.

Arbitration process can be triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. CAN_CTRL2[TASD] bit value may be changed to optimize the arbitration start point.
- During CAN BusOff state from TX_ERR_CNT=124 to 128. CAN_CTRL2[TASD] bit value may be changed to optimize the arbitration start point.
- During C/S write by CPU in BusIdle. First C/S write starts arbitration process and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, Tx arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, then the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and BusIdle state starts then an arbitration process is triggered. In this case the first and second C/S write in BusIdle will not restart the arbitration process. It is possible that there is not enough time to finish arbitration in WaitForBusIdle state and the next state is Idle. In this case the scan is not interrupted, and it is completed during BusIdle state. During this arbitration C/S write does not cause arbitration restart.
- Arbitration winner deactivation during a valid arbitration window.
- Upon exiting Freeze mode (first bit of the WaitForBusIdle state). If there is a re-synchronization during WaitForBusIdle, the arbitration process is restarted.

Arbitration process stops in the following situations:

- All Mailboxes were scanned
- A Tx active Mailbox is found in case of Lowest Buffer feature enabled
- Arbitration winner inactivation or abort during any arbitration process
- There was not enough time to finish Tx arbitration process (for instance, when a deactivation was performed near the end of frame). In this case arbitration process is pending.
- Error or Overload flag in the bus
- Low Power or Freeze mode request in Idle state

Arbitration is considered pending as described below:

- It was not possible to finish arbitration process in time
- C/S write during arbitration if write is performed in a MB whose number is lower than the Tx arbitration pointer
- Any C/S write if there is no Tx Arbitration process in progress
- Rx Match has just updated a Rx Code to Tx Code
- Entering Busoff state

C/S write during arbitration has the following effect:

- If C/S write is performed in the arbitration winner, a new process is restarted immediately.
- If C/S write is performed in a MB whose number is higher than the Tx arbitration pointer, the ongoing arbitration process will scan this MB as normal.

44.5.3 Receive process

To be able to receive CAN frames into a Mailbox, the CPU must prepare it for reception by executing the following steps:

1. If the Mailbox is active (either Tx or Rx) inactivate the Mailbox (see Mailbox inactivation), preferably with a safe inactivation (see Transmission abort mechanism).
2. Write the ID word
3. Write the EMPTY code (0b0100) to the CODE field of the Control and Status word to activate the Mailbox. No setup is required for EDL, BRS and ESI bits, they are overwritten by the respective bit fields in the received message.

After the MB is activated, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the Mailbox is updated by the *move-in* process (see Move-in) as follows:

1. The received Data field (8 bytes at most for Classical CAN message format and up to 64 bytes for CAN FD message format) is stored.
2. The received Identifier field is stored.
3. The value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the Mailbox's Time Stamp field.
4. The received SRR, IDE, RTR, EDL, BRS, ESI and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see Table 44-7 and Table 44-8 in Section Message buffer structure).
6. A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The recommended way for CPU servicing (read) the frame received in an Mailbox is using the following procedure:

1. Read the Control and Status word of that Mailbox.

2. Check if the BUSY bit is deasserted, indicating that the Mailbox is locked. Repeat step 1) while it is asserted. See Mailbox lock mechanism.
3. Read the contents of the Mailbox. Once Mailbox is locked now, its contents won't be modified by FlexCAN Move-in processes. See Move-in.
4. Acknowledge the proper flag at IFLAG registers.
5. Read the Free Running Timer. It is optional but recommended to unlock Mailbox as soon as possible and make it available for reception.

The CPU should poll for frame reception by the status flag bit for the specific Mailbox in one of the IFLAG Registers and not by the CODE field of that Mailbox. Polling the CODE field does not work because once a frame was received and the CPU services the Mailbox (by reading the C/S word followed by unlocking the Mailbox), the CODE field will not return to EMPTY. It will remain FULL, as explained in Table 44-7 . If the CPU tries to workaround this behavior by writing to the C/S word to force an EMPTY code after reading the Mailbox without a prior *safe inactivation*, a newly received frame matching the filter of that Mailbox may be lost.

CAUTION

In summary: *never do polling by reading directly the C/S word of the Mailboxes. Instead, read the IFLAG registers.*

Note that the received frame's Identifier field is always stored in the matching Mailbox, thus the contents of the ID field in an Mailbox may change if the match was due to masking. When CAN_MCR[SRXDIS] bit is asserted, FlexCAN will not store frames transmitted by itself in any MB, even if it contains a matching Rx Mailbox, and no interrupt flag or interrupt signal will be generated. Otherwise, when CAN_MCR[SRXDIS] bit is deasserted, FlexCAN can receive frames transmitted by itself if there exists a matching Rx Mailbox.

To be able to receive CAN frames through the Rx FIFO, the CPU must enable and configure the Rx FIFO during Freeze mode (see Rx FIFO). Upon receiving the Frames Available in Rx FIFO interrupt (see the description of the BUF5I bit "Frames available in Rx FIFO" bit in the CAN_IFLAG1 register), the CPU should service the received frame using the following procedure:

1. Read the Control and Status word (optional: needed only if a mask was used for IDE and RTR bits)
2. Read the ID field (optional: needed only if a mask was used)
3. Read the Data field

4. Read the CAN_RXFIR register (optional)
5. Clear the Frames Available in Rx FIFO interrupt by writing 1 to CAN_IFLAG1[BUF5I] bit (mandatory: releases the MB and allows the CPU to read the next Rx FIFO entry)

When CAN_MCR[DMA] is asserted, upon receiving a frame in FIFO, CAN_IFLAG1[BUF5I] generates a DMA request and does not generate a CPU interrupt (see Rx FIFO under DMA Operation). The CAN_IMASK1 bits in Rx FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the Control and Status word (read 0x80 address, optional)
2. Read the ID field (read 0x84 address, optional)
3. Read all Data Bytes (start read at 0x88 address, optional)
4. Read the last Data Bytes (read 0x8C address is mandatory)

44.5.4 Matching process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. If the FIFO is enabled, the priority of scanning can be selected between Mailboxes and FIFO filters. The matching starts from the lowest number Message Buffer toward the higher ones. If no match is found within the first structure then the other is scanned subsequently. In the event that the FIFO is full, the matching algorithm always looks for a matching MB outside the FIFO region.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- If the received frame is a remote frame, the start point is the CRC field of the frame
- If the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame
- If the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame

If a matching ID is found in the FIFO table or in one of the Mailboxes, the contents of the Rx SMB are transferred to the FIFO or to the matched Mailbox by the move-in process. If any CAN protocol error is detected then no match results are transferred to the FIFO or to the matched Mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and the active Rx Mailboxes (CODE is EMPTY, FULL, OVERRUN or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The Rx SMB has the same structure of a Mailbox. The reception structures (Rx FIFO or Mailboxes) associated with the matching elements that had a successful comparison are the *matched structures*. The *matching winner* is selected at the end of the scan among those matched structures and depends on conditions described ahead. See the following table.

Table 44-20. Matching architecture

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID[1]]	MB[CODE]
Mailbox	0	-	0	cmp[2]	no_cmp[3]	cmp_msk[4]	EMPTY or FULL or OVERRUN
Mailbox	0	-	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	0	-	cmp	no_cmp	cmp	RANSWER
Mailbox	1	1	0	cmp	no_cmp	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	1	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
FIFO[5]	-	-	-	cmp_msk	cmp_msk	cmp_msk	-

1. For Mailbox structure, If SMB[IDE] is asserted, the ID is 29 bits (ID Standard + ID Extended). If SMB[IDE] is negated, the ID is only 11 bits (ID Standard). For FIFO structure, the ID depends on IDAM.
2. cmp: Compares the Rx SMB contents with the MB contents regardless the masks.
3. no_cmp: The Rx SMB contents are not compared with the MB contents.
4. cmp_msk: Compares the Rx SMB contents with MB contents taking into account the masks.
5. SMB[IDE] and SMB[RTR] are not taken into account when IDAM is type C.

A reception structure is *free-to-receive* when any of the following conditions is satisfied:

- The CODE field of the Mailbox is EMPTY
- The CODE field of the Mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the CPU and unlocked as described in Mailbox lock mechanism)
- The CODE field of the Mailbox is either FULL or OVERRUN and an inactivation (see Mailbox inactivation) is performed
- The Rx FIFO is not full

The scan order for Mailboxes and Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for Mailboxes is affected by the CAN_MCR[IRMQ] bit. If it is negated, the matching winner is the first matched Mailbox regardless if it is free-to-receive or not. If it is asserted, the matching winner is selected according to the priority below:

1. the first free-to-receive matched Mailbox;
2. the last non free-to-receive matched Mailbox.

It is possible to select the priority of scan between Mailboxes and Rx FIFO by the CAN_CTRL2[MRP] bit.

If the selected priority is Rx FIFO first:

- If the Rx FIFO is a matched structure and is free-to-receive, then the Rx FIFO is the matching winner regardless of the scan for Mailboxes
- Otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched among Mailboxes as described above

If the selected priority is Mailboxes first:

- If a free-to-receive matched Mailbox is found, it is the matching winner regardless of the scan for Rx FIFO
- If no matched Mailbox is found, then the matching winner is searched in the scan for the Rx FIFO
- If both conditions above are not satisfied and a non free-to-receive matched Mailbox is found, then the matching winner determination is conditioned by the CAN_MCR[IRMQ] bit:
- - If CAN_MCR[IRMQ] bit is negated, the matching winner is the first matched Mailbox
  - If CAN_MCR[IRMQ] bit is asserted, the matching winner is the Rx FIFO if it is a free-to-receive matched structure; otherwise, the matching winner is the last non free-to-receive matched Mailbox

See the following table for a summary of matching possibilities.

Table 44-21. Matching possibilities and resulting reception structures

RFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception structure	Description
No FIFO, only MB, match is always MB first						
0	0	X[1]	None[2]	-[3]	None	Frame lost by no match
0	0	X	Free[4]	-	FirstMB	

Table continues on the next page...

Table 44-21. Matching possibilities and resulting reception structures (continued)

RFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception structure	Description
0	1	X	None	-	None	Frame lost by no match
0	1	X	Free	-	FirstMb	
0	1	X	NotFree	-	LastMB	Overrun
FIFO enabled, no match in FIFO is as if FIFO does not exist						
1	0	X	None	None[5]	None	Frame lost by no match
1	0	X	Free	None	FirstMB	
1	1	X	None	None	None	Frame lost by no match
1	1	X	Free	None	FirstMb	
1	1	X	NotFree	None	LastMB	Overrun
FIFO enabled, Queue disabled						
1	0	0	X	NotFull[6]	FIFO	
1	0	0	None	Full[7]	None	Frame lost by FIFO full (FIFO Overflow)
1	0	0	Free	Full	FirstMB	
1	0	0	NotFree	Full	FirstMB	
1	0	1	None	NotFull	FIFO	
1	0	1	None	Full	None	Frame lost by FIFO full (FIFO Overflow)
1	0	1	Free	X	FirstMB	
1	0	1	NotFree	X	FirtsMb	Overrun
FIFO enabled, Queue enabled						
1	1	0	X	NotFull	FIFO	
1	1	0	None	Full	None	Frame lost by FIFO full (FIFO Overflow)
1	1	0	Free	Full	FirstMB	
1	1	0	NotFree	Full	LastMb	Overrun
1	1	1	None	NotFull	FIFO	
1	1	1	Free	X	FirstMB	
1	1	1	NotFree	NotFull	FIFO	
1	1	1	NotFree	Full	LastMb	Overrun

1. This is a don't care condition.
2. Matched in MB "None" means that the frame has not matched any MB (free-to-receive or non-free-to-receive).
3. This is a forbidden condition.
4. Matched in MB "Free" means that the frame matched at least one MB free-to-receive regardless of whether it has matched MBs non-free-to-receive.
5. Matched in FIFO "None" means that the frame has not matched any filter in FIFO. It is as if the FIFO didn't exist (CAN_CTRL2[RFEN]=0).
6. Matched in FIFO "NotFull" means that the frame has matched a FIFO filter and has empty slots to receive it.

7. Matched in FIFO "Full" means that the frame has matched a FIFO filter but couldn't store it because it has no empty slots to receive it.

If a non-safe Mailbox inactivation (see Mailbox inactivation) occurs during matching process and the Mailbox inactivated is the temporary matching winner, then the temporary matching winner is invalidated. The matching elements scan is not stopped nor restarted, it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the FIFO is disabled, IRMQ is enabled and there are two MBs with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these MBs are the second and the fifth in the array. When the first message arrives, the matching algorithm finds the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive", so it keeps looking, finds MB number 5 and stores the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive", so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full featured FIFO) to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages are queued into the MBs. The CPU can examine the Time Stamp field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID Acceptance Masks. FlexCAN supports individual masking per MB. See the description of the Rx Individual Mask Registers (CAN_RXIMRx). During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is a "don't care". Note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed while the module is in Freeze mode; otherwise, they are blocked by hardware.

FlexCAN also supports an alternate masking scheme with only four mask registers (CAN_RXFGMASK, CAN_RXMGMASK, CAN_RX14MASK and CAN_RX15MASK) for backwards compatibility with legacy applications. This alternate masking scheme is enabled when the IRMQ bit in the CAN_MCR Register is negated.

44.5.5 Receive Process under Pretended Networking Mode

Pretended Networking mode adds specific wake up functionality in low power mode (Stop mode). When Pretended Network mode (PN) is enabled by asserting the PNET_EN bit in the Module Configuration Register (CAN_MCR)), FlexCAN continues processing Rx CAN messages under low power mode, able to detect specific wake up messages by filtering them against ID and payload target values using a pre-selected matching criteria. Wake up functionality is not available for messages in CAN FD format. While in Pretended Networking mode, CAN FD format messages are ignored.

PN registers are located in the 0x0B00 - 0x0B7C address range and can be written only in Freeze mode. These registers are used for writing PN configuration (both control and target values) prior entering to Pretended Networking mode, and for reading wake up flags and the received message ID and data when returning back to normal mode after wake up. The CPU must wait for CAN_MCR[LPMACK] to be negated before performing any access to FlexCAN PN registers.

PN control registers are described in Pretended Networking Control 1 Register (CAN_CTRL1_PN) and Pretended Networking Control 2 Register (CAN_CTRL2_PN). The control bit fields that configure the filtering criteria are:

- PLFS: payload filtering selection.
- IDFS: ID filtering selection.
- FCS: filtering combination selection.

PN target values are:

- FLT_IDE: IDE target value used to filter the incoming message by its format (standard or extended).
- FLT_RTR: RTR target value used to filter the incoming message by its type (data or remote frame).
- FLT_DLC_HI and FLT_DLC_LO: target DLC range used to filter the size of payload part of an incoming message.
- FLT_ID1: ID target value used to filter the incoming message ID (equal to, smaller than or equal, greater than or equal, or the lower limit value in an ID range).
- FLT_ID2: ID target value used as the upper limit in an ID range.
- PL1: Payload target value used to filter the incoming message payload (equal to, smaller than or equal, greater than or equal, or the lower limit value in a payload range).
- PL2: Payload target value used as the upper limit in a payload range.

IDE, RTR, ID and payload filters have their respective masks. These masks determine which bits are taken into account in equality comparisons ("1's" in certain mask positions) and which ones are don't care ("0's" in other mask positions). ID and payload masks are used only for exact ID and/or exact Payload comparisons.

The ID of Rx incoming messages can be filtered based on the following criteria:

- A match with the exact ID value by detecting the equality between the ID field of the incoming message and the content of target CAN_FLT_ID1 register. The ID mask is used.
- A match with the maximum range of ID, i.e. any message with ID value smaller than or equal to the content of target CAN_FLT_ID1 register is accepted. The ID mask is not used.
- A match with the minimum range of ID, i.e. any message with ID value greater than or equal to the content of target CAN_FLT_ID1 register is accepted. The ID mask is not used.
- A match inside a range of IDs, i.e. any message with an ID value that is greater than or equal to the content of target CAN_FLT_ID1 register and smaller than or equal to the content of target CAN_FLT_ID2_IDMASK register is accepted. The ID mask is not used.

See CAN_CTRL1_PN[IDFS] in Pretended Networking Control 1 Register (CAN_CTRL1_PN).

The above criteria for ID filtering must be coherent with FLT_IDE and FLT_RTR target values in CAN_FLT_ID1 register. Only Rx frames that match the respective IDE and RTR bits to the contents of FLT_IDE and FLT_RTR bit fields will be compared. When range of IDs is selected (CAN_CTRL1_PN[IDFS] = 11), both FLT_ID1 and FLT_ID2 are referred to the same FLT_IDE and FLT_RTR bits in CAN_FLT_ID1 register.

The ID mask is applied only to the exact ID comparison filtering option (CAN_CTRL1_PN[IDFS] = 00) to determine which bits are taken into account in the comparison. For the exact match option, the mask can select any bit within the ID field. For maximum range, minimum range and inside range comparisons, the ID mask is not considered.

The IDE and RTR masks are applied in both exact and range ID comparison filtering options to determine which bits are taken into account in comparison.

Similarly to the ID criteria, 64-bit data or payloads (PL) of Rx incoming messages can be filtered based on the following criteria:

- A match with the exact payload value by detecting the equality between the payload field of the incoming message and the content of PL1 register. The payload mask is used.

- A match with the maximum range of payload, i.e. any message with payload value smaller than or equal to the content of PL1 register is accepted. The payload mask is not used.
- A match with the minimum range of payload, i.e. any message with payload value greater than or equal to the content of PL1 register is accepted. The payload mask is not used.
- A match inside a range of payloads, i.e. any message with a payload value that is greater than or equal to the content of PL1 register and smaller than or equal to the content of PL2 register is accepted. The payload mask is not used.

See CAN_CTRL1_PN[PLFS] in Pretended Networking Control 1 Register (CAN_CTRL1_PN).

The above criteria for payload filtering must be coherent with FLT_DLC upper and lower limit values in CAN_FLT_DLC register. The payload of a Rx incoming message is filtered in accordance to the selected criteria only if the DLC value of the Rx incoming message is inside a DLC range:

- greater than or equal to the FLT_DLC_LO (lower limit) and
- lower than or equal to the FLT_DLC_HI (upper limit).

Conversely, a DLC value out of the specified range results in mismatch. By making FLT_DLC_LO = FLT_DLC_HI, only payloads of specified quantity of bytes will be filtered. DLC is not maskable.

When the inside range of payloads option is selected (CAN_CTRL1_PN[PLFS] = 11), both PL1 and PL2 are considered with the 8-byte data length. All the data bytes excluded by the DLC of the received message are considered with value zero.

Payload mask is only used in the exact match option (CAN_CTRL1_PN[PLFS] = 00) to select which bits or bytes in the 8-byte data field of both Rx incoming message and the contents of PL1 register are selected for matching. Mask length must be in accordance to the expected range of DLC values. For maximum range, minimum range and inside range comparisons, the payload mask is not considered.

When a remote frame is received by FlexCAN and the CAN_CTRL1[FCS] bit is configured to select the payload comparison, the payload filtering is not considered and the comparison results in a mismatch.

Rx incoming messages can also be filtered based upon the quantity and rate of message reception, specifically:

- Several messages that match the filtering criteria for ID or payload a predefined quantity of times. This quantity can be configured in the 1 to 255 range. See the Pretended Networking Control 1 Register (CAN_CTRL1_PN).
- No message matching the filtering criteria for ID or payload up to a timeout trigger. That is, non-reception of a matching message for a defined quantity of time. See the Pretended Networking Control 2 Register (CAN_CTRL2_PN).

FlexCAN can generate a wake up timeout event from an internal timer with associated comparator circuitry capable to generate a timeout flag when the counting reaches the pre-defined timeout value, as specified in CAN_CTRL2_PN[MATCHTO].

The above filtering criteria can be used together as follows:

- Message ID filtering only.
- Message ID filtering and Payload filtering.
- Message ID filtering only occurring N times.
- Message ID filtering and Payload filtering occurring N times.

The timeout counter runs concurrently with the reception filtering process. Both engines, timeout counter and message filtering, are independent. If an incoming message matches the selected filter criteria, the timeout counter keeps counting until the CPU wakes-up. Conversely, if the timeout counter reaches the target value then the message filtering process continue to filter incoming messages until the CPU wakes-up. The CAN_WU_MTC[MCOUNTER] field will report the number of matched messages occurred under Pretended Networking mode up to the moment the CPU wakes up.

Under Pretended Networking mode, the wake up event that may occur will set the respective wake up flag (see Pretended Networking Wake Up Match Register (CAN_WU_MTC)):

- In case of a successful matching in accordance to the selected filtering criteria, the CAN_WU_MTC[WUMF].
- In case of a timeout trigger, the CAN_WU_MTC[WTOF].

Any of these flags will generate interrupts to the CPU, provided the respective mask bits are enabled (WUMF_MSK or WTOF_MSK in CAN_CTRL1_PN register).

There are four WMB's (Wake up Message Buffers) used to store incoming messages in Pretended Networking mode. Up to four messages can be stored (see Pretended Networking Wake Up Message Buffer Registers (CAN_WMB0 - CAN_WMB3)). When CTRL1_PN[NMATCH] value is 1, just one message is received if matching the filtering criteria, and this message is stored in CAN_WMB0. If NMATCH value is between 2 and 4, CAN_WMB1, CAN_WMB2 and CAN_WMB3 are used to store the second,third and fourth matching messages, respectively. If NMATCH is greater than 4, the last four matching messages are stored in the WMBs, respecting the WMB index to indicate the

arrival order, the latest is stored in CAN_WMB3. Only the valid data bytes of the incoming match message is stored in data field of WMBs. The non-valid data bytes is read as zero. In case of DLC=0 and RTR=1 the data field is filled with zero. In any of the above cases, the wake up interrupt is generated just when the filtering criteria is completed and CAN_CTRL1_PN[WUMF_MSK] is enabled.

When a non-match wake-up event occurs (timeout or external) and MCOUNTER register is equal or greater than 4, the message stored in WMB0 does not have a valid content. The CAN_WMB0 is used as buffer for the current message in CAN bus. Messages received during Pretended Networkig mode don't have timestamps and respective field in the WMB structure must be ignored.

Under low power mode(Stop), all processes are shut down except for the PN functionality inside CAN_PE sub-block, that is kept clocked by the Oscillator clock (see Clock domains and restrictions). FlexCAN continues to receive Rx incoming messages and just compares them against the predefined target values and in accordance to the selected filtering criteria. The matching, arbitration, move-in and move-out processes, normally available in Normal mode, are not performed under Pretended Networking mode.

The FlexCAN under Pretended Networking reacts to messages on the CAN bus in the same manner as in Normal mode (i.e. generates acknowledge bits, detect and count errors, etc.).

44.5.6 Move process

There are two types of move process: move-in and move-out.

44.5.6.1 Move-in

The move-in process is the copy of a message received by an Rx SMB to a Rx Mailbox or FIFO that has matched it. If the move destination is the Rx FIFO, attributes of the message are also copied to the CAN_RXFIR FIFO. Each Rx SMB has its own move-in process, but only one is performed at a given time as described ahead. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (see Matching process) and all of the following conditions are true:

- The CAN bus has reached or let past either:
  - The second bit of Intermission field next to the frame that carried the message that is in the Rx SMB
  - The first bit of an overload frame next to the frame that carried the message that is in the Rx SMB

- There is no ongoing matching process
- The destination Mailbox is not locked by the CPU
- There is no ongoing move-in process from another Rx SMB. If more than one move-in processes are to be started at the same time both are performed and the newest substitutes the oldest.

The term *pending move-in* is used throughout the documentation and stands for a move-to-be that still does not satisfy all of the aforementioned conditions.

The move-in is cancelled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

- The destination Mailbox is inactivated after the CAN bus has reached the first bit of Intermission field next to the frame that carried the message and its matching process has finished
- There is a previous pending move-in to the same destination Mailbox
- The Rx SMB is receiving a frame transmitted by the FlexCAN itself and the self-reception is disabled (CAN_MCR[SRXDIS] bit is asserted)
- Any CAN protocol error is detected

Note that the pending move-in is not cancelled if the module enters Freeze or Low-Power mode. It only stays on hold waiting for exiting Freeze and Low-Power mode and to be unlocked. If an MB is unlocked during Freeze mode, the move-in happens immediately.

The move-in process is the execution by the FlexCAN of the following steps:

1. Push IDHIT into the RXFIR FIFO if the message is destined to the Rx FIFO.
2. Read all data words from the Rx SMB in accordance to the selected payload size for the Rx storage element.
3. Write all data words to the Rx Mailbox in accordance to the selected payload size for the Rx storage element. If the data size of the storage element is smaller than the original payload size described in the message's DLC field, the payload is truncated and the high order bytes that do not fit the destination size are lost.
4. Read the Control/Status and ID words from the Rx SMB.
5. Write Control/Status and ID words to the Rx Mailbox, and update the CODE field.

The move-in process is not atomic, in such a way that it is immediately cancelled by the inactivation of the destination Mailbox (see Mailbox inactivation) and in this case the Mailbox may be left partially updated, thus incoherent. The exception is if the move-in destination is an Rx FIFO Message Buffer, then the process cannot be cancelled.

The BUSY Bit (least significant bit of the CODE field) of the destination Message Buffer is asserted while the move-in is being performed to alert the CPU that the Message Buffer content is temporarily incoherent.

44.5.6.2 Move-out

The move-out process is the copy of the content from a Tx Mailbox to the Tx SMB when a message for transmission is available (see Section "Arbitration process"). The move-out occurs in the following conditions:

- The first bit of Intermission field
- During Bus Off state when TX Error Counter is in the 124 to 128 range
- During Bus Idle state
- During Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently out of Bus Idle state. In Bus Idle, the move-out has the lowest priority to the concurrent memory accesses.

44.5.7 Data coherence

In order to maintain data coherency and FlexCAN proper operation, the CPU must obey the rules described in Transmit process and Receive process.

44.5.7.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the CPU if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

Two primary conditions must be fulfilled in order to abort a transmission:

- CAN_MCR[AEN] bit must be asserted
- The first CPU action must be the writing of abort code (0b1001) into the CODE field of the Control and Status word.

Active MBs configured for transmission must be aborted first before they can be updated. If the abort code is written to a Mailbox that is currently being transmitted or to a Mailbox that was already loaded into the Tx SMB for transmission, the write operation is blocked and the transmission is not disturbed. However, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The module loses the bus arbitration
- There is an error during the transmission
- The module is put into Freeze mode

- The module enters the BusOff state
- There is an overload frame

If none of the conditions above are reached, the MB is transmitted correctly, the interrupt flag is set in the IFLAG register, and an interrupt to the CPU is generated (if enabled). The abort request is automatically cleared when the interrupt flag is set. On the other hand, if one of the above conditions is reached, the frame is not transmitted; therefore, the abort code is written into the CODE field, the interrupt flag is set in the IFLAG, and an interrupt is (optionally) generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, then the write operation is not blocked; therefore, the MB is updated and the interrupt flag is set. In this way the CPU just needs to read the abort code to make sure the active MB was *safely inactivated*. Although the AEN bit is asserted and the CPU wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One Mailbox is only aborted when the abort request is captured and kept pending until one of the previous conditions are satisfied.

The abort procedure can be summarized as follows:

- CPU checks the corresponding IFLAG and clears it, if asserted.
- CPU writes 0b1001 into the CODE field of the C/S word.
- CPU waits for the corresponding IFLAG indicating that the frame was either transmitted or aborted.
- CPU reads the CODE field to check if the frame was either transmitted (CODE=0b1000) or aborted (CODE=0b1001).
- It is necessary to clear the corresponding IFLAG in order to allow the MB to be reconfigured.
- It is necessary to reconfigure the EDL, BRS, and ESI bits of the aborted MB before transmitting it again.

44.5.7.2 Mailbox inactivation

Inactivation is a mechanism provided to protect the Mailbox against updates by the FlexCAN internal processes, thus allowing the CPU to rely on Mailbox data coherence after having updated it, even in Normal mode.

Inactivation of transmission Mailboxes must be performed just when MCR[AEN] bit is deasserted.

If a Mailbox is inactivated, it participates in neither the arbitration process nor the matching process until it is reactivated. See Transmit process and Receive process for more detailed instructions on how to inactivate and reactivate a Mailbox.

To inactivate a Mailbox, the CPU must update its CODE field to INACTIVE (either 0b0000 or 0b1000).

Because the user is not able to synchronize the CODE field update with the FlexCAN internal processes, an inactivation can have the following consequences:

- A frame in the bus that matches the filtering of the inactivated Rx Mailbox may be lost without notice, even if there are other Mailboxes with the same filter
- A frame containing the message within the inactivated Tx Mailbox may be transmitted without setting the respective IFLAG

In order to perform a *safe inactivation* and avoid the above consequences for Tx Mailboxes, the CPU must use the Transmission Abort mechanism (see Transmission abort mechanism).

The inactivation automatically unlocks the Mailbox (see Mailbox lock mechanism).

NOTE

Message Buffers that are part of the Rx FIFO cannot be inactivated. There is no write protection on the FIFO region by FlexCAN. CPU must maintain data coherency in the FIFO region when RFEN is asserted.

44.5.7.3 Mailbox lock mechanism

Other than Mailbox inactivation, FlexCAN has another data coherence mechanism for the receive process. When the CPU reads the Control and Status word of an Rx MB with codes FULL or OVERRUN, FlexCAN assumes that the CPU wants to read the whole MB in an atomic operation, and therefore it sets an internal lock flag for that MB. The lock is released when the CPU reads the Free Running Timer (global unlock operation), or when it reads the Control and Status word of another MB regardless of its code. A CPU write into the C/S word also unlocks the MB, but this procedure is not recommended for normal unlock use because it cancels a pending-move and potentially may lose a received message. The MB locking prevents a new frame from being written into the MB while the CPU is reading it.

NOTE

The locking mechanism applies only to Rx MBs that are not part of the FIFO and have a code different than INACTIVE (0b0000) or EMPTY[1] (0b0100). Also, Tx MBs can not be locked.

1. In previous FlexCAN versions, reading the C/S word locked the MB even if it was EMPTY. This behavior is maintained when the IRMQ bit is negated.

Suppose, for example, that the FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two MBs. Suppose now that the CPU decides to read MB number 5 and at the same time another message with the same ID is arriving. When the CPU reads the Control and Status word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no "free-to-receive" MBs, so it decides to override MB number 5. However, this MB is locked, so the new message can not be written there. It will remain in the Rx SMB waiting for the MB to be unlocked, and only then will be written to the MB.

If the MB is not unlocked in time and yet another new message with the same ID arrives, then the new message overwrites the one on the Rx SMB and there will be no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved-in from the Rx SMB to the MB, the BUSY bit on the CODE field is asserted. If the CPU reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is negated.

Note

If the BUSY bit is asserted or if the MB is empty, then reading the Control and Status word does not lock the MB.

Inactivation takes precedence over locking. If the CPU inactivates a locked Rx MB, then its lock status is negated and the MB is marked as invalid for the current matching round. Any pending message on the Rx SMB will not be transferred anymore to the MB. An MB is unlocked when the CPU reads the Free Running Timer Register (see Section "Free Running Timer Register (CAN_TIMER)"), or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during a low power mode (see Modes of operation), and it takes place only when the module resumes to Normal or Freeze modes.

44.5.8 Rx FIFO

The Rx FIFO is receive-only and is enabled by asserting the CAN_MCR[RFEN] bit. The reset value of this bit is zero to maintain software backward compatibility with previous versions of the module that did not have the FIFO feature.

CAUTION

Rx FIFO must not be enabled when CAN FD feature is enabled.

The FIFO is 6-message deep. The memory region occupied by the FIFO structure (both Message Buffers and FIFO engine) is described in Rx FIFO structure. The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a Message Buffer structure at the output of the FIFO.

The CAN_IFLAG1[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, the CPU can read the message (accessing the output of the FIFO as a Message Buffer) and the CAN_RXFIR register and then clear the interrupt. If there are more messages in the FIFO the act of clearing the interrupt updates the output of the FIFO with the next message and update the CAN_RXFIR with the attributes of that message, reissuing the interrupt to the CPU. Otherwise, the flag remains negated. The output of the FIFO is only valid whilst the CAN_IFLAG1[BUF5I] is asserted.

The CAN_IFLAG1[BUF6I] (Rx FIFO Warning) is asserted when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. The flag remains asserted until the CPU clears it.

The CAN_IFLAG1[BUF7I] (Rx FIFO Overflow) is asserted when an incoming message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. The flag remains asserted until the CPU clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is asserted too.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing work load. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to CAN_CTRL2[RFFN] setting, that can be configured to one of the following formats (see also Rx FIFO structure):

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)

- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

Note

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the FIFO has a corresponding IDHIT (Identifier Acceptance Filter Hit Indicator) that can read in the IDHIT field from C/S word, as shown in the Rx FIFO Structure description. Another way the CPU can obtain this information is by accessing the CAN_RXFIR register. The CAN_RXFIR[IDHIT] field refers to the message at the output of the FIFO and is valid while the CAN_IFLAG1[BUF5I] flag is asserted. The CAN_RXFIR register must be read only before clearing the flag, which guarantees that the information refers to the correct frame within the FIFO.

Up to 32 elements of the filter table are individually affected by the Individual Mask Registers (CAN_RXIMRx), according to the setting of CAN_CTRL2[RFFN], allowing very powerful filtering criteria to be defined. If the CAN_MCR[IRMQ] bit is negated, then the FIFO filter table is affected by CAN_RXFGMASK.

44.5.8.1 Rx FIFO under DMA Operation

The receive-only FIFO can support DMA, this feature is enabled by asserting both the CAN_MCR[RFEN] and CAN_MCR[DMA] bits. The reset value of CAN_MCR[DMA] bit is zero to maintain backward compatibility with previous versions of the module that did not have the DMA feature.

The DMA controller can read the received message by reading a Message Buffer structure at the FIFO output port at the 0x80-0x8C address range.

When CAN_MCR[DMA] is asserted the CPU must not access the FIFO output port address range. Before enabling the CAN_MCR[DMA], the CPU must service the IFLAGs asserted in the Rx FIFO region. Otherwise, these IFLAGs may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before disabling the CAN_MCR[DMA], the CPU must perform a clear FIFO operation.

The CAN_IFLAG1[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO, consequently a DMA request is generated simultaneously. Upon receiving the request, the DMA controller can read the message (accessing the output of the FIFO as a Message Buffer). The DMA reading process must end by reading address 0x8C, which clears the CAN_IFLAG1[BUF5I] and

updates both the FIFO output with the next message (if FIFO is not empty) and the CAN_RXFIR register with the attributes of the new message. If there are more messages stored in the FIFO, the CAN_IFLAG1[BUF5I] will be re-asserted and another DMA request is issued. Otherwise, the flag remains negated.

NOTE

CAN_RXFIR register contents cannot be read after DMA completes the FIFO read. The IDHIT information is also available in the C/S word at address 0x080 (see Rx FIFO structure.

The CAN_IFLAG1[BUF6I] and CAN_IFLAG1[BUF7I] are not used when the DMA feature is enabled.

When FlexCAN is working with DMA, the CPU does not receive any Rx FIFO interruption and must not clear the related IFLAGs. In addition, the related IMASKs are not used to mask the generation of DMA requests.

44.5.8.2 Clear FIFO Operation

When CAN_MCR[RFEN] is asserted, the clear FIFO operation is a feature used to empty FIFO contents. With CAN_MCR[RFEN] asserted the Clear FIFO occurs when the CPU writes 1 in CAN_IFLAG1[BUF0I]. This operation can only be performed in Freeze Mode and is blocked by hardware in other modes. This operation does not clear the FIFO IFLAGs, consequently the CPU must service all FIFO IFLAGs before execute the clear FIFO task.

When Rx FIFO is working with DMA, the clear FIFO operation clears the CAN_IFLAG1[BUF5I] and the DMA request is canceled.

CAUTION

Clear FIFO operation does not clear IFLAGs, except when CAN_MCR[DMA] is asserted, in this case only the CAN_IFLAG1[BUF5I] is cleared.

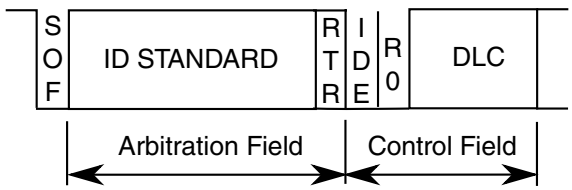
44.5.9 CAN protocol related features

This section describes the CAN protocol related features.

44.5.9.1 CAN FD ISO compliance

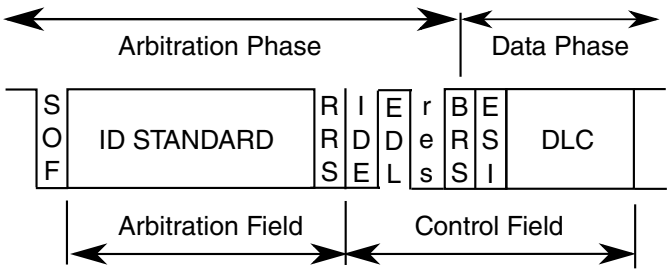
The CAN FD protocol has been improved to increase the failure detection capability that was in the original CAN FD protocol, which is also called non-ISO CAN FD by CAN in Automation (CiA). A three-bit stuff counter and a parity bit have been introduced in the improved CAN FD protocol, now called ISO CAN FD. The CRC calculation has also been modified. All these improvements make the ISO CAN FD protocol incompatible with the non-FD CAN FD protocol. The non-ISO CAN FD is still supported by FlexCAN so that it can be used mainly during an intermediate phase, for evaluation and development purposes.

Therefore, it is strongly recommended to configure FlexCAN to the ISO CAN FD protocol by setting the ISOCANFDEN field in the CAN_CTRL2 register.



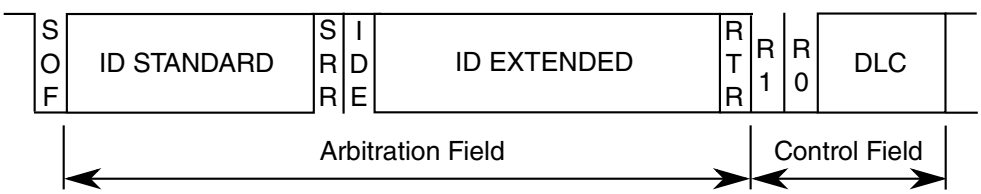
44.5.9.2 CAN FD frames

The ISO 11898-1 standard specifies the Classical Frame format compliant to ISO 11898-1 (2003) and introduces the CAN Flexible Data Rate Frame format. The Classical Frame format allows bit rates up to 1 Mbit/s and payloads up to 8 bytes per frame. The Flexible Data Rate Frame format allows bit rates higher than 1 Mbit/s and payloads longer than 8 bytes per frame. FlexCAN can receive and transmit CAN FD messages interleaved with Classical CAN messages.



There are three additional control bits in the CAN FD frame. The Extended Data Length (EDL) bit enables a longer data payload with different data length coding. The Bit Rate Switch (BRS) bit decides whether the bit rate is switched inside a CAN FD format frame. The Error State Indicator (ESI) flag is transmitted dominant by error active nodes, and recessive by error passive nodes. There is no Remote Frames (see Remote frames) in the CAN FD format. A message configured to transmit a Remote Frame is always sent out in the Classical CAN format. When a FD frame is received and matches a mailbox, the RTR bit in the receiving message buffer is negated. The RTR bit must be considered in classical frames only.

CAN FD messages may be formatted as long frames where the data field exceeds 8 bytes, and may range from 12 up to 64 bytes. They can also be configured to support bit rate switching, where the control field, the data field, and the CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and the end of the frame. Messages in Classical CAN format are limited to transport a maximum payload of 8 bytes at nominal rate. The following figure illustrates the message formats for Classical and FD frames with either standard or extended ID.



CAN Standard Format

CAN FD Standard Format

CAN Extended Format

CAN FD Extended Format

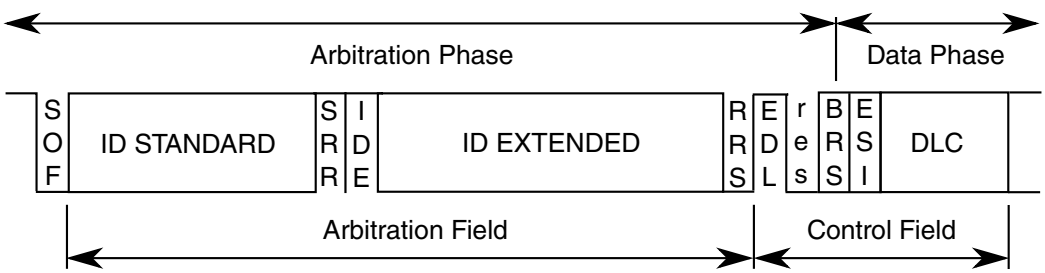


Figure 44-2. CAN message formats

The ability to receive and transmit CAN FD messages is enabled by the CAN_MCR[FDEN] bit. Either a recessive R0 bit in CAN frames with 11-bit identifiers or a recessive R1 bit in CAN frames with 29-bit identifiers are decoded as an EDL bit (not a reserved one). A CAN FD frame is recognized by a recessive EDL bit, while a

Classical CAN frame is recognized by a dominant EDL bit. The BRS bit specifies whether this frame switches the bit rate in its data phase. A long frame is decoded in accordance to the DLC field value (see DLC definition in Message buffer structure).

CAN FD messages can be transmitted with two different bit rates. The first part of a CAN FD frame, from the Start Of Frame (SOF) bit until the Bit Rate Switch (BRS) bit, also called the arbitration phase, is transmitted with the nominal bit rate based on a set of nominal CAN bit timing configuration values. The second part, from the BRS bit until the CRC Delimiter bit, also named the data phase, is transmitted with the data bit rate defined by a second set of CAN data bit timing configuration values. Finally, from the CRC Delimiter until the Intermission bits, the transmission resumes to nominal bit rate. In CAN FD frames with bit rate switching, the bit timing is changed inside the frame at the sample point of the BRS bit if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by the CAN_CBT register (also by CAN_CTRL1 register for backward compatibility). Upon detecting a recessive BRS bit, the CAN data bit timing is used as defined by the CAN_FDCBT register.

NOTE

If the length of the time quantum in the nominal bit timing and the length of the time quantum in the data bit timing are not identical, a quantization error of up to one time quantum of the arbitration phase may be present as a phase error. This situation can occur after the switch from arbitration to data phase and will last until the next synchronization event. Thus, the length of the time quantum should be the same in nominal and data bit timing in order to minimize the chance of error frames on the CAN bus, and to optimize the clock tolerance in networks that use FD frames.

CAN_FDCTRL[FDRATE] enables the transmission of all frames with bit rate switching if the BRS bit in the selected Tx MB is set. If FDRATE is negated, the transmission is performed at nominal rate regardless of the BRS bit value. The CAN_FDCTRL[FDRATE] bit can be written any time but takes effect only for the next message transmitted or received.

The nominal bit timing is resumed at either the sample point of the CRC Delimiter bit or when an error is detected, whichever occurs first. The following figure describes the mechanism for entering and leaving the data phase when BRS bit is recessive.

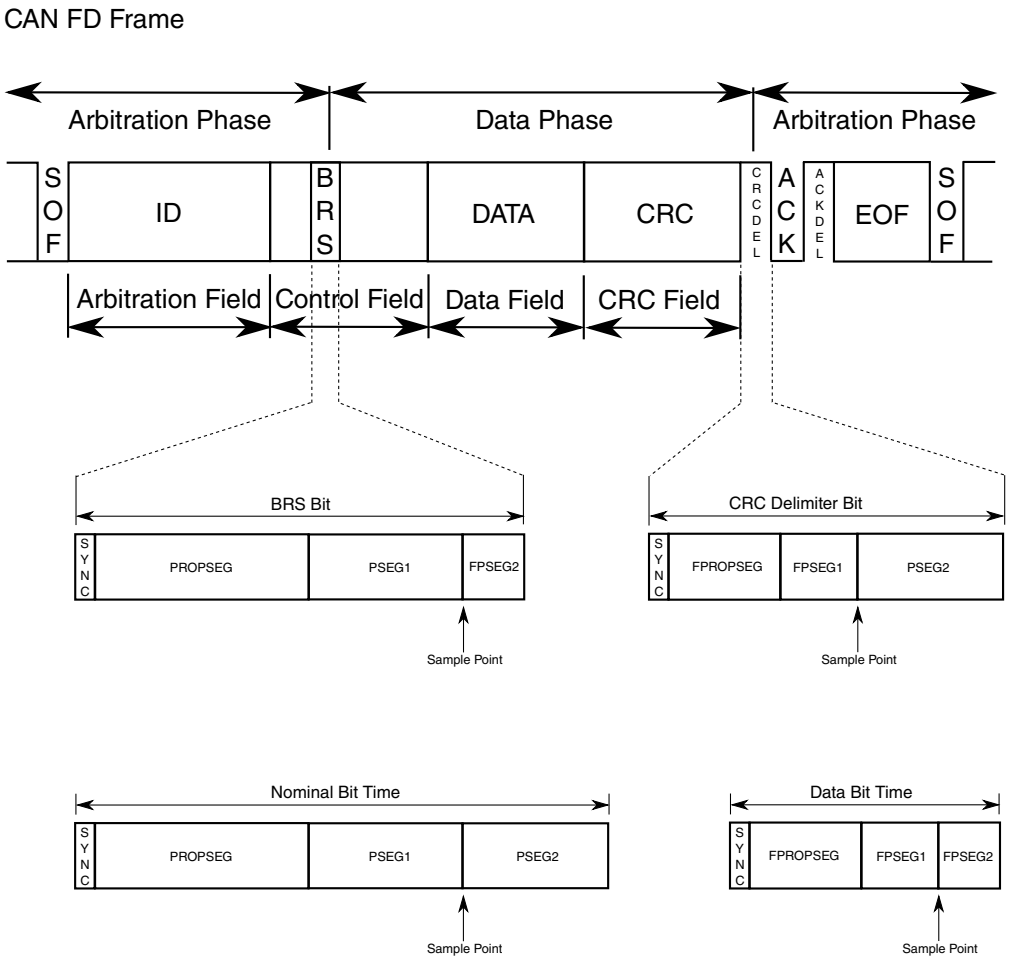

Figure 44-3. Bit rate switching mechanism for CAN FD messages

NOTE

In Classical CAN frames, the CRC delimiter is one single recessive bit. In CAN FD frames, the CRC delimiter may consist of one or two recessive bits. FlexCAN sends only one recessive bit as the CRC delimiter, but it accepts two recessive bits before the edge from recessive to dominant that starts the acknowledge slot. As a receiver, FlexCAN sends its acknowledge bit after the first CRC delimiter bit. In CAN FD frames, FlexCAN accepts a two-bit dominant ACK slot as a valid ACK to compensate for phase shifts between the receivers.

The maximum configurable bit rate in the CAN FD data phase depends on the clock frequency of CAN_PE sub-block. For example, with a CAN_PE clock frequency of 40MHz and the shortest configurable bit time of 8 time quanta, the bit rate in the data phase is 5 Mbit/s.

The value of the ESI bit is determined either by the transmitter's error state at the start of the transmission, if the frame is originated in the FlexCAN node, or by the original transmitting node in case FlexCAN is acting as a gateway for the message. If the transmitter is error passive, ESI is transmitted recessive; otherwise, it is transmitted dominant.

There are different CRC polynomials for different CAN frame formats. The first polynomial, CRC_15, is used for all frames in Classical CAN format. The second, CRC_17, is used for frames in CAN FD format with a data field up to sixteen bytes long. The third, CRC_21, is used for frames in CAN FD format with a data field longer than sixteen bytes. Each polynomial results in a Hamming Distance of 6. At the start of the frame, all three CRC polynomials are calculated concurrently. The CRC sequence to be transmitted is selected by the values of the EDL bit and the DLC bit field. When receiving a message, FlexCAN decodes EDL and DLC to select the adequate CRC polynomial to check for a CRC error.

In CAN FD format frames, stuff bits are included in the bit stream for CRC calculation. In Classical CAN format frames, stuff bits are not included. After the transmission of the last bit relevant to the CRC calculation, the CAN_FDCRC register stores the calculated CRC for the transmitted message, with the adequate length in accordance to the type of message, for both CAN FD and non-FD messages. The CAN_CRCR register reports a valid CRC for Classical CAN messages only.

In CAN FD format frames, the CAN bit stuffing method is changed for the CRC sequence so that the stuff bits are inserted at fixed positions. When FlexCAN is transmitting a CAN FD frame, a fixed stuff bit is inserted just before the first bit of the CRC sequence, even if the last bits of the preceding field do not fulfill the CAN stuff condition. Additional stuff bits are inserted after each fourth bit of the CRC sequence. The value of any fixed stuff bit is the inverse value of its preceding bit. When FlexCAN is receiving a CAN FD frame, it discards the fixed stuff bits from the bit stream for the CRC check. A Stuff Error is detected if the fixed stuff bit has the same value as its preceding bit.

FlexCAN detects errors in CAN FD frames the same way as in Classical CAN frames. The error counters RXERRCNT and TXERRCNT in the CAN_ECR register accumulate the counts of Rx and Tx errors, respectively, for both FD and non-FD frames indistinctly. There are two extra error counters (RXERRCNT_FAST and TXERRCNT_FAST) that accumulate Rx and Tx errors occurring in the data phase of CAN FD frames with the BRS bit set only. The rules for updating the error counters are the same for both CAN FD and non-FD frames (see CAN_ECR register).

Error Flags BITERR1, BITERR0, ACKERR, CRCERR, FRMERR and STFERR in the ESR1 register report errors in both CAN FD and non-FD frames. They also generate the ERRINT interrupt if CAN_CTRL1[ERRMSK] is asserted. The CAN_ESR1 register has

additional error flags (BITERR1_FAST, BITERR0_FAST, CRCERR_FAST, FRMERR_FAST and STFERR_FAST) to individually indicate the occurrence of errors in the data phase of CAN FD frames with the BRS bit set. There is no ACKERR detected in the data phase of a CAN FD frame. Fault confinement status reported in CAN_ESR1[FLTCONF] is the same for both CAN FD and Classical CAN frames, and is based on RXERRCNT and TXERRCNT error counters only. Information contained in RXERRCNT_FAST and TXERRCNT_FAST counters may be considered as status to help detect the error nature related to the bit rate value.

When FlexCAN is in the data phase, either transmitting or receiving a CAN FD message, and detects an error, it immediately switches back to the arbitration phase and to the nominal rate to start an Error Flag.

Resynchronization and Hard Synchronization occur in CAN FD frames in the same way as in Classical CAN ones. Additionally, a Hard Synchronization is also performed at the recessive to dominant edge from EDL to R0 in CAN FD format frames. FlexCAN does not resynchronize while transmitting in the CAN FD data phase.

44.5.9.3 Transceiver Delay Compensation

The CAN FD protocol allows the transmission and reception of data at a higher bit rate than the nominal rate used in the arbitration phase when the message's BRS bit is set. This feature enables the use of rates up to 8 Mbps.

During the data phase of a CAN FD frame, the Transmitter detects a bit error if it cannot receive its own latest transmitted bit at the sample point of that bit. When bit rate switching is enabled (BRS bit is asserted), the length of the CAN bit time in the data phase can become shorter than the transceiver's loop delay, thus impeding the correct comparison between the transmitted bit and the received bit within the current CAN bit time interval.

FlexCAN supports an optional Transceiver Delay Compensation (TDC) mechanism that defines a secondary sample point where the transmitted bit is correctly compared with the received bit in order to check for bit errors.

The TDC mechanism can be enabled by the CAN_FDCTRL[TDCEN] bit and is effective only during the data phase of FD frames having the BRS bit set. It has no effect either on non-FD frames, or on FD frames transmitted at normal bit rate. The TDC is active from the sample point of the BRS bit until the sample point of the CRC Delimiter bit, provided the respective message under transmission has the BRS bit set. When it is active, a comparison is done between the real received bit and the delayed transmitted bit, where the delay is calculated based on the measured transceiver loop delay.

NOTE

The actual value of the CRC Delimiter bit is disregarded by transmitters using the Transceiver Delay Compensation mechanism. A global error at the end of the CRC Field will cause the receivers to send error frames that the transmitter will detect during Acknowledge or End of Frame.

For every transmitted FD frame having the BRS bit set, the delay measurement is triggered by the transition from the recessive EDL bit to the dominant R0 bit (as shown in the next figure). The loop delay is measured in Protocol Engine (PE) clock periods (CANCLK, see Protocol timing), from the transmitted EDL-R0 edge to the received EDL-R0 edge. The position of the secondary sample point is defined by the measured loop delay time added to an offset value specified in CAN_FDCTRL[TDCOFF]. CAN_FDCTRL[TDCVAL] bit field stores the result of this calculation. The TDCVAL value saturates at its maximum value of 15 CANCLK when the delay measurement is too long.

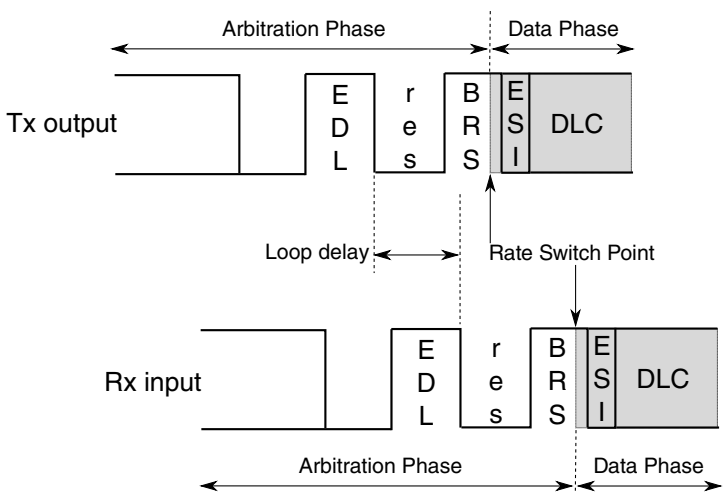

Figure 44-4. Transceiver loop delay measurement

The measured loop delay is not enough to be used to define the secondary sample point because it relates to the CAN bit edges. The transceiver delay compensation offset TDCOFF is used to shift the secondary sample point from the edge to an intermediate point inside the bit time (e.g. half of the bit time in the data phase), far away from its edges. Therefore, the TDCOFF value cannot be larger than the CAN bit duration in the data phase.

During the data phase of CAN FD frames with bit rate switching enabled, at the onset of every Tx CAN bit, the transmitted Tx bit value is temporarily stored in a buffer and a time countdown based on TDCVAL is started which ends with the comparison of the

received Rx bit (delayed by the external loop delay plus the specified offset) with the stored Tx bit. If a bit error is detected at the secondary sample point, the FlexCAN issues an error flag to the CAN bus at the next sample point.

During the arbitration phase the delay compensation is always disabled. The maximum delay which can be compensated by the FlexCAN's transceiver delay compensation during the data phase is 3 CAN bit times - 2 Tq. Beyond this limit, the CAN_FDCTRL[TDCFAIL] flag is set to indicate when the Transceiver Delay Compensation mechanism is out of range, unable to compensate the transceiver loop delay.

44.5.9.4 Remote frames

Remote frame is a special kind of frame. The user can program a mailbox to be a Remote Request Frame by configuring the mailbox as Transmit with the RTR bit set to '1'. After the remote request frame is transmitted successfully, the mailbox becomes a Receive Message Buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, it can be treated in three ways, depending on Remote Request Storing (CTRL2[RRS]) and Rx FIFO Enable (MCR[RFEN]) bits:

- If RRS is negated the frame's ID is compared to the IDs of the Transmit Message Buffers with the CODE field 0b1010. If there is a matching ID, then this mailbox frame will be transmitted. Note that if the matching mailbox has the RTR bit set, then FlexCAN will transmit a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. In the case that a remote request frame is received and matches a mailbox, this message buffer immediately enters the internal arbitration process, but is considered as a normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.
- If RRS is asserted the frame's ID is compared to the IDs of the receive mailboxes with the CODE field 0b0100, 0b0010 or 0b0110. If there is a matching ID, then this mailbox will store the remote frame in the same fashion of a data frame. No automatic remote response frame will be generated. The mask registers are used in the matching process.
- If RFEN is asserted FlexCAN will not generate an automatic response for remote request frames that match the FIFO filtering criteria. If the remote frame matches one of the target IDs, it will be stored in the FIFO and presented to the CPU. Note that for

filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote Request Frames are considered as normal frames, and generate a FIFO overflow when a successful reception occurs and the FIFO is already full.

NOTE

There is no remote frame in the CAN FD format. The RTR bit is replaced by a fixed dominant RRS bit. FlexCAN receives and transmits remote frames in the Classical CAN format.

44.5.9.5 Overload frames

FlexCAN does transmit overload frames due to detection of following conditions on CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission
- Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
- Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

44.5.9.6 Time stamp

The value of the Free Running Timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of "move-in" in the TIME STAMP field, providing network behavior with respect to time.

When the TIMER_SRC bit in CAN_CTRL2 register is asserted, the Free Running Timer is continuously clocked by an external time tick.

When the TIMER_SRC bit in CAN_CTRL2 register is negated, the Free Running Timer is clocked by the FlexCAN bit-clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The Free Running Timer is not incremented during Disable, Stop, and Freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization. See the TSYN description in Control 1 Register (CAN_CTRL1).

44.5.9.7 Protocol timing

The following figure shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule. The clock source bit CLKSRC in the CAN_CTRL1 Register defines whether the internal clock is connected to the output of a crystal oscillator (Oscillator Clock) or to the Peripheral Clock. In order to guarantee reliable operation, the clock source should be selected while the module is in Disable Mode (MDIS bit set in the Module Configuration Register).

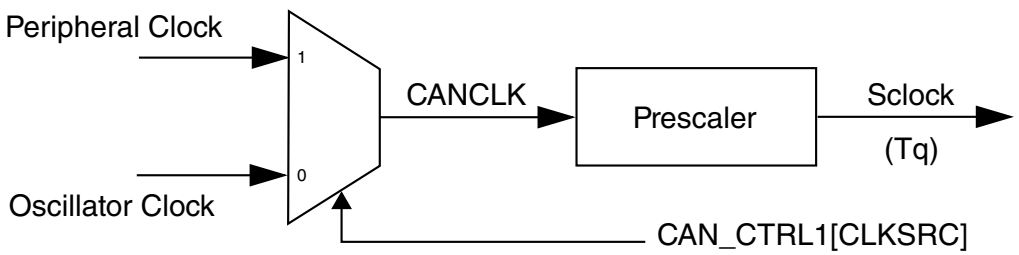

Figure 44-5. CAN engine clocking scheme

The oscillator clock should be selected whenever a tight tolerance (up to 0.1%) is required in the CAN bus timing. The crystal oscillator clock has better jitter performance than the peripheral clock.

The FlexCAN module supports a variety of means to setup bit timing parameters that are required by the CAN protocol. The Control 1 Register (CAN_CTRL1) has various fields used to control bit timing parameters: PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW.

The CAN Bit Timing register (CAN_CBT) extends the range of the CAN bit timing variables in CAN_CTRL1. The CAN FD Bit Timing register (CAN_FDCBT) provides a second set of CAN bit timing variables to be applied at the data phase of CAN FD frames with the Bit Rate Switch (BRS) set.

NOTE

When the CAN FD feature is enabled, always set CAN_CBT[BTF] and configure the CAN bit timing variables in CAN_CBT. See CAN Bit Timing Register (CAN_CBT).

The PRESDIV field (as well as its extended range EPRESDIV and FDPRESDIV for the data phase bits of CAN FD messages) defines the Prescaler Value (see the equation below) that generates the Serial Clock (Sclock), whose period defines the 'time quantum' used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time handled by the CAN engine.

$$Tq = \frac{(\text{PRESDIV} + 1)}{f_{CANCLK}}$$

The bit rate, which defines the rate the CAN message is either received or transmitted, is given by the formula:

CAN Bit Time = (Number of Time Quanta in 1 bit time) * Tq

$$\text{Bit Rate} = \frac{1}{\text{CAN Bit Time}}$$

A bit time is subdivided into three segments[1] (see Figure 44-6, Figure 44-7 and Table 44-22):

- SYNC_SEG: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section
- Time Segment 1: This segment includes the Propagation Segment and the Phase Segment 1 of the CAN standard. It can be programmed by setting the PROPSEG and the PSEG1 fields of the CAN_CTRL1 Register so that their sum (plus 2) is in the range of 2 to 16 time quanta. When CAN_CBT[BTF] bit is asserted, FlexCAN uses EPROPSEG and EPSEG1 fields from CAN_CBT register so that their sum (plus 2) is in the range of 2 to 96 time quanta. For messages in CAN FD format with the BRS bit set, FlexCAN uses FDPROPSEG and FDPSEG1 from CAN_FDCBT instead, so that their sum (plus 1) is in the range of 2 to 39 time quanta.
- Time Segment 2: This segment represents the Phase Segment 2 of the CAN standard. It can be programmed by setting the PSEG2 field of the CAN_CTRL1 Register (plus 1) to be 2 to 8 time quanta long. When CAN_CBT[BTF] bit is asserted, FlexCAN uses EPSEG2 fields of CAN_CBT register so that its value (plus 1) is in the range of 2 to 32 time quanta. For messages in CAN FD format with the BRS bit set, FlexCAN uses FDPSEG2 from CAN_FDCBT instead, so that its value (plus 1) is in the range of 2 to 8 time quanta. The Time Segment 2 cannot be smaller than the Information Processing Time (IPT), which value is 2 time quanta in FlexCAN.

NOTE

The bit time defined by the above time segments must not be smaller than 5 time quanta. For bit time calculations, use an

1. For further explanation of the underlying concepts, see ISO 11898-1. See also the CAN 2.0A/B protocol specification for bit timing.

Information Processing Time (IPT) of 2, which is the value implemented in the FlexCAN module.

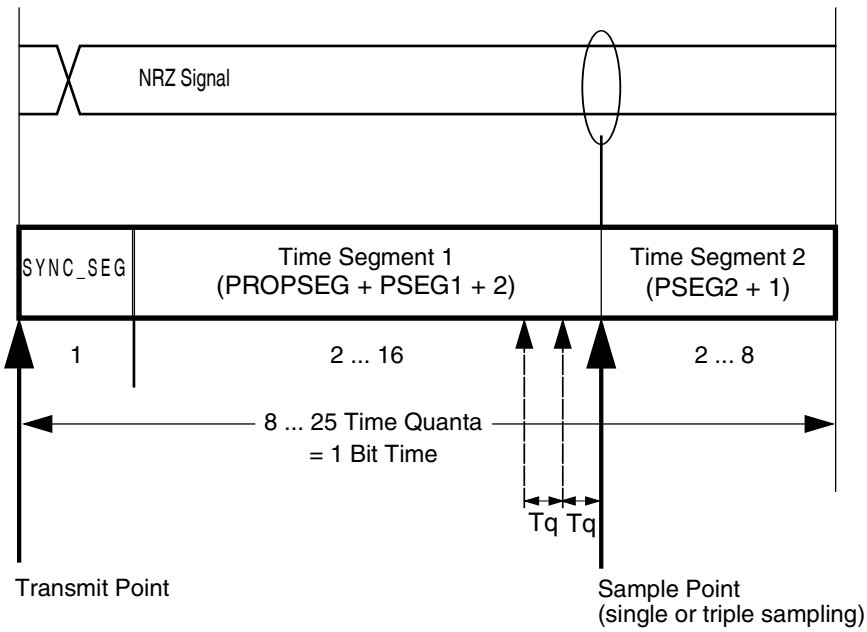

Figure 44-6. Segments within the bit time (example using CAN_CTRL1 bit timing variables for Classical CAN format)

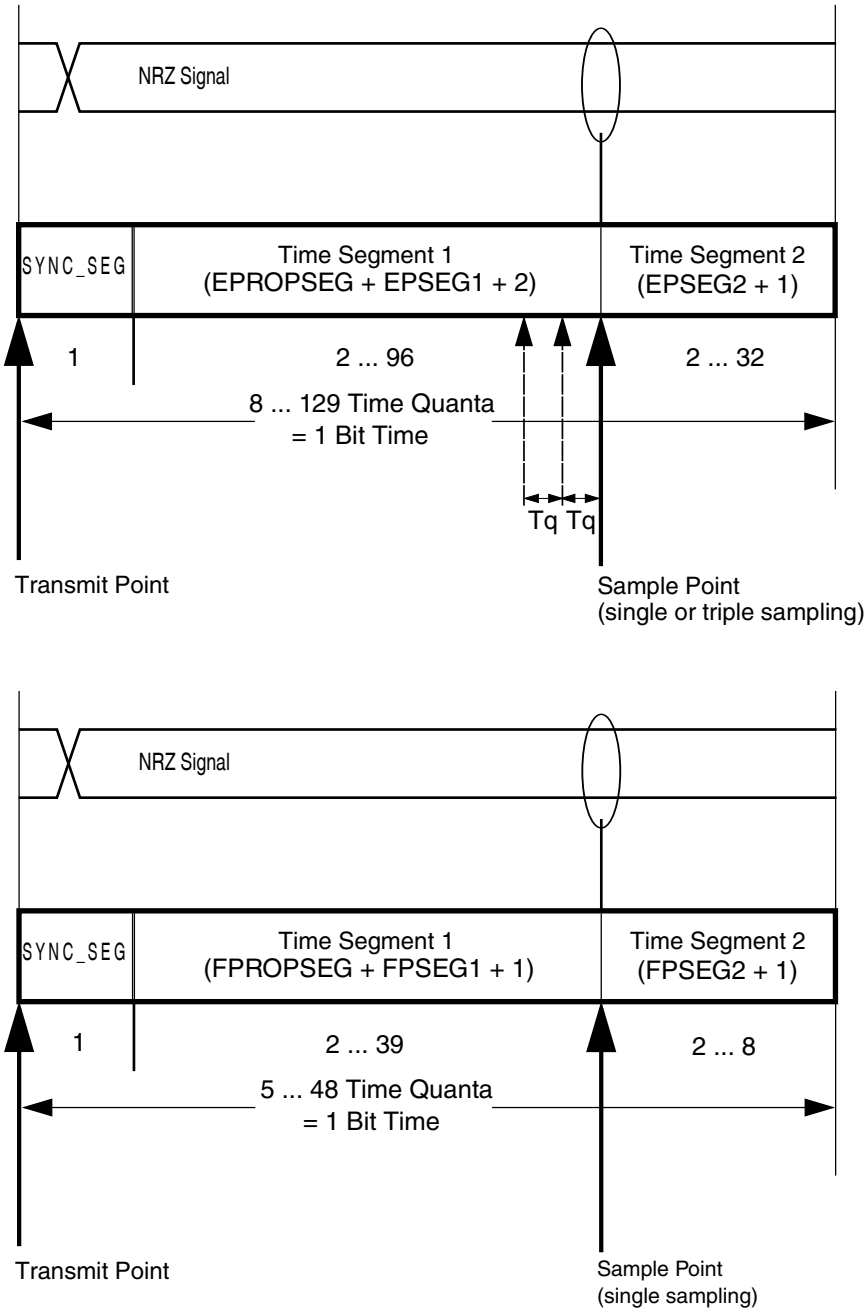

Figure 44-7. Segments within the bit time (example using CAN_CBT and CAN_FDCBT bit timing variables for CAN FD format)

Table 44-22. Time segment syntax

Syntax	Description
SYNC_SEG	System expects transitions to occur on the bus during this period.
TSEG1	Corresponds to the sum of PROPSEG and PSEG1.
TSEG2	Corresponds to the PSEG2 value.

Table continues on the next page...

Table 44-22. Time segment syntax (continued)

Syntax	Description
Transmit Point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample Point	A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

The following table gives some examples of the CAN compliant segment settings for Classical CAN format (Bosch CAN 2.0B) (non-FD) messages.

Table 44-23. Bosch CAN 2.0B standard compliant bit time segment settings

Time segment 1	Time segment 2	Re-synchronization jump width
5 .. 10	2	1 .. 2
4 .. 11	3	1 .. 3
5 .. 12	4	1 .. 4
6 .. 13	5	1 .. 4
7 .. 14	6	1 .. 4
8 .. 15	7	1 .. 4
9 .. 16	8	1 .. 4

Note

The user must ensure the bit time settings are in compliance with the CAN Protocol standard (ISO 11898-1).

Whenever CAN bit is used as a measure of time duration (e.g. estimating the occurrence of a CAN bit event in a message), the number of peripheral clocks in one CAN bit (NumClkBit) can be calculated as:

$$\text{NumClkBit} = \frac{f_{SYS}}{f_{CANCLK}} \text{ X } (\text{PRESDIV} + 1) \text{ X } (\text{PROPSEG} + \text{PSEG1} + \text{PSEG2} + 4)$$

where:

- NumClkBit is the number of peripheral clocks in one CAN bit;
- f_{CANCLK} is the Protocol Engine (PE) Clock (see Figure "CAN Engine Clocking Scheme"), in Hz;
- f_{SYS} is the frequency of operation of the system (CHI) clock, in Hz;
- PSEG1 is the value in CAN_CTRL1[PSEG1] field;
- PSEG2 is the value in CAN_CTRL1[PSEG2] field;
- PROPSEG is the value in CAN_CTRL1[PROPSEG] field;
- PRESDIV is the value in CAN_CTRL1[PRESDIV] field.

The formula above is also applicable to the alternative CAN bit timing variables described in the CAN Bit Timing Register (CAN_CBT) and also to the CAN FD Bit Timing Register (CAN_FDCBT).

For example, 180 CAN bits = (180 x NumClkBit) peripheral clock periods.

44.5.9.8 Arbitration and matching timing

During normal reception and transmission, the matching, arbitration, move-in and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

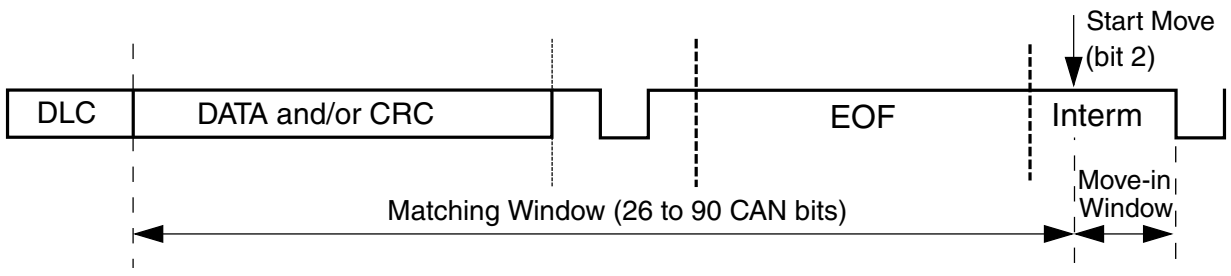

Figure 44-8. Matching and move-in time windows

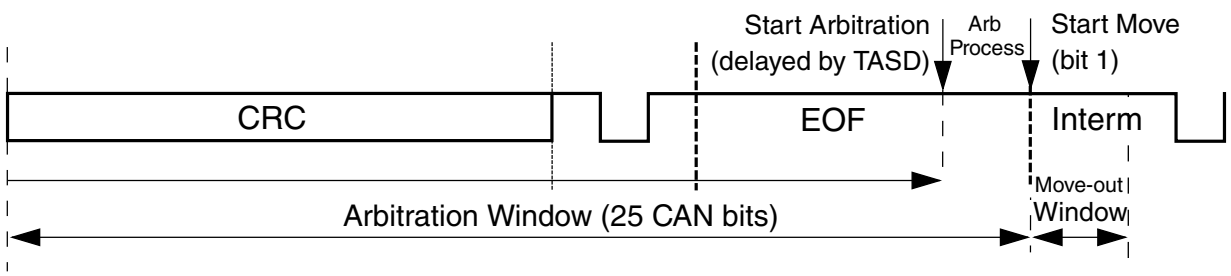

Figure 44-9. Arbitration and move-out time windows

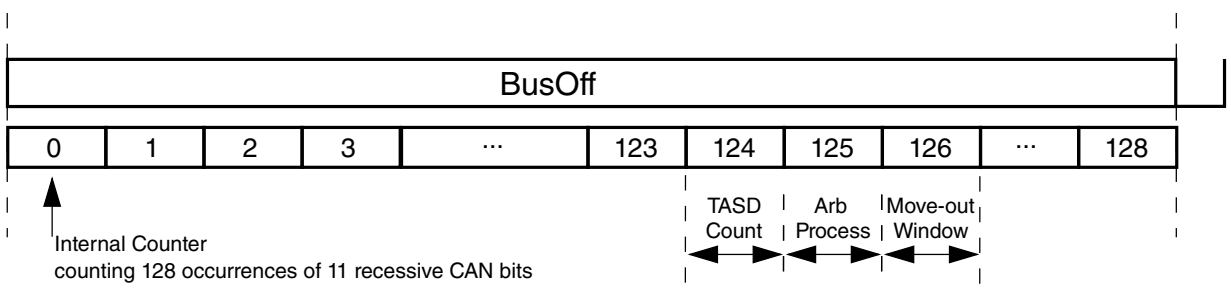

Figure 44-10. Arbitration at the end of bus off and move-out time windows

NOTE

In the preceding figures, the matching and arbitration timing does not take into account the delay caused by the concurrent

memory access due to the CPU or other internal FlexCAN sub-blocks.

44.5.9.9 Tx Arbitration start delay

The Tx Arbitration Start Delay (TASD) bit field in Control 2 register (CAN_CTRL2[TASD]) is a variable that indicates the number of CAN bits used by FlexCAN to delay the Tx Arbitration process start point from the first bit of CRC field of the current frame. This variable can be written only in Freeze mode because it is blocked by hardware in other modes.

The transmission performance is impacted by the ability of the CPU to reconfigure Message Buffers (MBs) for transmission after the end of the internal Arbitration process, where FlexCAN finds the winner MB for transmission (see Arbitration process). If the Arbitration ends too early before the first bit of Intermission field, then there is a chance that the CPU reconfigures some Tx MBs and the winner MB is no longer the best candidate to be transmitted.

TASD is useful to optimize the transmission performance by defining the Arbitration start point, as shown in the next figure, based on factors such as:

- The peripheral-to-oscillator clock ratio
- CAN bit timing variables that determine the CAN bit rate
- The number of Message Buffers (MBs) in use by the Matching and Arbitration processes.

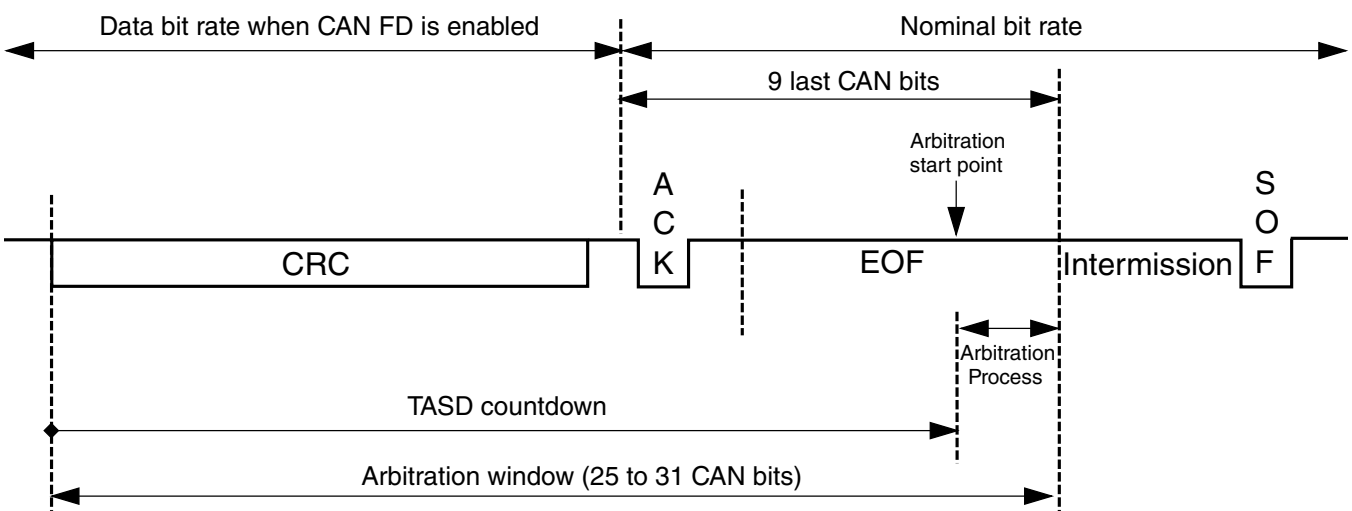

Figure 44-11. Optimal Tx Arbitration start point

The duration of an Arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and to the CAN bit rate, and inversely proportional to the peripheral clock frequency.

The optimal Arbitration timing is that in which the last MB is scanned right before the first bit of the Intermission field of a CAN frame. For instance, if there are few MBs and the peripheral/oscillator clock ratio is high and the CAN baud rate is low, then the Arbitration can be placed closer to the frame's end, adding more delay to its start point, and vice-versa.

If TASD is set to 0 then the Arbitration start is not delayed and more time is reserved for Arbitration. On the other hand, if TASD is close to 24 then the CPU can configure a Tx MB later and less time is reserved for Arbitration. If too little time is reserved for Arbitration the FlexCAN may be not be able to find a winner MB in time to be transmitted with the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal TASD value can be calculated as follows:

For CAN FD frames and $(MAXMB + 1) \leqslant NMB_{END}$

$$TASD = 31 - \frac{2 * (MAXMB + 1) + 4}{CPCB_N}$$

For CAN FD frames and $(MAXMB + 1) > NMB_{END}$

$$TASD = 22 - \frac{2 * (MAXMB + 1) - NMB_{END}}{CPCB_F}$$

For non-FD frames

$$TASD = 25 - \frac{2 * (MAXMB + 1) + 4}{CPCB}$$

where:

$$NMB_{END} = \frac{(9 * CPCB_N) - 4}{2}$$

$$BITRATE_N = \left(\frac{f_{CANCLK}}{[1 + (EPSEG1 + 1) + (EPSEG2 + 1) + (EPROPSEG + 1)] \times (EPRESDIV + 1)} \right)$$

$$BITRATE_F = \left(\frac{f_{CANCLK}}{[1 + (FPSEG1 + 1) + (FPSEG2 + 1) + FPROPSEG] \times (FPRESDIV + 1)} \right)$$

$$CPCB_N = \frac{f_{SYS}}{BITRATE_N}$$

$$CPCB_F = \frac{f_{SYS}}{BITRATE_F}$$

$$CPCB = CPCB_N$$

- MAXMB is the value in CAN_CTRL1[MAXMB] field
- NMB_{END} is the number of Message Buffers that can be scanned by the Arbitration process during the 9 last CAN bits at the end of a frame, see the figure above
- $BITRATE_N$ is the CAN bit rate in bits per second calculated by the nominal CAN bit time variables
- $BITRATE_F$ is the CAN bit rate in bits per second calculated by the data CAN bit time variables
- $CPCB_N$ is the number of peripheral clocks per CAN bit in nominal bit rate for CAN FD frames
- $CPCB_F$ is the number of peripheral clocks per CAN bit in data bit rate for CAN FD frames
- CPCB is the number of peripheral clocks per CAN bit for non-FD frames
- f_{CANCLK} is the oscillator clock, in Hz
- f_{SYS} is the peripheral clock, in Hz
- EPSEG1 is the value in CAN_CBT[EPSEG1] field (CAN_CTRL1[PSEG1] can also be used)
- EPSEG2 is the value in CAN_CBT[EPSEG2] field (CAN_CTRL1[PSEG2] can also be used)
- EPROPSEG is the value in CAN_CBT[EPROPSEG] field (CAN_CTRL1[PROPSEG] can also be used)

- EPRESDIV is the value in CAN_CBT[EPRESDIV] field (CAN_CTRL1[PRESDIV] can also be used)
- FPSEG1 is the value in CAN_FDCBT[FPSEG1] field
- FPSEG2 is the value in CAN_FDCBT[FPSEG2] field
- FPROPSEG is the value in CAN_FDCBT[FPROPSEG] field
- FPRESDIV is the value in CAN_FDCBT[FPRESDIV] field

See also Protocol timing for more details.

The following tables give the TASD value calculated for some configuration cases.

Case 1:

- Clock ratio = 2:1 (example: peripheral clock 80 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 44-24. TASD values:

Number of Message Buffers	TASD value	Maximum Bit Rate in Data Phase (Mbaud)
16	24	Invalid
32	24	8.0
64	23	8.0
96	22	8.0

Case 2:

- Clock ratio = 1:1 (example: peripheral clock 40 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 44-25. TASD values:

Number of Message Buffers	TASD value	Maximum Bit Rate in Data Phase (Mbaud)
16	24	Invalid
32	23	6.67
54	22	5.0
64	21	3.33
96	20	1.6

Case 3:

- Clock ratio = 2:1 (example: peripheral clock 40 MHz and oscillator clock 20 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 44-26. TASD values:

Number of Message Buffers	TASD value	Maximum Bit Rate in Data Phase (Mbaud)
16	24	Invalid
32	23	4.0
54	22	4.0
64	21	3.33
96	20	1.54

44.5.10 Clock domains and restrictions

The FlexCAN module has two clock domains asynchronous to each other:

- The Bus Domain feeds the Control Host Interface (CHI) submodule and is derived from the peripheral clock.
- The Oscillator Domain feeds the CAN Protocol Engine (PE) submodule and is derived directly from a crystal oscillator clock, so that very low jitter performance can be achieved on the CAN bus.

When CAN_CTRL1[CLKSRC] bit is set, synchronous operation occurs because both domains are connected to the peripheral clock (creating a 1:1 ratio between the peripheral and oscillator clocks).

When the two domains are connected to clocks with different frequencies and/or phases, there are restrictions on the frequency relationship between the two clock domains. In the case of asynchronous operation, the Bus Domain clock frequency must always be greater than the Oscillator Domain clock frequency.

NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

When doing matching and arbitration, FlexCAN needs to scan the whole Message Buffer memory during the time slot of one CAN frame, comprised of a number of CAN bits. In order to have sufficient time to do that, the following requirements must be observed:

- The peripheral clock frequency can not be smaller than the oscillator clock frequency
- There must be a minimum number of peripheral clocks per CAN bit, as specified in the table shown below

Table 44-27. Minimum number of peripheral clocks per CAN bit for Classical CAN format

Number of Mailboxes	Value of CAN_MCR[RFEN] bit	Minimum number of peripheral clocks per CAN bit
16	0	16
32	0	16
64	0	25
96	0	37
16	1	16
32	1	17
64	1	30
96	1	42

For classical frame format, the minimum number of peripheral clocks per CAN bit specified in the preceding table determines the minimum peripheral clock frequency for a given number of Mailboxes and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit, that can be defined by adjusting one or more of the bit timing values contained in either the Control 1 Register (CAN_CTRL1) or CAN Bit Time register (CAN_CBT). The time quantum (Tq) is defined in Protocol timing. The minimum number of time quanta per CAN bit must be 8; therefore, the oscillator clock frequency should be at least 8 times the CAN bit rate.

For CAN FD frame format, there are some constraints that need to be satisfied. The number of peripheral clocks per CAN bit in nominal bit rate (NumClkNomBit) can be calculated by the equation below.

$$\text{NumClkNomBit} = \frac{f_{SYS}}{f_{CANCLK}} \text{ X } (\text{PRESDIV} + 1) \text{ X } (\text{PROPSEG} + \text{PSEG1} + \text{PSEG2} + 4)$$

$$= \frac{f_{SYS}}{\text{NomBitRate}}$$

where PRESDIV, PSEG1 and PSEG2 are CAN bit time values in CTRL1 register. Alternatively, EPRESDIV, EPSEG1 and EPSEG2 values in CBT register can be used instead. NumClkNomBit can also be calculated as a function of the expected nominal bit rate used in the Arbitration Phase (NomBitRate) as shown in the equation above.

The number of CAN bits in the Data Phase of a FD Frames with the BRS bit set (fast CAN bits, in short) depends on the number of data bytes in the payload. The number of fast CAN bits (NumOfFastBits) can be determined in the table below. The less the

number of data bytes, the less the number of fast CAN bits, and less time is available for FlexCAN to scan the whole Message Buffer memory during the internal matching and arbitration processes.

Table 44-28. Number of fast CAN bits in a CAN FD frame

Minimum number of data bytes	DLC field	NumOfFastBits
0	0x0	21
1	0x1	29
2	0x2	37
3	0x3	45
4	0x4	53
5	0x5	61
6	0x6	69
7	0x7	77
8	0x8	85
12	0x9	117
16	0xA	149
20	0xB	186
24	0xC	218
32	0xD	282
48	0xE	410
64	0xF	538

The critical part of a CAN FD frame is during the Data Phase, where the CAN bit rate is faster than in the Arbitration Phase. The minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated to guarantee that enough time is available for FlexCAN to scan the Message Buffer memory during reception and transmission. The equation below calculates this constraint.

$$\text{MinNumClkFastBit}_A = \frac{(\ 8.5 \times \text{MaxNumOfMb}\ ) + 64 - (\ 9 \times \text{NumClkNomBit}\ )}{\text{NumOfFastBits}}$$

where MaxNumOfMb is the maximum number of available Mailboxes defined in CAN_MCR[MAXMB].

The clock domain crossing circuit between the CHI and PE sub-blocks also imposes a minimum number of peripheral clocks per fast CAN bit for the handshake mechanism to work properly without loosing status information through the interface, as shown in the equation below.

$$MinNumClkFastBit_B = 3 \times \left\langle 1 + \frac{f_{SYS}}{f_{CANCLK}} \right\rangle$$

Therefore, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) is determined by the larger of the two values calculated above.

$$MinNumClkFastBit = Maximum\ (\ MinNumClkFastBit_A, MinNumClkFastBit_B)$$

Then, the maximum CAN bit rate in the Data Phase of CAN FD frames (DataBitRateMAX) can be calculated as below.

$$DataBitRate_{MAX} = \frac{f_{CANCLK}}{ROUNDUP\left\langle \frac{MinNumClkFastBit \times f_{CANCLK}}{f_{SYS}} \right\rangle}$$

The peripheral and oscillator clock frequencies, the maximum number of mailboxes and the expected nominal bit rate affect the maximum data bit rate attainable by FlexCAN in CAN FD mode. Besides, the data bit rate depends on the minimum payload size of FD frames used in a given application.

To illustrate how the CAN FD bit rate is affected by the configuration of FlexCAN variables, an application example with the peripheral and oscillator clock frequencies set to 50 MHz and 40 MHz, respectively, is considered.

Step 1 - Considering the nominal bit rate as 1 Mbps, the number of peripheral clocks per CAN bit in nominal bit rate is calculated as below.

$$NumClkNomBit = \frac{50 \times 10^6}{1 \times 10^6} = 50$$

Step 2 - The number of fast CAN bits (NumOfFastBits) is determined in the table presented above. For example, if the minimum payload in FD frames is 8 bytes, then there are 85 CAN bits in the Data Phase.

Step 3 - Assuming the maximum number of mailboxes is 96, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated.

$$\text{MinNumClkFastBit}_A = \frac{(8.5 \text{ X } 96) + 64 - (9 \text{ X } 50)}{85} = 5.06$$

$$\text{MinNumClkFastBit}_B = 3 \text{ x } \left(1 + \frac{50}{40} \right) = 6.75$$

$$\text{MinNumClkFastBit} = \text{Maximum } (5.06, 6.75) = 6.75$$

Step 4 - The maximum CAN bit rate in the Data Phase can be finally found.

$$\text{DataBitRate}_{MAX} = \frac{40 \text{ x } 10^6}{\text{ROUNDUP} \left(\frac{6.75 \text{ x } 40 \text{ x } 10^6}{50 \text{ x } 10^6} \right)} = 6.667 \text{ Mbps}$$

As demonstrated in this example, even though the oscillator clock frequency (40 MHz) is adequate to generate a data rate of 8 Mbps in CAN FD mode, the specific FlexCAN configuration limits this rate to 6.667 Mbps. This limitation is mainly due to the low peripheral clock frequency that imposes the MinNumClkFastBitB bound.

The table below shows the maximum data rate for CAN FD according to clock frequencies, payload size and number of available mailboxes. See in this table that, for some cases, if the number of available mailboxes is reduced, the FlexCAN can then achieve a data rate up to 8 Mbps.

Table 44-29. Maximum CAN bit rate in Data Phase on CAN FD frames

Peripheral clock frequency (MHz)	Payload size	Number of available mailboxes	Maximum data rate (Mbps)
40	8	94	6.667
40	8	114	5.0
40	12	117	6.667
40	12	128	5.714

Table continues on the next page...

Table 44-29. Maximum CAN bit rate in Data Phase on CAN FD frames (continued)

Peripheral clock frequency (MHz)	Payload size	Number of available mailboxes	Maximum data rate (Mbps)
50	12 to 64	128	6.667
60	8	126	8.0
60	12	128	8.0
67	6	128	8.0
80	3	128	8.0
100	0	128	8.0

44.5.11 Modes of operation details

The FlexCAN module has functional modes and low-power modes. See Modes of operation for an introductory description of all the modes of operation. The following sub-sections contain functional details on Freeze mode and the low-power modes.

CAUTION

"Permanent Dominant" failure on CAN Bus line is not supported by FlexCAN. If a Low-Power request or Freeze mode request is done during a "Permanent Dominant", the corresponding acknowledge can never be asserted.

44.5.11.1 Freeze mode

This mode is requested either by the CPU through the assertion of the HALT bit in the CAN_MCR Register or when the chip is put into Debug mode. In both cases it is also necessary that the FRZ bit is asserted in the CAN_MCR Register and the module is not in a low-power mode.

The acknowledgement is obtained through the assertion by the FlexCAN of FRZ_ACK bit in the same register. The CPU must only consider the FlexCAN in Freeze mode when both request and acknowledgement conditions are satisfied.

When Freeze mode is requested, FlexCAN does the following:

- Waits to be in either Intermission, Passive Error, Bus Off or Idle state
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in does not prevent going to Freeze mode.
- Ignores the Rx input pin and drives the Tx pin as recessive

- Stops the prescaler, thus halting all CAN protocol activities
- Grants write access to the Error Counters Register, which is read-only in other modes
- Sets the NOT_RDY and FRZ_ACK bits in CAN_MCR

After requesting Freeze mode, the user must wait for the FRZ_ACK bit to be asserted in CAN_MCR before executing any other action, otherwise FlexCAN may operate in an unpredictable way. In Freeze mode, all memory mapped registers are accessible, except for CAN_CTRL1[CLKSRC] bit that can be read but cannot be written.

Exiting Freeze mode is done in one of the following ways:

- CPU negates the FRZ bit in the CAN_MCR Register
- The chip is removed from Debug Mode and/or the HALT bit is negated

The FRZ_ACK bit is negated after the protocol engine recognizes the negation of the freeze request. When out of Freeze mode, FlexCAN tries to re-synchronize to the CAN bus by waiting for 11 consecutive recessive bits.

44.5.11.2 Module Disable mode

This low power mode is normally used to temporarily disable a complete FlexCAN block, with no power consumption. It is requested by the CPU through the assertion of the CAN_MCR[MDIS] bit, and the acknowledgement is obtained through the assertion by the FlexCAN of the CAN_MCR[LPMACK] bit. The CPU must only consider the FlexCAN in Disable mode when both request and acknowledgement conditions are satisfied.

If the module is disabled during Freeze mode, it requests to disable the clocks to the PE and CHI sub-modules, sets the LPMACK bit and negates the FRZACK bit.

It is not recommended to use Module Disable mode under Pretended Networking mode. Negate the MDIS bit and wait for LPMACK to negate before setting CAN_MCR[PNET_EN].

If the module is disabled during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and then checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.

- Ignores its Rx input pin and drives its Tx pin as recessive
- Shuts down the clocks to the PE and CHI sub-modules
- Sets the NOTRDY and LPMACK bits in CAN_MCR

The Bus Interface Unit continues to operate, enabling the CPU to access memory mapped registers, except the Rx Mailboxes Global Mask Registers, the Rx Buffer 14 Mask Register, the Rx Buffer 15 Mask Register, the Rx FIFO Global Mask Register. The Rx FIFO Information Register, the Message Buffers, the Rx Individual Mask Registers, and the reserved words within RAM may not be accessed when the module is in Disable Mode. Exiting from this mode is done by negating the MDIS bit by the CPU, which causes the FlexCAN to request to resume the clocks and negate the LPMACK bit after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

44.5.11.3 Stop mode

This is a system low-power mode in which all chip clocks can be stopped for maximum power savings. The Stop mode is globally requested by the CPU and the acknowledgement is obtained through the assertion by the FlexCAN of a Stop Acknowledgement signal. The CPU must only consider the FlexCAN in Stop mode when both request and acknowledgement conditions are satisfied.

If FlexCAN receives the global Stop mode request during Freeze mode, it sets the LPMACK bit, negates the FRZACK bit and then sends the Stop Acknowledge signal to the CPU, in order to shut down the clocks globally.

If Stop mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Sets the NOTRDY and LPMACK bits in CAN_MCR
- Sends a Stop Acknowledge signal to the CPU, so that it can shut down the clocks globally

Stop mode is exited when the CPU resumes the clocks and removes the Stop Mode request. This can be as a result of the Self Wake mechanism.

In the Self Wake mechanism, if the SLFWAK bit in CAN_MCR Register was set at the time FlexCAN entered Stop mode, then upon detection of a recessive to dominant transition on the CAN bus, FlexCAN sets the WAKINT bit in the CAN_ESR Register and, if enabled by the WAKMSK bit in CAN_MCR, generates a Wake Up interrupt to the CPU. Upon receiving the interrupt, the CPU should resume the clocks and remove the Stop mode request. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up. The following table details the effect of SLFWAK and WAKMSK upon wake-up from Stop mode. Note that wake-up from Stop mode only works when both bits are asserted.

After the CAN protocol engine recognizes the negation of the Stop mode request, the FlexCAN negates the LPMACK bit. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up.

Table 44-30. Wake-up from Stop Mode

SLFWAK	WAKINT	WAKMSK	Chip clocks enabled	Wake-up interrupt generated
0	-	-	No	No
0	-	-	No	No
1	0	0	No	No
1	0	1	No	No
1	1	0	No	No
1	1	1	Yes	Yes

The sensitivity to CAN bus activity can be modified by applying a low-pass filter function to the Rx CAN input line while in Stop mode. See the WAKSRC bit in in the description of the Module Configuration Register (CAN_MCR). This feature can be used to protect FlexCAN from waking up due to short glitches on the CAN bus lines. Such glitches can result from electromagnetic interference within noisy environments.

44.5.11.4 Pretended Networking Mode

This is a special low power mode used to receive wake up messages with low power consumption. This mode can be selected to operate together with Stop mode. Before entering in one of these low power modes, the PNET_EN bit in CAN_MCR Register must be asserted. Once in low power mode, CHI sub-block is shut down and CAN_PE sub-block is kept active, so that the Rx receive process is still active to filter incoming messages (see Receive Process under Pretended Networking Mode) as defined by the

configuration registers (see Pretended Networking Control 1 Register (CAN_CTRL1_PN)). Upon detecting a wake up event, a Wake Up interrupt is issued to the system.

To enter in Pretended Networking mode FlexCAN must be in normal mode (neither in Freeze, nor in Disable mode). Under Pretended Networking mode, FlexCAN keeps itself synchronized with the CAN BUS in Stop mode. Then, when Stop mode is requested, FlexCAN performs the following steps:

- Waits to be in Idle state, or else waits for the third bit of Intermission, and then checks it to be recessive.
- Sets the LPM_ACK bit in CAN_MCR Register.
- Requests the shutdown of the CHI sub-module clock, while keeping the PE sub-module clock active.

FlexCAN can exit Pretended Networking mode by the following ways:

- The CPU removing the Stop Mode request.
- FlexCAN will wait until Bus Idle or third bit of Intermission state to negate CAN_MCR[LPM_ACK] bit.

The above exit ways can be triggered either by the FlexCAN action upon detecting a wake up event and issuing the respective interrupt, or by the CPU itself upon being waked up by another mean. In consequence, FlexCAN will wait until the Bus Idle state or until the third bit of Intermission state to negate CAN_MCR[LPM_ACK] bit and resume to the Normal mode. This procedure ensures that FlexCAN will be synchronized to the CAN bus after exiting the Pretended Networking mode. The CPU must wait for the CAN_MCR[LPM_ACK] bit to be negated before performing any access to FlexCAN.

When PNET_EN bit in CAN_MCR is asserted, the CPU must disable the Self Wake Up feature by configuring SLF_WAK=0 in CAN_MCR register (see Module Configuration Register).

44.5.12 Interrupts

The module has many interrupt sources: interrupts due to message buffers and interrupts due to the ORed interrupts from MBs, Bus Off, Bus Off Done, Error, Error Fast (errors detected in the data phase of CAN FD format messages with the BRS bit set), Wake Up, Wake Up Match, Wake Up Timeout, Tx Warning, and Rx Warning.

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception.

Each of the buffers has an assigned flag bit in the CAN_IFLAG registers. The bit is set when the corresponding buffer completes a successful transfer and is cleared when the CPU writes it to 1 (unless another interrupt is generated at the same time).

Note

It must be guaranteed that the CPU clears only the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Rx FIFO is enabled (CAN_MCR[RFEN] = 1) and DMA is disabled (CAN_MCR[DMA] = 0), the interrupts corresponding to MBs 0 to 7 have different meanings. Bit 24 of the CAN_IFLAG1 register becomes the "FIFO Overflow" flag; bit 25 becomes the "FIFO Warning" flag, bit 26 becomes the "Frames Available in FIFO" flag and bits 27-30 are unused. See the description of the Interrupt Flags 1 Register (CAN_IFLAG1) for more information.

If both Rx FIFO and DMA are enabled (CAN_MCR[RFEN] and CAN_MCR[DMA] = 1) the FlexCAN does not generate any FIFO interrupt. Bit 26 of the CAN_IFLAG1 register still indicates "Frames Available in FIFO" and generates a DMA request. Bits 24, 25, 27-30 are unused.

CAUTION

FIFO cannot be enabled when CAN FD feature is enabled.

For a combined interrupt where multiple MB interrupt sources are OR'd together, the interrupt is generated when any of the associated MBs (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the CAN_IFLAG registers to determine which MB or FIFO source caused the interrupt.

The interrupt sources for Bus Off, Bus Off Done, Error, Error Fast, Wake Up, Tx Warning and Rx Warning generate interrupts like the MB interrupt sources, and can be read from CAN_ESR1 register. The Bus Off, Error, Tx Warning, and Rx Warning interrupt mask bits are located in the CAN_CTRL1 Register; the Wake-Up interrupt mask bit is located in the CAN_MCR.

The interrupt sources for Pretended Networking (Wake up by Match Flag and Wake up by Timeout Flag) can be read in the CAN_WU_MTC Register and the respective interrupts masks bits are located in CAN_CTRL1_PN Register.

44.5.13 Bus interface

The CPU access to FlexCAN registers are subject to the following rules:

- Unrestricted read and write access to supervisor registers (registers identified with S/U in Table "Module Memory Map" in Supervisor Mode or with S only) results in access error.
- Read and write access to implemented reserved address space results in access error.
- Write access to positions whose bits are all currently read-only results in access error. If at least one of the bits is not read-only then no access error is issued. Write permission to positions or some of their bits can change depending on the mode of operation or transitory state. Refer to register and bit descriptions for details.
- Read and write access to unimplemented address space results in access error.
- Read and write access to RAM located positions during Low Power Mode results in access error.
- It is possible for the RXIMR memory region to be considered as general purpose memory and available for access. There are two ways of doing this:
  a. If CAN_MCR[IRMQ] is cleared, the individual masks (RXIMR) are disabled. In this case the RXIMR memory region is considered as general purpose memory.
  b. If CAN_MCR[MAXMB] is programmed with a value smaller than the available number of MBs, then the unused memory space can be used as general purpose RAM space. Note that reserved words within RAM cannot be used. As an example, suppose FlexCAN's RAM can support up to 16 MBs, CAN_CTRL2[RFFN] is 0x0, and CAN_MCR[MAXMB] is programmed with zero. The maximum number of MBs in this case becomes one. The RAM starts at 0x0080, and the space from 0x0080 to 0x008F is used by the one MB. The memory space from 0x0090 to 0x017F is available. The space between 0x0180 and 0x087F is reserved. The space from 0x0880 to 0x0883 is used by the one Individual Mask and the available memory in the Mask Registers space would be from 0x0884 to 0x08BF. From 0x08C0 through 0x09DF there are reserved words for internal use which cannot be used as general purpose RAM. As a general rule, free memory space for general purpose depends only on MAXMB.

44.6 Initialization/application information

This section provide instructions for initializing the FlexCAN module.

44.6.1 FlexCAN initialization sequence

The FlexCAN module may be reset in three ways:

- Chip level hard reset, which resets all memory mapped registers asynchronously
- SOFTRST bit in MCR, which resets some of the memory mapped registers synchronously. See Table 44-4 to see what registers are affected by soft reset.

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. The CAN_MCR[SOFTRST] bit remains asserted while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset can not be applied while clocks are shut down in a low power mode. The low power mode should be exited and the clocks resumed before applying soft reset.

The clock source should be selected while the module is in Disable mode (see CAN_CTRL1[CLKSRC] bit). After the clock source is selected and the module is enabled (CAN_MCR[MDIS] bit negated), FlexCAN automatically goes to Freeze mode. In Freeze mode, FlexCAN is un-synchronized to the CAN bus, the HALT and FRZ bits in CAN_MCR Register are set, the internal state machines are disabled and the FRZACK and NOTRDY bits in the CAN_MCR Register are set. The Tx pin is in recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Note that the Message Buffers and the Rx Individual Mask Registers are not affected by reset, so they are not automatically initialized.

For any configuration change/initialization it is required that FlexCAN is put into Freeze mode (see Freeze mode). The following is a generic initialization sequence applicable to the FlexCAN module:

- Initialize the Module Configuration Register (CAN_MCR)
  - Enable the individual filtering per MB and reception queue features by setting the IRMQ bit
  - Enable the warning interrupts by setting the WRNEN bit
  - If required, disable frame self reception by setting the SRXDIS bit
  - Enable the Rx FIFO by setting the RFEN bit
  - If Rx FIFO is enabled and DMA is required, set DMA bit
  - If Pretended Networking mode is required, set PNET_EN bit
  - Enable the abort mechanism by setting the AEN bit
  - Enable the local priority feature by setting the LPRIOEN bit

- Initialize the Control 1 Register (CAN_CTRL1) and optionally the CAN Bit Timing Register (CAN_CBT). Initialize also the CAN FD CAN Bit Timing Register (CAN_FDCBT).
  - Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, RJW
  - Optionally determine the bit timing parameters: EPROPSEG, EPSEG1, EPSEG2, ERJW
  - Determine the CAN FD bit timing parameters: FPROPSEG, FPSEG1, FPSEG2, FRJW
  - Determine the bit rate by programming the PRESDIV field and optionally the EPRESDIV field
  - Determine the CAN FD bit rate by programming the FPRESDIV field
  - Determine the internal arbitration mode (LBUF bit)
- Initialize the Message Buffers
  - The Control and Status word of all Message Buffers must be initialized
  - If Rx FIFO was enabled, the ID filter table must be initialized
  - Other entries in each Message Buffer should be initialized as required
- Initialize the Rx Individual Mask Registers (CAN_RXIMRn)
- Set required interrupt mask bits in the CAN_IMASK Registers (for all MB interrupts), in CAN_MCR Register for Wake-Up interrupt and in CAN_CTRL1 / CAN_CTRL2 Registers (for Bus Off and Error interrupts)
- If Pretended Networking mode is enabled, configure the necessary registers for selective Wake Up
- Negate the HALT bit in CAN_MCR

After the last step listed above, FlexCAN attempts to synchronize to the CAN bus.

Chapter 45
Inter-Integrated Circuit (I2C)

45.1 Chip-specific I2C information

45.1.1 I2C configurations

45.1.1.1 I2C's stop-stop ack protocol

I^2C module provides the acknowledgement to the stop request after the current ongoing transaction are successfully completed.

45.2 Overview

This chapter describes the Inter-Integrated Circuit (I^2C) bus module implemented on this chip and presents the following topics:

- Introduction to I^2C
- External signal descriptions
- Memory map and register definition
- Functional description
- Initialization/application information

45.3 Introduction to I^2C

This section presents the following topics:

- Definition: I²C module
- Advantages of the I²C bus
- Module block diagram
- Features
- Modes of operation
- Definition: I²C conditions

45.3.1 Definition: I²C module

The I²C module is a functional unit that provides a two-wire— serial data (SDA) and serial clock (SCL) — bidirectional serial bus that provides a simple and efficient method of data exchange between this chip and other devices, such as microcontrollers, EEPROMs, real-time clock devices, analog-to-digital converters, and LCDs.

45.3.2 Advantages of the I²C bus

The synchronous, multiple-master two-wire I²C bus:

- Minimizes interconnections between devices
- Allows the connection of additional devices to the bus for expansion and system development
- Includes collision detection and arbitration that prevent data corruption if two or more masters attempt to control the bus simultaneously
- Does not require an external address decoder

45.3.3 Module block diagram

The following figure shows a block diagram of the I²C module.

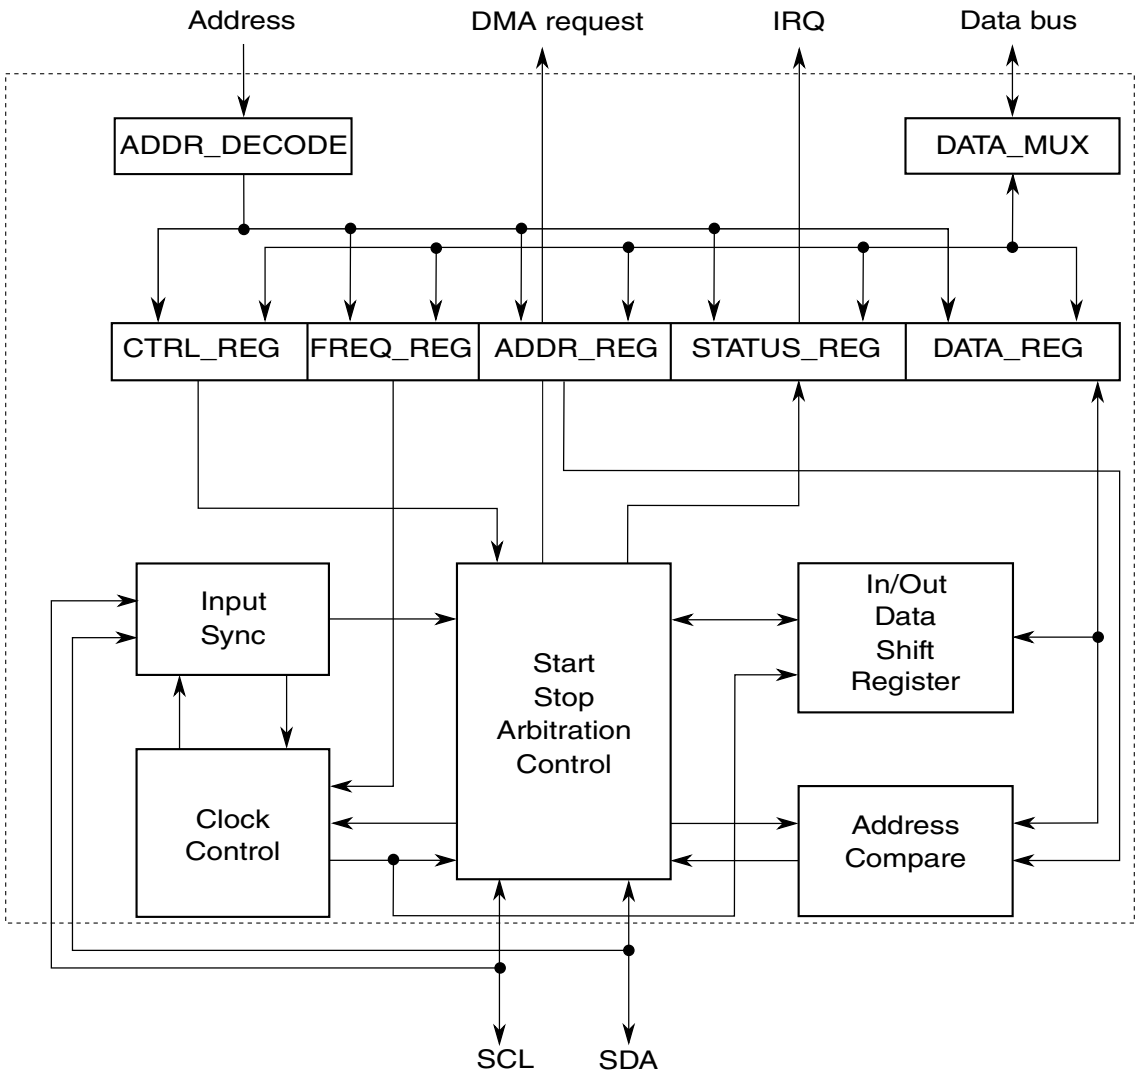

Figure 45-1. I²C block diagram

45.3.4 Features

The I²C module has the following key features:

- Compatible with I²C bus standard[1]
- Operating speeds
  - Up to 100 kbps in Standard Mode
  - Up to 400 kbps in Fast Mode

1. Compliant with I²C 2.0 standard with the exception that HS (high speed) mode is not supported

  - Operation at higher baud rates (up to a maximum of module clock/20) with reduced bus loading
  - Actual baud rate dependent on the SCL rise time (which depends on external pull-up resistor values and bus loading)
- Multi-master operation
- Software programmable for one of 256 different serial clock frequencies
- Software selectable acknowledge bit
- Interrupt driven byte-by-byte data transfer
- Arbitration lost interrupt with automatic mode switching from master to slave
- Calling address identification interrupt
- Start and stop signal generation/detection
- Repeated start signal generation
- Acknowledge bit generation/detection
- Bus busy detection
- Basic DMA interface
- Maximum communication length and the number of devices that can be connected are limited by a maximum bus capacitance of 400 pF

45.3.5 Modes of operation

The I^2C module supports the chip modes described in the following table.

Table 45-1. Chip modes supported by the I^2C module

Chip mode	Description	Important notes
RUN	Basic mode of operation	—
STOP	The lowest-power mode that allows the chip to turn off all the clocks to the I^2C module	The I^2C module can enter this mode when there are no active transfers (active data between valid START and STOP conditions) on the bus. See STOP mode.
DEBUG	Allows the chip to freeze all ongoing activities (such as an ongoing transaction, counter values, and register status) for debugging	See DEBUG mode.

In addition to chip modes, the I^{2}C module has several module-specific modes. These are described in the following table.

Table 45-2. Module-specific modes supported by the I^{2}C module

Module mode	Description	Important notes
Master mode	The I^{2}C module is the driver of the SDA line.	• Do not use the I^{2}C module's slave address as a calling address. • The I^{2}C module cannot be a master and a slave simultaneously.
Slave mode	The I^{2}C module is not the driver of the SDA line.	• Enable the I^{2}C module before a START condition from a non-I^{2}C master is detected. • By default the I^{2}C module performs as a slave receiver.

45.3.6 Definition: I^{2}C conditions

The following table shows the I^{2}C-specific conditions defined for the I^{2}C module.

Table 45-3. I^{2}C Conditions

Condition	Description
START	A condition that denotes the beginning of a new data transfer and awakens all slaves. Each data transfer contains several bytes of data. It is defined as a high-to-low transition of SDA while SCL is high, as shown in the following figure.
STOP	A condition generated by the master to terminate a transfer and free the bus. It is defined as a low-to-high transition of SDA while SCL is high, as shown in the following figure.
Repeated START	A START condition that is generated without a STOP condition to terminate the previous transfer.

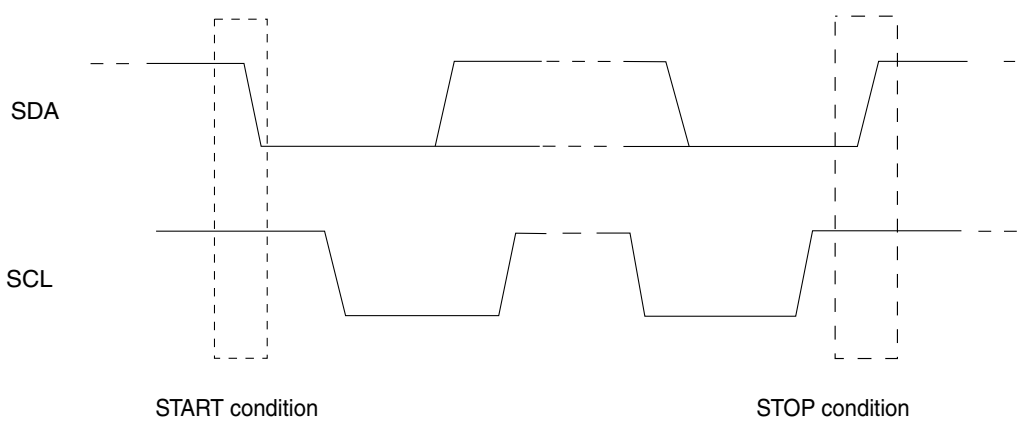

Figure 45-2. START and STOP conditions

45.4 External signal descriptions

This section presents the following topics:

- Signal overview
- Detailed external signal descriptions

45.4.1 Signal overview

The I^2C module uses the Serial Data (SDA) and Serial Clock (SCL) signals as a communication interconnect with other devices. The signal patterns driven on the SDA signal represent address, data, or read/write information at different stages of the protocol.

All devices connected to the SDA and SCL signals must have open-drain or open-collector outputs. The logical AND function is performed on both signals with external pull-up resistors. For the electrical characteristics of these signals, see the data sheet for this chip.

45.4.2 Detailed external signal descriptions

The SDA and SCL signals are described in the following table.

Table 45-4. External signal descriptions

Signal	Description
SCL	Bidirectional serial clock line of the module, compatible with the I^2C bus specification
SDA	Bidirectional serial data line of the module, compatible with the I^2C bus specification

45.5 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the I^2C module. It presents the following topics:

- Register accessibility
- Register figure conventions

- I2C Bus Address Register (I2C_IBAD)
- I2C Bus Frequency Divider Register (I2C_IBFD)
- I2C Bus Control Register (I2C_IBCR)
- I2C Bus Status Register (I2C_IBSR)
- I2C Bus Data I/O Register (I2C_IBDR)
- I2C Bus Interrupt Config Register (I2C_IBIC)
- I2C Bus Debug Register (I2C_IBDBG)

45.5.1 Register accessibility

Address location 0x0007 is a reserved location, but access to this location will not generate any bus error.

All registers are accessible via 8-bit, 16-bit, or 32-bit accesses. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries.

As an example, the IBFD is at address offset 0x01, and can be accessed in any of the following ways:

- 8-bit R/W access of address offset 0x0001
- Second byte of 16-bit R/W access of address offset 0x0000
- Second byte of 32-bit R/W access of address offset 0x0000

The IBFD register cannot be accessed by a 16- or 32-bit RW operation at address offset 0x0001 because those operations require an address aligned to a 16- or 32-bit boundary.

45.5.2 Register figure conventions

The register figures show the field structure using the conventions in the following figure.

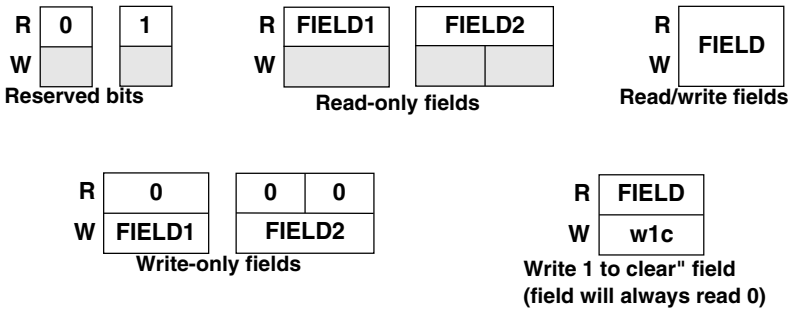

Figure 45-3. Register figure convention

The memory map for the I^{2}C module is given below. The total address for each register is the sum of the base address for the I^{2}C module and the address offset for each register.

I2C memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	I2C Bus Address Register (I2C_IBAD)	8	R/W	00h	45.5.3/1684
1	I2C Bus Frequency Divider Register (I2C_IBFD)	8	R/W	00h	45.5.4/1685
2	I2C Bus Control Register (I2C_IBCR)	8	R/W	80h	45.5.5/1685
3	I2C Bus Status Register (I2C_IBSR)	8	R/W	80h	45.5.6/1687
4	I2C Bus Data I/O Register (I2C_IBDR)	8	R/W	00h	45.5.7/1688
5	I2C Bus Interrupt Config Register (I2C_IBIC)	8	R/W	00h	45.5.8/1689
6	I2C Bus Debug Register (I2C_IBDBG)	8	R/W	00h	45.5.9/1690

45.5.3 I2C Bus Address Register (I2C_IBAD)

This register contains the address the I^{2}C Bus will respond to when addressed as a slave. This is not the address sent on the bus during the address transfer.

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7
Read	ADR							0
Write								
Reset	0	0	0	0	0	0	0	0

I2C_IBAD field descriptions

Field	Description
0–6 ADR	Slave Address. Specific slave address to be used by the I^{2}C Bus module.

Table continues on the next page...

I2C_IBAD field descriptions (continued)

Field	Description
	NOTE: The default mode of I^2C Bus is slave mode for an address match on the bus.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

45.5.4 I2C Bus Frequency Divider Register (I2C_IBFD)

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 1h offset = 1h

Bit	0	1	2	3	4	5	6	7
Read Write	IBC							
Reset	0	0	0	0	0	0	0	0

I2C_IBFD field descriptions

Field	Description
0–7 IBC	I-Bus Clock Rate. This field is used to prescale the bus clock for bit rate selection. See Clock rate and IBFD settings.

45.5.5 I2C Bus Control Register (I2C_IBCR)

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 2h offset = 2h

Bit	0	1	2	3	4	5	6	7
Read	MDIS	IBIE	MSSL	TXRX	NOACK	0	DMAEN	Reserved
Write						RSTA		
Reset	1	0	0	0	0	0	0	0

I2C_IBCR field descriptions

Field	Description
0 MDIS	Module disable. This bit controls the software reset of the entire I^2C Bus module. **NOTE:** If the I^2C Bus module is enabled in the middle of a byte transfer, the interface behaves as follows: slave mode ignores the current transfer on the bus and starts operating whenever a subsequent

Table continues on the next page...

I2C_IBCR field descriptions (continued)

Field	Description
	start condition is detected. Master mode will not be aware that the bus is busy, hence if a start cycle is initiated then the current bus cycle may become corrupt. This would ultimately result in either the current bus master or the I²C Bus module losing arbitration, after which, bus operation would return to normal. 0 The I²C Bus module is enabled. This bit must be cleared before any other IBCR bits have any effect 1 The module is reset and disabled. This is the power-on reset situation. When high, the interface is held in reset, but registers can still be accessed. Status register bits (IBSR) are not valid when module is disabled.
1 IBIE	I-Bus Interrupt Enable. 0 Interrupts from the I²C Bus module are disabled. This does not clear any currently pending interrupt condition. 1 Interrupts from the I²C Bus module are enabled. An I²C Bus interrupt occurs provided the IBIF bit in the status register is also set.
2 MSSL	Master/Slave mode select. When this bit is changed from 0 to 1, a START signal is generated on the bus and the master mode is selected. When this bit is changed from 1 to 0, a STOP signal is generated and the operation mode changes from master to slave. A STOP signal should be generated only if the IBIF flag is set. This field is cleared without generating a STOP signal when the master loses arbitration. 0 Slave Mode 1 Master Mode
3 TXRX	Transmit/Receive mode select. This bit selects the direction of master and slave transfers. When addressed as a slave this bit should be set by software according to the SRW bit in the status register. In master mode this bit should be set according to the type of transfer required. Therefore, for address cycles, this bit will always be high. 0 Receive 1 Transmit
4 NOACK	Data Acknowledge disable. This bit specifies the value driven onto SDA during data acknowledge cycles for both master and slave receivers. The I²C module will always acknowledge address matches, provided it is enabled, regardless of the value of NOACK. **NOTE:** Values written to this bit are only used when the I²C Bus is a receiver, not a transmitter. 0 An acknowledge signal will be sent out to the bus at the 9th clock bit after receiving one byte of data 1 No acknowledge signal response is sent (i.e., acknowledge bit = 1)
5 RSTA	Repeat Start. Writing a one to this bit will generate a repeated START condition on the bus, provided it is the current bus master. This bit will always be read as a low. Attempting a repeated start at the wrong time, if the bus is owned by another master, will result in loss of arbitration. 0 No effect 1 Generate repeat start cycle
6 DMAEN	DMA Enable. When this bit is set, the DMA Tx and Rx lines will be asserted when the I²C module requires data to be read or written to the data register. No Transfer Done interrupts will be generated when this bit is set, however an interrupt will be generated if the loss of arbitration or addressed as slave conditions occur. The DMA mode is only valid when the I²C module is configured as a Master and the DMA transfer still requires CPU intervention at the start and the end of each frame of data. See the DMA Application Information section for more details. 0 Disable the DMA TX/RX request signals 1 Enable the DMA TX/RX request signals

Table continues on the next page...

I2C_IBCR field descriptions (continued)

Field	Description
7 Reserved	This field is reserved. Although this bit supports read/write access, writing to this bit is not recommended, and can produce unexpected results.

45.5.6 I2C Bus Status Register (I2C_IBSR)

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 3h offset = 3h

Bit	0	1	2	3	4	5	6	7
Read	TCF	IAAS	IBB	IBAL	0	SRW	IBIF	RXAK
Write				w1c			w1c	
Reset	1	0	0	0	0	0	0	0

I2C_IBSR field descriptions

Field	Description
0 TCF	Transfer complete. While one byte of data is being transferred, this bit is cleared. It is set by the falling edge of the 9th clock of a byte transfer. **NOTE:** This bit is only valid during or immediately following a transfer to the I^2C module or from the I^2C module. 0 Transfer in progress 1 Transfer complete
1 IAAS	Addressed as a slave. When its own specific address (I-Bus Address Register) is matched with the calling address, this bit is set. The CPU is interrupted provided the IBIE is set. Then the CPU needs to check the SRW bit and set the TXRX field accordingly. Writing to the I-Bus Control Register clears this bit. 0 Not addressed 1 Addressed as a slave
2 IBB	Bus busy. This bit indicates the status of the bus. When a START signal is detected, IBB is set. If a STOP signal is detected, IBB is cleared and the bus enters idle state. **NOTE:** Software must ensure that the I^2C bus is idle by checking the IBSR[IBB] field (bus busy) before switching to master mode and attempting a START cycle. 0 Bus is Idle 1 Bus is busy

Table continues on the next page...

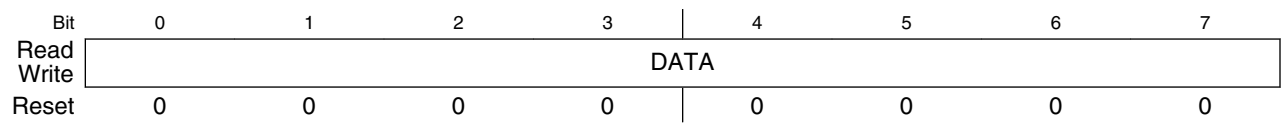
I2C_IBSR field descriptions (continued)

Field	Description
3 IBAL	Arbitration Lost. The arbitration lost bit (IBAL) is set by hardware when the arbitration procedure is lost. Arbitration is lost in the following circumstances: • SDA is sampled low when the master drives a high during an address or data transmit cycle. • SDA is sampled low when the master drives a high during the acknowledge bit of a data receive cycle. • A start cycle is attempted when the bus is busy. • A repeated start cycle is requested in slave mode. • A stop condition is detected when the master did not request it. This bit must be cleared by software, by writing a one to it. A write of zero has no effect.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 SRW	Slave Read/Write. When the IAAS bit is set, this bit indicates the value of the R/W command bit of the calling address sent from the master. This bit is only valid when the I-Bus is in slave mode, a complete address transfer has occurred with an address match and no other transfers have been initiated. By reading this field, the CPU can detect slave transmit/receive mode according to the command of the master. 0 Slave receive, master writing to slave 1 Slave transmit, master reading from slave
6 IBIF	I-Bus Interrupt Flag. The IBIF bit is set when one of the following conditions occurs: • Arbitration lost (IBAL bit set) • Byte transfer complete (TCF bit set and DMAEN bit not set) • Addressed as slave (IAAS bit set) • NoAck from Slave (MS & Tx bits set) • I^2C Bus going idle (IBB high-low transition and enabled by BIIE) A processor interrupt request will be caused if the IBIE bit is set. This bit must be cleared by software, by writing a one to it. A write of zero has no effect on this bit. In DMA mode (DMAEN set) a byte transfer complete condition will not trigger the setting of IBIF. All other conditions still apply.
7 RXAK	Received Acknowledge. This is the value of SDA during the acknowledge bit of a bus cycle. If the received acknowledge bit (RXAK) is low, it indicates an acknowledge signal has been received after the completion of 8 bits data transmission on the bus. If RXAK is high, it means no acknowledge signal is detected at the 9th clock. This bit is valid only after transfer is complete. 0 Acknowledge received 1 No acknowledge received

45.5.7 I2C Bus Data I/O Register (I2C_IBDR)

In master transmit mode, when data is written to the IBDR, a data transfer is initiated. The most significant bit is sent first. In master receive mode, reading this register initiates next byte data receiving. In slave mode, the same functions are available after an address match has occurred.

NOTE



The IBCR[TXRX] field must correctly reflect the desired direction of transfer in master and slave modes for the transmission to begin. For instance, if the I^2C is configured for master transmit but a master receive is desired, then reading the IBDR will not initiate the receive.

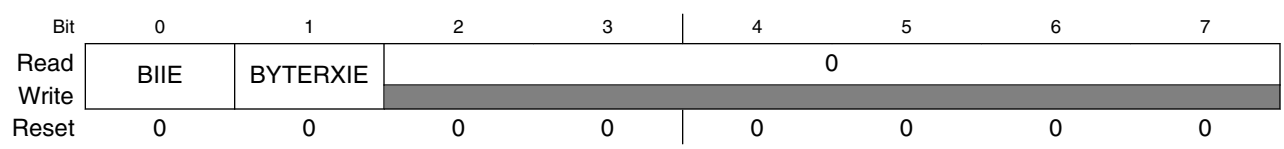
Reading the IBDR will return the most recent byte received while the I^2C is configured in either master receive or slave receive modes. The IBDR does not reflect every byte that is transmitted on the I^2C bus, nor can software verify that a byte has been written to the IBDR correctly by reading it back.

In master transmit mode, the first byte of data written to IBDR following assertion of MSSL is used for the address transfer and should comprise the calling address (in position DATA[7:1]) concatenated with the required R/ $\overline{W}$ bit (in position D0).

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 4h offset = 4h

I2C_IBDR field descriptions



Field	Description
0–7 DATA	Data transmitted or received

45.5.8 I2C Bus Interrupt Config Register (I2C_IBIC)

To program BIIE = 1, you must ensure that IBCR[MDIS] = 0.

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 5h offset = 5h

I2C_IBIC field descriptions

Field	Description
0 BIIE	Bus Idle Interrupt Enable bit. This config bit can be used to enable the generation of an interrupt once the I^2C bus becomes idle. Once this bit is set, an IBB high-low transition will set the IBIF bit. This feature can be used to signal to the CPU the completion of a STOP on the I^2C bus. 0 Bus Idle Interrupts disabled 1 Bus Idle Interrupts enabled
1 BYTERXIE	Byte receive interrupt enable This field is used to generate an interrupt every time the I^2C master/slave receives a new byte. This feature can be useful when an I^2C master is receiving data from a slave that is transmitting on an irregular basis. BYTERXIE is updated only when the I^2C is enabled (IBCR[MDIS]=0).
2–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

45.5.9 I2C Bus Debug Register (I2C_IBDBG)

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 6h offset = 6h

Bit	0	1	2	3
Read	0			
Write				
Reset	0	0	0	0

Bit	4	5	6	7
Read	0	BYTE_RX	IPG_DEBUG_HALTED	IPG_DEBUG_EN
Write		w1c		
Reset	0	0	0	0

I2C_IBDBG field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 BYTE_RX	This field gets set when an I^2C master/slave receives a new byte. An interrupt will be generated if IBIC[BYTERXIE] = 1.
6 IPG_DEBUG_ HALTED	Debug Halted Bit: This is s status bit which can be read back after asserting the debug enable signal so as to know if the IP has entered the debug mode or not. 0 IP is still executing a transaction 1 IP has entered the debug mode

Table continues on the next page...

I2C_IBDBG field descriptions (continued)

Field	Description
7 IPG_DEBUG_EN	Debug enable bit. This bit is used to enable IP enter the debug mode provided the IPG DEBUG signal is high. All the registers, counter values and status bits are frozen and can be accessed by the CPU. **NOTE:** If the assertion of this bit along with the IPG DEBUG signal happens in the middle of a transaction, IP enters the debug mode only after successful completion of the current transaction after which no further transaction can take place until the debug mode is exited. 0 Normal operation, Bus Idle Interrupts disabled 1 IP is in debug mode

45.6 Functional description

This section presents the following topics:

- Notes about module operation
- Transactions
- Arbitration procedure
- Clock behavior
- Interrupts
- DEBUG mode
- DMA interface

45.6.1 Notes about module operation

- The I^2C module always performs as a slave receiver by default, unless explicitly programmed to be a master or slave transmitter.
- When the I^2C module is acting as a master, it must not try to call its own slave address.

45.6.2 Transactions

This section presents the following topics:

- Protocol overview

- Transaction protocol definitions
- High-level protocol steps
- START condition
- Slave address transmission
- Data transmission
- STOP condition
- Repeated START condition

45.6.2.1 Protocol overview

The following figure shows the behavior of SCL and SDA during a typical I^2C transaction.

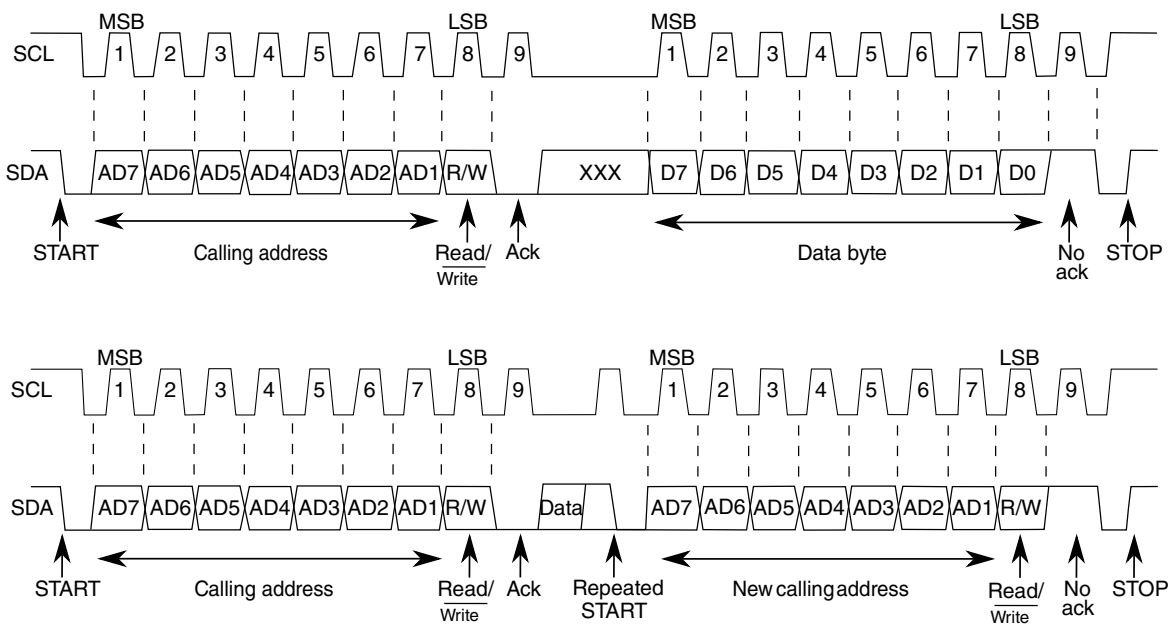


Figure 45-4. I^2C transaction protocol

45.6.2.2 Transaction protocol definitions

This section defines several important terms presented in Figure 45-4.

Table 45-5. I²C definitions

Term	Definition
START	A START condition, as defined in Section 1.2.6, Definition: I²C conditions"
STOP	A STOP condition, as defined in Section 1.2.6, Definition: I²C conditions"
Calling (slave) address	A seven-bit address used to identify a slave on the I²C bus. The requirements for specifying this address are presented in Section 1.5.2.3, I²C calling address requirements."
Read/write (R/W)	A bit that specifies the direction of the data transfer to the slave as follows: • 0=The data is being transferred from the master to the slave ("write") • 1=The data is being transferred from the slave to the master ("read")
Ack	A bit that specifies the acknowledgement of a calling address, indicated by pulling SDA low.

45.6.2.3 I²C calling address requirements

The calling addresses of the devices used on an I²C network are subject to the following requirements:

- Each slave must have a unique calling address.
- A master must not transmit a calling address that is the same as its own slave address.

45.6.2.4 High-level protocol steps

The I²C protocol conceptually supports two types of transfers, which are illustrated in Figure 45-4. The significant steps in these transfers are presented in the following table. Details of each of these steps are presented in subsequent sections.

Table 45-6. I²C high-level protocol steps

Standard Transfer	Repeated START Transfer
1. START condition	1. START condition
2. Slave target or general call address transmission	2. Slave target or general call address transmission
3. Acknowledgment from slave	3. Acknowledgment from slave
4. Data transfer	4. Data transfer
5. STOP condition	5. Repeated START condition
6. (repeat Steps 1–4)	6. (repeat Steps 2–4 as needed)
	7. STOP condition.
	8. (repeat Steps 1–7)

45.6.2.5 START condition

When the bus is free, that is, no master device is engaging the bus (both SCL and SDA lines are at logical high), a master may initiate communication by sending a START condition (see Definition: I^{2}C conditions). This signal denotes the beginning of a new data transfer (each data transfer may contain several bytes of data) and brings all slaves out of their idle states.

See Clock rate and IBFD settings and I2C Bus Frequency Divider Register (I2C_IBFD) for the associated timing requirements.

45.6.2.6 Slave address transmission

The master transmits the slave address on the next clock cycle after the START condition (see START condition). The process of slave address transmission is presented in the following table.

Table 45-7. Slave address transmission process

Step	Action
1	The master transmits the seven-bit slave address.
2	The master transmits the R/W bit.
3	Each slave examines the transmitted address and compares it to its own. If the addresses match, the slave device returns the acknowledge bit on the ninth SCL clock cycle.
4	The master waits for the acknowledge bit and determines the next step as follows: • The acknowledge bit is set: The master must initiate a data transfer followed by either a STOP condition or a repeated START condition. • The acknowledge bit is cleared: The master must wait for SCL to return to logic zero.

45.6.2.7 Data transmission

A data transfer session has the following characteristics:

- Can transmit one or more bytes of data
- Awakens all slaves
- Proceeds on a byte-by-byte basis in the direction specified by the R/W bit sent by the calling master

The transmitted data is subject to the following requirements:

- Each data byte must consist of 8 bits.
- Data bits can be changed only while SCL is low and must be held stable while SCL is high.
- One data bit is transmitted during one SCL clock pulse.
- The most significant bit (msb) must be transmitted first.
- Each data byte must be followed by an acknowledge bit on the ninth SCL clock pulse.

If the slave receiver does not acknowledge the master, the SDA line must be left high by the slave. The master can then generate a stop condition to abort the data transfer or a START condition (repeated START) to begin a new calling.

If the master receiver does not acknowledge the slave transmitter after a byte of transmission, the slave interprets that the end-of-data has been reached. Then the slave releases the SDA line for the master to generate a STOP or a START condition.

45.6.2.8 STOP condition

The master can terminate the communication by generating a STOP condition (see Definition: I^2C conditions). It can do so even if the slave has generated an acknowledge, at which point the slave must release the bus.

A master is not required to send a STOP condition at the end of every transfer. For more information, see Repeated START condition.

See Clock rate and IBFD settings and I2C Bus Frequency Divider Register (I2C_IBFD) for the associated timing requirements.

45.6.2.9 Repeated START condition

The I^2C protocol also supports a repeated START condition, which can be generated without a preceding STOP condition. A master device can use this condition to communicate with another slave or with the same slave in a different mode without releasing the bus. This condition is illustrated in the second timing diagram of Figure 45-4.

45.6.3 Arbitration procedure

The I^2C bus is a true multi-master bus that allows more than one master to be connected to it. If two or more masters try to control the bus at the same time, a clock synchronization procedure determines the bus clock, for which the low period is equal to the longest clock low period and the high is equal to the shortest one among the masters. The relative priority of the contending masters is determined by a data arbitration procedure. A bus master loses arbitration if it transmits logic "1" while another master transmits logic "0". The losing masters immediately switch over to slave mode and stop driving the SDA output. In this case, the transition from master to slave mode does not generate a STOP condition. Meanwhile, a status bit is set by hardware to indicate loss of arbitration.

45.6.4 Clock behavior

This section presents the following topics:

- Clock synchronization
- Clock stretching
- Handshaking
- Clock rate and IBFD settings

45.6.4.1 Clock synchronization

Due to the wired-AND logic on the SCL line, a high-to-low transition on the SCL line affects all devices connected on the bus. The devices begin counting their low period when the master drives the SCL line low. After a device has driven SCL low, it holds the SCL line low until the clock high state is reached.

However, the change of low-to-high in a device clock may not change the state of the SCL line if another device is still within its low period. Therefore, the synchronized clock signal, SCL, is held low by the device with the longest low period. Devices with shorter low periods enter a high wait state during this time (see the following figure). When all devices concerned have counted off their low period, the synchronized SCL line is released and pulled high. Then there is no difference between the devices' clocks and the state of the SCL line, and all the devices begin counting their high periods. The first device to complete its high period pulls the SCL line low again.

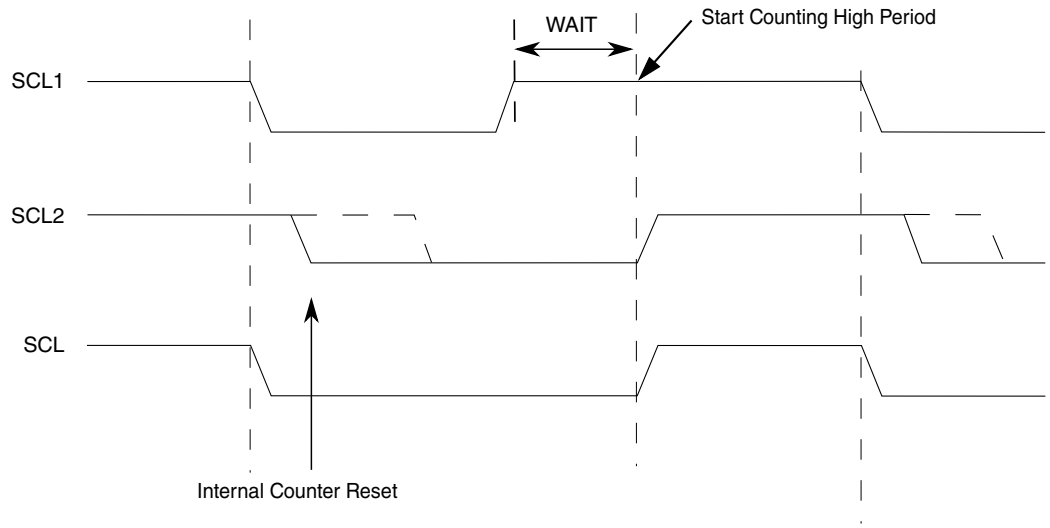

Figure 45-5. I²C bus clock synchronization

45.6.4.2 Clock stretching

The clock synchronization mechanism can be used by slaves to slow down the bit rate of a transfer. After the master has driven SCL low, the slave can drive SCL low for the required period and then release it. If the slave SCL low period is greater than the master SCL low period then the resulting SCL bus signal low period is stretched.

45.6.4.3 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfer. Slave devices may hold the SCL low after completion of one byte transfer (9 bits). In such cases, it halts the bus clock and forces the master clock into wait state until the slave releases the SCL line.

45.6.4.4 Clock rate and IBFD settings

45.6.4.4.1 Timing definitions

Table 45-8. Timing definitions relevant to clock rate and IBFD settings

Term	Definition
SCL Divider	The factor used to prescale the CPU clock for bit rate selection (see Figure 45-6 and Table 45-9)
SCL period	(CPU clock period) × (SCL Divider)

Table continues on the next page...

Table 45-8. Timing definitions relevant to clock rate and IBFD settings (continued)

Term	Definition
SCL Hold	The required number of CPU clocks to generate a START or STOP condition (see Figure 45-6 and Table 45-9)
SDA Hold	See Figure 45-7 and Table 45-9

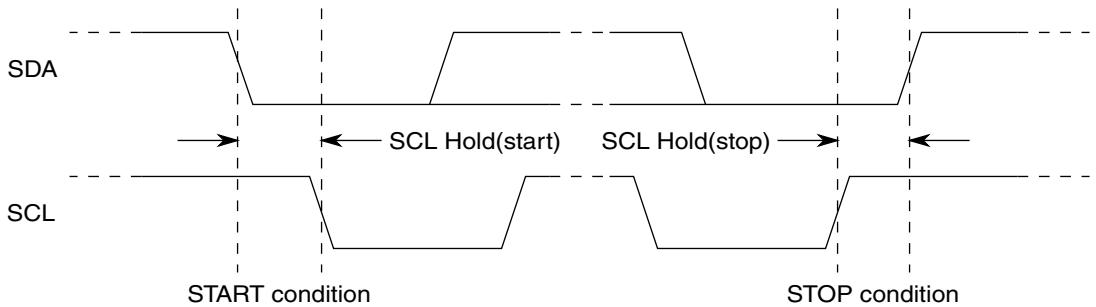

Figure 45-6. SCL Divider and SDA Hold

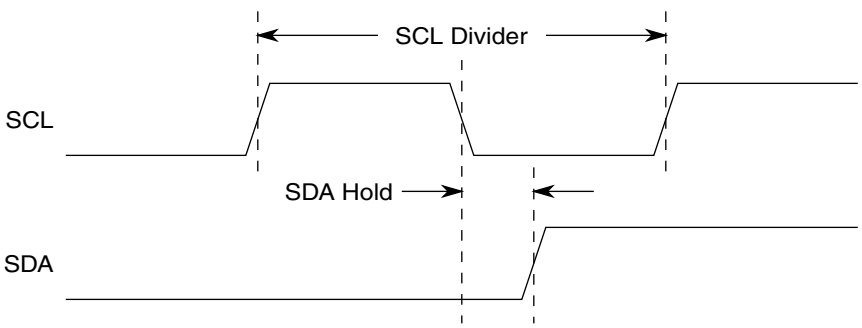

Figure 45-7. SDA Hold time

45.6.5 Interrupts

This section presents the following topics:

- Interrupt vector
- Interrupt description

45.6.5.1 Interrupt vector

The I^{2}C module uses only one interrupt vector.

Table 45-10. Interrupt summary

Interrupt	Offset	Vector	Priority	Source	Description
I^{2}C Interrupt	—	—	—	IBAL, TCF, IAAS, IBB bits in IBSR register	When any of IBAL, TCF or IAAS bits is set, an interrupt may be caused based on Arbitration lost, Transfer Complete or Address Detect conditions. If enabled by BIIE, the de-assertion of IBB can also cause an interrupt, indicating that the bus is idle.

45.6.5.2 Interrupt description

There are five types of internal interrupts in the I^{2}C. The interrupt service routine can determine the interrupt type by reading the Status register.

I^{2}C Interrupt can be generated on the following events:

- Arbitration Lost condition (IBAL bit set)
- Byte Transfer condition (TCF bit set and DMAEN bit not set)
- Address Detect condition (IAAS bit set)
- No Acknowledge from slave received when expected
- Bus Going Idle (IBB bit not set)

The I^{2}C interrupt is enabled by the IBCR[IBIE] bit. It must be cleared by writing '1' to the IBIF bit in the interrupt service routine. The Bus Going Idle interrupt needs to be additionally enabled by the IBIC[BIIE] bit.

45.6.6 STOP mode

This mode allows the software to put the I^{2}C module in power-down state. Once the STOP request is asserted, the I^{2}C module comes to a graceful halt after completing all the ongoing transactions.

As soon as the I^{2}C module enters STOP mode:

- The I^{2}C clock is disabled.
- No transaction can take place.
- All registers are inaccessible.

The I^{2}C module enters this mode only after successfully completing the current ongoing transaction, hence the low-power request is acknowledged once the STOP condition occurs. The user must ensure that the bus is free when STOP is requested. To request STOP for ongoing transmission the user must wait until the transmission is complete, followed by clearing of the IBCR[TXRX] field. See the figure below for more details.

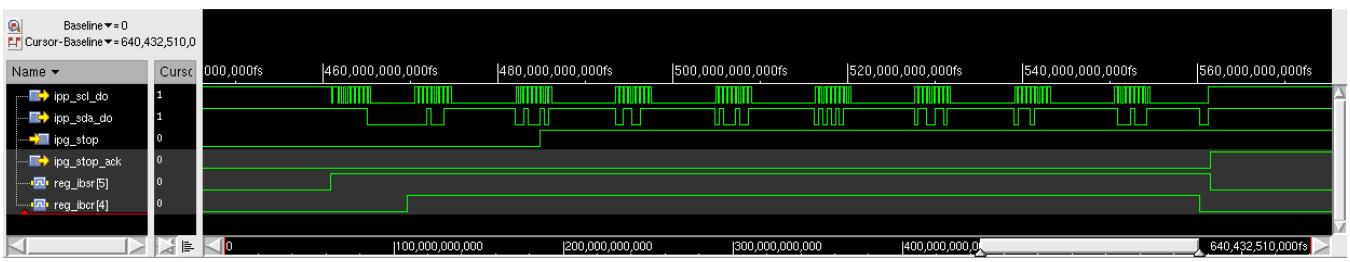

Figure 45-8. I^{2}C stop mode behavior when master is receiving and slave is transmitting

45.6.7 DEBUG mode

This mode allows CPU to debug the I^{2}C by freezing all the counters, registers and status bits. Once the Debug request is asserted along with IBDBG[IPG_DEBUG_EN] bit, I^{2}C comes to a graceful halt after completing all the ongoing transactions. A Debug halted signal IBDBG[IPG_DEBUG_HALTED] is also asserted to indicate that the debug request has been successfully serviced and is de-asserted when the Debug request is de-asserted.

As soon as the I^{2}C module enters DEBUG mode:

- No transaction can take place.
- All the registers, counters and status bits are frozen. They all can be accessed by the CPU to enable the debugging.

The I²C module enters this mode only after successfully completing the current ongoing transaction. For example, if the current transaction consists of 8 bytes and the debug mode was initiated by user at the time of the second byte, the IPG Debug Halted signal will be asserted after the 8th byte is transmitted/received. See the simulation result in Figure 45-9 for more details.

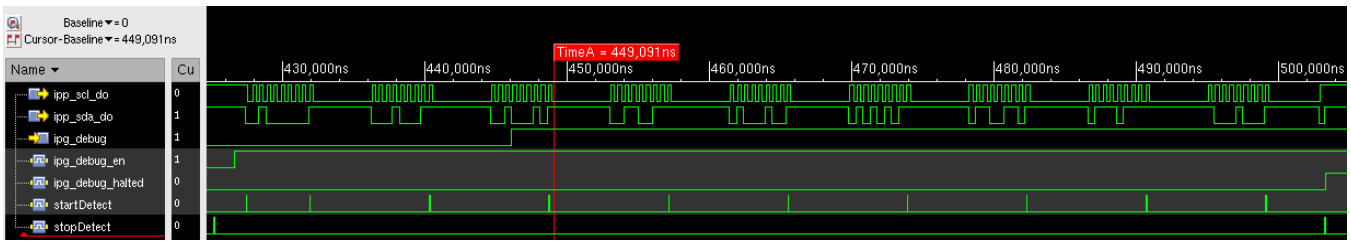

Figure 45-9. Simulation result of IPG Debug Halted in case of frame transmission

If any DMA transaction (transmit or receive) is in progress, and if the debug mode is requested while a byte is being transmitted or received, the I²C module enters DEBUG mode after completing the transmission or reception of the current byte. As soon as the module exits DEBUG mode, transmission or reception of the remaining bytes resumes. Please see the simulation snapshot shown in Figure 45-10 for details where the I²C is transmitting 8 bytes using DMA and DEBUG mode is requested while a second byte is being transmitted. DEBUG mode is entered after successfully transmitting the second byte (IPG Debug Halted signal asserted). As soon as the module exits DEBUG mode (IPG Debug Halted signal de-asserted), transmission resumes successfully.

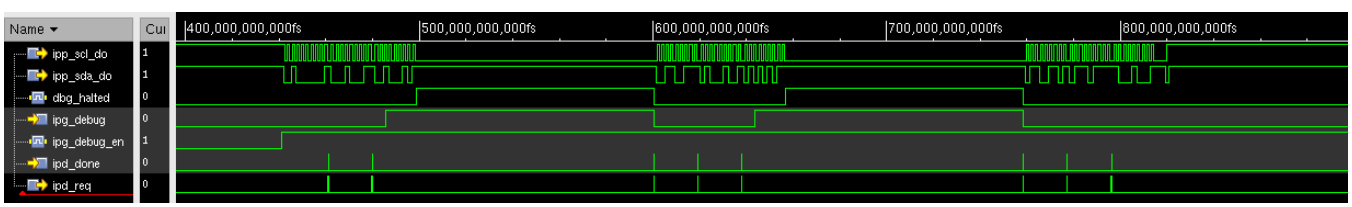

Figure 45-10. Simulation result of IPG Debug Halted in case of frame transmission using DMA

No more transaction can take place until the debug signal is de-asserted after which the I²C module starts functioning normally. There is a status halted signal IBDBG[IPG_DEBUG_HALTED] to indicate to the user that the I²C module has entered the DEBUG mode. See the following figure for more details.

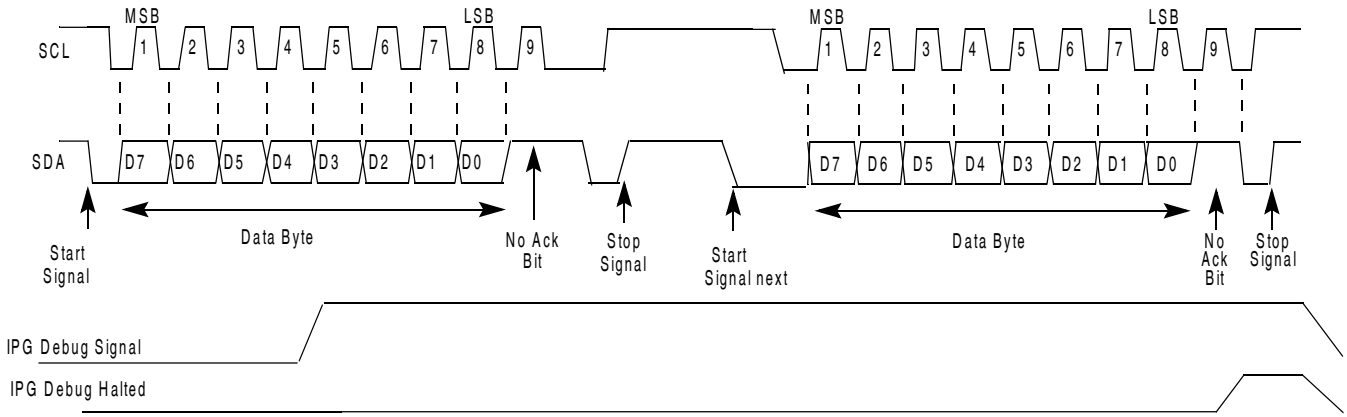

Figure 45-11. DEBUG mode

The following figure shows a case of DEBUG mode with repeated START transaction. In this case, if the debug signal is asserted in between the transaction, the entire transaction with multiple repeated start will be completed before the I^2C module enters DEBUG mode.

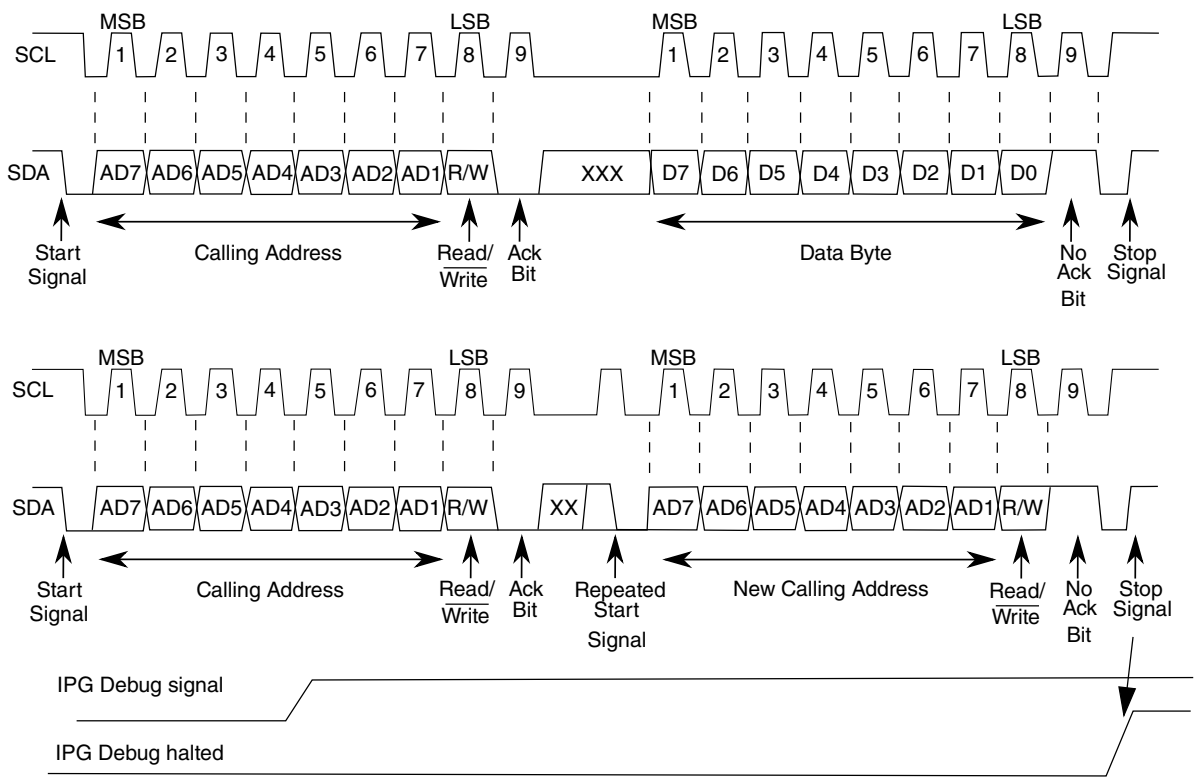

Figure 45-12. DEBUG mode with repeated start

45.6.8 DMA interface

A simple DMA interface is implemented so that the I^2C can request data transfers with minimal support from the CPU (see DMA application information). DMA mode is enabled by setting bit 1 in the Control Register (IBCR).

The DMA interface is operational when the I^2C module is configured for Master mode.

At least three bytes of data per frame must be transferred from/to the slave when using DMA mode, although in practice it will only be worthwhile using the DMA mode when there is a large number of data bytes to transfer per frame.

Two internal signals, TX request and RX request, are used to signal the DMA controller when the I^2C module requires data to be written or read from the data register.

Further details of the DMA interface can be found in the Initialization/application information, of this document.

45.7 Initialization/application information

This section presents the following topics:

- Recommended interrupt service flow
- General programming guidelines (for both master and slave mode)
- Programming guidelines specific to master mode
- Programming guidelines specific to slave mode
- DMA application information

45.7.1 Recommended interrupt service flow

The following figure shows a flowchart for the recommended I^2C interrupt service routine. Deviation from the flowchart may result in unpredictable I^2C bus behavior.

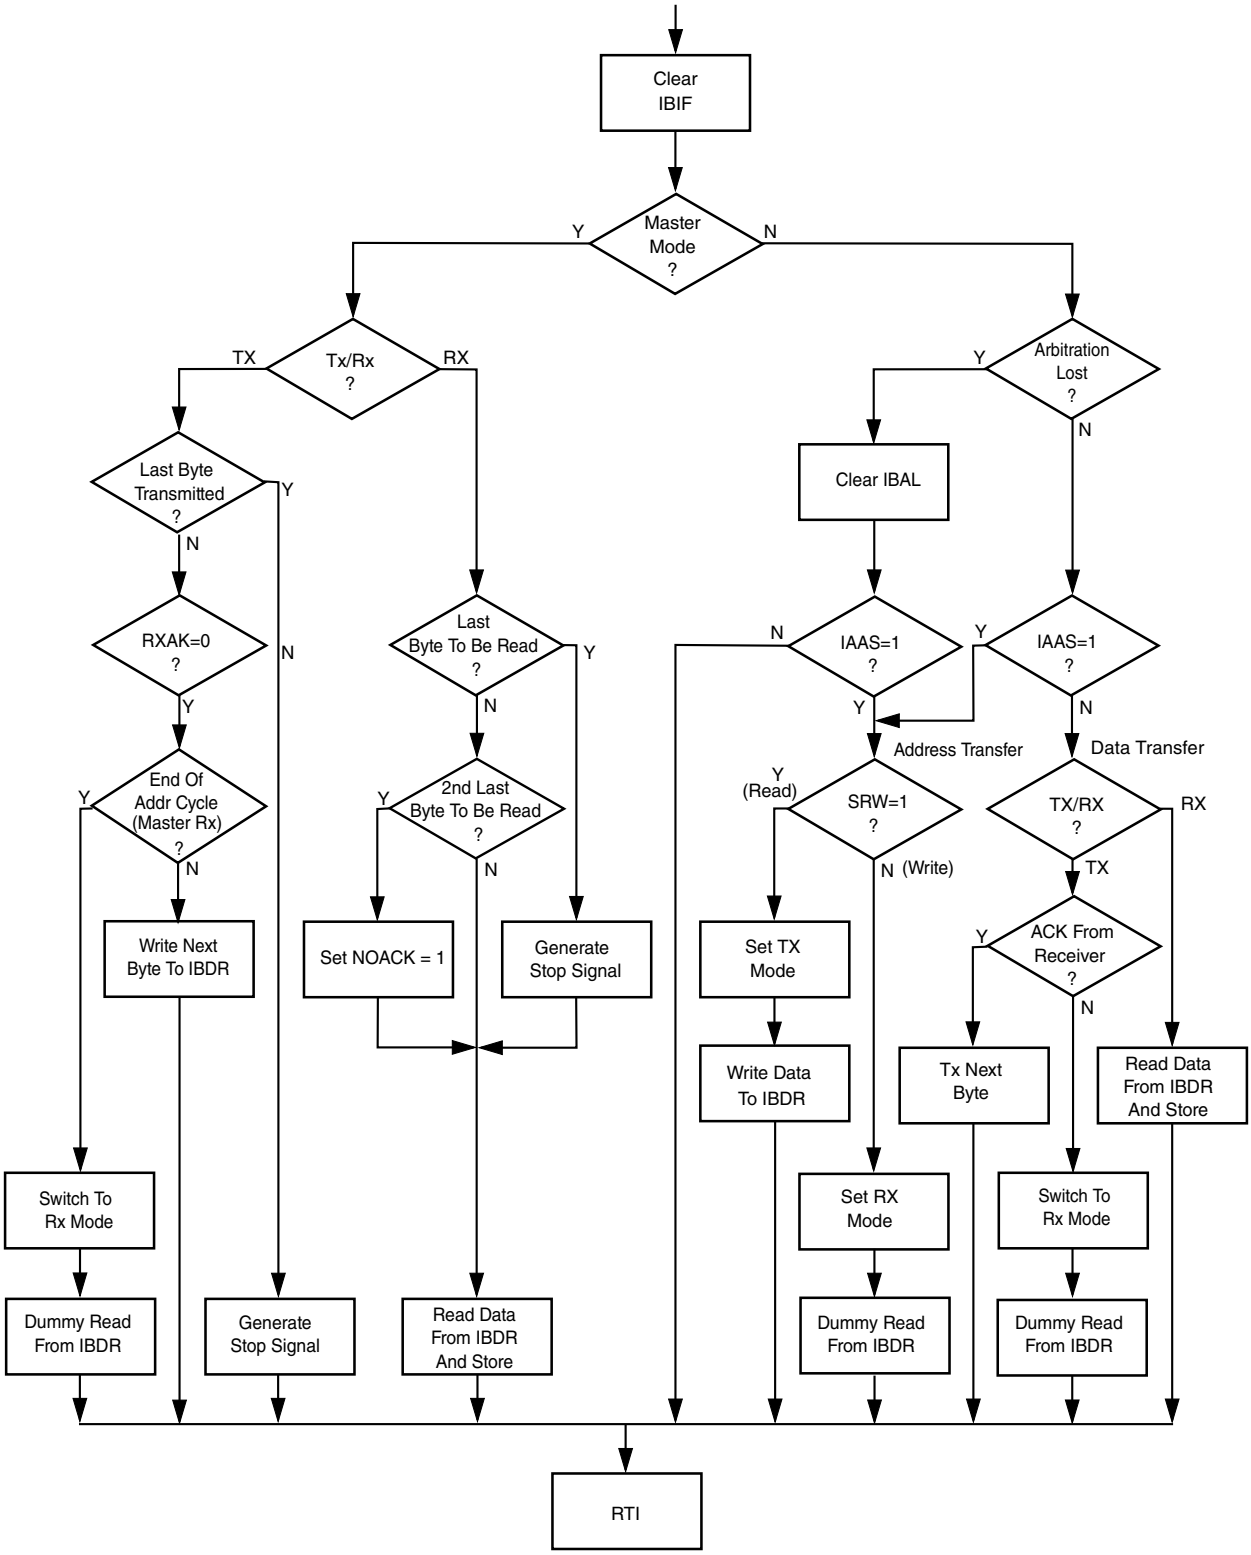

Figure 45-13. Recommended I²C interrupt service routine flowchart

45.7.2 General programming guidelines (for both master and slave mode)

This section provides programming guidelines recommended for the I2C module in both master and slave mode. It presents the following topics:

- Initializing the I2C module
- Software response after a transfer

45.7.2.1 Initializing the I2C module

The following table describes how to initialize the I2C module.

Table 45-11. I2C initialization procedure

Step	Action
1	Use I2C Bus Frequency Divider Register (I2C_IBFD) to select the required division ratio to obtain SCL frequency from the system clock.
2	Use I2C Bus Address Register (I2C_IBAD) to define the slave address.
3	Clear the MDIS field in I2C Bus Control Register (I2C_IBCR) to enable the I2C interface system.
4	Use I2C Bus Control Register (I2C_IBCR) to select Master/Slave mode, Transmit/Receive mode, and whether interrupts are enabled or disabled.
5	(Optional) Use I2C Bus Interrupt Config Register (I2C_IBIC) to further refine the interrupt behavior.

45.7.2.2 Software response after a transfer

Transmission or reception of a byte will set the data transferring bit (TCF) to 1, which indicates one byte communication is finished. The I2C Bus interrupt bit (IBIF) is set also; an interrupt will be generated if the interrupt function is enabled during initialization by setting the IBIE bit. The IBIF (interrupt flag) can be cleared by writing one (in the interrupt service routine, if interrupts are used).

The TCF bit will be cleared to indicate data transfer in progress whenever data register is written to in transmit mode, or during reading out from data register in receive mode. The TCF bit should not be used as a data transfer complete flag as the flag timing is dependent on a number of factors including the I2C bus frequency. This bit may not conclusively provide an indication of a transfer complete situation. It is recommended that transfer complete situations are detected using the IBIF flag.

Software may service the I^2C I/O in the main program by monitoring the IBIF bit if the interrupt function is disabled. Polling should monitor the IBIF bit rather than the TCF bit since their operation is different when arbitration is lost.

When a "Transfer Complete" interrupt occurs at the end of the address cycle, the master will always be in transmit mode, i.e. the address is transmitted. If master receive mode is required, indicated by R/W bit sent with slave calling address, then the Tx/Rx bit at Master side should be toggled at this stage. If Master does not receive an ACK from Slave, then transmission must be re-initiated or terminated.

In slave mode, IAAS bit will get set in IBSR if Slave address (IBAD) matches the Master calling address. This is an indication that Master-Slave data communication can now start. During address cycles (IBSR[IAAS]=1), the SRW bit in the status register is read to determine the direction of the subsequent transfer and the Tx/Rx bit is programmed accordingly. For slave mode data cycles (IBSR[IAAS]=0), the SRW bit is not valid. The Tx/Rx bit in the control register should be read to determine the direction of the current transfer.

45.7.3 Programming guidelines specific to master mode

This section presents the following topics:

- Generating START
- Transmit/receive sequence
- Generating STOP
- Generating repeated START
- Loss of arbitration

45.7.3.1 Generating START

After completion of the initialization procedure, serial data can be transmitted by selecting the 'master transmitter' mode. If the device is connected to a multi-master bus system, the state of the I^2C Bus Busy bit (IBB) must be tested to check whether the serial bus is free.

If the bus is free (IBB=0), the start condition and the first byte (the slave address) can be sent. The data written to the data register comprises the slave calling address and the LSB, which is set to indicate the direction of transfer required from the slave.

The bus free time (i.e., the time between a STOP condition and the following START condition) is built into the hardware that generates the START cycle. Depending on the relative frequencies of the system clock and the SCL period, it may be necessary to wait until the I^{2}C is busy after writing the calling address to the IBDR before proceeding with the following instructions. This is illustrated in the following example.

An example of the sequence of events which generates the START signal and transmits the first byte of data (slave address) is shown below:

```
while (IBSR[IBB]==1)                // wait in loop for IBB flag to clear
IBCR[MS/MSL] and IBCR[]Tx/Rx] = 1    // master and transmit mode, that is,
                                    // generate start condition
IBDR = calling_address              // send the calling address to the data register
while (bit 5, IBSR ==0)             // wait in loop for IBB flag to be set
```

45.7.3.2 Transmit/receive sequence

The following tables present the sequences for:

- Master transmit
- Master receive
- Slave transmit
- Slave receive

Table 45-12. Master transmit sequence

Step	Action
a	Use I2C Bus Frequency Divider Register (I2C_IBFD) to select the required division ratio to obtain SCL frequency from Platform clock/2.
b	Write 0 to the IBDIS field in I2C Bus Control Register (I2C_IBCR) to enable the I^{2}C interface system.
c	Use I2C Bus Control Register (I2C_IBCR) to select Master mode, Transmit mode, and interrupt enable.
d	Write 0 to the IBIF field in I2C Bus Status Register (I2C_IBSR).
e	Write data to I2C Bus Data I/O Register (I2C_IBDR).
f	Observe changes in the TCF field of I2C Bus Status Register (I2C_IBSR) : • When IBSR[TCF] becomes 0, the transfer is in progress. • When IBSR[TCF] becomes 1, the transfer is complete.
g	Wait until the IBIF field in I2C Bus Status Register (I2C_IBSR) becomes 1.
h	Read the fields in I2C Bus Status Register (I2C_IBSR) to determine what happened: • If TCF = 1, the transfer completed. • If RXAK = 1, a No Acknowledge condition occurred. • If IBB = 0, the bus transitioned from Busy to Idle state. • If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1). **NOTE:** You can ignore Address Detect (IAAS = 1) for master mode (it is valid only for slave mode).
i	Examine the RXAK field in I2C Bus Status Register (I2C_IBSR) for an acknowledgment from the slave.
j	Repeat steps d through i to transfer the next consecutive bytes of data.

Table 45-13. Master receive sequence

Step	Action
a	Follow steps a through i in Table 45-12 for address dispatch.
b	Write 0 to the IBIF field in I2C Bus Status Register (I2C_IBSR).
c	Write 0 to the TXRX field in I2C Bus Control Register (I2C_IBCR) to select Receive mode.
d	Perform a dummy read of I2C Bus Data I/O Register (I2C_IBDR) to initiate the receive operation.
e	Wait until the TCF field in I2C Bus Status Register (I2C_IBSR) becomes 1. (This proves that the transfer is complete.)
f	Wait until the IBIF field in I2C Bus Status Register (I2C_IBSR) becomes 1.
g	Read the fields in I2C Bus Status Register (I2C_IBSR) to determine what happened: • If TCF = 1, the reception completed. • If IBB = 0, the bus transitioned from Busy to Idle state. • If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1). **NOTE:** You can ignore the No Acknowledge condition (RXAK = 1) for receive mode.
h	Read I2C Bus Data I/O Register (I2C_IBDR) to determine the data received from the slave.

Table 45-14. Slave transmit sequence

Step	Action
a	Use I2C Bus Address Register (I2C_IBAD) to define the slave address.
b	Write 0 to the IBDIS field in I2C Bus Control Register (I2C_IBCR) to enable the I^2C interface system.
c	Examine fields in I2C Bus Status Register (I2C_IBSR) as follows: • If IAAS = 1, examine IBSR[SRW]. • If IAAS = 1 and SRW = 1, write 1 to IBCR[TXRX] to select Transmit mode.
d	Write data to I2C Bus Data I/O Register (I2C_IBDR).
e	Wait until the IBIF field in I2C Bus Status Register (I2C_IBSR) becomes 1.
f	Wait until the RXAK field in I2C Bus Status Register (I2C_IBSR) becomes 0.
g	Write 0 to the IBIF field in I2C Bus Status Register (I2C_IBSR).
h	Repeat steps d through g for the next consecutive data transfers.

Table 45-15. Slave receive sequence

Step	Action
a	Use I2C Bus Address Register (I2C_IBAD) to define the slave address.
b	Write 0 to the IBDIS field of I2C Bus Control Register (I2C_IBCR) to enable the I^2C interface system.
c	Examine fields in I2C Bus Status Register (I2C_IBSR) as follows: • If IAAS = 1, examine IBSR[SRW]. • If IAAS = 1 and SRW = 0, write 0 to IBCR[TXRX] to select Receive mode.
d	Write 0 to the IBIF field of I2C Bus Status Register (I2C_IBSR).
e	Perform a dummy read of I2C Bus Data I/O Register (I2C_IBDR) to initiate the receive operation.
f	Wait until the TCF field of I2C Bus Status Register (I2C_IBSR) becomes 1. (This proves that the transfer is complete.)
g	Wait until the IBIF field of I2C Bus Status Register (I2C_IBSR) becomes 1.

Table continues on the next page...

Table 45-15. Slave receive sequence (continued)

Step	Action
h	Read the fields in I2C Bus Status Register (I2C_IBSR) to determine what happened: • If TCF = 1, the reception completed. • If IBB = 0, the bus transitioned from Busy to Idle state. • If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1). **NOTE:** You can ignore the No Acknowledge condition (RXAK = 1) for receive mode.
i	Read I2C Bus Data I/O Register (I2C_IBDR) to determine the data received from the master.

45.7.3.3 Generating STOP

A data transfer ends with a STOP signal generated by the 'master' device. A master transmitter can simply generate a STOP signal after all the data has been transmitted. The following is an example showing how a STOP condition is generated by a master transmitter.

```
if (tx_count == 0) or      // check to see if all data bytes have been transmitted
  (bit 0, IBSR == 1) {     // or if no ACK generated
    clear bit 5, IBCR      // generate stop condition
  }
else {
 IBDR = data_to_transmit   // write byte of data to DATA register
   tx_count --             // decrement counter
 }                         // return from interrupt
```

If a master receiver wants to terminate a data transfer, it must inform the slave transmitter by not acknowledging the last byte of data which can be done by setting the NOACK bit in IBCR before reading the 2nd last byte of data. Before reading the last byte of data, a STOP signal must first be generated. The following is an example showing how a STOP signal is generated by a master receiver.

```
rx_count --             // decrease the rx counter
if (rx_count ==1)       // 2nd last byte to be read ?
 bit 3, IBCR = 1        // disable ACK
 if (rx_count == 0)     // last byte to be read ?
 bit 5, IBCR = 0        // generate stop signal
else
data_received = IBDR    // read RX data and store
```

45.7.3.4 Generating repeated START

At the end of data transfer, if the master still wants to communicate on the bus, it can generate another START signal followed by another slave address without first generating a STOP signal. A program example is as shown.

```
bit 2, IBCR = 1             // generate another start (restart)
IBDR == calling_address     // transmit the calling address
```

45.7.3.5 Loss of arbitration

If several masters try to engage the bus simultaneously, only one master wins and the others lose arbitration. The devices that lost arbitration are immediately switched to slave mode by the hardware. Their data output to the SDA line is stopped, but SCL is still generated until the end of the byte during which arbitration was lost. An interrupt occurs at the falling edge of the ninth clock of this transfer with IBAL=1 and MS/SL=0. If one master attempts to start transmission, while the bus is being engaged by another master, the hardware will inhibit the transmission, switch the MS/SL bit from 1 to 0 without generating a STOP condition, generate an interrupt to CPU, set the IBAL to indicate that the attempt to engage the bus is failed, and not set the TCF due to the loss of data during arbitration. When considering these cases, the slave service routine should test the IBAL first and the software should clear the IBAL bit if it is set.

45.7.4 Programming guidelines specific to slave mode

In the slave interrupt service routine, the module addressed as slave bit (IAAS) should be tested to check if a calling of its own address has just been received. If IAAS is set, software should set the transmit/receive mode select bit (Tx/Rx bit of IBCR) according to the R/W command bit (SRW). Writing to the IBCR clears IAAS automatically. Note that the only time IAAS is read as set is from the interrupt at the end of the address cycle where an address match occurred. Interrupts resulting from subsequent data transfers will have IAAS cleared. A data transfer may now be initiated by writing information to IBDR for slave transmits or dummy reading from IBDR in slave receive mode. The slave will drive SCL low in-between byte transfers, SCL is released when the IBDR is accessed in the required mode.

In slave transmitter routine, the received acknowledge bit (RXAK) must be tested before transmitting the next byte of data. Setting RXAK means an "end of data" signal from the master receiver, after which it must be switched from transmitter mode to receiver mode by software. A dummy read then releases the SCL line so that the master can generate a STOP signal.

45.7.5 DMA application information

The DMA interface on the I^2C is not completely autonomous and requires intervention from the CPU to start and to terminate the frame transfer. DMA mode is only valid for Master transmit and Master receive modes. Software must ensure that the DMAEN field in I2C Bus Control Register (I2C_IBCR) is not set when the I^2C module is configured in slave mode.

The DMA controller must only transfer one byte of data per Tx/Rx request. This is because there is no FIFO on the I^2C block.

The CPU should also keep the I^2C interrupt enabled during a DMA transfer to detect the arbitration lost condition and take action to recover from this situation. The DMAEN field in I2C Bus Control Register (I2C_IBCR) works as a disable for the transfer complete interrupt. This means that during normal transfers (no errors) there will always be either an interrupt or a request to the DMA controller, depending on the setting of the DMAEN field. All error conditions will trigger an interrupt and require CPU intervention. The address match condition will not occur in DMA mode as the I^2C should never be configured for slave operation.

The following sections detail how to set up a DMA transfer and what intervention is required from the CPU. It is assumed that the system DMA controller is capable of generating an interrupt after a certain number of DMA transfers have taken place.

The sections present the following topics:

- DMA mode, master transmit
- DMA mode, master reception
- Exiting DMA mode, system requirement considerations

45.7.5.1 DMA mode, master transmit

The following flow diagram details exactly the operation for using a DMA controller to transmit "n" data bytes to a slave. The first byte (the slave calling address) is always transmitted by the CPU. All subsequent data bytes (apart from the last data byte) can be transferred by the DMA controller. The last data byte must be transferred by the CPU.

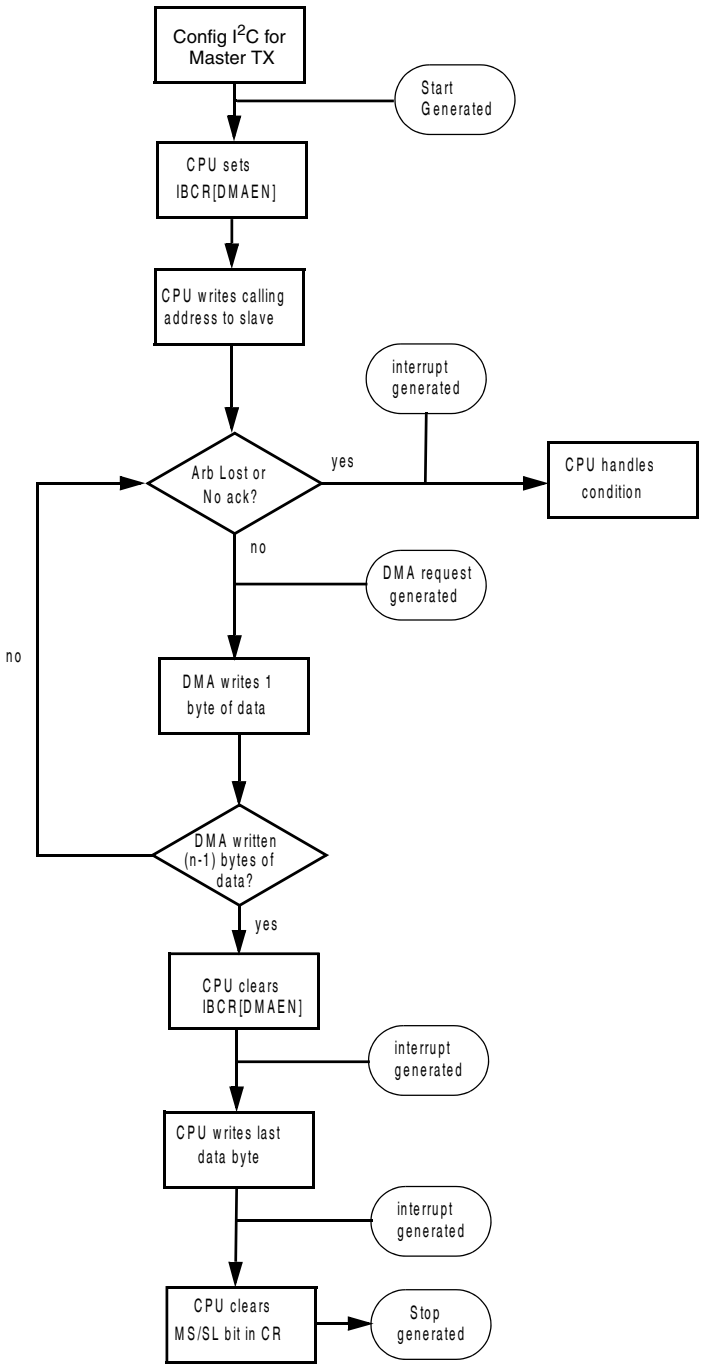

Figure 45-14. Flow-Chart of DMA mode master transmit

45.7.5.2 DMA mode, master reception

The following flow diagram details the exact operation for using a DMA controller to receive "n" data bytes from a slave. The first byte (the slave calling address) is always transmitted by the CPU. All subsequent data bytes (apart from the two last data bytes) can be read by the DMA controller. The last two data bytes must be transferred by the CPU.

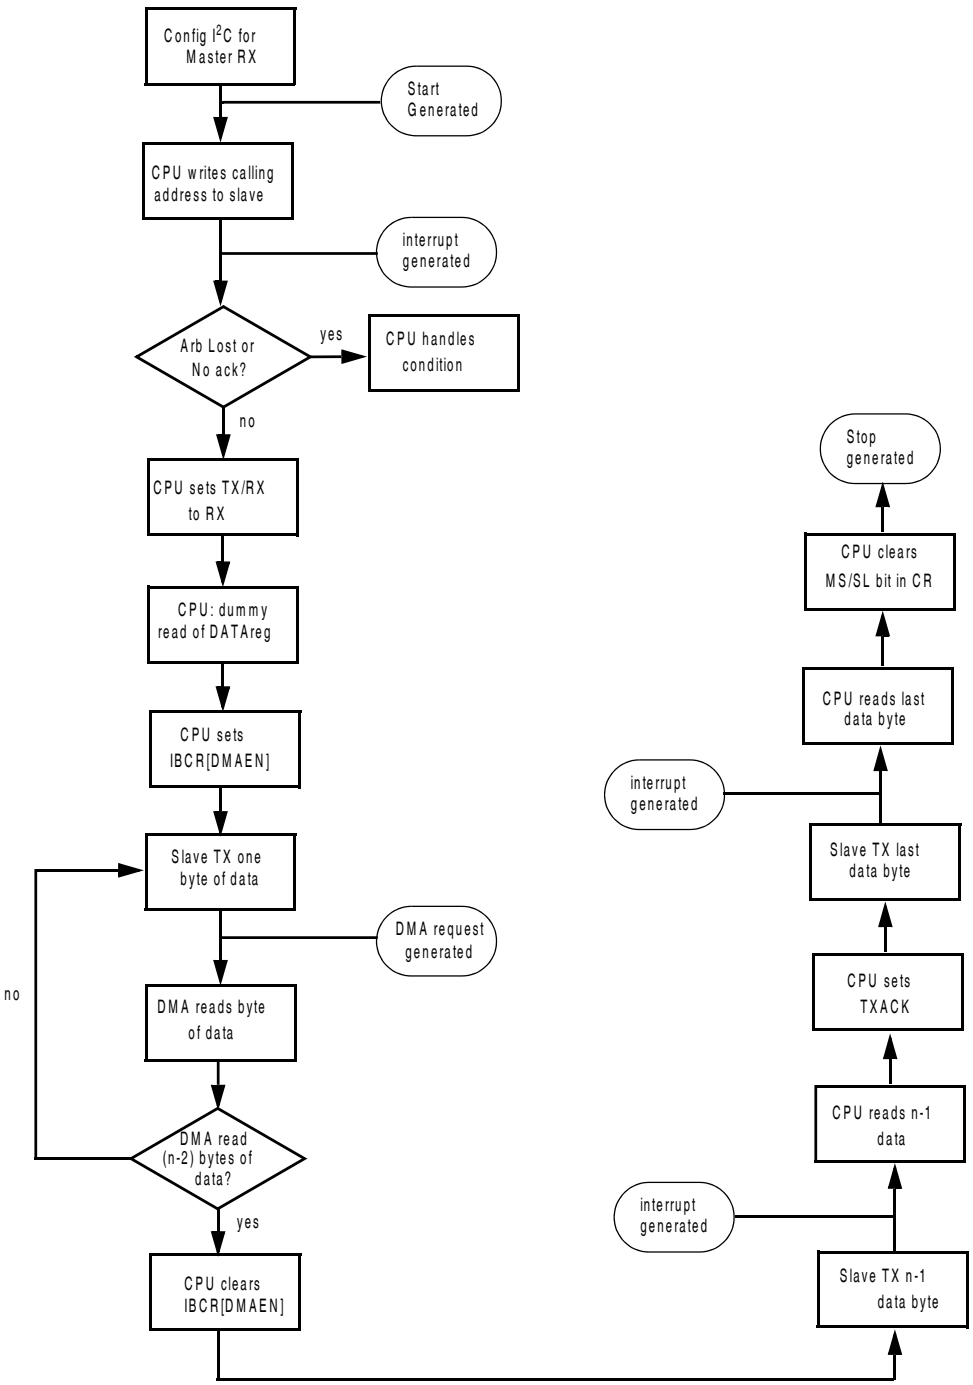

Figure 45-15. Flow-Chart of DMA mode master receive

45.7.5.3 Exiting DMA mode, system requirement considerations

As described above, the final transfers of both TX and RX transfers need to be handled via interrupt by the CPU. To change from DMA to interrupt driven transfers in the I^2C module, you have to disable the DMAEN bit in the IBCR register. The trigger to exit the DMA mode is that the programmed DMA Transfer Control Descriptor (TCD) has completed all its transfers to/from the I^2C module.

After the last DMA write (TX mode) to the I^2C the module will immediately start the next I^2C-bus transfer. The same is true for receive mode. After the DMA read from the IBDR register the module initiates the next I^2C-bus transfer. This results in two possible scenarios in the DMA mode exiting scheme.

1. Fast reaction

   The DMAEN bit is cleared before the next I^2C-bus transfer completes. In this case the module will raise an interrupt request to the CPU which can be serviced normally.

2. Slow reaction

   The DMAEN bit is cleared after the next I^2C-bus transfer has already completed. In this case, the module will not raise an interrupt request to the CPU. Instead the TCF bit can be read to determine that the transfer completed and the module is ready for further transfer.

What is fast/slow reaction?

The reaction time T_R for the system to disable DMAEN after the last DMA controller access to the I^2C is the time required for one byte transfer over the I^2C. For 'fast reaction' the disabling has to occur before the 9^{th} bit of the data transfer which is the ACK bit. So the time available is eight times the SCL period.

$$T_R = 8 \times T_{SCL}$$

In fast mode, with 400kbit/s, T_{SCL} is 2.5µs, so T_R is 20µs.

Depending on the system and DMA controller there are different possibilities for the de-assertion of DMAEN. Three options are:

1. CPU intervention via Interrupt

   The DMA controller is programmed to signal an interrupt to the CPU which is then responsible for the de-assertion of DMAEN. This scheme should be supported by most systems but it can result in a slow reaction time if other higher priority

interrupts interfere. Therefore the interrupt handling routine can become complicated as it has to check which of the two cases happened (check TCF bit) and act accordingly. In case of slow reaction you can force an interrupt for the I^2C in the interrupt controller to have the further transfer handled by the normal I^2C interrupt routine.

Note

The use of nested interrupts can still cause potential issues in this scenario, if someone tries to stall the DMA interrupt between the de-assertion and DMAEN bit and checks the TCF bit.

2. DMA channel linking

   If the Transfer control descriptor in the DMA controller that performs the data transfer is linked to another channel that does a write to IBCR to disable the DMAEN field, this might probably be the fastest system solution, but it uses two DMA channels.

   Note

   Here you have to make sure on system level that no higher priority DMA requests occur between the two linked TCDs as those could again create a scenario of slow reaction.

3. DMA scatter/gather process

   If the Transfer control descriptor in the DMA controller that performs the data transfer has the scatter/gather feature activated, this feature will initiate a reload of another TCD from system RAM after the completion of the first TCD. The new TCD will have its start bit already set and immediately start the required write to the IBCR to disable the DMAEN field. This TCD also has scatter/gather activated and is programmed to reload the initial TCD upon completion, bringing the system back into a "ready-for-I^2C-transfer" state. The advantage over the two other solutions is that this requires neither CPU intervention nor a second DMA channel. This comes at the cost of 64 bytes RAM (two TCDs), some system bus transfer overhead and a little increase in application code complexity.

Note

Here you have to make sure at system level that no higher priority DMA requests occur during the scatter/gather process, as those could again create a scenario of slow reaction.

Example latencies for a 32 MHz system with a full speed 32-bit AHB bus and an I^2C connected via half speed IPI bus:

- Accessing the I^2C from the DMA controller via IPI bus typically requires four cycles (consecutive accesses to the I^2C could be faster):

  $4 \times T_{IPI}$ = 4/16 MHz = 250 ns

- Reloading a new TCD (8 x 32-bit) via AHB to the DMA controller (scatter/gather process):

  $8 \times T_{AHD}$ = 8/32 MHz = 250 ns

Example latencies for a 150 MHz system with a full speed 32-bit AHB bus and an I^2C connected via half speed IPI bus:

- Accessing the I^2C from the DMA controller via IPI bus typically requires four cycles (consecutive accesses to the I^2C could be faster):

  $4 \times T_{IPI}$ = 4/150 MHz = 26.6 ns

- Reloading a new TCD (4 x 64-bit) via AHB to the DMA controller (scatter/gather process):

  $4 \times T_{AHD}$ = 4/150 MHz = 26.6 ns

With the DMA scatter/gather process the required IBCR access can be done in 0.5 µs, leaving a large margin of 19.5 µs for additional system delays. In this way, the slow reaction case can be prevented. The system user needs to decide which usage model best suits his overall requirement.

Chapter 46
LINFlexD

46.1 Chip-specific LINFlexD information

46.1.1 LINFlexD configurations

The device contains 16 LINFlexD instances. The following table shows the instantiation information for each module.

Table 46-1. LINFlexD configurations

Description	LINFlexD[0]	LINFlexD[1]	LINFlexD[2....15]
Number of filters implemented (Identifier Filter Control Register (LINFlexDx_IFCRn))	16	0	0
Number of Tx DMA channels	1	1	0
Number of Rx DMA channels	1	1	0
LIN operation mode	Master and Slave	Master only	Master only
Autosyncronization	Yes	No	No
DMA Support	Yes	Yes	No

UART Support - LINFlexD modules support UART operation up to 1 Mbps.

The LINFlex modules implemented on MPC5746C do not support communication with Special Word Length in UART mode set (UARTCR[WLS]=1) in buffer mode or in FIFO mode with UARTCR[WL1, WL0]=0,1.

NOTE

When LINFlex is in idle state the TX pins are set to high-impedance. If LIN transceiver does not have internal pull-up an external pull-up may be required.

LINFlexD expects the RX pin to be high whenever it is enabled via programming of MC_ME_PCTL. In case the SIUL programming is done after PCTL is enabled, WUF flag of LINSR register would be set.

46.1.2 LinflexD's stop-stop ack protocol

1. An acknowledgement to stop request is sent only after the current transfer/reception or DMA transfer request of the programmed data bytes is completed and the state machine goes to idle.
2. If the module reset is asserted the stop request is acknowledged immediately.

46.2 Introduction

The LINFlexD controller is designed to manage a high number of LIN messages efficiently with a minimum of CPU load. To reduce the CPU loading in Master mode, LINFlexD autonomously handles the LIN messages once software has triggered the header transmission, until the next header transmission request in transmitter mode or until checksum reception in the receiver mode.

The LINFlexD supports LIN protocol version 1.3, 2.0, and 2.1. It also consists of an 8-byte buffer for transmission/reception data.

The LINFlexD also provides support for some of the basic UART transfers of 8-bit, 9-bit, 16-bit, and 17-bit frames and also 12-bit data frame + parity reception in UART mode for MSC support.

The LINFlexD supports multi-channels and parametric DMA Tx/Rx interface in LIN/UART operating mode.

46.2.1 Glossary and acronyms

Table 46-2. Glossary and acronyms

Term	Description
LIN	Local interconnect network
UART	Universal asynchronous transmitter receiver
ID	LIN identifier field
DMA	Direct memory access
TCD	Transfer control descriptor
IPS	Peripheral Bus Interface

Table continues on the next page...

Table 46-2. Glossary and acronyms (continued)

Term	Description
IRQ	Interrupt request
FSM	Finite state machine
WS	Wait state
SW	Software
CPU	Central processing unit
SoC	System on a chip

46.2.2 References

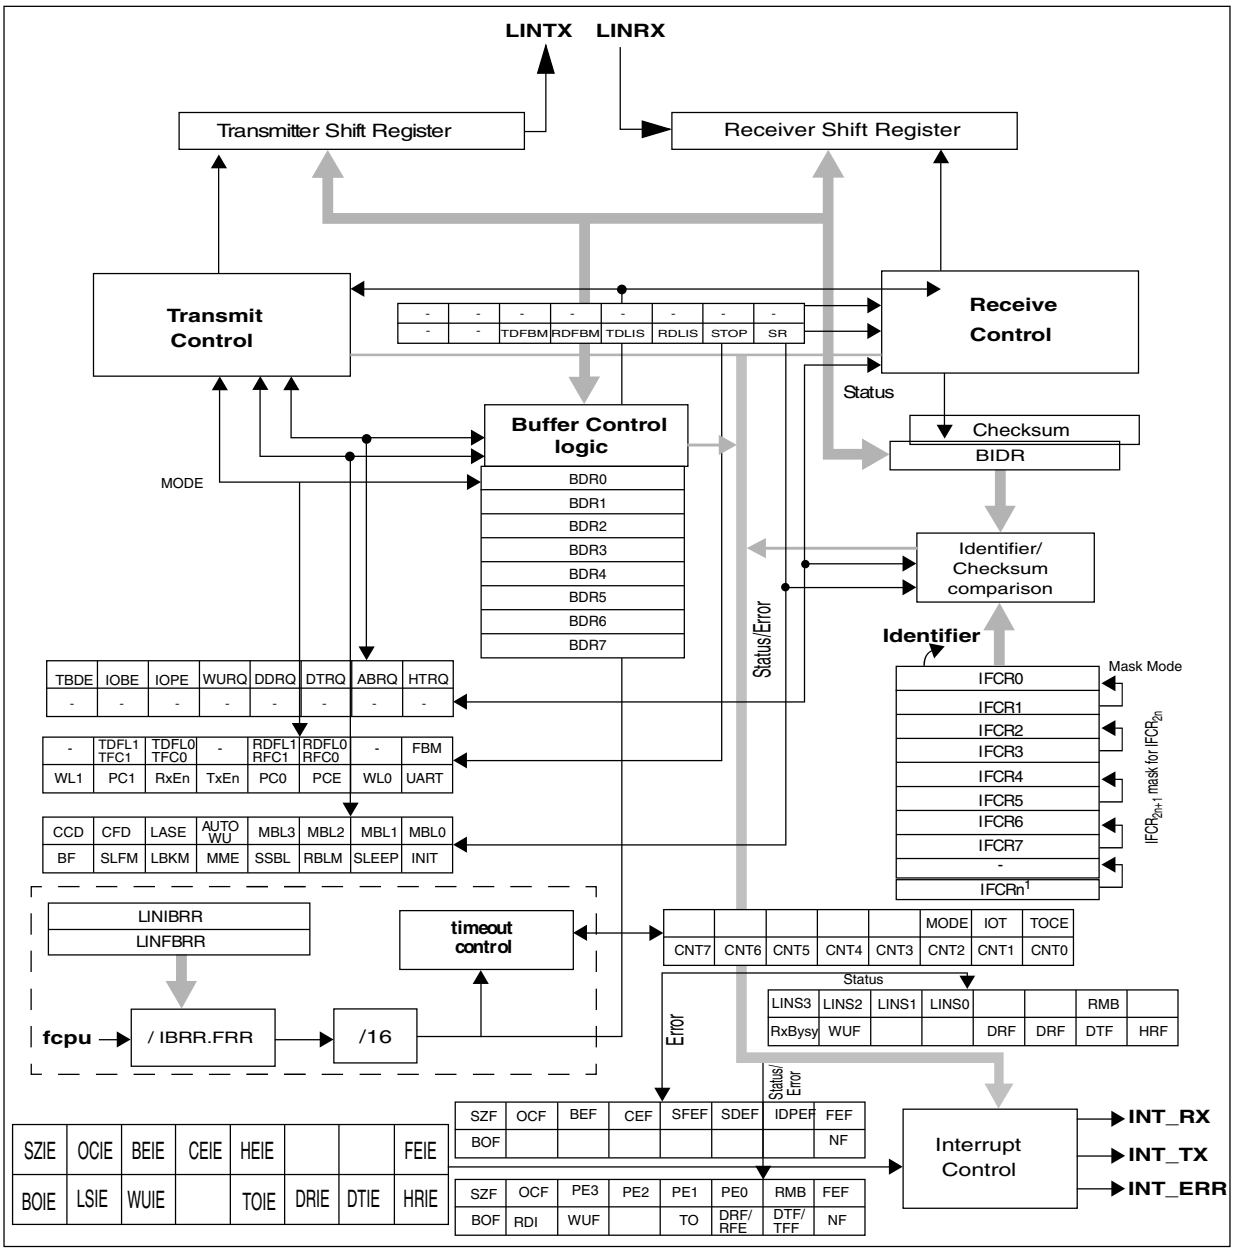

Figure 46-1. Block diagram

Notes:

1: The value of n depends on the no_of_filters. Refer to the chip configuration details to see the number of filters used in this device.

2: For LIN mode N = 16 and N is programmable by user in UART mode.

46.3 Main features

The LINFlexD controller can operate in several modes, each of which has a distinct set of features that are described in the following sections. In addition, the LINFlexD controller has several features common to all modes:

- Fractional baud rate generator
- 3 operating modes for power saving and configuration registers lock
  - Initialization
  - Normal
  - Sleep
- Test Mode:Loop Back
- Maskable interrupts
- A maximum of 16 possible identifiers can be programmed into the identifier list

46.3.1 LIN mode features

- Supports LIN protocol version 1.3, 2.0, and 2.1
- Bit rates up to 20 Kbit/s (LIN protocol)
- Master/Slave mode
- Classic and Enhanced Checksum calculation and check
- Single 8-byte buffer or FIFO for Transmission/Reception
- Timeout management
- Identifier filters
- DMA interface
- Supports a maximum of 16 possible identifiers
- Master mode with autonomous message handling
- Wakeup event on dominant bit detection
- True LIN field state machine

- Advanced LIN error detection
- Header, response, and frame timeout
- Slave mode
  - Autonomous header handling
  - Autonomous transmit/receive data handling
- Identifier filters for autonomous message handling in Slave mode
- Separate clock for baud rate calculation
  - The relationship “(2/3)* LIN_CLK > PBRIDGEx_CLK > 1/3*LIN_CLK” should be maintained.

46.3.2 UART mode features

- Full-duplex communication
- Baud rate is a function of baud clock, LINIBRR and LINFBRR registers - see Baud rate generation
- Separate clock for baud rate calculation
  - The relationship “(2/3)* LIN_CLK > PBRIDGEx_CLK > 1/3*LIN_CLK” should be maintained.
- 15/16/7/8 bits data, parity
- 1/2/3 stop bits
- 12-bit + parity reception
- 4-byte buffer for reception, 4-byte buffer for transmission
- 12-bit counter for timeout management
- The maximum baud rate achievable is 25 Mbit/s.
- For bit rate ≤ 6.25 Mbit/s
  - Sixteen times oversampling
  - 3:1 majority voting
- For 6.25 Mbit/s < bit rate ≤ 12.5 Mbit/s

- Reduced over sampling programmable by the user
- 3:1 majority voting for reduced over sampling of 8

- For 12.5 Mbit/s < bit rate ≤ 25 Mbit/s
  - Reduced over sampling programmable by the user
  - 1:1 voting for all reduced over sampling of 4, 5 and 6

46.4 Functional description

46.4.1 LIN protocol

The LIN (Local Interconnect Network) is a serial communication protocol. A LIN cluster consists of one master task and several slave tasks. A master node contains the master task as well as a slave task. All other nodes contain a slave task only. The master node decides when and which frame is transferred on the bus. The slave task provides the data to be transported by the frame.

46.4.1.1 Frames

A frame consists of a header provided by the master task and a response provided by the slave task. The header consists of a break, a sync pattern, and an identifier. The break is followed by the sync pattern and the sync pattern is followed by the identifier. The slave task associated with the identifier provides the response. The response consists of a data field and checksum. The slave task designated to receive the data associated with the identifier receives the response and verifies the checksum.

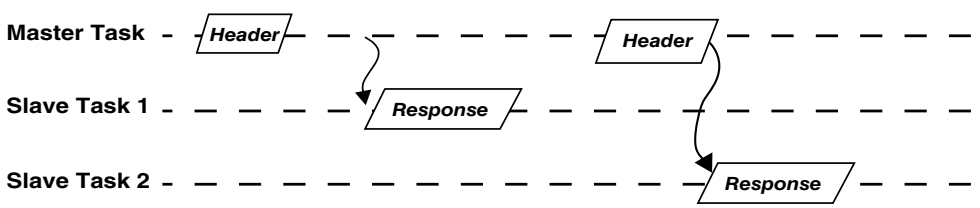

Figure 46-2. Frames

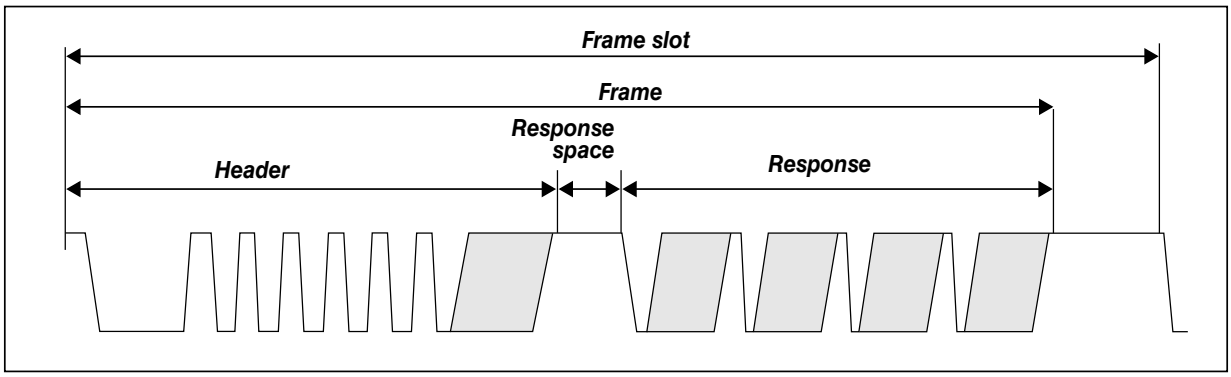

Figure 46-3. Structure of LIN frame

46.4.1.2 Data field

Each byte is transmitted as shown in Figure 46-4. The LSB of the data is sent first and the MSB is sent last. The start bit is encoded as a bit with value zero (dominant) and stop bit is encoded as bit value one (recessive).

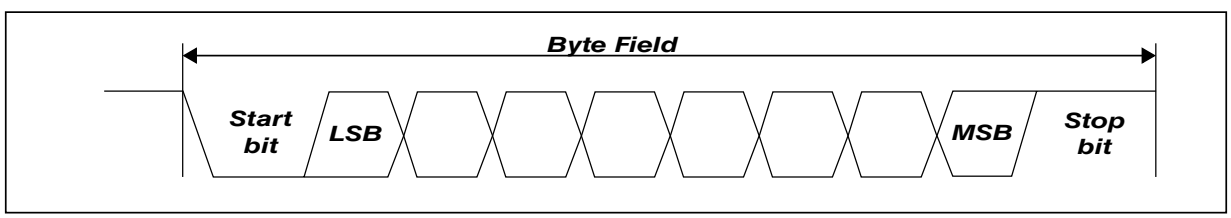

Figure 46-4. Structure of byte field

46.4.1.3 Break

The break symbol is used to signal the beginning of a new frame. It is the only field that does not comply with the above figure. The break is always generated by the master and shall be at least 13 bits of dominant value including the start bit, followed by a break delimiter as shown in Figure 46-5. The break delimiter must be of two-bit duration (to be compliant with LIN protocol 2.1).

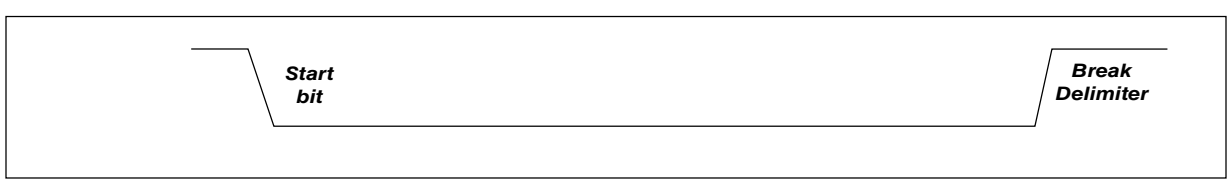

Figure 46-5. Break field

46.4.1.4 Sync byte

Sync is a byte field with the data value of 0x55.

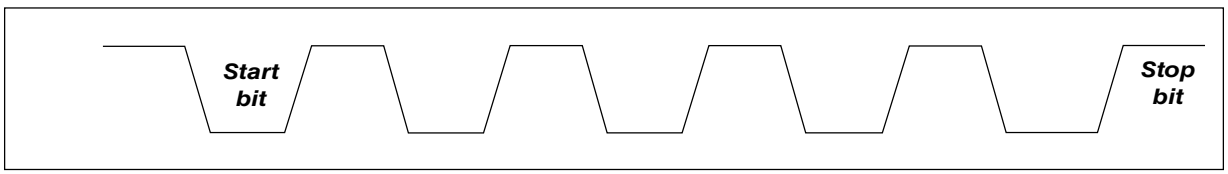

Figure 46-6. Sync byte field

46.4.1.5 Identifier

The Identifier field consists of two sub-fields, the identifier and the identifier parity. Bits 0 to 5 are the identifier and bits 6 and 7 indicate the parity.

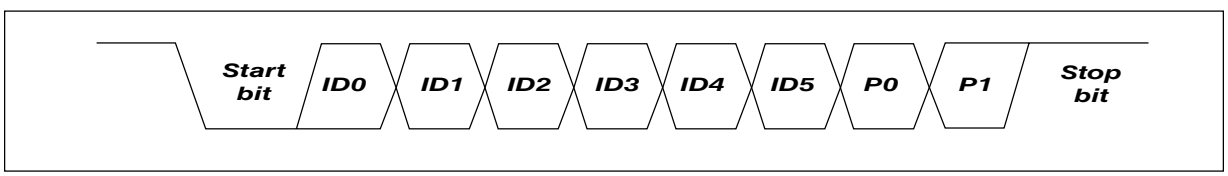

Figure 46-7. Identifier field

P0 = ID0 XOR ID1 XOR ID2 XOR ID4

P1 = NOT (ID1 XOR ID3 XOR ID4 XOR ID5)

46.4.1.6 Checksum

The last field of a frame is the checksum. The checksum contains the inverted 8-bit sum with carryover of all data bytes or all data bytes and the identifier. Checksum calculation over the data bytes only is called classic checksum and is used for communication with LIN 1.3 slaves. Checksum calculation over the data bytes and the protected identifier byte is called enhanced checksum and is used for communication with LIN 2.0 slaves.

46.4.2 LINFlexD features

46.4.2.1 Operating modes

The LINFlexD has three operating modes: **Initialization, Normal** and **Sleep** modes. After hardware reset, the LINFlexD enters sleep mode to reduce power consumption.

Initialization mode (INIT)

To enter this mode, software sets the INIT bit in the LINCR1. To exit the initialization mode, software should reset the INIT bit.

When in initialization mode, all message transfers to and from the LIN bus are stopped and the status of LIN bus output LINTX is recessive (high). If software invokes the initialization mode when a bus transfer is in progress, the transfer is aborted. The software should therefore check the LIN state before setting this bit.

To initialize the LINFlexD controller software must:

1. Set up the baud rate registers
2. Reset UART bit
3. Select the mode (master or slave)
4. Configure checksum control bits
5. Initialize the identifier list (Slave mode)

Normal mode (NM)

Once software has completed initialization of the LINFlexD controller, it can enter the Normal mode by clearing the INIT bit.

Sleep mode (SM)

Sleep mode in LINFlexD reduces power consumption. This mode is entered by setting the SLEEP bit in LINCR1. In this mode the LINFlexD clock is stopped. LINFlexD can be awakened from Sleep mode by clearing the SLEEP bit.

If software detects a wakeup pulse of 150 µs on the LIN Bus, it can request LINFlexD to wake up from Sleep mode. Refer to Wakeup management.

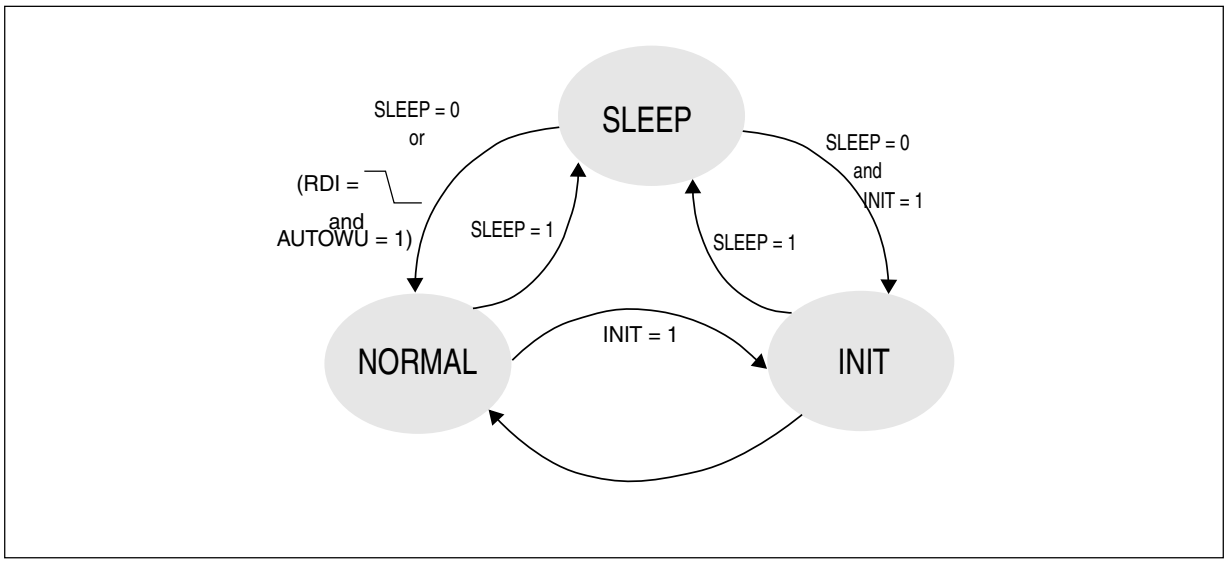

Figure 46-8. Operating modes

46.4.2.2 Test mode

Loop Back mode

This mode is entered by setting the LBKM bit in LINCR1. In this mode, the LINFlexD receives the Identifier and Data transmitted by itself and writes the same in the BIDR and Data buffers respectively. This mode is provided for selftest functions. Bit error is checked in this mode.

The LINFlexD ignores the LINRX signal. There is an internal feedback from its TX output to its RX input. The TX pin can be disconnected from LINTX pin by SIUL2 setting.

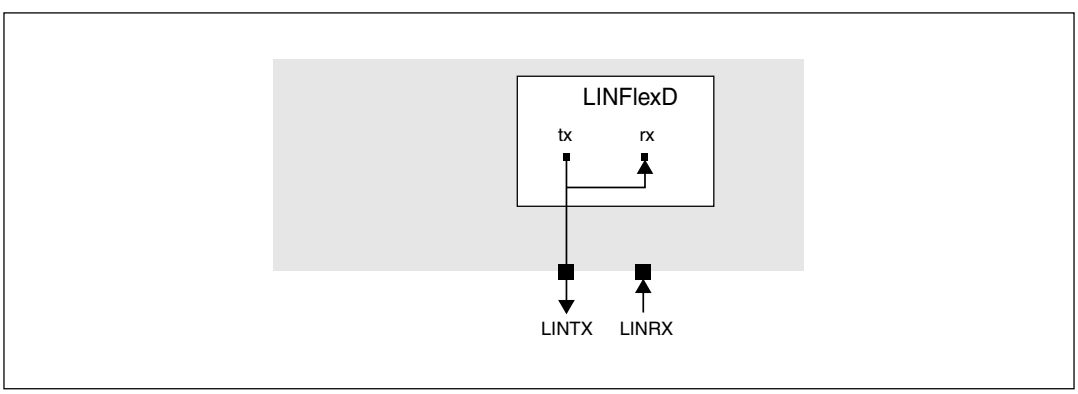

Figure 46-9. LINFlexD in Loop Back Mode

46.4.2.3 Master mode

Master mode is selected by means of the MME bit in LINCR1 register.

Header transmission

According to the LIN protocol any communication on the LIN bus is triggered by the master sending a header. The header is transmitted by the master task of a node while the response is transmitted by the slave task of a node.

To transmit the header, first program the Identifier, data field length, message direction and checksum enable in the BIDR register; then set the HTRQ bit in LINCR2. Once header transmission starts, the user should not modify BIDR register bits until the current frame is complete. The transmitted ID is also received by the master node and copied to BIDR.

Data transmission

When the master node is the publisher of the data corresponding to the Identifier sent by the master, then the slave task of the node should send the data in the response part of the frame. Hence software must provide the data to the LINFlexD before the header transmission is requested. The data to be transmitted is stored in the message buffer BDRL and BDRM. The number of bytes to be transmitted depends on the Data Field length in BIDR. The software uses the BIDR[CCS] bit to configure the checksum type (classic or enhanced) for each message.

If the response has been sent successfully, LINSR[DTF] is set. In case of error, the DTF flag is not set and the corresponding error flag is set in the LINESR (refer to error handling).

The direction of the message buffer is decided by the DIR bit in the BIDR. The transmitted data is also received by the same node and copied to the buffer.

Data reception

To receive data from a slave node, the master sends a header with the corresponding Identifier. The data received from the slave is stored in the message buffer and the status of the message is stored in the LINSR.

If the response has been received successfully, the LINSR (DRF) bit is set. In case of error, the DRF flag is not set and the corresponding error flag is set in the LINESR (refer to Error handling).

Data Discard

If the user wants to discard the data after header transmission, then the DDRQ bit in LINCR2 should be set.

46.4.2.4 Slave mode

This mode is selected when the MME bit of the LINCR1 register is cleared.

Data transmission

On header reception, the HRF bit is set and an RX interrupt is generated. The software must then:

1. Read the received ID in the BIDR register
2. Fill the BDR[0:x] register
3. Program the CCS and DIR bits in the BIDR register
4. Specify the data field length DFL bits in the BIDR register
5. Trigger the data transmission by setting the DTRQ bit

Note that the HRF bit should be reset only after the DTRQ bit is set. For the DTRQ to be effective, the HRF bit must be set. This is to ensure that DTRQ is not set randomly, but only after a header reception. It must be noted that you cannot set the DIR and DTRQ bits once RXbusy is asserted in LINSR.

Alternately, one or more Identifier filters are configured for transmission by setting the DIR bit, and activated by setting the enable bits in IFER. When at least one Identifier filter is active and configured for transmission and the received ID matches the filter, a TX interrupt is generated. The software can use the index in the IFMI register to point directly to the corresponding data array in the RAM and copy this data to the BDR[0:7].

The use of a filter saves software the processing time required to read the ID value in the BIDR, match it, and configure the data field length and checksum type.

If the number of filters provided by LINFlexD are not sufficient for the application, mask mode can be used for the filters.

The transmitted data is also received by the same node and copied to the buffer.

Data reception

When LINFlexD is the subscriber of the data of the received identifier, then on header reception the HRF flag is set and an RX interrupt is generated. The software must read the received ID from the BIDR register and specify the data field length before the reception of the stop bit of the first data byte. When the checksum is received, an RX

interrupt is generated for software to read the received data from BDR[0:7] and the RMB bit is set. Software must then release the data buffer by resetting the RMB bit in the LINSR.

When at least one identifier filter is active and configured for reception, an RX interrupt is generated only after the checksum reception. No interrupt request is generated on reception of the ID.

If the Identifier is filtered by software then you can discard the data by setting the DDRQ bit in the LINCR2, while HRF is set.

Note that for software filtering, software must decide the type of checksum (configure the CCS bit of the BIDR register) before reception of data. Otherwise the previous value of the CCS bit is considered while calculating checksum.

46.4.2.5 Errors

46.4.2.5.1 Header error

A header error is an error during the header reception. The error types are:

1. Sync Del error (SDEF)
2. Sync field error (SFEF)
3. Identifier Parity error (IDPEF)

Sync Del error (SDEF)

The delimiter should be 1 for at least one bit time; otherwise it is considered short and consequently the receiver discards synchronization on the current header. Hence the frame is discarded. An interrupt is generated if *HEIE* bit of LINEIER is set.

Sync field error (SFEF)

The SFEF error condition is monitored differently depending on whether autosynchronization (LASE) is ON or OFF.

Case 1: Autosynchronization ON (LASE bit of LINCR1 = 1):

When Autosynchronization is enabled, the SFEF flag indicates:

- The deviation error on the Sync Field is outside the LIN specification, which allows up to 14% of period deviation between the slave and master oscillators or
- An overflow has occurred during the Sync Field Measurement, which leads to an overflow of the divider registers.

Deviation error on the Sync Field

The deviation error is checked by comparing the current baud rate (relative to the slave oscillator) with the received LIN Sync Field (relative to the master oscillator).

This check is based on a measurement between the first falling edge and the last falling edge of the Sync Field. Let's refer to this period deviation as D.

If SFEF field is asserted it means that:

D > 14.0625%

If there is no error, it means that:

D < 14.84375%

If 14.0625% < D < 14.84375%, then the Sync Field could be either consistent or inconsistent depending on dephasing between the signal on the RDI line and the LIN_CLK.

Overflow during Sync Field Measurement

This check is based on the measurement of each bit time between both edges of the Sync Field. This checks that each of these bit times is large enough (more than 12 samples) compared to the bit time of the current baud rate.

Case 2: Autosynchronization OFF (LASE bit of LINCR1 = '0')

In this case the Sync character is received as a normal character. If the received character is 0x55 then the Sync Field is OK.

On any occurrence of an inconsistent Sync Field, the receiver immediately exits from Sync_Field state and the frame is consequently discarded. The SFEF bit of LINESR is set.

Identifier Parity error(IDPEF)

There are two parity bits in the identifier field. These bits are checked against the hardware-calculated parity over the other six bits of identifier, according to the formula:

P0 = ID0 XOR ID1 XOR ID2 XOR ID4

P1 = NOT (ID1 XOR ID3 XOR ID4 XOR ID5)

This parity is checked after the ID is transferred to the BIDR register (after stop of ID has been detected properly) and upon parity mismatch, the receiver state machine exits from Identifier state immediately if the IOPE bit of LINCR2 is set.

46.4.2.5.2 Bit error

This error is flagged in transmission mode when the value read back from the bus is different from the value transmitted. Bit error checking on each bit is guaranteed if transceiver delay is less than one bit time minus 6 LIN_CPU cycles. Bit error is not checked during break field transmission.

1-bit time at 20 Kbit/s = 50 µs

6 LIN_CLK cycles at 80 MHz = 75 ns

Thus, (1-bit time) - (6 LIN_CLK cycles) = 49.925 µs

Transmission of the frame is stopped after the corrupted bit if the IOBE bit in LINCR2 is set. If IOBE is reset, the transmitter continues to transmit in spite of the bit error. An interrupt is generated if the BEIER bit is set in LINIER.

Note

If the break delimiter is not detected by the master within one bit time after delimiter transmission due to transceiver delay or error on the bus, then a train of bit error interrupts are generated. In this case, the Identifier may not be replaced in the BIDR.

Similarly, if the start of a falling edge of data is not detected by the transmitter node within one bit time after start bit transmission, then a train of bit error interrupts are generated. In this case also, data and checksum replacements in the BDR and CFR respectively are not guaranteed.

46.4.2.5.3 Framing error

This error is flagged when a dominant state is sampled on stop bit of the current received character (sync field, identifier field, data field, checksum field). LINFlexD discards the current frame and returns to Idle state. An interrupt is generated if FEIE bit is set in LINEIER.

The byte that caused framing error is also shifted to the buffer but DRF is never set in this case.

46.4.2.5.4 Checksum error

This error is flagged when the checksum computed by hardware does not match the received checksum.

LINFlexD discards the received frame and returns to Idle state. An interrupt is generated if the CEIE bit is set in LINEIER.

46.4.2.5.5 Overrun error

Once the message buffer is full (RMB is set), the next valid message reception will lead to an overrun and the message will be lost. The hardware signals the overrun condition by setting the BOF bit. Which message is lost depends on the buffer lock function control bit RBLM.

If RBLM is cleared, the old message in the buffer is overwritten by the most recent message. If RBLM bit is set, the most recent message is discarded and the oldest message is available to the software. In the case of slave, if buffer is not released (RMB is not reset) before reception of next Identifier and if RBLM is set, then the ID along with the data is discarded.

46.4.2.5.6 Timeout error

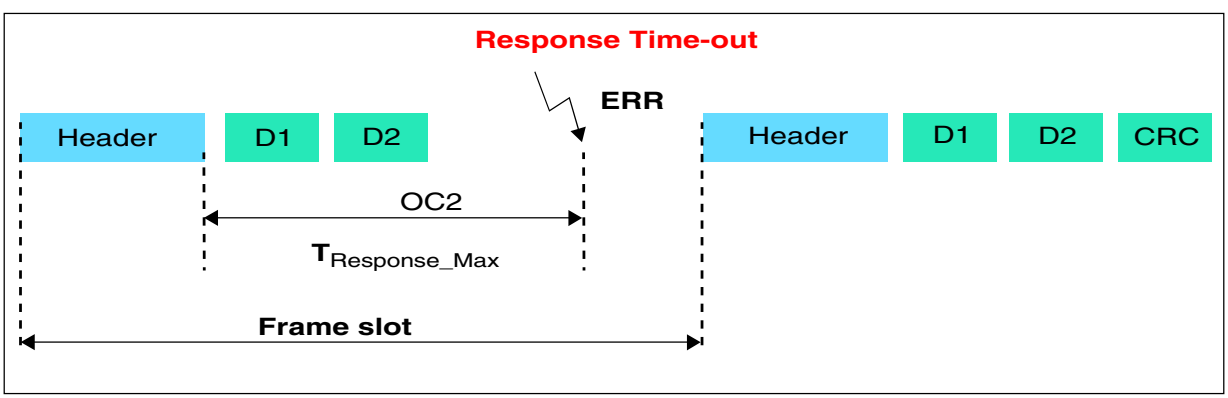

Figure 46-10. Incomplete response (for example, missing checksum)

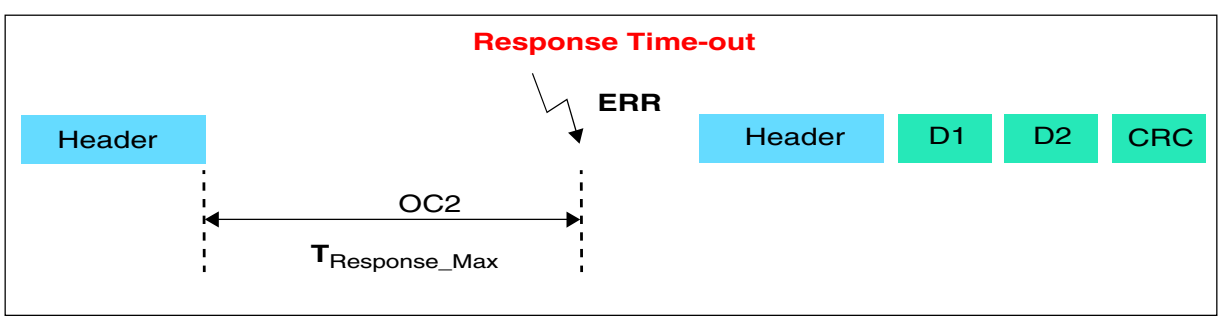

Figure 46-11. No response

Response timeout mechanism

- Master mode
  - OC2 is loaded with Nominal_time_out + LINFlexD_LINTCSR[CNT] at the end of the stop bit of the Identifier field (where nominal_time_out = 1.4 × ((DFL + 2) × 10 bit time).

    This loading takes place at the end of id field (and not at the beginning of data field). Moreover, the correct value, which depends on DFL, is loaded immediately. No further OC2 update is required.
  - In case of no response at all within this time (in other words, start of data is not received), timeout takes place when the counter reaches the OC2 value (no change compared to earlier implementation).
  - In case of an incomplete response, timeout also occurs when the counter reaches the OC2 value (no change compared to earlier implementation).
- Slave mode
  - **Case 1**: The received identifier is managed by a filter. The implementation can be similar to the master mode, because the DFL value is loaded by hardware. Thus, OC2 can be loaded with Nominal_time_out + LINFlexD_LINTCSR[CNT] at the end of the stop bit of the Identifier field (where nominal_time_out = 1.4 × ((DFL + 2) × 10 bit time))
  - **Case 2**: The received identifier is not managed by a filter. As the DFL value needs to be updated by software after the identifier field has been received, the implementation is the following:
    - At the end of the ID, OC2 is loaded with 36 (maximum possible response space) + LINFlexD_LINTCSR[CNT].
    - At the end of the first_data_byte it is reloaded again according to DFL
    - Before reloading, LINFlexD checks the count_val. If count value is higher than the value to be reloaded, timeout takes place immediately and no reloading occurs.

NOTE

The value of nominal_time_out (1.4 × ((DFL +2) × 10 bit time)) shown is as per the reset value of LINTOCR[RTO] and LINCR1[CFD]. It changes with change in value of LINTOCR[RTO] and LINCR1[CFD]. Here, 1.4 corresponds to (LINTOCR[RTO])/10 and 2 corresponds to (2- LINCR1[CFD])

Header timeout mechanism

- Master mode: As the header is generated by the LINFlexD, there are only two cases:
  - no error on the bus and timing is correct (nominal header length),
  - an error occurs on the bus and LINFlexD flags it in LINESR register (typically a bit error).

  Therefore there is no meaning of header timeout in master mode, so it is disabled.
- Slave mode
  - header_nominal = 13 + 2 + 10 + 10 = 35 Tbit
  - header_max = 1.4 × Header_nominal = 49 Tbit
  - taking into account a possible 14% clock deviation, header_max seen by LINFlexD is 49 × 1.14 = 56 Tbit
  - If the counter starts after 11 Tbit (break duration), the HTO value is 56 –11 = 45 Tbit.

  The reset value of HTO is 45, and this register can only be programmed in slave mode. Counter restarts after break duration and OC1 gets loaded with the value of HTO.

  As response space is not included in the response, frame timeout is no longer needed and is removed completely. Indeed, header timeout and response timeout cover all cases.

  The timeout counter can be used to detect other timeouts. In this case, the MODE bit must be reset and the output compare value can be updated in the LINTOCR register by software.

Stuck at zero timeout error

If the dominant pulse lasts for a time of at least 100 bits, the SZF bit in LINESR is set. If the same dominant pulse prolongs, the subsequent SZF setting will be 87 bit times apart (instead of 100 bit times).

46.4.2.5.7 Noise

During reception each bit is sampled 16 times and the value of the bit is obtained by taking the majority value of the 8^{th}, 9^{th} and 10^{th} samples. If any one of these three samples has a value different from the other two, this error is flagged.

When OSR = 8, majority of 2nd, 3rd, and 4th samples are taken into account to determine noise. Noise checking is disabled for all OSR less than eight.

This error is flagged when there is noise detected in the start bit (see LIN Error Status Register (LINFlexD_LINESR).

46.4.2.6 Identifier filtering

In LIN protocol the identifier of a message is not associated with the address of a node but is related to the content of the message. A transmitter broadcasts its message to all the receivers. Based on the header received, the receiver decides whether to receive or transmit a response (depending on the identifier value). If the message does not target the node, it should be discarded.

To fulfill this requirement, the LINFlexD provides configurable filters in order to eliminate software intervention. This hardware filtering saves CPU resources that would otherwise be required to perform filtering by software.

There are a maximum of 16 filters (depending on the generic no_of_filters) in the LINFlexD, which can be programmed by the user only during Initialization mode. In order to activate a filter the corresponding FACT bit in IFER needs to be set. There are two modes possible for each identifier depending on the corresponding IFM bit of IFMR.

Identifier list mode

If the n^{th} bit of IFMR is cleared, then filter number 2n and 2n+1 is in identifier list mode. In this mode, the maximum number of filters that can be configured for transmission/ reception equals no_of_filters, depending on the FACT bit of IFER. In this mode the identifier received should match bit by bit to the ID field of IFCR2n or IFCR2n+1 (if the corresponding FACT bit is set).

Identifier mask mode

If the number of filters required is more than no_of_filters, then filters should be configured in Mask mode. If the n^{th} bit of IFMR is set, then filter number 2n is the filter and 2n+1 acts as a mask for it. The FACT bit for filter 2n+1 has no effect in this case. In this mode, if the x^{th} bit of the mask is set, then the x^{th} bit of the received identifier must match the x^{th} bit of filter.

If there is a match of identifier with the mth filter in any mode, then m+1 is loaded in the IFMI register by hardware. No match condition is denoted by IFMI = 0.

Upon matching DFL (2:0), the CCS and DIR bits of the BIDR register are copied from the filter by hardware and from then on, the BIDR register is read-only until the end of the frame. Now if the DIR bit of BIDR is set, then a TXI interrupt is generated if the

HRIE bit of LINIER is set. In this case, software uses the IFMI register to transfer the relevant data from the RAM area to BDR, and after complete transfer the DTRQ bit of LINCR2 is set to start the transmission. If the DIR bit is cleared then an RXI interrupt is generated (provided DRIE bit of LINIER is set) when the checksum has been received and there is no checksum error.

In case of no filter match condition (IFMI = 0) and if the BF bit of LINCR1 is set, then an RXI is generated. Now it is the responsibility of software to configure BIDR and start transmission (by loading the BDR buffer and setting the DTRQ bit of LINCR2) or discard reception (by setting the DDRQ bit of LINCR2). If the BF bit is reset, then the receiver discards the received identifier and turns to Idle state in search of a new break.

Note

If one identifier matches with two filters (one is in the list and the other in Mask mode) then List mode prevails over Mask mode. In mask mode if two filters match with the identifier then the filter having the lower number prevails.

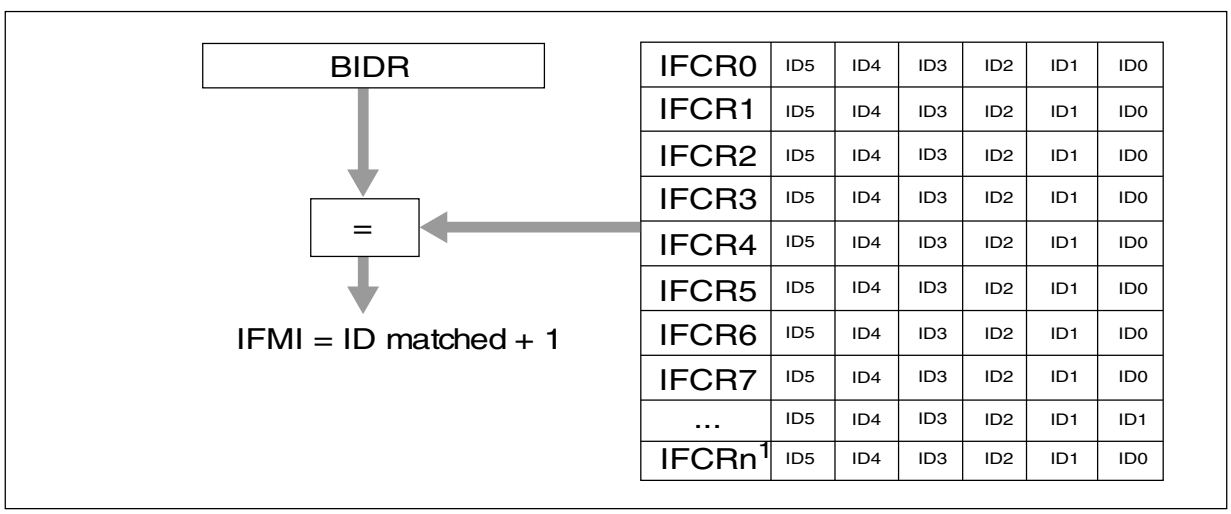

Figure 46-12. Identifier List mode

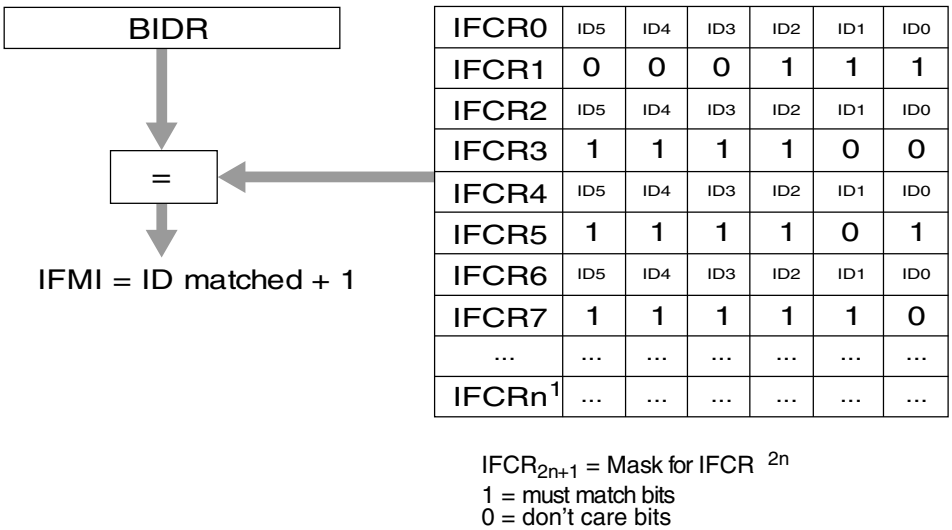

Figure 46-13. Identifier Mask mode

46.4.2.7 Start detection and break delimiter detection in receiver

There is a 10-bit-shift register sample register in the receiver that shifts signal data to the next least significant bit on each incoming sample.

0	0	0	1	x	1	x	0	x	1	
0	0	0	1	x	0	x	1	x	1	

Hence, a start is detected as soon as it is qualified with 1110 in the sample register and verified with at least two out of three predefined verification samples being zero. Similarly for delimiter detection, qualification samples are 0001 and at least two of the three verification samples are one. The Noise Flag is set if the start is verified with only two valid samples.

46.4.2.7.1 Start detection mechanism

The following steps are followed for detecting a start bit:

1. Refer to Table 46-3 for the status of the sample register (shift register) when count = 6
2. At this point, if RT1 (the first incoming sample) = 0 and the previous three samples already received are all ones, then it might be a start bit.
3. To make sure it is indeed a start bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority (i.e., 2) out of these 3 samples are equal to ‘0’, then start bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the “verification samples” which are checked at count = 6.

6. The sample register bits 9, 8, 7, and 6 are called “qualification samples” which are checked at count = 6.
7. At count = 9, if majority value of RT8, RT9, and RT10 is not equal to ‘0’ then Noise flag is set.

46.4.2.7.2 Break delimiter detection mechanism

The following steps are followed for detecting a delimiter bit:

1. Refer to Table 46-3 for the status of the sample register (shift register) when count = 6
2. At this point, if RT1 (the first incoming sample) = 1 and the previous three samples already received are all zeros, then it might be a delimiter bit.
3. To make sure it is indeed a delimiter bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority (i.e., 2) out of these 3 samples are equal to ‘1’, then delimiter bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the “verification samples” which are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called “qualification samples” which are checked at count = 6.

Hence, a start is detected as soon as it is qualified with 1110 in the sample register and verified with at least two out of three predefined verification samples being zero. Similarly for delimiter detection, qualification samples are 0001 and at least two out of the three verification samples are one. The Noise Flag is set if the start is verified with only two valid samples.

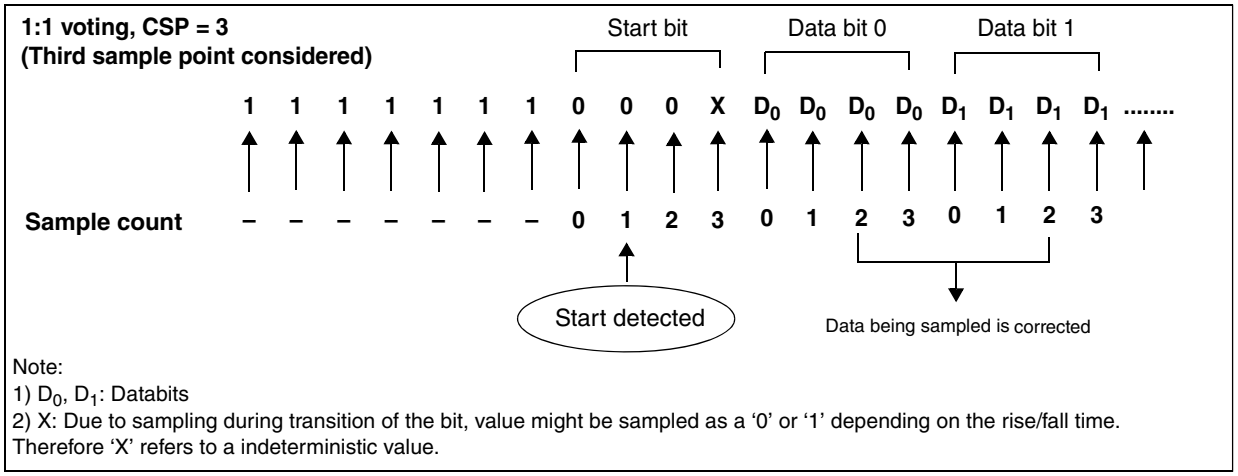

Figure 46-14. Start detection and sampling for over sampling rate = 4 (Case 1)

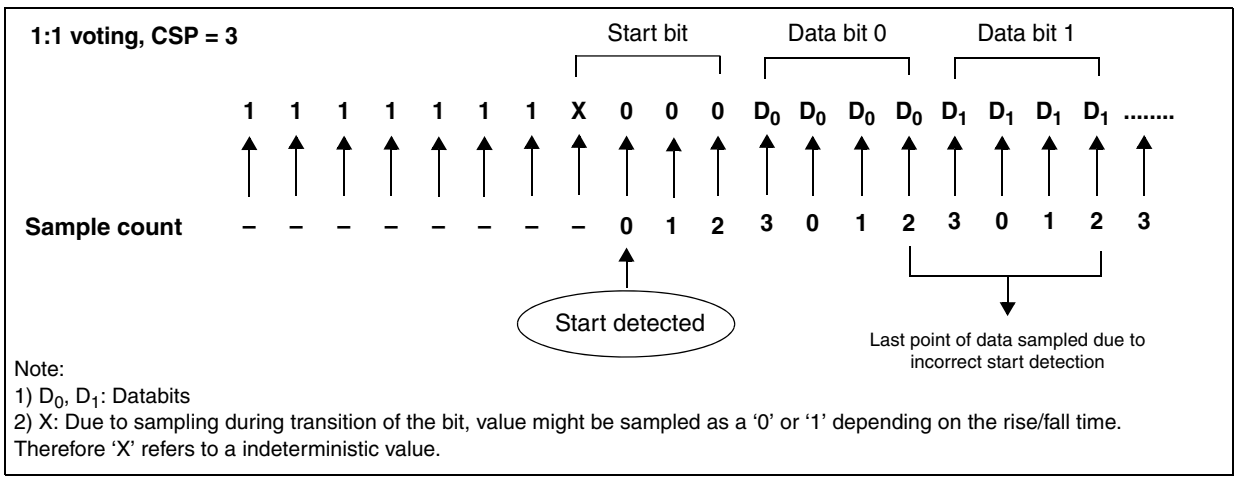

Figure 46-15. Start detection and sampling for over sampling rate = 4 (Case 2a)

The choice of the correct sample points depends on the external Rx signal quality. During the application development process, the error information indicated by the parity error can help to find the best setting for an application-specific hardware signal.

To sample at the correct point therefore, CSP has to be changed to two; resulting in the following situation:

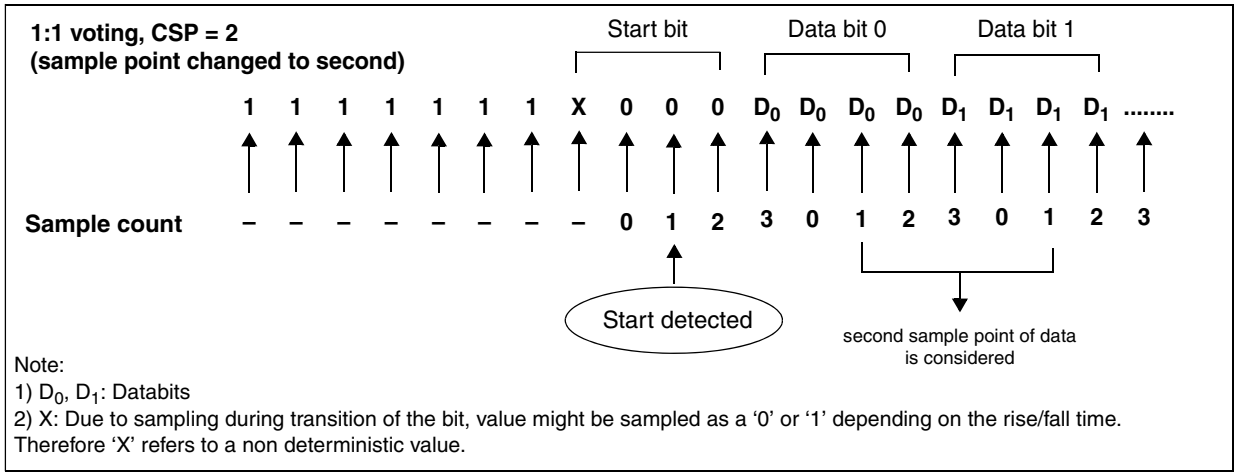

Figure 46-16. Start detection and sampling for over sampling rate = 4 (Case 2b)

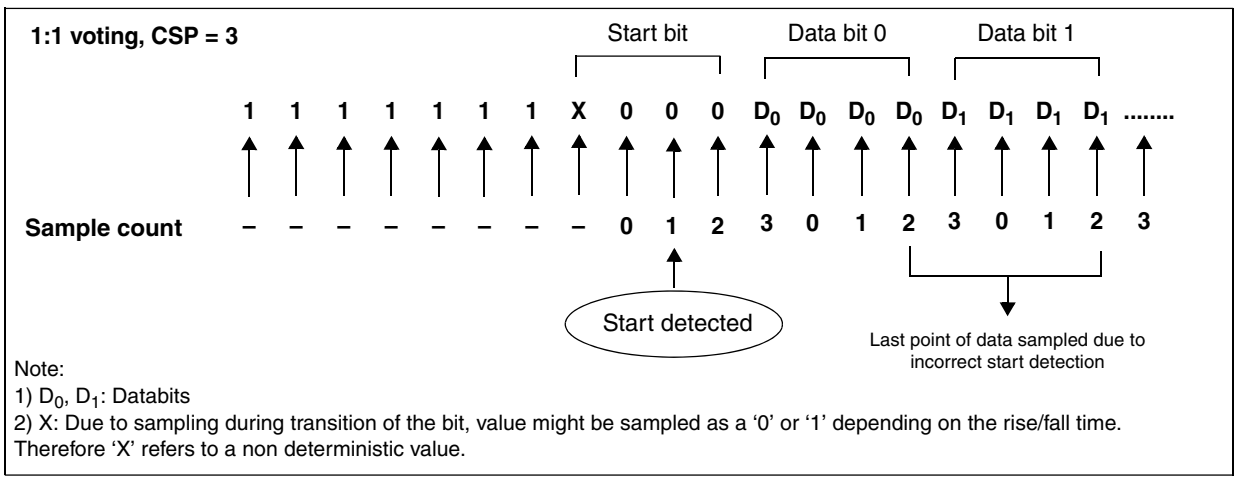

Figure 46-17. Start detection and sampling for over sampling rate = 4 (Case 3)

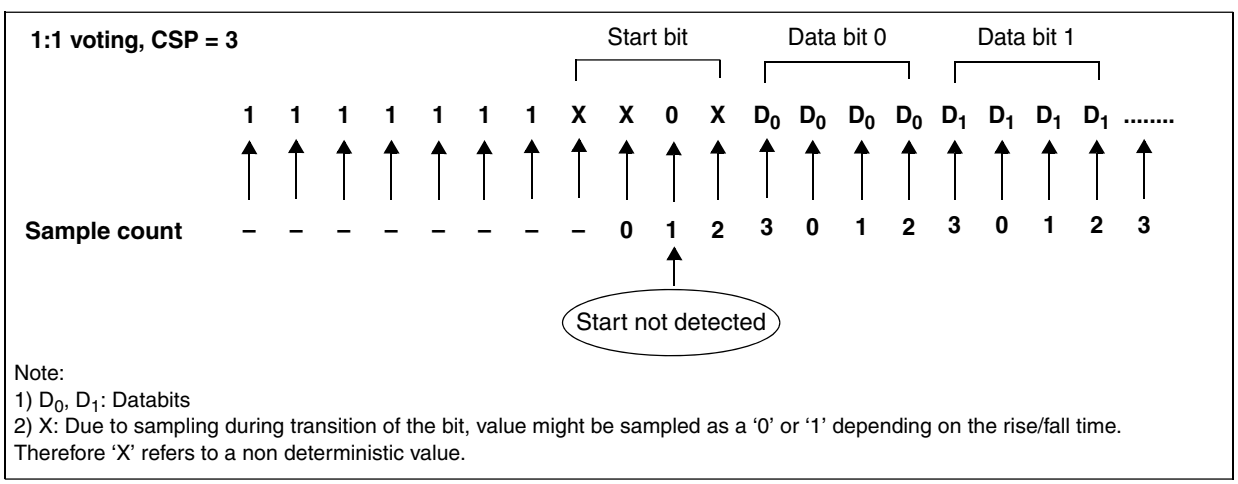

Figure 46-18. Start detection and sampling for over sampling rate = 4 (Case 4)

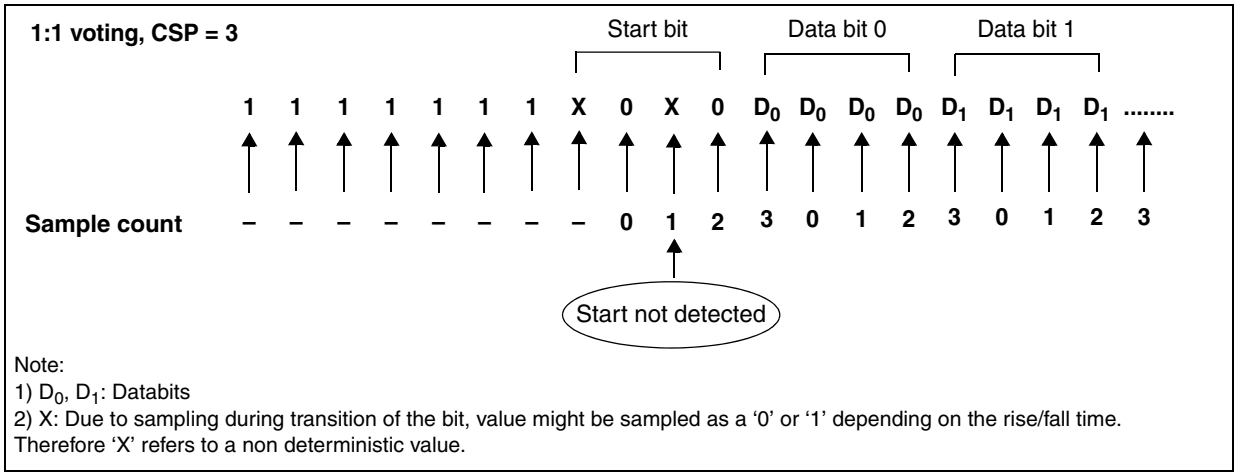

Figure 46-19. Start detection and sampling for over sampling rate = 4 (Case 5)

46.4.2.8 Baud rate generation

The LIN baud rate is programmed in two registers: the LIN Integer Baud Rate Register and the LIN Fraction baud rate register. The Baud Rate Registers can be programmed only during Initialization mode.

Baud rate is calculated with the following formula for both receiver and transmitter.

When ROSE = 1, Tx = Rx = LIN_CLK / (OSR × LDIV). When ROSE = 0, Tx = Rx = LIN_CLK / (16 × LDIV)

Where LIN_CLK is the frequency of the baud clock.

LDIV is an unsigned fixed point number. The mantissa is coded into 20 bits of LINIBRR and the fraction is coded on 4 bits of LINFBRR.

When reduced oversampling is enabled, LINFBRR should not be used and programmed to zero and LDIV contains only the integer part of LINIBRR.

For example: When ROSE = 0 (For LIN and UART mode): LDIV = 468.75 d, LIN_CLK = 36 MHz, LINIBRR = 468 d, LINFBRR = 12 *Baud rate = 36 MHz/ (16 × 468.75) = 4.8 Kbit/s*

For example: When ROSE = 1 (Only for UART mode): LDIV = 10 d, LIN_CLK = 80 MHz, LINIBRR = 4 d, OSR = 4, *Baud rate = LIN_CLK / (OSR × LDIV) = 80 MHz / (4 × 10) = 2 Mbit/s*

46.4.2.9 Automatic resynchronization

To automatically adjust the baud rate based on measurement of the LIN sync field, write the nominal Prescalar value (nominal baud rate) in LINIBRR and LINFBRR, then set the LASE bit in LINCR1 to enable automatic synchronization.

When auto synchronization is enabled, after each LIN Sync Del, the time duration between five falling edges on RDI is sampled on LIN_CLK.

46.4.2.10 Wakeup management

Any node in a sleeping LIN cluster may request a wakeup. The wakeup request is issued by forcing the bus to the dominant state for 250 μs to 5 ms. Every slave node should detect the wakeup request (a dominant pulse longer than 150 μs) and be ready to listen to bus commands within 100 ms, measured from the ending edge of the dominant pulse. The master also wakes on detecting a wakeup request and when the slaves are ready, starts sending frame headers to find out the cause of the wakeup. If the master does not issue a frame header within 150 ms from the wakeup request, then the node issuing a request may try issuing a new wakeup request.

In LINFlexD, a wakeup request can be generated by writing the wakeup character in BDR0 and setting the WURQ bit in LINCR2. On setting the WURQ bit, the character in BDR0 is transmitted. For LIN 2.0, character 0xF0 is sent as the wakeup character.

In LINFlexD, wakeup can be detected in two ways.

1. AUTOWU = 1 On detecting a falling edge in sleep mode, the SLEEP bit is cleared by hardware, the WUF flag is set, and an interrupt is generated if WUPIE is set. LINFlexD is now in normal mode and ready to receive frames.
2. AUTOWU = 0 On detecting a falling edge the WUF flag is set and an interrupt is generated (if WUPIE bit is set). It is then up to the software to clear the SLEEP bit.

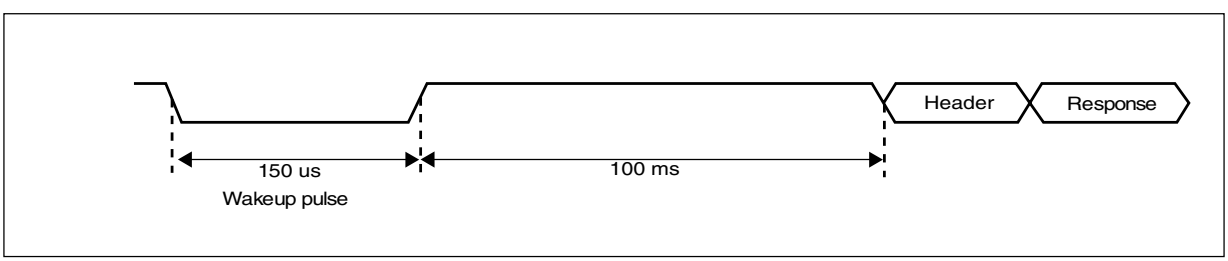

Figure 46-20. Wakeup sequence

46.4.3 Timer

There is an 8-bit counter which has different behavior in different modes as described below:

- **In Output Compare Mode (LINTCSR[MODE]= 1):**

  This counter is running even in Sleep and Initialization mode. The counter value which when matches the two software configurable output compare registers (LINOCR[OC1] or LINOCR[OC2]), generate output compare interrupt (LINESR[OCF]) provided TOCE bit in LINTCSR is set. Once an interrupt occurs subsequent interrupt is generated only when the application has reset the stuck FSM state.
- **In LIN Mode:**

  The software has no control over the TOCE bit and output compare registers are utilized for generation of LIN timeout interrupts (header, frame, response times out). In this case, if LIN moves to Sleep or Init state then this counter remains in Reset state. LIN mode has no meaning if UART is enabled, hence the counter will remain in Reset state.

46.4.4 UART mode

Main features in the UART mode are:

- Full duplex communication
- 8-bit frames, 9-bit frames, 13-bit frames, 16-bit frames, 17-bit frames
- Even/Odd/0/1 Parity
- User programmable over sampling rate to obtain the baud rate of up to 25 Mbit/s

46.4.4.1 8-bit data frames

The eighth bit can be a data or a parity bit. Even/Odd/0/1 parity can be selected by the PC[1:0] bit in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case.

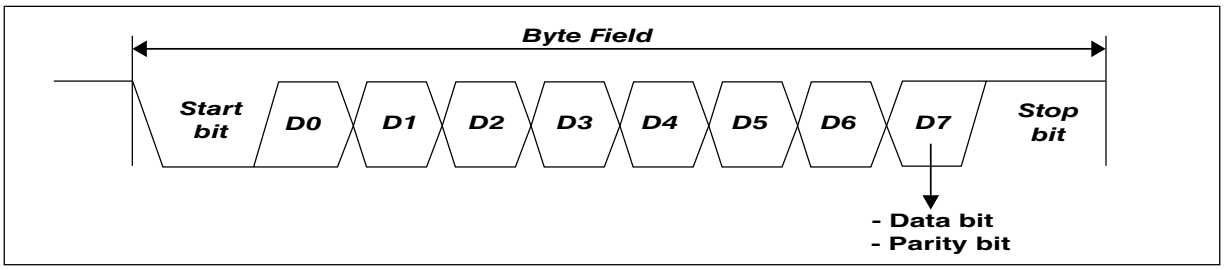

Figure 46-21. UART mode 8-bit data frame

46.4.4.2 9-bit frames

The ninth bit should be a parity bit. Even/Odd/0/1 Parity can be selected by the PC[1:0] field in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

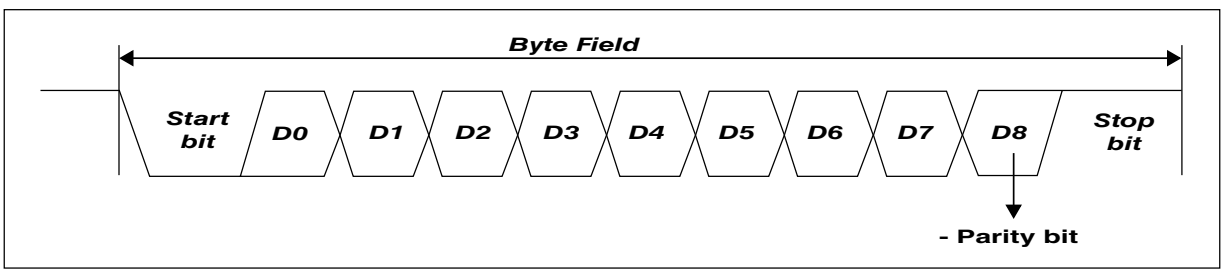

Figure 46-22. UART mode 9-bit data frame

46.4.4.3 16-bit data frames

The sixteenth bit can be a data or a parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

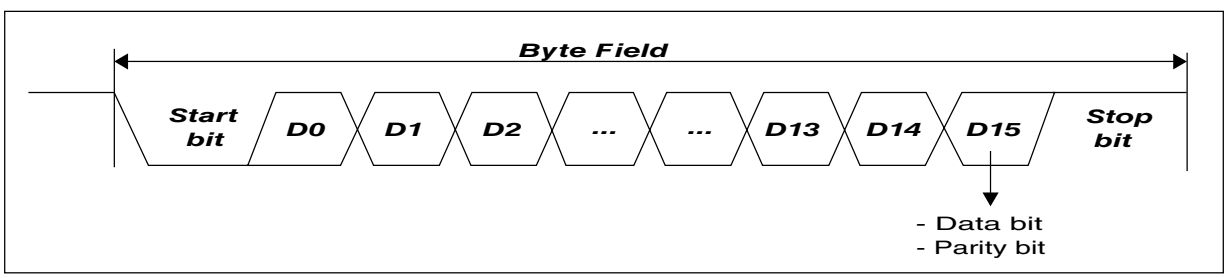

Figure 46-23. UART mode 16-bit data frame

46.4.4.4 17-bit frames

The seventeenth bit is the parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

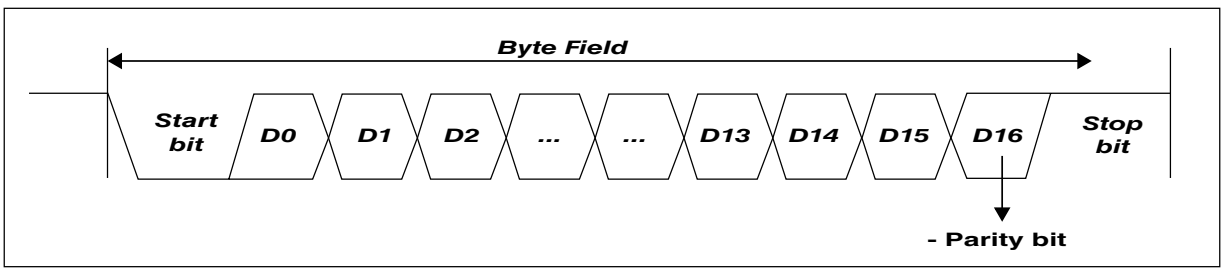

Figure 46-24. UART mode 17-bit data frame

46.4.4.5 13-bit frames

Whenever WLS is one, special word length is selected in UART mode. This bit enables 12-bit + parity bit reception only in FIFO mode.

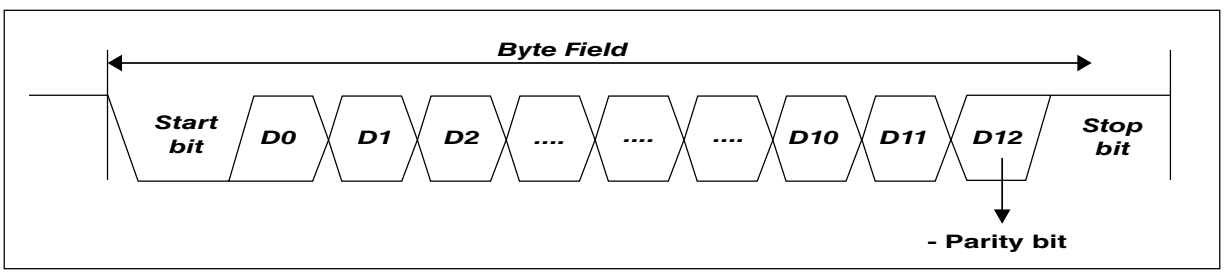

Figure 46-25. UART mode 13-bit data frame

46.4.4.6 Buffer in UART mode

The 8-byte buffer is divided into two parts: one for receiver and one for transmitter, as shown in the following figure:

Tx0	BDR0
Tx1	BDR1
Tx2	BDR2
Tx3	BDR3
Rx0	BDR4
Rx1	BDR5
Rx2	BDR6
Rx3	BDR7

Figure 46-26. Structure of 8-byte buffer

For 16-bit frames, the lower eight bits are written in BDR0 and upper eight bits in BDR1.

The same applies for reception.

46.4.4.7 UART transmitter

UART transmitter

In order to start transmission in the UART mode, UART bit should be set and the transmitter enable bit should be set. Transmission starts when the BDR0 (least significant data byte) is programmed and continues until the number of bytes/halfwords transmitted is equal to the value in the TDFL bits in UARTCR.

The transmit buffer is four bytes (when UARTCR[WL1] = 0) or two halfwords (when UARTCR[WL1] = 1), hence a maximum of four bytes (two halfwords) transmission can be triggered. Once the programmed number of bytes (halfwords) has been transmitted, the DTF flag is set in UARTSR. If the TxEn bit of UART is reset in the middle of a transmission, then the current transmission is completed and no further transmissions can be invoked.

The buffer can be configured in FIFO mode (mandatory when the DMA Tx is enabled) by setting the control bit UARTCR[TFBM].

NOTE

If TFF bit is set and a write is performed to the FIFO, the data transmitted may be erroneous.

Table 46-4. BDRL access in UART mode

IPS operation	Register	Mode (UARTCR[TFBM])	Word length (UARTCR[WL])	IPS operation result
Write Byte0	BDRL	FIFO	Byte	OK
Write Byte1-2-3	BDRL	FIFO	Byte	IPS transfer error
Write Half-word0-1	BDRL	FIFO	Byte	IPS transfer error
Write Word	BDRL	FIFO	Byte	IPS transfer error
Write Byte0-1-2-3	BDRL	FIFO	Half-word	IPS transfer error
Write Half-word0	BDRL	FIFO	Half-word	OK
Write Half-word1	BDRL	FIFO	Half-word	IPS transfer error
Write Word	BDRL	FIFO	Half-word	IPS transfer error
Read Byte0-1-2-3	BDRL	FIFO	Byte/Half-word	IPS transfer error
Read Half-word0-1	BDRL	FIFO	Byte/Half-word	IPS transfer error
Read Word	BDRL	FIFO	Byte/Half-word	IPS transfer error
Write Byte0-1-2-3	BDRL	BUFFER	Byte/Half-word	OK
Write Half-word0-1	BDRL	BUFFER	Byte/Half-word	OK

Table continues on the next page...

Table 46-4. BDRL access in UART mode (continued)

IPS operation	Register	Mode (UARTCR[TFBM])	Word length (UARTCR[WL])	IPS operation result
Write Word	BDRL	BUFFER	Byte/Half-word	OK
Read Byte0-1-2-3	BDRL	BUFFER	Byte/Half-word	OK
Read Half-word0-1	BDRL	BUFFER	Byte/Half-word	OK
Read Word	BDRL	BUFFER	Byte/Half-word	OK

In UART FIFO mode (UARTCR[TFBM] = 1), any read operation causes an IPS transfer error.

46.4.4.8 UART receiver

UART receiver

The reception of a data byte is started as soon as the user exits initialization mode, sets the RxEn bit, and detects start bit. There is a dedicated 4-byte (if UARTCR[WL1] = 0) or 2-half-words (if UARTCR[WL1] = 1) data buffer for received data. Once the programmed number (RDFL bits) of bytes have been received, the DRF flag is set in UARTSR and the current reception gets completed. RxEn bit needs to be set only to start the reception. The reception is automatically completed as soon as the programmed number (RDFL bits) of bytes have been received.

The buffer can be configured in FIFO mode (mandatory when the DMA Rx is enabled) by setting the control bit UARTCR[RFBM].

Table 46-5. BDRM access in UART mode

IPS operation	Register	Mode (UARTCR[RFBM])	Word length (UARTCR:WL)	IPS operation result
Read Byte4	BDRM	FIFO	Byte	OK
Read Byte5-6-7	BDRM	FIFO	Byte	IPS transfer error
Read Half-word2-3	BDRM	FIFO	Byte	IPS transfer error
Read Word	BDRM	FIFO	Byte	IPS transfer error
Read Byte4-5-6-7	BDRM	FIFO	Half-word	IPS transfer error
Read Half-word2	BDRM	FIFO	Half-word	OK
Read Half-word3	BDRM	FIFO	Half-word	IPS transfer error
Read Word	BDRM	FIFO	Half-word	IPS transfer error
Write Byte4-5-6-7	BDRM	FIFO	Byte/Half-word	IPS transfer error
Write Half-word2-3	BDRM	FIFO	Byte/Half-word	IPS transfer error
Write Word	BDRM	FIFO	Byte/Half-word	IPS transfer error
Read Byte4-5-6-7	BDRM	BUFFER	Byte/Half-word	OK

Table continues on the next page...

Table 46-5. BDRM access in UART mode (continued)

IPS operation	Register	Mode (UARTCR[RFBM])	Word length (UARTCR:WL)	IPS operation result
Read Half-word2-3	BDRM	BUFFER	Byte/Half-word	OK
Read Word	BDRM	BUFFER	Byte/Half-word	OK
Write Byte4-5-6-7	BDRM	BUFFER	Byte/Half-word	IPS transfer error
Write Half-word2-3	BDRM	BUFFER	Byte/Half-word	IPS transfer error
Write Word	BDRM	BUFFER	Byte/Half-word	IPS transfer error

Note

Refer to the layout of the registers BDRL and BDRM to identify the mapping between byte x and data bits of the registers BDRL/BDRM.

Note

- If the user does not know in advance how many bytes are to be received, RDFL should not be programmed in advance. The reset value of RDFL is zero. This will ensure that the reception will happen byte by byte. The state machine will move to the Idle state after each byte reception.
- If RDFL is programmed for a certain value but that number of bytes are not received, then reception will hang. In that case, software needs to take care of timeout by seeing the flag. Software has to set the sleep bit to move to Idle state.
- If a STOP request arrives in the middle of one reception, it is only acknowledged after all the programmed number of data bytes have received; it is not served immediately. If the programmed number of data bytes are not received, then software has to take care of timeout. When the state machine moves to Idle state, then only a stop request is served.
- If during reception of any byte a parity error occurs, then the corresponding PEx bit in UARTSR is set. No interrupt is generated in this case. If a framing error occurs in any byte (FE bit in UARTSR is set) then an interrupt is generated if FEIE bit in LINIER is set. As there is only one register bit for framing error, this interrupt will be helpful in identifying which byte has framing error.

- If the last received frame has not been read from the buffer (in other words, RMB is not reset by the user), then upon reception of the next byte, an overrun error occurs (BOF bit in UARTSR will be set) and one message is depending on RBLM bit of LINCR1. An interrupt is generated if the BOIE bit in LINIER is set.
- When WLS bit = 1, BDRM access depends on WL bit setting.
- When WLS bit = 1, WL = 0 or 1 should not be used, since this will lead to incorrect reception of data.
- When IPG_STOP is requested, for UART in FIFO mode, SW has to set the INIT bit in order to send the receiver to idle. This ensures that IPG_STOP_ACK is generated and IP enters STOP mode.

46.4.5 DMA interface

46.4.5.1 Main features

The LINFlexD DMA offers a parametric and programmable solution with the following distinctive features:

- LIN Master node, TX mode: single DMA channel
- LIN Master node, RX mode: single DMA channel
- LIN Slave node, TX mode: 1 to N DMA channel where N = max number of ID filters
- LIN Slave node, RX mode: 1 to N DMA channel where N = max number of ID filters
- UART node, TX mode: single DMA channel
- UART node, RX mode: single DMA channel + time-out

46.4.5.2 Definitions

Control/status register fields of the LINFlexD macrocell are described in Table 46-6 and Table 46-7.

Table 46-6. LINFlexD control/status fields description

Register	Field	Level	Description
LINCR2	DDRQ	High	Data discard request in reception mode
	DTRQ	High	Data transmission request (slave mode) of the LIN data field stored in BDRL/BDRM
	HTRQ	High	Header transmission request (master mode)
BIDR	DFL	—	Data field length: • 1 to 8 bytes: normal frames
	DIR	—	Direction of the data field: • 0 => reception • 1 => transmission
	CCS	—	Checksum type: • 0 enhanced • 1 classic
	ID[5:0]	—	Identifier.
LINSR	RMB	—	Buffer data ready to be read via CPU/DMA. • 0 buffer data is free • 1 buffer data is ready
	DRF	High	Data reception completed
	DTF	High	Data transmission completed
	HRF	High	Header received. Used in slave mode in case of Tx filter match.
IFMI	IFMIx	!= zero	Filter match index (slave mode).
UARTCR	FBM	—	FIFO/Buffer mode • 0 Buffer mode • 1 FIFO mode (mandatory in DMA mode)
UARTSR	RFE	—	Rx FIFO empty • 0 Rx FIFO not empty • 1 Rx FIFO empty
	TFF	—	Tx FIFO full • 0 Tx FIFO not full • 1 Tx FIFO full
DMATXE[2**TX_CH_NUM][1]		High	DMA Tx channel enable (read/write). In UART or LIN master mode only the channel 0 can be programmed. In LIN slave mode: # DMA TX channel = IFMI[3:0] -1.

Table continues on the next page...

Table 46-6. LINFlexD control/status fields description (continued)

Register	Field	Level	Description
			DMATXE[x] = 0b => TX channel x disabled DMATXE[x] = 1b => TX channel x enabled

DMARXE[2**RX_CH_NUM][1]		High	DMA Rx channel enable (read/write). In UART or LIN master mode only the channel 0 can be programmed.
			In LIN slave mode: # DMA RX channel = IFMI[3:0] -1.
			DMARXE[x] = 0b => RX channel x disabled
			DMARXE[x] = 1b => RX channel x enabled

1. ** stands for exponentiation.
1. ** stands for exponentiation

Table 46-7. LINFlexD DMA control fields description

Field	Mode	Value	Level	Description
DMA_TEN	LIN master Tx or UART Tx	DMATXE[0]	High	Logical AND between the 2 DMA enable bits (LINFlexD and eDMA).
DMA_TEN	LIN slave Tx	DMATXE[x] x = IFMI — 1	High	
DMA_REN	LIN master Rx or UART Rx	DMARXE[0]	High	
DMA_REN	LIN slave Rx	DMARXE[x] x = IFMI — 1	High	

Control/status fields of the TCD descriptors referred to in this document are described in Table 46-8.

Table 46-8. TCD control fields description

TCD Field	Level	Description
CITER[14:0]	—	Current "major" iteration count
BITER[14:0]	—	Beginning "major" iteration count
NBYTES[31:0]	—	Inner "minor" byte transfer count. Number of bytes to be transferred in each service request of the channel.
SADDR[31:0]	—	Source address
SOFF[15:0]	—	Source address signed offset applied to the current source address as each source read is completed.
SSIZE[2:0]	—	Source data transfer size 000 => 8-bit 001 => 16-bit

Table continues on the next page...

Table 46-8. TCD control fields description (continued)

TCD Field	Level	Description
		010 => 32-bit 011 => 64-bit
SLAST[31:0]	—	Last source address adjustment
DADDR[31:0]	—	Destination address
DOFF[15:0]	—	Destination address signed offset applied to the current destination address as each destination write is completed.
DSIZE[2:0]	—	Destination data transfer size 000 => 8-bit 001 => 16-bit 010 => 32-bit 011 => 64-bit
DLAST_SGA[31:0]	—	Last destination address adjustment or the memory address for the next TCD to be loaded into this channel (scatter/gather)
INT_MAJ	High	Enable an interrupt when major iteration count completes
START	High	The channel is explicitly started via a software initiated service request.
DONE	High	Channel done (the DMA has completed the outer major loop).
D_REQ	High	Disable request. If this flag is set the DMA hardware automatically clears the corresponding DMAERQ bit when the current major iteration count reaches zero.

46.4.5.3 Master node –TX mode

On a master node, in TX mode the DMA interface requires a single TX channel. Each TCD controls a single frame. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in the following figure.

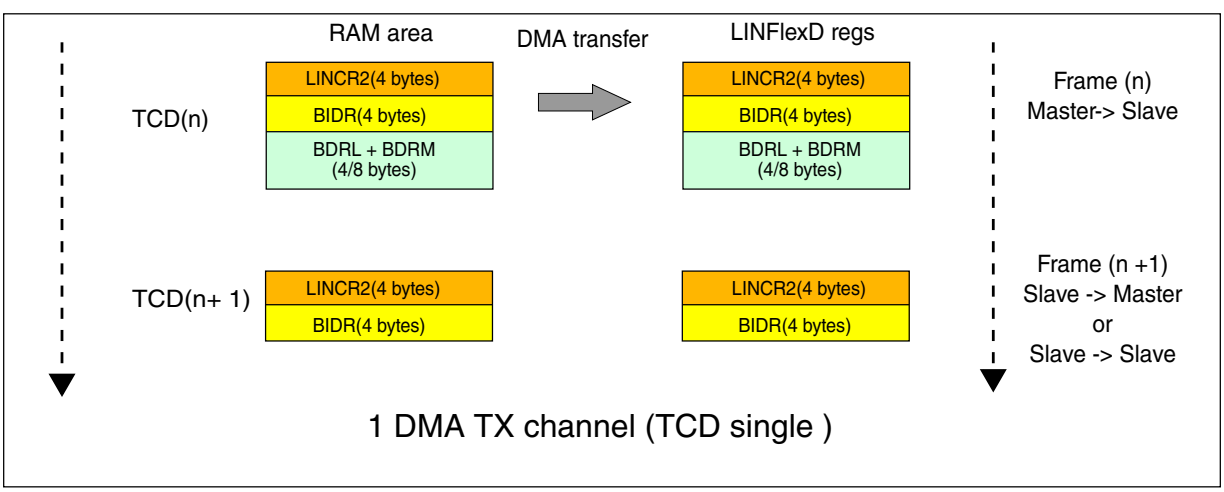

Figure 46-27. Master node –TX memory map

The TCD chain of the DMA Tx channel on a master node supports:

- Master to Slave: transmission of the entire frame (header + data)
- Slave to Master: transmission of the header; the data reception is controlled by the Rx channel on the master node
- Slave to Slave: transmission of the header

The following table provides the register settings of the LINCR2 and BIDR for each class of LIN frame.

Table 46-9. Master node – Tx mode – Register setting

LIN frame	LINCR2	BIDR
Master to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 1 (TX)
Slave to Master	DDRQ = 0 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)
Slave to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The concept FSM to control the DMA Tx interface is given in the following figure. DMA TX FSM moves to Idle state immediately at next clock edge if DMATXE[0] = 0. The TCD setting (word transfer) is given in Table 46-10. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 46-10. TCD setting – Master node – Tx mode

TCD Field	Value	Description
CITER[14:0]	1	Single iteration for the "major" loop
BITER[14:0]	1	Single iteration for the "major" loop
NBYTES[31:0]	[4 + 4] + 0/4/8 = N	Data buffer is stuffed with dummy bytes if the length is not word aligned. LINCR2 + BIDR + BDRL + BDRM
SADDR[31:0]	-	RAM address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer

Table continues on the next page...

Table 46-10. TCD setting – Master node – Tx mode (continued)

TCD Field	Value	Description
SLAST[31:0]	–N	
DADDR[31:0]	-	LINCR2 address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No SW request

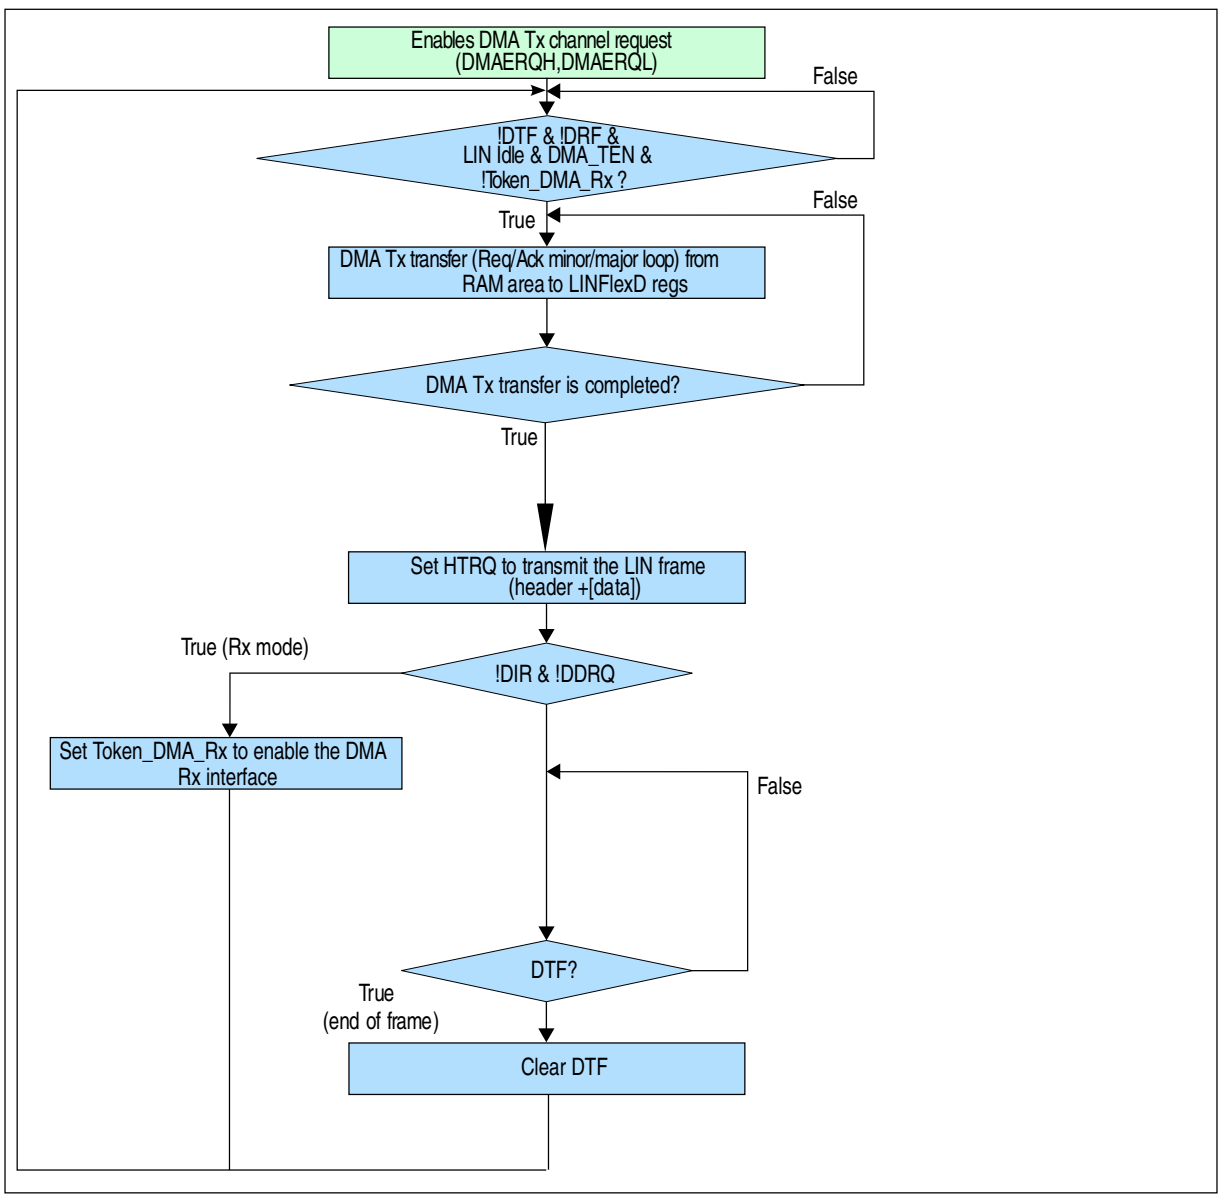

Figure 46-28. Master node – DMA Tx FSM (concept scheme)

46.4.5.4 Master node - RX mode

On a master node in RX mode, the DMA interface requires a single RX channel. Each TCD controls a single frame . The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in the following figure.

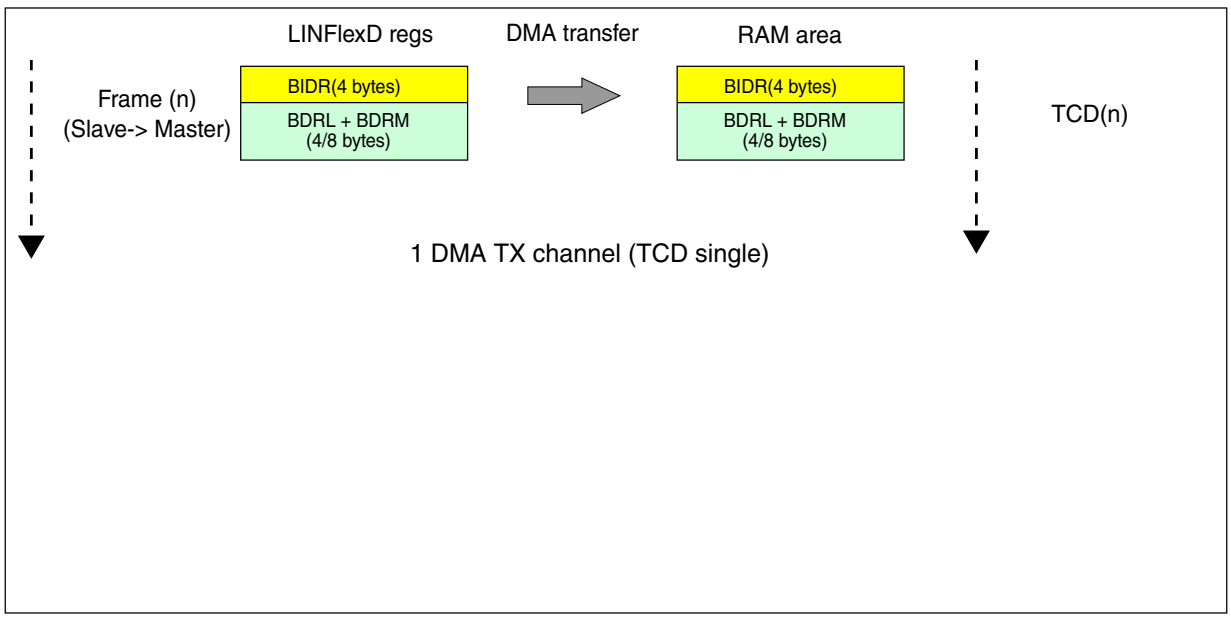

Figure 46-29. Master node – RX memory map

The TCD chain of the DMA Rx channel on a master node supports Slave to Master: reception of the data field of the header

The BIDR register is optionally copied into the RAM area. This BIDR field (part of FIFO data) contains the ID of each message, which only allows the CPU to figure out which ID the LINFlexD DMA received if the single DMA channel setup is used.

The concept FSM to control the DMA Rx interface is given in the following figure. DMA RX FSM moves to Idle state immediately at the next clock edge if DMARXE[0] = 0. The TCD setting (word transfer) is given in the next table. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 46-11. TCD setting – Master node – Rx mode

TCD Field	Value	Description
CITER[14:0]	1	Single iteration for the "major" loop
BITER[14:0]	1	Single iteration for the "major" loop
NBYTES[31:0]	[4] +4/8 = N	Data buffer is stuffed with dummy bytes if the length is not word aligned. BIDR + BDRL + BDRM

Table continues on the next page...

Table 46-11. TCD setting – Master node – Rx mode (continued)

TCD Field	Value	Description
SADDR[31:0]	—	BIDR address
SOFF[15:0]	4	Word increment

DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No SW request

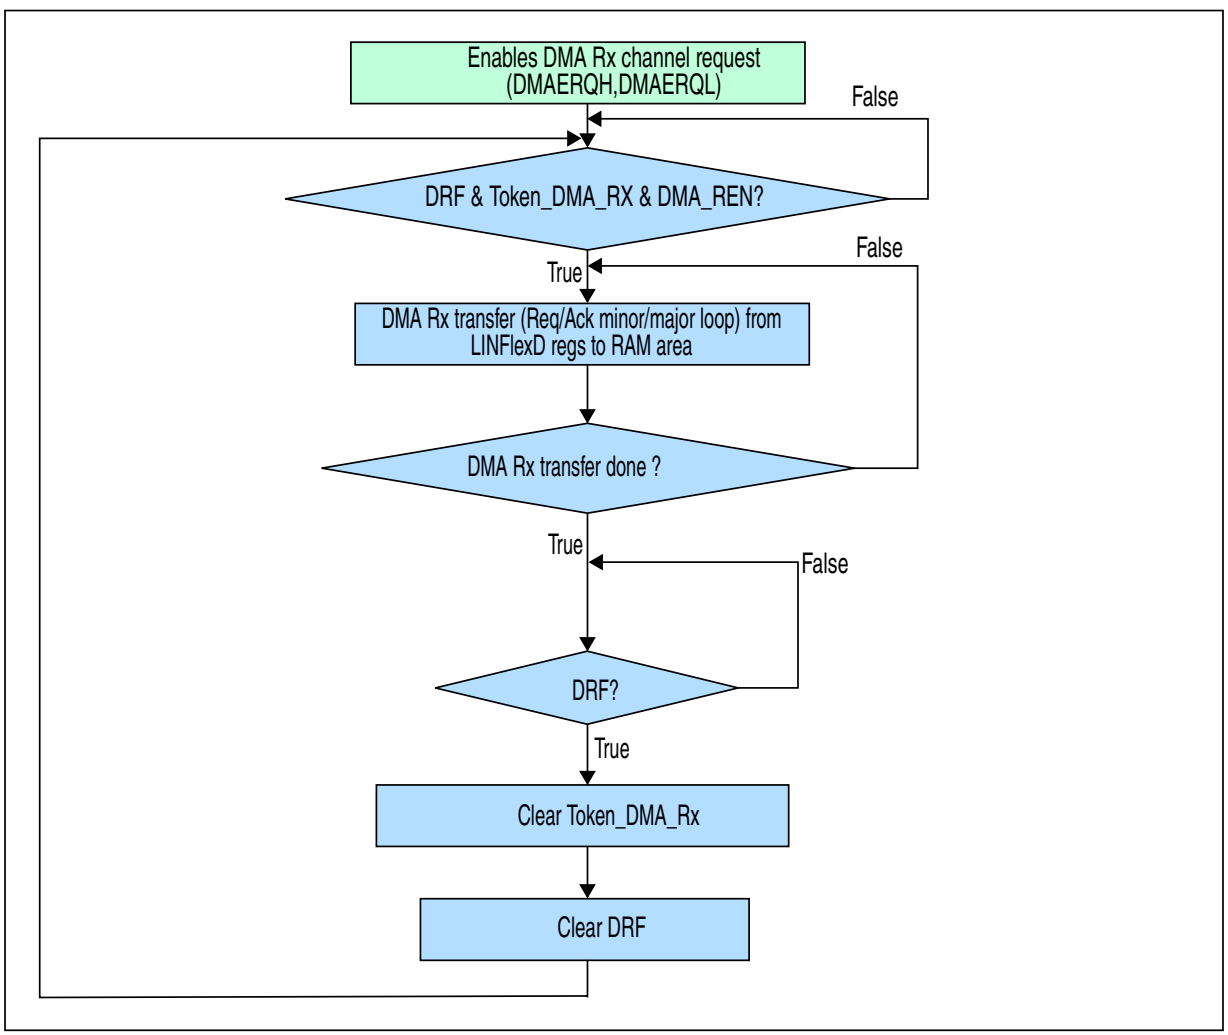

Figure 46-30. Master node – DMA Rx FSM (concept scheme)

46.4.5.5 Slave node – TX mode

On a slave node in TX mode, the DMA interface requires a DMA TX channel for each ID filter programmed in TX mode. In case a single DMA TX channel is available, a single ID field filter must be programmed in TX mode. Each TCD controls a single frame. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in the following figure.

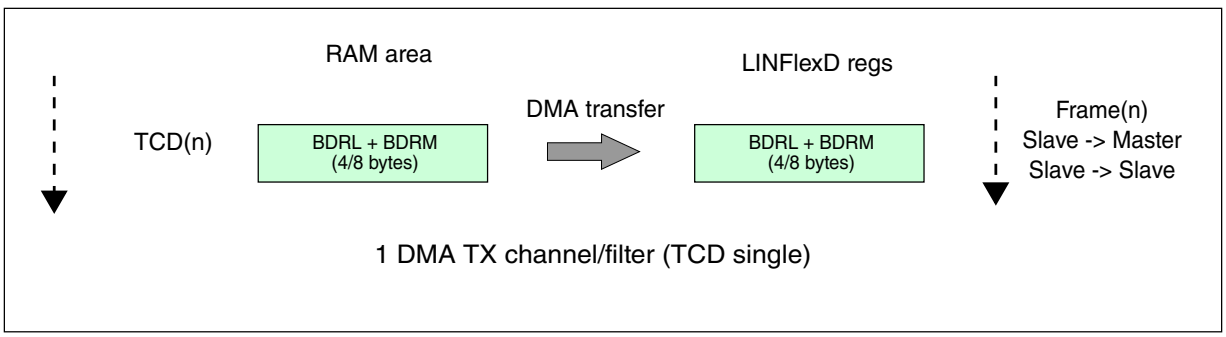

Figure 46-31. Slave node – TX memory map

The TCD chain of the DMA Tx channel on a slave node supports:

- Slave to Master: transmission of the data field
- Slave to Slave: transmission of the data field

The register setting of the LINCR2, IFER, IFMR, and IFCR registers is given in Table 46-12.

Table 46-12. Slave node – Tx mode – Register setting

LIN frame	LINCR2	IFER	IFMR	IFCR
Slave to Master or Slave to Slave	DDRQ = 0 DTRQ = 0 HTRQ = 0	To enable an ID filter (Tx mode) for each DMA TX channel	• Identifier list mode • Identifier mask mode	DFL = payload size ID = address CCS = checksum DIR = 1 (TX)

The concept FSM to control the DMA Tx interface is given in the following figure. DMA TX FSM moves to Idle state if DMATXE[x] = 0 where x = IFMI – 1.The TCD setting (word transfer) is given in Table 46-13. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 46-13. TCD setting – Slave node – Tx mode

TCD Field	Value	Description
CITER[14:0]	1	Single iteration for the "major" loop
BITER[14:0]	1	Single iteration for the "major" loop
NBYTES[31:0]	4/8 = N	Data buffer is stuffed with dummy bytes if the length is not word aligned. BDRL + BDRM
SADDR[31:0]	—	RAM address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	–N	—
DADDR[31:0]	—	BDRL address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain.
START	0	No SW request

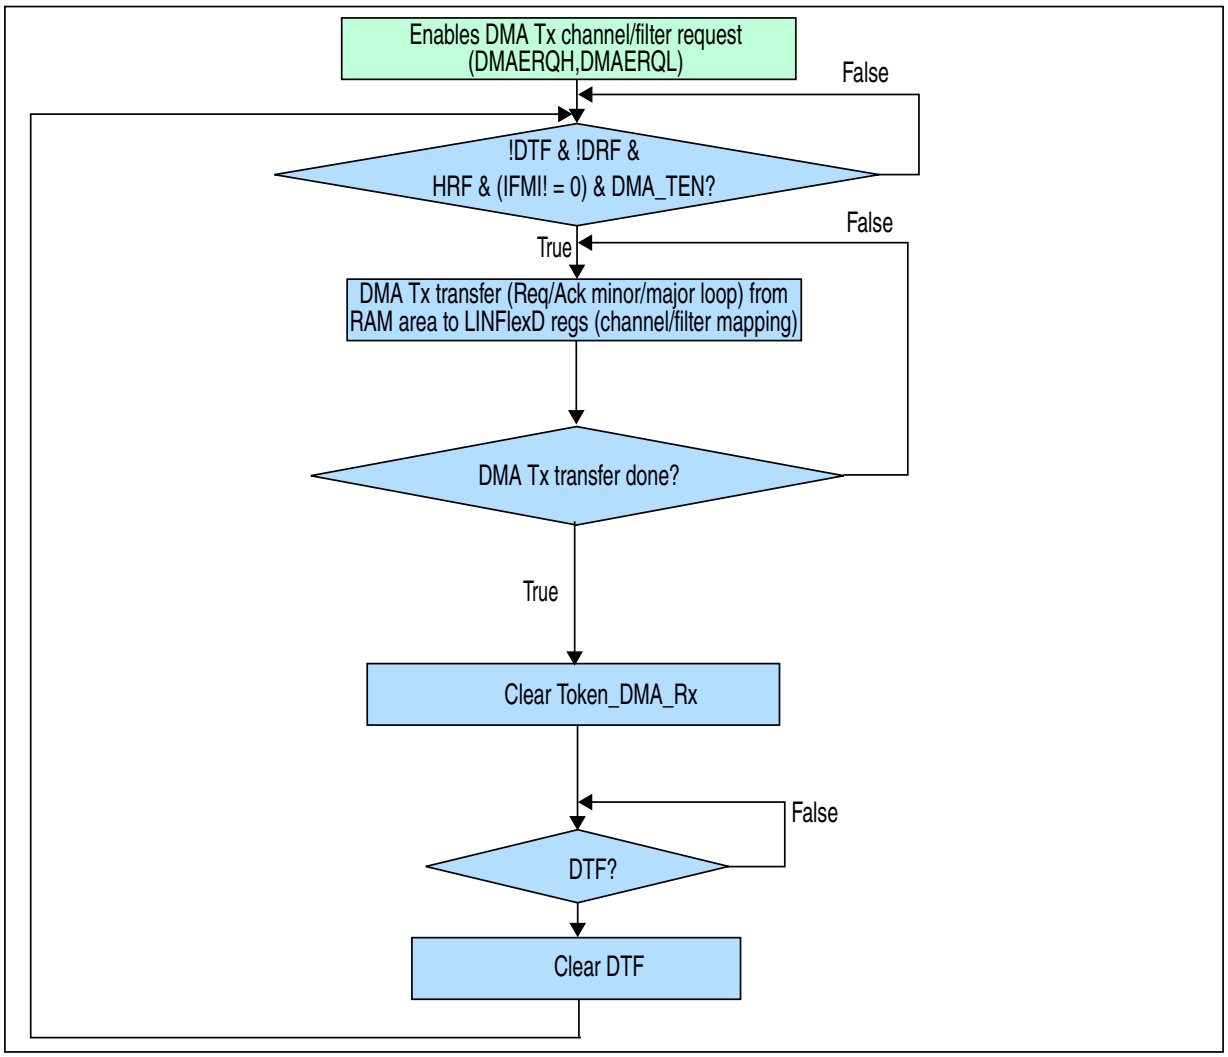

Figure 46-32. Slave node – DMA Tx FSM (concept scheme)

46.4.5.6 Slave node – RX mode

On a slave node in RX mode, the DMA interface requires a DMA RX channel for each ID filter programmed in RX mode. In case a single DMA RX channel is available, a single ID field filter must be programmed in RX mode. Each TCD controls a single frame. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in the following figure.

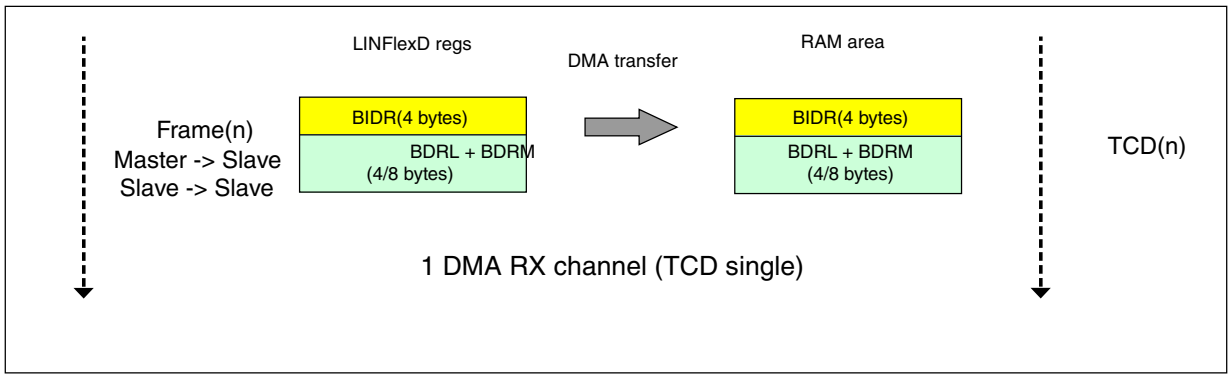

Figure 46-33. Slave node – RX memory map

The TCD chain of the DMA Rx channel on a slave node supports:

- Master to Slave: reception of the data field
- Slave to Slave: reception of the data field

The register setting of the LINCR2, IFER, IFMR, IFCR registers is given in Table 46-14.

Table 46-14. Slave node – Rx mode – Register setting

LIN frame	LINCR2	IFER	IFMR	IFCR
Master to Slave or Slave to Slave	DDRQ = 0 DTRQ = 0 HTRQ = 0	To enable an ID filter (Rx mode) for each DMA RX channel	• Identifier list mode • Identifier mask mode	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The concept FSM to control the DMA Rx interface is given in the following figure. DMA Rx FSM moves to Idle state if DMARXE[x] = 0 where x = IFMI – 1. The TCD setting (word transfer) is given in Table 46-15. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 46-15. TCD setting – Slave node – Rx mode

TCD Field	Value	Description
CITER[14:0]	1	Single iteration for the "major" loop
BITER[14:0]	1	Single iteration for the "major" loop
NBYTES[31:0]	[4] + 4/8 = N	Data buffer is stuffed with dummy bytes if the length is not word aligned. BIDR + BDRL + BDRM
SADDR[31:0]	—	BIDR address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	–N	—

Table continues on the next page...

Table 46-15. TCD setting – Slave node – Rx mode (continued)

TCD Field	Value	Description
DADDR[31:0]	—	RAM address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain.
START	0	No SW request

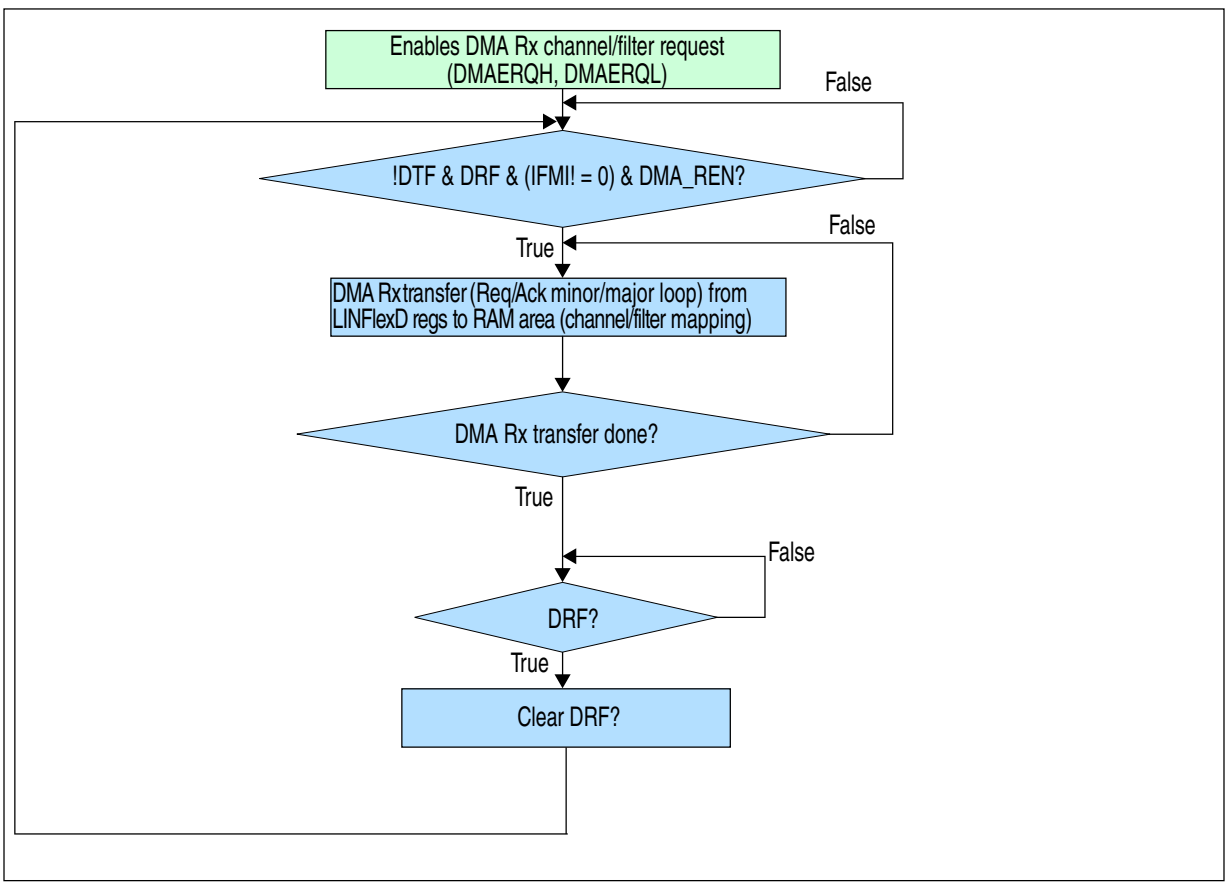

Figure 46-34. Slave node – DMA Rx FSM (concept scheme)

46.4.5.7 UART – TX mode

In UART TX mode, the DMA interface requires a DMA TX channel. A single TCD can control the transmission of an entire Tx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in Figure 46-35.

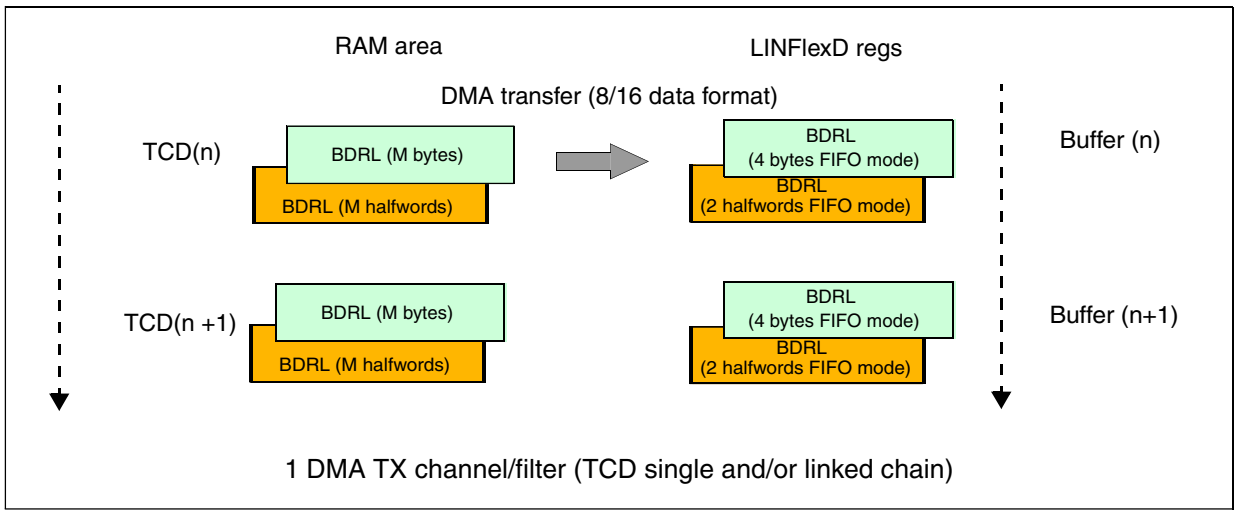

Figure 46-35. UART – TX memory map

The UART TX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Absorb the latency, following a DMA request (due to the DMA arbitration), to move data from the RAM to the FIFO
- Use low priority DMA channels

The Tx FIFO size is:

- 4 bytes in 8 bit data format
- 2 halfwords in 16-bit data format

A DMA request is triggered by FIFO-not-full (TX) status signals.

The concept FSM to control the DMA Tx interface is given in Figure 46-36. DMA Tx FSM will move to Idle state if DMATXE[0] = 0.The TCD setting (typical case) is given in Table 46-16. All other TCD fields = 0. The minor loop transfers a single byte/halfword as soon as a free entry is available in the Tx FIFO.

Table 46-16. TCD setting – UART – Tx mode

TCD Field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the "major" loop
BITER[14:0]	M		Multiple iterations for the "major" loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0]	-		RAM address

Table continues on the next page...

Table 46-16. TCD setting – UART – Tx mode (continued)

TCD Field	Value		Description
	8 bits data	16 bits data	
SOFF[15:0]	1	2	Byte/Half-word increment
SSIZE[2:0]	0	1	Byte/Half-word transfer
SLAST[31:0]	–M	–M × 2	-
DADDR[31:0]	-		BDRL address
DOFF[15:0]	0		No increment (FIFO)
DSIZE[2:0]	0	1	Byte/Half-word transfer
DLAST_SGA[31:0]	0		No scatter/gather processing
INT_MAJ	0/1		Interrupt disabled/enabled
D_REQ	1		Only on the last TCD of the chain.
START	0		No SW request

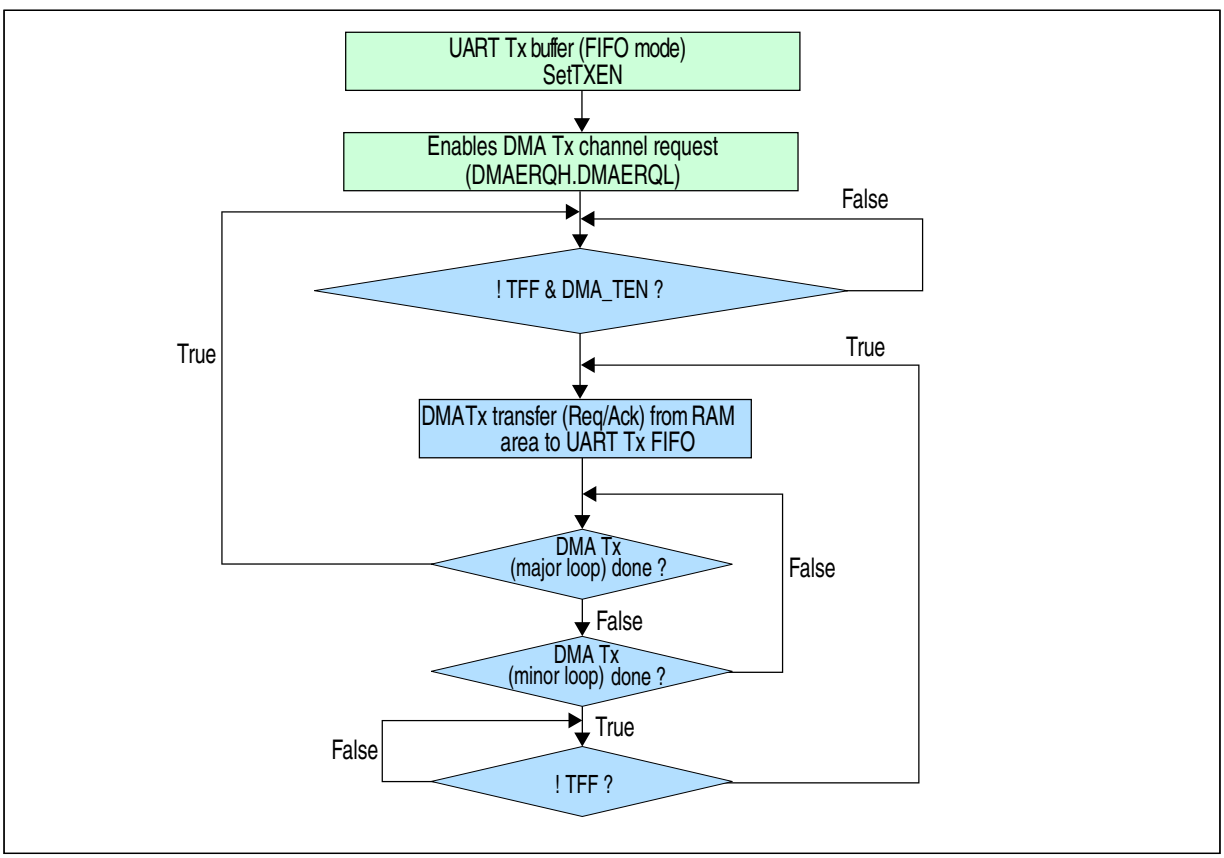

Figure 46-36. UART – DMA Tx FSM (concept scheme)

46.4.5.8 UART – RX mode

In UART RX mode, the DMA interface requires a DMA RX channel. A single TCD can control the reception of an entire Rx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in Table 46-17.

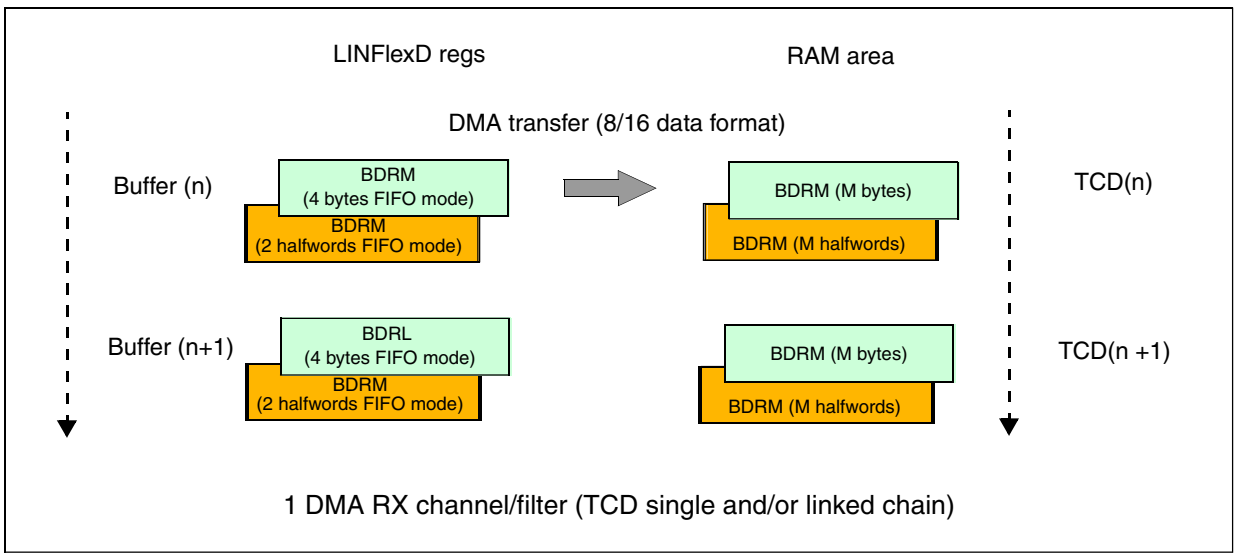

Figure 46-37. UART – RX memory map

The UART RX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Absorb the latency, following a DMA request (due to the DMA arbitration), to move data from the FIFO to the RAM
- Use low priority DMA channels

The Rx FIFO size is:

- 4 bytes in 8-bit data format

This will sufficient because just one byte allows a reaction time of about 3.8 µs (at 2 Mbit/s) (~450 clock cycles at 120 MHz) before the transmission is affected. A DMA request is triggered by FIFO and not by empty (Rx) status signals.

The concept FSM to control the DMA Rx interface is given in Figure 46-38. DMA Rx FSM will move to Idle state if DMARXE[0] = 0.The TCD setting (typical case) is given in the next table. All other TCD fields equal zero. The minor loop transfers a single byte/ halfword as soon an entry is available in the Rx FIFO. A new software reset bit is

required that allows the LINFlexD FSMs to be reset in case this timeout state is reached or in any other case. The timeout counter can be re-written by software at any time to extend the timeout period.

Table 46-17. TCD setting – UART – Rx mode

TCD Field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the "major" loop
BITER[14:0]	M		Multiple iterations for the "major" loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0]	-		BDRM address
SOFF[15:0]	0		No increment (FIFO)
SSIZE[2:0]	0	1	Byte/Half-word transfer
SLAST[31:0]	0		
DADDR[31:0]	-		RAM address
DOFF[15:0]	1	2	Byte/Half-word increment
DSIZE[2:0]	0	1	Byte/Half-word transfer
DLAST_SGA[31:0]	–M	–M × 2	No scatter/gather processing
INT_MAJ	0/1		Interrupt disabled/enabled
D_REQ	1		Only on the last TCD of the chain.
START	0		No SW request

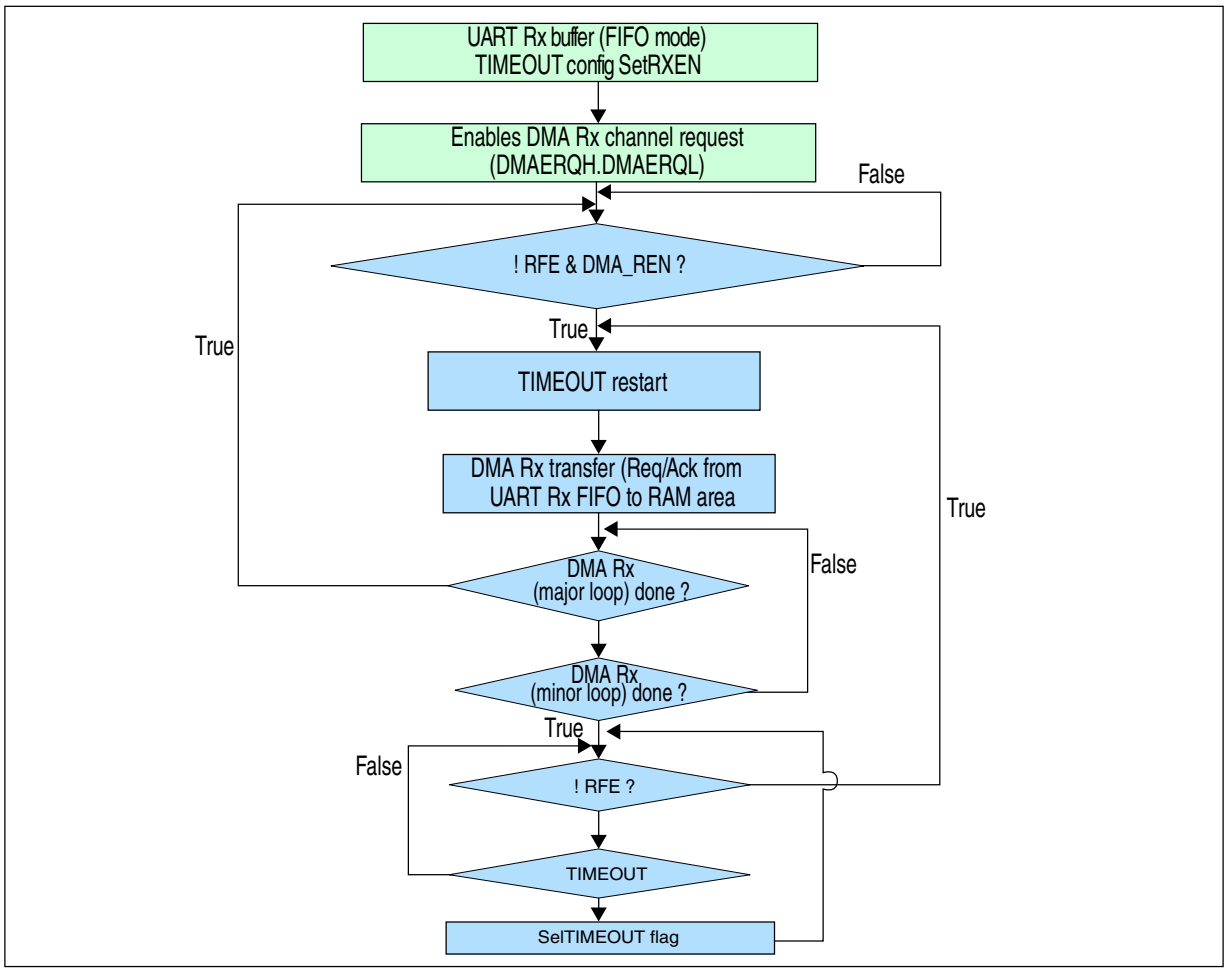

Figure 46-38. UART – DMA Rx FSM (concept scheme)

46.4.5.9 Use cases and limitations

- In LIN slave mode, the DMA capability can be used only if the ID filtering mode is activated. The number of ID filters enabled must be equal to the number of DMA channels enabled. The correspondence between channel number and ID filter is based on IFMI (identifier filter match index)
- In LIN master mode both the DMA channels (TX and RX) must be enabled in case the DMA capability is required
- In UART mode the DMA capability can be used only if the UART Tx/Rx buffers are configured as FIFOs
- DMA and CPU operating modes are mutually exclusive for the data/frame transfer on a UART or LIN node. Once a DMA transfer is finished the CPU can manage subsequent accesses

- Error management must always be executed via the CPU enabling the related error interrupt sources. DMA capability does not provide support for error management. Error management means checking status bits, handling IRQs, and potentially canceling DMA transfers
- The DMA programming model must be coherent with the TCD setting defined in this document
- When IPG_STOP is requested, SW has to first disable DMATXE/DMARXE channel registers, after the current minor loop finishes (indicated by the clearing of ACTIVE bit in DMA TCD register). This ensures that IPG_STOP_ACK is generated and IP enters STOP mode.

46.5 Memory map and register description

The following points should be considered for the below mentioned LINFlexD registers:

- Reset values are with-slave/without-slave (master only) format
- If not specified, then the bit can be configured for both master only and master/slave format; in other words, for both values of (generic) slave = 0 and (generic) slave = 1.

NOTE

In Master mode, the registers IFCR0-IFCR15 are not present and the corresponding absolute address of the below register changes as shown in the following table.

Table 46-18. Offsets of the register from offsets 8C to 9C

Register name	Master/slave mode	Master only mode
LINFlexD_GCR	0x8C	0x4C
LINFlexD_UARTPTO	0x90	0x50
LINFlexD_UARTCTO	0x94	0x54
LINFlexD_DMATXE	0x98	0x58
LINFlexD_DMARXE	0x9C	0x5C

NOTE

In Master Mode, read access to IFMI register and read/write access to IFER and IFMR registers would result in transfer error.

NOTE

Any access to A0 location will not generate a transfer error.

46.5.1 LIN Control Register 1 (LINFlexD_LINCR1)

LINCR1 consists of control bits used to configure features of the LINFlexD.

NOTE

When accessing the LINCR1 register, each reserved bit should be written to its original reset value.

Address: 0h base + 0h offset = 0h

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	CCD	CFD	LASE	AUTOWU	MBL				BF	Reserved	LBKM	MME	SSBL	RBLM	SLEEP	INIT
W																
Reset	0	0	0	0	0	0	0	0	1	0	0	*	0	0	1	0

* Notes:
- MME field: If slave = 0, then MME bit is 1, else MME bit is 0

LINFlexD_LINCR1 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 CCD	Checksum Calculation disable This bit can be written during Initialization mode only. It is read-only in Normal mode. Register bit can be read in any mode, written only in initialization mode. 0 Checksum calculation is done by hardware. When this bit is reset the LINCFR register is read only. 1 Checksum calculation is disabled. When this bit is set the LINCFR register is read/write. User can program this register to sent a software calculated checksum/CRC (provided CFD is reset).
17 CFD	Checksum field disable This bit can be configured during Initialization mode only. It is read-only in Normal mode. Register bit can be read in any mode, written only in initialization mode. 0 Checksum field is sent after the required number of data bytes are sent 1 No checksum field is sent in the frame
18 LASE	LIN Autosynchronization Enable This bit can be programmed in Initialization mode only. It is read-only in Normal mode. (Note: If generic auto_sync = 0, then this bit will always read a 0). Register bit can be read in any mode, written only in initialization mode. 0 Autosynchronization disabled 1 Autosynchronization enabled
19 AUTOWU	Auto Wakeup This bit can be configured during Initialization mode only. This bit is utilized in UART mode also. Register bit can be read in any mode, written only in initialization mode. 0 Sleep bit is cleared by software only 1 Sleep bit gets cleared by hardware whenever WUF bit of LINSR is set
20–23 MBL	Master Break Length These bits choose the length of the Sync break to be generated by the master. These bits can be programmed in Initialization mode only. They are read-only in Normal mode. Register bit can be read in any mode, written only in initialization mode. 0000 10-bit break length

Table continues on the next page...

LINFlexD_LINCR1 field descriptions (continued)

Field	Description
	0001 11-bit break length 0010 12-bit break length 0011 13-bit break length 0100 14-bit break length 0101 15-bit break length 0110 16-bit break length 0111 17-bit break length 1000 18-bit break length 1001 19-bit break length 1010 20-bit break length 1011 21-bit break length 1100 22-bit break length 1101 23-bit break length 1110 36-bit (cooling) break length 1111 50-bit break length
24 BF	By-pass filter This bit can be programmed during Initialization mode only. **NOTE:** If generic slave = 0 or no_of_filters = 0, then this bit will always read a 1, and cannot be programmed. Register bit can be read in any mode, written only in initialization mode. 0 No IRQ if ID does not match any filter 1 A RX IRQ is generated on ID not matching any filter
25 Reserved	This field is reserved. When accessing the LINCR1 register, each reserved bit should be written to its original reset value.
26 LBKM	Loop Back mode Refer to "Loop back mode" in Test mode . Note that this bit can be programmed only in Initialization mode. This bit is utilized in UART mode also. Register bit can be read in any mode, written only in initialization mode. 0 Loop Back Mode disabled 1 Loop Back mode enabled
27 MME	Master mode enable This bit can be programmed in Initialization mode only. It is read-only in Normal mode. **NOTE:** If generic slave = 0, then this bit will read a '1' always, and cannot be programmed. Register bit can be read in any mode, written only in initialization mode. 0 Slave Mode 1 Master Mode
28 SSBL	Slave Mode Sync Break Length This bit can be programmed in Initialization mode only. It is read only in Normal mode. Register bit can be read in any mode, written only in initialization mode. 0 11 bit break length 1 10 bit break length

Table continues on the next page...

LINFlexD_LINCR1 field descriptions (continued)

Field	Description
29 RBLM	Receiver Buffer Locked mode This bit can be programmed in Initialization mode only. It is read-only in Normal mode. This bit is utilized in UART mode also. Register bit can be read in any mode, written only in initialization mode. 0 Receiver Buffer not locked, next incoming message will overwrite the old one 1 Receiver buffer locked against overrun. Once the buffer is full the next incoming message will be discarded if buffer is not released — in other words, RMB is not reset by software.
30 SLEEP	Sleep Mode Request This bit is set by software to request LINFlexD to enter Sleep mode. This bit is cleared by software or hardware (if AUTOWU bit in LINCR1 and WUF bit in LINSR are set) to exit sleep mode. This bit is utilized in UART mode also.
31 INIT	Initialization Mode Request The software sets this bit to switch the hardware into Initialization mode. On clearing this bit (and if SLEEP bit is also zero) LINFlexD enters normal mode. This bit is utilized in UART mode also.

46.5.2 LIN Interrupt enable register (LINFlexD_LINIER)

LINFlexD_LINIER field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SZIE	Stuck at zero Interrupt Enable An interrupt is generated if this bit is set and the Stuck at Zero Flag (SZF) in LINESR or UARTSR is set.

Table continues on the next page...

LINFlexD_LINIER field descriptions (continued)

Field	Description
	0 No interrupt 1 Interrupt enabled
17 OCIE	Output Compare Interrupt Enable 0 No interrupt 1 Interrupt generated when OCF bit in LINESR or UARTSR is set
18 BEIE	Bit Error Interrupt Enable 0 No interrupt 1 Interrupt generated when BEF bit in LINESR is set
19 CEIE	Checksum Error Interrupt Enable An interrupt is generated if this bit is set and the Checksum Error Flag (CEF) is set in LINESR. 0 No interrupt 1 Interrupt enabled
20 HEIE	Header Error Interrupt Enable An interrupt is generated when this bit is set and either of the following flags are set SFEF, SDEF, IDPEF in LINESR are set. **NOTE:** If generic slave = 0, then this bit will always read a 0 and cannot be programmed. 0 No interrupt 1 Interrupt enabled
21–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 FEIE	Frame Error Interrupt Enable 0 No interrupt 1 Interrupt generated if Frame Error Flag (FEF) bit is set in LINESR or UARTSR
24 BOIE	Buffer Overrun Error Interrupt Enable An interrupt is generated if this bit is set and the Buffer Overrun Flag (BOF) is set in LINESR or UARTSR. 0 No interrupt 1 Interrupt enabled
25 LSIE	LIN state Interrupt enable Interrupt is generated only when entering the above fields. This interrupt can mainly be used for debugging purposes. The interrupt has no status flag. 0 No interrupt 1 Interrupt generated on entering the following states: Sync Del, Sync Field, Identifier field, Checksum
26 WUIE	Wakeup interrupt enable If this bit is set and the WUF in LINSR or UARTSR is set then an interrupt is generated. 0 No interrupt 1 Interrupt enabled
27 Reserved	This field is reserved.

Table continues on the next page...

LINFlexD_LINIER field descriptions (continued)

Field	Description
28 TOIE	Timeout Interrupt Enable An interrupt is generated if this bit is set and UARTSR[TO] status bit is set (in UART mode). 0 No interrupt 1 Interrupt enabled
29 DRIE	Data Reception complete Interrupt enable An interrupt is generated when this bit is set and Data Received flag (DRF) in LINSR or UARTSR is set. 0 No interrupt 1 Interrupt enabled
30 DTIE	Data Transmitted Interrupt enable An interrupt is generated when this bit is set and Data Transmitted flag (DTF) in LINSR or UARTSR is set. 0 No interrupt 1 Interrupt enabled
31 HRIE	Header Received Interrupt An interrupt is generated when this bit is set and the Header Received flag (HRF) in LINSR is set. **NOTE:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed. 0 No interrupt 1 Interrupt enabled

46.5.3 LIN Status Register (LINFlexD_LINSR)

This register consists of status bits indicating the state of the LINFlexD hardware.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0												AUTOSYNC_COMP	RDC		
W													w1c			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	LINS				0		RMB	DRBNE	RXbusy	RDI	WUF	0		DRF	DTF	HRF
W	1						w1c	w1c			w1c			w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	*	0	0	0	0	0	0

* Notes:
- RDI field: Reset value of RDI reflects the RX pin state

LINFlexD_LINSR field descriptions

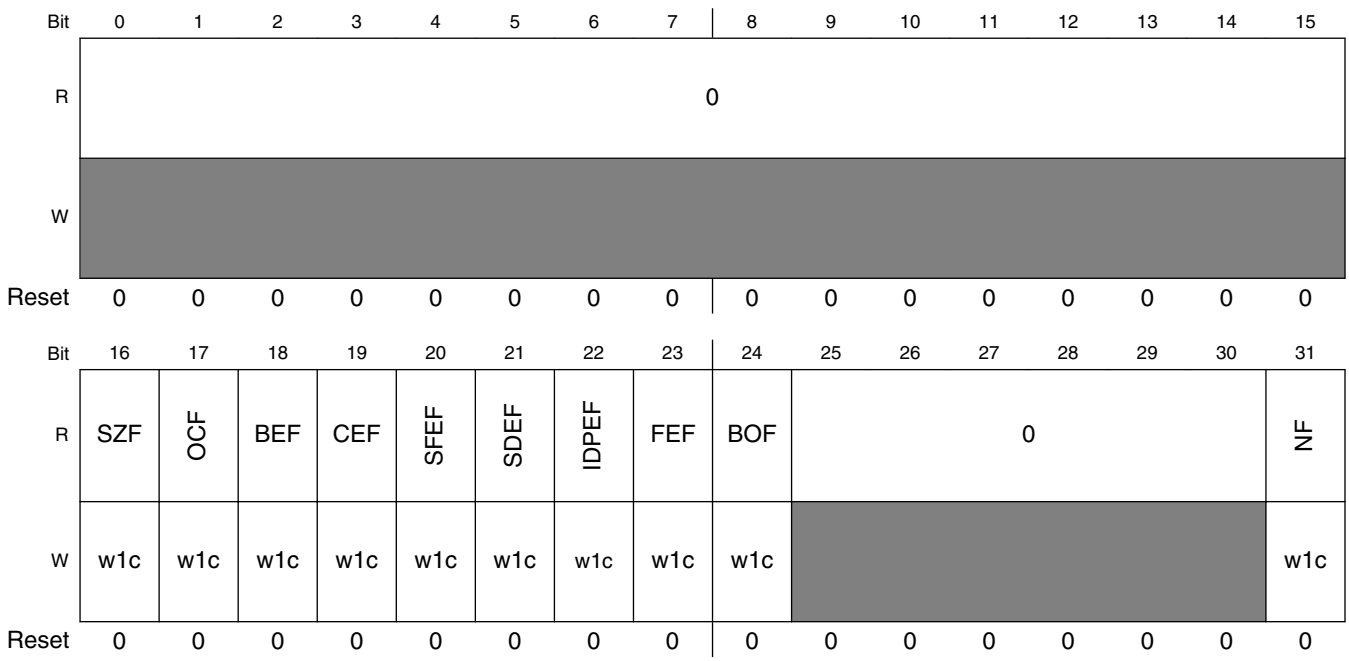
Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 AUTOSYNC_COMP	AUTOSYNC_COMP This bit is set after autosynchronization is complete and when the LASE bit in LINCR1 register is enabled. Only after this bit is set, the contents of LINIBRR and LINFBRR registers can be read in autosynchronization mode. **NOTE:** If autosynchronization is disabled, this bit is reserved.
13–15 RDC	Receive Data Byte Count RDC contains the number of entries (bytes) in the Receive data buffer in LIN mode. RDCx is a read-only field available for debug purposes. 000 1 byte 001 2 bytes 010 3 bytes 011 4 bytes 100 5 bytes 101 6 bytes 110 7 bytes 111 8 bytes

Table continues on the next page...

LINFlexD_LINSR field descriptions (continued)

Field	Description
16–19 LINS	LIN state In UART mode Idle, Init, Sleep, and Data Transmission/Reception states are flagged by the LIN status bits. **NOTE:** The value of this bit field doesn't change by any write operation to it. Writing 0xF to this bit field clears the Rx interrupt, only when set due to the LIN state event. 0000 Sleep mode: LINFlexD is in Sleep mode, to save power consumption. 0001 Init mode: LINFlexD is in Initialization mode. 0010 Idle mode: This mode is entered when: SLEEP bit and INIT bit are reset by software; Wakeup pulse has been received on RX pin (AUTOWU set); Previous frame transmission/reception has been completed/aborted 0011 Sync break: In slave mode, a falling edge followed by a dominant state has been detected. Receiving sync break. In slave mode, a falling edge followed by a dominant state has been detected. Receiving sync break. In master mode, sync break transmission ongoing. Note: In slave mode upon any error LIN state could be either Idle or Rec Break, depending on last bit detected on LIN_RX. If last bit detected is dominant then Rec_Break, otherwise Idle. 0100 Sync Del: In Slave mode, valid Sync break has been detected (10 bit or 11 bit). Waiting for a rising edge. In Master mode, Sync break transmission has been completed, sync delimiter transmission is ongoing. 0101 Sync Field: In Slave mode, a valid sync Del has been detected (recessive state for at least one bit time). Receiving sync field. In Master mode, sync field transmission ongoing. 0110 Identifier Field: In Slave mode, a valid sync field has been received. Receiving ID field. In Master mode, identifier transmission is ongoing. 0111 Header Reception/Transmission: In Slave mode, a valid header has been received and Identifier field is available in the BIDR. In Master mode, header transmitted. 1000 Data Reception/Data Transmission: In Receiver mode, reception ongoing. In Transmitter mode, response transmission ongoing. 1001 Checksum: Data transmission/reception completed, checksum transmission/reception ongoing.
20–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 RMB	Release Message Buffer 0 Buffer data is free. Reset by hardware in when in Initialization mode 1 Buffer data ready to be read by software. This bit should be cleared by software after reading the data received in the buffer.
23 DRBNE	Data Reception Buffer Not Empty Flag This bit is set by hardware as soon as the first byte of response has been received and stored in BDRL (when there is at least one data byte in reception buffer). Software should clear it after reading all the buffers. This bit is also reset by hardware in Initialization mode. This flag could be checked by software in case of a response timeout event.
24 RXbusy	Receiver Busy flag In Slave mode after header reception, if DIR bit is reset and reception starts, then this bit is set. In this case user cannot set the DTRQ bit. 0 Receiver is idle 1 Reception ongoing

Table continues on the next page...



LINFlexD_LINSR field descriptions (continued)

Field	Description
25 RDI	LIN Receive signal This bit reflects the current status of the Rx pin. **NOTE:** After reset is released, RDI reflects the actual value of Rx pin.
26 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the Rx pin. 1. When slave is in Sleep mode 2. When master is in Sleep mode or Idle mode It can be cleared by software. It gets reset by hardware in Initialization mode.
27–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 DRF	Data Reception Completed flag This bit is set by hardware and indicates that data reception has been completed. This flag should be cleared by software. This bit is also reset by hardware in Initialization mode. **NOTE:** In case framing error or checksum error occurs then this flag is not set.
30 DTF	Data Transmission Completed flag This bit is set by hardware and indicates that data transmission is completed. This flag should be cleared by software. This bit is also reset by hardware in Initialization mode. **NOTE:** For LIN mode, in case a bit error occurs (and IOBE is 1) then this flag is not set.
31 HRF	Header Received flag This bit is set when the header reception is completed. It should be cleared by software. This bit is set only when: a) All filters are inactive and Bypass filter (BF) bit is set b) No match in any filter and Bypass filter (BF) bit is set c) TX filter match At end of frame or frame aborted, if HRF is still set, it gets reset by hardware. This bit is also reset by hardware in Initialization mode. **NOTE:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.

46.5.4 LIN Error Status Register (LINFlexD_LINESR)

Refer to Errors for detailed description of all errors.

Address: 0h base + Ch offset = Ch

LINFlexD_LINESR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SZF	Stuck at Zero flag This bit is set when there is a stuck-at-zero timeout error. It should be reset by software.
17 OCF	Output Compare Flag 0: No output compare event occurred 1: In master mode, LINESR[OCF] flag is set when counter LINTCSR[CNT] has matched the content of LINOCR[OC2]. In slave mode, LINESR[OCF] is set when the content of the counter LINTCSR[CNT] has matched the content of LINOCR[OC1] or LINOCR[OC2]. This bit should be cleared by software. If this bit is set, MODE bit in LINTCSR is cleared, and the IOT bit of LINTCSR is set, then LINFlexD moves to Idle state. If the MODE bit in LINTCSR is clear, then OCF gets reset by hardware in Initialization mode; if the MODE bit is set, then OCF maintains its status irrespective of the LIN state.
18 BEF	Bit Error flag This bit is set by hardware when there is a bit error. It should be cleared by software. Reset by hardware in Initialization mode.

Table continues on the next page...

LINFlexD_LINESR field descriptions (continued)

Field	Description
19 CEF	Checksum Error flag This bit is set by hardware if the received checksum does not match the hardware-calculated checksum. It should be cleared by software. This error will never occur if CCD or CFD bit of LINCR1 is set. Reset by hardware in Initialization mode.
20 SFEF	Sync Field Error flag This bit is set by hardware when the received Sync Field is inconsistent. It should be cleared by software. Reset by hardware in Initialization mode. If generic slave = 0, then this bit will always read a 0, and cannot be programmed.
21 SDEF	Sync Delimiter Error flag This bit is set by hardware when the delimiter is too short (in other words, less than one bit time). It should be cleared by software. Reset by hardware in Initialization mode. **NOTE:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.
22 IDPEF	ID Parity Error flag This bit is set by hardware when there is an error in the ID parity. It should be cleared by software. **NOTE:** Header Error Interrupt is triggered for SFEF or SDEF or IDPEF flag is set and HEIE is set. If generic slave = 0, then this bit will always read a 0, and cannot be programmed. For generic slave = 1,this bit is reset by hardware in Initialization mode.
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. Reset by hardware in initialization mode.
24 BOF	Buffer overrun flag This bit is set by hardware when there is a new byte received and RMB bit is not cleared. It can be cleared by software. Reset by hardware in initialization mode.
25–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. Reset by hardware in Initialization mode.

46.5.5 UART Mode Control Register (LINFlexD_UARTCR)

NOTE

When accessing the UARTCR register, reserved bits should always be written to zero.

NOTE

- The LINFlexD module in UART mode does not support communication with Special Word Length (UARTCR[WLS] = 1) in buffer mode.
- The LINFlexD module in UART mode supports communication with Special Word Length (UARTCR[WLS] = 1) in FIFO mode only with UARTCR[WL1, WL0] = 1,1.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	MIS	CSP			OSR				ROSE	NEF			DTU_PCETX	SBUR		WLS

LINFlexD_UARTCR field descriptions

Field	Description
0 MIS	Monitor Idle State Register bit can be read in any mode, written only in initialization mode. 0 UARTCTO monitors the number of bits to be received. 1 UARTCTO monitors the idle state of the reception line.
1–3 CSP	Configurable Sample Point (i) These bits will decide the sample point during reduced over sampling. CSP can take the following range of values for a certain over sampling rate: **OSR** / **CSP** 4 / 2,3 5 / 2, 3, 4 6 / 3, 4, 5 8 / NA Register bit can be read in any mode, written only in initialization mode.

Table continues on the next page...

LINFlexD_UARTCR field descriptions (continued)

Field	Description
4–7 OSR	Over Sampling Rate These bits are programmable by the user to configure the number of samples taken for a bit when reduced over sampling is enabled. Allowed values are: 4, 5, 6 and 84 and 8 . Register bit can be read in any mode, written only in initialization mode.
8 ROSE	Reduced Over Sampling EnableRegister bit can be read in any mode, written only in initialization mode. 0 Each bit is over sampled sixteen times. 1 OSR bits decide the over sampling rate.
9–11 NEF	Number of expected frame These bits are used to configure the number of expected frames in UART reception mode. If the DTU bit is set, then the UART timeout counter will be reset after the configured number of frames have been received. Register bit can be read in any mode, written only in Initialization mode. Register bit is a read/write field.
12 DTU_PCETX	Disable Timeout in UART mode This bit can be programmed in Initialization mode only when the UART bit is set. There is an internal counter that gives the number of frames received. **In Buffer mode:** This timer gets reset whenever the number of bytes received (rec_byte_cnt) is equal to RDFL. At this point the DRF bit is also set and num_of_frames (number of frames received), rec_byte_cnt are reset. When num_of_frames equals NEF, Disable Timeout is generated. But this clears num_of_frames also. Thus the timer restarts again. The value of counter is 0 when it restarts. **In FIFO mode:** When num_of_frames equals NEF, Disable Timeout is generated which clears num_of_frames and causes the timer to restart again. The value of counter is 0 when it restarts. Notes: • Disable Timeout causes only the Timer to restart which enables Timeout again. • Timer reset means it resets and starts counting again and the Timeout is enabled. 0 Timeout has to be handled by software 1 Timeout in UART mode is disabled after the configured number of data frames are received
13–14 SBUR	Stop bits in UART reception mode When the UART is used for transmission and reception we have to set the same number of stop bits in GCR and SBUR. When the UART is used only as receiver, it is enough to set SBUR bits only. This bit can be programmed in the initialization mode only, when the UART bit is set. Register bit can be read in any mode, written only in Initialization mode. 00 1 stop bit 01 2 stop bits 10 3 stop bits 11 reserved
15 WLS	Special Word Length in UART mode

Table continues on the next page...

LINFlexD_UARTCR field descriptions (continued)

Field	Description
	This bit can be programmed in initialization mode only when the UART bit is set. If this bit is set, setting WL and PCE bits has no effect in UART reception although parity check is enabled by default in this mode and PC0/1 bits can be used to select the parity control. This bit is given the highest priority in UART reception mode. Register bit can be read in any mode, written only in Initialization mode. 0 This bit is disabled. 1 This bit enables 12-bit + parity bit in reception (UART mode) for MSC (Micro Second Channel upstream frame) support.
16–18 TDFL_TFC	Transmitter Data Field Length/TX FIFO Counter TDFL defines the number of bytes to be transmitted in UART buffer mode (TFBM = 0). TDFL is a read/write field. Bit 16 is reserved and not implemented. When the UART data length is configured as halfword (WL = 10 or WL = 11), only the configurations TDFL = x01 or TDFL = x11 are allowed. x00 : 1 byte x01 : 2 bytes x10 : 3 bytes x11 : 4 bytes Register bit is a read/write field. TFC contains the number of entries (bytes) of the Tx FIFO in UART FIFO mode (TFBM = 1). TFCx is a read-only field available for debug purposes. 000 : empty 001 : 1 byte 010 : 2 bytes 011 : 3 bytes 100 : 4 bytes Others : reserved TDFLTFC can be programmed and are significative only when the UART bit is set. Register bit can be read in any mode, written only in Initialization mode. **NOTE:** When a debugger is connected, this counter will decrement if TxFIFO is being read through the debugger. **NOTE:** In case of data path is functioning normally, RFC/TFC counters will be cleared internally by HW.
19–21 RDFL_RFC	Reception Data Field Length /RX FIFO Counter RDFL defines the number of bytes to be received in UART buffer mode (RFBM = 0). RDFL is a read/write field. Bit 19 is reserved and not implemented. When the UART data length is configured as halfword (WL = 10 or WL = 11), only the configurations RDFL = x01 or RDFL = x11 are allowed. x00 : 1 byte x01 : 2 bytes x10 : 3 bytes x11 : 4 bytes RFC contains the number of entries (bytes) of the Rx FIFO in UART FIFO mode (RFBM = 1). RFCx is a read-only field available for debug purposes. 000 : Empty

LINFlexD_UARTSR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SZF	Stuck at Zero flag This bit is set by hardware when 100 dominant bits are detected. It should be cleared by software. An interrupt will be generated if the SZIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
17 OCF	Output Compare Flag An interrupt will be generated if the OCIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set. **NOTE:** For Baud rate above 1 Mbit/s, this flag is not usable. 0 No output compare event occurred 1 The content of the counter has matched the content of LINOCR
18–21 PE	Parity Error flag These bits indicate if there is a Parity Error in the corresponding byte. No interrupt is generated if this error occurs. This bit will reflect the same value as in LINESR, when in initialization mode and UART bit set. **NOTE:** Parity is checked only after complete frame is received. Following are the conditions when WL bits = 01 or 11 (either PE0 or PE2 is only set). • When PE0 is set, it indicates Parity error in either first or second byte received • When PE2 is set, it indicates Parity error in either third or fourth byte received 0 No parity error 1 Parity error in the corresponding received byte
22 RMB	Release Message Buffer This bit should be cleared by software. This bit will reflect the same value as in LINSR, when in Initialization mode and the UART bit is set. 0 Buffer data is free 1 Buffer data ready to be read by software
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. It will generate an interrupt if the FEIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
24 BOF	FIFO/Buffer overrun flag This bit is set by hardware when there is a new byte received and the RMB bit is not cleared in UART buffer mode. In UART FIFO mode this bit is set when there is a new byte and the Rx FIFO is full. In UART FIFO mode, once Rx FIFO is full, the new received message will be discarded irrespective of the new value of the RBLM bit. In UART Rx Buffer mode, if RBLM is set then the new message received will be discarded; if RBLM is reset then the new message will overwrite the buffer. It can be cleared by software writing a 1. An interrupt is generated if the BOIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
25 RDI	Receiver Data Input signal This bit reflects the current status of the RX pin.

Table continues on the next page...

LINFlexD_UARTSR field descriptions (continued)

Field	Description
26 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the RX pin in sleep mode. It should be cleared by software. An interrupt will be generated if the WUIE bit in LINIER is set. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set.
27 RFNE	Receive FIFO Not Empty RFNE bit is set by hardware in UART FIFO mode (RFBM = 1), when there is at least one data byte present in the receive FIFO. RFNE is a read-only bit for debugging purposes. This flag can be used by software in case of a timeout event.
28 TO	Timeout This bit is set by hardware when a UART timeout occurs — in other words, the value of UARTCTO becomes equal to the preset value of the timeout (UARTPTO register setting). TO should be cleared by software. The SR bit should be used to reset the receiver fsm to Idle state in case of UART TIMEOUT for UART reception, depending on the application, in both buffer and FIFO mode. An interrupt will be generated when LINIER.TOIE bit is set on the Error interrupt line in UART mode.
29 DRFRFE	Data Reception Completed Flag /Rx FIFO Empty Flag DRF is set by hardware in UART buffer mode (RFBM = 0) and indicates that the number of bytes programmed in RDFL have been received. DRF should be cleared by software. An interrupt will be generated if the DRIE bit in LINIER is set. DRF bit is set when the configured number of valid stop bits are received for the last frame (number of frames is configurable by RDFL bits). DRF is set irrespective of framing error in case framing error is in the last STOP bit configured, parity error or overrun error. This bit will reflect the same value as in LINSR when in Initialization mode and the UART bit is set. Register bit can be read/cleared by software. Writing 1 clears contents. RFE is set by hardware in UART FIFO mode (RFBM = 1) when the RX FIFO is empty. RFE is a read-only bit for debugging purposes. It is internally used by the DMA RX interface.
30 DTFTFF	Data Transmission Completed Flag/ TX FIFO Full Flag DTF is set by hardware in UART buffer mode (TFBM = 0) and indicates that data transmission is completed. DTF should be cleared by software. An interrupt will be generated if the DTIE bit in LINIER is set. This bit will reflect the same value as in LINSR when in Initialization mode and the UART bit is set. Register bit can be read/cleared by software. Writing 1 clears contents. TFF is set by hardware in UART FIFO mode (TFBM = 1) when TX FIFO is full. TFF is a read-only bit for debugging purposes. It is internally used by the DMA TX interface.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. During reduced oversampling (ROSE bit = 1), it is enabled only when OSR = 8.

46.5.7 LIN Time-Out Control Status Register (LINFlexD_LINTCSR)

This register contains control and status bits for timeout feature.

NOTE

When the MODE bit is 0, any activity on the transmit or receive pins will cause an unwanted change in the value of the 8-bit field Output Compare Value 2 (OC2) of the LIN Output Compare register (LINOCR). The LINFlexD module is enabled in LIN mode and the value of the MODE bit of the LIN Timeout Control Status register (LINTCSR) is changed from ‘1’ to ‘0’, then the old value of the Output Compare Value 1 (OC1) and Output Compare Value 2 (OC2) of the LIN Output Compare register (LINOCR) is retained. As a consequence, if the module is reconfigured from UART to LIN mode, or LINTCSR MODE bit is changed from ‘1’ to ‘0’, an incorrect timeout exception is generated when a LIN communication starts. To avoid this, set mode bit to '1', then reconfigure the LINFlexD in LIN mode and then reset the MODE bit. Before switching LINTCSR[MODE] from 1 to 0 in between frames, load LINOCR with 0xFFFF.

Address: 0h base + 18h offset = 18h

LINFlexD_LINTCSR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 MODE	Time-out counter mode This bit can be configured only during initialization. Register bit can be read in any mode, written only in initialization mode. **NOTE:** Always set LINTCSR[MODE] to 1 when UARTCR[UART] is 1. **NOTE:** Before switching LINTCSR[MODE] from 1 to 0 in between frames, load LINOCR to 0xFFFF. 0 LIN mode 1 Output compare mode
22 IOT	Idle on timeout Register bit can be read in any mode, written only in initialization mode. This feature is applicable only when MODE bit in LINTCSR is cleared. 0 LIN state machine does not reset to Idle on timeout 1 LIN state machine resets to Idle on timeout event
23 TOCE	Time-out counter enable TOCE is always configurable by software in Initialization mode. If LIN state is other than INIT and if timer is configured in LIN mode, then hardware takes control of TOCE. 0 Time-out counter disable. OCF flag is not set on an output compare event. 1 Time-out counter enable. OCF flag is set if an output compare event occurs.
24–31 CNT	Counter Value These bits reflect the value of a counter used for timeout. **NOTE:** For proper functionality of this counter, LINIBRR should be >= 5.

46.5.8 LIN Output Compare Register (LINFlexD_LINOCR)

This register contains the value to be compared to the LINTCSR:CNT value. This register is writable by software only in Output Compare Mode.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:

- HTO field: HTO reset values:

  HTO resets to 0011100b in Master only mode, if generic slave = 0.

  HTO resets to 0101100b in Master/Slave mode, if generic slave = 1.

LINFlexD_LINTOCR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 RTO	Response timeout value This is the response timeout duration (in bit time) for 1 byte. The reset value is 0Eh = 14, corresponding to $T_{Response_Maximum} = 1.4 \times T_{Response_Nominal}$
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 HTO	Header timeout value This register contains the header timeout duration (in bit time). This register can be written only for Slave mode. If Master mode is enabled then these bits will always reflect 28 (1.4 x 10 bits of sync + 1.4 x 10 bits of ID). For slave, these bits should be programmed without considering 11 bits of break.

46.5.10 LIN Fractional Baud Rate Register (LINFlexD_LINFBRR)

This register consists of bits that decide the fractional part of the LIN Baud Rate. It can be programmed only in Initialization mode.

NOTE

When LASE bit is set, this register should be read only after AUTOSYNC_COMP bit in LINSR register is set to obtain the correct value.

NOTE

This register cannot be used when reduced oversampling is enabled (ROSE bit = 1)

Address: 0h base + 24h offset = 24h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

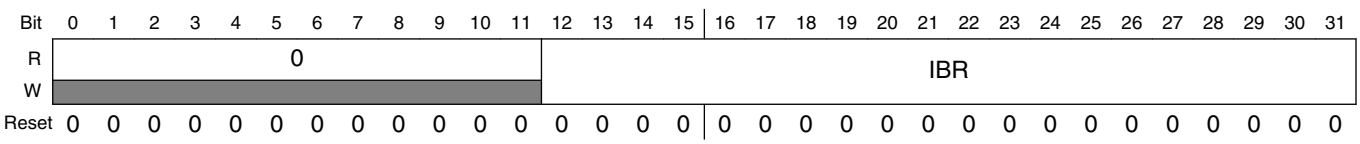
LINFlexD_LINFBRR field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 FBR	Fractional Baud rates Register bit can be read in any mode, written only in initialization mode. 0000 Fraction(LDIV) = 0 0001 Fraction(LDIV) = 1/16 0010 Fraction(LDIV) = 2/16 0011 Fraction(LDIV) = 3/16 0100 Fraction(LDIV) = 4/16 0101 Fraction(LDIV) = 5/16 0110 Fraction(LDIV) = 6/16 0111 Fraction(LDIV) = 7/16 1000 Fraction(LDIV) = 8/16 1001 Fraction(LDIV) = 9/16 1010 Fraction(LDIV) = 10/16 1011 Fraction(LDIV) = 11/16 1100 Fraction(LDIV) = 12/16 1101 Fraction(LDIV) = 13/16 1110 Fraction(LDIV) = 14/16 1111 Fraction(LDIV) = 15/16



46.5.11 LIN Integer Baud Rate Register (LINFlexD_LINIBRR)

This register consists of control bits that decide the baud rate along with the LINFBRR. It can be programmed only in Initialization mode.

NOTE

When LASE bit is set, this register should be read only after AUTOSYNC_COMP bit in LINSR register is set to obtain the correct value.

Address: 0h base + 28h offset = 28h

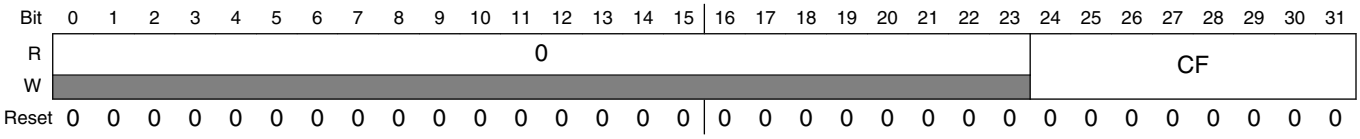
LINFlexD_LINIBRR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 IBR	Integer Baud rates These bits along with the fractional baud rate bits decide the LIN baud rate. IBR = 0h: LIN clock disabled IBR = 1h: Mantissa (LDIV) = 1 ... IBR = FFFFEh: Mantissa (LDIV) = 1048574 IBR = FFFFFh: Mantissa (LDIV) = 1048575 Register bit can be read in any mode, written only in initialization mode.

46.5.12 LIN Checksum Field Register (LINFlexD_LINCFR)

NOTE

There is a delay between 4 to 6 clock cycles of PBRIDGEx_CLK for the internal checksum's value (which is clocked with LIN_CLK/16 * LDIV) to reflect on LINCFR.



This register consists of checksum bits.

CFD	CCD	LINCHKSUM Read/write	Checksum sent
1	1	read/write	None

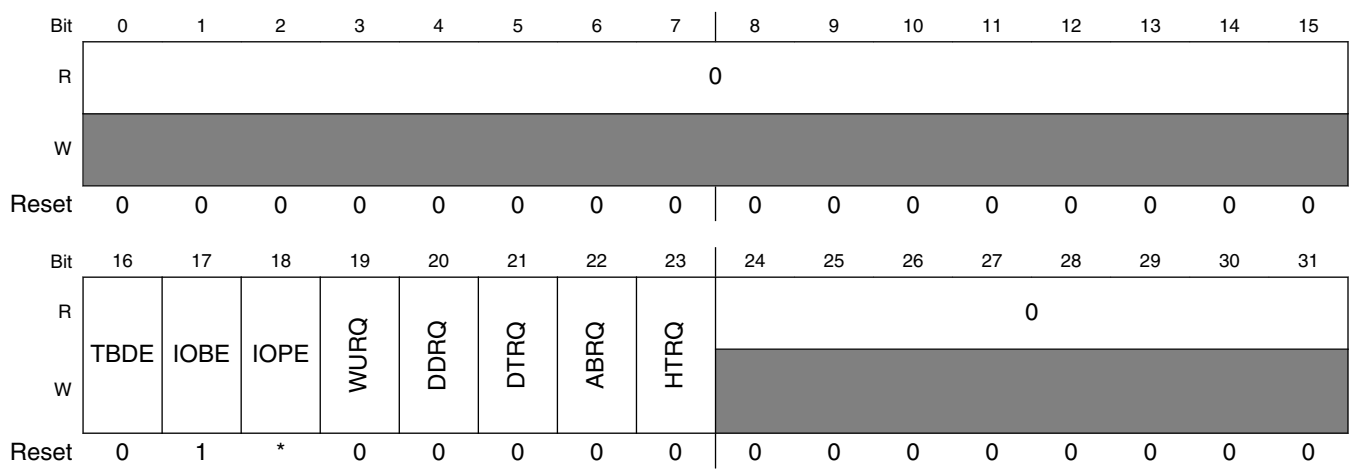
Table continues on the next page...

CFD	CCD	LINCHKSUM Read/write	Checksum sent
1	0	read-only	None
0	1	read/write	Programmed checksum
0	0	read-only	Calculated checksum

Address: 0h base + 2Ch offset = 2Ch

LINFlexD_LINCFR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 CF	Checksum bits When the CCD bit is reset these bits are read-only and are calculated by hardware. When the CCD bit is set, these bits can be written by software.



46.5.13 LIN Control Register 2 (LINFlexD_LINCR2)

This register includes control status bits related to buffer operations.

NOTE

When accessing the LINCR2 register, each reserved bit should be written to its original reset value.

Address: 0h base + 30h offset = 30h

* Notes:

- IOPE field: When slave = 0, this field always reads ‘0’ and cannot be programmed else this bit is programmable and reset value is 1.

LINFlexD_LINCR2 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 TBDE	Two Bit delimiter bit This bit can be set in Initialization mode only. Register bit can be read in any mode, written only in initialization mode. 0 Delimiter length in break field is 1 bit 1 Delimiter length in break field is 2 bits
17 IOBE	Idle on Bit Error This bit can be set in Initialization mode only. Register bit can be read in any mode, written only in initialization mode. 0 Bit Error does not reset LIN state machine 1 Bit Error resets LIN state machine
18 IOPE	Idle on Identifier Parity Error This bit can be set in Initialization mode only. Register bit can be read in any mode, written only in initialization mode. 0 Parity Error does not reset LIN state machine 1 Parity Error resets LIN state machine
19 WURQ	Wakeup Generate Request Setting this bit will generate a wakeup pulse. It is reset by hardware when the wakeup character has been transmitted. The character sent during wakeup is copied from BDRL (DATA0). Note that this bit cannot be set in Sleep mode — software has to exit Sleep mode before setting this bit. Bit Error is not checked when transmitting the wakeup request. Register bit can be read/set by software
20 DDRQ	Data Discard request Set by software to stop data reception if the frame does not concern the node. This bit is reset by hardware once LINFlexD ignores the response and moves to Idle state. For LIN slave this bit can be set only when HRF bit is set and Identifier is software-filtered. Register bit can be read/set by software
21 DTRQ	Data Transmission Request Set by software in slave mode to request the transmission of the LIN Data field stored in the Buffer data register. This bit can be set only when the HRF bit is set (to ensure that data transmission is requested only after a header reception). Cleared by hardware when the request has been completed, or on abort request or error condition. In Master mode, this bit is set by hardware when the DIR bit is set and header transmission is complete. Register bit can be read/set by software
22 ABRQ	Abort Request Set by software to abort the current transmission.

Table continues on the next page...

LINFlexD_LINCR2 field descriptions (continued)

Field	Description
	Cleared by hardware when the transmission has been aborted. LINFlexD aborts the transmission at the end of the current bit. This bit can abort a wakeup request also and can be used in UART mode also. Register bit can be read/set by software
23 HTRQ	Header Transmission Request Set by software to request the transmission of the LIN Header. Cleared by hardware when the request has been completed or on abort request. This bit has no effect in UART mode. **NOTE:** In master mode, if both HTRQ and ABRQ are set at the same time then ABRQ has no effect. Similarly, in slave mode after header reception, if DTRQ and ABRQ are simultaneously set then ABRQ has no effect.
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

46.5.14 Buffer Identifier Register (LINFlexD_BIDR)

This register contains the bits which provide information about the identifier of the transaction and other related information.

NOTE

All the fields (ID, CSS, DIR, DFL) of the BIDR register must be updated when an ID filter (enabled) in Slave mode (Tx or Rx) matches the ID received.

Address: 0h base + 34h offset = 34h

LINFlexD_BIDR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–18 Reserved	This field is reserved.
19–21 DFL	Data Field Length Number of data bytes in the response part of the frame.

Table continues on the next page...

LINFlexD_BIDR field descriptions (continued)

Field	Description
	DFL = Number of data bytes - 1
22 DIR	Direction This bit controls the direction of the data field. 0 LINFlexD receives the data and copy them in the BDR registers 1 LINFlexD transmits the data from the BDR registers
23 CCS	Classic Checksum This bit controls the type of checksum applied on the current message. 0 Enhanced Checksum covering Identifier and Data fields. This is compatible with LIN specification rev. 2.0 and higher. 1 Classic Checksum covering Data filed only. This is compatible with LIN specification 1.3 and lower.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 ID	Identifier Identifier part of the identifier field without the identifier parity. This field can be written only in Master mode (MME = '1').

46.5.15 Buffer Data Register Least Significant (LINFlexD_BDRL)

This register is a part of an 8-byte data buffer.

Address: 0h base + 38h offset = 38h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

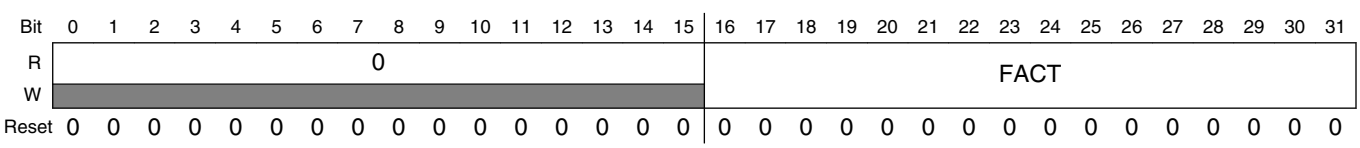
LINFlexD_BDRL field descriptions

Field	Description
0–7 DATA3	Data Byte 3 Data byte 3 of the data field.
8–15 DATA2	Data Byte 2 Data byte 2 of the data field.
16–23 DATA1	Data Byte 1 Data byte 1of the data field.
24–31 DATA0	Data Byte 0 Data byte 0 of the data field.

46.5.16 Buffer Data Register Most Significant (LINFlexD_BDRM)

This register is a part of an 8-byte data buffer.

Address: 0h base + 3Ch offset = 3Ch



LINFlexD_BDRM field descriptions

Field	Description
0–7 DATA7	Data Byte 7 Data byte 7 of the data field.
8–15 DATA6	Data Byte 6 Data byte 6 of the data field.
16–23 DATA5	Data Byte 5 Data byte 5of the data field.
24–31 DATA4	Data Byte 4 Data byte 4 of the data field.

46.5.17 Identifier Filter Enable Register (LINFlexD_IFER)

This register enables/disables a particular filter.

Address: 0h base + 40h offset = 40h

LINFlexD_IFER field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 FACT	Filter active The software sets the bit FACT[x] to activate the filter x in Identifier list mode. Register bit can be read in any mode, written only in initialization mode.

Table continues on the next page...

LINFlexD_IFER field descriptions (continued)

Field	Description
	1. In Identifier mask mode, FACT (2n+1) have no effect on the corresponding filters as they act as mask for the Identifier 2n. 2. The length of this field depends on the value of no_of_filters. 3. The register diagram depicts the maximum no_of_filters, which can be up to 16. **NOTE:** Refer to chip configuration details to see the number of filters used in the device.

46.5.18 Identifier Filter Match Index (LINFlexD_IFMI)

This register contains the index corresponding to the received ID. It can be used to read or write the data directly in RAM.

Address: 0h base + 44h offset = 44h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LINFlexD_IFMI field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 IFMI	Filter match index Upon a filter match with xth filter – IFMI[4:0] = x+1. On no match IFMI is equal to 00h. This register contains the index corresponding to the received identifier. It can be used to directly write or read the data in SRAM (see Slave mode for more details).

46.5.19 Identifier Filter Mode Register (LINFlexD_IFMR)

This register configures the modes of filters.

Address: 0h base + 48h offset = 48h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LINFlexD_IFMR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 IFM	Filter mode Register bit can be read in any mode, written only in initialization mode. 0 Filters 2n and 2n+1 are in identifier list mode 1 Filters 2n and 2n+1 are in mask mode, where filter 2n+1 is the mask for filter 2n

46.5.20 Identifier Filter Control Register (LINFlexD_IFCR*n*)

This register is read-only in normal mode and can be programmed only in Initialization mode.

Even-numbered instances (IFCR0, IFCR2, IFCR4, ...) of this register act as filters in both Identifier list and Identifier mask modes.

Odd-numbered instances (IFCR1, IFCR3, IFCR5, ...) of this register act:

- As filters in Identifier list mode
- As a mask for the preceding-numbered register in identifier mask mode

Refer to chip configuration details to see the number of filters used in the device.

Address: 0h base + 4Ch offset + (4d × i), where i=0d to 15d

LINFlexD_IFCR*n* field descriptions

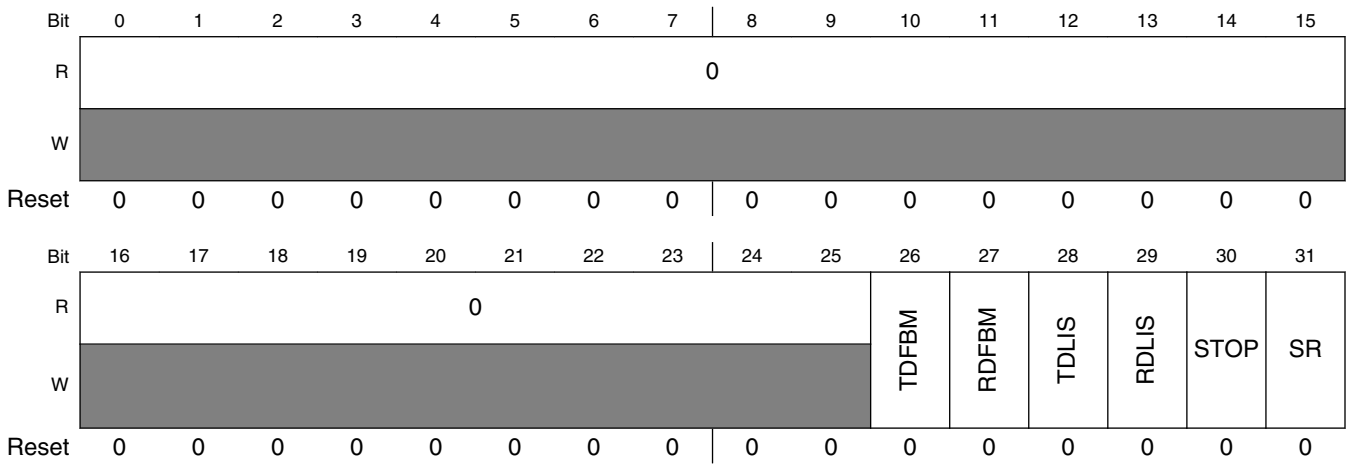
Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–18 Reserved	This field is reserved.
19–21 DFL	Data Field Length Number of data bytes in the response part of the frame. DFL = Number of data bytes - 1

Table continues on the next page...

LINFlexD_IFCR*n* field descriptions (continued)

Field	Description
	Register bit can be read in any mode, written only in initialization mode.
22 DIR	Direction This bit controls the direction of the data field. Register bit can be read in any mode, written only in initialization mode. 0 LINFlexD receives data and copies to the BDR registers 1 LINFlexD transmits data from the BDR registers
23 CCS	Classic Checksum This bit controls the type of checksum applied on the current message. Register bit can be read in any mode, written only in initialization mode. 0 Enhanced Checksum covering Identifier and Data fields. This is compatible with LIN specification rev. 2.0 and higher. 1 Classic Checksum covering Data field only. This is compatible with LIN specification 1.3 and lower.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 ID	Identifier Identifier part of the identifier field without the identifier parity. Register bit can be read in any mode, written only in initialization mode.

46.5.21 Global Control Register (LINFlexD_GCR)



This register is read-only in Normal mode and can be programmed only in Initialization mode. This is a global control register — in other words, the register configuration will be applied in LIN mode as well as in UART mode.

The address offset depends on the no_of_filters. Refer to the chip configuration details for the number of filters used in this device.

Table 46-19. Register fields reset by SR

Register	Comment
LINSR	All fields except RXbusy and AUTOSYNC_COMP are reset
LINESR	All fields are reset
LINTCSR	Only CNT[0:7] is reset
UARTSR	All fields except RFE & TFF are reset
UARTCR	Only TFC & RFC are reset
UARTCTO	All fields are reset

Address: 0h base + 8Ch offset = 8Ch

LINFlexD_GCR field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 TDFBM	Transmit data first bit MSB This bit controls the first bit of transmit data (payload only) as MSB/LSB in both UART and LIN modes. Register bit can be read in any mode, written only in initialization mode. 0 The first bit of transmitted data is LSB — in other words, the first bit transmitted is mapped on LSB bit (BDR (0), BDR (8), BDR (16), BDR (24)) 1 The first bit of transmitted data is MSB — in other words, the first bit transmitted is mapped on MSB bit (BDR (7), BDR (15), BDR (23), BDR (31))
27 RDFBM	Received data first bit MSB This bit controls the first bit of received data (payload only) as MSB/LSB both in UART and LIN modes. Register bit can be read in any mode, written only in initialization mode. 0 The first bit of received data is LSB — in other words, the first bit received is mapped on LSB bit (BDR (0), BDR (8), BDR (16), BDR (24)) 1 The first bit of received data is MSB — in other words, the first bit received is mapped on MSB bit (BDR (7), BDR (15), BDR (23), BDR (31))
28 TDLIS	Transmit data level inversion selection This bit controls the data inversion of transmitted data (payload only) in both UART and LIN modes. Register bit can be read in any mode, written only in initialization mode. 0 Transmitted data is not inverted 1 Transmitted data is inverted
29 RDLIS	Received data level inversion selection This bit controls the data inversion of received data (payload only) in both UART and LIN modes. Register bit can be read in any mode, written only in initialization mode. 0 Received data is not inverted 1 Received data is inverted

Table continues on the next page...

LINFlexD_GCR field descriptions (continued)

Field	Description
30 STOP	1/2 stop bit configuration This bit controls the number of stop bit transmitted data in both UART and LIN modes. The stop bit is configured for all the fields (Delimiter, Sync, ID, Checksum, Payload). Register bit can be read in any mode, written only in initialization mode. 0 1 stop bit 1 2 stop bits
31 SR	Soft reset SR executes a soft reset of the LINFlexD controller (FSMs, FIFO pointers, counters, timers, status and error registers) without modifying the configuration registers when a 1 write operation is performed. This bit should be cleared by software to perform further operations (this bit is not cleared by hardware). Register bit can be written only be software in initialization mode. Bit is always read 0 by software. Table 46-19 describes the register fields reset by SR.

46.5.22 UART Preset Timeout Register (LINFlexD_UARTPTO)

This register contains the preset value of the timeout register in UART mode and is programmed according to the number of bits to be received or to monitor the idle state of the reception line. This register can be written by software any time.

The address offset depends on no_of_filters. Refer to the chip configuration details to see the number of filters used in the device.

Address: 0h base + 90h offset = 90h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																PTO															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1

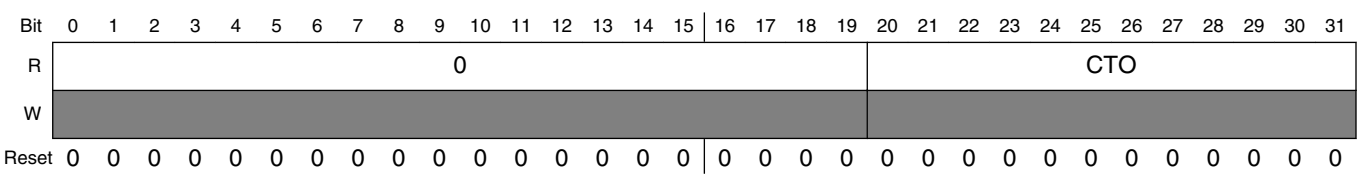
LINFlexD_UARTPTO field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 PTO	Preset Timeout PTO defines the preset value of timeout counter. A zero-value is forbidden, otherwise the UARTSR[TO] status bit is immediately set. Refer also to register UARTCTO.

46.5.23 UART Current Timeout Register (LINFlexD_UARTCTO)

This register contains the current timeout value in UART mode, and is used in conjunction with the UARTPTO register (see UART Preset Timeout Register (LINFlexD_UARTPTO) to monitor the number of bits received by UART or to monitor the idle state of the reception line. UART timeout works in both CPU and DMA modes.

The timeout counter:



- Starts at zero and counts upward
- Is clocked with LIN_CLK / (16 * LDIV) synchronized to PBRIDGEx_CLK (when ROSE = 0)
- Is clocked with LIN_CLK / (OSR * IBRR) synchronized to PBRIDGEx_CLK (when ROSE = 1)
- Is automatically enabled when UARTCR[RXEN] = 1

It is reset when:

- Number of frames received is equal to NEF bits
- UARTCTO becomes equal to UARTPTO
- Whenever UARTPTO is written
- When DRF is set and DTU bit = 1

The address offset depends on no_of_filters. Refer to chip configuration details to see the number of filters used in the device.

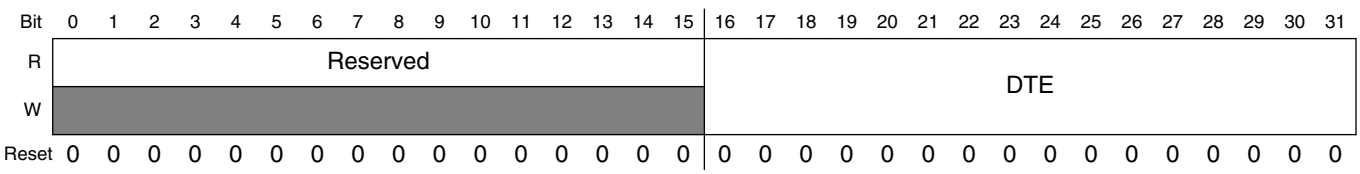
Address: 0h base + 94h offset = 94h

LINFlexD_UARTCTO field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 CTO	Current Timeout

Table continues on the next page...

LINFlexD_UARTCTO field descriptions (continued)



Field	Description
	CTO defines the current value of the timeout counter. CTO is a read-only field. CTO is reset every time UARTPTO is re-initialized, or UARTCTO = UARTPTO, or by hard/soft reset. When the CTO value matches the preset value (UARTPTO), the status bit UARTSR[TO] is set.

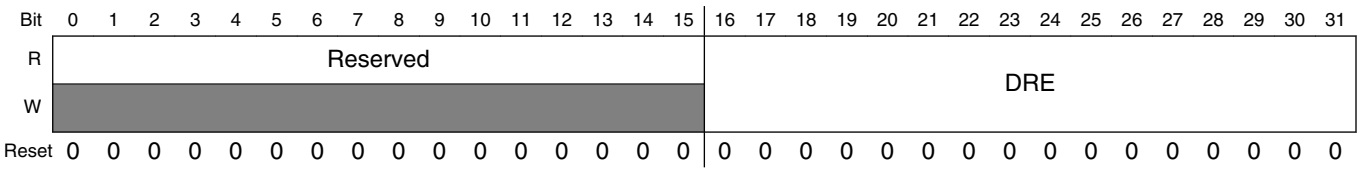
46.5.24 DMA Tx Enable Register (LINFlexD_DMATXE)

This register enables the DMA TX interface. This register can be written and read by software anytime.

The address offset depends on no_of_filters. Refer to chip configuration details to see the number of filters used in the device.

Address: 0h base + 98h offset = 98h

LINFlexD_DMATXE field descriptions



Field	Description
0–15 Reserved	This field is reserved. Reserved **NOTE:** The number of reserved bits varies, and is equal to 32 - $2^{TX_CH_NUM}$. These lies from 0 to (31 - $2^{TX_CH_NUM}$). Refer to the chip configuration details for the value of TX_CH_NUM used in this device.
16–31 DTE	DMA Tx channel Y enable **NOTE:** The actual size of the register DMATXE depends on the value of the static parameter TX_CH_NUM. The size is [$2^{TX_CH_NUM}$ - 1 : 0]. The position of these bits are (32 - $2^{TX_CH_NUM}$) to 31. When DMATXE = 0x00000000, the DMA TX interface FSM is forced (soft reset) in Idle state. **NOTE:** Refer to the chip configuration details for the value of TX_CH_NUM used in this device. 0 DMA Tx channel Y disabled 1 DMA Tx channel Y enabled

46.5.25 DMA Rx Enable Register (LINFlexD_DMARXE)

This register enables the DMA RX interface. This register can be written and read by software any time.

The address offset depends on no_of_filters. Refer to device configuration chapter to see the number of filters used in the device.

Address: 0h base + 9Ch offset = 9Ch

LINFlexD_DMARXE field descriptions

Field	Description
0–15 Reserved	This field is reserved. Reserved **NOTE:** The number of reserved bits varies, and is equal to 32 - $2^{RX_CH_NUM}$. These lies from 0 to (31 - $2^{RX_CH_NUM}$). Refer to the chip configuration details for the value of RX_CH_NUM used in this device.
16–31 DRE	DMA Rx channel Y enable **NOTE:** The actual size of the register DMARXE depends on the value of the static parameter RX_CH_NUM. The size is [$2^{RX_CH_NUM}$ -1 : 0]. The position of these bits are (32 - $2^{RX_CH_NUM}$) to 31. When DMARXE = 0x00000000, the DMA RX interface FSM is forced (soft reset) in Idle state. **NOTE:** Refer to the chip configuration details for the value of RX_CH_NUM used in this device. 0 DMA Rx channel Y disabled 1 DMA Rx channel Y enabled

46.6 Programming considerations

The next subsections describe the various configurations in which the LINFlexD module can be used.

46.6.1 Master node

LINFlexD acts as Master when the MME bit is set.

46.6.1.1 Transmitter

Transmitter Master Node - Transmitter configuration.

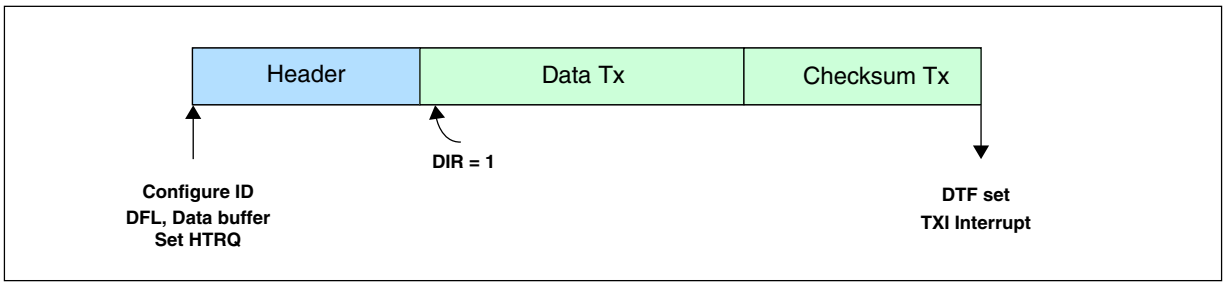


Figure 46-39. Master node – Transmitter configuration

46.6.1.2 Receiver

Receiver Master Mode - RX Configuration

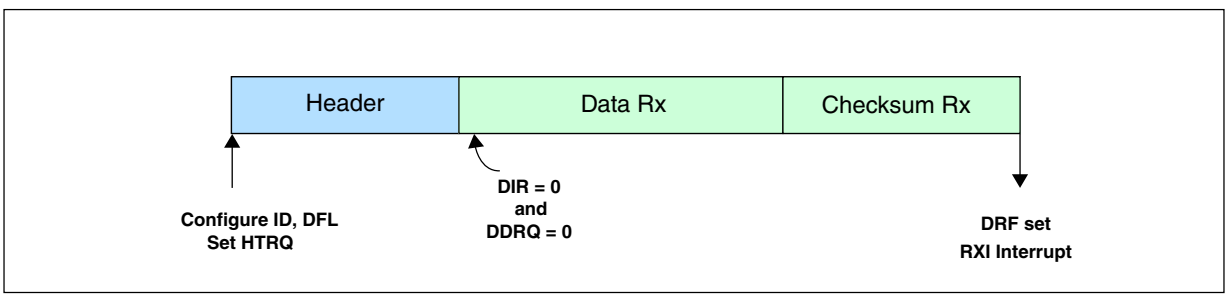

Figure 46-40. Master node – Receiver configuration

46.6.1.3 Transmitter, Bit Error

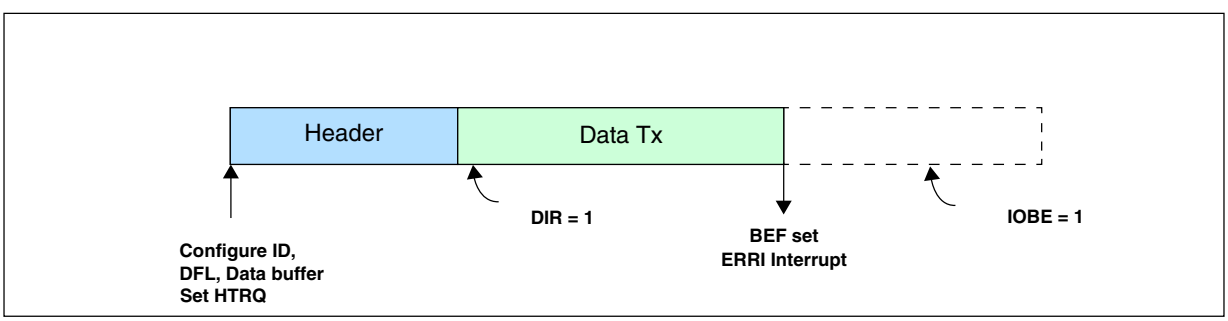

Figure 46-41. Master node – Transmitter, Bit Error configuration

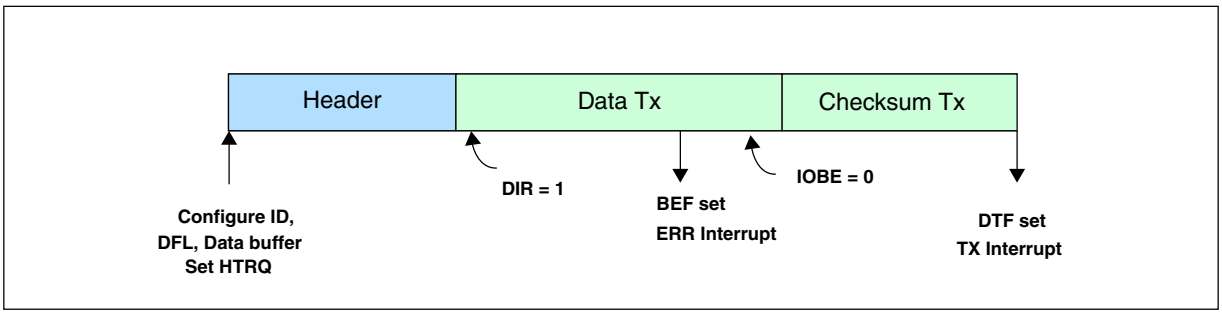

Figure 46-42. Master node – Transmitter, Checksum Error configuration

46.6.1.4 Receiver, Checksum Error

Checksum Error for Receiver.

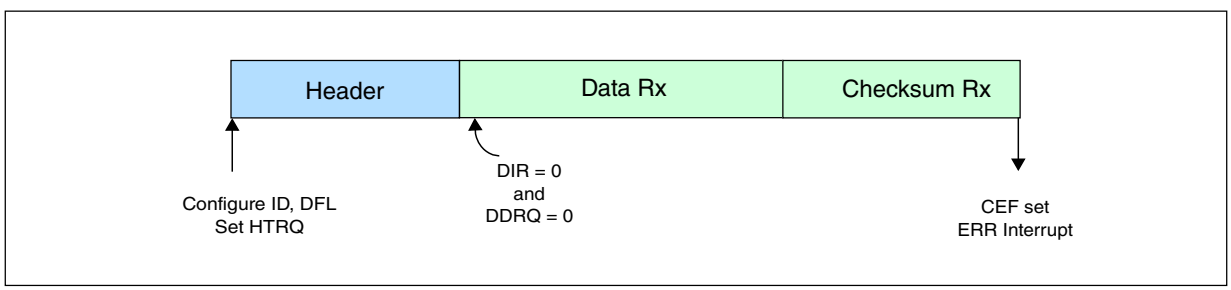

Figure 46-43. Master node – Receiver, Checksum Error configuration

46.6.2 Slave node

Slave node (transmitter).

46.6.2.1 Transmitter (no identifier filters)

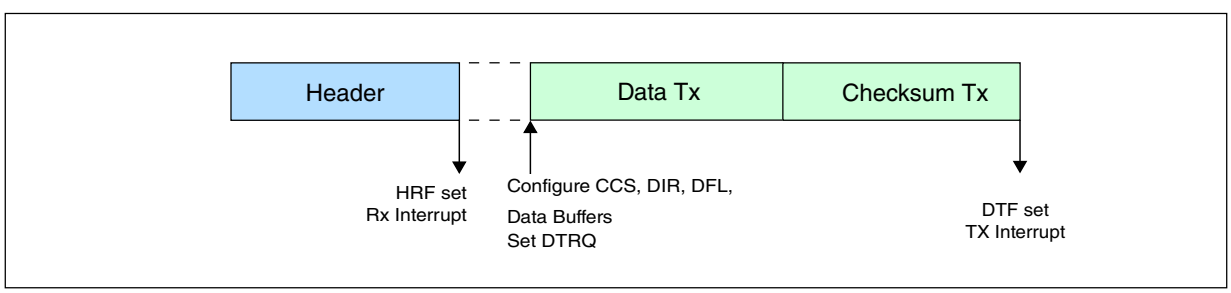

Figure 46-44. Slave node – Transmitter (no identifier filters) configuration

46.6.2.2 Receiver (no identifier filters)

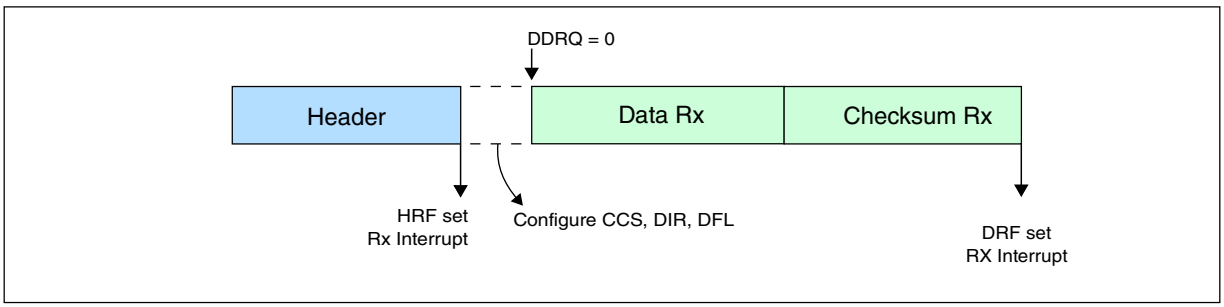

Figure 46-45. Slave node – Receiver (no identifier filters) configuration

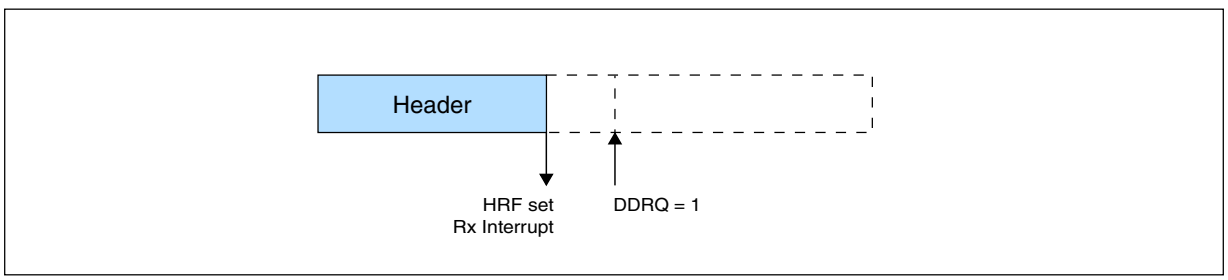

Figure 46-46. Slave node – Receiver (no identifier filters) configuration

46.6.2.3 No filters, Transmitter, Bit error

The following figure shows Slave node - No filters, Transmitter, Bit error configuration.

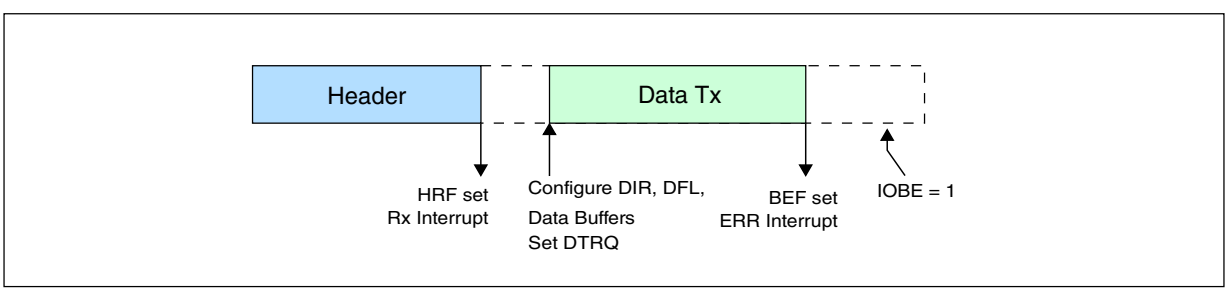

Figure 46-47. Slave node – No filters, Transmitter, Bit error configuration

46.6.2.4 No filters, Receiver, Checksum Error

The following figure shows Slave node - No filters, Receiver, Checksum error configuration.

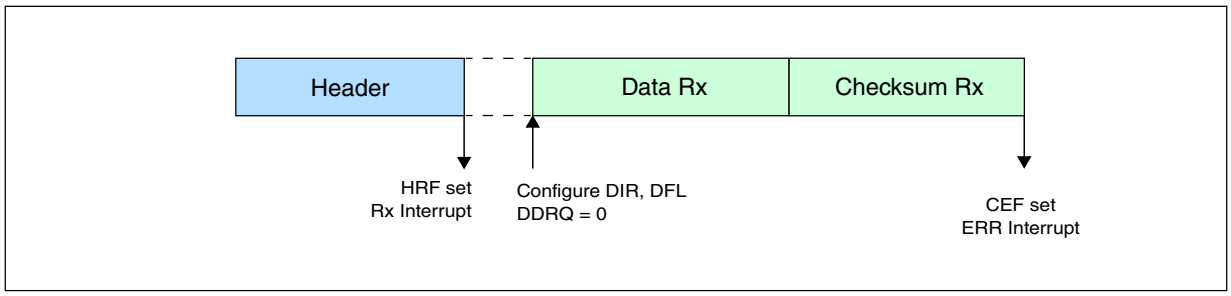

Figure 46-48. Slave node – No filters, Receiver, Checksum error configuration

46.6.2.5 At least one TX filter, BF is reset, ID matches filter

This configuration can be used in case slave never receives data, for example, sensor.

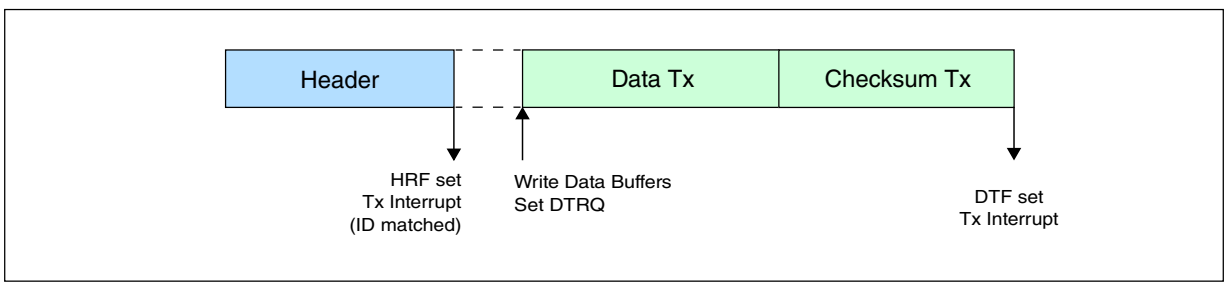

Figure 46-49. Slave node – one TX filter configuration

46.6.2.6 At least one RX filter, BF reset, ID matches filter

The following figure shows Slave node - one RX filter configuration.

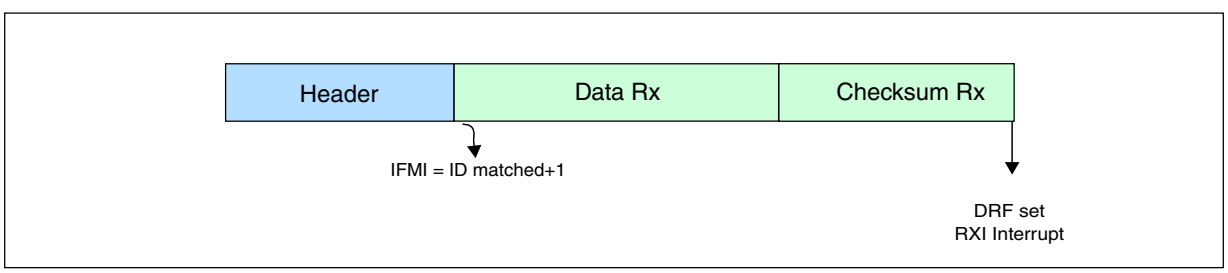

Figure 46-50. Slave node – one RX filter configuration

46.6.2.7 RX only, TX only, RX & TX filters, ID not matching filter, BF reset

The following figure shows RX only, TX only, RX and TX filters configuration.

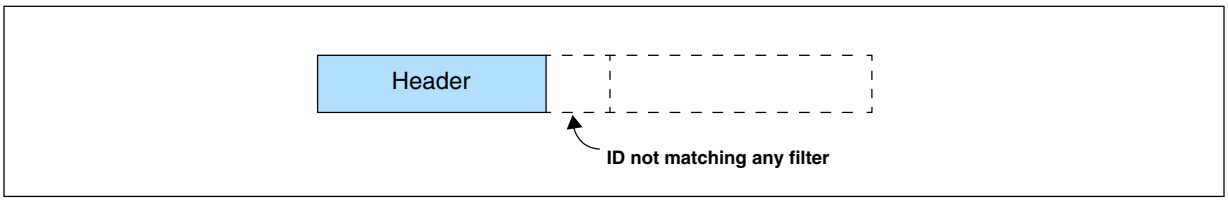

Figure 46-51. RX only, TX only, RX & TX filters configuration

46.6.2.8 TX filter, BF is set

This configuration is used when:

- All TX IDs are handled by filters.
- There are not enough other filters to handle all reception IDs.

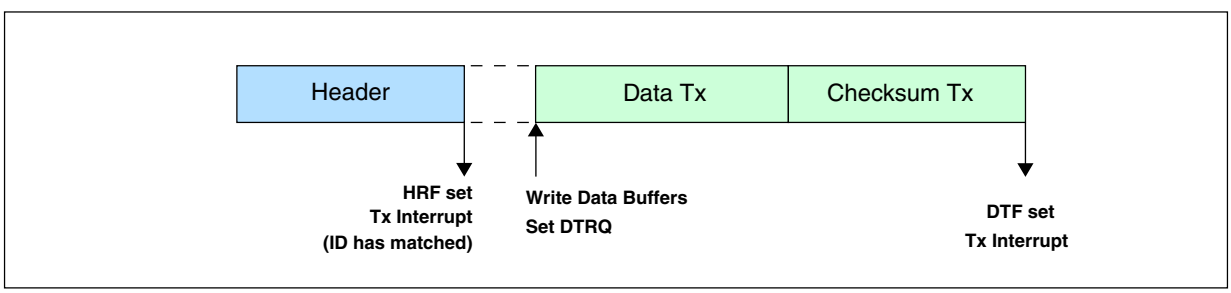

Figure 46-52. TX filter, BF is set configuration – ID has matched

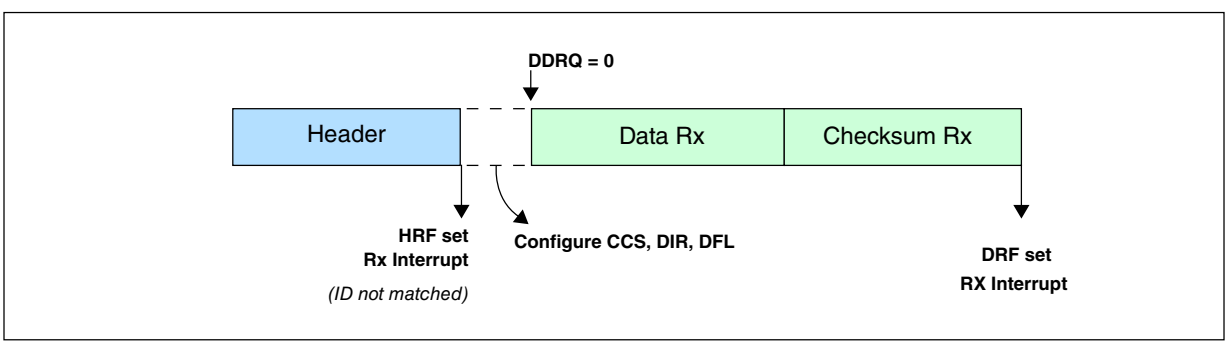

Figure 46-53. TX filter, BF is set configuration – ID not matched

46.6.2.9 RX filter, BF is set

The following figures show RX filter configurations.

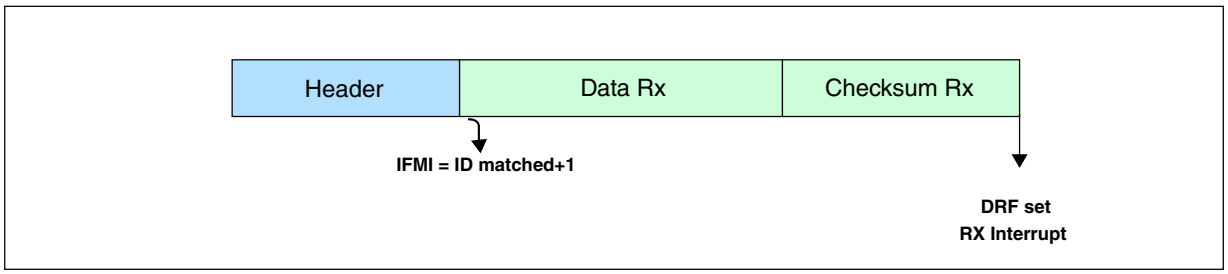

Figure 46-54. RX filter, BF is set configuration – ID matched

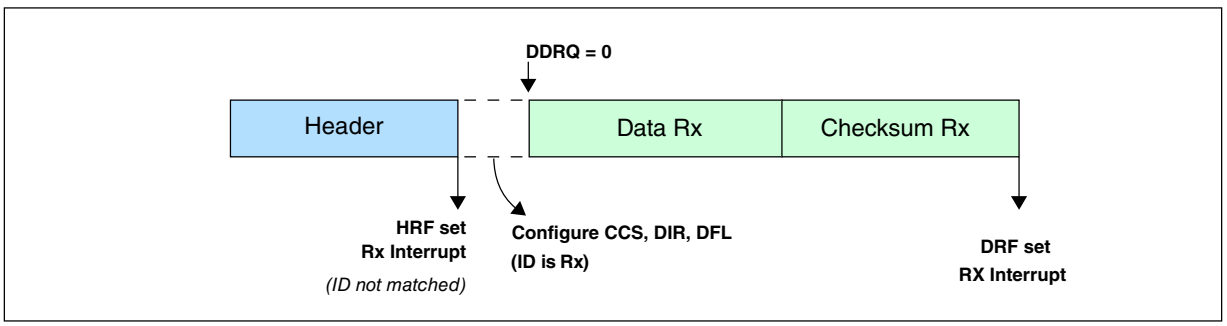

Figure 46-55. RX filter, BF is set configuration – ID not matched (ID is Rx)

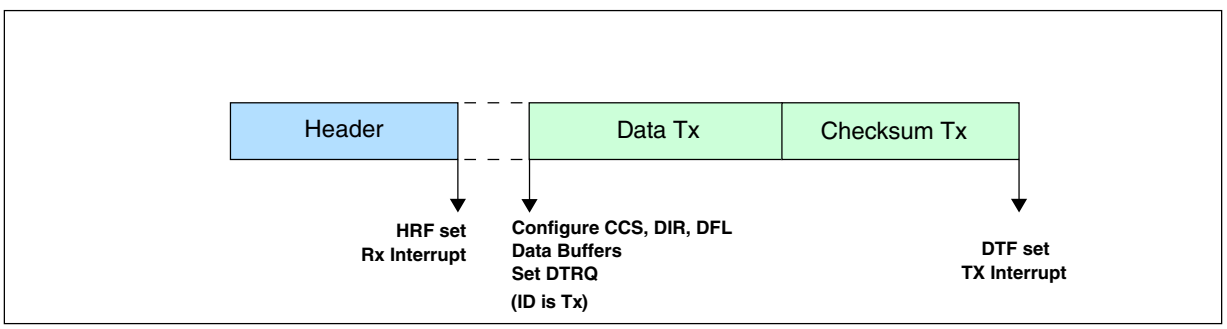

Figure 46-56. RX filter, BF is set configuration – (ID is Tx)

46.6.2.10 TX filter, RX filter, BF set

This configuration is used when:

- There are not enough filters.
- The filters are used for most frequently used IDs to reduce CPU usage.

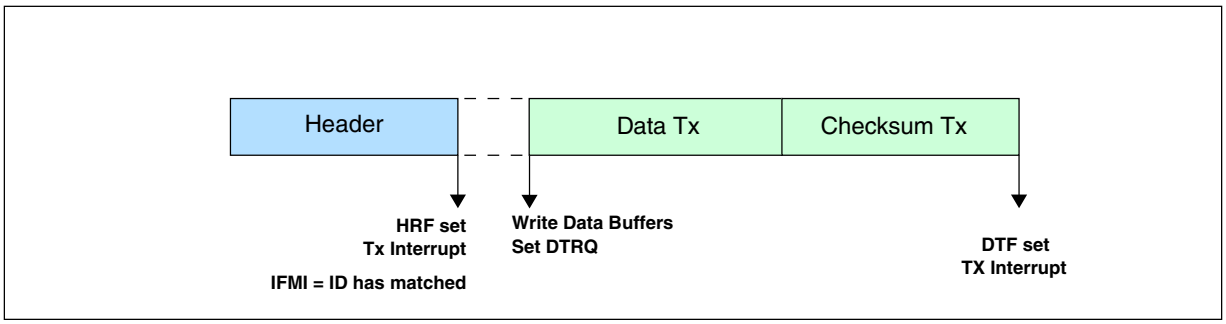

Figure 46-57. TX filter, RX filter, BF set configuration – (ID matched)

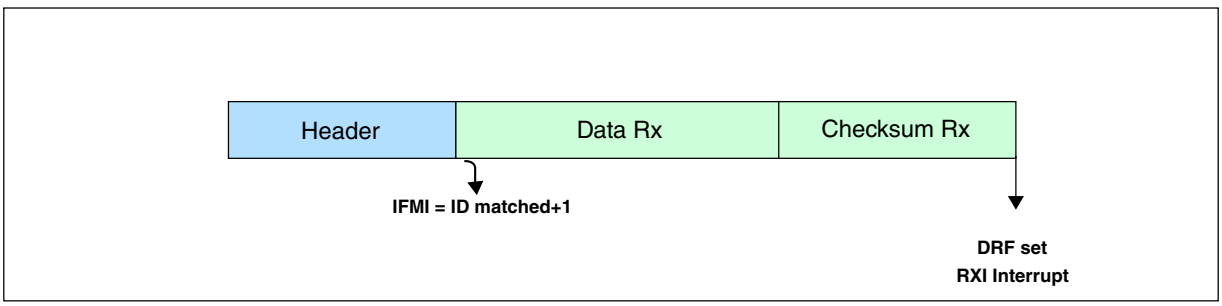

Figure 46-58. TX filter, RX filter, BF set configuration – (ID matched + 1)

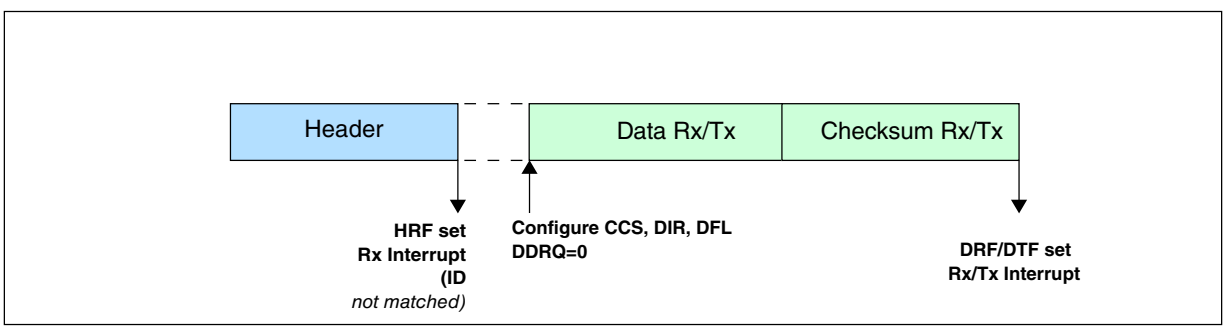

Figure 46-59. TX filter, RX filter, BF set configuration – (ID not matched, RX/TX Interrupt)

46.6.3 Timeout

Master Node: Response (during reception only) and frame timeout are checked.

Slave Node: Header, Response (during reception only), and frame timeout are checked.

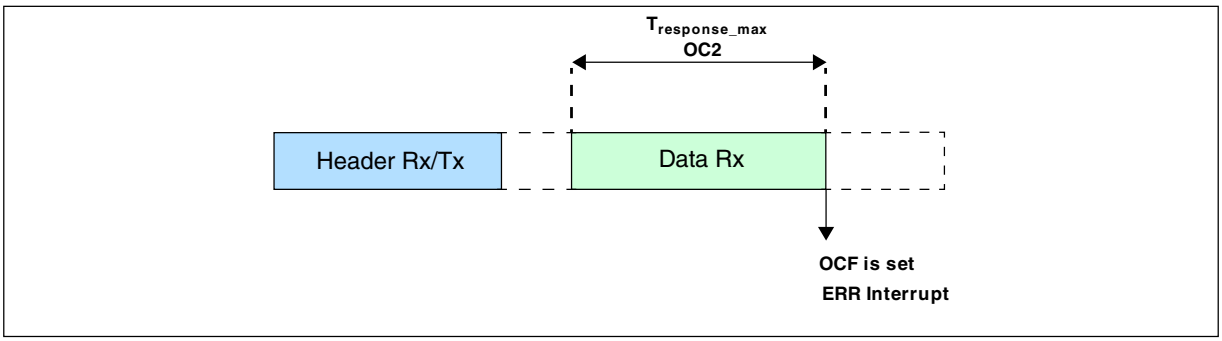

Figure 46-60. Response timeout

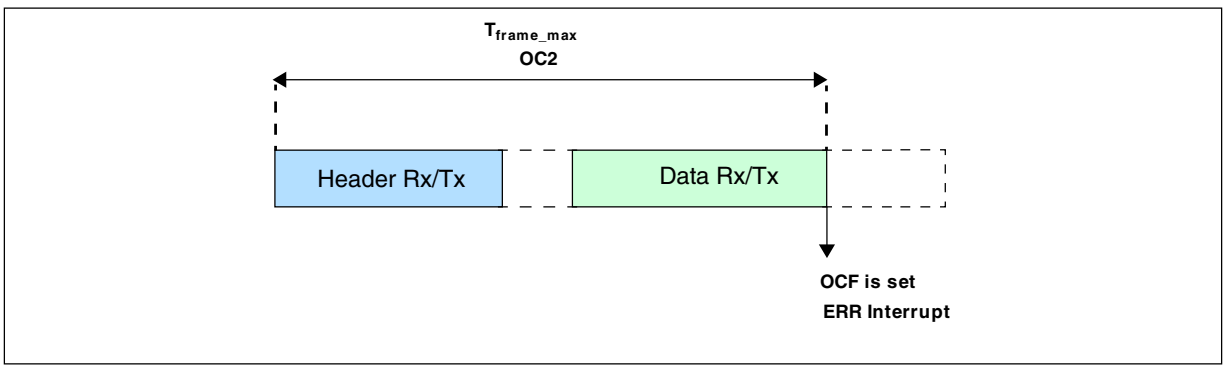

Figure 46-61. Frame timeout

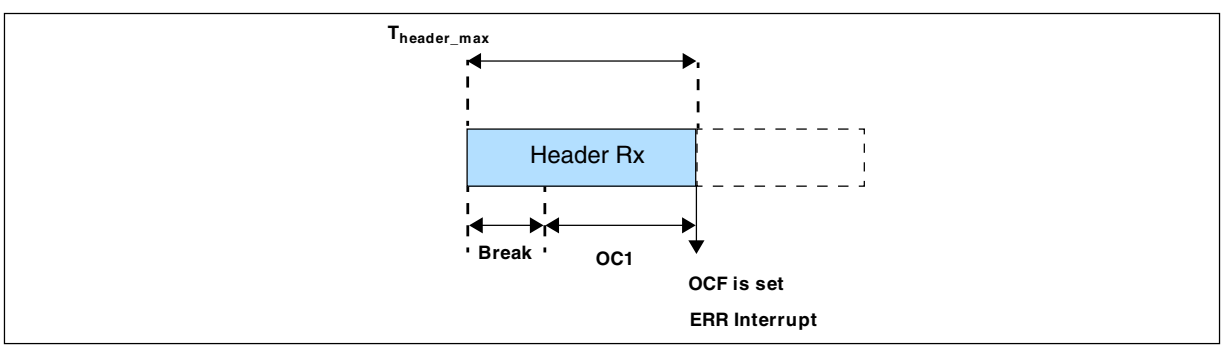

Figure 46-62. Header timeout

46.6.4 UART mode

The following figure shows UART mode configuration.

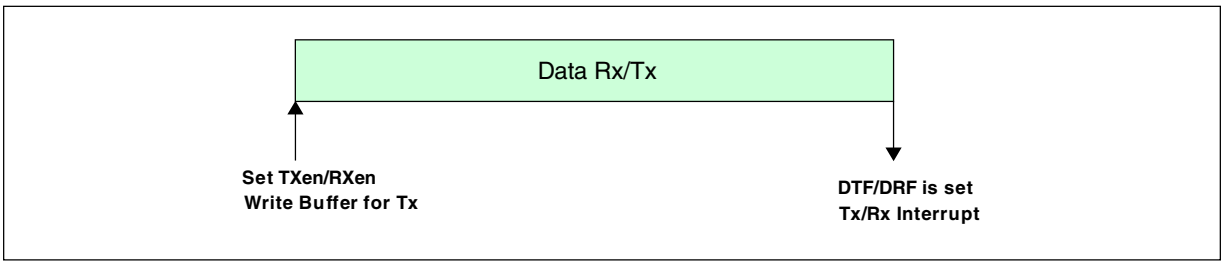

Figure 46-63. UART mode configuration

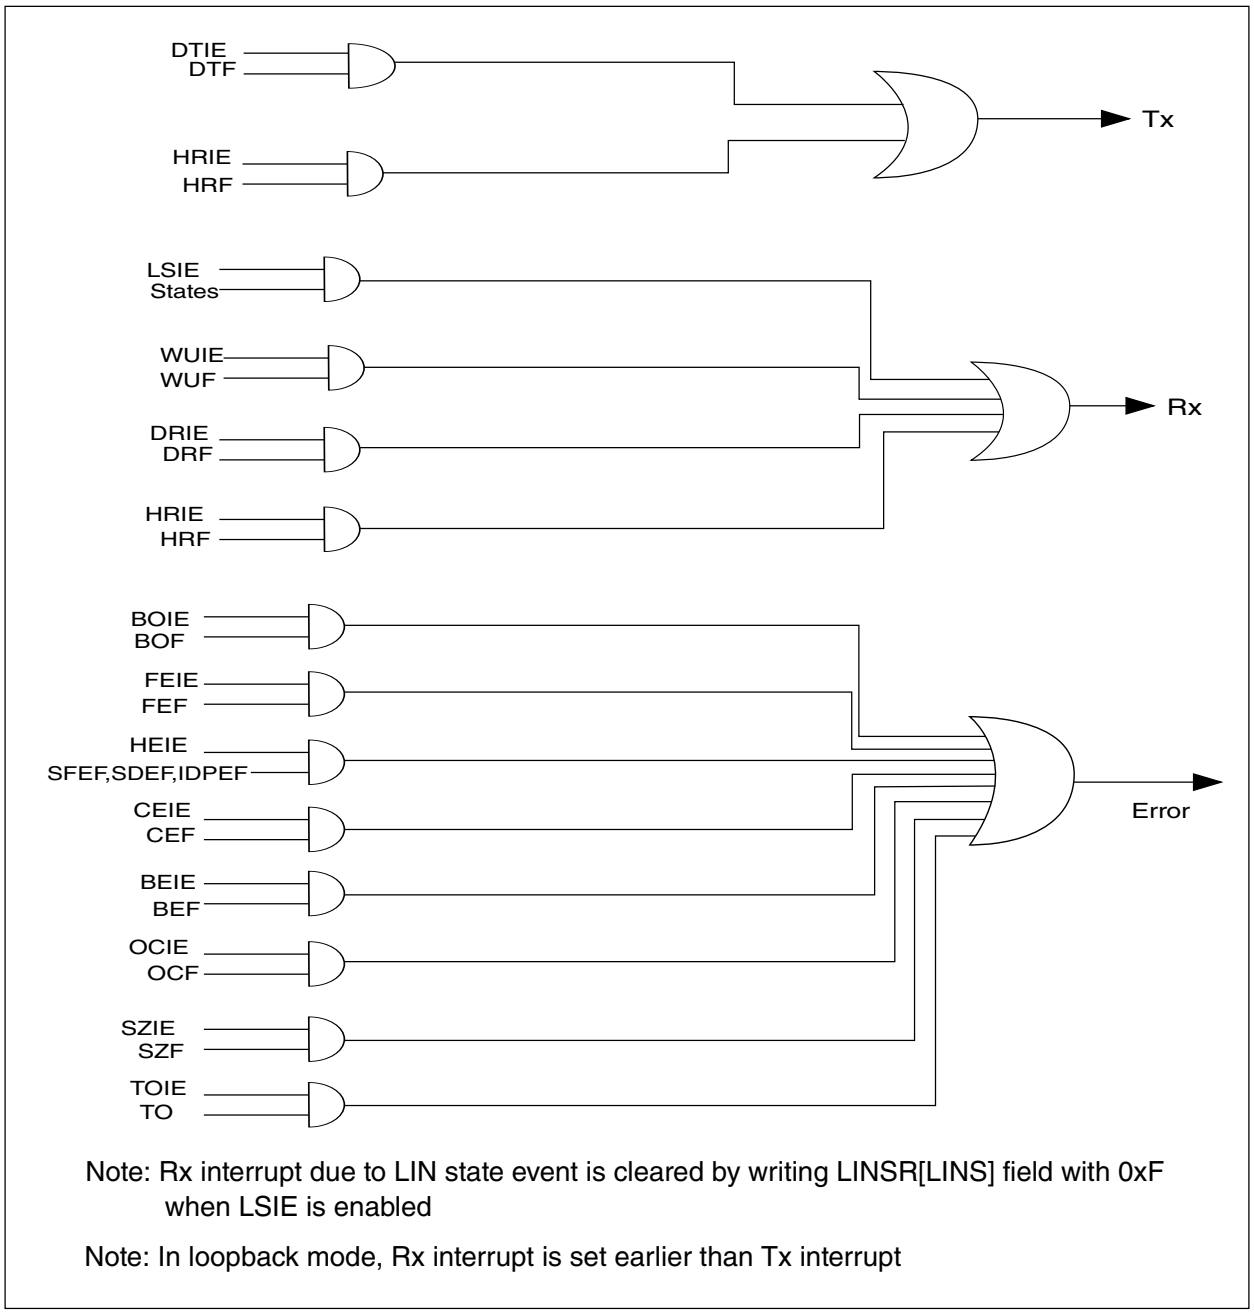

46.6.5 Interrupts

Interrupt section.

Table 46-20. Interrupts

Interrupt Event	Event flag	Enable control bit	Interrupt vector
Stuck at zero	SZF	SZIE	Error
Output compare	OCF	OCIE	Error
Bit error	BEF	BEIE	Error
Checksum error	CEF	CEIE	Error
Header error	SFEF orSDEF orIDPEF	HEIE	Error
Frame error	FEF	FEIE	Error
Buffer Overrun error	BOF	BOIE	Error
UART Timeout error	TO	TOIE	Error
Lin state	Sync Del, Sync Field,Identifier field or Checksum Field	LSIE	Rx
Wakeup	WUF	WUIE	Rx
Data Reception Complete	DRF	DRIE	Rx
Data transmitted	DTF	DTIE	Tx
Header received	HRF	HRIE	Rx
Header received	HRF	HRIE	Tx (if there is a filter match for Tx identifier)

The following figure shows an Interrupt Flow Diagram.

Note: Rx interrupt due to LIN state event is cleared by writing LINSR[LINS] field with 0xF when LSIE is enabled

Note: In loopback mode, Rx interrupt is set earlier than Tx interrupt

Figure 46-64. Interrupt diagram

46.6.6 LINFlexD Clock Tolerance

1. **Faster receiver tolerance:**
   In this case the receiver has a higher baud rate than the transmitter, thus the stop bit sampling starts already in the last transmitted payload bit. To ensure the correct noise and framing error free reception bit, the samples RS8, RS9, and RS10 must be located in the transmitted stop bit as shown in the following figure.

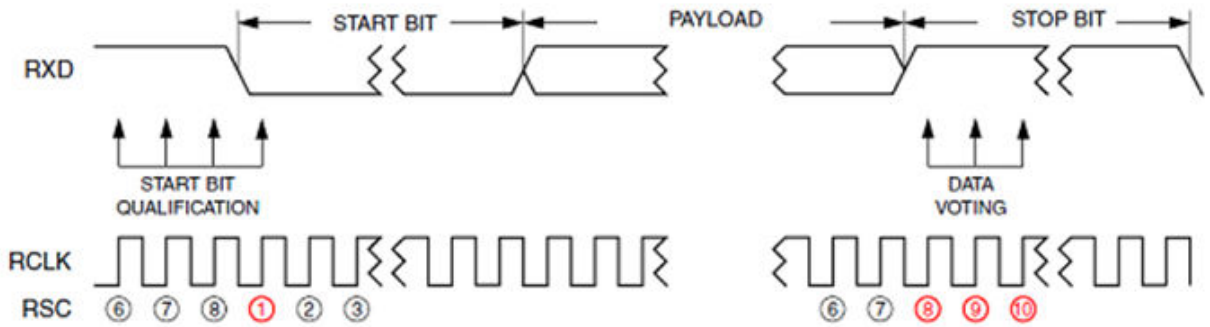

Figure 46-65. Faster receiver

2. **Slower receiver tolerance:**
   In this case the receiver has a slower baud rate than the transmitter, thus the stop bit sampling is still running while the next start bit is already transmitted. To ensure the correct noise and framing error free reception bit , the samples RS8, RS9, and RS10 must be located in the transmitted stop bit as shown in the following figure.

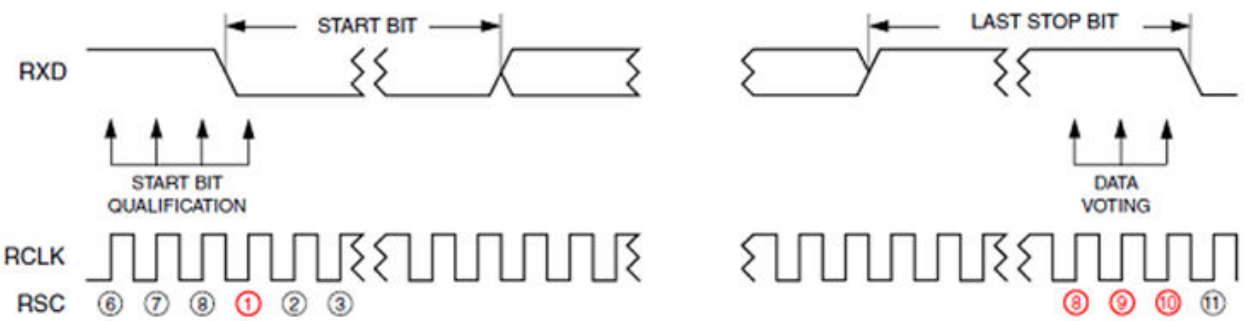

Figure 46-66. Slower receiver

Chapter 47
FlexRay

47.1 Chip-specific FlexRay information

47.1.1 FlexRay configuration

47.1.1.1 FlexRay byte swapping control

The endianess of the FlexRay AHB interface is controlled via the GPR register bits in the device.

Refer GPR Control Register (GPR_CTL) for details.

47.1.2 Stop Watch interface

For OS tick selection configuration implemented outside FlexRay stopwatch interface, see section: FlexRay OS tick selection

47.2 Introduction

This section provides a high-level summary of module features.

47.2.1 Reference

The following documents are referenced.

- *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*[1]

- Refer to this document for the all of the FlexRay related informaton including the configuration parameters and the allowed parameter ranges.
- *FlexRay Communications System Electrical Physical Layer Specification, Version 3.0*

47.2.2 Glossary

This section provides a list of terms used in this chapter.

Table 47-1. List of terms

Term	Definition
BCU	Buffer Control Unit. Handles message buffer access.
BMIF	Bus Master Interface. Provides master access to FlexRay memory area.
CC	Communication Controller
CDC	Clock Domain Crosser
CHI	Controller Host Interface
Cycle length in µT	The actual length of a cycle in µT for the ideal controller (+/- 0 ppm)
EBI	External Bus Interface
FlexRay Memory Area	Memory area to store the physical message buffer payload data, frame header, frame and slot status, and synchronization frame related tables.
FSS	Frame Start Sequence
HIF	Host Interface. Provides host access to controller.
Host	The FlexRay CC host MCU
Keyslot	Key slot is used to transmit the startup frame, sync frame, or designated single slot frame.
LUT	Look Up Table. Stores message buffer header index value.
LRAM	Look Up Table RAM. Module internal memory to store message buffer configuration data and data field offsets for individual message buffers and receive shadow buffers.
MB	Message Buffer
Mini-slot	An interval of time within the dynamic segment of the communication cycle that is of constant duration (in terms of macroticks) and that is used by the synchronized FTDMA media access scheme to manage media arbitration
MBIDX	Message Buffer Index: the position of a header field entry within the header area. If the header area is accessed as an array, this is the same as the array index of the entry.
MBNum	Message Buffer Number: Position of message buffer configuration registers within the register map. For example, Message Buffer Number 5 corresponds to the MBCCS5 register.
MCU	Microcontroller Unit
µT	Microtick
MT	Macrotick

Table continues on the next page...

1. The FlexRay Specifications have been developed for automotive applications.The FlexRay Specifications have been neither developed nor tested for non-automotive applications.

Table 47-1. List of terms (continued)

Term	Definition
MTS	Media Access Test Symbol
message frame	Frame with *Null Frame Indicator* set to 1
normal frame	null frame or message frame with both *Sync Frame Indicator* and *Startup Frame Indicator* set to 0
null frame	frame with *Null Frame Indicator* set to 0
NIT	Network Idle Time
PE	Protocol Engine
POC	Protocol Operation Control. Each state of the POC is denoted by POC:state
Rx	Reception
Slot	An interval of time during which access to a communication channel is granted exclusively to a specific node for the transmission of a frame with a frame ID corresponding to the slot.
SEQ	Sequencer Engine
SU	Status update
SECDED	Single-bit error correction, double-bit error detection
System Memory	Memory that contains the FlexRay Memory Area.
System Bus	Bus that connects the controller and System Memory
sync frame	null frame or message frame with *Sync Frame Indicator* set to 1
startup frame	null frame or message frame with both *Sync Frame Indicator* and *Startup Frame Indicator* set to 1
TCU	Time Control Unit
Tx	Transmission

47.2.3 Overview

The CC is a FlexRay communication controller that implements the FlexRay Communications System Protocol Specification, Version 2.1 Rev A.

The CC has three main components:

- *Controller host interface (CHI)*
- *Protocol engine (PE)*
- *Clock domain crossing unit (CDC)*

A block diagram of the CC with its surrounding modules is given in the below figure.

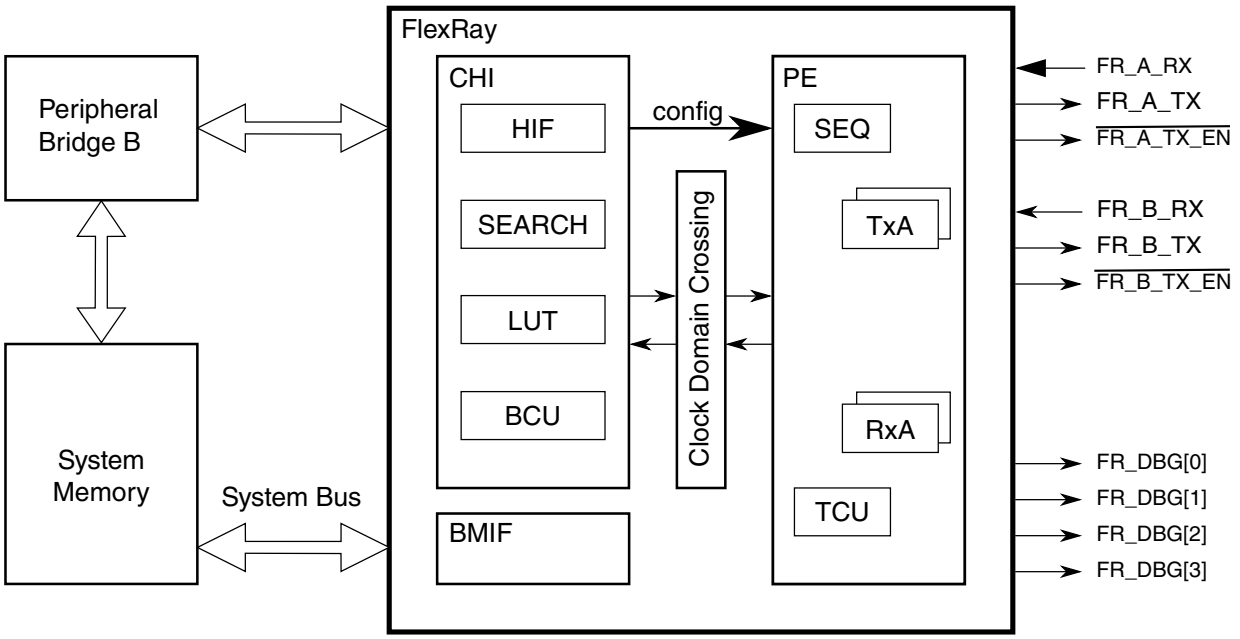

Figure 47-1. FlexRay block diagram

The protocol engine has two transmitter units TxA and TxB and two receiver units RxA and RxB for sending and receiving frames through the two FlexRay channels. The time control unit (TCU) is responsible for maintaining global clock synchronization to the FlexRay network. The overall activity of the PE is controlled by the sequencer engine (SEQ).

The controller host interface provides host access to the module's configuration, control, and status registers, as well as to the message buffer configuration, control, and status registers. The message buffers themselves, which contain the frame header and payload data received or to be transmitted, and the slot status information, are stored in the FlexRay memory area.

The clock domain crossing unit implements signal crossing from the CHI clock domain to the PE clock domain and vice versa, to allow for asynchronous PE and CHI clock domains.

The CC stores the frame header and payload data of frames received or of frames to be transmitted in the FlexRay memory area. The application accesses the FlexRay memory area to retrieve and provide the frames to be processed by the CC. In addition to the frame header and payload data, the CC stores the synchronization frame related tables in the FlexRay memory area for application processing.

The FlexRay memory area is located in the system memory of the MCU. The CC has access to the FlexRay memory area via its bus master interface (BMIF). The host provides the start address of the FlexRay memory area within the system memory by programming the System Memory Base Address Register (FR_SYMBADHR and

FR_SYMBADLR). All FlexRay memory area related offsets are stored in offset registers. The physical address pointer into the FlexRay memory area is calculated using the offset values the FlexRay memory base address.

Note

The CC does not provide a memory protection scheme for the FlexRay memory area.

47.2.4 Features

The CC provides the following features:

- *FlexRay Communications System Protocol Specification, Version 2.1 Rev A compliant protocol implementation*
- *FlexRay Communications System Electrical Physical Layer Specification, Version 3.0 compliant bus driver interface*
- Single channel support
  - FlexRay Port A can be configured to be connected either to physical FlexRay channel A or physical FlexRay channel B.
- Dual channel support
- FlexRay bus data rates of 10 Mbit/s, 8 Mbit/s, 5 Mbit/s, and 2.5 Mbit/s supported
- 128 configurable message buffers with
  - individual frame ID filtering
  - individual channel ID filtering
  - individual cycle counter filtering
- Message buffer header, status and payload data stored in dedicated FlexRay memory area
  - allows for flexible and efficient message buffer implementation
  - consistent data access ensured by means of buffer locking scheme
  - application can lock multiple buffers at the same time
- Size of message buffer payload data section configurable from 0 up to 254 bytes
- Two independent message buffer segments with configurable size of payload data section

    - each segment can contain message buffers assigned to the static segment and message buffers assigned to the dynamic segment at the same time
- Zero padding for transmit message buffers in static segment
    - applied when the frame payload length exceeds the size of the message buffer data section
- Transmit message buffers configurable with state/event semantics
- Message buffers can be configured as
    - receive message buffer
    - transmit message buffer
- Individual message buffer reconfiguration supported
    - means provided to safely disable individual message buffers
    - disabled message buffers can be reconfigured
- Two independent receive FIFOs
    - one receive FIFO per channel
    - up to 255 entries for each FIFO
    - global frame ID filtering, based on both value/mask filters and range filters
    - global channel ID filtering
    - global message ID filtering for the dynamic segment
- 4 configurable slot error counters
- 4 dedicated slot status indicators
    - used to observe slots without using receive message buffers
- Measured value indicators for the clock synchronization
    - internal synchronization frame ID and synchronization frame measurement tables can be copied into the FlexRay memory area
- Fractional macroticks are supported for clock correction
- Maskable interrupt sources provided via individual and combined interrupt lines
- 1 absolute timer
- 1 timer that can be configured to absolute or relative

- Error correction and error detection (SECDED ECC) for protocol engine data RAM
- Error detection (SECDED ECC) for CHI lookup table RAM

47.2.5 Modes of Operation

This section describes the basic operational power modes of the CC.

47.2.5.1 Disabled Mode

The CC enters the Disabled Mode during hard reset or when the host clears the ‘MEN’ field in the Module Configuration Register (FR_MCR). The host can clear this field by writing ‘0’ and only when the module is in POC:default config mode. The Disabled mode can be checked by reading the module enable field, MEN, in the Module Configuration Register (FR_MCR).

No communication is performed on the FlexRay bus.

All registers with the write access conditions *Any Time* and *Disabled Mode* can be accessed for writing as stated in the Memory Map and Register Description section.

The application configures the CC by accessing the configuration bits and fields in the Module Configuration Register (FR_MCR) as described in Module Initialization .

47.2.5.1.1 Leave Disabled Mode

The CC leaves the Disabled Mode and enters the Normal Mode, when the application writes 1 to the module enable bit MEN in the Module Configuration Register (FR_MCR)

Note

Once the CC is enabled, it can only be disabled during POC: default config.

47.2.5.2 Normal Mode

In this mode the CC is fully functional. The CC indicates that it is in Normal Mode by asserting the module enable bit MEN in the Module Configuration Register (FR_MCR).

47.2.5.2.1 Enter Normal Mode

This mode is entered when the application requests the CC to leave the Disabled Mode or when the MCU leaves the Stop Mode. If the Normal Mode was entered by leaving the Disabled Mode, the application has to perform the protocol initialization described in Protocol Initialization to achieve full FlexRay functionality.

Depending on the values of the SCM, CHA, and CHB bits in the Module Configuration Register (FR_MCR), the corresponding FlexRay bus driver ports are enabled and driven.

47.2.5.3 Stop Mode

The CC is in Stop Mode when the MCU is either in Full Stop or Pseudo Stop Mode. In this mode all CC clocks are stopped.{statement} No registers can be accessed. {statement} No communication is performed on the FlexRay Bus.

47.2.5.3.1 Enter Stop Mode

Before the application requests the MCU to enter one of the Stop Modes, it has to shut down the CC as described in Shut Down Sequence.

Note

If the CC is stopped during transmission of data, it is not guaranteed, that the FlexRay ports return to its inactive state before the clocks are stopped. This can result in the lockup of the FlexRay Bus.

47.2.5.3.2 Leave Stop Mode

The CC leaves the Stop Mode when the MCU leaves its Stop Mode and all clocks are reapplied to the CC. The CC enters the operational mode it was in before going into Stop Mode.

If the CC enters the Normal Mode, the application has to put the protocol engine into the default config state by the following sequence:

1. issue the DEFAULT_CONFIG command via Protocol Operation Control Register (FR_POCR)
2. wait for *POC:default config* in Protocol Status Register 0 (FR_PSR0)

Subsequently the application can reconfigure and/or reintegrate the FlexRay node into the FlexRay cluster.

47.3 External Signal Description

This section lists and describes the CC signals connected to external pins. These signals are summarized in the following table and described in detail in the Detailed Signal Descriptions section below.

NOTE

Please refer the device configuration of the reference manual for the exact module pin names.

NOTE

The off chip signals FR_A_RX, FR_A_TX, and $\overline{\text{FR_A_TX_EN}}$ are available on each package option. The availability of the other off-chip signals depends on the package option and is chip-specific.

Table 47-2. External Signal Properties

Name	Direction	Active	Reset	Function
FR_A_RX	Input	—	—	Receive Data Channel A
FR_A_TX	Output	—	1	Transmit Data Channel A
$\overline{\text{FR_A_TX_EN}}$	Output	Low	1	Transmit Enable Channel A
FR_B_RX	Input	—	—	Receive Data Channel B
FR_B_TX	Output	—	1	Transmit Data Channel B
$\overline{\text{FR_B_TX_EN}}$	Output	Low	1	Transmit Enable Channel B
FR_DBG[0]	Output	—	0	Debug Strobe Signal 0
FR_DBG[1]	Output	—	0	Debug Strobe Signal 1
FR_DBG[2]	Output	—	0	Debug Strobe Signal 2
FR_DBG[3]	Output	—	0	Debug Strobe Signal 3

47.3.1 Detailed Signal Descriptions

This section provides a detailed description of the CC signals, connected to external pins.

47.3.1.1 FR_A_RX — Receive Data Channel A

The FR_A_RX signal carries the receive data for channel A from the corresponding FlexRay bus driver.

47.3.1.2 FR_A_TX — Transmit Data Channel A

The FR_A_TX signal carries the transmit data for channel A to the corresponding FlexRay bus driver.

47.3.1.3 $\overline{\text{FR_A_TX_EN}}$ — Transmit Enable Channel A

The $\overline{\text{FR_A_TX_EN}}$ signal indicates to the FlexRay bus driver that the CC is attempting to transmit data on channel A.

47.3.1.4 FR_B_RX — Receive Data Channel B

The FR_B_RX signal carries the receive data for channel B from the corresponding FlexRay bus driver.

47.3.1.5 FR_B_TX — Transmit Data Channel B

The FR_B_TX signal carries the transmit data for channel B to the corresponding FlexRay bus driver

47.3.1.6 $\overline{\text{FR_B_TX_EN}}$ — Transmit Enable Channel B

The $\overline{\text{FR_B_TX_EN}}$ signal indicates to the FlexRay bus driver that the CC is attempting to transmit data on channel B.

47.3.1.7 FR_DBG[3], FR_DBG[2], FR_DBG[1], FR_DBG[0] — Strobe Signals

These signals provide the selected debug strobe signals. For details on the debug strobe signal selection refer to the Strobe Signal Support.

47.4 Controller Host Interface Clocking

The clock for the CHI is derived from the system bus clock and has the same phase and frequency as the system bus clock. There are two constraints for the minimum CHI clock frequency.

The first constraint corresponds to the number of utilized message buffers and is specified in Number of Usable Message Buffers.

The second constraint corresponds to the value of the TIMEOUT field in the System Memory Access Time-Out Register (FR_SYMATOR) and is specified in Configure System Memory Access Time-Out Register (FR_SYMATOR).

47.5 Protocol Engine Clocking

The clock for the protocol engine can be generated by two sources. The first source is the internal crystal oscillator and the second source is an internal PLL. The clock source to be used is selected by the clock source select bit CLKSEL in the Module Configuration Register (FR_MCR).

Note

See the Device clocking details for the exact clock sources used.

47.5.1 Oscillator Clocking

If the protocol engine is clocked by the internal crystal oscillator, a crystal or CMOS compatible clock must be connected to the oscillator pins. The crystal or clock must fulfill the requirements given by the *FlexRay Communications System Protocol Specification, Version* 2.1 Rev A.

47.5.2 PLL Clocking

If the protocol engine is clocked by the internal PLL, the PLL clock should be divided down appropriately and provided to the PE.

For more details, see the clocking chapter of the device reference manual.

47.6 Register Descriptions

This section provides detailed descriptions of all registers in ascending address order, presented as 16-bit wide entities.

Table 47-3. Register Access Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
R*	Reserved bit or field, will not be changed. Application must not write any value different from the reset value.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.

Table 47-4. Register Field Types

Convention	Description
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A flag bit that can be read, is cleared by writing a one, writing 0 has no effect.
Reset Value	
0	Resets to zero.
1	Resets to one.
-	Not defined after reset and not affected by reset.

47.6.1 Register Reset

All registers except the Message Buffer Cycle Counter Filter Register (FR_MBCCFR*n*), Message Buffer Frame ID Register (FR_MBFIDR*n*), and Message Buffer Index Register (FR_MBIDXR*n*) are reset to their reset value on system reset. The registers mentioned above are located in physical memory blocks and, thus, they are not affected by reset. For some register fields, additional reset conditions exist. These additional reset conditions are mentioned in the detailed description of the register. The additional reset conditions are explained in the table below.

Table 47-5. Additional Register Reset Conditions

Condition	Description
Protocol RUN Command	The register field is reset when the application writes to RUN command "0101" to the POCCMD field in the Protocol Operation Control Register (FR_POCR).
Message Buffer Disable	The register field is reset when the application has disabled the message buffer. This happens when the application writes 1 to the message buffer disable trigger bit FR_MBCCSRn[EDT] while the message buffer is enabled (FR_MBCCSRn[EDS] = 1) and the CC grants the disable to the application by clearing the FR_MBCCSRn[EDS] bit.

47.6.2 Register Write Access

This section describes the write access restriction terms that apply to all registers.

47.6.2.1 Register Write Access Restriction

For each register bit and register field, the write access conditions are specified in the detailed register description. A description of the write access conditions is given in the table below. If, for a specific register bit or field, none of the given write access conditions is fulfilled, any write attempt to this register bit or field is ignored without any notification. The values of the bits or fields are not changed. The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled. The condition term [A and B] indicates that the register or field can be written to if both conditions are fulfilled.

Table 47-6. Register Write Access Restrictions

Condition	Indication	Description
Any Time	-	No write access restriction.
Disabled Mode	FR_MCR[MEN] = 0	Write access only when CC is in Disabled Mode.
Normal Mode	FR_MCR[MEN] = 1	Write access only when CC is in Normal Mode.
POC:config	FR_PSR0[PROTSTATE] = *POC:config*	Write access only when Protocol is in the *POC:config* state.
MB_DIS	FR_MBCCSR[EDS] = 0	Write access only when related Message Buffer is disabled.
MB_LCK	FR_MBCCSRn[LCKS] = 1	Write access only when related Message Buffer is locked.
IDL	FR_EEIRICR[BSY] = 0	Write access only when ECC configuration is idle.

47.6.2.2 Register Write Access Requirements

All registers can be accessed with 8-bit, 16-bit and 32-bit wide operations.

For some of the registers, at least a 16-bit wide write access is required to ensure correct operation. This write access requirement is described in the Memory map and register definition section. If an 8-bit wide write access is performed to any of these registers, this access is ignored without notification.

47.6.2.3 Internal Register Access

The following memory mapped registers are used to access multiple internal registers.

- *Strobe Signal Control Register (FR_STBSCR)*
- *Slot Status Selection Register (FR_SSSR)*
- *Slot Status Counter Condition Register (FR_SSCCR)*
- *Receive Shadow Buffer Configuration Data*

Each of these memory mapped registers provides a SEL field and a WMD bit. The SEL field is used to select the internal register. The WMD bit controls the write mode. If the WMD bit is set to 0 during the write access, all fields of the internal register are updated. If the WMD bit set to 1, only the SEL field is changed. All other fields of the internal register remain unchanged. This allows for reading back the values of the selected internal register in a subsequent read access.

47.7 Memory map and register definition

The CC occupies 8 KB (8192 bytes) of address space starting at the CC base address defined by the memory map of the MCU. Address offset - 0x0Ah should not be accessed by application as corresponding feature/s are not available. Therefore, transfer error will not be generated at these offset/s.

NOTE

The following registers are 16-bit write accessible only.

Strobe Signal Control Register (FR_STBSCR)

PE DRAM Access Register (FR_PEDRAR)

PE DRAM Data Register (FR_PEDRDR)

Sync Frame ID Rejection Filter Register (FR_SFIDRFR)

Slot Status Selection Register (FR_SSSR)

Slot Status Counter Condition Register (FR_SSCCR)

Receive Shadow Buffer Index Register (FR_RSBIR)

Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)

Message Buffer Cycle Counter Filter Register (FR_MBCCFRn)

Message Buffer Frame ID Register (FR_MBFIDRn)

Message Buffer Index Register (FR_MBIDXRn)

Message Buffer Data Field Offset Register (FR_MBDORn)

LRAM ECC Error Test Register (FR_LEETRn)

FR memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

47.7.1 Module Version Register (FR_MVR)

This register provides the CC version number. The module version number is derived from the CHI version number and the PE version number.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	CHIVER								PEVER							
Write																
Reset	1	0	1	0	0	1	0	1	0	1	1	0	1	0	0	0

FR_MVR field descriptions

Field	Description
0–7 CHIVER	CHI Version Number. This field provides the version number of the controller host interface.
8–15 PEVER	PE Version Number. This field provides the version number of the protocol engine.

47.7.2 Module Configuration Register (FR_MCR)

This register defines the global configuration of the CC.

Write: SBFF, SCM, CHB, CHA, ECCE, FUM, FAM , CLKSEL , BITRATE: Disabled Mode and SFFE, MEN: Disabled Mode or POC: config

Address: 0h base + 2h offset = 2h

Bit	0	1	2	3	4	5	6	7
Read Write	MEN	SBFF	SCM	CHB	CHA	SFFE	ECCE	Reserved
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	FUM	FAM	0	CLKSEL	BITRATE			0
Write								
Reset	0	0	0	0	0	0	0	0

FR_MCR field descriptions

Field	Description
0 MEN	Module Enable. This bit indicates whether or not the CC is in the Disabled Mode. The application requests the CC to leave the Disabled Mode by writing 1 to this bit Before leaving the Disabled Mode, the

</table></td></tr>
</table>

Table continues on the next page...

FR_MCR field descriptions (continued)

Field	Description
4 CHA	Channel A Enable. protocol related parameter: pChannels The semantic of these control bits depends on the channel device mode controlled by the SCM bit and is given in the FlexRay channel selection table as seen above.
5 SFFE	Synchronization Frame Filter Enable. This bit controls the filtering for received synchronization frames. For details see Sync Frame Filtering . 0 Synchronization frame filtering disabled 1 Synchronization frame filtering enabled
6 ECCE	ECC Functionality Enable. This bit controls the ECC memory error detection functionality. For details see Memory Content Fault Detection . 0 ECC functionality (injection, detection, reporting, response) disabled 1 ECC functionality enabled
7 Reserved	Reserved bit, will not be changed. Application must not write any value different from the reset value. This field is reserved.
8 FUM	FIFO Update Mode. This bit controls the FIFO update behavior when the interrupt flags FR_GIFER[FAFAIF] and FR_GIFER[FAFBIF] are written by the application (see FIFO Update) 0 FIFOA/FIFOB is updated on writing 1 to FR_GIFER[FAFAIF] /FR_GIFER[FAFBIF] 1 FIFOA/FIFOB) is not updated on writing 1 to FR_GIFER[FAFAIF]/FR_GIFER[FAFBIF]
9 FAM	FIFO Address Mode. This bit controls the location of the system memory base address for the FIFOs. (see FIFO Configuration) 0 FIFO Base Address located in System Memory Base Address High Register (FR_SYMBADHR)) 1 FIFO Base Address located in Receive FIFO System Memory Base Address High Register (FR_RFSYMBADHR)
10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 CLKSEL	Protocol Engine Clock Source Select. This bit is used to select the clock source for the protocol engine. 0 PE clock source is generated by on-chip crystal oscillator. 1 PE clock source is generated by on-chip PLL.
12–14 BITRATE	FlexRay Bus Bit Rate. This bit field defines the FlexRay Bus Bit Rate. 000 10.0 Mbit/sec 001 5.0 Mbit/sec 010 2.5 Mbit/sec 011 8.0 Mbit/sec 100 reserved 101 reserved 110 reserved 111 reserved
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

47.7.3 System Memory Base Address High Register (FR_SYMBADHR)

NOTE

The system memory base address must be set before the CC is enabled.

The system memory base address registers (FR_SYMBADHR) define the base address of the FlexRay memory area within the system memory. The base address is used by the BMIF to calculate the physical memory address for system memory accesses.

The FR_SYMBADHR register contains the most significant bits of the base address.

Write: Disabled Mode

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	SMBA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SYMBADHR field descriptions

Field	Description
0–15 SMBA	System Memory Base Address high. This is the value of the system memory base address for the individual message buffers and sync frame table. This is the value of the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. It is defines as a byte address.

47.7.4 System Memory Base Address Low Register (FR_SYMBADLR)

NOTE

The system memory base address must be set before the CC is enabled.

The system memory base address registers (FR_SYMBADLR) define the base address of the FlexRay memory area within the system memory. The base address is used by the BMIF to calculate the physical memory address for system memory accesses.

The FR_SYMBADLR register contains the least significant bits of the base address.

Write: Disabled Mode

Address: 0h base + 6h offset = 6h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	SMBA												0			
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SYMBADLR field descriptions

Field	Description
0–11 SMBA	System Memory Base Address low. This is the value of the system memory base address for the individual message buffers and sync frame table. This is the value of the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. It is defines as a byte address.
12–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

47.7.5 Strobe Signal Control Register (FR_STBSCR)

Write: Anytime

This register is used to assign the individual protocol timing related strobe signals given in Table 47-8 to the external strobe ports. Each strobe signal can be assigned to at most one strobe port . Each write access to registers overwrites the previously written ENB and STBPSEL values for the signal indicated by SEL . If more than one strobe signal is assigned to one strobe port, the current values of the strobe signals are combined with a binary OR and presented at the strobe port . If no strobe signal is assigned to a strobe port, the strobe port carries logic 0 . For more detailed and timing information refer to Strobe Signal Support .

NOTE

In single channel device mode, channel B related strobe signals are undefined and should not be assigned to the strobe ports.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0	0			SEL				0			ENB	0		STBPSEL	
Write	WMD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_STBSCR field descriptions

Field	Description
0 WMD	Write Mode. This control bit defines the write mode of this register. 0 Write to all fields in this register on write access. 1 Write to SEL field only on write access.

FR_STBSCR field descriptions (continued)

Field	Description
14–15 STBPSEL	Strobe Port Select. This field selects the strobe port that the strobe signal selected by the SEL is assigned to. All strobe signals that are enabled and assigned to the same strobe port are combined with a binary OR operation. 00 assign selected signal to FR_DBG[0] 01 assign selected signal to FR_DBG[1] 10 assign selected signal to FR_DBG[2] 11 assign selected signal to FR_DBG[3]

47.7.6 Message Buffer Data Size Register (FR_MBDSR)

Write: POC:config

This register defines the size of the message buffer data section for the two message buffer segments in a number of two-byte entities.

The CC provides two independent segments for the individual message buffers. All individual message buffers within one segment have to have the same size for the message buffer data section. This size can be different for the two message buffer segments.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0	MBSEG2DS							0	MBSEG1DS						
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_MBDSR field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–7 MBSEG2DS	Message Buffer Segment 2 Data Size. The field defines the size of the message buffer data section in two-byte entities for message buffers within the second message buffer segment.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 MBSEG1DS	Message Buffer Segment 1 Data Size. The field defines the size of the message buffer data section in two-byte entities for message buffers within the first message buffer segment.

47.7.7 Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)

Write: POC:config

This register is used to define the last individual message buffer that belongs to the first message buffer segment and the number of the last used individual message buffer.

Address: 0h base + Eh offset = Eh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0	LAST_MB_SEG1							0	LAST_MB_UTIL						
Write																
Reset	0	1	1	1	1	1	1	1	0	1	1	1	1	1	1	1

FR_MBSSUTR field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–7 LAST_MB_SEG1	Last Message Buffer In Segment 1. This field defines the message buffer number of the last individual message buffer that is assigned to the first message buffer segment. The individual message buffers in the first segment correspond to the message buffer control registers FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, FR_MBIDXRn with n <= LAST_MB_SEG1. The first message buffer segment contains LAST_MB_SEG1+1 individual message buffers. **NOTE:** The first message buffer segment contains at least one individual message buffer. The individual message buffers in the second message buffer segment correspond to the message buffer control registers FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, FR_MBIDXRn with LAST_MB_SEG1 < n < 128 . **NOTE:** If LAST_MB_SEG1 = 127 all individual message buffers belong to the first message buffer segment and the second message buffer segment is empty.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 LAST_MB_UTIL	Last Message Buffer Utilized. This field defines the message buffer number of last utilized individual message buffer. The message buffer search engine examines all individual message buffer with a message buffer number n <= LAST_MB_UTIL. **NOTE:** If LAST_MB_UTIL=LAST_MB_SEG1 all individual message buffers belong to the first message buffer segment and the second message buffer segment is empty.

47.7.8 PE DRAM Access Register (FR_PEDRAR)

The PEDRAR register is used to trigger write and read operations on the PE data memory (PE DRAM). These operations are used for memory error injection and memory error observation.

Each write access to this registers initiates a read or write operation on the PE DRAM. The access done status bit DAD is cleared after the write access and is set if the PE DRAM access has been finished.

In case of an PE DRAM write access, the data provided in FR_PEDRDR are written into the PE DRAM, read back from the PE DRAM and are stored into the FR_PEDRDR.

In case of an PE DRAM read access, the requested data are read from PE DRAM and stored into the FR_PEDRDR.

For a detailed description refer to Memory Content Fault Detection

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	INST				ADDR											DAD
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_PEDRAR field descriptions

Field	Description
0–3 INST	PE DRAM Access Instruction. This field defines the operation to be executed on the PE DRAM. 0011 PE DRAM write: Write FR_PEDRDR[DATA] to PE DRAM address ADDR (16 bit) 0101 PE DRAM read: Read Data from PE DRAM address ADDR (16 bit) into FR_PEDRDR[DATA] other reserved
4–14 ADDR	PE DRAM Access Address. This field defines the address in the PE DRAM to be written to or read from.
15 DAD	PE DRAM Access Done. This status bit is cleared when the application has written to this register and is set when the PE DRAM access has finished. 0 PE DRAM access running 1 PE DRAM access done

47.7.9 PE DRAM Data Register (FR_PEDRDR)

This register provides the data to be written to or read from the PE DRAM by the access initiated by write access to the FR_PEDRAR.

Address: 0h base + 12h offset = 12h

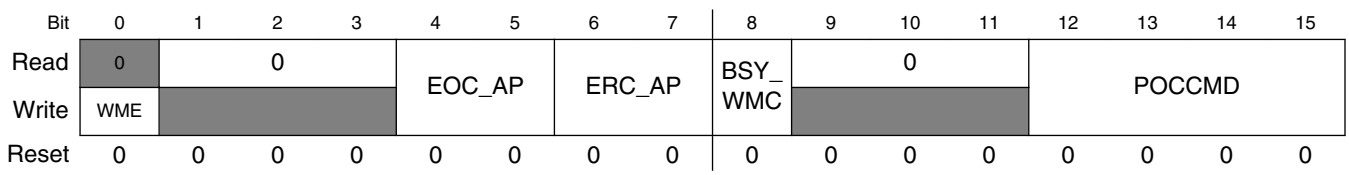
Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_PEDRDR field descriptions

Field	Description
0–15 DATA	Data to be written to or read from the PE DRAM by the access initiated by write access to the FR_PEDRAR.

47.7.10 Protocol Operation Control Register (FR_POCR)

The application uses this register to issue



- protocol control commands
- external clock correction commands

Protocol control commands are issued by writing to the POCCMD field. For more information on protocol control commands, see Protocol Control Command Execution .

External clock correction commands are issued by writing to the EOC_AP and ERC_AP fields. For more information on external clock correction, refer to External Clock Synchronization .

Write: Normal Mode

Address: 0h base + 14h offset = 14h

FR_POCR field descriptions

Field	Description
0 WME	Write Mode External Correction. This bit controls the write mode of the EOC_AP and ERC_AP fields. 0 Write to EOC_AP and ERC_AP fields on register write. 1 No write to EOC_AP and ERC_AP fields on register write.
1–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–5 EOC_AP	External Offset Correction Application. This field is used to trigger the application of the external offset correction value defined in the Protocol Configuration Register 29 (FR_PCR29). 00 do not apply external offset correction value 01 reserved 10 subtract external offset correction value 11 add external offset correction value
6–7 ERC_AP	External Rate Correction Application. This field is used to trigger application of the external rate correction value defined in the Protocol Configuration Register 21 (FR_PCR21) 00 do not apply external rate correction value 01 reserved 10 subtract external rate correction value 11 add external rate correction value
8 BSY_WMC	**NOTE:** The name and function of this field varies depending on whether it is being read or written.

Table continues on the next page...

FR_POCR field descriptions (continued)

Field	Description
	BSY (Read-Only). Protocol Control Command Busy. This status bit indicates the acceptance of the protocol control command issued by the application via the POCCMD field. The CC sets this status bit when the application has issued a protocol control command via the POCCMD field. The CC clears this status bit when protocol control command was accepted by the PE. When the application issues a protocol control command while the BSY bit is asserted, the CC ignores this command, sets the protocol command ignored error flag PCMI_EF in the CHI Error Flag Register (FR_CHIERFR) , and will not change the value of the POCCMD field. WMC (Write-Only) Protocol Control Command Write. This status bit indicates the acceptance of the protocol control command issued by the application via the POCCMD field. The CC sets this status bit when the application has issued a protocol control command via the POCCMD field. The CC clears this status bit when protocol control command was accepted by the PE. When the application issues a protocol control command while the BSY bit is asserted, the CC ignores this command, sets the protocol command ignored error flag PCMI_EF in the CHI Error Flag Register (FR_CHIERFR) , and will not change the value of the POCCMD field. 0 (Write-Only) Write to POCCMD field on register write. 1 (Write-Only) Do not write to POCCMD field on register write. 0 (Read-Only) Command write idle, command accepted and ready to receive new protocol command. 1 (Read-Only) Command write busy, command not yet accepted, not ready to receive new protocol command.
9–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 POCCMD	Protocol Control Command. The application writes to this field to issue a protocol control command to the PE. The CC sends the protocol command to the PE immediately. While the transfer is running, the BSY bit is set. 0000 ALLOW_COLDSTART. Immediately activate capability of node to cold start cluster. 0001 ALL_SLOTS. Delayed transition to the all slots transmission mode. (Delayed means on completion of current communication cycle.) 0010 CONFIG. Immediately transition to the POC:config state. 0011 FREEZE. Immediately transition to the POC:halt state. 0100 READY, CONFIG_COMPLETE. Immediately transition to the POC:ready state. 0101 RUN. Immediately transition to the POC:startup start state. 0110 DEFAULT_CONFIG. Immediately transition to the POC:default config state. 0111 HALT. Delayed transition to the POC:halt state 1000 WAKEUP. Immediately initiate the wakeup procedure. 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved

47.7.11 Global Interrupt Flag and Enable Register (FR_GIFER)

Write: Normal Mode

This register provides the means to control some of the interrupt request lines and provides the corresponding interrupt flags. The interrupt flags MIF, PRIF, CHIF, RBIF, and TBIF are the outcome of a binary OR of the related individual interrupt flags and interrupt enables . The generation scheme for these flags is depicted in Figure 47-33 . For more details on interrupt generation, see Interrupt Support . These flags are cleared automatically when all of the corresponding interrupt flags or interrupt enables in the related interrupt flag and enable registers are cleared by the application.

Address: 0h base + 16h offset = 16h

Bit	0	1	2	3	4	5	6	7
Read	MIF	PRIF	CHIF	WUPIF	FAFBIF	FAFAIF	RBIF	TBIF
Write				w1c	w1c	w1c		
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read Write	MIE	PRIE	CHIE	WUPIE	FAFBIE	FAFAIE	RBIE	TBIE
Reset	0	0	0	0	0	0	0	0

FR_GIFER field descriptions

Field	Description
0 MIF	Module Interrupt Flag. This interrupt flag is set if at least one of the other interrupt flags in this register and the related interrupt enable bit are set. 0 No interrupt flag and related interrupt enable bit are set 1 At least one of the other interrupt flags in this register and the related interrupt bit are set.
1 PRIF	Protocol Interrupt Flag. This interrupt flag is set if at least one of the individual flags in the Protocol Interrupt Flag Register 0 (FR_PIFR0) and Protocol Interrupt Flag Register 1 (FR_PIFR1) and the related interrupt enable bit are set. 0 No individual protocol interrupt flag and related interrupt enable bit are set. 1 At least one of the individual protocol interrupt flags and the related interrupt enable bit are set.
2 CHIF	CHI Interrupt Flag. This interrupt flag is set if at least one of the error flags in the CHI Error Flag Register (FR_CHIERFR) and the chi error interrupt enable bit FR_GIFER[CHIE] are set . 0 All CHI error flags are equal to 0 or the chi error interrupt is disabled. 1 At least one CHI error flag and the chi error interrupt enable are is set.
3 WUPIF	Wakeup Interrupt Flag. This interrupt flag is set when the CC has received a wakeup symbol on the FlexRay bus. The application can determine on which channel the wakeup symbol was received by reading the related wakeup flags WUB and WUA in the Protocol Status Register 3 (FR_PSR3). 0 No Wakeup symbol received on FlexRay bus 1 Wakeup symbol received on FlexRay bus
4 FAFBIF	Receive FIFO Channel B Almost Full Interrupt Flag. This interrupt flag is set when one of the following events occurs a) the current number of FIFO B entries is equal to or greater than the watermark defined by the WM field in the Receive FIFO Watermark and Selection Register (FR_RFWMSR), and the CC writes a received message into the FIFO B, or

Table continues on the next page...

FR_GIFER field descriptions (continued)

Field	Description
	b) the current number of FIFO B entries is at least 1 and the periodic timer as defined by Receive FIFO Periodic Timer Register (FR_RFPTR) expires. 0 no such event 1 FIFO B almost full event has occurred
5 FAFAIF	Receive FIFO Channel A Almost Full Interrupt Flag. This interrupt flag is set when one of the following events occurs a) the current number of FIFO A entries is equal to or greater than the watermark defined by the WM field in the Receive FIFO Watermark and Selection Register (FR_RFWMSR), and the CC writes a received message into the FIFO A, or b) the current number of FIFO B entries is at least 1 and the periodic timer as defined by Receive FIFO Periodic Timer Register (FR_RFPTR) expires. 0 no such event 1 FIFO A almost full event has occurred
6 RBIF	Receive Message Buffer Interrupt Flag. This interrupt flag is set if for at least one of the individual receive message buffers (FR_MBCCSRn[MTD] = 0) both the interrupt flag MBIF and the interrupt enable bit MBIE in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) are asserted. The application can not clear this interrupt flag directly, instead it is cleared by the CC when all of the interrupt flags MBIF of the individual receive message buffers are cleared by the application or if the application has cleared the related interrupt enables bit MBIE. 0 None of the individual receive message buffers has the MBIF and MBIE flag set. 1 At least one individual receive message buffer has the MBIF and MBIE flag set.
7 TBIF	Transmit Message Buffer Interrupt Flag. This flag is set if for at least one of the individual message buffers (FR_MBCCSRn[MTD] = 1) both the interrupt flag MBIF and the interrupt enable bit MBIE in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) are equal to 1. The application can not clear this interrupt flag directly, instead, this interrupt flag is cleared by the CC when either all of the individual interrupt flags MBIF of the individual transmit message buffers are cleared by the application or the application has cleared the related interrupt enables bit MBIE. 0 None of the individual transmit message buffers has the MBIF and MBIE flag set. 1 At least one individual transmit message buffer has the MBIF and MBIE flag set.
8 MIE	Module Interrupt Enable. This bit controls if the Module Interrupt line is asserted when the MIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
9 PRIE	Protocol Interrupt Enable. This bit controls if the Protocol Interrupt line is asserted when the PRIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
10 CHIE	CHI Interrupt Enable. This bit controls if the CHI Interrupt line is asserted when the CHIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
11 WUPIE	Wakeup Interrupt Enable. This bit controls if the Wakeup Interrupt line is asserted when the WUPIF flag is set. 0 Disable interrupt line 1 Enable interrupt line

Table continues on the next page...

FR_GIFER field descriptions (continued)

Field	Description
12 FAFBIE	Receive FIFO Channel B Almost Full Interrupt Enable. This bit controls if the RX FIFO B Almost Full Interrupt line is asserted when the FAFBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
13 FAFAIE	Receive FIFO Channel A Almost Full Interrupt Enable. This bit controls if the RX FIFO A Almost Full Interrupt line is asserted when the FAFAIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
14 RBIE	Receive Message Buffer Interrupt Enable. This bit controls if the Receive Message Buffer Interrupt line is asserted when the RBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
15 TBIE	Transmit Message Buffer Interrupt Enable. This bit controls if the Transmit Message Buffer Interrupt line is asserted when the TBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line

47.7.12 Protocol Interrupt Flag Register 0 (FR_PIFR0)

Write: Normal Mode

The register holds one set of the protocol-related individual interrupt flags.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7
Read	FATL_IF	INTL_IF	ILCF_IF	CSA_IF	MRC_IF	MOC_IF	CCL_IF	MXS_IF
Write	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	MTX_IF	LTXB_IF	LTXA_IF	TBVB_IF	TBVA_IF	TI2_IF	TI1_IF	CYS_IF
Write	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

FR_PIFR0 field descriptions

Field	Description
0 FATL_IF	Fatal Protocol Error Interrupt Flag. This flag is set when the protocol engine has detected a fatal protocol error. In this case, the protocol engine goes into the POC:halt state immediately. The fatal protocol errors are: 1) pLatestTx violation, as described in the MAC process of the FlexRay protocol

Table continues on the next page...

FR_PIFR0 field descriptions (continued)

Field	Description
	2) transmission across slot boundary violation, as described in the FSP process of the FlexRay protocol 0 No such event. 1 Fatal protocol error detected.
1 INTL_IF	Internal Protocol Error Interrupt Flag. This flag is set when the protocol engine has detected an internal protocol error. In this case, the protocol engine goes into the POC:halt state immediately. An internal protocol error occurs when the protocol engine has not finished a calculation and a new calculation is requested. This can be caused by a hardware error. 0 No such event. 1 Internal protocol error detected.
2 ILCF_IF	Illegal Protocol Configuration Interrupt Flag. This flag is set when the protocol engine has detected an illegal protocol configuration parameter setting. In this case, the protocol engine goes into the POC:halt state immediately. The protocol engine checks the listen_timeout value programmed into the Protocol Configuration Register 14 (FR_PCR14) and Protocol Configuration Register 15 (FR_PCR15) when the CONFIG_COMPLETE command was sent by the application via the Protocol Operation Control Register (FR_POCR). If the value of listen_timeout is equal to zero, the protocol configuration setting is considered as illegal. 0 No such event. 1 Illegal protocol configuration detected.
3 CSA_IF	Cold Start Abort Interrupt Flag. This flag is set when the configured number of allowed cold start attempts is reached and none of these attempts was successful. The number of allowed cold start attempts is configured by the coldstart_attempts field in the Protocol Configuration Register 3 (FR_PCR3). 0 No such event. 1 Cold start aborted and no more coldstart attempts allowed.
4 MRC_IF	Missing Rate Correction Interrupt Flag. This flag is set when an insufficient number of measurements is available for rate correction at the end of the communication cycle. 0 No such event 1 Insufficient number of measurements for rate correction detected
5 MOC_IF	Missing Offset Correction Interrupt Flag. This flag is set when an insufficient number of measurements is available for offset correction. This is related to the MISSING_TERM event in the CSP process for offset correction in the FlexRay protocol. 0 No such event. 1 Insufficient number of measurements for offset correction detected.
6 CCL_IF	Clock Correction Limit Reached Interrupt Flag. This flag is set when the internal calculated offset or rate calculation values have reached or exceeded its configured thresholds as given by the offset_coorection_out field in the Protocol Configuration Register 9 (FR_PCR9) and the rate_correction_out field in the Protocol Configuration Register 14 (FR_PCR14). 0 No such event. 1 Offset or rate correction limit reached.
7 MXS_IF	Max Sync Frames Detected Interrupt Flag. This flag is set when the number of synchronization frames detected in the current communication cycle exceeds the value of the node_sync_max field in the Protocol Configuration Register 30 (FR_PCR30). **NOTE:** Only synchronization frames that have passed the synchronization frame acceptance and rejection filters are taken into account.

Table continues on the next page...

FR_PIFR0 field descriptions (continued)

Field	Description
	0 No such event. 1 More than node_sync_max sync frames detected.
8 MTX_IF	Media Access Test Symbol Received Interrupt Flag. This flag is set when the MTS symbol was received on channel A or channel B. 0 No such event. 1 MTS symbol received.
9 LTXB_IF	pLatestTx Violation on Channel B Interrupt Flag. This flag is set when the frame transmission on channel B in the dynamic segment exceeds the dynamic segment boundary. This is related to the pLatestTx violation, as described in the MAC process of the FlexRay protocol. 0 No such event. 1 pLatestTx violation occurred on channel B.
10 LTXA_IF	pLatestTx Violation on Channel A Interrupt Flag. This flag is set when the frame transmission on channel A in the dynamic segment exceeds the dynamic segment boundary. This is related to the pLatestTx violation as described in the MAC process of the FlexRay protocol. 0 No such event. 1 pLatestTx violation occurred on channel A.
11 TBVB_IF	Transmission across boundary on channel B Interrupt Flag. This flag is set when the frame transmission on channel B crosses the slot boundary. This is related to the transmission across slot boundary violation as described in the FSP process of the FlexRay protocol. 0 No such event. 1 Transmission across boundary violation occurred on channel B.
12 TBVA_IF	Transmission across boundary on channel A Interrupt Flag. This flag is set when the frame transmission on channel A crosses the slot boundary. This is related to the transmission across slot boundary violation as described in the FSP process of the FlexRay protocol. 0 No such event. 1 Transmission across boundary violation occurred on channel A.
13 TI2_IF	Timer 2 Expired Interrupt Flag. This flag is set whenever timer 2 expires. 0 No such event. 1 Timer 2 has reached its time limit.
14 TI1_IF	Timer 1 Expired Interrupt Flag. This flag is set whenever timer 1 expires. 0 No such event 1 Timer 1 has reached its time limit
15 CYS_IF	Cycle Start Interrupt Flag. This flag is set when a communication cycle starts. 0 No such event 1 Communication cycle started.

47.7.13 Protocol Interrupt Flag Register 1 (FR_PIFR1)

Write: Normal Mode

The register holds one set of the protocol-related individual interrupt flags.

Address: 0h base + 1Ah offset = 1Ah

Bit	0	1	2	3	4	5	6	7
Read	EMC_IF	IPC_IF	PECF_IF	PSC_IF	SSI3_IF	SSI2_IF	SSI1_IF	SSI0_IF
Write	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	0		EVT_IF	ODT_IF	0			
Write			w1c	w1c				
Reset	0	0	0	0	0	0	0	0

FR_PIFR1 field descriptions

Field	Description
0 EMC_IF	Error Mode Changed Interrupt Flag. This flag is set when the value of the ERRMODE bit field in the Protocol Status Register 0 (FR_PSR0) is changed by the CC. 0 No such event. 1 ERRMODE field changed.
1 IPC_IF	Illegal Protocol Control Command Interrupt Flag. This flag is set when the PE tries to execute a protocol control command, which was issued via the POCCMD field of the Protocol Operation Control Register (FR_POCR), and detects that this protocol control command is not allowed in the current protocol state. In this case the command is not executed. For more details, see Protocol Control Command Execution . 0 No such event. 1 Illegal protocol control command detected.
2 PECF_IF	Protocol Engine Communication Failure Interrupt Flag. This flag is set if the CC has detected a communication failure between the PE and the CHI. 0 No such event. 1 Protocol Engine Communication Failure detected.
3 PSC_IF	Protocol State Changed Interrupt Flag. This flag is set when the protocol state in the PROTSTATE field in the Protocol Status Register 0 (FR_PSR0) has changed. 0 No such event. 1 Protocol state changed.
4 SSI3_IF	Slot Status Counter Incremented Interrupt Flag. Each of these flags is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Registers (FR_SSCRn) is incremented. 0 No such event. 1 The corresponding slot status counter has incremented.
5 SSI2_IF	Slot Status Counter Incremented Interrupt Flag. Each of these flags is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Registers (FR_SSCRn) is incremented. 0 No such event. 1 The corresponding slot status counter has incremented.
6 SSI1_IF	Slot Status Counter Incremented Interrupt Flag. Each of these flags is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Registers (FR_SSCRn) is incremented. 0 No such event. 1 The corresponding slot status counter has incremented.

Table continues on the next page...

FR_PIFR1 field descriptions (continued)

Field	Description
7 SSI0_IF	Slot Status Counter Incremented Interrupt Flag. Each of these flags is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Registers (FR_SSCRn) is incremented. 0 No such event. 1 The corresponding slot status counter has incremented.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 EVT_IF	Even Cycle Table Written Interrupt Flag. This flag is set if the CC has written the sync frame measurement / ID tables into the FlexRay memory area for the even cycle. 0 No such event. 1 Sync frame measurement table written
11 ODT_IF	Odd Cycle Table Written Interrupt Flag. This flag is set if the CC has written the sync frame measurement / ID tables into the FlexRay memory area for the odd cycle. 0 No such event. 1 Sync frame measurement table written
12–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

47.7.14 Protocol Interrupt Enable Register 0 (FR_PIER0)

Write: Anytime

This register defines whether or not the individual interrupt flags defined in the Protocol Interrupt Flag Register 0 (FR_PIFR0) can generate a protocol interrupt request.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7

Field	Description
3 PSC_IE	Protocol State Changed Interrupt Enable. This bit controls PSC_IF interrupt request generation. 0 interrupt request generation disabled 1 interrupt request generation enabled
4 SSI3_IE	Slot Status Counter Incremented Interrupt Enable. This bit controls SSI[3:0]_IF interrupt request generation. 0 interrupt request generation disabled 1 interrupt request generation enabled
5 SSI2_IE	Slot Status Counter Incremented Interrupt Enable. This bit controls SSI[3:0]_IF interrupt request generation. 0 interrupt request generation disabled 1 interrupt request generation enabled
6 SSI1_IE	Slot Status Counter Incremented Interrupt Enable. This bit controls SSI[3:0]_IF interrupt request generation. 0 interrupt request generation disabled 1 interrupt request generation enabled
7 SSI0_IE	Slot Status Counter Incremented Interrupt Enable. This bit controls SSI[3:0]_IF interrupt request generation. 0 interrupt request generation disabled 1 interrupt request generation enabled
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 EVT_IE	Even Cycle Table Written Interrupt Enable. This bit controls EVT_IF interrupt request generation. 0 interrupt request generation disabled 1 interrupt request generation enabled
11 ODT_IE	Odd Cycle Table Written Interrupt Enable. This bit controls ODT_IF interrupt request generation. 0 interrupt request generation disabled 1 interrupt request generation enabled
12–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

47.7.16 CHI Error Flag Register (FR_CHIERFR)

Write: Normal Mode

This register holds the CHI related error flags. The interrupt generation for each of these error flags is controlled by the CHI interrupt enable bit CHIE in the Global Interrupt Flag and Enable Register (FR_GIFER).

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7
Read	FRLB_EF	FRLA_EF	PCMI_EF	FOVB_EF	FOVA_EF	MBS_EF	MBU_EF	LCK_EF

Write		w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

FR_CHIERFR field descriptions

Field	Description
0 FRLB_EF	Frame Lost Channel B Error Flag. This flag is set if a complete frame was received on channel B but could not be stored in the selected individual message buffer because this message buffer is currently locked by the application. In this case, the frame and the related slot status information are lost. 0 No such event 1 Frame lost on channel B detected
1 FRLA_EF	Frame Lost Channel A Error Flag. This flag is set if a complete frame was received on channel A but could not be stored in the selected individual message buffer because this message buffer is currently locked by the application. In this case, the frame and the related slot status information are lost. 0 No such error 1 Frame lost on channel A detected
2 PCMI_EF	Protocol Command Ignored Error Flag. This flag is set if the application has issued a POC command by writing to the POCCMD field in the Protocol Operation Control Register (FR_POCR) while the BSY flag is equal to 1. In this case the command is ignored by the CC and is lost. 0 No such error 1 POC command ignored
3 FOVB_EF	Receive FIFO Overrun Channel B Error Flag. This flag is set when an overrun of the FIFO for channel B occurred. This error occurs if a semantically valid frame was received on channel B and matches the all criteria to be appended to the FIFO for channel B but the FIFO is full. In this case, the received frame and its related slot status information is lost. 0 No such error 1 FIFO overrun on channel B has been detected
4 FOVA_EF	Receive FIFO Overrun Channel A Error Flag. This flag is set when an overrun of the FIFO for channel A occurred. This error occurs if a semantically valid frame was received on channel A and matches the all criteria to be appended to the FIFO for channel A but the FIFO is full. In this case, the received frame and its related slot status information is lost. 0 No such error 1 FIFO overrun on channel B has been detected
5 MBS_EF	Message Buffer Search Error Flag. This flag is set if at least one of the following events occurs: a) The message buffer search engine is still running while the next search must be started due to the FlexRay protocol timing. b) A message buffer index greater than 131 is detected in the FR_MBIDXR[MBIDX] field of an found message buffer or in one of the FR_RSBIR[RSBIDX] fields.

Table continues on the next page...

FR_CHIERFR field descriptions (continued)

Field	Description
	Refer to Message Buffer Search Error for details. 0 No such event 1 Search engine active while search start appears or illegal message buffer index detected
6 MBU_EF	Message Buffer Utilization Error Flag. This flag is asserted if the application writes to a message buffer control field that is beyond the number of utilized message buffers programmed in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR). If the application writes to a FR_MBCCSRn register with n > LAST_MB_UTIL, the CC ignores the write attempt and asserts the message buffer utilization error flag MBU_EF in the CHI Error Flag Register (FR_CHIERFR). 0 No such event 1 Non-utilized message buffer enabled
7 LCK_EF	Lock Error Flag. This flag is set if the application tries to lock a message buffer that is already locked by the CC due to internal operations. In that case, the CC does not grant the lock to the application. The application must issue the lock request again. 0 No such error 1 Lock error detected
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 SBCF_EF	System Bus Communication Failure Error Flag. This flag is set if a system bus access was not finished within the required amount of time (see System Bus Access Timeout). 0 No such event 1 System bus access not finished in time
10 FID_EF	Frame ID Error Flag. This flag is set if the frame ID stored in the message buffer header area differs from the frame ID stored in the message buffer control register and "also an illegal CHI command RUN is issued in POC:normal active state". 0 No such error occurred 1 Frame ID error occurred
11 DPL_EF	Dynamic Payload Length Error Flag. This flag is set if the payload length written into the message buffer header field of a transmit message buffer assigned to the dynamic segment is greater than the maximum payload length for the dynamic segment as it is configured in the corresponding protocol configuration register field max_payload_length_dynamic in the Protocol Configuration Register 24 (FR_PCR24). 0 No such error occurred 1 Dynamic payload length error occurred
12 SPL_EF	Static Payload Length Error Flag. This flag is set if the payload length written into the message buffer header field of a transmit message buffer assigned to the static segment is different from the payload length for the static segment as it is configured in the corresponding protocol configuration register field payload_length_static in the Protocol Configuration Register 19 (FR_PCR19). 0 No such error occurred 1 Static payload length error occurred
13 NML_EF	Network Management Length Error Flag. This flag is set if the payload length written into the header structure of a receive message buffer assigned to the static segment is less than the configured length of the Network Management Vector as configured in the Network Management Vector Length Register (FR_NMVLR). In this case the received part of the Network Management Vector will be used to update the Network Management Vector.

Table continues on the next page...

FR_CHIERFR field descriptions (continued)

Field	Description
	0 No such error occurred 1 Network management length error occurred
14 NMF_EF	Network Management Frame Error Flag. This flag is set if a received message in the static segment with a Preamble Indicator flag PP asserted has its Null Frame indicator flag NF asserted as well. In this case, the Global Network Management Registers (see Network Management Vector Registers (FR_NMVR0-FR_NMVR5)) are not updated. 0 No such error occurred 1 Network management frame error occurred
15 ILSA_EF	Illegal System Bus Address Error Flag. This flag is set if the external system bus subsystem has detected an access to an illegal system bus address from the CC (see System Bus Illegal Address Access). 0 No such event 1 Illegal system bus address accessed

47.7.17 Message Buffer Interrupt Vector Register (FR_MBIVEC)

This register indicates the lowest numbered receive message buffer and the lowest numbered transmit message buffer that have their interrupt status flag MBIF and interrupt enable MBIE bits asserted. This means that message buffers with lower message buffer numbers have higher priority.

Address: 0h base + 22h offset = 22h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0	TBIVEC							0	RBIVEC						
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_MBIVEC field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–7 TBIVEC	Transmit Buffer Interrupt Vector. This field provides the number of the lowest numbered enabled transmit message buffer that has its interrupt status flag MBIF and its interrupt enable bit MBIE set. If there is no transmit message buffer with the interrupt status flag MBIF and the interrupt enable MBIE bits asserted, the value in this field is set to 0.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 RBIVEC	Receive Buffer Interrupt Vector. This field provides the message buffer number of the lowest numbered receive message buffer which has its interrupt flag MBIF and its interrupt enable bit MBIE asserted. If there is no receive message buffer with the interrupt status flag MBIF and the interrupt enable MBIE bits asserted, the value in this field is set to 0.

47.7.18 Channel A Status Error Counter Register (FR_CASERCR)

This register provides the channel status error counter for channel A. The protocol engine generates a slot status vector for each static slot, each dynamic slot, the symbol window, and the NIT. The slot status vector contains the four protocol related error indicator bits vSS!SyntaxError, vSS!ContentError, vSS!BViolation, and vSS!TxConflict. The CC increments the status error counter by 1 if, for a slot or segment, at least one error indicator bit is set to 1. The counter wraps around after it has reached the maximum value. For more information on slot status monitoring, see Slot Status Monitoring.

Address: 0h base + 24h offset = 24h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	CHAERSCNT															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_CASERCR field descriptions

Field	Description
0–15 CHAERSCNT	Channel A Status Error Counter. This field provides the current value channel status error counter. The counter value is updated within the first macrotick of the following slot or segment.

47.7.19 Channel B Status Error Counter Register (FR_CBSERCR)

This register provides the channel status error counter for channel B. The protocol engine generates a slot status vector for each static slot, each dynamic slot, the symbol window, and the NIT. The slot status vector contains the four protocol related error indicator bits vSS!SyntaxError, vSS!ContentError, vSS!BViolation, and vSS!TxConflict. The CC increments the status error counter by 1 if, for a slot or segment, at least one error indicator bit is set to 1. The counter wraps around after it has reached the maximum value. For more information on slot status monitoring see Slot Status Monitoring.

Address: 0h base + 26h offset = 26h

FR_PSR1 field descriptions

Field	Description
0 CSAA	Cold Start Attempt Aborted Flag. protocol related event: 'set coldstart abort indicator in CHI' This flag is set when the CC has aborted a cold start attempt. 0 No such event 1 Cold start attempt aborted
1 CSP	Leading Cold Start Path. This status bit is set when the CC has reached the POC:normal active state via the leading cold start path. This indicates that this node has started the network 0 No such event 1 POC:normal active reached from POC:startup state via leading cold start path
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 REMCSAT	Remaining Coldstart Attempts. protocol related variable: vRemainingColdstartAttempts This field provides the number of remaining cold start attempts that the CC will execute.
8 CPN	Leading Cold Start Path Noise. protocol related variable: vPOC!ColdstartNoise This status bit is set if the CC has reached the POC:normal active state via the leading cold start path under noise conditions. This indicates there was some activity on the FlexRay bus while the CC was starting up the cluster. 0 No such event 1 POC:normal active state was reached from POC:startup state via noisy leading cold start path
9 HHR	Host Halt Request Pending. protocol related variable: vPOC!CHIHaltRequest This status bit is set when CC receives the HALT command from the application via the Protocol Operation Control Register (FR_POCR). The CC clears this status bit after a hard reset condition or when the protocol is in the POC:default config state. 0 No such event 1 HALT command received

Table continues on the next page...

FR_PSR1 field descriptions (continued)

Field	Description
10 FRZ	Freeze Occurred. protocol related variable: vPOC!Freeze This status bit is set when the CC has reached the POC:halt state due to the host FREEZE command or due to an internal error condition requiring immediate halt. The CC clears this status bit after a hard reset condition or when the protocol is in the POC:default config state. 0 No such event 1 Immediate halt due to FREEZE or internal error condition
11–15 APTAC	Allow Passive to Active Counter. protocol related variable: vPOC!vAllowPassivetoActive This field provides the number of consecutive even/odd communication cycle pairs that have passed with valid rate and offset correction terms, but the protocol is still in the POC:normal passive state due to an application configured delay to enter POC:normal active state. This delay is defined by the allow_passive_to_active field in the Protocol Configuration Register 12 (FR_PCR12).

47.7.22 Protocol Status Register 2 (FR_PSR2)

This register provides a snapshot of status information about the Network Idle Time NIT, the Symbol Window and the clock synchronization. The NIT related status bits NBVB, NSEB, NBVA, and NSEA are updated by the CC after the end of the NIT and before the end of the first slot of the next communication cycle. The Symbol Window related status bits STCB, SBVB, SSEB, MTB, STCA, SBVA, SSEB, and MTA are updated by the CC after the end of the symbol window and before the end of the current communication cycle. If no symbol window is configured, the symbol window related status bits remain in their reset state. The clock synchronization related CLKCORRFAILCNT is updated by the CC after the end of the static segment and before the end of the current communication cycle.

Address: 0h base + 2Ch offset = 2Ch

FR_PSR2 field descriptions

Field	Description
0 NBVB	NIT Boundary Violation on Channel B. protocol related variable: vSS!BViolation for NIT on channel B This status bit is set when there was some media activity on the FlexRay bus channel B at the end of the NIT. 0 No such event 1 Media activity at boundaries detected
1 NSEB	NIT Syntax Error on Channel B. protocol related variable: vSS!SyntaxError for NIT on channel B This status bit is set when a syntax error was detected during NIT on channel B. 0 No such event 1 Syntax error detected
2 STCB	Symbol Window Transmit Conflict on Channel B. protocol related variable: vSS!TxConflict for symbol window on channel B This status bit is set if there was a transmission conflict during the symbol window on channel B. 0 No such event 1 Transmission conflict detected
3 SBVB	Symbol Window Boundary Violation on Channel B. protocol related variable: vSS!BViolation for symbol window on channel B This status bit is set if there was some media activity on the FlexRay bus channel B at the start or at the end of the symbol window. 0 No such event 1 Media activity at boundaries detected
4 SSEB	Symbol Window Syntax Error on Channel B. protocol related variable: vSS!SyntaxError for symbol window on channel B This status bit is set when a syntax error was detected during the symbol window on channel B. 0 No such event 1 Syntax error detected
5 MTB	Media Access Test Symbol MTS Received on Channel B. protocol related variable: vSS!ValidMTS for Symbol Window on channel B This status bit is set if the Media Access Test Symbol MTS was received in the symbol window on channel B. 0 No such event 1 MTS symbol received
6 NBVA	NIT Boundary Violation on Channel A. protocol related variable: vSS!BViolation for NIT on channel A This status bit is set when there was some media activity on the FlexRay bus channel A at the end of the NIT. 0 No such event 1 Media activity at boundaries detected
7 NSEA	NIT Syntax Error on Channel A. protocol related variable: vSS!SyntaxError for NIT on channel A This status bit is set when a syntax error was detected during NIT on channel A. 0 No such event 1 Syntax error detected

Table continues on the next page...

FR_PSR2 field descriptions (continued)

Field	Description
8 STCA	Symbol Window Transmit Conflict on Channel A. protocol related variable: vSS!TxConflict for symbol window on channel A This status bit is set if there was a transmission conflicts during the symbol window on channel A. 0 No such event 1 Transmission conflict detected
9 SBVA	Symbol Window Boundary Violation on Channel A. protocol related variable: vSS!BViolation for symbol window on channel A This status bit is set if there was some media activity on the FlexRay bus channel A at the start or at the end of the symbol window. 0 No such event 1 Media activity at boundaries detected
10 SSEA	Symbol Window Syntax Error on Channel A. protocol related variable: vSS!SyntaxError for symbol window on channel A This status bit is set when a syntax error was detected during the symbol window on channel A. 0 No such event 1 Syntax error detected
11 MTA	Media Access Test Symbol MTS Received on Channel A. protocol related variable: vSS!ValidMTS for symbol window on channel A This status bit is set if the Media Access Test Symbol MTS was received in the symbol window on channel A. 1 MTS symbol received 0 No such event
12–15 CKCORFCNT	Clock Correction Failed Counter. protocol related variable: vClockCorrectionFailed This field provides the number of consecutive even/odd communication cycle pairs that have passed without clock synchronization having performed an offset or a rate correction due to lack of synchronization frames. It is not incremented when it has reached the configured value of either max_without_clock_correction_fatal or max_without_clock_correction_passive as defined in the Protocol Configuration Register 8 (FR_PCR8). The CC resets this counter on a hard reset condition, when the protocol enters the POC:normal active state, or when both the rate and offset correction terms have been calculated successfully.

47.7.23 Protocol Status Register 3 (FR_PSR3)

Write: Normal Mode

This register provides aggregated channel status information as an accrued status of channel activity for all communication slots, regardless of whether they are assigned for transmission or subscribed for reception. It provides accrued information for the symbol window, the NIT, and the wakeup status.

Address: 0h base + 2Eh offset = 2Eh

FR_PSR3 field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 WUB	Wakeup Symbol Received on Channel B. This flag is set when a wakeup symbol was received on channel B. 0 No wakeup symbol received 1 Wakeup symbol received
3 ABVB	Aggregated Boundary Violation on Channel B. This flag is set when a boundary violation has been detected on channel B. Boundary violations are detected in the communication slots, the symbol window, and the NIT. 0 No boundary violation detected 1 Boundary violation detected
4 AACB	Aggregated Additional Communication on Channel B. This flag is set when at least one valid frame was received on channel B in a slot that also contained an additional communication with either syntax error, content error, or boundary violations. 0 No additional communication detected 1 Additional communication detected
5 ACEB	Aggregated Content Error on Channel B. This flag is set when a content error has been detected on channel B. Content errors are detected in the communication slots, the symbol window, and the NIT. 0 No content error detected 1 Content error detected
6 ASEB	Aggregated Syntax Error on Channel B. This flag is set when a syntax error has been detected on channel B. Syntax errors are detected in the communication slots, the symbol window and the NIT. 0 No syntax error detected 1 Syntax errors detected
7 AVFB	Aggregated Valid Frame on Channel B. This flag is set when a syntactically correct valid frame has been received in any static or dynamic slot through channel B. 1 At least one syntactically valid frame received 0 No syntactically valid frames received
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FR_PSR3 field descriptions (continued)

Field	Description
10 WUA	Wakeup Symbol Received on Channel A. This flag is set when a wakeup symbol was received on channel A. 0 No wakeup symbol received 1 Wakeup symbol received
11 ABVA	Aggregated Boundary Violation on Channel A. This flag is set when a boundary violation has been detected on channel A. Boundary violations are detected in the communication slots, the symbol window, and the NIT. 0 No boundary violation detected 1 Boundary violation detected
12 AACA	Aggregated Additional Communication on Channel A. This flag is set when a valid frame was received in a slot on channel A that also contained an additional communication with either syntax error, content error, or boundary violations. 0 No additional communication detected 1 Additional communication detected
13 ACEA	Aggregated Content Error on Channel A. This flag is set when a content error has been detected on channel A. Content errors are detected in the communication slots, the symbol window, and the NIT. 0 No content error detected 1 Content error detected
14 ASEA	Aggregated Syntax Error on Channel A. This flag is set when a syntax error has been detected on channel A. Syntax errors are detected in the communication slots, the symbol window, and the NIT. 0 No syntax error detected 1 Syntax errors detected
15 AVFA	Aggregated Valid Frame on Channel A. This flag is set when a syntactically correct valid frame has been received in any static or dynamic slot through channel A. 0 No syntactically valid frames received 1 At least one syntactically valid frame received

47.7.24 Macrotick Counter Register (FR_MTCTR)

This register provides the macrotick count of the current communication cycle.

Address: 0h base + 30h offset = 30h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0		MTCT													
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_MTCTR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 MTCT	Macrotick Counter. protocol related variable: vMacrotick This field provides the macrotick count of the current communication cycle.

47.7.25 Cycle Counter Register (FR_CYCTR)

This register provides the number of the current communication cycle.

Address: 0h base + 32h offset = 32h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0										CYCCNT					
Write

FR_SLTCTAR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 SLOTCNTA	Slot Counter Value for Channel A. protocol related variable: vSlotCounter for channel A This field provides the number of the current slot in the current communication cycle.

47.7.27 Slot Counter Channel B Register (FR_SLTCTBR)

This register provides the number of the current slot in the current communication cycle for channel B.

Address: 0h base + 36h offset = 36h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0					SLOTCNTB										
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SLTCTBR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 SLOTCNTB	Slot Counter Value for Channel B. protocol related variable: vSlotCounter for channel B This field provides the number of the current slot in the current communication cycle.

47.7.28 Rate Correction Value Register (FR_RTCORVR)

This register provides the sign extended rate correction value in microticks as it was calculated by the clock synchronization algorithm. The CC updates this register during the NIT of each odd numbered communication cycle.

Address: 0h base + 38h offset = 38h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	RATECORR															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RTCORVR field descriptions

Field	Description
0–15 RATECORR	Rate Correction Value. protocol related variable: vRateCorrection (before value limitation and external rate correction) This field provides the sign extended rate correction value in microticks as it was calculated by the clock synchronization algorithm. The value is represented in 2's complement format. This value does not include the value limitation and the application of the external rate correction. If the magnitude of the internally calculated rate correction value exceeds the limit given by rate_correction_out in the Protocol Configuration Register 13 (FR_PCR13), the clock correction reached limit interrupt flag CCL_IF is set in the Protocol Interrupt Flag Register 0 (FR_PIFR0). **NOTE:** If the CC was not able to calculate a new rate correction term due to a lack of synchronization frames, the RATECORR value is not updated.

47.7.29 Offset Correction Value Register (FR_OFCORVR)

This register provides the sign extended offset correction value in microticks as it was calculated by the clock synchronization algorithm. The CC updates this register during the NIT.

Address: 0h base + 3Ah offset = 3Ah

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	OFFSETCORR															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_OFCORVR field descriptions

Field	Description
0–15 OFFSETCORR	Offset Correction Value. protocol related variable: vOffsetCorrection (before value limitation and external offset correction) This field provides the sign extended offset correction value in microticks as it was calculated by the clock synchronization algorithm. The value is represented in 2's complement format. This value does not include the value limitation and the application of the external offset correction. If the magnitude of the internally calculated rate correction value exceeds the limit given by offset_correction_out field in the Protocol Configuration Register 29 (FR_PCR29), the clock correction reached limit interrupt flag CCL_IF is set in the Protocol Interrupt Flag Register 0 (FR_PIFR0). **NOTE:** If the CC was not able to calculate an new offset correction term due to a lack of synchronization frames, the OFFSETCORR value is not updated.

47.7.30 Combined Interrupt Flag Register (FR_CIFR)

This register provides five combined interrupt flags and a copy of three individual interrupt flags. The combined interrupt flags are the result of a binary OR of the values of other interrupt flags regardless of the state of the interrupt enable bits. The generation scheme for the combined interrupt flags is depicted in Figure 47-35 . The individual interrupt flags WUPIF, FAFBIF, and FAFAIF are copies of corresponding flags in the Global Interrupt Flag and Enable Register (FR_GIFER) and are provided here to simplify the application interrupt flag check. To clear the individual interrupt flags, the application must use the Global Interrupt Flag and Enable Register (FR_GIFER).

NOTE

The meanings of the combined status bits MIF, PRIF, CHIF, RBIF, and TBIF are different from those mentioned in the Global Interrupt Flag and Enable Register (FR_GIFER).

Address: 0h base + 3Ch offset = 3Ch

Bit	0	1	2	3	4	5	6	7
Read	0							
Write								
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	MIF	PRIF	CHIF	WUPIF	FAFBIF	FAFAIF	RBIF	TBIF
Write								
Reset	0	0	0	0	0	0	0	0

FR_CIFR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 MIF	Module Interrupt Flag. This flag is set if there is at least one interrupt source that has its interrupt flag asserted. 0 No interrupt source has its interrupt flag asserted 1 At least one interrupt source has its interrupt flag asserted
9 PRIF	Protocol Interrupt Flag. This flag is set if at least one of the individual protocol interrupt flags in the Protocol Interrupt Flag Register 0 (FR_PIFR0) or Protocol Interrupt Flag Register 1 (FR_PIFR1) is equal to 1. 0 All individual protocol interrupt flags are equal to 0 1 At least one of the individual protocol interrupt flags is equal to 1
10 CHIF	CHI Interrupt Flag. This flag is set if at least one of the individual CHI error flags in the CHI Error Flag Register (FR_CHIERFR) is equal to 1.

Table continues on the next page...

FR_CIFR field descriptions (continued)

Field	Description
	0 All CHI error flags are equal to 0 1 At least one CHI error flag is equal to 1
11 WUPIF	Wakeup Interrupt Flag. Provides the same value as FR_GIFER[WUPIF]
12 FAFBIF	Receive FIFO Channel B Almost Full Interrupt Flag. Provides the same value as FR_GIFER[FAFBIF]
13 FAFAIF	Receive FIFO Channel A Almost Full Interrupt Flag. Provides the same value as FR_GIFER[FAFAIF]
14 RBIF	Receive Message Buffer Interrupt Flag. This flag is set if for at least one of the individual receive message buffers (FR_MBCCSRn[MTD] = 0) the interrupt flag MBIF in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) is equal to 1. 0 None of the individual receive message buffers has the MBIF flag asserted. 1 At least one individual receive message buffers has the MBIF flag asserted.
15 TBIF	Transmit Message Buffer Interrupt Flag. This flag is set if for at least one of the individual transmit message buffers (FR_MBCCSRn[MTD] = 1) the interrupt flag MBIF in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) is equal to 1. 0 None of the individual transmit message buffers has the MBIF flag asserted. 1 At least one individual transmit message buffers has the MBIF flag asserted.

47.7.31 System Memory Access Time-Out Register (FR_SYMATOR)

Write: Disabled Mode

Address: 0h base + 3Eh offset = 3Eh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								TIMEOUT							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

FR_SYMATOR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 TIMEOUT	System Memory Access Time-Out. This value defines when a system bus access timout is detected. For a detailed description see Configure System Memory Access Time-Out Register (FR_SYMATOR) and System Bus Access Timeout .

47.7.32 Sync Frame Counter Register (FR_SFCNTR)

This register provides the number of synchronization frames that are used for clock synchronization in the last even and in the last odd numbered communication cycle. This register is updated after the start of the NIT and before 10 MT after offset correction start.

NOTE

If the application has locked the even synchronization table at the end of the static segment of an even communication cycle, the CC will not update the fields SFEVB and SFEVA.

NOTE

If the application has locked the odd synchronization table at the end of the static segment of an odd communication cycle, the CC will not update the values SFODB and SFODA.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	SFEVB				SFEVA				SFODB				SFODA			
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SFCNTR field descriptions

Field	Description
0–3 SFEVB	Sync Frames Channel B, even cycle. protocol related variable: size of (vsSyncIdListB for even cycle) This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.
4–7 SFEVA	Sync Frames Channel A, even cycle. protocol related variable: size of (vsSyncIdListA for even cycle) This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.
8–11 SFODB	Sync Frames Channel B, odd cycle. protocol related variable: size of (vsSyncIdListB for odd cycle) This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization .
12–15 SFODA	Sync Frames Channel A, odd cycle. protocol related variable: size of (vsSyncIdListA for odd cycle) This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization .

47.7.33 Sync Frame Table Offset Register (FR_SFTOR)

Write: POC:config

This register defines the FlexRay memory area related offset for sync frame tables. For more details, see Sync Frame ID and Sync Frame Deviation Tables .

Address: 0h base + 42h offset = 42h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	SFT_OFFSET															0
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SFTOR field descriptions

Field	Description
0–14 SFT_OFFSET	Sync Frame Table Offset. The offset of the Sync Frame Tables in the FlexRay memory area. This offset is required to be 16-bit aligned. Thus STF_OFFSET[0] is always 0.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

47.7.34 Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR)

Write: Normal Mode

This register provides configuration, control, and status information related to the generation and access of the clock sync ID tables and clock sync measurement tables. For a detailed description, see Sync Frame ID and Sync Frame Deviation Tables .

Address: 0h base + 44h offset = 44h

Bit	0	1	2	3	4	5	6	7
Read	0	0	CYCNUM					
Write	ELKT	OLKT						
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	ELKS	OLKS	EVAL	OVAL	0	0	SDVEN	SIDEN
Write						OPT		
Reset	0	0	0	0	0	0	0	0

FR_SFTCCSR field descriptions

Field	Description
0 ELKT	Even Cycle Tables Lock/Unlock Trigger. This trigger bit is used to lock and unlock the even cycle tables. 0 No effect 1 Triggers lock/unlock of the even cycle tables.
1 OLKT	Odd Cycle Tables Lock/Unlock Trigger. This trigger bit is used to lock and unlock the odd cycle tables. 0 No effect 1 Triggers lock/unlock of the odd cycle tables.

Table continues on the next page...

FR_SFTCCSR field descriptions (continued)

Field	Description
2–7 CYCNUM	Cycle Number. This field provides the number of the cycle in which the currently locked table was recorded. If none or both tables are locked, this value is related to the even cycle table.
8 ELKS	Even Cycle Tables Lock Status. This status bit indicates whether the application has locked the even cycle tables. 0 Application has not locked the even cycle tables. 1 Application has locked the even cycle tables.
9 OLKS	Odd Cycle Tables Lock Status. This status bit indicates whether the application has locked the odd cycle tables. 0 Application has not locked the odd cycle tables. 1 Application has locked the odd cycle tables.
10 EVAL	Even Cycle Tables Valid. This status bit indicates whether the Sync Frame ID and Sync Frame Deviation Tables for the even cycle are valid. The CC clears this status bit when it starts updating the tables, and sets this bit when it has finished the table update. 0 Tables are not valid (update is ongoing) 1 Tables are valid (consistent).
11 OVAL	Odd Cycle Tables Valid. This status bit indicates whether the Sync Frame ID and Sync Frame Deviation Tables for the odd cycle are valid. The CC clears this status bit when it starts updating the tables, and sets this bit when it has finished the table update. 0 Tables are not valid (update is ongoing) 1 Tables are valid (consistent).
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 OPT	One Pair Trigger. This trigger bit controls whether the CC writes continuously or only one pair of Sync Frame Tables into the FlexRay memory area. If this trigger is set to 1 while SDVEN or SIDEN is set to 1, the CC writes only one pair of the enabled Sync Frame Tables corresponding to the next even-odd-cycle pair into the FlexRay memory area. In this case, the CC clears the SDVEN or SIDEN bits immediately. If this trigger is set to 0 while SDVEN or SIDEN is set to 1, the CC writes continuously the enabled Sync Frame Tables into the FlexRay memory area. 0 Write continuously pairs of enabled Sync Frame Tables into FlexRay memory area. 1 Write only one pair of enabled Sync Frame Tables into FlexRay memory area.
14 SDVEN	Sync Frame Deviation Table Enable. This bit controls the generation of the Sync Frame Deviation Tables. The application must set this bit to request the CC to write the Sync Frame Deviation Tables into the FlexRay memory area. **NOTE:** If SDVEN is set to 1, then SIDEN must also be set to 1. 0 Do not write Sync Frame Deviation Tables 1 Write Sync Frame Deviation Tables into FlexRay memory area
15 SIDEN	Sync Frame ID Table Enable. This bit controls the generation of the Sync Frame ID Tables. The application must set this bit to 1 to request the CC to write the Sync Frame ID Tables into the FlexRay memory area. 0 Do not write Sync Frame ID Tables 1 Write Sync Frame ID Tables into FlexRay memory area

47.7.35 Sync Frame ID Rejection Filter Register (FR_SFIDRFR)

Write: Normal Mode

This register defines the Sync Frame Rejection Filter ID. The application must update this register outside of the static segment. If the application updates this register in the static segment, it can appear that the CC accepts the sync frame in the current cycle.

Address: 0h base + 46h offset = 46h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								SYNFRID							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SFIDRFR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 SYNFRID	Sync Frame Rejection ID. This field defines the frame ID of a frame that must not be used for clock synchronization. For details see Sync Frame Rejection Filtering .

47.7.36 Sync Frame ID Acceptance Filter Value Register (FR_SFIDAFVR)

Write: POC:config

This register defines the sync frame acceptance filter value. For details on filtering, see Sync Frame Filtering .

Address: 0h base + 48h offset = 48h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								FVAL							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SFIDAFVR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 FVAL	Filter Value. This field defines the value for the sync frame acceptance filtering.

47.7.37 Sync Frame ID Acceptance Filter Mask Register (FR_SFIDAFMR)

Write: POC:config

This register defines the sync frame acceptance filter mask. For details on filtering see Sync Frame Acceptance Filtering .

Address: 0h base + 4Ah offset = 4Ah

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0						FMSK									
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SFIDAFMR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 FMSK	Filter Mask. This field defines the mask for the sync frame acceptance filtering.

47.7.38 Network Management Vector Register (FR_NMVR*n*)

Each of these six registers holds one part of the Network Management Vector. The length of the Network Management Vector is configured in the Network Management Vector Length Register (FR_NMVLR). If FR_NMVLR is programmed with a value that is less than 12 bytes, the remaining bytes of the Network Management Vector Registers (FR_NMVR0-FR_NMVR5), which are not used for the Network Management Vector accumulating, will remain 0.

The NMVR provides accrued information over all received NMVs in the last communication cycle. All NMVs received in one cycle are ORed into the NMVR. The NMVR is updated at the end of the communication cycle.

Address: 0h base + 4Ch offset + (2d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	NMVP															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_NMVR*n* field descriptions

Field	Description
0–15 NMVP	Network Management Vector Part. The mapping between the Network Management Vector Registers (FR_NMVR0-FR_NMVR5) and the receive message buffer payload bytes in NMV[0:11] is depicted in the following table.

Table 47-9. Mapping of NMVRn to the Received Payload Bytes NMVn

NMVRn Register	NMVn Received Payload
FR_NMVR0[NMVP[15:8]]	NMV0
FR_NMVR0[NMVP[7:0]]	NMV1
FR_NMVR1[NMVP[15:8]]	NMV2
FR_NMVR1[NMVP[7:0]]	NMV3
...	
FR_NMVR5[NMVP[15:8]]	NMV10
FR_NMVR5[NMVP[7:0]]	NMV11

47.7.39 Network Management Vector Length Register (FR_NMVLR)

Write: POC:config

This register defines the length of the network management vector in bytes.

Address: 0h base + 58h offset = 58h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0												NMVL			
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_NMVLR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 NMVL	Network Management Vector Length. protocol related variable: gNetworkManagementVectorLength This field defines the length of the Network Management Vector in bytes. Legal values are between 0 and 12.

47.7.40 Timer Configuration and Control Register (FR_TICCR)

Write: T2_CFG: POC:config T2_REP, T1_REP, T1SP, T2SP, T1TR, T2TR: Normal Mode

This register is used to configure and control the two timers T1 and T2. For timer details, see Timer Support . The Timer T1 is an absolute timer. The Timer T2 can be configured as an absolute or relative timer.

NOTE

Both timers are deactivated immediately when the protocol enters a state different from POC:normal active or POC:normal passive.

Address: 0h base + 5Ah offset = 5Ah

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0		T2_CFG	T2_REP	0	0	0	T2ST	0			T1_REP	0	0	0	T1ST
Write						T2SP	T2TR							T1SP	T1TR	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_TICCR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 T2_CFG	Timer T2 Configuration. This bit configures the timebase mode of Timer T2. 0 T2 is absolute timer. 1 T2 is relative timer.
3 T2_REP	Timer T2 Repetitive Mode. This bit configures the repetition mode of Timer T2. 0 T2 is non repetitive 1 T2 is repetitive
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 T2SP	Timer T2 Stop. This trigger bit is used to stop timer T2. 0 no effect 1 stop timer T2
6 T2TR	Timer T2 Trigger. This trigger bit is used to start timer T2. 0 no effect 1 start timer T2
7 T2ST	Timer T2 State. This status bit provides the current state of timer T2. 0 timer T2 is idle 1 timer T2 is running
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 T1_REP	Timer T1 Repetitive Mode. This bit configures the repetition mode of timer T1. 0 T1 is non repetitive 1 T1 is repetitive

Table continues on the next page...

FR_TICCR field descriptions (continued)

Field	Description
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 T1SP	Timer T1 Stop. This trigger bit is used to stop timer T1. 0 no effect 1 stop timer T1
14 T1TR	Timer T1 Trigger. This trigger bit is used to start timer T1. 0 no effect 1 start timer T1
15 T1ST	Timer T1 State. This status bit provides the current state of timer T1. 0 timer T1 is idle 1 timer T1 is running

47.7.41 Timer 1 Cycle Set Register (FR_TI1CYSR)

Write: Anytime

This register defines the cycle filter value and the cycle filter mask for timer T1. For a detailed description of timer T1, refer to Absolute Timer T1 .

NOTE

If the application modifies the value in this register while the timer is running, the change becomes effective immediately and timer T1 will expire according to the changed value.

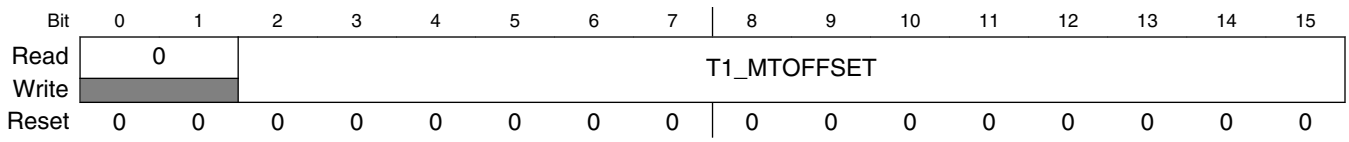
Address: 0h base + 5Ch offset = 5Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0		T1_CYC_VAL						0		T1_CYC_MSK					
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_TI1CYSR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 T1_CYC_VAL	Timer T1 Cycle Filter Value. This field defines the cycle filter value for timer T1.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 T1_CYC_MSK	Timer T1 Cycle Filter Mask. This field defines the cycle filter mask for timer T1.

47.7.42 Timer 1 Macrotick Offset Register (FR_TI1MTOR)



Write: Anytime

This register holds the macrotick offset value for timer T1. For a detailed description of timer T1, refer to Absolute Timer T1 .

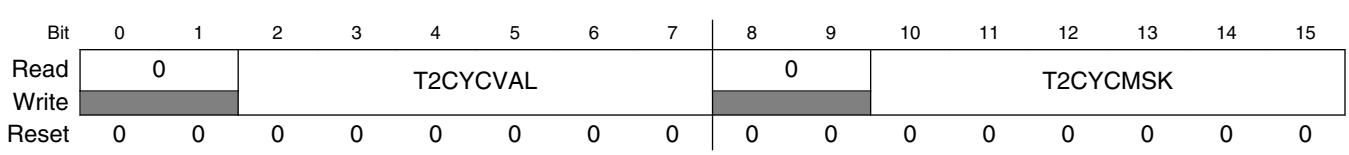
NOTE

If the application modifies the value in this register while the timer is running, the change becomes effective immediately and timer T1 will expire according to the changed value.

Address: 0h base + 5Eh offset = 5Eh

FR_TI1MTOR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 T1_MTOFFSET	Timer 1 Macrotick Offset. This field defines the macrotick offset value for timer 1.



47.7.43 Timer 2 Configuration Register 0 (Absolute Timer Configuration) (FR_TI2CR0_ABS)

The content of this register depends on the value of the T2_CFG bit in the Timer Configuration and Control Register (FR_TICCR). For a detailed description of timer T2, .

NOTE

If timer T2 is configured as an absolute timer and the application modifies the values in this register while the timer is running, the change becomes effective immediately and timer T2 will expire according to the changed values.

Address: 0h base + 60h offset = 60h

FR_TI2CR0_ABS field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 T2CYCVAL	Timer T2 Cycle Filter Mask
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 T2CYCMSK	Timer T2 Cycle Filter Mask

47.7.44 Timer 2 Configuration Register 0 (Relative Timer Configuration) (FR_TI2CR0_REL)

Write: Anytime

The content of this register depends on the value of the T2_CFG bit in the Timer Configuration and Control Register (FR_TICCR). For a detailed description of timer T2, refer to Relative Timer T2.

NOTE

If timer T2 is configured as a relative timer and the application changes the values in this register while the timer is running, the change becomes effective when the timer has expired according to the old values.

Address: 0h base + 60h offset = 60h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	T2MTCNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_TI2CR0_REL field descriptions

Field	Description
0–15 T2MTCNT	Timer T2 Macrotick High Word

47.7.45 Timer 2 Configuration Register 1 (Absolute Timer Configuration) (FR_TI2CR1_ABS)

Write: Anytime

The content of this register depends on the value of the T2_CFG bit in the Timer Configuration and Control Register (FR_TICCR). For a detailed description of timer T2, refer to Absolute Timer T2

NOTE

If timer T2 is configured as an absolute timer and the application modifies the values in this register while the timer is running, the change becomes effective immediately and the timer T2 will expire according to the changed values.

Address: 0h base + 62h offset = 62h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_TI2CR1_REL field descriptions

Field	Description
0–15 T2MTCNT	Timer T2 Macrotick Low Word

47.7.47 Slot Status Selection Register (FR_SSSR)

Write: Anytime

This register is used to access the four internal non-memory mapped slot status selection registers FR_SSSR0 to FR_SSSR3. Each internal register selects a slot, or symbol window/NIT, whose status vector will be saved in the corresponding Slot Status Registers (FR_SSR0-FR_SSR7) according to Slot Status Selection Register (FR_SSSR) . For a detailed description of slot status monitoring, refer to Slot Status Monitoring .

Table 47-10. Mapping Between FR_SSSRn and FR_SSRn

Internal Slot Status Selection Register	Write the Slot Status of the Slot Selected by FR_SSSRn for each			
	Even Communication Cycle		Odd Communication Cycle	
	For Channel B to	For Channel A to	For Channel B to	For Channel A to
FR_SSSR0	FR_SSR0[15:8]	FR_SSR0[7:0]	FR_SSR1[15:8]	FR_SSR1[7:0]
FR_SSSR1	FR_SSR2[15:8]	FR_SSR2[7:0]	FR_SSR3[15:8]	FR_SSR3[7:0]

FR_SSSR field descriptions

Field	Description
0 WMD	Write Mode. This control bit defines the write mode of this register. 0 Write to all fields in this register on write access. 1 Write to SEL field only on write access.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FR_SSSR field descriptions (continued)

Field	Description
2–3 SEL	Selector. This field selects one of the four internal slot status selection registers for access. 00 select FR_SSSR0. 01 select FR_SSSR1. 10 select FR_SSSR2. 11 select FR_SSSR3.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 SLOTNUMBER	Slot Number. This field specifies the number of the slot whose status will be saved in the corresponding slot status registers. **NOTE:** If this value is set to 0, the related slot status register provides the status of the symbol window after the NIT start, and provides the status of the NIT after the cycle start.

47.7.48 Slot Status Counter Condition Register (FR_SSCCR)

Write: Anytime

This register is used to access and program the four internal non-memory mapped Slot Status Counter Condition Registers FR_SSCCR0 to FR_SSCCR3. Each of these four internal slot status counter condition registers defines the mode and the conditions for incrementing the counter in the corresponding Slot Status Counter Registers (FR_SSCR0-FR_SSCR3). The correspondence is given in Slot Status Counter Condition Register (FR_SSCCR) . For a detailed description of slot status counters, refer to Slot Status Counter Registers .

Table 47-11. Mapping between internal FR_SSCCRn and FR_SSCRn

Condition Register	Condition Defined for Register
FR_SSCCR0	FR_SSCR0
FR_SSCCR1	FR_SSCR1
FR_SSCCR2	FR_SSCR2
FR_SSCCR3	FR_SSCR3

Address: 0h base + 66h offset = 66h

FR_SSCCR field descriptions

Field	Description
0 WMD	Write Mode. This control bit defines the write mode of this register. 0 Write to all fields in this register on write access. 1 Write to SEL field only on write access.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–3 SEL	Selector. This field selects one of the four internal slot counter condition registers for access. 00 select FR_SSCCR0. 01 select FR_SSCCR1. 10 select FR_SSCCR2. 11 select FR_SSCCR3.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–6 CNTCFG	Counter Configuration. These bit field controls the channel related incrementing of the slot status counter. 00 increment by 1 if condition is fulfilled on channel A. 01 increment by 1 if condition is fulfilled on channel B. 10 increment by 1 if condition is fulfilled on at least one channel. 11 increment by 2 if condition is fulfilled on both channels channel; increment by 1 if condition is fulfilled on only one channel.
7 MCY	Multi Cycle Selection. This bit defines whether the slot status counter accumulates over multiple communication cycles or provides information for the previous communication cycle only. 0 The Slot Status Counter provides information for the previous communication cycle only. 1 The Slot Status Counter accumulates over multiple communication cycles.
8 VFR	Valid Frame Restriction. This bit is used to restrict the counter to received valid frames. 0 The counter is not restricted to valid frames only. 1 The counter is restricted to valid frames only.
9 SYF	Sync Frame Restriction. This bit is used to restrict the counter to received frames with the sync frame indicator bit set to 1. 0 The counter is not restricted with respect to the sync frame indicator bit. 1 The counter is restricted to frames with the sync frame indicator bit set to 1.
10 NUF	Null Frame Restriction. This bit is used to restrict the counter to received frames with the null frame indicator bit set to 0. 0 The counter is not restricted with respect to the null frame indicator bit. 1 The counter is restricted to frames with the null frame indicator bit set to 0.
11 SUF	Startup Frame Restriction. This bit is used to restrict the counter to received frames with the startup frame indicator bit set to 1. 0 The counter is not restricted with respect to the startup frame indicator bit. 1 The counter is restricted to received frames with the startup frame indicator bit set to 1.
12–15 STATUSMASK	Slot Status Mask. This bit field is used to enable the counter with respect to the four slot status error indicator bits. STATUSMASK[3] - This bit enables the counting for slots with the syntax error indicator bit set to 1. STATUSMASK[2] - This bit enables the counting for slots with the content error indicator bit set to 1.

Table continues on the next page...

FR_SSCCR field descriptions (continued)

Field	Description
	STATUSMASK[1] - This bit enables the counting for slots with the boundary violation indicator bit set to 1. STATUSMASK[0] - This bit enables the counting for slots with the transmission conflict indicator bit set to 1.

47.7.49 Slot Status Register (FR_SSR*n*)

Each Slot Status Register (SSR) holds the status vector of the slot specified in the corresponding internal slot status selection register, which can be programmed using the Slot Status Selection Register (FR_SSSR). Each register is updated after the end of the corresponding slot as shown in Figure 47-31 . The register bits are directly related to the protocol variables and described in more detail in Slot Status Monitoring .

Address: 0h base + 68h offset + (2d × i), where i=0d to 7d

15 TCA	Transmission Conflict on Channel A. protocol related variable: vSS!TxConflict channel A 0 vSS!TxConflict = 0 1 vSS!TxConflict = 1

47.7.50 Slot Status Counter Register (FR_SSCR*n*)

Each of these four registers provides the slot status counter value for the previous communication cycle(s) and is updated at the cycle start. The provided value depends on the control bits and fields in the related internal slot status counter condition register FR_SSCCRn, which can be programmed by using the Slot Status Counter Condition Register (FR_SSCCR). For more details, see Slot Status Counter Registers .

NOTE

If the counter has reached its maximum value 0xFFFF and is in the multicycle mode, i.e. FR_SSCCRn[MCY] = 1, the counter is not reset to 0x0000. The application can reset the counter by clearing the FR_SSCCRn[MCY] bit and waiting for the next cycle start, when the CC clears the counter. Subsequently, the counter can be set into the multicycle mode again.

NOTE

Address: 0h base + 78h offset + (2d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	SLOTSTATUSCNT															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SSCR*n* field descriptions

Field	Description
0–15 SLOTSTATUSCNT	Slot Status Counter. This field provides the current value of the Slot Status Counter.

47.7.51 MTS A Configuration Register (FR_MTSACFR)

Write: MTE: Anytime; CYCCNTMSK,CYCCNTVAL: POC:config

This register controls the transmission of the Media Access Test Symbol MTS on channel A. For more details, see MTS Generation .

Address: 0h base + 80h offset = 80h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	MTE	0	CYCCNTMSK						0		CYCCNTVAL					
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_MTSACFR field descriptions

Field	Description
0 MTE	Media Access Test Symbol Transmission Enable. This control bit is used to enable and disable the transmission of the Media Access Test Symbol in the selected set of cycles. 0 MTS transmission disabled 1 MTS transmission enabled
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 CYCCNTMSK	Cycle Counter Mask. This field provides the filter mask for the MTS cycle count filter.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 CYCCNTVAL	Cycle Counter Value. This field provides the filter value for the MTS cycle count filter.

47.7.52 MTS B Configuration Register (FR_MTSBCFR)

Write: MTE: Anytime; CYCCNTMSK,CYCCNTVAL: POC:config

This register controls the transmission of the Media Access Test Symbol MTS on channel B. For more details, see MTS Generation .

Address: 0h base + 82h offset = 82h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	MTE	0	CYCCNTMSK						0		CYCCNTVAL					
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_MTSBCFR field descriptions

Field	Description
0 MTE	Media Access Test Symbol Transmission Enable. This control bit is used to enable and disable the transmission of the Media Access Test Symbol in the selected set of cycles. 0 MTS transmission disabled 1 MTS transmission enabled
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 CYCCNTMSK	Cycle Counter Mask. This field provides the filter mask for the MTS cycle count filter.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 CYCCNTVAL	Cycle Counter Value. This field provides the filter value for the MTS cycle count filter.

47.7.53 Receive Shadow Buffer Index Register (FR_RSBIR)

Write: WMD, SEL: Any Time; RSBIDX: POC:config

This register is used to provide and retrieve the indices of the message buffer header fields currently associated with the receive shadow buffers . For more details on the receive shadow buffer concept, refer to Receive Shadow Buffers Concept .

Address: 0h base + 84h offset = 84h

Bit	0	1	2	3	4	5	6	7
Read Write	WMD	Reserved	SEL		Reserved			
Reset	0	0	0	0	0	0	0	0

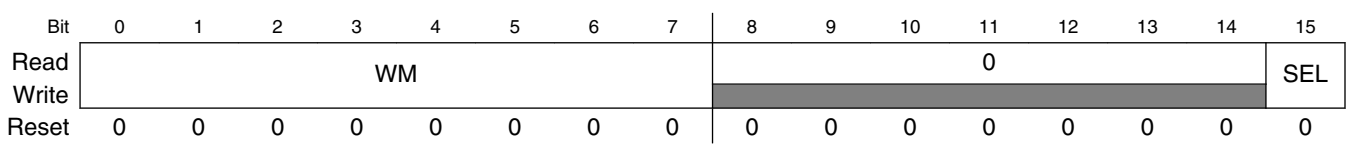
Bit	8	9	10	11	12	13	14	15
Read Write	RSBIDX							
Reset	0	0	0	0	0	0	0	0

FR_RSBIR field descriptions

Field	Description
0 WMD	Write Mode. This bit controls the write mode for this register. 0 update SEL and RSBIDX field on register write 1 update only SEL field on register write
1 Reserved	This field is reserved.
2–3 SEL	Selector. This field is used to select the internal receive shadow buffer index register for access. 00 FR_RSBIR_A1. receive shadow buffer index register for channel A, segment 1 01 FR_RSBIR_A2. receive shadow buffer index register for channel A, segment 2 10 FR_RSBIR_B1. receive shadow buffer index register for channel B, segment 1 11 FR_RSBIR_B2. receive shadow buffer index register for channel B, segment 2
4–7 Reserved	This field is reserved.
8–15 RSBIDX	RSBIDXA1/RSBIDXA2/RSBIDXB1/RSBIDXB2- Receive Shadow Buffer Index Receive Shadow Buffer Index. This field contains the current index of the message buffer header field of the receive shadow message buffer selected by the SEL field. The CC uses this index to determine the physical location of the shadow buffer header field in the FlexRay memory area. The CC will update this field during receive operation.The application provides initial message buffer header index value in the configuration phase. CC: Updates the message buffer header index after successful reception. Application: Provides initial message buffer header index. Legal Values are 0 <= i <= 131 . Illegal values will be detected during the message buffer search.

47.7.54 Receive FIFO Watermark and Selection Register (FR_RFWMSR)

Write: WMA/WMB: POC:config, SEL: Anytime



This register is used to

- select a receiver FIFO for subsequent programming access through the receiver FIFO configuration registers summarized in Receive FIFO Watermark and Selection Register (FR_RFWMSR) .
- to define the watermark for the selected FIFO.

Table 47-12. SEL Controlled Receiver FIFO Registers

Register
Receive FIFO Start Index Register (FR_RFSIR)
Receive FIFO Depth and Size Register (FR_RFDSR)
Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR)
Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR)
Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR)
Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR)
Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)
Receive FIFO Range Filter Control Register (FR_RFRFCTR)

Address: 0h base + 86h offset = 86h

FR_RFWMSR field descriptions

Field	Description
0–7 WM	WMA/WMB - Watermark This field defines the watermark value for the selected FIFO. This value is used to control the generation of the almost full interrupt flags.
8–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 SEL	Select. This control bit selects the receiver FIFO for subsequent programming. 0 Receiver FIFO for channel A selected 1 Receiver FIFO for channel B selected

47.7.55 Receive FIFO Start Index Register (FR_RFSIR)

Write: POC:config

This register defines the message buffer header index of the first message buffer of the selected FIFO.

Address: 0h base + 88h offset = 88h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								SIDX							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFSIR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 SIDX	SIDXA/SIDXB - Start Index This field defines the number of the message buffer header field of the first message buffer of the selected FIFO. The CC uses the value of the SIDX field to determine the physical location of the receiver FIFO's first message buffer header field.

47.7.56 Receive FIFO Depth and Size Register (FR_RFDSR)

Write: POC:config

This register defines the structure of the selected FIFO, i.e. the number of entries and the size of each entry .

Address: 0h base + 8Ah offset = 8Ah

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	FIFO_DEPTH								0	ENTRY_SIZE						
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFDSR field descriptions

Field	Description
0–7 FIFO_DEPTH	FIFO_DEPTHA/FIFO_DEPTHB - FIFO Depth FIFO Depth. This field defines the depth of the selected FIFO, i.e. the number of entries. Note: If the FIFO_DEPTH is configured to 0, FR_RFFIDRFMR[FIDRFMSK] must be configured to 0 too, to ensure that no frames are received into the FIFO.

Table continues on the next page...

FR_RFDSR field descriptions (continued)

Field	Description
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 ENTRY_SIZE	ENTRY_SIZEA/ENTRY_SIZEB - Entry Size This field defines the size of the frame data sections for the selected FIFO in 2 byte entities.

47.7.57 Receive FIFO A Read Index Register (FR_RFARIR)

This register provides the message buffer header index of the next available FIFO A entry that the application can read.

NOTE

If the FIFO is empty, the RDIDX field points to an physical message buffer with invalid content.

Address: 0h base + 8Ch offset = 8Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0						RDIDX									
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFARIR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 RDIDX	Read Index. This field provides the message buffer header index of the next available FIFO message buffer that the application can read.

47.7.58 Receive FIFO B Read Index Register (FR_RFBRIR)

This register provides the message buffer header index of the next available FIFO B entry that the application can read.

NOTE

If the FIFO is empty, the RDIDX field points to an physical message buffer with invalid content.

Address: 0h base + 8Eh offset = 8Eh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								RDIDX							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFBRIR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 RDIDX	Read Index. This field provides the message buffer header index of the next available FIFO message buffer that the application can read.

47.7.59 Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR)

Write: POC:config

This register defines the filter value for the message ID acceptance filter of the selected FIFO. For details on message ID filtering see FIFO Filtering .

Address: 0h base + 90h offset = 90h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	MIDAFVAL															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFMIDAFVR field descriptions

Field	Description
0–15 MIDAFVAL	MIDAFVALA/MIDAFVALB - Message ID Acceptance Filter Value Filter value for the message ID acceptance filter.

47.7.60 Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR)

Write: POC:config

This register defines the filter mask for the message ID acceptance filter of the selected FIFO. For details on message ID filtering see FIFO Filtering .

Address: 0h base + 92h offset = 92h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	MIDAFMSK															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFMIDAFMR field descriptions

Field	Description
0–15 MIDAFMSK	MIDAFMSKA/MIDAFMSKB - Message ID Acceptance Filter Mask Filter mask for the message ID acceptance filter.

47.7.61 Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR)

Write: POC:config

This register defines the filter value for the frame ID rejection filter of the selected FIFO. For details on frame ID filtering see FIFO Filtering .

Address: 0h base + 94h offset = 94h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0					FIDRFVAL										
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFFIDRFVR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 FIDRFVAL	FIDRFVALA/FIDRFVALB - Frame ID Rejection Filter Value Filter value for the frame ID rejection filter.

47.7.62 Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR)

Write: POC:config

This register defines the filter mask for the frame ID rejection filter of the selected FIFO. For details on frame ID filtering see FIFO Filtering .

Address: 0h base + 96h offset = 96h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0					FIDRFMSK										
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFFIDRFMR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 FIDRFMSK	Frame ID Rejection Filter Mask. Filter mask for the frame ID rejection filter.

47.7.63 Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)

Write: WMD, IBD, SEL: Any Time; SID: POC:config

This register provides access to the four internal frame ID range filter boundary registers of the selected FIFO. For details on frame ID range filter see FIFO Filtering .

Address: 0h base + 98h offset = 98h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0	IBD	SEL		0	SID										
Write	WMD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFRFCFR field descriptions

Field	Description
0 WMD	Write Mode. This control bit defines the write mode of this register. 0 Write to all fields in this register on write access. 1 Write to SEL and IBD field only on write access.
1 IBD	Interval Boundary. This control bit selects the interval boundary to be programmed with the SID value. 0 program lower interval boundary 1 program upper interval boundary
2–3 SEL	Filter Selector. This control field selects the frame ID range filter to be accessed. 00 select frame ID range filter 0. 01 select frame ID range filter 1. 10 select frame ID range filter 2. 11 select frame ID range filter 3.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FR_RFRFCFR field descriptions (continued)

Field	Description
5–15 SID	Slot ID Defines the IBD-selected frame ID boundary value for the SEL-selected range filter.

47.7.64 Receive FIFO Range Filter Control Register (FR_RFRFCTR)

Write: Anytime

This register is used to enable and disable each frame ID range filter and to define whether it is running as acceptance or rejection filter.

Address: 0h base + 9Ah offset = 9Ah

Bit	0	1	2	3	4	5	6	7
Read	0				F3MD	F2MD	F1MD	F0MD
Write								
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	0				F3EN	F2EN	F1EN	F0EN
Write								
Reset	0	0	0	0	0	0	0	0

FR_RFRFCTR field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 F3MD	Range Filter 3 Mode. This control bit defines the filter mode of the frame ID range filter 3. 0 range filter 3 runs as acceptance filter 1 range filter 3 runs as rejection filter
5 F2MD	Range Filter 2 Mode. This control bit defines the filter mode of the frame ID range filter 2. 0 range filter 2 runs as acceptance filter 1 range filter 2 runs as rejection filter
6 F1MD	Range Filter 1 Mode. This control bit defines the filter mode of the frame ID range filter 1. 0 range filter 1 runs as acceptance filter 1 range filter 1 runs as rejection filter
7 F0MD	Range Filter 0 Mode. This control bit defines the filter mode of the frame ID range filter 0. 0 range filter 0 runs as acceptance filter 1 range filter 0 runs as rejection filter
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FR_RFRFCTR field descriptions (continued)

Field	Description
12 F3EN	Range Filter 3 Enable. This control bit is used to enable and disable the frame ID range filter 3. 0 range filter 3 disabled 1 range filter 3 enabled
13 F2EN	Range Filter 2 Enable. This control bit is used to enable and disable the frame ID range filter 2. 0 range filter 2 disabled 1 range filter 2 enabled
14 F1EN	Range Filter 1 Enable. This control bit is used to enable and disable the frame ID range filter 1. 0 range filter 1 disabled 1 range filter 1 enabled
15 F0EN	Range Filter 0 Enable. This control bit is used to enable and disable the frame ID range filter 0. 0 range filter 0 disabled 1 range filter 0 enabled

47.7.65 Last Dynamic Transmit Slot Channel A Register (FR_LDTXSLAR)

This register provides the number of the last transmission slot in the dynamic segment for channel A. This register is updated after the end of the dynamic segment and before the start of the next communication cycle.

Address: 0h base + 9Ch offset = 9Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

FR_LDTXSLAR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 LDYNTXSLOTA	Last Dynamic Transmission Slot Channel A. protocol related variable: zLastDynTxSlot channel A Number of the last transmission slot in the dynamic segment for channel A. If no frame was transmitted during the dynamic segment on channel A, the value of this field is set to 0.

47.7.66 Last Dynamic Transmit Slot Channel B Register (FR_LDTXSLBR)

This register provides the number of the last transmission slot in the dynamic segment for channel B. This register is updated after the end of the dynamic segment and before the start of the next communication cycle.

Address: 0h base + 9Eh offset = 9Eh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
0–4 cluster_drift_ damping	pClusterDriftDamping
5–11 max_payload_ length_dynamic	pPayloadLengthDynMax
12–15 micro_per_cycle_ min	pMicroPerCycle - pdMaxDrift

47.7.92 Protocol Configuration Register 25 (FR_PCR25)

Write: POC:config

The protocol configuration registers (FR_PCRn) provide the necessary configuration information to the protocol engine. The individual values in the registers are described in Protocol Configuration Register 0 (FR_PCR0) .

Address: 0h base + D2h offset = D2h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	micro_per_cycle_min															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_PCR25 field descriptions

Field	Description
0–15 micro_per_cycle_ min	pMicroPerCycle - pdMaxDrift

47.7.93 Protocol Configuration Register 26 (FR_PCR26)

Write: POC:config

The protocol configuration registers (FR_PCRn) provide the necessary configuration information to the protocol engine. The individual values in the registers are described in Protocol Configuration Register 0 (FR_PCR0) .

Address: 0h base + D4h offset = D4h

Bit	0	1	2	3	4	5	6	7
Read Write	allow_halt_due_to_clock	comp_accepted_startup_range_b						
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read Write	comp_accepted_startup_range_b				micro_per_cycle_max			
Reset	0	0	0	0	0	0	0	0

FR_PCR26 field descriptions

Field	Description
0 allow_halt_due_to_clock	pAllowHaltDueToClock
1–11 comp_accepted_startup_range_b	pdAcceptedStartupRange - pDelayCompensation[B]
12–15 micro_per_cycle_max	pMicroPerCycle + pdMaxDrift

47.7.94 Protocol Configuration Register 27 (FR_PCR27)

Write: POC:config

The protocol configuration registers (FR_PCRn) provide the necessary configuration information to the protocol engine. The individual values in the registers are described in Protocol Configuration Register 0 (FR_PCR0) .

Address: 0h base + D6h offset = D6h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	micro_per_cycle_max															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_PCR27 field descriptions

Field	Description
0–15 micro_per_cycle_max	pMicroPerCycle + pdMaxDrift

47.7.95 Protocol Configuration Register 28 (FR_PCR28)

Write: POC:config

The protocol configuration registers (FR_PCRn) provide the necessary configuration information to the protocol engine. The individual values in the registers are described in Protocol Configuration Register 0 (FR_PCR0) .

Address: 0h base + D8h offset = D8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	dynamic_slot_idle_phase		macro_after_offset_correction													
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_PCR28 field descriptions

Field	Description
0–1 dynamic_slot_idle_phase	gdDynamicSlotIdlePhase.
2–15 macro_after_offset_correction	gMacroPerCycle - gOffsetCorrectionStart

47.7.96 Protocol Configuration Register 29 (FR_PCR29)

Write: POC:config

The protocol configuration registers (FR_PCRn) provide the necessary configuration information to the protocol engine. The individual values in the registers are described in Protocol Configuration Register 0 (FR_PCR0) .

Address: 0h base + DAh offset = DAh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	extern_offset_correction			minislots_max												
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_PCR29 field descriptions

Field	Description
0–2 extern_offset_correction	pExternOffsetCorrection

Table continues on the next page...

FR_PCR29 field descriptions (continued)

Field	Description
3–15 minislots_max	gNumberOfMinislots - 1

47.7.97 Protocol Configuration Register 30 (FR_PCR30)

Write: POC:config

The protocol configuration registers (FR_PCRn) provide the necessary configuration information to the protocol engine. The individual values in the registers are described in Protocol Configuration Register 0 (FR_PCR0) .

Address: 0h base + DCh offset = DCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0												sync_node_max			
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_PCR30 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 sync_node_max	gSyncNodeMax

47.7.98 StopWatch Count High Register (FR_STPWHR)

Address: 0h base + DEh offset = DEh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	STPW_S_H															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_STPWHR field descriptions

Field	Description
0–15 STPW_S_H	StopWatch Count High These are the high 16 bits of the stopwatch counter running on system clock. See Stop Watch Count Low Register (STPWLR) for the low 16 bits. This counter starts on cycle start even and stops on an external event “OS_tick”. When all 32 bits of the stopwatch counter (in STPWHR and STPWLR) are read, the counter automatically clears. For details, please see StopWatch Function section.

47.7.99 Stop Watch Count Low Register (FR_STPWLR)

Address: 0h base + E0h offset = E0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	STPW_S_L															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_STPWLR field descriptions

Field	Description
0–15 STPW_S_L	StopWatch Count Low These are the low 16 bits of the stopwatch counter running on system clock. See Stop Watch Count High Register (STPWHR) for the high 16 bits. This counter starts on cycle start even and stops on an external event “OS_tick”. When all 32 bits of the stopwatch counter (in STPWHR and STPWLR) are read, the counter automatically clears. For details, please see StopWatch Function section.

47.7.100 Protocol Event Output Enable and StopWatch Control Register (FR_PEOER)

Write: Anytime

This register defines whether or not the Event output ports are enabled based on the events such as Cycle start and Timer1 and Timer2 expiry (see Timer Support for details).

Address: 0h base + E2h offset = E2h

Bit	0	1	2	3	4	5	6	7
Read	1							STPW_EN
Write								
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	0					TIM2_EE	TIM1_EE	CYC_EE
Write								
Reset	0	0	0	0	0	0	0	0

FR_PEOER field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
7 STPW_EN	Stopwatch count Enable This bit controls the stopwatch counter.

Table continues on the next page...

FR_PEOER field descriptions (continued)

Field	Description
	0 Stopwatch counter disabled 1 Stopwatch counter enabled
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 TIM2_EE	Timer 2 expired Event Output Enable- This bit controls the event on port "fr_evt_tim2" 0 Timer 2 expired event out disabled 1 Timer 2 expired event out enabled
14 TIM1_EE	Timer 1 expired Event Output Enable- This bit controls the event on port "fr_evt_tim1" 0 Timer 1 expired event out disabled 1 Timer 1 expired event out enabled
15 CYC_EE	Cycle Start Event Output Enable- This bit controls the event on port "fr_evt_cyc" 0 Cycle start event out disabled 1 Cycle start event out enabled

47.7.101 Receive FIFO Start Data Offset Register (FR_RFSDOR)

Write: POC:config

NOTE

Since all data fields of the FIFO are of equal length and are located at subsequent system memory addresses the content of the FR_RFSDOR corresponds to the start address of payload area of the selected FIFO.

Address: 0h base + E6h offset = E6h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	SDO															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFSDOR field descriptions

Field	Description
0–15 SDO	SDOA/SDOB - Start Data Field Offset Start Data Field Offset. This field defines the data field offset of the header field of the first message buffer of the selected FIFO. The CC uses the value of the SDO field to determine the physical location of the receiver FIFO's first message buffer header field. For configuration constraints see Configure Data Field Offsets .

47.7.102 Receive FIFO System Memory Base Address High Register (FR_RFSYMBADHR)

These registers define the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. The system memory base address is used by the BMIF to calculate the physical memory address for system memory accesses for the FIFOs.

Write: Disabled Mode

Address: 0h base + E8h offset = E8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	SMBA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFSYMBADHR field descriptions

Field	Description
0–15 SMBA	System Memory Base Address. This is the value of the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. It is defines as a byte address.

47.7.103 Receive FIFO System Memory Base Address Low Register (FR_RFSYMBADLR)

These registers define the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. The system memory base address is used by the BMIF to calculate the physical memory address for system memory accesses for the FIFOs.

Write: Disabled Mode

Address: 0h base + EAh offset = EAh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	SMBA												0			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFSYMBADLR field descriptions

Field	Description
0–11 SMBA	System Memory Base Address. This is the value of the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. It is defines as a byte address.
12–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

47.7.104 Receive FIFO Periodic Timer Register (FR_RFPTR)

Write: POC:config

This register holds periodic timer duration for the periodic FIFO timer. The periodic timer applies to both FIFOs (see FIFO Periodic Timer).

Address: 0h base + ECh offset = ECh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0		PTD													
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFPTR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 PTD	Periodic Timer Duration. This value defines the periodic timer duration in terms of macroticks. 0000 timer stays expired 3FFF timer never expires other timer expires after specified number of macroticks, expires and is restarted at each cycle start

47.7.105 Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)

This register provides the current fill level of the two receiver FIFOs and is used to pop a number of entries from the FIFOs

If the pop count value PCA/PCB is greater than the current FIFO fill level FLB/FLA, than the FIFO is empty after the update. No notification is given that not the required number of entries was removed.

.

Address: 0h base + EEh offset = EEh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	FLB_or_PCB								FLA_or_PCA							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFFLPCR field descriptions

Field	Description
0–7 FLB_or_PCB	**NOTE:** The name and function of the fields in this register vary depending on whether they are being read or written. See the following table for details.

Operation	Sub-Field	Description
Read	0-7 FLB	Fill Level FIFO B. This field provides the current number of entries in the FIFO B.
	-	-
Write	0-7 PCB	Pop Count FIFO B. This field defines the number of entries to be removed from FIFO B.
	-	-

Field	Description
8–15 FLA_or_PCA	

Operation	Sub-Field	Description
Read	-	-
	8-15 FLA	Fill Level FIFO A- This field provides the current number of entries in the FIFO A.
Write	-	-
	8-15 PCA	Pop Count FIFO A - This field defines the number of entries to be removed from FIFO A.

47.7.106 ECC Error Interrupt Flag and Enable Register (FR_EEIFER)

This register provides the means to control the ECC related interrupt request lines and provides the corresponding interrupt flags. The interrupt flags are cleared by writing 1, which resets the corresponding report registers. For a detailed description see Memory Error Reporting .

Address: 0h base + F0h offset = F0h

Bit	0	1	2	3	4	5	6	7
Read	LRNE_OF	LRCE_OF	DRNE_OF	DRCE_OF	LRNE_IF	LRCE_IF	DRNE_IF	DRCE_IF
Write	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	0				LRNE_IE	LRCE_IE	DRNE_IE	DRCE_IE
Write								
Reset	0	0	0	0	0	0	0	0

FR_EEIFER field descriptions

Field	Description
0 LRNE_OF	LRAM Non-Corrected Error Overflow Flag. This flag is set to 1 when at least one of the following events appears: a) memory errors are detected but not corrected on CHI LRAM and interrupt flag LRNE_IF is already 1. b) memory errors are detected but not corrected on at least two banks of CHI LRAM 0 no such event 1 Non-Corrected Error overflow detected on CHI LRAM
1 LRCE_OF	LRAM Corrected Error Overflow Flag. This flag is set to 1 when at least one of the following events appears a) memory errors are detected and corrected on CHI LRAM and interrupt flag LRCE_IF is already 1. b) memory errors are detected and corrected on at least two banks of CHI LRAM **NOTE:** Error Correction not implemented on CHI LRAM, flag will never be asserted. 0 no such event 1 Corrected Error overflow detected on CHI LRAM
2 DRNE_OF	DRAM Non-Corrected Error Overflow Flag. This flag is set to 1 when at least one of the following events appears: a) memory errors are detected but not corrected on PE DRAM and interrupt flag DRNE_IF is already 1. b) memory errors are detected but not corrected on at least two banks of the PE DRAM 0 no such event 1 Non-Corrected Error overflow detected on PE DRAM

Table continues on the next page...

FR_EEIFER field descriptions (continued)

Field	Description
3 DRCE_OF	DRAM Corrected Error Overflow Flag. This flag is set to 1 when at least one of the following events appears: a) memory errors are detected and corrected on PE DRAM and interrupt flag DRCE_IF is already 1. b) memory errors are detected and corrected on at least two banks of PE DRAM 0 no such event 1 Corrected Error overflow detected on PE DRAM
4 LRNE_IF	LRAM Non-Corrected Error Interrupt Flag. This interrupt flag is set to 1 when a memory error is detected but not corrected on the CHI LRAM. 0 no such event 1 Non-Corrected Error detected on CHI LRAM
5 LRCE_IF	LRAM Corrected Error Interrupt Flag. This interrupt flag is set to 1 when a memory error is detected and corrected on the CHI LRAM. **NOTE:** Error Correction not implemented on CHI LRAM, flag will never be asserted. 0 no such event 1 Corrected Error detected on CHI LRAM
6 DRNE_IF	DRAM Non-Corrected Error Interrupt Flag. This interrupt flag is set to 1 when a memory error is detected but not corrected on PE DRAM. 0 no such event 1 Non-Corrected Error detected on PE DRAM
7 DRCE_IF	DRAM Corrected Error Interrupt Flag. This interrupt flag is set to 1 when a memory error is detected and corrected on PE DRAM. 0 no such event 1 Corrected Error detected on PE DRAM
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 LRNE_IE	LRAM Non-Corrected Error Interrupt Enable. This flag controls if the LRAM Non-Corrected Error Interrupt line is asserted when the LRNE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line
13 LRCE_IE	LRAM Corrected Error Interrupt Enable. This flag controls if the LRAM Corrected Error Interrupt line is asserted when the LRCE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line
14 DRNE_IE	DRAM Non-Corrected Error Interrupt Enable. This flag controls if the DRAM Non-Corrected Error Interrupt line is asserted when the DRNE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line
15 DRCE_IE	DRAM Corrected Error Interrupt Enable. This flag controls if the DRAM Corrected Error Interrupt line is asserted when the DRCE_IF flag is set.

Table continues on the next page...

FR_EEIFER field descriptions (continued)

Field	Description
	0 Disable interrupt line 1 Enable interrupt line

47.7.107 ECC Error Report and Injection Control Register (FR_EERICR)

This register configures the error injection and error reporting and provides the selector for the content of the report registers.

Address: 0h base + F2h offset = F2h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	BSY	0					ERS		0			ERM	0		EIM	EIE
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_EERICR field descriptions

Field	Description
0 BSY	Register Update Busy- This field indicates the current state of the ECC configuration update and controls the register write access condition IDL specified in " Register Write Access 0 ECC configuration is idle 1 ECC configuration is running
1–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–7 ERS	Error Report Select. This field selects the content of the ECC Error reporting registers. 00 show PE DRAM non-corrected error information 01 show PE DRAM corrected error information 10 show CHI LRAM non-corrected error information 11 show CHI LRAM corrected error information
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 ERM	Error Report Mode. This bit configures the type of data written into the internal error report registers on the detection of a memory error. 0 store data and code as delivered by ecc decoding logic. 1 store data and code as read from the memory.
12–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 EIM	Error Injection Mode. This bit configures the ECC error injection mode.

Table continues on the next page...

FR_EERICR field descriptions (continued)

Field	Description
	0 use FR_EEIDR[DATA] and FR_EEICR[CODE] as XOR distortion pattern for error injection. 1 use FR_EEIDR[DATA] and FR_EEICR[CODE] as write value for error injection.
15 EIE	Error Injection Enable. This bit configures the ECC error injection on the memories. 0 Error injection disabled 1 Error injection enabled

47.7.108 ECC Error Report Address Register (FR_EERAR)

This register provides the memory identifier, bank, and address for which the memory error is reported.

Address: 0h base + F4h offset = F4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	MID	BANK			ADDR											
Write																
Reset	0	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0

FR_EERAR field descriptions

Field	Description
0 MID	Memory Identifier. This flag provides the memory instance for which the memory error is reported. 0 PE DRAM 1 CHI LRAM
1–3 BANK	Memory Bank. This field provides the BANK for which the memory error is reported. 111 reset value, indicates no error found after reset. For MID=0: 000 PE DRAM [7:0] 001 PE DRAM [15:8] others - not used For MID=1: Refer to the following table for the assignment of the LRAM banks.

Table 47-15. LRAM Bank Value for MID = 1

BANK	Register		
000	FR_MBCCFR(2n)	FR_MBDOR(6n)	FR_LEETR0
001	FR_MBFIDR(2n)	FR_MBDOR(6n + 1)	FR_LEETR1
010	FR_MBIDXR(2n)	FR_MBDOR(6n + 2)	FR_LEETR2
011	FR_MBCCFR(2n+1)	FR_MBDOR(6n + 3)	FR_LEETR3

Table continues on the next page...

FR_EERAR field descriptions (continued)

Field	Description
	Table 47-15. LRAM Bank Value for MID = 1 (continued)

BANK	Register		
100	FR_MBFIDR(2n+1)	FR_MBDOR(6n + 4)	FR_LEETR4
101	FR_MBIDXR(2n+1)	FR_MBDOR(6n + 5)	FR_LEETR5
110	Not Used	Not Used	Not Used
111			

4–15 ADDR	Memory Address. This field provides the address of the failing memory location.

47.7.109 ECC Error Report Data Register (FR_EERDR)

This register provides the data related information of the reported memory read access. The assignment of the bits depends on the selected memory and memory bank as shown in ECC Error Report Data Register (FR_EERDR) .

Table 47-16. Valid Bits in FR_EERDR[DATA] / FR_EEIDR[DATA] field

MEM	BANK	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PE DRAM	0									PE DRAM[7:0]							
PE DRAM	1									PE DRAM[15:8]

CHI LRAM	5									FR_MBIDXR(2n+1)[MBIDX]							
CHI LRAM	5	FR_MBDOR(6n+5)															
CHI LRAM	5	FR_LEETR5															

Address: 0h base + F6h offset = F6h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	DATA															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_EERDR field descriptions

Field	Description
0–15 DATA	Data. The content of this field depends on the report mode selected by FR_EERICR[ERM] ERM=0: Ecc Data, shows data as generated by the ecc decoding logic. ERM=1: Memory Data, shows data as read from the memory.

47.7.110 ECC Error Report Code Register (FR_EERCR)

This register provides the ECC related information of the reported memory read access.

Address: 0h base + F8h offset = F8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0											CODE				
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_EERCR field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 CODE	Code. The content of this field depends on the report mode selected by FR_EERICR[ERM] ERM=0: Syndrome. Shows the ecc syndrome generated by the ecc decoding logic. The coding of the PE DRAM syndrome is shown in PE DRAM Syndrome . The coding of the CHI LRAM syndrome is shown in CHI LRAM Syndrome . ERM=1: Checkbits. Shows the ecc checkbits read from the memory.

47.7.111 ECC Error Injection Address Register (FR_EEIAR)

This register defines the memory module, bank, and address where the ECC error has to be injected.

Address: 0h base + FAh offset = FAh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	MID	BANK			ADDR											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_EEIAR field descriptions

Field	Description
0 MID	Memory Identifier. This flag defines the memory instance for ECC error injection. 0 PE DRAM 1 CHI LRAM
1–3 BANK	Memory Bank. This field defines the memory bank for ECC error injection. For MID=0: 000 BANK0: PE DRAM [7:0] 001 BANK1: PE DRAM [15:8] others reserved For MID=1: Refer to ECC Error Report Address Register (FR_EERAR) for the assignment of the LRAM banks.
4–15 ADDR	Memory Address. This flag defines the memory address for ECC error injection.

47.7.112 ECC Error Injection Data Register (FR_EEIDR)

This register defines the data distortion pattern for the error injection write. The number of valid bits depends on the selected memory and memory bank as shown in ECC Error Report Data Register (FR_EERDR) .

NOTE

The effect of the error injected depends from the LRAM content at the address accessed and from the module internal usage of the data. Refer to Memory Error Response for details.

Address: 0h base + FCh offset = FCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_EEIDR field descriptions

Field	Description
0–15 DATA	Data. The content of this field depends on the error injection mode selected by FR_EERICR[EIM]. EIM=0: This field defines the XOR distortion pattern for the data written into the memory. EIM=1: This field defines the data to be written into the memory.

47.7.113 ECC Error Injection Code Register (FR_EEICR)

This register defines the ECC code distortion pattern for the error injection write.

Address: 0h base + FEh offset = FEh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0											CODE				
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_EEICR field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 CODE	Code. The content of this field depends on the error injection mode selected by FR_EERICR[EIM]. EIM=0: This field defines the XOR distortion pattern for the ecc checkbits written into the memory. EIM=1: This field defines the ecc checkbits written into the memory.

47.7.114 Message Buffer Configuration, Control, Status Register (FR_MBCCSR*n*)

Write: MTD: POC:config or MB_DIS CMT: MB_LCK or MB_DIS EDT, LCKT, MBIE, MBIF: Normal Mode

The content of these registers is composed of message buffer configuration data, message buffer control data, message buffer status information, and message buffer interrupt flags. A detailed description of all flags can be found in Individual Message Buffer Functional Description.

If the application writes 1 to the EDT bit, no write access to the other register bits is performed.

If the application writes 0 to the EDT bit and 1 to the LCKT bit, no write access to the other bits is performed.

Address: 0h base + 800h offset + (8d × i), where i=0d to 127d

Bit	0	1	2	3	4	5	6	7
Read	0			MTD	CMT		0	MBIE
Write						EDT	LCKT	
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	0			DUP	DVAL	EDS	LCKS	MBIF
Write								w1c
Reset	0	0	0	0	0	0	0	0

FR_MBCCSR*n* field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 MTD	Message Buffer Transfer Direction. This bit configures the transfer direction of a message buffer. 0 Receive message buffer 1 Transmit message buffer
4 CMT	Commit for Transmission. This bit indicates if the transmit message buffer data are ready for transmission. **NOTE:** This bit is read/write but may be modified by hardware other than by a reset. 0 Message buffer data not ready for transmission 1 Message buffer data ready for transmission
5 EDT	Enable/Disable Trigger. If the application writes 1 to this bit, a message buffer enable or disable is triggered, depending on the current value of the EDS status bit. 0 No effect 1 Message buffer enable or disable is triggered
6 LCKT	Lock/Unlock Trigger. If the application writes 1 to this bit and writes 0 to the EDT bit, a message buffer lock or unlock is triggered, depending on the current value of the LCKS status bit. 0 No effect 1 Message buffer lock or unlock is triggered
7 MBIE	Message Buffer Interrupt Enable. This control bit defines whether the message buffer will generate an interrupt request when its MBIF flag is set. 0 Interrupt request generation disabled 1 Interrupt request generation enabled
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FR_MBCCSR*n* field descriptions (continued)

Field	Description
11 DUP	Data Updated. This status bit indicates whether the frame header in the message buffer header field and the data in the message buffer data field were updated after a frame reception. 0 Frame Header and Message buffer data field not updated 1 Frame Header and Message buffer data field updated
12 DVAL	Data Valid. For receive message buffers this status bit indicates whether the message buffer data field contains valid frame data. For transmit message buffers the status bit indicates if a message is transferred again due to the state transmission mode of the message buffer. 0 receive message buffer contains no valid frame data / message is transmitted for the first time 1 receive message buffer contains valid frame data / message will be transferred again
13 EDS	Enable/Disable Status. This status bit indicates whether the message buffer is enabled or disabled. 0 Message buffer is disabled. 1 Message buffer is enabled.
14 LCKS	Lock Status. This status bit indicates the current lock status of the message buffer. 0 Message buffer is not locked by the application. 1 Message buffer is locked by the application.
15 MBIF	Message Buffer Interrupt Flag. This flag is set when the slot status field of the message buffer was updated after frame transmission or reception, or when a transmit message buffer was just enabled by the application. 0 No such event 1 Slot status field updated or transmit message buffer just enabled

47.7.115 Message Buffer Cycle Counter Filter Register (FR_MBCCFR*n*)

NOTE

After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

Write: POC:config or MB_DIS

This register contains message buffer configuration data for the transmission mode, the channel assignment, and for the cycle counter filtering. For detailed information on cycle counter filtering, refer to Message Buffer Cycle Counter Filtering .

NOTE

If at least one message buffer assigned to a certain slot is assigned to both channels, then all message buffers assigned to this slot have to be assigned to both channels. Otherwise, the

message buffer configuration is illegal and the result of the message buffer search is not defined.

Table 47-17. Channel Assignment Description

CHA	CHB	Transmit Message Buffer		Receive Message Buffer	
		static segment	dynamic segment	static segment	dynamic segment
1	1	transmit on both channel A and channel B	transmit on channel A only	store first valid frame received on either channel A or channel B	store first valid frame received on channel A, ignore channel B
0	1	transmit on channel B	transmit on channel B	store first valid frame received on channel B	store first valid frame received on channel B
1	0	transmit on channel A	transmit on channel A	store first valid frame received on channel A	store first valid frame received on channel A
0	0	no frame transmission	no frame transmission	no frame stored	no frame stored

Address: 0h base + 802h offset + (8d × i), where i=0d to 127d

Bit	0	1	2	3	4	5	6	7
Read Write	MTM	CHA	CHB	CCFE	CCFMSK			
Reset	0*	0*	0*	0*	0*	0*	0*	0*

Bit	8	9	10	11	12	13	14	15
Read Write	CCFMSK		CCFVAL					
Reset	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

FR_MBCCFR*n* field descriptions

Field	Description
0 MTM	Message Buffer Transmission Mode. This control bit applies only to transmit message buffers and defines the transmission mode. 0 Event transmission mode 1 State transmission mode
1 CHA	Channel Assignment. In conjunction with the CHB field, defines the channel assignment and control the receive and transmit behavior of the message buffer according to Message Buffer Cycle Counter Filter Register (FR_MBCCFR*n*) .
2 CHB	Channel Assignment. In conjunction with the CHB field, defines the channel assignment and control the receive and transmit behavior of the message buffer according to Message Buffer Cycle Counter Filter Register (FR_MBCCFR*n*) .
3 CCFE	Cycle Counter Filtering Enable. This control bit is used to enable and disable the cycle counter filtering. 0 Cycle counter filtering disabled 1 Cycle counter filtering enabled

Table continues on the next page...

FR_MBCCFR*n* field descriptions (continued)

Field	Description
4–9 CCFMSK	Cycle Counter Filtering Mask. This field defines the filter mask for the cycle counter filtering.
10–15 CCFVAL	Cycle Counter Filtering Value. This field defines the filter value for the cycle counter filtering.

47.7.116 Message Buffer Frame ID Register (FR_MBFIDR*n*)

NOTE

After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

Write: POC:config or MB_DIS

Address: 0h base + 804h offset + (8d × i), where i=0d to 127d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0					FID										
Write																
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

FR_MBFIDR*n* field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 FID	Frame ID. The semantic of this field depends on the message buffer transfer type. • Receive Message Buffer: This field is used as a filter value to determine if the message buffer is used for reception of a message received in a slot with the slot ID equal to FID. • Transmit Message Buffer: This field is used to determine the slot in which the message in this message buffer should be transmitted.

47.7.117 Message Buffer Index Register (FR_MBIDXR*n*)

NOTE

After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

Write: POC:config or MB_DIS

Address: 0h base + 806h offset + (8d × i), where i=0d to 127d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								MBIDX							
Write																
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

FR_MBIDXR*n* field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 MBIDX	Message Buffer Index. This field provides the index of the message buffer header field of the physical message buffer that is currently associated with this message buffer. The application writes the index of the initially associated message buffer header field into this register. The CC updates this register after frame reception or transmission. Legal Values are 0 <= i <= 131 . Illegal values will be detected during the message buffer search.

47.7.118 Message Buffer Data Field Offset Register (FR_MBDOR*n*)

NOTE

After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

Write: POC:config

Address: 0h base + 1000h offset + (2d × i), where i=0d to 131d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	MBDO															
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

FR_MBDOR*n* field descriptions

Field	Description
0–15 MBDO	Message Buffer Data Field Offset. This field provides the data field offset belonging to a particular Message Buffer Index. For configuration constraints see Configure Data Field Offsets .

47.7.119 LRAM ECC Error Test Register (FR_LEETR*n*)

NOTE

After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

Address: 0h base + 1108h offset + (2d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	LEETD															
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

FR_LEETR*n* field descriptions

Field	Description
0–15 LEETD	LRAM ECC Error Test Data. This field contains the LRAM data belonging to the test register located in LRAM Bank n.

47.8 Functional Description

This section provides a detailed description of the functionality implemented in the CC.

47.8.1 Message Buffer Concept

The CC uses a data structure called a *message buffer* to store frame data, configuration, control, and status data. Each message buffer consists of two parts, the *message buffer control data* and the *physical message buffer*. The message buffer control data are located in dedicated registers. The structure of the message buffer control data depends on the message buffer type and is described in the Message Buffer Types section. The physical message buffer is located in the FlexRay memory area and is described in the next section.

47.8.2 Physical Message Buffer

All FlexRay messages and related frame and slot status information of received frames and of frames to be transmitted to the FlexRay bus are stored in data structures called *physical message buffers*. The physical message buffers are located in the FlexRay memory area.The structure of a physical message buffer is depicted in the figure below.

A physical message buffer consists of two fields, the *message buffer header field* and the *message buffer data field*. The message buffer header field contains the *frame header* and the *slot status*. The message buffer data field contains the *frame data*.

The connection between the two fields is established by the *data field offset*.

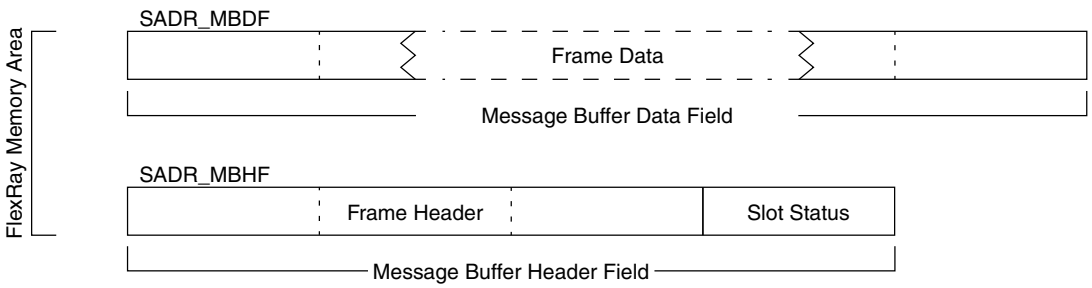

Figure 47-2. Physical Message Buffer Structure

47.8.2.1 Message Buffer Header Field

The message buffer header field is a contiguous region in the FlexRay memory area and occupies eight bytes. It contains the frame header, and the slot status. Its structure is shown in the above figure. The physical start address *SADR_MBHF* of the message buffer header field must be 16-bit aligned.

47.8.2.1.1 Frame Header

The frame header occupies the first six bytes in the message buffer header field. It contains all FlexRay frame header related information according to the *FlexRay Communications System Protocol Specification, Version*2.1 Rev A. A detailed description of the usage and the content of the frame header is provided in Frame Header Description section.

47.8.2.1.2 Slot Status

The slot status occupies the last two bytes of the message buffer header field. It provides the slot and frame status related information according to the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*. A detailed description of the content and usage of the slot status is provided in the Slot Status Description section.

47.8.2.2 Message Buffer Data Field

The message buffer data field is a contiguous area of 2-byte entities. This field contains the frame payload data, or a part of it, of the frame to be transmitted to or received from the FlexRay bus. The minimum length of this field depends on the specific message buffer configuration and is specified in the message buffer descriptions given in the following section.

47.8.3 Message Buffer Types

The CC provides three different types of message buffers.

- *Individual Message Buffers*
- *Receive Shadow Buffers*
- *Receive FIFO Buffers*

For each message buffer type the structure of the physical message buffer is identical. The message buffer types differ only in the structure and content of message buffer control data, which control the related physical message buffer. The message buffer control data are described in the following sections.

47.8.3.1 Individual Message Buffers

The individual message buffers are used for all types of frame transmission and for dedicated frame reception based on individual filter settings for each message buffer. The CC supports three types of individual message buffers, which are described in the Individual Message Buffer Functional Description section.

Each individual message buffer consists of two parts, the physical message buffer, which is located in the FlexRay memory area, and the message buffer control data, which are located in dedicated registers. The structure of an individual message buffer is given in the figure below.

Each individual message buffer has a message buffer number n assigned, which determines the set of message buffer control registers associated to this individual message buffer. The individual message buffer with message buffer number *n* is controlled by the registers FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, and FR_MBIDXRn.

The connection between the message buffer control registers and the physical message buffer is established by the message buffer index field MBIDX in the Message Buffer Index Registers (FR_MBIDXRn). The start address SADR_MBHF of the related message buffer header field in the FlexRay memory area is determined according to this equation:

$$SADR_MBHF = (FR_MBIDXRn[MBIDX] \times 8) + SMBA$$

Equation 9

The data field belonging to a particular physical message buffer is characterized by the data field offset. For each physical message buffer with MBIDX i the FR_MBDORi contains the offset of the corresponding message buffer data field with respect to the CC FlexRay memory area base address as provided by SMBA field in the System Memory Base Address Register (FR_SYMBADR).

The data field offset is used to determine the start address SADR_MBDF of the corresponding message buffer data field in the FlexRay memory area according to this equation:

$$SADR_MBDF = [DataFieldOffset] + SMBA$$

Equation 10

The FR_MBDORn are stored in the module internal memory LRAM. Refer to CHI LRAM Initialization for the setup of the data field offset values.

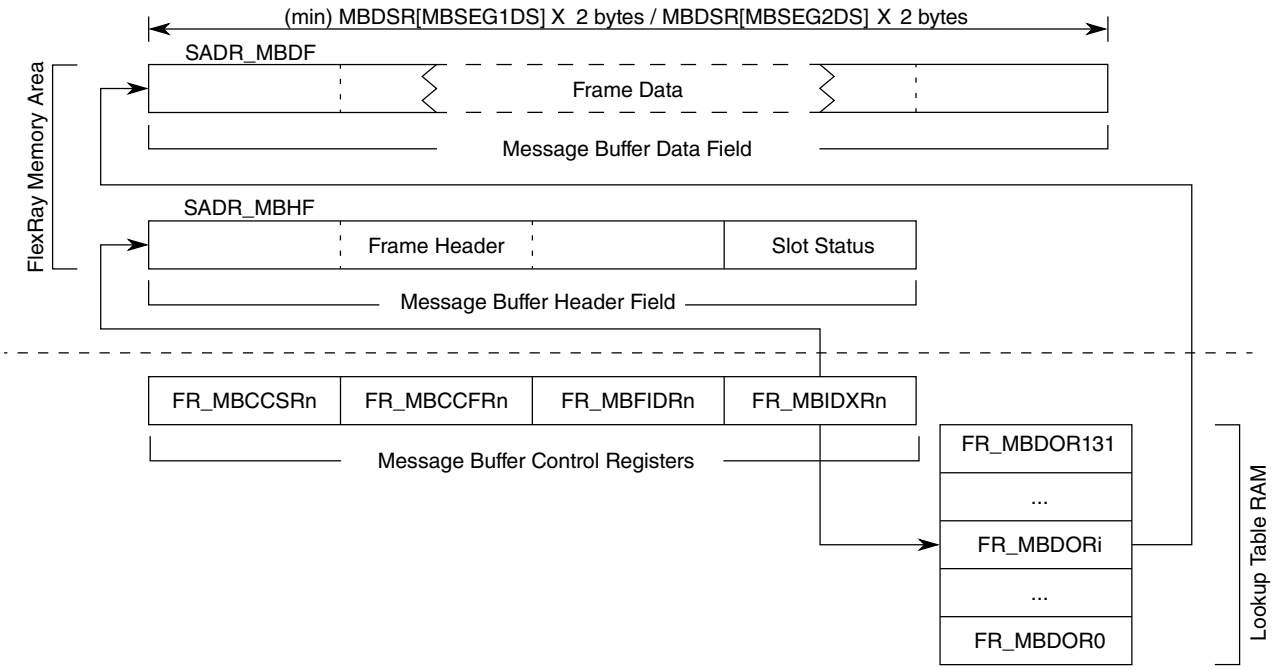

Figure 47-3. Individual Message Buffer Structure

47.8.3.1.1 Individual Message Buffer Segments

The set of the individual message buffers can be split up into two message buffer segments using the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR). All individual message buffers with a message buffer number n ≤ FR_MBSSUTR[LAST_MB_SEG1] belong to the first message buffer segment. All individual message buffers with a message buffer number n > FR_MBSSUTR[LAST_MB_SEG1] belong to the second message buffer segment. The following rules apply to the length of the message buffer data field:

- *all physical message buffers associated to individual message buffers that belong to the same message buffer segment must have message buffer data fields of the same length*
- *the minimum length of the message buffer data field for individual message buffers in the first message buffer segment is 2 × FR_MBDSR[MBSEG1DS] bytes*
- *the minimum length of the message buffer data field for individual message buffers assigned to the second segment is 2 × FR_MBDSR[MBSEG2DS] bytes.*

47.8.3.2 Receive Shadow Buffers

The receive shadow buffers are required for the frame reception process for individual message buffers. The CC provides four receive shadow buffers, one receive shadow buffer per channel and per message buffer segment.

Each receive shadow buffer consists of two parts, the physical message buffer located in the FlexRay memory area and the receive shadow buffer control registers located in dedicated registers. The structure of a receive shadow buffer is shown in the figure below. The four internal shadow buffer control registers can be accessed by the Receive Shadow Buffer Index Register (FR_RSBIR).

The connection between the receive shadow buffer control register and the physical message buffer for the selected receive shadow buffer is established by the receive shadow buffer index field RSBIDX in the Receive Shadow Buffer Index Register (FR_RSBIR). The start address SADR_MBHF of the related message buffer header field in the FlexRay memory area is determined according to this equation:

$$SADR_MBHF = (FR_RSBIR[RSBIDX] \times 8) + SMBA$$

Equation 11

The length required for the message buffer data field depends on the message buffer segment that the receive shadow buffer is assigned to. For the receive shadow buffers assigned to the first message buffer segment, the length must be the same as for the individual message buffers assigned to the first message buffer segment. For the receive shadow buffers assigned to the second message buffer segment, the length must be the same as for the individual message buffers assigned to the second message buffer segment. The receive shadow buffer assignment is described in Receive Shadow Buffer Index Register (FR_RSBIR).

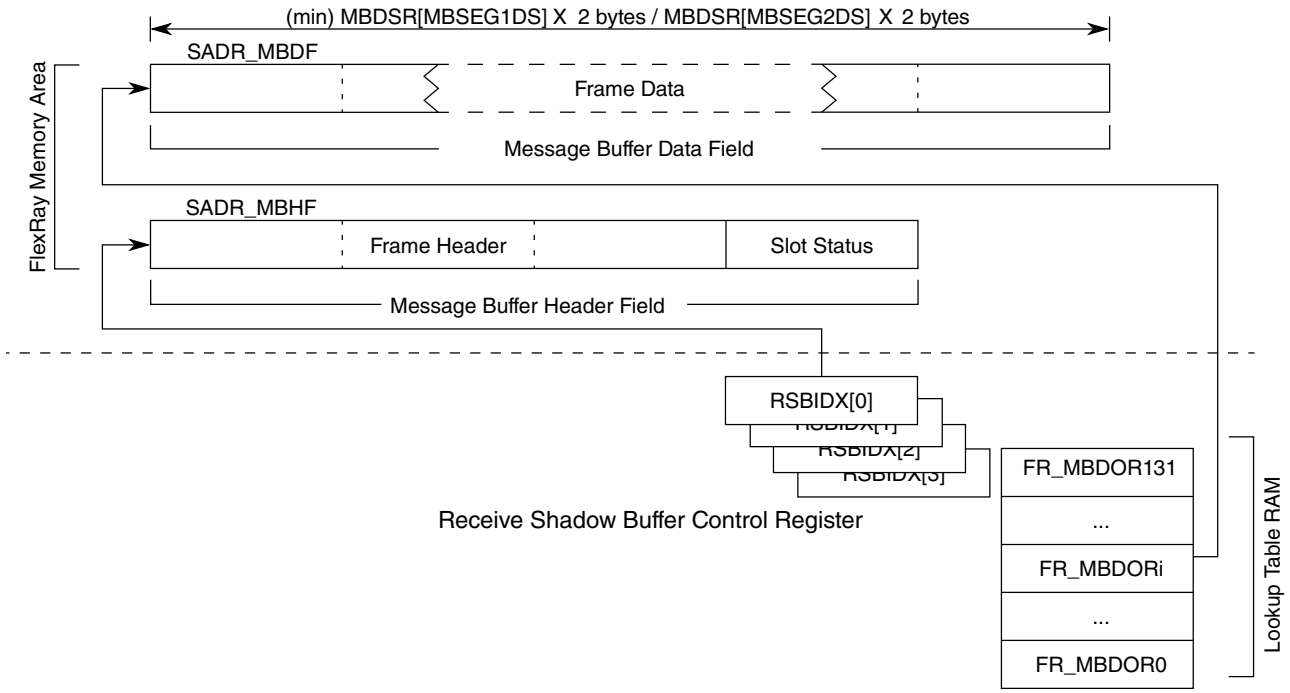

Figure 47-4. Receive Shadow Buffer Structure

47.8.3.3 Receive FIFO

The receive FIFO implements a frame reception system based on the FIFO concept. The CC provides two independent receive FIFOs, one per channel.

A receive FIFO consists of a set of physical message buffers in the FlexRay memory area and a set of receive FIFO control registers located in dedicated registers. The structure of a receive FIFO is given in the Receive FIFO Structure figure, later in this section.

The connection between the receive FIFO control registers and the set of physical message buffers is established by the Receive FIFO Start Index Register (FR_RFSIR), the Receive FIFO Depth and Size Register (FR_RFDSR), and the Receive FIFO A Read Index Register (FR_RFARIR) / Receive FIFO B Read Index Register (FR_RFBRIR).

The system memory base address SMBA valid for the receive FIFOs is defined by the system memory base address register selected by the FIFO address mode bit FR_MCR[FAM] in the Module Configuration Register.

The start byte address SADR_MBHF[1] of the first message buffer header field that belongs to the receive FIFO is determined according to Equation 12 on page 1984.

$$SADR_MBHF[1] = (8 \times FR_RFSIR[SIDX]) + SMBA$$

Equation 12

The start byte address SADR_MBHF[n] of the last message buffer header field that belongs to the receive FIFO in the FlexRay memory area is determined according Equation 13 on page 1985 .

$$SADR_MBHF[n] = (8 \times (FR_RFSIR[SIDX] + FR_RFDSR[FIFO_DEPTH])) + SMBA$$

Equation 13

The required information to access the current entry of the FIFO is given in the following registers:

- *The registers Receive FIFO A Read Index Register (FR_RFARIR) and Receive FIFO B Read Index Register (FR_RFBRIR) provide the index of the physical message buffer belonging to the current entry.*

  The data field offset belonging to the current FIFO entry RF_DFO[X] must be calculated using the current read index i according to the following formula:

$$RF_DFO[X] = FR_RFSDOR[X] + (FR_RFDSR[X][ENTRY_SIZE] \times 2) \times i - FR_RFSIDX[X])$$

Equation 14

Note

The current read index loops up starting at the number given in the FR_RD[A/B]RDIDX register for the required number of entries.

Refer to FIFO Update for details about updating the FIFO read pointer.

All message buffer header fields assigned to a receive FIFO are within a contiguous region defined by FR_RFSIR[SIDX] and FR_RFDSR[FIFO_DEPTH].

The data sections of all FIFO entries within on receive FIFO are of the same length defined by FR_RFDSR[FIFO_SIZE].

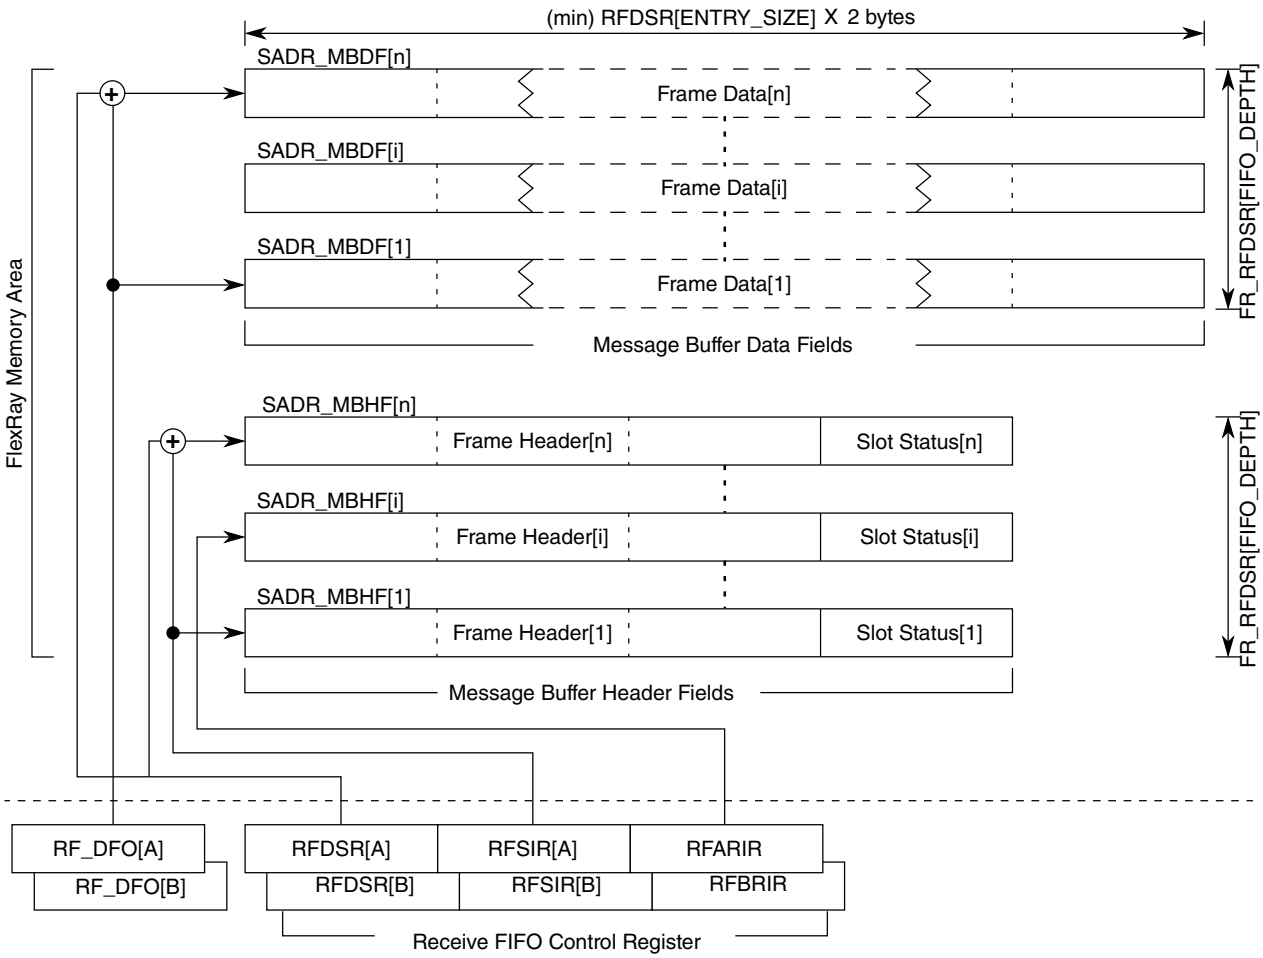

Figure 47-5. Receive FIFO Structure

Note

The actual values of the data field offsets RF_DFO[A/B] need to be calculated according to Equation 14 on page 1985. They are not stored in a register.

47.8.3.4 Message Buffer Configuration and Control Data

This section describes the configuration and control data for each message buffer type.

47.8.3.4.1 Individual Message Buffer Configuration Data

Before an individual message buffer can be used for transmission or reception, it must be configured. There is a set of common configuration parameters that applies to all individual message buffers and a set of configuration parameters that applies to each message buffer individually.

47.8.3.4.1.1 Common Configuration Data

The set of common configuration data for individual message buffers is located in the following registers.

- *Message Buffer Data Size Register (FR_MBDSR)*

  The MBSEG2DS and MBSEG1DS fields define the minimum length of the message buffer data field with respect to the message buffer segment.

- *Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)*

  The LAST_MB_SEG1 and LAST_MB_UTIL fields define the segmentation of the individual message buffers and the number of individual message buffers that are used. For more details, see Individual Message Buffer Segments.

47.8.3.4.1.2 Specific Configuration Data

The set of message buffer specific configuration data for individual message buffers is located in the following registers.

- *Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn)*

  The MTD bit configures the message buffer type.

- *Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn)*

  The MTM, CHA, CHB bits configure the transmission mode and the channel assignment. The CCFE, CCFMSK, and CCFVAL bits and fields configure the cycle counter filter.

- *Message Buffer Frame ID Registers (FR_MBFIDRn)*

  For a transmit message buffer, the FID field is used to determine the slot in which the message in this message buffer will be transmitted.

- *Message Buffer Index Registers (FR_MBIDXRn)This MBIDX field provides the index of the message buffer header field of the physical message buffer that is currently associated with this message buffer.*

47.8.3.5 Individual Message Buffer Control Data

During normal operation, each individual message buffer can be controlled by the control and trigger bits CMT, LCKT, EDT, and MBIE in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn).

47.8.3.6 Receive Shadow Buffer Configuration Data

Before frame reception into the individual message buffers can be performed, the receive shadow buffers must be configured. The configuration data are provided by the Receive Shadow Buffer Index Register (FR_RSBIR). For each receive shadow buffer, the application provides the message buffer header index. When the protocol is in the *POC:normal active* or *POC:normal passive* state, the receive shadow buffers are under full CC control.

47.8.3.7 Receive FIFO Control and Configuration Data

This section describes the configuration and control data for the two receive FIFOs.

47.8.3.7.1 Receive FIFO Configuration Data

The CC provides two functional independent receive FIFOs, one per channel. The FIFOs have a common subset of configuration data:

- *Receive FIFO Periodic Timer Register (FR_RFPTR)*

Each FIFO has its own set of configuration data. The configuration data are located in the following registers:

- *Receive FIFO Watermark and Selection Register (FR_RFWMSR)*
- *Receive FIFO Start Index Register (FR_RFSIR)*
- *Receive FIFO Start Data Offset Register (FR_RFSDOR)*
- *Receive FIFO Depth and Size Register (FR_RFDSR)*
- *Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR)*
- *Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR)*
- *Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR)*

- *Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR)*
- *Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)*

47.8.3.7.2 Receive FIFO Control Data

The application can access the FIFOs at any time using the control bits in the following registers:

- *Global Interrupt Flag and Enable Register (FR_GIFER)*
- *Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)*

47.8.3.7.3 Receive FIFO Status Data

The current status of the receive fifo is provided in the following register:

- *Global Interrupt Flag and Enable Register (FR_GIFER)*
- *Receive FIFO A Read Index Register (FR_RFARIR)*
- *Receive FIFO B Read Index Register (FR_RFBRIR)*
- *Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)*

47.8.4 FlexRay Memory Area Layout

The CC supports a wide range of possible layouts for the FlexRay memory area. Two basic layout modes can be selected by the FIFO address mode bit FR_MCR[FAM].

47.8.4.1 FlexRay Memory Area Layout (FR_MCR[FAM] = 0)

In the figure given below, shows an example layout for the FIFO address mode FR_MCR[FAM]=0. In this mode, the following set of rules applies to the layout of the FlexRay memory area:

- The FlexRay memory area is one contiguous region.
- The FlexRay memory area size is maximum 64 KB.
- The FlexRay memory area starts at a 16 byte boundary

The FlexRay memory area contains three areas: the *message buffer header area*, the *message buffer data area*, and the *sync frame table area*.

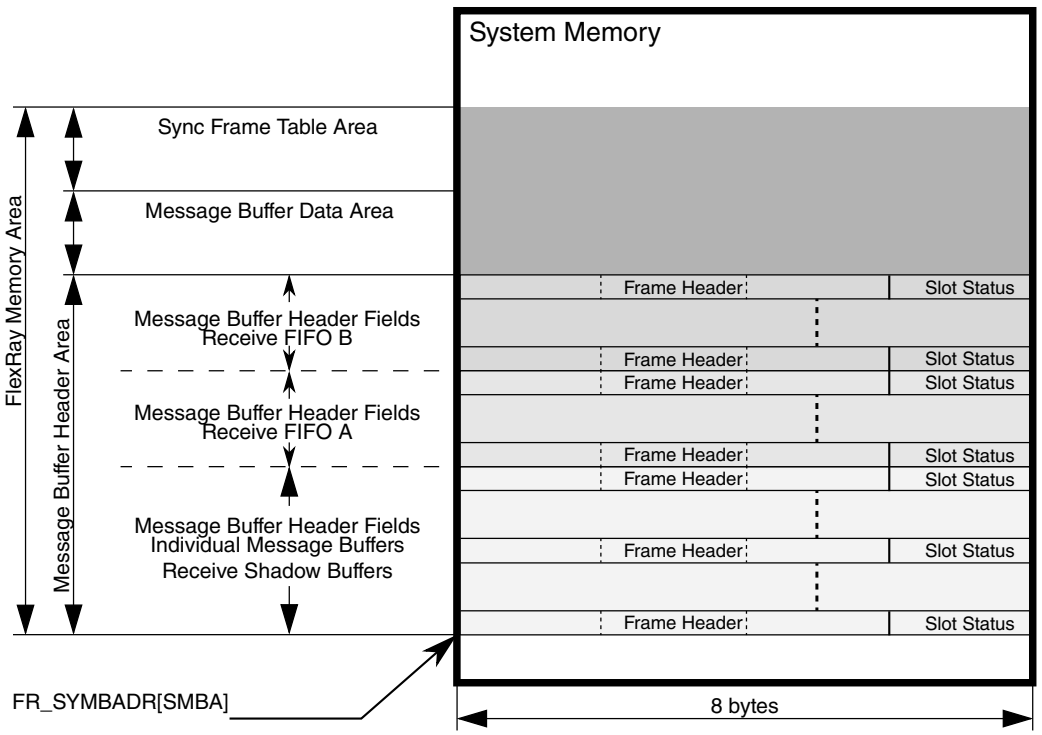

Figure 47-6. Example of FlexRay Memory Area Layout (FR_MCR[FAM] = 0)

47.8.4.2 FlexRay Memory Area Layout (FR_MCR[FAM] = 1)

The following figure shows an example layout for the FIFO address mode FR_MCR[FAM]=1. The following set of rules applies to the layout of the FlexRay memory area:

- The FlexRay memory area consists of two contiguous regions.
- The size of each region is maximum 64 KB.
- Each region start at a 16 byte boundary.

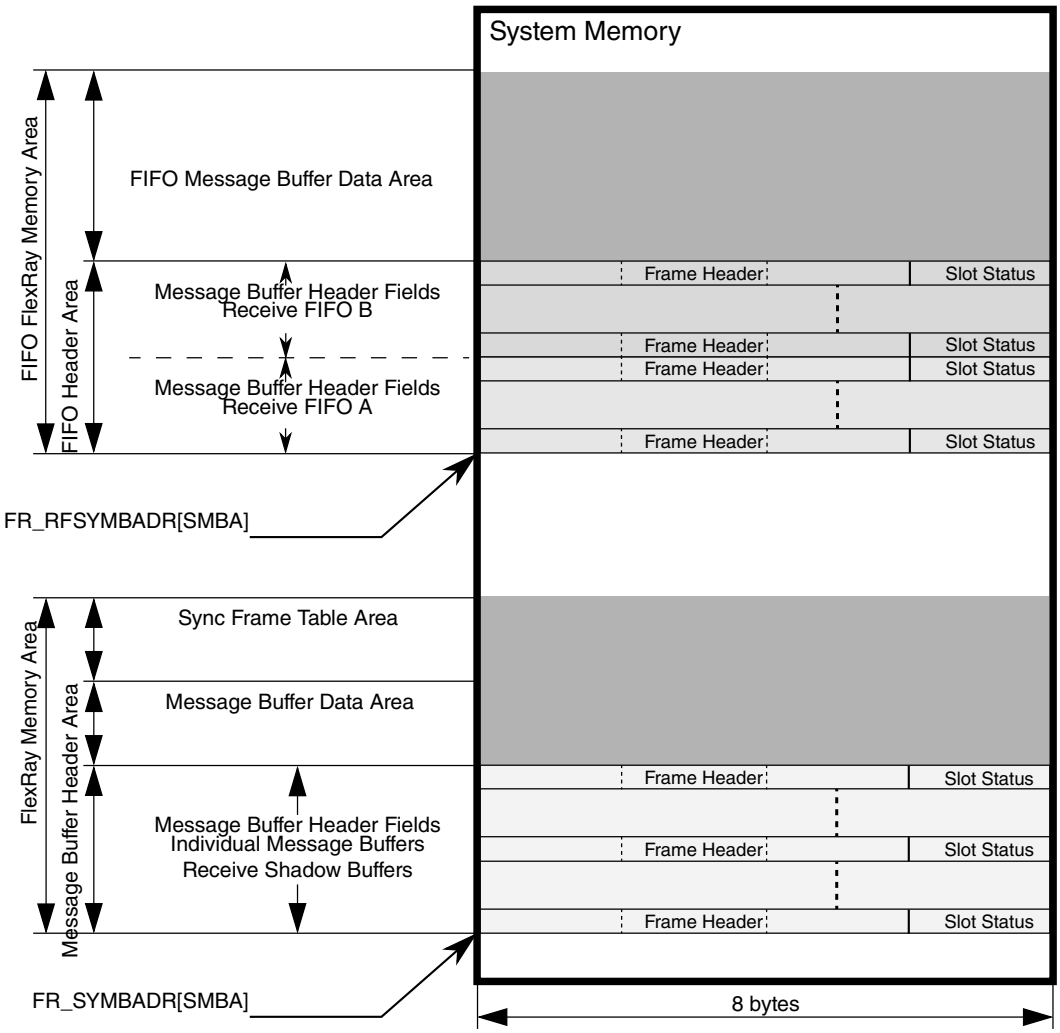

Figure 47-7. Example of FlexRay Memory Area Layout (FR_MCR[FAM] = 1)

47.8.4.3 Message Buffer Header Area (FR_MCR[FAM] = 0)

The message buffer header area contains all message buffer header fields of the physical message buffers for all message buffer types. The following rules apply to the message buffer header fields for the three type of message buffers.

1. The start byte address SADR_MBHF of each message buffer header field for *individual message buffers* and *receive shadow buffers* must fulfill Equation 15 on page 1991.

$$SADR_MBHF = (i \times 8) + FR_SYMBADR[SMBA]; (0 \le i \le 131)$$

Equation 15

2. The start byte address SADR_MBHF of each message buffer header field for the *FIFO* must fulfill Equation 15 on page 1991.

$$SADR_MBHF = (i \times 8) + FR_SYMBADR[SMBA]; (0 \le i \le 1023)$$

Equation 16

$$SADR_MBHF = (i \times 8) + FR_SYMBADR[SMBA]; (0 \le i \le 1023)$$

Equation 17

3. The message buffer header fields for each FIFO have to be a contiguous area.

47.8.4.4 Message Buffer Header Area (FR_MCR[FAM] = 1)

The message buffer header area contains all message buffer header fields of the physical message buffers for the individual message buffers and receiver shadow buffers. The following rules apply to the message buffer header fields for the two type of message buffers.

1. The start address SADR_MBHF of each message buffer header field for individual message buffers and receive shadow buffers must fulfill Equation 18 on page 1992.

$$SADR_MBHF = (i \times 8) + FR_SYMBADR[SMBA]; (0 \le i \le 131)$$

Equation 18

47.8.4.5 FIFO Message Buffer Header Area (FR_MCR[FAM] = 1)

The FIFO message buffer header area contains all message buffer header fields of the physical message buffers for the FIFO. The following rules apply to the FIFO message buffer header fields.

1. The start byte address SADR_MBHF of each message buffer header field for the FIFO must fulfill the following equation:Equation 19 on page 1992.

$$SADR_MBHF = (i\gamma 8) + FR_RFSYMBADR[SMBA]; (0 \le i \le 1023)$$

Equation 19

2. The message buffer header fields for each FIFO have to be a contiguous area.

47.8.4.6 Message Buffer Data Area

The message buffer data area contains all the message buffer data fields of the physical message buffers. Each message buffer data field must start at a 16-bit boundary.

47.8.4.7 Sync Frame Table Area

The sync frame table area is used to provide a copy of the internal sync frame tables for application access. Refer to Sync Frame ID and Sync Frame Deviation Tables for the description of the sync frame table area.

47.8.5 Physical Message Buffer Description

This section provides a detailed description of the usage and the content of the two parts of a physical message buffer, the message buffer header field and the message buffer data field.

47.8.5.1 Message Buffer Protection and Data Consistency

The physical message buffers are located in the FlexRay memory area. The CC provides no means to protect the FlexRay memory area from uncontrolled or illegal host or other client write access. To ensure data consistency of the physical message buffers, the application must follow the write access scheme that is given in the description of each of the physical message buffer fields.

47.8.5.2 Message Buffer Header Field Description

This section provides a detailed description of the usage and content of the message buffer header field. A description of the structure of the message buffer header fields is given in Message Buffer Header Field. Each message buffer header field consists of two sections: the frame header section and the slot status section.

47.8.5.2.1 Frame Header Description

Frame header content, access, and checks are discussed in this section.

47.8.5.2.1.1 Frame Header Content

The semantic and content of the frame header section depends on the message buffer type.

For individual receive message buffers and receive FIFOs, the frame header receives the frame header data of the *first valid frame* received on the assigned channels.

For receive shadow buffers, the frame header receives the frame header data of the current frame received regardless of whether the frame is valid or not.

For transmit message buffers, the application writes the frame header of the frame to be transmitted into this location. The frame header will be read out when the frame is transferred to the FlexRay bus.

The structure of the frame header in the message buffer header field for receive message buffers and the receive FIFO is given in the figure below. A detailed description is given in Table 47-22.

Table 47-18. Frame Header Structure (Receive Message Buffer and Receive FIFO)

0x0	R	PPI	NUF	SYF	SUF	FID		
0x2	0	0	CYCCNT			0	PLDLEN	
0x4	0	0	0	0	0	HDCRC		

The structure of the frame header in the message buffer header field for transmit message buffers is given in the following figure. A detailed description is given in Table 47-23. The checks that will be performed are described in Frame Header Checks.

Table 47-19. Frame Header Structure (Transmit Message Buffer)

0x0	R	PPI	NUF	SYF	SUF	FID [1]		
0x2			CYCCNT				PLDLEN [2]	
0x4						HDCRC		

= not used

1. checked
2. checked if not static

The structure of the frame header in the message buffer header field for transmit message buffers assigned to key slot is given in the figure below.

Table 47-20. Frame Header Structure (Transmit Message Buffer for Key Slot)

0x0	R	PPI	NUF	SYF	SUF	FID		
0x2			CYCCNT				PLDLEN	
0x4						HDCRC		

= not used

47.8.5.2.1.2 Frame Header Access

The frame header is located in the FlexRay memory area. To ensure data consistency, the application must follow the write access scheme described below.

For receive message buffers, receive shadow buffers, and receive FIFOs, the application must not write to the frame header field.

For transmit message buffers, the application must follow the write access restrictions given in the following table. This table shows the condition under which the application can write to the frame header entries without corrupting the FlexRay message transmission.

Table 47-21. Frame Header Write Access Constraints (Transmit Message Buffer)

Field	Static Segment	Dynamic Segment
FID	*POC:config* or MB_DIS	
PPI, PLDLEN, HDCRC	*POC:config* or MB_DIS or	MB_LCK

47.8.5.2.1.3 Frame Header Checks

As shown in Table 47-19 and Table 47-20 not all fields in the message buffer frame header are used for transmission. Some fields in the message buffer frame header are ignored, some are used for transmission, and some of them are checked for correct values. All checks that will be performed are described below.

For message buffers assigned to the key slot, no checks will be performed.

The value of the FID field must be equal to the value of the corresponding Message Buffer Frame ID Registers (FR_MBFIDRn). If the CC detects a mismatch while transmitting the frame header, it will set the frame ID error flag FID_EF in the CHI Error Flag Register (FR_CHIERFR). The value of the FID field will be ignored and replaced by the value provided in the Message Buffer Frame ID Registers (FR_MBFIDRn).

For transmit message buffers assigned to the *static* segment, the PLDLEN value must be equal to the value of the payload_length_static field in the Protocol Configuration Register 19 (FR_PCR19). If this is not fulfilled, the static payload length error flag SPL_EF in the CHI Error Flag Register (FR_CHIERFR) is set when the message buffer is under transmission. A syntactically and semantically correct frame is generated with payload_length_static payload words and the payload length field in the transmitted frame header set to payload_length_static.

For transmit message buffers assigned to the *dynamic* segment, the PLDLEN value must be less than or equal to the value of the max_payload_length_dynamic field in the Protocol Configuration Register 24 (FR_PCR24). If this is not fulfilled, the dynamic payload length error flag DPL_EF in the CHI Error Flag Register (FR_CHIERFR) is set

when the message buffer is under transmission. A syntactically and semantically correct dynamic frame is generated with PLDLEN payload words and the payload length field in the frame header set to PLDLEN.

Table 47-22. Frame Header Field Descriptions (Receive Message Buffer and Receive FFO)

Field	Description
R	**Reserved Bit** — This is the value of the *Reserved bit* of the received frame stored in the message buffer
PPI	**Payload Preamble Indicator** — This is the value of the *Payload Preamble Indicator* of the received frame stored in the message buffer.
NUF	**Null Frame Indicator** — This is the value of the *Null Frame Indicator* of the received frame stored in the message buffer.
SYF	**Sync Frame Indicator** — This is the value of the *Sync Frame Indicator* of the received frame stored in the message buffer.
SUF	**Startup Frame Indicator** — This is the value of the *Startup Frame Indicator* of the received frame stored in the message buffer.
FID	**Frame ID** — This is the value of the *Frame ID* field of the received frame stored in the message buffer.
CYCCNT	**Cycle Count** — This is the number of the communication cycle in which the frame stored in the message buffer was received.
PLDLEN	**Payload Length** — This is the value of the *Payload Length* field of the received frame stored in the message buffer.
HDCRC	**Header CRC** — This is the value of the *Header CRC* field of the received frame stored in the message buffer.

Table 47-23. Frame Header Field Descriptions (Transmit Message Buffer)

Field	Description
R	**Reserved Bit** — This bit is not used, the value of the *Reserved bit* is generated internally according to *FlexRay Communications System Protocol Specification, Version*2.1 Rev A.
PPI	**Payload Preamble Indicator** — This bit provides the value of the *Payload Preamble Indicator* for the frame transmitted from the message buffer.
NUF	**Null Frame Indicator** — This bit is not used, the value of the *Null Frame Indicator* is generated internally according to *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.
SYF	**Sync Frame Indicator** — This bit is not used, the value of the *Sync Frame Indicator* is generated internally according to *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.
SUF	**Startup Frame Indicator** — This bit is not used, the value of the *Startup Frame Indicator* is generated internally according to *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.
FID	**Frame ID** — This field is checked as described in Frame Header Checks.
CYCCNT	**Cycle Count** — This field is not used, the value of the transmitted *Cycle Count* field is taken from the internal communication cycle counter.
PLDLEN	**Payload Length** — This field is checked and used as described in Frame Header Checks.
HDCRC	**Header CRC** — This field provides the value of the *Header CRC* field for the frame transmitted from the message buffer.

47.8.5.2.2 Slot Status Description

The slot status is a read-only structure for the application and a write-only structure for the CC. The meaning and content of the slot status in the message buffer header field depends on the message buffer type.

47.8.5.2.2.1 Receive Message Buffer and Receive FIFO Slot Status Description

This section describes the slot status structure for the individual receive message buffers and receive FIFOs. The content of the slot status structure for receive message buffers depends on the message buffer type and on the channel assignment for individual receive message buffers as given in the next table.

Table 47-24. Receive Message Buffer Slot Status Content

Receive Message Buffer Type	Slot Status Content
Individual Receive Message Buffer assigned to both channels FR_MBCCFRn[CHA]=1 and FR_MBCCFRn[CHB]=1	see Table 47-25
Individual Receive Message Buffer assigned to channel A FR_MBCCFRn[CHA]=1 and FR_MBCCFRn[CHB]=0	see Table 47-26
Individual Receive Message Buffer assigned to channel B FR_MBCCFRn[CHA]=0 and FR_MBCCFRn[CHB]=1	see Table 47-27
Receive FIFO Channel A Message Buffer	see Table 47-26
Receive FIFO Channel B Message Buffer	see Table 47-27

The meaning of the bits in the slot status structure is explained in the Receive Message Buffer Slot Status Field Description table below.

Table 47-25. Receive Message Buffer Slot Status Structure (ChAB)

47.8.5.2.2.2 Transmit Message Buffer Slot Status Description

This section describes the slot status structure for transmit message buffers. Only the TCA and TCB status bits are directly related to the transmission process. All other status bits in this structure are related to a receive process that may have occurred. The content of the slot status structure for transmit message buffers depends on the channel assignment as given in the table below.

Table 47-29. Transmit Message Buffer Slot Status Content

Transmit Message Buffer Type	Slot Status Content
Individual Transmit Message Buffer assigned to both channels FR_MBCCFRn[CHA]=1 and FR_MBCCFRn[CHB]=1	see Table 47-30
Individual Transmit Message Buffer assigned to channel A FR_MBCCFRn[CHA]=1 and FR_MBCCFRn[CHB]=0	see Table 47-31
Individual Transmit Message Buffer assigned to channel B FR_MBCCFRn[CHA]=0 and FR_MBCCFRn[CHB]=1	see Table 47-32

The meaning of the bits in the slot status structure is described in the Transmit Message Buffer Slot Status Structure Field Descriptions table.

47.8.5.3 Message Buffer Data Field Description

The message buffer data field is used to store the frame payload data, or a part of it, of the frame to be transmitted to or received from the FlexRay bus. The minimum required length of this field depends on the message buffer type that the physical message buffer is assigned to and is given in the table below. The structure of the message buffer data field is given in the next figure.

Table 47-34. Message Buffer Data Field Minimum Length

physical message buffer assigned to	minimum length defined by
Individual Message Buffer in Segment 1	FR_MBDSR[MBSEG1DS]

Table continues on the next page...

Table 47-34. Message Buffer Data Field Minimum Length (continued)

physical message buffer assigned to	minimum length defined by
Receive Shadow Buffer in Segment 1	FR_MBDSR[MBSEG1DS]
Individual Message Buffer in Segment 2	FR_MBDSR[MBSEG2DS]
Receive Shadow Buffer in Segment 2	FR_MBDSR[MBSEG2DS]
Receive FIFO for channel A	FR_RFDSR[ENTRY_SIZE] (FR_RFWMSR[SEL] = 0)
Receive FIFO for channel B	FR_RFDSR[ENTRY_SIZE] (FR_RFWMSR[SEL] = 1)

Note

The CC will not access any locations outside the message buffer data field boundaries given in the table above.

Table 47-35. Message Buffer Data Field Structure

0x0	DATA0 / MID0 / NMV0	DATA1 / MID1 / NMV1
0x2	DATA2 / NMV2	DATA3 / NMV3
…	…	…
0xN-2	DATA N-2	DATA N-1

The message buffer data field is located in the FlexRay memory area; thus, the CC has no means to control application write access to the field. To ensure data consistency, the application must follow a write and read access scheme.

47.8.5.3.1 Message Buffer Data Field Read Access

For transmit message buffers, the CC will not modify the content of the Message Buffer Data Field. Thus the application can read back the data at any time without any impact on data consistency.

For receive message buffers the application must lock the related receive message buffer and retrieve the message buffer header index from the Message Buffer Index Registers (FR_MBIDXRn). While the message buffer is locked, the CC will not update the Message Buffer Data Field.

For receive FIFOs, the application can read the message buffer indicated by the Receive FIFO A Read Index Register (FR_RFARIR) or the Receive FIFO B Read Index Register (FR_RFBRIR) when the related fill levels in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) indicate an non-empty FIFO.

47.8.5.3.2 Message Buffer Data Field Write Access

For receive message buffers, receive shadow buffers, and receive FIFOs, the application must not write to the message buffer data field.

For transmit message buffers, the application must follow the write access restrictions given in the Frame Data Write Access Constraints table below.

Table 47-36. Frame Data Write Access Constraints

Field	CC/MB State
DATA, MID, NMV	*POC:config* or MB_DIS or MB_LCK

Table 47-37. Frame Data Field Descriptions

Field	Description
DATA 0, DATA 1, … DATA N-1	**Message Data** — Provides the message data received or to be transmitted.For receive message buffer and receive FIFOs, this field provides the message data received for this message buffer. For transmit message buffers, the field provides the message data to be transmitted.
MID 0, MID 1	**Message Identifier** — If the payload preamble bit PPI is set in the message buffer frame header, the MID field holds the message ID of a dynamic frame located in the message buffer. The receive FIFO filter uses the received message ID for message ID filtering.
NMV 0, NMV 1, … NMV 11	**Network Management Vector** — If the payload preamble bit PPI is set in the message buffer frame header, the network management vector field holds the network management vector of a static frame located in the message buffer. **Note:** The MID and NMV bytes replace the corresponding DATA bytes.

47.8.6 Individual Message Buffer Functional Description

The CC provides these basic types of individual message buffers:

1. Transmit Message Buffers
2. Receive Message Buffers

Before an individual message buffer can be used, it must be configured by the application. After the initial configuration, the message buffer can be reconfigured later. The set of the configuration data for individual message buffers is given in Individual Message Buffer Configuration Data.

47.8.6.1 Individual Message Buffer Configuration

The individual message buffer configuration consists of two steps. The first step is the allocation of the required amount of memory for the FlexRay memory area. The second step is the programming of the message buffer configuration registers, which is described in this section.

47.8.6.1.1 Common Configuration Data

One part of the message buffer configuration data is common to all individual message buffers and the receive shadow buffers. These data can only be set when the protocol is in the *POC:config* state.

The application configures the number of utilized individual message buffers by writing the message buffer number of the last utilized message buffer into the LAST_MB_UTIL field in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).

The application configures the size of the two segments of individual message buffers by writing the message buffer number of the last message buffer in the first segment into the LAST_MB_SEG1 field in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).

The application configures the length of the message buffer data fields for both of the message buffer segments by writing to the MBSEG2DS and MBSEG1DS fields in the Message Buffer Data Size Register (FR_MBDSR).

Depending on the current receive functionality of the CC, the application must configure the receive shadow buffers. For each segment and for each channel with at least one individual receive message buffer assigned, the application must configure the related receive shadow buffer using the Receive Shadow Buffer Index Register (FR_RSBIR).

47.8.6.1.2 Specific Configuration Data

The second part of the message buffer configuration data is specific for each message buffer.

These data can be changed only when either

- *the protocol is in the POC:config state or*
- *the message buffer is disabled, i.e. FR_MBCCSRn[EDS] = 0*

The individual message buffer type is defined by the MTD and MBT bits in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) as given in the following table.

Table 47-38. Individual Message Buffer Types

FR_MBCCSRn		Individual Message Buffer Description
MTD	MBT	
0	0	Receive Message Buffer
0	1	Reserved
1	0	Transmit Message Buffer
1	1	Reserved

The message buffer specific configuration data are

1. MTD bits in Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn)
2. all fields and bits in Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn)
3. all fields and bits in Message Buffer Frame ID Registers (FR_MBFIDRn)
4. all fields and bits in Message Buffer Index Registers (FR_MBIDXRn)

The meaning of the specific configuration data depends on the message buffer type, as given in the detailed message buffer type descriptions in the Transmit Message Buffers section and Receive Message Buffers section.

47.8.6.2 Transmit Message Buffers

The section provides a detailed description of the functionality of single buffered transmit message buffers.

A transmit message buffer is used by the application to provide message data to the CC that will be transmitted over the FlexRay Bus. The CC uses the transmit message buffers to provide information about the transmission process and status information about the slot in which message was transmitted.

The individual message buffer with message buffer number n is configured to be a transmit message buffer by the following settings:

- $FR__MBCCSRn[MBT] = 0(singlebufferedmessagebuffer)$
- $FR_MBCCSRn[MDT] = 1(transmitmessagebuffer)$

47.8.6.2.1 Access Regions

To certain message buffer fields, both the application and the CC have access. To ensure data consistency, a message buffer locking scheme is implemented, which is used to control the access to the data, control, and status bits of a message buffer. The access regions for transmit message buffers are depicted in the figure below. A description of the regions is given in Table 47-40. If an region is active as indicated in Table 47-41, the access scheme given for that region applies to the message buffer.

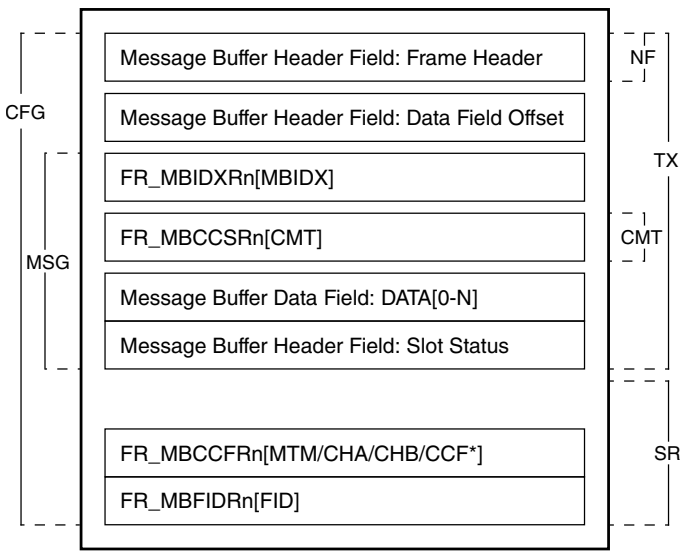

Figure 47-8. Transmit Message Buffer Access Regions

Table 47-39. Transmit Message Buffer Access Regions Description

Region	Access from		Region used for
	Application	Module	
CFG	read/write	-	Message Buffer Configuration
MSG	read/write	-	Message Data and Slot Status Access
NF	-	read-only	Message Header Access for Null Frame Transmission
TX	-	read/write	Message Transmission and Slot Status Update
CM	-	read-only	Message Buffer Validation
SR	-	read-only	Message Buffer Search

The trigger bits FR_MBCCSRn[EDT] and FR_MBCCSRn[LCKT], and the interrupt enable bit FR_MBCCSRn[MBIE] are not under access control and can be accessed from the application at any time. The status bits FR_MBCCSRn[EDS] and FR_MBCCSRn[LCKS] are not under access control and can be accessed from the CC at any time.

The interrupt flag FR_MBCCSRn[MBIF] is not under access control and can be accessed from the application and the CC at any time. CC clear access has higher priority.

The CC restricts its access to the regions depending on the current state of the message buffer. The application must adhere to these restrictions in order to ensure data consistency. The transmit message buffer states are given in the next figure. A description of the states is given in Table 47-40, which also provides the access scheme for the access regions.

The status bits FR_MBCCSRn[EDS] and FR_MBCCSRn[LCKS] provide the application with the required message buffer status information. The internal status information is not visible to the application.

47.8.6.2.2 Message Buffer States

This section describes the transmit message buffer states and provides a state diagram.

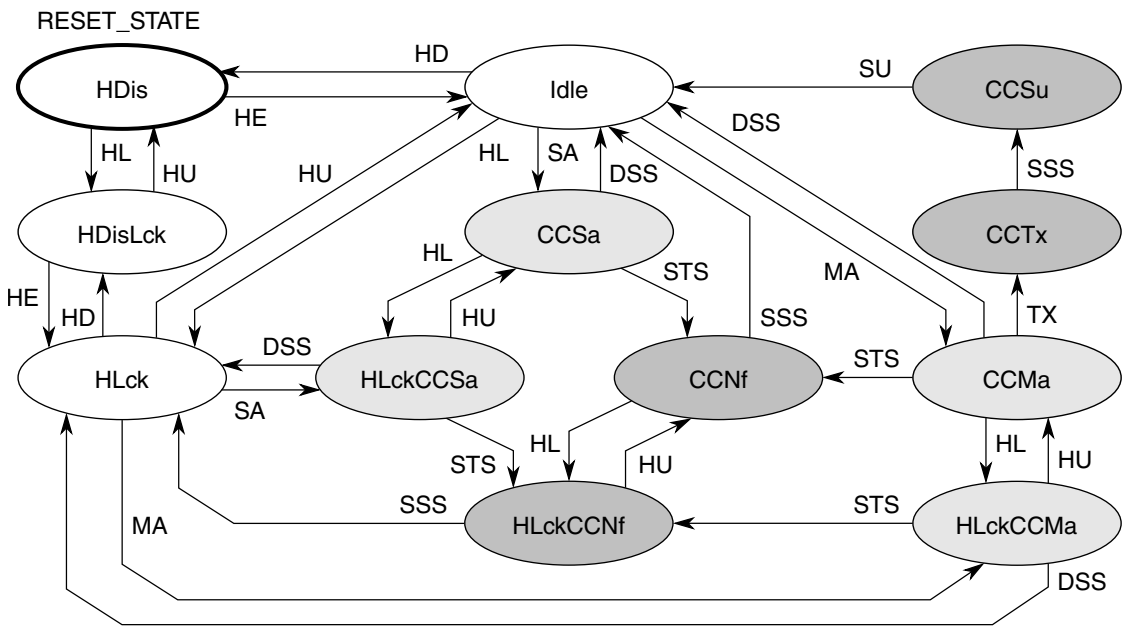

Figure 47-9. Transmit Message Buffer States

Table 47-40. Transmit Message Buffer State Description (Sheet 1 of 2)

State	FR_MBCCSRn		Access Region		Description
	EDS	LCKS	Appl.	Module	
Idle	1	0	–	CM,SR	**Idle** - Message Buffer is idle. Included in message buffer search.
HDis	0	0	CFG	–	**Disabled** - Message Buffer under configuration. Excluded from message buffer search.
HDisLck	0	1	CFG	–	**Disabled and Locked** - Message Buffer under configuration.Excluded from message buffer search.
HLck	1	1	MSG	SR	**Locked** - Applications access to data, control, and status.Included in message buffer search.

Table continues on the next page...

Table 47-40. Transmit Message Buffer State Description (Sheet 1 of 2) (continued)

State	FR_MBCCSRn		Access Region		Description
	EDS	LCKS	Appl.	Module	
CCSa	1	0	–	–	**Slot Assigned** - Message buffer assigned to next static slot.Ready for Null Frame transmission.
HLckCCSa	1	1	MSG	–	**Locked and Slot Assigned** - Applications access to data, control, and status.Message buffer assigned to next static slot
CCNf	1	0	–	NF	**Null Frame Transmission** Header is used for null frame transmission.
HLckCCNf	1	1	MSG	NF	**Locked and Null Frame Transmission** - Applications access to data, control, and status. Header is used for null frame transmission.
CCMa	1	0	–	CM	**Message Available** - Message buffer is assigned to next slot and cycle counter filter matches.
HLckCCMa	1	1	MSG	–	**Locked and Message Available** - Applications access to data, control, and status. Message buffer is assigned to next slot and cycle counter filter matches.
CCTx	1	0	–	TX	**Message Transmission** - Message buffer data transmit. Payload data from buffer transmitted
CCSu	1	0	–	TX	**Status Update** - Message buffer status update. Update of status flags, the slot status field, and the header index.

47.8.6.2.3 Message Buffer Transitions

Application transitions, module transitions, and transition priorities are discussed in this section.

47.8.6.2.3.1 Application Transitions

The application transitions can be triggered by the application using the commands described in the table below. The application issues the commands by writing to the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn). Only one command can be issued with one write access. Each command is executed immediately. If the command is ignored, it must be issued again.

47.8.6.2.3.1.1 Message Buffer Enable and Disable

The enable and disable commands issued by writing 1 to the trigger bit FR_MBCCSRn[EDT]. The transition that will be triggered by each of these command depends on the current value of the status bit FR_MBCCSRn[EDS]. If the command triggers the disable transition HD and the message buffer is in one of the states CCSa,

HLckCCSa, CCMa, HLckCCMa, CCNf, HLckCCNf, or CCTx, the disable transition has no effect (command is ignored) and the message buffer state is not changed. No notification is given to the application.

47.8.6.2.3.1.2 Message Buffer Lock and Unlock

The lock and unlock commands issued by writing 1 to the trigger bit FR_MBCCSRn[LCKT]. The transition that will be triggered by each of these commands depends on the current value of the status bit FR_MBCCSRn[LCKS]. If the command triggers the lock transition HL and the message buffer is in the state CCTx, the lock transition has no effect (command is ignored) and message buffer state is not changed. In this case, the message buffer lock error flag LCK_EF in the CHI Error Flag Register (FR_CHIERFR) is set.

Table 47-41. Transmit Message Buffer Application Transitions

Transition	Command	Condition	Description
HE	FR_MBCCSRn[EDT]:= 1	FR_MBCCSRn[EDS] = 0	Application triggers message buffer enable.
HD		FR_MBCCSRn[EDS] = 1	Application triggers message buffer disable.
HL	FR_MBCCSRn[LCKT]:= 1	FR_MBCCSRn[LCKS] = 0	Application triggers message buffer lock.
HU		FR_MBCCSRn[LCKS] = 1	Application triggers message buffer unlock.

47.8.6.2.3.2 Module Transitions

The module transitions that can be triggered by the CC are described in the following table. Each transition will be triggered for certain message buffers when the related condition is fulfilled.

Table 47-42. Transmit Message Buffer Module Transitions

Transition	Condition	Description
SA	slot match andstatic slot	**Slot Assigned** - Message buffer is assigned to next static slot.
MA	slot match andCycleCounter match	**Message Available** - Message buffer is assigned to next slot and cycle counter filter matches.
TX	slot start and FR_MBCCSRn[CMT] = 1	**Transmission Slot Start** - Slot Start and commit bit CMT is set. In case of a dynamic slot, pLatestTx is not exceeded.
SU	status updated	**Status Updated** - Slot Status field and message buffer status flags updated. Interrupt flag set.
STS	static slot start	**Static Slot Start** - Start of static slot.
DSS	dynamic slot start orsymbol window start orNIT start	**Dynamic Slot or Segment Start.** - Start of dynamic slot or symbol window or NIT.
SSS	slot start orsymbol window start orNIT start	**Slot or Segment Start** - Start of static slot or dynamic slot or symbol window or NIT.

47.8.6.2.3.3 Transition Priorities

The application can trigger only one transition at a time. There is no need to specify priorities among them.

As shown in the first part of the next table, the module transitions have a higher priority than the application transitions. For all states except the CCMa state, both a lock/unlock transition HL/HD and a module transition can be executed at the same time. The result state is reached by first applying the application transition and subsequently the module transition to the intermediately reached state. For example, if the message buffer is in the HLck state and the application unlocks the message buffer by the HU transition and the module triggers the slot assigned transition SA, the intermediate state is Idle and the resulting state is CCSa.

The priorities among the module transitions is given in the second part of the table below.

Table 47-43. Transmit Message Buffer Transition Priorities

State	Priorities	Description
module vs. application		
Idle, HLck	SA > HD	Slot Assigned > Message Buffer Disable
	MA > HD	Message Available > Message Buffer Disable
CCMa	TX > HL	Transmission Start > Message Buffer Lock
module internal		
Idle, HLck	MA > SA	Message Available > Slot Assigned
CCMa	TX > STS	Transmission Slot Start > Static Slot Start
	TX > DSS	Transmission Slot Start > Dynamic Slot Start

47.8.6.2.4 Transmit Message Setup

To transmit a message over the FlexRay bus, the application writes the message data into the message buffer data field and sets the commit bit CMT in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn). The physical access to the message buffer data field is described in Individual Message Buffers.

As indicated by Table 47-33, the application shall write to the message buffer data field and change the commit bit CMT only if the transmit message buffer is in one of the states HDis, HDisLck, HLck, HLckCCSa, HLckCCMa, or HLckCCMa. The application can change the state of a message buffer if it issues the appropriate commands shown in Table 47-33. The state change is indicated through the FR_MBCCSRn[EDS] and FR_MBCCSRn[LCKS] status bits.

If the transmit message buffer enters one of the states HDis, HDisLck, HLck, HLckCCSa, HLckCCMa, or HLckCCMa the FR_MBCCSRn[DVAL] flag is negated.

47.8.6.2.5 Message Transmission

As a result of the message buffer search described in Individual Message Buffer Search, the CC triggers the message available transition MA for up to two transmit message buffers. This changes the message buffer state from Idle to CCMa and the message buffers can be used for message transmission in the next slot.

The CC transmits a message from a message buffer if both of the following two conditions are fulfilled at the start of the transmission slot:

1. the message buffer is in the message available state CCMa
2. the message data are still valid, i.e. FR_MBCCSRn[CMT] = 1

In this case, the CC triggers the TX transition and changes the message buffer state to CCTx. A transmit message buffer timing and state change diagram for message transmission is given in the "Message Transmission Timing" figure below. In this example, the message buffer with message buffer number n is Idle at the start of the search slot, matches the slot and cycle number of the next slot, and message buffer data are valid, i.e. FR_MBCCSRn[CMT] = 1.

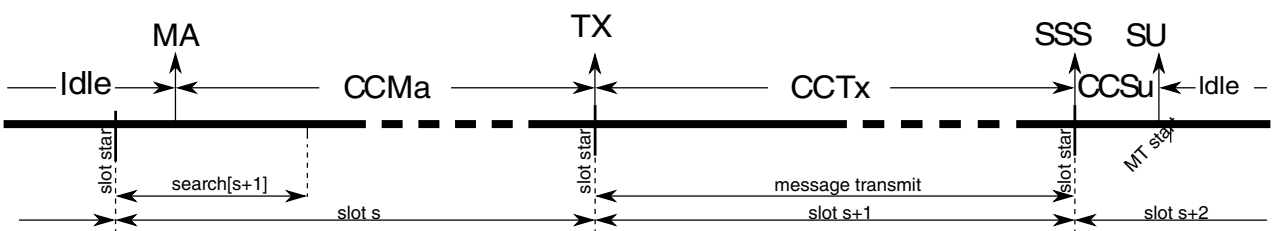

Figure 47-10. Message Transmission Timing

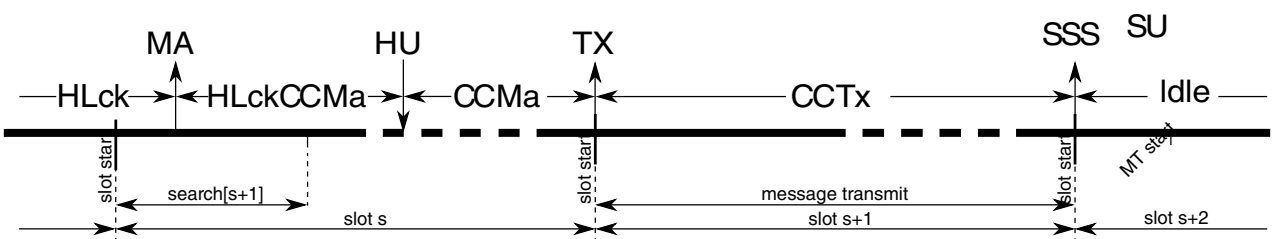

Figure 47-11. Message Transmission from HLck state with unlock

The amount of message data read from the FlexRay memory area and transferred to the FlexRay bus is determined by the following three items

1. the message buffer segment that the message buffer is assigned to, as defined by the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).
2. the message buffer data field size, as defined by the related field of the Message Buffer Data Size Register (FR_MBDSR)
3. the value of the PLDLEN field in the message buffer header field, as described in Frame Header Description

If a message buffer is assigned to message buffer segment 1, and PLDLEN > MBSEG1DS, then 2 × MBSEG1DS bytes will be read from the message buffer data field and zero padding is used for the remaining bytes for the FlexRay bus transfer. If PLDLEN <= MBSEG1DS, the CC reads and transfers 2 ×PLDLEN bytes. The same holds for segment 2 and MBSEG2DS.

47.8.6.2.6 Null Frame Transmission

A static slot with slot number S is assigned to the CC for channel A, if at least one transmit message buffer is configured with the FR_MBFIDRn[FID] set to S and FR_MBCCFRn[CHA] set to 1. A Null Frame is transmitted in the static slot S on channel A, if this slot is assigned to the CC for channel A, and all transmit message buffers with FR_MBFIDRn[FID] = s and FR_MBCCFRn[CHA] = 1 are either not committed, i.e FR_MBCCSRn[CMT] = 0, or locked by the application, i.e. FR_MBCCSRn[LCKS] = 1, or the cycle counter filter is enabled and does not match.

Additionally, the application can clear the commit bit of a message buffer that is in the CCMa state, which is called *uncommit* or *transmit abort*. This message buffer will be used for null frame transmission.

As a result of the message buffer search described in Individual Message Buffer Search, the CC triggers the slot assigned transition SA for up to two transmit message buffers if at least one of the conditions mentioned above is fulfilled for these message buffers. The transition SA changes the message buffer states from either Idle to CCSa or from HLck to HLckCCSa. In each case, these message buffers will be used for null frame transmission in the next slot. A message buffer timing and state change diagram for null frame transmission from Idle state is given in the figure below.

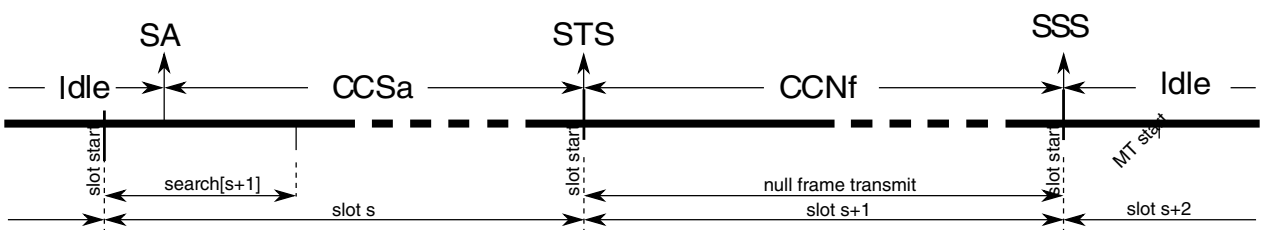

Figure 47-12. Null Frame Transmission from Idle state

A message buffer timing and state change diagram for null frame transmission from HLck state is given in the following figure.

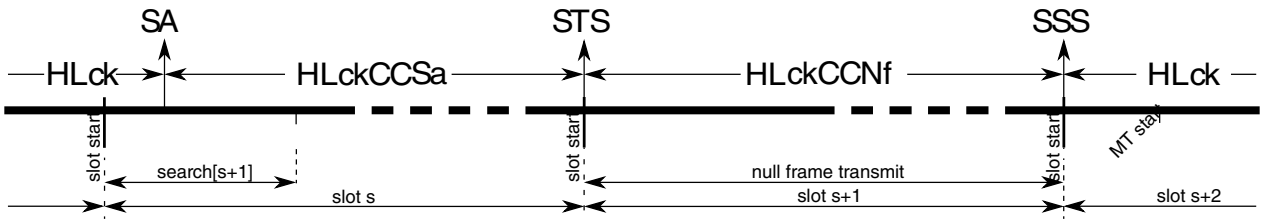

Figure 47-13. Null Frame Transmission from HLck state

If a transmit message buffer is in the CCSa or HLckCCSa state at the start of the transmission slot, a null frame is transmitted in any case, even if the message buffer is unlocked or committed before the transmission slot starts. A transmit message buffer timing and state change diagram for null frame transmission for this case is given in the next figure.

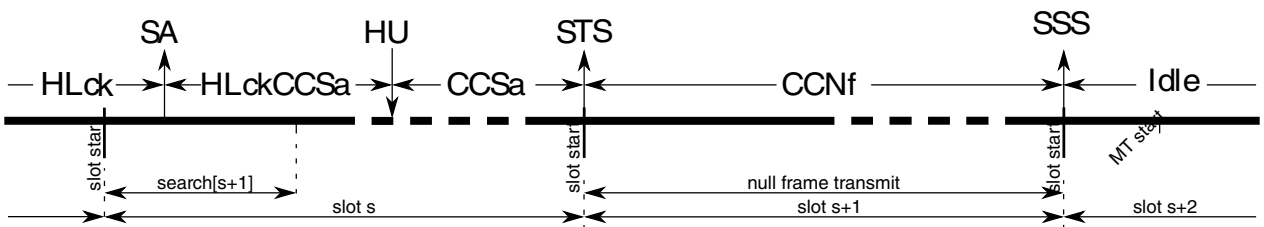

Figure 47-14. Null Frame Transmission from HLck state with unlock

Since the null frame transmission will not use the message buffer data, the application can lock/unlock the message buffer during null frame transmission. A transmit message buffer timing and state change diagram for null frame transmission for this case is given in the figure below.

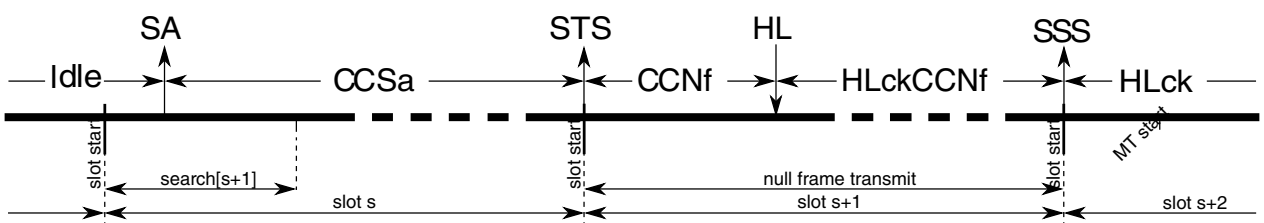

Figure 47-15. Null Frame Transmission from Idle state with locking

47.8.6.2.7 Message Buffer Status Update

After the end of each slot, the PE generates the slot status vector. Depending on the this status, the transmitted frame type, and the amount of transmitted data, the message buffer status is updated.

47.8.6.2.7.1 Message Buffer Status Update after Complete Message Transmission

The term complete message transmission refers to the fact that all payload data stored in the message buffer were send to FlexRay bus. In this case, the CC updates the slot status field of the message buffer and triggers the status updated transition SU. With the SU transition, the CC sets the message buffer interrupt flag FR_MBCCSRn[MBIF] to indicate the successful message transmission.

Depending on the transmission mode flag FR_MBCCFRn[MTM], the CC changes the commit flag FR_MBCCSRn[CMT] and the valid flag FR_MBCCSRn[DVAL]. If the FR_MBCCFRn[MTM] flag is negated, the message buffer is in the *event transmission mode*. In this case, each committed message is transmitted only once. The commit flag FR_MBCCSRn[CMT] is cleared with the SU transition. If the FR_MBCCFRn[MTM] flag is asserted, the message buffer is in the *state transmission mode*. In this case, each committed message is transmitted as long as the application provides new data or locks the message buffers. The CC will not clear the FR_MBCCSRn[CMT] flag at the end of transmission and will set the valid flag FR_MBCCSRn[DVAL] to indicate that the message will be transmitted again.

47.8.6.2.7.2 Message Buffer Status Update after Incomplete Message Transmission

The term incomplete message transmission refers to the fact that not all payload data that should be transmitted were send to FlexRay bus. This may be caused by the following regular conditions in the dynamic segment:

1. The transmission slot starts in a minislot with a minislot number greater than *pLatestTx*.
2. The transmission slot did not exist in the dynamic segment at all.

In any of these two aforementioned conditions occur, the status of the message buffer is not changed at all with the SU transition. The slot status field is not updated, the status and control flags are not changed, and the interrupt flag is not set.

Additionally, an incomplete message transmission can be caused by internal communication errors. If those errors occur, the Protocol Engine Communication Failure Interrupt Flag PECF_IF is set in the Protocol Interrupt Flag Register 1 (FR_PIFR1).

47.8.6.2.7.3 Message Buffer Status Update after Null Frame Transmission

After the transmission of a null frame, the status of the message buffer that was used for the null frame transmission is not changed at all. The slot status field is not updated, the status and control flags are not changed, and the interrupt flag is not set.

47.8.6.3 Receive Message Buffers

The section provides a detailed description of the functionality of the receive message buffers. If receive message buffers are used it is required to configure the related receive shadow buffer as described in Receive Shadow Buffers.

A receive message buffer is used to receive a message from the FlexRay Bus based on individual filter criteria. The CC uses the receive message buffer to provide the following data to the application.

1. message data received
2. information about the reception process
3. status information about the slot in which the message was received

A individual message buffer with message buffer number *n* is configured as a receive message buffer by the following configuration settings

$$FR_MBCCSRn[MTD] = 0 (receive message buffer)$$

Equation 20

To certain message buffer fields, both the application and the CC have access. To ensure data consistency, a message buffer locking scheme is implemented that is used to control the access to the data, control, and status bits of a message buffer. The access regions for receive message buffers are depicted in the figure below. A description of the regions is given in the following table. If a region is active as indicated in the "Receive Message Buffer States and Access (Sheet 2 of 2)" table below, the access scheme given for that region applies to the message buffer.

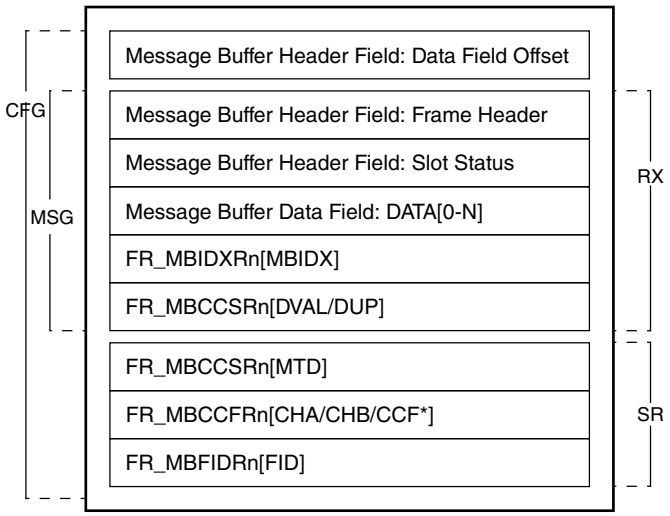

Figure 47-16. Receive Message Buffer Access Regions

Table 47-44. Receive Message Buffer Access Region Description

Region	Access from		Region used for
	Application	Module	
CFG	read/write	-	Message Buffer Configuration, Message Data and Status Access
MSG	read/write	-	Message Data, Header, and Status Access
RX	-	write-only	Message Reception and Status Update
SR	-	read-only	Message Buffer Search Data

The trigger bits FR_MBCCSRn[EDT] and FR_MBCCSRn[LCKT] and the interrupt enable bit FR_MBCCSRn[MBIE] are not under access control and can be accessed from the application at any time. The status bits FR_MBCCSRn[EDS] and FR_MBCCSRn[LCKS] are not under access control and can be accessed from the CC at any time.

The interrupt flag FR_MBCCSRn[MBIF] is not under access control and can be accessed from the application and the CC at any time. CC set access has higher priority.

The CC restricts its access to the regions depending on the current state of the message buffer. The application must adhere to these restrictions in order to ensure data consistency. The receive message buffer states are given in the figure below. A description of the message buffer states is given in Table 47-40, which also provides the access scheme for the access regions.

The status bits FR_MBCCSRn[EDS] and FR_MBCCSRn[LCKS] provide the application with the required status information. The internal status information is not visible to the application.

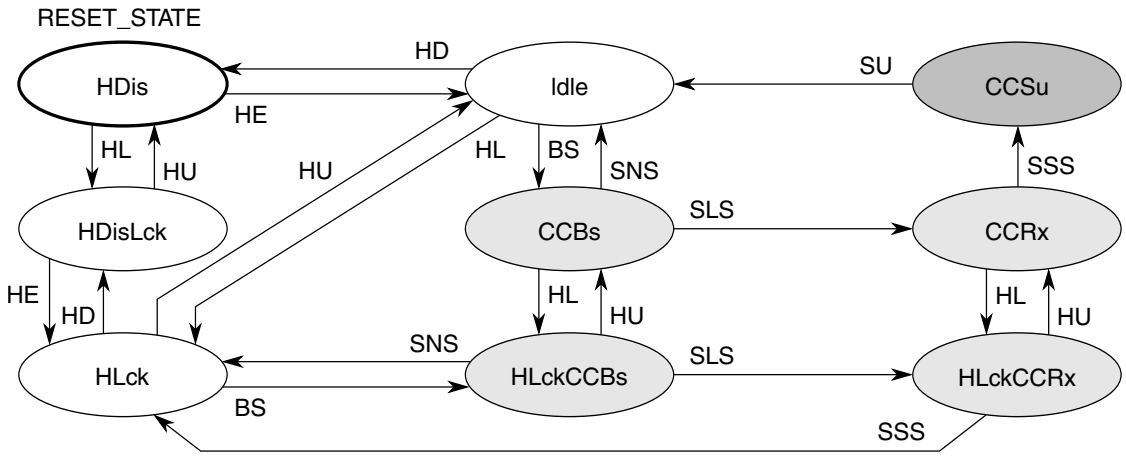

Figure 47-17. Receive Message Buffer States

Table 47-45. Receive Message Buffer States and Access (Sheet 2 of 2)

State	FR_MBCCSRn		Access from		Description
	EDS	LCKS	Appl.	Module	
Idle	1	0	–	SR	**Idle** - Message Buffer is idle. Included in message buffer search.
HDis	0	0	CFG	–	**Disabled** - Message Buffer under configuration. Excluded from message buffer search.
HDisLck	0	1	CFG	–	**Disabled and Locked** - Message Buffer under configuration.Excluded from message buffer search.
HLck	1	1	MSG	–	**Locked** - Applications access to data, control, and status.Included in message buffer search.
CCBs	1	0	–	–	**Buffer Subscribed** - Message buffer subscribed for reception. Filter matches next (slot, cycle, channel) tuple.
HLckCCBs	1	1	MSG	–	**Locked and Buffer Subscribed** - Applications access to data, control, and status. Message buffer subscribed for reception.
CCRx	1	0	–	–	**Message Receive** - Message data received into related shadow buffer.
HLckCCRx	1	1	MSG	–	**Locked and Message Receive** - Applications access to data, control, and status. Message data received into related shadow buffer.
CCSu	1	0	–	RX	**Status Update** - Message buffer status update. Update of status flags, the slot status field, and the header index.

47.8.6.3.1 Message Buffer Transitions

Application transitions, message buffer enable and disable, message buffer lock and unlock, module transitions, and transition priorities are discussed in this section.

47.8.6.3.1.1 Application Transitions

The application transitions that can be triggered by the application using the commands described in Table 47-41. The application issues the commands by writing to the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn). Only one command can be issued with one write access. Each command is executed immediately. If the command is ignored, it must be issued again.

47.8.6.3.1.2 Message Buffer Enable and Disable

The enable and disable commands issued by writing 1 to the trigger bit FR_MBCCSRn[EDT]. The transition that will be triggered by each of these command depends on the current value of the status bit FR_MBCCSRn[EDS]. If the command triggers the disable transition HD and the message buffer is in one of the states CCBs, HLckCCBs, or CCRx, the disable transition has no effect (command is ignored) and the message buffer state is not changed. No notification is given to the application.

47.8.6.3.1.3 Message Buffer Lock and Unlock

The lock and unlock commands issued by writing 1 to the trigger bit FR_MBCCSRn[LCKT]. The transition that will be triggered by each of these commands depends on the current value of the status bit FR_MBCCSRn[LCKS]. If the command triggers the lock transition HL while the message buffer is in the state CCRx, the lock transition has no effect (command is ignored) and message buffer state is not changed. In this case, the message buffer lock error flag LCK_EF in the CHI Error Flag Register (FR_CHIERFR) is set.

Table 47-46. Receive Message Buffer Application Transitions

Transition	Host Command	Condition	Description
HE	FR_MBCCSRn[EDT]:= 1	FR_MBCCSRn[EDS] = 0	Application triggers message buffer enable.
HD		FR_MBCCSRn[EDS] = 1	Application triggers message buffer disable.
HL	FR_MBCCSRn[LCKT]: = 1	FR_MBCCSRn[LCKS] = 0	Application triggers message buffer lock.
HU		FR_MBCCSRn[LCKS] = 1	Application triggers message buffer unlock.

47.8.6.3.1.4 Module Transitions

The module transitions that can be triggered by the CC are described in the next table. Each transition will be triggered for certain message buffers when the related condition is fulfilled.

Table 47-47. Receive Message Buffer Module Transitions

Transition	Condition	Description
BS	slot match and CycleCounter match	**Buffer Subscribed** - The message buffer filter matches next slot and cycle.
SLS	slot start	**Slot Start** - Start of either Static Slot or Dynamic Slot.
SNS	symbol window start or NIT start	**Symbol Window or NIT Start** - Start of either Symbol Window or NIT.
SSS	slot start or symbol window start or NIT start	**Slot or Segment Start** - Start of either Static Slot, Dynamic Slot, Symbol Window, or NIT.
SU	status updated	**Status Updated** - Slot Status field, message buffer status flags, header index updated. Interrupt flag set.

47.8.6.3.1.5 Transition Priorities

The application can trigger only one transition at a time. There is no need to specify priorities among them.

As shown in the table below, the module transitions have a higher priority than the application transitions. For all states except the CCRx state, a module transition and the application lock/unlock transition HL/HU and can be executed at the same time. The result state is reached by first applying the module transition and subsequently the application transition to the intermediately reached state. For example, if the message buffer is in the buffer subscribed state CCBs and the module triggers the slot start transition SLS at the same time as the application locks the message buffer by the HL transition, the intermediate state is CCRx and the resulting state is locked buffer subscribed state HLckCCRx.

Table 47-48. Receive Message Buffer Transition Priorities

State	Priorities	Description
module vs. application		
Idle	BS > HD	Buffer Subscribed > Message Buffer Disable
HLck	BS > HD	Buffer Subscribed > Message Buffer Disable
CCRx	SSS > HL	Slot or Segment Start > Message Buffer Lock

47.8.6.3.2 Message Reception

As a result of the message buffer search, the CC changes the state of up to two enabled receive message buffers from either idle state Idle or locked state HLck to the either subscribed state CCBs or locked buffer subscribed state HLckCCBs by triggering the buffer subscribed transition BS.

If the receive message buffers for the next slot are assigned to both channels, then at most one receive message buffer is changed to a buffer subscribed state.

If more than one matching message buffers assigned to a certain channel, then only the message buffer with the lowest message buffer number is in one of the states mentioned above.

With the start of the next static or dynamic slot the module trigger the slot start transition SLS. This changes the state of the subscribed receive message buffers from either CCBs to CCRx or from HLckCCBs to HLckCCRx, respectively.

During the reception slot, the received frame data are written into the shadow buffers. For details on receive shadow buffers, see Receive Shadow Buffers Concept. The data and status of the receive message buffers that are the CCRx or HLckCCRx are not modified in the reception slot.

47.8.6.3.3 Message Buffer Update

With the start of the next static or dynamic slot or with the start of the symbol window or NIT, the module triggers the slot or segment start transition SSS. This transition changes the state of the receiving receive message buffers from either CCRx to CCSu or from HLckCCRx to HLck, respectively.

If a message buffer was in the locked state HLckCCRx, no update will be performed. The received data are lost. This is indicated by setting the Frame Lost Channel A/B Error Flag FRLA_EF/FRLB_EF in the CHI Error Flag Register (FR_CHIERFR).

If a message buffer was in the CCRx state it is now in the CCSu state. After the evaluation of the slot status provided by the PE the message buffer is updated. The message buffer update depends on the slot status bits and the segment the message buffer is assigned to. This is described in Table 47-51.

Table 47-49. Receive Message Buffer Update (Continued)

vSS!ValidFrame	*vRF!Header! NFIndicator*	Update description
1	1	**Valid non-null frame received.** - Message Buffer Data Field updated. - Frame Header Field updated. - Slot Status Field updated. - DUP:= 1 - DVAL:= 1 - MBIF:= 1
1	0	**Valid null frame received.**

Table continues on the next page...

Table 47-49. Receive Message Buffer Update (Continued) (continued)

vSS!ValidFrame	*vRF!Header! NFIndicator*	Update description
		- Message Buffer Data Field *not* updated. - Frame Header Field *not* updated. - Slot Status Field updated. - DUP:= 0 - DVAL *not* changed - MBIF:= 1
0	x	**No valid frame received.** - Message Buffer Data Field not updated. - Frame Header Field not updated. - Slot Status Field updated. - DUP:= 0 - DVAL *not* changed. - MBIF:= 1, if the slot was not an empty dynamic slot. **Note:** An empty dynamic slot is indicated by the following frame and slot status bit values: *vSS!ValidFrame* = 0 and *vSS!SyntaxError* = 0 and *vSS! ContentError* = 0 and *vSS!BViolation* = 0.

Note

If the number of the last slot in the current communication cycle on a given channel is n, then all receive message buffers assigned to this channel with FR_MBFIDRn[FID] > *n* will not be updated at all.

When the receive message buffer update has finished the status updated transition SU is triggered, which changes the buffer state from CCSu to Idle. An example receive message buffer timing and state change diagram for a normal frame reception is given in the following figure.

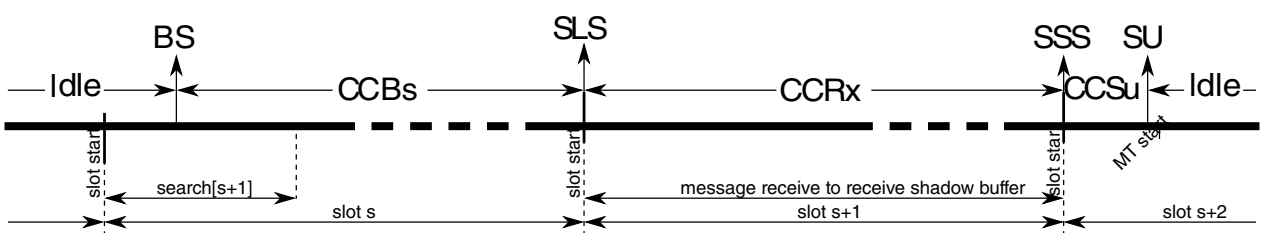

Figure 47-18. Message Reception Timing

The amount of message data written into the message buffer data field of the receive shadow buffer is determined by the following two items:

1. the message buffer segment that the message buffer is assigned to, as defined by the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).
2. the message buffer data field size, as defined by the related field of the Message Buffer Data Size Register (FR_MBDSR)
3. the number of bytes received over the FlexRay bus

If the message buffer is assigned to the message buffer segment 1, and the number of received bytes is greater than 2 ×FR_MBDSR.MBSEG1DS, the CC writes only 2 × FR_MBDSR.MBSEG1DS bytes into the message buffer data field of the receive shadow buffer. If the number of received bytes is less than 2 × FR_MBDSR.MBSEG1DS, the CC writes only the received number of bytes and will not change the trailing bytes in the message buffer data field of the receive shadow buffer. The same holds for the message buffer segment 2 with FR_MBDSR.MBSEG2DS.

47.8.6.3.4 Received Message Access

To access the message data received over the FlexRay bus, the application reads the message data stored in the message buffer data field of the corresponding receive message buffer. The access to the message buffer data field is described in Individual Message Buffers.

The application can read the message buffer data field if the receive message buffer is one of the states HDis, HDisLck, or HLck. If the message buffer is in one of these states, the CC will not change the content of the message buffer.

47.8.6.3.5 Receive Shadow Buffers Concept

The receive shadow buffer concept applies only to individual receive message buffers. The intention of this concept is to ensure that only syntactically and semantically valid received non-null frames are presented to the application in a receive message buffer. The basic structure of a receive shadow buffer is described in Receive Shadow Buffers.

The receive shadow buffers temporarily store the received frame header and message data. After the slot boundary the slot status information is generated. If the slot status information indicates the reception of the valid non-null frame (see Table 47-49), the CC writes the slot status into the slot status field of the receive shadow buffer and exchanges the content of the Message Buffer Index Registers (FR_MBIDXRn) with the content of the corresponding internal shadow buffer index register. In all other cases, the CC writes the slot status into the identified receive message buffer, depending on the slot status and the FlexRay segment the message buffer is assigned to.

The shadow buffer concept, with its index exchange, results in the fact that the FlexRay memory area located message buffer associated to an individual receive message buffer changes after successful reception of a valid frame. This means that the message buffer area in the FlexRay memory area accessed by the application for reading the received message is different from the initial setting of the message buffer. Therefore, the application must not rely on the index information written initially into the Message Buffer Index Registers (FR_MBIDXRn). Instead, the index of the message buffer header field must be fetched from the Message Buffer Index Registers (FR_MBIDXRn).

47.8.7 Individual Message Buffer Search

This section provides a detailed description of the message buffer search algorithm.

The message buffer search determines for each enabled channel if a slot s in a communication cycle c is assigned for frame or null frame transmission or if it is subscribed for frame reception on that channel.

The message buffer search is a sequential algorithm which is invoked at the following protocol related events:

1. NIT start
2. slot start in the static segment
3. minislot start in the dynamic segment

The message buffer search within the NIT searches for message buffers assigned or subscribed to slot 1. The message buffer search within slot *n* searches for message buffers assigned or subscribed to slot *n+1*.

In general, the message buffer search for the next slot *n* considers only message buffers which are

1. enabled, i.e. FR_MBCCSRn[EDS] = 1, and
2. matches the next slot *n*, i.e. FR_MBFIDRn[FID] = *n*, and

On top of that, for the static segment only those message buffers are considered, that match the condition of at least one row of the "Message Buffer Search Priority (static segment)" table shown below. For the dynamic segment only those message buffers are considered, that match the condition of at least one row of the next "Message Buffer Search Priority (dynamic segment)" table. These message buffers are called *matching* message buffers.

For each enabled channel the message buffer search may identify multiple *matching* message buffers. Among all matching message buffers the message buffers with highest priority according to the "Message Buffer Search Priority (static segment)" table for the static segment and according to the "Message Buffer Search Priority (dynamic segment)" table for the dynamic segment are selected.

Table 47-50. Message Buffer Search Priority (static segment)

Priority	MTD	LCKS	CMT	CCFM[1]	Description	Transition
(highest) 0	1	0	1	1	transmit buffer, matches cycle count, not locked and committed	MA
1	1	-	0	1	transmit buffer, matches cycle count, not committed	SA
	1	1	-	1	transmit buffer, matches cycle count, locked	SA
2	1	-	-	-	transmit buffer	SA
3	0	0	n/a	1	receive buffer, matches cycle count, not locked	SB
(lowest) 4	0	1	n/a	1	receive buffer, matches cycle count, locked	SB

1. Cycle Counter Filter Match, see Message Buffer Cycle Counter Filtering.

Table 47-51. Message Buffer Search Priority (dynamic segment)

Priority	MTD	LCKS	CMT	CCFM[1]	Description	Transition
(highest) 0	1	0	1	1	transmit buffer, matches cycle count, not locked and committed	MA
1	0	0	n/a	1	receive buffer, matches cycle count, not locked	SB
(lowest) 2	0	1	n/a	1	receive buffer, matches cycle count, locked	SB

1. Cycle Counter Filter Match, see Message Buffer Cycle Counter Filtering.

If there are multiple message buffer with highest priority, the message buffer with the lowest message buffer number is selected. All message buffer which have the highest priority must have a consistent channel assignment as specified in Message Buffer Channel Assignment Consistency.

Depending on the message buffer channel assignment the same message buffer can be found for both channel A and channel B. In this case, this message buffer is used as described in Individual Message Buffers.

47.8.7.1 Message Buffer Cycle Counter Filtering

The message buffer cycle counter filter is a value-mask filter defined by the CCFE, CCFMSK, and CCFVAL fields in the Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn). This filter determines a set of communication cycles in which the

message buffer is considered for message reception or message transmission. If the cycle counter filter is disabled, i.e. CCFE = 0, this set of cycles consists of all communication cycles.

If the cycle counter filter of a message buffer does not match a certain communication cycle number, this message buffer is not considered for message transmission or reception in that communication cycle. In case of a transmit message buffer assigned to a slot in the static segment, though, this buffer is added to the matching message buffers to indicate the slot assignment and to trigger the null frame transmission.

The cycle counter filter of a message buffer matches the communication cycle with the number CYCCNT if at least one of the following conditions evaluates to true:

$$MBCCFRn[CCFE] = 0$$

$$CYCCNT \,\&\, MBCCFRn[CCFMSK] = MBCCFRn[CCFVAL] \,\&\, MBCCFRn[CCFMSK]$$

47.8.7.2 Message Buffer Channel Assignment Consistency

The message buffer channel assignment given by the CHA and CHB bits in the Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn) defines the channels on which the message buffer will receive or transmit. The message buffer with number *n* transmits or receives on channel A if FR_MBCCFRn[CHA] = 1 and transmits or receives on channel B if FR_MBCCFRn[CHB] = 1.

To ensure correct message buffer operation, all message buffers assigned to the same slot and with the same priority must have a *consistent* channel assignment. That means they must be either assigned to one channel only, or must be assigned to *both* channels. The behavior of the message buffer search is not defined, if both types of channel assignments occur for one slot and priority. An inconsistent channel assignment for message buffer 0 and message buffer 1 is depicted in the figure below.

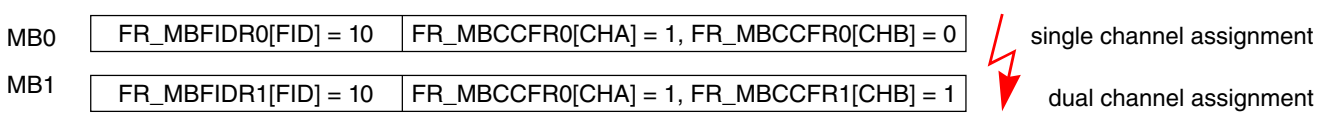

Figure 47-19. Inconsistent Channel Assignment

47.8.7.3 Node Related Slot Multiplexing

The term *Node Related Slot Multiplexing* applies to the dynamic segment only and refers to the functionality if there are transmit as well as receive message buffers are configured for the same slot.

According to Table 47-51 the transmit buffer is only found if the cycle counter filter matches, and the buffer is not locked and committed. In all other cases, the receive buffer will be found. Thus, if the block has no data to transmit in a dynamic slot, it is able to receive frames on that slot.

47.8.7.4 Message Buffer Search Error

There are two kinds of errors which may occur during message buffer search[1].

47.8.7.4.1 Message Buffer Search Start while Running

If the message buffer search is running in slot *n-1* and the next message buffer search start event appears due to the start of slot *n*, the message buffer search engine is stopped and the Message Buffer Search Error Flag MBS_EF is set in the CHI Error Flag Register (FR_CHIERFR). As a result of this stop, no individual message buffer is identified for transmission or reception in slot *n*. Additionally, the search engine will not be started in slot *n*, and consequently no individual message buffer is identified for transmission or reception in slot *n+1*.

A message buffer search error appears only if the CHI frequency is too slow to allow the search through all message buffers to be completed within the NIT or a minislot.

For more details of minimum required CHI frequency see Number of Usable Message Buffers.

47.8.7.4.2 Illegal Message Buffer Index Found

If the message buffer search has finished the message buffer search in slot *n-1*, it retrieves the data offset values for the found message buffers and the receive shadow buffers. If one of these message buffers contains an illegal message buffer index, the Message Buffer Search Error Flag MBS_EF is set in the CHI Error Flag Register (FR_CHIERFR) is set and no individual message buffer is identified for transmission or reception in slot *n*. The legal message buffer index values for the individual and receive shadow buffers are specified in the Receive Shadow Buffer Index Register section (FR_RSBIR) and the Message Buffer Index Registers sections (FR_MBIDXRn).

1. The FIFO reception is not affected by the search errors. Additionally, if no rx buffer has been found due to an search error, the received frame is considered for FIFO reception.

47.8.8 Individual Message Buffer Reconfiguration

The initial configuration of each individual message buffer can be changed even when the protocol is not in the *POC:config* state. This is referred to as individual message buffer *reconfiguration*. The configuration bits and fields that can be changed are given in the section on Specific Configuration Data. The common configuration data given in the section on Specific Configuration Data can not be reconfigured when the protocol is out of the *POC:config* state.

47.8.8.1 Reconfiguration Schemes

Depending on the target and destination basic state of the message buffer that is to be reconfigured, there are three reconfiguration schemes.

47.8.8.1.1 Basic Type Not Changed (RC1)

A reconfiguration will not change the basic type of the individual message buffer, if the message buffer transfer direction bit FR_MBCCSRn[MTD] are not changed. This type of reconfiguration is denoted by RC1 in Figure 47-20. Transmit and receive message buffers can be RC1-reconfigured when in the HDis or HDisLck state.

47.8.8.1.2 Buffer Type Not Changed (RC2)

A reconfiguration will not change the buffer type of the individual message buffer. This type of reconfiguration is denoted by RC2 in the figure below. It applies to transmit and receive message buffers. Transmit and receive message buffers can be RC2-reconfigured when in the HDis or HDisLck state.

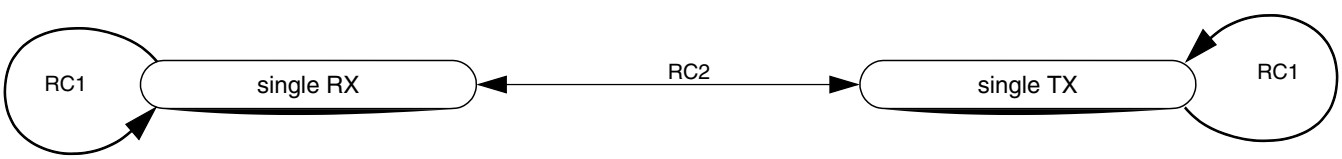

Figure 47-20. Message Buffer Reconfiguration Scheme

47.8.9 Receive FIFOs

This section provides the functional description of the two receive FIFOs.

47.8.9.1 Overview

The two receive FIFOs implement the queued message buffer concept defined by the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*. One FIFO is assigned to channel A, the other FIFO is assigned to channel B. Both FIFOs work completely independent from each other.

The message buffer structure of each FIFO is described in Receive FIFO. The area in the FlexRay memory area for each of the two FIFOs is characterized by:

- *The FIFO system memory base address*
- *The index of the first FIFO entry given by Receive FIFO Start Index Register (FR_RFSIR)*
- *The data field offset of the data field belonging to the first FIFO entry given by Receive FIFO Start Data Offset Register (FR_RFSDOR)*
- *The number of FIFO entries and the length of each FIFO entry as given by Receive FIFO Depth and Size Register (FR_RFDSR)*

47.8.9.2 FIFO Configuration

The FIFOs can be configured for two different locations of the system memory base address via the FIFO address mode bit FAM in the Module Configuration Register (FR_MCR).

47.8.9.2.1 Single System Memory Base Address Mode

This mode is configured, when the FIFO address mode flag FR_MCR[FAM] is set to 0. In this mode, the location of the system memory base address for the FIFO buffers is System Memory Base Address Register (FR_SYMBADR).

47.8.9.2.2 Dual System Memory Base Address Mode

This mode is configured, when the FIFO address mode flag FR_MCR[FAM] is set to 1. In this mode, the location of the system memory base address for the FIFO buffers is Receive FIFO System Memory Base Address Register (FR_RFSYMBADR).

The FIFO control and configuration data are given in Receive FIFO Control and Configuration Data. The configuration of the FIFOs consists of two steps.

The first step is the allocation of the required amount of FlexRay memory area for the FlexRay window. This includes the allocation of the message buffer header area and the allocation of the message buffer data fields. For more details see FlexRay Memory Area Layout.

The second step is the programming of the configuration data register while the PE is in *POC:config*.

The following steps configure the layout of the FIFO.

- Configure the FIFO update and address modes in Module Configuration Register (FR_MCR)
- Configure the FIFO system memory base address
- Configure the Receive FIFO Start Index Register (FR_RFSIR) with the first message buffer header index that belongs to the FIFO
- Configure the Receive FIFO Start Data Offset Register (FR_RFSDOR) with the data field offset of the data field belonging to the first message buffer that belongs to the FIFO
- Configure the Receive FIFO Depth and Size Register (FR_RFDSR) with FIFO entry size
- Configure the Receive FIFO Depth and Size Register (FR_RFDSR) with FIFO depth
- Configure the FIFO Filters

47.8.9.3 FIFO Periodic Timer

The FIFO periodic timer is used to generate an FIFO almost-full interrupt at certain point in time, if the almost-full watermark is not reached, but the FIFO is not empty. This can be used to prevent frames from get stuck in the FIFO for a long time.

The FIFO periodic timer is configured via the Receive FIFO Periodic Timer Register (FR_RFPTR). If the periodic timer duration FR_RFPTR[PTD] is configured to 0x0000, the periodic timer is continuously expired. If the periodic timer duration FR_RFPTR[PTD] is configured to 0x3FFF, the periodic timer never expires. If the periodic timer is configured to a value *ptd*, greater than 0x0000 and smaller 0x3FFF, the periodic timer expires and is restarted at the start of every communication cycle, and expires and is restarted after *ptd* macroticks have been elapsed.

47.8.9.4 FIFO Reception

The FIFO reception is a CC internal operation.

A message frame reception is directed into the FIFO, if no individual message buffer is assigned for transmission or subscribed for reception for the current slot. In this case the FIFO filter path shown in Figure 47-21 is activated.

If the FIFO filter path indicates that the received frame has to be appended to the FIFO and the FIFO is not full, the CC writes the received frame header into the message buffer header field indicated by the CC internal FIFO write index. The frame payload data are written into the corresponding message buffer data field. If the status of the received frame indicates a valid non-null frame, the slot status information is written into the message buffer header field and the CC internal FIFO write index is updated by 1 and the fifo fill level FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) is incremented. If the status of the received frame indicates an invalid or null frame, the frame is not appended to the FIFO.

47.8.9.5 FIFO Almost-Full Interrupt Generation

If the fifo fill level FLA (FLB) is updated after a frame reception and exceeds the FIFO watermark level WM, i.e. FLA>WM_A (FLB>WM_B), then the FIFO almost-full interrupt flag FR_GIFER[FAFAIF] (FR_GIFER[FAFBIF]) is asserted.

If the periodic timer expires, and FIFOA (FIFOB) is not empty, i.e. FLA>0 (FLB>0), then the FIFO almost-full interrupt flag FR_GIFER[FAFAIF] (FR_GIFER[FAFBIF]) is asserted.

47.8.9.6 FIFO Overflow Error Generation

If the FIFOA (FIFOB) is full, i.e. FLA=$FIFO_DEPTH_A$ (FLB=$FIFO_DEPTH_B$) and the conditions for a FIFO reception as described in FIFO Reception are fulfilled, then the fifo overflow error flag FR_CHIERFR[FOVA_EF] (FR_CHIERFR[FOVB_EF]) is asserted.

47.8.9.7 FIFO Message Access

The FIFOA (FIFOB) contains valid messages if the FIFO fill level given in the fields FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) is greater than 0. The Receive FIFO A Read Index Register (FR_RFARIR) and the

(Receive FIFO B Read Index Register (FR_RFBRIR)) point to a message buffer with valid content and the oldest frames stored in the FIFO.The respective read data field offsets can be calculated according to Equation 1-125.

If the FIFO fill level FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) is 0, than the FIFOA (FIFOB) contains no valid messages and the corresponding read index register Receive FIFO A Read Index Register (FR_RFARIR) or (Receive FIFO B Read Index Register (FR_RFBRIR) point to a message buffer with invalid content. In this case the application must not read data from this FIFO.

To access the oldest message in the FIFOA (FIFOB), the application first reads the read index RDIDX out of the Receive FIFO A Read Index Register (FR_RFARIR) (Receive FIFO B Read Index Register (FR_RFBRIR)). This read index points to the message buffer header field of the oldest message buffer that contains valid received message data. The data field offset belonging to this message buffer must be calculated by the application according to Equation 1-125. The application can access the message data as described in Receive FIFO. When the application has read the message buffer data and status information, it can update the FIFO as described in FIFO Update.

47.8.9.8 FIFO Update

The application updates the FIFOA (FIFOB) by writing a pop count value *pc* different from 0 to the PCA (PCB) field in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR).

As a result of the this operation, the CC removes the oldest *pc* entries from FIFOA (FIFOB).

If the specified pop count value *pc* is greater than the current fill level *fl* provided in FLA (FAB) field, then only *fl* entries are removed from the FIFOA (FIFOB), the remaining *fl-pc* requested pop operations are discarded without any notification. In this case FIFOA (FIFOB) is empty after the update operation.

The read index in the Receive FIFO A Read Index Register (FR_RFARIR) (Receive FIFO B Read Index Register (FR_RFBRIR)) is incremented by the number of removed items. If the read index reaches the top of the FIFO, it wraps around to the FIFO start index defined in Receive FIFO Start Index Register (FR_RFSIR) automatically.

47.8.9.8.1 FIFO Interrupt Flag Update

The FIFO Interrupt Flag Update mode is configured, when the FIFO update mode flag FR_MCR[FUM] is set to 0. In this mode FIFOA (FIFOB) will be updated by 1 entry, when the interrupt flag FR_GIFER[FAFAIF] (FR_GIFER[FAFBIF]) is written with 1 by the application.

If the FIFO is empty, the update request is ignored without any notification.

The read index in the Receive FIFO A Read Index Register (FR_RFARIR) (Receive FIFO B Read Index Register (FR_RFBRIR)) is incremented by 1, if the FIFO was not empty. If the read index reaches the top of the FIFO, it wraps around to the FIFO start index automatically.

47.8.9.9 FIFO Filtering

The FIFO filtering is activated after all enabled individual receive message buffers have been searched without success for a message buffer to receive the current frame.

The CC provides three sets of FIFO filters. The FIFO filters are applied to valid non-null frames only. The FIFO will not receive invalid or null-frames. For each FIFO filter, the pass criteria is specified in the related section given below. Only frames that have passed all filters will be appended to the FIFO. The FIFO filter path is depicted in the figure below.

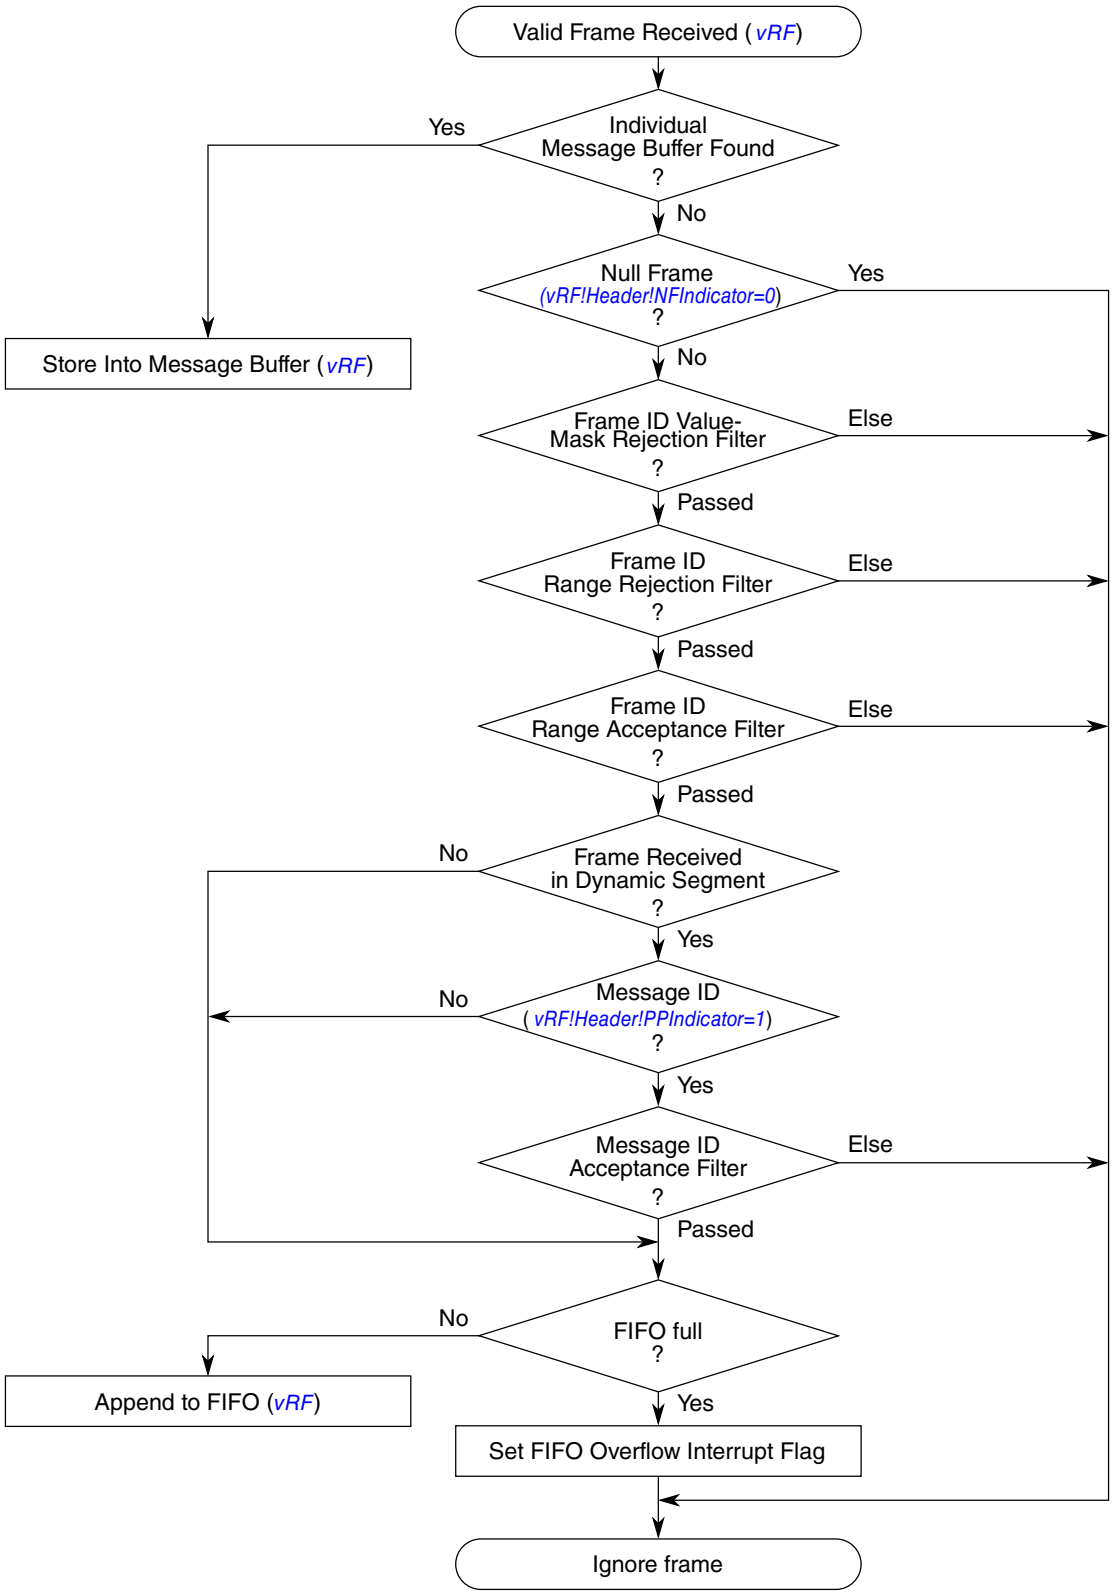

Figure 47-21. Received Frame FIFO Filter Path

A received frame passes the FIFO filtering if it has passed all three type of filter.

47.8.9.9.1 RX FIFO Frame ID Value-Mask Rejection Filter

The frame ID value-mask rejection filter is a value-mask filter and is defined by the fields in the Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR) and the Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR). Each received frame with a frame ID FID that does not match the value-mask filter value passes the filter, i.e. is not rejected.

Consequently, a received valid frame with the frame ID FID passes the RX FIFO Frame ID Value-Mask Rejection Filter if Equation 21 on page 2034 is fulfilled.

$$FID \,\&\, FR_RFFIDRFMR[FIDRFMSK] \neq FR_RFFIDRFVR[FIDRFVAL] \,\&\, FR_RFFIDRFMR[FIDRFMSK]$$

Equation 21

The RX FIFO Frame ID Value-Mask Rejection Filter can be configured to pass all frames by the following settings.

$$FR_RFFIDRFVR[FIDRFVAL] = 0x000 \text{ and } FR_RFFIDRFMR[FIDRFMSK] = 0x7FF$$

Equation 22

Using the settings above, only the frame with frame ID 0 will be rejected, which is an invalid frame. All other frames will pass.

The RX FIFO Frame ID Value-Mask Rejection Filter can be configured to reject all frames by the following settings.

$$FR_RFFIDRFMR[FIDRFMSK] = 0x000$$

Equation 23

Using these settings, Equation 21 on page 2034 can never be fulfilled (0!= 0) and thus all frames are rejected; no frame will pass. This is the reset value for the RX FIFO.

47.8.9.9.2 RX FIFO Frame ID Range Rejection Filter

Each of the four RX FIFO Frame ID Range filters can be configured as a rejection filter. The filters are configured by the Receive FIFO Range Filter Configuration Register (FR_RFRFCFR) and controlled by the Receive FIFO Range Filter Control Register (FR_RFRFCTR). The RX FIFO Frame ID range filters apply to all received valid frames. A received frame with the frame ID FID passes the RX FIFO Frame ID Range rejection filters if either no rejection filter is enabled, or, for all of the enabled RX FIFO Frame ID Range rejection filters, i.e. FR_RFRFCTR[FiMD] = 1 and FR_RFRFCTR[FiEN] = 1, Equation 24 on page 2035 is fulfilled.

$$FID < FR_RFRFCFR_{SEL}[SID_{IBD=0}]) or (FR_RFRFCFR_{SEL}[SID_{IBD=1}] < FID)$$

Equation 24

Consequently, all frames with a frame ID that fulfills Equation 25 on page 2035 for at least one of the enabled rejection filters will be rejected and thus not pass.

$$FR_RFRFCFR_{SEL}[SID_{IBD=0}] \leq FID \leq FR_RFRFCFR_{SEL}[SID_{IBD=1}]$$

Equation 25

47.8.9.9.3 RX FIFO Frame ID Range Acceptance filter

Each of the four RX FIFO Frame ID Range filters can be configured as an acceptance filter. The filters are configured by the Receive FIFO Range Filter Configuration Register (FR_RFRFCFR) and controlled by the Receive FIFO Range Filter Control Register (FR_RFRFCTR). The RX FIFO Frame ID range filters apply to all received valid frames. A received frame with the frame ID FID passes the RX FIFO Frame ID Range acceptance filters if either no acceptance filter is enabled, or, for at least one of the enabled RX FIFO Frame ID Range acceptance filters, i.e. FR_RFRFCTR[FiMD] = 0 and FR_RFRFCTR[FiEN] = 1, Equation 26 on page 2035 is fulfilled.

$$FR_RFRFCFR_{SEL}[SID_{IBD=0}] \leq FID \leq FR_RFRFCFR_{SEL}[SID_{IBD=1}]$$

Equation 26

47.8.9.9.4 RX FIFO Message ID Acceptance Filter

The RX FIFO Message ID Acceptance Filter is a value-mask filter and is defined by the Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR) and the Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR). This filter applies only to valid frames received in the dynamic segment with the payload preamble indicator bit PPI set to 1. All other frames will pass this filter.

A received valid frame in the dynamic segment with the payload preamble indicator bit PPI set to 1 and with the message ID MID (the first two bytes of the payload) will pass the RX FIFO Message ID Acceptance Filter if Equation 27 on page 2035 is fulfilled.

$$MID \,\&\, FR_RFMIDAFMR[MIDAFMSK] = FR_RFMIDAFMR[MIDAFVAL] \,\&\, FR_RFMIDAFMR[MIDAFMSK]$$

Equation 27

The RX FIFO Message ID Acceptance Filter can be configured to accept all frames by setting

$$FR_RFMIDAFMR[MIDAFMSK] := 0x000$$

Equation 28

Using these settings, Equation 27 on page 2035 is always fulfilled and all frames will pass.

47.8.10 Channel Device Modes

This section describes the two FlexRay channel device modes that are supported by the CC.

47.8.10.1 Dual Channel Device Mode

In the dual channel device mode, both FlexRay ports are connected to physical FlexRay bus lines. The FlexRay port consisting of FR_A_RX, FR_A_TX, and $\overline{\text{FR_A_TX_EN}}$ is connected to the physical bus channel A and the FlexRay port consisting of FR_B_RX, FR_B_TX, and $\overline{\text{FR_B_TX_EN}}$ is connected to the physical bus channel B. The dual channel system is shown in the following figure.

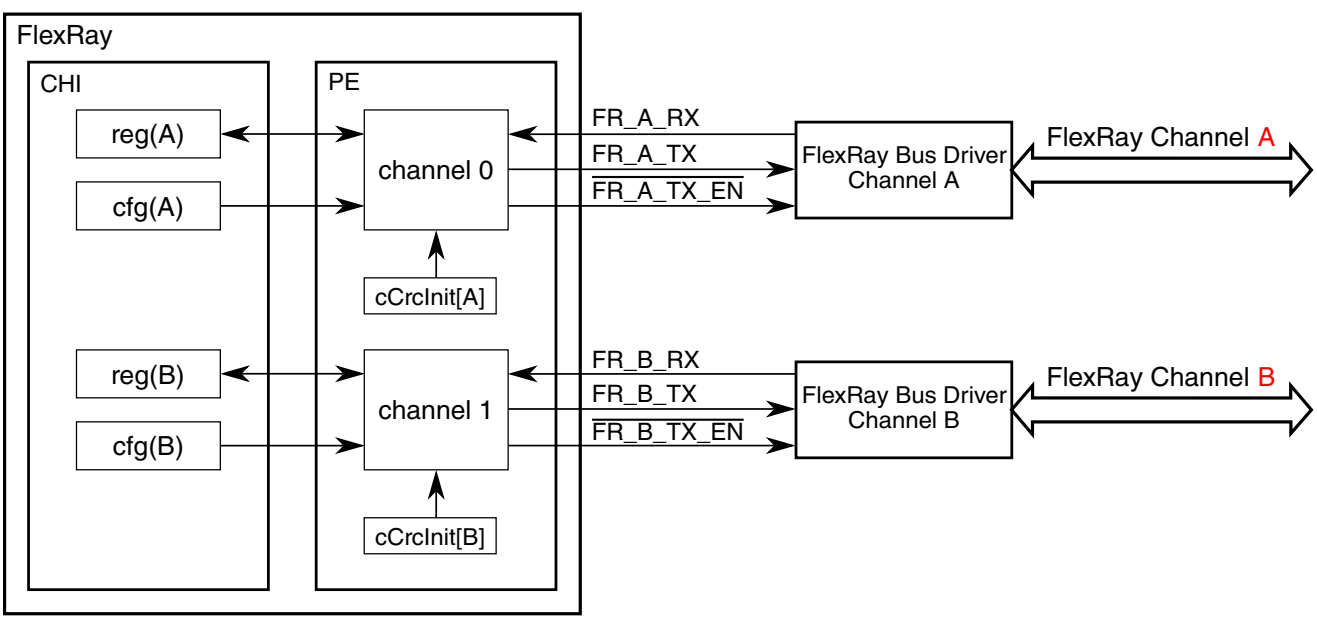

Figure 47-22. Dual Channel Device Mode

47.8.10.2 Single Channel Device Mode

The single channel device mode supports devices that have only one FlexRay port available. This FlexRay port consists of the signals FR_A_RX, FR_A_TX, and $\overline{\text{FR_A_TX_EN}}$ and can be connected to either the physical bus channel A (shown in the "Single Channel Device Mode (Channel A)" figure below) or the physical bus channel B (shown in the "Single Channel Device Mode (Channel B)" figure below).

If the device is configured as a single channel device by setting FR_MCR[SCM] to 1, only the internal channel A and the FlexRay Port A is used. Depending on the setting of FR_MCR[CHA] and FR_MCR[CHB], the internal channel A behaves either as a FlexRay Channel A or FlexRay Channel B. The bit FR_MCR[CHA] must be set, if the FlexRay Port A is connected to a FlexRay Channel A. The bit FR_MCR[CHB] must be set if the FlexRay Port A is connected to a FlexRay Channel B. The two FlexRay channels differ only in the initial value for the frame CRC *cCrcInit*. For a single channel device, the application can access and configure only the registers related to internal channel A.

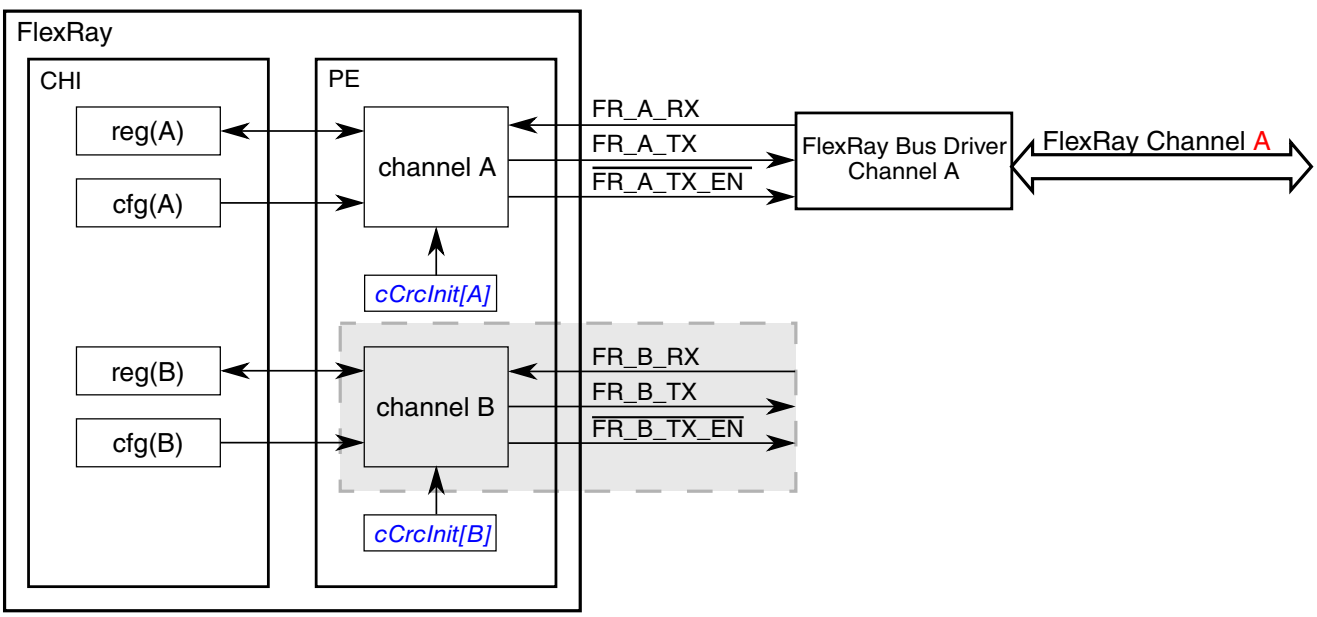

Figure 47-23. Single Channel Device Mode (Channel A)

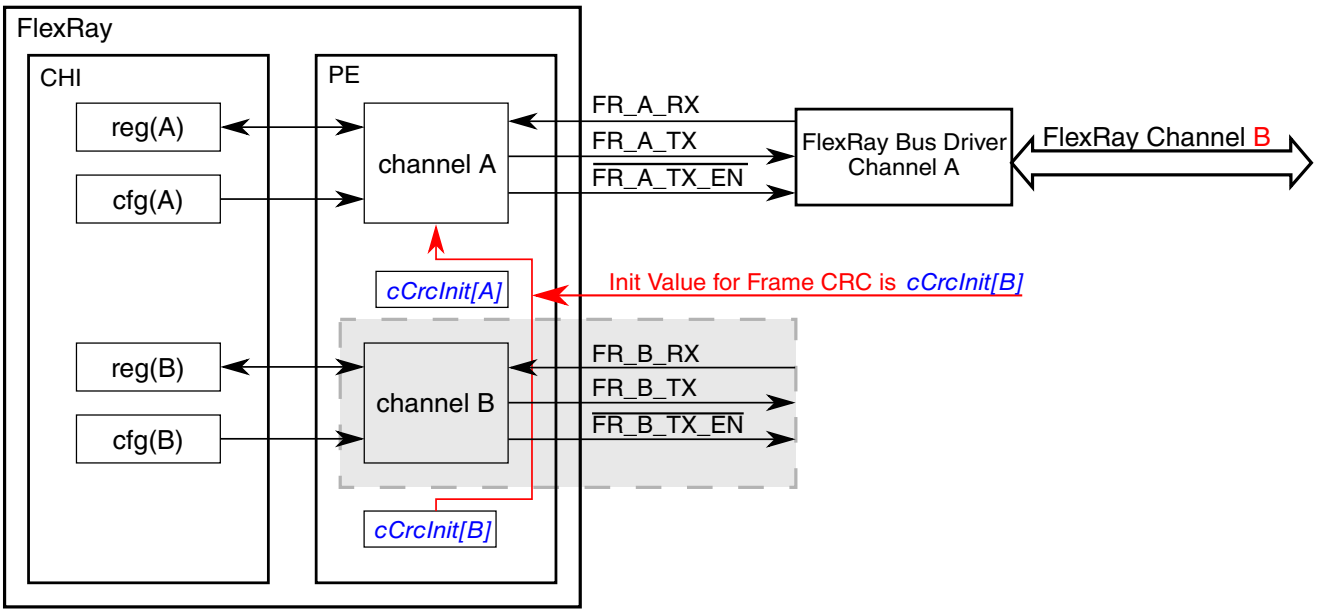

Figure 47-24. Single Channel Device Mode (Channel B)

47.8.11 External Clock Synchronization

The application of the external rate and offset correction is triggered when the application writes to the EOC_AP and ERC_AP fields in the Protocol Operation Control Register (FR_POCR). The PE applies the external correction values in the next even-odd cycle pair as shown in the "External Offset Correction Write and Application Timing" figure and the "External Rate Correction Write and Application Timing" figures below.

Note

The values provided in the EOC_AP and ERC_AP fields are the values that were written from the application most recently. If these value were already applied, they will not be applied in the current cycle pair again.

If the offset correction applied in the NIT of cycle 2n+1 shall be affect by the external offset correction, the EOC_AP field must be written to after the start of cycle 2n and before the end of the static segment of cycle 2n+1. If this field is written to after the end of the static segment of cycle 2n+1, it is not guaranteed that the external correction value is applied in cycle 2n+1. If the value is not applied in cycle 2n+1, then the value will be applied in the cycle 2n+3. Refer to the following for timing details.

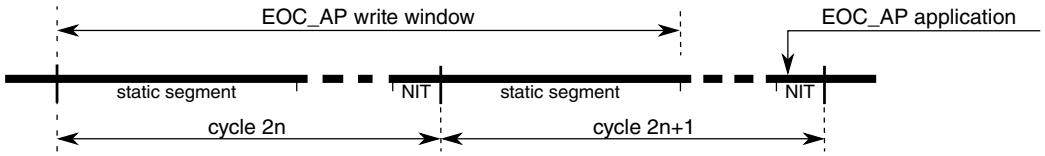

Figure 47-25. External Offset Correction Write and Application Timing

If the rate correction for the cycle pair [2n+2, 2n+3] shall be affect by the external offset correction, the ERC_AP field must be written to after the start of cycle 2n and before the end of the static segment start of cycle 2n+1. If this field is written to after the end of the static segment of cycle 2n+1, it is not guaranteed that the external correction value is applied in cycle pair [2n+2, 2n+3]. If the value is not applied for cycle pair [2n+2, 2n+3], then the value will be applied for cycle pair [2n+4, 2n+5]. Refer to the following for details.

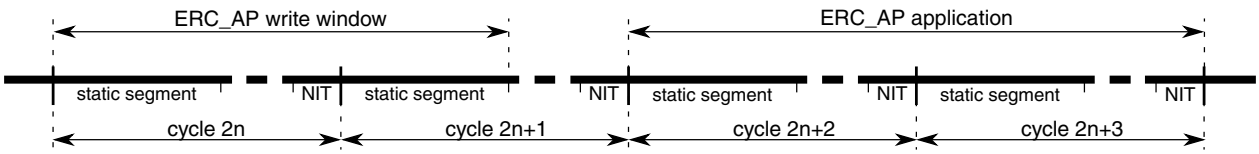

Figure 47-26. External Rate Correction Write and Application Timing

47.8.12 Sync Frame ID and Sync Frame Deviation Tables

The FlexRay protocol requires the provision of a snapshot of the Synchronization Frame ID tables for the even and odd communication cycle for both channels. The CC provides the means to write a copy of these internal tables into the FlexRay memory area and ensures application access to consistent tables by means of table locking. Once the application has locked the table successfully, the CC will not overwrite these tables and the application can read a consistent snapshot.

Note

Only synchronization frames that have passed the synchronization frame filters are considered for clock synchronization and appear in the sync frame tables.

47.8.12.1 Sync Frame ID Table Content

The Sync Frame ID Table is a snapshot of the protocol related variables *vsSyncIdListA* and *vsSyncIdListB* for each even and odd communication cycle. This table provides a list of the frame IDs of the synchronization frames received on the corresponding channel and cycle that are used for the clock synchronization.

47.8.12.2 Sync Frame Deviation Table Content

The Sync Frame Deviation Table is a snapshot of the protocol related variable zsDev(id)(oe)(ch)!Value. Each Sync Frame Deviation Table entry provides the deviation value for the sync frame, with the frame ID presented in the corresponding entry in the Sync Frame ID Table.

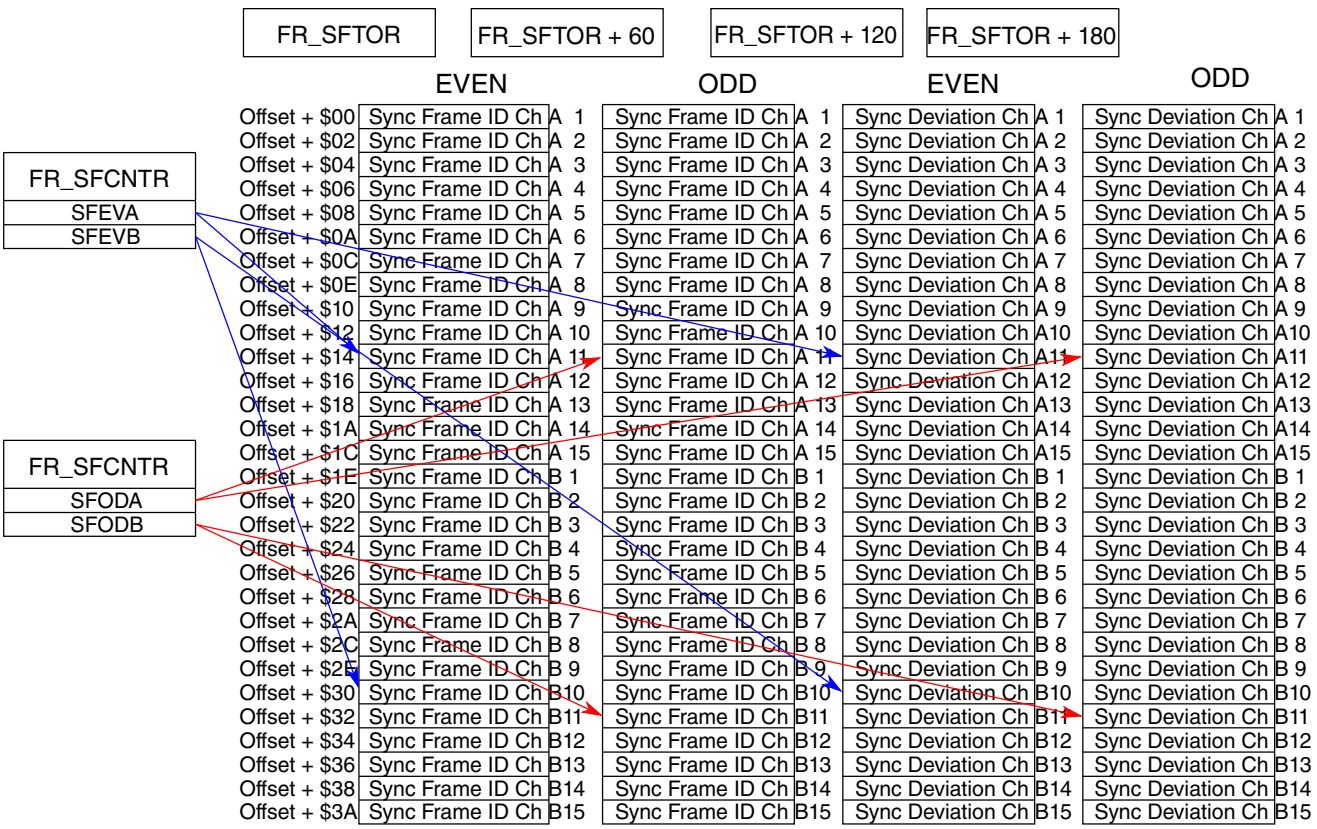

Figure 47-27. Sync Table Memory Layout

47.8.12.3 Sync Frame ID and Sync Frame Deviation Table Setup

The CC writes a copy of the internal synchronization frame ID and deviation tables into the FlexRay memory area if requested by the application. The application must provide the appropriate amount of FlexRay memory area for the tables. The memory layout of the tables is given in Figure 47-27. Each table occupies 120 16-bit entries.

While the protocol is in *POC:config* state, the application must program the offsets for the tables into the Sync Frame Table Offset Register (FR_SFTOR).

47.8.12.4 Sync Frame ID and Sync Frame Deviation Table Generation

The application controls the generation process of the Sync Frame ID and Sync Frame Deviation Tables into the FlexRay memory area using the Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR). A summary of the copy modes is given in the table below.

Table 47-52. Sync Frame Table Generation Modes

FR_SFTCCSR			Description
OPT	SDVEN	SIDEN	
0	0	0	No Sync Frame Table copy
0	0	1	Sync Frame ID Tables will be copied continuously
0	1	0	Reserved
0	1	1	Sync Frame ID Tables and Sync Frame Deviation Tables will be copied continuously
1	0	0	No Sync Frame Table copy
1	0	1	Sync Frame ID Tables for next even-odd-cycle pair will be copied
1	1	0	Reserved
1	1	1	Sync Frame ID Tables and Sync Frame Deviation Tables for next even-odd-cycle pair will be copied

The Sync Frame Table generation process is described in the following for the even cycle. The same sequence applies to the odd cycle.

If the application has enabled the sync frame table generation by setting FR_SFTCCSR[SIDEN] to 1, the CC starts the update of the even cycle related tables after the start of the NIT of the next even cycle. The CC checks if the application has locked the tables by reading the FR_SFTCCSR[ELKS] lock status bit. If this bit is set, the CC will not update the table in this cycle. If this bit is cleared, the CC locks this table and starts the table update. To indicate that these tables are currently updated and may contain inconsistent data, the CC clears the even table valid status bit FR_SFTCCSR[EVAL]. Once all table entries related to the even cycle have been transferred into the FlexRay memory area, the CC sets the even table valid bit FR_SFTCCSR[EVAL] and the Even Cycle Table Written Interrupt Flag EVT_IF in the Protocol Interrupt Flag Register 1 (FR_PIFR1). If the interrupt enable flag EVT_IE is set, an interrupt request is generated.

To read the generated tables, the application must lock the tables to prevent the CC from updating these tables. The locking is initiated by writing a 1 to the even table lock trigger FR_SFTCCSR[ELKT]. When the even table is not currently updated by the CC, the lock is granted and the even table lock status bit FR_SFTCCSR[ELKS] is set. This indicates that the application has successfully locked the even sync tables and the corresponding

status information fields SFRA, SFRB in the Sync Frame Counter Register (FR_SFCNTR). The value in the FR_SFTCCSR[CYCNUM] field provides the number of the cycle that this table is related to.

The number of available table entries per channel is provided in the FR_SFCNTR[SFEVA] and FR_SFCNTR[SFEVB] fields. The application can now start to read the sync table data from the locations given in Figure 47-27.

After reading all the data from the locked tables, the application must unlock the table by writing to the even table lock trigger FR_SFTCCSR[ELKT] again. The even table lock status bit FR_SFTCCSR[ELKS] is reset immediately.

If the sync frame table generation is disabled, the table valid bits FR_SFTCCSR[EVAL] and FR_SFTCCSR[EVAL] are reset when the counter values in the Sync Frame Counter Register (FR_SFCNTR) are updated. This is done because the tables stored in the FlexRay memory area are no longer related to the values in the Sync Frame Counter Register (FR_SFCNTR).

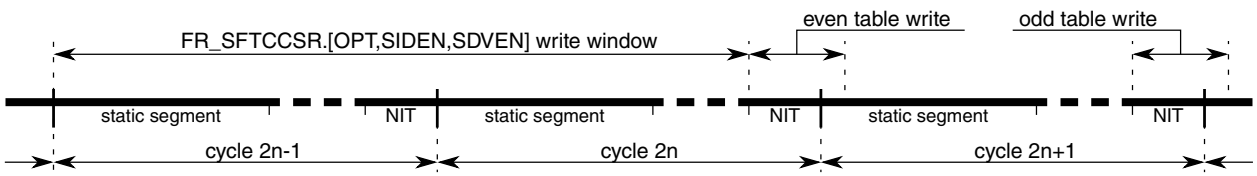

Figure 47-28. Sync Frame Table Trigger and Generation Timing

47.8.12.5 Sync Frame Table Access

The sync frame tables will be transferred into the FlexRay memory area during the table write windows shown in Figure 47-27. During the table write, the application can not lock the table that is currently written. If the application locks the table outside of the table write window, the lock is granted immediately.

47.8.12.5.1 Sync Frame Table Locking and Unlocking

The application locks the even/odd sync frame table by writing 1 to the lock trigger bit ELKT/OLKT in the Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR). If the affected table is not currently written to the FlexRay memory area, the lock is granted immediately, and the lock status bit ELKS/OLKS is set. If the affected table is currently written to the FlexRay memory area, the lock is not granted. In this case, the application must issue the lock request again until the lock is granted.

The application unlocks the even/odd sync frame table by writing 1 to the lock trigger bit ELKT/OLKT. The lock status bit ELKS/OLKS is cleared immediately.

47.8.13 MTS Generation

The CC provides a flexible means to request the transmission of the Media Access Test Symbol MTS in the symbol window on channel A or channel B.

The application can configure the set of communication cycles in which the MTS will be transmitted over the FlexRay bus by programming the CYCCNTMSK and CYCCNTVAL fields in the MTS A Configuration Register (FR_MTSACFR) and MTS B Configuration Register (FR_MTSBCFR).

The application enables or disables the generation of the MTS on either channel by setting or clearing the MTE control bit in the MTS A Configuration Register (FR_MTSACFR) or MTS B Configuration Register (FR_MTSBCFR). If an MTS is to be transmitted in a certain communication cycle, the application must set the MTE control bit during the static segment of the preceding communication cycle.

The MTS is transmitted over channel A in the communication cycle with number CYCCNT, if the following equations are fulfilled.

$$FR_PSR0[PROTSTATE] = POC:\ normalactive$$

Equation 29

$$FR_MTSACRF[MTE] = 1$$

Equation 30

$$CYCCNT \,\&\, FR_MTSACFR[CYCCNTMSK] = FR_MTSACFR[CYCCNTVAL] \,\&\, FR_MTSACFR[CYCCNTMSK]$$

Equation 31

The MTS is transmitted over channel B in the communication cycle with number CYCCNT, if the following equations are fulfilled.

$$FR_MTSBCRF[MTE] = 1$$

Equation 32

$$CYCCNT \,\&\, FR_MTSBCFR[CYCCNTMSK] = FR_MTSBCFR[CYCCNTVAL] \,\&\, FR_MTSBCFR[CYCCNTMSK]$$

Equation 33

47.8.14 Key Slot Transmission

Key slot assignment, transmission in POC:startup state, and transmission in POC:normal active state are discussed in this section.

47.8.14.1 Key Slot Assignment

A key slot is assigned to the CC if the key_slot_id field in the Protocol Configuration Register 18 (FR_PCR18) is configured with a value greater than 0 and less or equal to number_of_static_slots in Protocol Configuration Register 2 (FR_PCR2), otherwise no key slot is assigned.

47.8.14.2 Key Slot Transmission in POC:startup

If a key slot is assigned and the CC is in the *POC:startup* state, startup null frames will be transmitted as specified by FlexRay Communications System Protocol Specification, Version *2.1 Rev A* .

47.8.14.3 Key Slot Transmission in POC:normal active

If a key slot is assigned and the CC is in *POC:normal active*, a frame of the type as shown in the following table is transmitted. If a transmit message buffer is configured for the key slot and a valid message is available, a message frame is transmitted (see Message Transmission). If no transmit message buffer is configured for the key slot or no valid message is available, a null frame is transmitted (see Null Frame Transmission).

Table 47-53. Key Slot Frame Type

FR_PCR11[key_slot_used_for_sync]	FR_PCR11[key_slot_used_for_startup]	key slot frame type
0	0	normal frame
0	1	normal frame1[1]
1	0	sync frame
1	1	startup frame

1. The frame transmitted has an semantically incorrect header and will be detected as an invalid frame at the receiver.

47.8.15 Sync Frame Filtering

Each received synchronization frame must pass the Sync Frame Acceptance Filter and the Sync Frame Rejection Filter before it is considered for clock synchronization. If the synchronization frame filtering is globally disabled, i.e. the SFFE control bit in the Module Configuration Register (FR_MCR) is cleared, all received synchronization

frames are considered for clock synchronization. If a received synchronization frame did not pass at least one of the two filters, this frame is processed as a normal frame and is not considered for clock synchronization.

47.8.15.1 Sync Frame Acceptance Filtering

The synchronization frame acceptance filter is implemented as a value-mask filter. The value is configured in the Sync Frame ID Acceptance Filter Value Register (FR_SFIDAFVR) and the mask is configured in the Sync Frame ID Acceptance Filter Mask Register (FR_SFIDAFMR). A received synchronization frame with the frame ID FID passes the sync frame acceptance filter, if the following equations evaluates to true.

$$FR_MCR[SFFE] = 0$$

Equation 34

$$FID \,\&\, FR_SFIDAFMR[FMSK] = FR_SFIDAFVR[FVAL] \,\&\, FR_SFIDAFMR[FMSK]$$

Equation 35

Note

Sync frames are transmitted in the static segment only. Thus FID <= 1023.

47.8.15.2 Sync Frame Rejection Filtering

The synchronization frame rejection filter is a comparator. The compare value is defined by the Sync Frame ID Rejection Filter Register (FR_SFIDRFR). A received synchronization frame with the frame ID FID passes the sync frame rejection filter if the following equations evaluates to true.

$$FR_MCR[SFFE] = 0$$

Equation 36

$$FID \neq FR_SFIDRFR[SYNFRID]$$

Equation 37

Note

Sync frames are transmitted in the static segment only. Thus FID <= 1023.

47.8.16 Strobe Signal Support

The CC provides a number of strobe signals for observing internal protocol timing related signals in the protocol engine. The signals are listed and described in the Strobe Signal Mapping table, located in the Register Descriptions section.

47.8.16.1 Strobe Signal Assignment

Each of the strobe signals listed in the Strobe Signal Mapping table, located in the Register Descriptions section, can be assigned to one of the four strobe ports using the Strobe Signal Control Register (FR_STBSCR). To assign multiple strobe signals, the application must write multiple times to the Strobe Signal Control Register (FR_STBSCR) with appropriate settings.

To read out the current settings for a strobe signal with number N, the application must execute the following sequence.

1. Write to FR_STBSCR with WMD = 1 and SEL = N. (updates SEL field only)
2. Read STBCSR.

   The SEL field provides N and the ENB and STBPSEL fields provides the settings for signal N.

47.8.16.2 Strobe Signal Timing

This section provides detailed timing information of the strobe signals with respect to the protocol engine clock.

The strobe signals display internal PE signals. Due to the internal architecture of the PE, some signals are generated several PE clock cycles before the actual action is performed on the FlexRay Bus. These signals are listed in the Strobe Signal Mapping table, located in the Register Descriptions section, with a negative clock offset. An example waveform is given in the following figure.

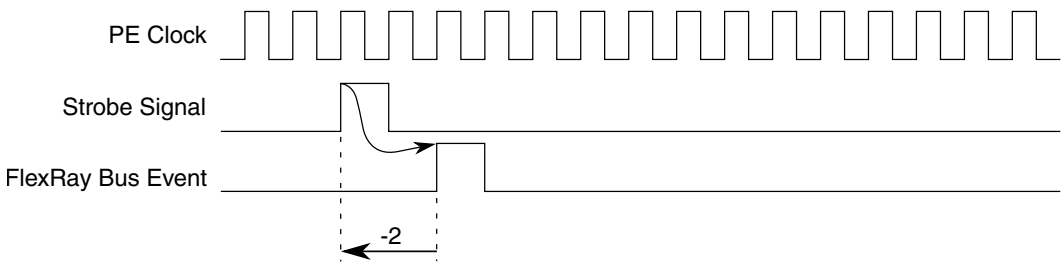

Figure 47-29. Strobe Signal Timing (type = pulse, clk_offset = -2)

Other signals refer to events that occurred on the FlexRay Bus some cycles before the strobe signal is changed. These signals are listed in the Strobe Signal Mapping table, located in the Register Descriptions section, with a positive clock offset. An example waveform is given in the figure below.

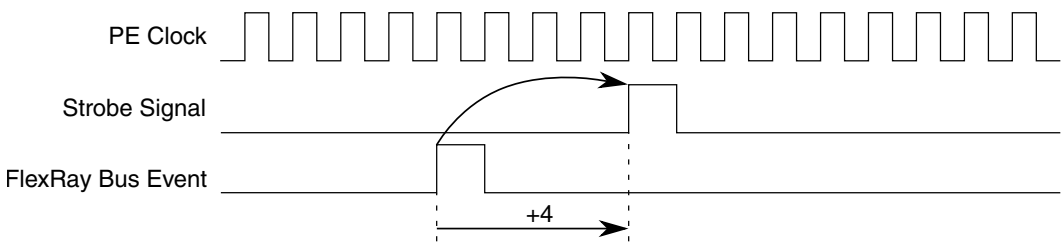

Figure 47-30. Strobe Signal Timing (type = pulse, clk_offset = +4)

47.8.17 Timer Support

The CC provides two timers, which run on the FlexRay time base. Each timer generates a maskable interrupt when it reaches a configured point in time. Timer T1 is an absolute timer. Timer T2 can be configured to be an absolute or a relative timer. Both timers can be configured to be repetitive. In the non-repetitive mode, timer stops if it expires. In repetitive mode, timer is restarted when it expires.

Both timers are active only when the protocol is in *POC:normal active* or *POC:normal passive* state. If the protocol is not in one of these modes, the timers are stopped. The application must restart the timers when the protocol has reached the *POC:normal active* or *POC:normal passive* state.

47.8.17.1 Absolute Timer T1

The absolute timer T1 has the protocol cycle count and the macrotick count as the time base. The timer 1 interrupt flag TI1_IF in the Protocol Interrupt Flag Register 0 (FR_PIFR0) is set at the macrotick start event, if the following equations are fulfilled.

$$CYCTR[CTCCNT] \& FR_TI1CYSR[T1_CYC_MSK] = FR_TI1CYSR[T1_CYC_VAL] \& FR_TI1CYSR[T1_CYC_MSK]$$

Equation 38

$$FR_MTCTR[MTCT] = FR_TI1MTOR[T1_MTOFFSET]$$

Equation 39

If the timer 1 interrupt enable bit TI1_IE in the Protocol Interrupt Enable Register 0 (FR_PIER0) is asserted, an interrupt request is generated.

The status bit T1ST is set when the timer is triggered, and is cleared when the timer expires and is non-repetitive. If the timer expires but is repetitive, the T1ST bit is not cleared and the timer is restarted immediately. The T1ST is cleared when the timer is stopped.

The corresponding Interrupt condition (i.e., when the abovementioned equations are fulfilled) also leads to an event out indication on an output port (*fr_evt_tim1*) based on the [TIM1_EE] bit of the Protocol Event Output Enable Register (FR_PEOER).

47.8.17.2 Absolute / Relative Timer T2

The timer T2 can be configured to be an absolute or relative timer by setting the T2_CFG control bit in the Timer Configuration and Control Register (FR_TICCR). The status bit T2ST is set when the timer is triggered, and is cleared when the timer expires and is non-repetitive. If the timer expires but is repetitive, the T2ST bit is not cleared and the timer is restarted immediately. The T2ST is cleared when the timer is stopped.

47.8.17.2.1 Absolute Timer T2

If timer T2 is configured as an absolute timer, it has the same functionality timer T1 but the configuration from Timer 2 Configuration Register 0 (FR_TI2CR0) and Timer 2 Configuration Register 1 (FR_TI2CR1) is used. On expiration of timer T2, the interrupt flag TI2_IF in the Protocol Interrupt Flag Register 0 (FR_PIFR0) is set. If the timer 1 interrupt enable bit TI1_IE in the Protocol Interrupt Enable Register 0 (FR_PIER0) is asserted, an interrupt request is generated.

The corresponding Interrupt condition for T2 also leads to an event out indication on an output port (*fr_evt_tim2*) based on the [TIM2_EE] bit of the Protocol Event Output Enable Register (FR_PEOER).

47.8.17.2.2 Relative Timer T2

If the timer T2 is configured as a relative timer, the interrupt flag TI2_IF in the Protocol Interrupt Flag Register 0 (FR_PIFR0) is set, when the programmed amount of macroticks MT[31:0], defined by Timer 2 Configuration Register 0 (FR_TI2CR0) and Timer 2 Configuration Register 1 (FR_TI2CR1), has expired since the trigger or restart of timer 2. The relative timer is implemented as a down counter and expires when it has reached 0. At the macrotick start event, the value of MT[31:0] is checked and then decremented. Thus, if the timer is started with MT[31:0] == 0, it expires at the next macrotick start.

The corresponding Interrupt condition for T2 also leads to an event out indication on an output port (*fr_evt_tim2*) based on the [TIM2_EE] bit of the Protocol Event Output Enable Register (FR_PEOER).

47.8.18 Slot Status Monitoring

The CC provides several means for slot status monitoring. All slot status monitors use the same slot status vector provided by the PE. The PE provides a slot status vector for each static slot, for each dynamic slot, for the symbol window, and for the NIT, on a per channel base. The content of the slot status vector is described in the "Slot Status Content" table below. The PE provides the slot status vector within the first macrotick after the end of the related slot/window/NIT, as shown in the below figure.

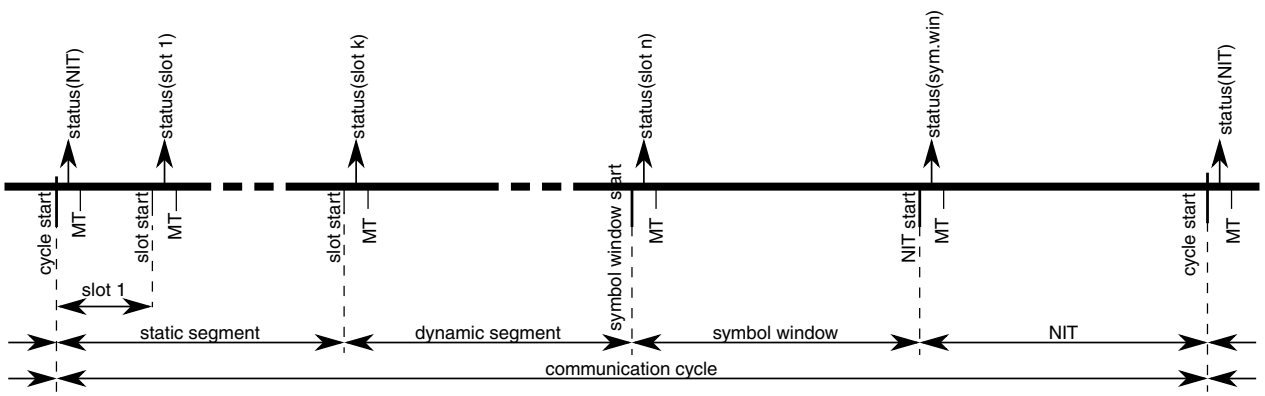

Figure 47-31. Slot Status Vector Update

Note

The slot status for the NIT of cycle n is provided after the start of cycle n+1.

Table 47-54. Slot Status Content

	Status Content
static /dynamic Slot	**slot related status**

Table continues on the next page...

Table 47-54. Slot Status Content (continued)

	Status Content
	vSS!ValidFrame - valid frame received
	vSS!SyntaxError - syntax error occurred while receiving
	vSS!ContentError - content error occurred while receiving
	vSS!BViolation - boundary violation while receiving
	for slots in which the module transmits:
	vSS!TxConflict - reception ongoing while transmission starts
	for slots in which the module does not transmit:
	vSS!TxConflict - reception ongoing while transmission starts
	first valid - channel that has received the first valid frame
	received frame related status
	extracted from
	a)header of valid frame, if vSS!ValidFrame = 1
	b) last received header, if vSS!ValidFrame = 0
	c) set to 0, if nothing was received
	vRF!Header!NFIndicator - Null Frame Indicator (0 for null frame)
	vRF!Header!SuFIndicator - Startup Frame Indicator
	vRF!Header!SyFIndicator - Sync Frame Indicator
Symbol Window	**window related status**
	vSS!ValidFrame - always 0
	vSS!ContentError - content error occurred while receiving
	vSS!SyntaxError - syntax error occurred while receiving
	vSS!BViolation - boundary violation while receiving
	vSS!TxConflict - reception ongoing while transmission starts
	received symbol related status
	vSS!ValidMTS - valid Media Test Access Symbol received
	received frame related status
	see static/dynamic slot
NIT	**NIT related status**
	vSS!ValidFrame - always 0
	vSS!ContentError - content error occurred while receiving
	vSS!SyntaxError - syntax error occurred while receiving
	vSS!BViolation - boundary violation while receiving
	vSS!TxConflict - always 0
	received frame related status
	see static/dynamic slot

47.8.18.1 Channel Status Error Counter Registers

The two channel status error counter registers, Channel A Status Error Counter Register (FR_CASERCR) and Channel B Status Error Counter Register (FR_CBSERCR), incremented by one, if at least one of four slot status error bits, *vSS!SyntaxError, vSS! ContentError, vSS!BViolation*, or *vSS!TxConflict* is set to 1. The status vectors for all slots in the static and dynamic segment, in the symbol window, and in the NIT are taken into account. The counters wrap round after they have reached the maximum value.

47.8.18.2 Protocol Status Registers

The Protocol Status Register 2 (FR_PSR2) provides slot status information about the Network Idle Time NIT and the Symbol Window. The Protocol Status Register 3 (FR_PSR3) provides aggregated slot status information.

47.8.18.3 Slot Status Registers

The eight slot status registers, Slot Status Registers (FR_SSR0–FR_SSR7), can be used to observe the status of static slots, dynamic slots, the symbol window, or the NIT without individual message buffers. These registers provide all slot status related and received frame / symbol related status information, as given in Table 47-54, except of the *first valid* indicator for non-transmission slots.

47.8.18.4 Slot Status Counter Registers

The CC provides four slot status error counter registers, Slot Status Counter Registers (FR_SSCR0–FR_SSCR3). Each of these slot status counter registers is updated with the value of an internal slot status counter at the start of a communication cycle. The internal slot status counter is incremented if its increment condition, defined by the Slot Status Counter Condition Register (FR_SSCCR), matches the status vector provided by the PE. All static slots, the symbol window, and the NIT status are taken into account. *Dynamic* slots are *excluded*. The internal slot status counting and update timing is shown in the figure below.

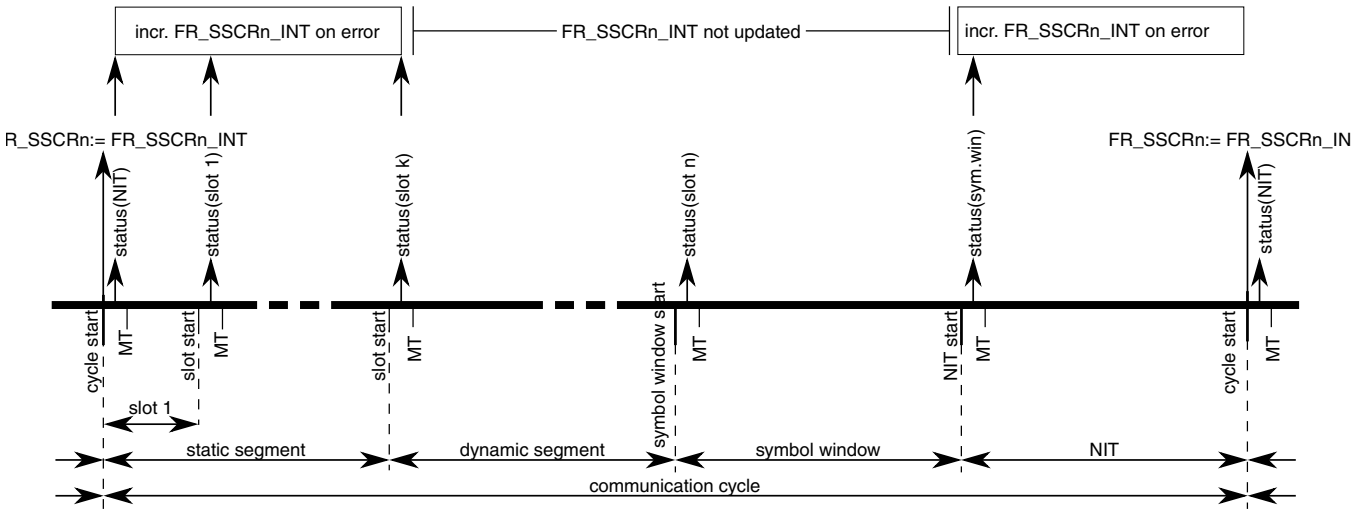

Figure 47-32. Slot Status Counting and FR_SSCRn Update

The PE provides the status of the NIT in the first slot of the next cycle. Due to these facts, the FR_SSCRn register reflects, in cycle n, the status of the NIT of cycle n-2, and the status of all static slots and the symbol window of cycle n-1.

The increment condition for each slot status counter consists of two parts, the frame related condition part and the slot related condition part. The internal slot status counter FR_SSCRn_INT is incremented if at least one of the conditions is fulfilled:

1. frame related condition:

   (FR_SSCCRn[VFR] | FR_SSCCRn[SYF] | FR_SSCCRn[NUF] | FR_SSCCRn[SUF]) // count on frame condition

   = 1;

   and

   ((~FR_SSCCRn[VFR] | vSS!ValidFrame) & // valid frame restriction

   (~FR_SSCCRn[SYF] | vRF!Header!SyFIndicator) & // sync frame indicator restriction

   (~FR_SSCCRn[NUF] | ~vRF!Header!NFIndicator) & // null frame indicator restriction

   (~FR_SSCCRn[SUF] | vRF!Header!SuFIndicator)) // startup frame indicator restriction

   = 1;

Note

The indicator bits SYF, NUF, and SUF are valid only when a valid frame was received. Thus it is required to set the VFR always, whenever count on frame condition is used.

slot related condition:

((FR_SSCCRn[STATUSMASK[3]] & vSS!SyntaxError) | // increment on syntax error

(FR_SSCCRn[STATUSMASK[2]] & vSS!ContentError) | // increment on content error

(FR_SSCCRn[STATUSMASK[1]] & vSS!BViolation) | // increment on boundary violation

(FR_SSCCRn[STATUSMASK[0]] & vSS!TxConflict)) // increment on transmission conflict

= 1;

If the slot status counter is in single cycle mode, i.e. FR_SSCCRn[MCY] = 0, the internal slot status counter FR_SSCRn_INT is reset at each cycle start. If the slot status counter is in the multicycle mode, i.e. FR_SSCCRn[MCY] = 1, the counter is not reset and incremented, until the maximum value is reached.

47.8.18.5 Message Buffer Slot Status Field

Each individual message buffer and each FIFO message buffer provides a slot status field, which provides the information shown in Table 47-54 for the static/dynamic slot. The update conditions for the slot status field depend on the message buffer type. Refer to the Message Buffer Update Sections in Individual Message Buffer Configuration Data.

47.8.19 System Bus Access

This section provides a description of the system bus accesses failures and the related CC behavior. System bus access failures may occur when the CC transfers data to or from the FlexRay memory area.

The system bus access failure types are described in System Bus Access Failure Types.

The behavior of the CC after the occurrence of a system bus access failure is described in System Bus Access Failure Response.

47.8.19.1 System Bus Access Failure Types

This section describes the two types of system bus access failures.

47.8.19.1.1 System Bus Illegal Address Access

A system bus illegal address access is detected when the CC has used an illegal or invalid address to access the FlexRay system memory area. There are three conditions which are treated as a system bus illegal address access:

- The system bus subsystem detects an CC access to an illegal system memory address.
- The CC detects the usage of an data field offset with the value of 0.
- The CC detects a memory error while reading a data field offset from the CHI LRAM memory (see CHI LRAM Error Response after CC Read).

If a system bus illegal address access is detected, the CC sets the ILSA_EF flag in the CHI Error Flag Register (FR_CHIERFR).

47.8.19.1.2 System Bus Access Timeout

A system bus access timout is detected if an access to the FlexRay memory area is not finished in time. The timeout value is derived from the SYMATOR[TIMEOUT] setting (see Configure System Memory Access Time-Out Register (FR_SYMATOR)).

If a system bus access timout is detected, the CC sets the SBCF_EF flag in the CHI Error Flag Register (FR_CHIERFR).

47.8.19.2 System Bus Access Failure Response

This section describes the two types of behavior of the CC after the occurrence of a system bus access failure. The actual behavior is defined by the SBFF bit in the Module Configuration Register (FR_MCR).

47.8.19.2.1 Continue after System Bus Access Failure

If the SBFF bit in the Module Configuration Register (FR_MCR) is 0, the CC will continue its operation after the occurrence of the system bus access failure, but will not generate any system bus accesses until the start of the next communication cycle.Since no

data are read from or written to the FlexRay memory area, no messages are received or transmitted. Consequently, none of the individual message buffers or receive FIFOs will be updated until the next communication cycle starts.

If a frame is under transmission when the system bus failure occurs, a correct frame is generated with the remaining header and frame data are replaced by all zeros. Depending on the point in time this can affect the PPI bit, the Header CRC, the Payload Length in case of an dynamic slot, and the payload data. Starting from the next slot in the current cycle, no frames will be transmitted and received, except for the key slot, where a sync or startup null-frame is transmitted, if the key slot is assigned.

If a frame is received when the system bus failure occurs, the reception is aborted and the related receive message buffer is not updated.

Normal operation is resumed after the start of next communication cycle.

47.8.19.2.2 Freeze after System Bus Access Failure

If the SBFF bit in the Module Configuration Register (FR_MCR) is set to 1, the CC will go into the freeze mode immediately after the occurrence of one of the system bus access failures.

47.8.20 Interrupt Support

The CC provides 172 individual interrupt sources and five combined interrupt sources.

47.8.20.1 Individual Interrupt Sources

Message buffer interrupts are discussed in this section.

47.8.20.1.1 Message Buffer Interrupts

The CC provides 128 message buffer interrupt sources.

Each individual message buffer provides an interrupt flag FR_MBCCSRn[MBIF] and an interrupt enable bit FR_MBCCSRn[MBIE]. The CC sets the interrupt flag when the slot status of the message buffer was updated. If the interrupt enable bit is asserted, an interrupt request is generated.

47.8.20.1.2 FIFO Interrupts

The CC provides 2 FIFO interrupt sources.

Each of the 2 FIFO provides a Receive FIFO Almost Full Interrupt Flag. The CC sets the Receive FIFO Almost Full Interrupt Flags (FR_GIFER[FAFBIF], FR_GIFER[FAFAIF]) in the Global Interrupt Flag and Enable Register (FR_GIFER) if the corresponding Receive FIFO fill level exceeds the defined watermark.

47.8.20.1.3 Wakeup Interrupt

The CC provides one interrupt source related to the wakeup.

The CC sets the Wakeup Interrupt Flag FR_GIFER[WUPIF] when it has received a wakeup symbol on the FlexRay bus. The CC generates an interrupt request if the interrupt enable bit FR_GIFER[WUPIE] is asserted.

47.8.20.1.4 Protocol Interrupts

The CC provides 25 interrupt sources for protocol related events. For details, see Protocol Interrupt Flag Register 0 (FR_PIFR0) and Protocol Interrupt Flag Register 1 (FR_PIFR1). Each interrupt source has its own interrupt enable bit.

47.8.20.1.5 CHI Interrupts

The CC provides 16 interrupt sources for CHI related error events. For details, see CHI Error Flag Register (FR_CHIERFR). There is one common interrupt enable bit FR_GIFER[CHIE] for all CHI error interrupt sources.

47.8.20.2 Combined Interrupt Sources

Each combined interrupt source generates an interrupt request only when at least one of the interrupt sources that is combined generates an interrupt request.

47.8.20.2.1 Receive Message Buffer Interrupt

The Receive Message Buffer Interrupt request is generated when at least one of the individual receive message buffers generates an interrupt request MBXIRQ[n] and the interrupt enable bit FR_GIFER[RBIE] is set.

47.8.20.2.2 Transmit Message Buffer Interrupt

The Transmit Message Buffer Interrupt request is generated when at least one of the individual transmit message buffers generates an interrupt request MBXIRQ[n] and the interrupt enable bit FR_GIFER[TBIE] is asserted.

47.8.20.2.3 Protocol Interrupt

The Protocol Interrupt request is generated when at least one of the individual protocol interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[PRIE] is set..

47.8.20.2.4 CHI Interrupt

The CHI Interrupt request is generated when at least one of the individual chi error interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[CHIE] is set.

47.8.20.2.5 Module Interrupt

The Module Interrupt request is generated if at least one of the combined interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[MIE] is set.

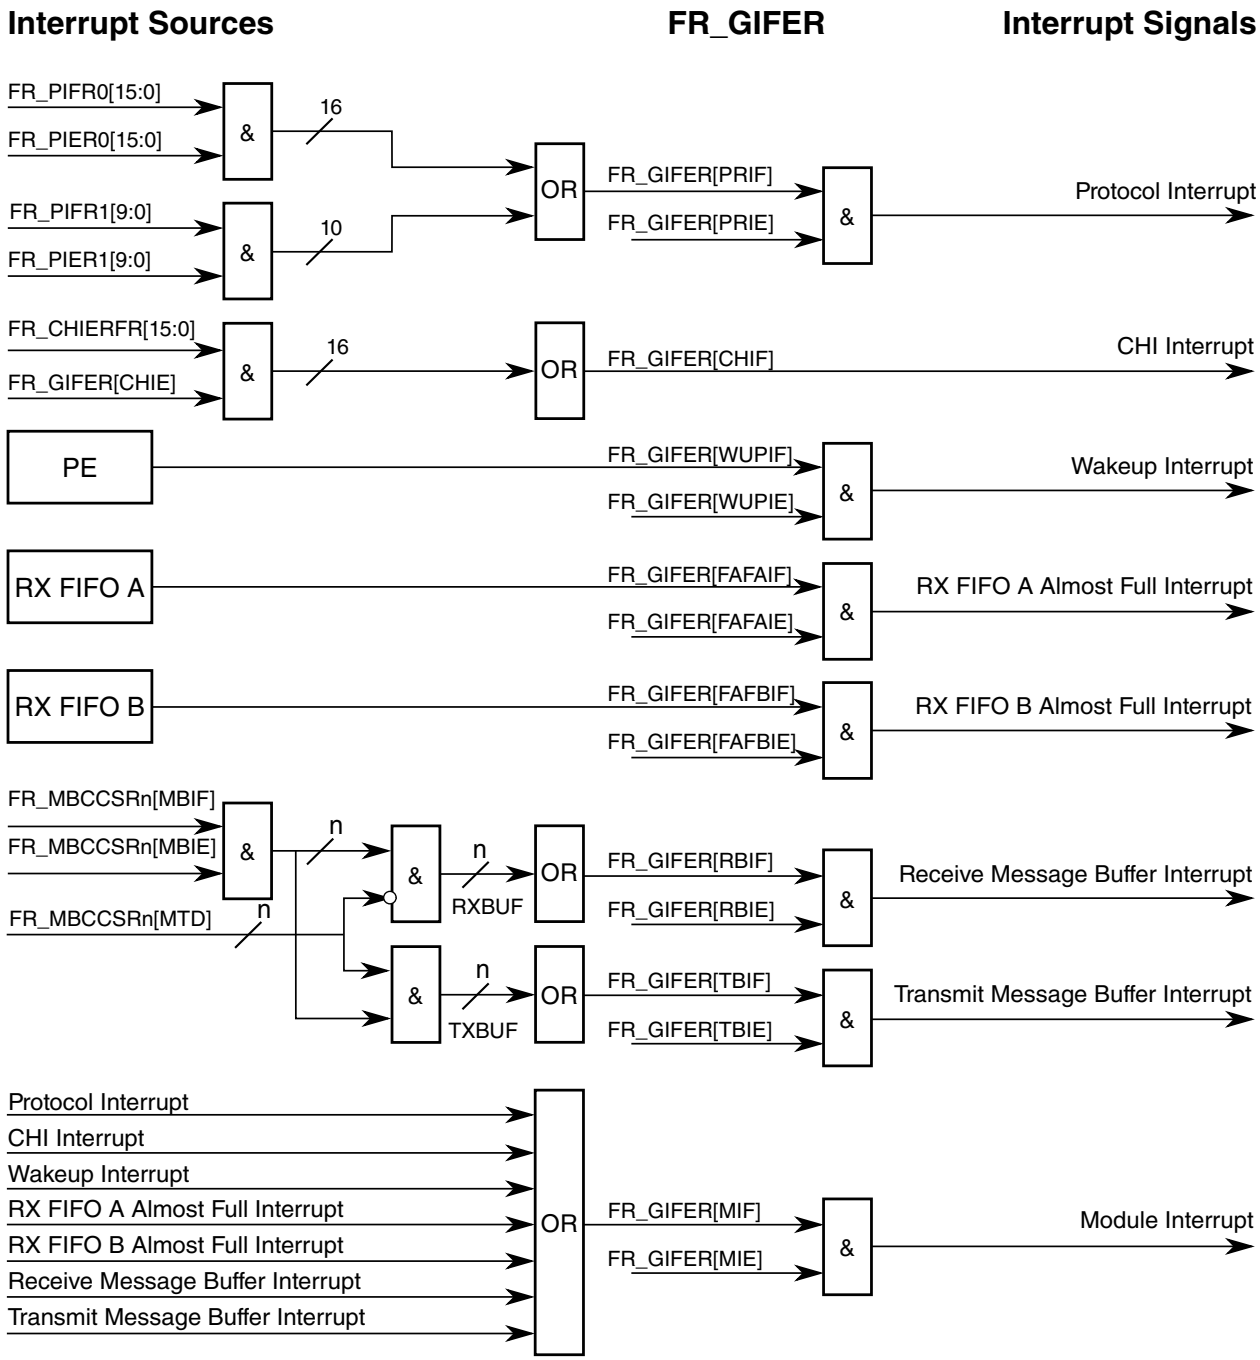

Figure 47-33. Scheme of FR_GIFER interrupt signal generation

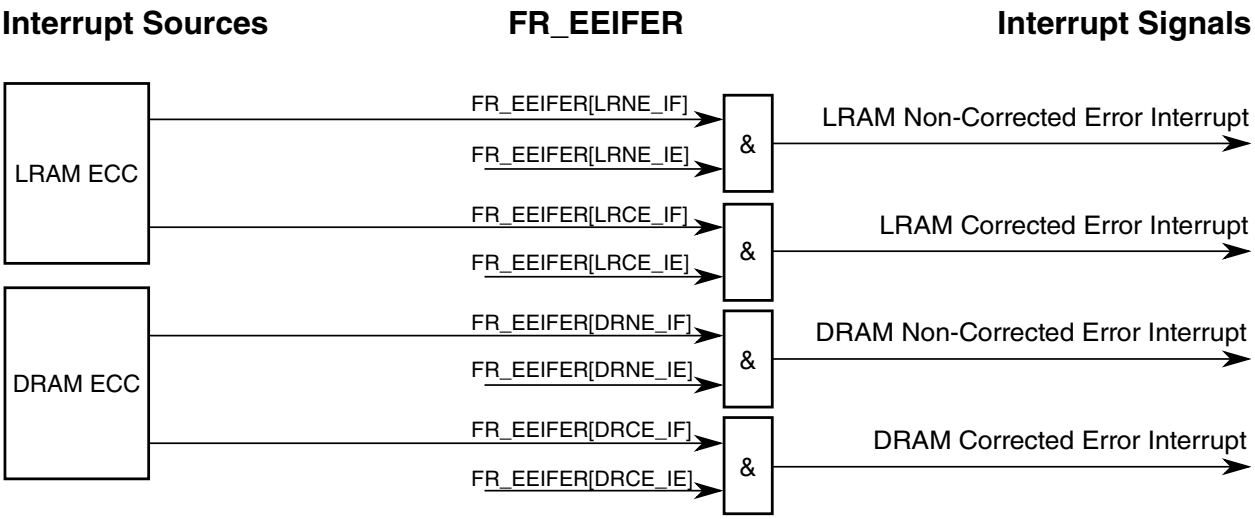

Figure 47-34. Scheme of FR_EEIFER interrupt signal generation

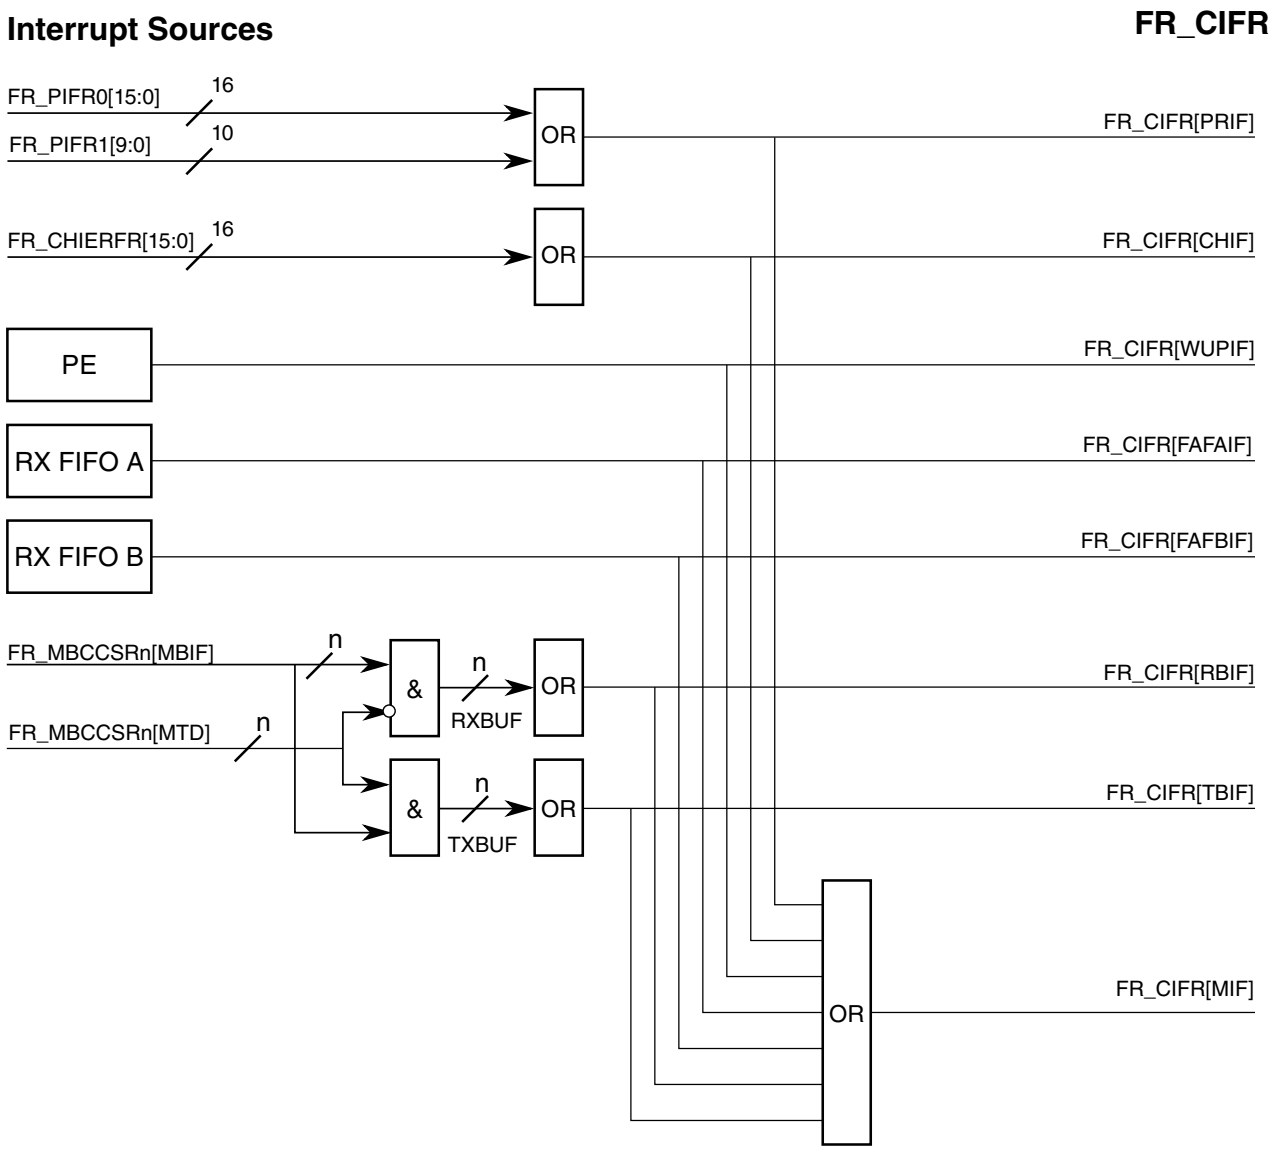

Figure 47-35. Scheme of FR_CIFR flags generation

47.8.21 Lower Bit Rate Support

The CC supports a number of lower bit rates on the FlexRay bus channels. The lower bit rates are implemented by modifying the duration of the microtick *pdMicrotick*, the number of samples per microtick *pSamplesPerMicrotick*, the number of samples per bit *cSamplesPerBit*, and the strobe offset *cStrobeOffset*. The application configures the FlexRay channel bit rate by setting the BITRATE field in the Module Configuration Register (FR_MCR). The protocol values are set internally. The available bit rates, the related BITRATE field configuration settings and related protocol parameter values are shown in the "FlexRay Channel Bit Rate Control" table below.

Table 47-55. FlexRay Channel Bit Rate Control

FlexRay Channel Bit Rate [Mbit/s]	FR_MCR[BITRATE]	*pdMicrotick [ns]*	*gdSampleClockPeriod [ns]*	*pSamplesPerMicrotick*	*cSamplesPerBit*	*cStrobeOffset*
10.0	000	25.0	12.5	2	8	5
8.0	011	25.0	12.5	2	10	6
5.0	001	25.0	25.0	1	8	5
2.5	010	50.0	50.0	1	8	5

Note

The bit rate of 8 Mbit/s is not defined by the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.

47.8.22 PE Data Memory (PE DRAM)

The PE Data Memory (PE DRAM) is 128 word, 16-bit wide memory with byte access, which contains the program data of the PE internal CPU. The PE DRAM is divided into two banks, 8-bit each. The memory data [7:0] are assigned to BANK0, the memory data [15:8] are assigned to BANK1.

Table 47-56. PE DRAM Layout

ADDR	BANK1	BANK0
0x00	byte1	byte0
0x01	byte3	byte2
…		
0x7F	byte255	byte254

The FlexRay module provides means to access the PE DRAM from the application. The PE DRAM application access is initiated and controlled via PE DRAM Access Register (FR_PEDRAR) and PE DRAM Access Register (FR_PEDRAR). This functionality is used to check the memory error detection.

47.8.22.1 PE DRAM Read Access

A read access from the PE DRAM can be initiated in any protocol state. The following sequence describes a read access from the PE DRAM address 0x70.

1. FR_PEDRAR:= 0x50E0;

   // INST=0x5; ADDR=070

2. wait until FR_PEDRAR[DAD] == 1;

   // wait for end of PE DRAM access

3. val = FR_PEDRDR[DATA];

   // read PE DRAM data

The read access is handled by the PE internal CPU with the lowest execution priority. This may cause an response delay with a maximum of 1000 PE clock cycle (25us).

47.8.22.2 PE DRAM Write Access

A write access into the PE DRAM can be initiated in any protocol state. The following sequence describes a write access to the PE DRAM address 0x70.

1. FR_PEDRDR:= DATA;

   // write value to be written into data register

2. FR_PEDRAR:= 0x30E0;

   // INST=0x3; ADDR=0x70

3. wait until FR_PEDRAR[DAD] == 1;

   // wait for end of PE DRAM access

4. val = FR_PEDRDR[DATA];

   // read back PE DRAM data

The write access is handled by the PE internal CPU with the lowest execution priority. This may causes an response delay with a maximum of 1000 PE clock cycle (25us).

If the conditions given in PE DRAM Write Access Limitations are fulfilled, the data provided in PE DRAM Access Regsiter (FR_PEDRAR) are written into the PE DRAM, read back in the next clock cycle and stored into the PE DRAM Access Register (FR_PEDRAR). Otherwise, data are not written into the PE DRAM and 0x0000 is stored into the PE DRAM Access Register (FR_PEDRAR).

47.8.22.3 PE DRAM Write Access Limitations

The PE DRAM is used by the protocol engine if the module is not in *POC:default config* state. The only address not used by the protocol engine is 0x70. To prevent the corruption of protocol engine data the following PE DRAM write access limitations apply for application writes.

1. When the module is in *POC:default config* state, all PE DRAM addresses are writable.
2. When the module is not *in POC:default config* state, only PE DRAM address 0x70 is writable.

47.8.23 CHI Lookup-Table Memory (CHI LRAM)

The CHI Lookup-Table Memory (CHI LRAM) is an CHI internal memory which contains the message buffer configuration data and the data field offsets for the physical message buffers. The configuration data for two message buffers or 6 data field offsets are contained in one memory row. The CHI LRAM is divided into 6 memory BANKs.

Table 47-57. CHI LRAM Layout

ADR	BANK5	BANK4	BANK3	BANK2	BANK1	BANK0
0x00	FR_MBIDXR1	FR_MBFIDR1	FR_MBCCFR1	FR_MBIDXR0	FR_MBFIDR0	FR_MBCCFR0
0x01	FR_MBIDXR3	FR_MBFIDR3	FR_MBCCFR3	FR_MBIDXR2	FR_MBFIDR2	FR_MBCCFR2
…						
0x3F	FR_MBIDXR127	FR_MBFIDR127	FR_MBCCFR127	FR_MBIDXR126	FR_MBFIDR126	FR_MBCCFR126
0x40	FR_MBDOR5	FR_MBDOR4	FR_MBDOR3	FR_MBDOR2	FR_MBDOR1	FR_MBDOR0
…						
0x55	FR_MBDOR131	FR_MBDOR130	FR_MBDOR129	FR_MBDOR128	FR_MBDOR127	FR_MBDOR126
0x56	FR_LEETR5	FR_LEETR4	FR_LEETR3	FR_LEETR2	FR_LEETR1	FR_LEETR0

47.8.23.1 CHI LRAM Read and Write Access

The CHI LRAM is accessed by the application via regular register read and write accesses.

47.8.24 Memory Content Fault Detection

The FlexRay module provides integrated memory content error detection for both the CHI LRAM and PE DRAM, and memory content error correction for the PE DRAM. The memory error detection for the CHI LRAM uses an standard Hamming code with a Hamming distance of 3 and detects all single-bit and double-bit errors (SEDDED) . The memory error detection and correction for the PE DRAM uses an enhanced Hamming code with a Hamming distance of 4 and detects and corrects all single-bit errors and detects all double-bit errors (SECDED).

This section describes the reporting of the occurrence of memory content errors, the reaction of the module on the occurrence, and how the application can inject memory errors in order to trigger the report and response behavior.

47.8.24.1 Memory Error Types

A memory error is the distortion of one or more bits read out of the memory. The reading of the values of all zeros and all ones is considered as an special case. The FlexRay module detects and indicates the memory errors as shown in the "Detected Memory Error Types" table below. The entries on the top have higher priority.

Each memory read access reads out *all* banks of the addressed row, and runs error detection on *all* banks, even in the case that the application has triggered a read from only one bank. This may lead to the reporting of an memory error if at least one bank contains a memory error, even if an error free bank has been read.

Table 47-58. Detected Memory Error Types

Memory	Priority	Memory Data	Indication
CHI LRAM	0 (highest)	All Zero's	Non-Corrected Error
PE DRAM			Non-Corrected Error
CHI LRAM		All One's	Non-Corrected Error
PE DRAM			
CHI LRAM	1 (lowest)	One Bit Flipped	Non-Corrected Error
PE DRAM			Corrected Error

Table continues on the next page...

Table 47-58. Detected Memory Error Types (continued)

Memory	Priority	Memory Data	Indication
CHI LRAM		Two Bits Flipped	Non-Corrected Error
PE DRAM			
CHI LRAM		Three or more Bits Flipped	one out of {No error, Non-Corrected Error}, defined by coding given in CHI LRAM Checkbits and CHI LRAM Syndrome
PE DRAM			one out of {No error, Corrected Error, Non-Corrected Error}, defined by coding given in PE DRAM Checkbits and PE DRAM Syndrome

47.8.24.2 Memory Error Reporting

The memory error reporting is enabled only if the ECC functionality enable bit ECCE in the Module Configuration Register (FR_MCR) is set.

For each of the two memories exists two sets of internal registers to store the detection of one corrected and one non-corrected memory error.

If a memory error is detected, the module checks whether the related error interrupt flag in the ECC Error Interrupt Flag and Enable Register (FR_EEIFER) is set.

- *If the error interrupt flag is set, the related internal error reporting register is not updated and the related error overflow flag is set to 1 to indicate a loss of error condition.*
- *If the error interrupt flag is not set, the internal reporting register is updated and the error interrupt flag is set to 1. If two or more memory errors of the same type are detected, the error for the bank with the lower bank number will be reported, and the error overflow flag will be set to 1.*

If a memory error is detected for at least two banks of one memory, the related error overflow flag is set to 1 to indicate a loss of error condition.

In addition to above the Error indications (corrected / non corrected) along with the failing address is sent out from the module for external error logging and corrective actions by the Software.

47.8.24.2.1 PE DRAM Checkbits

The coding of the checkbits reported in ECC Error Report Code Register (FR_EERCR) for PE DRAM memory errors is shown in Table 47-58. This table shows the implemented enhanced Hamming code. If the error injection was applied to distort the checkbits, then the distorted checkbits are reported.

Table 47-59. PE DRAM checkbits coding

CODE	CODE				DATA							
	3	2	1	0	7	6	5	4	3	2	1	0
4[1]	X	X	X	X	X	X	X	X	X	X	X	X
3[2]	-	-	-	-	X	X	X	X	-	-	-	-
2	-	-	-	-	X	-	-	-	X	X	X	-
1	-	-	-	-	-	X	X	-	X	X	-	X
0	-	-	-	-	-	X	-	X	X	-	X	X

1. The checkbit CODE[4] is set to 1 if and only if there is a even number of 1's in columns with X.
2. The checkbits CODE[3]… CODE[0] are set to 1 if and only if there is a odd number of 1's in all columns with X.

This coding of the checkbit ensures that neither 0x000 nor 0xFFF are valid code words and written into the memory.

47.8.24.2.2 PE DRAM Syndrome

The coding of the syndrome reported in ECC Error Report Code Register (FR_EERCR) for PE DRAM memory errors is shown in the following table.

Table 47-60. FR_EERCR[CODE] PE DRAM Syndrome Coding

FR_EERCR[CODE]		Description
[4]	[3:0]	
0x1	0x0	No Error (Never appears in error report registers)
0x0	0x0	If data == 0: Non Corrected Error (Dedicated Handling of All Zero Code Word) If data!= 0: Corrected Error (Parity Bit 4)
0x0	0x1	Corrected Error (Parity Bit 0)
0x0	0x2	Corrected Error (Parity Bit 1)
0x0	0x3	Corrected Error (Data Bit 0)
0x0	0x4	Corrected Error (Parity Bit 2)
0x0	0x5	Corrected Error (Data Bit 1)
0x0	0x6	Corrected Error (Data Bit 2)
0x0	0x7	Corrected Error (Data Bit 3)
0x0	0x8	Corrected Error (Parity Bit 3)
0x0	0x9	Corrected Error (Data Bit 4)

Table continues on the next page...

Table 47-60. FR_EERCR[CODE] PE DRAM Syndrome Coding (continued)

FR_EERCR[CODE]		Description
[4]	[3:0]	
0x0	0xA	Corrected Error (Data Bit 5)
0x0	0xB	Corrected Error (Data Bit 6)
0x0	0xC	Corrected Error (Data Bit 7)
0x0	0xD-0xF	Non-Corrected Error
0x1	0x1-0xF	Non-Corrected Error

47.8.24.2.3 CHI LRAM Checkbits

The coding of the checkbits reported in ECC Error Report Code Register (FR_EERCR) for CHI LRAM memory errors is shown in the table below. This table shows the implemented Hamming code. If the error injection was applied to distort the checkbits, then the distorted checkbits are reported.

Table 47-61. CHI LRAM checkbits coding

CODE[1]	DATA															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
4	X	X	X	X	X	-	-	-	-	-	-	-	-	-	-	-
3	-	-	-	-	-	X	X	X	X	X	X	X	-	-	-	-
2	X	X	-	-	-	X	X	X	X	-	-	-	X	X	X	-
1	-	-	X	X	-	X	X	-	-	X	X	-	X	X	-	X
0	X	-	X	-	X	X	-	X	-	X	-	X	X	-	X	X

1. The checkbit CODE[n] is set to 1 if and only if there is a odd number of 1's in all columns with X.

47.8.24.2.4 CHI LRAM Syndrome

The coding of the syndrome reported in ECC Error Report Code Register (FR_EERCR) for CHI LRAM memory errors is shown in the next table.

Table 47-62. FR_EERCR[CODE] CHI LRAM Syndrome Coding

FR_EERCR[CODE]	Description
0x00	No Error (Never appears in error report registers)
0x01-0x1F	Non Corrected Error

47.8.24.3 Memory Error Response

The memory error response is enabled only when the ECC functionality enable bit ECCE in the Module Configuration Register (FR_MCR) is set.

In case of the detection of a *corrected* memory error, the FlexRay module continues its normal operation using the corrected data word. This section describes the behavior of the FlexRay module after the detection of a *non-corrected* memory error.

47.8.24.3.1 CHI LRAM Error Response after CC Read

When the CC is out of the *POC:default config* state, it reads the configuration data and the data field offsets of all utilized message buffers in every slot and in the NIT. If a non-corrected memory error is detected during this module read access the error response of the module depends from LRAM location where the error occurred.

- *If the LRAM address belongs to physical message buffer configuration data the FlexRay module will consider the affected message buffer as disabled for the current search and will exclude this buffer from the search. The configuration of the affected message buffer is not changed.*

  If the affected message buffer is a tx message buffer, no frame will be transmitted from this message buffer in the next slot. If the affected message buffer is a rx message buffer, no frame will be received to this message buffer in the next slot.

- *If the LRAM address belongs to the data field offset area and the related physical message buffer is used for Rx or Tx the first access to the system memory caused by payload read or write yields to the assertion of the FR_CHIERFR[ILSA_EF]. No memory access occurs w.r.t. payload access is performed for the complete frame.*

47.8.24.3.2 CHI LRAM Error Response after Application Read

The application can read the content of the CHI LRAM via reading the FR_MBCCFRn, FR_MBFIDRn, FR_MBIDXRn, FR_MBDORn, and FR_LEETRn registers. If a non-corrected memory error is detected during this kind of read access, the module indicates the detected memory error, delivers the non-corrected data read and continues its normal operation.

47.8.24.3.3 PE DRAM Error Response after CC Read

If the CC detects an non-corrected memory error during internal read of program data which is contained in PE DRAM, this is considered as an fatal protocol error and the module enters the protocol freeze state immediately.

47.8.24.3.4 PE DRAM Error Response after Application Read in *POC:default config* state

If the CC detects an non-corrected memory error during an application triggered read from any PE DRAM address and the protocol is in the *POC:default config* state, this is considered as an fatal protocol error and the module enters the protocol freeze state. This behavior allows for checking the freeze functionality in case of the detection of non-corrected errors.

47.8.24.3.5 PE DRAM Error Response after Application Read out of *POC:default config*

If the CC detects an non-corrected memory error during an application triggered read from any PE DRAM address, and the protocol is not in the *POC:default config* state, this error is not considered as an fatal error and the protocol state is not changed. This prevents any interference of the running protocol by PE DRAM error injection reads.

47.8.25 Memory Fault Injection

The error injection functionality is used by the application to inject data errors into the memories to trigger and check the memory error detection functionality.

The error injection is enabled only if the ECC functionality enable bit ECCE in the Module Configuration Register (FR_MCR) and the error injection enable control bit EIE in the ECC Error Report and Injection Control Register (FR_EERICR) are set.

The error injection mode is configured by the EIM configuration bit in the ECC Error Report and Injection Control Register (FR_EERICR).

When the error injection is enabled, each write access to the configured memory location will be distorted.

The injector has the same behavior for FlexRay module memory writes and application memory writes.

47.8.25.1 CHI LRAM Error Injection

The following sequence describes an memory error injection sequence for the CHI LRAM memory. This sequence consists of the setup of the error injector followed by an application triggered write access to provoke an distortion of the memory content. The content of the CHI LRAM is described in Table 47-57.

When the CC is in *POC:default config*, there are no limitations for the error injection and no impacts of error injection to the application. For error injection out of *POC:default config* see Memory Fault Injection out of POC:default config.

Injector Setup:

1. FR_MCR[ECCE]:= 1;

   // enable ECC functionality

2. FR_EERICR[EIE]:=I_MODE;

   // configure error injection mode

3. FR_EEIAR[MID]:= 1;

   // select CHI LRAM for error injection

4. FR_EEIAR[BANK]:= I_BANK;

   // select bank for error injection; I_BANK = {0,1,2,3,4,5}

5. FR_EEIAR[ADDR]:= I_ADDR;

   // select address for error injection; I_ADDR <= 0x 56

6. FR_EEIDR[DATA]:= D_DIST;

   // define data distortion pattern

7. FR_EEICR[CODE]:= C_DIST;

   // define checkbit distortion pattern

8. FR_EERICR[EIE]:=1;

   // enable error injection

Application Write Access:

If (I_BANK==0) -> FR_MBCCFR(2n) / FR_MBDOR(6k) / FR_LEETR0 := DATA;

If (I_BANK==1) -> FR_MBFIDR(2n) / FR_MBDOR(6k+1) / FR_LEETR1 := DATA;

If (I_BANK==2) -> FR_MBIDXR(2n) / FR_MBDOR(6k+2) / FR_LEETR2 := DATA;

If (I_BANK==3) -> FR_MBCCFR(2n+1) / FR_MBDOR(6k+3) / FR_LEETR3 := DATA;

If (I_BANK==4) -> FR_MBFIDR(2n+1) / FR_MBDOR(6k+4) / FR_LEETR4 := DATA;

If (I_BANK==5) -> FR_MBIDXR(2n+1) / FR_MBDOR(6k+5) / FR_LEETR5 := DATA;

// write DATA to the defined injection bank and injection address (see Table 47-57).

47.8.25.2 PE DRAM Error Injection

The following sequence describes an memory error injection sequence for the PE DRAM memory. This sequence consists of the setup of the error injector followed by an application triggered write access to provoke an distortion of the memory content.

When the FlexRay module is in *POC:default config*, there are no limitations for the error injection and no impacts of error injection to the application. For error injection out of *POC:default config* see PE DRAM Error Injection out of POC:default config.

Injector Setup:

1. FR_MCR[ECCE]:= 1;

   // enable ECC functionality

2. FR_EERICR[EIE]:=I_MODE;

   // configure error injection mode

3. FR_EEIAR[MID]:= 0;

   // select PE DRAM for error injection

4. FR_EEIAR[BANK]:= I_BANK;

   // define bank for error injection; I_BANK = {0,1}

5. FR_EEIAR[ADDR]:= I_ADDR;

   // define address for error injection; I_ADDR <= 0x7F

6. FR_EEIDR[DATA]:= D_DIST;

   // define data distortion pattern

7. FR_EEICR[CODE]:= C_DIST;

   // define checkbit distortion pattern

8. FR_EERICR[EIE]:=1;

   // enable error injection

Application Write Access (e.g. I_ADDR=0x70):

1. FR_PEDRAR:= 0x30E0;

   // INST=0x3; ADDR=0x70

2. wait until FR_PEDRAR[DAD] == 1;

   // wait for end of PE DRAM access

3. val = FR_PEDRDR[DATA]; |

   // get read back PE DRAM data

Note

The write access to the PE DRAM triggers an subsequent read access from PE DRAM in the next cycle, which triggers the detection of the distorted data.

47.8.26 StopWatch function

FlexRay supports a StopWatch function to facilitate OS synchronization to the FlexRay network. This provides a capability to capture the time difference in system clocks between the operating system timer tick and the FlexRay time base. This allows the software synchronization handler to adjust the OS clock to sync with the FR macrotick and are fulfilled.

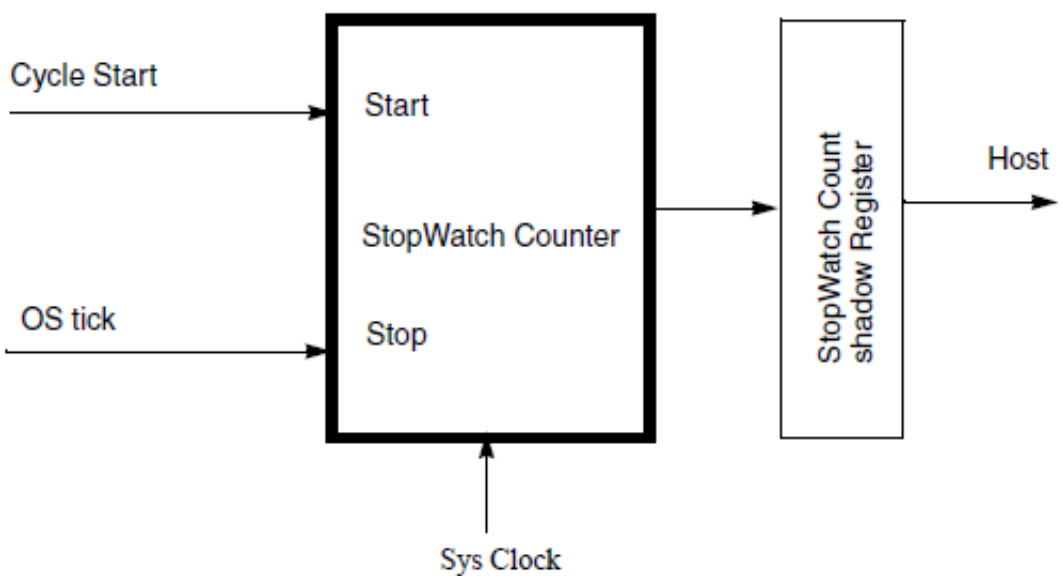

Figure 47-36. StopWatch counter logic

As shown below, there is a 32 bit stopwatch counter that resets and starts with each cycle start. This counter runs on the system clock and increments every cycle until an OS tick event is received, after which the counter halts and the count value is transferred to a shadow register. The shadow register (Stop Watch Count Register (FR_STPWR)) holds the counter value till the host reads all the 32 bits, after which it automatically gets cleared. The StopWatch logic is controlled through a control bit STPW_EN in the FR_PEOER (Protocol Event Output Enable and StopWatch Control Register (FR_PEOER). The counter runs only when this bit is set. The following figure shows the actual timing of the stopwatch counter logic operation.

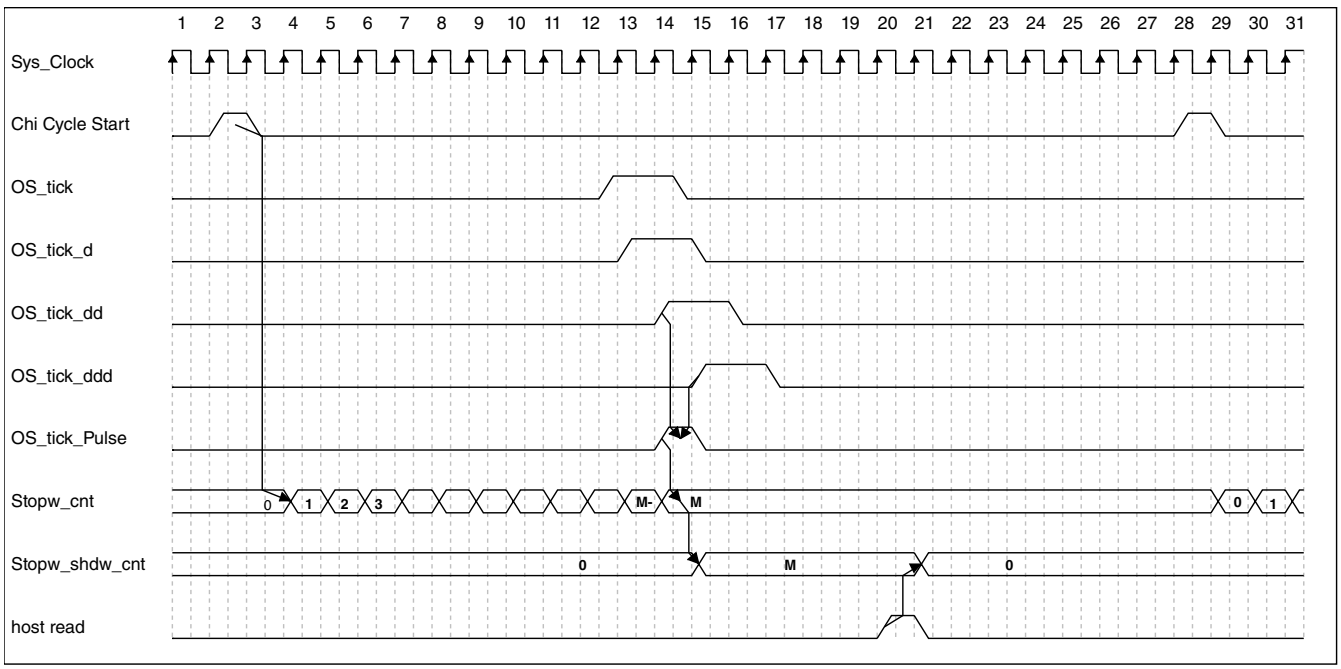

Figure 47-37. StopWatch function timing diagram

NOTE

'Host read' implies that all 32 bits have been read out completely. Any partial read (i.e for 8/16 bits access) will not clear the StopWatch count register.

NOTE

If cycle start and OS tick occurs simultaneously, timer will remain at 0. But OS_tick has a 2 stage synchronizer and cycle_start has a single stage synchronizer into chi clock domain. So simultaneously here means OS_tick_pulse and chi_cycle_start occurring at the same cycle.

47.9 Application Information

Module operation is discussed in this section.

47.9.1 Module Configuration

This section describes essential parts of the module configuration.

47.9.1.1 Configure System Memory Access Time-Out Register (FR_SYMATOR)

To ensure reliable operation of the CC, the application must ensure that the TIMEOUT value in System Memory Access Time-Out Register (FR_SYMATOR) and the CHI clock frequency f_{CHI} in MHz fulfill this equation[1] :

$$0 \le \mathrm{SYMATOR}[\mathrm{TIMEOUT}] \le \lfloor 0.45 \cdot f_{\mathrm{CHI}} - 8 \rfloor$$

Equation 40

For a given SYMATOR[TIMEOUT] value, f_{CHI} can be increased without causing unreliable operation of the CC. The same holds for reducing the SYMATOR[TIMEOUT] value for a given f_{CHI}.

Some examples for maximum values of the SYMATOR[TIMEOUT] for a minimum CHI frequency are given in the table below.

Table 47-63. Maximum SYMATOR[TIMEOUT] examples

f_{CHI}	SYMATOR[TIMEOUT]	f_{CHI}	SYMATOR[TIMEOUT]
>= 18 MHz	0	>= 100 MHz	<= 37
>= 23 MHz	<= 2	>= 120 MHz	<= 46
>= 27 MHz	<= 4	>= 140 MHz	<= 55
>= 32 MHz	<= 6	>= 160 MHz	<= 64
>= 60 MHz	<= 19	>= 180 MHz	<= 73
>= 80 MHz	<= 28	>= 200 MHz	<= 82

1. See Controller Host Interface Clocking for all constraints of minimum CHI clock frequency.

47.9.1.1.1 System Bus Wait State Constraints

The SYMATOR[TIMEOUT] value corresponds directly to a certain acceptable number of wait states on the system bus.

For single channel configurations and if the sync frame table generation functionality is *not* used (FR_SFTCCSR[SDVEN,SIDEN] = 0) no timeout will be detected if less than 2 × SYMATOR[TIMEOUT]+1 wait states will be seen on the system bus for each system bus access.

For dual channel configurations, or if the sync frame table generation functionality is used, no timeout will be detected if less than SYMATOR[TIMEOUT]-1 wait states will be seen on the system bus for each system bus access.

47.9.1.2 Configure Data Field Offsets

The data field offsets are located in the Message Buffer Data Field Offset Registers (FR_MBDORn) and Receive FIFO Start Data Offset Register (FR_RFSDOR). The application has to configure the data field offset values for all message buffers which are used.

When the module is enabled, the initilization value of the FR_MBDORn[MBDO] and FR_RFSDOR[SDO] is 0. This value is considered to be illegal (see System Bus Illegal Address Access).

47.9.2 Initialization Sequence

This section describes the required steps to initialize the CC. The first subsection describes the steps required after a module reset, the second section describes the steps required after preceding shutdown of the CC.

47.9.2.1 Module Initialization

This section describes the module related initialization steps after a system reset.

1. Configure CC.
    a. configure the control bits in the Module Configuration Register (FR_MCR)
    b. configure the system memory base address in System Memory Base Address Register (FR_SYMBADR)
2. Enable the CC.

a. write 1 to the module enable bit MEN in the Module Configuration Register (FR_MCR)

The CC now enters the Normal Mode. The application can commence with the protocol initialization described in Protocol Initialization.

47.9.2.2 Protocol Initialization

This section describes the protocol related initialization steps.

1. Configure the Protocol Engine.
   a. issue CONFIG command via Protocol Operation Control Register (FR_POCR)
   b. wait for *POC:config* in Protocol Status Register 0 (FR_PSR0)
   c. configure the FR_PCR0,…, FR_PCR30 registers to set all protocol parameters
2. Configure the Message Buffers and FIFOs.
   a. set the number of message buffers used and the message buffer segmentation in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)
   b. define the message buffer data size in the Message Buffer Data Size Register (FR_MBDSR)
   c. configure each message buffer by setting the configuration values in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn), Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn), Message Buffer Frame ID Registers (FR_MBFIDRn), Message Buffer Index Registers (FR_MBIDXRn)
   d. configure the FIFOs
   e. issue CONFIG_COMPLETE command via Protocol Operation Control Register (FR_POCR)
   f. wait for *POC:ready* in Protocol Status Register 0 (FR_PSR0)

After this sequence, the CC is configured as a FlexRay node and is ready to integrate into the FlexRay cluster.

47.9.2.3 CHI LRAM Initialization

The initialization of the CHI LRAM is performed by the CC when it leaves the Disabled Mode. The unitization runs for 87 CHI clock cycles. All fields in the FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, FR_MBDORn, and LEETRn registers are initialized to 0. All application read or write accesses to these registers are delayed until the initialization is finished.

47.9.2.4 PE DRAM Initialization

The PE DRAM initialization is performed by the CC in the *POC:default config* state. This initialization runs for 4.8 µs, and will delay the state transition from *POC:default config* into *POC:config*.

47.9.3 Memory Fault Injection out of POC:default config

This section provides information for application driven memory fault injection out if *POC:default config*. The CC provides means to inject memory faults from the application without any impacts to the internal protocol operation of the CC.

47.9.3.1 CHI LRAM Error Injection out of POC:default config

The CC will never perform any internal read access from the LRAM ECC Error Test Registers (FR_LEETRn). Any memory errors injected into these CHI LRAM locations will never be detected by internal access, independent from the protocol state.

The application should use these registers and related CHI LRAM location to inject memory errors into the CHI LRAM. The injection sequence is described in CHI LRAM Error Injection.

47.9.3.2 PE DRAM Error Injection out of POC:default config

The CC will never perform any internal read access from the PE DRAM address 0x70. This is the only one PE DRAM address writable by the application out of the *POC:default config* state.

The application should use these PE DRAM location to inject memory errors into the PE DRAM. The injection sequence is described in PE DRAM Error Injection.

47.9.4 Shut Down Sequence

This section describes a secure shut down sequence to stop the CC gracefully. The main targets of this sequence are

- *finish all ongoing reception and transmission*
- *do not corrupt FlexRay bus and do not disturb ongoing FlexRay bus communication*

For a graceful shutdown the application shall perform the following tasks:

1. Disable all enabled message buffers.
   a. repeatedly write 1 to FR_MBCCSRn[EDT] until FR_MBCCSRn[EDS] == 0.
2. Stop Protocol Engine.
   a. issue HALT command via Protocol Operation Control Register (FR_POCR)
   b. wait for *POC:halt* in Protocol Status Register 0 (FR_PSR0)

47.9.5 Number of Usable Message Buffers

This section describes the required minimum CHI clock frequency for a specified number of utilized message buffers configured in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR), a configured mini-slot length *gdMinislot*, and a configured nominal macrotick length *gdMacrotick*[1].

Additional constraints for the minimum CHI clock frequency are given in Controller Host Interface Clocking.

The CC uses a sequential search algorithm to determine the individual message buffer assigned or subscribed to the next slot. This search is started at the start of slot and must be finished before the start of the next slot.

The shortest FlexRay slot is a corrected empty dynamic slot. An corrected empty dynamic slot is a mini-slot and consists of gdMinislot corrected macroticks with a duration of *gdMacrotick*. The minimum duration of an corrected macrotick is $gdMacrotick_{min}$ = 39 µT. This results in a minimum length of an correct slot

$$\Delta_{slotmin} = 39 \bullet pdMicrotick \bullet gdMinislot$$

Equation 41

1. See Controller Host Interface Clocking for all constraints of minimum CHI clock frequency.

The message buffer search engine runs on the CHI clock and evaluates one individual message buffer per CHI clock cycle. For internal status update operations and to account for clock domain crossing jitter, an additional amount of 27 CHI clock cycles is required to ensure correct search engine operation.

For a given number of utilized message buffers FR_MBSSUTR[LAST_MB_UTIL] + 1 and for a given CHI clock frequency f_{chi}, this results in a search duration of

$$\Delta_{search} = \frac{1}{f_{chi}} \bullet (FR_MBSSUTR[LAST_MB_UTIL] + 27)$$

Equation 42

The message buffer search must be finished within one slot which requires fulfillment of this equation::

$$\Delta_{search} \leq \Delta_{slotmin}$$

Equation 43

This results in the formula given below which determines the required minimum CHI frequency for a given number of message buffers that are utilized.

$$f_{chi} \geq \frac{(FR_MBSSUTR[LAST_MB_UTIL]+27)}{39 \bullet pdMicrotick \bullet gdMinislot}$$

Equation 44

The required minimum CHI Clock frequency for a selected set of relevant protocol parameters and for the LAST_MB_UTIL field in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR) set to 127 is given in the following table.

Table 47-64. Minimum fchi [MHz] examples (128 message buffers used)

pdMicrotick [ns]	*gdMinislot*					
	2	**3**	**4**	**5**	**6**	**7**
25.0	79.5	53	39.8	31.8	26.5	22.8
50.0	39.8	26.5	19.9	15.9	13.3	11.4

Note

If the minimum CHI frequency is not met the CHIERFR[MBS_EF] flag is set. Refer to the CHI Error Flag Register (FR_CHIERFR) for details.

47.9.6 Protocol Control Command Execution

This section considers the issues of the protocol control command execution.

The application issues any of the protocol control commands listed in the POCCMD field of the FR_POCR Field Descriptions table, located in the Register Descriptions section, by writing the command to the POCCMD field of the Protocol Operation Control Register (FR_POCR). As a result the CC sets the BSY bit while the command is transferred to the PE. When the PE has accepted the command, the BSY flag is cleared. All commands are accepted by the PE.

The PE maintains a protocol command vector. For each command that was accepted by the PE, the PE sets the corresponding command bit in the protocol command vector. If a command is issued while the corresponding command bit is set, the command is not queued and is lost.

If the command execution block of the PE is idle, it selects the next accepted protocol command with the highest priority from the current protocol command vector according to the protocol control command priorities given in the next table. If the current protocol state does not allow the execution of this protocol command (see POC state changes in *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*) the CC asserts the illegal protocol command interrupt flag IPC_IF in the Protocol Interrupt Flag Register 1 (FR_PIFR1). The protocol command is not executed in this case.

Some protocol commands may be interrupted by other commands or the detection of a fatal protocol error as indicated by the table below. If the application issues the FREEZE or READY command, or if the PE detects a fatal protocol error, some commands already stored in the command vector will be removed from this vector.

Table 47-65. Protocol Control Command Priorities

Protocol Command	Priority	Interrupted By	Cleared and Terminated By
FREEZE	(highest) 1	none	
READY	2		
CONFIG_COMPLETE	3		
ALL_SLOTS	4	FREEZE, READY, CONFIG_COMPLET, fatal protocol error	FREEZE, READY, CONFIG_COMPLETE,fatal protocol error
ALLOW_COLDSTART	5		
RUN	6		FREEZE, fatal protocol error
WAKEUP	7		FREEZE, fatal protocol error
DEFAULT_CONFIG	8		FREEZE, fatal protocol error
CONFIG	9		
HALT	(lowest) 10		FREEZE, READY, CONFIG_COMPLETE,fatal protocol error

47.9.7 Message Buffer Search On Simple Message Buffer Configuration

This sections describes the message buffer search behavior for a simplified message buffer configuration. The FIFO behavior is not considered in this section.

47.9.7.1 Simple Message Buffer Configuration

A simple message buffer configuration is a configuration that has at most one transmit message buffer and at most one receive message buffer assigned to a slot *S*. The simple configuration used in this section utilizes two message buffers, one single buffered transmit message buffer and one receive message buffer.

The transmit message buffer has the message buffer number *t* and has following configuration

Table 47-66. Transmit Buffer Configuration

Register	Field	Value	Description
FR_MBCCSR*t*	MTD	1	transmit buffer
FR_MBCCFR*t*	MTM	0	event transition mode
	CHA	1	assigned to channel A
	CHB	0	not assigned to channel B
	CCFE	1	cycle counter filter enabled
	CCFMSK	000011	cycle set = {4n} = {0,4,8,12,…}
	CCFVAL	000000	
FR_MBFIDR*t*	FID	*S*	assigned to slot S

The availability of data in the transmit buffer is indicated by the commit bit FR_MBCCSRt[CMT] and the lock bit FR_MBCCSRt[LCKS].

The receive message buffer has the message buffer number r and has following configuration

Table 47-67. Receive Buffer Configuration

Register	Field	Value	Description
FR_MBCCSR*r*	MTD	0	receive buffer
FR_MBCCFR*r*	MTM	-	n/a
	CHA	1	assigned to channel A
	CHB	0	not assigned to channel B
	CCFE	1	cycle counter filter enabled
	CCFMSK	000001	cycle set = {2n} = {0,2,4,6,…}

Table continues on the next page...

Table 47-67. Receive Buffer Configuration (continued)

Register	Field	Value	Description
	CCFVAL	000000	
FR_MBFIDR*r*	FID	*S*	subscribed slot

Furthermore the assumption is that both message buffers are enabled (FR_MBCCSRt[EDS] = 1 and FR_MBCCSRr[EDS] = 1)

Note

The cycle set {4n+2} = {2,6,10,…} is assigned to the receive buffer only.

The cycle set {4n} = {0,4,8,12,…} is assigned to both buffers.

47.9.7.2 Behavior in static segment

In this case, both message buffers are assigned to a slot *S* in the *static* segment.

The configuration of a transmit buffer for a static slot *S* assigns this slot to the node as a transmit slot. The FlexRay protocol requires:

- When a slot occurs, if the slot is assigned to a node on a channel that node must transmit either a normal frame or a null frame on that channel. Specifically, a null frame will be sent if there is no data ready, or if there is no match on a transmit filter (cycle counter filtering, for example).

Regardless of the availability of data and the cycle counter filter, the node will transmit a frame in the static slot *S*. In any case, the result of the message buffer search will be the transmit message buffer *t*. The receive message buffer *r* will not be found, no reception is possible.

47.9.7.3 Behavior in dynamic segment

In this case, both message buffers are assigned to a slot *S* in the *dynamic* segment. The FlexRay protocol requires:

- When a slot occurs, if a slot is assigned to a node on a channel that node only transmits a frame on that channel if there is data ready and there is a match on relevant transmit filters (no null frames are sent).

The transmission of a frame in the dynamic segment is determined by the availability of data and the match of the cycle counter filter of the transmit message buffer.

47.9.7.3.1 Transmit Data Not Available

If transmit data are *not available*, i.e. the transmit buffer is not committed FR_MBCCSR*t*[CMT]=0 and/or locked FR_MBCCSR*t*[LCKS]=1,

1. for the cycles in the set {4n}, which is assigned to both buffers, the receive buffer will be found and the node can receive data, and
2. for the cycles in the set {4n+2}, which is assigned to the receive buffer only, the receive buffer will be found and the node can receive data.

The receive cycles are shown in the following figure.

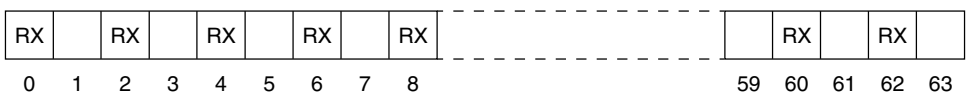

Figure 47-38. Transmit Data Not Available

47.9.7.3.2 Transmit Data Available

If transmit data are *available*, i.e. the transmit buffer is committed FR_MBCCSR*t*[CMT]=1 and not locked FR_MBCCSR*t*[LCKS]=0,

1. for the cycles in the set {4n}, which is assigned to both buffers, the transmit buffer will be found and the node transmits data.
2. for the cycles in the set {4n+2}, which is assigned to the receive buffer only, the receive buffer will be found and the node can receive data.

The receive and transmit cycles are shown in the following figure.

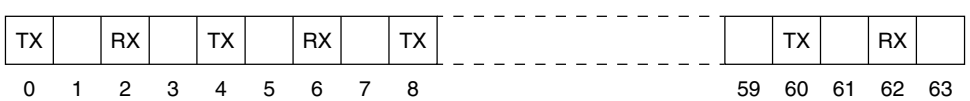

Figure 47-39. Transmit Data Available

Chapter 48
Synchronous Audio Interface (SAI)

48.1 Chip-specific SAI information

48.1.1 SAI configuration

The device instantiates three Synchronous Audio Interface (SAI) modules. The first Synchronous Audio Interface (SAI0) module supports up to 4 channels either with parallel data bits or using the AC97 mode with a single data bit and time division multiplexing (TDM).

In addition two more Synchronous Audio Interfaces are instantiated (SAI1 and SAI2) allowing one channel input or output each. All SAI instances can operate in asynchronous or synchronous mode. In synchronous mode SAI2 can control either SAI1 and SAI0 or only SAI1.

In total, the device can support up to 6 (stereo) audio channels (up to 6 data pins).

Table 48-1. SAI_0 configuration

Feature	Value
Channel supported	4
FIFO size	8
FRAME length	Maximum of 16 words per frame
Frame Synchronization	I2S, AC97, and CODEC/DSP interfaces
Multiple SAI Synchronous Mode	Supported but only SAI_2 can be the master for the multiple SAI synchronous modes.

Table 48-2. SAI_1 and SAI_2 configuration

Feature	Value
Channel supported	1
FIFO size	8

Table continues on the next page...

Table 48-2. SAI_1 and SAI_2 configuration (continued)

Feature	Value
FRAME length	Maximum of 16 words per frame
Frame Synchronization	I2S and CODEC/DSP interfaces
Multiple SAI Synchronous Mode	Supported but only SAI_2 can be the master for the multiple SAI synchronous modes.

48.1.1.1 Timer interface

The timer interface is used to create closed loop control with the Fractional Clock Dividers (FCD)s.

48.1.2 SAI's stop-stop ack protocol

If stop mode request is asserted :

- Transmitter and receiver will complete the existing frame and then disable internal bit clock and then acknowledges the stop request.
- If transmitter and receiver are disabled (TE=0, RE=0) then they will acknowledges the stop request immediately.

48.2 Introduction

The I^2S (or I2S) module provides a synchronous audio interface (SAI) that supports full-duplex serial interfaces with frame synchronization such as I^2S, AC97, TDM, and codec/DSP interfaces.

48.2.1 Features

Note that some of the features are not supported across all SAI instances; see the chip-specific information in the first section of this chapter.

NOTE

About data lines and audio channels: Typically there are one or more data lines for TX and RX sides of the SAI peripheral, depending on the device's design. Each SAI data line may support 1 - 32 audio channels (or audio words).

- Transmitter with independent bit clock and frame sync supporting 4 data lines

- Receiver with independent bit clock and frame sync supporting 4 data lines
- Maximum Frame Size of 16 words
- Word size of between 8-bits and 32-bits
- Word size configured separately for first word and remaining words in frame
- Asynchronous 8 × 32-bit FIFO for each transmit and receive channel
- Supports graceful restart after FIFO error
- Supports automatic restart after FIFO error without software intervention
- Supports packing of 8-bit and 16-bit data into each 32-bit FIFO word
- Supports combining multiple data channel FIFOs into single data channel FIFO

48.2.2 Block diagram

The following block diagram also shows the module clocks.

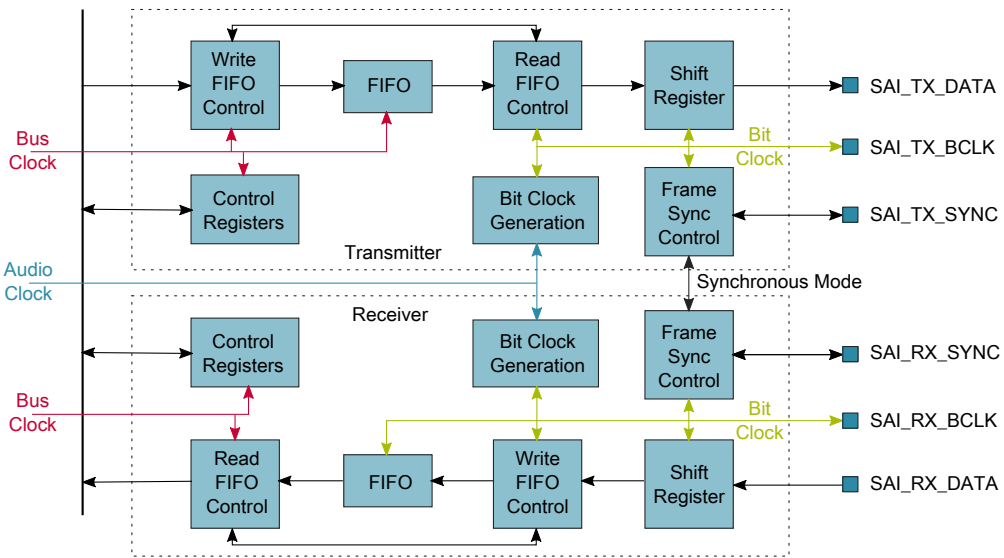

Figure 48-1. I²S/SAI block diagram

48.2.3 Modes of operation

The module operates in these power modes: Run mode, stop modes, and Debug mode.

48.2.3.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.

48.2.3.2 Stop modes

In Stop mode, the transmitter is disabled after completing the current transmit frame, and, the receiver is disabled after completing the current receive frame. Entry into Stop mode is prevented–not acknowledged–while waiting for the transmitter and receiver to be disabled at the end of the current frame.

48.2.3.3 Debug mode

In Debug mode, the SAI transmitter and/or receiver can continue operating provided the Debug Enable bit is set. When TCSR[DBGE] or RCSR[DBGE] bit is clear and Debug mode is entered, the SAI is disabled after completing the current transmit or receive frame. The transmitter and receiver bit clocks are not affected by Debug mode.

48.3 External signals

Name	Function	I/O
SAI_TX_BCLK	Transmit Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
SAI_TX_SYNC	Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
SAI_TX_DATA[3:0]	Transmit Data. The transmit data is generated synchronously by the bit clock and is tristated whenever not transmitting a word.	O
SAI_RX_BCLK	Receive Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
SAI_RX_SYNC	Receive Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
SAI_RX_DATA[3:0]	Receive Data. The receive data is sampled synchronously by the bit clock.	I
SAI_MCLK	Audio Master Clock. The master clock is an input when externally generated and an output when internally generated.	I/O

48.4 Memory map and register definition

A read or write access to an address from offset 0x108 and above will result in a bus error.

I2S memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	SAI Transmit Control Register (I2S_TCSR)	32	R/W	0000_0000h	48.4.1/2091

48.4.1 SAI Transmit Control Register (I2S_TCSR)

Address: 0h base + 0h offset = 0h

I2S_TCSR field descriptions

Field	Description
0 TE	Transmitter Enable Enables/disables the transmitter. When software clears this field, the transmitter remains enabled, and this bit remains set, until the end of the current frame. 0 Transmitter is disabled. 1 Transmitter is enabled, or transmitter has been disabled and has not yet reached end of frame.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 DBGE	Debug Enable Enables/disables transmitter operation in Debug mode. The transmit bit clock is not affected by debug mode. 0 Transmitter is disabled in Debug mode, after completing the current frame. 1 Transmitter is enabled in Debug mode.

Table continues on the next page...

I2S_TCSR field descriptions (continued)

Field	Description
3 BCE	Bit Clock Enable Enables the transmit bit clock, separately from the TE. This field is automatically set whenever TE is set. When software clears this field, the transmit bit clock remains enabled, and this bit remains set, until the end of the current frame. 0 Transmit bit clock is disabled. 1 Transmit bit clock is enabled.
4–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 FR	FIFO Reset Resets the FIFO pointers. Reading this field will always return zero. FIFO pointers should only be reset when the transmitter is disabled or the FIFO error flag is set. 0 No effect. 1 FIFO reset.
7 SR	Software Reset When set, resets the internal transmitter logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers. 0 No effect. 1 Software reset.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag. 0 Start of word not detected. 1 Start of word detected.
12 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0 Sync error not detected. 1 Frame sync error detected.
13 FEF	FIFO Error Flag Indicates that an enabled transmit FIFO has underrun. Write a logic 1 to this field to clear this flag. 0 Transmit underrun not detected. 1 Transmit underrun detected.
14 FWF	FIFO Warning Flag Indicates that an enabled transmit FIFO is empty. 0 No enabled transmit FIFO is empty. 1 Enabled transmit FIFO is empty.

Table continues on the next page...

I2S_TCSR field descriptions (continued)

Field	Description
15 FRF	FIFO Request Flag Indicates that the number of words in an enabled transmit channel FIFO is less than or equal to the transmit FIFO watermark. 0 Transmit FIFO watermark has not been reached. 1 Transmit FIFO watermark has been reached.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0 Disables interrupt. 1 Enables interrupt.
20 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0 Disables interrupt. 1 Enables interrupt.
21 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
22 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
23 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 FWDE	FIFO Warning DMA Enable Enables/disables DMA requests. 0 Disables the DMA request. 1 Enables the DMA request.
31 FRDE	FIFO Request DMA Enable

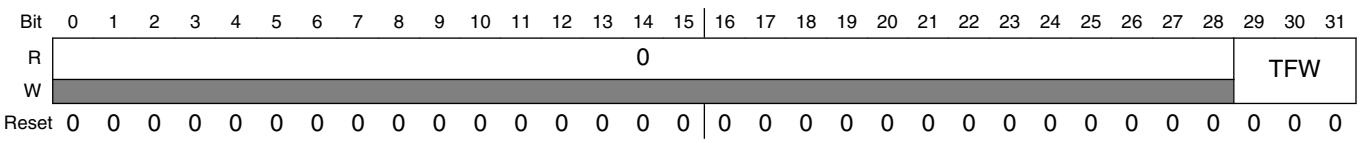

Table continues on the next page...

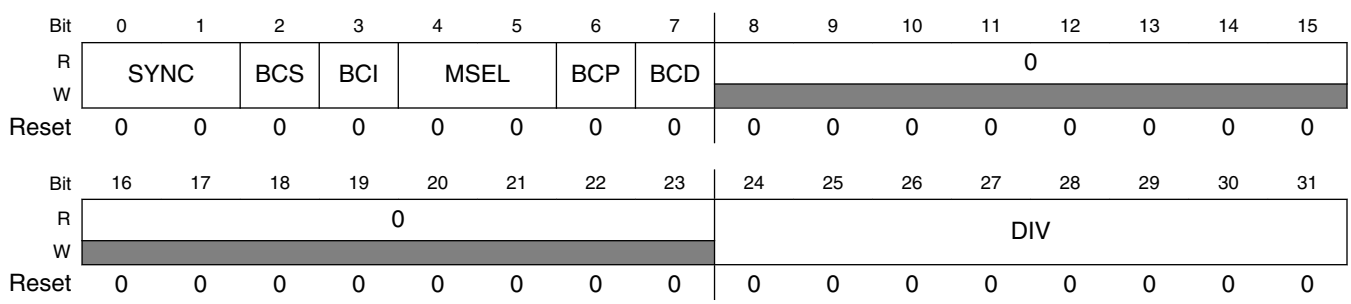
I2S_TCSR field descriptions (continued)

Field	Description
	Enables/disables DMA requests. 0 Disables the DMA request. 1 Enables the DMA request.

48.4.2 SAI Transmit Configuration 1 Register (I2S_TCR1)

Address: 0h base + 4h offset = 4h



I2S_TCR1 field descriptions

Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 TFW	Transmit FIFO Watermark Configures the watermark level for all enabled transmit channels.

48.4.3 SAI Transmit Configuration 2 Register (I2S_TCR2)

This register must not be altered when TCSR[TE] is set.

Address: 0h base + 8h offset = 8h

I2S_TCR2 field descriptions

Field	Description
0–1 SYNC	Synchronous Mode

Table continues on the next page...

I2S_TCR2 field descriptions (continued)

Field	Description
	Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the receiver or other SAI peripheral must be configured for asynchronous operation. 00 Asynchronous mode. 01 Synchronous with receiver. 10 Synchronous with another SAI transmitter. 11 Synchronous with another SAI receiver.
2 BCS	Bit Clock Swap This field swaps the bit clock used by the transmitter. When the transmitter is configured in asynchronous mode and this bit is set, the transmitter is clocked by the receiver bit clock (SAI_RX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the transmitter continues to use the transmit frame sync (SAI_TX_SYNC). When the transmitter is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the transmitter bit clock (SAI_TX_BCLK) but use the receiver frame sync (SAI_RX_SYNC). This field has no effect when synchronous to another SAI peripheral. 0 Use the normal bit clock source. 1 Swap the bit clock source.
3 BCI	Bit Clock Input When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the transmitter is delayed by the pad output delay (the transmitter is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. The slave mode timing from the datasheet should be used for the transmitter when this bit is set. In synchronous mode, this bit allows the transmitter to use the slave mode timing from the datasheet, while the receiver uses the master mode timing. This field has no effect when configured for an externally generated bit clock or when synchronous to another SAI peripheral . 0 No effect. 1 Internal logic is clocked as if bit clock was externally generated.
4–5 MSEL	MCLK Select Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE:** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the meaning of each option. 00 Bus Clock selected. 01 Master Clock (MCLK) 1 option selected. 10 Master Clock (MCLK) 2 option selected. 11 Master Clock (MCLK) 3 option selected.
6 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0 Bit clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1 Bit clock is active low with drive outputs on falling edge and sample inputs on rising edge.

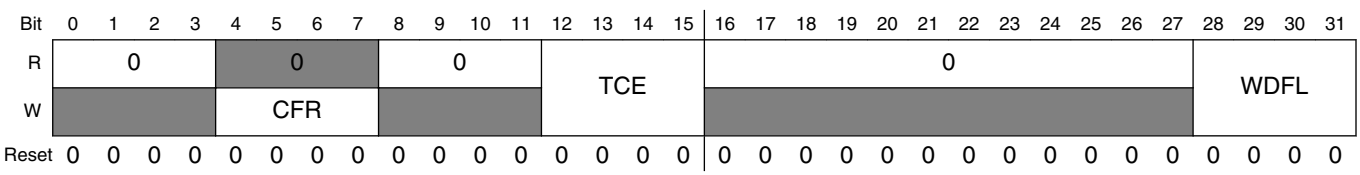


Table continues on the next page...

I2S_TCR2 field descriptions (continued)

Field	Description
7 BCD	Bit Clock Direction Configures the direction of the bit clock. 0 Bit clock is generated externally in Slave mode. 1 Bit clock is generated internally in Master mode.
8–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.

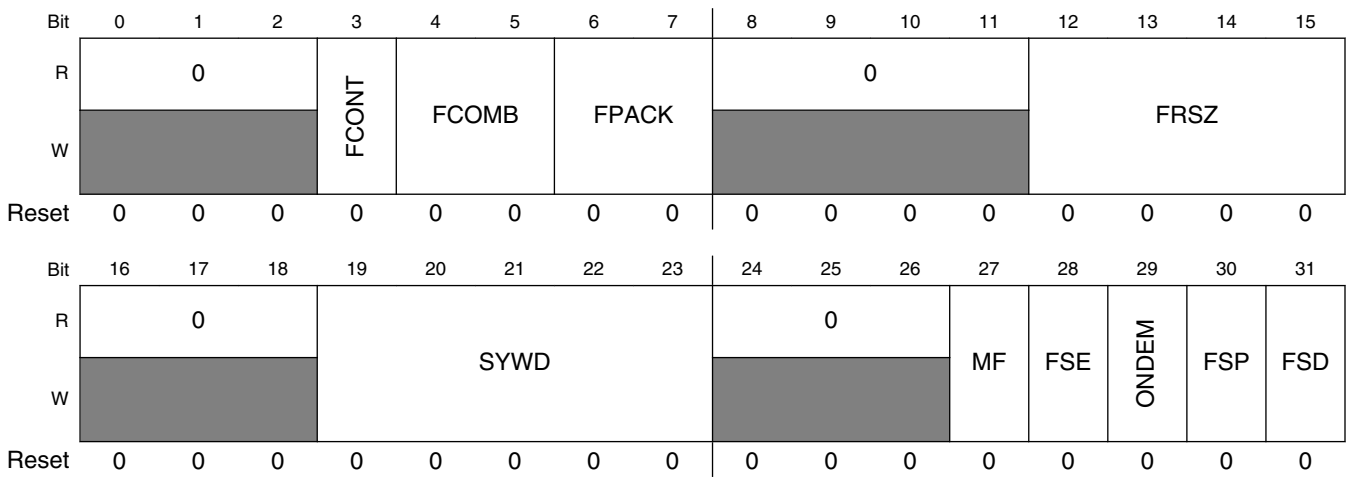
48.4.4 SAI Transmit Configuration 3 Register (I2S_TCR3)

Address: 0h base + Ch offset = Ch

I2S_TCR3 field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 CFR	Channel FIFO Reset Resets the FIFO pointers for a specific channel. Reading this field will always return zero. FIFO pointers should only be reset when a channel is disabled or the FIFO error flag is set. 0 No effect. 1 Transmit data channel N FIFO is reset.
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 TCE	Transmit Channel Enable Enables the corresponding data channel for transmit operation. A channel must be enabled before its FIFO is accessed. Changing this field will take effect immediately for generating the FIFO request and warning flags, but at the end of each frame for transmit operation. 0 Transmit data channel N is disabled. 1 Transmit data channel N is enabled.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...



I2S_TCR3 field descriptions (continued)

Field	Description
28–31 WDFL	Word Flag Configuration Configures which word sets the start of word flag. The value written must be one less than the word number. For example, writing 0 configures the first word in the frame. When configured to a value greater than TCR4[FRSZ], then the start of word flag is never set.

48.4.5 SAI Transmit Configuration 4 Register (I2S_TCR4)

This register must not be altered when TCSR[TE] is set.

Address: 0h base + 10h offset = 10h

I2S_TCR4 field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 FCONT	FIFO Continue on Error Configures when the SAI will continue transmitting after a FIFO error has been detected. 0 On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared. 1 On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.
4–5 FCOMB	FIFO Combine Mode When FIFO combine mode is enabled for FIFO writes, software writing to any FIFO data register will alternate the write among the enabled data channel FIFOs. For example, if two data channels are enabled then the first write will be performed to the first enabled data channel FIFO and the second write will be performed to the second enabled data channel FIFO. Reseting the FIFO or disabling FIFO combine mode for FIFO writes will reset the pointer back to the first enabled data channel.

Table continues on the next page...

I2S_TCR4 field descriptions (continued)

Field	Description
	When FIFO combine mode is enabled for FIFO reads from the transmit shift registers, the transmit data channel output will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked word will be transmitted from the first enabled data channel FIFO and the second unmasked word will be transmitted from the second enabled data channel FIFO. Since the first word of the frame is always transmitted from the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels. 00 FIFO combine mode disabled. 01 FIFO combine mode enabled on FIFO reads (from transmit shift registers). 10 FIFO combine mode enabled on FIFO writes (by software). 11 FIFO combine mode enabled on FIFO reads (from transmit shift registers) and writes (by software).
6–7 FPACK	FIFO Packing Mode Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are loaded from the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO write pointer will only increment when the full 32-bit FIFO word has been written by software. 00 FIFO packing is disabled 01 Reserved 10 8-bit FIFO packing is enabled 11 16-bit FIFO packing is enabled
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 FRSZ	Frame size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 16 words.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 SYWD	Sync Width Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 MF	MSB First Configures whether the LSB or the MSB is transmitted first. 0 LSB is transmitted first. 1 MSB is transmitted first.
28 FSE	Frame Sync Early 0 Frame sync asserts with the first bit of the frame. 1 Frame sync asserts one bit before the first bit of the frame.
29 ONDEM	On Demand Mode

Table continues on the next page...

I2S_TCR4 field descriptions (continued)

Field	Description
	When set, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is clear. 0 Internal frame sync is generated continuously. 1 Internal frame sync is generated when the FIFO warning flag is clear.
30 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0 Frame sync is active high. 1 Frame sync is active low.
31 FSD	Frame Sync Direction Configures the direction of the frame sync. 0 Frame sync is generated externally in Slave mode. 1 Frame sync is generated internally in Master mode.

48.4.6 SAI Transmit Configuration 5 Register (I2S_TCR5)

This register must not be altered when TCSR[TE] is set.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

I2S_TCR5 field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 WNW	Word N Width Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 W0W	Word 0 Width Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

I2S_TCR5 field descriptions (continued)

Field	Description
19–23 FBT	First Bit Shifted Configures the bit index for the first bit transmitted for each word in the frame. If configured for MSB First, the index of the next bit transmitted is one less than the current bit transmitted. If configured for LSB First, the index of the next bit transmitted is one more than the current bit transmitted. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First.
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.4.7 SAI Transmit Data Register (I2S_TDR*n*)

Address: 0h base + 20h offset + (4d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W	TDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2S_TDR*n* field descriptions

Field	Description
0–31 TDR	Transmit Data Register The corresponding TCR3[TCE] bit must be set before accessing the channel's transmit data register. Writes to this register when the transmit FIFO is not full will push the data written into the transmit data FIFO. Writes to this register when the transmit FIFO is full are ignored.

48.4.8 SAI Transmit FIFO Register (I2S_TFR*n*)

The MSB of the read and write pointers is used to distinguish between FIFO full and empty conditions. If the read and write pointers are identical, then the FIFO is empty. If the read and write pointers are identical except for the MSB, then the FIFO is full.

Address: 0h base + 40h offset + (4d × i), where i=0d to 3d

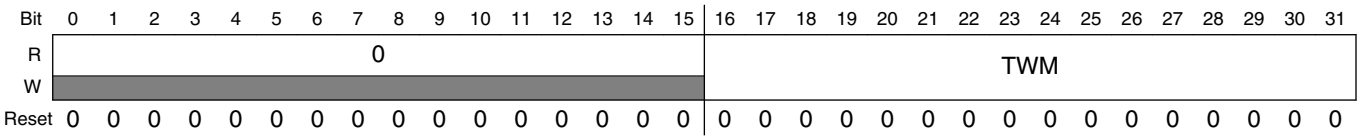
I2S_TFR*n* field descriptions

Field	Description
0 WCP	Write Channel Pointer When FIFO Combine mode is enabled for writes, indicates that this data channel is the next FIFO to be written. 0 No effect. 1 FIFO combine is enabled for FIFO writes and this FIFO will be written on the next FIFO write.
1–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 WFP	Write FIFO Pointer FIFO write pointer for transmit data channel.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 RFP	Read FIFO Pointer FIFO read pointer for transmit data channel.



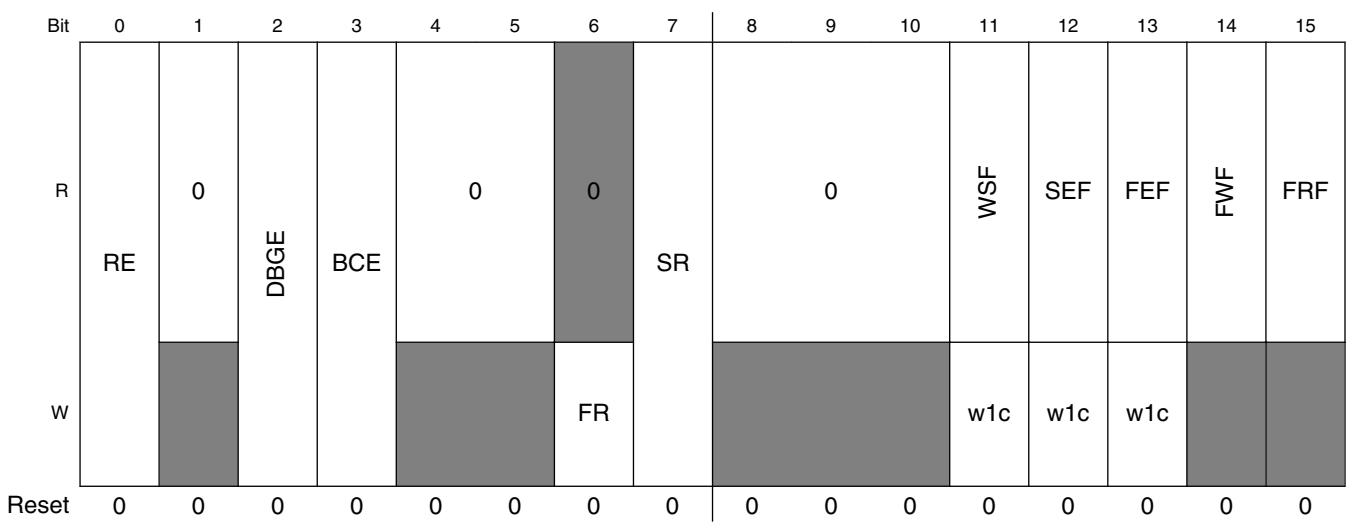
48.4.9 SAI Transmit Mask Register (I2S_TMR)

This register is double-buffered and updates:

1. When TCSR[TE] is first set
2. At the end of each frame.

This allows the masked words in each frame to change from frame to frame.

Address: 0h base + 60h offset = 60h



I2S_TMR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TWM	Transmit Word Mask Configures whether the transmit word is masked (transmit data pin tristated and transmit data not read from FIFO) for the corresponding word in the frame. 0 Word N is enabled. 1 Word N is masked. The transmit data pins are tri-stated when masked.

48.4.10 SAI Receive Control Register (I2S_RCSR)

Address: 0h base + 80h offset = 80h

I2S_RCSR field descriptions

Field	Description
0 RE	Receiver Enable Enables/disables the receiver. When software clears this field, the receiver remains enabled, and this bit remains set, until the end of the current frame. 0 Receiver is disabled. 1 Receiver is enabled, or receiver has been disabled and has not yet reached end of frame.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 DBGE	Debug Enable Enables/disables receiver operation in Debug mode. The receive bit clock is not affected by Debug mode. 0 Receiver is disabled in Debug mode, after completing the current frame. 1 Receiver is enabled in Debug mode.
3 BCE	Bit Clock Enable Enables the receive bit clock, separately from RE. This field is automatically set whenever RE is set. When software clears this field, the receive bit clock remains enabled, and this field remains set, until the end of the current frame. 0 Receive bit clock is disabled. 1 Receive bit clock is enabled.
4–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 FR	FIFO Reset Resets the FIFO pointers. Reading this field will always return zero. FIFO pointers should only be reset when the receiver is disabled or the FIFO error flag is set. 0 No effect. 1 FIFO reset.
7 SR	Software Reset Resets the internal receiver logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers. 0 No effect. 1 Software reset.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag. 0 Start of word not detected. 1 Start of word detected.
12 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag.

Table continues on the next page...

I2S_RCSR field descriptions (continued)

Field	Description
	0 Sync error not detected. 1 Frame sync error detected.
13 FEF	FIFO Error Flag Indicates that an enabled receive FIFO has overflowed. Write a logic 1 to this field to clear this flag. 0 Receive overflow not detected. 1 Receive overflow detected.
14 FWF	FIFO Warning Flag Indicates that an enabled receive FIFO is full. 0 No enabled receive FIFO is full. 1 Enabled receive FIFO is full.
15 FRF	FIFO Request Flag Indicates that the number of words in an enabled receive channel FIFO is greater than the receive FIFO watermark. 0 Receive FIFO watermark not reached. 1 Receive FIFO watermark has been reached.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0 Disables interrupt. 1 Enables interrupt.
20 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0 Disables interrupt. 1 Enables interrupt.
21 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
22 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
23 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts.

Table continues on the next page...

I2S_RCSR field descriptions (continued)

Field	Description
	0 Disables the interrupt. 1 Enables the interrupt.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 FWDE	FIFO Warning DMA Enable Enables/disables DMA requests. 0 Disables the DMA request. 1 Enables the DMA request.
31 FRDE	FIFO Request DMA Enable Enables/disables DMA requests. 0 Disables the DMA request. 1 Enables the DMA request.

48.4.11 SAI Receive Configuration 1 Register (I2S_RCR1)

Address: 0h base + 84h offset = 84h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2S_RCR2 field descriptions

Field	Description
0–1 SYNC	Synchronous Mode Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the transmitter or other SAI peripheral must be configured for asynchronous operation. 00 Asynchronous mode. 01 Synchronous with transmitter. 10 Synchronous with another SAI receiver. 11 Synchronous with another SAI transmitter.
2 BCS	Bit Clock Swap This field swaps the bit clock used by the receiver. When the receiver is configured in asynchronous mode and this bit is set, the receiver is clocked by the transmitter bit clock (SAI_TX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the receiver continues to use the receiver frame sync (SAI_RX_SYNC). When the receiver is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the receiver bit clock (SAI_RX_BCLK) but use the transmitter frame sync (SAI_TX_SYNC). This field has no effect when synchronous to another SAI peripheral. 0 Use the normal bit clock source. 1 Swap the bit clock source.
3 BCI	Bit Clock Input When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the receiver is delayed by the pad output delay (the receiver is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. The slave mode timing from the datasheet should be used for the receiver when this bit is set. In synchronous mode, this bit allows the receiver to use the slave mode timing from the datasheet, while the transmitter uses the master mode timing. This field has no effect when configured for an externally generated bit clock or when synchronous to another SAI peripheral .

Table continues on the next page...

I2S_RCR2 field descriptions (continued)

Field	Description
	0 No effect. 1 Internal logic is clocked as if bit clock was externally generated.
4–5 MSEL	MCLK Select Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE:** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the availability and chip-specific meaning of each option. 00 Bus Clock selected. 01 Master Clock (MCLK) 1 option selected. 10 Master Clock (MCLK) 2 option selected. 11 Master Clock (MCLK) 3 option selected.
6 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0 Bit Clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1 Bit Clock is active low with drive outputs on falling edge and sample inputs on rising edge.
7 BCD	Bit Clock Direction Configures the direction of the bit clock. 0 Bit clock is generated externally in Slave mode. 1 Bit clock is generated internally in Master mode.
8–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.

48.4.13 SAI Receive Configuration 3 Register (I2S_RCR3)

Address: 0h base + 8Ch offset = 8Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

I2S_RCR3 field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

I2S_RCR3 field descriptions (continued)

Field	Description
4–7 CFR	Channel FIFO Reset Resets the FIFO pointers for a specific channel. Reading this field will always return zero. FIFO pointers should only be reset when a channel is disabled or the FIFO error flag is set. 0 No effect. 1 Receive data channel N FIFO is reset.
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 RCE	Receive Channel Enable Enables the corresponding data channel for receive operation. A channel must be enabled before its FIFO is accessed. Changing this field will take effect immediately for generating the FIFO request and warning flags, but at the end of each frame for receive operation. 0 Receive data channel N is disabled. 1 Receive data channel N is enabled.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 WDFL	Word Flag Configuration Configures which word the start of word flag is set. The value written should be one less than the word number (for example, write zero to configure for the first word in the frame). When configured to a value greater than the Frame Size field, then the start of word flag is never set.

48.4.14 SAI Receive Configuration 4 Register (I2S_RCR4)

This register must not be altered when RCSR[RE] is set.

Address: 0h base + 90h offset = 90h

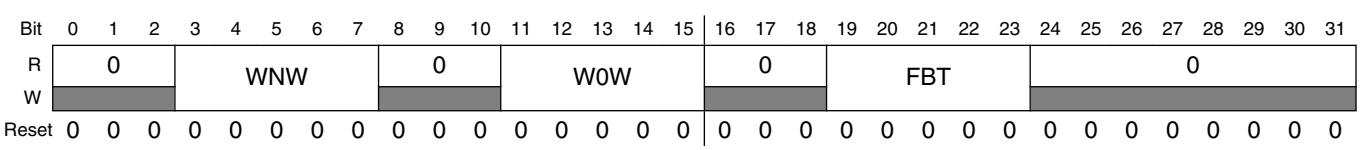
Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0			FCONT	FCOMB		FPACK		0				FRSZ			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0			SYWD					0			MF	FSE	ONDEM	FSP	FSD
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2S_RCR4 field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 FCONT	FIFO Continue on Error Configures when the SAI will continue receiving after a FIFO error has been detected. 0 On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared. 1 On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.
4–5 FCOMB	FIFO Combine Mode When FIFO combine mode is enabled for FIFO reads, software reading any FIFO data register will alternate the read among the enabled data channel FIFOs. For example, if two data channels are enabled then the first read will be performed to the first enabled data channel FIFO and the second read will be performed to the second enabled data channel FIFO. Reseting the FIFO or disabling FIFO combine mode for FIFO reads will reset the pointer back to the first enabled data channel. When FIFO combine mode is enabled for FIFO writes from the receive shift registers, the first enabled data channel input will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked received word will be stored in the first enabled data channel FIFO and the second unmasked received word will be stored in the second enabled data channel FIFO. Since the first word of the frame is always stored in the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels. 00 FIFO combine mode disabled. 01 FIFO combine mode enabled on FIFO writes (from receive shift registers). 10 FIFO combine mode enabled on FIFO reads (by software). 11 FIFO combine mode enabled on FIFO writes (from receive shift registers) and reads (by software).
6–7 FPACK	FIFO Packing Mode Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are stored to the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO read pointer will only increment when the full 32-bit FIFO word has been read by software. 00 FIFO packing is disabled 01 Reserved. 10 8-bit FIFO packing is enabled 11 16-bit FIFO packing is enabled
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 FRSZ	Frame Size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 16 words.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 SYWD	Sync Width

Table continues on the next page...



I2S_RCR4 field descriptions (continued)

Field	Description
	Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 MF	MSB First Configures whether the LSB or the MSB is received first. 0 LSB is received first. 1 MSB is received first.
28 FSE	Frame Sync Early 0 Frame sync asserts with the first bit of the frame. 1 Frame sync asserts one bit before the first bit of the frame.
29 ONDEM	On Demand Mode When set, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is clear. 0 Internal frame sync is generated continuously. 1 Internal frame sync is generated when the FIFO warning flag is clear.
30 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0 Frame sync is active high. 1 Frame sync is active low.
31 FSD	Frame Sync Direction Configures the direction of the frame sync. 0 Frame Sync is generated externally in Slave mode. 1 Frame Sync is generated internally in Master mode.

48.4.15 SAI Receive Configuration 5 Register (I2S_RCR5)

This register must not be altered when RCSR[RE] is set.

Address: 0h base + 94h offset = 94h

I2S_RCR5 field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 WNW	Word N Width Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 W0W	Word 0 Width Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 FBT	First Bit Shifted Configures the bit index for the first bit received for each word in the frame. If configured for MSB First, the index of the next bit received is one less than the current bit received. If configured for LSB First, the index of the next bit received is one more than the current bit received. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First.
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.4.16 SAI Receive Data Register (I2S_RDR*n*)

Reading this register introduces one additional peripheral clock wait state on each read.

Address: 0h base + A0h offset + (4d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2S_RDR*n* field descriptions

Field	Description
0–31 RDR	Receive Data Register The corresponding RCR3[RCE] bit must be set before accessing the channel's receive data register. Reads from this register when the receive FIFO is not empty will return the data from the top of the receive FIFO. Reads from this register when the receive FIFO is empty are ignored.

48.4.17 SAI Receive FIFO Register (I2S_RFR*n*)

The MSB of the read and write pointers is used to distinguish between FIFO full and empty conditions. If the read and write pointers are identical, then the FIFO is empty. If the read and write pointers are identical except for the MSB, then the FIFO is full.

Address: 0h base + C0h offset + (4d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0												WFP			
W

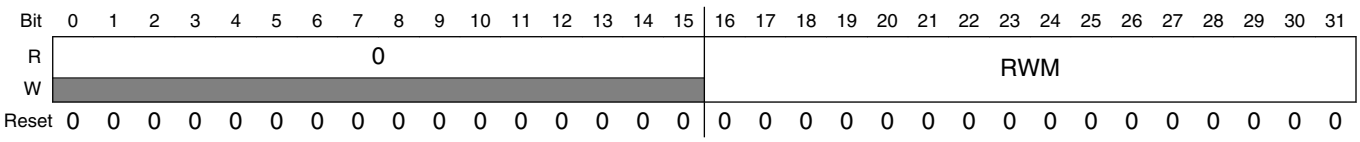
R	RCP	0											RFP			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2S_RFR*n* field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 WFP	Write FIFO Pointer FIFO write pointer for receive data channel.
16 RCP	Receive Channel Pointer When FIFO Combine mode is enabled for reads, indicates that this data channel is the next FIFO to be read. 0 No effect. 1 FIFO combine is enabled for FIFO reads and this FIFO will be read on the next FIFO read.
17–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 RFP	Read FIFO Pointer FIFO read pointer for receive data channel.



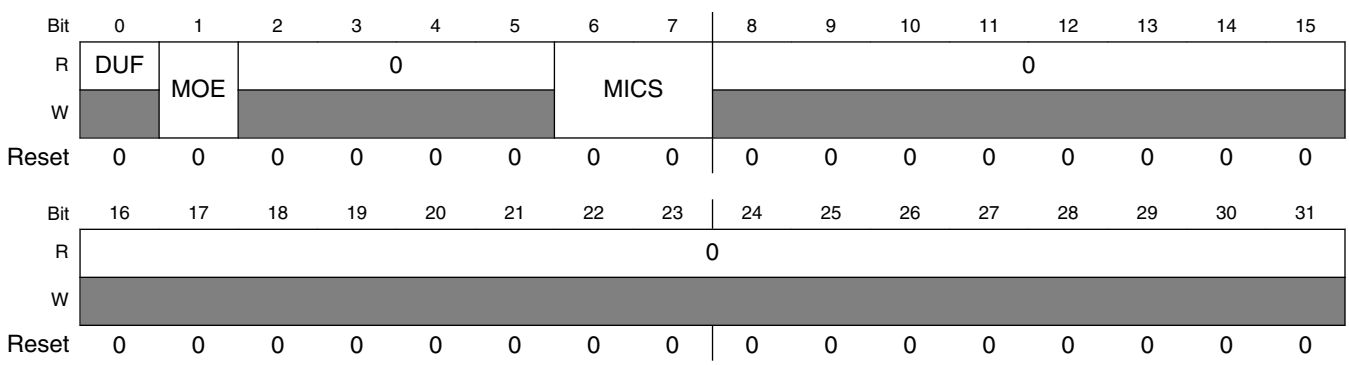
48.4.18 SAI Receive Mask Register (I2S_RMR)

This register is double-buffered and updates:

1. When RCSR[RE] is first set
2. At the end of each frame

This allows the masked words in each frame to change from frame to frame.

Address: 0h base + E0h offset = E0h



I2S_RMR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 RWM	Receive Word Mask Configures whether the receive word is masked (received data ignored and not written to receive FIFO) for the corresponding word in the frame. 0 Word N is enabled. 1 Word N is masked.

48.4.19 SAI MCLK Control Register (I2S_MCR)

The MCLK Control Register (MCR) controls the clock source and direction of the audio master clock.

Address: 0h base + 100h offset = 100h

I2S_MCR field descriptions

Field	Description
0 DUF	Divider Update Flag Provides the status of on-the-fly updates to the MCLK divider ratio. 0 MCLK divider ratio is not being updated currently. 1 MCLK divider ratio is updating on-the-fly. Further updates to the MCLK divider ratio are blocked while this flag remains set.
1 MOE	MCLK Output Enable

Table continues on the next page...

I2S_MCR field descriptions (continued)

Field	Description
	Enables the MCLK divider and configures the MCLK signal pin as an output. When software clears this field, it remains set until the MCLK divider is fully disabled. 0 MCLK signal pin is configured as an input that bypasses the MCLK divider. 1 MCLK signal pin is configured as an output from the MCLK divider and the MCLK divider is enabled.
2–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–7 MICS	MCLK Input Clock Select Selects the clock input to the MCLK divider. This field cannot be changed while the MCLK divider is enabled. See the chip-specific information for the connections to these inputs. 00 MCLK divider input clock 0 is selected. 01 Reserved 10 MCLK divider input clock 2 is selected. 11 MCLK divider input clock 3 is selected.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.4.20 SAI MCLK Divide Register (I2S_MDR)

The MCLK Divide Register (MDR) configures the MCLK divide ratio. Although the MDR can be changed when the MCLK divider clock is enabled, additional writes to the MDR are blocked while MCR[DUF] is set. Writes to the MDR when the MCLK divided clock is disabled do not set MCR[DUF].

Address: 0h base + 104h offset = 104h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0											FRACT					DIVIDE															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2S_MDR field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–19 FRACT	MCLK Fraction Sets the MCLK divide ratio such that: MCLK output = MCLK input * ((FRACT + 1) / (DIVIDE + 1)). FRACT must be set equal or less than the value in the DIVIDE field. **NOTE:** When using fractional divide values, the MCLK duty cycle will not always be 50/50. See Audio master clock.
20–31 DIVIDE	MCLK Divide

Table continues on the next page...

I2S_MDR field descriptions (continued)

Field	Description
	Sets the MCLK divide ratio such that: MCLK output = MCLK input * ((FRACT + 1) / (DIVIDE + 1)). FRACT must be set equal or less than the value in the DIVIDE field. **NOTE:** When using fractional divide values, the MCLK duty cycle will not always be 50/50. See Audio master clock.

48.5 Functional description

This section provides a complete functional description of the block.

48.5.1 SAI clocking

The SAI clocks include:

- The audio master clock
- The bit clock
- The bus clock

48.5.1.1 Audio master clock

The audio master clock is used to generate the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio master clocks to generate the bit clock.

Each SAI peripheral can control the input clock selection, pin direction and divide ratio of one audio master clock. The input clock selection and pin direction cannot be altered if an SAI module using that audio master clock has been enabled. The MCLK divide ratio can be altered while an SAI is using that master clock, although the change in the divide ratio takes several cycles. MCR[DUF] can be polled to determine when the divide ratio change has completed.

The audio master clock generation and selection is chip-specific. Refer to chip-specific clocking information about how the audio master clocks are generated. A typical implementation appears in the following figure.

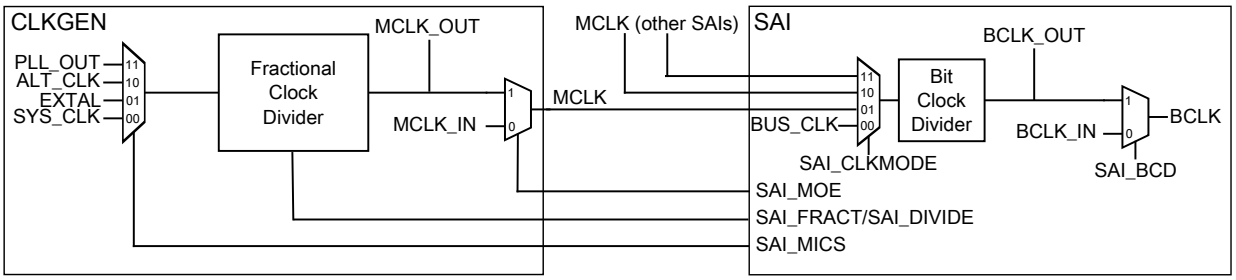


Figure 48-2. SAI master clock generation

The MCLK fractional clock divider uses both clock edges from the input clock to generate a divided down clock that will approximate the output frequency, but without creating any new clock edges. Configuring FRACT and DIVIDE to the same value will result in a divide by 1 clock, while configuring FRACT higher than DIVIDE is not supported. The duty cycle can range from 66/33 when FRACT is set to one less than DIVIDE down to 50/50 for integer divide ratios, and will approach 50/50 for large non-integer divide ratios. There is no cycle to cycle jitter or duty cycle variance when the divide ratio is an integer or half integer, otherwise the divider output will oscillate between the two divided frequencies that are the closest integer or half integer divisors of the divider input clock frequency. The maximum jitter is therefore equal to half the divider input clock period, since both edges of the input clock are used in generating the divided clock.

48.5.1.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that can be generated internally from an audio master clock or supplied externally. There is also the option for synchronous bit clock and frame sync operation between the receiver and transmitter or between multiple SAI peripherals.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames

If the SAI transmitter or receiver is using an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously.

48.5.1.3 Bus clock

The bus clock is used by the control and configuration registers and to generate synchronous interrupts and DMA requests.

NOTE

Although there is no specific minimum bus clock frequency specified, the bus clock frequency must be fast enough (relative to the bit clock frequency) to ensure that the FIFOs can be serviced, without generating either a transmitter FIFO underrun or receiver FIFO overflow condition.

48.5.2 SAI resets

The SAI is asynchronously reset on system reset. The SAI has a software reset and a FIFO reset.

48.5.2.1 Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

The SAI receiver includes a software reset that resets all receiver internal logic, including the bit clock generation, status flags and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

48.5.2.2 FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the same value as the FIFO read pointer. This empties the FIFO contents and is to be used after TCSR[FEF] is set, and before the FIFO is re-initialized and TCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI transmitter can also reset the FIFO of individual data channels by setting the appropriate TCR3[CFR] bit. This should only be done when the corresponding TCR3[TCE] bit is clear.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the same value as the FIFO write pointer. This empties the FIFO contents and is to be used after the RCSR[FEF] is set and any remaining data has been read from the FIFO, and before the RCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI receiver can also reset the FIFO of individual data channels by setting the appropriate RCR3[CFR] bit. This should only be done when the corresponding RCR3[RCE] bit is clear.

48.5.3 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other or synchronously to other SAI peripherals.

48.5.3.1 Synchronous mode

The SAI transmitter and receiver can be configured to operate with synchronous bit clock and frame sync.

If the transmitter bit clock and frame sync are to be used by both the transmitter and receiver:

- The transmitter must be configured for asynchronous operation and the receiver for synchronous operation.
- In synchronous mode, the receiver is enabled only when both the transmitter and receiver are enabled.
- It is recommended that the transmitter is the last enabled and the first disabled.

If the receiver bit clock and frame sync are to be used by both the transmitter and receiver:

- The receiver must be configured for asynchronous operation and the transmitter for synchronous operation.
- In synchronous mode, the transmitter is enabled only when both the receiver and transmitter are both enabled.
- It is recommended that the receiver is the last enabled and the first disabled.

When operating in synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The transmitter and receiver otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

48.5.3.2 Multiple SAI Synchronous mode

Synchronous operation between multiple SAI peripherals is not supported on all devices. This mode requires the source of the bit clock and frame sync to be configured for asynchronous operation and the remaining users of the bit clock and frame sync to be configured for synchronous operation.

Synchronous operation between multiple SAI transmitters or receivers also requires the source of the bit clock and frame sync to be enabled for any of the synchronous transmitters or receivers to also be enabled. It is recommended that the source of the bit clock and frame sync is the last enabled and the first disabled.

When operating in synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The separate SAI peripherals otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

48.5.4 Frame sync configuration

When enabled, the SAI continuously transmits and/or receives frames of data. Each frame consists of a fixed number of words and each word consists of a fixed number of bits. Within each frame, any given word can be masked causing the receiver to ignore that word and the transmitter to tri-state for the duration of that word.

The frame sync signal is used to indicate the start of each frame. A valid frame sync requires a rising edge (if active high) or falling edge (if active low) to be detected and the transmitter or receiver cannot be busy with a previous frame. A valid frame sync is also ignored (slave mode) or not generated (master mode) for the first four bit clock cycles after enabling the transmitter or receiver.

The transmitter and receiver frame sync can be configured independently with any of the following options:

- Externally generated or internally generated
- Active high or active low
- Assert with the first bit in frame or asserts one bit early
- Assert for a duration between 1 bit clock and the first word length
- Frame length from 1 to 16 words per frame
- Word length to support 8 to 32 bits per word
    - First word length and remaining word lengths can be configured separately
- Words can be configured to transmit/receive MSB first or LSB first

These configuration options cannot be changed after the SAI transmitter or receiver is enabled.

48.5.5 Data FIFO

Each transmit and receive channel includes a FIFO of size 8 × 32-bit. The FIFO data is accessed using the SAI Transmit/Receive Data Registers.

48.5.5.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit wide register through the use of the First Bit Shifted configuration field, which selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required First Bit Shifted configuration are illustrated in Figure 48-3 for LSB First configurations and Figure 48-4 for MSB First configurations.

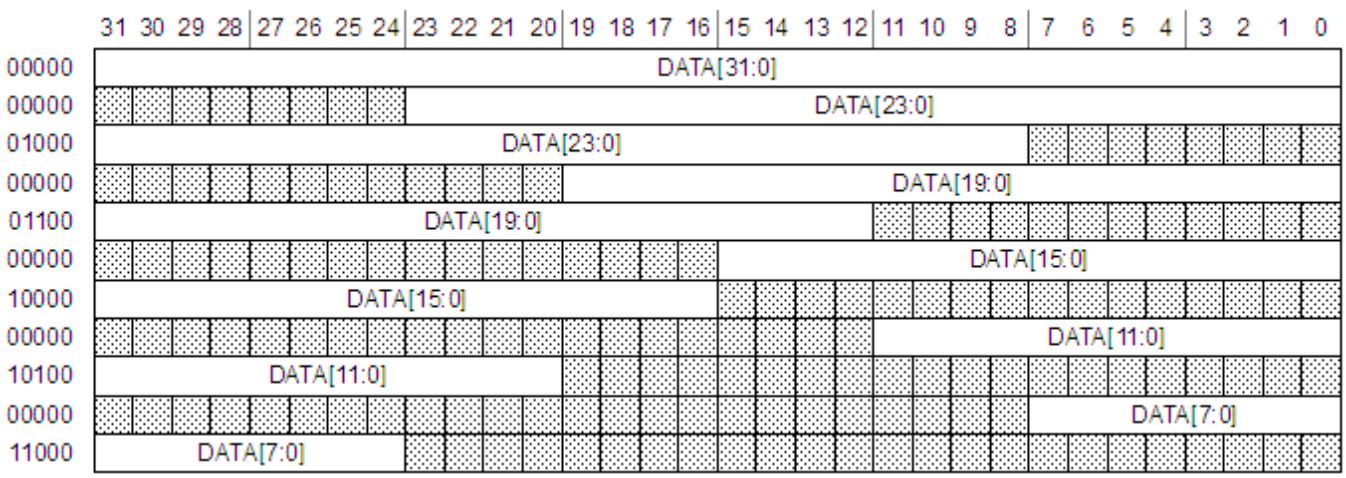

Figure 48-3. SAI first bit shifted, LSB first

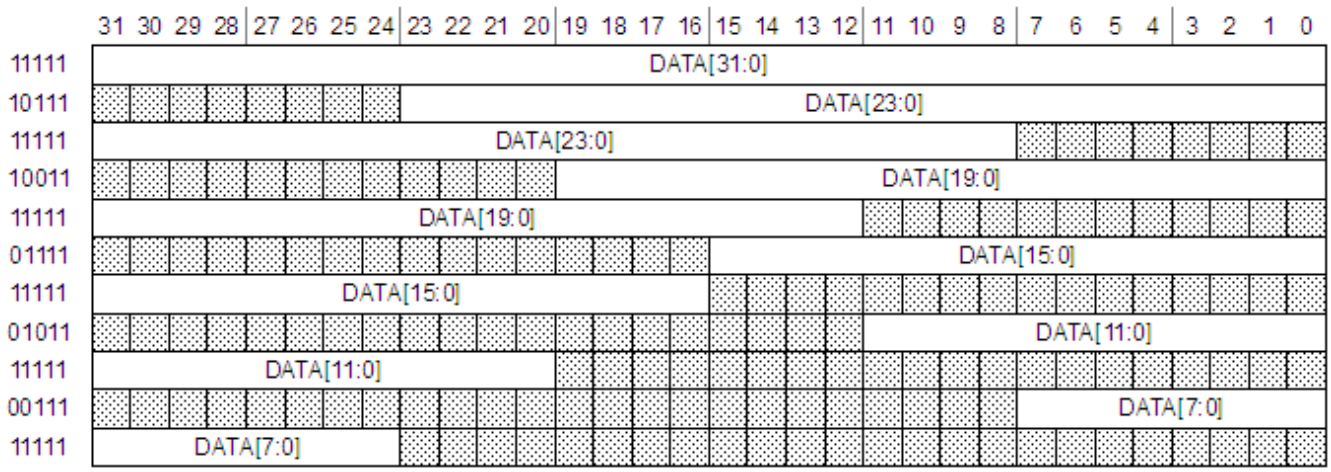

Figure 48-4. SAI first bit shifted, MSB first

48.5.5.2 FIFO pointers

When writing to a TDR, the WFP of the corresponding TFR increments after each valid write. The SAI supports 8-bit, 16-bit and 32-bit writes to the TDR and the FIFO pointer will increment after each individual write. Note that 8-bit writes should only be used when transmitting up to 8-bit data and 16-bit writes should only be used when transmitting up to 16-bit data.

Writes to a TDR are ignored if the corresponding bit of TCR3[TCE] is clear or if the FIFO is full. If the Transmit FIFO is empty, the TDR must be written at least three bit clocks before the start of the next unmasked word to avoid a FIFO underrun.

When reading an RDR, the RFP of the corresponding RFR increments after each valid read. The SAI supports 8-bit, 16-bit and 32-bit reads from the RDR and the FIFO pointer will increment after each individual read. Note that 8-bit reads should only be used when receiving up to 8-bit data and 16-bit reads should only be used when receiving up to 16-bit data.

Reads from an RDR are ignored if the corresponding bit of RCR3[RCE] is clear or if the FIFO is empty. If the Receive FIFO is full, the RDR must be read at least three bit clocks before the end of an unmasked word to avoid a FIFO overrun.

48.5.5.3 FIFO packing

FIFO packing supports storing multiple 8-bit or 16-bit data words in one 32-bit FIFO word for the transmitter and/or receiver. While this can be emulated by adjusting the number of bits per word and number of words per frame (for example, one 32-bit word

per frame versus two 16-bit words per frame), FIFO packing does not require even multiples of words per frame and fully supports word masking. When FIFO packing is enabled, the FIFO pointers only increment when the full 32-bit FIFO word has been written (transmit) or read (receive) by software, supporting scenarios where different words within each frame are loaded/stored in different areas of memory.

When 16-bit FIFO packing is enabled for transmit, the transmit shift register is loaded at the start of each frame and after every second unmasked transmit word. The first word transmitted is taken from 16-bit word at byte offset $0 (first bit is selected by TCFG5[FBT] must be configured within this 16-bit word) and the second word transmitted is taken from the 16-bit word at byte offset $2 (first bit is selected by TCSR5[FBT][3:0]). The transmitter will transmit logic zero until the start of the next word once the 16-bit word has been transmitted.

When 16-bit FIFO packing is enabled for receive, the receive shift register is stored after every second unmasked received word, and at the end of each frame if there is an odd number of unmasked received words in each frame. The first word received is stored in the 16-bit word at byte offset $0 (first bit is selected by RCFG5[FBT] and must be configured within this 16-bit word) and the second word received is stored in the 16-bit word at byte offset $2 (first bit is selected by RCSR5[FBT][3:0]). The receiver will ignore received data until the start of the next word once the 16-bit word has been received.

The 8-bit FIFO packing is similar to 16-bit packing except four words are loaded or stored into each 32-bit FIFO word. The first word is loaded/stored in byte offset $0, second word in byte offset $1, third word in byte offset $2 and fourth word in byte offset $3. The TCFG5[FBT] and/or RCFG5[FBT] must be configured within byte offset $0.

48.5.5.4 FIFO Combine

FIFO combining mode allows the separate FIFOs for multiple data channels to be used as a single FIFO for either software accesses or a single data channel or both. Note that the enabled data channels must be contiguous and data channel 0 must be enabled when FIFO Combine mode is enabled.

Combining FIFOs for software access (writing transmit FIFO registers, reading receive FIFO registers) allows a DMA controller or software to read or write multiple FIFOs without incrementing the address that is accessed. Once enabled, the first software access to a FIFO register will access the first enabled channel FIFO, while the second access to a FIFO register will access the second enabled channel FIFO. This continues until software

accesses the last enabled channel FIFO and the pointer resets back to the first enabled channel FIFO. To reset the pointer manually, software can reset the FIFOs or disable the FIFO combining on software accesses.

Combining FIFOs for transmit data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with identical data output on each enabled data channel. The transmit shift registers for all enabled data channels are loaded at the start of each frame and every N unmasked words (where N is the number of enabled data channels). The first word transmitted is loaded from the first enabled channel FIFO, while the second word transmitted is loaded from the second enabled channel FIFO, and so on until the end of the frame. Since the first word in each frame is always loaded from the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Combining FIFOs for receive data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with received data from channel 0 stored into each enabled data channel. The receive shift register for all enabled data channels are stored after every N unmasked words (where N is the number of enabled data channels). The first word received is stored to the first enabled channel FIFO, while the second word received is stored to the second enabled channel FIFO, and so on until the end of the frame. Since the first word in each frame is always stored the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Note that combining FIFOs for data channels will load or store each channel FIFO at the same time. This means that FIFO error conditions are only checked every N words (where N is the number of enabled data channels) and that the FIFO warning and request flags will assert if any of the enabled data channel meets the warning flag or request flag conditions.

48.5.6 Word mask register

The SAI transmitter and receiver each contain a word mask register, namely TMR and RMR, that can be used to mask any word in the frame. Because the word mask register is double buffered, software can update it before the end of each frame to mask a particular word in the next frame.

The TMR causes the Transmit Data pin to be tri-stated for the length of each selected word and the transmit FIFO is not read for masked words.

The RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

48.5.7 Interrupts and DMA requests

The SAI transmitter and receiver generate separate interrupts and separate DMA requests, but support the same status flags.

48.5.7.1 FIFO request flag

The FIFO request flag is set based on the number of entries in the FIFO and the FIFO watermark configuration.

The transmit FIFO request flag is set when the number of entries in any of the enabled transmit FIFOs is less than or equal to the transmit FIFO watermark configuration and is cleared when the number of entries in each enabled transmit FIFO is greater than the transmit FIFO watermark configuration.

The receive FIFO request flag is set when the number of entries in any of the enabled receive FIFOs is greater than the receive FIFO watermark configuration and is cleared when the number of entries in each enabled receive FIFO is less than or equal to the receive FIFO watermark configuration.

The FIFO request flag can generate an interrupt or a DMA request.

48.5.7.2 FIFO warning flag

The FIFO warning flag is set based on the number of entries in the FIFO.

The transmit warning flag is set when the number of entries in any of the enabled transmit FIFOs is empty and is cleared when the number of entries in each enabled transmit FIFO is not empty.

The receive warning flag is set when the number of entries in any of the enabled receive FIFOs is full and is cleared when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an Interrupt or a DMA request.

48.5.7.3 FIFO error flag

The transmit FIFO error flag is set when the any of the enabled transmit FIFOs underflow. After it is set, all enabled transmit channels will transmit zero until TCSR[FEF] is cleared and the next transmit frame starts. All enabled transmit FIFOs must be reset and initialized with new data before TCSR[FEF] is cleared.

When TCR4[FCONT] is set, the FIFO will continue transmitting data following an underflow without software intervention. To ensure that data is transmitted in the correct order, the transmitter will continue from the same word number in the frame that caused the FIFO to underflow, but only after new data has been written to the transmit FIFO. Software should still clear the TCSR[FEF] flag, but without reinitializing the transmit FIFOs.

RCSR[FEF] is set when the any of the enabled receive FIFOs overflow. After it is set, all enabled receive channels discard received data until RCSR[FEF] is cleared and the next next receive frame starts. All enabled receive FIFOs should be emptied before RCSR[FEF] is cleared.

When RCR4[FCONT] is set, the FIFO will continue receiving data following an overflow without software intervention. To ensure that data is received in the correct order, the receiver will continue from the same word number in the frame that caused the FIFO to overflow, but only after data has been read from the receive FIFO. Software should still clear the RCSR[FEF] flag, but without emptying the receive FIFOs.

The FIFO error flag can generate only an interrupt.

48.5.7.4 Sync error flag

The sync error flag, TCSR[SEF] or RCSR[SEF], is set when configured for an externally generated frame sync and the external frame sync asserts when the transmitter or receiver is busy with the previous frame. The external frame sync assertion is ignored and the sync error flag is set. When the sync error flag is set, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

The sync error flag can generate an interrupt only.

48.5.7.5 Word start flag

The word start flag is set at the start of the second bit clock for the selected word, as configured by the Word Flag register field.

The word start flag can generate an interrupt only.

Chapter 49
Periodic Interrupt Timer (PIT-RTI)

49.1 Chip-specific PIT-RTI information

49.1.1 PIT configuration

The device has a single instantiation of the PIT_RTI with 16 x PIT timers/channels, each 32 bits in length, and a 32-bit Real Time Interrupt (RTI) channel that can be clocked from an FXOSC. Consecutive channels can be chained to build 64-bit timers. This is controlled by software.

The reset value for the PIT_MCR register is 0x0000_0006. This value overrides the reset value that is shown in the body of this chapter.

RTI supports wakeup even when the system clock in gated in STOP mode.

49.1.2 Input Output

This section describes the input output requirements for PIT_RTI. The PIT_RTI has no dedicated inputs except the clocks. All the PIT instances are capable of generating periodic interrupts. However, PIT_0 to PIT_15 channels are also routed to generate trigger to specific peripherals as listed in the table below.

Table 49-1. PIT Trigger Allocation

PIT Channel	Peripheral	Comments
PIT_0	DMA_TRIGGER #1	DMA Periodic trigger mode
PIT_1	DMA_TRIGGER#2	DMA Periodic trigger mode
PIT_4	DMA_TRIGGER#3	DMA Periodic trigger mode
PIT_5	DMA_TRIGGER#4	DMA Periodic trigger mode
PIT_3	BCTU[23]	BCTU input trigger number 23
PIT_7	BCTU[55]	BCTU input trigger number 55

Table continues on the next page...

Table 49-1. PIT Trigger Allocation (continued)

PIT Channel	Peripheral	Comments
PIT_2	ADC 10-bit	Injection channels
PIT_6	ADC 12-bit	Injection channels
PIT_9	DSPI_0	Hardware trigger mode
PIT_10	DSPI_1	Hardware trigger mode
PIT_11	DSPI_2	Hardware trigger mode
PIT_12	DSPI_3	Hardware trigger mode
PIT_13	FlexRay	Stopwatch feature
PIT_14	FlexCAN_0, FlexCAN_1, FlexCAN_2, FlexCAN_3	FlexCAN
PIT_15	FlexCAN_4, FlexCAN_5, FlexCAN_6, FlexCAN_7	FlexCAN

49.1.3 PIT-RTI's stop-stop ack protocol

If RTI clock is present the stop request acknowledgement is generated "2 FXOSC clock Cycles" after the request, whereas if the clock is absent the acknowledgement is asserted immediately.

49.2 Introduction

The PIT module is an array of timers that can be used to raise interrupts and triggers. It includes a dedicated Real Time Interrupt Timer (RTI), which runs on a separate clock and can be used for system wakeup in STOP mode.

49.2.1 Block diagram

The following figure shows the block diagram of the PIT-RTI module.

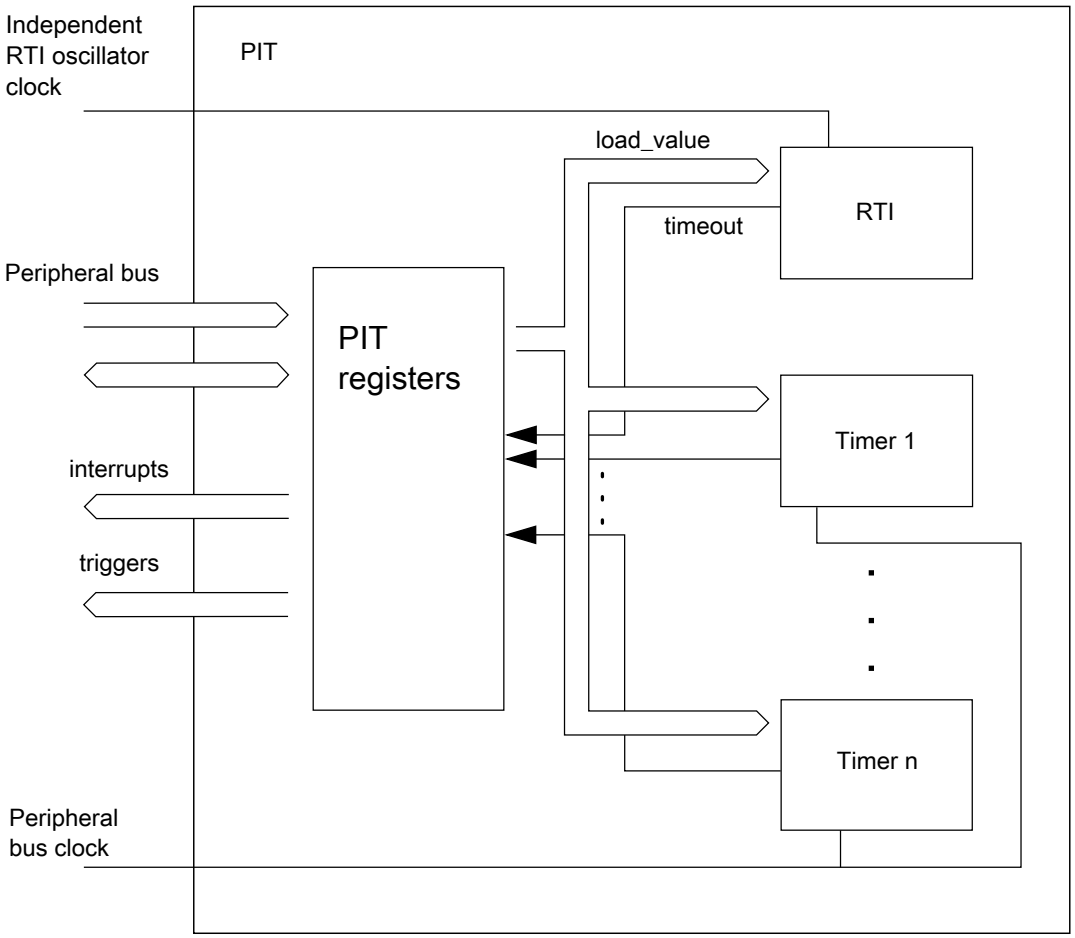

Figure 49-1. Block diagram of the PIT-RTI

NOTE

See the chip-specific PIT information for the number of PIT channels used in this MCU.

49.2.2 Features

The main features of this block are:

- One RTI (Real-Time Interrupt) timer to wakeup the CPU in stop mode
- Ability of timers to generate trigger pulses
- Ability of timers to generate interrupts
- Maskable interrupts
- Option to raise RTI interrupt, even when the bus clock is switched off

- Power saving with a separate input clock for the RTI timer. All other timers share one common core clock.
- Independent timeout periods for each timer

49.3 Signal description

The PIT module has no external pins.

49.4 Memory map/register description

This section provides a detailed description of all registers accessible in the PIT_RTI module.

- Reserved registers will read as 0, writes will have no effect.
- See the chip-specific PIT information for the number of PIT channels used in this MCU.
- The RTI registers should be programmed only when the RTI clock is running.

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
1FC	Timer Flag Register (PIT_TFLG15)	32	R/W	0000_0000h	49.4.11/ 2139

49.4.1 PIT Module Control Register (PIT_MCR)

This register enables or disables the PIT timer clocks and controls the timers when the PIT enters the Debug mode.

Access: User read/write

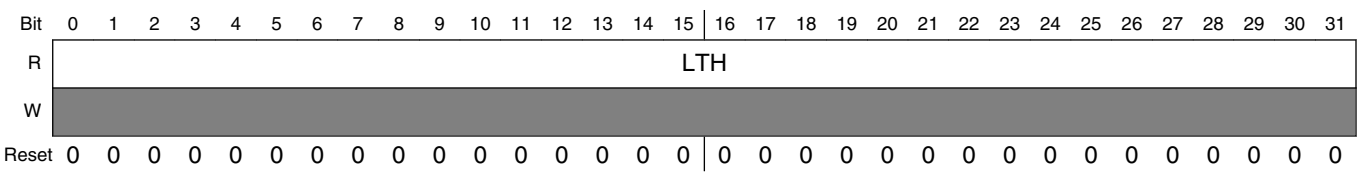
Address: 0h base + 0h offset = 0h

PIT_MCR field descriptions

Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 MDIS_RTI	Module Disable - RTI section This is used to disable the RTI timer. This bit must be enabled before any RTI setup is done. 0 Clock for RTI Timers is enabled 1 Clock for RTI Timers is disabled
30 MDIS	Module Disable - (PIT section) Disables the standard timers.The RTI timer is not affected by this field. This field must be enabled before any other setup is done. **NOTE:** Always write to this bit after at least 3 bus clock cycles of enabling the PIT clock gate in the device clock generation module.

Table continues on the next page...

PIT_MCR field descriptions (continued)



Field	Description
	0 Clock for standard PIT timers is enabled. 1 Clock for standard PIT timers is disabled.
31 FRZ	Freeze Allows the timers to be stopped when the device enters the Debug mode. 0 Timers continue to run in Debug mode. 1 Timers are stopped in Debug mode.

49.4.2 PIT Upper Lifetime Timer Register (PIT_LTMR64H)

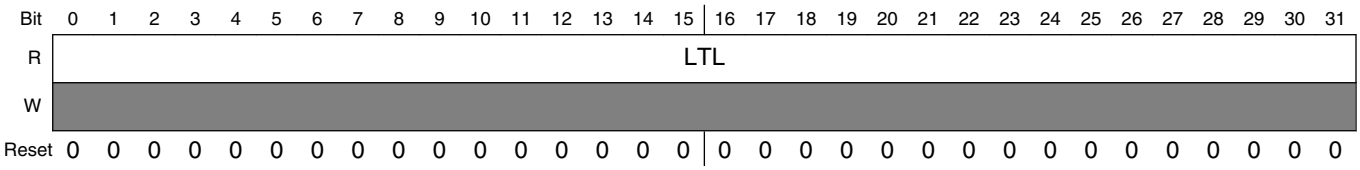
This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit lifetimer.

Access: User read only

Address: 0h base + E0h offset = E0h

PIT_LTMR64H field descriptions

Field	Description
0–31 LTH	Life Timer value Shows the timer value of timer 1. If this register is read at a time t1, LTMR64L shows the value of timer 0 at time t1.



49.4.3 PIT Lower Lifetime Timer Register (PIT_LTMR64L)

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit lifetimer.

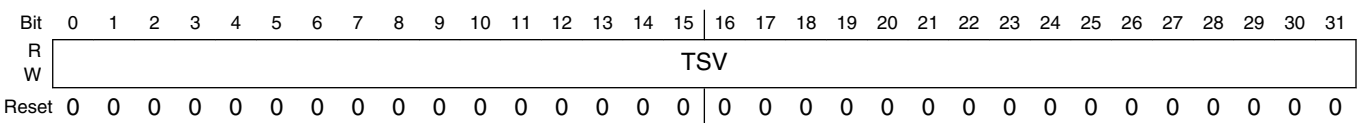
To use LTMR64H and LTMR64L, timer 0 and timer 1 need to be chained. To obtain the correct value, first read LTMR64H and then LTMR64L. LTMR64H will have the value of CVAL1 at the time of the first access, LTMR64L will have the value of CVAL0 at the time of the first access, therefore the application does not need to worry about carry-over effects of the running counter.

Access: User read only

Address: 0h base + E4h offset = E4h

PIT_LTMR64L field descriptions

Field	Description
0–31 LTL	Life Timer value Shows the value of timer 0 at the time LTMR64H was last read. It will only update if LTMR64H is read.



49.4.4 Timer Load Value Register (PIT_RTI_LDVAL)

These registers select the timeout period for the timer interrupts.

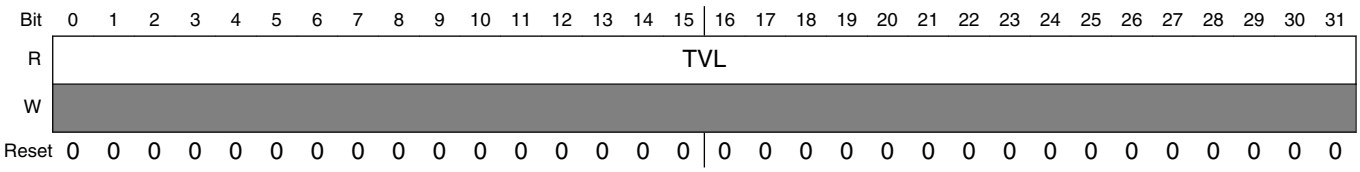
In the case of the RTI, it will take several cycles until this value is synchronized into the RTI clock domain. For all other timers the value change is visible immediately. The synchronisation mechanism allows 0 wait states in this case.

Access: User read/write

Address: 0h base + F0h offset = F0h

PIT_RTI_LDVAL field descriptions

Field	Description
0–31 TSV	Timer Start Value Sets the timer start value. The timer will count down until it reaches 0, then it will generate an interrupt and load this register value again. Writing a new value to this register will not restart the timer; instead the value will be loaded after the timer expires. To abort the current cycle and start a timer period with the new value, the timer must be disabled and enabled again. **NOTE:** The RTI timer must not be set to a value lower than 32 cycles, otherwise interrupts may be lost, as it takes several cycles to clear the RTI interrupt. For the other timers, this limit does not apply, however there will be practical limits, since the processor will require several cycles to service an interrupt.



49.4.5 Current Timer Value Register (PIT_RTI_CVAL)

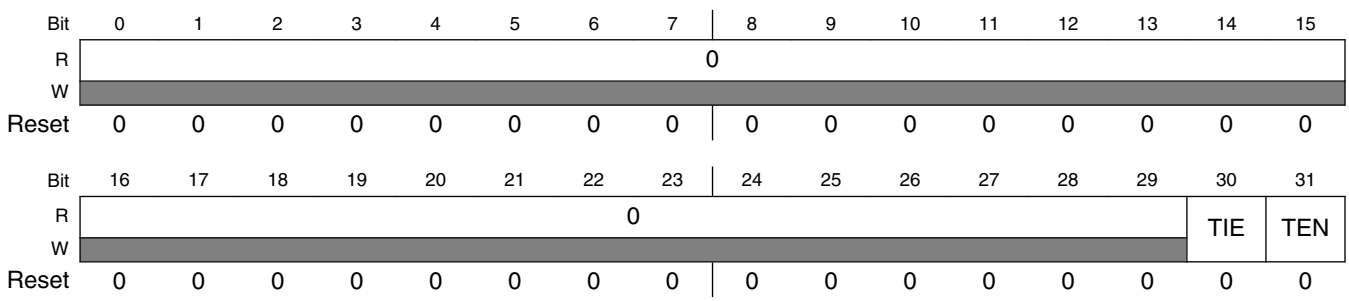
These registers indicate the current timer position.

For the RTI timers, they show a value which is several cycles old, since it originates from a potentially different clock domain.

Access: User read only

Address: 0h base + F4h offset = F4h

PIT_RTI_CVAL field descriptions



Field	Description
0–31 TVL	Current Timer Value Represents the current timer value, if the timer is enabled. **NOTE:** • If the timer is disabled, do not use this field as its value is unreliable. • The timer uses a downcounter. The timer values are frozen in Debug mode if MCR[FRZ] is set.

49.4.6 Timer Control Register (PIT_RTI_TCTRL)

These registers contain the control bits for each timer.

Access: User read/write

Address: 0h base + F8h offset = F8h

PIT_RTI_TCTRL field descriptions

Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 TIE	Timer Interrupt Enable When an interrupt is pending or, RTI_TFLG[TIF] is set, enabling the interrupt will immediately cause an interrupt event. To avoid this, the associated RTI_TFLG[TIF] flag must be cleared first.

Table continues on the next page...

PIT_RTI_TCTRL field descriptions (continued)

Field	Description
	0 Interrupt requests from the RTI Timer are disabled. 1 Interrupt will be requested whenever TIF is set.
31 TEN	Timer Enable Bit This bit enables or disables the timer. 0 RTI Timer is disabled. 1 RTI Timer is active.

49.4.7 Timer Flag Register (PIT_RTI_TFLG)

These registers hold the PIT interrupt flags.

Access: User read/write

Address: 0h base + FCh offset = FCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0															TIF
W																w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PIT_RTI_TFLG field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 TIF	Timer Interrupt Flag. TIF is set to 1 at the end of the timer period. This flag can be cleared only by writing it with 1 . Writing 0 has no effect. If enabled (TIE = 1), TIF causes an interrupt request. 0 Time-out has not yet occurred. 1 Time-out has occurred.

49.4.8 Timer Load Value Register (PIT_LDVAL*n*)

These registers select the timeout period for the timer interrupts.

Access: User read/write

Address: 0h base + 100h offset + (16d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PIT_LDVAL*n* field descriptions

Field	Description
0–31 TSV	Timer Start Value Sets the timer start value. The timer will count down until it reaches 0, then it will generate an interrupt and load this register value again. Writing a new value to this register will not restart the timer; instead the value will be loaded after the timer expires. To abort the current cycle and start a timer period with the new value, the timer must be disabled and enabled again.

49.4.9 Current Timer Value Register (PIT_CVAL*n*)

These registers indicate the current timer position.

Access: User read only

Address: 0h base + 104h offset + (16d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PIT_TCTRL*n* field descriptions

Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 CHN	Chain Mode When activated, Timer n-1 needs to expire before timer n can decrement by 1. Timer 0 cannot be chained. The RTI timer cannot be chained. 0 Timer is not chained. 1 Timer is chained to previous timer. For example, for Channel 2, if this field is set, Timer 2 is chained to Timer 1.
30 TIE	Timer Interrupt Enable When an interrupt is pending, or, TFLGn[TIF] is set, enabling the interrupt will immediately cause an interrupt event. To avoid this, the associated TFLGn[TIF] must be cleared first. 0 Interrupt requests from Timer n are disabled. 1 Interrupt will be requested whenever TIF is set.
31 TEN	Timer Enable Enables or disables the timer. 0 Timer n is disabled. 1 Timer n is enabled.

49.4.11 Timer Flag Register (PIT_TFLG*n*)

These registers hold the PIT interrupt flags.

Access: User read/write

Address: 0h base + 10Ch offset + (16d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PIT_TFLG*n* field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 TIF	Timer Interrupt Flag Sets to 1 at the end of the timer period. Writing 1 to this flag clears it. Writing 0 has no effect. If enabled, or, when TCTRLn[TIE] = 1, TIF causes an interrupt request. 0 Timeout has not yet occurred. 1 Timeout has occurred.

49.5 Functional description

This section provides the functional description of the module.

49.5.1 General operation

This section gives detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses and interrupts. Each interrupt is available on a separate interrupt line. Additionally the RTI timer can be used to wake up the processor.

49.5.1.1 Timers / RTI

The timers generate triggers at periodic intervals, when enabled. The timers load the start values as specified in their LDVAL registers, count down to 0 and then load the respective start value again. Each time a timer reaches 0, it will generate a trigger pulse and set the interrupt flag.

All interrupts can be enabled or masked by setting TCTRLn[TIE]. A new interrupt can be generated only after the previous one is cleared. Since in the case of the RTI, clearing the interrupt crosses clock domains, a minimum load value of 32 must be maintained.

If desired, the current counter value of the timer can be read via the CVAL registers. The value of the RTI counter can be delayed considerably, as it is synchronized to the bus clock from the RTI clock domain.

The counter period can be restarted, by first disabling, and then enabling the timer with TCTRLn[TEN]. See the following figure.

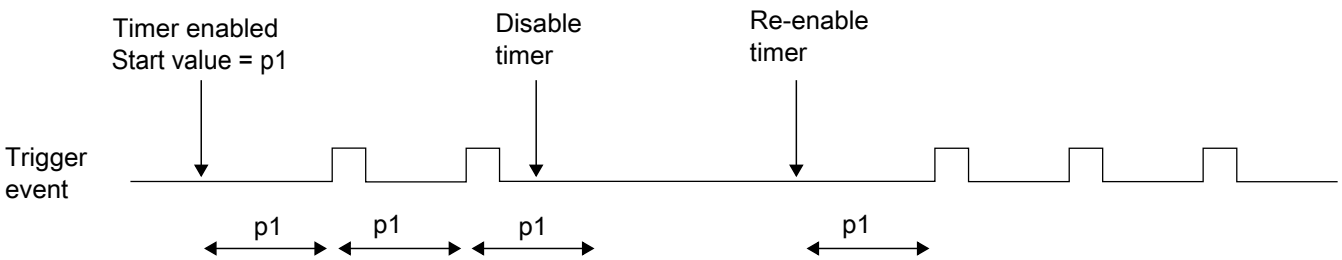

Figure 49-2. Stopping and starting a timer

The counter period of a running timer can be modified, by first disabling the timer, setting a new load value, and then enabling the timer again. See the following figure.

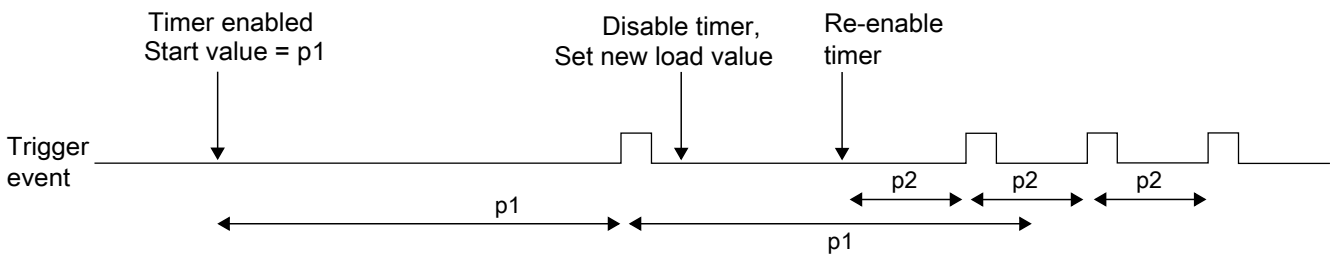

Figure 49-3. Modifying running timer period

It is also possible to change the counter period without restarting the timer by writing LDVAL with the new load value. This value will then be loaded after the next trigger event. See the following figure.

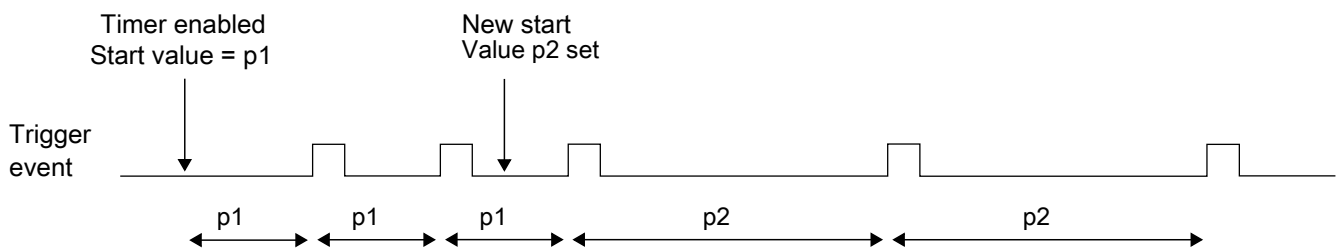

Figure 49-4. Dynamically setting a new load value

49.5.1.2 Debug mode

In Debug mode, the timers will be frozen based on MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system, for example, the timer values, and then continue the operation.

49.5.2 Interrupts

All the timers support interrupt generation. The RTI is typically used for system wakeup, but can be used for interrupt generation as well. See the MCU specification for related vector addresses and priorities.

Timer interrupts can be enabled by setting TCTRLn[TIE]. TFLGn[TIF] are set to 1 when a timeout occurs on the associated timer, and are cleared to 0 by writing a 1 to the corresponding TFLGn[TIF].

The PIT_RTI generates a real time interrupt when the selected interrupt time period elapses. The RTI interrupt is disabled locally by setting TCTCRLn[TIE] to zero. The real time interrupt flag (TIF) is set to 1 when a timeout occurs, and is cleared by writing a 1 to the corresponding TFLGn[TIF]. The flag will be set regardless whether the interrupt is enabled.

The RTI can be used for periodic wakeup from STOP mode. It can also be used to generate a general-purpose interrupt.

49.5.3 Chained timers

When a timer has chain mode enabled, it will only count after the previous timer has expired. So if timer n-1 has counted down to 0, counter n will decrement the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer.

49.6 Initialization and application information

In the example configuration:

- The PIT clock has a frequency of 50 MHz.
- The RTI clock has a frequency of 10 MHz.

- The RTI creates a wakeup interrupt every 500 ms.
- Timer 1 creates an interrupt every 5.12 ms.
- Timer 3 creates a trigger event every 30 ms.

The PIT module must be activated by writing a 0 to MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns and the 10 MHz frequency equates to a clock period of 100 ns. Therefore, the RTI timer needs to trigger every 500 ms/100 ns = 5,000,000 cycles. Timer 1 needs to trigger every 5.12 ms/20 ns = 256,000 cycles and Timer 3 every 30 ms/20 ns = 1,500,000 cycles. The value for the LDVAL register trigger is calculated as:

LDVAL trigger = (period / clock period) -1

This means RTI LDVAL will be written with 004C4B3F hex; LDVAL1 and LDVAL3 must be written with 0x0003E7FF and 0x0016E35F respectively.

To generate the wakeup interrupt, the interrupt line must be enabled by writing 1 to the RTI TIE bit in the TCTRL register. To start the RTI, the TEN in the RTI TCTRL register must also be set.

The interrupt for Timer 1 is enabled by setting TCTRL1[TIE]. The timer is started by writing 1 to TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore, Timer 3 is started by writing a 1 to TCTRL3[TEN]. TCTRL3[TIE] stays at 0.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// RTI
PIT_RTI_LDVAL = 0x004C4B3F; // setup RTI for 5000000 cycles
PIT_RTI_TCTRL = PIT_TIE; // let RTI generate interrupts
PIT_RTI_TCTRL |= PIT_TEN; // start RTI

// Timer 1
PIT_LDVAL1 = 0x0003E7FF; // setup timer 1 for 256000 cycles
PIT_TCTRL1 = TIE; // enable Timer 1 interrupts
PIT_TCTRL1 |= TEN; // start Timer 1

// Timer 3
PIT_LDVAL3 = 0x0016E35F; // setup timer 3 for 1500000 cycles
PIT_TCTRL3 |= TEN; // start Timer 3
```

49.7 Example configuration for chained timers

In the example configuration:

- The PIT clock has a frequency of 100 MHz.
- Timers 1 and 2 are available.
- An interrupt shall be raised every 1 minute.

The PIT module needs to be activated by writing a 0 to MCR[MDIS].

The 100 MHz clock frequency equates to a clock period of 10 ns, so the PIT needs to count for 6000 million cycles, which is more than a single timer can do. So, Timer 1 is set up to trigger every 6 s (600 million cycles). Timer 2 is chained to Timer 1 and programmed to trigger 10 times.

The value for the LDVAL register trigger is calculated as number of cycles-1, so LDVAL1 receives the value 0x23C345FF and LDVAL2 receives the value 0x00000009.

The interrupt for Timer 2 is enabled by setting TCTRL2[TIE], the Chain mode is activated by setting TCTRL2[CHN], and the timer is started by writing a 1 to TCTRL2[TEN]. TCTRL1[TEN] needs to be set, and TCTRL1[CHN] and TCTRL1[TIE] are cleared.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 2
PIT_LDVAL2 = 0x00000009; // setup Timer 2 for 10 counts
PIT_TCTRL2 = TIE; // enable Timer 2 interrupt
PIT_TCTRL2 |= CHN; // chain Timer 2 to Timer 1
PIT_TCTRL2 |= TEN; // start Timer 2

// Timer 1
PIT_LDVAL1 = 0x23C345FF; // setup Timer 1 for 600 000 000 cycles
PIT_TCTRL1 = TEN; // start Timer 1
```

49.8 Example configuration for the lifetime timer

To configure the lifetimer timer, channels 0 and 1 need to be chained together.

First the PIT module needs to be activated by writing a 0 to the MDIS bit in the CTRL register, then the LDVAL registers need to be set to the maximum value.

The timer is a downcounter.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0; // disable timer 1 interrupts
PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN; // start timer 1

// Timer 0
PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0 for maximum counting period
PIT_TCTRL0 = TEN; // start timer 0
```

To access the lifetime, read first LTMR64H and then LTMR64L.

```
current_uptime = PIT_LTMR64H<<32;
current_uptime = current_uptime + PIT_LTMR64L;
```

Chapter 50
Software Watchdog Timer (SWT)

50.1 Chip-specific SWT information

50.1.1 SWT configuration

The device has three SWTs as shown in the following table.

Table 50-1. SWT Configuration Instances

Instance	Description
SWT0	Intended for Core0.
SWT1	Intended for Core1.
HSM_SWT	Dedicated for HSM.

Each SWT is clocked by the SIRC. SWT_0, and SWT_1 could be serviced by any core, however, HSM_SWT can be serviced only by HSM.

The default configuration for the SWT_0 is enabled out of power on reset. The default configuration for the SWT_1 is disabled out of power on reset. However, it is possible to configure the default position of SWT_0 only via a DCF record.

The default configuration for the HSM_SWT is enabled out of power on reset only if HSM is enabled. For more information on HSM, refer Security Reference Manual.

In device STANDBY and LPU modes, only SWT_0 is available.

NOTE

SWT should be disabled before SIRC is disabled during any mode transition.

50.1.2 SWT register reset value

The register reset values for the SWT registers that are device specific are shown below. This information overrides the reset values given in SWT Memory map section. All other registers reset values are shown in the SWT Memory map section.

SWT_0 Time-out register (SWT_0_TO) resets to 0x0000_0A00h.

SWT_1 Time-out register (SWT_1_TO) resets to 0x0000_0A00h.

SWT_HSM Time-out register (SWT_HSM_TO) resets to 0x0000_1000h.

SWT_0 Control register (SWT_0_CR) resets to FF00_011Bh. However, the value of SWT_0_CR[WEN] depends on the DCF record bit SWT_0_WDG_DIS of the UTEST_MISC register.

SWT_1 Control register (SWT_1_CR) resets to FF00_010Ah.

SWT_HSM Control register (SWT_HSM_CR) resets to 1000_004Fh.

50.1.3 Service mode watchpoint input

Each SWT comes out of reset in 'Fixed Service Sequence' mode (SWT_CR[SMD] =2’b00), but the Instruction Address Compare 8 (IAC8) register (SPR 568) can be used forservicing by using the SWT jd_watchpt input.

To use SWT address execution modes for this purpose, the e200z4/z2 core IAC8 register signal jd_watchpt[15] is connected to the SWT jd_watchpt input. (See Watchpoint Support section for details.) The jd_watchpt[15] signal tells the SWT that an IAC8 compare occurred.

Set SWT_CR[SMD] to one of the following so the SWT is serviced by executing code at the address loaded into the IAC8 register:

- 2’b10 for Fixed Address Execution; the IAC8 register cannot be updated while the watchdog is enabled. If the SWT is in 'Fixed Address Execution' mode, an SWT output signal tells the core; this ‘freezes’ changes to the IAC8 register when the SWT is enabled.
- 2’b11 for Incremental Address Execution; the IAC8 register can be updated.

50.2 Introduction

This section provides an overview, list of features, and modes of operation for the SWT.

50.2.1 Overview

The Software Watchdog Timer (SWT) is a peripheral module that can prevent system lockup in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. When enabled, the SWT requires periodic execution of a watchdog servicing operation. The servicing operation resets the timer to a specified time-out period. If this servicing action does not occur before the timer expires, the SWT generates an interrupt or hardware reset request. The SWT can be configured to generate a reset request or interrupt on an initial time-out. The SWT always generates a reset request on a second consecutive time-out.

50.2.2 Features

The SWT has the following features:

- 32-bit time-out register to set the time-out period
- Programmable selection of window mode or regular servicing
- Programmable selection of reset or interrupt on an initial time-out
- Programmable selection of the servicing mode
- Master access protection
- Hard and soft configuration lock bits
- Reset configuration inputs allow timer to be enabled out of reset

50.2.3 Modes of operation

The SWT supports three device modes of operation: normal, debug and stop. When the SWT is enabled in normal mode, its counter runs continuously. In debug mode, operation of the counter is controlled by the FRZ bit in the SWT_CR. If the FRZ bit is set, the counter is stopped in debug mode, otherwise it continues to run. In stop mode, operation of the counter is controlled by the STP bit in the SWT_CR. If the STP bit is set, the counter is stopped in stop mode, otherwise it continues to run.

50.3 External signal description

The SWT module does not have any external interface signals.

50.4 Memory Map and Registers

The SWT programming model has seven 32-bit registers. The programming model can be accessed using only 32-bit (word) accesses.

Any of the following attempted accesses are invalid:

- References using non-32-bit access sizes
- Writes to read-only registers
- Writes of incorrect values to SWT_SR when the SWT is enabled
- Accesses to reserved addresses
- Accesses by masters without permission

For an enabled SWT, an invalid access generates a reset request if SWT_CR[RIA] is 1. An invalid access generates a bus error if SWT_CR[RIA] is 0.

If either HLK or SLK in SWT_CR is 1, then the SWT_CR, SWT_TO, SWT_WN, and SWT_SK registers are read-only.

SWT memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	SWT Control Register (SWT_CR)	32	R/W	See section	50.4.1/2151
4	SWT Interrupt Register (SWT_IR)	32	R/W	0000_0000h	50.4.2/2154
8	SWT Time-out Register (SWT_TO)	32	R/W	See section	50.4.3/2155
C	SWT Window Register (SWT_WN)	32	R/W	0000_0000h	50.4.4/2155
10	SWT Service Register (SWT_SR)	32	W	0000_0000h	50.4.5/2156
14	SWT Counter Output Register (SWT_CO)	32	R	0000_0000h	50.4.6/2156
18	SWT Service Key Register (SWT_SK)	32	R/W	0000_0000h	50.4.7/2157

50.4.1 SWT Control Register (SWT_CR)

NOTE

The reset value of this register is implementation specific. See the chip-specific SWT information.

The SWT_CR contains fields for configuring and controlling the SWT.

This register is read-only if either SWT_CR[HLK] or SWT_CR[SLK] is 1.

Address: 0h base + 0h offset = 0h

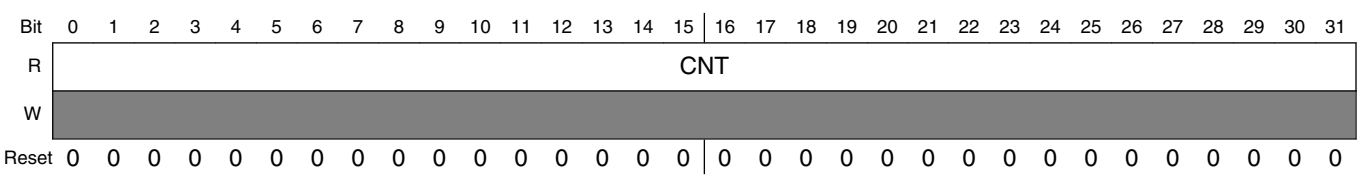
SWT_WN field descriptions

Field	Description
0–31 WST	Window Start Value When window mode is enabled, the service sequence can only be written when the internal down counter is less than this value.

50.4.5 SWT Service Register (SWT_SR)

The SWT Service (SWT_SR) register is the target for service operation writes used to reset the watchdog timer.

Address: 0h base + 10h offset = 10h



SWT_SR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 WSC	Watchdog Service Code This field is used to service the watchdog and to clear the Soft Lock bit (SWT_CR[SLK]). If the SWT_CR[SMD] field is 01b, two pseudorandom key values are written to service the watchdog; see Functional description for details. Otherwise, the sequence 0xA602 followed by 0xB480 is written to the WSC field. To clear the Soft Lock bit (SWT_CR[SLK]), the value 0xC520 followed by 0xD928 is written to the WSC field. When read, the WSC field always returns zero.

50.4.6 SWT Counter Output Register (SWT_CO)

The SWT Counter Output (SWT_CO) register is a read-only register that shows the value of the internal down counter when the SWT is disabled.

Address: 0h base + 14h offset = 14h

SWT_CO field descriptions

Field	Description
0–31 CNT	Watchdog Count When the watchdog is disabled (SWT_CR[WEN] is 0), this field shows the value of the internal down counter. When the watchdog is enabled (SWT_CR[WEN] is 1), this field is cleared (the value is

SWT_CO field descriptions (continued)

Field	Description
	0x0000_0000). Values in this field can lag behind the internal counter value for up to 6 system clock cycles plus 8 counter clock cycles. Therefore, the value read from this field immediately after disabling the watchdog may be higher than the actual value of the internal counter.

50.4.7 SWT Service Key Register (SWT_SK)

The SWT Service Key (SWT_SK) register holds the previous (or initial) service key value. This register is read-only if either SWT_CR[HLK] or SWT_CR[SLK] is 1.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SWT_SK field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 SK	Service Key This field is the previous (or initial) service key value used in keyed service mode. If SWT_CR[SMD] is 01b, the next key value to be written to the SWT_SR is (17*SK+3) mod 2^{16} .

50.5 Functional description

50.5.1 Introduction

The SWT is a 32-bit window watchdog timer designed to enable the system to recover in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. It includes:

- a control register (SWT_CR),
- an interrupt register (SWT_IR),
- a time-out register (SWT_TO),
- a window register (SWT_WN),
- a service register (SWT_SR),

- a counter output register (SWT_CO), and
- a service key register (SWT_SK).

Accesses to SWT registers occur with no peripheral bus wait states. (The peripheral bus bridge may add one or more system wait states.) However, due to synchronization logic in the SWT design, recognition of the service sequence or configuration changes may require up to three system plus seven counter clock cycles.

50.5.1.1 SWT_CR register

The SWT_CR register includes bits to enable the timer, set configuration options, and lock configuration of the module. The watchdog is enabled by setting the SWT_CR[WEN] bit. The reset value of the SWT_CR[WEN] bit is device specific.[3] If the reset value of this bit is 1, the watchdog starts operation automatically after reset is released. Some devices can be configured to clear this bit automatically during the boot process.

50.5.1.2 SWT_TO register

The SWT_TO register holds the watchdog time-out period in clock cycles unless the value is less than 0x100, in which case the time-out period is set to 0x100. When the SWT is enabled, the time-out period is loaded into an internal 32-bit down counter each time a valid service operation is performed. See the Configuration section to determine the source that is used to clock the down counter.

50.5.1.3 SWT_CO register

The SWT_CO register shows the value of the down counter when the watchdog is disabled. When the watchdog is enabled this register is cleared. The value shown in this register can lag behind the value in the internal counter for up to six system plus eight counter clock cycles.

The SWT_CO register can be used during a software self test of the SWT. For example, the SWT can be enabled and not serviced for a fixed period of time less than the time-out value. Then the SWT can be disabled (SWT_CR[WEN] cleared) and the value of the SWT_CO register read to determine if the internal down counter is working properly.

3. See the chip-specific SWT information.

50.5.2 Configuration locking

The configuration of the SWT can be locked through use of either a soft lock or a hard lock. In either case, when locked, the SWT_CR, SWT_TO, SWT_WN and SWT_SK registers are read-only.

50.5.2.1 Hard lock

The hard lock is enabled by setting the SWT_CR[HLK] bit, which can only be cleared by a reset.

50.5.2.2 Soft lock

The soft lock is enabled by setting the SWT_CR[SLK] bit and is cleared by writing the unlock sequence to the service register.

50.5.3 Unlock sequence

The unlock sequence is a write of 0xC520 followed by a write of 0xD928 to the SWT_SR[WSC] field. There is no timing requirement between the two writes. The unlock sequence logic ignores service sequence writes and recognizes the 0xC520, 0xD928 sequence regardless of previous writes. The unlock sequence can be written at any time and does not require the SWT_CR[WEN] bit to be set.

50.5.4 Servicing operations

When enabled, the SWT requires periodic execution of a servicing operation that is determined by the SWT_CR[SMD] field. Properly servicing the watchdog loads the internal down counter with the time-out period. The servicing modes are:

- fixed service sequence
- keyed service sequence
- fixed execution address
- incremental execution address

50.5.4.1 Fixed service sequence mode

If the SWT_CR[SMD] field is 00b, the fixed service sequence mode is selected, which requires writing 0xA602, then 0xB480 to the SWT_SR[WSC] field to service the watchdog. There is no timing requirement between the two writes and the service sequence logic ignores unlock sequence writes.

50.5.4.2 Keyed service sequence mode

If the SWT_CR[SMD] field is 01b, then the keyed service sequence mode is selected, which requires writing two pseudorandom keys to the SWT_SR[WSC] field to service the watchdog. The key values are determined by the pseudorandom key generator defined by the equation in the following figure. This algorithm will generate a sequence of 2^{16} different key values before repeating. The state of the key generator is held in the SWT_SK register. For example, if SWT_SK[SK] is 0x0100, then the service sequence keys are 0x1103, 0x2136. In this mode, each time a valid key is written to the SWT_SR register, the SWT_SK register is updated. So, after servicing the watchdog by writing 0x1103 and then 0x2136 to the SWT_SR[WSC] field, SWT_SK[SK] is 0x2136 and the next key sequence is 0x3499, 0x7E2C.

$$SK_{n+1} = (17 \times SK_n + 3) \bmod 2^{16}$$

Figure 50-1. Pseudorandom Key Generator

50.5.4.3 Fixed execution address mode

If the SWT_CR[SMD] field is set to 10b, the fixed execution address mode is selected, which requires executing code at the address loaded into the designated IAC register to service the watchdog. In this mode, the IAC register cannot be updated while the watchdog is enabled.

50.5.4.4 Incremental execution address mode

If the SWT_CR[SMD] field is set to 11b, the incremental execution address mode is selected, which requires executing code at the address loaded into the designated IAC register to service the watchdog. In this mode, the IAC register can be updated while the watchdog is enabled.

50.5.4.5 Window mode

If window mode is enabled (SWT_CR[WND] bit is 1), the service sequence must be applied in the last part of the time-out period defined by SWT_WN.

- The window is open when the down counter is less than the value in SWT_WN.
- Outside this window, service sequence writes are invalid accesses and generate a bus error or reset request depending on the value of SWT_CR[RIA].

For example, if SWT_TO is set to 5000 and SWT_WN is set to 1000, the service sequence must be applied in the last 20% of the time-out period.

Synchronization logic in the watchdog design slightly delays when the window opens. This delay could be up to 3 system clock cycles plus 4 counter clock cycles.

50.5.5 Time-out

The Interrupt Then Reset bit (SWT_CR[ITR]) controls the SWT's action taken when a time-out occurs.

- If the SWT_CR[ITR] bit is 0, the SWT generates a reset request immediately on any time-out.
- If the SWT_CR[ITR] bit is 1, an initial time-out causes the SWT to generate an interrupt and load the down counter with the time-out period.
  - The interrupt is indicated by the Time-out Interrupt Flag (SWT_IR[TIF]).
  - Clear the interrupt by writing 1 to SWT_IR[TIF].

  If the service sequence is not written before the second consecutive time-out, the SWT generates a reset request.

50.5.6 Initialization

All registers should be initialized before setting the SWT_CR[WEN] bit to enable the watchdog. Registers can be initialized in any sequence.

Chapter 51
Real Time Clock (RTC-API)

51.1 Chip-specific RTC-API information

51.1.1 RTC Configuration

The device contains one RTC and one API, where both can perform 32-bit comparisons. Both RTC and API timers can generate interrupts as well as wakeup from low power modes. API can also be used in conjunction with the Comparator module. In STANDBY0/LPU_STANDBY modes configurations, the API is configured to generate a START / NEXT type signal to inform the Comparator module that a 'compare' must be carried out. See Interaction with RTC API to cause wakeup for details.

NOTE

After functional resets, software would be able to read the correct value of the counter after three RTC clocks.

51.1.2 RTC register reset value

All register reset values for the RTC registers that are device specific are shown below. All other registers reset values are shown in the RTC Memory chapter.

RTC Control register resets to 0x0000_ 0000h.

51.1.3 Seamless RTC operation across functional and destructive resets

MPC5746C supports seamless RTC operation across functional and destructive reset with FIRC, SIRC and SXOSC . To support this feature using SXOSC, software should program GPR_CTL[RTC_SXOSC_FREE_RUNNING]. Using SIRC, this feature is limited to SIRC_CTL[SIRCDIV] as divide by 1.

NOTE

SXOSC should be turned ON (by MC_ME clock configurations) before configuring this GPR_CTL[RTC_SXOSC_ FREE_RUNNING] bit.

NOTE

MPC5746C does not support seamless RTC operation across functional and destructive reset using FXOSC.

51.1.4 RTC-API's stop-stop ack protocol

The RTC module provides the acknowledgement as soon as the stop request is made, however the RTC module remains functional.

51.2 Introduction

51.2.1 Overview

The RTC is a free running counter used for time keeping applications. The RTC may be configured to generate an interrupt at a pre-defined interval. The RTC also supports an autonomous periodic interrupt function used to generate an interrupt request.

51.2.2 Features

RTC features include:

- 32 bit counter
- 4 selectable counter clock sources
  - 128 KHz SIRC
  - 32 KHz SXOSC
  - 16 MHz FIRC
  - 8-40 MHz FXOSC
- Optional 512 prescalar and optional 32 prescalar connected in series in the clock path feeding the 32 bit counter.
- 32 bit counter supports times up to greater than 1.5 months with 1 ms resolution.
- 32 bit compare value to support interrupt intervals of 1 second up to greater than 1 hr with 1 second resolution.

- RTC interrupt with interrupt enable.
- Counter runs in all modes of operation.
- RTC status and control register are reset only by POR
- RTC counter is reset when counter is disabled by software and by POR.
- Autonomous periodic interrupt support includes:
  - 32 bit compare value to support wakeup intervals of 1.0 ms to 1 second
  - Wakeup logic has separate enable to support changing compare value while RTC running
  - API interrupt with interrupt enable
  - API compare value can be modified while RTC is running
- Optional interrupt for RTC match, API match, and RTC rollover.

51.2.3 Block Diagram

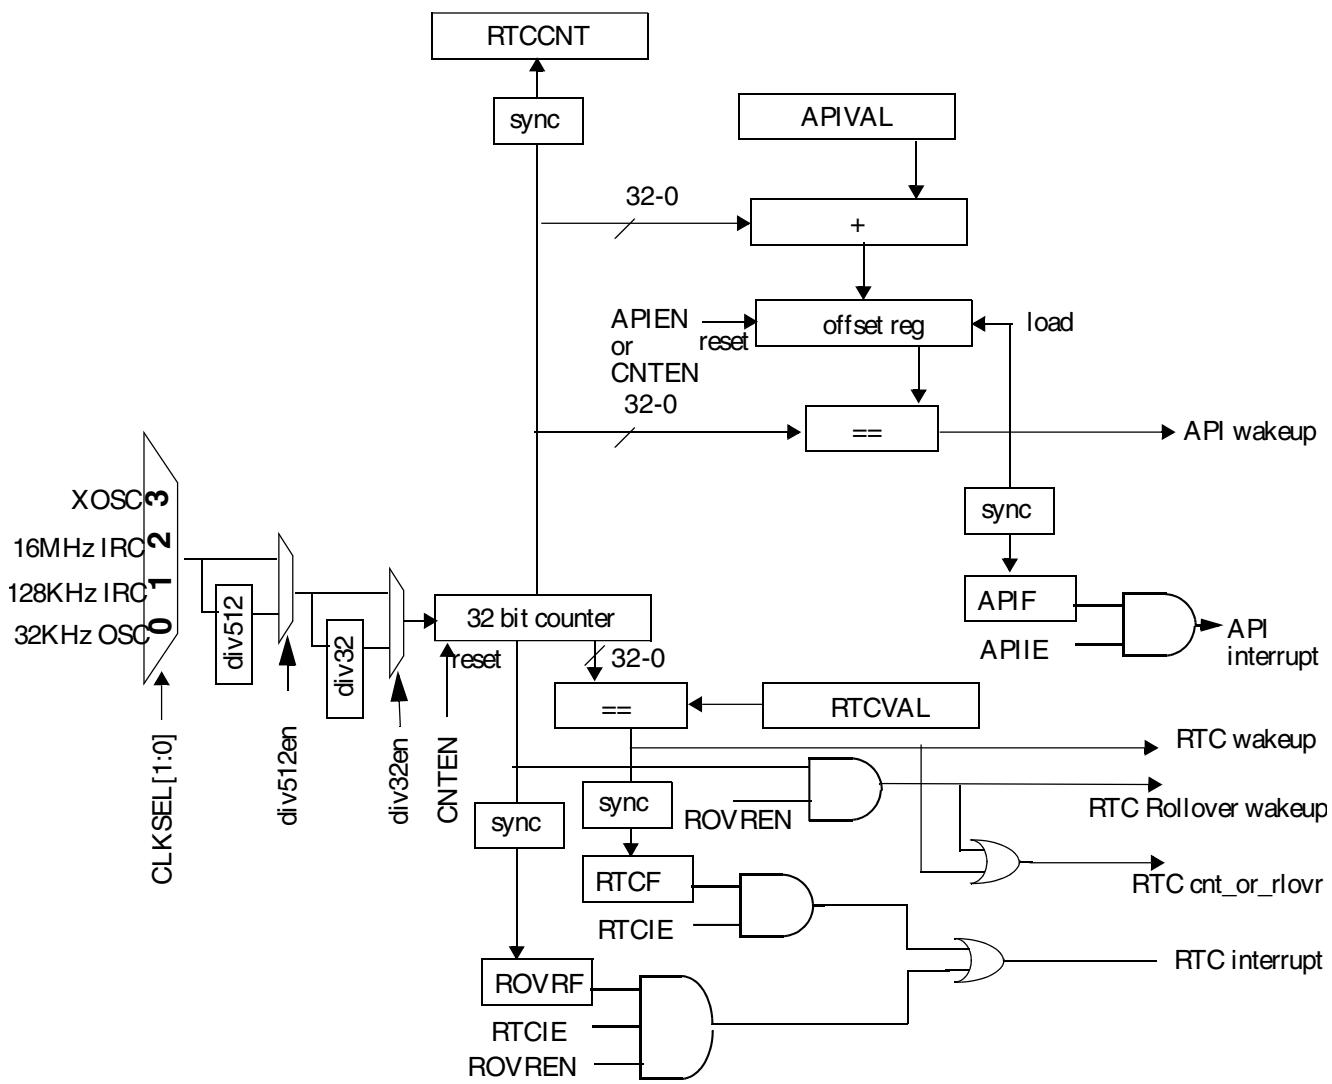

Figure 51-1. Block diagram

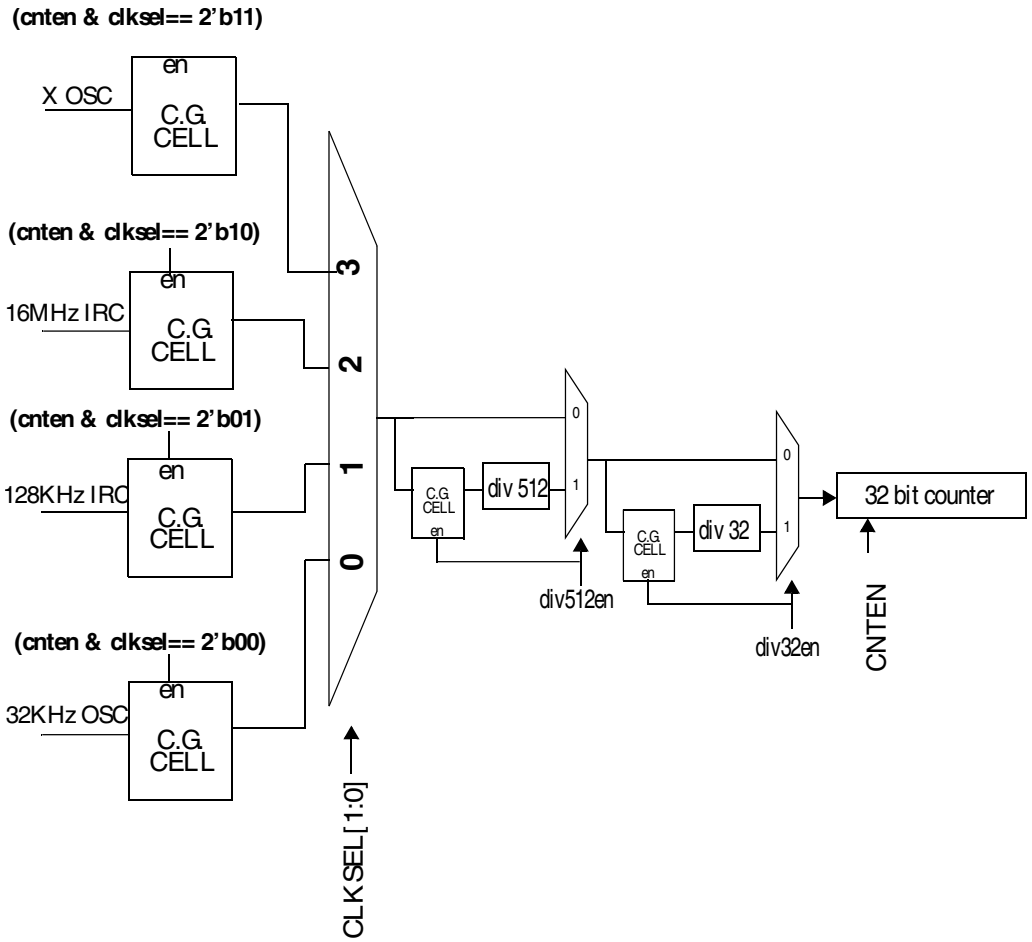

Figure 51-2. Clock gating for RTC clocks

51.2.4 Modes of Operation

51.2.4.1 Functional Mode

All RTC registers can read or written . The RTC/API and associated interrupts are optionally enabled.

51.2.4.2 Debug Mode

On entering into the debug mode the RTC counter freezes on the last valid count if the RTCC[FRZEN] is set. On exit from debug mode counter continues from the frozen value.

51.3 Memory Map and Registers

RTC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	RTC Supervisor Control register (RTC_RTCSUPV)	32	R/W	8000_0000h	51.3.1/2167
4	RTC Control register (RTC_RTCC)	32	R/W	See section	51.3.2/2168

RTC_RTCSUPV field descriptions (continued)

Field	Description
	0 All registers are accessible in both user as well as supervisor mode 1 All other registers are accessible in supervisor mode only
Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

51.3.2 RTC Control register (RTC_RTCC)

Address: 0h base + 4h offset = 4h

RTC_RTCC field descriptions

Field	Description
31 CNTEN	Counter Enable. The CNTEN bit enable the RTC counter. Making CNTEN bit 1'b0 has the effect of asynchronously resetting (synchronous reset negation) all the RTC and API logic. This allows for the RTC configuration and clock source selection to be updated without causing synchronization issues. 0 Counter disabled. 1 Counter enabled.
30 RTCIE	RTC Interrupt Enable. The RTCIE bit enables interrupts requests to the system if RTCF is asserted. 0 RTC interrupts disabled. 1 RTC interrupts enabled.
29 FRZEN	Freeze Enable Bit. The counter freezes on entering the debug mode on the last valid count value if the FRZEN bit is set. After coming of the debug mode counter starts from the frozen value.

Table continues on the next page...

RTC_RTCC field descriptions (continued)

Field	Description
	0 Counter does not freeze in debug mode. 1 Counter freezes in debug mode.
28 ROVREN	Counter Roll Over Wakeup/Interrupt Enable. The ROVREN bit enables wakeup and interrupt requests when the RTC has rolled over from 0xffff_ffff to 0x0000_0000. The RTCIE bit must also be set in order to generate an interrupt from a counter rollover. 0 RTC rollover wakeup/interrupt disabled 1 RTC rollover wakeup/interrupt enabled.
27–16 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
15 APIEN	Autonomous Periodic Interrupt Enable. The APIEN bit enables the autonomous periodic interrupt function. 0 API disabled. 1 API enabled.
14 APIIE	API Interrupt Enable. The APIIE bit enables interrupts requests to the system if APIF is asserted. 0 API interrupts disabled. 1 API interrupts enabled.
13–12 CLKSEL[1:0]	Clock Select. The CLKSEL[1:0] bits select the clock source for the RTC. CLKSEL may only be updated when CNTEN is 0. The user should ensure that oscillator is enabled before selecting it as a clock source for RTC. 00 32 KHz (Slow)XOSC 01 128KHz (Slow)IRC 10 16MHz (Fast)IRC 11 8-40MHz (Fast)OSC
11 DIV512EN	Divide by 512 enable. The DIV512En bit enables the 512 clock divider. DIV512EN may only be updated when CNTEN is 0. 0 Divide by 512 is disabled. 1 Divide by 512 is enabled
10 DIV32EN	Divide by 32 enable. The DIV32En bit enables the 32 clock divider.DIV32EN may only be updated when CNTEN is 0. 0 Divide by 32 is disabled. 1 Divide by 32 is enabled.
9–1 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

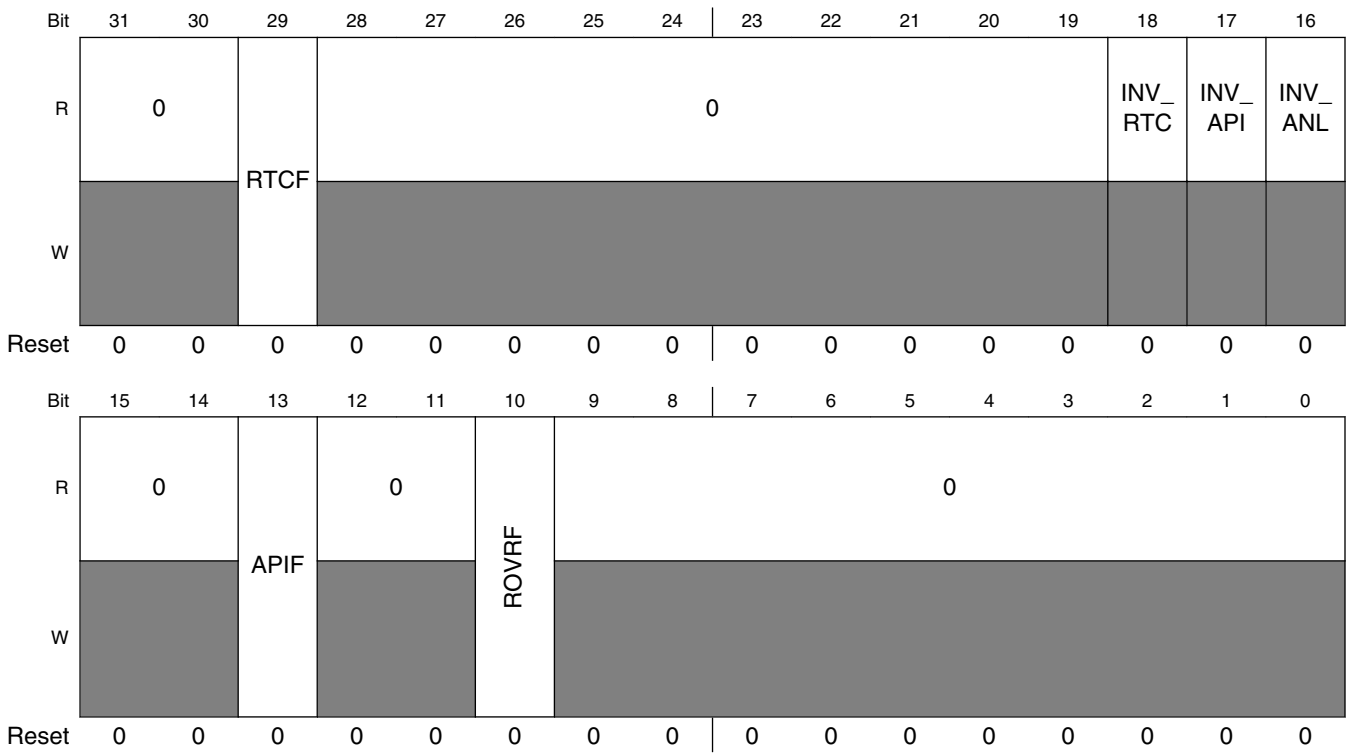

Table continues on the next page...

RTC_RTCC field descriptions (continued)

Field	Description
0 TRIG_EN	Trigger enable for Analog Comparator This bit when set will enable the trigger signal from RTC to Analog Comparator Block 0 Trigger enable is disabled 1 Trigger enable is enabled

Address: 0h base + 8h offset = 8h

RTC_RTCS field descriptions

Field	Description
31–30 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
29 RTCF	RTC Interrupt Flag. The RTCF bit indicates that the RTC counter has reached the counter value matching RTCVAL. RTCF is cleared by writing a 1 to RTCF. Writing a 0 to RTCF has no effect. 0 RTC counter is not equal to RTCVAL. 1 RTC counter matches RTCVAL.

Table continues on the next page...

RTC_RTCS field descriptions (continued)

Field	Description
28–19 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
18 INV_RTC	Invalid rtc write This bit becomes value 1 after a value has been written to the RTCVAL register and the synchronization process is continuing. During this synchronization period, any attempt to write to the RTCVAL register again will be ignored.
17 INV_API	Invalid APIVAL write This bit becomes value 1 after a value has been written to the APIVAL register and the synchronization process is continuing. During this synchronization period, any attempt to write to the APIVAL register again will be ignored.
16 INV_ANL	Invalid ANLCMP write This bit becomes value 1 after a value has been written to the ANLCMP_CNT register and the synchronization process is continuing. During this synchronization period, any attempt to write to the ANLCMP_CNT register again will be ignored.
15–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 APIF	API Interrupt Flag. The APIF bit indicates that the RTC counter has reached the counter value matching API offset value. APIF is cleared by writing a 1 to APIF. Writing a 0 to APIF has no effect. 0 Counter is not equal to API offset value. 1 Counter matches the API offset value.
12–11 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
10 ROVRF	Counter Roll Over Interrupt Flag. The ROVRF bit indicates that the RTC has rolled over from 0xffff_ffff to 0x0000_0000. ROVRF is cleared by writing a 1 to ROVRF. 0 RTC has not rolled over 1 RTC has rolled over
Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

51.3.4 RTC Counter register (RTC_RTCCNT)

Address: 0h base + Ch offset = Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RTCCNT[31:0]																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

RTC_RTCCNT field descriptions

Field	Description
RTCCNT[31:0]	RTC Counter Value. Due to the clock synchronization, the RTCCNT value may actually represent a previous counter value.

51.3.5 API Compare Value register (RTC_APIVAL)

The APIVAL bits are compared to the RTC counter bits and if a match occurrs, an interrupt/wakeup request is asserted.

Address: 0h base + 10h offset = 10h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	APIVAL																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

RTC_APIVAL field descriptions

Field	Description
APIVAL	API Compare Value. The APIVAL bits are compared to the RTC counter bits and if a match occurrs, an interrupt/wakeup request is asserted. **NOTE:** API functionality is active only when APIVAL is non zero. The first API interrupt takes two more cycles because of synchronization of APIVAL to rtc clock. After that, interrupts are periodic in nature and it takes APIVAL+1 cycles. Minimum supported value of APIVAL is 4. This is due to synchronization issues.

51.3.6 RTC Compare Value register (RTC_RTCVAL)

The RTCVAL bits are compared to the RTC counter bits and if a match occurs, RTCF is set. The minimum value of RTCVAL should be 4.

Address: 0h base + 14h offset = 14h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	RTCVAL																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

RTC_RTCVAL field descriptions

Field	Description
RTCVAL	RTC Compare Value. The RTCVAL bits are compared to the RTC counter bits and if a match occurs, RTCF is set.

51.3.7 RTC Analogue comparator count register (RTC_ANLCMP_CNT)

Address: 0h base + 18h offset = 18h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ANLCMP																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

RTC_ANLCMP_CNT field descriptions

Field	Description
ANLCMP	Analog Comparator Count Trigger from RTC to Analog Comparator block is generated as per the number of API clocks programmed into this register.

51.4 Functional Description

51.4.1 RTC

The RTC consists of a 32 bit free running counter enabled with the RTCC[CNTEN] bit (CNTEN when negated asynchronously resets the counter and synchronously enables the counter when enabled.) The value of the counter may be read via the RTCCNT register. Note that due to the clock synchronization, the RTCCNT value may actually represent a previous counter value. The difference between the counter and the read value depends on ratio of counter clock and Bus clock. Maximum possible difference between the two is 6 count values.

The clock source to the counter is selected with the RTCC[CLKSEL] field, which gives four options for clocking the RTC/API. The four clock sources are assumed to be one 16MHz source, one 32KHz source, one 128KHz source and one XOSC source. The output of the clock mux can be optionally divided by combination of 512 and 32 to give a 1ms RTC/API count period for different clock sources. Note that the RTCC[CNTEN] bit must be disabled when the RTC/API clock source is switched.

When the counter value for counter bits 31-0 match the 32-bit value in the RTCVAL[RTCVAL] field, then the RTCS[RTCF] interrupt flag bit is set (after proper clock synchronization). If the RTCC[RTCIE] interrupt enable bit is set, then the RTC interrupt request is generated. The RTC supports interrupt requests in the range of 1s to 4096s (> 1 hr.) with a 1s resolution. RTCVAL register can be written only when RTCS[INV_RTC] bit is clear. Initially RTCS[INV_RTC]=0, and hence RTCVAL can be written once and hence RTCS[INV_RTC] gets set. This bit can now be cleared only by enabling the RTC counter. Once the counter is enabled, RTCVAL can be written anytime now, untill RTC is disabled again. RTCVAL is first synchronized to rtc clock domain hence if RTCVAL is updated at the point where a counter match is due to happen in next two rtc clocks because of previous RTCVAL, RTIF flag will be set. However if the RTCVAL is updated at the point where no counter match is due as per the previous RTCVAL, the RTCF flag will be set when counter matches the new RTCVAL.

A rollover wakeup and/or interrupt can be generated when the RTC transitions from a count of 0xFFFF_FFFF to 0x0000_0000. The rollover flag is enabled by setting the RTCC[ROVREN] bit. An interrupt request is generated for an RTC counter rollover when both the RTCC[ROVREN] and RTCC[RTCIE] bits are set.

A trigger enable for the analog comparator block is also provided as an output from RTC API. A 32 bit counter starts incrementing if the RTCC[TRIG_EN] bit is set and the API asserts the wakeup signal. This counter will count up to the value programmed in the ANLCMP_CNT register and then will assert the trigger signal to Analog Comparator. This trigger is cleared on the next wakeup signal assertion.

All the flags and counter values are synchronized with Bus clock. It is assumed that the Bus clock frequency is always more than or equal to the RTC clock used to run the counter.

51.4.2 API functional description

Setting RTCC[APIEN] bit enables the autonomous interrupt function. The 32-bit RTCC[APIVAL] field selects the time interval for triggering an interrupt and/or wakeup event. Since the RTC is a free running counter, the APIVAL is added to the current count to calculate an offset. When the counter reaches the offset count, a interrupt and/or wakeup request is generated. Then the offset value is recalculated and again re-triggers a new request when the new value is reached. API function is enabled only when CNTEN and APIEN is asserted and APIVAL is non-zero. APIVAL can be updated anytime. After updation of APIVAL, the first API interrupt will be generated according the previous value. From the second interrupt onwards the API interrupt is generated with new APIVAL. When a compare is reached, the RTCS[APIF] interrupt flag bit is set (after proper clock synchronization). If the RTCC[APIIE] interrupt enable bit is set, then the API interrupt request is generated.

When the CNTEN is deasserted API function is reset.

Chapter 52
System Timer Module (STM)

52.1 Chip-specific STM information

52.1.1 STM configuration

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel.

The device includes two STMs, one for each core, with four 32-bit compare channels in each STM.

Table 52-1. System Timer Module (STM) instances

Instance	Description	Number of Channels	Number of Registers (32-bit)
STM_0	Intended for Z4 core in the high-speed computational clock domain.	4	14
STM_1	Intended for Z2 core in the peripheral clock domain.	4	14

52.1.1.1 STM Counter

In device STANDBY and LPU modes, only STM_0 is available.

NOTE

If any STM is enabled, then it should be re-initialized before entering into any low power mode (all STOP and STANDBY modes) so that the timer doesn't cause abort of the mode transitions.

52.1.2 STM register reset value

All register reset values for the STM registers that are device specific are shown below. All other registers reset values are shown in the STM Memory chapter

STM_0 Control register (SWT_0_TO) resets to 0x0000_ 0000h.

STM_1 Control register (SWT_1_TO) resets to 0x0000_ 0000h.

52.2 Introduction

This section provides an overview, list of features, and modes of operation for the STM.

52.2.1 Overview

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel.

52.2.2 Features

The STM has the following features:

- One 32-bit up counter with 8-bit prescaler
- Four 32-bit compare channels
- Independent interrupt source for each channel
- Counter can be stopped in debug mode
- Programmable selection of system clock or FXOSC clock for timer operation

52.2.3 Modes of operation

The STM supports two device modes of operation: normal and debug. When the STM is enabled in normal mode, its counter runs continuously. In debug mode, operation of the counter is controlled by the FRZ bit in the STM_CR register. If the FRZ bit is set, the counter is stopped in debug mode, otherwise it continues to run.

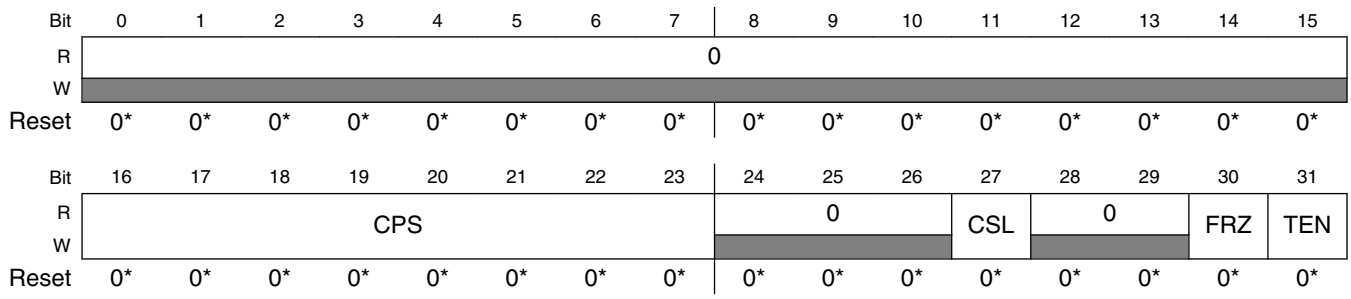
52.3 External signal description

The STM does not have any external interface signals.

52.4 Memory map and registers

The STM programming model includes a group of 32-bit registers—a module control register, a counter value register, and three registers for each channel.

The STM registers can only be accessed using 32-bit (word) accesses. Attempted references using a different size or to a reserved address generates a bus error termination.



STM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	STM Control Register (STM_CR)	32	R/W	See section	52.4.1/2180

38	STM Channel Compare Register (STM_CMP2)	32	R/W	0000_0000h	52.4.5/2183
40	STM Channel Control Register (STM_CCR3)	32	R/W	0000_0000h	52.4.3/2182
44	STM Channel Interrupt Register (STM_CIR3)	32	w1c	0000_0000h	52.4.4/2182
48	STM Channel Compare Register (STM_CMP3)	32	R/W	0000_0000h	52.4.5/2183

52.4.1 STM Control Register (STM_CR)

The STM Control Register includes the prescale value, freeze control and timer enable bits.

Address: 0h base + 0h offset = 0h

* Notes:
- The reset value is implementation specific. See the Configuration information.

STM_CR field descriptions

Field	Description
0–15 Reserved	This read-only field is reserved and always has the value 0.
16–23 CPS	Counter Prescaler. Selects the clock divide value for the prescaler (1 - 256). 0x00 Divide system clock by 1 0x01 Divide system clock by 2 ---------- 0xFF Divide system clock by 256
24–26 Reserved	This read-only field is reserved and always has the value 0.
27 CSL	Clock Selection. Selects the clock that drives the internal timer. 0 System clock. 1 FXOSC clock.
28–29 Reserved	This read-only field is reserved and always has the value 0.
30 FRZ	Freeze. Allows the timer counter to be stopped when the device enters debug mode. **NOTE:** When the MCU enters debug mode, the STM is notified and uses the FRZ bit to determine counter mode.

Table continues on the next page...

STM_CR field descriptions (continued)

Field	Description
	0 STM counter continues to run in debug mode. 1 STM counter is stopped in debug mode.
31 TEN	Timer counter Enabled. 0 Counter is disabled. 1 Counter is enabled.

52.4.2 STM Count Register (STM_CNT)

The STM Count Register holds the timer count value.

NOTE

Due to two clock sources and different clock domains, Values in this field can lag behind the internal counter value for up to six system plus eight counter clock cycles. Therefore, the value read from this field immediately after may be lower than the actual value of the internal counter.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

STM_CIR*n* field descriptions

Field	Description
0–30 Reserved	This read-only field is reserved and always has the value 0.
31 CIF	Channel Interrupt Flag 0 No interrupt request. 1 Interrupt request due to a match on the channel.

52.4.5 STM Channel Compare Register (STM_CMP*n*)

The STM channel compare register (STM_CMPn) holds the compare value for channel n.

Address: 0h base + 18h offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	CMP																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

STM_CMP*n* field descriptions

Field	Description
0–31 CMP	Compare value for channel n. If the STM_CCRn[CEN] bit is set and the STM_CMPn register matches the STM_CNT register, a channel interrupt request is generated and the STM_CIRn[CIF] bit is set.

52.5 Functional description

The STM has one 32-bit up counter (STM_CNT) that is used as the time base for all channels. When enabled, the counter increments at the frequency of the clock selected by STM_CR[CSL] divided by a prescale value. The STM_CR[CPS] field sets the divider to any value in the range from 1 to 256. The counter is enabled with the STM_CR[TEN] bit. When enabled in normal mode the counter continuously increments. When enabled in debug mode the counter operation is controlled by the STM_CR[FRZ] bit. When the STM_CR[FRZ] bit is set, the counter is stopped in debug mode, otherwise it continues to run in debug mode. The counter rolls over at 0xFFFF_FFFF to 0x0000_0000 with no restrictions at this boundary.

The STM has four identical compare channels. Each channel includes a channel control register (STM_CCR*n*), a channel interrupt register (STM_CIR*n*), and a channel compare register (STM_CMP*n*). The channel is enabled by setting the STM_CCR*n*[CEN] bit. When enabled, the channel will set the STM_CIR*n*[CIF] bit and generate an interrupt request when the channel compare register matches the timer counter. The interrupt request is cleared by writing a 1 to the STM_CIR*n*[CIF] bit. A write of 0 to the STM_CIR*n*[CIF] bit has no effect.

Note

The STM counter does not advance when the system clock selected by STM_CR[CSL] is stopped.

Chapter 53
Reset Generation Module (MC_RGM)

53.1 Introduction

53.1.1 Overview

The reset generation module (MC_RGM) centralizes the different reset sources and manages the reset sequence of the chip. It provides a register interface and the reset sequencer. Various registers are available to monitor and control the chip reset sequence. The reset sequencer is a state machine which controls the different phases (PHASE0, PHASE1, PHASE2, PHASE3, and IDLE) of the reset sequence and controls the reset signals generated in the system.

The following figure shows the MC_RGM block diagram.

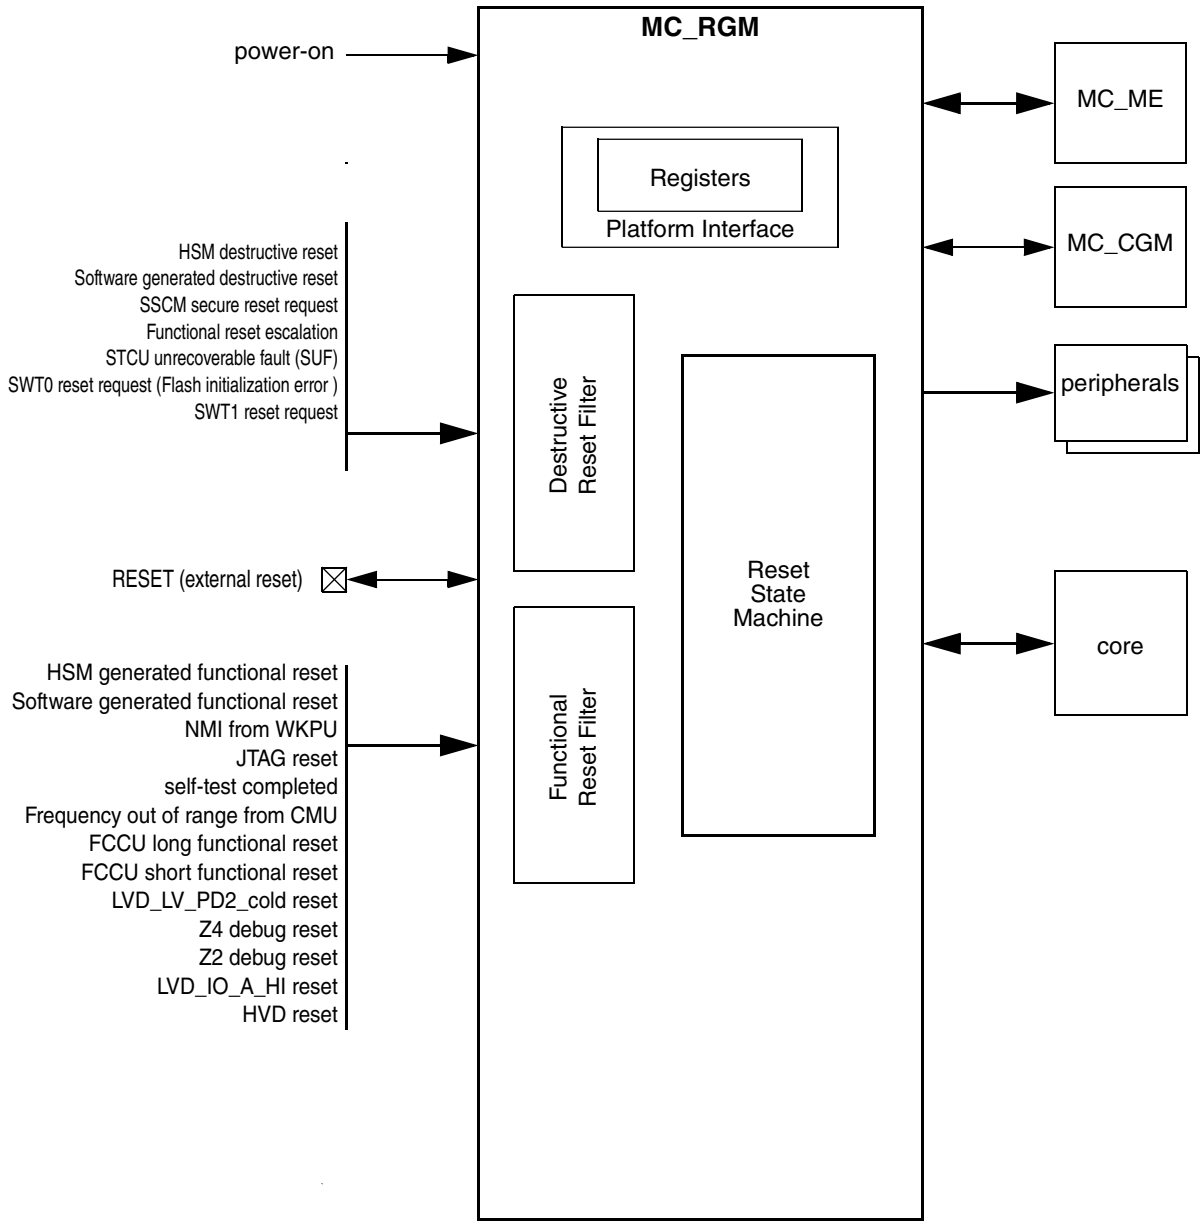

Figure 53-1. MC_RGM Block Diagram

53.1.2 Features

The MC_RGM contains the functionality for the following features:

- 'Destructive' resets management
- 'Functional' resets management
- Signaling of reset events after each reset sequence (reset status flags)
- Conversion of reset events to SAFE mode or interrupt request events

- short reset sequence configuration
- Bidirectional reset behavior configuration
- Boot mode capture on RESET deassertion
- Configurable escalation of recurring ‘functional’ resets to ‘destructive’ reset
- Configurable escalation of recurring ‘destructive’ resets to keep chip in reset state until next power-on reset

53.1.3 Reset Sources

The different reset sources are organized into two families: 'destructive' and 'functional'.

- A 'destructive' reset source is associated with an event related to a critical - usually hardware - error or dysfunction. When a 'destructive' reset event occurs, the full reset sequence is applied to the chip starting from PHASE0. This resets the full chip ensuring a safe start-up state for both digital and analog modules, and the memory content must be considered to be unknown. 'Destructive' resets are
  - power-on reset
  - HSM destructive reset
  - Software-generated destructive reset
  - SSCM secure reset request
  - 'functional' reset escalation
  - STCU unrecoverable fault (SUF)
  - SWT0 reset request (Flash initialization error)
  - SWT1 reset request
- A 'functional' reset source is associated with an event related to a less-critical - usually non-hardware - error or dysfunction. When a 'functional' reset event occurs, a partial reset sequence is applied to the chip starting from PHASE1. In this case, most digital modules are reset normally, while the state of analog modules or specific digital modules (e.g., debug modules, flash modules) as well as the system memory content is preserved. 'Functional' resets are
  - external reset
  - HSM-generated functional reset

- Software-generated functional reset
- NMI[3] from WKPU
- JTAG reset
- Self-test completed
- Frequency out of range from CMU
- FCCU long functional reset
- FCCU short functional reset
- LVD_LV_PD2_cold reset
- Z4A debug reset
- Z2 debug reset
- LVD_IO_A_HI reset
- HVD_LV_cold reset

When a reset is triggered, the MC_RGM state machine is activated and proceeds through the different phases (i.e., PHASEn states). Each phase is associated with a particular chip reset being provided to the system. A phase is completed when all corresponding phase completion gates from either the system or internal to the MC_RGM are acknowledged. The chip reset associated with the phase is then released, and the state machine proceeds to the next phase up to entering the IDLE phase. During this entire process, the MC_ME state machine is held in RESET mode. Only at the end of the reset sequence, when the IDLE phase is reached, does the MC_ME enter the DRUN mode.

Alternatively, it is possible for software to configure some reset source events to be converted from a reset to either a SAFE mode request issued to the MC_ME or to an interrupt issued to the core (see 'Functional' Event Reset Disable Register (MC_RGM_FERD) and 'Functional' Event Reset DisableAlternate Request Status Register (MC_RGM_FEAR)) for 'functional' resets.

53.2 External Signal Description

The MC_RGM interfaces to the bidirectional reset pin RESET.

53.3 Memory Map and Register Definition

Any access to unused registers as well as write accesses to read-only registers will:

- not change register content
- cause a transfer error

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the RGM_DES[8:15] register bits may be accessed as a word at address offset 0x000, as a half-word at address offset 0x002, or as a byte at address offset 0x003.

Some fields may be read-only, and their reset value of '1' or '0' and the corresponding behavior cannot be changed.

NOTE

The access defined for all the registers in the following table is for the User mode. For Supervisor and Test modes, please refer to the individual registers.

NOTE

Reserved fields should always be written with their reset values only.

NOTE

The following registers are reset to their default values during POR event only:

- RGM_DES
- RGM_FES
- RGM_DRET

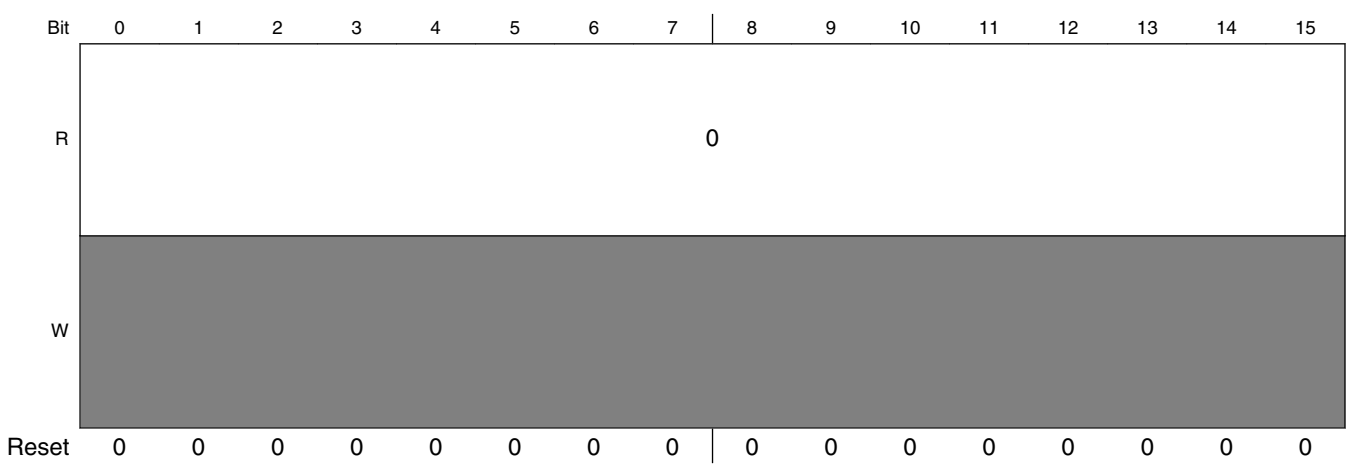
26 F_FUNC_ESC	Flag for Functional Reset Escalation 0 No functional reset escalation event has occurred since either the last clear or the last power-on reset assertion. 1 A functional reset escalation event has occurred.
27 F_SSCM_SEC	Flag for SSCM Secure Reset Request 0 No SSCM Secure Reset Request event has occurred since either the last clear or the last power-on reset assertion. 1 An SSCM Secure Reset Request event has occurred.
28 F_SOFT_DEST	Flag for Software Generated Destructive Reset 0 No Software generated destructive reset event has occurred since either the last clear or the last power-on reset assertion. 1 A Software generated destructive reset event has occurred.

Table continues on the next page...

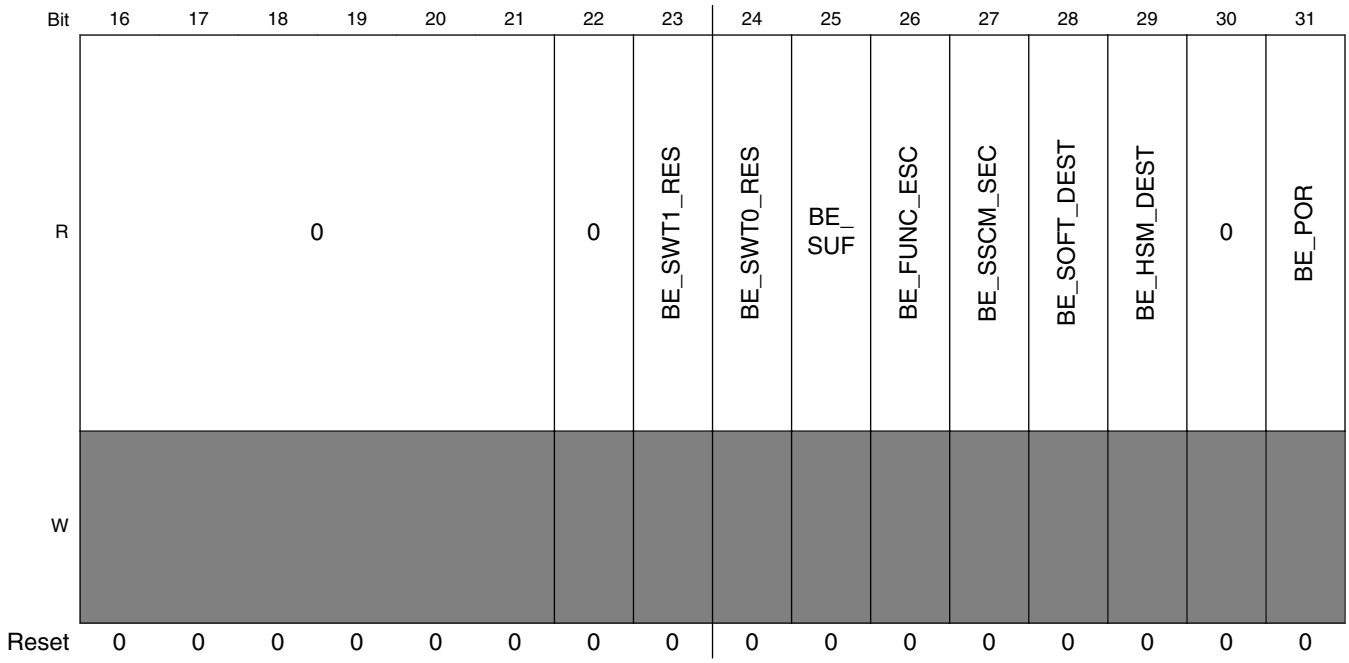
MC_RGM_DES field descriptions (continued)

Field	Description
29 F_HSM_DEST	Flag for HSM Destructive Reset 0 No HSM destructive reset event has occurred since either the last clear or the last power-on reset assertion. 1 A HSM destructive reset event has occurred.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 F_POR	Flag for Power-On Reset 0 No power-on event has occurred since the last clear. 1 A power-on event has occurred.

53.3.2 'Destructive' Bidirectional Reset Enable Register (MC_RGM_DBRE)



This register enables the generation of an external reset on ‘destructive’ reset. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.



This register is reset only on power-on.

Access:

User read, Supervior read/write, Test read/write

Address: 0h base + 30h offset = 30h

MC_RGM_DBRE field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 BE_SWT1_RES	Bidirectional Reset Enable for SWT1 Reset 0 RESET is asserted on SWT1 Reset event if the reset is enabled.
24 BE_SWT0_RES	Bidirectional Reset Enable for SWT0 (Flash Initialization Failure) Reset 0 RESET is asserted on SWT0 (Flash Initialization Failure) Reset event if the reset is enabled.
25 BE_SUF	Bidirectional Reset Enable for SUF (STCU unrecoverable fault) 0 RESET is asserted on SUF (STCU unrecoverable fault) event if the reset is enabled.
26 BE_FUNC_ESC	Bidirectional Reset Enable for Functional Reset Escalation 0 RESET is asserted on a functional reset escalation event if the reset is enabled.
27 BE_SSCM_SEC	Bidirectional Reset Enable for SSCM Secure Reset Request 0 RESET is asserted on SSCM Secure Reset Request event if the reset is enabled.
28 BE_SOFT_DEST	Bidirectional Reset Enable for Software Generated Destructive Reset 0 RESET is asserted on a Software generated destructive reset event if the reset is enabled.
29 BE_HSM_DEST	Bidirectional Reset Enable for HSM Generated Functional Reset 0 RESET is asserted on a HSM genrated functional reset event if the reset is enabled.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

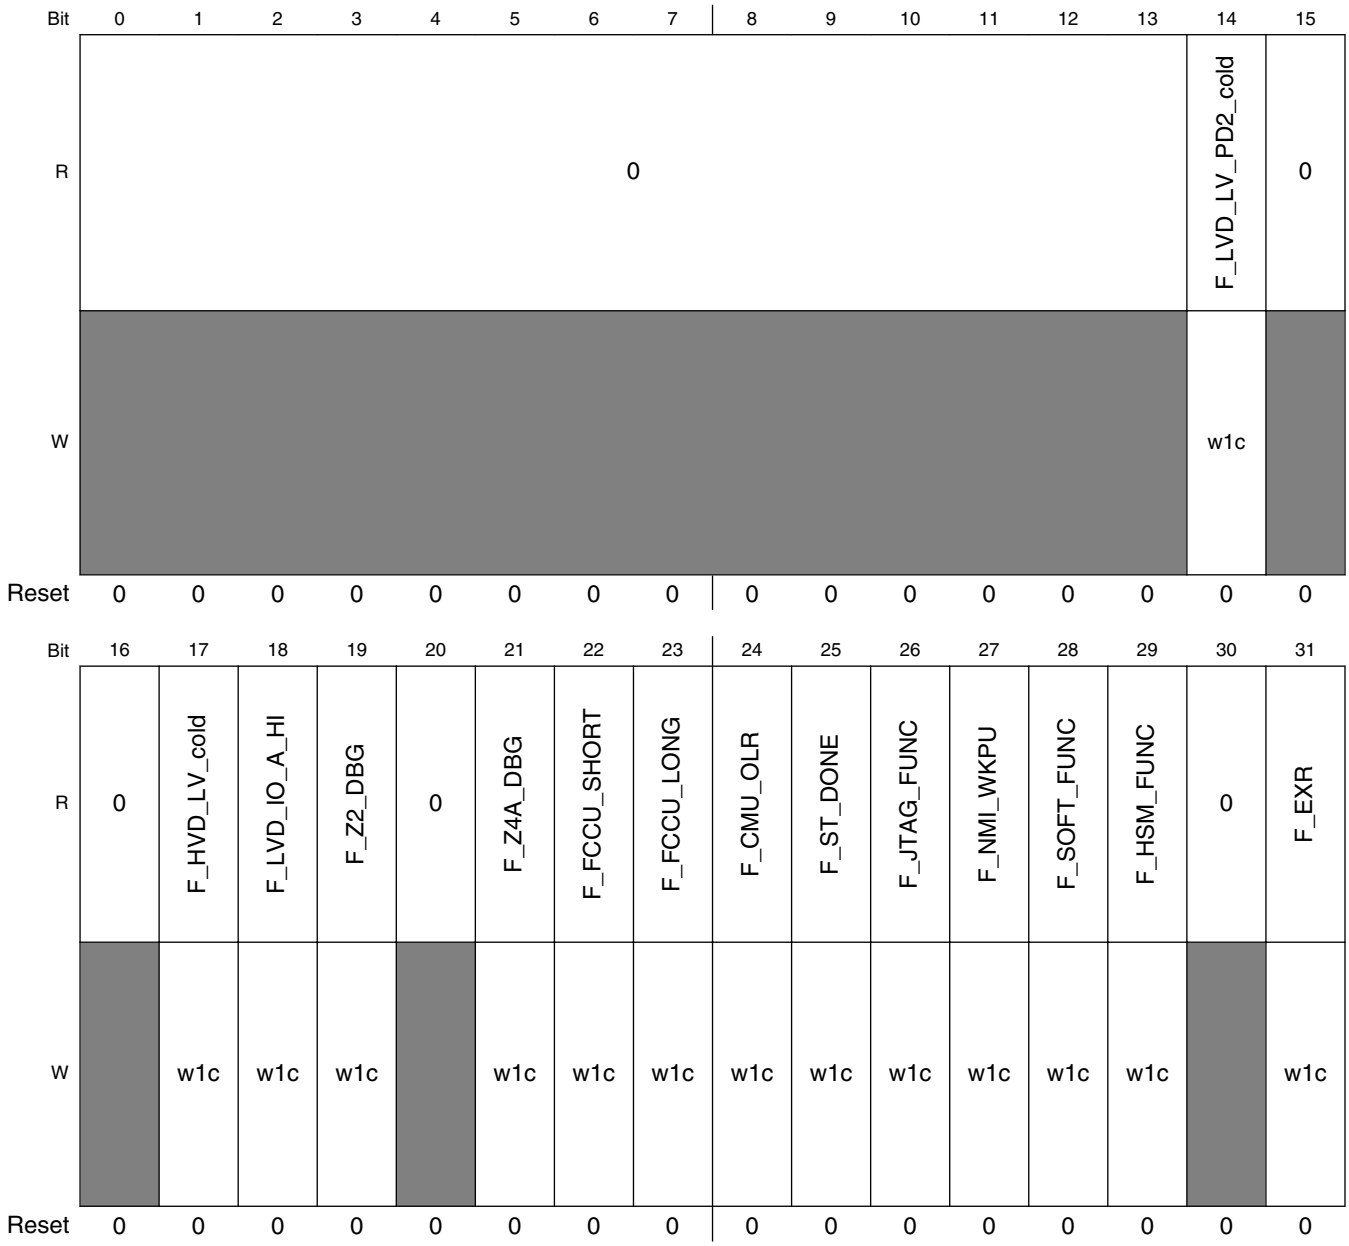
MC_RGM_DBRE field descriptions (continued)

Field	Description
31 BE_POR	Bidirectional Power-On Reset 0 No power-on event has occurred since the last clear.

53.3.3 'Functional' Event Status Register (MC_RGM_FES)

This register contains the status of the ‘functional’ reset sources, including those configured to not generate a reset sequence. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Register bits are cleared on write ‘1’ if the triggering event has already been cleared at the source.

This register is reset only on power-on.



NOTE

If a ‘functional’ reset source is configured to generate a SAFE mode request or an interrupt request, software needs to clear the event in the source module at least three system clock cycles before it clears the associated RGM_FES status bit in order to avoid multiple SAFE mode requests or interrupts for the same event. In order to avoid having to count cycles, it is good practice for software to check whether the RGM_FES has been properly cleared, and if not, clear it again.

Access:

User read, Supervior read/write, Test read/write

Address: 0h base + 300h offset = 300h

MC_RGM_FES field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 F_LVD_LV_ PD2_cold	Flag for PD2 LVD at cold point 0 No PD2 LVD at cold point event has occurred since either the last clear or the last ‘destructive’ reset assertion. 1 A PD2 LVD at cold point event has occurred
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

MC_RGM_FES field descriptions (continued)

Field	Description
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 F_HVD_LV_cold	Flag for High Voltage Detect 0 No High Voltage Detect event has occurred since either the last clear or the last ‘destructive’ reset assertion. 1 A High Voltage Detect event has occurred.
18 F_LVD_IO_A_HI	Flag for Low-Voltage Detect IOs 0 No Low-Voltage Detect IOs event has occurred since either the last clear or the last ‘destructive’ reset assertion. 1 Low-Voltage Detect IOs event has occurred.
19 F_Z2_DBG	Flag for Z2 Debug Reset 0 No Z2 Debug Reset event has occurred since either the last clear or the last ‘destructive’ reset assertion. 1 A Z2 Debug Reset event has occurred.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 F_Z4A_DBG	Flag for Z4A Debug Reset 0 No Z4A Debug Reset event has occurred since either the last clear or the last ‘destructive’ reset assertion. 1 A Z4A Debug Reset event has occurred.
22 F_FCCU_ SHORT	Flag for FCCU Short Functional Reset 0 No FCCU short functional reset event has occurred since either the last clear or the last ‘destructive’ reset assertion. 1 A FCCU short functional reset event has occurred.
23 F_FCCU_LONG	Flag for FCCU Long Functional Reset 0 No FCCU long functional reset event has occurred since either the last clear or the last ‘destructive’ reset assertion. 1 A FCCU long functional reset event has occurred.
24 F_CMU_OLR	Flag for OSC Frequency less than RC 0 No OSC Frequency less than RC event has occurred since either the last clear or the last ‘destructive’ reset assertion. 1 A OSC Frequency less than RC event has occurred.
25 F_ST_DONE	Flag for Selt Test Completed 0 No Selt test completed event has occurred since either the last clear or the last ‘destructive’ reset assertion. 1 A Selt test completed event has occurred.
26 F_JTAG_FUNC	Flag for JTAG Functional Reset 0 No JTAG Functional Reset event has occurred since either the last clear or the last ‘destructive’ reset assertion. 1 A JTAG Functional Reset event has occurred. For example, the EXTEST, HIGHZ, and CLAMP instructions cause a JTAG 'functional' reset event to occur, which sets this field to 1.

Table continues on the next page...

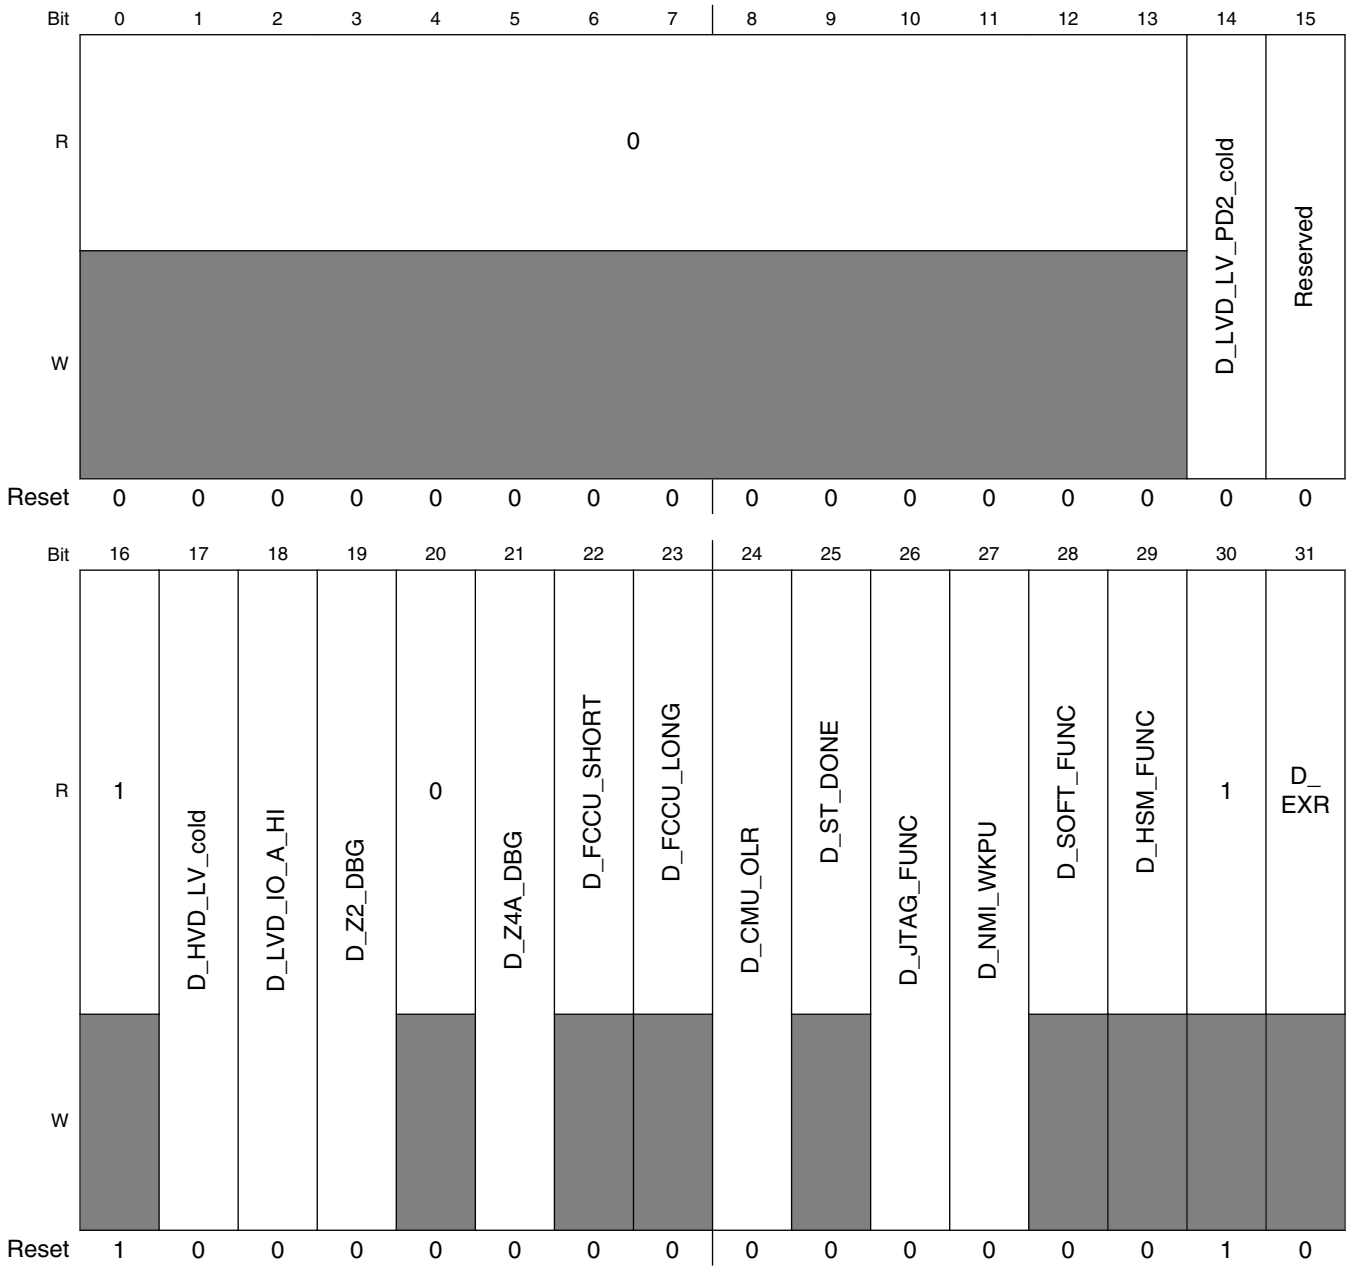
MC_RGM_FES field descriptions (continued)

Field	Description
27 F_NMI_WKPU	Flag for Non Maskable Interrupt from Wakeup Unit 0 No Non Maskable Interrupt from Wakeup Unit event has occurred since either the last clear or the last 'destructive' reset assertion. 1 A Non Maskable Interrupt from Wakeup Unit event has occurred.
28 F_SOFT_FUNC	Flag for Software Generated Functional Reset 0 No Software generated functional reset event has occurred since either the last clear or the last destructive' reset assertion. 1 A Software generated functional reset event has occurred.
29 F_HSM_FUNC	Flag for HSM Generated Functional Reset 0 No HSM genrated functional reset event has occurred since either the last clear or the last 'destructive' reset assertion. 1 A HSM genrated functional reset event has occurred.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 F_EXR	Flag for External Reset 0 No External reset event has occurred since either the last clear or the last 'destructive' reset assertion. 1 An external reset event has occurred.

53.3.4 'Functional' Event Reset Disable Register (MC_RGM_FERD)

This register provides dedicated bits to disable 'functional' reset sources.When a 'functional' reset source is disabled, the associated 'functional' event will trigger either a SAFE mode request or an interrupt request (see 'Functional' Event Reset DisableAlternate Request Status Register (MC_RGM_FEAR)). It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Each byte can be written only once after a 'destructive' or power-on reset.

This register is reset only on power-on and any 'destructive' reset.



NOTE

It is important to clear the RGM_FES register before setting any of the bits in the RGM_FERD register to '1'. Otherwise a redundant SAFE mode request or interrupt request may occur.

Access:

User read, Supervior read/write, Test read/write

Address: 0h base + 310h offset = 310h

MC_RGM_FERD field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 D_LVD_LV_ PD2_cold	Disable PD2 LVD at cold point 0 A PD2 LVD at cold point event triggers a reset sequence. 1 A PD2 LVD at cold point event generates either a SAFE mode or an interrupt request depending on the value of RGM_FEAR.AR_Z4A_DBG.
15 Reserved	This field is reserved.

Table continues on the next page...

MC_RGM_FERD field descriptions (continued)

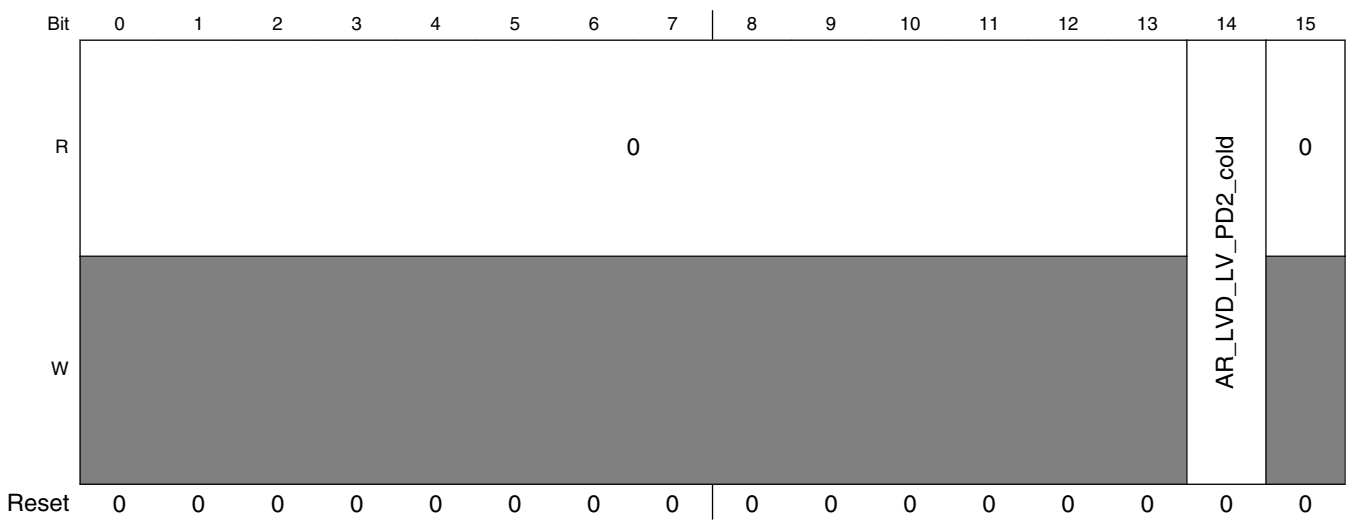
Field	Description
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
17 D_HVD_LV_cold	Disable High Voltage Detect 0 A High Voltage Detect event triggers a reset sequence. 1 A High Voltage Detect event generates either a SAFE mode or an interrupt request depending on the value of RGM_FEAR.AR_HVD_LV_cold.
18 D_LVD_IO_A_HI	Disable Low Voltage Detect IOs 0 A Low Voltage Detect IOs event triggers a reset sequence. 1 A Low Voltage Detect IOs event generates either a SAFE mode or an interrupt request depending on the value of RGM_FEAR.AR_LVD_IO.
19 D_Z2_DBG	Disable Z2 Debug Rreset 0 A Z2 Debug Reset event triggers a reset sequence. 1 A Z2 Debug Reset event generates either a SAFE mode or an interrupt request depending on the value of RGM_FEAR.AR_Z2_DBG.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 D_Z4A_DBG	Disable Z4A Debug Reset 0 A Z4A Debug Reset event triggers a reset sequence. 1 A Z4A Debug Reset event generates either a SAFE mode or an interrupt request depending on the value of RGM_FEAR.AR_Z4A_DBG.
22 D_FCCU_ SHORT	Disable FCCU Short Functional Reset 0 A FCCU short functional reset event triggers a reset sequence.
23 D_FCCU_LONG	Disable FCCU Long Functional Reset 0 A FCCU long functional reset event triggers a reset sequence.
24 D_CMU_OLR	Disable OSC Frequency less than RC **NOTE** In case OLR is configured as safe mode request, Exit from SAFE mode should be always done via any functional Reset to avoid any unpredictable behavior. 0 OSC Frequency less than RC event triggers a reset sequence. 1 OSC Frequency less than RC event generates either a SAFE mode or an interrupt request depending on the value of RGM_FEAR.AR_CMU_OLR.
25 D_ST_DONE	Disable Selt Test Completed 0 A Selt test completed event triggers a reset sequence.
26 D_JTAG_FUNC	Disable JTAG Functional Reset 0 JTAG Functional Reset event triggers a reset sequence. 1 JTAG Functional Reset event generates either a SAFE mode or an interrupt request depending on the value of RGM_FEAR.AR_JTAG_FUNC.
27 D_NMI_WKPU	Disable Non Maskable Interrupt from Wakeup Unit

Table continues on the next page...

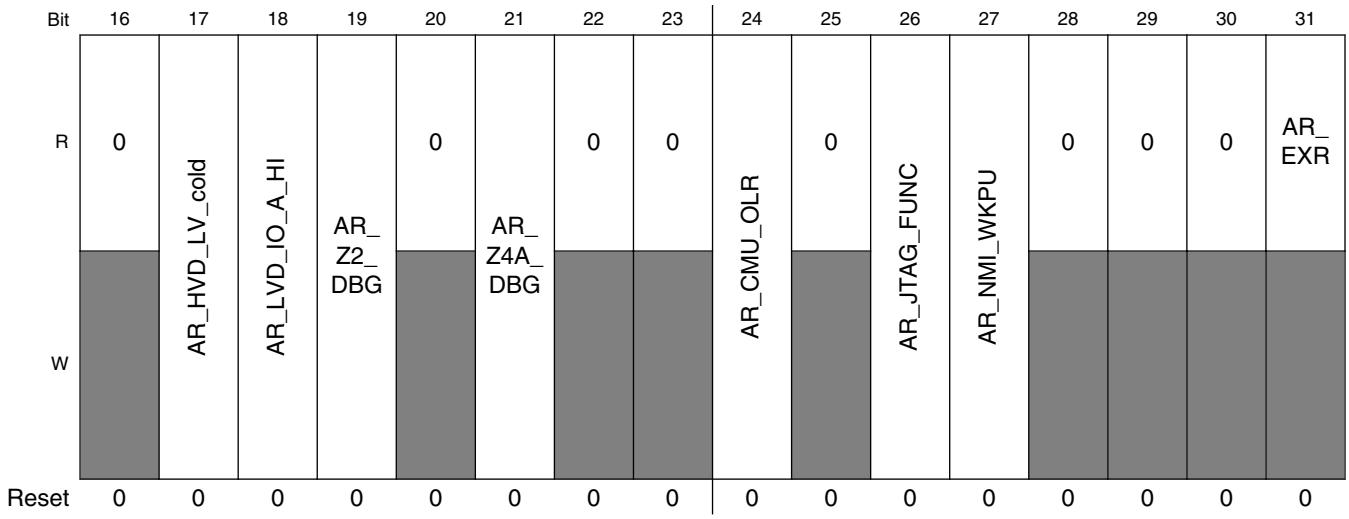
MC_RGM_FERD field descriptions (continued)

Field	Description
	0 A Non Maskable Interrupt from Wakeup Unit event triggers a reset sequence. 1 A Non Maskable Interrupt from Wakeup Unit event generates either a SAFE mode or an interrupt request depending on the value of RGM_FEAR.AR_NMI_WKPU.
28 D_SOFT_FUNC	Disable Software Generated Functional Reset 0 A Software generated functional reset event triggers a reset sequence.
29 D_HSM_FUNC	Disable HSM Genrated Functional Reset 0 A HSM genrated functional reset event triggers a reset sequence
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
31 D_EXR	Disable External Reset 0 No External reset event has occurred since either the last clear or the last ‘destructive’ reset assertion.

53.3.5 'Functional' Event Reset DisableAlternate Request Status Register (MC_RGM_FEAR)



This register defines an alternate request to be generated when a reset on a ‘functional’ event has been disabled. The alternate request can be either a SAFE mode request to MC_ME or an interrupt request to the system. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.



This register is reset only on power-on and any ‘destructive’ reset.

Access:

User read, Supervior read/write, Test read/write

Address: 0h base + 320h offset = 320h

MC_RGM_FEAR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 AR_LVD_LV_PD2_cold	Alternate Request for PD2 LVD at cold point 0 Generate a SAFE mode request on PD2 LVD at cold point event if the reset is disabled. 1 Generate an interrupt request on PD2 LVD at cold point event if the reset is disabled.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 AR_HVD_LV_cold	Alternate Request for High Voltage Detect 0 Generate a SAFE mode request on a High Voltage Detect event if the reset is disabled. 1 Generate an interrupt request on High Voltage Detect event if the reset is disabled.
18 AR_LVD_IO_A_HI	Alternate Request for Low Voltage Detect IOs 0 Generate a SAFE mode request on Low Voltage Detect IOs event if the reset is disabled. 1 Generate an interrupt request on Low Voltage Detect IOs event if the reset is disabled.
19 AR_Z2_DBG	Alternate Request for Z2 Debug Reset 0 Generate a SAFE mode request on Z2 Debug Reset event if the reset is disabled. 1 Generate an interrupt request on Z2 Debug Reset event if the reset is disabled.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 AR_Z4A_DBG	Alternate Request for Z4A Debug Reset 0 Generate a SAFE mode request on Z4A Debug Reset event if the reset is disabled. 1 Generate an interrupt request on ZA Debug Reset event if the reset is disabled.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

Field	Description
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 BE_HVD_LV_cold	Bidirectional Reset Enable for High Voltage Detect 0 RESET is asserted on a High Voltage Detect event if the reset is enabled. 1 RESET is not asserted on a High Voltage Detect event.
18 BE_LVD_IO_A_HI	Bidirectional Reset Enable for Low Voltage Detect IOs 0 RESET is asserted on a Low Voltage Detect IOs event if the reset is enabled. 1 RESET is not asserted on a Low Voltage Detect IOs event.
19 BE_Z2_DBG	Bidirectional Reset Enable for Z2 debug reset 0 RESET is asserted on a Z2 debug reset event if the reset is enabled. 1 RESET is not asserted on a Z2 debug reset event.
20 Reserved	This field is reserved.
21 BE_Z4A_DBG	Bidirectional Reset Enable for Z4A Debug Reset 0 RESET is asserted on a Z4A debug reset event if the reset is enabled. 1 RESET is not asserted on a Z4A debug reset event.
22 BE_FCCU_SHORT	Bidirectional Reset Enable for FCCU Short Functional Reset 0 RESET is asserted on a FCCU short functional reset event if the reset is enabled. 1 RESET is not asserted on a FCCU Short Functional Reset event.
23 BE_FCCU_LONG	Bidirectional Reset Enable for FCCU Long Functional Reset 0 RESET is asserted on a FCCU long functional reset event if the reset is enabled. 1 RESET is not asserted on a FCCU long functional reset event.
24 BE_CMU_OLR	Bidirectional Reset Enable for OSC Frequency less than RC 0 RESET is asserted on an OSC Frequency less than RC event if the reset is enabled. 1 RESET is not asserted on an OSC Frequency less than RC event.
25 BE_ST_DONE	Bidirectional Reset Enable for Selt Test Completed This read-only field always has value 0. 0 RESET is asserted on Selt Test Completed event if the reset is enabled.
26 BE_JTAG_FUNC	Bidirectional Reset Enable for JTAG Function 0 RESET is asserted on a JTAG Function event if the reset is enabled.. 1 RESET is not asserted on a JTAG Function event.
27 BE_NMI_WKPU	Bidirectional Reset Enable for Non Maskable Interrupt from Wakeup Unit 0 RESET is asserted on Non Maskable Interrupt from Wakeup Unit event if the reset is enabled. 1 RESET is not asserted on Non Maskable Interrupt from Wakeup Unit event.
28 BE_SOFT_FUNC	Bidirectional Reset Enable for Software Generated Functional Reset 0 RESET is asserted on a Software generated destructive reset event if the reset is enabled. 1 RESET is not asserted on a Software generated destructive reset event.

Table continues on the next page...

MC_RGM_FBRE field descriptions (continued)

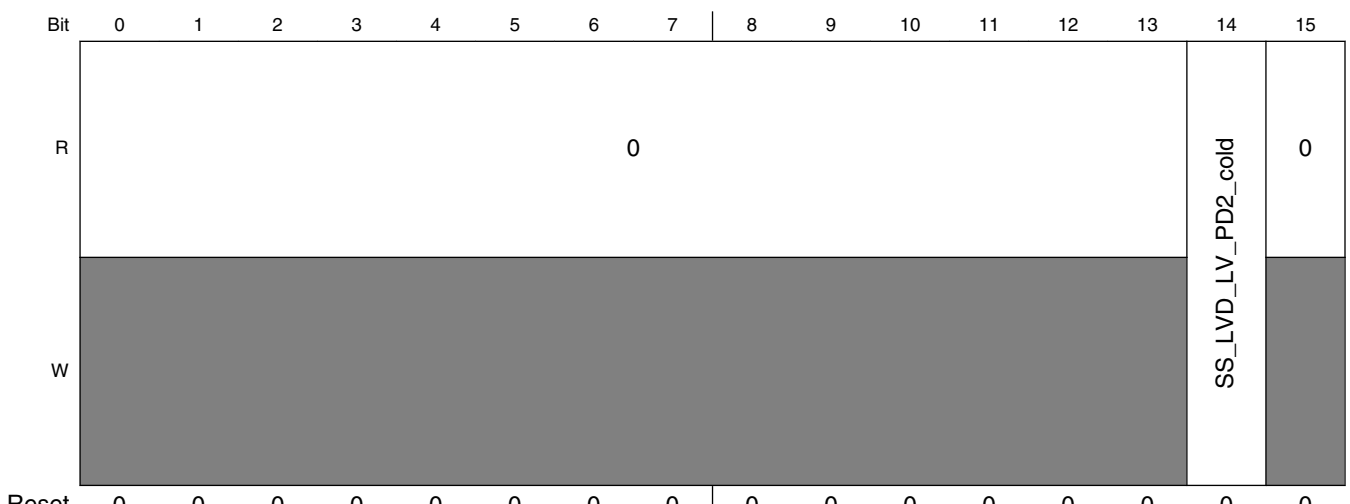
Field	Description
29 BE_HSM_FUNC	Bidirectional Reset Enable for HSM Generated Functional Reset 0 RESET is asserted on a HSM genrated functional reset event if the reset is enabled. 1 RESET is not asserted on a HSM genrated functional reset event.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 BE_EXR	Flag for External Reset 0 RESET is asserted on External reset event if the reset is enabled.

53.3.7 'Functional' Event Short Sequence Register (MC_RGM_FESS)

This register defines which reset sequence will be done when a ‘functional’ reset sequence is triggered. The ‘functional’ reset sequence can either start from PHASE1 or from PHASE3, skipping PHASE1 and PHASE2.

NOTE

This could be useful for a fast reset sequence, for example to skip flash reset.



It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read in user mode.

This register is reset only on power-on and any ‘destructive’ reset.

Access:

User read, Supervior read/write, Test read/write

Address: 0h base + 340h offset = 340h

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

MC_RGM_FESS field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 SS_LVD_LV_PD2_cold	Short Sequence for PD2 LVD at Cold Point 0 The reset sequence triggered by a PD2 LVD at Cold Point event will start from PHASE1. 1 The reset sequence triggered by a PD2 LVD at Cold Point event will start from PHASE3, skipping PHASE1 and PHASE2.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 SS_HVD_LV_cold	Short Sequence for High Voltage Detect IOs 0 The reset sequence triggered by a high Voltage Detect IOs event will start from PHASE1. 1 The reset sequence triggered by a high Voltage Detect IOs event will start from PHASE3, skipping PHASE1 and PHASE2.
18 SS_LVD_IO_A_HI	Short Sequence for Low Voltage Detect IOs 0 The reset sequence triggered by a Low Voltage Detect IOs event will start from PHASE1. 1 The reset sequence triggered by a Low Voltage Detect IOs event will start from PHASE3, skipping PHASE1 and PHASE2.
19 SS_Z2_DBG	Short Sequence for Z2 Debug Reset 0 The reset sequence triggered by a Z2 Debug Reset event will start from PHASE1. 1 The reset sequence triggered by a Z2 Debug Reset event will start from PHASE3, skipping PHASE1 and PHASE2.

Table continues on the next page...

MC_RGM_FESS field descriptions (continued)

Field	Description
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 SS_Z4A_DBG	Short Sequence for Z4A Debug Reset 0 The reset sequence triggered by a Z4A Debug Reset event will start from PHASE1. 1 The reset sequence triggered by a Z4A Debug Reset event will start from PHASE3, skipping PHASE1 and PHASE2.
22 SS_FCCU_ SHORT	Short Sequence for FCCU Short Functional Reset 1 The reset sequence triggered by a FCCU short functional reset event will start from PHASE3, skipping PHASE1 and PHASE2.
23 SS_FCCU_ LONG	Short Sequence for FCCU Long Functional Reset 0 The reset sequence triggered by a FCCU long functional reset event will start from PHASE1.
24 SS_CMU_OLR	Short Sequence for OSC Frequency less than RC 0 The reset sequence triggered by a OSC Frequency less than RC event will start from PHASE1. 1 The reset sequence triggered by OSC Frequency less than RC event will start from PHASE3, skipping PHASE1 and PHASE2.
25 SS_ST_DONE	Short Sequence for Selt Test Completed 0 The reset sequence triggered by a Selt test completed event will start from PHASE1.
26 SS_FUNC_JTAG	Short Sequence for JTAG Functional Reset 0 The reset sequence triggered by a JTAG Functional Reset event will start from PHASE1. 1 The reset sequence triggered by a JTAG Functional Reset event will start from PHASE3, skipping PHASE1 and PHASE2.
27 SS_NMI_WKPU	Short Sequence for Non Maskable Interrupt 3 Wakeup Unit 0 The reset sequence triggered by a Non Maskable Interrupt Wakeup Unit event will start from PHASE1. 1 The reset sequence triggered by a Non Maskable Interrupt 3 Wakeup Unit event will start from PHASE3, skipping PHASE1 and PHASE2.
28 SS_SOFT_FUNC	Short Sequence for Software Generated Functional Reset 0 The reset sequence triggered by a Software generated functional reset event will start from PHASE1. 1 The reset sequence triggered by a Software generated functional reset event will start from PHASE3, skipping PHASE1 and PHASE2.
29 SS_HSM_FUNC	Short Sequence for HSM Genrated Functional Reset 1 The reset sequence triggered by a HSM genrated functional reset event will start from PHASE3, skipping PHASE1 and PHASE2.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 SS_EXR	Short Sequence for External Reset 0 The reset sequence triggered by an External reset reset event will start from PHASE1. 1 The reset sequence triggered by an External reset reset event will start from PHASE3, skipping PHASE1 and PHASE2.

53.3.8 'Functional' Reset Escalation Threshold Register (MC_RGM_FRET)

This register sets the threshold for ‘functional’ reset escalation to a ‘destructive’ reset. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

Writing a non-zero value to the FRET field will enable the ‘functional’ reset escalation function. Writing any value to this register will reset the ‘functional’ reset counter. See Functional’ Reset Escalation for details on the ‘functional’ reset escalation function.

This register is reset only on power-on and any ‘destructive’ reset.

Access:

User read, Supervior read/write, Test read/write

Address: 0h base + 604h offset = 604h

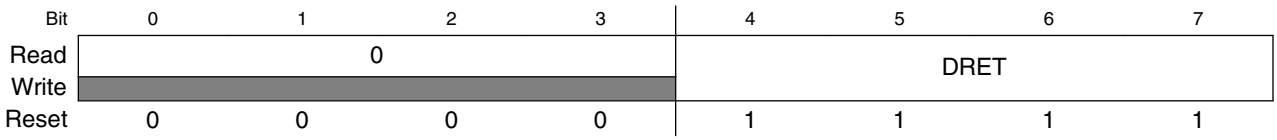
Bit	0	1	2	3	4	5	6	7
Read	0				FRET			
Write								
Reset	0	0	0	0	1	1	1	1

MC_RGM_FRET field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 FRET	‘Functional’ Reset Escalation Threshold — If the value of this field is 0, the ‘functional’ reset escalation function is disabled. Any other value is the number of ‘functional’ resets which will cause a ‘destructive’ reset if the RGM_FRET register isn’t written to beforehand.

53.3.9 'Destructive' Reset Escalation Threshold Register (MC_RGM_DRET)

This register sets the threshold for ‘destructive’ reset escalation to keeping the chip in the reset state until the next power-on reset triggers a new reset sequence. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.



Writing a non-zero value to the DRET field will enable the ‘destructive’ reset escalation function. Writing any value to this register will reset the ‘destructive’ reset counter. See Destructive’ Reset Escalation” for details on the ‘destructive’ reset escalation function.

This register is reset only on power-on.

Access:

User read, Supervior read/write, Test read/write

Address: 0h base + 608h offset = 608h

MC_RGM_DRET field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 DRET	'Destructive' Reset Escalation Threshold — If the value of this field is 0, the 'destructive' reset escalation function is disabled. Any other value is the number of 'destructive' resets which will keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the RGM_DRET register isn't written to beforehand.

53.4 Functional Description

53.4.1 Reset State Machine

The main role of the MC_RGM is the generation of the reset sequence which ensures that the correct parts of the chip are reset based on the reset source event. This is summarized in the following table.

Table 53-1. MC_RGM Reset Implications

Source	What Gets Reset	External Reset Assertion[1]
power-on reset	all	yes
'destructive' resets	all except some clock/reset management	programmable[2]
external reset	all except some clock/reset management and debug logic	programmable
'functional' resets	all except some clock/reset management and debug logic	programmable[3]
shortened 'functional' resets[4]	flip-flops except some clock/reset management and flash	programmable[3]

1. 'External reset assertion' means that the RESET (external reset) pin is asserted by the MC_RGM from the start of the reset sequence until the end of reset PHASE3.
2. The assertion of the external reset is controlled via the RGM_DBRE register.
3. The assertion of the external reset is controlled via the RGM_FBRE register.
4. The short sequence is enabled via the RGM_FESS register.

Note

JTAG logic has its own independent reset control and is not controlled by the MC_RGM in any way.

The reset sequence is comprised of five phases managed by a state machine, which ensures that all phases are correctly processed through waiting for a minimum duration and until all processes that need to occur during that phase have been completed before proceeding to the next phase.

The state machine used to produce the reset sequence is shown in the following figure.

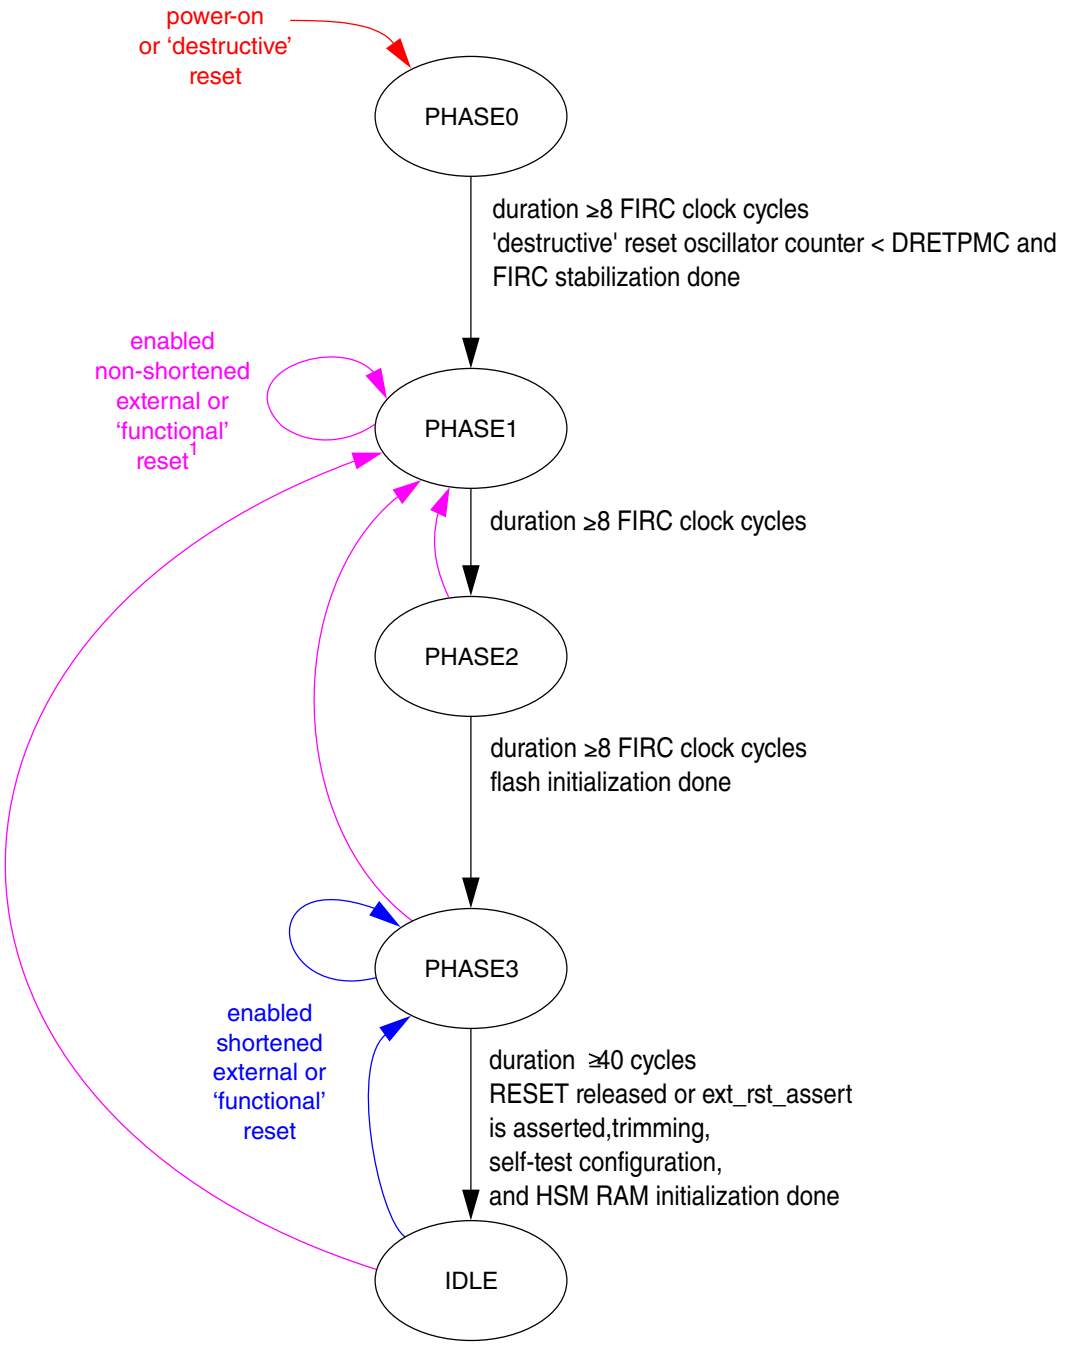


Figure 53-2. MC_RGM State Machine

53.4.1.1 PHASE0 Phase

This phase is entered immediately from any phase on a power-on or enabled 'destructive' reset event. The reset state machine exits PHASE0 and enters PHASE1 on verification of the following:

- All enabled 'destructive' resets have been processed

- All processes that need to be done in PHASE0 are completed
    - PMC and FIRC (16 MHz internal RC oscillator) stabilization
- A minimum of eight FIRC clock cycles have elapsed since power-up completion and the last enabled 'destructive' reset event
- The ‘destructive’ reset escalator counter has not reached the value in the DRET field of the RGM_DRET register

53.4.1.2 PHASE1 Phase

This phase is entered either on exit from PHASE0 or immediately from PHASE2, PHASE3, or IDLE on a non-masked external or 'functional' reset event if it has not been configured to trigger a 'short' sequence. The reset state machine exits PHASE1 and enters PHASE2 on verification of the following:

- All enabled, non-shortened 'functional' resets have been processed
- A minimum of 8 FIRC clock cycles have elapsed since the last enabled external or non-shortened 'functional' reset event

53.4.1.3 PHASE2 Phase

This phase is entered on exit from PHASE1. The reset state machine exits PHASE2 and enters PHASE3 on verification of the following:

- all processes that need to be done in PHASE2 are completed
    - flash initialization
- a minimum of 8 FIRC clock cycles have elapsed since entering PHASE2

53.4.1.4 PHASE3 Phase

This phase is a entered either on exit from PHASE2 or immediately from IDLE on an enabled, shortened 'functional' reset event. The reset state machine exits PHASE3 and enters IDLE on verification of the following:

- All processes that need to be done in PHASE3 are completed

- Trimming, start-up self test configuration, and HSM RAM initialization

- A minimum of forty FIRC clock cycles have elapsed since the last enabled, shortened 'functional' reset event
- RESET is not asserted, except if ext_rst_assert is asserted

53.4.1.5 IDLE Phase

This is the final phase and is entered on exit from PHASE3. When this phase is reached, the MC_RGM releases control of the system to the platform and waits for new reset events that can trigger a reset sequence.

53.4.2 'Destructive' Resets

A 'destructive' reset indicates that an event has occurred after which critical register or memory content can no longer be guaranteed.

The status flag associated with a given 'destructive' reset event (RGM_DES.F_<destructive reset> bit) is set when the 'destructive' reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, and it is software's responsibility to determine which reset source is the most critical for the application.

The chip’s low-voltage detector threshold ensures that when the reset corresponding to the core supply low-voltage detect is enabled, the supply is sufficient to have the ‘destructive’ event correctly propagated through the digital logic. Therefore, if a given ‘destructive’ reset is enabled, the MC_RGM ensures that the associated reset event will be correctly triggered to the full system. However, if the given ‘destructive’ reset is disabled and the voltage goes below the digital functional threshold, functionality can no longer be ensured, and the reset may or may not be asserted.

An enabled 'destructive’ reset will trigger a reset sequence starting from the beginning of PHASE0.

53.4.3 External Reset

The MC_RGM manages the external reset coming from RESET. The detection of a falling edge on RESET will start the reset sequence from the beginning of PHASE1.

The status flag associated with the external reset falling edge event (RGM_FES.F_EXR bit) is set when the external reset is asserted and the power-on reset is not asserted.

An external reset will normally trigger a reset sequence starting from the beginning of PHASE1. Nevertheless, the RGM_FESS register enables the further configuring of the reset sequence triggered by the external reset. When RGM_FESS.SS_EXR is set, the external reset will trigger a reset sequence starting directly from the beginning of PHASE3, skipping PHASE1 and PHASE2. This can be useful especially when an external reset should not reset the flash.

The MC_RGM may also assert the external reset if the reset sequence was triggered by one of the following:

- a power-on reset
- a 'destructive' reset event configured via the RGM_DBRE register to assert the external reset
- an external reset event
- a ‘functional’ reset event configured via the RGM_FBRE register to assert the external reset

In this case, RESET is asserted until all conditions for exiting PHASE3 have been met with the exception of the RESET assertion check.

In addition, the MC_RGM asserts RESET when ext_rst_assert is asserted.

53.4.4 'Functional' Resets

A 'functional' reset indicates that an event has occurred after which it can be guaranteed that critical register and memory content is still intact.

The status flag associated with a given 'functional' reset event (RGM_FES.F_<functional reset> bit) is set when the 'functional' reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, and it is software's responsibility to determine which reset source is the most critical for the application.

A given 'functional' reset can be optionally disabled by software writing bit RGM_FERD.D_<functional reset>.

Note

The RGM_FERD register can be written only once between two power-on reset events.

An enabled 'functional' reset will normally trigger a reset sequence starting from the beginning of PHASE1. Nevertheless, the RGM_FESS register enables the further configuring of the reset sequence triggered by a 'functional' reset. When RGM_FESS.SS_<functional reset> is set, the associated 'functional' reset will trigger a reset sequence starting directly from the beginning of PHASE3, skipping PHASE1 and PHASE2. This can be useful especially in case a 'functional' reset should not reset the flash module.

See the MC_ME chapter for details on the STANDBY0 and DRUN modes.

53.4.5 Alternate Event Generation

The MC_RGM provides alternative events to be generated on reset source assertion. When a reset source is asserted, the MC_RGM normally enters the reset sequence. Alternatively, it is possible for some reset source events to be converted from a reset to either a SAFE mode request issued to the MC_ME or to an interrupt request issued to the core.

Alternate event selection for a given reset source is made via the RGM_FERD and RGM_FEAR registers as shown in the following table.

Table 53-2. MC_RGM Alternate Event Selection

RGM_FERD Bit Value	RGM_FEAR Bit Value	Generated Event
0	X	reset
1	0	SAFE mode request
1	1	interrupt request

The alternate event is cleared by deasserting the source of the request (i.e., at the reset source that caused the alternate request) and also clearing the appropriate RGM_FES status bit.

Note

SAFE mode requests are generated regardless of whether the system clock is running. Interrupt requests are gnerated with the system clock, and therefore, if the system clock was disabled at the time of the event, the interrupt request isn't asserted until the system clock is re-enabled.

Note

If a masked 'destructive' reset event which is configured to generate a SAFE mode/interrupt request occurs during PHASE0, it is ignored, and the MC_RGM will not send any safe mode/interrupt request to the MC_ME.

Note

If a masked 'functional' reset event which is configured to generate a SAFE mode/interrupt request occurs during PHASE1, it is ignored, and the MC_RGM will not send any safe mode/interrupt request to the MC_ME.

53.4.6 'Functional' Reset Escalation

'Functional' reset escalation can be used to generate a 'destructive' reset if a number of 'functional' or external resets has occurred between software writes to the RGM_FRET register. This function is enabled by writing a non-zero value to the FRET field of this register.

Once 'functional' reset escalation has been enabled, the MC_RGM increases a counter on each 'functional' or external reset which causes a reset sequence to be initiated (i.e., entrance into PHASE1 or PHASE3 from the IDLE phase) if the func_rst_escalation output is connected to one of the dest_rst inputs. This counter is cleared on a write of any value to the RGM_FRET register and on any power-on or 'destructive' reset. If the counter reaches the value in the RGM_FRET register's FRET field, the MC_RGM starts a reset sequence at PHASE0 and asserts the F_EDR bit in the RGM_DES register.

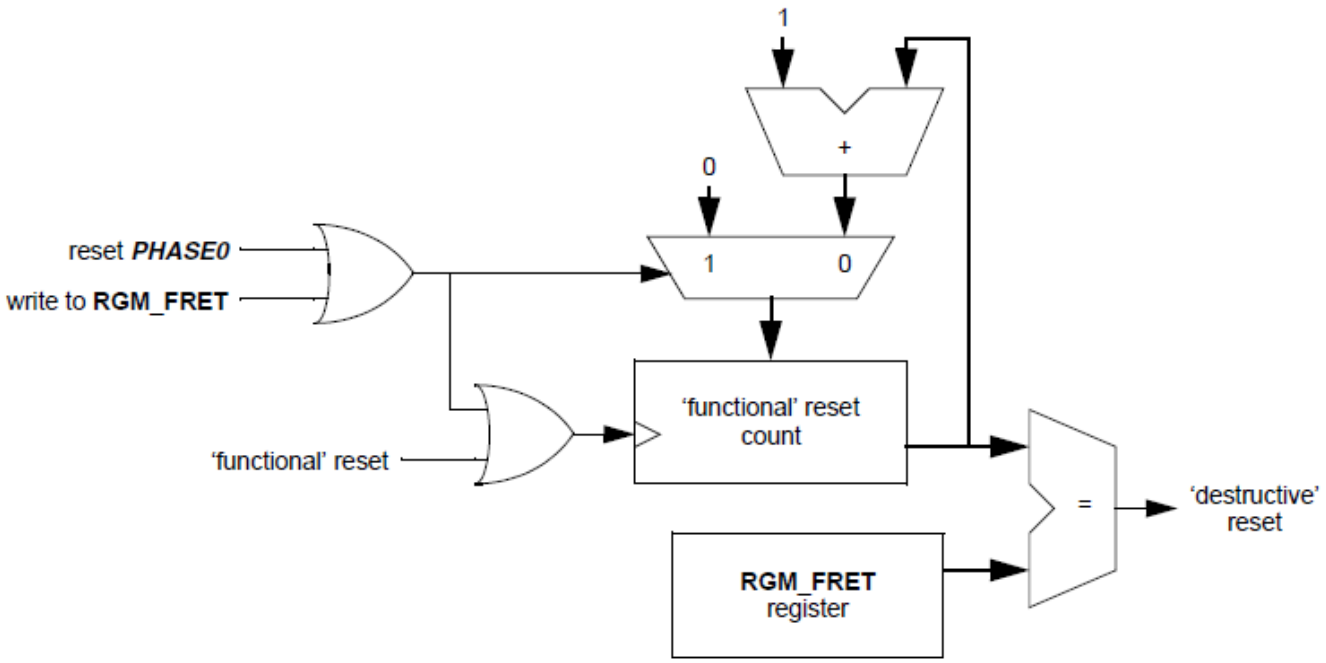

Figure 53-3. MC_RGM 'Functional' Reset Escalation to 'Destructive' Reset

53.4.7 'Destructive' Reset Escalation

'Destructive' reset escalation can be used to keep the chip in the reset state until the power-on triggers a reset sequence if a number of 'destructive' resets has occurred between software writes to the RGM_DRET register. This function is enabled by writing a non-zero value to the DRET field of this register.

Once 'destructive' reset escalation has been enabled, the MC_RGM increases a counter on each 'destructive' reset which causes a reset sequence to be initiated (i.e., entrance into PHASE0 from the IDLE phase) or an ongoing reset sequence to restart (i.e., entrance into PHASE0 from PHASE1, PHASE2, or PHASE3). This counter is cleared on a write of any value to the RGM_DRET register and on any power-on reset. If the counter reaches the value in the RGM_DRET register's DRET field, the MC_RGM enters reset PHASE0 and stays there until the next power-on reset occurs.

On a power-on reset, the dest_rst_escalation output is deasserted. It is asserted by the MC_RGM when the counter reaches the value in the RGM_DRET register's DRET field. It is not deasserted until the next power-on reset.

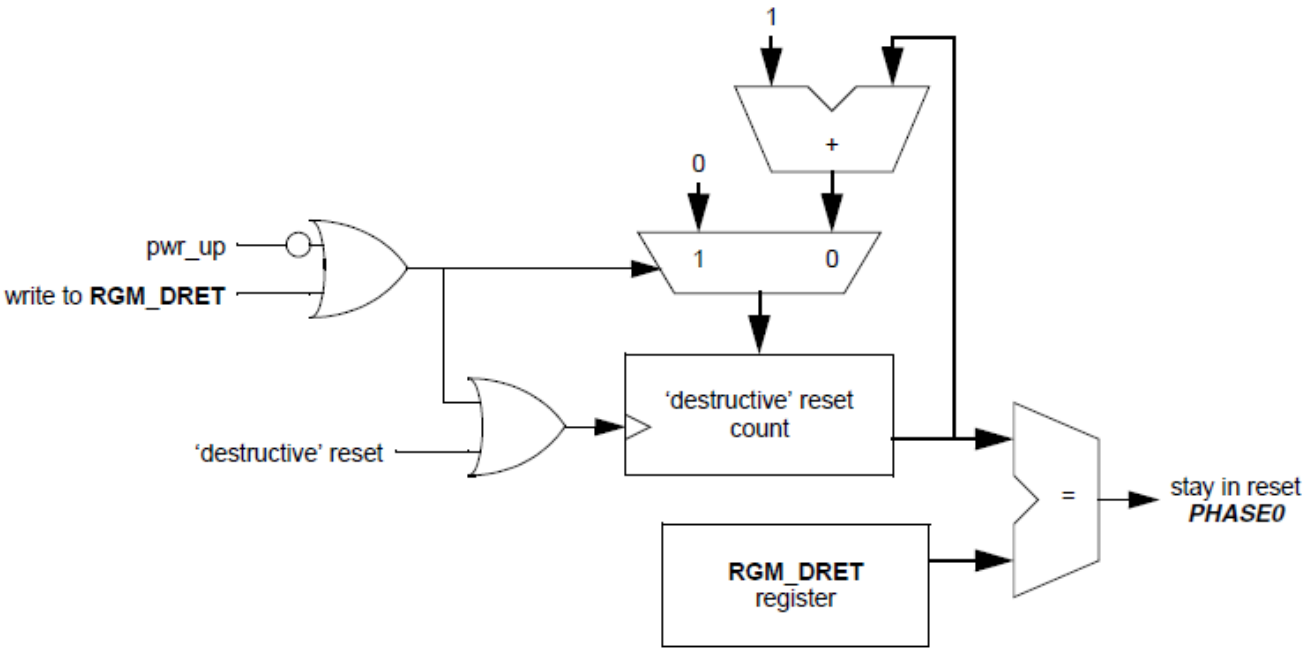

Figure 53-4. MC_RGM 'Destructive ' Reset Escalation to Stay in PHASE0

Chapter 54
System Status and Configuration Module (SSCM)

54.1 Chip-specific SSCM information

54.1.1 System Status and Configuration Module (SSCM) configuration

This section summarizes the System Status and Configuration Module (SSCM) configuration. There is one instance of the SSCM module on the MCU.

The SSCM reads the DCF records during boot and then automatically switch to Booting Core to BAF.

The device specific reset value for the SSCM_MEMCONFIG register are shown in the table Table 54-1.

Table 54-1. SSCM_MEMCONFIG reset value

Field	Field Definition	Value
JPIN	JTAG Part ID	084h
MREV	Minor Revision	0000b

The device specific reset value for the SSCM_UOPS register are shown in the table Table 54-2.

Table 54-2. SSCM_UOPS reset value

Register	Reset Value
SSCM_UOPS	0000_ 0600

Table 54-3 shows the address locations that the SSCM uses to search for startup information.

Table 54-3. SSCM startup information addresses

Description	Address
The location at which the SSCM will look for the UTEST records (UTEST_OFFSET).	0040_0300h
Location of the Boot Assist code in flash memory (BAF)	0040_4000h

NOTE

SSCM_STATUS[NXEN] will be set if any of the cores has Nexus enabled.

54.2 Introduction

54.2.1 Overview

The System Status and Configuration Module (SSCM) is pictured in the figure below.

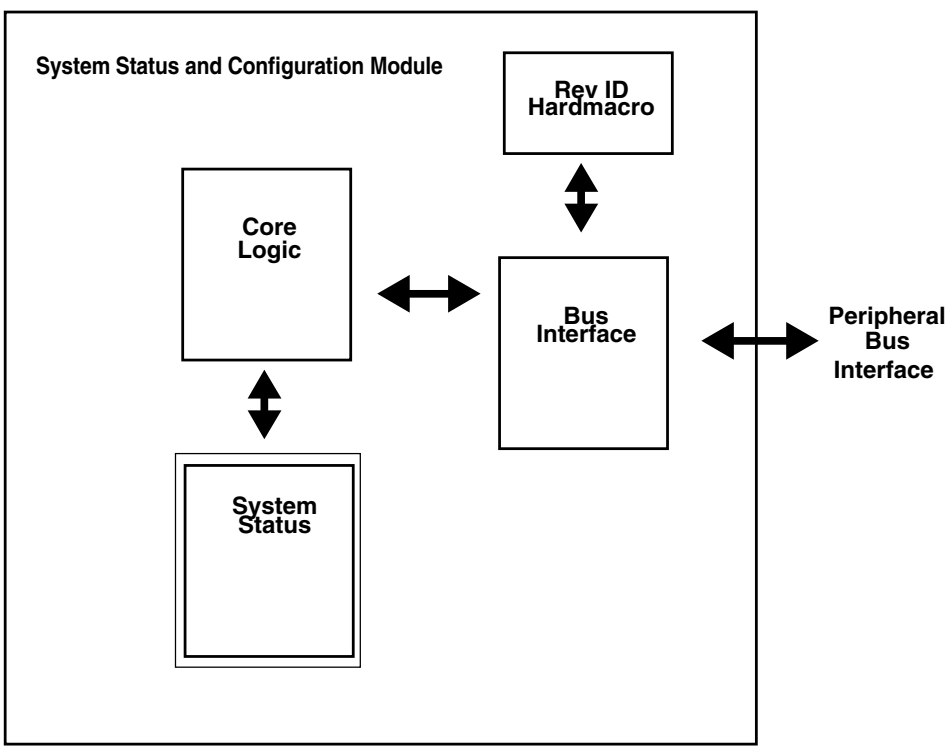

Figure 54-1. SSCM block diagram

54.2.2 Glossary

The table below shows a glossary of terms used through out the text.

Table 54-4. Glossary

Term	Definition
0011b	Binary numbers
0Fh	Hexadecimal numbers
Pin	External physical connection.
Signal	Electronic construct whose state or change in state conveys information.
X	In certain contexts, such as a signal encoding, this indicates a don't care. For example, if a field is binary coded X001b, the state of the first bit is a don't care.
y	y is used for a place holder of 1 hex digit for unknown values.

54.2.3 Features

The SSCM includes these distinct features:

- System Configuration and Status
  - Device Mode and System Status
  - Determine HSM boot vector
  - Decodes the Device Life Cycle
- Debug Status Port enable and selection
- Bus abort enable/disable

54.2.4 Modes of operation

The SSCM operates identically in all system modes.

54.3 External signal description

The SSCM provides a set of pins for the debug port (see Debug Status Port Register (DEBUGPORT) for details).

54.4 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the SSCM.

The table below shows the memory map for the SSCM. Note that all addresses are offsets; the absolute address may be calculated by adding the specified offset to the base address of the SSCM.

NOTE

All registers are accessible via 8-bit, 16-bit or 32-bit reads and/or writes. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries. As an example, the STATUS register is accessible by a 16-bit read or write, SSCM Base + 02h, but performing a 16-bit access to SSCM Base + 0003h is illegal (that is, you should not make any transfer that is not aligned to burst size boundary).

NOTE

SSCM does not generate transfer errors in all memory holes.

NOTE

Reserved IPS register access is prohibited.

SSCM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	SSCM System Status (SSCM_STATUS)	16	R	See section	54.4.1/2223

34	Life Cycle Status Register (SSCM_LCSTAT)	32	R	See section	54.4.7/2228

54.4.1 SSCM System Status (SSCM_STATUS)

The System Status register reflects the current state of the system.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7
Read	0	CER	0	0	NXEN	1	Reserved	0
Write		w1c						
Reset	0	0	0	0	*	1	*	0

Bit	8	9	10	11	12	13	14	15
Read	BMODE			1	0	0	0	
Write								
Reset	*	*	*	1	0	0	0	0

* Notes:
- BMODE field: Reset value depends on the device status after leaving reset.
- Reserved field: This field can reset to 0 or 1.
- NXEN field: Reset value depends on the device status after leaving reset.

SSCM_STATUS field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 CER	Configuration Error This field indicates that the SSCM has detected a configuration error during reset while loading initial device configuration. See the chip-specific SSCM information for details about sources of the error. If a non-permanent error is detected, this bit can be cleared by writing a 1. 0 No configuration problem detected by the SSCM 1 Device configuration is not correct
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 NXEN	Processor 0 Nexus enable status 0 Processor 0 Nexus disabled. 1 Processor 0 Nexus enabled
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
6 Reserved	This field is reserved. This field is for internal use. Users should ignore read values and should not attempt to write the field.

Table continues on the next page...

SSCM_STATUS field descriptions (continued)

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–10 BMODE	Device Boot Mode This field is only updated during reset. 101 Boot from BootFlash
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

54.4.2 SSCM System Memory and ID Register (SSCM_MEMCONFIG)

The System Memory and ID register is a read-only register which reflects the memory configuration of the system. It also contains the JTAG part ID.

Address: 0h base + 2h offset = 2h

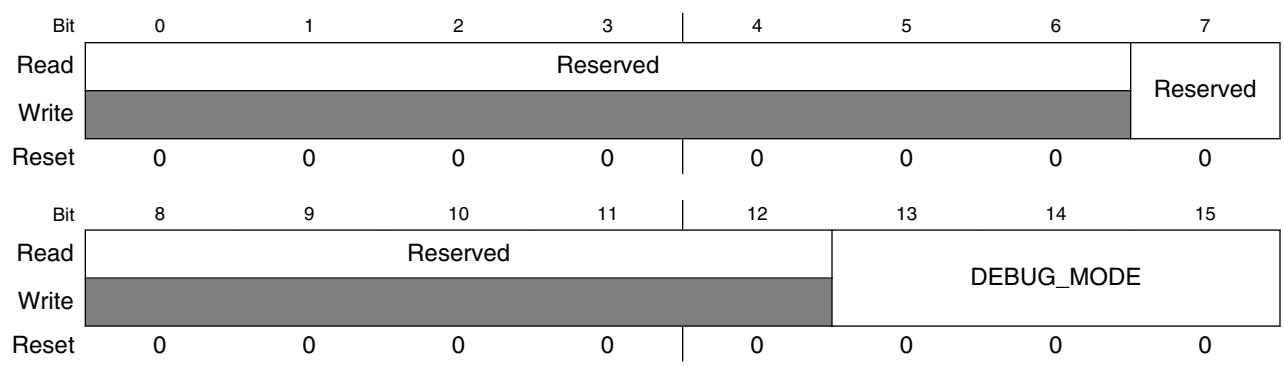
Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	JPIN										1	MREV				0
Write																
Reset	*	*	*	*	*	*	*	*	*	*	1	*	*	*	*	0

* Notes:
- MREV field: Reset value can be found in the SSCM Configuration section.
- JPIN field: Reset value reflects the JTAG part ID of the device.

SSCM_MEMCONFIG field descriptions

Field	Description
0–9 JPIN	JTAG Part ID Number **NOTE:** Reset value reflects the JTAG part ID of the device.
10 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
11–14 MREV	Minor Mask Revision
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

54.4.3 SSCM Debug Status Port Register (SSCM_DEBUGPORT)



The Debug Status Port register is used to (optionally) provide debug data on a set of pins.

Table 54-5. Debug status port modes

Pin [1]	Mode 1	Mode 2	Mode 3	Mode 4	Mode 5	Mode 6	Mode 7
0	STATUS[0]	STATUS[8]	MEMCONFIG[0]	MEMCONFIG[8]	Reserved	Reserved	Reserved
1	STATUS[1]	STATUS[9]	MEMCONFIG[1]	MEMCONFIG[9]	Reserved	Reserved	Reserved
2	STATUS[2]	STATUS[10]	MEMCONFIG[2]	MEMCONFIG[10]	Reserved	Reserved	Reserved
3	STATUS[3]	STATUS[11]	MEMCONFIG[3]	MEMCONFIG[11]	Reserved	Reserved	Reserved
4	STATUS[4]	STATUS[12]	MEMCONFIG[4]	MEMCONFIG[12]	Reserved	Reserved	Reserved
5	STATUS[5]	STATUS[13]	MEMCONFIG[5]	MEMCONFIG[13]	Reserved	Reserved	Reserved
6	STATUS[6]	STATUS[14]	MEMCONFIG[6]	MEMCONFIG[14]	Reserved	Reserved	Reserved
7	STATUS[7]	STATUS[15]	MEMCONFIG[7]	MEMCONFIG[15]	Reserved	Reserved	Reserved

1. All signals are active high, unless otherwise noted

Address: 0h base + 8h offset = 8h

SSCM_DEBUGPORT field descriptions

Field	Description
0–6 Reserved	This field is reserved.
7 Reserved	This field is reserved.
8–12 Reserved	This field is reserved.

Table continues on the next page...

SSCM_DEBUGPORT field descriptions (continued)

13–15 DEBUG_MODE	Debug Status Port Mode. This field selects the alternate debug functionality for the Debug Status Port Table 54-5 describes the functionality of the Debug Status Port in each mode. 000 Undefined 001 Mode 1 selected 010 Mode 2 selected 011 Mode 3 selected 100 Mode 4 selected 101 Mode 5 selected 110 Mode 6 selected 111 Mode 7 selected

54.4.4 SSCM HSM and User Option Status Register (SSCM_UOPS)

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0												HSB			HSE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	*	*	*	*

* Notes:
- HSE field: Values are determined by DCF record and life cycle - default is 0.
- HSB field: Values are determined by DCF record and life cycle - default is 0.

SSCM_UOPS field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–30 HSB	HSM Boot Configuration These bits can be set via DCF record (see HSM documentation). All combinations not listed below are reserved. 000 When the device is in BAF mode, BAF will not wait for HSM ready flag before allowing application code to start. 001 When the device is in BAF mode, BAF waits for HSM ready flag before allowing application code to start.

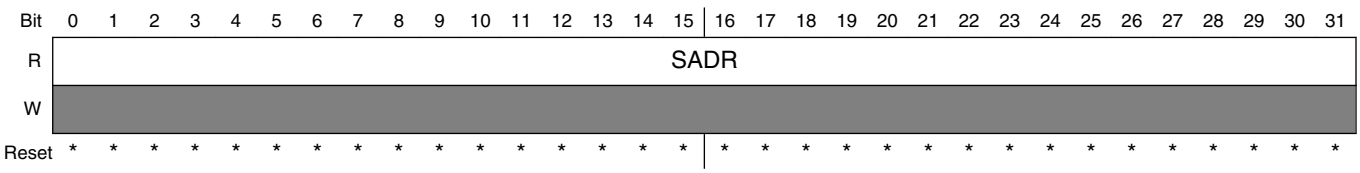

Table continues on the next page...

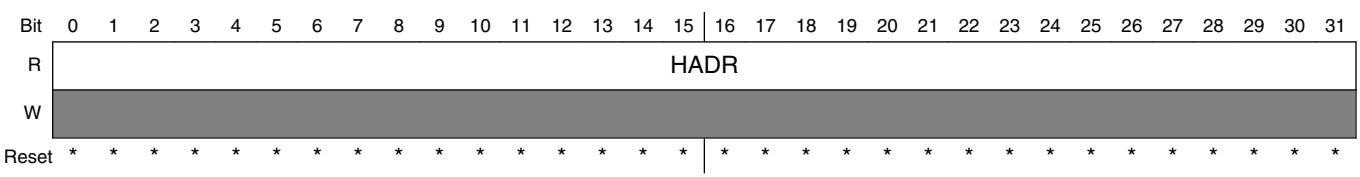
SSCM_UOPS field descriptions (continued)

Field	Description
31 HSE	HSM Enabled HSE is set to 1 if HSM is enabled via DCF record

54.4.5 Processor Start Address Register (SSCM_PSA)

Address: 0h base + 28h offset = 28h



* Notes:
- SADR field: Reset value is the start address

SSCM_PSA field descriptions

Field	Description
0–31 SADR	Processor Start Address The boot processor will start executing application code from this address. In BAF mode this will show the start address of the BAF code.

54.4.6 SSCM HSM Start Address Register (SSCM_HSA)

Address: 0h base + 30h offset = 30h

* Notes:
- HADR field: HSM Start Address

SSCM_HSA field descriptions

Field	Description
0–31 HADR	HSM Start Address HSM will start executing application code from this address. The value of this register is determined by the HSM boot header search.

54.4.7 Life Cycle Status Register (SSCM_LCSTAT)

Address: 0h base + 34h offset = 34h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0						Reserved		0					LC		
W																
Reset	0	0	0	0	0	0	*	*	0	0	0	0	0	*	*	*

* Notes:
- LC field: Reset value is the Life Cycle of the device, and is unaffected by reset.
- Reserved field: Reset Value is '11' for a valid secured part.

SSCM_LCSTAT field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 Reserved	This field is reserved.
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 LC	Life Cycle Determined by the SSCM by reading the LC slots. The encoding is: 000 Failure Analysis 001 Reserved 010 OEM Production 011 Customer Delivery 100 Reserved 101 Reserved 110 MCU Production 111 In Field

54.5 Functional description

The primary purpose of the SSCM is to provide information about the current state and configuration of the system that may be useful for configuring application software and for debug of the system.

54.5.1 DCF mechanism

The DCF mechanism has been developed to handle settings of device parameters via OTP flash memory.

Starting at location UTEST_OFFSET the user can store a series of DCF records - the device will process these records during the system reset sequence before the CPU leaves reset. The first record needs to be a start record followed by an application-specific number of data records as required, and finally a stop record.

Each record is 64 bits in length. Table 54-6 shows the DCF start record. The start record must be placed at UTEST_OFFSET to indicate to the device that the following data records should be processed.

Table 54-6. DCF start record

0:31
05AA 55AFh
0:31
0000 0000h

The data records are structured similar to a CPU write instruction - 15 bits of client select, 15 bits of address, 32 bits of payload data plus a STOP bit - See Table 54-7. In a data record the STOP bit must always be programmed to 0. Some clients support a parity bit.

Table 54-7. Format of a DCF data record

0:31			
WDATA[31:0]			
0:14	15:29	30	31
CS[14:0]	ADDR[16:2]	PRTY	STOP

The stop record indicates that processing should stop. The general format of the stop record is shown in Table 54-8. Only the STOP bit needs to be 1 in order to form a stop record – All other bits are ignored. An unprogrammed location in UTEST flash will be interpreted as a stop record.

Table 54-8. DCF stop record

0:30	31
rsvd	1

Table continues on the next page...

Table 54-8. DCF stop record (continued)

0:31
rsvd

If *n* data records are to be stored in UTEST, the data structure must be as shown in Table 54-9.

Table 54-9. Series of DCF records in UTEST

ADDR offset	DATA			
00h	05AA 55AFh			
04h	0000 0000h			STOP=0
08h	WDATA[31:0]			
0Ch	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
10h	WDATA[31:0]			
14h	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
…	…			
8n - 1 + 0h	reserved			
8n - 1 + 4h	reserved			1
8n + 0h				
8n + 4h				

There must never be an unprogrammed record in the data structure, as that would be interpreted as a stop record, so subsequent records would be ignored. This allows programming the records in several sessions, each time appending new records at the end of the list, as shown in Figure 54-2.

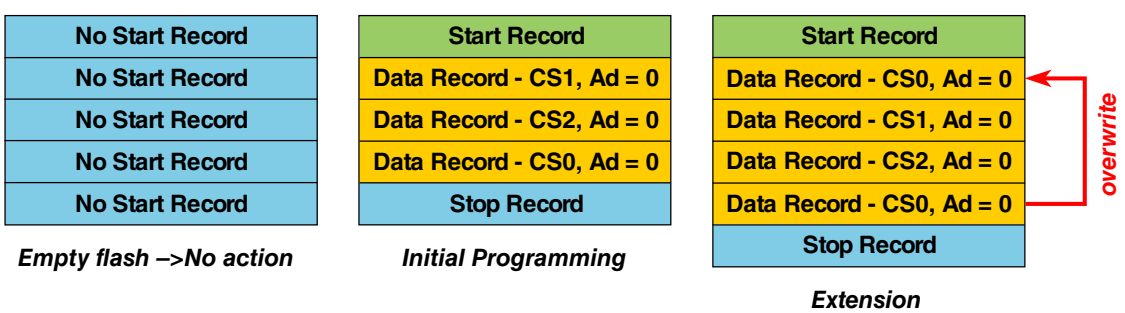


Figure 54-2. Appending DCF records

In this case, a record may overwrite a client's value which was already set by a previous record. However whether such an operation is allowed depends on the rules given for the client - some clients are write-once, only allow setting bits but not clearing, and so on.

The parity bit (PRTY) is required for some DCF records. The parity scheme used is even parity, so the number of 1s in the WDATA and PRTY fields needs to be even. (For example, if the WDATA field has the value 0000_0001h then the PRTY field needs to be set to 1, so that the total number of 1s is even.)

NOTE

When programming DCF records, ensure that programming is not interrupted and can complete without error.

54.5.2 Boot mode functionality

The device supports the following boot modes for the main boot core:

- Boot Assisted by Flash (BAF) - The device will boot from UTest NVM Flash Block, (interface with the HSM if available) and perform device setup.

If booting is not possible with the selected configuration (for example, no Boot ID is found in the selected boot location) then the device will enter static mode.

If the HSM is enabled via DCF record, the HSM will boot from the location found via the HSM boot header search. HSM boot header search.

54.5.3 BAF configuration

By default the device will boot from BAF.

In BAF mode (SSCM_STATUS[BMODE]=101b), the boot core will start executing BAF code at the location shown in the configuration section of the “Boot Assist Flash (BAF)” chapter.

54.5.4 HSM boot header search

The SSCM searches the code flash memory of the HSM module for a valid boot header (see the SSCM section of the “Device Configuration” chapter for address(es)) and provides the boot vector to the CPU of the HSM module.

The HSM Boot Header has the format as described in the table below.

Table 54-10. Boot header structure

00h	Boot Header ID	
08h	Reserved	Start Address
10h	Reserved for Configuration Bits	

A valid Boot Header ID has the value FFFF_0000_FFFF_0000h.

The first valid Boot Header found is the one which is passed to the HSM CPU. In order to switch from one Boot Header to a Boot Header at a higher address, the Boot Header at the lower address must be invalidated. This can be achieved by over-programming the Boot Header ID location with 0000_0000_0000_0000h. Since this value results in the same ECC encoding it will still be possible to read the location without causing an ECC error.

54.5.5 Life Cycle

The SSCM will determine the Life Cycle (LC) of the device by reading the LC slots from the UTEST flash memory. The read operation is done during the reset phase with normal timings and it is protected by operating monitors. In addition, a set of sanity checks executed over the LC read data guarantee the integrity of the final LC value.

At the end of the reset phase, the LC can have one of the following values:

- MCU Production
- Customer Delivery
- OEM Production
- In Field
- Failure Analysis

Life cycle can only be moved in the direction shown below:

Figure 54-3. Life cycle sequence

The LC is written into 5 slots, 128 bits each, at fixed locations in the UTEST flash memory block. Each LC slot is read in one single atomic operation and it is organized into two fields:

- the valid field
- the invalid field

Depending on the possible combination of the data programmed into these fields, each LC slot can have one of the possible 4 statuses as seen in Table 54-11.

Table 54-11. LC slot status

LC slots		LC slot value
Valid field (64 bits)	Invalid field (64 bits)	
Erased	Erased	Erased
Marked	Erased	Active
Marked	Marked	Inactive
Any other values		Illegal

"Marked" in this case means that the value has been programmed with the bit pattern 55AA_50AF_55AA_50AFh. "Erased" is detected by the bit pattern FFFF_FFFF_FFFF_FFFFh. Table 54-12 shows how the slots are arranged in memory.

Table 54-12. LC slots in memory

Offset	LC slot word
00h	Valid[31:0]
04h	Valid[63:32]
08h	Invalid[31:0]
0Ch	Invalid[63:32]

The Life Cycle is determined as shown in Table 54-13

NOTE

"Erased" means the slot returns all 1s.

Table 54-13. LC slots

LC slot 0 MCU Production	LC slot 1 Customer Delivery	LC slot 2 OEM Production	LC slot 3 In Field	LC slot 4 Failure Analysis	Resulting life cycle
Active	Erased	Erased	Erased	Erased	MCU Production
Inactive	**Active**	Erased	Erased	Erased	Customer Delivery
Inactive	Inactive	**Active**	Erased	Erased	OEM Production
Inactive	Inactive	Inactive	**Active**	Erased	In Field
Inactive	Inactive	Inactive	Inactive	**Active**	Failure Analysis
Erased	Erased	Erased	Erased	Erased	System Reset
Illegal[1]	Illegal	Illegal	Illegal	Erased	In Field

1. Any value programmed other than shown in table above for Erased, Active, and Inactive would be treated as illegal.

NOTE

When programming Life Cycle, ensure that programming is not interrupted and can complete without error.

NOTE

Any other combination of values will result in a system reset.

NOTE

No one should program “ILLEGAL” even if able to do that. Device behavior is not guaranteed for these combinations.

54.6 Initialization and application information

54.6.1 Reset

The reset state of each individual bit appears in the detailed register descriptions.

54.7 Additional safety measures

54.7.1 Spurious reset protection

The SSCM implements protection against spurious module resets (for example, resets which only effect the SSCM, but not other modules) by gating the state machines status with the expected status of the MC_RGM. If a spurious reset occurs, the SSCM will not interfere with the flash memory bus or overwrite configuration registers. However, internal SSCM status will be lost.

Chapter 55
Boot Assist Flash (BAF)

55.1 Chip-specific BAF information

55.1.1 BAF configuration

55.1.2 BAF memory map

The BAF is located in a 16 KB block of flash that is mapped adjacent to the UTEST flash memory block. It is one time programmable (OTP) and is programmed during factory test. The address space and memory used by the BAF code are shown in Table 55-1.

Table 55-1. BAF memory map

BAF component	Address
BAF address range	0040_4000h – 0040_7FFFh
BAF version number	0040_4000h
BAF code entry point	0040_4100h
BAF code exit point	4007_FD80h
BAF data area and stack	4007_FD00h – 4007_FFFFh

55.1.3 LinFLEXD_0 pin configuration

Table 55-2 shows the device pin configurations for LINFlexD_0 module.

Table 55-2. LINFlexD_0 pin configuration

Pads	Reset Function	Initial Serial Boot mode	
		Function	Pad configuration
PB[0]	GPIO Input buffer off Output buffer off	LIN0TX	Output Push/Pull medium no pullup/pulldown
PB[1]	GPIO Input buffer off Output buffer off	LIN0RX	Input:- pullup hystersis

55.1.4 Search boot header and boot options

The BAF searches the flash memory for the boot header, checking the first word location at the addresses mentioned in the table below. The blocks are searched in the order shown in Table 55-3. Once a Boot Header is found, no further blocks are searched.

Table 55-3. Locations of boot headers

Search order	Block	Address
1	16KB Code Flash block	00F8_C000h[1]
2	32KB Code Flash block	00FC_0000
3	32KB Code Flash block	00FD_8000
4	64KB Code Flash block	00FE_0000
5	16KB Code Flash block	00F9_0000h
6	16KB Code Flash block	00F9_4000h
7	16KB Code Flash block	00F9_8000h
8	16KB Code Flash block	00F9_C000h
9	16KB Code Flash block	00FA_0000h
10	16KB Code Flash block	00FA_4000h
11	16KB Code Flash block	00FA_8000h

1. Location 00F8_C000h will be searched when HSM is not enabled, otherwise it will be skipped.

The first header found that contains the value 005Ah in the first halfword is valid for booting. The whole header structure is shown in Table 55-4.

Table 55-4. Boot header structure

Address Offset	Contents
00h	Boot Header Configuration (see Table 55-5)
04h	CPU2 Reset Vector
08h	Configuration Bits

Table continues on the next page...

Table 55-4. Boot header structure (continued)

Address Offset	Contents
0Ch	Configuration Bits
10h	CPU0 Reset Vector
18h	Reserved for future use

The first header found that contains the value 005Ah in the first halfword is valid for booting. The whole header structure is shown in Table 55-5

Table 55-5. Boot header configuration

Offset 00h															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0				0				5				A			
16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
0				0				0				0	0	CPU0	CPU2

Table 55-6. Boot header configuration field description

Field	Description
CPU0	CPU0 is enabled (will start execution at CPU0 Reset Vector)
CPU2	CPU2 is enabled (will start execution at CPU2 Reset Vector)

The cores that are enabled in the boot header configuration field are enabled by programming MC_ME_CCTL*n*[DRUN] register to run in all DRUN modes and their reset vector is set in register MC_ME_CADDR*n*. Then, the memory area of the BAF is protected from execution for functional safety considerations. This is achieved by disabling BAF execution in PFLASH control register3 (PFLASHC_PFCR3[BAF_DIS]). Finally, a mode change (from DRUN to DRUN again) is requested from the MC_ME module to activate the new core configuration and make the cores jump to their respective reset vectors. At this point the BAF has finished its operation.

55.1.5 MPC5746C cores/BAF CPU*n*

This chapter uses the term CPU*n* (n=0, 1, or 2) when referring to a specific processor core. See Table 55-7 for details specific to the MPC5746C device.

Table 55-7. MPC5746C core to BAF CPU*n* relationships

CPU*n*	MPC5746C core
CPU0	e200z420 (Z4)
CPU2	e200z210 (Z2)

55.1.5.1 BAF dependent reset values

The register values may be changed during execution of BAF. The table below provides typical register values for such modules.

Table 55-8. BAF execution dependent reset values

Register	Remark
MC_ME_IS	Typically: 0x1 during Flash Boot may have other faults set due to SAFE and NMI Handling
MC_ME_IMTS	Typically 0x0 during Flash Boot; may have 0x1 if BAF enters to SAFE
MC_ME_DMTS[PREVIOUS_MODE]	SAFE or DRUN
MC_ME_GS[CURENT_MODE]	SAFE or DRUN
MC_ME_CS, MC_ME_CCTLX, MC_ME_CADDRX	Undefined, Customer specific configuration
PRAMC0_PRC1[FT_DIS]	0: During Boot 1: Fast PLL STBY Exit
FCCU_NCF	Z4A Machine Check Fault when boot with NMI fault already latched not otherwise
FXOSC_CTL	I_OSC set. After Serial Boot only.
PFLASH_PFCR3	BAF_DIS = 1

55.1.6 BAF NMI event handling

BAF executes under different conditions viz. Power-On-Reset (POR), Destructive Reset or any Functional Reset (Long or Short). Due to device configuration, there can be a case where pending FCCU NMI events are latched in the device. These NMI events are masked as described in NMI/WKPU interface. When BAF issues device mode transition to transfer control to application (MC_ME_CADDR *x* [RMC] = 1), the FCCU NMI event gets unmasked causing exception until RMC take effect and resets the core. The exception to CPU0 causes an additional fault (CPU0 Machine check) to be latched in the FCCU. Reset to the core also masks FCCU NMI Reaction.

As a workaround, the application can install a CALLBACK – BAF callback DCF client to initialize FCCU fault reaction to default state (No reaction for NMI Faults). This ensures that NMI faults occurring (during the BAF execution) are logged in the system. Application, then in its boot code, can take corrective action and re-initialize FCCU.

As a best practice, application must check for any pending FCCU events and clear them.

55.2 Introduction

The MCU is booted through a collaboration of several blocks, hardware, and firmware. The first boot phases are performed by a state machine inside the System Status and Configuration Module (SSCM). Once completed, SSCM sends the reset vector to the boot core, which sets the program counter to the BAF code starting address.

One of the first tasks executed by BAF is a read to the DCF records starting address, i.e., 0040_0300h. An uncorrectable ECC error associated with the DCF records starting address indicates an invalid boot scenario. Prior to control being passed to BAF, SSCM parses DCF records after obtaining the DCF records starting address. If an uncorrectable ECC error results, the SSCM is unable to process any DCF records, including mandatory DCF records and customer DCF records, making any boot sequence executed subsequent to the ECC error invalid. If BAF code detects an uncorrectable ECC error at the DCF records starting address, it issues a destructive reset via the MC_ME module.

In addition to checking the DCF records starting address for an uncorrectable ECC error, the BAF clears any ECC errors latched in the C55FMC flash memory's MCR register during SSCM processing.

The BAF code then checks the life cycle of the device. If the life cycle is FAIL_ANALYSIS, the BAF enters a loop in which it services the watchdog. The BAF does not execute further since the read access to flash memory boot sectors for the cores may be disabled if the device life cycle is FAIL_ANALYSIS. Otherwise, it searches for a boot header and boots the application code in internal flash memory.

If no boot header is found in internal flash memory, it downloads application code serially using the LINFlexD module (see Serial boot configuration for configuration details).

55.3 BAF image header

BAF image contains a 256-byte header starting from the BAF version number (see table "BAF memory map" table in the "BAF Configuration" section of this chapter). The header contains important information such as BAF version. The BAF header is explained in Table 55-9.

Table 55-9. BAF image header

Address offset	Size (bits)	Field description
0000h	32	BAF image version
0004h – 00FFh	Reserved	

55.3.1 BAF image version

The BAF version is a 32-bit field in the image header at the BAF starting address (see the "BAF memory map" table in the "BAF Configuration" section of this chapter). The 32-bit field is explained in Table 55-10.

Table 55-10. BAF image version

Field	Description
[0:7]	Major Number: This field contains the major version number for the BAF image
[8:15]	Minor Number: This field contains the minor version number for the BAF image
[16:23]	BAF Type: This field contains customer specific information.
[24:31]	Reserved

55.4 Functional description

A functional description of the BAF modes is contained in the following sections.

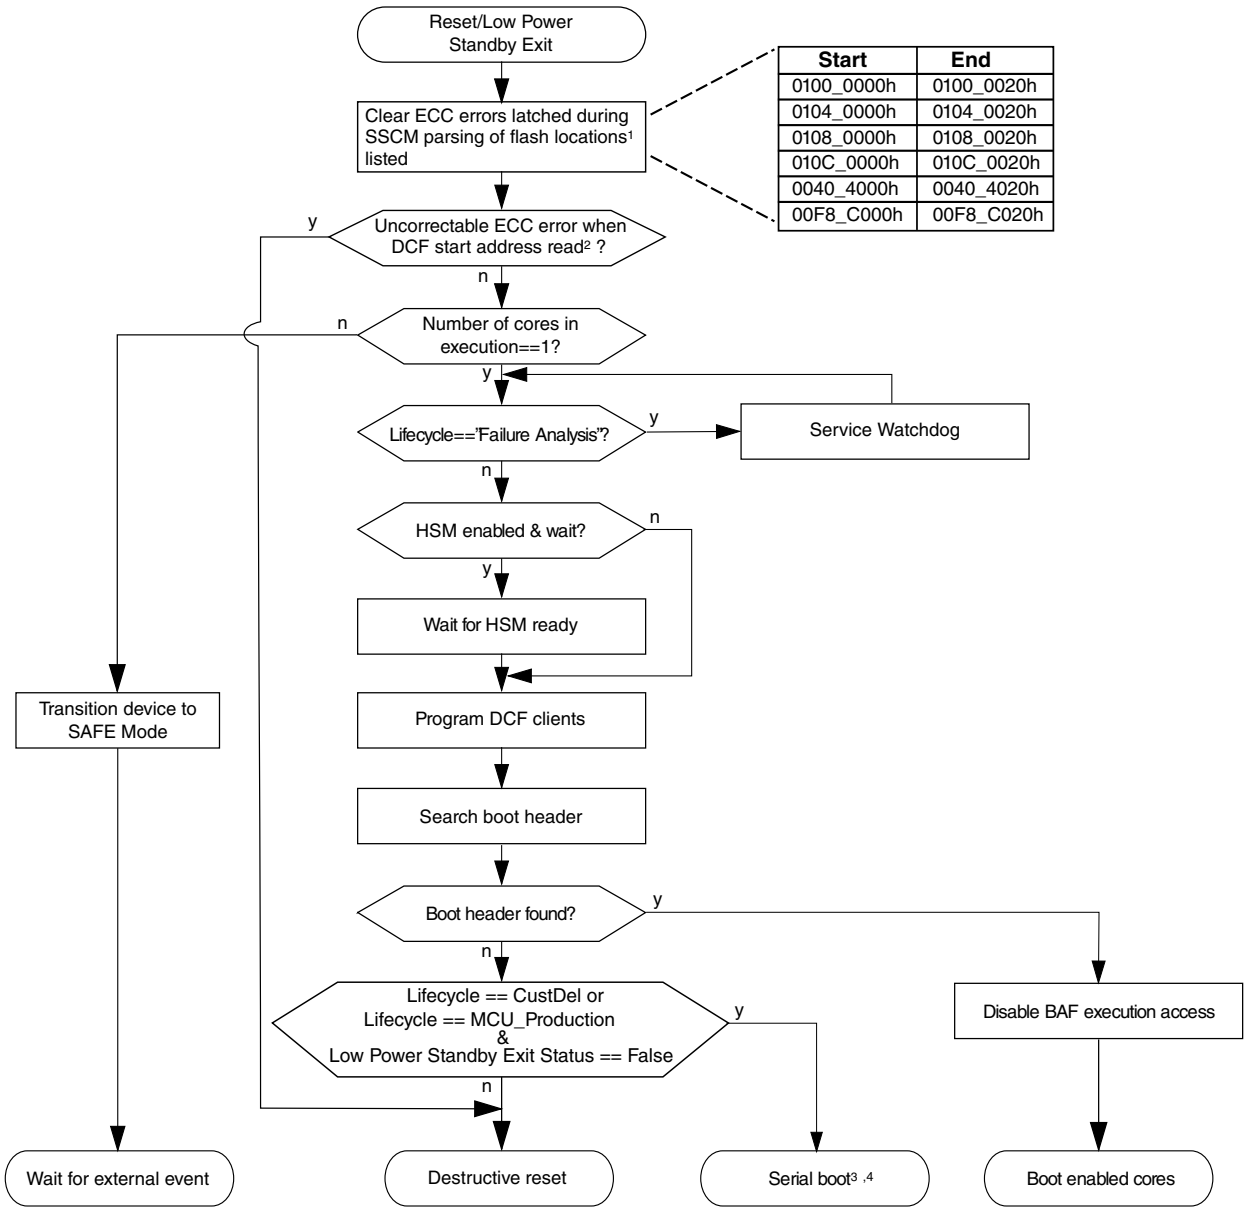
55.4.1 Boot modes

Depending on the state and the content of its flash memory the device can enter one of four different boot modes:

- Boot from internal flash – If the internal flash contains application code with a valid boot header, the application is booted. The boot header contains flags that enable/ disable individual cores and their reset vectors.

- Serial boot – If no valid boot header is found and the current life cycle phase of the device is CUST_DEL (Customer Delivery) or MCU Production, an attempt is made to download the application by a serial protocol over LINFlexD physical interface. The downloaded code is then executed by the initial boot core.
- Static mode – The device enters power safe mode and waits for an external reset.
- Standby Exit Mode – The BAF optionally supports booting when the chip exits standby mode. This mode is entered when the user programs the BAF start address in the Mode Entry Core Address register (MC_ME_CADDR*x*). This mode is supported when software programs only one core out of standby exit and its corresponding MC_ME_CADDR*x* register is programmed with the BAF Entry Point (see table 'BAF memory map' at the beginning of this chapter). If multiple cores are programmed to execute at standby exit, and one or multiple cores are programmed to execute BAF, then the BAF treats this as an error condition and places the chip in safe mode (MC_ME_SAFE_MC) and wait for event.

55.4.2 Device initialization



The BAF performs a minimal initialization of core registers and clocks required to enter the above described boot modes, then attempts to interact and the Hardware Security Module (HSM) in the following way:

1. BAF checks for multiple cores in execution. If more than one core is executing, the device is put in SAFE mode and executes a wait instruction in a loop.
2. HSM: If the HSM is enabled and the "wait for HSM" flag is present, then the boot core waits for the HSM to become ready. It optionally executes a random instruction sequence to create random noise on the instruction bus while waiting.
3. BAF sets up the exception vector table to catch machine check exceptions, which may occur if there are any uncorrectable ECC errors in the BAF execution path. In the event of an uncorrectable ECC error, the BAF issues a destructive reset from the machine check exception handler if the exception is due to the reading of instructions from the BAF region. If an exception occurs during reading of the Boot header, the BAF ignores the ECC error and jumps to next boot header. If the machine check exception occurs due to any other reason during BAF execution, the BAF will still issue a destructive reset. BAF programs the Mode Entry module’s MC_ME_MCTL[TARGET_MODE] to issue a destructive reset.
4. BAF uses memory of the system RAM as in the 'BAF memory map' table (at the beginning of this chapter) for its stack, data and any code that executes from volatile memory. During the BAF start-up procedure, it initializes this section of memory so that there is no ECC error when BAF accesses this memory area.

5. BAF enables instruction cache and branch prediction when executing on Z4 cores. When executing on Z2 core (out of Standby), BAF enables Branch prediction. Both Cache and Branch prediction are disabled before releasing the control to the application.
6. In case of standby exit, BAF checks the source of system clock. If the system clock is sourced from, PLL then RAM wait state is set to 1.

55.4.3 Flow of control

Figure 55-1 shows the overall flow of control in the BAF. The individual steps are explained in the following sections.

1) These locations are scanned by SSCM for its internal operations.
2) DCF records start address can be either the start of DCF records in UTEST flash or the address specified by the Soft DCF Record Start Address. See "Soft DCF clients" section.
3) Serial boot is not available on all devices. Please check the product reference manual for details.
4) SWT0 is disabled after serial boot regardless of the configuration specified in the UTEST_MISC[SWT0_WDG_DIS] register field.

Figure 55-1. Flow of control

55.4.4 Optionally remap calibration RAM

BAF supports remapping of Calibration RAM through Soft DCF Records.

55.4.5 Optionally wait for HSM

If the HSM is enabled (SSCM_UOPS[HSE] = 1), the boot core will need to wait for the HSM to become ready (if SSCM_UOPS[HSB = 1]). The core then polls the HSM until a ready flag is set. Both SSCM registers can be set by a DCF record. The boot core polls the HSM to HOST FLAGS register (HSM_HSM2HTF) until its least significant bit is set. The boot core also services the watchdog while polling the HSM_HSM2HTF register. This is just in case the HSM is not ready in 16 ms, servicing the watchdog prevents the system going to reset.

55.4.6 BAF SAFE mode event handling

BAF executes under different conditions viz. Power-On-Reset (POR), Destructive Reset or any Functional Reset (Long or Short).

Due to device configuration, the device mode can be SAFE or DRUN during BAF execution. BAF issues a DRUN Mode transition to enable any peripheral or transfer control to application. If the device mode is SAFE or changes to SAFE during ongoing DRUN mode transition, then BAF issues an additional SAFE mode transition. After BAF execution when the control is transferred to the application, the device mode can be either SAFE or DRUN. It is recommended that the application (in its bootstrap) should take necessary action after idenitifying the current mode.

NOTE

Safe mode handling is only available in Flash Boot use case. Serial boot mode does not support SAFE mode handling as XOSC is disabled in SAFE mode.

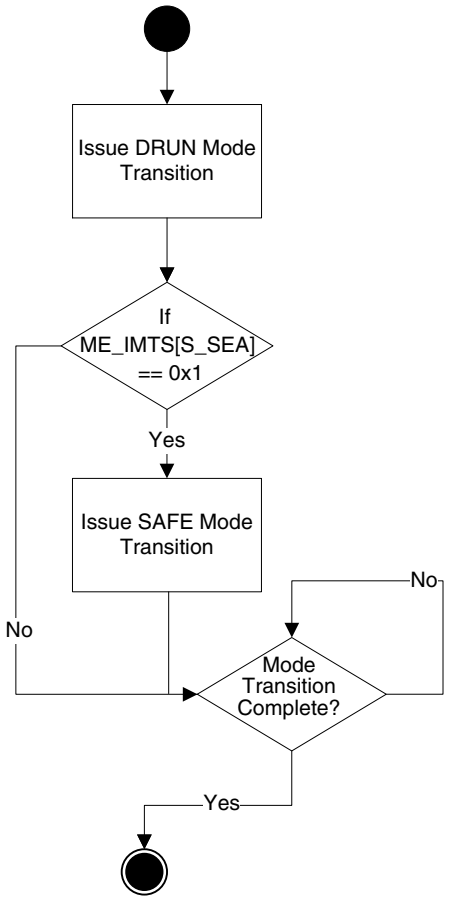


Figure 55-2. SAFE Mode Handling

55.4.7 Initialization of BAF DCF clients

55.4.7.1 Soft DCF clients

DCF clients are 32-bit hardware registers that are written by the SSCM during reset with data that is stored in DCF record format in UTEST region of flash memory. These DCF records are used to configure module registers, and select device operating modes.

The BAF extends the DCF record concept by implementing soft DCF clients. The 64-bit DCF records include:

- 32-bits of data
- 15-bit chip select field (selects the module which implements the DCF clients)
- 15-bit address field (selects a specific DCF client within the selected module)
- Parity bit (not used with UTEST DCF records)
- Stop bit (to indicate the end of DCF record has been reached)

As part of its execution flow, BAF searches through the list of DCF records in UTEST flash to determine if any of the records are to be processed by BAF.

The search starts at one of two addresses: either the start address of DCF records in UTEST (DCF Start Record), or the address specified in UTEST (Soft DCF Record Start Address). If either of the two least significant bits of the 32-bit address stored at the Soft DCF Record Start Address is set, the default start address at the DCF Start Record is used. If the two least significant bits are clear, this 32-bit value is assumed to be the start address of the search.

The default setting of the two least significant bits is 11b (erased value of flash memory is FFFF_FFFFh). A user may intentionally program a dummy address with the least two significant bits set in order to disable the search for an alternate address (as the UTEST block is OTP). Valid search start address must start on a 4-byte boundary.

The DCF record search finishes when a DCF record is read with a STOP bit set. The STOP bit may be set because that memory location is not programmed yet (so the list can be added to) or it can be an intentionally programmed STOP record to indicate that no more records are added to the list. BAF does not execute the DCF record with STOP bit set. BAF parses the STOP bit before parsing the rest of the records.

BAF uses Chip Select 14 (CS14) for BAF DCF clients. For records with CS14 asserted, the BAF uses the address field (address[14:0]) in DCF records to determine how to process the 32-bits of data. The soft DCF clients programmed by BAF are listed in Table 55-11.

A group of four Soft DCF clients is used to provide a mechanism to write configuration information to address locations. The first DCF client receive 32-bit address information. The next three DCF Clients receive the data that is to be written to the address contained in the first client. The three data clients allow 32-bit, 16-bit and 8-bit data to be written to the address in the first client. These four clients can be accessed repeatedly to write whole string of data to memory.

A set of two Soft DCF Clients are used to provide the functionality of remapping calibration RAM. The first DCF record is used to specify the address where the Platform Flash Calibration Remap Descriptor (PFCRD) image is stored. The second soft DCF client provides the address of the function that performs the remapping. The details can be found in section DCF client - PFCRD_IMAGE.

The serial boot DCF client provides a mechanism which can configure the BAF to perform serial boot or boot from internal flash. Details can be viewed in SER_BOOT_CBACK – BAF serial boot DCF client.

Table 55-11. BAF DCF client list

Address	Name	Label	Description
0000h – 01FFh	Reserved	—	Reserved for future use
0200h	Address	ADDR	The address to which DATA*n* is written.
0201h	32-bit data	DATA32	The 32-bit data that is written to ADDR.
0202h	16-bit data	DATA16	The 16-bit data that is written to ADDR.
0203h	8-bit data	DATA8	The 8-bit data that is written to ADDR.
0204h – 020Fh	Reserved	—	Reserved for future use.
0210h	Callback Address	CALLBACK	The address of a callback function.
0211h	Serial boot Callback address	SER_BOOT_CBACK	The address of serial boot callback function.
0212h	Platform Flash Calibration Remap Descriptor Image	PFCRD_IMAGE_ADDR	The address where Platform Flash Calibration Remap Descriptor Image is stored.
0213h	Platform Flash Remap Callback	PFCRD_REMAP_CALLBACK	The address to the Platform Flash Calibration Remap Callback function.
0214h – 7FFFh	Reserved	—	Reserved for future use.

NOTE

BAF boots with a watchdog timeout window set to 16ms. Parsing more and more DCF Records may increase boot time. But it should be taken care that number of DCF records should not be very high as it can cause watchdog window timeout.

55.4.7.2 BAF DCF client - ADDRESS

BAF parses the DCF records. If BAF finds a DCF record with CS14 set and Address field as 0200h while parsing, BAF programs this DCF client. This client is written with a 32-bit address from the Data section of DCF record. This 32-bit address is used in conjunction with any one of the DATA32, DATA16 or DATA8 DCF Data clients. BAF does not immediately use the ADDRESS information, but it is stored and used later in conjunction with a DATAX DCF client (DATA32, DATA16 or DATA8). Then BAF writes the data to the address in memory specified by this ADDRESS DCF client.

The user can create a series of data writes to memory by programming a series of DCF records consisting of pairs of records. The first DCF record of the pair writes to ADDR to provide the address. The second DCF record of the pair writes to the DATA client (DATAX) to provide the data. Subsequent pairs of DCF records can be programmed to write to more memory locations. The number of pairs of DCF records that can be programmed is only limited by the amount UTEST space set aside for DCF records.

Table 55-12. BAF DCF ADDR client configuration

DCF Client Address 0200h															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
ADDR[0:15]															
16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
ADDR[16:31]															

Table 55-13. BAF DCF ADDR client description

Field	Description
ADDR[0:31]	32-Bit Address DCF client. This Address value is used in conjunction with a DATAX value. The BAF writes DATAX value to ADDRESS value in the memory space of the MCU

55.4.7.3 BAF DCF client - DATAX

CAUTION

While using DATAX DCF records, it should be taken in account that BAF does not take care of ECC scheme and can generate ECC, if write is performed in memory locations which are protected by ECC and are not pre-initialized as required.

55.4.7.3.1 DATA32 – 32-bit data DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0201h while parsing, BAF programs this 32-bit DCF client. BAF takes the memory address provided by the ADDR client and writes this 32-bit data to the address. (Only 32-bit aligned writes are supported)

Table 55-14. DATA32 DCF client configuration

DCF Client Address 0201h															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 55-15. DATA32 DCF client description

Field	Description
DATA[0:31]	32-Bit DCF Data

55.4.7.3.2 DATA16 – 16-bit data DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0202h while parsing, BAF programs this 16-bit DCF client. BAF takes the memory address provided by the ADDR client and writes least significant 16-bit data to the address. Data in the 16 most significant bits are ignored. (Only 16-bit aligned writes are supported)

Table 55-16. DATA16 DCF client configuration

DCF Client Address 0202h

Table 55-17. DATA16 DCF client description

Field	Description
DATA[0:15]	32-Bit DCF Data

55.4.7.3.3 DATA8 – 8-bit data DCF client

The BAF parses the DCF records. During parsing, if the BAF finds a record with CS14 set and address field equal to 0203h, the BAF programs this 8-bit DCF client. The BAF takes the memory address provided by the ADDR client, and writes least significant 8-bit data to the address. Data in the 24 most significant bits are ignored.

Table 55-18. DATA8 DCF client configuration

Table 55-19. DATA8 DCF client description

Field	Description
DATA[0:7]	8-Bit DCF Data

55.4.7.4 CALLBACK – BAF callback DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0210h while parsing, BAF programs this callback DCF client. This client is written with a 32-bit start address of a function which is invoked by BAF. The BAF code checks the start address is within the UTEST or within the BAF flash memory blocks, and then passes program flow to this address. If the address is found to be outside the UTEST and BAF flash memory blocks, no function call is executed. The callback is aborted and BAF moves on to the next DCF records. The function that is called is expected to comply with Power.org EABI and to terminate in an orderly manner. An incorrectly written function causes unpredictable operations in BAF. No parameters are passed to this function and no return value is expected.

Warning

Excessively long callback functions could cause the watchdog timer to time-out and cause a reset.

BAF executes the callback function as the DCF records are parsed. Therefore several callback functions maybe executed by writing several DCF records that write to the callback DCF clients. The callback functions are executed in the same order as the DCF records.

55.4.7.5 SER_BOOT_CBACK – BAF serial boot DCF client

The BAF parses DCF records. If it finds a record with CS14 set and an address field of 0211h during parsing, the BAF programs this serial boot DCF client. This DCF client is written with a 32-bit start address of a function which is invoked by the BAF. The BAF code checks to see if the start address is within the UTEST or BAF flash memory blocks, then program flow is passed to this address if it is within either of these blocks. If the address is outside the the UTEST and BAF flash memory blocks, no function call is executed. The DCF client execution is aborted, and the BAF moves to the next DCF record. The function that is called is expected to comply with Power.org EABI and to terminate in an orderly manner. An incorrectly written function causes unpredictable operations in the BAF.

Warning

No parameters are passed to the function invoked by the BAF.

Excessively long callback functions could cause the watchdog timer to time-out and cause a reset.

The serial boot callback function returns a character value. The return value informs BAF if serial or normal internal flash boot should be executed (see Table 55-20 for details).

Table 55-20. Serial boot callback function return value definition

Return values	Description
00h	Boot from internal flash using standard search for boot record (see "Search boot header and boot options" at the beginning of this chapter).
01h	Serial boot using LINFlexD (in UART mode). See Optionally perform serial boot for details.
02h – FFh	Reserved

55.4.7.6 DCF client - PFCRD_IMAGE

55.4.7.6.1 PFCRD_IMAGE_ADDR – BAF Platform Flash Calibration Remap Image Address DCF Client

The BAF parses DCF records. If BAF finds a record with CS14 set and address field as 0212h, BAF programs this DCF Client. The client is written with 32-bit address from the data section of the DCF record. The 32-bit address is not used immediately but the value is stored and later used in conjunction with Platform Flash Calibration Remap Callback DCF record. Then BAF uses these user specified value to perform Platform Flash Calibration Remap.

The user can have multiple PFCRD_IMAGE_ADDR DCF clients programmed in the UTEST Area. Only the last DCF Client programmed before PFCRD_REMAP_CALLBACK will be used. The number of pairs of DCF records that can be programmed is only limited to the amount of UTEST space set aside for DCF records.

The address specified in this DCF record must lie in the UTEST region.

The format of Platform Flash Calibration Remap Descriptor Image is shown in Table 55-21.

Table 55-21. Remap configuration table

Address offset	Name	Contents
00h	Reserved	Reserved
04h	ADDR_SWID	Address of 64-bit ID Value in SW Flash
08h	DATAID	64-bit ID value of the calibration data
0Ch		

Table continues on the next page...

Table 55-21. Remap configuration table (continued)

Address offset	Name	Contents
10h	PFCRDE	CRD Enable Flags
14h	LSTARTADDR0	PFCRD0, Logical start address
18h	PSTARTADDR0	PFCRD0, Physical start address
1Ch	CRDSize0	PFCRD0, Master Enable and CRDSize0
20h	LSTARTADDR1	PFCRD1, Logical start address
24h	PSTARTADDR1	PFCRD1, Physical start address
28h	CRDSize1	PFCRD1, Master Enable and CRDSize1
…	…	…
68h	LSTARTADDR7	PFCRD7, Logical start address
6Ch	PSTARTADDR7	PFCRD7, Physical start address
70h	CRDSize7	PFCRD7, Master Enable and CRDSize7

NOTE

For definition of LSTARTADDR, PSTARTADDR and CRDSize, see Flash memory controller

Table 55-22. DCF Platform Flash Calibration Remap Descriptor Image Address

DCF Client Address 0212h															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Address[0:15]

Address[16:31]															

55.4.7.6.2 PFCRD_REMAP_CALBACK – BAF Platform Flash Calibration Remap Callback DCF Client

The parses DCF Records. If BAF finds a record with CS14 set and address field as 0213h, BAF programs this DCF Client. The client is written with 32 bit start address of a function which is invoked by the BAF. Following checks are performed by the BAF code before executing the function call:

- The start address of the function specified by this DCF client must be within the UTEST area or BAF Flash memory blocks.
- PFCRD_IMAGE_ADDR DCF record is programmed correctly before this DCF Client.

If either of the checks fails, BAF then moves forward to parse the next DCF record. The function that is called is expected to comply with Power.org EABI and to terminate in an orderly manner. An incorrectly written function may cause unpredictable operations in the BAF.

NOTE

The address to the remap configuration table specified in PFCRD_IMAGE_ADDR DCF record is passed as a parameter to the function invoked by the BAF.

Excessively long callback functions could cause the watchdog timer to time-out and cause a reset.

This callback function returns no value to the BAF.

Table 55-23. DCF Platform Flash Calibration Remap Callback Function

DCF Client Address 0213h															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Address[0:15]															
16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
Address[16:31]															

Customer can either chose to implement its own remap function or make use of the default sample implementation is provided in BAF. The entry point to the sample function is shown in Table 55-24.

Table 55-24. PFRCD entry point

Address	Description
0040_40C0h	Platform Flash Calibration Remap Callback Function address

There is no restriction on number of times Platform Flash Calibration DCF record pair is programmed. It is only limited by the available size in the UTEST Area.

NOTE

Only the last DCF record pair programmed will be effective.

55.4.7.6.3 Implementation details of BAF supplied remap function

Input to the function is the pointer to Table 55-21. Figure 55-3 shows the flowchart of the default sample implementation.

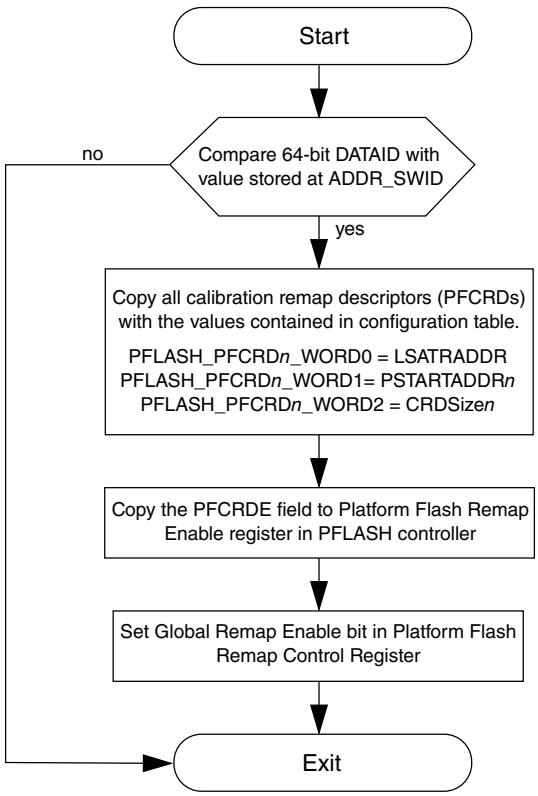

Figure 55-3. BAF supplied Calibration Remap Flowchart

55.4.8 Optionally perform serial boot

If no boot header is found in any of the locations mentioned above, the BAF determines the Life Cycle status of the device. If the Life Cycle is in CUST_DELIV (Customer Delivery) or MCU Production, it attempts a serial boot. Otherwise, the boot has failed and BAF issues a destructive reset.

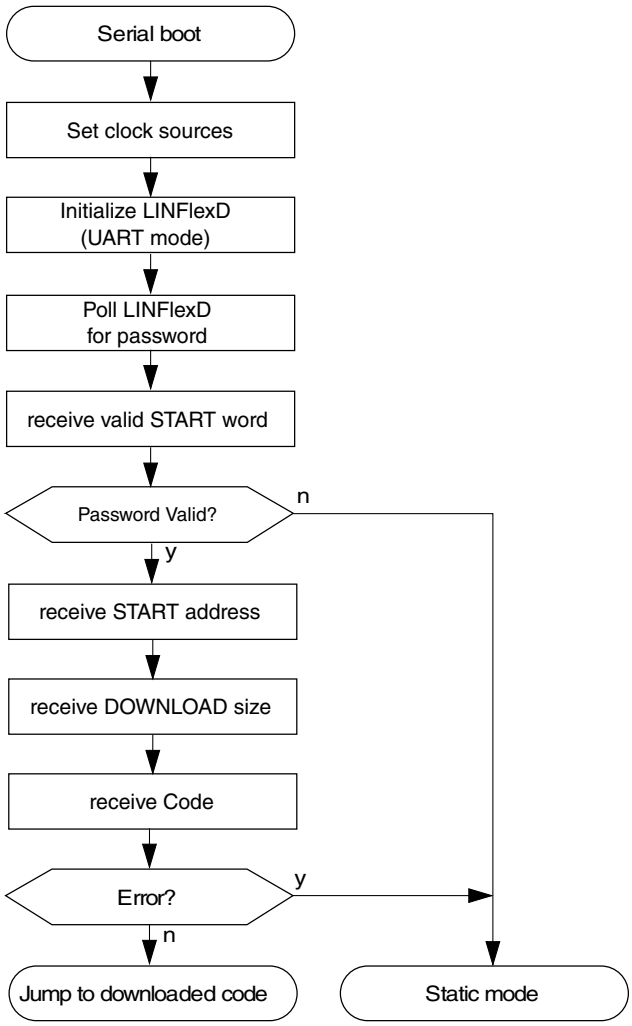

Figure 55-4. Flow of control during serial boot

The clock source in the MC_CGM module is configured and the PADs are set up for LINFlexD and signals (see Serial boot configuration for details), then the code is downloaded using LINFlexD in Serial Boot mode. In the absence of errors causing the device to be placed in Static mode, the device state is restored to resemble the out-of-reset state and the downloaded code is executed.

Serial boot allows the download of application to internal SRAM via the LINFlexD interface. After downloading the application image to SRAM, the BAF jumps to the start address provided as part of download protocol mentioned below and executes the downloaded application.

At the start of the process, LINFlexD is configured in passive listening mode. As soon as the interface receives a valid message, the receiving interface is configured in full Tx and Rx mode.

The BAF program:

- Checks if the first byte is FEh of the password. If not, continue polling.

55.4.8.1 Serial boot mode protocol

NOTE

Serial boot is not allowed from standby mode exit.

From a high-level perspective, the download protocol over LIN interface follows steps below:

1. Host transmits the 64-bit password to MCU.
2. Host transmits start address, size of downloaded code in bytes, NO_ECHO bit and VLE bit to MCU.
3. Host transmits a sequence of data bytes that are to be executed.
4. CPU0 executes code from start address provided in 2

NO_ECHO bit signifies if actual download data to be echoed or not. If NO_ECHO bit is set, then data will not be echoed otherwise if NO_ECHO bit is clear, then data will be echoed.

Each step must be complete before the next step starts.

55.4.8.2 LINFlexD download protocol

The communication is performed in half-duplex mode, Any transmission from the host is followed by the MCU transmission:

1. The host sends data to the MCU and starts waiting.
2. The MCU echoes the received 8-byte of password, 4-byte of load address and 4-byte of VLE-bit, NO_ECHO bit and 30-bit of download size to the host. The MCU echoes actual download data depending upon NO_ECHO bit.
3. The host verifies whether the echo is correct.
   - If the data is correct, the host can send the next byte of data.
   - If data is not correct, it is assumed the MCU has not correctly received the data and the only practical option is for the Host to reset the MCU and start again.

A more detailed description of these steps follows.

All multi-byte data structures are sent with MSB first.

The tool sends data in the following order:

1. 8 bytes that represent the password.
2. 4 bytes that represent the start address where the code is to be downloaded.

3. 4 bytes that represent the number of bytes to be downloaded, NO_ECHO bit and the VLE bit.
4. x bytes of code that is downloaded to SRAM and executed, (x must match the value specified in 3).

55.4.8.3 Download 64-bit password and password check

The first 64 bits received represent the password. The MCU only supports public passwords. The received password is always compared with the public password FEED_FACE_CAFE_BEEFh.

- If the correct password is received, BAF continues its task.
- If an incorrect password is supplied, BAF puts the device into static mode(low power safe mode).
- If 64 bits of password data is not received after approximately 30s, BAF causes a destructive reset of the MCU.

55.4.8.4 Download start address, VLE bit, NO_ECHO bit and code size

After the password, the next 8 bytes received by the MCU contains a 32-bit start address, the VLE mode bit, NO_ECHO bit and 30-bit code length as shown in Table 55-25.

The VLE bit (Variable Length Encoding) is used to indicate for which instruction set the downloaded code is compiled. The UART serial boot protocol supports download of VLE Code (VLE = 1) and BookE Code (VLE = 0).

The MCU only supports VLE code, i.e VLE=1.

The NO_ECHO bit is used to indicate if download data should be echoed by the MCU. If the NO_ECHO bit is set (for example, NO_ECHO = 1), then only 8 bytes of password, 4 bytes of download address, and 4 bytes of download size are echoed, but download data is not echoed. If the NO_ECHO bit is clear, then every byte sent to the MCU must be echoed.

The start address defines where the received data is stored and where the MCU branches after the download is finished. BAF ignores the three LSB bits of download address to avoid ECC on download address. But BAF does not align the address while jumping to application for executing. So, download address should be passed as 64-bit aligned for proper execution.

The Length defines how many data bytes have to be loaded.

Table 55-25. Start address, VLE bit, NO_ECHO bit and download size in bytes

Bytes 0-3															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
START_ADDRESS[31:16]															
16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
START_ADDRESS[15:0]															
Bytes 4-7															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
VLE	NO_ECHO	CODE_LENGTH[29:16]													
16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
CODE_LENGTH[15:0]															

55.4.8.5 Download data

Each byte of data received is downloaded into device SRAM starting from the address specified in the previous protocol step. It is not verified whether the provided address is a valid address in SRAM or is writable.

The address increments until the number of bytes of data received matches the code length specified in the previous protocol step.

Since the SRAM is protected by 64-bit wide Error Correction Code (ECC), BAF always writes to SRAM grouped in 64-bit double-words. If the last byte does not fall into a 64-bit boundary, the BAF fills it with zero’s and renders the data aligned on a 64-bit boundary. After the last data is written to SRAM, the BAF writes a dummy double-word (0000_0000_0000_0000h) to the next address location. This is written to avoid possible ECC error during core prefetch.

55.4.8.6 Execute code

The BAF program waits for the last echo message transmission being completed. Then it restores the initial MCU configuration and jumps to the loaded code at Start Address which was received in step 2 of the protocol. At this point the BAF has finished its tasks and MCU is controlled by new code executing from SRAM.

55.4.9 Serial boot configuration

55.4.9.1 LINFlexD configuration

Boot using UART protocol is implemented by the LINFlexD module.

NOTE

See the pin configuration table at the beginning of this chapter for pins used by the LINFlexD module.

When Serial Boot mode is started the LINFlexD_Rx pin is configured as an input and muxed to the LINFlexD module. The LINFlexD_Tx pin remains in a passive input state until the first byte of protocol is received. It is then configured as an output and muxed to LINFlexD module. The application may not be using the Serial Boot Mode function, and may be using the pin used by LINFlexD_Tx as an input, which may have some external hardware driving the pin. Inadvertently driving this pin as an output would cause contention and possible damage.

The LINFlexD module operates in half-duplex mode. The interface is either transmitting a byte or receiving a byte, but never both at the same time. It is expected that LINFlexD pins are connected to a physical layer bus driver/receiver (PHY). Many PHYs enforce half-duplex mode by using a single data channel for both transmitting and receiving data (such as LIN or CAN). The side effect of this is that all data transmitted on the Tx pin is also received on the Rx pin. To prevent the LINFlexD module from receiving its own transmission, the Rx pin is blocked during transmission.

The LINFlexD controller is configured to operate at a baud rate of f_{XOSC} / 832, using an 8-bit data frame with no parity bit and 1 stop bit.

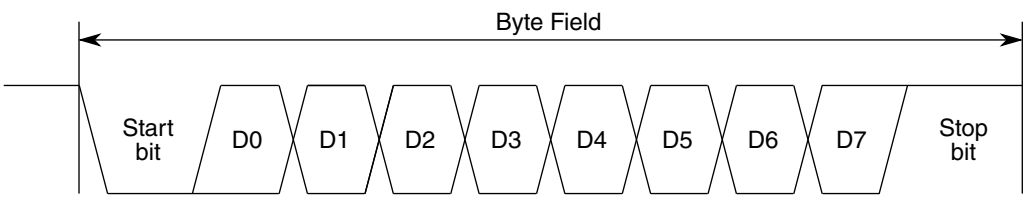

Figure 55-5. LINFlexD bit timing in UART mode

55.4.9.2 LINFlexD pin configuration

Please see the BAF configuration at the beginning of this chapter for pin details.

55.4.9.3 Baud rates

The LINFlexD baud rate is set by the frequency of an external crystal oscillator / 832. Table 55-26 shows some possible baud rates.

Table 55-26. LINFLexD baud rates

Crystal frequency	LINFlexD baud rate
8 MHz	9600 baud
12 MHz	14,400 baud
16 MHz	19,200 baud
20 MHz	24,000 baud
40 MHz	48,000 baud

55.4.9.4 Protocol summary

Table 55-27 summarizes the LINFlexD protocol and BAF action during this boot mode.

Table 55-27. LINFlexD serial boot mode download protocol

Protocol steps	Host message sent	BAF response message	Action
1	64-bit password (MSB first)	64-bit password (MSB first)	Password checked for validity and compared with stored password.
2	32-bit store address	32-bit store address	Load address is stored for future use.
3	VLE bit + NO_ECHO bit + 30 bits of download data size in bytes (MSB first)	VLE bit + NO_ECHO bit + 30 bits of download data size in bytes (MSB first)	Size of download is stored for future use. Verify VLE bit.
4	8 bits of raw binary data	If NO_ECHO bit is set, data is echoed, otherwise data is not echoed.	8 x 8 bits of data are packed into 64-bit double-words. These double-words are stored in SRAM starting from the Load address. The Load address increments until the number of data received and stored matches the size as specified in the previous steps.
5	none	none	Branch to downloaded code

55.5 Resources

- Clocks
  - Several clock configurations are made depending on the boot mode of the BAF. All settings are restored before execution of the application code (in flash memory or received via serial download).

- LINFlexD
  - The LINFlexD module is used if serial boot mode is entered. This can be through failing to find a valid boot header, or from the SER_BOOT_CBACK callback function. All settings are restored before the application code in system RAM is executed.
- PFLASH
  - PFLash module is used to disable BAF execution. This module is also used to perform Calibration RAM Remap. (see Optionally remap calibration RAM).
- Interrupts
  - No interrupts/exceptions are used or enabled, except the Machine Check exception, to handle ECC errors.
- SEMA4
  - BAF uses Semaphores when it detects multiple cores executing out of standby exit use case. Semaphores are used to synchronize and safely bring the SoC into SAFE mode.
- SRAM Controller
  - BAF sets the RAM Wait state to 1 in Standby exit when system clock is sourced from PLL.

Chapter 56
Nexus Crossbar Multi-Master Client (NXMC)

56.1 Chip-specific NXMC information

56.1.1 NXMC block connections

To provide Nexus data trace messaging from bus masters on the master ports of the crossbar (XBAR) that do not inherently have a trace client, a Nexus Crossbar Multi-Master Client (NXMC) monitors traffic into the master port of the XBAR. Trace messages transmitted over the Nexus interface (or stored in trace memory) include which NXMC generated the message as well as an identifier for the pre-concentrator source of the message.

The following figure shows a block diagram illustrating the NXMC integration.

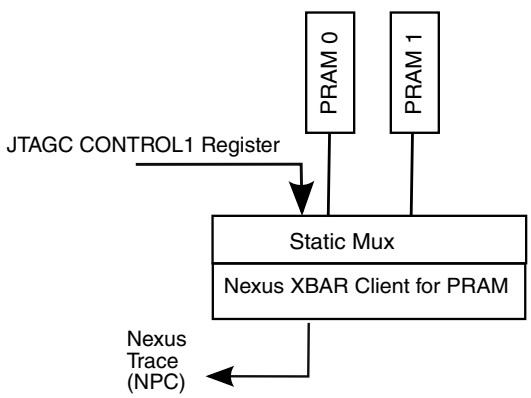

Figure 56-1. NXMC integration block diagram

56.1.2 NXMC source and master client IDs

The values of the trace master ID or in-circuit client ID, along with the Nexus message source identifier for the different clients are shown in the following table.

Table 56-1. NXMC source and master client IDs

Master Name	Master ID	Source ID
e200Z4	0000	4'b0000
e200Z2	0001	4'b0010
eDMA	0100	4'b1100
Ethernet	0101	4'b1100
FlexRAY	0110	4'b1100
Debug e200Z4	1000	4'b1100
Debug e200Z2	1001	4'b1100

56.2 Introduction

The Nexus Crossbar Multi-master Client (NXMC) module provides real-time trace capabilities in compliance with the IEEE-ISTO Nexus 5001-2012 standard. This module provides development support capabilities for devices without requiring address and data pins for internal visibility. A portion of the pin interface is also compliant with the IEEE 1149.1 JTAG standard. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port.

Many bus masters start accesses to internal address locations via the system bus. The NXMC module monitors the system bus and provides real-time trace information to debug or development tools.

56.2.1 Features

The NXMC module is compliant with the IEEE-ISTO 5001-2012 standard. The following features are implemented:

- Data trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to (selected) internal memory resources.
- Multi-master tracing capability for multiple master accesses
- HSM master(s) filtering from the tracing function based on external control
- Watchpoint messaging based on internal/external triggers, via the auxiliary pins
- Watchpoint trigger events out based on internal/external triggers
- Watchpoint trigger enable of data trace messaging
- Start or stop of Tracing (Data Trace, Watchpoint Trace) based on internal triggers.
- Optional timestamping of the messages based on timer value and controls received at the interface

- Nexus Auxiliary port for higher data throughput
  - One $\overline{\text{EVTO}}$ (Watchpoint Event) pin
  - One $\overline{\text{EVTI}}$ (Event In) pin
- Registers for data trace, watchpoint generation, and watchpoint trigger
- All features controllable and configurable via the JTAG port

56.3 External signal description

This section details information regarding the standard ports and protocol. The NXMC pin interface provides the function of transmitting messages from the messages queues to NPC. It is also responsible for handshaking with the message queues.

The NXMC module implements the following signals:

- One $\overline{\text{EVTI}}$
- One $\overline{\text{EVTO}}$

These pins are described in Table 56-3.

All NXMC input functionality is controlled through the JTAG port in compliance with IEEE 1149.1 (see IEEE 1149.1 (JTAG) Test Access Port for details). A separate JTAG TAP controller is instantiated within the NXMC. The following table describes the JTAG pins.

Table 56-2. JTAG pins for NXMC

JTAG port	Input/ output	Description
TDO	O	The Test Data Output (TDO) pin is the serial output for test instructions and data. TDO is three-stateable and is actively driven in the shift-IR and shift-DR controller states. TDO changes on the falling edge of TCK.
TDI	I	The Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK and has an internal pull-up resistor.
TMS	I	The Test Mode Select (TMS) input pin is used to sequence the JTAG test controllers' state machine. TMS is sampled on the rising edge of TCK and has an internal pull-up resistor.
TCK	I	The Test Clock (TCK) input pin is used to synchronize the test logic, and control register access through the JTAG port.
TRST	I	The Test Reset ($\overline{\text{TRST}}$) input pin is used to asynchronously initialize the JTAG controller. The $\overline{\text{TRST}}$ pin has an internal pull-down resistor.

Table 56-3. NXMC Auxiliary pins

Auxiliary port	Input/ output	Description
EVTO	O	Event Out ($\overline{\text{EVTO}}$) is an output which, when asserted, indicates one of two events has occurred based on the EOC bits in the DC Register: • one of the internal or external watchpoints has occurred and EOC = 2'b00 • system-level debug mode was entered (ipg_debug) and EOC = 2'b01 $\overline{\text{EVTO}}$ is held asserted for one cycle.
EVTI	I	Event In ($\overline{\text{EVTI}}$) is an input which initiates synchronization messages. If the Nexus module is enabled at reset, (see Enabling NXMC operation), assertion initiates data trace synchronization messages (provided data trace is enabled).

56.4 Supported messages and TCODEs

The NXMC pins allow for flexible transfer operations via public messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2012 standard defines a set of public messages. The NXMC block supports the public TCODEs listed in the following table. The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

Table 56-4. Supported public TCODEs

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Data Trace - Data Write Message	6	6	TCODE	fixed	TCODE number = 58
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 56-5)
	1	32	U-ADDR	variable	Unique portion of the data write address
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Read Message	6	6	TCODE	fixed	TCODE number = 59
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 56-5)

Table continues on the next page...

Table 56-4. Supported public TCODEs (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
	1	32	U-ADDR	variable	Unique portion of the data read address
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	ETYPE	fixed	Error type (See Table 56-6)
	14	14	ECODE	fixed	Error code (See Table 56-7)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Write Message w/ Sync	6	6	TCODE	fixed	TCODE number = 60
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 56-5)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Read Message w/ Sync	6	6	TCODE	fixed	TCODE number = 61
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 56-5)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	1	8	WPHIT	variable	Watchpoint source(s) number (See Table 56-23)
	1	26	TSTAMP	variable	Timestamp (Optional)

Table 56-5. Data trace size (DSZ) encodings (TCODE = 58, 59, 60, 61)

DSZ	Transfer size
001	8-bit
010	16-bit
011	32-bit
100	64-bit
000, 101-111	Reserved

Table 56-6. Error Type (ETYPE) encodings (applicable to all error messages)

ETYPE	Description
0000	Queue overrun caused message (one or more) to be lost
0001	Contention with higher priority message caused message(s) to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus register unimplemented)
0110–1111	Reserved

Table 56-7. Error Code (ECODE) encodings (applicable based on error source)

ECODE		Description[1]
13 to 8	7 to 0	
Source (SRC)		
000000	XXXXXXX1	Watchpoint Message(s) lost
000000	XXXXXX1X	Data Trace Message(s) lost
000000	XXXXX1XX	Reserved
000000	XXXX1XXX	Reserved
000000	XXX1XXXX	Reserved
000000	XX1XXXXX	Reserved

CKSRCn	X1XXXXXX	Reserved
CKSRCn	1XXXXXXX	Reserved

1. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

56.5 Register description

This section describes the NXMC register definition. Nexus registers are accessed using the JTAG port in compliance with IEEE 1149.1. See IEEE 1149.1 (JTAG) Test Access Port for details. The complete list of registers is shown in this table.

Table 56-8. NXMC registers

Nexus register	Nexus access opcode (hex)	Read/ write	Read address (hex)	Write address (hex)
Development Control 1 (DC1)	2	R/W	04	05
Development Control 2 (DC2)	3	R/W	06	07
Watchpoint Trigger (WT)	B	R/W	16	17
Data Trace Control (DTC)	D	R/W	1A	1B
Data Trace Start Address1 (DTSA1)	E	R/W	1C	1D
Data Trace Start Address2 (DTSA2)	F	R/W	1E	1F
Data Trace End Address1 (DTEA1)	12	R/W	24	25
Data Trace End Address2 (DTEA2)	13	R/W	26	27
Breakpoint/Watchpoint Control Register1 (BWC1)	16	R/W	2C	2D
Breakpoint/Watchpoint Control Register2 (BWC2)	17	R/W	2E	2F
Breakpoint/Watchpoint Address Register1 (BWA1)	1E	R/W	3C	3D
Breakpoint/Watchpoint Address Register2 (BWA2)	1F	R/W	3E	3F

56.5.1 Development control register 1 (DC1)

The Development Control Registers control the basic development features of the NXMC module. This table shows the format of the DC1.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

56.5.2 Development control register 2 (DC2)

The Development Control Registers control the basic development features of the NXMC module. This table shows the format of the DC2.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	EWC								0	0	0	0	0	0	0	0

R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DC2 is described in this table.

Table 56-10. DC2 register field description

Field	Description	
31:24	$\overline{\text{EVTO}}$ Watchpoint Configuration[1].	
EWC	00000000	No Watchpoints trigger $\overline{\text{EVTO}}$
	1XXXXXXX	Reserved (This is read/write field, so default value must not be changed for normal operation)
	X1XXXXXX	Reserved (This is read/write field, so default value must not be changed for normal operation)
	XX1XXXXX	Reserved (This is read/write field, so default value must not be changed for normal operation)
	XXX1XXXX	Reserved (This is read/write field, so default value must not be changed for normal operation)
	XXXX1XXX	Internal Watchpoint #1 triggers $\overline{\text{EVTO}}$
	XXXXX1XX	Internal Watchpoint #2 triggers $\overline{\text{EVTO}}$
	XXXXXX1X	Reserved (This is read/write field, so default value must not be changed for normal operation)
	XXXXXXX1	Reserved (This is read/write field, so default value must not be changed for normal operation)
23:1	Reserved for future functionality (read as 0)	
0	Reserved for future functionality (Read/Write – default values must not be changed for normal operation)	

1. The EOC bits in DC1 must be programmed to trigger EVTO on watchpoint occurrence for the EWC bits to have any effect.

56.5.3 Watchpoint trigger register (WT)

The Watchpoint Trigger Register allows the watchpoints defined either internally to the NXMC module or by an external module to trigger actions. These watchpoints can control data trace enable and disable.

The WT bits can be used to produce an address related window for triggering trace messages. This table shows the format of the WT register.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

19:0	Reserved for future functionality (read as 0)

1. The WT bits only enable data trace if the TM bits in the Development Control Register (DC) have not already been set to enable data trace.

56.5.4 Data trace control register (DTC)

The Data Trace Control Register controls whether DTM messages are restricted to reads, writes or both for a user programmable address range. There are two data trace channels controlled by the DTC for the NXMC module. This table shows the format of the DTC register.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	RWT1		RWT2		0	0	0	ME	0	0			MID				0	0	0	0	0	0	0	0	RC1	RC2	0	0	0	0	0	0
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DTC register is described in this table.

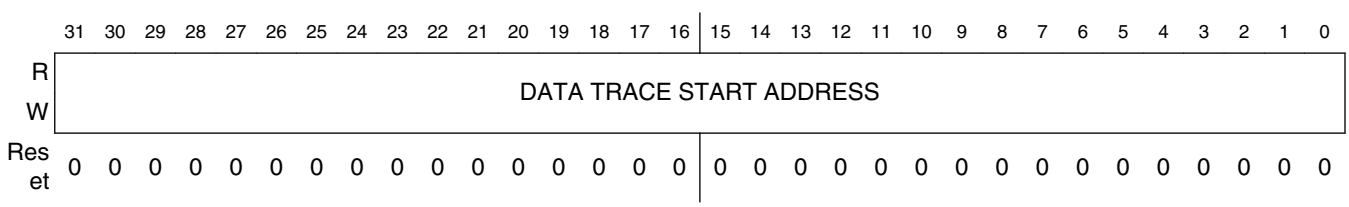

Table 56-12. DTC field description

Field	Description
31:30 RWT1	Read/Write Trace 1. 00 No trace messages generated x1 Enable data read trace 1x Enable data write trace
29:28 RWT2	Read/Write Trace 2. 00 No trace messages generated x1 Enable data read trace 1x Enable data write trace
27:25	Reserved for future functionality
24 MME	Multi Master Tracing enable. 0 Tracing enabled only for Master with ID = MID (DTC[19:16]) 1 Tracing enabled for all the Masters
23:20	Reserved for future functionality
19:16 MID	ID of the system bus Master to be traced[1]
15:8	Reserved for future functionality
7 RC1	Range Control 1. 0 Condition trace on address within range (endpoints inclusive) 1 Condition trace on address outside of range (endpoints exclusive)
6 RC2	Range Control 2. 0 Condition trace on address within range (endpoints inclusive) 1 Condition trace on address outside of range (endpoints exclusive)
5:0	Reserved for future functionality

1. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

56.5.5 Data trace start address registers 1 and 2 (DTSA1 and DTSA2)

The Data Trace Start Address Registers define the start addresses for each trace channel. This table shows the format of the DTSA1 and DTSA2 registers.

56.5.6 Data trace end address registers 1 and 2 (DTEA1 and DTEA2)

The Data Trace End Address Registers define the end addresses for each Trace channel. This table shows the format of the DTEA1 and DTEA2 registers.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA TRACE END ADDRESS																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This table illustrates the range that are selected for data trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 56-13. Data trace address range options

Programmed values	Range control bit value	Range selected
DTSA ≤ DTEA	0	DTSA -> <- DTEA
DTSA ≤ DTEA	1	<- DTSA DTEA ->
DTSA > DTEA	N/A	Invalid range—no trace

Note

DTSA must be less than (or equal to) DTEA in order to guarantee correct data write/read traces.

When the range control bit is 0 (internal range), accesses to DTSA and DTEA addresses are traced. When the range control bit is 1 (external range), accesses to DTSA and DTEA are not traced.

56.5.7 Breakpoint/watchpoint control register 1 (BWC1)

Breakpoint/watchpoint control register 1 controls the attributes for generation of NXMC watchpoint#1. This table shows the format of the BWC1 register.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	BWE1		BRW1		0	0	0	0	0	0	0	0	0	0	BWR1		BWT1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

56.5.9 Breakpoint/watchpoint address registers 1 and 2 (BWA1 and BWA2)

The Breakpoint/Watchpoint Address Registers are compared with system bus addresses in order to generate internal watchpoints. This table shows the format of the BWA1 and BWA2 registers.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	BREAKPOINT / WATCHPOINT ADDRESS																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

56.5.10 Unimplemented registers

Unimplemented registers are those with client select and index value combinations other than those listed in Table 56-8. For unimplemented registers, the NXMC module drives TDO to zero during the SHIFT-DR state. It also transmits an error message with the invalid access opcode encoding (ETYPE = 0101).

56.6 Programming considerations (RESET)

If NXMC register configuration is to occur during system reset (as opposed to debug mode), all NXMC configuration should be completed between the negation of $\overline{\text{TRST}}$ and system reset de-assertion. The JTAG ID register should be read by the tool after negation of $\overline{\text{TRST}}$ and should be programmed before deassertion of system reset.

56.6.1 IEEE 1149.1 (JTAG) Test Access Port

The NXMC module uses the IEEE 1149.1 TAP controller for accessing Nexus resources. The JTAG signals themselves are shared by all TAP controllers on the device. The NXMC module implements a 4-bit Instruction Register (IR). The valid instructions and method for register access are outlined in NXMC register access via JTAG.

56.6.2 Enabling NXMC operation

The Nexus module is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once enabled, the module is ready to accept control input via the JTAG pins.

The Nexus module is disabled when the JTAG state machine reaches the Test-Logic-Reset state. This state can be reached by the assertion of the $\overline{\text{TRST}}$ pin or by cycling through the state machine using the TMS pin. The Nexus module is also disabled if a Power-on-Reset (POR) event occurs.

If the NXMC module is disabled, no trace output is provided. Nexus registers are not available for reads or writes.

56.6.3 Enabling NXMC TAP controller

Assertion of a Power-on-Reset signal or assertion of the $\overline{\text{TRST}}$ pin resets all TAP controllers. Upon exit from the Test-Logic-Reset state, the IR value is loaded with the JTAG ID. When the NXMC TAP is accessed, this information helps the development tool obtain information about the Nexus module it is accessing, such as version, sequence, feature set, etc.

56.6.4 NXMC register access via JTAG

Access to Nexus register resources is enabled by loading a single instruction into the JTAG Instruction Register (IR).

Once the JTAG NEXUS-ACCESS instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in Table 56-8.

Reading/writing of a Nexus register then requires two passes through the Data-Scan (DR) path of the JTAG state machine.

1. The first pass through the DR selects the Nexus register to be accessed by providing an index (see Table 56-8), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the format shown below.

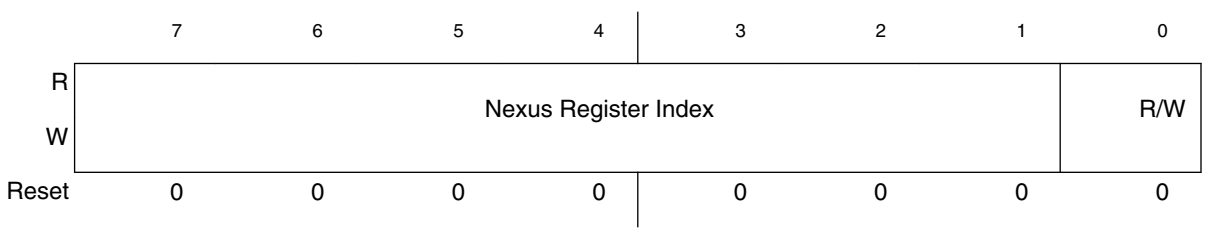

Table 56-16. JTAG DR field description for Nexus register access

Field	Description
Nexus Register Index	Selected from values in Table 56-8
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.

a. During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the Capture-DR state.

b. During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the Update-DR state.

56.7 Functional description

The following sections describe the functionality of the NXMC module.

56.7.1 Data trace

This section describes the data trace mechanism supported by the NXMC module. Data trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the IEEE-ISTO 5001-2012 standard.

56.7.1.1 Data trace messaging (DTM)

NXMC data trace messaging is accomplished by snooping the system bus and storing the information for qualifying accesses (based on enabled features and matching target addresses). The NXMC module traces all data access that meet the selected range and attributes.

56.7.1.2 DTM message formats

The NXMC block supports five types of DTM messages:

- Data write
- Data read
- Data write synchronization
- Data read synchronization
- Error messages

56.7.1.2.1 Data write and data read messages

The data write and data read messages contain the data write/read value and the address of the write/read access, relative to the previous data trace message. The DATA field is considered fixed based on the DSZ encodings to either 8, 16, 32 , 64. The TSTAMP field is 26 bits. Data write message and data read message information is messaged out in the format shown in the following figure. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

Table 56-17. DTM message format for DATA width = 64 bits

8/16/32/64 bits	1–32 bits	3 bits	4 bits	4 bits	6 bits
DATA	U-ADDR	DSZ	MASTER	SRC	TCODE (111010 or 111011)

TSTAMP is another optional field which is inserted based on the controls received from the NPC, see Timestamping feature.

56.7.1.2.2 Data trace with non-contiguous byte strobes asserted

The v6 extensions to AMBA 2.0 allow system bus transfers with bytes non-asserted byte strobes in between asserted byte strobes. The NXMC does not support transfers with non-contiguous byte strobes asserted. In such a condition, the invalid bytes in the DATA packet are driven to the value of 0xFF.

56.7.1.2.3 DTM overflow error messages

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards incoming messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a data trace message attempts to enter the queue while it is being emptied, the error message incorporates the data trace only error encoding (ECODE = 00000000000010). If a watchpoint also attempts to be queued while the FIFO is being emptied, then the error message incorporates error encoding (ECODE = 00000000000011).

Error information is messaged out in the format shown in this figure. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

Table 56-18. DTM error message format (fixed length = 28 bits)

14 bits	4 bits	4 bits	6 bits
ECODE	ETYPE	SRC	TCODE (001000)

NOTE

The internal queue FIFO is very small. This causes FIFO overflows whenever Trace is enabled on any of the AHB clients and the AHB master module generates >4 burst accesses. If the customer is experiencing a lot of overflow error messages the amount of data snooped by the NXMC should be reduced.

56.7.1.2.4 Data trace synchronization messages

A data trace write/read with synchronization message is messaged via the auxiliary port (provided data trace is enabled) for the following conditions (see Table 56-20):

- Initial data trace message upon exit from system reset or whenever data trace is enabled is a synchronization message.
- Upon returning from a low power state, the first data trace message is a synchronization message.
- Upon returning from debug mode, the first data trace message is a synchronization message.
- After occurrence of queue overrun (can be caused by any trace message), the first data trace message is a synchronization message.
- After the periodic data trace counter has expired indicating 255 without-sync data trace messages have occurred since the last with-sync message occurred.
- Upon assertion of the event in (EVTI) pin, the first data trace message is a synchronization message if the EIC bits of the DC Register have enabled this feature.
- Upon data trace write/read after the previous DTM Message was lost due to a collision while entering the FIFO between the DTM message and any of the following: error message, or watchpoint message or peripheral message. This is a very rare occurrence and possible only in case of continuous burst on the system bus as well as watchpoint events which is unrealistic.

Data trace synchronization messages provide the full address (without leading zeros) and ensure that development tools fully synchronize with data trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write/read with synchronization messages is shown in the following figure. The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

Table 56-19. Data write/read with synchronization message format

8-64 bits	1–32 bits	3 bits	4 bits	4 bits	6 bits
DATA	F-ADDR	DSZ	MASTER	SRC	TCODE (111100 or 111101)

Exception conditions that result in data trace synchronization are summarized in this table.

Table 56-20. Data trace exception summary

Exception condition	Exception handling
System Reset Negation	At the negation of JTAG reset ($\overline{\text{TRST}}$), queue pointers, counters, state machines, and registers within the NXMC module are reset. If data trace is enabled, the first data trace message is a data write/read with synchronization message.
Data Trace Enabled	The first data trace message (after data trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a low power mode or debug mode the next data trace message is converted to a data write/read with synchronization message.
Queue Overrun	An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue is a data write/read with synchronization message.
Periodic Data Trace Synchronization	A forced synchronization occurs periodically after 255 data trace messages have been queued. A data write/read with synchronization message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, an $\overline{\text{EVTI}}$ assertion initiates a data write/read with synchronization message upon the next data write/read (if data trace is enabled and the EIC bits of the DC Register have enabled this feature).
Collision Priority	All messages have the following priority: Error > WPM > DTM. Although a very rare occurrence, during simultaneous burst lower priority messages can be lost due to burst of high priority messages. Proper error messages are generated and in case of DTM lost a subsequent read/write queues a data write/read with synchronization message.

56.7.1.3 Enabling data trace messaging operation

Data trace messaging can be enabled in one of three ways:

- Setting the TM field of the DC Register via JTAG to enable data trace (DC[1]).

- Using the DTS field of the WT Register to enable data trace on watchpoint hits (either watchpoints configured within the NXMC module or external watchpoint inputs controlled by the device).
- By toggling the external start control, which in turn sets the TM field of the DC register to enable data trace. (The TM bit clears and hence the data tracing stops on the toggle of external stop control. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note

When enabling the DTM, either via JTAG or external start/stop control, it is important to make sure that all the other controls (i.e. DTC, DTSA/E1/2 and WT register fields) are correctly configured to ensure correct DTM functionality.

56.7.1.4 DTM queueing

The NXMC implements a programmable depth queue for queuing all messages. Messages that enter the queue are transmitted via the auxiliary pins in the order in which they are queued.

Note

If multiple trace messages need to be queued at the same time, watchpoint messages have the highest priority (WPM > DTM).

56.7.1.5 Relative addressing

The relative address feature is compliant with IEEE-ISTO 5001-2012 and is designed to reduce the number of bits transmitted for addresses of data trace messages. The address transmitted is relative to the address of the previous data trace message. It is generated by XORing the new address with the previous address, and then using only the results up to the most significant 1 in the result. To recreate this address, an XOR of the (most-significant 0-padded) message address with the previously decoded address gives the current address.

For example, if the previous address (A1) = 0x0003FC01, the new address (A2) = 0x0003F365 as shown in this figure.

Message Generation:

A1 = 0000 0000 0000 0011 1111 1100 0000 0001
A2 = 0000 0000 0000 0011 1111 0011 0110 0101

A1 ⊕ A2 = 0000 0000 0000 0000 0000 1111 0110 0100

Address Message (M1) = 1111 0110 0100

Address Re-creation:

A1 ⊕ M1 = A2
A1 = 0000 0000 0000 0011 1111 1100 0000 0001
M1 = 0000 0000 0000 0000 0000 1111 0110 0100

A2 = 0000 0000 0000 0011 1111 0011 0110 0101

Figure 56-2. Relative addressing example

56.7.1.6 Data trace windowing

Data write/read messages are enabled via the RWT1(2) field in the Data Trace Control Register (DTC) for each DTM channel. Data trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC1(2) field in the DTC. All system bus DMA initiated read/write accesses which fall inside or outside these address ranges, as programmed, are candidates to be traced.

56.7.1.7 System bus cycle special cases

The system bus cycle special cases are shown in this table.

Table 56-21. System Bus cycle special cases

Special case	Action
System bus cycle with data error	Data trace message discarded
System bus cycle completed without error	Cycle captured and transmitted
System bus cycle is an instruction fetch	Cycle ignored

56.7.1.8 System bus multi-master tracing

DTM tracing can be done either for all the masters or for a single master (indicated by the MID field of the DTC register) based on the DTC register MME field. In case of single master, the correct value needs to be configured in the MID register before enabling the data trace operation.

The MASTER field of the DTM message (see figure in Data write and data read messages for an example) indicates the system bus master for which the trace has been generated. For each masters (0 to 15) there is a parameter associated (MSID0-15) for indicating its actual ID, which finally gets inserted in the MASTER field. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

56.7.1.9 HSM master filtering

For security reasons, certain HSM masters need to be disabled or filtered from data tracing operations.

56.7.2 Watchpoint support

The NXMC module provides watchpoint messaging via the auxiliary pins, as defined by IEEE-ISTO 5001-2012. Watchpoint messages can be generated by either using the NXMC defined internal watchpoints or by externally defined watchpoint signals.

56.7.2.1 Watchpoint messaging

Enabling watchpoint messaging is accomplished by setting the WEN bit in the DC Register. This bit is set either via JTAG write 1 access or external start indication, and cleared via JTAG write 0 access or external start indication. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note

In case of enabling the watchpoint messaging, either via JTAG or external start/stop control, it is important to make sure that all the other Watch Point Message (WPM) controls (i.e. BWC1/2, BWA1/2 register fields) are configured with the correct values in order to ensure correct WPM operation.

Watchpoint setting is supported through two methods:

- Internal watchpoints—Using the BWC1(2) registers, two independently controlled internal watchpoints can be initialized. When a system bus access address matches on BWA1(2), a watchpoint message is transmitted. The system bus multi-master or single master controls applies here too as explained for DTM (in System bus multi-master tracing).
- External watchpoints—The NXMC module supports two external watchpoint inputs. The optional logic to generate these watchpoint signals is implemented at the device level. The watchpoints are described in the device-specific chapter that describes how the modules are configured. If either of these signals asserts (i.e, on 0-to-1 transition), a watchpoint message is transmitted.

The Nexus module provides watchpoint messaging using the IEEE-ISTO 5001 defined TCODE. When any of the four possible watchpoint sources asserts, a message is sent to the queue to be messaged out. This message indicates the watchpoint number as shown in Table 56-22 and Table 56-23.

Table 56-22. Watchpoint message format (fixed length = 18 bits)

8 bits	4 bits	6 bits
WPHIT (RRRRXXXX)	SRC	TCODE (001111)

Table 56-23. Watchpoint source description

Watchpoint source (8-bits)	Watchpoint description
RRRRXXX1[1]	External Watchpoint #1(device defined)
RRRRXX1X	External Watchpoint #2 (device defined)
RRRRX1XX	Internal Watchpoint #1 (BWA1 match)
RRRR1XXX	Internal Watchpoint #2 (BWA2 match)

1. R = reserved for future use (insert 0s).

56.7.2.2 Watchpoint error message

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a watchpoint message attempts to enter the queue while it is being emptied, the error message incorporates the watchpoint only error encoding (ECODE = 00000000000001). If a data trace message also attempts to enter the queue while it is being emptied, the error message incorporates error encoding (00000000000011). Error information is messaged out in the format shown in this figure.

Table 56-24. Error message format (fixed length = 28 bits)

14 bits	4 bits	4 bits	6 bits
ECODE	ETYPE	SRC	TCODE (001000)

56.7.3 Timestamping feature

This feature allows a timestamp packet to be appended to all messages, based on the timer value and controls received externally from the NPC. If enabled, this packet is added as the last field to all the outgoing messages. The TSTAMP packet width is 26 bits.

The TSTAMP packet is appended at the end of a message during message formatting, before transfer. This figure shows an example of ICTM message with a TSTAMP field.

Table 56-25. Message with TSTAMP field example

26 bits	1–44 bits	6 bits	4 bits	6 bits
TSTAMP	CKDATAn	CKSRCn	SRC	TCODE (100010)

The enable or disable indication should remain static for the complete debug session. Dynamically enabling or disabling of the timestamping is not allowed during running debug tracing. The following steps allow seamless enabling/disabling of the timestamping:

1. All tracing (DTM/WPM/ICTM) must be disabled
2. Wait for the internal queues to be emptied (no further request is asserted at the auxiliary interface)
3. Change the timestamp enable indication to assert/deassert
4. Enable the required tracing controls (via TM, PME0 etc. control bits)

Chapter 57
JTAG Controller (JTAGC)

57.1 Chip-specific JTAG information

57.1.1 JTAG Controller (JTAGC) configuration

The device contains one JTAGC module. The JTAGC is the Nexus1 interface between the debugger tool and other Nexus1 clients on the device. The JTAGC implements a number of instructions to enable debugger access to those other clients, as described in the following sections.

The JTAGC CONTROL1 register is used to control timestamping and select which PRAM AHB transactions are monitored, as described below.

57.1.2 JTAGC Control 1 register

The JTAGC Control 1 register is a 32-bit shift register path from TDI to TDO selected when the ENABLE_CONTROL1 instruction is active. The default reset value of the JTAGC Control 1 register is 0. The Control 1 register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state.

TMZ2	Timestamp Mode for Z2 core. Defines Timestamping granularity. 00 Add timestamp to every message 01 Add timestamp to every 4th message 10 Add timestamp to every 16th message 11 Add timestamp to every 64th message
TEZ2	Z2 core Timestamp Enable. 0 Timestamping is disabled 1 Timestamping is enabled
TMZ4	Timestamp Mode for Z4 core. Defines Timestamping granularity. 00 Add timestamp to every message 01 Add timestamp to every 4th message 10 Add timestamp to every 16th message 11 Add timestamp to every 64th message
TEZ4	Z4 core Timestamp Enable. 0 Timestamping is disabled 1 Timestamping is enabled
SNOOP	Used to select the pram AHB bus for snooping. 00 No snooping (Default) 01 Snooping of PRAM0 AHB transactions 10 Snooping of PRAM1 AHB transactions 11 No snooping (Default)

57.2 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

57.2.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. Refer to the chip-specific configuration information as well as Register description for more information about the JTAGC registers.

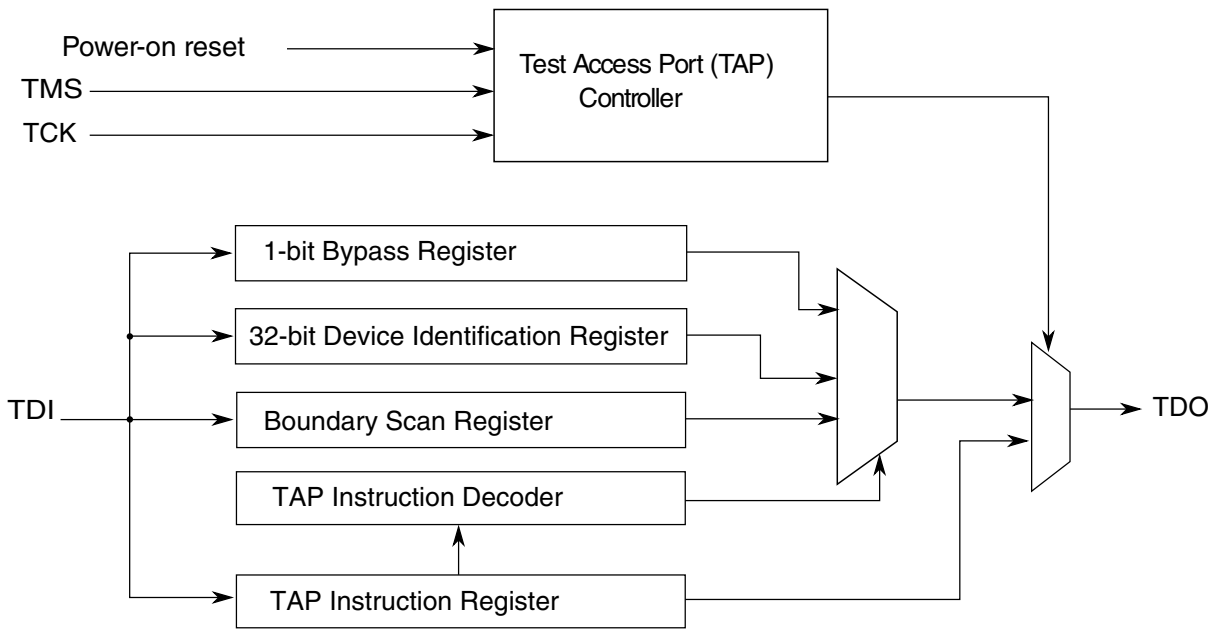

Figure 57-1. JTAG (IEEE 1149.1) block diagram

57.2.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to Table 57-5 for a list of supported instructions.
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- JTAG_PASSWORD register
- Control 1 register

- Bypass register, boundary scan register, data registers, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

57.2.3 Modes of operation

The JTAGC block uses a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

57.2.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered
- The instruction register is loaded with the IDCODE instruction

57.2.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in JTAGC block instructions.

57.2.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

57.3 External signal description

The JTAGC consists of a set of signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 57-2. JTAG signal properties

Name	I/O	Function	Reset State
TCK	Input	Test Clock	Weak pullup
TDI	Input	Test Data In	Weak pullup
TDO	Output	Test Data Out	High Z[1]
TMS	Input	Test Mode Select	Weak pullup

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

57.3.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

57.3.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

57.3.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in TAP controller state machine.

57.3.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

57.4 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

57.4.1 Instruction register

The JTAGC block uses a 6-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 000001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	5	4	3	2	1	0
R	0	0	0	0	0	1
W	Instruction Code					
Reset:	0	0	0	0	0	1

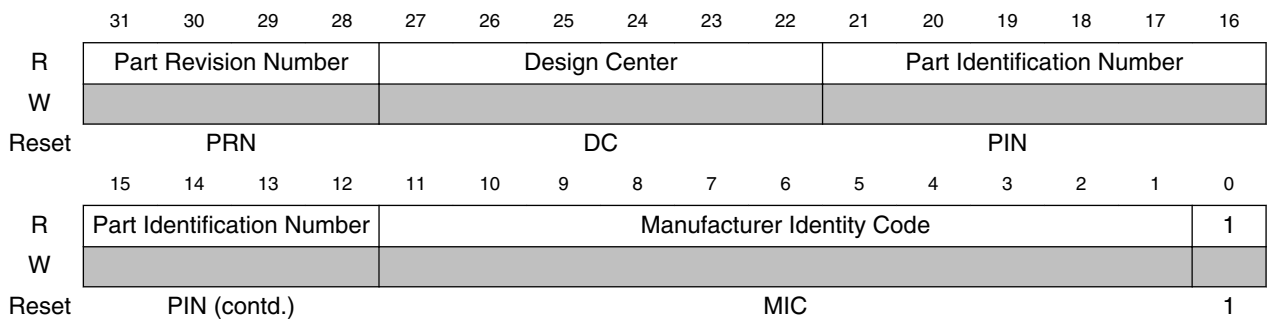

Figure 57-2. Instruction register

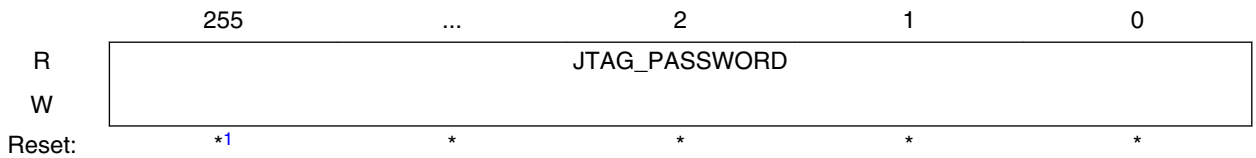
57.4.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

57.4.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.



The following table describes the device identification register functions.

Table 57-3. Device identification register field descriptions

Field	Description
PRN	Part Revision Number. Contains the revision number of the part. Value is 0x1.
DC	Design Center. Indicates the design center. Value is 0x26.
PIN	Part Identification Number. Contains the part number of the device. 0x84.
MIC	Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID. Value is 0x00E.
IDCODE ID	IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1.

57.4.4 JTAG_PASSWORD register

The JTAG_PASSWORD register is a 256-bit shift register path from TDI to TDO selected when the ENABLE_JTAG_PASSWORD instruction is active. The default reset value of the JTAG_PASSWORD register is 256'b0. The JTAG_PASSWORD register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state. Once the ENABLE_JTAG_PASSWORD instruction is executed, the register value remains valid until a JTAG reset occurs. The operation of this register is described in the security documentation.

1. The reset value of JTAG_PASSWORD is 256 'b0.

The following table describes the JTAG_PASSWORD register functions.

Table 57-4. JTAG_PASSWORD register field descriptions

Field	Description
JTAG_PASSWORD	JTAG Password. The JTAG_PASSWORD bits are used to provide the JTAG password for security.

57.4.5 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in Boundary scan. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

57.5 Functional description

This section explains the JTAGC functional description.

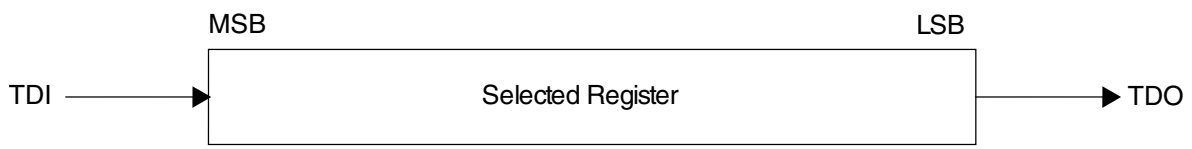
57.5.1 JTAGC reset configuration

While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

57.5.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to ACCESS_AUX_x instructions.

Data is shifted between TDI and TDO though the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.



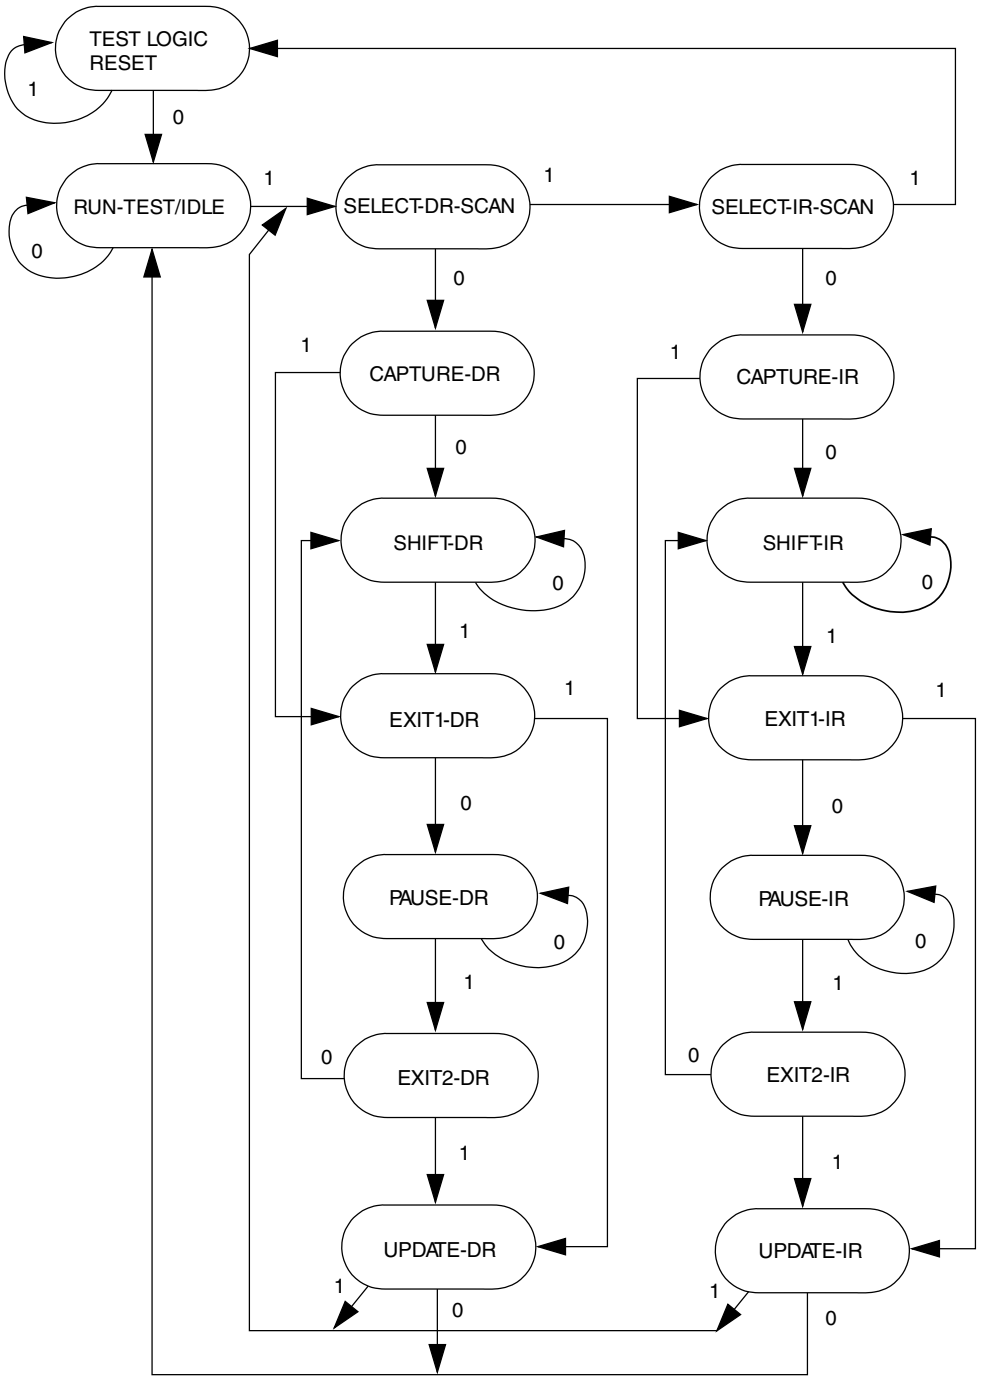


Figure 57-3. Shifting data through a register

57.5.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 57-4. IEEE 1149.1-2001 TAP controller finite state machine

57.5.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting the JTAGC enable to a logic 1 value.

57.5.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

57.5.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 57-5. General 6-bit JTAG instructions

Instruction	Code[5:0]	Instruction Summary
IDCODE	000001	Selects device identification register for shift
SAMPLE/PRELOAD	000010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	000011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	000100	Selects boundary scan register and applies preloaded values to output pins. **NOTE:** Execution of this instruction asserts functional reset.
Factory debug reserved	000101	Intended for factory debug only
Factory debug reserved	000110	Intended for factory debug only
ENABLE_JTAG_PASSWORD	000111	Selects JTAG_PASSWORD register
HIGHZ	001001	Selects bypass register and three-states all output pins. **NOTE:** Execution of this instruction asserts functional reset.
Factory debug reserved	001010	Intended for factory debug only
CLAMP	001100	Selects bypass register and applies preloaded values to output pins. **NOTE:** Execution of this instruction asserts functional reset.

Table continues on the next page...

Table 57-5. General 6-bit JTAG instructions (continued)

Instruction	Code[5:0]	Instruction Summary
ENABLE_CONTROL1	001110	Enables access to Control 1 register
Reserved	001111	Reserved
BYPASS	111111	Selects bypass register for data operations
Reserved[1]	All other opcodes	Decoded to select bypass register
ACCESS_AUX_x	100000-111110	Grants one of the auxiliary TAP controllers ownership of the TAP

1. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

The ACCESS_AUX instructions are described in the chip configuration debug information.

57.5.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

57.5.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- The SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

57.5.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

57.5.4.4 EXTEST External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

57.5.4.5 ENABLE_JTAG_PASSWORD instruction

The ENABLE_JTAG_PASSWORD instruction selects the JTAG_PASSWORD register for connection as the shift path between TDI and TDO.

57.5.4.6 ENABLE_CONTROL1 instruction

The ENABLE_CONTROL1 instruction selects the Control 1 register for connection as the shift path between TDI and TDO.

57.5.4.7 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (e.g., high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

57.5.4.8 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

57.5.4.9 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers. When this instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

57.5.4.10 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

57.5.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

57.6 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Place the JTAGC in reset through TAP controller state machine transitions controlled by TMS
2. Load the appropriate instruction for the test or action to be performed

Chapter 58
JTAG Data Communication (JDC)

58.1 Introduction

The JTAG Data Communication (JDC) module provides the capability to move register data between the IPS and JTAG domains. This facilitates communication between internal resources that access memory mapped register space and an external tool that accesses the JTAG port.

58.2 Overview

The JDC module consists of IPS accessible registers, JTAG accessible registers, and associated logic to coordinate movement of data from one register domain to another.

The JDC implements the following IPS data registers, occupying separate memory space:

- 32-bit memory mapped register that can be read or written via IPS (JOUT_IPS), and whose contents are ported out for capture into a JTAG register (JOUT) to be read via the JTAG port.
- 32-bit memory mapped register that can only be read via IPS (JIN_IPS), and whose contents are loaded from a JTAG register (JIN).

In addition to the data registers themselves, logic is implemented to indicate when new data has been shifted in via the JTAG port and is ready to be read from the JIN_IPS register, and when new data has been written to the JOUT_IPS register and is ready to be read via the JTAG port. The state of these flags is captured into a status register (MSR), and also provided to a JTAG register (JOUT) for tool visibility.

There is a single bus interface to port register data out to the JTAGC, and a single bus interface to port data in from the JTAGC. The architecture is shown in the following figure.

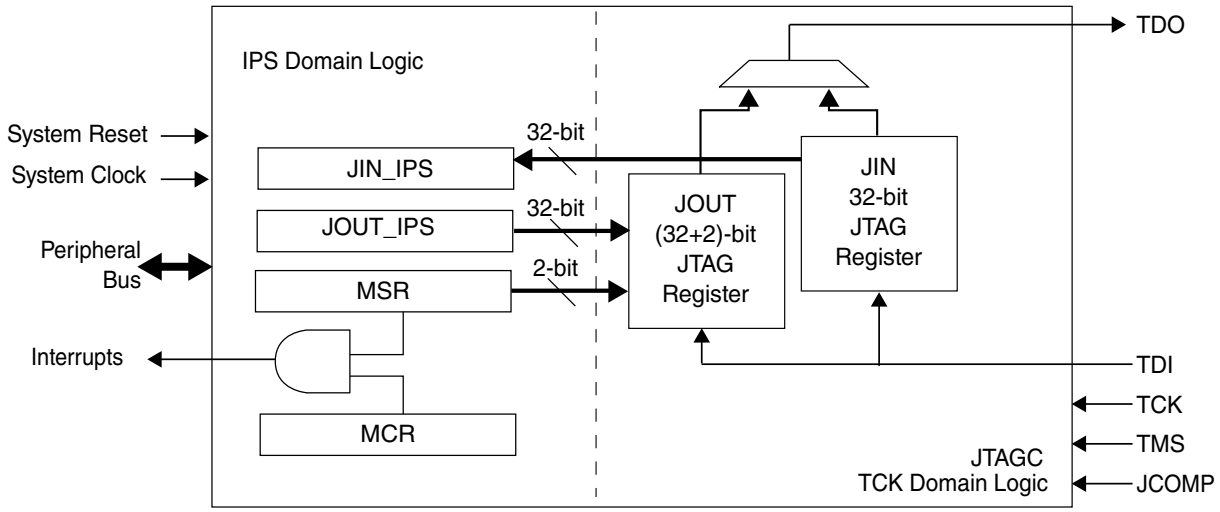

Figure 58-1. JDC block diagram

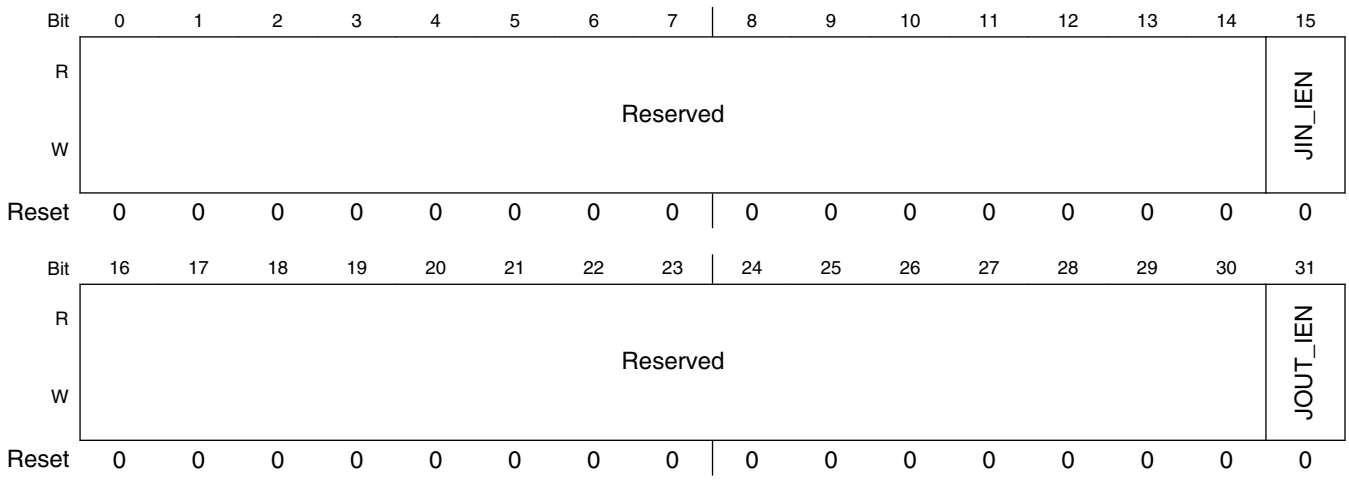
58.3 Memory mapped registers

Four 32-bit registers are implemented. Only 32-bit accesses are valid. The effects of access that are not 32 bits are not defined.



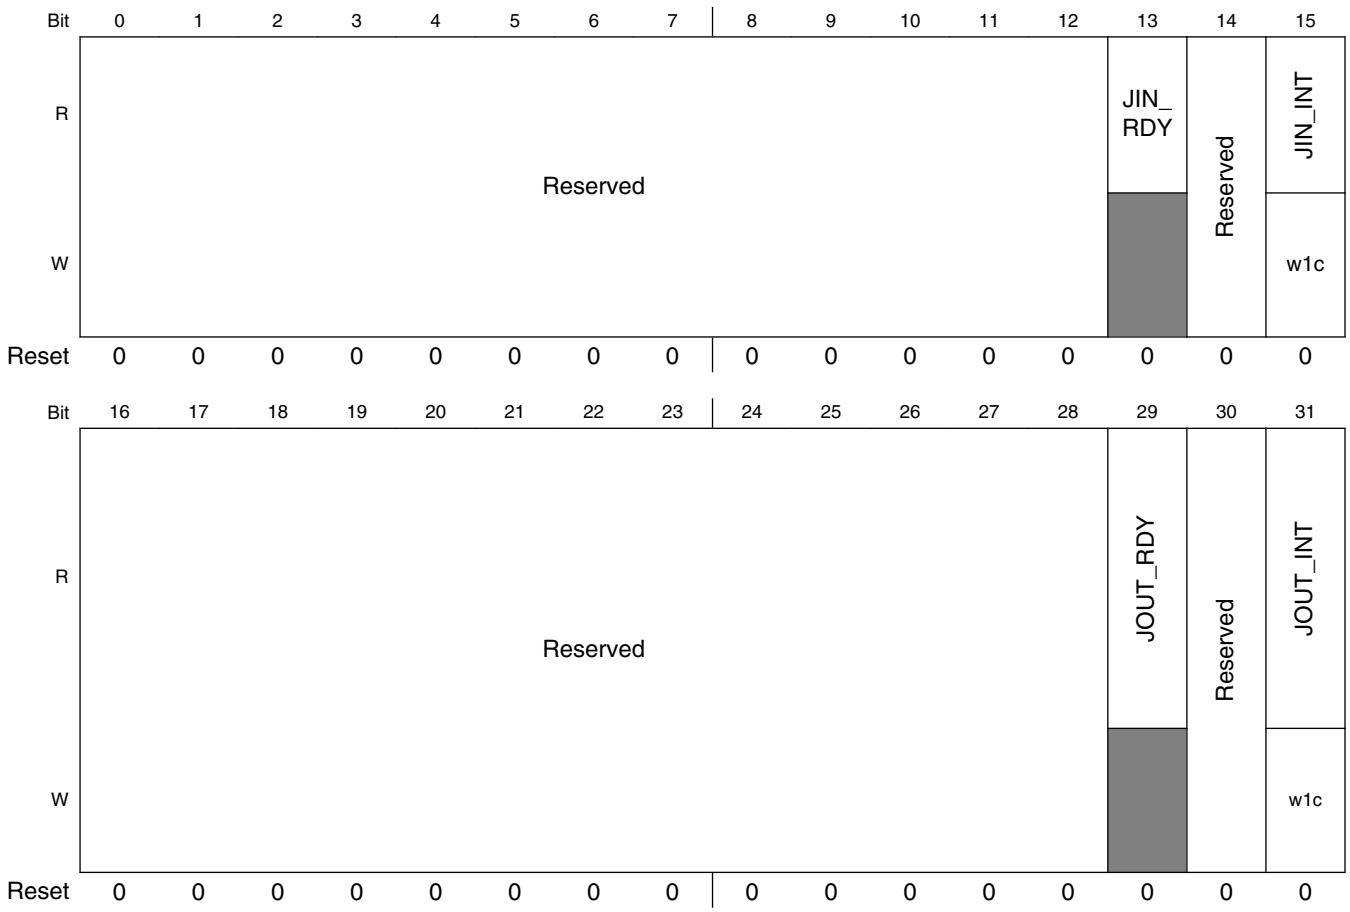
JDC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Module Configuration Register (JDC_MCR)	32	R/W	0000_0000h	58.3.1/2307
4	Module Status Register (JDC_MSR)	32	R/W	0000_0000h	58.3.2/2308
8	JTAG Output Data Register (JDC_JOUT_IPS)	32	R/W	0000_0000h	58.3.3/2309
C	JTAG Input Data Register (JDC_JIN_IPS)	32	R	0000_0000h	58.3.4/2310

58.3.1 Module Configuration Register (JDC_MCR)

The MCR is used to enable the interrupt outputs of the JDC. This register is reset by system destructive reset.

Address: 0h base + 0h offset = 0h



JDC_MCR field descriptions

Field	Description
0–14 Reserved	This field is reserved.
15 JIN_IEN	JIN Interrupt Enable. 0 Setting of MSR[JIN_INT] bit does not assert the JIN interrupt 1 Setting of MSR[JIN_INT] bit asserts the JIN interrupt
16–30 Reserved	This field is reserved.
31 JOUT_IEN	JOUT Interrupt Enable. 0 Setting of MSR[JOUT_INT] bit does not assert the JOUT interrupt 1 Setting of MSR[JOUT_INT] bit asserts the JOUT interrupt

58.3.2 Module Status Register (JDC_MSR)

The MSR holds the JTAG register status and interrupt bits. This register is reset by system destructive reset.

Address: 0h base + 4h offset = 4h

JDC_MSR field descriptions

Field	Description
0–12 Reserved	This field is reserved.
13 JIN_RDY	JIN Ready (read only). 0 Cleared upon software read of JIN_IPS contents via IPS 1 Set when new data is written to the JIN_IPS register
14 Reserved	This field is reserved.
15 JIN_INT	JIN Interrupt.

Table continues on the next page...

JDC_MSR field descriptions (continued)

Field	Description
	0 Cleared by writing logic 1 1 Set when new data is written to the JIN_IPS register
16–28 Reserved	This field is reserved.
29 JOUT_RDY	JOUT Ready (read only). 0 Cleared upon tool read of JOUT register via JTAG port 1 Set when new data is written to the JOUT_IPS register
30 Reserved	This field is reserved.
31 JOUT_INT	JOUT Interrupt. 0 Cleared by writing logic 1 1 Set when JOUT_RDY bit is cleared by tool reading JOUT register

58.3.3 JTAG Output Data Register (JDC_JOUT_IPS)

The JOUT_IPS register holds data written via IPS. The JOUT_IPS contents are ported out and captured into the JOUT register to be read via the JTAG port. This register is reset by system destructive reset.

Address: 0h base + 8h offset = 8h

JDC_JIN_IPS field descriptions

Field	Description
0–31 Data	JIN_IPS data.

58.4 Non-Memory mapped register definition

The JDC also implements two JTAG accessible registers that are not memory mapped. One JTAG register is used to shift in data to be placed in the JIN_IPS register. The other JTAG register captures data from the JOUT_IPS register and ready status from the MSR to be shifted out via the JTAG port.

58.4.1 JTAG output data register (JOUT)

The JOUT register captures data from the JOUT_IPS register upon execution of the JOUT_READ JTAG instruction. It also holds the JIN_RDY and JOUT_RDY status bits. This register is reset by system destructive reset and JTAG reset. The following figure shows the format of the JOUT register.

	33	…	2	1	0
R W	JOUT_IPS Data			JIN_RDY	JOUT_RDY
Reset	*[1]	*	*	*	*

1. The reset value of the JOUT register is 34'b0.

The JOUT register is described in the following table.

Table 58-1. JOUT JTAG register field descriptions

Field	Description
JOUT_IPS Data	Data value from JOUT_IPS register
JIN_RDY	State of JIN_RDY bit from MSR
JOUT_RDY	State of JOUT_RDY bit from MSR

58.4.2 JTAG input data register (JIN)

Data is written to the JIN register via JTAG during execution of the JIN_WRITE JTAG instruction. The JIN data is later captured in the JIN_IPS register to be read via IPS. This register is reset by system destructive reset and JTAG reset. The following figure shows the format of the JIN register.

	31	…	0
R W	JIN Data		
Reset	*[1]	*	*

1. The reset value of the JIN register is 32'b0.

The JIN register is described in the following table.

Table 58-2. JIN JTAG register field descriptions

Field	Description
JIN Data	Contains data to be captured in JIN_IPS register upon exit of Update-DR state when executing WRITE_JIN JTAG instruction.

58.5 Functional description

The JDC module provides the ability to shift in data via the JTAG port and capture that data into a memory mapped register that can be accessed via IPS. It also provides the ability to capture data written to a memory mapped register into a JTAG shift register for output via the JTAG port. An overview of the module functionality is described below.

- A software write to the JOUT_IPS register sets the JOUT_RDY flag bit, indicating new data is available to be read from the JOUT register via the JTAG port. The state of the JOUT_RDY bit is reflected in the MSR and also ported out to the JOUT register. A JTAG read of the JOUT register via execution of the JOUT_READ

instruction with a JOUT_RDY bit whose value is logic 1 indicates the register contains new data. The JOUT_RDY flag bit is cleared upon exit of the Capture-DR JTAG state during execution of the JOUT_READ instruction. Clearing the JOUT_RDY bit indicates to software that a new data value can be written to the JOUT_IPS register.

- A JTAG write to the JIN register via execution of the JIN_READ JTAG instruction updates the contents of the JIN_IPS register upon exit of the Update-DR state. An update of the JIN_IPS register sets the JIN_RDY flag bit, indicating new data is available to be read via IPS. The state of the JIN_RDY bit is reflected in the MSR register and also ported out to the JOUT register. The JIN_RDY flag bit is cleared upon software read of the JIN_IPS register. A JTAG read of the JOUT register with a JIN_RDY value of logic 0 indicates new data can be written to the JIN register.

58.5.1 JTAG register access

Refer to the JTAGC documentation for information on how to access the JTAG registers.

58.5.1.1 JDC block instructions

The JDC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 58-3. JTAG instructions

Instruction	Code[4:0]	Instruction Summary
Reserved	00001	Factory debug reserved
JOUT_READ	00010	Selects JOUT data register. Data from JOUT_IPS is captured into JOUT data register upon entry to Capture-DR state while JOUT_READ is active.
JIN_WRITE	01110	Selects JIN data register. Data from JIN is captured into JIN_IPS upon exit of Update-DR state while JIN_WRITE is active.
BYPASS	11111	Selects bypass register for data operations
Reserved	All other opcodes	Decoded to select bypass register

58.6 Use case example

A summary of how the JDC can be used to interact with the Hardware Security Module (HSM) to perform challenge/response password authorization is as follows:

1. After exit of reset, all registers are at their reset values. JIN_RDY bit value of 0 indicates the tool may write data to the JIN register. JOUT_RDY bit value of 0 indicates that software may write data to the JOUT_IPS register.
2. The MCR register is programmed to enable JOUT and JIN interrupts, or not.
3. Once the tool is ready to start the authorization process, it writes a value to the JIN register via execution of the JTAGC JIN_WRITE instruction.
4. Software monitors the state of the JIN_RDY bit or enables the JIN interrupt and uses the interrupt assertion as a trigger to start the authorization process.
5. Check if a Flash program/erase operation is in progress. If a Flash program/erase operation is in progress, wait for it to complete.
6. Once the authorization process is started, software writes the first JOUT value to the JOUT_IPS register. This sets the JOUT_RDY bit value to 1.
7. Following the initial tool write to the JIN register, the tool polls the JOUT register to determine when software has provided a challenge word. Upon reading the JOUT register with JOUT_RDY bit set, the tool records the data value to be used to generate the appropriate response. The read of the JOUT register clears the JOUT_RDY bit. The clearing of the JOUT_RDY bit also sets the JOUT_INT bit and asserts the JOUT interrupt if the MCR[JOUT_IEN] is set.
8. With the JOUT_RDY bit cleared, software may now provide the next challenge word.
9. Once the tool has generated a response word, it uses the value of the JIN_RDY bit from the JOUT register read to determine when it can perform a write to the JIN register to provide the response.
10. The HSM can provide additional challenge words and read back the corresponding response words as needed, repeating the process.

Simply providing a password without using the challenge/response protocol can be done in a similar way. The tool provides 32-bits of the password at a time with each write to the JIN register, and monitors the JIN_RDY bit value of the JOUT register to determine when the next JIN register value can be written. There is no need for software to write the JOUT_IPS register in this case.

59.3 Introduction

The CJTAG module implements parts of the IEEE 1149.7 standard for test and debug capabilities. IEEE 1149.7 defines enhanced test and debug capabilities which are backwards compatible with IEEE P1149.1. This standard is also known as "Compact JTAG" or "CJTAG".

The module implements the following parts of the IEEE 1149.7 standard:

- IEEE 1149.1 compliant behavior while allowing multiple on-chip TAP controllers
- Ability to assert test reset
- Improved system scan performance with one-bit IR and DR chip bypass paths

- Physical connection of a Debug and Test System (external tool) to a running system without corrupting its operation
- Operation with both 4-pin and 2-pin scan topologies

59.3.1 Types of operation

The 1149.7 standard provides a scalable and flexible solution to meet the needs of varied component and system complexities. There are three types of operation:

- **Compliant**
  - Compliant with the IEEE 1149.1 standard
  - Four-pin operation using the "Standard Protocol" — IEEE 1149.1 signaling where TCK, TMS, TDI and TDO signals transfer control/data information
  - More than one TAPC may be associated with the TAP (once made visible by private instructions)
- **Extended**
  - Compatible with the IEEE 1149.1 standard
  - Four-pin operation using the "Standard Protocol" — IEEE 1149.1 signaling where TCK, TMS, TDI(C) and TDO(C) signals transfer control/data information
  - Additional test/debug functions
- **Advanced**
  - Two-pin operation using the "Advanced Protocol" — signaling where TCK(C) and TMS(C) signals transfer control/data information
  - The TMS(C) signal is operated in a bidirectional manner with the TMS, TDI and TDO TAP information serialized and transferred via this signal

59.3.2 Deployment by class

The TAP.7 capabilities are deployed using five capability classes (T0–T4), each matching the needs of certain scan topologies and mixes of 1149.1 TAPs and 1149.7 TAPs. The classes provide the following capability:

- **Compliant Operation** – provides behavior compliant with the IEEE 1149.1-2001 standard:
  - **Class T0** – 1149.1 compliance when multiple TAPs are used on the same chip.
- **Extended Operation** – extends the capabilities of the IEEE 1149.1-2001 standard:
  - **Class T1** – T0 + Test access port power management, functional reset, and test reset.
  - **Class T2** – T1 + Chip bypass (1-bit) for IR/DR Scans + hot-connection with no errors..
  - **Class T3** – T2 + Star operation (TAPs are paralleled) with series equivalent scans for test.
- **Advanced Operation** – adds capabilities addressing test and debug needs in complex environments:
  - **Class T4** – T3 + Scan with two pins with the Advanced Protocol. A number of protocol optimizations maximize scan performance. TDI(C)/TDO(C) pins are optional and may have programmable function when implemented.

59.3.3 1149.7 TAP signals

The TAP signals for the T0–T4 TAP.7 classes are listed in the following table. Signal names that end in “C” are associated with expanded functionality (beyond the functionality provided by the IEEE 1149.1 standard).

The table uses the following notation:

- M = Mandatory signal
- MC = Mandatory signal with expanded functionality
- O = Optional signal
- OC = Optional signal with expanded functionality

The CJTAG module provides T4 capability and implements the following pins:

- TCKC
- TDIC
- TDOC
- TMSC

Table 59-2. TAP.7 signal list

Signal name	Description	Class				
		T4	T3	T2	T1	T0
TCK/TCKC	Test clock	MC	M	M	M	M
TMS/TMSC	Test mode select	MC	M	M	M	M
TDI/TDIC	Test data input	OC	MC	M	M	M
TDO/TDOC	Test data output	OC	MC	M	M	M
Mandatory signal count (minimum)		2	4	4	4	4

59.3.4 TAP.7 architecture

The TAP.7 hardware architecture is shown in the following figure. It is described with the hardware layers listed below:

- **STL – System Test Logic** – Logic with 1149.1 compliant behavior and underlying TAP hierarchy (T0 capabilities). Provides an IEEE 1149.1 interface for the T0 TAP. 7. This logic is outside the CJTAG module.
- **RSU – Reset and Selection Unit** – A hardware layer that is placed between the APU, EPU, or STL and the TAP.7 signals (Added as an option to support the use of the Control Protocol) Provides reset and TAP.7 Controller selection services.
- **EPU – Extended Protocol Unit** – A hardware layer that is placed between the STL and the TAP.7 signals. (Added for T1, T2, and T3 capabilities). Provides an IEEE 1149.1 interface for the T1–T3 TAP.7s.
- **APU – Advanced Protocol Unit** – A hardware layer that is placed between the STL/EPU and the TAP.7 signals (added for T4 capabilities). Provides a T4 TAP.7 interface that is either narrow or wide, with the wide version providing an IEEE 1149.1 interface.

The CJTAG module supports T4 functionality that includes STL, RSU, EPU, and APU hardware layers.

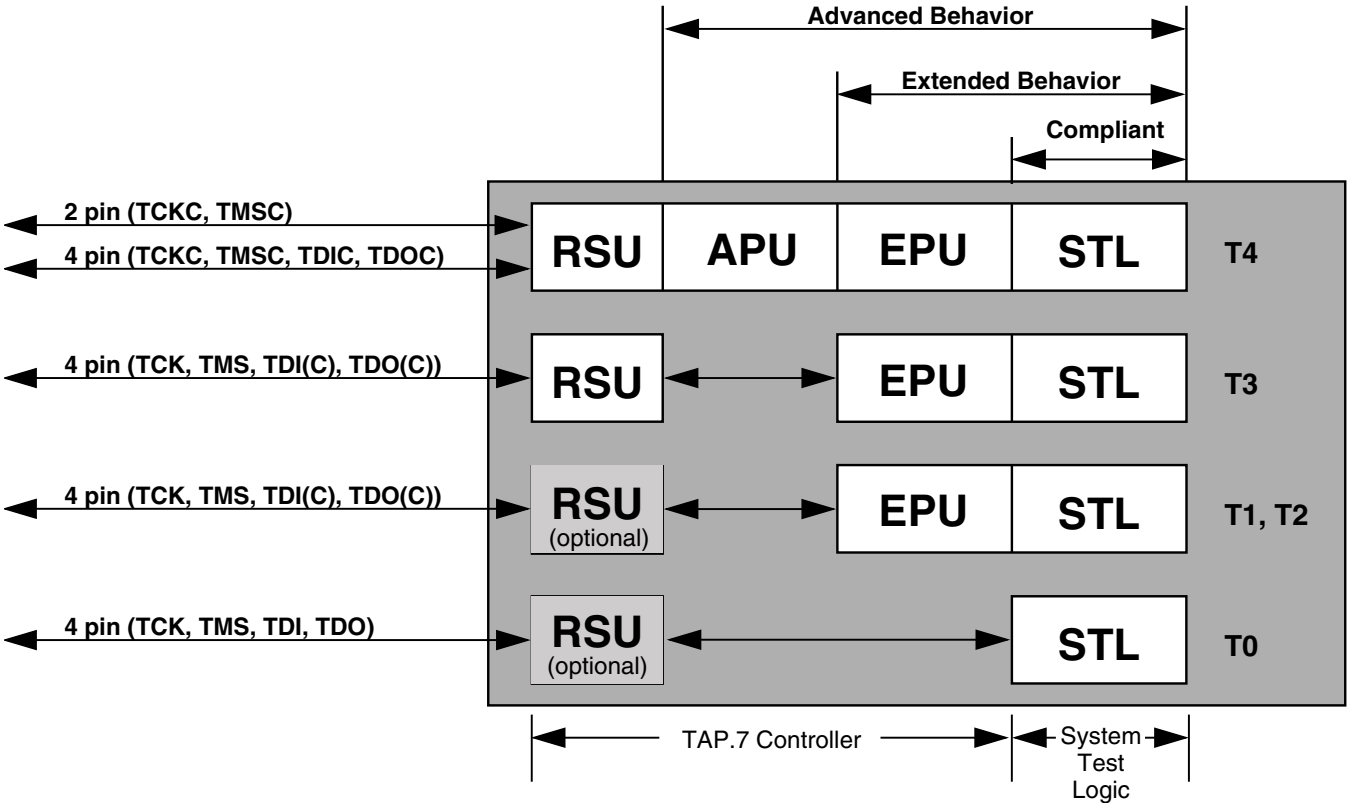

Figure 59-1. TAP.7 Controller Architecture

59.3.5 Protocols

The TAP.7 architecture utilizes the three protocols shown in the following figure.

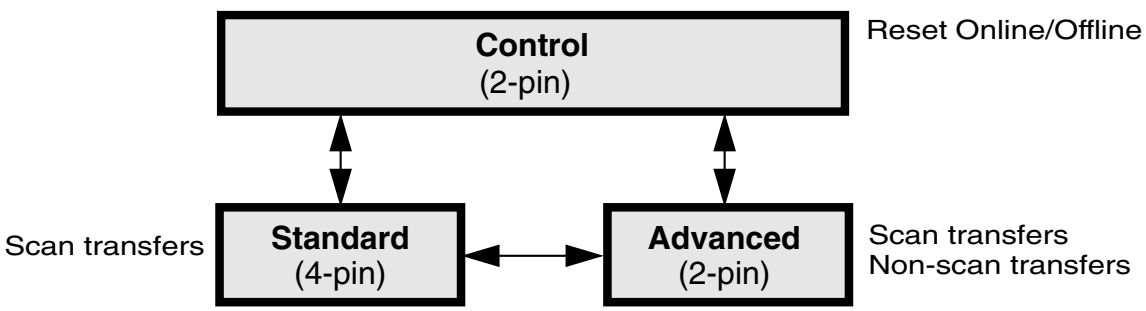

Figure 59-2. TAP.7 Behaviors

The Standard Protocol transfers data with the TMS(C) signal value being sampled with a TCK(C) edge. The Advanced and Control Protocols use both data transferred with the TMS(C) signal value being sampled with a TCK(C) signal edge and escape sequences. The Standard Protocol may be used to switch to the use of the Advanced Protocol and

vice versa. The Control Protocol can also be used to switch between the use of the Standard and the Advanced Protocol. The mandatory and optional deployment of these protocols with the TAP.7 classes is shown in the following table.

Table 59-3. Class/protocol relationship

Class	Protocol		
	Standard	Control	Advanced
T0 – T2	Mandatory	Optional	N/A
T3	Mandatory	Mandatory	N/A
T4	Mandatory	Mandatory	Mandatory

The CJTAG module implements T4 functionality and supports the Standard, Advanced, and Control Protocols.

59.3.5.1 Standard Protocol

The Standard Protocol is the signaling defined by the IEEE 1149.1 standard. This protocol is also used to implement TAP.7 commands using only the TCK(C) and TMS(C) signals in a manner that does not require either TAP.7 controller instruction or data registers. The TAP.7 controller does not add bits to the scan paths of underlying technology. The Standard Protocol can be used to manage the TAP.7 controller functionality independent of the function associated with the availability of the TDI and TDO signals. The Standard Protocol supports STL data transfers only when these signals are present and provide the 1149.1 functionality defined by the IEEE 1149.1 standard.

59.3.5.2 Advanced Protocol

The Advanced Protocol supports both STL data transfers and management of the TAP.7 controller functionality with both the 2-signal (narrow) and 4-signal (wide) configurations. The Advanced Protocol serializes the TMS, TDI, and TDO information used with the Standard Protocol using only the TCK(C) and TMS(C) signals. A number of additional scan formats provide bit sequences optimized for specific use cases. Each of these additional scan formats affects the TMSC signaling sequences.

59.3.5.3 Control Protocol

The Control Protocol uses Escape sequences to reset the TAP.7 controller, place a TAP.7 controller offline or online, and indicate End of Transmission (EOT) with the Advanced Protocol. The characteristics of this protocol provide Hot-Connect-Protection by requiring a preamble of alternating ones and zeroes preceding a selection escape when a TAP controller is started up offline.

59.4 Operating models

The following figure illustrates a simplified view of the CJTAG operating model.

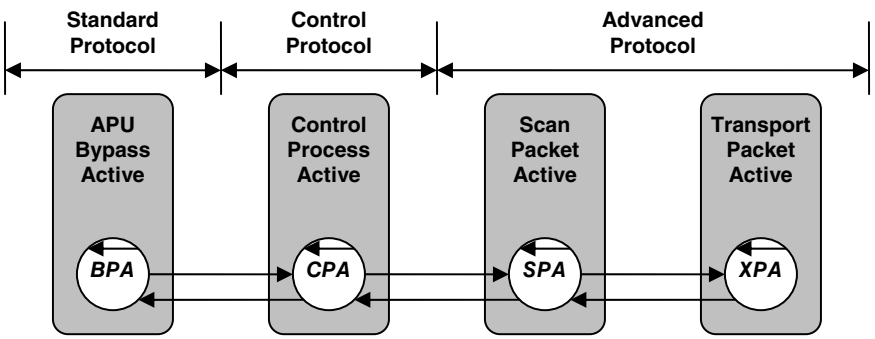

Figure 59-3. CJTAG operating model

59.5 CJTAG implementation summary

The CJTAG module is a T4 TAP.7 controller that implements the following functions.

59.5.1 T0 functions

- IDCODE. - implemented in chip level TAPC (JTAGC module)
- 1149.1 Compliance at start-up
- Isolating / Excluding of embedded TAPs – implemented in chip level TAPC (JTAGC module)
- Operation with other technologies and scan topologies
- Multiple embedded TAPs

59.5.2 T1 functions

- EPU Command processing
- EPU Class-Specific Registers
- Asserting a test reset to the STL (TRESET Register)

59.5.3 T2 functions

- "Super Bypass" function – JScan0, JScan1, JScan2 scan formats. Allows the STL to be coupled or decoupled.

59.5.4 T3 functions

- Generation of a TAP.7 controller reset with a Reset Escape Sequence
- JScan3 Scan Format

59.5.5 T4 functions

- TMSC sampling on rising edge or falling edge of TCKC
- MScan (For test and debug)
- OScan 0-7
- TDIC and TDOC / Alternate pin function multiplexing (wide 4 only)

59.6 Ancillary services

59.6.1 Overview

Ancillary services are pertinent to any TAP.7 controller implemented with an RSU, such as the CJTAG module.

Ancillary services include:

- Resets
- Start-up options

- Escape sequences
- TAPC state machine

59.6.2 Resets

The TAP.7 controller reset function expands the reset function provided by the IEEE 1149.1 standard to provide additional reset types. It supports six reset types, Type-0 – Type-5, listed below. It can be implemented with as few as two reset types (Type-2 and Type-4), or as many as six reset types (all types) of reset inputs: This is determined by the class and options implemented.

The CJTAG module utilizes Type-0, Type-2, Type-3, Type-4, and Type-5 resets.

- **Type-0** – Reset of the TAP.7 by power management logic (power-on reset)
- **Type-1** – Chip level generated Test Reset. (equivalent to Type-2)
- **Type-2** – Externally generated Test Reset (nTRST/nTRST_PD pin)
- **Type-3** – TAP.7 controller generated reset
- **Type-4** – *Test-Logic-Reset* state
- **Type-5** – TAP.7 Controller TReset Register reset of the CLTAPC.

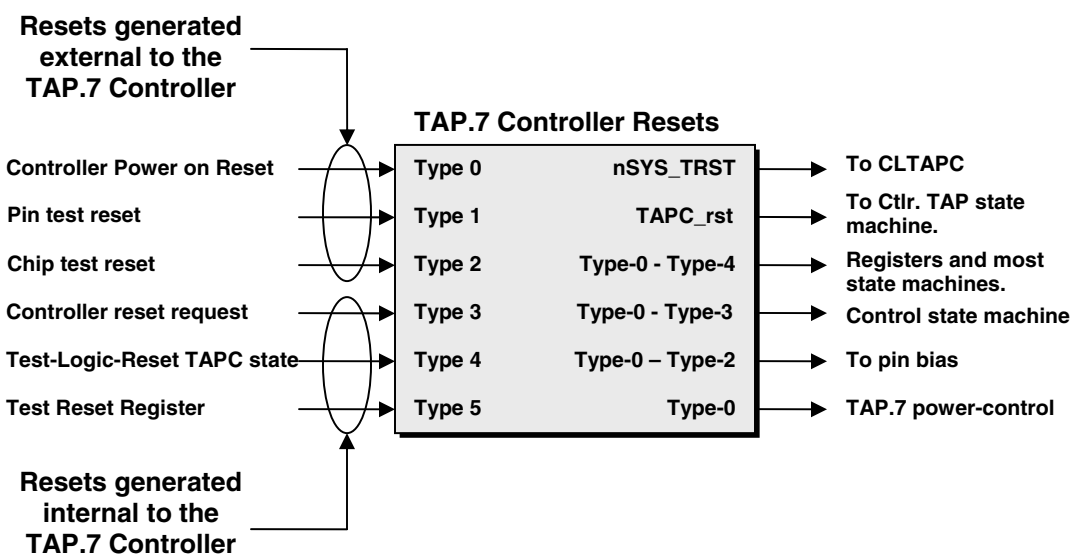

Figure 59-4. Conceptual view of the EPU reset logic and state machines

59.6.2.1 Type 5 reset

A Type-5 reset affects only the STL via the nSYS_TRST pin. It is asserted when the TRESET Register value is a logic 1. This register is set to its inactive state by reset Types 0-4.

59.6.2.2 Type 4 reset

A Type-4 reset is created by the *Test-Logic-Reset* state. It does not affect the TAP.7 TAPC state machine state as this state is the source of this reset, nor does it cause the assertion of the nSYS_TRST signal. It does however affect the coupling and decoupling of the STL. The Type-4 reset initializes the TAP.7 registers and most controller state machines. It affects but does not initialize the control state machine managing TAP.7 controller selection. It also establishes the default operating conditions.

59.6.2.3 Type 3 reset

A Type-3 reset is created by reset requests generated by the TAP.7 controller. A Type-3 reset performs the functions associated with a Type-4 reset and creates the *Test-Logic-Reset* state.

A Type-3 reset is generated in response to reset requests generated by EPU and APU logic

- A reset escape sequence
- Reset protocol sequences (delay packet directive, check packet directive)

A Type-3 reset request is generated with a reset escape sequence. This function is similar to but not the same as the reset function generated by a test reset pin. The Advanced Protocol includes certain bit patterns that initiate Type-3 resets. These bit patterns assist in the initialization of the TAP.7 controller when the TCKC signal is sourced by the TS and the external tool/TS connection is broken. The external tool may also generate these sequences, if desired, while the external tool/TS connection remains intact. These reset requests cause a Type-3 reset that is one clock wide.

With this being the case, consideration may be given to integrating the CJTAG module without the use of the Test Reset signal (nTRST/nTRST_PD pin).

59.6.2.4 Type 2 reset

A Type-2 reset is created by chip level logic to initialize the TAP.7 controller when TAP.7 power control is not implemented. It is unimplemented otherwise. It performs all of the functions of the Type-3 reset in addition to initializing the escape sequence detection logic.

59.6.2.5 Type 1 reset

A Type-1 reset is created with either the nTRST or nTRST_PD pin. It is not created when neither of these pins is implemented. It performs all of the functions of the Type-2 reset. It initiates TAP.7 controller power down provided the TAP.7 power control mode permits power down.

59.6.2.6 Type 0 reset

A Type-0 reset is implemented when TAP.7 controller power down is implemented. It performs all of the functions of a Type-1 reset and also initializes the TAP.7 power control logic.

59.6.2.7 Reset State Machine

The Reset State Machine assists in the translation of the reset inputs to the reset outputs. It handles Type-3 reset controller reset requests. The state machine state assures Type-0, Type-1, and Type-2 resets are forwarded to the STL without modifying their duration.

This state machine allows a Type-3 reset only when its state is “T3 Reset” (two TCK(C) falling edges have occurred in the absence of a Type-0, Type-1, and Type-2 reset).

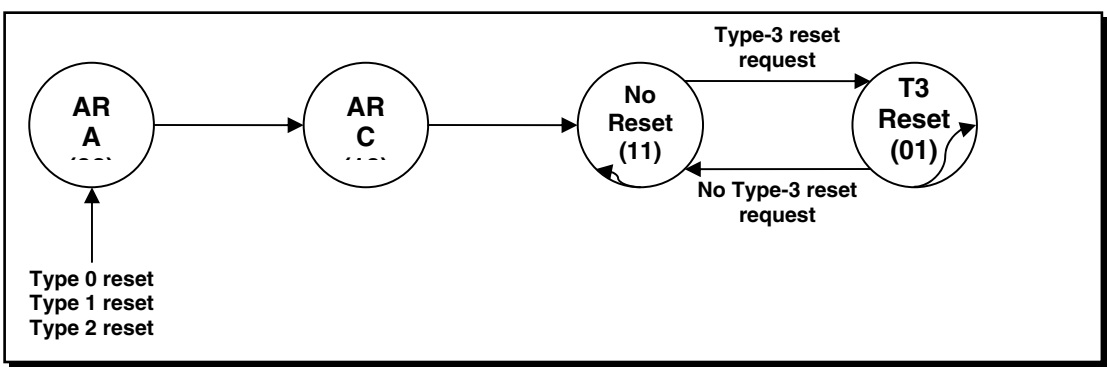

Figure 59-5. Reset state machine

Table 59-4. Reset state descriptions

Reset state		Description
ARA	Async. Reset Asserted	An async. reset has occurred or is occurring
ARC	Async. Reset Completed	An async. reset has occurred and has been released
No Reset	No Reset	No Reset
T3 Reset	Type-3 Reset	A Type-3 reset request has been processed.

Type-0, Type-1, and Type-2 resets are fully asynchronous. These resets are passed directly to nSYS_TRST without modification. The Type-3, Type-4, and Type-5 resets are fully synchronous.

The effects of the TAP.7 controller reset types are shown in the following table.

Table 59-5. Reset effects

Reset	CLTAPC	Pin-Hi-Z	State Machines other than CSM	Control State Machine (CSM)	TAPC SM State	Escape Sequence Detection	Power Control State
Type-5	Yes	–	–	–	–	–	–
Type-4	–	Yes	Yes	–	–	–	–
Type-3	Yes	Yes	Yes	Yes	Yes	–	–
Type-2	Yes	Yes	Yes	Yes	Yes	Yes	–
Type-1	Yes	Yes	Yes	Yes	Yes	Yes	–
Type-0	Yes	Yes	Yes	Yes	Yes	Yes	Yes

59.6.3 Start-up Options

59.6.3.1 Overview

The TAP.7 start-up options are shown in the following table. The only startup option currently supported by the CJTAG module is 1149.1 Compliant.

Table 59-6. Start-up Options

Start-up Option	Description
1149.1 Compliant	TAP.1 signal functionality, the CLTAPC is coupled
1149.1 Compatible	TAP.7 signal functionality, the CLTAPC is decoupled

Table continues on the next page...

Table 59-6. Start-up Options (continued)

Start-up Option	Description
1149.1 Protocol Compatible	No, or alternate TDIC/TDOC signal functionality, the CLTAPC is decoupled.
Offline-at-Start-up (Dormant)	The TAP.7 controller is offline and awaits synchronization to external tool operation so as to be placed online, the CLTAPC is decoupled after its state is moved to *Run-Test/Idle*

59.6.3.2 1149.1 Compliant start-up

Start-up behavior with the 1149.1 Compliant behavior start-up option:

- 1149.1-specific behavior / Standard protocol
- The TAPC finite state machine operated in lock step with the CLTAPC finite state machine.
- The TDIC and TDOC pins are present and provide the TDI and TDO function.
- The CLTAPC is coupled at start-up.

With this start-up option, the TAP.7 controller may be programmed and the scan topology may be interrogated. If the scan topology is known to be the Series Scan Topology at power-up, the TAP.7 can be operated as though it is a TAP.1.

Table 59-7. Reset values for TAP.7 startup options

Start-up Option	Type-0 – Type-3 Reset?	Default TAP.7 and TAP.7 controller characteristics				
		TAP.7 Controller online	CLTAPC Coupled	SGC Reg. == 1	SCNFMT	Initial TMSC pin bias
1149.1 Compliant	x	Yes	Yes	Yes	JScan0	PU

59.6.4 RSU operation

The RSU uses TCKC and TMSC with the control protocol for configuration control.

59.6.4.1 General Operation

From a very high level, the RSU enables the remainder of the TAP.7 functionality when the TAP.7 controller is Online and disables the remainder of the TAP.7 functionality otherwise. The RSU either consumes or discards the TMS(C) information while the TAP. 7 controller is Offline. The relationship of the escape sequence detection, technology selection logic, and the underlying technology is shown in the following figure.

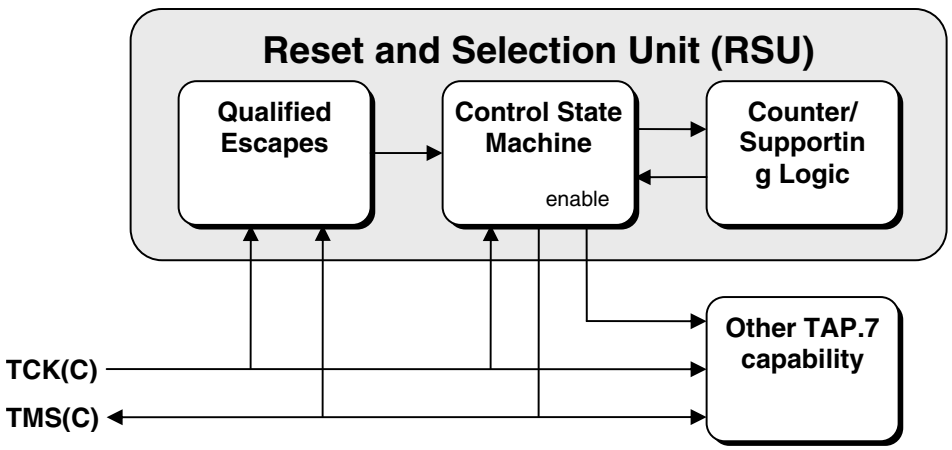

Figure 59-6. Conceptual view of technology selection mechanism

59.6.4.2 Common Signaling Across Technologies

With the TAP.7 architecture, the signaling conventions chosen for technology selection is multiple data transitions of the TMS(C) signal while the TCK(C) signal is a logic 1. The common signaling space is available when the external tool sources the TCK(C) signal as it is capable of creating these signaling conventions. It is unavailable when the TS sources the TCK(C) signal as the external tool cannot stop the TCKC signal at a logic 1 to create these signaling conventions.

59.6.4.3 Escape Sequence Detection

TAP.7 TAPC interprets the count of the number of TMS(C) edges while TCK(C) is a logic 1 as one of four escape sequences. Each escape sequence has a different function and TMSC edge count. These escape sequences, their edge counts, and their functions are described below:

- **Custom** (2 or 3 edges) – Ends scan and transport transfers with a TAP.7 controller, may be used for other purposes with another technology.
- **Reset** (> 7 edges) – Resets all technologies (generates a Type-3 TAP.7 TAPC reset)

The external tool creates an escape sequence by generating one or more TMS(C) edge pairs while the TCK(C) signal is a logic 1 value. Even and odd TMS(C) edge counts beginning with two are given the same meaning.

An escape sequence:

- Can be detected only when a Type-0, Type-1 or Type-2 reset is **not** asserted.
- Begins and ends while the TCK(C) is a logic 1.
- Uses TMS(C) as a clock while the TCK(C) is a logic 1.
- Overlays additional control information onto the normal information that is transferred with the TCK(C) and the TMS(C) without changing the normal information.
- Must be detected when TCK(C) is a logic 1 regardless of the TCK(C) and TMS(C) drive histories.

59.6.4.3.1 Custom escape sequence

An online technology can use the custom escape sequence in any manner it chooses. It is used as the End of Transmission (EOT) of certain data types (formats OScan4-7) with T4 and above TAP.7s.

59.6.4.3.2 Reset escape sequences

A reset event initializes all technologies sharing the TCK(C) and TMS(C) connectivity. A reset escape sequence resets the technology. It is recommended that this reset occur with the falling edge of TCKC. With a TAP.7 controller a reset escape sequence generates a Type-3 reset beginning with the falling edge of TCK(C) following the asynchronous detection of the event.

59.6.5 TAPC State Machine

T1 and above TAP.7s require knowledge of the TAPC state machine state. With T2 and above TAPs this knowledge must be developed independently of the CLTAPC. This is generally accomplished by implementing a TAPC state machine within the EPU. This TAPC state machine provides the function of the state machine within a standard 1149.1 TAPC. It is recommended that this state machine is implemented to change state on the falling edge of TCK(C) as this has numerous advantages to a TAP.7 controller. The EPU does not contain 1149.1 Instruction or Data Registers. The APU controls the state changes of this TAPC state machine with T4 and above TAP.7s.

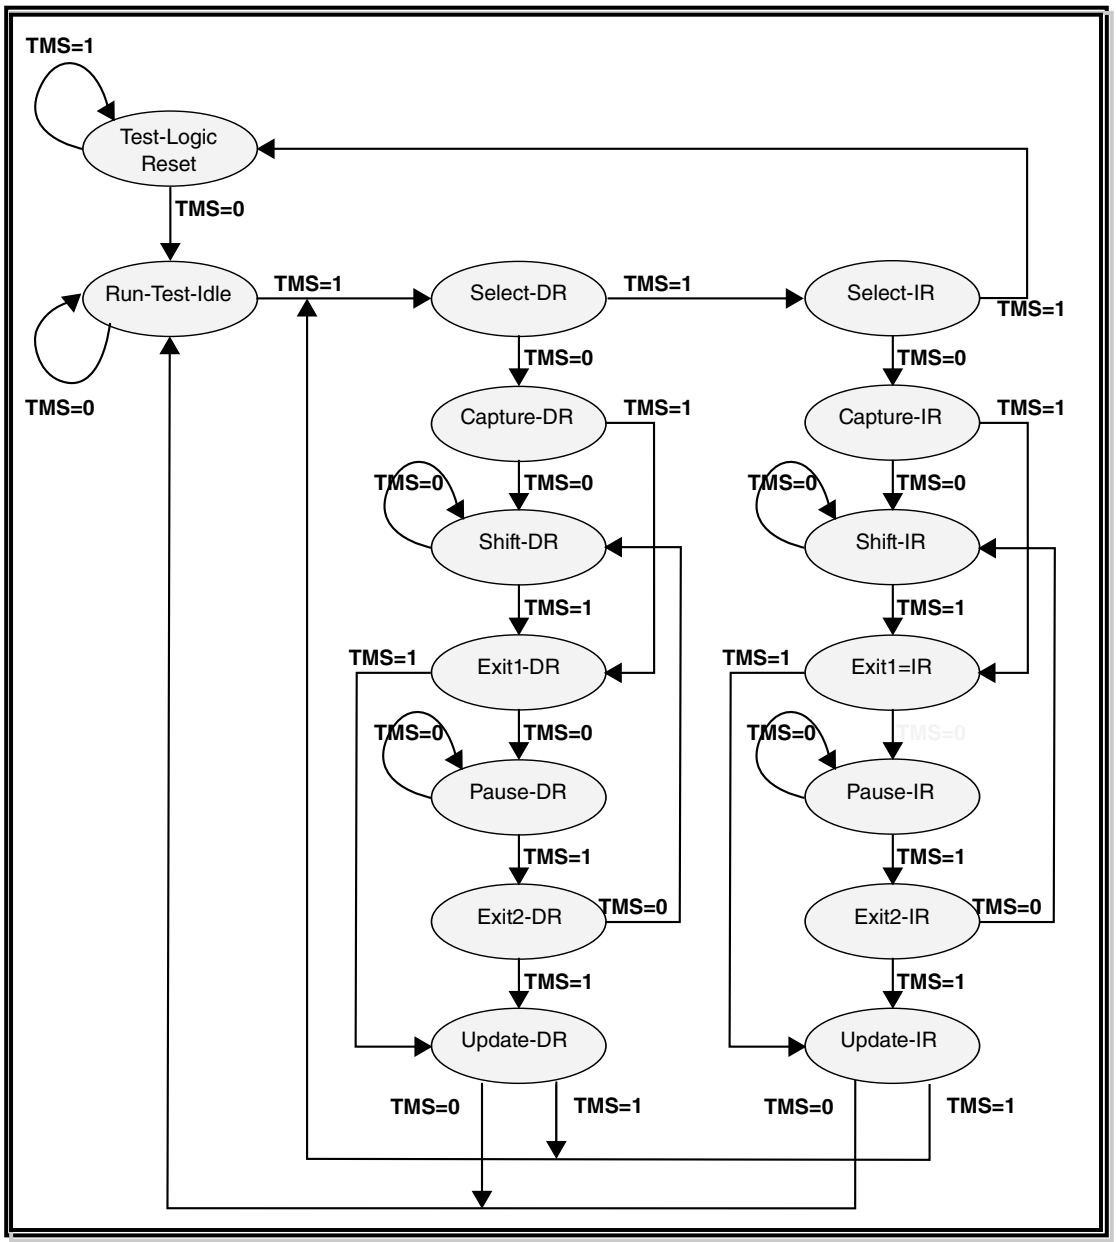

Figure 59-7. Falling edge TAP controller state machine

59.7 EPU (Extended Protocol Unit) Operation

59.7.1 EPU Operation

The EPU adds functionality to the BYPASS and IDCODE instructions.

59.7.1.1 Zero-bit DR-Scans (ZBS)

A zero-bit DR-Scan (ZBS) is a TAPC-state sequence that begins with the *Select-DR-Scan* state and ends with an exit from the *Update-DR* state without an intervening *Shift-DR* state. The external tool controls the EPU using ZBSs.

The use of ZBSs can begin immediately following the *Test-Logic-Reset* state since this state initializes the Instruction Registers of TAPs with either the *BYPASS* or *IDCODE* instructions.

59.7.1.2 Utilizing ZBSs for TAP.7 Controller Functionality

Beginning with a ZBS count of zero, the ZBS count is incremented with each consecutive occurrence of a ZBS without encountering a *Shift-DR* state. This count cannot be incremented past seven. *Run-Test/Idle* is the only state that may occur between consecutive occurrences of ZBSs without terminating the count of consecutive ZBSs.

59.7.1.3 Locking the ZBS Count

When a DR-Scan containing a *Shift-DR* state occurs, and the ZBS count is greater than zero, the ZBS count is not incremented when the *Update-DR* state is reached. It is instead locked at its current value. ZBSs occurring after locking the ZBS count do not affect the locked ZBS count. Locking the ZBS count is the equivalent of storing the count for subsequent use.

59.7.1.4 Control levels

Locking the ZBS count activates a control level that is equal to the locked ZBS count (1-7) when ZBSs are being used for TAP.7 functionality and merely locks the ZBS count otherwise.

1. ZBSs may be used by the STL or another function
2. TAP.7 command generation
3. Reserved control level
4. Accesses to optional TAP.7 scan paths
5. Accesses to optional TAP.7 scan paths

6. Force offline operation (optional)
7. External tool uses

Control level one may be used by the STL since there is no TAP.7 controller functionality associated with this control level.

Control level two enables DR-Scans to create TAP.7 commands. A portfolio of these commands supports the deployment of TAP.7 controllers in the Series or Star Scan Topologies. These commands manage TAP.7 controller registers and perform other functions.

Control level three is reserved for use with a subsequent specification revision.

Control levels four and five provide access to custom (private) scan paths when access to these paths is permitted by a TAP.7 register bit used for this purpose. The EPU provides a 1-bit scan path otherwise. No other EPU functionality is associated with these control levels. The CJTAG module does not support the use of this control level.

Control level six may be optionally used to force offline operation with a TAP.7 controller that supports this capability. The EPU provides a 1-bit scan path for this control level. The CJTAG module does not support the use of this control level.

Control level seven is reserved for external tool use. With this control level, external tool capabilities may be managed using the same infrastructure used to manage TAP.7 controller capability. The EPU provides a 1-bit scan path for this control levels.

59.7.1.5 Exiting a Control Level

A control level is exited when one of the following occurs:

- The *Select-IR-Scan* TAP.7 controller state
- The *Test-Logic-Reset* state
- Certain TAP.7 controller commands (Exit Control Level – ECL register bit)
- An event that synchronizes the operation of TAP.7 controllers

59.7.1.6 Zeroing the ZBS Count

Events causing an exit from a control level also zero the ZBS count. Scan Selection Directives (SSDs) associated with T3 and above TAP.7s zero the ZBS count when the control level has not been locked.

59.7.1.7 Utilizing ZBSs within the STL

After the *Test-Logic-Reset* state, ZBSs are used for basic EPU control. ZBSs that are intended for TAP.7 use are henceforth called "***TAP.7 ZBSs***". ZBSs that are intended for other uses are henceforth called "***Other ZBSs***". Two TAP.7 registers enable the STL's use of ZBSs. Storing these registers causes a control level exit, zeroes the ZBS count, and enables the use of Other ZBSs. Storing the Suspend Register (**SUSPEND**) suspends the use of control levels. Storing the ZBS Inhibit Register (**ZBSINH**) inhibits ZBS detection.

When either of these methods is used, the *Test-Logic-Reset* state enables the use of TAP. 7 ZBSs in addition to initializing the TAP.7 controller.

The operation of the TAP.7 controller changes with the use of these two paths.

When the System Path is used:

- A count of eight consecutive ZBSs is used to create a logic 0 SUSPEND Register value.
- The CLTAPC supplies the TAP.7 scan path and controls the drive of TDO(C), provided it is not bypasses.
- The EPU supplies the TAP.7 scan path (a one bit bypass) when the CLTAPC is bypassed.
- Functions supporting Boundary Scan in a Star Scan Topology are enabled.

When the EPU Path is used:

- When the control level has not been locked, the TDO(C) signal remains high-impedance.
- The command control level may be created
- When commands are used, the TDO(C) signal remains high-impedance except during *Shift-DR* states within CR-Scans, and remains high impedance at other times.
- Auxiliary scan paths may be accessed with control levels four and five.

59.7.2 EPU Registers

59.7.2.1 Global

A global register is a register whose value is stored at the same time and with the same value as registers with the same name in all TAP.7 TAPCs sharing an external tool connection. They are stored using TAP.7 TAPC commands dedicated for this purpose. These commands store a single global register. Global registers manage TAP.7 TAPC functions that affect the synchronized operation of a TAP.7 TAPC. An example of a global register is the Scan Format (SCN_FMT) Register used to define the TAPC signal protocol.

A second means of storing all global registers is available. The selection of the TAP.7 TAPC with the technology selection function stores either the Scan Format register value (short form) or all global registers (long form). Storing all global registers provides a simple means to synchronize the values of all global registers when Technology Selection causes a non-operating TAP.7 TAPC to become operational while other TAPCs are operational.

59.7.2.2 Local

Local registers manage TAP.7 TAPC functions that do not affect the synchronized operation of TAP.7 TAPCs. Local registers are conditionally stored using TAP.7 controller commands dedicated for this purpose. These commands provide for changing the value of these registers one a time with a unique value in a Series Scan Topology based on the TAPC's position on the scan chain. Local registers are stored with a unique value in a Star Scan Topology based on a TAPC address assigned to the TAPC.

Registers programmed with commands are described in this section. The CJTAG module implements all mandatory T4 registers as well as the optional APFC, TRESET, and RDBACK0 registers.There are 16 mandatory and 10 optional registers that can be grouped in classes as shown in Read-only – Configuration and register read back..

- **Control** – TAP.7 controller behaviors and characteristics.
- **Options** – Control of optional functions.
- **Select** – Controls the selection of a TAP.7 for Scan and execution of conditional commands.
- **Read-only** – Configuration and register read back.

Table 59-8. TAP.7 controller register list (managed with commands)

Register type	Global/local	Width	Register mnemonic	Name
Control	Global	1	ECL	Exit Control Level
		1	SUSPEND	Suspend
		1	ZBSINH	ZBS Detect Inhibit
		5	SCNFMT	Scan Format
		1	SSDE	SSD Enable
		2	DLYC	Delay control
		2	RDYC	Ready Control
Options	Local	1	TRESET	Test Reset
		2	APFC	Aux. Pin Func. Cntl.
Select	Local	1	CGM	Cond. Group Member
		1	SGC	Scan Group Candidate
		1	SEDGE	Sampling Edge
Read-only	Local	32	RDBACK0	Read-back 0
		32	RDBACK1	Read-back 1
		32	CNFG0	Configuration Register 0

M = Mandatory register

O = Optional register

59.7.2.3 Register Descriptions

59.7.2.3.1 Exit Control Level (ECL)

Storing this register zeroes the ZBS count and unlocks the control level.

This register is set using the STMC command. It remains logic 1 only momentarily before immediately returning to logic 0.

This register is cleared by a global register load.

59.7.2.3.2 Suspend (SUSPEND)

Setting this register suspends the use of control levels. When this register is a logic 1, the "System Path" (STL) is used.

1 – Suspend use of control levels. Enables "System Path."

0 – Enable use of control levels.

SUSPEND is set with the STMC command.

This register is cleared when 8 consecutive ZBSs are detected without the locking of the ZBS count.

This register is cleared by a global register load.

59.7.2.3.3 ZBS Inhibit (ZBSINH)

Storing to ZBSINH inhibits ZBS detection.

1 – Inhibit ZBS detection.

0 – Enable ZBS detection.

ZBSINH is set with the STMC command.

This register is cleared by a global register load.

59.7.2.3.4 Scan Format (SCNFMT[4:0])

Set using Store Scan Format (STFMT) command.

Read using Scan String (SCNS) command.

Table 59-9. Scan Format Register Values

TAPC.7 Class	SCNFMT	Description
T2–T4	00000	**JScan0:** • 1149.1 Compliant Operation. • Requests the coupling of the CLTAPC when the Run-Test/Idle state is reached.
	00001	**JScan1:** • 1149.1 Compatible Operation • Requests the decoupling of the CLTAPC when the Run-Test/Idle state is reached.
	00010	**JScan2:** • 1149.1 Compatible Operation. • Requests the coupling or decoupling of the CLTAPC when the Run-Test/Idle state is reached based on the value of the CACT register
T3–T4	00011	**JScan3:**

Table continues on the next page...

Table 59-9. Scan Format Register Values (continued)

TAPC.7 Class	SCNFMT	Description
		• Non-compatible 1149.1 Operation • Allows the detection of a T2 TAP.7 controller that is deployed in a Star-4 topology. • Enables TDOC signal behavior that prevents drive conflicts in a Star-4 Scan Topology. • Enables the use of SSDs
T4	01000	**OScan0** • Data rate dependent components • Single TAP.7 communication • Debug and Test applications
	01001	**OScan1** • TAP.1 components • Single/Multi-TAP.7 communication • Debug and Test applications
	01010	**OScan2** • TAP.1 components • No TDI or TDO in non-shift states • Debug applications
	01011	**OScan3** • TAP.1 components • No TDI in non-shift states • No TDO in any state
T4	01100	**OScan4** • Data rate dependent components • Single TAP.7 communication • Debug and Test applications
	01101	**OScan5** • TAP.1 components • Single/Multi-TAP.7 communication • Debug and Test applications
	01110	**OScan6** • TAP.1 components • No TDI or TDO in non-shift states • Debug applications

Table continues on the next page...

Table 59-9. Scan Format Register Values (continued)

TAPC.7 Class	SCNFMT	Description
	01111	**OScan7** • TAP.1 components • No TDI in non-shift states • No TDO in any state
	10000	**MScan** • Data rate dependent components • Multi TAP.7 communication • Directed CID assignment • Virtually any IP with compliant or non-compliant 1149.1 behavior
	10001 – 11111	**Reserved**

The use of a Scan Format value other than 00000b – 10000 shall not change the value of the SCNFMT Register.

59.7.2.3.5 Scan Selection Directive Enable (SSDE)

This register specifies whether the Scan Selection State may be managed using the scan selection directives.

0 – Scan selection directives are not enabled.

1 – Scan selection directives are enabled.

This register is set using the STMC command.

This register is read using SCNS (Scan String), RDBACK0.

59.7.2.3.6 Delay Control (DLYC[1:0])

The Delay Control register provides a means for the external tool to delay the completion of an SP. This delay is essentially an external tool stall. This delay may be zero, one, two, or n TCKC periods. This delay is especially useful when the TCKC is sourced by the TS and a Standard-to-Advanced Protocol adapter is added to an external tool supporting only the Standard Protocol. It allows an external tool design additional time to receive TDO, advance the external tool TAPC state, receive TMS and TDI information, and begin generation of a new SP payload. The DLYC register should be programmed before the use of the Advanced Protocol begins after the use of the Standard Protocol.

Set using the STMC command.

Read using SCNS, RDBACK0

Bits 18-17 of the "Global Register."

59.7.2.3.7 Ready Control (RDYC[1:0])

The Ready Control register defines behavior exhibited in the SP payload output bit frames when the STL stall opportunities (RDY bits) are included as control information. This register defines the number of additional bits inserted in these bit frames. These bits provide more time for a high-performance external tool to ascertain whether the TAP.7 controller is ready to complete the SP payload. The use of these bits makes a high-performance external tool design easier as input and output buffer delays play less of a role in limiting the TAP.7 controller performance. The RDYC register should be programmed before the use of the Advanced Protocol begins.

Set using the STMC command.

Read using SCNS, RDBACK0.

Bits 18-17 of the Global register state.

59.7.2.3.8 Test Reset (TRESET)

Asserts a test reset to the STL.

0 – The nSYS_TRST and SYS_TMS signals presented to the STL is not influenced by this bit.

1 – The nSYS_TRST presented to the STL is asserted and the SYS_TMS signal is a logic 1.

Set using the STC1 command.

The effects of the TRESET Register may be modified by a private TAP.7 controller register. When this private register is unimplemented or has a value of zero, the TRESET register causes the maximum initialization of the STL with nSYS_TRST and the SYS_TMS logic 1 value. Otherwise, the value of the private register may modify the function of the TRESET Register bit.

When the TRESET Register is a logic 1, the STL scan path appears broken as the state of CLTAPC remains *Test-Logic-Reset* while the EPUTAPC state progression continues. When the operation of the EPUTAPC and CLTAPC controllers is coupled, as with a T1 TAP.7, the state of these two TAPCs may be resynchronized to the *Run-Test/Idle* state by:

- An STC1 Command that sets the TRESET Register value to a logic 0.
- A stay in the Run-Test/Idle state of two or more SYS_TCK periods immediately following the Update-DR state of this command

A failure to follow the guidelines is considered a programming error and will result in erroneous system operation. The EPUTAPC and CLTAPC states will not be synchronized as they progress through the state diagram.

59.7.2.3.9 Auxiliary Pin Function Control (APFC[1:0])

This register enables TDI and TDO alternate functions when 2-pin TAP.7 operation is selected.

0x – TDI and TDO have JTAG function.

1x – TDI and TDO have alternate function.

Set using STC2 command.

Read using SCNS, RDBACK0.

59.7.2.3.10 Conditional Group Member (CGM)

Used by STC1, STC2, STTESTM, and EXC3 – EXC0 commands as the “condition” for updating registers.

Set and cleared using MCM and SCNB commands.

Read using SCNS, RDBACK0.

59.7.2.3.11 Scan Group Candidate (SGC)

This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used.

- **0** – Decoupling action.
- **1** – Coupling action.

Set and cleared using STMC, MSC, and SCNB commands.

Read using SCNS, RDBACK0.

59.7.2.3.12 Sampling Edge (SEDGE)

The Sampling Edge register defines the TCKC edge used to sample the TMSC input.

- **0** – Sample TMSC on the TCKC falling edge.
- **1** – Sample TMSC on the TCKC rising edge.

Set and cleared using STC1 command.

Read using SCNS, RDBACK0

59.7.2.3.13 Read Back 0 (RDBACK0)

Non-transport related register information.

Read using SCNS command.

Unimplemented registers shall read back as "0".

Table 59-10. RDBACK register format

Bit	Width	Register Mnemonic	Name
4:0	5	SCNFMT	Scan Format
6:5	2	PWRMODE	Power-control Modes

NC = No Change

DF = Default Scan Format

DM = Default Power Control Mode

DCA = Default Coupling Action

DT = Default Topology

DP = Default Pin Function

59.7.3 EPU Commands

There are two command types:

- Two Part Commands
- Three Part Commands

Any number of two-part and three part commands may be issued in any combination before the command control level is exited. If the command control level is exited before a two- or three-part command is completed, the command is aborted and becomes a NOP.

59.7.3.1 Two Part Commands

TAP.7 controller commands are 10-bit values. The 10-bit commands are created by two consecutive DR-Scans when the control level is locked at the command control level (two). The first DR-Scan provides a five-bit command opcode. The second DR-Scan provides a five-bit operand. These two scans are called the command part one (CP1) and command part two (CP2), respectively. A command created entirely with these two scans is called a two-part command.

59.7.3.2 Three Part Commands

Some commands are used to send and/or receive data values other than values embedded in the command's operand. These commands are called three-part commands. With these commands, CP1 and CP2 are followed by an additional DR-Scan to transport a data value to or from an EPU scan path. When used for this purpose, the DR-Scan is called a Control Register Scan (CR-Scan). The CR-Scan is a minimum of zero bits in length with there being no maximum length. The CR-Scan path is described in SECTION.

59.7.3.3 Command Sequence

The two 5-bit values concatenated to create the 10-bit command represent the number of Shift-DR states between the *Capture-DR* and *Update-DR* states of CP1 and CP2. The count within CP1 creates the MSBs of the command while the count within CP2 creates the LSBs of the command. The command is decoded when the *Update-DR* state of the second DR-Scan is reached. A determination as to whether the command is a two- or three-part command is made at this point. The command format is shown in the following figure.

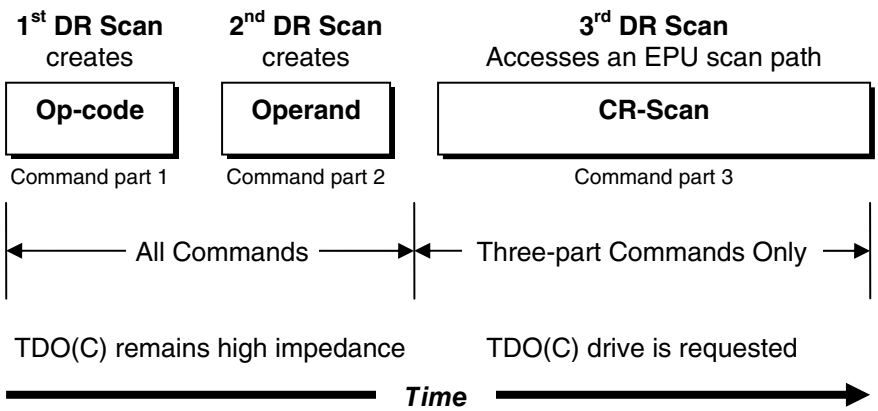

Figure 59-8. DR_Scan sequence used for command creation

The 10-bit command created by CP1 and CP2 determines the command's function and whether the command is a two- or three-part command. If the command is a two part command, the function specified by the command is performed when command part 2 completes. If the command is a three-part command, the DR-Scan following CP2 performs a TAP.7 controller function designated by the 10-bit controller command. This DR-Scan is called a ***Control-Register Scan*** (CR-Scan) and can be any length. A CR-Scan has many of the attributes of the DR-Scan as it moves data between the external tool and TAP.7 controller and accesses various EPU scan paths. There are many two part commands, but only three three-part commands, each having a special purpose.

59.7.3.4 Commands

There are 11 mandatory and 5 optional commands that can be grouped in classes as shown in the following list:

- Store – The operand is stored in a register or causes an action.
- Select – Controls participation of Scan and conditional command execution.
- Scan – Inputs and outputs with a CR-Scan.
- Enumerate – Controller ID allocation and de-allocation.
- Private – Commands available for chip-specific definition.

The definition of the commands with their operands is shown in the following table.

Table 59-13. – TAP.7 controller command list

Command class	Opcode count	Mnemonic	Name	TAP.7 class			
				1	2	3	4
Store	0x00	STMC	Store Miscellaneous Control	M	M	M	M
	0x01	STC1	Store Conditional 1-bit	M	M	M	M
	0x02	STC2	Store Conditional 2-bit	M	M	M	M
	0x03	STFMT	Store Format	-	M	M	M
	0x04	STDCST	Store Data Channel State	-	-	-	-
Select	0x06	MCM	Make Cond. Group Member	M	M	M	M
	0x07	MSC	Make Scan Group Candidate	-	M	M	M
Scan	0x08	SCNB	Scan Bit	M	M	M	M
	0x09	SCNS	Scan String	M	M	M	M
Enumerate[1]	0x0A	CIDA	Allocate Controller ID	-	-	M	M
	0x0B	CIDD	De-allocate Controller ID	-	-	M	M
Reserved	0x0C–0x1F	Reserved	Reserved	-	-	-	-

1. Enumerate commands are not currently supported by the CJTAG module.

59.7.3.4.1 Store Commands

Store commands are two-part commands that are available in both Star and Series Scan Topologies. The Store Miscellaneous Control (STMC) Command performs control functions that affect all TAP.7 controllers sharing an external tool connection. It stores values in one-bit and two-bit registers.

The Store Conditional 1 bit (STC1) and Store Conditional 2 bit (STC2) Commands store one-bit and two-bit values in registers, respectively. These commands operate two ways:

1. Unconditionally storing registers in all TAP.7 controllers or
2. Storing registers in only the TAP.7 controllers that have a logic 1 Conditional Group Member (CGM) Register value.

The Store Format (STFMT) Command unconditionally stores a five-bit Scan Format value.

The Store Data Channel State (STDCST) Command stores a five-bit value identifying the states supporting transport.

59.7.3.4.2 Select Commands

Select commands are two-part commands that are available in both Star and Series Scan Topologies. Their primary use is to select TAP.7 controllers of interest in a Star Scan Topology. These commands define the TAP.7 controller(s) participating in scans and the TAP.7 controllers that conditionally execute STC1 and STC2 Commands.

The Make Conditional Group Member (MCM) Command specifies which TAP.7 controllers execute store conditional commands as it manages the Command and Path Enable (CAPE) Register. This register also affects the execution of private commands and is utilized in EPU scan path selection.

The Make Scan Group Candidate (MSC) command manages the SGC register. This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used. Select commands execute only when the CIDI Register is a logic 0, indicating the TAP.7 controller's CID is valid, and are treated as no operations otherwise.

59.7.3.4.3 Scan Commands

Scan commands are three-part commands that are available in both Star and Series Scan Topologies. The CR-Scan portion of Scan Bit (SCNB) and Scan String (SCNS) Commands is used to set and test bits (SCNB) or transfer strings of bits (SCNS). The commands may be used to access both public and private registers.

59.7.3.5 Command Definitions

59.7.3.5.1 Store Commands

59.7.3.5.1.1 Store Miscellaneous Control Command (STMC)

Table 59-14. Store Miscellaneous Control

STMC		Store Miscellaneous Control				
Opcode	**Operand**	**bbb**		**x**	**y**	**Description**
00000	bbb x y	000	StateCtl	0	0	NOP
				0	1	ExitCmdLev(ECL)
				1	0	Exit/Suspend (SUSPEND) = 1
				1	1	ZBS Inhibit (ZBSINH) = 1
		001	ScanCtl	0	-	SGC = y
				1	-	CGM = y

Table continues on the next page...

Table 59-14. Store Miscellaneous Control (continued)

STMC		Store Miscellaneous Control				
Opcode	**Operand**	**bbb**		**x**	**y**	**Description**
		010	RdyCtl	-	-	RDYC = xy
		011	DlyCtl	-	-	DLYC = xy
		100	ScnFunc	0	-	SSDE = y
				1	0	Star-4 Topology Test
				1	1	Reserved
		101	Reserved	-	-	Reserved
		110				
		111				

59.7.3.5.1.2 Store Conditional 1-bit (STC1)

Table 59-15. Store Conditional 1 bit (STC1)

STC1		Store Conditional 1 bit

59.7.3.5.2 Select Commands

This section describes the select commands with their operands.

59.7.3.5.2.1 Make Conditional Group Member (MCM)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the CGM bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The CGM Register is also stored with the STMC and SCNB commands.

Table 59-18. Make Conditional Group Member (MCM)

MCM		Conditional Group Member	
Opcode	Operand	m	Description
00110	m iiii	0	CGM bit of the non-targeted controller is cleared
		1	CGM bit of the targeted controller is set. CGM bit of a non-targeted controller is unaffected.

59.7.3.5.2.2 Make Scan Group Candidate (MSC)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the SGC bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The SGC Register is also stored with the STMC and SCNB commands.

Table 59-19. Make Scan Group Candidate (MSC)

MSC		Make Scan Group Candidate	
Opcode	**Operand**	**m**	**Description**
00111	m iiii	0	SGC bit of the non-targeted controller is cleared
		1	SGC bit of the targeted controller is set. SGC bit of a non-targeted controller is unaffected.

59.7.3.5.3 Scan Commands

59.7.3.5.3.1 Scan Bit (SCNB)

This is a 3-part command. The operand chooses the bit to be read or written by the CR-Scan.

Table 59-20. Scan Bit (SCNB)

SCNB			Scan Bit		
Opcode	**Operand**	**CR-Scan**	**yyyyy**	**Description**	**R/W**
01000	yyyyy	-	0	Scan Group Candidate (SGC)	Write only
		-	1	Conditional Group Member (CGM)	Write only
		-	2	CNFG[0]	Read only
		-	3	CNFG[1] (not implemented)	Read only
		-	4	CNFG[2] (not implemented)	Read only
		-	5	CNFG[3] (not implemented)	Read only
		-	6	Functional reset requested (FRESETR) (not implemented)	Read only
		-	7	Series topology detect	Write only
		-	15 – 8	Reserved	Read only

59.7.3.5.3.2 Scan String (SCNS)

This is a 3-part command. The operand chooses the string to be read or written by the CR-Scan.

Table 59-21. Scan String (SCNS)

SCNS			Scan String		
Opcode	**Operand**	**CR-Scan**	**yyyyy**	**Description**	**R/W**
01001	yyyyy	-	0	RDBACK[0] Register [31:0]	Read only

Table continues on the next page...

Table 59-21. Scan String (SCNS) (continued)

SCNS			Scan String		
Opcode	Operand	CR-Scan	yyyyy	Description	R/W
		-	1	RDBACK[1] Register [31:0] (not implemented)	Read only
		-	2	CNFG[0] Register [31:0]	Read only
		-	3	CNFG[1] Register [31:0] (not implemented)	Read only
		-	4	CNFG[2] Register [31:0] (not implemented)	Read only
		-	5	CNFG[3] Register [31:0] (not implemented)	Read only
		-	6 - 7	Reserved (read logic 0)	Read only
		-	31 - 8	Private – available for customization	

59.7.4 EPU operating states

The TAP.7 controller and STL share the use of ZBSs. The EPU has three operating states as shown in the following figure:

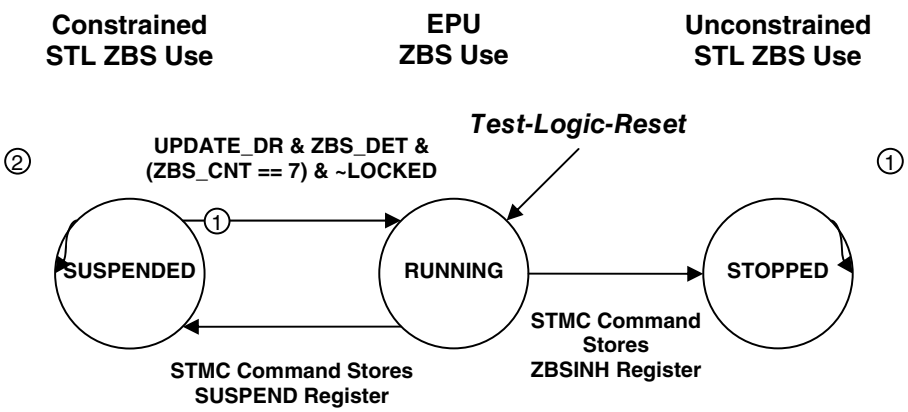

Figure 59-9. EPU operating states

The values of the SUSPEND and ZBSINH Registers determine the type of operation as shown in the following table. The Test-Logic-Reset state sets the SUSPEND and ZBSINH Register values to a logic 0.

Table 59-22. ZBS use state characteristics with both TAP.7 and other ZBS use

ZBSINH	SUSPEND	EPU operating State	ZBS use by:	Until
0	0	RUNNING	EPU	Command allocates to STL

Table continues on the next page...

Table 59-22. ZBS use state characteristics with both TAP.7 and other ZBS use (continued)

ZBSINH	SUSPEND	EPU operating State	ZBS use by:	Until
0	1	SUSPENDED	STL	ZBS sequence allocates to EPU
1	0	STOPPED	STL	Test-Logic-Reset state allocates to EPU
1	1	Not possible		

59.7.5 System and EPU Paths

The System path is utilized when the external tool requires access to system (STL) resources. This path is used when either the SUSPEND Register is a logic 1 or the ZBS count is less than or equal to one. The EPU path is used otherwise.

The EPU scan path is constructed from five types of EPU scan paths:

- **Bypass** – A 1-bit scan path
- **Bit** – Supports set and test bit operations (a 1-bit shift register)
- **String** – Support 32-bit reads or 32-bit writes
- **Enumerate** – A 36-bit scan path that transports a TAPC address with T3 and above TAP.7s
- **Auxiliary** – An n-bit scan path that transports 1 – n bits using a conventional IEEE 1149.1 style DR-Scan path using Control Levels 4 and 5.

59.8 APU (Advanced Protocol Unit) Operation

59.8.1 Overview

The Advanced Protocol Unit (APU) is placed between the EPU and the RSU to create the T4 TAP.7 controller. The APU delivers advanced capabilities with a number of operating modes (new scan formats) that utilize the Standard Protocol and the Advanced Protocol in both the narrow and wide T4 TAP.7 versions.

The APU enables scan transfers with two signals by serializing the information related to a TAPC state machine state. It provides a number of serialization formats to balance scan flexibility and scan performance. It multiplexes the use of the TMSC signal for T4 TAP.7 controller functions. The serialization is bypassed to provide T3 TAP.7 capability.

With a wide TAP.7, the chip architect may choose to implement the TDIC and TDOC signal functions as fixed functionality (the T3 TDIC and TDOC functions) or as programmable between the T3 TDIC and TDOC signal functions and an alternate function using a TAP.7 controller register. In this case, the default signal function may be either of the programmable choices. Programmable TDIC and TDOC functionality provides a means to fully utilize these signals in any scan topology as the T3 TAP.7 functionality is fully supported.

The entire EPU infrastructure (i.e., ZBS detection, control-level management, and command generation) is utilized when either the Standard Protocol or the Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state machine state progression. The EPU is unaware of the APU's existence. All T4 features are managed outside of the EPU.

The TAP.7 serialization schemes are specified with scan formats that complement the JScan 0-3 Scan Formats inherited from the T3 TAP.7. The scan formats are called advanced scan formats as they support two-signal operation.

Two groups of scan formats (MScan and OScan0-7) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. The OScan Scan Format is broken into two groups with the same function, one group has better performance but may only be used with an external tool sourced TCKC. The external tool chooses a scan format that matches the constraints imposed by the application, chip components, and possibly the external tool itself.

The MScan and OScan formats address Test and Debug use cases. The mandatory MScan and OScan0-1 formats emphasize flexibility over performance. The remaining optional Oscan2-7 formats emphasize performance over flexibility by not transmitting unneeded information such as TDI and TDO in non-shift TAPC state machine states.

The optional capabilities added with T4 and above TAP.7s change the bit sequences seen at the TAP.7 signals. A TAP.7 controller comprehends only the bit sequences generated by the use of the features it supports. It is never exposed to bit sequences it does not comprehend. A check for supporting an enabled feature is made before the feature is used (alters the bit sequences). When a T4 TAP.7 controller detects the use of an unsupported scan format, it halts its operation and places itself in a state where its operation may be resumed. This state is henceforth called "offline". A TAP.7 controller that is not offline is henceforth called "online". While offline the TAP.7 controller awaits the detection of a

special signaling sequence called the Online Activation Protocol. This protocol sequence places an offline TAP.7 controller online and synchronizes the operation of all online TAP.7s.

The Advanced Protocol Unit supports the stall of a transfer by both the external tool and STL at any TAPC state.

The APU provides the following functions:

- Bypass (for operation with the Standard Protocol)
- Scan control (for SP use)
- Configuration Control (for CP use)

The Scan Control, Configuration Control, and Transport Control functions are idled when the Standard Protocol is used as the Bypass Function connects the TCKC and TMSC pins to the EPU.

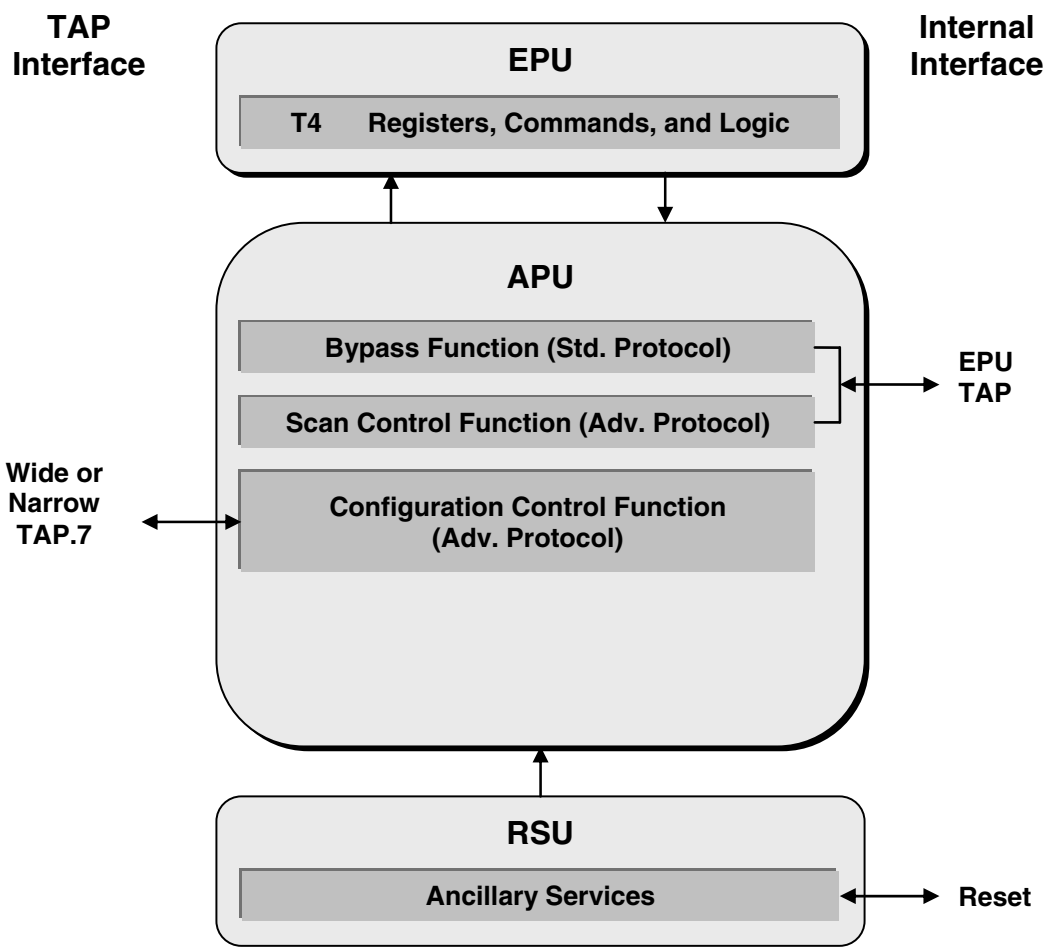

Figure 59-10. Conceptual block diagram of the APU functions

The APU's internal interface includes a connection to EPU registers, the EPU's TAP interface, connections to chip-level data channels (when they are implemented), and reset signaling with the EPU. The APU's TAP interface provides mutually exclusive use of the TMSC pin for:

- Bypass Function
- Scan Control Function
- Configuration Control Function

When the Standard Protocol is used, the APU's Bypass function connects the EPU directly to the TAP.7 pins. When the TDIC and TDOC pin functions are not available (narrow TAP.7 or TDIC and TDOC pin functions are an alternate function), the APU sources a logic 1 to the EPU inputs associated with these pins.

When the Advanced Protocol is used, the APU multiplexes the use of the TMSC pin between the other APU functions. Scan Control acts as a serial to parallel converter, translating the parallel information at the EPU's TAP interface into bidirectional serial transfers. Since the Scan Control is literally a protocol adaptor, the entire EPU infrastructure (ZBS detection, control-level management, and command generation) is utilized when either the Standard or Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state progression.

59.8.2 Operation

The conceptual view of the APU operation is shown in the following figure.

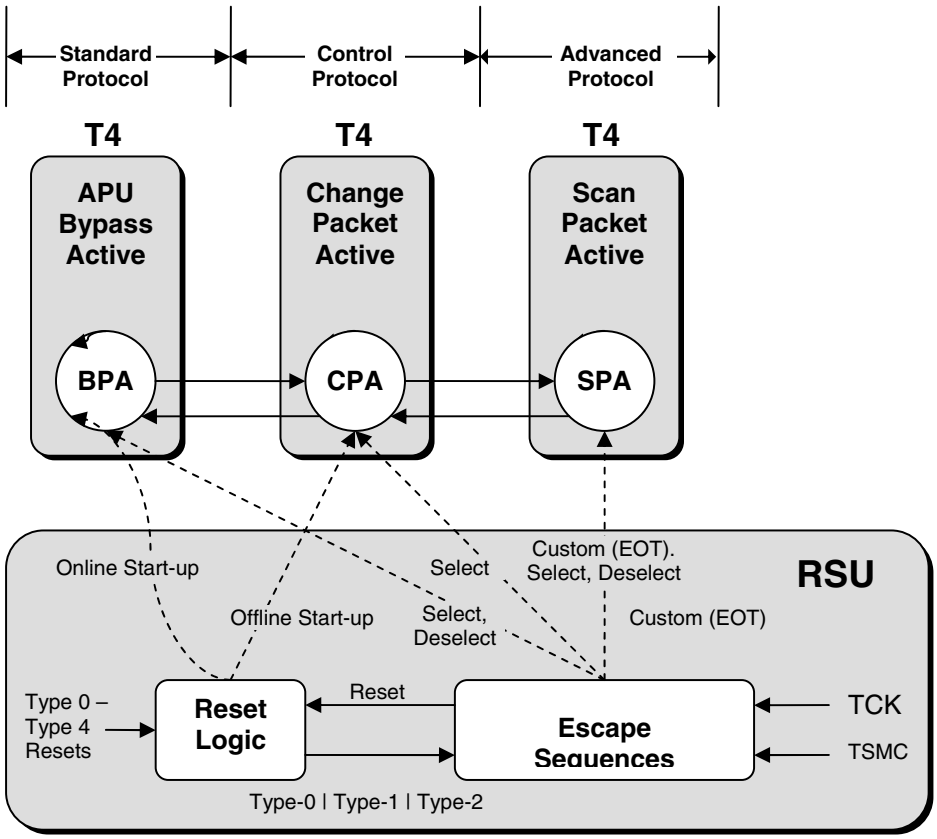

Figure 59-11. Conceptual view of APU operation

The APU operating states managing the use of the TAP pins and the ancillary (RSU) services use of the TMSC pin.

APU operating states:

- ***BPA*** – **B**y**P**ass **A**ctive
- ***CPA*** – **C**hange **P**acket **A**ctive
- ***SPA*** – **S**can **P**acket **A**ctive

59.8.2.1 BPA

The *BPA* state allocates the use of the TMSC pin to the Standard Protocol. This state is entered two ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up online.
- From the CPA state when a TAP.7 controller register write specifies the use of the Standard Protocol.

59.8.2.2 CPA

The *CPA* state allocates the use of the TMSC pin to a CP. This state is entered in one of three ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up offline.
- A value specifying the use of the Advanced Protocol is written to the SCNFMT Register when using the Standard Protocol.
- A TAP.7 controller register write occurs when using the Advanced Protocol.

59.8.2.3 SPA

The SPA state allocates the use of the TMSC pin to an SP. This state is entered when the SCNFMT Register specifies the use of the Advance Protocol when a CP ends.

59.8.3 Escape sequences

Escape-sequence detection provides services to the Reset Logic, Scan, Configuration Control, and Transport Control functions as outlined below:

- **Scan and Transport Control** – End of Transfer (EOT) escape sequence detected.
- **Configuration Control** – Synchronize Advanced Protocol (SAP) escape sequence.
- **Reset Logic** – Reset (RES) escape sequence detected.

An EOT escape sequence is used to increase the efficiency of OScan Scan formats.

An SAP escape sequence is used to place TAP.7 controllers online.

A RES escape sequence asynchronously causes generation of a Type-3 Reset. Following a RES escape sequence, the drive of the TMSC pin is inhibited so it is not driven when TCKC becomes a logic 0 immediately following the RES escape sequence.

59.8.4 Signal behaviors

The TCKC signal:

- The test clock

The TMSC signal:

- An input when the Standard Protocol is used
- Bi-directional when the Advanced Protocol is used

The TDI and TDO signals:

- Deleted with a narrow TAP.7
- One of two functions with a wide TAP.7
  - Fixed – as the TAP.7 TDIC and TDOC pin functions, or
  - Programmable – as the TAP.7 TDIC and TDOC signal functions or alternate functions with a TAP.7 controller reset establishing the default signal function.

59.8.5 APU Functions

59.8.5.1 Bypass Active (BPA) Function

When the Standard Protocol is used, the APU connects the EPU inputs and outputs directly to the TAP.7 pins. If the TDIC and TDOC pin functions are not present (e.g., a narrow TAP.7 or the TDIC and TDOC pins have an alternate function assigned to them), the APU provides a logic 1 to the EPU for unsupported pin functions and ignores the EPU's TDO output data.

59.8.5.2 Scan Packet Active (SPA) Function

The Scan Control function is encapsulated within the Scan Packet Active (SPA) state. With the Standard Protocol, the external tool and TAP.7 exchange the scan information associated with a single TAPC state machine state in one TCK period using the TMS(C), TDI(C), and TDO(C) pins. With the Advanced Protocol all or part of this information is exchanged serially within a Scan Packet (SP) as shown in . There is a one to one correspondence between SPs and TAPC state machine state changes, except when the SPA state precedes the CPA state. In this case the SP preceding a CP does not advance the TAPC state machine state.

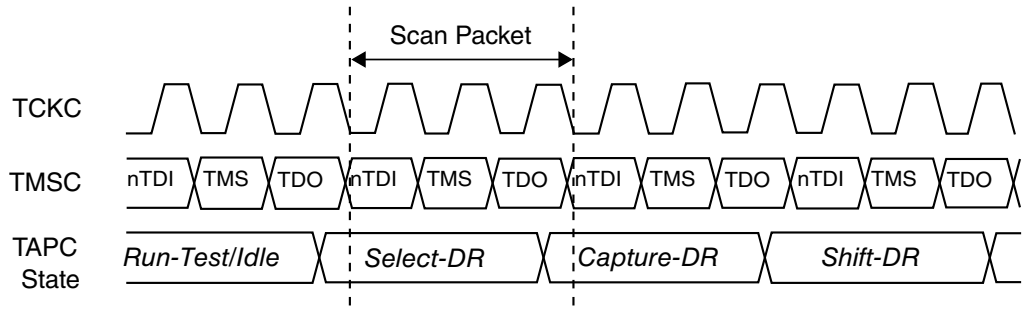

Figure 59-12. Scan Packet Sequence

A comparison of the parallel transfer of TAP information with the Standard Protocol and the serialization and de-serialization of the TAP information using the TCKC and TMSC pins with the Advanced Protocol is shown in FIGURE. The IEEE 1149.1 signals between the EPU and STL are prefixed with SYS_.

The APU manages the serialization and de-serialization of the scan information. The APU converts the TDI and TMS information within a Scan Packet (SP) into the TMS and TDI information presented to the EPU. It converts the combination of the EPU TDO and EPU TDO_OE signals into the TDO information in the same SP. If the EPU indicates that the TDO pin drive is not enabled, logic 1 TDO data is created, otherwise the TDO data is the supplied by either the EPU or STL.

Information within a Scan Packet is first passed from the external tool to the TAP.7 followed by information passed from the TAP.7 to the external tool. In this example the scan format specifies the exchange of the TMS, TDI, and TDO TAPC information. Each TAPC state machine state takes three TCKC periods. Other scan formats specify the exchange of different mixes of information. Control information is added with the most flexible scan formats. Some scan formats send less information and consequently take fewer TCKC periods.

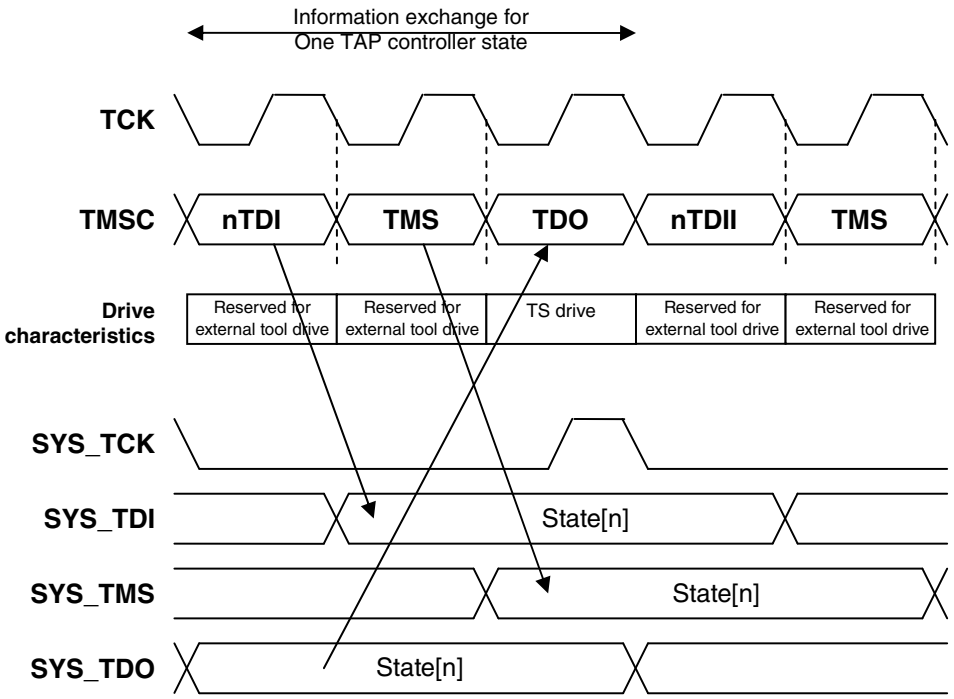

Figure 59-13. Serialization and De-serialization of Scan Packet Information

In order to produce comparable TAPC state machine state rates with a TAP.1 and TAP.7 controller:

- Full-cycle timing between the external tool and TAP.7 allows operation at higher TCKC frequencies.
- The number of bits transferred to advance a TAPC state machine is minimized. (reaching as few as one for some scan formats.)

The TAP.7 controller provides both full-cycle bit timing (falling TCKC edge to falling TCKC edge) and half-cycle bit timing (falling TCKC edge to rising TCKC edge), with a TAP.7 register used to define the type of timing used. Half-cycle timing is used as the default following a TAP.7 controller reset. The TCKC frequency is reduced to accommodate half-cycle timing.

With full-cycle timing, the TMSC input and output data are both output with and sampled with the falling edge of the TCKC. This means that the entire TCKC period may be spent transferring a bit from the external tool to the TAP.7 or vice-versa. The TCKC frequency can therefore be maximized when full-cycle timing is used. With half-cycle timing, the APU samples the TMSC input data with the rising edge of the TCKC and outputs TMSC data with the falling edge of TCKC.

Minimizing the number of bits transferred per TAPC state machine state is affected by a number of factors. The information that must be transferred per TAPC state machine state varies for different test and debug applications. Also, with some test and debug

applications, all TAPC state machine states do not require that the same amount of information be transferred. This is especially true with debug applications where specialized use of the TAP is more likely.

59.8.5.3 Control Process Active (CPA) Function

While using the Advanced Protocol, all TAP.7 configuration changes occur within the CPA state. All online and offline transitions also occur while in the CPA state. When entering the CPA state from the BPA or SPA state, the CPA state checks for the use of supported features affecting the Advanced Protocol. The CPA state is exited when the enabled features affecting the Advanced Protocol are supported.

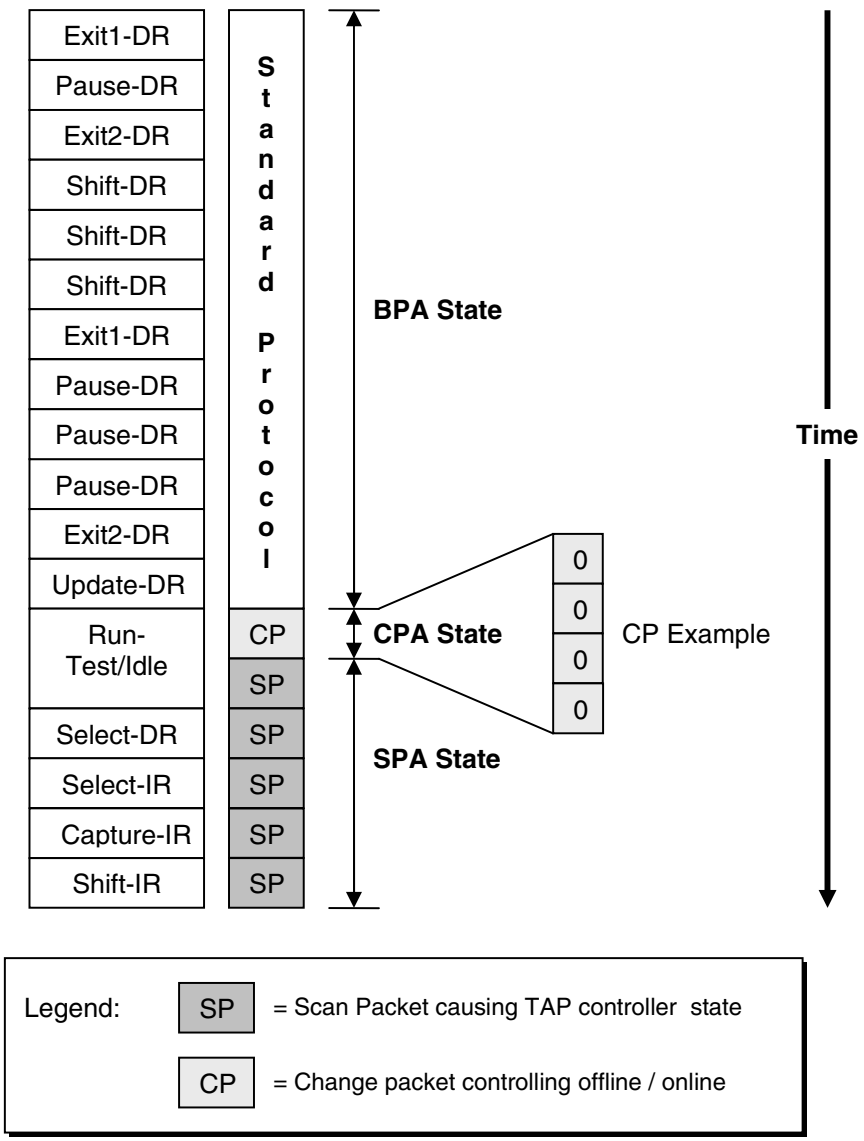

Figure 59-14. CPA State Entry from BPA State with Continued Online Operation

An SP preceding a CP does not advance the TAPC state machine state. This SP performs housekeeping functions that assure the contents of the SP preceding this SP have been fully utilized. This has significance when the SP contains control information that allows the STL to stall the completion of a SP.

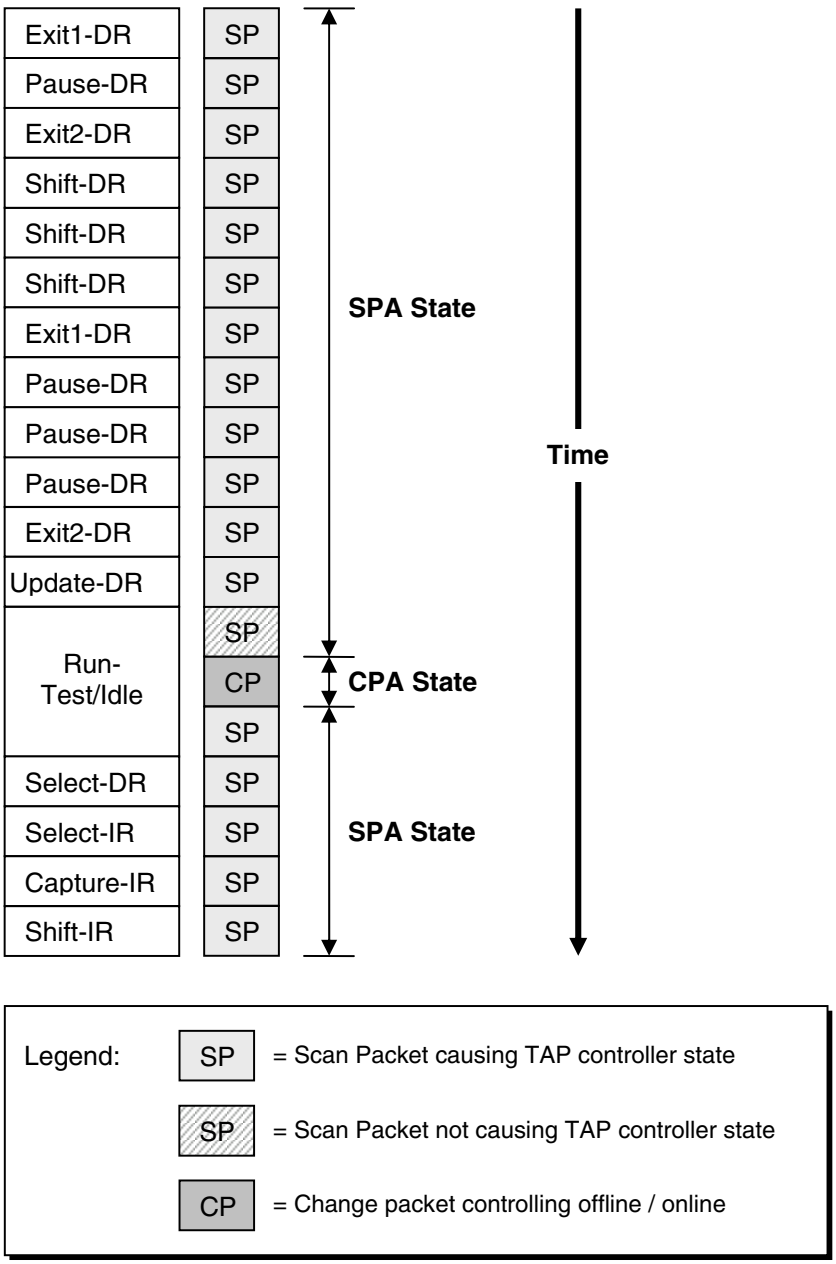

Figure 59-15. CPA State Entry from the SPA State with Continued Online Operation

When an unsupported feature is enabled, the TAP.7 controller is placed offline. This suspends the TAP.7 controller's operation at a point where its operation may later be synchronized to the remainder of the system. The APU stops advancing the EPU's and CLTAPC's TAPC state machine state while offline. It also suspends Data Channels activity while offline. The detection of the appropriate Online Activation Protocol while

the TAP.7 controller is offline places the TAP.7 controller online and causes an exit from the CPA state to the SPA state. An offline to online transition initiates the use of a predefined set of mandatory features in all online TAP.7 controllers to assure they operate synchronously.

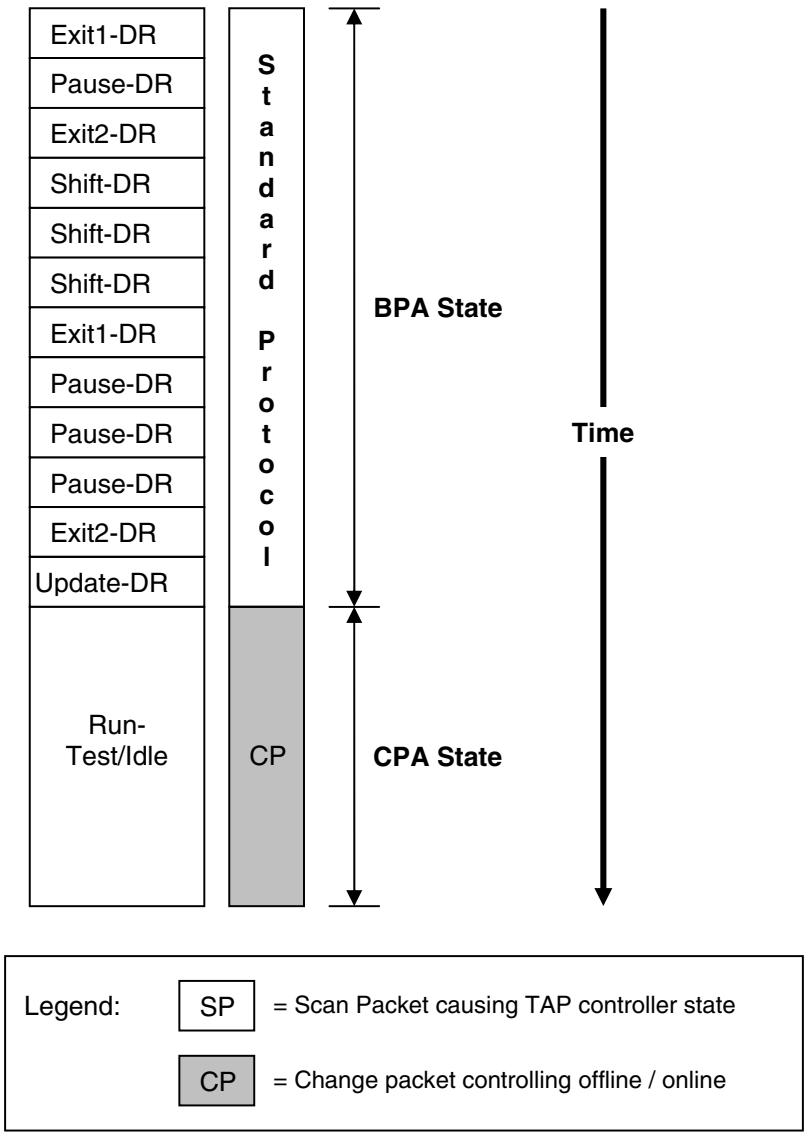

Figure 59-16. CPA State Entry from the BPA State with Offline Operation

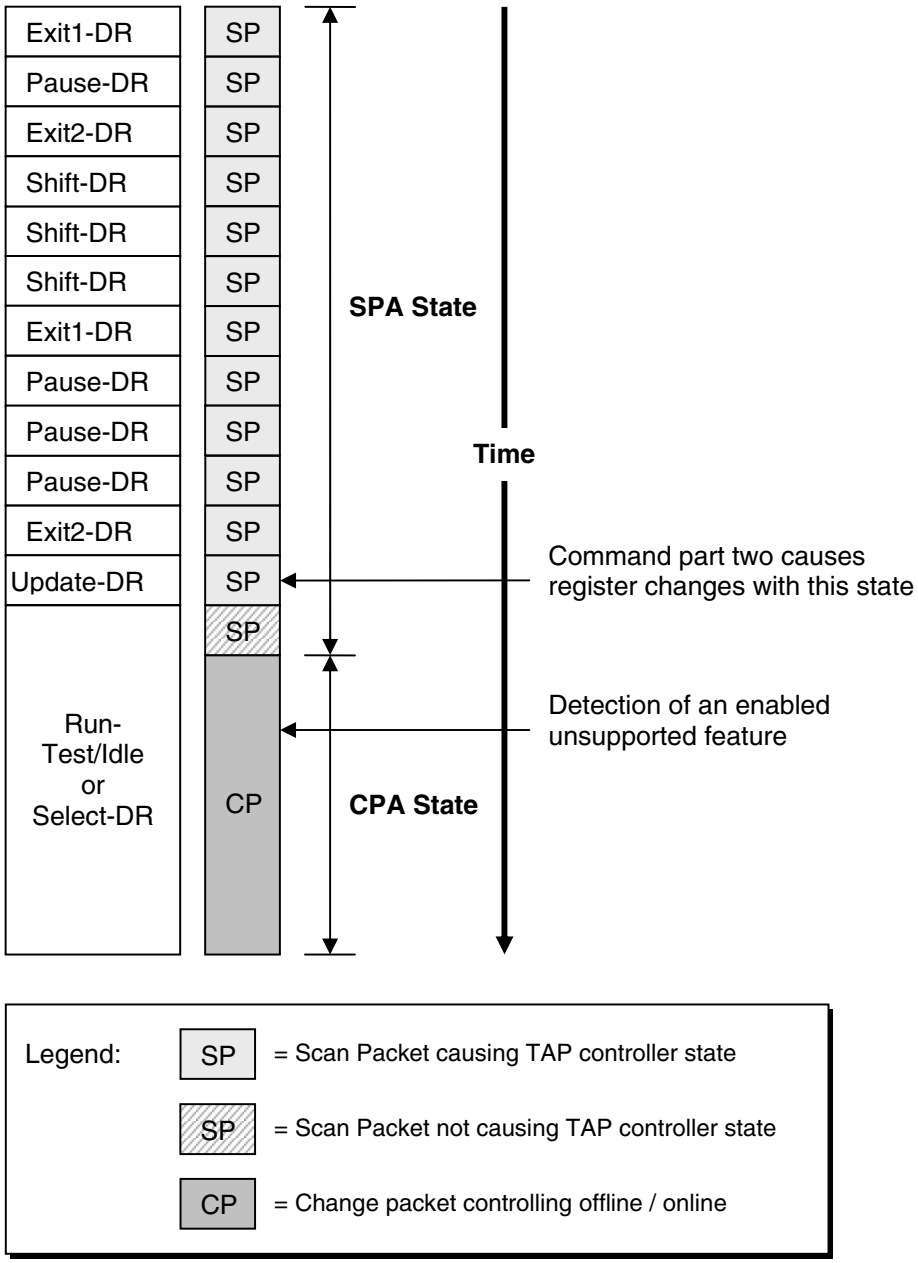

Figure 59-17. CPA State Entry from the SPA State with Offline Operation

A TAP.7 controller reset places the TAP.7 controller offline when the offline at start-up option is used. From this point the TAP.7 controller awaits being placed online.

59.8.6 Configuration Change Packets (CP)

A Change Packet (CP) is composed of three element types:

- **Preamble** – A 1-bit value that is a don't care. This bit facilitates a Standard to Advanced Protocol change with some external tool implementations.

- **Body** – Two or more bits representing one or more CP directives
  - **00** – CP_END
  - **01** – CP_NOP (extends the body by 1-bit)
  - **10** – CP_NOP (extends the body by 1-bit)
  - **11** – CP_RES (Generate a Type-3 TAP.7 controller reset coincident with the post amble bit.
- **Post amble** – A 1-bit value that is a don't care. This bit facilitates and Advanced to Standard Protocol change with some external tool implementations.

A minimum-length CP has a Preamble, a 2-bit Body, and a Post amble. This can be as simple as four logic zero values.

59.8.7 Scan Packet

A Scan Packet defines the period of TMSC pin activity where control information exchanged by the external tool and TAP.7 controller affects the TAPC state, except when the SP precedes a Change Packet. The external tool should view the Scan Packet as:

- Exchanging only the necessary TAPC information (TMS, TDI, and TDO or some subset thereof)
- Causing an advance of the TAP.7 TAPC state when it is not followed by a Change Packet.
- Causing an advance of the STL TAPC state when it is not followed by a Change Packet and when the STL is coupled.

With this perspective, the external tool views Scan Packets as running a virtual TAPC state machine at the TAP.7 pins. The effects of each Scan Packet take effect when the Scan Packet completes. The real TAP.7 and STL controller state machine states may change state before or after the virtual state machine.

59.8.8 SP Format

A SP serially exchanges the TDI, TMS, and TDO or a subset thereof, between the external tool and TAP.7 controller. Control information may be added to this exchange. A SP has three parts:

- **Payload** – Data + Control information (all scan formats), the payload content is varied to trade-off performance and flexibility. RDY bit(s) within the payload are included with some scan formats to provide the STL a means to stall progression of the TAPC state.
- **Delay** – Control information (optional) providing separation of adjacent payloads in time. Delay elements support simple external tool implementations where a delay element is used to stall progression of the TAPC state while it develops a new SP following the completion of the prior payload.

The header elements, delay elements, and control information within the payload element is consumed by the TAP.7 controller. This and other control information within the SP payload is not visible to the EPU and STL TAPCs.

59.8.8.1 Payload Element Content

59.8.8.1.1 Input and Output Bit Frames

An input bit frame is sourced by the external tool and an output bit frame is sourced by the TAP.7 controller. The payload may contain and input bit frame, an output bit frame, or both. When an input bet frame arrives at the TAP.7 controller, the TDI and TMS information within it is presented in parallel to the TAP.1 controllers within the EPU and STL. The output bit frame begins when the input frame is completed. The payload is completed when the EPU and STL are ready to utilize this information and the TDO data needed to complete the output bit frame is available. This process is repeated for each SP.

With input bit frames, MScan and OScan scan formats have no control bits input bit frames.

With output bit frames:

- TDO information passed to the external tool is a logic 1 when the EPU indicates the TDO pin would be high impedance.
- RDY bits provide TAP.7 stall opportunities with MScan and some OScan formats.
- PC0 and PC1 bits are added to MScan scan formats to allow Wire-ANDed output.

59.8.8.1.2 Varying the content of input and output bit frames

The various scan formats (MScan, OScan0-7) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. These scan formats vary the content of SPs to balance flexibility and performance for different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. The MScan and OScan scan formats determine the factors affecting the payload content as shown in the following table.

Table 59-23. Factors determining the SP payload content

Scan format	Payload content determined by the:	
	TAPC state	Header
MScan	–	–
OScan	Yes	–

59.8.8.2 Delay Element Content

A delay element can be zero, one, two, or n bits in length. One and two bit delay elements are fixed length with neither the external tool or TAP.7 controller driving the TMSC pin. The TMSC pin is kept at the last value driven by either the external tool or TS. With an n-bit delay elements, the external tool drives the TMSC pin for the first n-1 bits and may drive the TMSC pin the nth bit. With an n-bit delay element the string of delay element bits is a series of directives virtually the same as those used by a CP (DLY_NOP, DLY_END, and DLY_RES).

59.8.8.3 Scan Formats

59.8.8.3.1 Overview

Scan formats utilizing the Advanced Protocol address different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. In one extreme two types of control information, the first allowing the stall of the completion of the Scan Packet, and the second supporting the Wire-AND of TAP.7 controller output are added to the TMS, TDI, and TDO information within the Scan Packet. In the other extreme, the external tool may minimize the information transferred for each TAPC state using its understanding of the application and transfer only the data of interest. In some cases the transfer of only one bit of information per TAPC is

required. There are a number of scan formats that operate between these two extremes. The external tool chooses a scan format that best matches the performance/functionality needs of the application.

The scan formats added to specify the use of the Advance Protocol are listed below:

- **MScan** – Maximum flexibility.
- **OScan0-7** – Optimized for test and debug applications.

These scan formats provide seven different functions. Five factors have influenced the definition of these scan formats:

- Supporting the capabilities of the IEEE1149.x and IEEE 1532 Standards.
- Providing the STL and external tool an opportunity to stall the TAPC state progression.
- Providing a minimum pin count and scalable functionality.
- Maximizing the efficiency of scan operations utilized for applications debug operations.
- Providing a rich set of capability for high end applications debug.

The performance and flexibility of MScan and OScan scan formats are shown in Table 59-24 and Table 59-26. The performance and flexibility of these scan formats are given subjective/approximate ratings in these tables. These ratings range from least to best. Use cases for these scan formats are also included in these tables.

59.8.8.3.2 MScan scan formats

The MScan scan format provides a universal scan function. It is the most flexible but lowest-performance scan format. The Scan Packets used by these scan formats are packed with data and control information and is the same for all TAPC states. This scan format accommodates the deployment of IEEE 1149.1 IP with non-compliant behavior within the STL. The STL is allowed to stall the TAPC state progression (to pace the arrival of Scan Packets with its ability to process them), and uses Wire-ANDed Output.

Table 59-24. MScan scan format use case summary

Scan format	Supporting	Performance	Flexibility	TCKC source
MScan	STL Stalls	Least	Best	External tool or TS
	Test			
	Non-compliant behavior STL IP			

Table continues on the next page...

Table 59-24. MScan scan format use case summary (continued)

Scan format	Supporting	Performance	Flexibility	TCKC source
	Multi-chip debug communication			
	Controller ID Allocation			

Table 59-25. MScan Scan Packet content

	Non-shift TAP controller states							Shift TAP controller states					
MScan	nTDI	TMS	PC0	RDY	PC1	TDO		nTDI	TMS	PC0	RDY	PC1	TDO

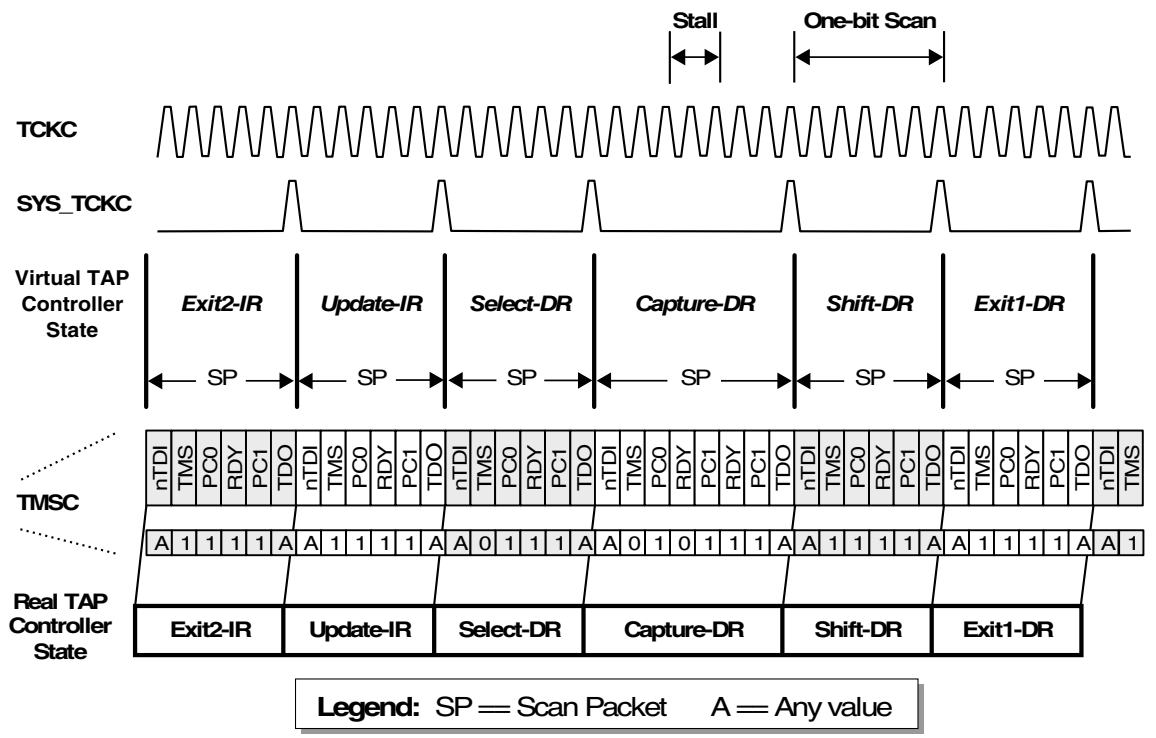

Figure 59-18. MScan Transaction

59.8.8.3.3 OScan Scan Formats

The OScan scan formats provide optimization choices where no knowledge of the data content of the scan exchange is needed. The Scan Packet content of these scan formats is modulated by a combination of the scan format and the TAPC state for some OScan scan formats. For instance, TDI data and TDO data is not exchanged for non-shift TAPC states and included in shift TAPC states in certain OScan formats. The modulation of Scan Packet content with TAPC state varies by scan format.

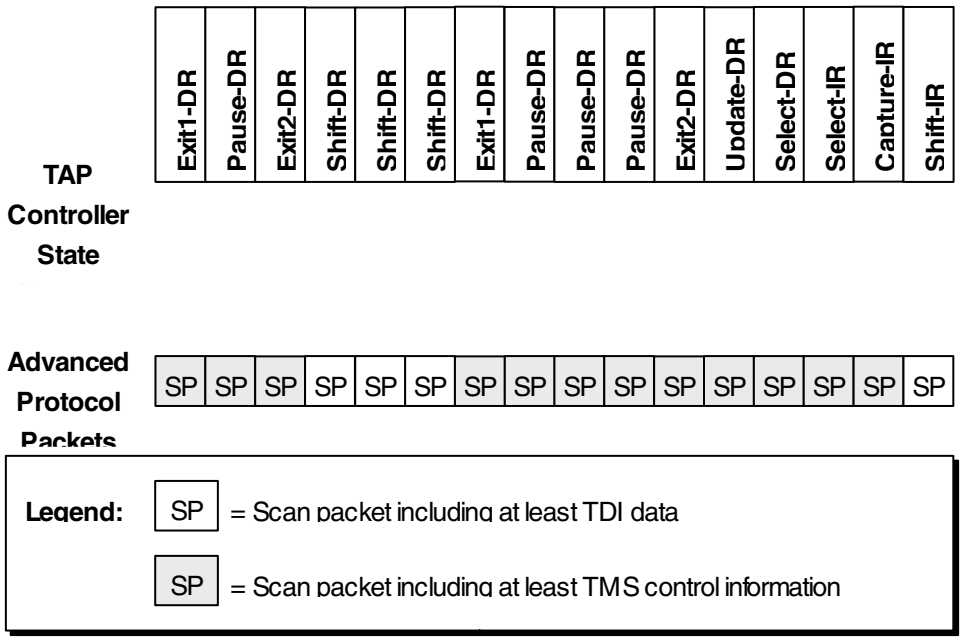

Figure 59-19. OScan Scan Packet content/TAPC state relationships

OScan scan formats replicate four functions in two forms:

- **OScan0 – OScan3:** Providing the best performance for a test clock source by the target system.
- **OScan 4 – OScan7:** Providing the best performance for a test clock sourced by the external tool.

The OScan4 – OScan7 scan formats are more efficient, as EOT escape sequences are used to identify an exit from the Shift-xR TAPC state. A Scan Packet associated with the Shift-xR TAPC state does not include a TMS bit. Instead, and EOT escape sequence overlaid on an nTDI bit causes an exit from shift TAPC state with no exit from this state occurring otherwise. A look at the 32-bit DR-Scan shows the impact of this optimization. A total of 96 bits are required when each Scan Packet associated with a Shift TAPC state when TMS is included in these Scan Packets while a total of 64 bits are required when TMS is not included in these Scan Packets. Assuming the EOT escape adds the equivalent of three bit periods, the number of TCK periods fo this transfer is 67/96 or roughly 70% of the total without this optimization.

These scan formats may only be used with an external tool sourced TCKC as EOTs are utilized to improve its performance. The OScan0 – OScan3 Scan Formats always have a TMS bit included in the Scan Packet. The OScan scan format use case summary is shown in the following table.

Table 59-26. OScan scan format use case summary

Scan Format	Supporting	Performance	Flexibility	TCKC Source
OScan0	Stalls	↓	Best	External tool
OScan1	Test		↑	
OScan2	Debug Performance			
OScan3	Debug Downloads (input only)	Best		
OScan4	Stalls	↓	Best	External tool or TS
OScan5	Test		↑	
OScan6	Debug Performance			
OScan7	Debug Downloads (input only)	Best		

Certain OScan optimizations are applied in a hierarchical manner.

- **Optimization I:** OScan1/OScan5 – RDY bit(s) and their trailing ONE bits are deleted from all Scan Packets.
- **Optimization II:** OScan2/OScan6 – Optimization I + nTDI and TDO bits are deleted from Scan Packets associated with non-shift TAPC states.
- **Optimization III:** OScan3/OScan7 – Optimization II + TDO bits are deleted from Scan Packets.
- **Optimization IV:** OScan4 – OScan7 – TMS bits are deleted from Scan Packets associated with shift TAPC states.

Table 59-27. OScan Scan Format "Payload"

59.9 Functional Description

This section combines the information given in the Ancillary Services, EPU Operation, and APU Operation sections into a single reference for performing common TAP.7 tasks.

59.9.1 Switching from Standard Protocol to Advanced Protocol

Upon exit of Type-0 to Type-4 reset, the CJTAG begins operation in Standard Protocol 4-pin mode. The following steps are required to move from Standard Protocol 4-pin mode to Advanced Protocol (either 4-pin or 2-pin) mode.

The first step required to move to the Advanced Protocol is to change the CJTAG control level to control level 2 via zero-bit scans (ZBS), as described in Control levels.

After the control level is set tocontrol level 2, TAP.7 commands can be executed as described in EPU Commands. Execution of the Store Scan Format (STFMT) to set the scan format to any OSCAN0-7 or MSCAN format begins the switch from the Standard Protocol to the Advanced Protocol.

Once the STFMT command is executed selecting an Advanced Protocol scan format, the CJTAG transitions to the intermediate Control Protocol mode. The Control Protocol uses TMS inputs to control Configuration Change Packets as described in Control Process Active (CPA) Function and Configuration Change Packets (CP). Loading a change packet body value of 00 (CP_END) results in the switch to the Advanced Protocol.

If Advanced Protocol 2-pin operation is desired, the APFC register should be written to a value of 10 or 11 prior to the execution of the STFMT command that selects an advanced scan format. The APFC register is written via the Store Conditional 2-bit (STC2) command described in Store Conditional 2-bit (STC2).

Chapter 60
Nexus Port Controller (NPC)

60.1 Chip-specific NPC information

60.1.1 NPC configuration

This device contains two instances of the NPC module: NPC_0 and NPC_1. NPC_0 is responsible for the traces and interaction with pads and remains in full power domain. NPC_1 exists in always on domain and is used for low power handshaking with the debugger.

The NPC_PCR for NPC_0 is shown below.

Register index: 127

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

60.1.2 EVTO sharing - Pulse time

In this device, whenever a Nexus client drives EVTO input of NPC for one S80 period, the NPC drives EVTO on pad for one S80 period on the following clock.

60.1.3 Trace messages for transactions with error responses

For transactions of trace clients which result in error responses, traces may or may not be generated. Such transactions will be reported to MEMU.

The Nexus clients in this device do not perform speculative execution. When speculative execution is done, a trace message may be output before it is known whether the branch was actually taken. Since the Nexus clients in this device do not support it, the CANCEL field is not present in the trace messages of this device.

60.1.4 Trace loss during resets

Whenever reset occurs (reset which breaks debugger trace connection) and nexus tracing is ON, debug trace data stored in internal FIFO corresponding to instructions executed before reset instruction will be lost.

60.1.5 EVTI_IN pin

EVTI_IN is an active low signal. The NPC Port Configuration Register's EVT_EN bit configures the EVTI_IN and EVTO_B pins for EVTI/EVTO port functionality. If it is chosen by the user to not use this configuration and to use the SIUL_MSCR configuration register for this purpose, then it is recommended that the user also sets the PUE and PUS bits to 1 along with setting the IBE and SSS configurations. Otherwise, a 0 event may be seen in EVTI_IN which will trigger the EVTI functions in chip.

60.2 Introduction

The following figure is a block diagram of the Nexus Port Controller (NPC) block.

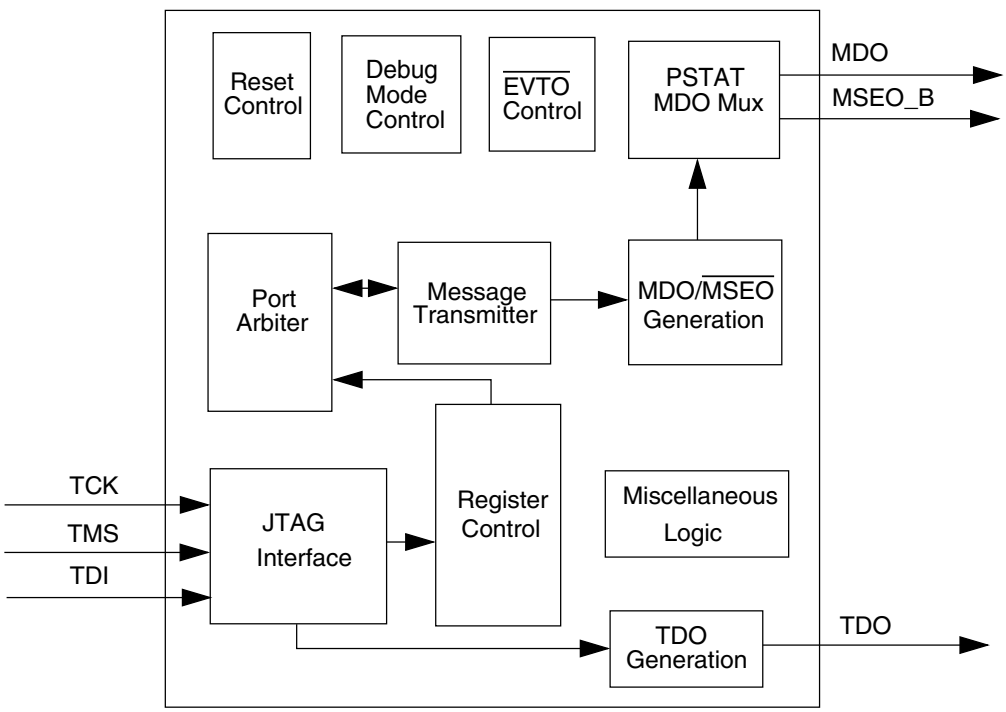

Figure 60-1. Nexus Port Controller Block Diagram

60.2.1 Overview

On a system-on-a-chip device, there are often multiple blocks that require development support. Each of these blocks implements a development interface based on the IEEE-ISTO 5001-2001 standard. The blocks share input and output ports that interface with the

development tool. The NPC controls the usage of the input and output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

60.2.2 Features

The NPC block performs the following functions:

- Controls arbitration for ownership of the Nexus Output Port
- Nexus Device Identification Register and Messaging
- Generates MCKO enable and frequency division control signals
- Controls sharing of $\overline{\text{EVTO}}$
- Generates an MCKO clock gating control signal to enable gating of MCKO when the auxiliary output port is idle
- Control of the device-wide debug mode
- Generates asynchronous reset signal for Nexus blocks based on censorship status, and power-on reset status
- System clock status indication via MDO[0] following power-on reset
- Provides Nexus support for censorship mode

60.2.3 Modes of operation

The NPC block uses the censorship status signal and an internal power-on reset indication as its primary reset signals. Upon exit of reset, the mode of operation is determined by the Port Configuration Register (PCR) settings.

60.2.3.1 Reset

The NPC block is asynchronously placed in reset when either power-on reset is asserted , the device enters censored mode , or the TAP controller state machine is in the Test-Logic-Reset state. Holding TMS high for 5 consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state.

Following negation of power-on reset, the NPC remains in reset until the system clock achieves lock. The NPC is unaffected by other sources of reset. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state
- The output port pins are negated
- The TDI, TMS, and TCK TAP inputs are ignored (when in power-on reset, censored mode
- Registers default back to their reset values

60.2.3.2 Disabled-Port Mode

In disabled-port mode, output pin port enable signals are negated, thereby disabling message transmission. Any debug feature that generates messages can not be used. The primary features available are class 1 features and read/write access to the registers. Class 1 features include the ability to trigger a breakpoint event indication through $\overline{\text{EVTO}}$.

60.2.3.3 Full-Port Mode

Full-port mode (FPM) is entered by asserting the MCKO_EN and FPM bits in the PCR. In All trace features are enabled or can be enabled by writing the configuration registers via the TAP. The number of MDO pins available is device-specific.

60.2.3.4 Reduced-Port Mode

Reduced-port mode (RPM) is entered by asserting the MCKO_EN bit and negating the FPM bit in the PCR. All trace features are enabled or can be enabled by writing the configuration registers via the TAP. The number of MDO pins available is device-specific.

60.2.3.5 Censored Mode

In censored mode, it should not be possible to read the contents of internal Flash externally. The NPC and all other Nexus blocks are held in reset when in censored mode , preventing Nexus read/write to memory mapped resources and the transmission of Nexus trace messages.

60.3 External signal description

60.3.1 Overview

The NPC pin interface provides for the transmission of messages from Nexus blocks to the external development tools and for access to Nexus client registers. The NPC pin definition is outlined in the following table. Pull information for the JTAG signals can be found in the JTAG chapter.

Table 60-3. NPC Signal Properties

Name	Port	Function	Reset State
EVTO_B	Nexus	Event Out pin	0b1
MDO	Auxiliary	Message Data Out pins	0[1]
MSEO	Auxiliary	Message Start/End Out pins	0b11
TCK	JTAG	Test Clock Input	—
TDI	JTAG	Test Data Input	—
TDO	JTAG	Test Data Output	High Z[2]
TMS	JTAG	Test Mode Select Input	—

1. Following a power-on reset, MDO[0] remains asserted until power-on reset is exited and the system clock achieves lock.
2. TDO output buffer enable is negated when the NPC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented on TDO at the SoC level.

60.3.2 Detailed signal descriptions

This section describes each of the signals listed in Table 60-3 in more detail. Note that the JTAG test clock (TCK) input from the pin is not a direct input to the NPC. The NPC requires two separate input clocks for TCK clocked logic, one for posedge (rising edge TCK) logic and one for negedge (falling edge TCK) logic. Both clocks are derived from the pin TCK, and generated external to the NPC.

60.3.2.1 EVTO_B — Event Out

Event Out ($\overline{\text{EVTO}}$) is an output pin that is asserted upon breakpoint occurrence to provide breakpoint status indication. The $\overline{\text{EVTO}}$ output of the NPC is generated based on the values of the individual $\overline{\text{EVTO}}$ signals from all Nexus blocks that implement the signal.

60.3.2.2 MDO — Message Data Out

Message Data Out (MDO) are output pins used for uploading OTM, BTM, DTM, and other messages to the development tool. The development tool should sample MDO on the rising edge of MCKO. The width of the MDO bus used is determined by reset configuration.

60.3.2.3 MSEO_B — Message Start/End Out

Message Start/End Out ($\overline{\text{MSEO}}$) is an output pin that indicates when a message on the MDO pins has started, when a variable length packet has ended, or when the message has ended. The development tool should sample $\overline{\text{MSEO}}$ on the rising edge of MCKO.

60.3.2.4 TCK — Test Clock Input

Test Clock Input (TCK) pin is used to synchronize the test logic and control register access through the JTAG port.

60.3.2.5 TDI — Test Data Input

Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK.

60.3.2.6 TDO — Nexus Test Data Output

Test Data Output (TDO) pin transmits serial output for instructions and data. TDO is three-stateable and is actively driven in the SHIFT-IR and SHIFT-DR controller states. TDO is updated on the falling edge of TCK and sampled by the development tool on the rising edge of TCK.

60.3.2.7 TMS — Test Mode Select

Test Mode Select Input (TMS) pin is used to sequence the IEEE 1149.1-2001 TAP controller state machine. TMS is sampled on the rising edge of TCK.

60.4 Register definition

This section provides a detailed description of the NPC registers accessible to the end user. Individual bit-level descriptions and reset states of the registers are included.

The following table shows the NPC registers by index values. The registers are not memory-mapped and can only be accessed via the TAP. The NPC block does not implement the client select control register because the value does not matter when accessing the registers.

Note that the bypass and instruction registers have no index values. These registers are not accessed in the same manner as Nexus client registers. Refer to the individual register descriptions for more detail.

Table 60-4. NPC registers

Index	Register
0	Device ID Register (DID)
127	Port Configuration Register (PCR)

60.4.1 Register descriptions

This section consists of NPC register descriptions.

60.4.1.1 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS instruction or any unimplemented instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

60.4.1.2 Instruction register

The NPC block uses a 4-bit instruction register as shown in the following table. The instruction register is accessed via the SELECT_IR_SCAN path of the tap controller state machine, and allows instructions to be loaded into the block to enable the NPC for register access (NEXUS_ENABLE) or select the bypass register as the shift path from TDI to TDO (BYPASS or unimplemented instructions).

Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in synchronous loading of the BYPASS instruction. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the BYPASS instruction. During the Capture-IR TAP controller state, the instruction register is loaded with the value of the previously executed instruction, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	3	2	1	0
R	Previous Instruction Opcode			
W	Instruction Opcode			
Reset:	BYPASS Instruction Opcode (0xF)			

60.4.1.3 Nexus Device ID (DID) Register

The device identification register, shown in the following figure, allows the part revision number, design center, part identification number, and manufacturer identity code of the part to be determined through the output port.

Register index: 0

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Part Revision Number				Design Center						Part Identification Number					
W																
Reset	PRN				DC						PIN					

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Part Identification Number				Manufacturer Identity Code											1
W																
Reset	PIN (cont'd)				0	0	0	0	0	0	0	1	1	1	0	1

Table 60-7. DID field descriptions

Bit	Name	Description
31:28	PRN	Part Revision Number These bits contain the revision number of the part
27:22	DC	Design Center These bits indicate the device design center
21:12	PIN	Part Identification Number These bits contain the part number of the device
11:1	MIC	Manufacturer Identity Code These bits contain the reduced Joint Electron Device Engineering Council (JEDEC) ID for NXP, 0xE.
0	Bit [0]	IDCODE Register ID Bit [0] identifies this register as the device identification register and not the bypass register

60.4.1.4 Port Configuration Register (PCR)

Register index: 127

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	FPM	MCKO_GT	MCKO_EN	MCKO_DIV			EVT_EN	Reserved	Reserved	0	0	0	Reserved		0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved	0	0	0	0	0	Reserved	Reserved	0	0	0	0	0	0	0	Reserved
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The PCR, shown in the figure above, is used to select the NPC mode of operation, enable MCKO and select the MCKO frequency, and enable or disable MCKO gating. This register should be configured as soon as the NPC is enabled.

NOTE

The mode or clock division must not be modified after MCKO has been enabled. Changing the mode or clock division while MCKO is enabled can produce unpredictable results.

Table 60-9. PCR field descriptions

Bit	Name	Description
31	FPM	Full Port Mode The value of the FPM bit determines if the auxiliary output port uses the full MDO port or a reduced MDO port to transmit messages. 0 A subset of MDO pins are used to transmit messages 1 All MDO pins are used to transmit messages
30	MCKO_GT	MCKO Clock Gating Control This bit is used to enable or disable MCKO clock gating. If clock gating is enabled, the MCKO clock is gated when the NPC is in enabled mode but not actively transmitting messages on the auxiliary output port. When clock gating is disabled, MCKO is allowed to run even if no auxiliary output port messages are being transmitted. 0 MCKO gating is disabled 1 MCKO gating is enabled
29	MCKO_EN	MCKO Enable This bit enables the MCKO clock to run. When enabled, the frequency of MCKO is determined by the MCKO_DIV field. 0 MCKO clock is driven to zero 1 MCKO clock is enabled
28:26	MCKO_DIV	MCKO Division Factor The value of this signal determines the frequency of MCKO relative to the system clock frequency when MCKO_EN is asserted. Table 60-10 shows the meaning of MCKO_DIV Values. In this table, SYS_CLK represents the system clock frequency.
25	EVT_EN	EVTO/EVTI Enable This bit enables the EVTO/EVTI port functions. 0 EVTO/EVTI port disabled 1 EVTO/EVTI port enabled

60.5 Functional Description

60.5.1 NPC reset configuration

The NPC is placed in disabled mode upon exit of reset. If message transmission via the output port is desired, a write to the PCR is then required to enable the NPC and select the mode of operation. Asserting MCKO_EN places the NPC in enabled mode and enables MCKO. The frequency of MCKO is selected by writing the MCKO_DIV field. Asserting or negating the FPM bit selects full-port or reduced-port mode, respectively.

The following table describes the NPC reset configuration options.

Table 60-11. NPC reset configuration options

Power On Reset status asserted?	MCKO_EN bit of the Port Configuration Register	FPM bit of the Port Configuration Register	Configuration
yes	X	X	Reset
no	0	X	Disabled
no	1	1	Full-Port Mode
no	1	0	Reduced-Port Mode

60.5.2 Auxiliary Output Port

The auxiliary output port is shared by each of the Nexus modules on the device. The NPC communicates with each of the Nexus modules and arbitrates for access to the port.

60.5.2.1 Output Message Protocol

The protocol for transmitting messages via the auxiliary port is accomplished with the $\overline{\text{MSEO}}$ functions. The $\overline{\text{MSEO}}$ pins are used to signal the end of variable-length packets and the end of messages. They are not required to indicate the end of fixed-length packets. MDO and $\overline{\text{MSEO}}$ are sampled on the rising edge of MCKO.

The following figure illustrates the state diagram for $\overline{\text{MSEO}}$ transfers. All transitions not included in the figure are reserved, and must not be used.

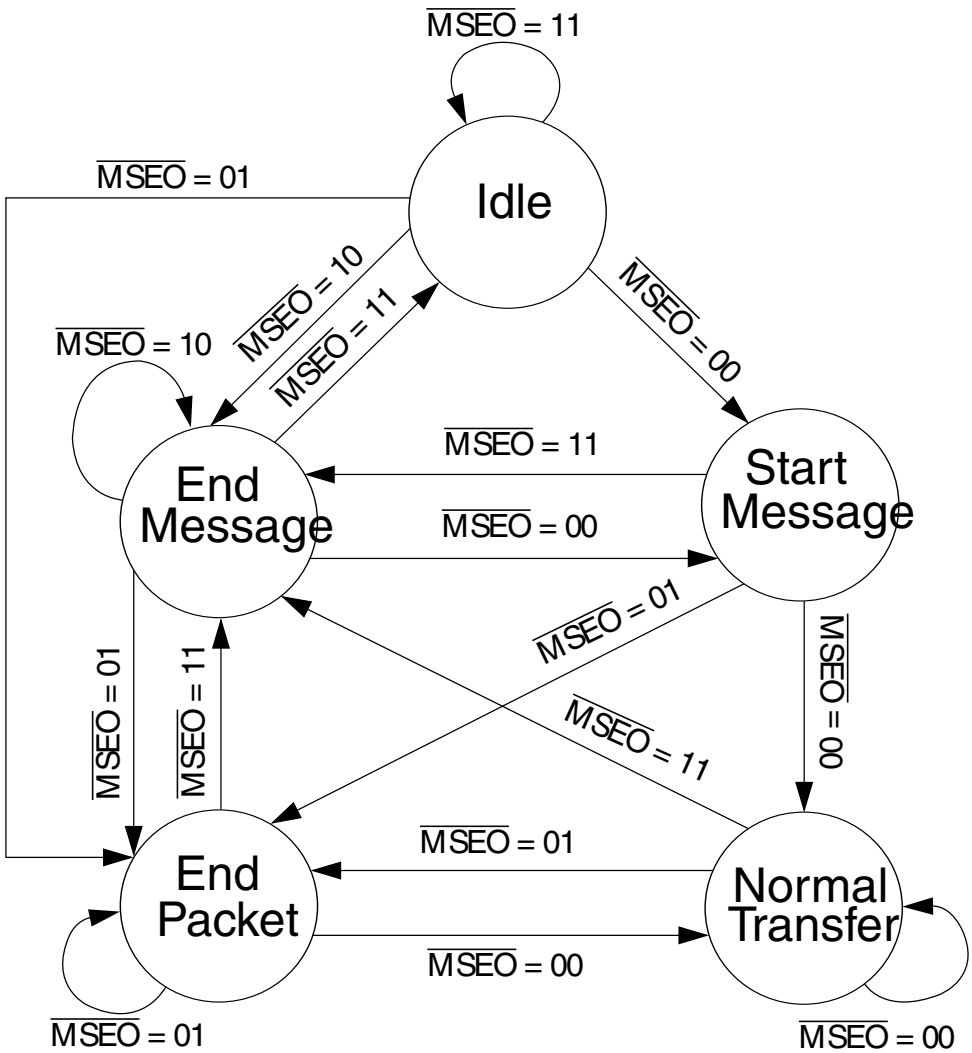

Figure 60-2. $\overline{\text{MSEO}}$ Transfers (for 2-bit $\overline{\text{MSEO}}$)

60.5.2.2 Output Messages

In addition to sending out messages generated in other Nexus blocks, the NPC can also output the device ID message contained in the device ID register on the MDO pins. The device ID message can also be sent out serially through TDO.

Figure 60-3 describes the device ID output message that the NPC can transmit on the auxiliary port. The TCODE is the first packet transmitted.

Message Name	Min. Packet Size (bits)	Max Packet Size (bits)	Packet Type	Packet Name	Packet Description
Device ID Message	6	6	fixed	TCODE	Value = 1
	32	32	fixed	ID	DID register contents

Figure 60-3. NPC output messages

60.5.2.3 Rules of Message

- A variable-sized field within a message must end on a port boundary. (Port boundaries depend on the number of MDO pins active with the current reset configuration.)
- A variable-sized field may start within a port boundary only when following a fixed-length field.
- Super-fields must end on a port boundary.
- When a variable-length field is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest order bit so that it can end on a port boundary.
- Multiple fixed-length packets may start and/or end on a single clock.
- When any packet follows a variable-length packet, it must start on a port boundary.
- The field containing the TCODE number is always transferred out first, followed by subsequent fields of information.
- Within a field, the lowest significant bits are shifted out first. The following figure shows the transmission sequence of a message that is made up of a TCODE followed by two fields.

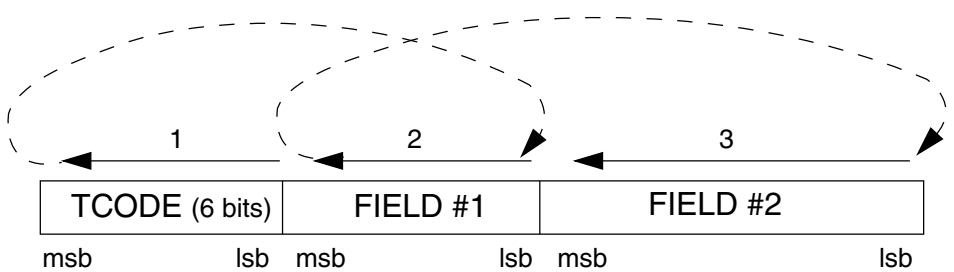

Figure 60-4. Transmission Sequence of Messages

60.5.3 IEEE 1149.1-2001 (JTAG) TAP

The NPC block uses the IEEE 1149.1-2001 test access port (TAP) for accessing registers. Each of the individual Nexus blocks on the device implements a TAP controller for accessing its registers as well. TAP signals include TCK, TDI, TMS, and TDO. There may also be other blocks on the MCU that use the TAP and implement a TAP controller.

Refer to the IEEE 1149.1-2001 specification for further detail on electrical and pin protocol compliance requirements.

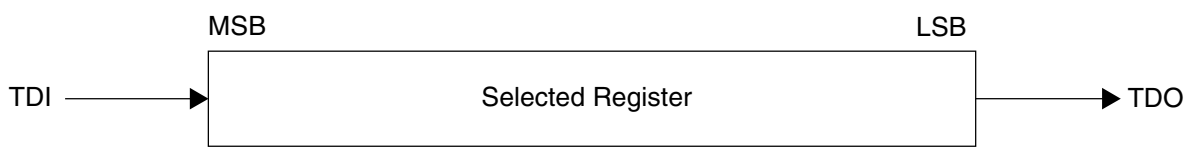
The NPC implements a Nexus controller state machine that transitions based on the state of the IEEE 1149.1-2001 state machine shown in Figure 60-6 . The Nexus controller state machine is defined by the IEEE-ISTO 5001-2001 standard. It is shown in Figure 60-7.

The instructions implemented by the NPC TAP controller are listed in the following table. The value of the NEXUS-ENABLE instruction is 0b0000. Each unimplemented instruction acts like the BYPASS instruction. The size of the NPC instruction register is 4 bits.

Table 60-12. Implemented Instructions

Instruction Name	Private/Public	Opcode	Description
NEXUS-ENABLE	public	0x0	Activate Nexus controller state machine to read and write NPC registers.
BYPASS	private	0xF	NPC BYPASS instruction. Also the value loaded into the NPC IR upon exit of reset.

Data is shifted between TDI and TDO starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.



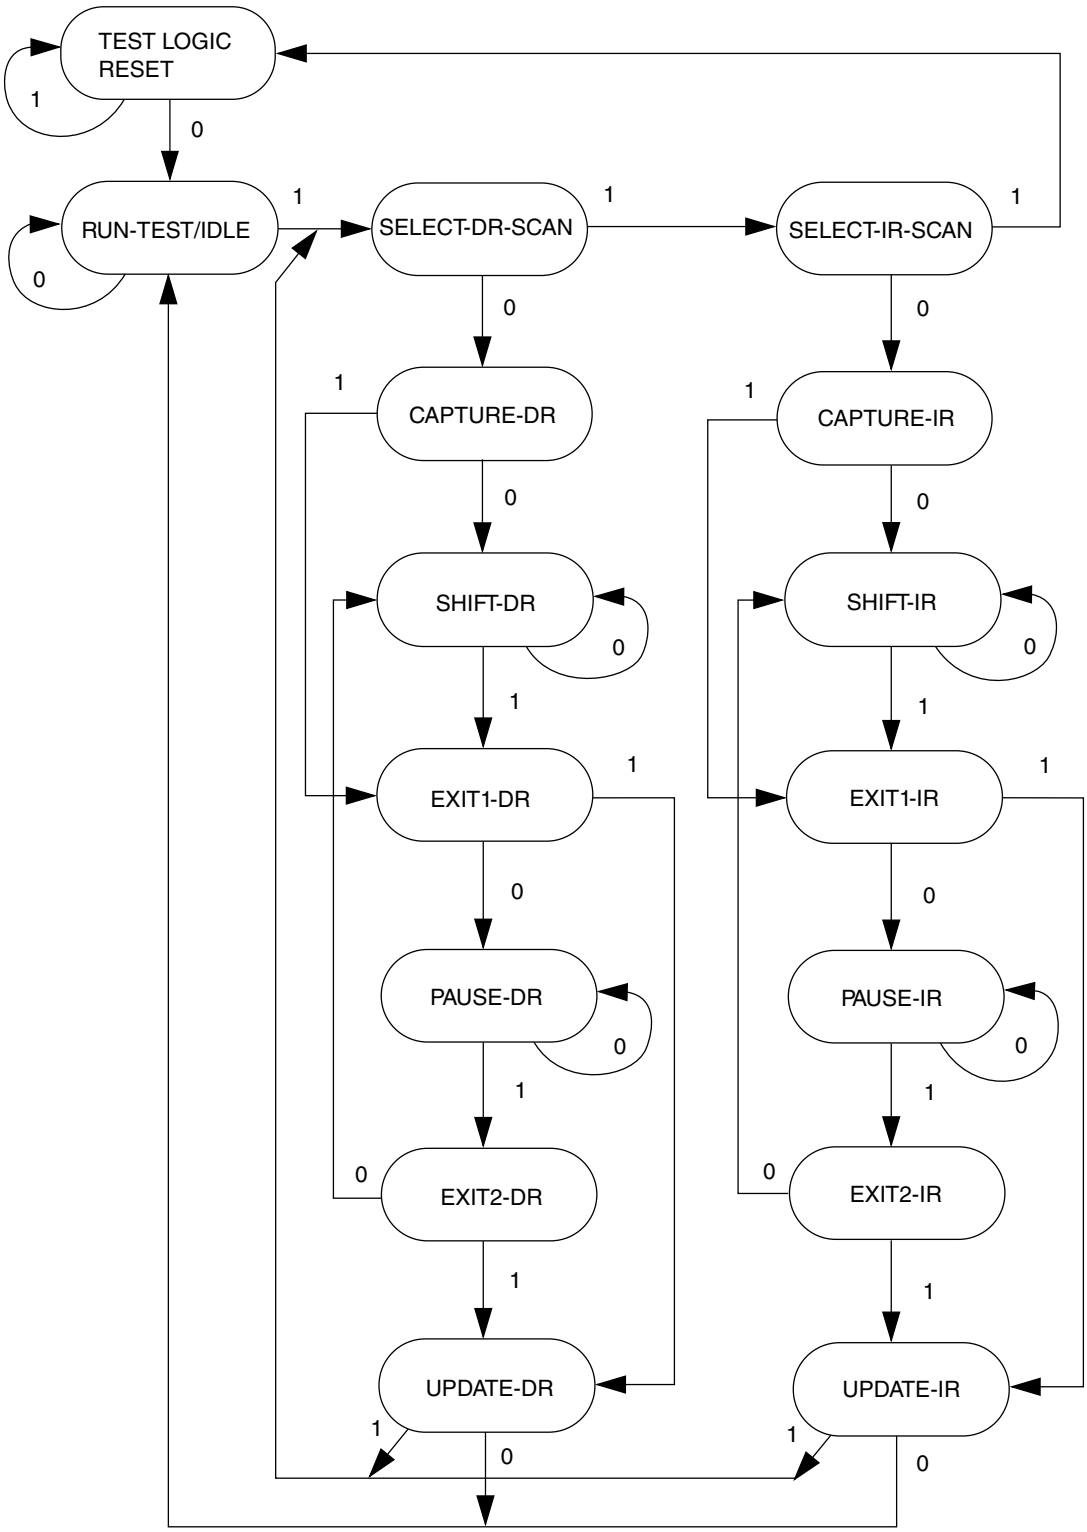


Figure 60-5. Shifting Data Into Register

60.5.3.1 Enabling the NPC TAP controller

Assertion of the power-on reset signal or entry into censored mode resets the NPC TAP controller. When not in power-on reset or censored mode, the NPC TAP controller is enabled by exiting the Test-Logic-Reset state. Loading the NEXUS-ENABLE instruction then grants access to Nexus debug.

NOTE: The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 60-6. IEEE 1149.1-2001 TAP Controller State Machine

60.5.3.2 Retrieving device IDCODE

The Nexus TAP controller does not implement the IDCODE instruction. However, the device identification message can be output by the NPC through the output port or shifted out serially by accessing the Nexus Device ID register through the TAP.

Transmission of the device identification message on the auxiliary output port MDO pins occurs immediately after a write to the PCR, if the NPC is enabled for auxiliary port mode. Transmission of the device identification message serially via the TAP is achieved by performing a read of the register contents as described in Selecting a Nexus Client Register.

60.5.3.3 Loading NEXUS-ENABLE Instruction

Access to the NPC registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in Figure 60-7, transitions to the REG_SELECT state. The Nexus controller has three states: idle, register select, and data access. Table 60-13 illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

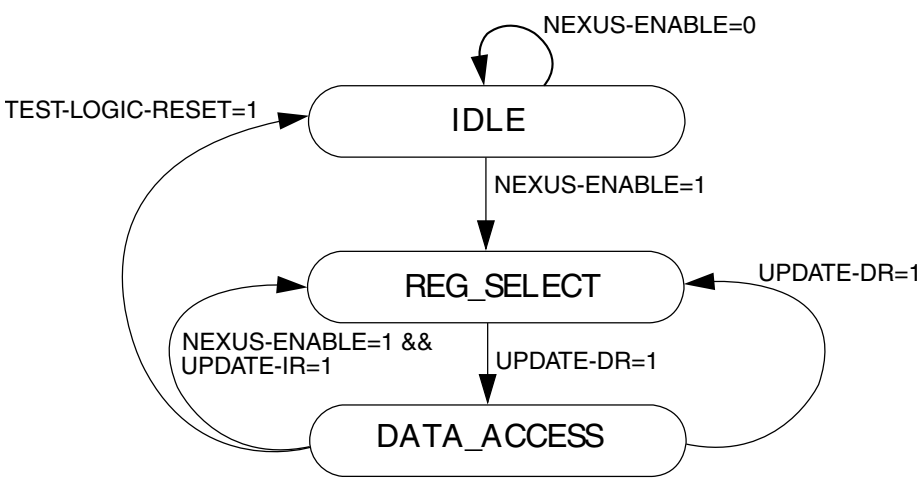

Figure 60-7. NEXUS Controller State Machine

Table 60-13. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction

Table continues on the next page...

Table 60-13. Loading NEXUS-ENABLE instruction (continued)

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS_ENABLE instruction.
3 TCKS				
8	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
9	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
10	0	RUN-TEST/IDLE	REG_SELECT	Ready to be read/write Nexus registers

60.5.3.4 Selecting a Nexus Client Register

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows development tool access to all Nexus registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus Controller defaults to the REG_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in the following table. The read/write control bit is set to 1 for writes and 0 for reads.

MSB	LSB
7-bit register index	R/W

Figure 60-8. IEEE 1149.1 Controller Command Input

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state. When reading a register, the register value is loaded into the JTAG shifter during the CAPTURE-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

The following table illustrates a sequence which writes a 32-bit value to a register.

Table 60-14. Write to a 32-Bit Nexus Client Register

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input.
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 6 bits of register index shifted in.
7 TCKs				
11	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
12	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
13	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
14	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
15	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
47	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.
48	1	UPDATE-DR	DATA_ACCESS	Value written to register
49	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register.

60.5.4 Nexus JTAG Port Sharing

Each of the individual Nexus blocks on the device implements a TAP controller for accessing its registers. When Nexus has ownership of the TAP, only the block whose NEXUS-ENABLE instruction is loaded has control of the TAP. This allows the interface to all of these individual TAP controllers to appear to be a single port from outside the device. If no register is selected as the shift path for a Nexus block, that block acts like a single-bit shift register, or bypass register.

60.5.5 MCKO Control

MCKO is an output clock to the development tools used for the timing of $\overline{\text{MSEO}}$ and MDO pin functions. MCKO is derived from the system clock and its frequency is determined by the value of the MCKO_DIV field in the PCR. Possible operating frequencies include system clock, one-half system clock, one-quarter system clock, and one-eighth system clock speed.

The NPC also generates an MCKO clock gating control output signal. This output can be used by the MCKO generation logic to gate the transmission of MCKO when the auxiliary port is enabled but not transmitting messages. The setting of the MCKO_GT bit inside the PCR determines whether or not MCKO gating control is active. The MCKO_GT bit resets to a logic 0. In this state gating of MCKO is disabled. To enable gating of MCKO, the MCKO_GT bit in the PCR is written to a logic 1.

60.5.6 $\overline{\text{EVTO}}$ Sharing

The NPC block controls sharing of the $\overline{\text{EVTO}}$ output between all Nexus clients that produce an $\overline{\text{EVTO}}$ signal. The NPC assumes incoming $\overline{\text{EVTO}}$ signals will be asserted for one system clock period. After receiving a single clock period of asserted $\overline{\text{EVTO}}$ from any Nexus client, the NPC latches the result, and drives $\overline{\text{EVTO}}$ for one MCKO period on the following clock. When there is no active MCKO, such as in disabled mode, the NPC drives $\overline{\text{EVTO}}$ for two system clock periods. $\overline{\text{EVTO}}$ sharing is active as long as the NPC is not in reset.

60.5.7 System Clock Locked Indication

Following a power-on reset, MDO[0] can be monitored to provide the lock status of the system clock. MDO[0] is driven to a logic 1 until the system clock achieves lock after exiting power-on reset. Once the system clock is locked, MDO[0] is negated and tools may begin Nexus configuration. Loss of lock conditions that occur subsequent to the exit of power-on reset and the initial lock of the system clock do not cause a Nexus reset, and therefore do not result in MDO[0] driven high.

60.6 Initialization/Application Information

60.6.1 Accessing NPC tool-mapped registers

To initialize the TAP for Nexus register accesses, the following sequence is required:

1. Enable the Nexus TAP controller
2. Load the TAP controller with the NEXUS-ENABLE instruction

To write control data to NPC tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and set the write bit to select the register with a pass through the SELECT-DR-SCAN path in the TAP controller state machine.
2. Write the register value with a second pass through the SELECT-DR-SCAN path. Note that the prior value of this register is shifted out during the write.

To read status and control data from NPC tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and clear the write bit to select register with a pass through SELECT-DR-SCAN path in the TAP controller state machine.
2. Read the register value with a second pass through the SELECT-DR-SCAN path. Data shifted in is ignored.

See the IEEE-ISTO 5001-2001 standard for more detail.

Chapter 61
Core Complex Overview

61.1 Overview of the e200z210n3 and e200z4204n3 cores

The e200z processor family is a set of CPU cores that implement low-cost versions of the Power architecture.

This chapter briefly discusses the e200z210n3 and e200z4204n3 cores as implemented on this device. Separate chapters discuss the processing models, debug capabilities, and Nexus 3+ units for each core.

This device uses one e200z4204n3 core (z4204n3) operating at speeds as high as 160 MHz, and one e200z210n3 core (z210n3) operating at a speed as high as 80 MHz.

All cores on the device implement a 32-bit PowerISA 2.06 VLE-compliant design with 32-bit general purpose registers (GPRs). The VLE (variable-length encoding) ISA provides improved code density. The VLE ISA is further documented in *PowerISA 2.06*, a separate document.

Note

The z4204n3 core is a dual-issue core. The z210n3 core is a single-issue core.

61.2 z210n3 microarchitecture summary

The z210n3 core utilizes a four-stage instruction pipeline, with one stage for execution. The Instruction Fetch, Instruction Decode/Register file Read/ EA Calc, Execute / Memory Access, and Register Writeback stages operate in an overlapped fashion, allowing single clock instruction execution for most instructions.

The integer execution unit consists of a 32-bit Arithmetic Unit (AU), a Logic Unit (LU), a 32-bit Barrel shifter (Shifter), a Mask-Insertion Unit (MIU), a Condition Register manipulation Unit (CRU), a Count-Leading-Zeros unit (CLZ), and result feed-forward hardware. The Integer EU1 also supports hardware division and an 8x32 Hardware Multiplier array.

Most arithmetic and logical operations are executed in a single cycle with the exception of the divide instructions. A Count-Leading-Zeros unit operates in a single clock cycle.

The Instruction Unit contains a PC incrementer and dedicated Branch Address adders to minimize delays during change of flow operations. Sequential prefetching is performed to ensure a supply of instructions into the execution pipeline. Branch target prefetching is performed to accelerate taken branches. Prefetched instructions are placed into an instruction buffer.

Branch target addresses are calculated in parallel with branch instruction decode, resulting in execution time of two clocks for taken branches. Conditional branches which are not taken execute in a single clock. Branches with successful BTB target prefetching have an effective execution time of one clock if correctly predicted.

Memory load and store operations are provided for byte, halfword, and word (32-bit) data with automatic zero or sign extension of byte and halfword load data as well as optional byte reversal of data. These instructions are pipelined to allow effective single cycle throughput. Load and store multiple word instructions allow low overhead context save and restore operations, and utilize 64-bit data transfers when possible. The load/store unit contains a dedicated effective address adder to allow effective address generation to be optimized.

The Condition Register unit supports the condition register (CR) and condition register operations defined by the PowerPC architecture. The condition register consists of eight 4-bit fields that reflect the results of certain operations, such as move, integer compare, arithmetic, and logical instructions, and provide a mechanism for testing and branching.

Vectored and autovectored interrupts are supported by the CPU. Vectored interrupt support is provided to allow multiple interrupt sources to have unique interrupt handlers invoked with no software overhead.

61.2.1 Overview of the e200z210n3 core

The e200z210n3 core (z210n3) is a single-issue 32-bit PowerISA 2.06 VLE-compliant design with 32-bit general purpose registers (GPRs). The z210n3 core implements the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in *PowerISA 2.06*, a separate document.

The z210n3 core integrates an integer execution unit, a branch control unit, an instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining three read and two write operations per clock. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

The z210n3 core contains a Nexus Class 3+ real-time debug module with support for program and data trace features and extensive trace controls.

Note

Instruction and data cache are not implemented on the z210n3 core.

The following lists some of the key features of the z210n3 core:

- Single-issue 32-bit PowerISA 2.06-VLE compliant CPU
- In-order execution and retirement
- Precise exception handling
- Branch processing unit
  - Dedicated branch address calculation adder
  - Branch target prefetching using BTB
- Load/store unit
  - Single-cycle load latency
  - Misaligned access support
- 32-bit General Purpose Register file
- Dual AHB 2.v6 64-bit Instruction-side and Data-side System buses
- Performance Monitor APU supporting execution profiling
- Nexus Class 3+ Real-time Development Unit
- Power management
  - Low power design - extensive clock gating
  - Power saving modes: halt, stop, wait
  - Dynamic power management of execution units
- Testability
  - Synthesizeable, MuxD scan design

61.2.2 z210n3 instruction unit features

The features of the z210n3 instruction unit are:

- Support for fetching two 32-bit instruction per clock cycle
- Instruction buffer that holds as many as eight 32-bit instructions
- Dedicated PC incrementer that supports instruction prefetches
- Branch unit with dedicated branch address adder and branch lookahead logic (BTB) to support single-cycle execution of successfully predicted branches
- Saturation Instructions Extension to provide scalar saturating arithmetic support to the PowerISA. Instructions supports add and subtract functionality for both signed and unsigned word, halfword, and byte data types. These instructions are used by compilers to avoid sign extension or zero extension operations when operating on data types which are smaller than the implemented register size.

61.2.3 z210n3 integer unit features

The z210n3 integer unit supports single-cycle execution of most integer instructions:

- 32-bit AU for arithmetic and comparison operations
- 32-bit LU for logical operations
- 32-bit priority encoder for the count leading zero's function
- 32-bit single-cycle barrel shifter for static shifts and rotates
- 32-bit mask unit for data masking and insertion
- Divider logic for signed and unsigned divide in 5-34 clock cycles with minimized execution timing
- Pipelined 8 x 32 hardware multiplier array supports 32x32->32 multiply with 2-4 clock cycle latency

61.2.4 z210n3 load/store unit features

The z210n3 load/store units support load, store, and the load multiple / store multiple instructions:

- 32-bit effective address adder for data memory address calculations
- Dedicated 64-bit interface to memory supports saving and restoring of as many as two registers per clock cycle for load multiple and store multiple word instructions and context save/restore instructions
- Pipelined operation to support throughput of one load or store operation per clock cycle

61.2.5 z210n3 performance monitor features

The z210n3 performance monitor provides the following features:

- Four configurable 32-bit performance monitor counters, each capable of counting selected CPU subsystem events
- Performance Monitor interrupt
- Ability to configure performance monitor resources for debugger use
- Hardware input signals for qualification of counting by individual counters
- Hardware output signals to indicate counter overflows
- Dedicated watchpoint outputs for each counter with programmable periodicity
- Trigger On/Off control for each counter based on subsystem events

Note

Since the z210n3 core does not implement caches, the available selectable event types represent a subset of the selectable event types on the z4204n3 core.

61.2.6 z210n3 system bus features

The features of the z210n3 system bus interface are as follows:

- Independent instruction and data interfaces
- Advanced microcontroller bus architecture AMBA AHB2.v6 protocol
- 32-bit address bus, 64-bit instruction-side and data-side system buses
- Data interface provides separate uni-directional read and write data buses
- Support for HCLK running at a slower rate than CPU clock

Note

These are identical to the z4204n3 system bus features.

61.3 z4204n3 microarchitecture summary

Each z4204n3 core utilizes a five-stage instruction pipeline, with two stages for execution.

Note

The z210n3 core utilizes a four-stage instruction pipeline, with one stage for execution.

The Instruction Fetch, Instruction Decode/Register file Read/ EA Calc, Execute 0/ Memory Access 0, Execute1/Memory Access1, and Register Writeback stages operate in an overlapped fashion, allowing single clock instruction execution for most instructions.

The integer execution units each consists of a 32-bit Arithmetic Unit (AU), a Logic Unit (LU), a 32-bit Barrel shifter (Shifter), a Mask-Insertion Unit (MIU), a Condition Register manipulation Unit (CRU), a Count-Leading-Zeros unit (CLZ), and result feed-forward hardware. The Integer EU1 also supports hardware division and a 32x32 Hardware Multiplier array.

Most arithmetic and logical operations are executed in a single cycle with the exception of multiply, which is implemented with a pipelined hardware array, and the divide instructions. A Count-Leading-Zeros unit operates in a single clock cycle.

The Instruction Unit contains a PC incrementer and dedicated Branch Address adders to minimize delays during change of flow operations. Sequential prefetching is performed to ensure a supply of instructions into the execution pipeline. Branch target prefetching is performed to accelerate taken branches. Prefetched instructions are placed into an instruction buffer.

Branch target addresses are calculated in parallel with branch instruction decode, resulting in execution time of two clocks for correctly predicted taken branches. Conditional branches that are not taken will execute in a single clock. Branches with successful BTB target prefetching have an effective execution time of one clock if correctly predicted.

Memory load and store operations are provided for byte, halfword, and word (32-bit) data with automatic zero or sign extension of byte and halfword load data as well as optional byte reversal of data. These instructions are pipelined to allow effective single cycle throughput. Load and store multiple word instructions allow low overhead context save and restore operations, and utilize 64-bit data transfers when possible. The load/store unit contains a dedicated effective address adder to allow effective address generation to be optimized.

The Condition Register unit supports the condition register (CR) and condition register operations defined by the PowerPC architecture. The condition register consists of eight 4-bit fields that reflect the results of certain operations, such as move, integer and floating-point compare, arithmetic, and logical instructions, and provide a mechanism for testing and branching.

Vectored and autovectored interrupts are supported by the CPU. Vectored interrupt support is provided to allow multiple interrupt sources to have unique interrupt handlers invoked with no software overhead.

The EFPU2 APU supports 32-bit IEEE-754 single-precision floating-point formats, supports scalar single-precision floating-point operations, and operates in a pipelined fashion. The general purpose register file is used for source and destination operands, and a unified storage model is used for scalar single-precision floating-point data types of 32-bits and the normal integer type. Low latency floating-point add, subtract, mixed add/subtract, sum, diff, min, max, multiply, multiply-add, multiply-sub, divide, square root, compare, and conversion operations are provided, and most operations can be pipelined.

61.3.1 Overview of the e200z4204n3

The e200z4204n3 core (z4204n3) is a dual-issue 32-bit PowerISA 2.06 VLE compliant design with 32-bit general purpose registers (GPRs). The z4204n3 core implements the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in PowerISA 2.06, a separate document.

Embedded Floating-point (EFPU2) APUs in each the z4204n3 cores support real-time single-precision floating-point embedded numerics operations using the general-purpose registers. Each z4204n3 core integrates a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

The z4204n3 cores each contain an 8 KB Instruction cache and a 4 KB Data cache, and a Nexus Class 3+ real-time debug module with support for program and data trace features and extensive trace controls.

61.3.2 z4204n3 instruction unit features

The features of the z4204n3 instruction units are:

- Support for fetching two 32-bit instruction per clock cycle
- Instruction buffer that holds as many as eight 32-bit instructions
- Dedicated PC incrementer that supports instruction prefetches

- Branch unit with dedicated branch address adder and branch lookahead logic (BTB) to support single-cycle execution of successfully predicted branches
- Saturation Instructions Extension to provide scalar saturating arithmetic support to the PowerISA. Instructions supports add and subtract functionality for both signed and unsigned word, halfword, and byte data types. These instructions are used by compilers to avoid sign extension or zero extension operations when operating on data types which are smaller than the implemented register size.

61.3.3 z4204n3 integer unit features

The z4204n3 integer units support single-cycle execution of most integer instructions:

- 32-bit AU for arithmetic and comparison operations
- 32-bit LU for logical operations
- 32-bit priority encoder for the count leading zero's function
- 32-bit single-cycle barrel shifter for static shifts and rotates
- 32-bit mask unit for data masking and insertion
- Divider logic for signed and unsigned divide in 4-14 clocks with minimized execution timing (EU1 only)
- Pipelined 32x32 hardware multiplier array supports 32x32->32 multiply with 2 clock latency, 1 clock throughput (EU1 only)

61.3.4 z210n3 load/store unit features

The z210n3 load/store units support load, store, and the load multiple / store multiple instructions:

- 32-bit effective address adder for data memory address calculations
- Dedicated 64-bit interface to memory supports saving and restoring of as many as two registers per clock cycle for load multiple and store multiple word instructions and context save/restore instructions
- Pipelined operation to support throughput of one load or store operation per clock cycle

61.3.5 z4204n3 EFPU2 floating-point unit features

The z4204n3 embedded floating-point unit (EFPU2) supports pipelined operation of most floating-point operations, allowing a throughput of one floating-point operation per cycle, and supports a variety of operations:

- Supports IEEE754 single-precision data format
- Supports IEEE754 half-precision format for conversion two and from single-precision format
- EFPU2 instructions utilize the 32-bit GPRs for minimized context save/restore overhead
- Provides low latency pipelined scalar floating-point add, subtract, add/sub, sub/add, multiply, multiply-add, min, max, absolute value, compare, and conversion instructions with single-cycle throughput
- Default results mode for real-time applications allows for exception-free operations when underflow or overflows occur
- Trap Enable controls allow for trapping of various operation exceptions and emulation of IEEE754 boundary case results
- Floating-point Divide and Square root logic operating in 13 (FP div) and 11 (FP sqrt) clocks

Note

The EFPU2 is not implemented on the z210n3 core.

61.3.6 z4204n3 cache features

The z4204n3 caches provide the following features:

- 2-way set-associative Instruction and Data caches (8 KB ICache, 4 KB DCache)
- Writethrough support
- 8-entry store buffer
- Linefill buffer
- 32-bit address bus plus attributes and control
- Separate uni-directional 64-bit read data bus and 64-bit write data bus
- Support for way locking

- Support for Write allocation policies
- Support for multi-bit EDC with Correction/Auto-invalidation capability
- Hardware debug cache invalidate support for the data cache

Note

Instruction and data caches are not implemented on the z210n3 core.

61.3.7 z4204n3 performance monitor features

The z4204n3 performance monitor provides the following features:

- Four configurable 32-bit performance monitor counters, each capable of counting selected CPU subsystem events
- Performance Monitor interrupt
- Ability to configure performance monitor resources for debugger use
- Hardware input signals for qualification of counting by individual counters
- Hardware output signals to indicate counter overflows
- Dedicated watchpoint outputs for each counter with programmable periodicity
- Trigger On/Off control for each counter based on subsystem events
- Multiple selectable event types including:
  - Number of clocks, CPU stall cycles
  - Number of instructions completed
  - Number of interrupts taken
  - Number of memory accesses (by type)
  - Number of instruction or data cache misses
  - Number of cycles with 0, 1, or 2 instructions issued
  - Number of instructions in a given class completed (ldst, branch, integer, FP, etc.)
  - Number cache linefills
  - Many other event types

Note

For the z4204n3 core, selectable event types represent a superset of the selectable event types on the z210n3 core, since the z210n3 core does not have caches.

61.3.8 z4204n3 system bus features

The features of the z4204n3 system bus interface are as follows:

- Independent instruction and data interfaces
- Advanced microcontroller bus architecture AMBA AHB2.v6 protocol
- 32-bit address bus, 64-bit instruction-side and data-side system buses
- Data interface provides separate uni-directional read and write data buses
- Support for HCLK running at a slower rate than CPU clock

Note

These are identical to the z210n3 system bus features.

Chapter 62
Z2 Core description

62.1 Overview of the e200z210n3 core

The e200z210n3 is a single-issue 32-bit *Power ISA 2.06* VLE compliant design with 32-bit general-purpose registers (GPRs). The e200z210n3 core implements the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in *Power ISA 2.06*, a separate document.

The e200z210n3 core integrates an integer execution unit, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining three read and two write operations per clock cycle. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

The e200z210n3 core contains a Nexus Class 3+ real-time debug module with support for program and data trace features as well as extensive trace controls.

62.2 Register model

This section describes the registers implemented in the e200z210n3 core. The *Power ISA 2.06* architecture defines register-to-register operations for all computational instructions.

Figure 62-1 and Figure 62-2 show the complete e200z210n3 register set, all of which are accessible in supervisor mode. Figure 62-3 and Figure 62-4 show the subset of registers accessible in user mode. The number to the right of the special-purpose registers (SPRs) is the decimal number used in the instruction syntax to access the register (for example, the integer exception register (XER) is SPR 1).

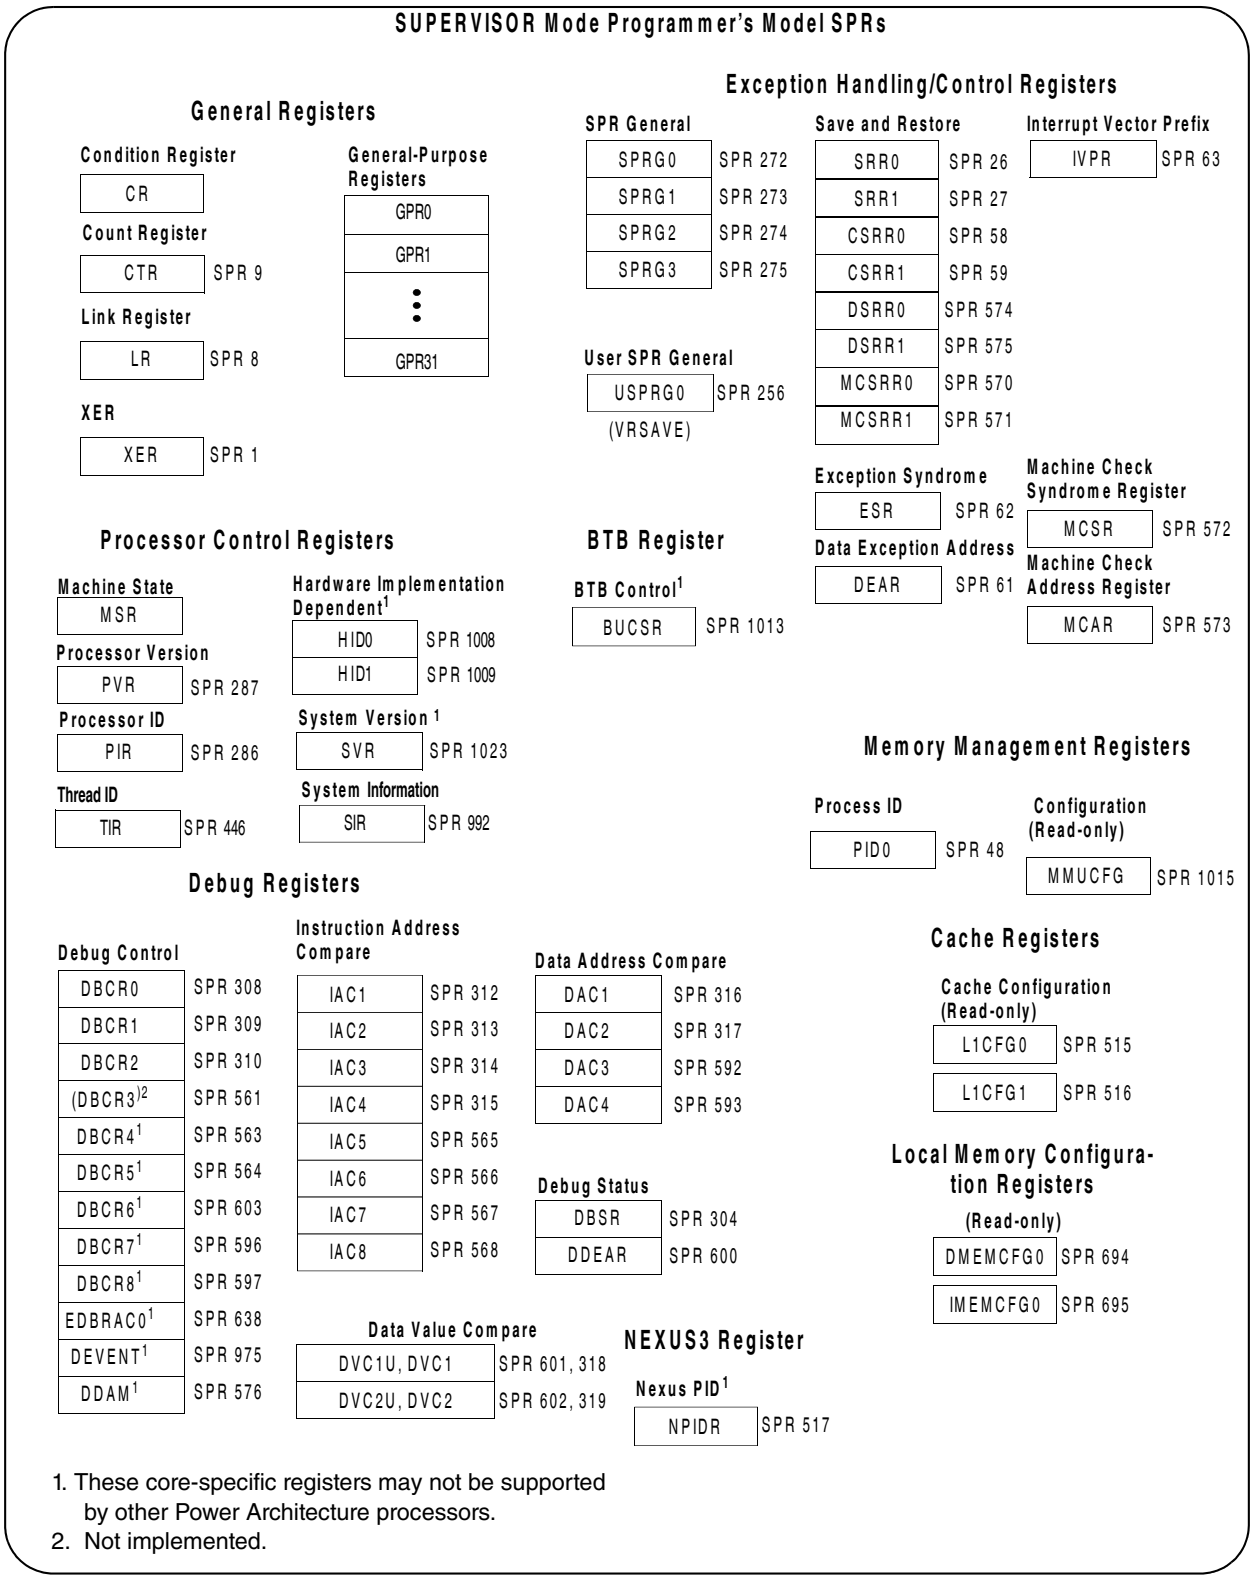

Figure 62-1. e200z210n3 Supervisor Mode Programmer's Model SPRs

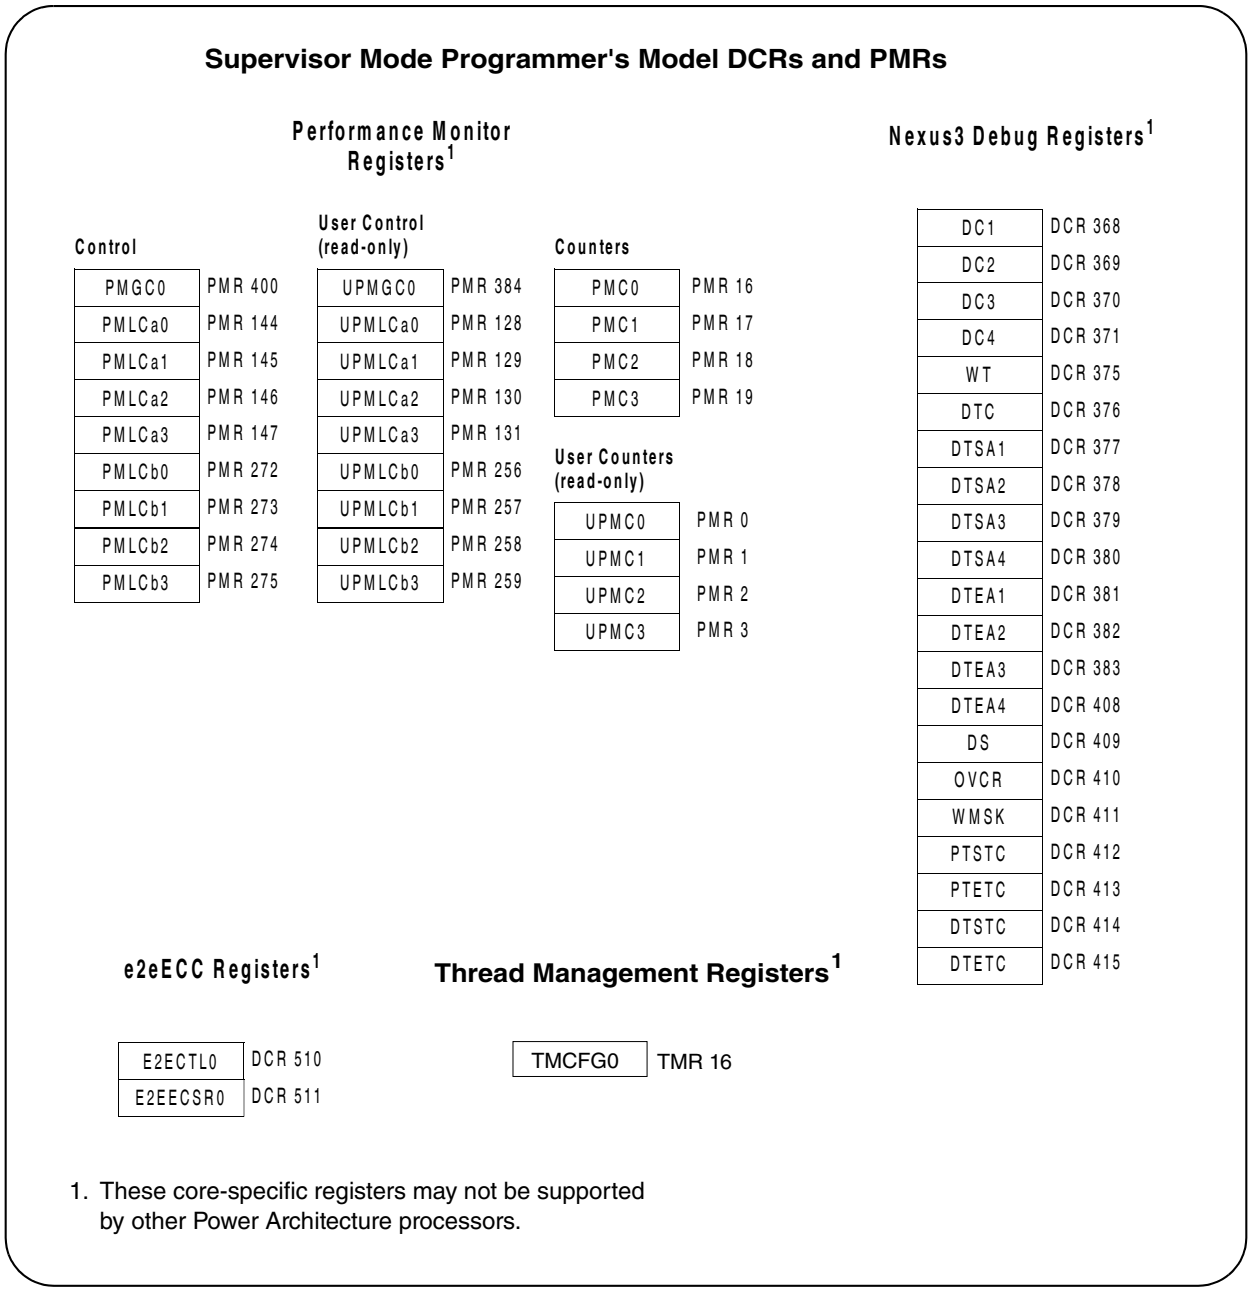

Figure 62-2. e200z210n3 Supervisor Mode Programmer's Model DCRs and PMRs

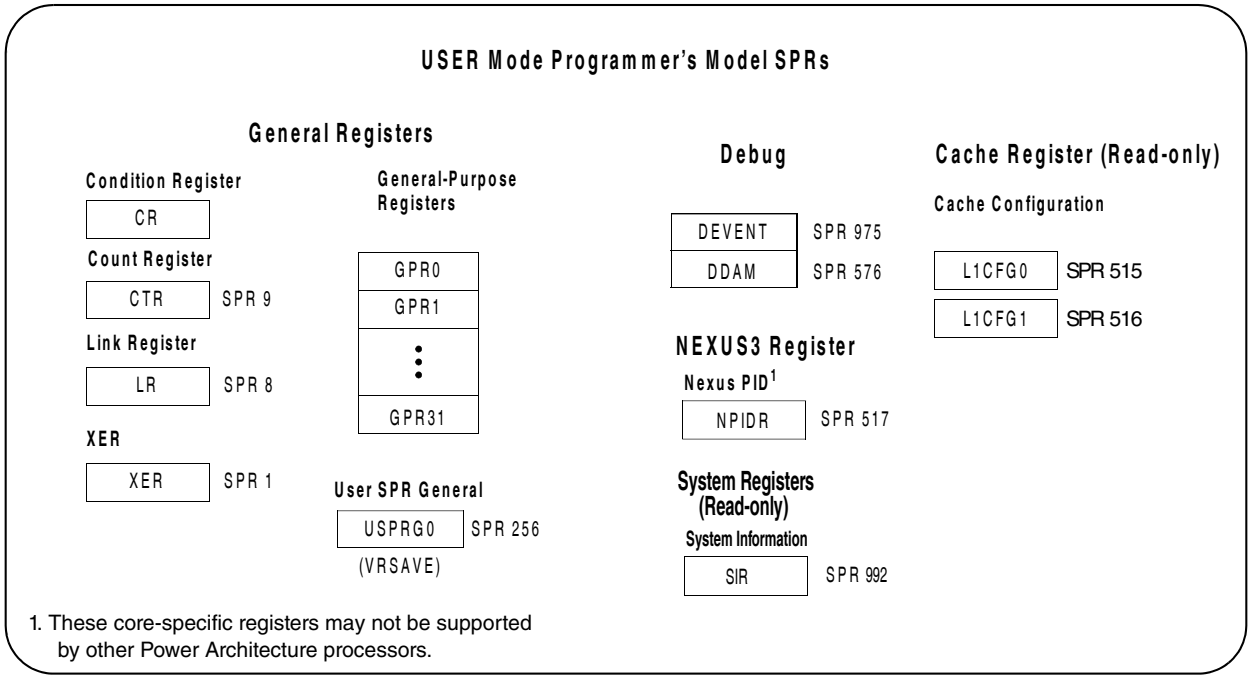

Figure 62-3. e200z210n3 User Mode Programmer's Model SPRs

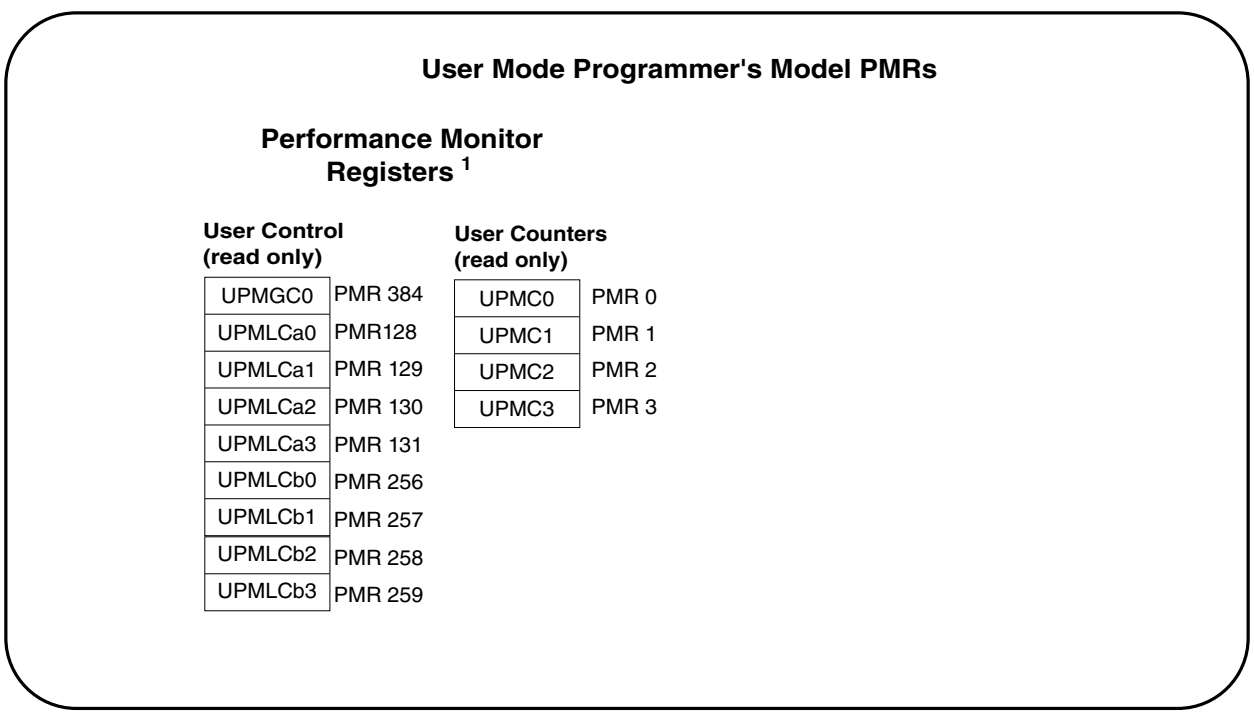

Figure 62-4. e200z210n3 User Mode Programmer's Model PMRs

62.2.1 Branch Unit Control and Status Register (BUCSR)

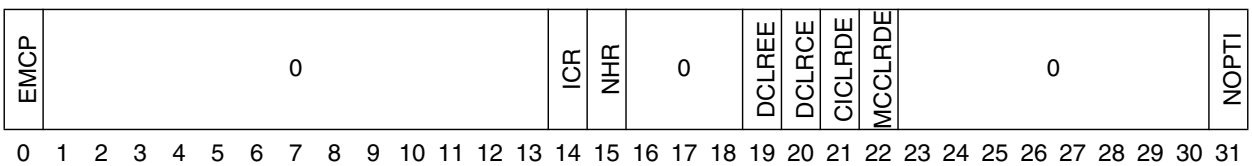
The BUCSR register is used for general control and status of the branch target buffer (BTB). The BTB is detailed in . The BUCSR is shown in the following figure.

SPR — 1013; Read/Write; Reset — 0x0

Figure 62-5. Branch Unit Control and Status Register (BUCSR)

The BUCSR fields are defined in the following table.

Table 62-1. Branch Unit Control and Status Register (BUCSR)



Bits	Name	Description
0:21 [32:53]	-	Reserved
22 [54]	BBFI	Branch target buffer flash invalidate. When written to a '1', BBFI flash clears the valid bit of all entries in the branch target buffer; clearing occurs regardless of the value of the enable bit (BPEN). Note: BBFI is always read as 0.
23:25 [55:57]	-	Reserved
26:27 [58:59]	BALLOC	Branch Target Buffer Allocation Control. This field controls BTB allocation for branch acceleration when BPEN = 1. Note that BTB hits are not affected by the settings of this field. 00 Branch Target Buffer allocation for all branches is enabled. 01 Branch Target Buffer allocation is disabled for backward branches. 10 Branch Target Buffer allocation is disabled for forward branches. 11 Branch Target Buffer allocation is disabled for both branch directions.
28 [60]	-	Reserved
29:30 [61:62]	BPRED	Branch Prediction Control (Static). This field controls operation of static prediction mechanism on a BTB miss. When a branch is predicted as taken, fetching of the predicted target location will be performed for branch acceleration. BPRED operates independently of BPEN, and with a BPEN setting of 0, will be used to perform static prediction of all unresolved branches. 00 Branch predicted taken on BTB miss for all branches. 01 Branch predicted taken on BTB miss only for forward branches. 10 Branch predicted taken on BTB miss only for backward branches. 11 Branch predicted not taken on BTB miss for both branch directions. **NOTE:** BTB hits are not affected by the settings of this field. Note also that for certain applications, setting BPRED to a non-default value may result in improved performance.
31 [63]	BPEN	Branch target buffer prediction enable. When the BPEN bit is cleared, no hits will be generated from the BTB, and no new entries will be allocated. Entries are not automatically invalidated when BPEN is cleared; the BBFI bit controls entry invalidation. BPEN operates independently of BPRED, and will be used even with a BPRED setting of 00.

Table 62-1. Branch Unit Control and Status Register (BUCSR)

Bits	Name	Description
		0 Branch target buffer prediction disabled 1 Branch target buffer prediction enabled (enables BTB to predict branches)

62.2.2 Hardware Implementation Dependent Register 0 (HID0)

The HID0 register is a core implementation dependent register used for various configuration and control functions. It is shown in the following figure.

SPR - 1008; Read/Write; Reset - 0x0

Figure 62-6. Hardware Implementation Dependent Register 0 (HID0)

The HID0 fields are defined in the following table.

Table 62-2. Hardware Implementation-Dependent Register 0

Bits	Name	Description
0 [32]	EMCP	Enable machine check pin (p_mcp_b) 0 p_mcp_b pin is disabled. 1 p_mcp_b pin is enabled. Asserting p_mcp_b causes a machine check interrupt to be reported.
1:13 [33:45]	-	Reserved
14 [46]	ICR	Interrupt Inputs Clear Reservation 0 External Input, Critical Input, and Non-Maskable Interrupts do not affect reservation status 1 External Input, Critical Input, and Non-Maskable Interrupts clear an outstanding reservation
15 [47]	NHR	Not hardware reset 0 indicates to a reset exception handler that a reset occurred if software had previously set this bit 1 indicates to a reset exception handler that no reset occurred if software had previously set this bit Provided for software use. Set anytime by software, cleared by reset.
16:18 [48:50]	-	Reserved
19 [51]	DCLREE	Debug Interrupt Clears MSR_{EE} 0 MSR_{EE} unaffected by Debug Interrupt 1 MSR_{EE} cleared by Debug Interrupt

Table continues on the next page...

Table 62-2. Hardware Implementation-Dependent Register 0 (continued)

Bits	Name	Description
		This bit controls whether Debug interrupts force External Input interrupts to be disabled, or whether they remain unaffected.
20 [52]	DCLRCE	Debug Interrupt Clears MSR_{CE} 0 MSR_{CE} unaffected by Debug Interrupt 1 MSR_{CE} cleared by Debug Interrupt This bit controls whether Debug interrupts force Critical interrupts to be disabled, or whether they remain unaffected.
21 [53]	CICLRDE	Critical Interrupt Clears MSR_{DE} 0 MSR_{DE} unaffected by Critical class interrupt 1 MSR_{DE} cleared by Critical class interrupt This bit controls whether Critical interrupts force Debug interrupts to be disabled, or whether they remain unaffected. Machine Check interrupts have a separate control bit. Note that if Critical Interrupt Debug events are enabled ($DBCR0_{CIRPT}$ set), and MSR_{DE} is set at the time of a Critical Input Critical interrupt, a debug event will be generated after the Critical Interrupt Handler has been fetched, and the Debug handler will be executed first. In this case, $DSRR0_{DE}$ will have been cleared, such that after returning from the debug handler, the Critical interrupt handler will not be run with MSR_{DE} enabled.
22 [54]	MCCLRDE	Machine Check Interrupt Clears MSR_{DE} 0 MSR_{DE} unaffected by Machine Check interrupt 1 MSR_{DE} cleared by Machine Check interrupt This bit controls whether Machine Check interrupts force Debug interrupts to be disabled, or whether they remain unaffected.
23:30 [58:62]	-	Reserved
31 [63]	NOPTI	No-op Touch Instructions 0 icbt, dcbt, dcbtst instructions operate normally 1 icbt, dcbt, dcbtst instructions are no-oped This bit only affects the icbt, dcbt, and dcbtst instructions.

62.2.3 Hardware Implementation Dependent Register 1 (HID1)

The HID1 register is used for bus configuration and system control. It is shown in the following figure.

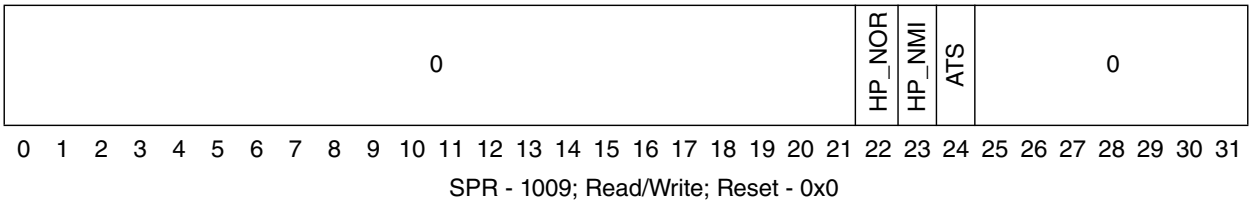


Figure 62-7. Hardware Implementation Dependent Register 1 (HID1)

The HID1 fields are defined in the following table.

Table 62-3. Hardware Implementation-Dependent Register 1

Bits	Name	Description
0:21 [32:53]	-	Reserved
22 [54]	HP_NOR	High priority elevation for normal and external interrupts 0 - High priority elevation for normal and external interrupts is disabled 1 - High priority elevation for normal and external interrupts is enabled The HP_NOR bitfield enables temporary elevation of the processor's crossbar priority. The relevant Master x field for the processor must also be enabled in the XBAR_CRSn HPEx bitfield. The platform logic elevates the processor's crossbar priority from the time of the IRQ assertion until the appropriate return instruction has been executed. For normal interrupts , the hardware supports the stacking of up to 4 interrupts. No hardware support of stacking for critical or NMI interrupts is provided. These bits may need external synchronization. **NOTE:** Must be used in conjunction with the XBAR_CRSn HPEx setting
23 [55]	HP_NMI	High priority elevation for NMI and critical interrupts 0 - High priority elevation for NMI and critical interrupts is disabled 1 - High priority elevation for NMI and critical interrupts is enabled The HP_NMI bitfield enables temporary elevation of the processor's crossbar priority. The relevant Master x field for the processor must also be enabled in the XBAR_CRSn HPEx bitfield. The platform logic elevates the processor's crossbar priority from the time of the IRQ assertion until the appropriate return instruction has been executed. For normal interrupts , the hardware supports the stacking of up to 4 interrupts. No hardware support of stacking for critical or NMI interrupts is provided These bits may need external synchronization. **NOTE:** Must be used in conjunction with the XBAR_CRSn HPEx setting
24 [56]	ATS	Atomic status (read-only) Indicates state of the reservation bit in the load/store unit.
25:31 [57:63]	-	Reserved

62.3 Single-issue operation

The instruction issue unit attempts to issue an instruction to the execution units each cycle. Source operands for each of the instructions are provided from the GPRs or from the operand feed-forward muxes. Data or resource hazards may create stall conditions that cause instruction issue to be stalled for one or more cycles until the hazard is eliminated.

The execution units write the result of a finished instruction onto the proper result bus and into the destination registers. The writeback logic retires an instruction when the instruction has finished execution. As many as two results can be simultaneously written.

62.4 Instruction timing

Instruction timing in number of processor clock cycles for various instruction classes is shown in Table 62-4. Pipelined instructions are shown with cycles of total latency and throughput cycles. Divide and multiply instructions are not pipelined and block other instructions from executing during execution.

Load/store multiple instruction cycles are represented as a fixed number of cycles plus a variable number of cycles where *n* is the number of words accessed by the instruction. In addition, cycle times marked with & require variable number of additional cycles due to serialization.

Table 62-4. Instruction class cycle counts

Class of Instructions	Latency	Throughput	Special notes
integer: **add**, **sub**, **shift**, **rotate**, **logical**, **cntlzw**	1	1	—
integer: **compare**	1	1	—
Branch	2/1	2/1	Correct branch lookahead allows single-cycle execution. Worst-case mispredicted branch is 2 cycles.
multiply	2—4	2—4	Data-dependent timing
CR logical	1	1	—
loads (non-multiple)	1	1	—
load multiple	2 + *n*/2 (max)	2 + *n*/2 (max)	Actual timing depends on *n* and address alignment.
stores (non-multiple)	1	1	—

62.5 Exceptions

Interrupts implemented in e200z210n3 and the exception conditions that cause them are listed in the following table.

Table 62-7. Exceptions and Conditions

Interrupt type	Interrupt vector offset value	Causing conditions
System reset	none, vector to [p_rstbase[0:29]] || 2'b00	Reset
Critical Input	0x00[1]	**p_critint_b** is asserted and MSR_{CE} = 1.
Machine check	0x10	1. **p_mcp_b** transitions from negated to asserted 2. ISI or Bus Error on first instruction fetch for an exception handler 3. External bus error 4. Stack limit check failure
Machine check (NMI)	0x10	Non-Maskable Interrupt

Table continues on the next page...

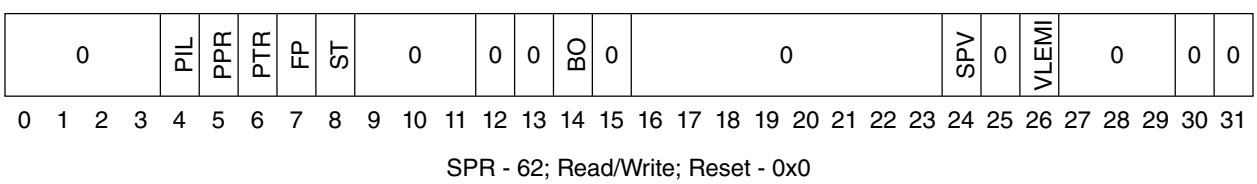

Table 62-7. Exceptions and Conditions (continued)

Interrupt type	Interrupt vector offset value	Causing conditions
Data Storage	0x20	Access control
Instruction Storage	0x30	Access control
External Input	0x40[2]	Interrupt Controller interrupt and MSR_{EE} = 1
Alignment	0x50	1. **lmw**, **stmw** not word aligned 2. **lwarx** or **stwcx.** not word aligned, **lharx** or **sthcx.** not halfword aligned 3. **dcbz**
Program	0x60	Illegal, Privileged, Trap
Performance Monitor	0x70	Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$ = 0
System call	0x80	Execution of the System Call (**se_sc**) instruction
Debug	0x90	Trap, Instruction Address Compare, Data Address Compare, Instruction Complete, Branch Taken, Return from Interrupt, Interrupt Taken, Debug Counter, External Debug Event, Unconditional Debug Event, Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$ = 1
EFPU Data Exception	0xA0	Reserved for future processor use
EFPU Round Exception	0xB0	Reserved for future processor use
TBD	0xC0–0xF0	Reserved for future processor use

1. Autovectored Critical Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.
2. Autovectored External Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.

62.5.1 Exception Syndrome Register (ESR)

The Exception Syndrome Register (ESR) provides a *syndrome* to differentiate between exceptions that can generate the same interrupt type.

SPR - 62; Read/Write; Reset - 0x0

Figure 62-8. Exception Syndrome Register (ESR)

The ESR bits are defined in the following table.

Table 62-8. ESR field descriptions

Bit(s)	Name	Description	Associated interrupt type
0:3	—	Reserved	—
4	PIL	Illegal Instruction exception	Program

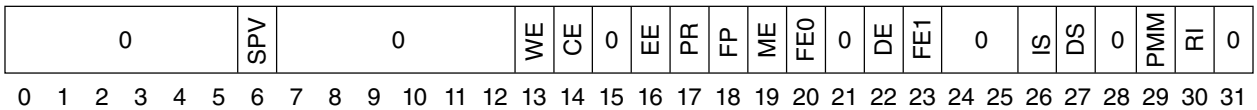

Table continues on the next page...

Table 62-8. ESR field descriptions (continued)

31	—	Reserved	—

62.5.2 Machine State Register (MSR)

The Machine State Register defines the state of the processor. The e200z210n3 MSR is shown in the following figure.

Read/Write; Reset - 0x0

Figure 62-9. Machine State Register (MSR)

The MSR bits are defined in the following table.

Table 62-9. MSR field descriptions

Bit(s)	Name	Description
0:5	—	Reserved
6	SPV	SP/Embedded FP/Vector available 0 SP/Embedded FP Double/Vector unit is unavailable. The processor cannot execute SP/Embedded FP Double or Vector Unit instructions. 1 SP/Embedded FP Double/Vector unit is available. The processor can execute SP/Embedded FP Double or Vector Unit instructions. **NOTE:** The e200z210n3 processor does not support these units in hardware. An Illegal Instruction exception is generated for attempted execution of these instructions regardless of the setting of SPV. SPV is ignored, but cleared on exceptions.
7:12	—	Reserved
13	WE	Wait State (Power management) enable. **NOTE:** this bit is implementation dependent and is being phased out. It will be removed in a future release. Currently it is implemented as a writeable bit, and is ignored, but cleared on exceptions.
14	CE	Critical Interrupt Enable 0 Critical Input interrupts are disabled. 1 Critical Input interrupts are enabled.
15	—	Reserved
16	EE	External Interrupt Enable 0 External Input interrupts are disabled. 1 External Input interrupts are enabled.
17	PR	Problem State 0 The processor is in supervisor mode, can execute any instruction, and can access any resource (e.g. GPRs, SPRs, MSR, etc.). 1 The processor is in user mode, cannot execute any privileged instruction, and cannot access any privileged resource.
18	FP	Floating-Point Available 0 Floating point unit is unavailable. The processor cannot execute floating-point instructions, including floating-point loads, stores, and moves. 1 Floating Point unit is available. The processor can execute floating-point instructions. **NOTE:** The e200z210n3 processor does not support the PowerISA 2.06 floating point unit in hardware, and an Illegal Instruction exception is generated for attempted execution of PowerISA 2.06 floating point instructions regardless of the setting of FP. FP is ignored, but cleared on exceptions.

Table continues on the next page...

Table 62-9. MSR field descriptions (continued)

Bit(s)	Name	Description
19	ME	Machine Check Enable 0 Asynchronous Machine Check interrupts are disabled. 1 Asynchronous Machine Check interrupts are enabled.
20	FE0	Floating-point exception mode 0 (not used) **NOTE:** The e200z210n3 processor does not support the PowerISA 2.06 floating point unit in hardware, thus FE0 is ignored, but cleared on exceptions.
21	—	Reserved
22	DE	Debug Interrupt Enable 0 Debug interrupts are disabled. 1 Debug interrupts are enabled.
23	FE1	Floating-point exception mode 1 (not used) **NOTE:** The e200z210n3 processor does not support the PowerISA 2.06 floating point unit in hardware, thus FE1 is ignored, but cleared on exceptions.
24:25	—	Reserved
26	IS	Instruction Address Space 0 The processor directs all instruction fetches to address space 0. 1 The processor directs all instruction fetches to address space 1. **NOTE:** The e200z210n3 processor does not support Address Spaces, thus the IS bit is ignored, but cleared on exceptions.
27	DS	Data Address Space 0 The processor directs all data storage accesses to address space 0. 1 The processor directs all data storage accesses to address space 1. **NOTE:** The e200z210n3 processor does not support Address Spaces, thus the DS bit is ignored, but cleared on exceptions.
28	—	Reserved
29	PMM	PMM Performance monitor mark bit System software can set PMM when a marked process is running to enable statistics to be gathered only during the execution of the marked process. MSR_{PR} and MSR_{PMM} together define a state that the processor (supervisor or user) and the process (marked or unmarked) may be in at any time. If this state matches an individual state specified in the PMLCa*n* Performance Monitor registers, the state for which monitoring is enabled, counting is enabled.
30	RI	Recoverable Interrupt This bit is provided for software use to detect nested machine check exception conditions. This bit is cleared by hardware when a Machine Check interrupt is taken.
31	—	Reserved

62.5.3 Machine Check Syndrome Register (MCSR)

When the processor takes a machine check interrupt, it updates the Machine Check Syndrome Register (MCSR) to differentiate between machine check conditions. The MCSR is shown in the following figure.

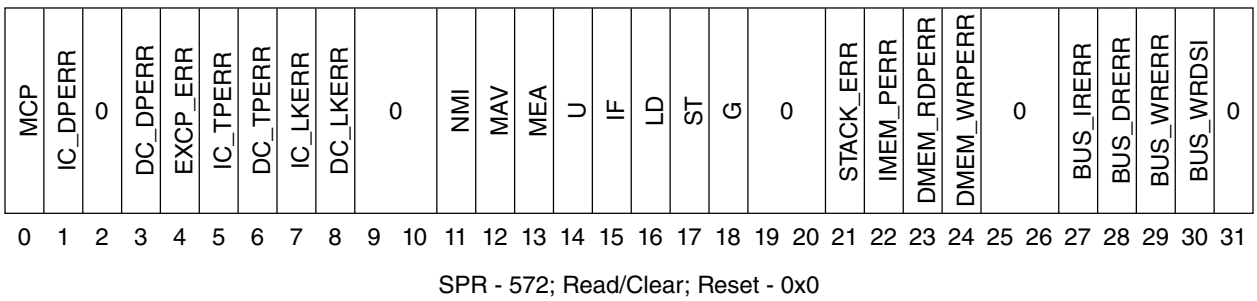

Figure 62-10. Machine Check Syndrome Register (MCSR)

The following table describes MCSR fields. The MCSR indicates the source of a machine check condition.

All bits in the MCSR are implemented as "write 1 to clear." Software in the machine check handler is expected to clear the MCSR bits it has sampled prior to re-enabling MSR_{ME} to avoid a redundant machine check exception and to prepare for updated status bit information on the next machine check interrupt.

Note that any set bit in the MCSR other than status-type bits will cause a subsequent machine check interrupt once $MSR_{ME} = 1$.

Table 62-10. Machine Check Syndrome Register (MCSR) field descriptions

Bit	Name	Description	Exception type[1]	Recoverable
0	MCP	Machine check input pin	Async Mchk	Maybe
1	IC_DPERR[2]	Instruction Cache data array parity error	Async Mchk	Precise
2	—	Reserved	—	—
3	DC_DPERR[3]	Data Cache data array parity error	Async Mchk	Maybe
4	EXCP_ERR	ISI or Bus Error on first instruction fetch for an exception handler	Async Mchk	Precise
5	IC_TPERR[2]	Instruction Cache Tag parity error	Async Mchk	Precise
6	DC_TPERR[3]	Data Cache Tag parity error	Async Mchk	Maybe
7	IC_LKERR[2]	Instruction Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the I-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—
8	DC_LKERR[3]	Data Cache Lock error	Async Mchk	—

Table continues on the next page...

Table 62-10. Machine Check Syndrome Register (MCSR) field descriptions (continued)

Bit	Name	Description	Exception type[1]	Recoverable
		Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the D-Cache for certain situations. May also be set on locked line refill error.		
9:10	—	Reserved	—	—
11	NMI	NMI input pin	NMI	—
12	MAV	MCAR Address Valid Indicates that the address contained in the MCAR was updated by hardware to correspond to the first detected Async Mchk error condition	Status	—
13	MEA	MCAR holds Effective Address If MAV = 1, MEA = 1 indicates that the MCAR contains an effective address and MEA = 0 indicates that the MCAR contains a physical address[4]	Status	—
14	U	User Indicates the value captured in MCAR was generated in user mode.	Status	—
15	IF	Instruction Fetch Error Report An error occurred during the fetch of an instruction and the instruction attempted to execute. MCSRR0 contains the instruction address.	Error Report	Precise
16	LD	Load type instruction Error Report An error occurred during the attempt to execute the load type instruction located at the address stored in MCSRR0. This could be due to a stack limit check error, or an external bus error.	Error Report	Precise
17	ST	Store type instruction Error Report An error occurred during the attempt to execute the store type instruction located at the address stored in MCSRR0. This could be due to a stack limit check error, or on certain external bus errors.	Error Report	Precise
18	G	Guarded instruction Error Report An error occurred during the attempt to execute the load or store type instruction located at the address stored in MCSRR0 and the access was guarded and encountered an error on the external bus.	Error Report	Precise
19:20	—	Reserved	—	—
21	STACK_ERR	Stack Access Limit Check Error Indicates a limit check failure on a CPU data access using R1 in the <EA> calculation.	Async Mchk	Precise
22	IMEM_PERR[5]	Instruction Mem (IMEM) Parity Error	Async Mchk	Precise

Table continues on the next page...

Table 62-10. Machine Check Syndrome Register (MCSR) field descriptions (continued)

Bit	Name	Description	Exception type[1]	Recoverable
		Indicates an uncorrectable error in the IMEM on a CPU port access.		
23	DMEM_RDPERR6	Data Mem (DMEM) Parity Error Indicates an uncorrectable error in the DMEM on a CPU port read access.	Async Mchk	Precise
24	DMEM_WRPERR6	Data Mem (DMEM) Write Parity Error Indicates an uncorrectable error in the DMEM on a CPU port write access.	Async Mchk	Maybe
25:26	—	Reserved	—	—
27	BUS_IRERR[2]	Read bus error on Instruction recovery linefill	Async Mchk	Precise if data used
28	BUS_DRERR	Read bus error on data load	Async Mchk	Precise if data used
29	BUS_WRERR	Write bus error on store to bus	Async Mchk	Unlikely
30	BUS_WRDSI	Write bus error on buffered store to bus with DSI signaled. Set concurrently with BUS_WRERR for this case	Async Mchk	Unlikely
31	—	Reserved	—	—

1. The Exception Type indicates the exception type associated with a given syndrome bit.
   - "Error Report" indicates that this bit is only set for error report exceptions which cause machine check interrupts. These bits are only updated when the machine check interrupt is actually taken. Error report exceptions are not gated by MSR_{ME}. These are synchronous exceptions. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.
   - "Status" indicates that this bit provides additional status information regarding the logging of a machine check exception. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.
   - "NMI" indicates that this bit is only set for the non-maskable interrupt type exception which causes a machine check interrupt. This bit is only updated when the machine check interrupt is actually taken. NMI exceptions are not gated by MSR_{ME}. This is an asynchronous exception. This bit will remain set until cleared by software writing a '1' to the bit position.
   - "Async Mchk" indicates that this bit is set for an asynchronous machine check exception. These bits are set immediately upon detection of the error. Once any "Async Mchk" bit is set in the MCSR, a machine check interrupt will occur if MSR_{ME} = 1. If MSR_{ME} = 0, the machine check exception will remain pending. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.
2. Will not be set by e200z210n3 since no instruction cache is present.
3. Will not be set by e200z210n3 since no data cache is present.
4. Note that since no address translation mechanism is present on e200z210n3, the MEA value is always set to '0'.
5. Will not be set by e200z210n3 since no local instruction memory is present.
6. Will not be set by e200z210n3 since no local data memory is present.

62.5.4 Interrupt Vector Prefix Registers (IVPR)

The Interrupt Vector Prefix Register is used during interrupt processing for determining the starting address of a software handler used to handle an interrupt. The value of the Vector Offset selected for a particular interrupt type is concatenated with the Vector Base value held in the IVPR to form an instruction address from which execution is to begin. The format of IVPR is shown in the following figure.

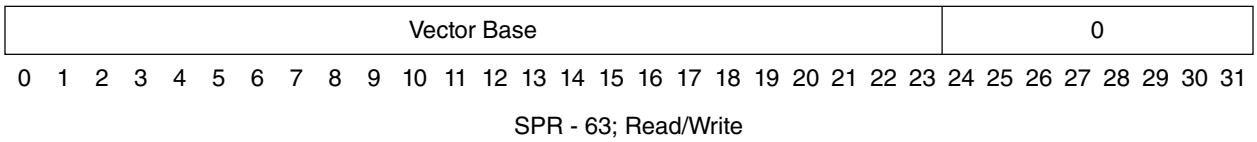

Figure 62-11. Interrupt Vector Prefix Register (IVPR)

The IVPR fields are defined in the following table.

Table 62-11. IVPR field descriptions

Bit(s)	Name	Description
0:23 (32:55)	Vector Base	Vector Base This field is used to define the base location of the vector table, aligned to a 256-byte boundary. This field provides the high-order 24 bits of the location of all interrupt handlers (unless hardware vectoring is used). The vector offset value appropriate for the type of exception being processed is concatenated with the IVPR Vector Base to form the address of the handler in memory. For hardware-vectored interrupts, the value of the supplied interrupt vector is logically OR'ed with the low order bits of the Vec Base Field to determine the interrupt handler address.
24:31 (56:63)	—	Reserved

62.5.5 Interrupt Definitions

62.5.5.1 Critical Input Interrupt (offset 0x00)

A Critical Input exception is signaled to the processor by the assertion of the critical interrupt pin. If the exception is enabled by MSR_{CE}, the Critical Input interrupt is taken.

A Critical Input interrupt may be delayed by other higher priority exceptions or if MSR_{CE} is cleared when the exception occurs.

The following table lists register settings when a Critical Input interrupt is taken.

Table 62-12. Critical Input Interrupt—register settings

Register	Setting description					
CSRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.					
CSRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	0	FE0	0	DS	0
	EE	0	DE	—/0[1]	PMM	0
	PR	0			RI	—

1. Clearing of DE is optionally supported by control in HID0.

The MSR_{DE} bit is not automatically cleared by a Critical Input interrupt, but it can be configured to be cleared via the HID0 register ($HID0_{CICLRDE}$).

62.5.5.2 Machine Check Interrupt (offset 0x10)

The EIS Machine Check APU defines a separate set of save/restore registers (MCSRR0/1), a Machine Check Syndrome Register (MCSR) to record the source(s) of machine checks, and a Machine Check Address Register (MCAR) to hold an address associated with a machine check for certain classes of machine checks. Return from Machine Check instructions (**se_rfmci**) are also provided to support returns using MCSRR0/1.

The MSR_{DE} bit is not automatically cleared by a Machine Check exception, but it can be configured to be cleared or left unchanged via the HID0 register ($HID0_{MCCLRDE}$).

When a Machine Check interrupt is taken, registers are updated as shown in the following table.

Table 62-13. Machine Check Interrupt—register settings

Register	Setting description					
MCSRR0	On a best-effort basis, set to the address of some instruction that was executing or about to be executing when the machine check condition occurred.					
MCSRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0

Table continues on the next page...

62.5.5.5 External Input Interrupt (offset 0x40)

An External Input exception is signaled to the processor by the assertion of an interrupt from the interrupt controller. The input is a level-sensitive signal expected to remain asserted until the core acknowledges the external interrupt. If the input is negated early, recognition of the interrupt request is not guaranteed. When the core detects the exception, if the exception is enabled by MSR_{EE}, it takes the External Input interrupt.

An External Input interrupt may be delayed by other higher priority exceptions or if MSR_{EE} is cleared when the exception occurs.

The following table lists register settings when an External Input interrupt is taken.

Table 62-16. External Input Interrupt—Register Settings

Register	Setting description					
SRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.

62.5.5.6 Alignment Interrupt (offset 0x50)

An Alignment exception is generated when any of the following occurs:

- The operand of **lmw** or **stmw** is not word aligned.
- The operand of **lwarx** or **stwcx.** is not word aligned.
- The operand of **lharx** or **sthcx.** is not halfword aligned.
- Execution of a **dcbz** instruction is attempted.

The following table lists register settings when an alignment interrupt is taken.

Table 62-17. Alignment Interrupt—register settings

Vector	$IVPR_{0:23}$ || 0x50					

62.5.5.7 Program Interrupt (offset 0x60)

A program interrupt occurs when no higher priority exception exists and one or more of the following exception conditions occur:

- Illegal Instruction exception

- Privileged Instruction exception
- Trap exception

The e200z210n3 will invoke an Illegal Instruction program exception on attempted execution of the following instructions:

- Unimplemented instructions
- An instruction from the illegal instruction class
- **mtspr** and **mfspr** instructions with an undefined SPR specified
- **mtdcr** and **mfdcr** instructions with an undefined DCR specified

The e200z210n3 will invoke a Privileged Instruction program exception on attempted execution of the following instructions when $MSR_{PR} = 1$ (user mode):

- A privileged instruction
- **mtspr** and **mfspr** instructions that specify a SPRN value with $SPRN_5 = 1$ (even if the SPR is undefined)

The e200z210n3 will invoke a Trap exception on execution of the **tw** instruction if the trap conditions are met and the exception is not also enabled as a Debug interrupt.

The core will invoke an Illegal instruction program exception on attempted execution of the instructions **lswi**, **lswx**, **stswi**, **stswx**, **mfapidi**, **mfdcrx**, **mtdcrx**, or on any *Power ISA 2.06* floating-point instruction. All other defined or allocated instructions that are not implemented by core will cause an illegal instruction program exception.

The following table lists register settings when a Program interrupt is taken.

62.5.5.8 Performance Monitor Interrupt (offset 0x70)

A performance monitor interrupt that may be generated by an enabled condition or event. An enabled condition or event is as follows:

A PMC*x* register overflow condition occurs with the following settings:

- PMLCax_{CE} = 11; that is, for the given counter the overflow condition is enabled.
- PMCx_{OV} = 11; that is, the given counter indicates an overflow.

For a performance monitor interrupt to be signaled on an enabled condition or event, $PMGC0_{PMIE}$ must be set.

Although an exception condition may occur with MSR_{EE} = 0, the interrupt cannot be taken until MSR_{EE} = 1.

The priority of the performance monitor interrupt is below all other asynchronous interrupts.

The following table lists register settings when an performance monitor interrupt is taken.

Table 62-19. Performance Monitor Interrupt—Register Settings

Register	Setting description					
SRR0/ DSRR0[1]	Set to the effective address of the next instruction to be executed.

62.5.5.13 System Reset Interrupt

The System Reset exception is a non-maskable, asynchronous exception signaled to the processor through the assertion of system-defined signals.

A System Reset may be initiated by either a software reset or during power-on reset.

When a reset request occurs, the processor branches to the system reset exception vector without attempting to reach a recoverable state. If reset occurs during normal operation, all operations cease and the machine state is lost.

The following table lists register settings when a System Reset interrupt is taken.

Table 62-24. System Reset Interrupt—register settings

62.6 End-to-End ECC Support

This section describes end-to-end error detection and correction capability (e2eECC) enhancements to address additional diagnostic capabilities for the next generation of embedded designs.

62.6.1 End-to-End ECC control and configuration

e2eECC is controlled by a set of privileged device control registers (DCRs) accessed using the **mfdcr** and **mtdcr** instructions. These registers and the operation of various features are described in the following subsections.

62.6.1.1 End-to-End ECC Control Register 0 (E2ECTL0)

The End-to-End ECC Control Register 0 (E2ECTL0) controls operation of the e2eECC logic.

DCR - 510; Read/Write; Reset - 0x5 || p_e2e_rstcfg[0:3]; Privileged

Figure 62-12. e2eECC Control Register 0 (E2ECTL0)

Table 62-25. E2ECTL0 field descriptions

Bits	Name	Description
0:27	—	Reserved
28	IDAC	Instruction Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Instruction AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[0]** input.
29	IECCEN	Instruction ECC Enable Field 0 End-to-End ECC is disabled for the Instruction interface. No checking of instruction fetch data is performed.

Table continues on the next page...

Table 62-25. E2ECTL0 field descriptions (continued)

Bits	Name	Description
		1 End-to-End ECC is enabled for performing error detection and correction on the Instruction interface. Checking of instruction fetch data is performed with correction of single-bit data errors. Detection of any address errors or uncorrectable multi-bit data errors cause a machine check to be generated if the instruction fetch information is attempted to be used for instruction decoding and execution. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[1]** input.
30	DDAC	Data Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Data AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[2]** input.
31	DECCEN	Data ECC Enable Field 0 End-to-End ECC is disabled for the Data interface. No checking of read data is performed. Writes will still generate the proper check bit values to be supplied to external storage devices. 1 End-to-End ECC is enabled for performing error detection and correction on the Data interface. Checking of read data is performed with correction of single-bit data errors. Detection of any address errors, or uncorrectable multi-bit data errors cause a machine check to be generated. Writes generate the proper check bit values to be supplied to external storage devices. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[3]** input.

e2eECC is enabled by setting the [I,D]ECCEN bit of the E2ECTL0 DCR to a 1. On reset, e2eECC operation may be disabled from detecting or correcting errors based on reset configuration inputs, and no exceptions will be signaled for nonzero calculated syndrome values. This allows for the proper initialization of stored checkbits in any volatile storage by the CPU without causing error conditions due to uninitialized storage. Following the initialization, software may enable e2eECC operation by writing the appropriate values to the $E2ECTL0_{[I,D]ECCEN}$ control bits.

The $E2ECTL0_{[I,D]DAC}$ control bits can be used to remove the address checking component of the ECC logic for the Instruction AHB and Data AHB when address inclusion is not desired.

62.6.1.2 End-to-End ECC fault injection by software

Fault injection provides a way to test error recovery and portions of the error detection/correction logic by intentionally injecting parity errors into the driven checkbit information on the external bus during write operations. No provision is made to generate internal errors on read data due to timing issues; instead, software may intentionally generate errors in the checkbit values to emulate data, address, or checkbit error on external bus write cycles, and read back the written data to cause an error to be detected.

The End-to-End ECC Error Control/Status Register (E2EECSR0) controls operation of the e2eECC error injection logic. It allows for generation of a single error injection operation on the next CPU data write to the external bus only, or for a series of error injection write operations to the external bus, using the WRC and INVC control fields. The WRCHKBIT/CHKINVT field controls which of the **p_hwchkbit[7:0]** outputs are affected.

Control is provided to allow for either inverting the value(s) of one or more of the checkbit outputs **p_hwchkbit[7:0]** in hardware on one or more external write accesses, or for software to directly supply checkbit values to be used for the external write access(es).

The End-to-End ECC Error Control/Status Register (E2EECSR0) also supports access to raw checkbit values via the RCHKBIT status field. This field is updated with checkbit values received on each CPU data read operation to the external bus. For the case of an external read access that receives an ERROR response (HRESP=ERR), the RCHKBIT field is written with all zeros.

Note that Nexus 3 accesses do not cause error injection or the capture of read checkbits, regardless of the settings of the E2EECSR0 register.

The following figure shows the layout of E2EECSR0.

0	RCHKBIT	0	WRC	INVC	0	WCHKBIT/CHKINVT
0 1 2 3	4 5 6 7 8 9 10 11	12 13 14 15	16	17	18 19	20 21 22 23	24 25 26 27 28 29 30 31

DCR - 511; Read/Write; Reset - 0x0; Privileged

Bits	Name	Description
		external memories by performing CPU load operations and then accessing this field prior to the next load operation (assuming interrupts are masked). If the CPU receives an ERROR response (HRESP=ERR) on an external read access, the RCHKBIT field is written with all zeros.
12:15	—	Reserved
16:17	WRC	Write Control 00 No write checkbit substitution is performed by this control bit 01 Checkbit substitution is performed for the next CPU external write access (only) by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. Software must clear this field before rewriting to 01 in order to generate a subsequent checkbit substitution operation. 10 Checkbit substitution is performed for each CPU external write access while this field remains set to 10 by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11 Reserved Note: Checkbit substitution has priority over Error injection
18:19	INVC	Invert Control 00 No error injection is performed by this control bit 01 Error injection is performed for the next CPU external write access (only) by modifying **p_hwchkbit[7:0]** based on CHKINVT. Software must clear this field before rewriting to 01 in order to generate a subsequent error injection operation. 10 Error injection is performed for each CPU external write access while this field remains set to 10 by modifying **p_hwchkbit[7:0]** based on CHKINVT. This field must be cleared by software to discontinue further fault injection. 11 Reserved Note: Checkbit substitution has priority over Error injection
20:23	—	Reserved
24:31	WCHKBIT/ CHKINVT	Write Checkbits / Checkbit Invert Mask This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. This field corresponds bit-wise to **p_hwchkbit[7:0]**. For Checkbit inversion operations via error injection: 0 Checkbit is driven normally 1 Checkbit is inverted before being driven out on **p_hwchkbit[7:0]** when error injection occurs.

Chapter 63
Z4 Core description

63.1 Overview of the e200z4204n3 core

The e200z4204n3 is a dual-issue 32-bit PowerISA 2.06 VLE compliant design with 32-bit general-purpose registers (GPRs). The e200z4204n3 core implements the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in *PowerISA 2.06* , a separate document.

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision floating-point embedded numerics operations using the general-purpose registers.

The e200z4204n3 processor integrates a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock cycle. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

The e200z4204n3 contains an 8 KB Instruction Cache and a 4 KB Data Cache, as well as a Nexus Class 3+ real-time debug module with support for program and data trace features as well as extensive trace controls.

63.2 Register model

This section describes the registers implemented in the e200z4204n3 core. The PowerISA 2.06 architecture defines register-to-register operations for all computational instructions.

The e200z4204n3 extends usage of the general purpose registers to support EFPU operations on the 32-bit GPR registers.

Figure 63-1 and Figure 63-2 show the complete e200z4204n3 register set, all of which are accessible in supervisor mode. Figure 63-3 and Figure 63-4 show the subset of registers accessible in user mode. The number to the right of the special-purpose registers (SPRs) is the decimal number used in the instruction syntax to access the register (for example, the integer exception register (XER) is SPR 1).

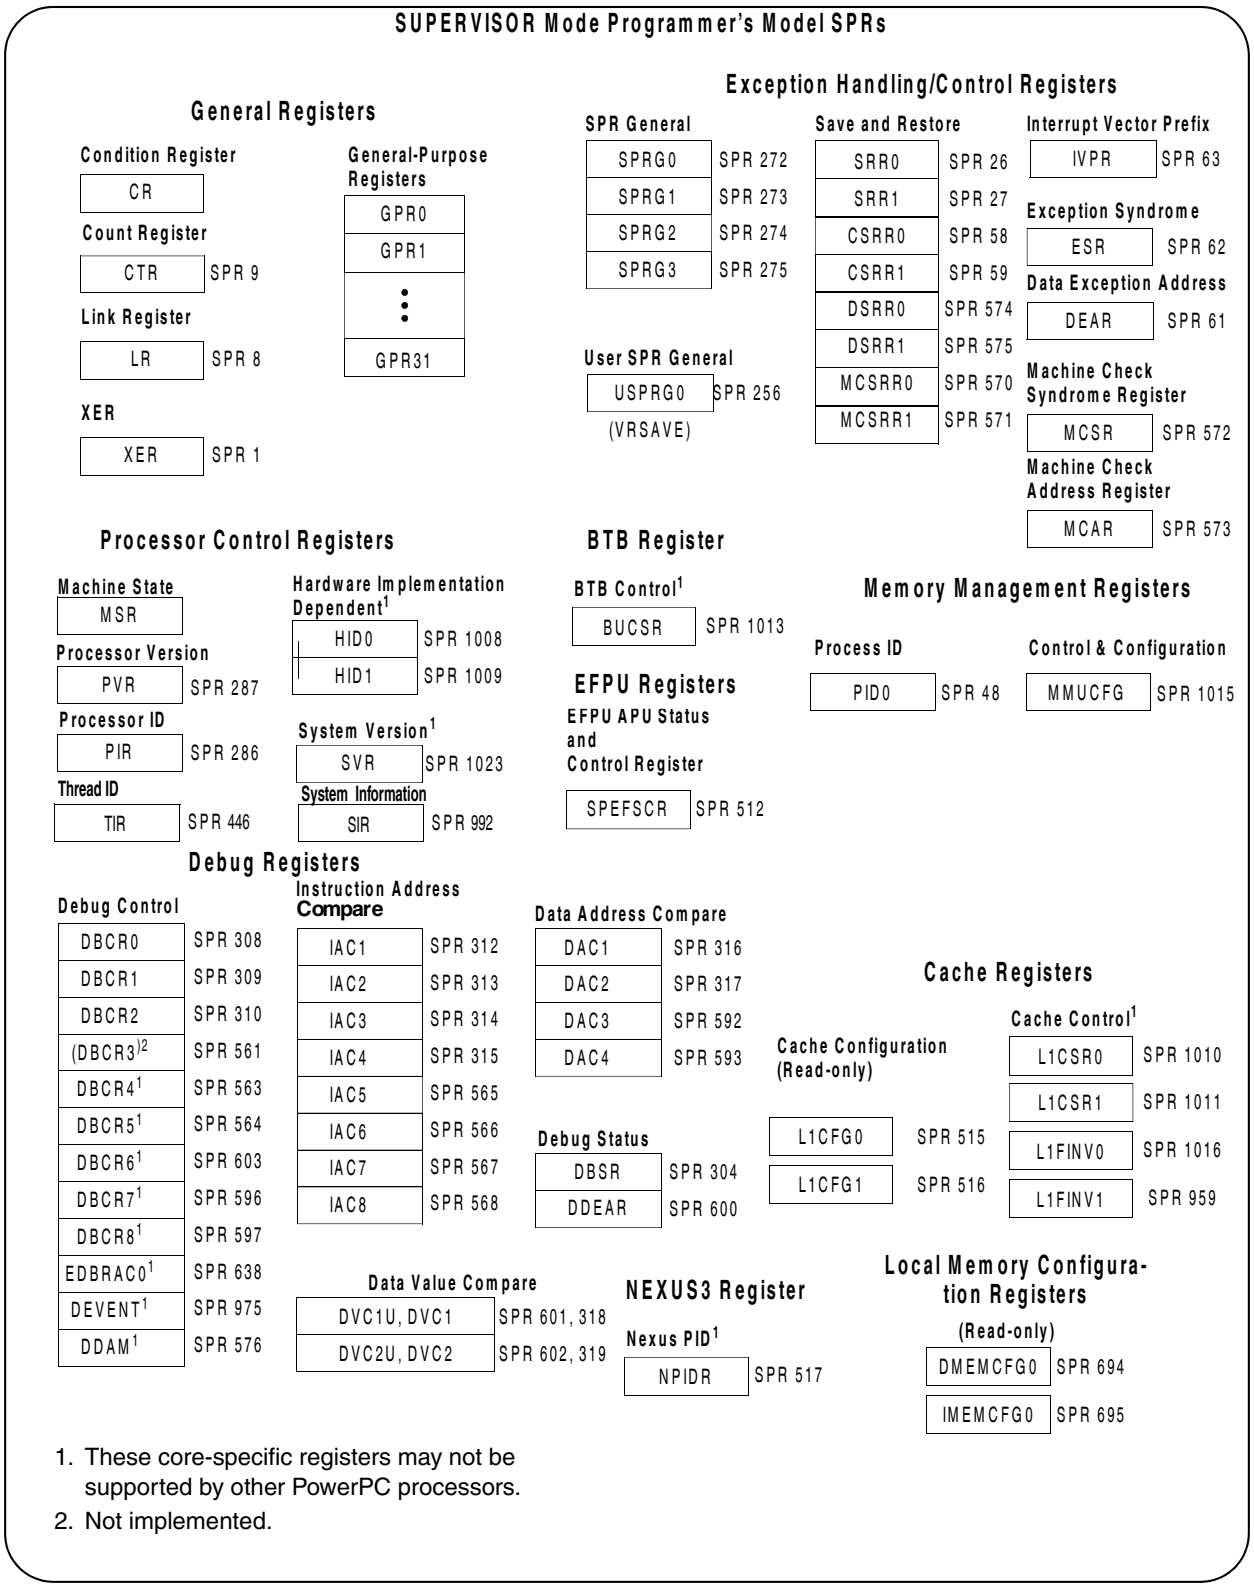

Figure 63-1. e200z4204n3 Supervisor Mode Programmer's Model SPRs

63.2.1 Hardware Implementation Dependent Register 0 (HID0)

The HID0 register is a core implementation dependent register used for various configuration and control functions. It is shown in the following figure.

SPR - 1008; Read/Write; Reset - 0x0

Figure 63-5. Hardware Implementation Dependent Register 0 (HID0)

The HID0 fields are defined in the following table.

Table 63-1. Hardware Implementation-Dependent Register 0

Bits	Name	Description
0 [32]	EMCP	Enable machine check pin (p_mcp_b) 0 p_mcp_b pin is disabled. 1 p_mcp_b pin is enabled. Asserting p_mcp_b causes a machine check interrupt to be reported.
1:13 [33:45]	-	Reserved
14 [46]	ICR	Interrupt Inputs Clear Reservation 0 External Input, Critical Input, and Non-Maskable Interrupts do not affect reservation status 1 External Input, Critical Input, and Non-Maskable Interrupts clear an outstanding reservation
15 [47]	NHR	Not hardware reset 0 indicates to a reset exception handler that a reset occurred if software had previously set this bit 1 indicates to a reset exception handler that no reset occurred if software had previously set this bit Provided for software use. Set anytime by software, cleared by reset.
16:18 [48:50]	-	Reserved
19 [51]	DCLREE	Debug Interrupt Clears MSR_{EE} 0 MSR_{EE} unaffected by Debug Interrupt 1 MSR_{EE} cleared by Debug Interrupt This bit controls whether Debug interrupts force External Input interrupts to be disabled, or whether they remain unaffected.
20 [52]	DCLRCE	Debug Interrupt Clears MSR_{CE} 0 MSR_{CE} unaffected by Debug Interrupt 1 MSR_{CE} cleared by Debug Interrupt This bit controls whether Debug interrupts force Critical interrupts to be disabled, or whether they remain unaffected.
21 [53]	CICLRDE	Critical Interrupt Clears MSR_{DE} 0 MSR_{DE} unaffected by Critical class interrupt 1 MSR_{DE} cleared by Critical class interrupt This bit controls whether Critical interrupts force Debug interrupts to be disabled, or whether they remain unaffected. Machine Check interrupts have a separate control bit.

Table continues on the next page...

Table 63-1. Hardware Implementation-Dependent Register 0 (continued)

Bits	Name	Description
		Note that if Critical Interrupt Debug events are enabled ($DBCR0_{CIRPT}$ set), and MSR_{DE} is set at the time of a Critical Input Critical interrupt, a debug event will be generated after the Critical Interrupt Handler has been fetched, and the Debug handler will be executed first. In this case, $DSRR0_{DE}$ will have been cleared, such that after returning from the debug handler, the Critical interrupt handler will not be run with MSR_{DE} enabled.
22 [54]	MCCLRDE	Machine Check Interrupt Clears MSR_{DE} 0 MSR_{DE} unaffected by Machine Check interrupt 1 MSR_{DE} cleared by Machine Check interrupt This bit controls whether Machine Check interrupts force Debug interrupts to be disabled, or whether they remain unaffected.
23:30 [58:62]	-	Reserved
31 [63]	NOPTI	No-op Touch Instructions 0 icbt, dcbt, dcbtst instructions operate normally 1 icbt, dcbt, dcbtst instructions are no-oped This bit only affects the icbt, dcbt, and dcbtst instructions.

63.2.2 Hardware Implementation Dependent Register 1 (HID1)

The HID1 register is used for bus configuration and system control. It is shown in the following figure.

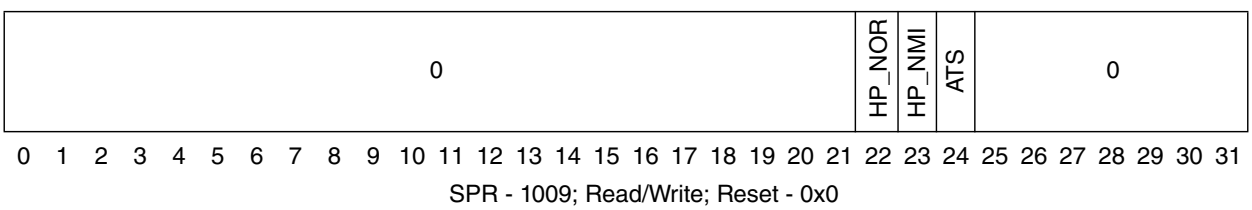

Figure 63-6. Hardware Implementation Dependent Register 1 (HID1)

The HID1 fields are defined in the following table.

Table 63-2. Hardware Implementation-Dependent Register 1

Bits	Name	Description
0:21 [32:53]	-	Reserved
22 [54]	HP_NOR	High priority elevation for normal and external interrupts 0 - High priority elevation for normal and external interrupts is disabled 1 - High priority elevation for normal and external interrupts is enabled

Table continues on the next page...

Table 63-2. Hardware Implementation-Dependent Register 1 (continued)

Bits	Name	Description
		The HP_NOR bitfield enables temporary elevation of the processor's crossbar priority. The relevant Master x field for the processor must also be enabled in the XBAR_CRSn HPEx bitfield. The platform logic elevates the processor's crossbar priority from the time of the IRQ assertion until the appropriate return instruction has been executed. For normal interrupts , the hardware supports the stacking of up to 4 interrupts. No hardware support of stacking for critical or NMI interrupts is provided. These bits may need external synchronization. **NOTE:** Must be used in conjunction with the XBAR_CRSn HPEx setting
23 [55]	HP_NMI	High priority elevation for NMI and critical interrupts 0 - High priority elevation for NMI and critical interrupts is disabled 1 - High priority elevation for NMI and critical interrupts is enabled The HP_NMI bitfield enables temporary elevation of the processor's crossbar priority. The relevant Master x field for the processor must also be enabled in the XBAR_CRSn HPEx bitfield. The platform logic elevates the processor's crossbar priority from the time of the IRQ assertion until the appropriate return instruction has been executed. For normal interrupts , the hardware supports the stacking of up to 4 interrupts. No hardware support of stacking for critical or NMI interrupts is provided These bits may need external synchronization. **NOTE:** Must be used in conjunction with the XBAR_CRSn HPEx setting
24 [56]	ATS	Atomic status (read-only) Indicates state of the reservation bit in the load/store unit.
25:31 [57:63]	-	Reserved

63.3 Instruction timing

Instruction timing in number of processor clock cycles for various instruction classes is shown in the following table. Pipelined instructions are shown with cycles of total latency and throughput cycles. Divide and multiply instructions are not pipelined and block other instructions from executing during execution. Load/store multiple instruction cycles are represented as a fixed number of cycles plus a variable number of cycles where *n* is the number of words accessed by the instruction. In addition, cycle times marked with & require variable number of additional cycles due to serialization.

Table 63-3. Instruction class cycle counts

Class of Instructions	Latency	Throughput	Special Notes
integer: **add, sub, shift, rotate, logical, cntlzw**	1	1	
integer: compare	1	1	

Table continues on the next page...

Table 63-3. Instruction class cycle counts (continued)

Class of Instructions	Latency	Throughput	Special Notes
Branch	3/2/1	3/2/1	Correct branch lookahead allows single cycle execution worst-case mispredicted branch is 3 cycles
multiply (saturating/non-saturating)	2	1	
divide	4-14	4-14	
CR logical	1	1	
loads (non-multiple)	2	1

3. Plus additional synchronization time.

63.4 Dual-issue operation

The instruction issue unit attempts to issue a pair of instructions to the execution units each cycle. Source operands for each of the instructions are provided from the GPRs or from the operand feed-forward muxes. Data or resource hazards may create stall conditions that cause instruction issue to be stalled for one or more cycles until the hazard is eliminated.

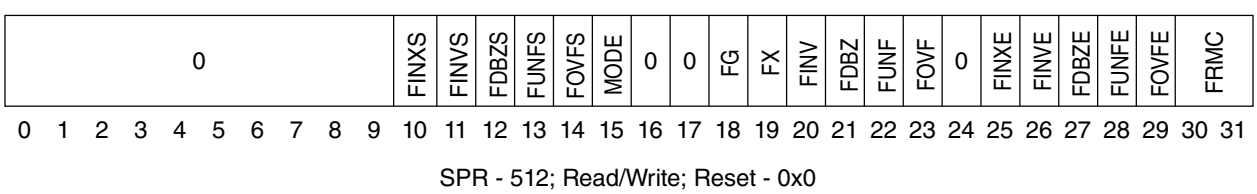
The execution units write the result of a finished instruction onto the proper result bus and into the destination registers. The writeback logic retires an instruction when the instruction has finished execution. As many as three results can be simultaneously written.

Two execution units are provided to allow dual issue of most instructions. Only a single load/store unit is provided. Only a single integer multiply and divide unit is provided, thus a pair of multiply or divide instructions cannot issue simultaneously. In addition, the divide unit is blocking.

The following table shows the concurrent instruction issue capabilities. Note that data dependencies between instructions will generally preclude dual-issue of those instructions.

Table 63-6. Concurrent instruction issue capabilities

Class of instruction	Branch	Load/Store	Scalar integer	Scalar float	Special
Branch	—	yes	yes	yes	—
Load/Store	yes	—	yes	yes	—
Scalar integer	yes	yes	yes[1]	yes	—
Scalar float	yes	yes	yes	—	—
Special	—	—	—	—	—



1. Excludes multiply or divide class instructions occurring in both issue slots.

63.5 Reservation instructions and cache interactions

If the CPU supports reservation instruction functionality, the CPU treats reservation instruction (**lbarx**, **lharx**, **lwarx**, **stbcx**, **sthcx**, and **stwcx**) accesses as though they were cache-inhibited, and forces a cache miss. A reservation access is always issued to the bus. This is done to allow external reservation logic to be built that properly signals a reservation failure. The bus access will be treated as a single-beat transfer.

63.6 Signal Processing Extension/Embedded Floating-point Status and Control Register (SPEFSCR)

Status and control for embedded floating-point operations use the SPEFSCR. The SPEFSCR is implemented as special-purpose register (SPR) number 512 and is read and written by the **mfspr** and **mtspr** instructions. The SPEFSCR is shown in the following figure.

SPR - 512; Read/Write; Reset - 0x0

Figure 63-7. EFPU Status and Control Register (SPEFSCR)

The SPEFSCR bits are defined in the following table.

Table 63-7. EFPU Status and Control Register field descriptions

Bits	Name	Description
0:9 (32:41)	—	Reserved
10 (42)	FINXS	Embedded Floating-point Inexact Sticky Flag The FINXS bit is set to 1 whenever the execution of a floating-point instruction delivers an inexact result and no Floating-point Data exception is taken, or if the result of a Floating-point instruction results in overflow (FOVF = 1), but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1), but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. The FINXS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
11 (43)	FINVS	Embedded Floating-point Invalid Operation Sticky Flag The FINVS bit is set to a 1 when a floating-point instruction sets the FINV bit to 1. The FINVS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
12 (44)	FDBZS	Embedded Floating-point Divide by Zero Sticky Flag The FDBZS bit is set to 1 when a floating-point divide instruction sets the FDBZ bit to 1. The FDBZS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
13 (45)	FUNFS	Embedded Floating-point Underflow Sticky Flag The FUNFS bit is set to 1 when a floating-point instruction sets the FUNF bit to 1. The FUNFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
14 (46)	FOVFS	Embedded Floating-point Overflow Sticky Flag The FOVFS bit is set to 1 when a floating-point instruction sets the FOVF bit to 1. The FOVFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
15 (47)	MODE	Embedded Floating-point Operating Mode This bit controls the operating mode of the EFPU. The e200z4204n3 supports only mode 0. Software should read the value of this bit after writing it to determine if the implementation supports the selected mode. Implementations will return the value written if the selected mode is a supported mode, otherwise the value read will indicate the hardware supported mode. 0 Default hardware results operating mode 1 IEEE754 hardware results operating mode (not supported by e200 core)
16 (48)	—	Reserved
17 (49)	—	Reserved
18 (50)	FG	Embedded Floating-point Guard bit FG is supplied for use by the Floating-point Round exception handler. FG is zeroed if a Floating-point Data Exception occurs.
19 (51)	FX	Embedded Floating-point Sticky bit FX is supplied for use by the Floating-point Round exception handler. FX is zeroed if a Floating-point Data Exception occurs.
20 (52)	FINV	Embedded Floating-point Invalid Operation / Input error

Table continues on the next page...

Table 63-7. EFPU Status and Control Register field descriptions (continued)

Bits	Name	Description
		In mode 0, the FINV bit is set to 1 if the A or B operand of a floating-point instruction is Infinity, NaN, or Denorm, or if the operation is a divide and the dividend and divisor are both 0. In mode 1, the FINV bit is set on an IEEE754 invalid operation (IEEE754-1985 sec7.1).
21 (53)	FDBZ	Embedded Floating-point Divide by Zero The FDBZ bit is set to 1 when a floating-point divide instruction executed with divisor of 0, and the l dividend is a finite non-zero number.
22 (54)	FUNF	Embedded Floating-point Underflow The FUNF bit is set to 1 when the execution of a floating-point instruction results in an underflow.
23 (55)	FOVF	Embedded Floating-point Overflow The FOVF bit is set to 1 when the execution of a floating-point instruction results in an overflow.
24 (56)	—	Reserved
25 (57)	FINXE	Embedded Floating-point Inexact Exception Enable If the exception is enabled, a Floating-point Round exception is taken if the result of a Floating-point instruction does not result in overflow or underflow, and the result is inexact (FG | FX = 1), or if the result of a Floating-point instruction does result in overflow (FOVF = 1) but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1 or FUNFH = 1) but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. 0 Exception disabled 1 Exception enabled
26 (58)	FINVE	Embedded Floating-point Invalid Operation / Input Error Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FINV bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
27 (59)	FDBZE	Embedded Floating-point Divide by Zero Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FDBZ bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
28 (60)	FUNFE	Embedded Floating-point Underflow Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FUNF bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
29 (61)	FOVFE	Embedded Floating-point Overflow Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FOVF bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
30:31	FRMC	Embedded Floating-point Rounding Mode Control

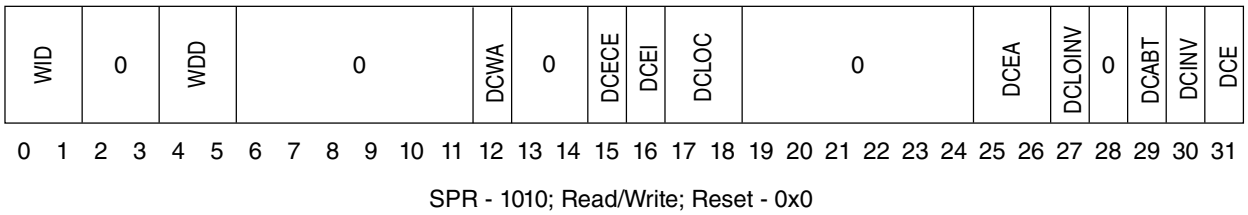
Table 63-7. EFPU Status and Control Register field descriptions

Bits	Name	Description
(62:63)		00 Round to Nearest 01 Round toward Zero 10 Round toward +Infinity 11 Round toward -Infinity

63.7 Cache

This section describes the cache registers, cache control instructions, and various cache operations.

63.7.1 Cache overview



The e200z4204n3 core supports an 8 KB 2-way set-associative instruction cache and a 4 KB 2-way set-associative data cache with a 32-byte line size. The caches improve system performance by providing low-latency data to the e200z4204n3 instruction and data pipelines, which decouples processor performance from system memory performance.

The e200z4204n3 core also contains an 8-entry store buffer to decouple store completion to the processor from store completion on the data interface to further improve system performance.

Instruction and data addresses from the processor are used to index the cache arrays. If the access address matches a valid cache tag entry, the access hits in the cache.

63.7.2 L1 Cache Control and Status Register 0 (L1CSR0)

The L1 Cache Control and Status Register 0 (L1CSR0) is a 32-bit register used for general control of the data cache and for disabling ways in both caches. The L1CSR0 register is accessed using a **mfspr** or **mtspr** instruction. The L1CSR0 register is shown in the following figure.

SPR - 1010; Read/Write; Reset - 0x0

Figure 63-8. L1 Cache Control and Status Register 0 (L1CSR0)

The L1CSR0 fields are described in the following table.

Table 63-8. L1CSR0 field descriptions

Bits	Name	Description
0:1	WID	Way Instruction Disable Bit 0 corresponds to way 0. Bit 1 corresponds to way 1. The WID bits may be used for locking ways of the instruction cache, and also affect the replacement policy of the instruction cache. 0 The corresponding way in the instruction cache is available for replacement by instruction miss line fills. 1 The corresponding way instruction cache is not available for replacement by instruction miss line fills.
2:3	—	Reserved[1]
4:5	WDD	Way Data Disable Bit 4 corresponds to way 0. Bit 5 corresponds to way 1. The WDD bits may be used for locking ways of the data cache, and also affect the replacement policy of the data cache. 0 The corresponding way in the data cache is available for replacement by data miss line fills. 1 The corresponding way in the data cache is not available for replacement by data miss line fills.
6:11	—	Reserved[2]
12	DCWA	Data Cache Write Allocation Policy This bit also controls merging of store data into the linefill buffer while a cache linefill is in progress. Store data will not be merged when write allocation is disabled. 0 Cache line allocation on a cacheable write miss is disabled 1 Cache line allocation on a cacheable write miss is enabled
13:14	—	Reserved[2]
15	DCECE	Data Cache Error Checking Enable 0 Error Checking is disabled 1 Error Checking is enabled
16	DCEI	Data Cache Error Injection

Table continues on the next page...

Table 63-8. L1CSR0 field descriptions (continued)

Bits	Name	Description
		DCEI will cause injection of errors regardless of the setting of DCECE, although reporting of errors will be masked while DCECE = 0. 0 Cache Error Injection is disabled 1 A double-bit error will be injected on each write into the cache data array by inverting the two uppermost parity check bits (p_dchk[0:1]). This includes writes due to store hits as well as writes due to cache line refills.
17:18	DCLOC	Data Cache Lockout Control **Note:** For the **dcbi** and **dcbf** instructions, and for specialized load/store instructions, no lockout operation is performed, regardless of the occurrence of EDC/ECC error conditions, and errors are handled in the same manner as when lockout is disabled. **Note:** When operating in MC mode (DCEA = 00), detected errors on cache-inhibited accesses will not cause a data cache line to be locked out, instead the cache line contents are ignored. 00 Cache line lockout is disabled (and array LO indicators are ignored). 01 Cache line lockout is enabled. Cache lines with any tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. 10 Cache line lockout is enabled. Cache lines with any tag or data errors will have the corresponding lockout indicators set. A Machine check will still be generated for an error if the operation would have normally generated one. 11 Cache line lockout is enabled. Cache lines with uncorrectable tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. If a correctable tag error occurs, and is re-detected on recycling the access after a correction cycle for the tag is performed, the line is locked out regardless of detecting a single-bit or multi-bit error.
19:24	—	Reserved[2]
25:26	DCEA	Data Cache Error Action 00 Error Detection causes Machine Check exception. 01 Error Detection causes Correction/Auto-invalidation. No machine check is generated for most cases. Correction is performed for single-bit tag errors, and lines with multi-bit tag errors are invalidated. Correction is performed for single or multi-bit data errors on cache hits by reloading of the line. 10 Reserved 11 Reserved
27	DCLOINV	Data Cache Lockout Indicator Invalidate When written to a 1 in conjunction with writing DCINV to a 1, a cache lockout indicator invalidation operation is initiated by hardware, and the LO bits are cleared, removing all line lockout status. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation

Table continues on the next page...

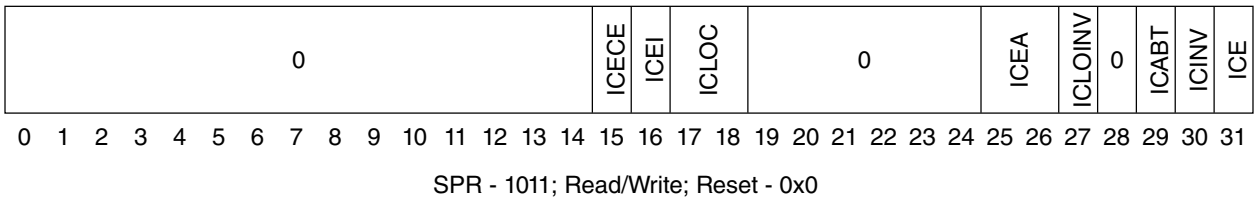


Table 63-8. L1CSR0 field descriptions (continued)

Bits	Name	Description
		operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the data cache enable (DCE) value. When DCINV = 0: Reserved, do not set to 1 When DCINV = 1: 0 No cache lockout bit invalidate 1 Cache lockout indicator invalidation operation
28	—	Reserved[2]
29	DCABT	Data Cache Operation Aborted Indicates a Cache Invalidate operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.
30	DCINV	Data Cache Invalidate When written to a 1, a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the data cache enable (DCE) value. 0 No cache invalidate 1 Cache invalidation operation
31	DCE	Data Cache Enable When disabled, cache lookups are not performed for normal load or store accesses.Other L1CSR0 cache control operations are still available. Also, operation of the store buffer is not affected by DCE. 0 Cache is disabled 1 Cache is enabled

1. These bits are not implemented and should be written with zero for future compatibility.

63.7.3 L1 Cache Control and Status Register 1 (L1CSR1)

The L1 Cache Control and Status Register 1 (L1CSR1) is a 32-bit register used for general control of the instruction cache. The L1CSR1 register is accessed using a **mfspr** or **mtspr** instruction. The L1CSR1 register is shown in the following figure.

SPR - 1011; Read/Write; Reset - 0x0

Figure 63-9. L1 Cache Control and Status Register 1 (L1CSR1)

The L1CSR1 fields are described in the following table.

Table 63-9. L1CSR1 field descriptions

Bits	Name	Description
0:14	—	Reserved[1]
15	ICECE	Instruction Cache Error Checking Enable 0 Error Checking is disabled 1 Error Checking is enabled
16	ICEI	Instruction Cache Error Injection Enable ICEI will cause injection of errors regardless of the setting of ICECE, although reporting of errors will be masked when ICECE = 0. 0 Cache Error Injection is disabled 1 A double-bit error will be injected into each doubleword written into the cache by inverting the two uppermost parity check bits.
17:18	ICLOC	Instruction Cache Lockout Control **Note:** For the **icbi** instruction, no lockout operation is performed, regardless of the occurrence of EDC/ECC error conditions, and errors are handled in the same manner as when lockout is disabled. See ECC/EDC Error Handling for Cache Control Operations and Instructions. **Note:** When operating in MC mode (ICEA = 00), detected errors on cache-inhibited accesses will not cause an instruction cache line to be locked out, instead the cache line contents are ignored. 00 Cache line lockout is disabled (and array LO indicators are ignored). 01 Cache line lockout is enabled. Cache lines with any tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. 10 Cache line lockout is enabled. Cache lines with any tag or data errors will have the corresponding lockout indicators set. A Machine check will still be generated for an error if the operation would have normally generated one. 11 Cache line lockout is enabled. Cache lines with uncorrectable tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. If a correctable tag error occurs, and is re-detected on recycling the access after a correction cycle for the tag is performed, the line is locked out regardless of detecting a single-bit or multi-bit error.
19:24	—	Reserved[1]

Table continues on the next page...

Table 63-9. L1CSR1 field descriptions (continued)

Bits	Name	Description
25:26	ICEA	Instruction Cache Error Action 00 Error Detection causes Machine Check exception. 01 Error Detection causes Correction/Auto-invalidation. No machine check is generated for most cases. Correction is performed for single-bit tag errors, and lines with multi-bit tag errors are invalidated. Correction is performed for single or multi-bit data errors on cache hits by reloading of the line. 10 Reserved 11 Reserved
27	ICLOINV	Instruction Cache Lockout Indicator Invalidate When written to a 1 in conjunction with writing ICINV to a 1, a cache lockout indicator invalidation operation is initiated by hardware, and the LO bits are cleared, removing all line lockout status. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the instruction cache enable (ICE) value. When ICINV = 0: Reserved, do not set to 1 When ICINV = 1: 0 No cache lockout bit invalidate 1 Cache lockout indicator invalidation operation
28	—	Reserved[1]
29	ICABT	Instruction Cache Operation Aborted Indicates a Cache Invalidate operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.
30	ICINV	Instruction Cache Invalidate When written to a 1, a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 130 cycles to complete. Invalidation occurs regardless of the enable (ICE) value. 0 No cache invalidate 1 Cache invalidation operation
31	ICE	Instruction Cache Enable When disabled, cache lookups are not performed for instruction accesses. Other L1CSR1 cache control operations are still available and are not affected by ICE. 0 Cache is disabled 1 Cache is enabled

1. These bits are not implemented and should be written with zero for future compatibility.

63.7.4 L1 Cache Configuration Register 0 (L1CFG0)

The L1 Cache Configuration Register 0 (L1CFG0) is a 32-bit read-only register. L1CFG0 provides information about the configuration of the e200z4204n3 L1 data cache design. The contents of the L1CFG0 register can be read using a **mfspr** instruction. The L1CFG0 register is shown in the following figure.

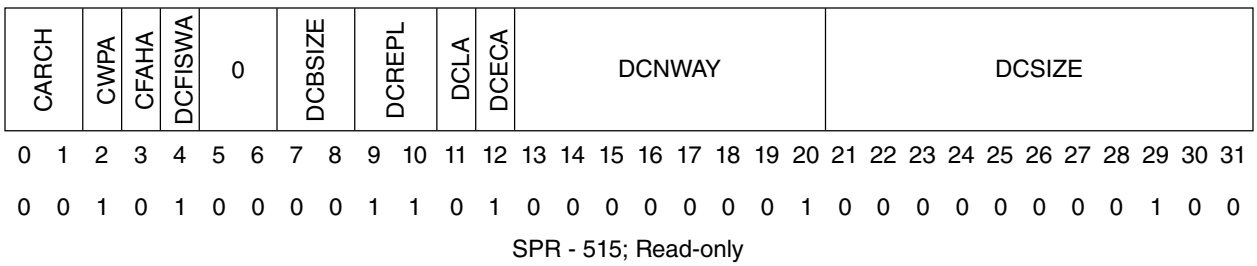

Figure 63-10. L1 Cache Configuration Register 0 (L1CFG0)

The L1CFG0 bits are described in the following table.

Table 63-10. L1CFG0 field descriptions

Bits	Name	Description
0:1	CARCH	Cache Architecture 00 The cache architecture is Harvard
2	CWPA	Cache Way Partitioning Available 1 The caches support partitioning of way availability for I/D accesses
3	DCFAHA	Data Cache Flush All by Hardware Available 0 The data cache does not support Flush All in Hardware
4	DCFISWA	Data Cache Flush/Invalidate by Set and Way Available 1 The data cache supports invalidation by Set and Way via L1FINV0
5:6	—	Reserved - read as zeros
7:8	DCBSIZE	Data Cache Block Size 00 The data cache implements a block size of 32 bytes
9:10	DCREPL	Data Cache Replacement Policy 11 The data cache implements a FIFO replacement policy
11	DCLA	Data Cache Locking APU Available 0 The data cache does not implement the line locking APU
12	DCECA	Data Cache Error Checking Available 1 The data cache implements error checking
13:20	DCNWAY	Data Cache Number of Ways 0x01 The data cache is 2-way set-associative
21:31	DCSIZE	Data Cache Size 0x004 The size of the data cache is 4 KB

63.7.5 L1 Cache Configuration Register 1 (L1CFG1)

The L1 Cache Configuration Register 1 (L1CFG1) is a 32-bit read-only register. L1CFG1 provides information about the configuration of the e200z4204n3 L1 instruction cache design. The contents of the L1CFG1 register can be read using a **mfspr** instruction. The L1CFG1 register is shown in the following figure.

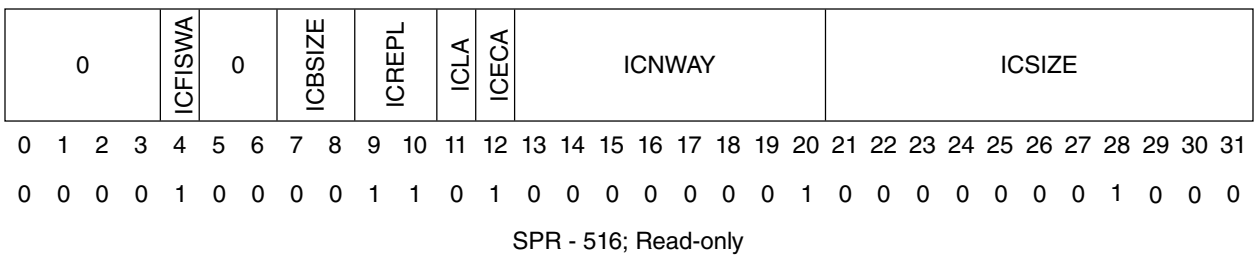

Figure 63-11. L1 Cache Configuration Register 1 (L1CFG1)

The L1CFG1 fields are described in the following table.

Table 63-11. L1CFG1 field descriptions

Bits	Name	Description
0:3	—	Reserved - read as zeros
4	ICFISWA	Instruction Cache Flush/Invalidate by Set and Way Available 1 The instruction cache supports invalidation by Set and Way via L1FINV1
5:6	—	Reserved - read as zeros
7:8	ICBSIZE	Instruction Cache Block Size 00 The instruction cache implements a block size of 32 bytes
9:10	ICREPL	Instruction Cache Replacement Policy 11 The instruction cache implements a FIFO replacement policy
11	ICLA	Instruction Cache Locking APU Available 0 The instruction cache does not implement the line locking APU
12	ICECA	Instruction Cache Error Checking Available 1 The instruction cache implements error checking
13:20	ICNWAY	Instruction Cache Number of Ways 0x01 The instruction cache is 2-way set-associative
21:31	ICSIZE	Instruction Cache Size 0x008 The size of the instruction cache is 8 KB

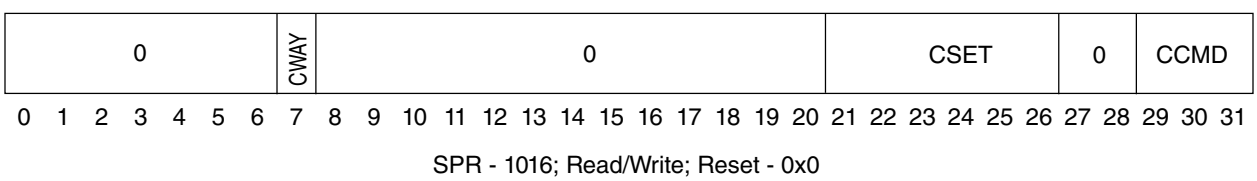
63.7.6 Data cache software coherency

Data cache coherency is supported through software operations to invalidate lines using either a **dcbi** or **dcbf** instruction, or by using the L1FINV0 control register.

Data cache misses will force the store buffer to empty prior to performing the access.

63.7.7 Data cache hardware coherency

Data cache coherency is not supported in hardware. Software operations must generally be used to maintain coherency. Debug support is provided, however, for a D-Cache line invalidation operation requested by an external hardware debugger. When requested by an external hardware debugger tool operating through the OnCE port, an individual cache line invalidation operation will be scheduled to occur at the next available D-Cache access cycle.



63.7.8 Cache invalidate by set and way

The e200z4204n3 supports cache set/way invalidation under software control. The caches may be invalidated by index and way through a **mtspr l1finv{0,1}** instruction.

The L1 Flush and Invalidate Control Registers (L1FINV{0.1}) are 32-bit SPRs used to select a cache set and way to be invalidated. This function is available even when a cache is disabled. L1FINV0 is used for data cache operations, while L1FINV1 is used for instruction cache operations.

63.7.8.1 L1 Flush and Invalidate Control Register 0 (L1FINV0)

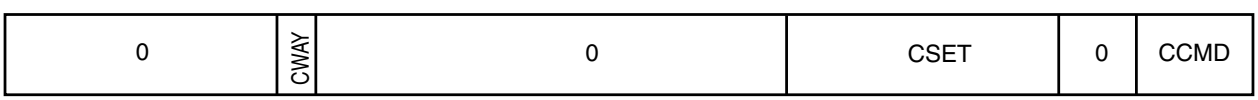
The SPR number for L1FINV0 is 1016 in decimal. The L1FINV0 register is shown in the following figure.

SPR - 1016; Read/Write; Reset - 0x0

Figure 63-12. L1 Flush/Invalidate Register 0 (L1FINV0)

The L1FINV0 bits are described in the following table.

Table 63-12. L1FINV0 field descriptions



Bits	Name	Description
0:6	—	Reserved[1] for way extension
7	CWAY	Cache Way Specifies the data cache way to be selected
8:20	—	Reserved[1] for set extension
21:26	CSET	Cache Set Specifies the cache set to be selected
27:28	—	Reserved[1] for set/command extension
29:31	CCMD	Cache Command 000 = The data contained in this entry is invalidated. LO bits are unaffected 001 Reserved 01x Reserved 100 Reserved 101 The data contained in this entry is invalidated. LO bits are cleared 11x Reserved

1. These bits are not implemented and should be written with zero for future compatibility.

For invalidation operations via L1FINV0, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error. Invalidations conditionally affect the state of the lockout bits (LO).

63.7.8.2 L1 Flush and Invalidate Control Register 1 (L1FINV1)

The L1FINV1 register is shown in following figure.

SPR - 959; Read/Write; Reset - 0x0

Figure 63-13. L1 Flush/Invalidate Register 1 (L1FINV1)

The L1FINV1 bits are described in the following table.

Table 63-13. L1FINV1 field descriptions

Bits	Name	Description
0:6	—	Reserved for way extension
7	CWAY	Cache Way

Table continues on the next page...

Table 63-13. L1FINV1 field descriptions (continued)

Bits	Name	Description
		Specifies the instruction cache way to be selected
8:19	—	Reserved[1] for set extension
20:26	CSET	Cache Set Specifies the instruction cache set to be selected
27:28	—	Reserved[1] for set/command extension
29:31	CCMD	Cache Command 000 The data contained in this entry is invalidated. LO bits are unaffected 001 Reserved 01x Reserved 100 Reserved 101 The data contained in this entry is invalidated. LO bits are cleared 11x Reserved

1. These bits are not implemented and should be written with zero for future compatibility.

For invalidation operations via L1FINV1, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error. Invalidations conditionally affect the state of the lockout bits (LO).

63.7.9 Cache EDC/ECC parity protection

Cache parity protection is supported for both the tag and data arrays of each cache. Seven parity check bits are provided for each tag entry for the tag arrays of both caches to support error detection and correction (ECC - SECDED). Eight parity check bits are provided for each doubleword in the data arrays of the I-Cache, and each word in the data arrays of the D-Cache, which are used for single- and double-bit error detection (EDC - DED, double error detection). Utilizing ECC/EDC protection, many multi-bit errors are also detected.

The error detection codes also cover the cache index address of the cache line, providing additional protection against addressing errors. If any type of error (including a single-bit error in one of the index bits) is encountered in one of the index address bits, it is treated as an uncorrectable tag ECC error to protect against internal addressing failures. No attempt will be made to correct single-bit errors where the syndrome indicates an index address bit.

Tag ECC and data EDC checking is controlled by the L1CSR0[DCECE] and L1CSR1[ICECE] control fields. When error checking is enabled, checking is performed on each cache access. Errors are not signaled by the respective cache when cache error checking is disabled for that cache (L1CSR $\{0, 1\}_{[D,I]CECE} = 0$).

If an uncorrectable tag ECC error is detected on any portion of a tag accessed during cache lookups performed because of instruction fetching, normal loads, or normal stores, a tag ECC error is signaled, regardless of whether a cache hit or miss occurs. Otherwise, if a cache hit for an instruction fetch or a normal load occurs and a data EDC error is detected on any portion of the accessed data, a parity error is also signaled.

Store hits to the D-Cache will be placed into one of the RMW buffers to support EDC checkbit operation. If the store is a partial-width store, the cache data word corresponding to the address of the store is read into the next available buffer, the store data is merged, and the new EDC checkbits for the word are calculated. If the store is a full-width store, no read of the cache data is performed, since the store will overwrite the full EDC data granularity, and the EDC checkbits can be computed directly. Buffers are managed on a FIFO basis. If no buffer is available to hold the store data, a stall is incurred while a buffer (or two if possible) is written back to the cache to be freed for holding the new store. Buffers are written back to the D-Cache during otherwise idle cycles when two buffers are occupied, providing a simple form of store gathering.

Signaling of an ECC error or EDC error may cause a Machine Check exception to occur. One or more syndrome bits may be set in the Machine Check Syndrome register, or may instead result in a correction/auto-invalidation operation and not result in an exception being signaled. Both may occur, depending on the error action control setting in the appropriate cache control register.

63.7.9.1 Cache line lockout

In addition to the ECC/EDC protection employed for the caches, each cache line in the I-Cache and D-Cache has a lockout indicator composed of a redundant set of lockout bits. These lockout bits can selectively be set when certain errors occur in either the tag or the data portion of the cache line. Use of the lockout function and control over error conditions that cause a lockout to occur are controlled by $L1CSR\{0,1\}_{[D,I]CLOC}$. When the lockout function is enabled, lines that encounter selected tag ECC or data EDC errors on normal instruction fetch. load. or store accesses will have their lockout bits set. When the lockout indicator is set, the line will not be replaced and will remain in an invalid state, effectively disabling it. Also, future tag ECC or data EDC errors on the line are ignored. Cache-inhibited accesses will only set lockout indicators on lines not in a locked way. In addition, no lockout indicators are set by cache-inhibited accesses when operating in machine check mode.

When operating in machine check mode, if lockout controls are enabled via $L1CSR\{0,1\}_{[D.I]CLOC]}$, lockout bit parity errors on any line detected on a cacheable cache lookup will generate a machine check exception.

If correction/auto-invalidation is instead enabled, on each cache lookup operation for an instruction fetch or normal load or store access, if a single- or double-bit lockout bit parity error is detected in one or more ways and lockout controls are enabled, the lockout error(s) will be corrected by rewriting all lockout bits to the asserted state, and no machine check is generated, unless the line is in a locked way. If a line in a locked way incurs a LO bit parity error, a machine check will be generated to ensure that any possible new lockout of the line is reported. For non-cacheable accesses, lockout bit parity errors will only be corrected for lines not in a locked way. Lockout bit parity errors do not generate a machine check for non-cacheable accesses in either error action mode, thus lockout bit correction is not performed for lockout bit parity errors detected on a line in a locked way.

In addition, to avoid certain exception conditions and for consistency with error reporting, specialized load/store accesses do not set LO bits; instead, cache contents are ignored for lines with those errors. Cache flush and invalidate instructions do not report or correct lockout bit parity errors. For both of these cases, a future cacheable normal access will perform the lockout function if required.

63.7.10 Cache error injection

Cache error injection provides a way to test error recovery by intentionally injecting parity errors into the instruction and/or data cache.

Error injection into the instruction cache operates as follows:

- If $L1CSR1_{ICEI}$ is set, any instruction cache line fill to the instruction cache data has the associated two most significant parity check bits inverted in the instruction cache data array for each doubleword loaded.

Error injection for the data cache operates as follows:

- If $L1CSR0_{DCEI}$ is set, any cache line fill to the data cache data array has the associated two most significant parity check bits inverted in the data array for each word loaded. Additionally, inverted parity bits are generated for any data stored into the data cache data array on a store hit.

Cache parity error injection is not performed for cache debug write accesses, since parity bit values written can be directly controlled.

In order to clear the parity errors, a cache invalidation or an invalidation of the lines that could have had an injected parity error may be performed. Line invalidation may be performed by an **icbi/dcbi** instruction or an L1FINV{0.1} invalidation operation.

63.8 Exceptions

Interrupts implemented in the e200z4204n3 core and the exception conditions that cause them are listed in the following table.

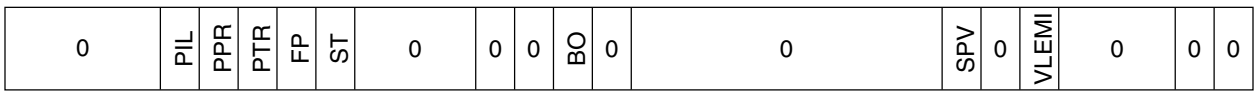


Table 63-14. Exceptions and conditions

Interrupt type	Interrupt vector offset value	Causing conditions
System reset	none, vector to [p_rstbase[0:29]] || 2'b00	Reset
Critical Input	0x00[1]	**p_critint_b** is asserted and MSR_{CE} = 1.
Machine check	0x10	1. **p_mcp_b** transitions from negated to asserted 2. ISI or Bus Error on first instruction fetch for an exception handler 3. Parity Error signaled on Cache access 4. External bus error 5. Stack limit check failure
Machine check (NMI)	0x10	Non-Maskable Interrupt
Data Storage	0x20	Access control
Instruction Storage	0x30	Access control
External Input	0x40[2]	Interrupt Controller interrupt and MSR_{EE} = 1
Alignment	0x50	1. **lmw**, **stmw** not word aligned 2. **lwarx** or **stwcx.** not word aligned, **lharx** or **sthcx.** not halfword aligned 3. **dcbz**
Program	0x60	Illegal, Privileged, Trap
Performance Monitor	0x70	Performance Monitor Enabled Condition or Event w/PMGC0[UDI] = 0
System call	0x80	Execution of the System Call (**se_sc**) instruction
Debug	0x90	Trap, Instruction Address Compare, Data Address Compare, Instruction Complete, Branch Taken, Return from Interrupt, Interrupt Taken, Debug Counter, External Debug Event, Unconditional Debug Event, Performance Monitor Enabled Condition or Event w/ $PMGC0_{UDI}$ = 1
EFPU Data Exception	0xA0	Embedded Floating-point Data Exception
EFPU Round Exception	0xB0	Embedded Floating-point Round Exception
TBD	0xC0–0xF0	Reserved for future processor use

1. Autovectored Critical Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.
2. Autovectored External Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.

63.8.1 Exception Syndrome Register (ESR)

The Exception Syndrome Register (ESR) provides a *syndrome* to differentiate between exceptions that can generate the same interrupt type.

SPR - 62; Read/Write; Reset - 0x0

Figure 63-14. Exception Syndrome Register (ESR)

The ESR bits are defined in the following table.

Table 63-15. ESR field descriptions

Bit(s)	Name	Description	Associated interrupt type
0:3	—	Reserved	—
4	PIL	Illegal Instruction exception For e200z4204n3, PIL is used for both illegal and unimplemented instructions.	Program
5	PPR	Privileged Instruction exception	Program
6	PTR	Trap exception	Program
7	FP	Floating-point operation	Program
8	ST	Store operation	Alignment Data Storage
9:11	—	Reserved	—
12	—	Reserved	—
13	—	Reserved	—

63.8.2 Machine State Register (MSR)

The Machine State Register defines the state of the processor. The e200z4204n3 MSR is shown in the following figure.

Read/Write; Reset - 0x0

Figure 63-15. Machine State Register (MSR)

The MSR bits are defined in the following table.

Table 63-16. MSR field descriptions

Bit(s)	Name	Description
0:5	—	Reserved
6	SPV	SP/Embedded FP/Vector available 0 SP/Embedded FP Double/Vector unit is unavailable. The processor cannot execute SP/ Embedded FP Double or Vector Unit instructions. 1 SP/Embedded FP Double/Vector unit is available. The processor can execute SP/ Embedded FP Double or Vector Unit instructions. **NOTE:** For e200z4204n3, these units are not supported in hardware, and an Illegal Instruction exception will be generated for attempted execution of these instructions regardless of the setting of SPV. SPV is ignored, but cleared on exceptions.
7:12	—	Reserved
13	WE	Wait State (Power management) enable. **NOTE:** This bit is implementation dependent and is being phased out. It will be removed in a future release. Currently it is implemented as a writeable bit, and is ignored, but cleared on exceptions.
14	CE	Critical Interrupt Enable 0 Critical Input interrupts are disabled. 1 Critical Input interrupts are enabled.

Table continues on the next page...

Table 63-16. MSR field descriptions (continued)

Bit(s)	Name	Description
15	—	Reserved
16	EE	External Interrupt Enable 0 External Input interrupts are disabled. 1 External Input interrupts are enabled.
17	PR	Problem State 0 The processor is in supervisor mode, can execute any instruction, and can access any resource (e.g. GPRs, SPRs, MSR, etc.). 1 The processor is in user mode, cannot execute any privileged instruction, and cannot access any privileged resource.
18	FP	0 Floating point unit is unavailable. The processor cannot execute floating-point instructions, including floating-point loads, stores, and moves. 1 Floating Point unit is available. The processor can execute floating-point instructions. **NOTE:** For e200z4204n3, the PowerISA 2.06 floating point unit is not supported in hardware, and an Illegal Instruction exception will be generated for attempted execution of PowerISA 2.06 floating point instructions regardless of the setting of FP. FP is ignored, but cleared on exceptions.
19	ME	Machine Check Enable 0 Asynchronous Machine Check interrupts are disabled. 1 Asynchronous Machine Check interrupts are enabled.
20	FE0	Floating-point exception mode 0 (not used by Zen) **NOTE:** for e200z4204n3, the PowerISA 2.06 floating point unit is not supported in hardware, thus FE0 is ignored, but cleared on exceptions.
21	—	Reserved
22	DE	Debug Interrupt Enable 0 Debug interrupts are disabled. 1 Debug interrupts are enabled.
23	FE1	Floating-point exception mode 1 (not used by Zen) **NOTE:** For e200z4204n3, the PowerISA 2.06 floating point unit is not supported in hardware, thus FE1 is ignored, but cleared on exceptions.
24:25	—	Reserved
26	IS	Instruction Address Space 0 The processor directs all instruction fetches to address space 0. 1 The processor directs all instruction fetches to address space 1. **NOTE:** For e200z4204n3, Address Spaces are not supported, thus the IS bit is ignored, but cleared on exceptions.
27	DS	Data Address Space 0 The processor directs all data storage accesses to address space 0. 1 The processor directs all data storage accesses to address space 1. **NOTE:** For e200z4204n3, Address Spaces are not supported, thus the DS bit is ignored, but cleared on exceptions.
28	—	Reserved

Table continues on the next page...

Table 63-16. MSR field descriptions (continued)

Bit(s)	Name	Description
29	PMM	Performance monitor mark bit System software can set PMM when a marked process is running to enable statistics to be gathered only during the execution of the marked process. MSR_{PR} and MSR_{PMM} together define a state that the processor (supervisor or user) and the process (marked or unmarked) may be in at any time. If this state matches an individual state specified in the PMLCa*n* Performance Monitor registers, the state for which monitoring is enabled, counting is enabled.
30	RI	Recoverable Interrupt This bit is provided for software use to detect nested machine check exception conditions. This bit is cleared by hardware when a Machine Check interrupt is taken.
31	—	Reserved

63.8.3 Machine Check Syndrome Register (MCSR)

When the processor takes a machine check interrupt, it updates the Machine Check Syndrome Register (MCSR) to differentiate between machine check conditions. The MCSR is shown in the following figure.

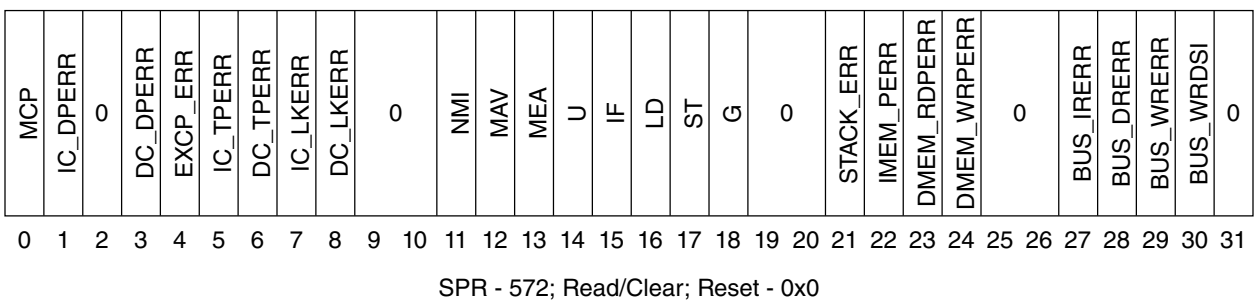

Figure 63-16. Machine Check Syndrome Register (MCSR)

The following table describes MCSR fields. The MCSR indicates the source of a machine check condition.

All bits in the MCSR are implemented as "write 1 to clear." Software in the machine check handler is expected to clear the MCSR bits it has sampled prior to re-enabling MSR[ME] to avoid a redundant machine check exception and to prepare for updated status bit information on the next machine check interrupt.

Note that any set bit in the MCSR other than status-type bits will cause a subsequent machine check interrupt once MSR[ME] = 1.

Table 63-17. Machine Check Syndrome Register (MCSR) field descriptions

Bit	Name	Description	Exception type[1]	Recoverable
0	MCP	Machine check input pin	Async Mchk	Maybe
1	IC_DPERR	Instruction Cache data array parity error	Async Mchk	Precise
2	—	Reserved	—	—
3	DC_DPERR	Data Cache data array parity error	Async Mchk	Maybe
4	EXCP_ERR	ISI or Bus Error on first instruction fetch for an exception handler	Async Mchk	Precise
5	IC_TPERR	Instruction Cache Tag parity error	Async Mchk	Precise
6	DC_TPERR	Data Cache Tag parity error	Async Mchk	Maybe
7	IC_LKERR	Instruction Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the I-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—
8	DC_LKERR	Data Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the D-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—
9:10	—	Reserved	—	—
11	NMI	NMI input pin	NMI	—
12	MAV	MCAR Address Valid Indicates that the address contained in the MCAR was updated by hardware to correspond to the first detected Async Mchk error condition	Status	—
13	MEA	MCAR holds Effective Address If MAV = 1, MEA = 1 indicates that the MCAR contains an effective address and MEA = 0 indicates that the MCAR contains a physical address[2]	Status	—
14	U	User Indicates the value captured in MCAR was generated in user mode.	Status	—
15	IF	Instruction Fetch Error Report An error occurred during the fetch of an instruction and the instruction attempted to execute. This could be due to an internal parity error, or an external bus error. MCSRR0 contains the instruction address.	Error Report	Precise
16	LD	Load type instruction Error Report An error occurred during the attempt to execute the load type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or an external bus error.	Error Report	Precise
17	ST	Store type instruction Error Report	Error Report	Precise

Table 63-17. Machine Check Syndrome Register (MCSR) field descriptions (continued)

Bit	Name	Description	Exception type[1]	Recoverable
		An error occurred during the attempt to execute the store type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or on certain external bus errors.		
18	G	Guarded instruction Error Report An error occurred during the attempt to execute the load or store type instruction located at the address stored in MCSRR0 and the access was guarded and encountered an error on the external bus.	Error Report	Precise
19:20	—	Reserved	—	—
21	STACK_ERR	Stack Access Limit Check Error Indicates a limit check failure on a CPU data access using R1 in the <EA> calculation.	Async Mchk	Precise
22	IMEM_PERR[3]	Instruction Mem (IMEM) Parity Error Indicates an uncorrectable error in the IMEM on a CPU port access.	Async Mchk	Precise
23	DMEM_RDPERR[4]	Data Mem (DMEM) Parity Error Indicates an uncorrectable error in the DMEM on a CPU port read access.	Async Mchk	Precise
24	DMEM_WRPERR	Data Mem (DMEM) Write Parity Error Indicates an uncorrectable error in the DMEM on a CPU port write access.	Async Mchk	Maybe
25:26	—	Reserved	—	—
27	BUS_IRERR	Read bus error on Instruction recovery linefill	Async Mchk	Precise if data used
28	BUS_DRERR	Read bus error on data load or linefill	Async Mchk	Precise if data used
29	BUS_WRERR	Write bus error on store to bus	Async Mchk	Unlikely
30	BUS_WRDSI	Write bus error on buffered store to bus with DSI signaled. Set concurrently with BUS_WRERR for this case	Async Mchk	Unlikely
31	—	Reserved	—	—

1. Indicates the exception type associated with a given syndrome bit.
   - "Error Report" indicates that this bit is only set for error report exceptions which cause machine check interrupts. These bits are only updated when the machine check interrupt is actually taken. Error report exceptions are not gated by MSR[ME]. These are synchronous exceptions. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.
   - "Status" indicates that this bit is provides additional status information regarding the logging of a machine check exception. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.

- "NMI" indicates that this bit is only set for the non-maskable interrupt type exception which causes a machine check interrupt. This bit is only updated when the machine check interrupt is actually taken. NMI exceptions are not gated by MSR[ME]. This is an asynchronous exception. This bit will remain set until cleared by software writing a '1' to the bit position.
- "Async Mchk" indicates that this bit is set for an asynchronous machine check exception. These bits are set immediately upon detection of the error. Once any "Async Mchk" bit is set in the MCSR, a machine check interrupt will occur if MSR[ME]= 1. If MSR[ME] = 0, the machine check exception will remain pending. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.

2. Note that since no address translation mechanism is present on e200z4204n3, the MEA value is always set to 0.
3. Will not be set by e200z4204n3 since no local instruction memory is present.
4. Note that since no local data memory is present on e200z4204n3.

63.8.4 Interrupt Vector Prefix Registers (IVPR)

The Interrupt Vector Prefix Register is used during interrupt processing for determining the starting address of a software handler used to handle an interrupt. The value of the Vector Offset selected for a particular interrupt type is concatenated with the Vector Base value held in the IVPR to form an instruction address from which execution is to begin. The format of IVPR is shown in the following figure.

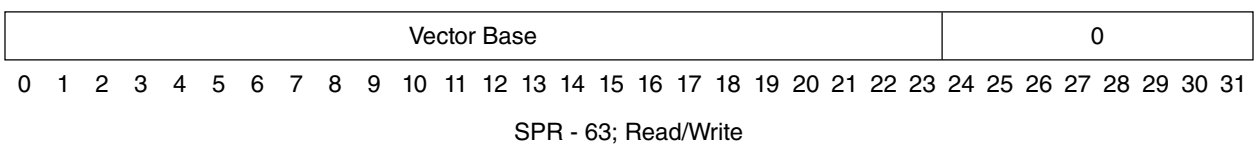

Figure 63-17. Interrupt Vector Prefix Register (IVPR)

The IVPR fields are defined in the following table.

Table 63-18. IVPR field descriptions

Bit(s)	Name	Description
0:23 (32:55)	Vector Base	Vector Base This field is used to define the base location of the vector table, aligned to a 256-byte boundary. This field provides the high-order 24 bits of the location of all interrupt handlers (unless hardware vectoring is used). The vector offset value appropriate for the type of exception being processed is concatenated with the IVPR Vector Base to form the address of the handler in memory. For hardware-vectored interrupts, the value of the supplied interrupt vector is logically ORed with the low order bits of the Vec Base Field to determine the interrupt handler address.
24:31 (56:63)	—	Reserved

63.8.5 Interrupt definitions

63.8.5.1 Critical Input Interrupt (Offset 0x00)

A Critical Input exception is signalled to the processor by the assertion of the critical interrupt pin (**p_critint_b**). When e200z4204n3 detects the exception, if the exception is enabled by MSRCE, the core takes the Critical Input interrupt. The **p_critint_b** input is a level-sensitive signal expected to remain asserted until the core acknowledges the interrupt. If **p_critint_b** is negated early, recognition of the interrupt request is not guaranteed. After the core begins execution of the critical interrupt handler, the system can safely negate **p_critint_b**.

A Critical Input interrupt may be delayed by other higher priority exceptions or if MSR_{CE} is cleared when the exception occurs.

The following table lists register settings when a Critical Input interrupt is taken.

Table 63-19. Critical Input Interrupt - Register Settings

Register	Setting Description		
CSRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.		
CSRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE 0 EE 0 PR 0	FP 0 ME — FE0 0 DE —/0[1]	FE1 0 IS 0 DS 0 PMM 0 RI —
ESR	Unchanged		
MCSR	Unchanged		
DEAR	Unchanged		
Vector	$IVPR_{0:23}$ || 0x00 (autovectored) $IVPR_{0:15}$ || ($IVPR_{16:29}$ | **p_voffset[0:13])** || 2‘b00 (non-autovectored)		

1. Clearing of DE is optionally supported by control in HID0.

The MSR_{DE} bit is not automatically cleared by a Critical Input interrupt, but can be configured to be cleared via the HID0 register ($HID0_{CICLRDE}$).

0x00 is the vector offset used by autovectored Critical Input interrupts to determine the interrupt handler location. e200z4204n3 also provides the capability to directly vector Critical Input interrupts to multiple handlers by allowing a Critical Input interrupt request to be accompanied by a vector offset. The **p_voffset[0:13]** input signals are used to form the interrupt vector when a Critical Input interrupt request is not autovectored (**p_avec_b** negated when **p_critint_b** asserted).

63.8.5.2 Machine Check interrupt (offset 0x10)

The EIS Machine Check APU defines a separate set of save/restore registers (MCSRR0/1), a Machine Check Syndrome Register (MCSR) to record the source(s) of machine checks, and a Machine Check Address Register (MCAR) to hold an address associated with a machine check for certain classes of machine checks. Return from Machine Check instructions (**se_rfmci**) are also provided to support returns using MCSRR0/1.

The MSR[DE] bit is not automatically cleared by a Machine Check exception, but it can be configured to be cleared or left unchanged via the HID0 register (HID0[MCCLRDE]).

When a Machine Check interrupt is taken, registers are updated as shown in the following table.

Table 63-20. Machine Check interrupt—register settings

Register	Setting description					
MCSRR0	On a best-effort basis, set to the address of some instruction that was executing or about to be executing when the machine check condition occurred.					
MCSRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	0	IS	0
	CE	0	FE0	0	DS	0
	EE	0	DE	0/—[1]	PMM	0
	PR	0			RI	0
ESR	Unchanged					
MCSR	Updated to reflect the source(s) of a machine check. Hardware only sets appropriate bits, no previously set bits are cleared by hardware.					
Vector	IVPR[0:23] || 0x10					

1. Clearing of DE is optionally supported by control in HID0.

63.8.5.3 Data Storage interrupt (offset 0x20)

A Data Storage interrupt (DSI) may occur if no higher priority exception exists and a Read or Write Access Control exception condition exists.

The following table lists register settings when a DSI is taken.

Table 63-21. Data Storage interrupt—register settings

Register	Setting description
SRR0	Set to the effective address of the excepting load/store instruction.
SRR1	Set to the contents of the MSR at the time of the interrupt

Table continues on the next page...

Table 63-21. Data Storage interrupt—register settings (continued)

Register	Setting description					
MSR	SPV	0	FP	0	FE1	0

DEAR	Unchanged					
Vector	IVPR[0:23] || 0x30					

63.8.5.5 External Input interrupt (offset 0x40)

An External Input exception is signaled to the processor by the assertion of an interrupt from the interrupt controller. The input is a level-sensitive signal expected to remain asserted until the core acknowledges the external interrupt. If the input is negated early, recognition of the interrupt request is not guaranteed. When the core detects the exception, if the exception is enabled by MSR[EE], it takes the External Input interrupt.

An External Input interrupt may be delayed by other higher priority exceptions or if MSR[EE] is cleared when the exception occurs.

The following table lists register settings when an External Input interrupt is taken.

Table 63-23. External Input interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.					
SRR1	Set to the contents of the MSR at the time of the interrupt

63.8.5.6 Alignment interrupt (offset 0x50)

An Alignment exception is generated when any of the following occurs:

- The operand of **lmw** or **stmw** is not word aligned.
- The operand of **lwarx** or **stwcx.** is not word aligned.
- The operand of **lharx** or **sthcx.** is not halfword aligned.
- Execution of a **dcbz** instruction is attempted.

The following table lists register settings when an alignment interrupt is taken.

Table 63-24. Alignment interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting load/store/**dcbz** instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	[ST], VLEMI. All other bits cleared.					
MCSR	Unchanged					
DEAR	Set to the effective address of a byte of the load or store access causing the violation.					
Vector	IVPR[0:23] || 0x50					

63.8.5.7 Program interrupt (offset 0x60)

A program interrupt occurs when no higher priority exception exists and one or more of the following exception conditions occur:

- Illegal Instruction exception
- Privileged Instruction exception
- Trap exception

The e200z4204n3 core will invoke an Illegal Instruction program exception on attempted execution of the following instructions:

- Unimplemented instructions
- An instruction from the illegal instruction class
- **mtspr** and **mfspr** instructions with an undefined SPR specified
- **mtdcr** and **mfdcr** instructions with an undefined DCR specified

The e200z4204n3 core will invoke a Privileged Instruction program exception on attempted execution of the following instructions when MSR[PR] = 1 (user mode):

- A privileged instruction
- **mtspr** and **mfspr** instructions that specify a SPRN value with SPRN[5] = 1 (even if the SPR is undefined)

The e200z4204n3 core will invoke an Trap exception on execution of the **tw** instruction if the trap conditions are met and the exception is not also enabled as a Debug interrupt.

The e200z4204n3 core will invoke an Illegal instruction program exception on attempted execution of the instructions **lswi**, **lswx**, **stswi**, **stswx**, **mfapidi**, **mfdcrx**, **mtdcrx**, or on any PowerISA 2.0 floating-point instruction. All other defined or allocated instructions that are not implemented by core will cause an illegal instruction program exception.

The following table lists register settings when a Program interrupt is taken.

Table 63-25. Program interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting instruction.

DEAR	Unchanged					
Vector	IVPR[0:23] || 0x60					

63.8.5.8 Performance Monitor interrupt (offset 0x70)

A performance monitor interrupt can be generated by an enabled condition or event. An enabled condition or event is as follows:

A PMC*x* register overflow condition occurs with the following settings:

- PMLCa*x*[CE] = 11; that is, for the given counter the overflow condition is enabled.
- PMC*x*[OV] = 11; that is, the given counter indicates an overflow.

For a performance monitor interrupt to be signaled on an enabled condition or event, PMGC0[PMIE] must be set.

Although an exception condition may occur with MSR[EE] = 0, the interrupt cannot be taken until MSR[EE] = 1.

The priority of the performance monitor interrupt is below all other asynchronous interrupts.

The following table lists register settings when an performance monitor interrupt is taken.

Table 63-26. Performance Monitor interrupt—register settings

Register	Setting description					
SRR0/ DSRR0[1]	Set to the effective address of the next instruction to be executed.					
SRR1/ DSRR1[1]	Set to the contents of the MSR at the time of the interrupt.

63.8.5.13 System Reset interrupt

The System Reset exception is a non-maskable, asynchronous exception signaled to the processor through the assertion of system-defined signals.

A System Reset may be initiated by either a software reset or during power-on reset.

When a reset request occurs, the processor branches to the system reset exception vector without attempting to reach a recoverable state. If reset occurs during normal operation, all operations cease and the machine state is lost.

The following table lists register settings when a System Reset interrupt is taken.

Table 63-31. System Reset interrupt—register settings

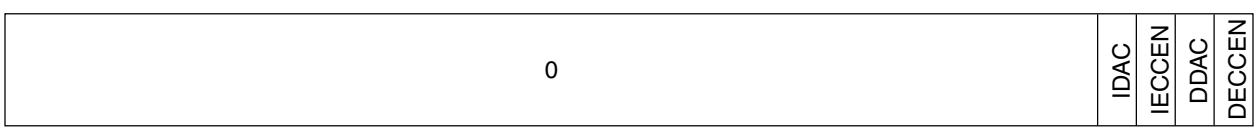
63.9 End-to-End ECC support



This section describes end-to-end error detection and correction capability (e2eECC) enhancements to address additional diagnostic capabilities for the next generation of embedded designs.

63.9.1 End-to-End ECC control and configuration

e2eECC is controlled by a set of privileged device control registers (DCRs) accessed using the **mfdcr** and **mtdcr** instructions. These registers and the operation of various features are described in the following subsections.

63.9.1.1 End-to-End ECC Control Register 0 (E2ECTL0)

The End-to-End ECC Control Register 0 (E2ECTL0) controls operation of the e2eECC logic.

DCR - 510; Read/Write; Reset - 0x5 || p_e2e_rstcfg[0:3]; Privileged

Figure 63-18. e2eECC Control Register 0 (E2ECTL0)

Table 63-32. E2ECTL0 field descriptions

Bits	Name	Description
0:27	—	Reserved
28	IDAC	Instruction Disable Address Checking

Table continues on the next page...

Table 63-32. E2ECTL0 field descriptions (continued)

Bits	Name	Description
		This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Instruction AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[0]** input.
29	IECCEN	Instruction ECC Enable Field 0 End-to-End ECC is disabled for the Instruction interface. No checking of instruction fetch data is performed. 1 End-to-End ECC is enabled for performing error detection and correction on the Instruction interface. Checking of instruction fetch data is performed with correction of single-bit data errors. Detection of any address errors or uncorrectable multi-bit data errors cause a machine check to be generated if the instruction fetch information is attempted to be used for instruction decoding and execution. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[1]** input.
30	DDAC	Data Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Data AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[2]** input.
31	DECCEN	Data ECC Enable Field 0 End-to-End ECC is disabled for the data interface. No checking of read data is performed. Writes will still generate the proper check bit values to be supplied to external storage devices. 1 End-to-End ECC is enabled for performing error detection and correction on the data interface. Checking of read data is performed with correction of single-bit data errors. Detection of any address errors, or uncorrectable multi-bit data errors cause a machine check to be generated. Writes generate the proper check bit values to be supplied to external storage devices. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[3]** input.

e2eECC is enabled by setting the IECCEN or DECCEN bit of the E2ECTL0 DCR to a 1. On reset, e2eECC operation may be disabled from detecting or correcting errors based on reset configuration inputs, and no exceptions will be signaled for nonzero calculated syndrome values. This allows for the proper initialization of stored checkbits in any volatile storage by the CPU without causing error conditions due to uninitialized storage. Following the initialization, software may enable e2eECC operation by writing the appropriate values to the E2ECTL0[IECCEN] or E2ECTL0[DECCEN] control bits.

The E2ECTL0[IDAC] or E2ECTL0[DDAC] control bits can be used to remove the address checking component of the ECC logic for the Instruction AHB and Data AHB when address inclusion is not desired.

63.9.1.2 End-to-End ECC error generation by software

Error generation provides a way to test error recovery and portions of the error detection/correction logic by intentionally injecting parity errors into the driven checkbit information on the external bus during write operations. No provision is made to generate internal errors on read data due to timing issues; instead, software may intentionally generate errors in the checkbit values to emulate data, address, or checkbit error on external bus write cycles, and read back the written data to cause an error to be detected.

The End-to-End ECC Error Control/Status Register (E2EECSR0) controls operation of the e2eECC error injection logic. It allows for generation of a single error injection operation on the next CPU data write to the external bus only, or for a series of error injection write operations to the external bus, using the WRC and INVC control fields. The WRCHKBIT/CHKINVT field controls which of the **p_hwchkbit[7:0]** outputs are affected.

Control is provided to allow for either inverting the value(s) of one or more of the checkbit outputs **p_hwchkbit[7:0]** in hardware on one or more external write accesses, or for software to directly supply checkbit values to be used for the external write access(es).

The End-to-End ECC Error Control/Status Register (E2EECSR0) also supports access to raw checkbit values via the RCHKBIT status field. This field is updated with checkbit values received on each CPU data read operation to the external bus (but not on cache hits).

Note that Nexus 3 accesses do not cause error injection or the capture of read checkbits, regardless of the settings of the E2EECSR0 register.

The following figure shows the layout of E2EECSR0.

0	RCHKBIT	0	WRC	INVC	0	WCHKBIT/CHKINVT
0 1 2 3	4 5 6 7 8 9 10 11	12 13 14 15	16 17	18 19	20 21 22 23	24 25 26 27 28 29 30 31

DCR - 511; Read/Write; Reset - 0x0; Privileged

Figure 63-19. e2eECC Error Control/Status Register 0 (E2EECSR0)

Table 63-33. E2EECSR0 field descriptions

Bits	Name	Description
0:3	—	Reserved
4:11	RCHKBIT	Read Checkbits This field provides the raw checkbits received on the last CPU data access to external memory via the Data BIU. This field corresponds bit-wise to **p_hrchkbit[7:0]** for external reads. Software may use this information to determine the stored checkbits of external memories by performing CPU load operations and then accessing this field prior to the next load operation (assuming interrupts are masked).
12:15	—	Reserved
16:17	WRC	Write Control 00 No write checkbit substitution is performed by this control bit 01 Checkbit substitution is performed for the next CPU external write access (only) by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. Software must clear this field before rewriting to 01 in order to generate a subsequent checkbit substitution operation. 10 Checkbit substitution is performed for each CPU external write access while this field remains set to 10 by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11 Reserved Note: Checkbit substitution has priority over Error injection
18:19	INVC	Invert Control 00 No error injection is performed by this control bit 01 Error injection is performed for the next CPU external write access (only) by modifying **p_hwchkbit[7:0]** based on CHKINVT. Software must clear this field before rewriting to 01 in order to generate a subsequent error injection operation. 10 Error injection is performed for each CPU external write access while this field remains set to 10 by modifying **p_hwchkbit[7:0]** based on CHKINVT. This field must be cleared by software to discontinue further error generation. 11 Reserved Note: Checkbit substitution has priority over Error injection
20:23	—	Reserved
24:31	WCHKBIT/ CHKINVT	Write Checkbits / Checkbit Invert Mask This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. This field corresponds bit-wise to **p_hwchkbit[7:0]**. For Checkbit inversion operations via error injection: 0 Checkbit is driven normally 1 Checkbit is inverted before being driven out on **p_hwchkbit[7:0]** when error injection occurs.

Chapter 64
Z2 Core Debug Support

64.1 Overview

Internal debug support in the e200z210n3 core allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. For software based debugging, debug facilities consisting of a set of software accessible debug registers and interrupt mechanisms are provided. These facilities are also available to a hardware based debugger which communicates using a modified IEEE 1149.1 Test Access Port (TAP) controller and pin interface. When hardware debug is enabled, the debug facilities controlled by hardware are protected from software modification.

Software debug facilities are defined as part of *Power ISA 2.06*. e200z210n3 supports a subset of these defined facilities. In addition to the facilities defined in *Power ISA 2.06*, e200z210n3 provides additional flexibility and functionality in the form of additional instruction breakpoints, linked instruction and data breakpoints, and extended range and value masking. These features are also available to a hardware-based debugger.

When not being used for debugging purposes, a portion of the debug facilities may be configured to provide a stack limit checking mechanism.

64.1.1 Software Debug Facilities

e200z210n3 provides debug facilities to enable hardware and software debug functions, such as instruction and data breakpoints and program single stepping. The debug facilities consist of a set of debug control registers (DBCR0–2,4–8, EDBRAC0), a set of address compare registers (IAC1–8, DAC1–4), a set of 64-bit data value compare registers (DVC1, DVC2), a Debug Status Register (DBSR) for enabling and recording various kinds of debug events, a Debug Data Effective Address Register (DDEAR), and a special Debug interrupt type built into the interrupt mechanism.

The debug facilities also provide a mechanism for software-controlled processor reset, and debug mode entry. In addition, the Performance Monitor may be configured to utilize the debug interrupt type.

Software debug facilities are enabled by setting the internal debug mode bit in Debug Control register 0 ($DBCR0_{IDM}$). When internal debug mode is enabled, debug events can occur, and can be enabled to record exceptions in the Debug Status register (DBSR). If enabled by MSR_{DE}, these recorded exceptions cause Debug interrupts to occur. When $DBCR0_{IDM}$ is cleared (and $EDBCR0_{EDM}$ is cleared as well), no debug events occur, and no status flags are set in DBSR unless already set. In addition, when $DBCR0_{IDM}$ is cleared (or is overridden by $EDBCR0_{EDM}$ being set and EDBRAC0 indicating no resource is "owned" by software) no Debug interrupts will occur, regardless of the contents of DBSR. A software Debug interrupt handler may access all system resources and perform necessary functions appropriate for system debug.

64.1.1.1 *Power ISA 2.06* Compatibility

The e200z210n3 core implements a subset of the *Power ISA 2.06* internal debug features. The following restrictions on functionality are present:

- Instruction address compares do not support compare on physical (real) addresses.
- Data address compares do not support compare on physical (real) addresses.

64.1.2 Additional Debug Facilities

In addition to the debug functionality defined in *Power ISA 2.06*, e200z210n3 provides capability to link instruction and data breakpoints, provides additional instruction and data breakpoints, extended range and value masking, multiple watchpoint outputs, provides capability for the Performance Monitor to generate debug events, and allows for sharing of debug resources between software and a hardware debugger. (See Sharing Debug Resources by Software/Hardware.) A data trace port is also provided.

64.1.2.1 Data Trace Port

The data trace port interface is provided to assist in implementing extended debug watchpoint/breakpoint/trace capture capability with logic external to the e200z210n3 core. This port provides information corresponding to each read or write access completed without error by the CPU. In order to report data accesses, the Nexus 3 DTC register DI control bit must be set to trace data accesses, not instruction accesses (i.e. the

normal setting. See the "Data Trace Control Register (DTC)" section in the Core (e200z210n3) Nexus 3 Module chapter. The data trace port will report aligned accesses and misaligned accesses as one access, unless the two portions of a misaligned access are non-contiguous, such as when the second portion of the misaligned access is to address 0.

64.1.3 Hardware Debug Facilities

The e200z210n3 core contains facilities that allow for external test and debugging. A modified IEEE 1149.1 control interface is used to communicate with the core resources. This interface is implemented through a standard IEEE 1149.1 TAP (test access port) controller.

By using public instructions, the external debugger can freeze or halt the e200z210n3 core, read and write internal state and debug facilities, single-step instructions, and resume normal execution.

Hardware Debug is enabled by setting the External Debug Mode enable bit in External Debug Control register 0 ($EDBCR0_{EDM}$), which is also aliased to $DBCR0_{EDM}$. Setting $EDBCR0_{EDM}$ overrides the Internal Debug Mode enable bit $DBCR0_{IDM}$ unless resources are provided back to software via the settings in EDBRAC0. When the Hardware Debug facility is enabled, software is blocked from modifying the "hardware-owned" debug facilities. In addition, since resources are "owned" by the hardware debugger, inconsistent values may be present if software attempts to read "hardware-owned" debug-related resources.

When hardware debug is enabled by setting $EDBCR0_{EDM}$=1, the control registers and resources described in Debug registers are reserved for use by the external debugger. The same events described in Software Debug Events and Exceptions are also used for external debugging, but exceptions are not generated to running software. Hardware-owned debug events enabled in the respective DBCR0–8 registers are recorded in the EDBSR0 register (not the DBSR) regardless of MSR_{DE}, and no debug interrupts are generated unless a) the resource is granted back to software via EDBRAC0 settings, and b) debug mode entry is not masked by the corresponding event bit in EDBSRMSK0. Instead, the CPU will enter debug mode when an enabled event causes a EDBSR0 bit to become set. $EDBCR0_{EDM}$, EDBSR0, EDBSRMSK0, EDDEAR, and EDBRAC0 may only be written through the OnCE port.

[SCG_NX_DEBUG_ACCESS]Access to most debug resources (registers) requires that the CPU clock (**m_clk**) be running in order to perform write accesses from the external hardware debugger.[end]

64.1.4 Sharing Debug Resources by Software/Hardware

Debug resources may be shared by a hardware debugger and software debug based on the settings of debug control register EDBRAC0. When $EDBCR0_{EDM}$ is set, EDBRAC0 settings determine which debug resources are allocated to software and which resources remain under exclusive hardware control. Software-owned resources which set DBSR bits when $DBCR0_{IDM}$=1 will cause a debug interrupt to occur when enabled with MSR_{DE}. Hardware-owned resources which set EDBSR0 bits when $EDBCR0_{EDM}$=1 will cause an entry into debug mode if the event is not masked in EDBSRMSK0. EDBRAC0 is read-only by software. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Hardware-owned resources will set status bits in the EDBSR0 register instead of in DBSR, and will report the effective address of data breakpoints in EDDEAR instead of DDEAR. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers are performed.

64.1.4.1 Simultaneous Hardware and Software Debug Event Handing

Since it is possible that a "hardware-owned" resource can produce a debug event in conjunction with a software-owned resource producing a different debug event simultaneously, a priority ordering mechanism is implemented which guarantees that the hardware event is handled as soon as possible, while preserving the recognition of the software event. The CPU will give highest priority to the software event initially in order to reach a recoverable boundary, and then will give highest priority to the hardware event in order to enter debug mode as near the point of event occurrence as possible. This is implemented by allowing software exception handing to begin internal to the CPU and to reach the point where the current program counter and MSR values have been saved into DSRR0/1, and the new PC pointing to the debug interrupt handler, along with the new MSR updates. At this point, hardware priority takes over, and the CPU enters debug mode.

The following figure shows the e200z210n3 debug resources.

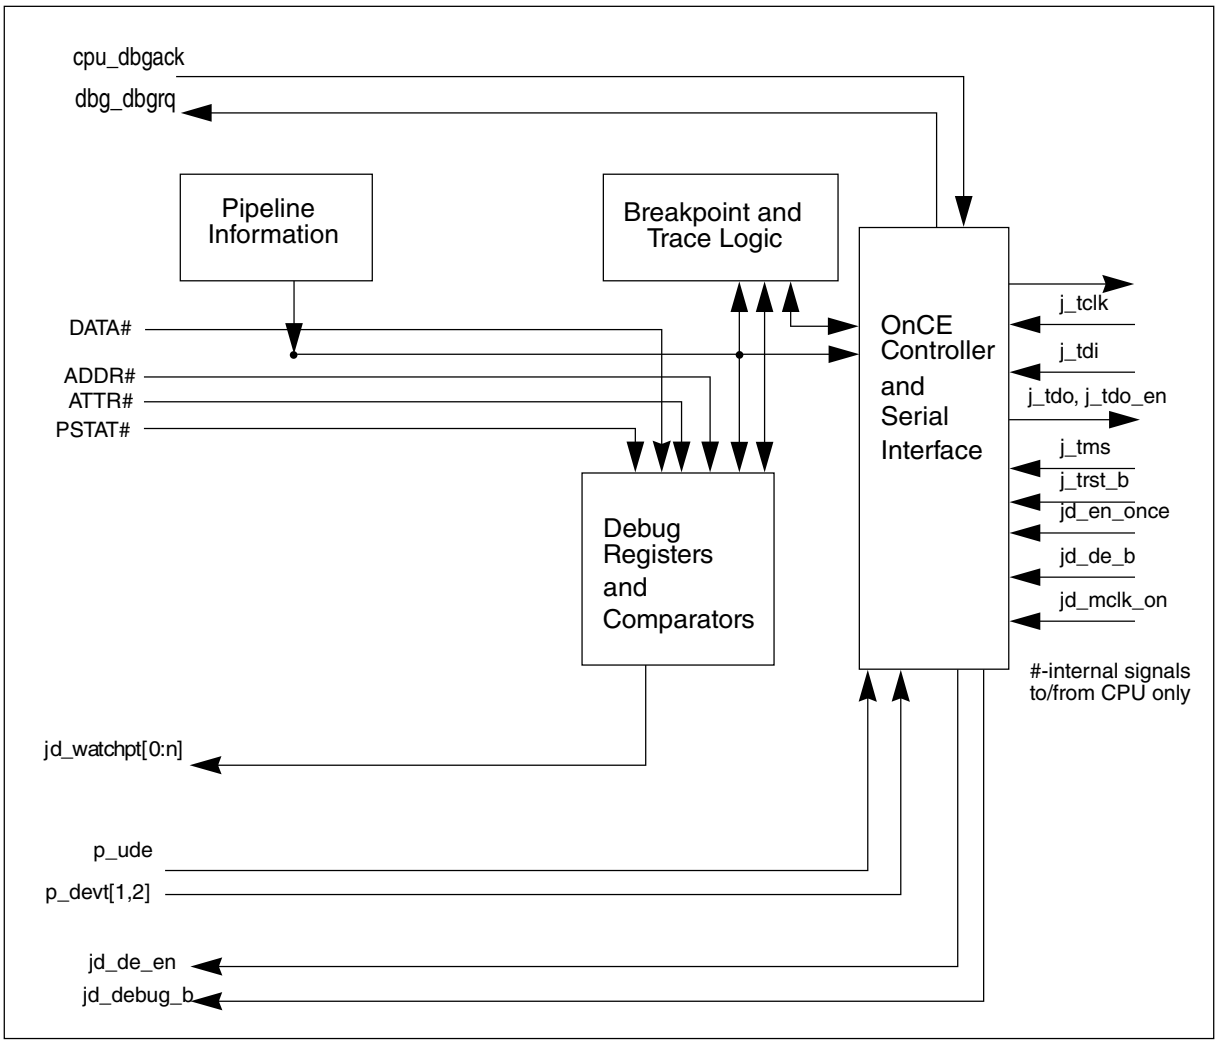


Figure 64-1. e200z210n3 Debug Resources

64.2 Software Debug Events and Exceptions

Software debug events and exceptions are available when internal debug mode is enabled ($DBCR0_{IDM}$=1) and not overridden by external debug mode ($EDBCR0_{EDM}$ must either be cleared or corresponding resources must be allocated to software debug by the settings in EDBRAC0). When enabled, debug events cause debug exceptions to be recorded in the Debug Status Register. Specific event types are enabled by the Debug Control Registers (DBCR0–8). The Unconditional Debug Event (UDE) is an exception to this rule; it is always enabled. Once a Debug Status Register (DBSR) bit is set by a debug resource which is "owned" by software (other than MRR, DAC_OFST, or VLES), if Debug interrupts are enabled by MSR_{DE}, a Debug interrupt will be generated. The debug interrupt handler is responsible for ensuring that multiple repeated debug interrupts do not occur by clearing the DBSR as appropriate.

Certain debug events are not allowed to occur when MSR_{DE}=0 and $DBCR0_{IDM}$=1. In such situations, no debug exception occurs and thus no DBSR bit is set. Other debug events may cause debug exceptions and set DBSR bits regardless of the state of MSR_{DE}. A Debug interrupt will be delayed until MSR_{DE} is later set to '1'.

When a Debug Status Register bit is set while MSR_{DE}=0, an Imprecise Debug Event flag ($DBSR_{IDE}$) will also be set to indicate that an exception bit in the Debug Status Register was set while Debug interrupts were disabled. Debug interrupt handler software can use this bit to determine whether the address recorded in Debug Save/Restore Register 0 is an address associated with the instruction causing the debug exception, or the address of the instruction which enabled a delayed Debug interrupt by setting the MSR_{DE} bit. A **mtmsr** or **mtdbcr0** which causes both MSR_{DE} and $DBCR0_{IDM}$ to become set, enabling precise debug mode, may cause an Imprecise (Delayed) Debug exception to be generated due to an earlier recorded event in the Debug Status register.

There are eight types of debug events defined by *Power ISA 2.06*:

1. Instruction Address Compare debug events
2. Data Address Compare debug events
3. Trap debug events
4. Branch Taken debug events
5. Instruction Complete debug events
6. Interrupt/Critical Interrupt Taken debug events
7. Return/Critical Return debug events
8. Unconditional debug events

In addition, e200z210n3 defines additional debug events:

- The External debug events DEVT1 and DEVT2 which are described in External debug event.
- The Performance Monitor Interrupt event PMI which is described in Performance Monitor Interrupt debug event.

The e200z210n3 debug configuration supports most of these event types. Unsupported *Power ISA 2.06* defined functionality is as follows:

- Instruction Address Compare and Data Address Compare *Real address* mode is not supported

A brief description of each of the event types follows.

64.2.1 Instruction Address Compare Event

Instruction Address Compare debug events occur when enabled and execution is attempted of an instruction at an address that meets the criteria specified in the DBCR0, DBCR1, DBCR5, DBCR6, and IAC1–8 Registers. Instruction Address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. IAC events will not occur when an instruction would not have normally begun execution due to a higher priority exception at an instruction boundary.

IAC compares perform a 31-bit compare for VLE instruction storage accesses. Each halfword fetched by the instruction fetch unit will be marked with a set of bits indicating whether an Instruction Address Compare occurred on that halfword. Debug exceptions will occur if enabled and a 16-bit instruction, or the first halfword of a 32-bit instruction, is tagged with an IAC hit.

64.2.2 Data Address Compare Event

Data Address Compare debug events occur when enabled and execution of a load or store class instruction results in a data access that meets the criteria specified in the DBCR0, DBCR2, DBCR4, DBCR7–8, DAC1–4, DVC1, and DVC2 Registers. Data address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. Four address compare values (DAC1–4) are provided.

The effective address of the load or store operation is recorded in the DDEAR register when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set.

Note

In contrast to the *Power ISA 2.06* definition, Data Address Compare events on e200z210n3 do not prevent the load or store class instruction from completing. If a load or store class

instruction completes successfully without a Data Storage interrupt, Data Address Compare exceptions are reported at the completion of the instruction. If the exception results in a precise Debug interrupt, the address value saved in DSRR0 is the address of the instruction following the load or store class instruction. For DVC DAC events, the exception can be imprecisely reported even further past the load or store class instruction generating the event (without necessarily affecting $DBSR_{IDE}$) and the saved address value can point to a subsequent instruction past the next instruction. This occurrence is indicated in the $DBSR_{DAC_OFST}$ field.

If a load or store class instruction does not complete successfully due to a Data Storage exception or a machine check condition for the load or store, and a Data Address Compare debug exception also occurs, the result is an imprecise Debug interrupt, the address value saved in DSRR0 is the address of the load or store class instruction, and the $DBSR_{IDE}$ bit will be set. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note

DAC events will not be recorded if a load multiple word or store multiple word instruction is interrupted prior to completion by a critical input or external input interrupt.

Note

DAC events are not signaled on the second portion of a misaligned load or store that is broken up into two separate accesses.

Note

DAC[1,2] events are not signaled if DVC[1,2]M is non-zero and a DSI exception occurs on the load or store, since the load or store access is not performed. For a **lmw** or **stmw** transfer however, if a DVC successfully occurs on a transfer and a later transfer encounters a DSI exception, the DAC event will be reported, since a successful data value compare took place.

Note

Due to internal pipeline status, for a reported DAC event on a **lmw** or **stmw** transfer, the value stored in the DDEAR/EDDEAR will be the effective address of the first transfer of the sequence, and not necessarily the precise transfer that caused the DAC event.

64.2.2.1 Data Address Compare Event Status Updates

Data Address Compare debug events with Data Value compares can be reported ambiguously in several circumstances involving issuing a sequence of load or store class instructions. Due to the CPU pipeline and the delay in performing the data value compare following completion of the access, if the first load or store class instruction generates a DVC DAC, a second and possibly third load or store class instruction may also generate a DAC or DVC DAC event, or may generate a DSI exception with or without a simultaneous DAC event.

Also, since non-load/store instructions may be dual-issued in combination with a load/store instruction, the actual number of additional instructions that are completed following a recognized DVC DAC on a load/store instruction may vary from 0 to 5. This value will be reported in the $DBSR_{DAC_OFST}$ field when the DVC DAC status is recorded.

Table 64-1 outlines the settings of the DBSR, DSRR0 saved value, and potential updating of the ESR register for various exception cases on sequences of load/store class instructions. Not all exception combinations are covered in the table, such as IAC, ISI, or Alignment exceptions on subsequent instructions. In general these exceptions will cause further instruction issue to be halted, execution of the excepting instruction to be aborted, and reporting of these exceptions will be masked. The saved DSRR0 value will point to this excepting instruction, and the exception(s) may be regenerated after returning from the debug interrupt handler and attempting to re-execute the instruction pointed to by DSRR0.

Table 64-1. DAC events and Resultant Updates

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DSI, no DAC	—	—	Take DSI exception, no DBSR update. Update ESR.

Table continues on the next page...

Table 64-1. DAC events and Resultant Updates (continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DSI, with DACx	—	—	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST not set. DSRR0 points to 1st load/store class instruction. No ESR update.
DACx	—	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update.
DVC DACx	No exceptions, any instruction	No exceptions, Non-ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. No ESR update.
DVC DACx	No exceptions	No exceptions, Ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b010. DSRR0 points to instruction after 3rd instruction. No ESR update.
DVC DACx	DSI, no DAC	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DSI, with DACy	—	Take Debug exception, DBSR update setting DACx. DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DACy	—	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Normal Ldst	Non-Ldst instruction	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Normal Ldst	Ldst instruction,no exception	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Normal Ldst	DSI Error, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. No ESR update. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.

Table continues on the next page...

Table 64-1. DAC events and Resultant Updates (continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DVC DACx	DVC DACy,Normal Ldst	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Ldst multiple (lmw, stmw)	Any instruction including ld/st	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	Any instruction(no exception)	DSI, with or without DAC,Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. No ESR update. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	Any instruction(no exception)	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

64.2.3 Linked Instruction Address Compare and Data Address Compare Events

Data Address Compare 1, 2, 3, and 4 debug events may be 'linked' with an Instruction Address Compare event by setting the DAC[1–4]LNK control bits in DBCR2 and DBCR8 to further refine when a Data Address Compare debug event is generated. DAC1 may be linked with IAC1, DAC2 (when not used as a mask or range bounds register) may be linked with IAC3. DAC3 may be linked with IAC5, DAC4 (when not used as a mask or range bounds register) may be linked with IAC7. When linked, a DAC debug event occurs when the same instruction that generates the DAC 'hit' also generates a corresponding linked IAC 'hit'. When linked, the IAC event is not recorded in the Debug Status register, regardless of whether a corresponding linked DAC event occurs, or whether the IAC event enable is set.
