MPC5746C Reference Manual

Supports MPC5744B, MPC5745B, MPC5746B, MPC5744C, MPC5745C and MPC5746C

Document Number: MPC5746CRM
Rev. 4, 12/2016

Contents

Section number **Title** **Page**

Chapter 1
About This Manual

1.1 Audience 95

1.2 Organization 95

1.3 Module descriptions 95

1.3.1 Example: chip-specific information that clarifies content in the same chapter 96

1.3.2 Example: chip-specific information that refers to a different chapter 97

1.4 Register descriptions 98

1.5 Conventions 99

1.5.1 Notes, Cautions, and Warnings 99

1.5.2 Numbering systems 99

1.5.3 Typographic notation 100

1.5.4 Special terms 100

Chapter 2
Introduction

2.1 Introduction 103

2.1.1 Target Applications 103

2.2 Block diagram 103

2.3 Family comparison 104

2.4 Feature list 108

2.5 Package Options 110

2.6 Modes of Operation 110

Chapter 3
Memory Map

3.1 Introduction 115

3.2 System memory map 115

3.3 NVM memory map 116

3.4 UTEST Memory Map 118

3.5 RAM memory map ... 119
3.6 Peripheral Bridges A and B memory maps ... 120
3.6.1 Peripheral Bridge A memory map ... 120
3.6.2 Peripheral Bridge B memory map ... 124
3.7 MC_CGM mapped peripherals memory map ... 125
3.8 PCU mapped peripherals memory map ... 125
3.9 DMAMUX mapped peripherals memory map ... 126

Chapter 4
Signal Description

4.1 Generic pins/balls ... 127
4.1.1 MSCR assignments ... 127
4.2 PAD keeping feature in LPU/STANDBY mode ... 128

Chapter 5
Security Overview

5.1 Introduction ... 133
5.2 Basic security ... 133
5.3 Advanced security ... 133
5.4 Detailed security information ... 134

Chapter 6
Platform Overview

6.1 Introduction ... 135
6.2 User/Privilege Access ... 136

Chapter 7
Power Management Overview

7.1 Introduction ... 139
7.1.1 Features ... 140
7.2 Power domains ... 141
7.2.1 Power Domain0 (PD0) ... 142
7.2.2 Power Domain1 (PD1) ... 142
7.2.3 Power Domain2 (PD2) ... 142

7.2.4 Flash HV power domain ... 143
7.2.5 SRAM domains ... 143
7.2.6 SRAM Configuration ... 143
7.3 User operating modes, power domains, and clock gating ... 144
7.4 Voltage regulators ... 146
7.4.1 FPREG voltage regulator ... 146
7.4.2 Internal regulation (Internal ballast) ... 148
7.4.3 LPREG voltage regulator ... 148
7.4.4 ULPREG voltage regulator ... 148
7.4.5 Flash voltage regulator ... 149
7.4.6 Regulation mode decoding scheme ... 149
7.4.7 Voltage monitoring ... 150
7.4.8 Applications and Low Power Modes ... 152
7.5 External Regulation ... 152
7.5.1 PORST in EXTERNAL REGULATION ... 152
7.5.2 External regulator contol ... 153
7.6 Accelerated Low Power Exit ... 154

Chapter 8
Low Power Subsystem (LPU)

8.1 Introduction ... 157
8.2 Block diagram ... 157
8.3 Features ... 158
8.4 Modes of operation ... 160
8.5 Transition to LPU mode ... 161
8.6 Exit from LPU Modes ... 165
8.7 Clocking ... 166
8.7.1 LPU System Clock Generation ... 166
8.7.2 FlexCAN0 Clocking ... 168
8.7.3 LinFlexD Clocking ... 168

8.7.4 SPI_0 Clocking ... 168
8.7.5 LPU clock source control ... 169
8.8 Reset ... 169
8.9 Interrupts ... 170
8.10 Boot ... 171
8.11 LPU Controller (LPU_CTL) ... 171
8.11.1 Memory map and register definition ... 171
8.11.2 LPU Mode Control Register (LPU_MCTL) ... 172
8.11.3 LPU Run Configuration Register (LPU_RUN_CF) ... 174
8.11.4 LPU Stop Configuration Register (LPU_STOP_CF) ... 176
8.11.5 LPU Standby Configuration Register (LPU_STANDBY_CF) ... 177
8.11.6 LPU Status Register (LPU_SR) ... 178
8.11.7 LPU Interrupt control register (LPU_ICR) ... 181
8.11.8 Module Disable (LPU_MDIS) ... 183

Chapter 9
Clocking Overview

9.1 Introduction ... 185
9.2 System clock generation ... 186
9.3 Dynamic Frequency Scaling ... 187
9.3.1 Overview ... 187
9.3.2 Linear DFS Configuration ... 189
9.3.3 Non-Linear DFS Configuration ... 190
9.3.4 DFS Limitations ... 191
9.3.5 NLDFS Abort on Interrupt ... 191
9.4 Peripheral clock generation ... 191
9.4.1 Overview ... 191
9.4.2 Enabling/Disabling of peripherals and clock sources ... 192
9.4.3 Communication interfaces ... 192
9.4.4 Timers Clock ... 199

9.4.5 ADC/BCTU/eMIOS clocking....202
9.4.6 CLKOUT clocking....202
9.4.7 HSM clocking....204
9.4.8 LPU clocking....204
9.5 MC_CGM registers....204
9.6 Built-In Self-Test clocking....205
9.7 System Clock Distribution....205
9.7.1 JTAG Frequencies....207
9.7.2 Peripheral Clock Restrictions....208
9.8 Default clock configuration....208
9.9 Clock sources....209
9.9.1 PLL....209
9.9.2 Fast External Oscillator (FXOSC)....211
9.9.3 Slow external oscillator (SXOSC)....212
9.9.4 16 MHz internal RC oscillator (FIRC)....213
9.9.5 128 kHz internal RC (SIRC)....214
9.10 Clock monitoring....215
9.10.1 CMU configuration....215
9.11 Loss of system clock behavior....218
9.11.1 Loss of PLL lock/FXOSC clock....218
9.11.2 Loss of FIRC clock....218

Chapter 10
Embedded Memories

10.1 Overview....221
10.2 System SRAM....221
10.2.1 SRAM Controller (PRAMC)....222
10.2.2 Overlay SRAM....223
10.3 Flash memory....224
10.3.1 Flash memory controller....225

10.3.2 Flash memory array ... 226
10.3.3 Flash organization ... 227
10.3.4 UTest NVM memory space ... 228
10.3.5 Overlay flash memory ... 229
10.4 End-to-end Error Correction Code (e2eECC) ... 229
10.5 Security features ... 232

Chapter 11
Device Configuration Format (DCF) records

11.1 Introduction ... 233
11.2 DCF clients ... 234
11.2.1 Safety features of DCF clients ... 234
11.2.2 DCF client modification rules ... 235
11.3 DCF record structure ... 236
11.4 DCF records sequence ... 237
11.5 Chip configuration records ... 239
11.5.1 External Regulation Exit Trim Wait (PMCDIG_ERETW) ... 239
11.5.2 Security and serial boot mode records ... 240
11.5.3 STCU configuration records ... 240

Chapter 12
Debug Overview

12.1 Introduction ... 241
12.2 Features ... 243
12.3 Debug scheme ... 244
12.4 Modes of operation ... 245
12.4.1 Nexus Reset Mode ... 245
12.4.2 Full-port Mode ... 246
12.4.3 Reduced-port Mode ... 246
12.4.4 Disabled-Port Mode ... 246
12.4.5 Multi mode nexus TAP ... 246

12.5 External signal description....247
12.6 Memory Map and Registers....248
12.7 Functional Description....248
12.7.1 Enabling Nexus Clients for TAP Access....248
12.7.2 TAP Sharing....248
12.7.3 Configuring the NDI for Nexus Messaging....249
12.7.4 TCK clock relation with NPC clock....249
12.7.5 Programmable MCKO frequency....249
12.7.6 Cross Triggering Control....251
12.7.7 Time Stamping....252
12.8 Nexus Port Controller (NPC)....253
12.8.1 NPC Handshake module....253
12.9 e200z4 core and e200z2 core debug support....258
12.10 JTAG Controller (JTAGC)....258
12.11 JTAG ID....258
12.12 CJTAGC....259
12.13 JDC....259
12.14 Debug implementation....259
12.14.1 Debug Capabilities....259
12.14.2 Debug port....260
12.15 Nexus Class 3+ Auxiliary Port....260
12.16 e200z2 Nexus 3....261
12.17 e200z4 Nexus 3....262
12.18 Nexus Crossbar Multi-master Client (NXMC)....262

Chapter 13
Reset and Boot Overview

13.1 Introduction....265
13.1.1 Global Reset....265
13.1.2 Local Reset....265

13.1.3 Reset sources....265
13.2 Global Reset Process....268
13.2.1 Overview....268
13.2.2 Reset Process Modules....269
13.2.3 Reset Process Sequences....271
13.2.4 Reset Process State Transitions....272
13.2.5 Module Status During Reset Process....282
13.3 Boot....283
13.3.1 Power Up....283
13.3.2 Exit from STANDBY/LPU_STANDBY to DRUN....283
13.3.3 Exit from LPU STANDBY to LPU_RUN....284
13.3.4 Entry from RUNx/DRUN to LPU_RUN....284
13.3.5 Interrupt Vector Prefix retention during STANDBY....284

Chapter 14
Functional Safety

14.1 Introduction....285

Chapter 15
System Integration Unit Lite2 (SIUL2)

15.1 Introduction....287
15.1.1 Overview....287
15.1.2 Features....289
15.1.3 Register protection....290
15.2 Memory map and register description....291
15.2.1 SIUL2 MCU ID Register #1 (SIUL2_MIDR1)....338
15.2.2 SIUL2 MCU ID Register #2 (SIUL2_MIDR2)....339
15.2.3 SIUL2 Interrupt Status Flag Register0 (SIUL2_ISR0)....340
15.2.4 SIUL2 Interrupt Request Enable Register0 (SIUL2_IRER0)....344
15.2.5 SIUL2 Interrupt Request Select Register0 (SIUL2_IRSR0)....347
15.2.6 SIUL2 Interrupt Rising-Edge Event Enable Register 0 (SIUL2_IREER0)....350

15.2.7 SIUL2 Interrupt Falling-Edge Event Enable Register 0 (SIUL2_IFEER0)..... 353
15.2.8 SIUL2 Interrupt Filter Enable Register 0 (SIUL2_IFER0)..... 356
15.2.9 SIUL2 Interrupt Filter Maximum Counter Register (SIUL2_IFMCR*n*)..... 358
15.2.10 SIUL2 Interrupt Filter Clock Prescaler Register (SIUL2_IFCPR)..... 359
15.2.11 SIUL2 Multiplexed Signal Configuration Register (SIUL2_MSCR*n*)..... 360
15.2.12 SIUL2 Input Multiplexed Signal Configuration Register (SIUL2_IMCR*n*)..... 362
15.2.13 SIUL2 GPIO Pad Data Output Register (SIUL2_GPDO*n*)..... 365
15.2.14 SIUL2 GPIO Pad Data Input Register (SIUL2_GPDI*n*)..... 366
15.2.15 SIUL2 Parallel GPIO Pad Data Out Register (SIUL2_PGPDO*n*)..... 368
15.2.16 SIUL2 Parallel GPIO Pad Data In Register (SIUL2_PGPDI*n*)..... 369
15.2.17 SIUL2 Masked Parallel GPIO Pad Data Out Register (SIUL2_MPGPDO*n*)..... 369
15.3 Functional description..... 370
15.3.1 General..... 370
15.3.2 Pad Control..... 370
15.3.3 General Purpose Input and Output Pads (GPIO)..... 371
15.3.4 External Interrupts Requests (REQ Pins)..... 372

Chapter 16
Crossbar Switch (AXBS)

16.1 Chip-specific AXBS information..... 377
16.1.1 Crossbar Switch configuration..... 377
16.1.2 AXBS 0 Master and Slave assignments..... 378
16.1.3 PRS register reset values..... 379
16.1.4 CRS register reset values..... 379
16.2 Introduction..... 380
16.2.1 Features..... 380
16.3 Memory Map / Register Definition..... 380
16.3.1 Priority Registers Slave (AXBS_PRS*n*)..... 382
16.3.2 Control Register (AXBS_CRS*n*)..... 385
16.3.3 Master General Purpose Control Register (AXBS_MGPCR*n*)..... 387

16.4 Functional Description....388
16.4.1 General operation....388
16.4.2 Register coherency....389
16.4.3 Arbitration....389
16.5 Initialization/application information....392

Chapter 17
Peripheral Bridge

17.1 Chip-specific PBridge information....395
17.1.1 PBRIDGE Configuration....395
17.1.2 Register reset values....395
17.2 Introduction....399
17.2.1 Features....399
17.2.2 General operation....399
17.3 Memory map/register definition....400
17.3.1 Master Privilege Register A (AIPS_MPRA)....402
17.3.2 Master Privilege Register B (AIPS_MPRB)....405
17.3.3 Peripheral Access Control Register (AIPS_PACR*n*)....407
17.3.4 Off-Platform Peripheral Access Control Register (AIPS_OPACR*n*)....412
17.4 Functional description....418
17.4.1 Access support....418

Chapter 18
Decorated Storage Memory Controller (DSMC)

18.1 Introduction....419
18.2 Decorated stores: st[b,h,w]d{cb}x rS,rA,rB....421
18.2.1 Bit Field Insert (BFINS) into an 8, 16 or 32-bit memory container....422
18.3 DSMC instantiations....426

Chapter 19
Intelligent AHB Gasket (IAHBG)

19.1 Chip-specific IAHBG information....429
19.1.1 IAHBG configuration....429

19.1.2 IAHBG clock selection ratios..... 429
19.1.3 IAHBG features enabled by Platform Configuration Module (PCM)..... 430
19.2 Introduction..... 430
19.3 Timing modes..... 430
19.3.1 1:1..... 431
19.3.2 2:1..... 431
19.3.3 1:2..... 431

Chapter 20
System Memory Protection Unit (SMPU)

20.1 Chip-specific SMPU information..... 433
20.1.1 System Memory Protection Unit (SMPU) configuration..... 433
20.2 Overview..... 435
20.2.1 Block diagram..... 435
20.2.2 Features..... 436
20.3 Memory map/register definition..... 436
20.3.1 Control/Error Status Register 0 (SMPU_CES0)..... 442
20.3.2 Control/Error Status Register 1 (SMPU_CES1)..... 443
20.3.3 Error Address Register, Bus Master (SMPU_ERR_ADR*n*)..... 443
20.3.4 Error Attribute Detail Register, Bus Master (SMPU_ERR_ADTL*n*)..... 444
20.3.5 Error Attribute Control Detail Register, Bus Master (SMPU_ERR_ACDL*n*)..... 445
20.3.6 Region Descriptor n, Word 0 (SMPU_RGD*n*_WRD0)..... 446
20.3.7 Region Descriptor n, Word 1 (SMPU_RGD*n*_WRD1)..... 447
20.3.8 Region Descriptor n, Word 2 (SMPU_RD_*n*W2)..... 447
20.3.9 Region Descriptor n, Word 3 (SMPU_RGD*n*_WRD3)..... 449
20.3.10 Region Descriptor n, Word 4 (SMPU_RGD*n*_WRD4)..... 450
20.3.11 Region Descriptor n, Word 5 (SMPU_RGD*n*_WRD5)..... 451
20.4 Functional description..... 452
20.4.1 Access evaluation macro..... 452
20.4.2 Putting it all together and error terminations..... 454

20.5 Initialization information..... 455
20.6 Application information.....455

Chapter 21
Semaphores2 (SEMA42)

21.1 Introduction.....457
21.1.1 Features..... 457
21.2 Memory map/register definition..... 459
21.2.1 Gate Register (SEMA42_GATE*n*)..... 459
21.2.2 Reset Gate Write (SEMA42_RSTGT_W).....460
21.2.3 Reset Gate Read (SEMA42_RSTGT_R).....462
21.3 Functional description.....463

Chapter 22
Platform Configuration Module (PCM)

22.1 Memory map and register definition.....465
22.1.1 Bus Bridge Configuration Register 0 (PCM_IAHB_BE0).....466
22.1.2 Bus Bridge Configuration Register 1 (PCM_IAHB_BE1).....468
22.1.3 IPS Clock Gating Module Enable 0 Register (PCM_IPS_CGM_EN0)..... 470

Chapter 23
Interrupt Controller (INTC)

23.1 Chip-specific INTC information.....473
23.1.1 INTC configuration.....473
23.1.2 INTC interrupt sources.....473
23.1.3 INTC implemented registers.....485
23.1.4 Interrupts handling during mode transitions..... 486
23.2 Introduction.....486
23.3 Block diagram.....487
23.4 Features.....488
23.5 Modes of operation..... 489
23.5.1 Software vector mode..... 489
23.5.2 Hardware vector mode.....490

23.6 Memory map and register definition....490
23.6.1 INTC Block Configuration Register (INTC_BCR)....534
23.6.2 INTC Master Protection Register (INTC_MPROT)....535
23.6.3 INTC Current Priority Register for Processor 0 (INTC_CPR0)....536
23.6.4 INTC Current Priority Register for Processor 1 (INTC_CPR1)....537
23.6.5 INTC Interrupt Acknowledge Register for Processor 0 (INTC_IACKR0)....538
23.6.6 INTC Interrupt Acknowledge Register for Processor 1 (INTC_IACKR1)....539
23.6.7 INTC End Of Interrupt Register for Processor 0 (INTC_EOIR0)....540
23.6.8 INTC End Of Interrupt Register for Processor 1 (INTC_EOIR1)....541
23.6.9 INTC Software Set/Clear Interrupt Register (INTC_SSCIR*n*)....541
23.6.10 INTC Priority Select Register (INTC_PSR*n*)....543
23.7 Functional description....544
23.7.1 Interrupt request sources....544
23.7.2 Priority management....546
23.7.3 Handshaking with processor....548
23.8 Initialization/application information....551
23.8.1 Initialization flow....551
23.8.2 Interrupt exception handler....552
23.8.3 ISR, RTOS, and task hierarchy....553
23.8.4 Order of execution....554
23.8.5 Priority ceiling protocol....555
23.8.6 Selecting priorities according to request rates and deadlines....558
23.8.7 Software-settable interrupt requests....559
23.8.8 Lowering priority within an ISR....560
23.8.9 Negating an interrupt request outside of its ISR....561
23.8.10 Examining LIFO contents....561
23.9 Interrupt sources....562

Chapter 24
Wakeup Unit (WKPU)

24.1 Chip-specific WKPU information ... 563
24.1.1 Wakeup configuration ... 563
24.1.2 NMI configuration ... 563
24.1.3 Interrupts ... 564
24.1.4 Wakeup Sources for various modes ... 566
24.1.5 NMI on standby exit ... 566
24.1.6 Register reset values ... 567
24.1.7 Pull control of wakeup pads ... 567
24.2 Introduction ... 568
24.3 Features ... 569
24.4 External signal description ... 570
24.5 WKPU memory map and register definition ... 570
24.5.1 NMI Status Flag Register (WKPU_NSR) ... 570
24.5.2 NMI Configuration Register (WKPU_NCR) ... 572
24.5.3 Wakeup/Interrupt Status Flag Register (WKPU_WISR) ... 575
24.5.4 Interrupt Request Enable Register (WKPU_IRER) ... 576
24.5.5 Wakeup Request Enable Register (WKPU_WRER) ... 577
24.5.6 Wakeup/Interrupt Rising-Edge Event Enable Register (WKPU_WIREER) ... 577
24.5.7 Wakeup/Interrupt Falling-Edge Event Enable Register (WKPU_WIFEER) ... 578
24.5.8 Wakeup/Interrupt Filter Enable Register (WKPU_WIFER) ... 578
24.5.9 Wakeup/Interrupt Pull Enable Register (WKPU_WIPER) ... 579
24.6 Functional description ... 579
24.6.1 Non-maskable interrupts ... 579
24.7 Initialization Information ... 581
24.7.1 Glitch Filter and Pad Configuration ... 581
24.7.2 Non-Maskable Interrupts ... 581
24.7.3 Reset Request ... 582

Chapter 25
PLL Digital Interface (PLLDIG)

25.1 Introduction....583
25.2 Block Diagram....583
25.3 Features....583
25.4 Modes of operation....584
25.4.1 Normal mode with reference, PLL enabled....584
25.5 Memory map and register definition....584
25.5.1 PLL Calibration Register 3 (PLLDIG_PLLCAL3)....585
25.5.2 PLLDIG PLL Control Register (PLLDIG_PLLCR)....586
25.5.3 PLLDIG PLL Status Register (PLLDIG_PLLSR)....588
25.5.4 PLLDIG PLL Divider Register (PLLDIG_PLLDV)....590
25.5.5 PLLDIG PLL Frequency Modulation Register (PLLDIG_PLLFM)....592
25.5.6 PLLDIG PLL Fractional Divide Register (PLLDIG_PLLFD)....594
25.6 Functional description....595
25.6.1 Input clock frequency....596
25.6.2 Clock configuration....596
25.6.3 Fault Collection and Control Unit (FCCU)....597
25.6.4 Frequency modulation....597
25.6.5 PLL Wakeup from low power mode....598
25.6.6 Calibration feature....598
25.7 Initialization information....599

Chapter 26
Slow Internal 128 kHz Oscillator (SIRC)

26.1 Introduction....601
26.2 Features....601
26.3 Memory map and register definition....601
26.3.1 Control register (SIRC_CTL)....601
26.4 Functional description....603

Chapter 27
Fast Internal 16 MHz RC Oscillator (FIRC)

27.1 Introduction....605
27.2 Features....605
27.3 Memory map and register definition....605
27.3.1 Control register (FIRC_CTL)....606
27.4 Functional description....607

Chapter 28
Slow External 32 KHz Oscillator (SXOSC)

28.1 Introduction....609
28.2 Features....609
28.3 Memory map and register definition....609
28.3.1 SXOSC_CTL....610
28.4 Functional description....611

Chapter 29
Fast OSC Digital Interface (FXOSC)

29.1 Introduction....613
29.2 Functional description....613
29.2.1 Oscillator power-down control and status....614
29.2.2 Oscillator startup delay....614
29.2.3 Oscillator clock available interrupt....614
29.2.4 Oscillator bypass mode....615
29.2.5 Crystal oscillator mode selection....615
29.2.6 Oscillator divider....616
29.3 Memory map and register definition....617
29.3.1 FXOSC Control Register (FXOSC_CTL)....617

Chapter 30
Clock Monitor Unit (CMU)

30.1 Introduction....621
30.1.1 Main features....622
30.2 Block diagram....622
30.3 Signals....622

30.4 Register description and memory map..... 623
30.4.1 CMU Control Status Register (CMU_CSR)..... 624
30.4.2 CMU Frequency Display Register (CMU_FDR)..... 625
30.4.3 CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)..... 626
30.4.4 CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)..... 626
30.4.5 CMU Interrupt Status Register (CMU_ISR)..... 627
30.4.6 CMU Measurement Duration Register (CMU_MDR)..... 629
30.5 Functional description..... 629
30.5.1 Frequency meter..... 629
30.5.2 CLKMN0_RMT supervisor..... 630
30.5.3 CLKMN1 supervisor..... 630

Chapter 31
Clock Generation Module (MC_CGM)

31.1 Introduction..... 633
31.1.1 Overview..... 633
31.1.2 Features..... 634
31.2 External Signal Description..... 635
31.3 Memory Map and Register Definition..... 635
31.3.1 Clockout 1 Select Register (MC_CGM_CLKOUT1_SC)..... 637
31.3.2 CLKOUT1_DC Configuration Register (MC_CGM_CLKOUT1_DC)..... 638
31.3.3 Auxiliary Clock 5 Select Control Register (MC_CGM_AC5_SC)..... 639
31.3.4 Auxiliary Clock 5 Select Status Register (MC_CGM_AC5_SS)..... 640
31.3.5 System Clock Divider 6 Configuration Register (MC_CGM_SC_DC6)..... 641
31.3.6 Auxiliary Clock 8 Select Control Register (MC_CGM_AC8_SC)..... 641
31.3.7 Auxiliary Clock 8 Select Status Register (MC_CGM_AC8_SS)..... 642
31.3.8 Auxiliary Clock 9 Select Control Register (MC_CGM_AC9_SC)..... 643
31.3.9 Auxiliary Clock 9 Select Status Register (MC_CGM_AC9_SS)..... 644
31.3.10 PCS Switch Duration Register (MC_CGM_PCS_SDUR)..... 645
31.3.11 PCS Divider Change Register 1 (MC_CGM_PCS_DIVC1)..... 646

31.3.12 PCS Divider End Register 1 (MC_CGM_PCS_DIVE1)....646
31.3.13 PCS Divider Start Register 1 (MC_CGM_PCS_DIVS1)....647
31.3.14 PCS Divider Change Register 2 (MC_CGM_PCS_DIVC2)....648
31.3.15 PCS Divider End Register 2 (MC_CGM_PCS_DIVE2)....648
31.3.16 PCS Divider Start Register 2 (MC_CGM_PCS_DIVS2)....649
31.3.17 Divider Update Abort Register (MC_CGM_DIV_UPD_ABRTD)....650
31.3.18 System Clock Divider Ratio Change Register (MC_CGM_SC_DIV_RC)....651
31.3.19 Divider Update Type Register (MC_CGM_DIV_UPD_TYPE)....653
31.3.20 Divider Update Trigger Register (MC_CGM_DIV_UPD_TRIG)....654
31.3.21 Divider Update Status Register (MC_CGM_DIV_UPD_STAT)....655
31.3.22 System Clock Select Status Register (MC_CGM_SC_SS)....656
31.3.23 System Clock Divider 0 Configuration Register (MC_CGM_SC_DC0)....657
31.3.24 System Clock Divider 1 Configuration Register (MC_CGM_SC_DC1)....658
31.3.25 System Clock Divider 2 Configuration Register (MC_CGM_SC_DC2)....659
31.3.26 System Clock Divider 3 Configuration Register (MC_CGM_SC_DC3)....660
31.3.27 System Clock Divider 4 Configuration Register (MC_CGM_SC_DC4)....661
31.3.28 System Clock Divider 5 Configuration Register (MC_CGM_SC_DC5)....662
31.3.29 Auxiliary Clock 2 Select Control Register (MC_CGM_AC2_SC)....663
31.3.30 Auxiliary Clock 2 Select Status Register (MC_CGM_AC2_SS)....664
31.3.31 Auxiliary Clock 3 Select Status Register (MC_CGM_AC3_SS)....665
31.3.32 Auxiliary Clock 6 Select Control Register (MC_CGM_AC6_SC)....665
31.3.33 Auxiliary Clock 6 Select Status Register (MC_CGM_AC6_SS)....666
31.3.34 Aux Clock 6 Divider Configuration 0 for CLKOUT_0 (MC_CGM_AC6_DC0)....667
31.4 Functional Description....668
31.4.1 System Clock Generation....668
31.4.2 Auxiliary Clock Generation....674
31.4.3 Dividers Functional Description....676
31.4.4 Halt Abort....676

Chapter 32

Input Glitch Filter

32.1 Introduction....679
32.2 Block Diagram....679
32.3 Input Glitch Filter overview....680
32.3.1 Interaction with other peripherals....680
32.3.2 Mode of operation....680
32.4 Memory map....683
32.4.1 Module Configuration Register (IGF_MCR*n*)....684
32.4.2 Module Status Register (IGF_MSR*n*)....687
32.4.3 Prescaler Register (IGF_PRESR*n*)....688
32.4.4 Rising edge Threshold Register (IGF_RTHR*n*)....689
32.4.5 Falling edge Threshold Register (IGF_FTHR)....689
32.5 Functional description....689
32.5.1 Input double sampling....690
32.5.2 Filter types....690
32.5.3 Application....694
32.5.4 Programming guidelines....697
32.5.5 On-the-fly filter reconfiguration....697
32.6 Power saving mode....698
32.6.1 STOP mode....698

Chapter 33
HF - Interface

33.1 Chip specific HFIF information....701
33.1.1 Module Interconnect....701
33.2 Introduction....703
33.3 Block Diagram....703
33.4 Overview....705
33.4.1 Receiving Data....705
33.4.2 Transmitting Data....707

33.5 Functional Description....708
33.5.1 Clock Generation....708
33.5.2 Signal Level Timeout Detection....709
33.5.3 Pulse Detection....709
33.5.4 Interrupts....710
33.6 Memory Map and Registers....710
33.6.1 Clock Configuration Register (HFInterface_CCR)....711
33.6.2 Short Pulse Detector Configuration Register (HFInterface_SPDCR)....712
33.6.3 Long Pulse Detector Configuration Register (HFInterface_LPDCR)....713
33.6.4 Low-level Timeout Detector Configuration Register (HFInterface_LTDCR)....714
33.6.5 High-level Timeout Detector Configuration Register (HFInterface_HTDCR)....715
33.6.6 Interrupt Enable Register (HFInterface_IER)....716
33.6.7 Interrupt Status Register (HFInterface_ISR)....717

Chapter 34
Analog-to-Digital Converter (ADC)

34.1 Chip-specific ADC information....719
34.1.1 ADC configuration....719
34.1.2 Feature comparison....719
34.1.3 ADC register reset values....720
34.1.4 SARADC control registers....721
34.1.5 ADC channel mapping....725
34.1.6 ADC_0 valid control register bits....728
34.1.7 ADC_1 valid control register bits....738
34.1.8 BCTU Interface....746
34.1.9 DMA interface....746
34.1.10 ADC's stop-stop ack protocol....746
34.2 Introduction....746
34.3 Overview....746
34.3.1 Parts of the ADC....746

34.3.2 ADC clock signals ... 747
34.3.3 About ADC channels ... 748
34.4 Features ... 750
34.5 Memory Map/Register Definition ... 751
34.5.1 Main Configuration Register (ADC_MCR) ... 760
34.5.2 Main Status register (ADC_MSR) ... 763
34.5.3 Interrupt Status Register (ADC_ISR) ... 765
34.5.4 Channel Pending register 0 (ADC_CEOCFR0) ... 766
34.5.5 Channel Pending register 1 (ADC_CEOCFR1) ... 769
34.5.6 Channel Pending register 2 (ADC_CEOCFR2) ... 772
34.5.7 Interrupt Mask Register (ADC_IMR) ... 775
34.5.8 Channel Interrupt Mask Register 0 (ADC_CIMR0) ... 775
34.5.9 Channel Interrupt Mask Register 1 (ADC_CIMR1) ... 778
34.5.10 Channel Interrupt Mask Register 2 (ADC_CIMR2) ... 780
34.5.11 Watchdog Threshold Interrupt Status Register (ADC_WTISR) ... 783
34.5.12 Watchdog Threshold Interrupt Mask Register (ADC_WTIMR) ... 785
34.5.13 DMA Enable register (ADC_DMAE) ... 786
34.5.14 DMA Channel Select Register 0 (ADC_DMAR0) ... 787
34.5.15 DMA Channel Select Register 1 (ADC_DMAR1) ... 789
34.5.16 DMA Channel Select Register 2 (ADC_DMAR2) ... 792
34.5.17 Threshold Register (ADC_THRHLR*n*) ... 794
34.5.18 Presampling Control Register (ADC_PSCR) ... 795
34.5.19 Presampling register 0 (ADC_PSR0) ... 796
34.5.20 Presampling register 1 (ADC_PSR1) ... 798
34.5.21 Presampling register 2 (ADC_PSR2) ... 801
34.5.22 Conversion Timing Register 0 (ADC_CTR0) ... 803
34.5.23 Conversion Timing Register 1 (ADC_CTR1) ... 804
34.5.24 Conversion Timing Register 2 (ADC_CTR2) ... 804
34.5.25 Normal Conversion Mask Register 0 (ADC_NCMR0) ... 805

34.5.26 Normal Conversion Mask Register 1 (ADC_NCMR1)....807
34.5.27 Normal Conversion Mask Register 2 (ADC_NCMR2)....810
34.5.28 Injected Conversion Mask Register 0 (ADC_JCMR0)....812
34.5.29 Injected Conversion Mask Register 1 (ADC_JCMR1)....814
34.5.30 Injected Conversion Mask Register 2 (ADC_JCMR2)....817
34.5.31 Decode Signals Delay Register (ADC_DSDR)....820
34.5.32 Power Down Exit Delay Register (ADC_PDEDR)....820
34.5.33 Channel Data Register *n* (Precision Channels) (ADC_CDR*n*)....821
34.5.34 Channel Data Register *n* (Internal Channels) (ADC_CDR*n*)....823
34.5.35 Channel Data Register *n* (External Channels) (ADC_CDR*n*)....825
34.5.36 Threshold Register (ADC_THRHLR*n*)....826
34.5.37 Channel Watchdog Select Register 0 (ADC_CWSELR0)....826
34.5.38 Channel Watchdog Select Register 1 (ADC_CWSELR1)....827
34.5.39 Channel Watchdog Select Register 2 (ADC_CWSELR2)....828
34.5.40 Channel Watchdog Select Register 4 (ADC_CWSELR4)....829
34.5.41 Channel Watchdog Select Register 5 (ADC_CWSELR5)....830
34.5.42 Channel Watchdog Select Register 6 (ADC_CWSELR6)....831
34.5.43 Channel Watchdog Select Register 7 (ADC_CWSELR7)....832
34.5.44 Channel Watchdog Select Register 8 (ADC_CWSELR8)....833
34.5.45 Channel Watchdog Select Register 9 (ADC_CWSELR9)....834
34.5.46 Channel Watchdog Select Register 10 (ADC_CWSELR10)....835
34.5.47 Channel Watchdog Select Register 11 (ADC_CWSELR11)....836
34.5.48 Channel Watchdog Enable Register 0 (ADC_CWENR0)....837
34.5.49 Channel Watchdog Enable Register 1 (ADC_CWENR1)....840
34.5.50 Channel Watchdog Enable Register 2 (ADC_CWENR2)....842
34.5.51 Analog Watchdog Out of Range Register 0 (ADC_AWORR0)....845
34.5.52 Analog Watchdog Out of Range Register 1 (ADC_AWORR1)....848
34.5.53 Analog Watchdog Out of Range Register 2 (ADC_AWORR2)....850
34.5.54 Calibration, BIST Control and status Register (ADC_CALBISTREG)....853

34.5.55 Offset and Gain User Register (ADC_OFSGNUSR)..... 855
34.6 Functional description..... 856
34.6.1 Conversion..... 856
34.6.2 Crosstriggering Unit interface..... 862
34.6.3 ADC clock prescaler and sample time settings..... 864
34.6.4 Presampling..... 865
34.6.5 Programmable analog watchdog..... 866
34.6.6 DMA functionality..... 868
34.6.7 Interrupts..... 869
34.6.8 External Decode signals Delay..... 870
34.6.9 Power-Down mode..... 871
34.6.10 Auto-Clock-Off mode..... 871
34.6.11 Calibration..... 872
34.6.12 Conversion time..... 874
34.6.13 Conversion data processing..... 876
34.7 Clock frequency..... 877

Chapter 35
Analog Comparator (CMP)

35.1 Chip-specific CMP information..... 879
35.1.1 CMP configuration..... 879
35.1.2 CMP input output connections..... 880
35.1.3 CMP "VIN1" and "VIN2" references..... 881
35.1.4 Interaction with RTC API to cause wakeup..... 882
35.1.5 CMP Window control..... 883
35.2 Introduction..... 883
35.3 Features..... 884
35.3.1 CMP features..... 884
35.3.2 6-bit DAC key features..... 885
35.3.3 ANMUX key features..... 885

35.4 CMP, DAC, and ANMUX diagram....885
35.5 CMP block diagram....886
35.6 CMP pin descriptions....888
35.6.1 External pins....888
35.7 CMP functional modes....889
35.7.1 Disabled mode (# 1)....890
35.7.2 Continuous mode (#s 2A & 2B)....890
35.7.3 Sampled, Non-Filtered mode (#s 3A & 3B)....891
35.7.4 Sampled, Filtered mode (#s 4A & 4B)....893
35.7.5 Windowed mode (#s 5A & 5B)....895
35.7.6 Windowed/Resampled mode (# 6)....897
35.7.7 Windowed/Filtered mode (#7)....897
35.8 Memory map/register definitions....898
35.8.1 CMP Control Register 0 (CMP_C0)....899
35.8.2 CMP Control Register 1 (CMP_C1)....902
35.8.3 CMP Control Register 2 (CMP_C2)....904
35.9 CMP functional description....907
35.9.1 Initialization....907
35.9.2 Low-pass filter....907
35.10 Interrupts....910
35.11 DMA support....910
35.12 DAC functional description....910
35.12.1 Digital-to-analog converter block diagram....910
35.12.2 Voltage reference source select....911
35.13 DAC resets....911
35.14 DAC clocks....911
35.15 DAC interrupts....912
35.16 Trigger mode....912

Chapter 36

Body Cross triggering unit (BCTU)

36.1 Chip-specific BCTU information ... 915
36.1.1 BCTU configuration ... 915
36.1.2 Trigger sources ... 915
36.1.3 BCTU's stop-stop ack protocol ... 917
36.2 Introduction ... 917
36.3 BCTU overview ... 918
36.4 BCTU Interacting with other peripherals ... 919
36.5 BCTU Modes of operation ... 920
36.5.1 Configuration Mode ... 921
36.5.2 Normal Mode ... 921
36.5.3 Low Power Mode ... 921
36.6 Memory Map ... 922
36.6.1 Module Configuration Register (BCTU_MCR) ... 925
36.6.2 Module Status register (BCTU_MSR) ... 927
36.6.3 Trigger Configuration Register (BCTU_TRGCFG_*n*) ... 931
36.6.4 Write Protection register (BCTU_WRPROT) ... 933
36.6.5 Software Trigger register 1 (BCTU_SFTRGR1) ... 934
36.6.6 Software Trigger register 2 (BCTU_SFTRGR2) ... 937
36.6.7 ADC0 Result Data register (BCTU_ADC0DR) ... 940
36.6.8 ADC1 result data register (BCTU_ADC1DR) ... 941
36.6.9 LIST Size Status register (BCTU_LISTSTAR) ... 942
36.6.10 LIST Channel Address Register (BCTU_LISTCHR_*n*) ... 943
36.7 Functional description ... 944
36.7.1 Trigger Configuration ... 944
36.7.2 Trigger priority and multiplexing ... 945
36.7.3 Conversion LIST ... 947
36.7.4 ADC conversion results access ... 949
36.7.5 Trigger clearing mechanism ... 950

36.7.6 On-the-fly reconfiguration of BCTU registers 951
36.7.7 Multiple Parallel Conversions 952
36.8 Interrupts and DMA requests 953

Chapter 37
Configurable Enhanced Modular IO Subsystem (eMIOS)

37.1 Chip-specific eMIOS information 955
37.1.1 eMIOS configuration 955
37.1.2 Channel types 955
37.1.3 DMA channel configuration 957
37.1.4 Channel configuration 958
37.1.5 eMIOS disabling 958
37.1.6 Serialization 959
37.1.7 BCTU Interface 964
37.1.8 EMIOS register reset value 964
37.2 Introduction 964
37.2.1 Overview 964
37.2.2 Features 967
37.2.3 Modes of operation 967
37.3 Memory map / register definition 968
37.3.1 Memory map 968
37.4 Control Memory Map and Registers 969
37.4.1 eMIOS Module Configuration Register (eMIOS_MCR) 970
37.4.2 eMIOS Global FLAG Register (eMIOS_GFLAG) 972
37.4.3 eMIOS Output Update Disable register (eMIOS_OUDIS) 972
37.4.4 eMIOS Disable Channel register (eMIOS_UCDIS) 973
37.5 Unified Channels Memory Map and Registers 973
37.5.1 eMIOS UC A register n (eMIOS_A*n*) 979
37.5.2 eMIOS UC B register n (eMIOS_B*n*) 980
37.5.3 eMIOS CNT register n (eMIOS_CNT*n*) 981

37.5.4 eMIOS UC Control register n (eMIOS_C*n*)....982
37.5.5 eMIOS UC Status register n (eMIOS_S*n*)....988
37.5.6 eMIOS Alternate Address register n (eMIOS_ALTA*n*)....989
37.5.7 eMIOS UC Control 2 register n (eMIOS_C2_*n*)....990
37.6 Functional Description....991
37.6.1 Unified Channel (UC)....993
37.6.2 IP Bus Interface Unit (BIU)....1032
37.6.3 Global Clock Prescaler Submodule (GCP)....1033
37.7 Initialization/Application Information....1033
37.7.1 Considerations....1033
37.7.2 Application Information....1034

Chapter 38
Power Control Unit (MC_PCU)

38.1 Introduction....1039
38.1.1 Overview....1039
38.1.2 Features....1040

Chapter 39
Power Management Controller digital interface (PMCDIG)

39.1 Overview....1041
39.2 Features....1041
39.3 Memory Map and Registers....1042
39.3.1 RAM Domain Configuration Register (PMCDIG_RDCR)....1042
39.3.2 Supply Gauge Status Register (PMCDIG_SGSR)....1043
39.3.3 MISC Control Register (PMCDIG_MCR)....1047
39.4 Functional description....1048
39.4.1 Analog PMC interface....1049
39.4.2 Power-up Sequence....1049

Chapter 40
Mode Entry Module (MC_ME)

40.1 Introduction....1051

40.1.1 Overview....1051
40.1.2 Features....1053
40.1.3 Use Cases....1053
40.1.4 Modes of Operation....1060
40.2 External Signal Description....1062
40.3 Memory Map and Register Definition....1062
40.3.1 Global Status Register (MC_ME_GS)....1067
40.3.2 Mode Control Register (MC_ME_MCTL)....1070
40.3.3 Mode Enable Register (MC_ME_ME)....1072
40.3.4 Interrupt Status Register (MC_ME_IS)....1074
40.3.5 Interrupt Mask Register (MC_ME_IM)....1075
40.3.6 Invalid Mode Transition Status Register (MC_ME_IMTS)....1077
40.3.7 Debug Mode Transition Status Register (MC_ME_DMTS)....1079
40.3.8 RESET Mode Configuration Register (MC_ME_RESET_MC)....1084
40.3.9 SAFE Mode Configuration Register (MC_ME_SAFE_MC)....1086
40.3.10 DRUN Mode Configuration Register (MC_ME_DRUN_MC)....1088
40.3.11 RUN0 Mode Configuration Register (MC_ME_RUN0_MC)....1091
40.3.12 RUN1 Mode Configuration Register (MC_ME_RUN1_MC)....1093
40.3.13 RUN2 Mode Configuration Register (MC_ME_RUN2_MC)....1096
40.3.14 RUN3 Mode Configuration Register (MC_ME_RUN3_MC)....1098
40.3.15 STOP0 Mode Configuration Register (MC_ME_STOP_MC)....1100
40.3.16 STANDBY0 Mode Configuration Register (MC_ME_STANDBY_MC)....1103
40.3.17 Peripheral Status Register 0 (MC_ME_PS0)....1105
40.3.18 Peripheral Status Register 1 (MC_ME_PS1)....1108
40.3.19 Peripheral Status Register 2 (MC_ME_PS2)....1110
40.3.20 Peripheral Status Register 3 (MC_ME_PS3)....1112
40.3.21 Run Peripheral Configuration Register (MC_ME_RUN_PC*n*)....1114
40.3.22 Low-Power Peripheral Configuration Register (MC_ME_LP_PC*n*)....1115
40.3.23 BCTU Peripheral Control Register (MC_ME_PCTL0)....1116

40.3.24 eMIOS_0 Peripheral Control Register (MC_ME_PCTL1)..... 1117
40.3.25 eMIOS_1 Peripheral Control Register (MC_ME_PCTL2)..... 1118
40.3.26 SAI0 Peripheral Control Register (MC_ME_PCTL10).....1119
40.3.27 SAI1 Peripheral Control Register (MC_ME_PCTL11).....1120
40.3.28 SAI2 Peripheral Control Register (MC_ME_PCTL12).....1121
40.3.29 ENET Peripheral Control Register (MC_ME_PCTL15).....1122
40.3.30 CMP_0 Peripheral Control Register (MC_ME_PCTL20).....1123
40.3.31 CMP_1 Peripheral Control Register (MC_ME_PCTL21).....1124
40.3.32 CMP_2 Peripheral Control Register (MC_ME_PCTL22).....1125
40.3.33 ADC_0 Peripheral Control Register (MC_ME_PCTL24).....1126
40.3.34 ADC_1 Peripheral Control Register (MC_ME_PCTL25).....1127
40.3.35 FlexRay Peripheral Control Register (MC_ME_PCTL28)..... 1128
40.3.36 IIC_0 Peripheral Control Register (MC_ME_PCTL30).....1129
40.3.37 IIC_1 Peripheral Control Register (MC_ME_PCTL31).....1130
40.3.38 IIC_2 Peripheral Control Register (MC_ME_PCTL32).....1131
40.3.39 IIC_3 Peripheral Control Register (MC_ME_PCTL33).....1132
40.3.40 DSPI_0 Peripheral Control Register (MC_ME_PCTL40)..... 1133
40.3.41 DSPI_1 Peripheral Control Register (MC_ME_PCTL41)..... 1134
40.3.42 DSPI_2 Peripheral Control Register (MC_ME_PCTL42)..... 1135
40.3.43 DSPI_3 Peripheral Control Register (MC_ME_PCTL43)..... 1136
40.3.44 LIN_0 Peripheral Control Register (MC_ME_PCTL50)..... 1137
40.3.45 LIN_1 Peripheral Control Register (MC_ME_PCTL51)..... 1138
40.3.46 LIN_2 Peripheral Control Register (MC_ME_PCTL52)..... 1139
40.3.47 LIN_3 Peripheral Control Register (MC_ME_PCTL53)..... 1140
40.3.48 LIN_4 Peripheral Control Register (MC_ME_PCTL54)..... 1141
40.3.49 LIN_5 Peripheral Control Register (MC_ME_PCTL55)..... 1142
40.3.50 LIN_6 Peripheral Control Register (MC_ME_PCTL56)..... 1143
40.3.51 LIN_7 Peripheral Control Register (MC_ME_PCTL57)..... 1144
40.3.52 LIN 8 Peripheral Control Register (MC_ME_PCTL58)..... 1145

40.3.53 LIN_9 Peripheral Control Register (MC_ME_PCTL59)..... 1146
40.3.54 LIN_10 Peripheral Control Register (MC_ME_PCTL60)..... 1147
40.3.55 LIN_11 Peripheral Control Register (MC_ME_PCTL61)..... 1148
40.3.56 LIN 12 Peripheral Control Register (MC_ME_PCTL62)..... 1149
40.3.57 LIN_13 Peripheral Control Register (MC_ME_PCTL63)..... 1150
40.3.58 LIN 14 Peripheral Control Register (MC_ME_PCTL64)..... 1151
40.3.59 LIN_15 Peripheral Control Register (MC_ME_PCTL65)..... 1152
40.3.60 FLEXCAN_0 Peripheral Control Register (MC_ME_PCTL70).....1153
40.3.61 FLEXCAN_1 Peripheral Control Register (MC_ME_PCTL71).....1154
40.3.62 FLEXCAN_2 Peripheral Control Register (MC_ME_PCTL72).....1155
40.3.63 FLEXCAN_3 Peripheral Control Register (MC_ME_PCTL73).....1156
40.3.64 FLEXCAN_4 Peripheral Control Register (MC_ME_PCTL74).....1157
40.3.65 FLEXCAN_5 Peripheral Control Register (MC_ME_PCTL75).....1158
40.3.66 FLEXCAN_6 Peripheral Control Register (MC_ME_PCTL76).....1159
40.3.67 FLEXCAN_7 Peripheral Control Register (MC_ME_PCTL77).....1160
40.3.68 JDC Control Register (MC_ME_PCTL82)..... 1161
40.3.69 MEMU_0 Control Register (MC_ME_PCTL83)..... 1162
40.3.70 CRC Control Register (MC_ME_PCTL84)..... 1163
40.3.71 DMAMUX Control Register (MC_ME_PCTL90).....1164
40.3.72 PIT_RTI_0 Control Register (MC_ME_PCTL91)..... 1165
40.3.73 WKPU Control Register (MC_ME_PCTL93).....1166
40.3.74 SPI0 Control Register (MC_ME_PCTL96).....1167
40.3.75 SPI1 Control Register (MC_ME_PCTL97).....1168
40.3.76 SPI2 Control Register (MC_ME_PCTL98).....1169
40.3.77 SPI3 Control Register (MC_ME_PCTL99).....1170
40.3.78 RTC-API Control Register (MC_ME_PCTL102).....1171
40.3.79 MEMU_1 Control Register (MC_ME_PCTL105)..... 1172
40.3.80 Core Status Register (MC_ME_CS)..... 1174
40.3.81 Core1 Control Register (MC_ME_CCTL1)..... 1175

40.3.82 Core3 Control Register (MC_ME_CCTL3)..... 1176
40.3.83 CORE1 Address Register (MC_ME_CADDR1)..... 1178
40.3.84 CORE3 Address Register (MC_ME_CADDR3)..... 1179
40.4 Functional Description..... 1180
40.4.1 Mode Transition Request..... 1180
40.4.2 Modes Details..... 1181
40.4.3 Mode Transition Process..... 1187
40.4.4 Software Considerations for Preventing the Blocking of Mode Transitions..... 1200
40.4.5 Protection of Mode Configuration Registers..... 1202
40.4.6 Mode Transition Interrupts..... 1203
40.4.7 Peripheral Clock Gating..... 1206
40.4.8 Initialization/Application Example..... 1207

Chapter 41
General Programmable Registers (GPR)

41.1 Overview..... 1211
41.2 Memory map and register definition..... 1211
41.2.1 GPR Control Register (GPR_CTL)..... 1212
41.2.2 GPR Status Register (GPR_STAT)..... 1215
41.2.3 GPR Control Register1 (GPR_CTL1)..... 1216
41.2.4 GPR SLEEP Register (GPR_SLEEP)..... 1216

Chapter 42
Deserial Serial Peripheral Interface (DSPI)

42.1 Chip-specific DSPI information..... 1219
42.1.1 DSPI and SPI configuration..... 1219
42.1.2 DSPI configuration..... 1219
42.1.3 SPI configuration..... 1220
42.1.4 DSPI and SPI registers..... 1220
42.1.5 DSPI's stop-stop ack protocol..... 1222
42.2 Introduction..... 1222

42.2.1 Block Diagram ... 1222
42.2.2 Features ... 1223
42.2.3 Interface configurations ... 1226
42.2.4 Modes of Operation ... 1227
42.3 Module signal descriptions ... 1229
42.3.1 HT—Hardware Trigger ... 1229
42.3.2 PCS0/SS—Peripheral Chip Select/Slave Select ... 1230
42.3.3 PCS1–PCS3—Peripheral Chip Selects 1–3 ... 1230
42.3.4 PCS4/MTRIG—Peripheral Chip Select 4/Master Trigger ... 1230
42.3.5 PCS5/PCSS—Peripheral Chip Select 5/Peripheral Chip Select Strobe ... 1230
42.3.6 SCK—Serial Clock ... 1231
42.3.7 SIN—Serial Input ... 1231
42.3.8 SOUT—Serial Output ... 1231
42.4 Memory Map/Register Definition ... 1231
42.4.1 Module Configuration Register (DSPI_MCR) ... 1235
42.4.2 Transfer Count Register (DSPI_TCR) ... 1238
42.4.3 Clock and Transfer Attributes Register (In Master Mode) (DSPI_CTAR*n*) ... 1239
42.4.4 Clock and Transfer Attributes Register (In Slave Mode) (DSPI_CTAR*n*_SLAVE) ... 1244
42.4.5 Status Register (DSPI_SR) ... 1246
42.4.6 DMA/Interrupt Request Select and Enable Register (DSPI_RSER) ... 1250
42.4.7 PUSH TX FIFO Register In Master Mode (DSPI_PUSHR) ... 1253
42.4.8 PUSH TX FIFO Register In Slave Mode (DSPI_PUSHR_SLAVE) ... 1255
42.4.9 POP RX FIFO Register (DSPI_POPR) ... 1256
42.4.10 Transmit FIFO Registers (DSPI_TXFR*n*) ... 1256
42.4.11 Receive FIFO Registers (DSPI_RXFR*n*) ... 1257
42.4.12 DSI Configuration Register 0 (DSPI_DSICR0) ... 1258
42.4.13 DSI Serialization Data Register 0 (DSPI_SDR0) ... 1261
42.4.14 DSI Alternate Serialization Data Register 0 (DSPI_ASDR0) ... 1261
42.4.15 DSI Transmit Comparison Register 0 (DSPI_COMPR0) ... 1262

42.4.16 DSI Deserialization Data Register 0 (DSPI_DDR0)..... 1262
42.4.17 DSI Configuration Register 1 (DSPI_DSICR1)..... 1263
42.4.18 DSI Serialization Source Select Register 0 (DSPI_SSR0)..... 1265
42.4.19 DSI Parallel Input Select Register 0 (DSPI_PISR0)..... 1265
42.4.20 DSI Parallel Input Select Register 1 (DSPI_PISR1)..... 1266
42.4.21 DSI Parallel Input Select Register 2 (DSPI_PISR2)..... 1267
42.4.22 DSI Parallel Input Select Register 3 (DSPI_PISR3)..... 1268
42.4.23 DSI Deserialized Data Interrupt Mask Register 0 (DSPI_DIMR0)..... 1269
42.4.24 DSI Deserialized Data Polarity Interrupt Register 0 (DSPI_DPIR0)..... 1269
42.4.25 DSI Serialization Data Register 1 (DSPI_SDR1)..... 1270
42.4.26 DSI Alternate Serialization Data Register 1 (DSPI_ASDR1)..... 1271
42.4.27 DSI Transmit Comparison Register 1 (DSPI_COMPR1)..... 1271
42.4.28 DSI Deserialization Data Register 1 (DSPI_DDR1)..... 1272
42.4.29 DSI Serialization Source Select Register 1 (DSPI_SSR1)..... 1273
42.4.30 DSI Parallel Input Select Register 4 (DSPI_PISR4)..... 1273
42.4.31 DSI Parallel Input Select Register 5 (DSPI_PISR5)..... 1274
42.4.32 DSI Parallel Input Select Register 6 (DSPI_PISR6)..... 1275
42.4.33 DSI Parallel Input Select Register 7 (DSPI_PISR7)..... 1276
42.4.34 DSI Deserialized Data Interrupt Mask Register 1 (DSPI_DIMR1)..... 1277
42.4.35 DSI Deserialized Data Polarity Interrupt Register 1 (DSPI_DPIR1)..... 1278
42.4.36 Clock and Transfer Attributes Register Extended (DSPI_CTARE*n*)..... 1278
42.4.37 Status Register Extended (DSPI_SREX)..... 1280
42.4.38 Trigger Register (DSPI_TRIG)..... 1281
42.4.39 Time Slot Length Register (DSPI_TSL)..... 1282
42.4.40 Time Slot Configuration Register (DSPI_TS_CONF)..... 1283
42.5 Functional description..... 1285
42.5.1 Start and Stop of module transfers..... 1286
42.5.2 Serial Peripheral Interface (SPI) configuration..... 1287
42.5.3 Deserial Serial Interface (DSI) Configuration..... 1292

42.5.4 Combined Serial Interface (CSI) Configuration ... 1302
42.5.5 Module baud rate and clock delay generation ... 1304
42.5.6 Transfer formats ... 1307
42.5.7 Continuous Serial Communications Clock ... 1319
42.5.8 Slave Mode Operation Constraints ... 1321
42.5.9 Timed Serial Bus (TSB) ... 1321
42.5.10 Interleaved TSB (ITSB) Mode ... 1324
42.5.11 Parity Generation and Check ... 1333
42.5.12 Interrupts/DMA requests ... 1334
42.5.13 Power saving features ... 1339
42.6 Initialization/application information ... 1340
42.6.1 How to manage queues ... 1340
42.6.2 Switching Master and Slave mode ... 1341
42.6.3 Initializing Module in Master/Slave Modes ... 1341
42.6.4 Baud rate settings ... 1341
42.6.5 Delay settings ... 1342
42.6.6 Calculation of FIFO pointer addresses ... 1343

Chapter 43
Ethernet MAC (ENET)

43.1 Chip-specific ENET information ... 1347
43.1.1 ENET Configuration ... 1347
43.1.2 ENET Interrupt mapping ... 1347
43.1.3 ENET's stop-stop ack protocol ... 1348
43.1.4 Recieve Parser Match Array Table Depth ... 1348
43.2 Introduction ... 1349
43.3 Overview ... 1349
43.3.1 Features ... 1349
43.3.2 Block diagram ... 1352
43.4 External signal description ... 1353

43.5 Memory map/register definition..... 1355
43.5.1 Interrupt Event Register (ENET_EIR)..... 1362
43.5.2 Interrupt Mask Register (ENET_EIMR)..... 1365
43.5.3 Receive Descriptor Active Register - Ring 0 (ENET_RDAR)..... 1369
43.5.4 Transmit Descriptor Active Register - Ring 0 (ENET_TDAR)..... 1370
43.5.5 Ethernet Control Register (ENET_ECR)..... 1371
43.5.6 MII Management Frame Register (ENET_MMFR)..... 1373
43.5.7 MII Speed Control Register (ENET_MSCR)..... 1374
43.5.8 MIB Control Register (ENET_MIBC)..... 1376
43.5.9 Receive Control Register (ENET_RCR)..... 1377
43.5.10 Transmit Control Register (ENET_TCR)..... 1380
43.5.11 Physical Address Lower Register (ENET_PALR)..... 1382
43.5.12 Physical Address Upper Register (ENET_PAUR)..... 1382
43.5.13 Opcode/Pause Duration Register (ENET_OPD)..... 1383
43.5.14 Transmit Interrupt Coalescing Register (ENET_TXIC*n*)..... 1383
43.5.15 Receive Interrupt Coalescing Register (ENET_RXIC*n*)..... 1384
43.5.16 Descriptor Individual Upper Address Register (ENET_IAUR)..... 1385
43.5.17 Descriptor Individual Lower Address Register (ENET_IALR)..... 1386
43.5.18 Descriptor Group Upper Address Register (ENET_GAUR)..... 1386
43.5.19 Descriptor Group Lower Address Register (ENET_GALR)..... 1387
43.5.20 Transmit FIFO Watermark Register (ENET_TFWR)..... 1387
43.5.21 Receive Descriptor Ring 1 Start Register (ENET_RDSR1)..... 1388
43.5.22 Transmit Buffer Descriptor Ring 1 Start Register (ENET_TDSR1)..... 1389
43.5.23 Maximum Receive Buffer Size Register - Ring 1 (ENET_MRBR1)..... 1390
43.5.24 Receive Descriptor Ring 2 Start Register (ENET_RDSR2)..... 1391
43.5.25 Transmit Buffer Descriptor Ring 2 Start Register (ENET_TDSR2)..... 1391
43.5.26 Maximum Receive Buffer Size Register - Ring 2 (ENET_MRBR2)..... 1392
43.5.27 Receive Descriptor Ring 0 Start Register (ENET_RDSR)..... 1393
43.5.28 Transmit Buffer Descriptor Ring 0 Start Register (ENET_TDSR)..... 1394

43.5.29 Maximum Receive Buffer Size Register - Ring 0 (ENET_MRBR)..... 1394
43.5.30 Receive FIFO Section Full Threshold (ENET_RSFL)..... 1395
43.5.31 Receive FIFO Section Empty Threshold (ENET_RSEM)..... 1396
43.5.32 Receive FIFO Almost Empty Threshold (ENET_RAEM)..... 1396
43.5.33 Receive FIFO Almost Full Threshold (ENET_RAFL)..... 1397
43.5.34 Transmit FIFO Section Empty Threshold (ENET_TSEM)..... 1397
43.5.35 Transmit FIFO Almost Empty Threshold (ENET_TAEM)..... 1398
43.5.36 Transmit FIFO Almost Full Threshold (ENET_TAFL)..... 1398
43.5.37 Transmit Inter-Packet Gap (ENET_TIPG)..... 1399
43.5.38 Frame Truncation Length (ENET_FTRL)..... 1399
43.5.39 Transmit Accelerator Function Configuration (ENET_TACC)..... 1400
43.5.40 Receive Accelerator Function Configuration (ENET_RACC)..... 1401
43.5.41 Receive Classification Match Register for Class n (ENET_RCMR*n*)..... 1403
43.5.42 DMA Class Based Configuration (ENET_DMA*n*CFG)..... 1404
43.5.43 Receive Descriptor Active Register - Ring 1 (ENET_RDAR1)..... 1406
43.5.44 Transmit Descriptor Active Register - Ring 1 (ENET_TDAR1)..... 1406
43.5.45 Receive Descriptor Active Register - Ring 2 (ENET_RDAR2)..... 1408
43.5.46 Transmit Descriptor Active Register - Ring 2 (ENET_TDAR2)..... 1409
43.5.47 QOS Scheme (ENET_QOS)..... 1409
43.5.48 Reserved Statistic Register (ENET_RMON_T_DROP)..... 1411
43.5.49 Tx Packet Count Statistic Register (ENET_RMON_T_PACKETS)..... 1411
43.5.50 Tx Broadcast Packets Statistic Register (ENET_RMON_T_BC_PKT)..... 1412
43.5.51 Tx Multicast Packets Statistic Register (ENET_RMON_T_MC_PKT)..... 1412
43.5.52 Tx Packets with CRC/Align Error Statistic Register (ENET_RMON_T_CRC_ALIGN)..... 1413
43.5.53 Tx Packets Less Than Bytes and Good CRC Statistic Register (ENET_RMON_T_UNDERSIZE)..... 1413
43.5.54 Tx Packets GT MAX_FL bytes and Good CRC Statistic Register (ENET_RMON_T_OVERSIZE)..... 1414
43.5.55 Tx Packets Less Than 64 Bytes and Bad CRC Statistic Register (ENET_RMON_T_FRAG)..... 1414
43.5.56 Tx Packets Greater Than MAX_FL bytes and Bad CRC Statistic Register (ENET_RMON_T_JAB)..... 1415
43.5.57 Tx Collision Count Statistic Register (ENET_RMON_T_COL)..... 1415

43.5.58 Tx 64-Byte Packets Statistic Register (ENET_RMON_T_P64)..... 1416
43.5.59 Tx 65- to 127-byte Packets Statistic Register (ENET_RMON_T_P65TO127)..... 1416
43.5.60 Tx 128- to 255-byte Packets Statistic Register (ENET_RMON_T_P128TO255)..... 1417
43.5.61 Tx 256- to 511-byte Packets Statistic Register (ENET_RMON_T_P256TO511)..... 1417
43.5.62 Tx 512- to 1023-byte Packets Statistic Register (ENET_RMON_T_P512TO1023)..... 1418
43.5.63 Tx 1024- to 2047-byte Packets Statistic Register (ENET_RMON_T_P1024TO2047)..... 1418
43.5.64 Tx Packets Greater Than 2048 Bytes Statistic Register (ENET_RMON_T_P_GTE2048)..... 1419
43.5.65 Tx Octets Statistic Register (ENET_RMON_T_OCTETS)..... 1419
43.5.66 Reserved Statistic Register (ENET_IEEE_T_DROP)..... 1419
43.5.67 Frames Transmitted OK Statistic Register (ENET_IEEE_T_FRAME_OK)..... 1420
43.5.68 Frames Transmitted with Single Collision Statistic Register (ENET_IEEE_T_1COL)..... 1420
43.5.69 Frames Transmitted with Multiple Collisions Statistic Register (ENET_IEEE_T_MCOL)..... 1421
43.5.70 Frames Transmitted after Deferral Delay Statistic Register (ENET_IEEE_T_DEF)..... 1421
43.5.71 Frames Transmitted with Late Collision Statistic Register (ENET_IEEE_T_LCOL)..... 1422
43.5.72 Frames Transmitted with Excessive Collisions Statistic Register (ENET_IEEE_T_EXCOL)..... 1422
43.5.73 Frames Transmitted with Tx FIFO Underrun Statistic Register (ENET_IEEE_T_MACERR)..... 1423
43.5.74 Frames Transmitted with Carrier Sense Error Statistic Register (ENET_IEEE_T_CSERR)..... 1423
43.5.75 Reserved Statistic Register (ENET_IEEE_T_SQE)..... 1424
43.5.76 Flow Control Pause Frames Transmitted Statistic Register (ENET_IEEE_T_FDXFC)..... 1424
43.5.77 Octet Count for Frames Transmitted w/o Error Statistic Register (ENET_IEEE_T_OCTETS_OK)..... 1425
43.5.78 Rx Packet Count Statistic Register (ENET_RMON_R_PACKETS)..... 1425
43.5.79 Rx Broadcast Packets Statistic Register (ENET_RMON_R_BC_PKT)..... 1426
43.5.80 Rx Multicast Packets Statistic Register (ENET_RMON_R_MC_PKT)..... 1426
43.5.81 Rx Packets with CRC/Align Error Statistic Register (ENET_RMON_R_CRC_ALIGN)..... 1427
43.5.82 Rx Packets with Less Than 64 Bytes and Good CRC Statistic Register (ENET_RMON_R_UNDERSIZE)..... 1427
43.5.83 Rx Packets Greater Than MAX_FL and Good CRC Statistic Register (ENET_RMON_R_OVERSIZE). 1428
43.5.84 Rx Packets Less Than 64 Bytes and Bad CRC Statistic Register (ENET_RMON_R_FRAG)..... 1428
43.5.85 Rx Packets Greater Than MAX_FL Bytes and Bad CRC Statistic Register (ENET_RMON_R_JAB)..... 1429

43.5.86 Reserved Statistic Register (ENET_RMON_R_RESVD_0)..... 1429
43.5.87 Rx 64-Byte Packets Statistic Register (ENET_RMON_R_P64)..... 1429
43.5.88 Rx 65- to 127-Byte Packets Statistic Register (ENET_RMON_R_P65TO127)..... 1430
43.5.89 Rx 128- to 255-Byte Packets Statistic Register (ENET_RMON_R_P128TO255)..... 1430
43.5.90 Rx 256- to 511-Byte Packets Statistic Register (ENET_RMON_R_P256TO511)..... 1431
43.5.91 Rx 512- to 1023-Byte Packets Statistic Register (ENET_RMON_R_P512TO1023)..... 1431
43.5.92 Rx 1024- to 2047-Byte Packets Statistic Register (ENET_RMON_R_P1024TO2047)..... 1432
43.5.93 Rx Packets Greater than 2048 Bytes Statistic Register (ENET_RMON_R_P_GTE2048)..... 1432
43.5.94 Rx Octets Statistic Register (ENET_RMON_R_OCTETS)..... 1433
43.5.95 Frames not Counted Correctly Statistic Register (ENET_IEEE_R_DROP)..... 1433
43.5.96 Frames Received OK Statistic Register (ENET_IEEE_R_FRAME_OK)..... 1434
43.5.97 Frames Received with CRC Error Statistic Register (ENET_IEEE_R_CRC)..... 1434
43.5.98 Frames Received with Alignment Error Statistic Register (ENET_IEEE_R_ALIGN)..... 1435
43.5.99 Receive FIFO Overflow Count Statistic Register (ENET_IEEE_R_MACERR)..... 1435
43.5.100 Flow Control Pause Frames Received Statistic Register (ENET_IEEE_R_FDXFC)..... 1436
43.5.101 Octet Count for Frames Received without Error Statistic Register (ENET_IEEE_R_OCTETS_OK)..... 1436
43.5.102 Adjustable Timer Control Register (ENET_ATCR)..... 1436
43.5.103 Timer Value Register (ENET_ATVR)..... 1438
43.5.104 Timer Offset Register (ENET_ATOFF)..... 1439
43.5.105 Timer Period Register (ENET_ATPER)..... 1439
43.5.106 Timer Correction Register (ENET_ATCOR)..... 1440
43.5.107 Time-Stamping Clock Period Register (ENET_ATINC)..... 1440
43.5.108 Timestamp of Last Transmitted Frame (ENET_ATSTMP)..... 1441
43.5.109 Pattern Match Data Register (ENET_MDATA)..... 1441
43.5.110 Match Entry Mask Register (ENET_MMASK)..... 1442
43.5.111 Match Entry Rules Configuration Register (ENET_MCONFIG)..... 1442
43.5.112 Match Entry Read/Write Command Register (ENET_MENTRYRW)..... 1443
43.5.113 Receive Parser Control Register (ENET_RXPCTL)..... 1444
43.5.114 Maximum Frame Offset (ENET_MAXFRMOFF)..... 1446

43.5.115 Receive Parser Status (ENET_RXPARST)..... 1447
43.5.116 Parser Discard Count (ENET_PARSDSCD)..... 1448
43.5.117 Parser Accept Count 0 (ENET_PRSACPT0)..... 1449
43.5.118 Parser Reject Count 0 (ENET_PRSRJCT0)..... 1449
43.5.119 Parser Accept Count 1 (ENET_PRSACPT1)..... 1450
43.5.120 Parser Reject Count 1 (ENET_PRSRJCT1)..... 1450
43.5.121 Parser Accept Count 2 (ENET_PRSACPT2)..... 1451
43.5.122 Parser Reject Count 2 (ENET_PRSRJCT2)..... 1451
43.5.123 Timer Global Status Register (ENET_TGSR)..... 1452
43.5.124 Timer Control Status Register (ENET_TCSR*n*)..... 1453
43.5.125 Timer Compare Capture Register (ENET_TCCR*n*)..... 1454
43.6 Functional description..... 1455
43.6.1 Ethernet MAC frame formats..... 1455
43.6.2 IP and higher layers frame format..... 1458
43.6.3 IEEE 1588 message formats..... 1462
43.6.4 MAC receive..... 1466
43.6.5 MAC transmit..... 1475
43.6.6 Full-duplex flow control operation..... 1481
43.6.7 Magic packet detection..... 1483
43.6.8 IP accelerator functions..... 1484
43.6.9 Resets and stop controls..... 1488
43.6.10 IEEE 1588 functions..... 1491
43.6.11 FIFO thresholds..... 1495
43.6.12 Loopback options..... 1498
43.6.13 Legacy buffer descriptors..... 1499
43.6.14 Enhanced buffer descriptors..... 1500
43.6.15 Client FIFO application interface..... 1507
43.6.16 FIFO protection..... 1510
43.6.17 Reference clock..... 1512

43.6.18 PHY management interface ... 1512
43.6.19 Ethernet interfaces ... 1515
43.6.20 AVB configuration ... 1519
43.6.21 Interrupt coalescence ... 1520

Chapter 44
FlexCAN

44.1 Chip-specific FlexCAN information ... 1523
44.1.1 FlexCAN configuration ... 1523
44.1.2 Requirements for entering FlexCAN modes: Freeze, Module Disable, Stop ... 1524
44.1.3 External time tick ... 1526
44.1.4 FlexCAN's stop-stop ack protocol ... 1527
44.2 Introduction ... 1527
44.2.1 Overview ... 1528
44.2.2 FlexCAN module features ... 1529
44.2.3 Modes of operation ... 1531
44.3 FlexCAN signal descriptions ... 1533
44.3.1 CAN Rx ... 1533
44.3.2 CAN Tx ... 1533
44.4 Memory map/register definition ... 1533
44.4.1 FlexCAN memory mapping ... 1533
44.4.2 Module Configuration Register (CAN_MCR) ... 1542
44.4.3 Control 1 register (CAN_CTRL1) ... 1547
44.4.4 Free Running Timer (CAN_TIMER) ... 1551
44.4.5 Rx Mailboxes Global Mask Register (CAN_RXMGMASK) ... 1552
44.4.6 Rx 14 Mask register (CAN_RX14MASK) ... 1553
44.4.7 Rx 15 Mask register (CAN_RX15MASK) ... 1554
44.4.8 Error Counter (CAN_ECR) ... 1555
44.4.9 Error and Status 1 register (CAN_ESR1) ... 1557
44.4.10 Interrupt Masks 2 register (CAN_IMASK2) ... 1564

44.4.11 Interrupt Masks 1 register (CAN_IMASK1)..... 1564
44.4.12 Interrupt Flags 2 register (CAN_IFLAG2)..... 1565
44.4.13 Interrupt Flags 1 register (CAN_IFLAG1)..... 1566
44.4.14 Control 2 register (CAN_CTRL2)..... 1569
44.4.15 Error and Status 2 register (CAN_ESR2)..... 1572
44.4.16 CRC Register (CAN_CRCR)..... 1574
44.4.17 Rx FIFO Global Mask register (CAN_RXFGMASK)..... 1574
44.4.18 Rx FIFO Information Register (CAN_RXFIR)..... 1575
44.4.19 CAN Bit Timing Register (CAN_CBT)..... 1576
44.4.20 Interrupt Masks 3 Register (CAN_IMASK3)..... 1578
44.4.21 Interrupt Flags 3 Register (CAN_IFLAG3)..... 1579
44.4.22 Rx Individual Mask Registers (CAN_RXIMR*n*)..... 1579
44.4.23 Pretended Networking Control 1 Register (CAN_CTRL1_PN)..... 1581
44.4.24 Pretended Networking Control 2 Register (CAN_CTRL2_PN)..... 1582
44.4.25 Pretended Networking Wake Up Match Register (CAN_WU_MTC)..... 1583
44.4.26 Pretended Networking ID Filter 1 Register (CAN_FLT_ID1)..... 1585
44.4.27 Pretended Networking DLC Filter Register (CAN_FLT_DLC)..... 1586
44.4.28 Pretended Networking Payload Low Filter 1 Register (CAN_PL1_LO)..... 1587
44.4.29 Pretended Networking Payload High Filter 1 Register (CAN_PL1_HI)..... 1587
44.4.30 Pretended Networking ID Filter 2 Register / ID Mask Register (CAN_FLT_ID2_IDMASK)..... 1588
44.4.31 Pretended Networking Payload Low Filter 2 Register / Payload Low Mask Register (CAN_PL2_PLMASK_LO)..... 1589
44.4.32 Pretended Networking Payload High Filter 2 low order bits / Payload High Mask Register (CAN_PL2_PLMASK_HI)..... 1590
44.4.33 Wake Up Message Buffer Register for C/S (CAN_WMB*n*_CS)..... 1590
44.4.34 Wake Up Message Buffer Register for ID (CAN_WMB*n*_ID)..... 1591
44.4.35 Wake Up Message Buffer Register for Data 0-3 (CAN_WMB*n*_D03)..... 1592
44.4.36 Wake Up Message Buffer Register Data 4-7 (CAN_WMB*n*_D47)..... 1593
44.4.37 CAN FD Control Register (CAN_FDCTRL)..... 1593

44.4.38 CAN FD Bit Timing Register (CAN_FDCBT)..... 1597
44.4.39 CAN FD CRC Register (CAN_FDCRC)..... 1599
44.4.40 Message buffer structure..... 1601
44.4.41 FlexCAN Memory Partition for CAN FD..... 1607
44.4.42 FlexCAN message buffer memory map..... 1609
44.4.43 Rx FIFO structure..... 1615
44.5 Functional description..... 1617
44.5.1 Transmit process..... 1618
44.5.2 Arbitration process..... 1619
44.5.3 Receive process..... 1623
44.5.4 Matching process..... 1625
44.5.5 Receive Process under Pretended Networking Mode..... 1629
44.5.6 Move process..... 1634
44.5.7 Data coherence..... 1636
44.5.8 Rx FIFO..... 1639
44.5.9 CAN protocol related features..... 1642
44.5.10 Clock domains and restrictions..... 1662
44.5.11 Modes of operation details..... 1667
44.5.12 Interrupts..... 1671
44.5.13 Bus interface..... 1672
44.6 Initialization/application information..... 1673
44.6.1 FlexCAN initialization sequence..... 1673

Chapter 45
Inter-Integrated Circuit (I2C)

45.1 Chip-specific I2C information..... 1677
45.1.1 I2C configurations..... 1677
45.2 Overview..... 1677
45.3 Introduction to I2C..... 1677
45.3.1 Definition: I2C module..... 1678

45.3.2 Advantages of the I2C bus ... 1678
45.3.3 Module block diagram ... 1678
45.3.4 Features ... 1679
45.3.5 Modes of operation ... 1680
45.3.6 Definition: I2C conditions ... 1681
45.4 External signal descriptions ... 1682
45.4.1 Signal overview ... 1682
45.4.2 Detailed external signal descriptions ... 1682
45.5 Memory map and register definition ... 1682
45.5.1 Register accessibility ... 1683
45.5.2 Register figure conventions ... 1683
45.5.3 I2C Bus Address Register (I2C_IBAD) ... 1684
45.5.4 I2C Bus Frequency Divider Register (I2C_IBFD) ... 1685
45.5.5 I2C Bus Control Register (I2C_IBCR) ... 1685
45.5.6 I2C Bus Status Register (I2C_IBSR) ... 1687
45.5.7 I2C Bus Data I/O Register (I2C_IBDR) ... 1688
45.5.8 I2C Bus Interrupt Config Register (I2C_IBIC) ... 1689
45.5.9 I2C Bus Debug Register (I2C_IBDBG) ... 1690
45.6 Functional description ... 1691
45.6.1 Notes about module operation ... 1691
45.6.2 Transactions ... 1691
45.6.3 Arbitration procedure ... 1695
45.6.4 Clock behavior ... 1696
45.6.5 Interrupts ... 1703
45.6.6 STOP mode ... 1704
45.6.7 DEBUG mode ... 1705
45.6.8 DMA interface ... 1707
45.7 Initialization/application information ... 1708
45.7.1 Recommended interrupt service flow ... 1708

45.7.2 General programming guidelines (for both master and slave mode)....1709
45.7.3 Programming guidelines specific to master mode....1711
45.7.4 Programming guidelines specific to slave mode....1715
45.7.5 DMA application information....1715

Chapter 46
LINFlexD

46.1 Chip-specific LINFlexD information....1723
46.1.1 LINFlexD configurations....1723
46.1.2 LinflexD's stop-stop ack protocol....1724
46.2 Introduction....1724
46.2.1 Glossary and acronyms....1724
46.2.2 References....1725
46.3 Main features....1727
46.3.1 LIN mode features....1727
46.3.2 UART mode features....1728
46.4 Functional description....1729
46.4.1 LIN protocol....1729
46.4.2 LINFlexD features....1731
46.4.3 Timer....1751
46.4.4 UART mode....1751
46.4.5 DMA interface....1757
46.5 Memory map and register description....1775
46.5.1 LIN Control Register 1 (LINFlexD_LINCR1)....1777
46.5.2 LIN Interrupt enable register (LINFlexD_LINIER)....1780
46.5.3 LIN Status Register (LINFlexD_LINSR)....1782
46.5.4 LIN Error Status Register (LINFlexD_LINESR)....1786
46.5.5 UART Mode Control Register (LINFlexD_UARTCR)....1787
46.5.6 UART Mode Status Register (LINFlexD_UARTSR)....1793
46.5.7 LIN Time-Out Control Status Register (LINFlexD_LINTCSR)....1795

46.5.8 LIN Output Compare Register (LINFlexD_LINOCR)....1797
46.5.9 LIN Time-Out Control Register (LINFlexD_LINTOCR)....1798
46.5.10 LIN Fractional Baud Rate Register (LINFlexD_LINFBRR)....1799
46.5.11 LIN Integer Baud Rate Register (LINFlexD_LINIBRR)....1800
46.5.12 LIN Checksum Field Register (LINFlexD_LINCFR)....1800
46.5.13 LIN Control Register 2 (LINFlexD_LINCR2)....1801
46.5.14 Buffer Identifier Register (LINFlexD_BIDR)....1803
46.5.15 Buffer Data Register Least Significant (LINFlexD_BDRL)....1804
46.5.16 Buffer Data Register Most Significant (LINFlexD_BDRM)....1805
46.5.17 Identifier Filter Enable Register (LINFlexD_IFER)....1805
46.5.18 Identifier Filter Match Index (LINFlexD_IFMI)....1806
46.5.19 Identifier Filter Mode Register (LINFlexD_IFMR)....1806
46.5.20 Identifier Filter Control Register (LINFlexD_IFCR*n*)....1807
46.5.21 Global Control Register (LINFlexD_GCR)....1808
46.5.22 UART Preset Timeout Register (LINFlexD_UARTPTO)....1810
46.5.23 UART Current Timeout Register (LINFlexD_UARTCTO)....1811
46.5.24 DMA Tx Enable Register (LINFlexD_DMATXE)....1812
46.5.25 DMA Rx Enable Register (LINFlexD_DMARXE)....1812
46.6 Programming considerations....1813
46.6.1 Master node....1813
46.6.2 Slave node....1815
46.6.3 Timeout....1820
46.6.4 UART mode....1821
46.6.5 Interrupts....1822
46.6.6 LINFlexD Clock Tolerance....1823

Chapter 47
FlexRay

47.1 Chip-specific FlexRay information....1825
47.1.1 FlexRay configuration....1825

47.1.2 Stop Watch interface....1825
47.2 Introduction....1825
47.2.1 Reference....1825
47.2.2 Glossary....1826
47.2.3 Overview....1827
47.2.4 Features....1829
47.2.5 Modes of Operation....1831
47.3 External Signal Description....1833
47.3.1 Detailed Signal Descriptions....1833
47.4 Controller Host Interface Clocking....1835
47.5 Protocol Engine Clocking....1835
47.5.1 Oscillator Clocking....1835
47.5.2 PLL Clocking....1835
47.6 Register Descriptions....1836
47.6.1 Register Reset....1836
47.6.2 Register Write Access....1837
47.7 Memory map and register definition....1838
47.7.1 Module Version Register (FR_MVR)....1875
47.7.2 Module Configuration Register (FR_MCR)....1875
47.7.3 System Memory Base Address High Register (FR_SYMBADHR)....1878
47.7.4 System Memory Base Address Low Register (FR_SYMBADLR)....1878
47.7.5 Strobe Signal Control Register (FR_STBSCR)....1879
47.7.6 Message Buffer Data Size Register (FR_MBDSR)....1881
47.7.7 Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)....1881
47.7.8 PE DRAM Access Register (FR_PEDRAR)....1882
47.7.9 PE DRAM Data Register (FR_PEDRDR)....1883
47.7.10 Protocol Operation Control Register (FR_POCR)....1884
47.7.11 Global Interrupt Flag and Enable Register (FR_GIFER)....1885
47.7.12 Protocol Interrupt Flag Register 0 (FR_PIFR0)....1888

47.7.13 Protocol Interrupt Flag Register 1 (FR_PIFR1)....1890
47.7.14 Protocol Interrupt Enable Register 0 (FR_PIER0)....1892
47.7.15 Protocol Interrupt Enable Register 1 (FR_PIER1)....1894
47.7.16 CHI Error Flag Register (FR_CHIERFR)....1895
47.7.17 Message Buffer Interrupt Vector Register (FR_MBIVEC)....1898
47.7.18 Channel A Status Error Counter Register (FR_CASERCR)....1899
47.7.19 Channel B Status Error Counter Register (FR_CBSERCR)....1899
47.7.20 Protocol Status Register 0 (FR_PSR0)....1900
47.7.21 Protocol Status Register 1 (FR_PSR1)....1902
47.7.22 Protocol Status Register 2 (FR_PSR2)....1903
47.7.23 Protocol Status Register 3 (FR_PSR3)....1905
47.7.24 Macrotick Counter Register (FR_MTCTR)....1907
47.7.25 Cycle Counter Register (FR_CYCTR)....1908
47.7.26 Slot Counter Channel A Register (FR_SLTCTAR)....1908
47.7.27 Slot Counter Channel B Register (FR_SLTCTBR)....1909
47.7.28 Rate Correction Value Register (FR_RTCORVR)....1909
47.7.29 Offset Correction Value Register (FR_OFCORVR)....1910
47.7.30 Combined Interrupt Flag Register (FR_CIFR)....1911
47.7.31 System Memory Access Time-Out Register (FR_SYMATOR)....1912
47.7.32 Sync Frame Counter Register (FR_SFCNTR)....1913
47.7.33 Sync Frame Table Offset Register (FR_SFTOR)....1913
47.7.34 Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR)....1914
47.7.35 Sync Frame ID Rejection Filter Register (FR_SFIDRFR)....1916
47.7.36 Sync Frame ID Acceptance Filter Value Register (FR_SFIDAFVR)....1916
47.7.37 Sync Frame ID Acceptance Filter Mask Register (FR_SFIDAFMR)....1917
47.7.38 Network Management Vector Register (FR_NMVR*n*)....1917
47.7.39 Network Management Vector Length Register (FR_NMVLR)....1918
47.7.40 Timer Configuration and Control Register (FR_TICCR)....1918
47.7.41 Timer 1 Cycle Set Register (FR_TI1CYSR)....1920

47.7.42 Timer 1 Macrotick Offset Register (FR_TI1MTOR)..... 1921
47.7.43 Timer 2 Configuration Register 0 (Absolute Timer Configuration) (FR_TI2CR0_ABS)..... 1921
47.7.44 Timer 2 Configuration Register 0 (Relative Timer Configuration) (FR_TI2CR0_REL).....1922
47.7.45 Timer 2 Configuration Register 1 (Absolute Timer Configuration) (FR_TI2CR1_ABS)..... 1922
47.7.46 Timer 2 Configuration Register 1 (Relative Timer Configuration) (FR_TI2CR1_REL).....1923
47.7.47 Slot Status Selection Register (FR_SSSR)..... 1924
47.7.48 Slot Status Counter Condition Register (FR_SSCCR)..... 1925
47.7.49 Slot Status Register (FR_SSR*n*)..... 1927
47.7.50 Slot Status Counter Register (FR_SSCR*n*)..... 1929
47.7.51 MTS A Configuration Register (FR_MTSACFR).....1929
47.7.52 MTS B Configuration Register (FR_MTSBCFR)..... 1930
47.7.53 Receive Shadow Buffer Index Register (FR_RSBIR)..... 1931
47.7.54 Receive FIFO Watermark and Selection Register (FR_RFWMSR)..... 1932
47.7.55 Receive FIFO Start Index Register (FR_RFSIR)..... 1933
47.7.56 Receive FIFO Depth and Size Register (FR_RFDSR)..... 1933
47.7.57 Receive FIFO A Read Index Register (FR_RFARIR).....1934
47.7.58 Receive FIFO B Read Index Register (FR_RFBRIR)..... 1934
47.7.59 Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR).....1935
47.7.60 Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR).....1935
47.7.61 Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR)..... 1936
47.7.62 Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR)..... 1936
47.7.63 Receive FIFO Range Filter Configuration Register (FR_RFRFCFR).....1937
47.7.64 Receive FIFO Range Filter Control Register (FR_RFRFCTR).....1938
47.7.65 Last Dynamic Transmit Slot Channel A Register (FR_LDTXSLAR)..... 1939
47.7.66 Last Dynamic Transmit Slot Channel B Register (FR_LDTXSLBR).....1940
47.7.67 Protocol Configuration Register 0 (FR_PCR0)..... 1940
47.7.68 Protocol Configuration Register 1 (FR_PCR1)..... 1943
47.7.69 Protocol Configuration Register 2 (FR_PCR2)..... 1943
47.7.70 Protocol Configuration Register 3 (FR_PCR3)..... 1944

47.7.71 Protocol Configuration Register 4 (FR_PCR4)..... 1944
47.7.72 Protocol Configuration Register 5 (FR_PCR5)..... 1945
47.7.73 Protocol Configuration Register 6 (FR_PCR6)..... 1945
47.7.74 Protocol Configuration Register 7 (FR_PCR7)..... 1946
47.7.75 Protocol Configuration Register 8 (FR_PCR8)..... 1946
47.7.76 Protocol Configuration Register 9 (FR_PCR9)..... 1947
47.7.77 Protocol Configuration Register 10 (FR_PCR10)..... 1948
47.7.78 Protocol Configuration Register 11 (FR_PCR11)..... 1948
47.7.79 Protocol Configuration Register 12 (FR_PCR12)..... 1949
47.7.80 Protocol Configuration Register 13 (FR_PCR13)..... 1950
47.7.81 Protocol Configuration Register 14 (FR_PCR14)..... 1950
47.7.82 Protocol Configuration Register 15 (FR_PCR15)..... 1951
47.7.83 Protocol Configuration Register 16 (FR_PCR16)..... 1951
47.7.84 Protocol Configuration Register 17 (FR_PCR17)..... 1952
47.7.85 Protocol Configuration Register 18 (FR_PCR18)..... 1952
47.7.86 Protocol Configuration Register 19 (FR_PCR19)..... 1953
47.7.87 Protocol Configuration Register 20 (FR_PCR20)..... 1953
47.7.88 Protocol Configuration Register 21 (FR_PCR21)..... 1954
47.7.89 Protocol Configuration Register 22 (FR_PCR22)..... 1954
47.7.90 Protocol Configuration Register 23 (FR_PCR23)..... 1955
47.7.91 Protocol Configuration Register 24 (FR_PCR24)..... 1955
47.7.92 Protocol Configuration Register 25 (FR_PCR25)..... 1956
47.7.93 Protocol Configuration Register 26 (FR_PCR26)..... 1956
47.7.94 Protocol Configuration Register 27 (FR_PCR27)..... 1957
47.7.95 Protocol Configuration Register 28 (FR_PCR28)..... 1958
47.7.96 Protocol Configuration Register 29 (FR_PCR29)..... 1958
47.7.97 Protocol Configuration Register 30 (FR_PCR30)..... 1959
47.7.98 StopWatch Count High Register (FR_STPWHR)..... 1959
47.7.99 Stop Watch Count Low Register (FR_STPWLR)..... 1960

47.7.100 Protocol Event Output Enable and StopWatch Control Register (FR_PEOER)..... 1960
47.7.101 Receive FIFO Start Data Offset Register (FR_RFSDOR).....1961
47.7.102 Receive FIFO System Memory Base Address High Register (FR_RFSYMBADHR)..... 1962
47.7.103 Receive FIFO System Memory Base Address Low Register (FR_RFSYMBADLR)..... 1962
47.7.104 Receive FIFO Periodic Timer Register (FR_RFPTR).....1963
47.7.105 Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR).....1963
47.7.106 ECC Error Interrupt Flag and Enable Register (FR_EEIFER)..... 1965
47.7.107 ECC Error Report and Injection Control Register (FR_EERICR)..... 1967
47.7.108 ECC Error Report Address Register (FR_EERAR)..... 1968
47.7.109 ECC Error Report Data Register (FR_EERDR)..... 1969
47.7.110 ECC Error Report Code Register (FR_EERCR)..... 1970
47.7.111 ECC Error Injection Address Register (FR_EEIAR)..... 1971
47.7.112 ECC Error Injection Data Register (FR_EEIDR)..... 1971
47.7.113 ECC Error Injection Code Register (FR_EEICR)..... 1972
47.7.114 Message Buffer Configuration, Control, Status Register (FR_MBCCSR*n*)..... 1972
47.7.115 Message Buffer Cycle Counter Filter Register (FR_MBCCFR*n*)..... 1974
47.7.116 Message Buffer Frame ID Register (FR_MBFIDR*n*).....1976
47.7.117 Message Buffer Index Register (FR_MBIDXR*n*)..... 1976
47.7.118 Message Buffer Data Field Offset Register (FR_MBDOR*n*)..... 1977
47.7.119 LRAM ECC Error Test Register (FR_LEETR*n*).....1978
47.8 Functional Description.....1978
47.8.1 Message Buffer Concept..... 1978
47.8.2 Physical Message Buffer.....1978
47.8.3 Message Buffer Types..... 1980
47.8.4 FlexRay Memory Area Layout..... 1989
47.8.5 Physical Message Buffer Description..... 1993
47.8.6 Individual Message Buffer Functional Description..... 2003
47.8.7 Individual Message Buffer Search..... 2023
47.8.8 Individual Message Buffer Reconfiguration..... 2026

47.8.9 Receive FIFOs....2027
47.8.10 Channel Device Modes....2036
47.8.11 External Clock Synchronization....2038
47.8.12 Sync Frame ID and Sync Frame Deviation Tables....2039
47.8.13 MTS Generation....2043
47.8.14 Key Slot Transmission....2043
47.8.15 Sync Frame Filtering....2044
47.8.16 Strobe Signal Support....2046
47.8.17 Timer Support....2047
47.8.18 Slot Status Monitoring....2049
47.8.19 System Bus Access....2053
47.8.20 Interrupt Support....2055
47.8.21 Lower Bit Rate Support....2060
47.8.22 PE Data Memory (PE DRAM)....2061
47.8.23 CHI Lookup-Table Memory (CHI LRAM)....2063
47.8.24 Memory Content Fault Detection....2064
47.8.25 Memory Fault Injection....2069
47.8.26 StopWatch function....2072
47.9 Application Information....2074
47.9.1 Module Configuration....2074
47.9.2 Initialization Sequence....2075
47.9.3 Memory Fault Injection out of POC:default config....2077
47.9.4 Shut Down Sequence....2078
47.9.5 Number of Usable Message Buffers....2078
47.9.6 Protocol Control Command Execution....2079
47.9.7 Message Buffer Search On Simple Message Buffer Configuration....2080

Chapter 48
Synchronous Audio Interface (SAI)

48.1 Chip-specific SAI information....2085

48.1.1 SAI configuration....2085
48.1.2 SAI's stop-stop ack protocol....2086
48.2 Introduction....2086
48.2.1 Features....2086
48.2.2 Block diagram....2087
48.2.3 Modes of operation....2087
48.3 External signals....2088
48.4 Memory map and register definition....2089
48.4.1 SAI Transmit Control Register (I2S_TCSR)....2091
48.4.2 SAI Transmit Configuration 1 Register (I2S_TCR1)....2094
48.4.3 SAI Transmit Configuration 2 Register (I2S_TCR2)....2094
48.4.4 SAI Transmit Configuration 3 Register (I2S_TCR3)....2096
48.4.5 SAI Transmit Configuration 4 Register (I2S_TCR4)....2097
48.4.6 SAI Transmit Configuration 5 Register (I2S_TCR5)....2099
48.4.7 SAI Transmit Data Register (I2S_TDR*n*)....2100
48.4.8 SAI Transmit FIFO Register (I2S_TFR*n*)....2101
48.4.9 SAI Transmit Mask Register (I2S_TMR)....2101
48.4.10 SAI Receive Control Register (I2S_RCSR)....2102
48.4.11 SAI Receive Configuration 1 Register (I2S_RCR1)....2105
48.4.12 SAI Receive Configuration 2 Register (I2S_RCR2)....2106
48.4.13 SAI Receive Configuration 3 Register (I2S_RCR3)....2107
48.4.14 SAI Receive Configuration 4 Register (I2S_RCR4)....2108
48.4.15 SAI Receive Configuration 5 Register (I2S_RCR5)....2110
48.4.16 SAI Receive Data Register (I2S_RDR*n*)....2111
48.4.17 SAI Receive FIFO Register (I2S_RFR*n*)....2112
48.4.18 SAI Receive Mask Register (I2S_RMR)....2112
48.4.19 SAI MCLK Control Register (I2S_MCR)....2113
48.4.20 SAI MCLK Divide Register (I2S_MDR)....2114
48.5 Functional description....2115

48.5.1 SAI clocking ... 2115
48.5.2 SAI resets ... 2117
48.5.3 Synchronous modes ... 2118
48.5.4 Frame sync configuration ... 2119
48.5.5 Data FIFO ... 2120
48.5.6 Word mask register ... 2123
48.5.7 Interrupts and DMA requests ... 2124

Chapter 49
Periodic Interrupt Timer (PIT-RTI)

49.1 Chip-specific PIT-RTI information ... 2127
49.1.1 PIT configuration ... 2127
49.1.2 Input Output ... 2127
49.1.3 PIT-RTI's stop-stop ack protocol ... 2128
49.2 Introduction ... 2128
49.2.1 Block diagram ... 2128
49.2.2 Features ... 2129
49.3 Signal description ... 2130
49.4 Memory map/register description ... 2130
49.4.1 PIT Module Control Register (PIT_MCR) ... 2133
49.4.2 PIT Upper Lifetime Timer Register (PIT_LTMR64H) ... 2134
49.4.3 PIT Lower Lifetime Timer Register (PIT_LTMR64L) ... 2134
49.4.4 Timer Load Value Register (PIT_RTI_LDVAL) ... 2135
49.4.5 Current Timer Value Register (PIT_RTI_CVAL) ... 2135
49.4.6 Timer Control Register (PIT_RTI_TCTRL) ... 2136
49.4.7 Timer Flag Register (PIT_RTI_TFLG) ... 2137
49.4.8 Timer Load Value Register (PIT_LDVAL*n*) ... 2137
49.4.9 Current Timer Value Register (PIT_CVAL*n*) ... 2138
49.4.10 Timer Control Register (PIT_TCTRL*n*) ... 2138
49.4.11 Timer Flag Register (PIT_TFLG*n*) ... 2139

49.5 Functional description....2140
49.5.1 General operation....2140
49.5.2 Interrupts....2142
49.5.3 Chained timers....2142
49.6 Initialization and application information....2142
49.7 Example configuration for chained timers....2144
49.8 Example configuration for the lifetime timer....2144

Chapter 50
Software Watchdog Timer (SWT)

50.1 Chip-specific SWT information....2147
50.1.1 SWT configuration....2147
50.1.2 SWT register reset value....2148
50.1.3 Service mode watchpoint input....2148
50.2 Introduction....2148
50.2.1 Overview....2149
50.2.2 Features....2149
50.2.3 Modes of operation....2149
50.3 External signal description....2150
50.4 Memory Map and Registers....2150
50.4.1 SWT Control Register (SWT_CR)....2151
50.4.2 SWT Interrupt Register (SWT_IR)....2154
50.4.3 SWT Time-out Register (SWT_TO)....2155
50.4.4 SWT Window Register (SWT_WN)....2155
50.4.5 SWT Service Register (SWT_SR)....2156
50.4.6 SWT Counter Output Register (SWT_CO)....2156
50.4.7 SWT Service Key Register (SWT_SK)....2157
50.5 Functional description....2157
50.5.1 Introduction....2157
50.5.2 Configuration locking....2158

50.5.3 Unlock sequence 2159
50.5.4 Servicing operations 2159
50.5.5 Time-out 2161
50.5.6 Initialization 2161

Chapter 51
Real Time Clock (RTC-API)

51.1 Chip-specific RTC-API information 2163
51.1.1 RTC Configuration 2163
51.1.2 RTC register reset value 2163
51.1.3 Seamless RTC operation across functional and destructive resets 2163
51.1.4 RTC-API's stop-stop ack protocol 2164
51.2 Introduction 2164
51.2.1 Overview 2164
51.2.2 Features 2164
51.2.3 Block Diagram 2165
51.2.4 Modes of Operation 2166
51.3 Memory Map and Registers 2167
51.3.1 RTC Supervisor Control register (RTC_RTCSUPV) 2167
51.3.2 RTC Control register (RTC_RTCC) 2168
51.3.3 RTC Status register (RTC_RTCS) 2170
51.3.4 RTC Counter register (RTC_RTCCNT) 2172
51.3.5 API Compare Value register (RTC_APIVAL) 2172
51.3.6 RTC Compare Value register (RTC_RTCVAL) 2173
51.3.7 RTC Analogue comparator count register (RTC_ANLCMP_CNT) 2173
51.4 Functional Description 2173
51.4.1 RTC 2173
51.4.2 API functional description 2175

Chapter 52
System Timer Module (STM)

52.1 Chip-specific STM information....2177
52.1.1 STM configuration....2177
52.1.2 STM register reset value....2178
52.2 Introduction....2178
52.2.1 Overview....2178
52.2.2 Features....2178
52.2.3 Modes of operation....2178
52.3 External signal description....2179
52.4 Memory map and registers....2179
52.4.1 STM Control Register (STM_CR)....2180
52.4.2 STM Count Register (STM_CNT)....2181
52.4.3 STM Channel Control Register (STM_CCR*n*)....2182
52.4.4 STM Channel Interrupt Register (STM_CIR*n*)....2182
52.4.5 STM Channel Compare Register (STM_CMP*n*)....2183
52.5 Functional description....2183

Chapter 53
Reset Generation Module (MC_RGM)

53.1 Introduction....2185
53.1.1 Overview....2185
53.1.2 Features....2186
53.1.3 Reset Sources....2187
53.2 External Signal Description....2188
53.3 Memory Map and Register Definition....2189
53.3.1 'Destructive' Event Status Register (MC_RGM_DES)....2190
53.3.2 'Destructive' Bidirectional Reset Enable Register (MC_RGM_DBRE)....2192
53.3.3 'Functional' Event Status Register (MC_RGM_FES)....2194
53.3.4 'Functional' Event Reset Disable Register (MC_RGM_FERD)....2197
53.3.5 'Functional' Event Reset DisableAlternate Request Status Register (MC_RGM_FEAR)....2200
53.3.6 'Functional' Bidirectional Reset Enable Register (MC_RGM_FBRE)....2202

53.3.7 'Functional' Event Short Sequence Register (MC_RGM_FESS) 2205
53.3.8 'Functional' Reset Escalation Threshold Register (MC_RGM_FRET) 2208
53.3.9 'Destructive' Reset Escalation Threshold Register (MC_RGM_DRET) 2208
53.4 Functional Description 2209
53.4.1 Reset State Machine 2209
53.4.2 'Destructive' Resets 2213
53.4.3 External Reset 2213
53.4.4 'Functional' Resets 2214
53.4.5 Alternate Event Generation 2215
53.4.6 'Functional' Reset Escalation 2216
53.4.7 'Destructive' Reset Escalation 2217

Chapter 54
System Status and Configuration Module (SSCM)

54.1 Chip-specific SSCM information 2219
54.1.1 System Status and Configuration Module (SSCM) configuration 2219
54.2 Introduction 2220
54.2.1 Overview 2220
54.2.2 Glossary 2220
54.2.3 Features 2221
54.2.4 Modes of operation 2221
54.3 External signal description 2221
54.4 Memory map and register definition 2222
54.4.1 SSCM System Status (SSCM_STATUS) 2223
54.4.2 SSCM System Memory and ID Register (SSCM_MEMCONFIG) 2224
54.4.3 SSCM Debug Status Port Register (SSCM_DEBUGPORT) 2225
54.4.4 SSCM HSM and User Option Status Register (SSCM_UOPS) 2226
54.4.5 Processor Start Address Register (SSCM_PSA) 2227
54.4.6 SSCM HSM Start Address Register (SSCM_HSA) 2227
54.4.7 Life Cycle Status Register (SSCM_LCSTAT) 2228

54.5 Functional description....2228
54.5.1 DCF mechanism....2229
54.5.2 Boot mode functionality....2231
54.5.3 BAF configuration....2231
54.5.4 HSM boot header search....2231
54.5.5 Life Cycle....2232
54.6 Initialization and application information....2234
54.6.1 Reset....2234
54.7 Additional safety measures....2234
54.7.1 Spurious reset protection....2234

Chapter 55
Boot Assist Flash (BAF)

55.1 Chip-specific BAF information....2235
55.1.1 BAF configuration....2235
55.1.2 BAF memory map....2235
55.1.3 LinFLEXD_0 pin configuration....2235
55.1.4 Search boot header and boot options....2236
55.1.5 MPC5746C cores/BAF CPUn....2237
55.1.6 BAF NMI event handling....2238
55.2 Introduction....2239
55.3 BAF image header....2240
55.3.1 BAF image version....2240
55.4 Functional description....2240
55.4.1 Boot modes....2240
55.4.2 Device initialization....2241
55.4.3 Flow of control....2242
55.4.4 Optionally remap calibration RAM....2243
55.4.5 Optionally wait for HSM....2243
55.4.6 BAF SAFE mode event handling....2244

55.4.7 Initialization of BAF DCF clients....2245
55.4.8 Optionally perform serial boot....2254
55.4.9 Serial boot configuration....2258
55.5 Resources....2260

Chapter 56
Nexus Crossbar Multi-Master Client (NXMC)

56.1 Chip-specific NXMC information....2263
56.1.1 NXMC block connections....2263
56.1.2 NXMC source and master client IDs....2263
56.2 Introduction....2264
56.2.1 Features....2264
56.3 External signal description....2265
56.4 Supported messages and TCODEs....2266
56.5 Register description....2269
56.5.1 Development control register 1 (DC1)....2269
56.5.2 Development control register 2 (DC2)....2270
56.5.3 Watchpoint trigger register (WT)....2271
56.5.4 Data trace control register (DTC)....2272
56.5.5 Data trace start address registers 1 and 2 (DTSA1 and DTSA2)....2273
56.5.6 Data trace end address registers 1 and 2 (DTEA1 and DTEA2)....2273
56.5.7 Breakpoint/watchpoint control register 1 (BWC1)....2274
56.5.8 Breakpoint/watchpoint control register 2 (BWC2)....2275
56.5.9 Breakpoint/watchpoint address registers 1 and 2 (BWA1 and BWA2)....2276
56.5.10 Unimplemented registers....2276
56.6 Programming considerations (RESET)....2277
56.6.1 IEEE 1149.1 (JTAG) Test Access Port....2277
56.6.2 Enabling NXMC operation....2277
56.6.3 Enabling NXMC TAP controller....2277
56.6.4 NXMC register access via JTAG....2278

56.7 Functional description....2279
56.7.1 Data trace.... 2279
56.7.2 Watchpoint support.... 2285
56.7.3 Timestamping feature.... 2287

Chapter 57
JTAG Controller (JTAGC)

57.1 Chip-specific JTAG information.... 2289
57.1.1 JTAG Controller (JTAGC) configuration....2289
57.1.2 JTAGC Control 1 register.... 2289
57.2 Introduction....2290
57.2.1 Block diagram.... 2291
57.2.2 Features.... 2291
57.2.3 Modes of operation.... 2292
57.3 External signal description....2293
57.3.1 TCK—Test clock input....2293
57.3.2 TDI—Test data input.... 2293
57.3.3 TDO—Test data output....2294
57.3.4 TMS—Test mode select....2294
57.4 Register description.... 2294
57.4.1 Instruction register.... 2294
57.4.2 Bypass register.... 2295
57.4.3 Device identification register.... 2295
57.4.4 JTAG_PASSWORD register.... 2296
57.4.5 Boundary scan register....2296
57.5 Functional description....2296
57.5.1 JTAGC reset configuration.... 2297
57.5.2 IEEE 1149.1-2001 (JTAG) Test Access Port.... 2297
57.5.3 TAP controller state machine....2297
57.5.4 JTAGC block instructions....2299

57.5.5 Boundary scan....2302
57.6 Initialization/Application information....2303

Chapter 58
JTAG Data Communication (JDC)

58.1 Introduction....2305
58.2 Overview....2305
58.3 Memory mapped registers....2306
58.3.1 Module Configuration Register (JDC_MCR)....2307
58.3.2 Module Status Register (JDC_MSR)....2308
58.3.3 JTAG Output Data Register (JDC_JOUT_IPS)....2309
58.3.4 JTAG Input Data Register (JDC_JIN_IPS)....2310
58.4 Non-Memory mapped register definition....2310
58.4.1 JTAG output data register (JOUT)....2310
58.4.2 JTAG input data register (JIN)....2311
58.5 Functional description....2311
58.5.1 JTAG register access....2312
58.6 Use case example....2312

Chapter 59
IEEE 1149.7 Compact JTAG Test Access Port Controller (CJTAG)

59.1 References....2315
59.2 Abbreviations....2315
59.3 Introduction....2316
59.3.1 Types of operation....2317
59.3.2 Deployment by class....2317
59.3.3 1149.7 TAP signals....2318
59.3.4 TAP.7 architecture....2319
59.3.5 Protocols....2320
59.4 Operating models....2322
59.5 CJTAG implementation summary....2322

59.5.1 T0 functions ... 2322
59.5.2 T1 functions ... 2323
59.5.3 T2 functions ... 2323
59.5.4 T3 functions ... 2323
59.5.5 T4 functions ... 2323
59.6 Ancillary services ... 2323
59.6.1 Overview ... 2323
59.6.2 Resets ... 2324
59.6.3 Start-up Options ... 2327
59.6.4 RSU operation ... 2328
59.6.5 TAPC State Machine ... 2330
59.7 EPU (Extended Protocol Unit) Operation ... 2331
59.7.1 EPU Operation ... 2331
59.7.2 EPU Registers ... 2334
59.7.3 EPU Commands ... 2345
59.7.4 EPU operating states ... 2353
59.7.5 System and EPU Paths ... 2354
59.8 APU (Advanced Protocol Unit) Operation ... 2354
59.8.1 Overview ... 2354
59.8.2 Operation ... 2357
59.8.3 Escape sequences ... 2359
59.8.4 Signal behaviors ... 2359
59.8.5 APU Functions ... 2360
59.8.6 Configuration Change Packets (CP) ... 2366
59.8.7 Scan Packet ... 2367
59.8.8 SP Format ... 2367
59.9 Functional Description ... 2374
59.9.1 Switching from Standard Protocol to Advanced Protocol ... 2374

Chapter 60

Nexus Port Controller (NPC)

60.1 Chip-specific NPC information ... 2375
60.1.1 NPC configuration ... 2375
60.1.2 EVTO sharing - Pulse time ... 2376
60.1.3 Trace messages for transactions with error responses ... 2376
60.1.4 Trace loss during resets ... 2376
60.1.5 EVTI_IN pin ... 2377
60.2 Introduction ... 2377
60.2.1 Overview ... 2377
60.2.2 Features ... 2378
60.2.3 Modes of operation ... 2378
60.3 External signal description ... 2380
60.3.1 Overview ... 2380
60.3.2 Detailed signal descriptions ... 2380
60.4 Register definition ... 2382
60.4.1 Register descriptions ... 2382
60.5 Functional Description ... 2386
60.5.1 NPC reset configuration ... 2386
60.5.2 Auxiliary Output Port ... 2386
60.5.3 IEEE 1149.1-2001 (JTAG) TAP ... 2389
60.5.4 Nexus JTAG Port Sharing ... 2393
60.5.5 MCKO Control ... 2393
60.5.6 EVTO Sharing ... 2394
60.5.7 System Clock Locked Indication ... 2394
60.6 Initialization/Application Information ... 2394
60.6.1 Accessing NPC tool-mapped registers ... 2394

Chapter 61
Core Complex Overview

61.1 Overview of the e200z210n3 and e200z4204n3 cores ... 2397

61.2 z210n3 microarchitecture summary....2397
61.2.1 Overview of the e200z210n3 core....2398
61.2.2 z210n3 instruction unit features....2400
61.2.3 z210n3 integer unit features....2400
61.2.4 z210n3 load/store unit features....2400
61.2.5 z210n3 performance monitor features....2401
61.2.6 z210n3 system bus features....2401
61.3 z4204n3 microarchitecture summary....2401
61.3.1 Overview of the e200z4204n3....2403
61.3.2 z4204n3 instruction unit features....2403
61.3.3 z4204n3 integer unit features....2404
61.3.4 z210n3 load/store unit features....2404
61.3.5 z4204n3 EFPU2 floating-point unit features....2404
61.3.6 z4204n3 cache features....2405
61.3.7 z4204n3 performance monitor features....2406
61.3.8 z4204n3 system bus features....2407

Chapter 62
Z2 Core description

62.1 Overview of the e200z210n3 core....2409
62.2 Register model....2409
62.2.1 Branch Unit Control and Status Register (BUCSR)....2412
62.2.2 Hardware Implementation Dependent Register 0 (HID0)....2414
62.2.3 Hardware Implementation Dependent Register 1 (HID1)....2415
62.3 Single-issue operation....2417
62.4 Instruction timing....2417
62.5 Exceptions....2424
62.5.1 Exception Syndrome Register (ESR)....2425
62.5.2 Machine State Register (MSR)....2426
62.5.3 Machine Check Syndrome Register (MCSR)....2428

62.5.4 Interrupt Vector Prefix Registers (IVPR) 2431
62.5.5 Interrupt Definitions 2432
62.6 End-to-End ECC Support 2443
62.6.1 End-to-End ECC control and configuration 2443

Chapter 63
Z4 Core description

63.1 Overview of the e200z4204n3 core 2447
63.2 Register model 2447
63.2.1 Hardware Implementation Dependent Register 0 (HID0) 2451
63.2.2 Hardware Implementation Dependent Register 1 (HID1) 2453
63.3 Instruction timing 2454
63.4 Dual-issue operation 2461
63.5 Reservation instructions and cache interactions 2462
63.6 Signal Processing Extension/Embedded Floating-point Status and Control Register (SPEFSCR) 2462
63.7 Cache 2465
63.7.1 Cache overview 2465
63.7.2 L1 Cache Control and Status Register 0 (L1CSR0) 2465
63.7.3 L1 Cache Control and Status Register 1 (L1CSR1) 2468
63.7.4 L1 Cache Configuration Register 0 (L1CFG0) 2471
63.7.5 L1 Cache Configuration Register 1 (L1CFG1) 2472
63.7.6 Data cache software coherency 2472
63.7.7 Data cache hardware coherency 2473
63.7.8 Cache invalidate by set and way 2473
63.7.9 Cache EDC/ECC parity protection 2475
63.7.10 Cache error injection 2477
63.8 Exceptions 2478
63.8.1 Exception Syndrome Register (ESR) 2478
63.8.2 Machine State Register (MSR) 2480
63.8.3 Machine Check Syndrome Register (MCSR) 2482

63.8.4 Interrupt Vector Prefix Registers (IVPR)..... 2485
63.8.5 Interrupt definitions.....2485
63.9 End-to-End ECC support..... 2496
63.9.1 End-to-End ECC control and configuration.....2496

Chapter 64
Z2 Core Debug Support

64.1 Overview.....2501
64.1.1 Software Debug Facilities.....2501
64.1.2 Additional Debug Facilities..... 2502
64.1.3 Hardware Debug Facilities.....2503
64.1.4 Sharing Debug Resources by Software/Hardware.....2503
64.2 Software Debug Events and Exceptions.....2505
64.2.1 Instruction Address Compare Event..... 2507
64.2.2 Data Address Compare Event..... 2507
64.2.3 Linked Instruction Address Compare and Data Address Compare Events..... 2511
64.2.4 Trap Debug Event..... 2512
64.2.5 Branch Taken Debug Event..... 2512
64.2.6 Instruction Complete Debug Event.....2512
64.2.7 Interrupt Taken Debug Event.....2513
64.2.8 Critical Interrupt Taken Debug Event.....2513
64.2.9 Return Debug Event.....2513
64.2.10 Critical Return Debug Event.....2514
64.2.11 External debug event.....2514
64.2.12 Unconditional debug event..... 2514
64.2.13 Performance Monitor Interrupt debug event.....2515
64.3 Debug registers..... 2515
64.3.1 Debug Address and Value Registers.....2516
64.3.2 Debug Control and Status registers.....2517
64.3.3 External Debug Resource Allocation Control Register (EDBRAC0)..... 2540

64.3.4 Debug Event Select Register (DEVENT)....2547
64.3.5 Debug Data Acquisition Message Register (DDAM)....2548
64.4 Using Debug Resources for Stack Limit Checking....2549
64.5 External Debug Support....2551
64.5.1 External Debug Registers....2553
64.5.2 OnCE Introduction....2559
64.5.3 JTAG/OnCE Pins....2561
64.5.4 OnCE Internal Interface Signals....2562
64.5.5 OnCE Interface Signals....2562
64.5.6 OnCE Controller and serial interface....2565
64.5.7 Access to Debug Resources....2572
64.5.8 Methods of Entering Debug Mode....2574
64.5.9 CPU Status and Control Scan Chain Register (CPUSCR)....2576
64.5.10 Reserved Registers (Reserved)....2583
64.6 Watchpoint Support....2583
64.7 Basic Steps for Enabling, Using, and Exiting External Debug Mode....2586

Chapter 65
Z4 Core Debug Support

65.1 Overview....2589
65.1.1 Software Debug Facilities....2589
65.1.2 Additional Debug Facilities....2590
65.1.3 Hardware Debug Facilities....2591
65.1.4 Sharing Debug Resources by Software/Hardware....2591
65.2 Software Debug Events and Exceptions....2593
65.2.1 Instruction Address Compare Event....2595
65.2.2 Data Address Compare Event....2595
65.2.3 Linked Instruction Address Compare and Data Address Compare Events....2604
65.2.4 Trap Debug Event....2605
65.2.5 Branch Taken Debug Event....2605

65.2.6 Instruction Complete Debug Event....2606
65.2.7 Interrupt Taken Debug Event....2606
65.2.8 Critical Interrupt Taken Debug Event....2607
65.2.9 Return Debug Event....2607
65.2.10 Critical Return Debug Event....2607
65.2.11 External debug event....2608
65.2.12 Unconditional debug event....2608
65.2.13 Performance Monitor Interrupt debug event....2608
65.3 Debug registers....2609
65.3.1 Debug Address and Value Registers....2609
65.3.2 Debug Control and Status registers....2610
65.3.3 External Debug Resource Allocation Control Register (EDBRAC0)....2633
65.3.4 Debug Event Select Register (DEVENT)....2640
65.3.5 Debug Data Acquisition Message Register (DDAM)....2641
65.4 Using Debug Resources for Stack Limit Checking....2642
65.5 External Debug Support....2645
65.5.1 External Debug Registers....2646
65.5.2 OnCE Introduction....2652
65.5.3 JTAG/OnCE Pins....2655
65.5.4 OnCE Internal Interface Signals....2655
65.5.5 OnCE Interface Signals....2656
65.5.6 OnCE Controller and serial interface....2659
65.5.7 Access to Debug Resources....2666
65.5.8 Methods of Entering Debug Mode....2668
65.5.9 CPU Status and Control Scan Chain Register (CPUSCR)....2670
65.5.10 Reserved Registers (Reserved)....2677
65.6 Watchpoint Support....2677
65.7 Cache Array Access During Debug....2680
65.8 Basic Steps for Enabling, Using, and Exiting External Debug Mode....2680

Chapter 66
Z2 Nexus 3 Module

66.1 Introduction....2683
66.1.1 General description....2683
66.1.2 Terms and definitions....2683
66.1.3 Feature list....2684
66.1.4 Functional block diagram....2686
66.2 Enabling Nexus 3 operation....2687
66.2.1 Interaction with Low Power Modes....2688
66.3 TCODEs supported....2689
66.4 Nexus 3 Programmer's model....2694
66.4.1 Client Select Control (CSC) register....2696
66.4.2 Port Configuration Register (PCR) - reference only....2696
66.4.3 Nexus Development Control Register 1 (DC1)....2697
66.4.4 Nexus Development Control Registers 2 & 3 (DC2, DC3)....2699
66.4.5 Nexus Development Control Register 4 (DC4)....2701
66.4.6 Development Status Register (DS)....2702
66.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers....2703
66.4.8 Nexus Watchpoint Mask (WMSK) register....2710
66.4.9 Nexus Overrun Control Register (OVCR)....2711
66.4.10 Data Trace Control Register (DTC) register....2712
66.4.11 Data Trace Start Address Registers (DTSA1-4)....2714
66.4.12 Data Trace End Address (DTEA1-4) registers....2715
66.4.13 Read/Write Access Control/Status (RWCS) register....2716
66.4.14 Read/Write Access Data (RWD) register....2718
66.4.15 Read/Write Access Address (RWA)....2719
66.5 Nexus 3 Register Access via JTAG/OnCE....2720
66.6 Nexus 3 Register Access via Software....2720
66.7 Nexus message fields....2721

66.7.1 TCODE Field ... 2721
66.7.2 Source ID Field (SRC) ... 2721
66.7.3 Relative Address Field (U-ADDR) ... 2721
66.7.4 Full Address Field (F-ADDR) ... 2722
66.7.5 Timestamp field (TSTAMP) ... 2723
66.8 Nexus Message Queues ... 2723
66.8.1 Message Queue Overrun ... 2724
66.8.2 CPU Stall ... 2724
66.8.3 Message Suppression ... 2724
66.8.4 Nexus Message Priority ... 2725
66.8.5 Data Acquisition Message Priority Loss Response ... 2726
66.8.6 Ownership Trace Message Priority Loss Response ... 2726
66.8.7 Program Trace Message Priority Loss Response ... 2727
66.8.8 Program Trace Sync Message Priority Loss Response ... 2727
66.8.9 Data Trace Message Priority Loss Response ... 2727
66.9 Debug Status messages ... 2727
66.10 Error messages ... 2728
66.11 Ownership trace ... 2728
66.11.1 Overview ... 2728
66.11.2 Ownership Trace Messaging (OTM) ... 2728
66.12 Program trace ... 2730
66.12.1 Branch Trace Messaging types ... 2730
66.12.2 BTM Message For mats ... 2733
66.12.3 Program Trace Message Fields ... 2734
66.12.4 Resource Full Messages ... 2735
66.12.5 Program Correlation Messages ... 2736
66.12.6 Program Trace Overflow Error messages ... 2738
66.12.7 Program Trace Synchronization messages ... 2738
66.12.8 Program Trace Direct/Indirect Branch with Sync messages ... 2740

66.12.9 Enabling Program Trace ... 2741
66.12.10 Program Trace Timing Diagrams (2 MDO / 1 MSEO configuration) ... 2741
66.13 Data Trace ... 2743
66.13.1 Data Trace Messaging (DTM) ... 2743
66.13.2 DTM Message formats ... 2743
66.13.3 DTM Operation ... 2747
66.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration) ... 2748
66.14 Data Acquisition messaging ... 2749
66.14.1 Data Acquisition ID Tag field ... 2749
66.14.2 Data Acquisition Data field ... 2750
66.14.3 Data Acquisition Trace event ... 2750
66.15 Watchpoint Trace messaging ... 2750
66.15.1 Watchpoint Timing Diagram (2 MDO / 1 MSEO configuration) ... 2752
66.16 Nexus 3 Read/Write access to memory-mapped resources ... 2753
66.16.1 Single write access ... 2753
66.16.2 Block write access ... 2754
66.16.3 Single read access ... 2755
66.16.4 Block read access ... 2756
66.16.5 Error handling ... 2757
66.16.6 Read/Write access error message ... 2758
66.17 Nexus 3 pin interface ... 2759
66.17.1 Pins implemented ... 2759
66.17.2 Pin protocol ... 2761
66.18 Rules for output messages ... 2763
66.19 Auxiliary port arbitration ... 2764
66.20 Examples ... 2764
66.21 Electrical characteristics ... 2767
66.22 IEEE 1149.1 (JTAG) RD/WR sequences ... 2767
66.22.1 JTAG sequence for accessing internal Nexus registers ... 2768

66.22.2 JTAG sequence for read access of memory-mapped resources....2768
66.22.3 JTAG sequence for write access of memory-mapped resources....2768

Chapter 67
Z4 Nexus 3 Module

67.1 Introduction....2771
67.1.1 General Description....2771
67.1.2 Terms and Definitions....2771
67.1.3 Feature List....2772
67.1.4 Functional Block Diagram....2774
67.2 Enabling Nexus 3 Operation....2775
67.2.1 Interaction with Low Power Modes....2776
67.3 TCODEs supported....2777
67.4 Nexus 3 Programmer's Model....2782
67.4.1 Client Select Control (CSC) register....2783
67.4.2 Port Configuration Register (PCR) - reference only....2784
67.4.3 Nexus Development Control Register 1 (DC1)....2785
67.4.4 Nexus Development Control Registers 2 and 3 (DC2, DC3)....2786
67.4.5 Nexus Development Control Register 4 (DC4)....2788
67.4.6 Development Status Register (DS)....2789
67.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers....2790
67.4.8 Nexus Watchpoint Mask (WMSK) register....2797
67.4.9 Nexus Overrun Control Register (OVCR)....2798
67.4.10 Data Trace Control Register (DTC) register....2799
67.4.11 Data Trace Start Address Registers (DTSA1-4)....2802
67.4.12 Data Trace End Address (DTEA1-4) registers....2802
67.4.13 Read/Write Access Control/Status (RWCS) register....2803
67.4.14 Read/Write Access Data (RWD) register....2805
67.4.15 Read/Write Access Address (RWA)....2807
67.5 Nexus 3 Register Access via JTAG/OnCE....2807

67.6 Nexus 3 Register Access via Software ... 2808
67.7 Nexus Message Fields ... 2808
67.7.1 TCODE Field ... 2808
67.7.2 Source ID Field (SRC) ... 2808
67.7.3 Relative Address Field (U-ADDR) ... 2809
67.7.4 Full Address Field (F-ADDR) ... 2810
67.8 Nexus Message Queues ... 2810
67.8.1 Message Queue Overrun ... 2811
67.8.2 CPU Stall ... 2811
67.8.3 Message Suppression ... 2811
67.8.4 Nexus Message Priority ... 2812
67.8.5 Data Acquisition Message Priority Loss Response ... 2813
67.8.6 Ownership Trace Message Priority Loss Response ... 2813
67.8.7 Program Trace Message Priority Loss Response ... 2814
67.8.8 Program Trace Sync Message Priority Loss Response ... 2814
67.8.9 Data Trace Message Priority Loss Response ... 2814
67.9 Debug Status messages ... 2814
67.10 Error messages ... 2815
67.11 Ownership trace ... 2815
67.11.1 Overview ... 2815
67.11.2 Ownership Trace Messaging (OTM) ... 2815
67.12 Program trace ... 2817
67.12.1 Branch Trace Messaging types ... 2817
67.12.2 BTM Message For mats ... 2820
67.12.3 Program Trace Message Fields ... 2821
67.12.4 Resource Full Messages ... 2822
67.12.5 Program Correlation Messages ... 2823
67.12.6 Program Trace Overflow Error messages ... 2825
67.12.7 Program Trace Synchronization messages ... 2825

67.12.8 Program Trace Direct/Indirect Branch with Sync messages....2827
67.12.9 Enabling Program Trace....2828
67.12.10 Program Trace Timing Diagrams (2 MDO / 1 MSEO configuration)....2828
67.13 Data Trace....2830
67.13.1 Data Trace Messaging (DTM)....2830
67.13.2 DTM Message formats....2830
67.13.3 DTM Operation....2834
67.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration)....2835
67.14 Data Acquisition messaging....2836
67.14.1 Data Acquisition ID Tag field....2836
67.14.2 Data Acquisition Data field....2836
67.14.3 Data Acquisition Trace event....2836
67.15 Watchpoint Trace messaging....2837
67.15.1 Watchpoint Timing Diagram (2 MDO / 1 MSEO configuration)....2839
67.16 Nexus 3 Read/Write access to memory-mapped resources....2839
67.16.1 Single write access....2840
67.16.2 Block write access....2841
67.16.3 Single read access....2842
67.16.4 Block read access....2843
67.16.5 Error handling....2844
67.16.6 Read/Write access error message....2845
67.17 Nexus 3 pin interface....2845
67.17.1 Pins implemented....2846
67.17.2 Pin protocol....2848
67.18 Rules for output messages....2850
67.19 Auxiliary port arbitration....2851
67.20 Examples....2851
67.21 Electrical characteristics....2854
67.22 IEEE 1149.1 (JTAG) RD/WR sequences....2854

67.22.1 JTAG sequence for accessing internal Nexus registers.... 2855
67.22.2 JTAG sequence for read access of memory-mapped resources.... 2855
67.22.3 JTAG sequence for write access of memory-mapped resources.... 2855

Chapter 68
Enhanced Direct Memory Access (eDMA)

68.1 Introduction.... 2857
68.1.1 eDMA system block diagram.... 2857
68.1.2 Block parts.... 2858
68.1.3 Features.... 2859
68.2 Modes of operation.... 2860
68.3 Memory map/register definition.... 2861
68.3.1 TCD memory.... 2861
68.3.2 TCD initialization.... 2861
68.3.3 TCD structure.... 2861
68.3.4 Reserved memory and bit fields.... 2862
68.3.5 Control Register (DMA_CR).... 2889
68.3.6 Error Status Register (DMA_ES).... 2892
68.3.7 Enable Request Register (DMA_ERQ).... 2895
68.3.8 Enable Error Interrupt Register (DMA_EEI).... 2898
68.3.9 Set Enable Request Register (DMA_SERQ).... 2902
68.3.10 Clear Enable Request Register (DMA_CERQ).... 2903
68.3.11 Set Enable Error Interrupt Register (DMA_SEEI).... 2904
68.3.12 Clear Enable Error Interrupt Register (DMA_CEEI).... 2905
68.3.13 Clear Interrupt Request Register (DMA_CINT).... 2906
68.3.14 Clear Error Register (DMA_CERR).... 2907
68.3.15 Set START Bit Register (DMA_SSRT).... 2908
68.3.16 Clear DONE Status Bit Register (DMA_CDNE).... 2909
68.3.17 Interrupt Request Register (DMA_INT).... 2910
68.3.18 Error Register (DMA_ERR).... 2913

68.3.19 Hardware Request Status Register (DMA_HRS)..... 2917
68.3.20 Channel n Priority Register (DMA_DCHPRI*n*)..... 2923
68.3.21 Channel n Master ID Register (DMA_DCHMID*n*)..... 2924
68.3.22 TCD Source Address (DMA_TCD*n*_SADDR)..... 2925
68.3.23 TCD Transfer Attributes (DMA_TCD*n*_ATTR)..... 2925
68.3.24 TCD Signed Source Address Offset (DMA_TCD*n*_SOFF)..... 2926
68.3.25 TCD Minor Byte Count (Minor Loop Mapping Disabled) (DMA_TCD*n*_NBYTES_MLNO)..... 2927
68.3.26 TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled) (DMA_TCD*n*_NBYTES_MLOFFNO)..... 2927
68.3.27 TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled) (DMA_TCD*n*_NBYTES_MLOFFYES)..... 2929
68.3.28 TCD Last Source Address Adjustment (DMA_TCD*n*_SLAST)..... 2930
68.3.29 TCD Destination Address (DMA_TCD*n*_DADDR)..... 2930
68.3.30 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD*n*_CITER_ELINKYES)..... 2931
68.3.31 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCD*n*_CITER_ELINKNO)..... 2932
68.3.32 TCD Signed Destination Address Offset (DMA_TCD*n*_DOFF)..... 2933
68.3.33 TCD Last Destination Address Adjustment/Scatter Gather Address (DMA_TCD*n*_DLASTSGA)..... 2933
68.3.34 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD*n*_BITER_ELINKYES)..... 2934
68.3.35 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCD*n*_BITER_ELINKNO)..... 2935
68.3.36 TCD Control and Status (DMA_TCD*n*_CSR)..... 2936
68.4 Functional description..... 2938
68.4.1 eDMA basic data flow..... 2938
68.4.2 Fault reporting and handling..... 2941
68.4.3 Channel preemption..... 2944
68.5 Initialization/application information..... 2944
68.5.1 eDMA initialization..... 2944

68.5.2 Programming errors ... 2946
68.5.3 Arbitration mode considerations ... 2947
68.5.4 Performing DMA transfers ... 2948
68.5.5 Monitoring transfer descriptor status ... 2952
68.5.6 Channel Linking ... 2954
68.5.7 Dynamic programming ... 2955

Chapter 69
Direct Memory Access Multiplexer

69.1 Chip-specific DMA MUX information ... 2961
69.1.1 DMA MUX configuration ... 2961
69.2 Introduction ... 2963
69.2.1 Overview ... 2963
69.2.2 Features ... 2964
69.2.3 Modes of operation ... 2964
69.3 External signal description ... 2965
69.4 Memory map/register definition ... 2965
69.4.1 Channel Configuration register (DMAMUX_CHCFG*n*) ... 2966
69.5 Functional description ... 2967
69.5.1 DMA channels with periodic triggering capability ... 2967
69.5.2 DMA channels with no triggering capability ... 2969
69.5.3 Always-enabled DMA sources ... 2970
69.6 Initialization/application information ... 2971
69.6.1 Reset ... 2971
69.6.2 Enabling and configuring sources ... 2971

Chapter 70
PRAMC

70.1 Chip-specific PRAMC information ... 2975
70.1.1 Register reset value ... 2975
70.2 Introduction ... 2975

70.3 SRAM controller memory map and register definition....2977
70.3.1 Platform RAM Configuration Register 1 (PRAMC_PRCR1)....2977
70.4 Functional description....2979
70.4.1 Read and Write operations....2979
70.4.2 Writes....2980
70.5 Initialization/application information....2982
70.6 Reliability considerations....2982
70.6.1 Hsiao ECC algorithm....2982
70.6.2 Transaction monitor....2985

Chapter 71
Flash memory controller

71.1 Chip-specific Flash memory controller information....2987
71.1.1 Master IDs....2987
71.2 Introduction....2987
71.3 Features....2988
71.4 Block diagrams....2988
71.5 Flash memory controller memory map....2989
71.5.1 Platform Flash Configuration Register 1 (PFLASH_PFCR1)....2993
71.5.2 Platform Flash Configuration Register 2 (PFLASH_PFCR2)....2996
71.5.3 Platform Flash Configuration Register 3 (PFLASH_PFCR3)....2999
71.5.4 Platform Flash Access Protection Register (PFLASH_PFAPR)....3001
71.5.5 Platform Flash Remap Control Register (PFLASH_PFCRCR)....3004
71.5.6 Platform Flash Remap Descriptor Enable Register (PFLASH_PFCRDE)....3006
71.5.7 Platform Flash Configuration Register 4 (PFLASH_PFCR4)....3009
71.5.8 Platform Flash Calibration Region Descriptor n Word0 (PFLASH_PFCRD*n*_Word0)....3012
71.5.9 Platform Flash Calibration Region Descriptor n Word1 (PFLASH_PFCRD*n*_Word1)....3013
71.5.10 Platform Flash Calibration Region Descriptor n Word2 (PFLASH_PFCRD*n*_Word2)....3014
71.6 Functional description....3019
71.6.1 Basic interface protocol....3020

71.6.2 Access protections....3020
71.6.3 Security module exclusive control....3022
71.6.4 Security Module Alternate Programming Interface....3022
71.6.5 Access pipelining....3023
71.6.6 Line read buffers and prefetch operation....3024
71.6.7 Instruction/Data prefetch triggering....3025
71.6.8 Per-Master prefetch triggering....3025
71.6.9 Buffer allocation....3025
71.6.10 PFlash calibration remap support....3026
71.6.11 Reliability considerations....3028
71.6.12 ECC on data flash accesses....3033
71.6.13 Array integrity considerations....3034

Chapter 72
Embedded Flash Memory

72.1 Chip-specific Embedded Flash memory information....3035
72.1.1 Embedded Flash Memory configuration....3035
72.1.2 Register bit mapping....3035
72.1.3 C55FMC_LOCK0 and C55FMC_SEL0 register bit mapping....3035
72.1.4 C55FMC_LOCK1 and C55FMC_SEL1 register bit mapping....3036
72.1.5 C55FMC_LOCK2 and C55FMC_SEL2 register bit mapping....3037
72.1.6 C55FMC_LOCK3 and C55FMC_SEL3 register bit mapping....3038
72.1.7 Embedded Flash Memory register reset value....3039
72.2 Introduction....3039
72.2.1 Overview....3040
72.2.2 Features....3041
72.2.3 Modes of operation....3041
72.3 UTest NVM block....3042
72.4 Test mode disable seal....3042
72.5 Memory map and register definition....3043

72.5.1 Module Configuration Register (C55FMC_MCR)....3045
72.5.2 Extended Module Configuration Register (C55FMC_MCRE)....3050
72.5.3 Lock 0 register (C55FMC_LOCK0)....3053
72.5.4 Lock 1 register (C55FMC_LOCK1)....3055
72.5.5 Lock 2 register (C55FMC_LOCK2)....3055
72.5.6 Lock 3 register (C55FMC_LOCK3)....3056
72.5.7 Select 0 register (C55FMC_SEL0)....3057
72.5.8 Select 1 register (C55FMC_SEL1)....3058
72.5.9 Select 2 register (C55FMC_SEL2)....3059
72.5.10 Select 3 register (C55FMC_SEL3)....3060
72.5.11 Address register (C55FMC_ADR)....3061
72.5.12 UTest 0 register (C55FMC_UT0)....3063
72.5.13 UMISR register (C55FMC_UM*n*)....3066
72.5.14 UMISR register (C55FMC_UM9)....3067
72.5.15 Over-Program Protection 0 register (C55FMC_OPP0)....3068
72.5.16 Over-Program Protection 1 register (C55FMC_OPP1)....3069
72.5.17 Over-Program Protection 2 register (C55FMC_OPP2)....3070
72.5.18 Over-Program Protection 3 register (C55FMC_OPP3)....3070
72.5.19 Test Mode Disable Password Check register (C55FMC_TMD)....3071
72.6 Functional Description....3072
72.6.1 User Mode....3073
72.6.2 Low Power mode....3081
72.6.3 UTest mode....3081
72.7 Initialization information....3086

Chapter 73
Memory Error Management Unit (MEMU)

73.1 Chip-specific MEMU information....3087
73.1.1 MEMU configuration....3087
73.1.2 MEMU system connections....3087

73.1.3 MEMU error sources ... 3088
73.1.4 Reporting table implementation ... 3088
73.1.5 Concurrent overflow register (OFLW) implementation for MEMU_0 ... 3089
73.1.6 Concurrent overflow register (OFLW) implementation for MEMU_1 ... 3091
73.1.7 MEMU_0 registers ... 3092
73.1.8 MEMU_1 registers ... 3094
73.2 Introduction ... 3095
73.3 Features ... 3096
73.4 Block diagram ... 3097
73.5 Design overview ... 3097
73.6 External signal description ... 3101
73.7 Memory map and register definition ... 3102
73.7.1 Overview ... 3102
73.7.2 Control register (MEMU_CTRL) ... 3106
73.7.3 Error flag register (MEMU_ERR_FLAG) ... 3106
73.7.4 Debug register (MEMU_DEBUG) ... 3110
73.7.5 System RAM correctable error reporting table status register (MEMU_SYS_RAM_CERR_STS*n*) ... 3112
73.7.6 System RAM correctable error reporting table address register (MEMU_SYS_RAM_CERR_ADDR*n*) ... 3113
73.7.7 System RAM uncorrectable error reporting table status register (MEMU_SYS_RAM_UNCERR_STS) ... 3113
73.7.8 System RAM uncorrectable error reporting table address register (MEMU_SYS_RAM_UNCERR_ADDR) ... 3114
73.7.9 System RAM concurrent overflow register (MEMU_SYS_RAM_OFLW*n*) ... 3114
73.7.10 Peripheral RAM correctable error reporting table status register (MEMU_PERIPH_RAM_CERR_STS*n*) ... 3115
73.7.11 Peripheral RAM correctable error reporting table address register (MEMU_PERIPH_RAM_CERR_ADDR*n*) ... 3116
73.7.12 Peripheral RAM uncorrectable error reporting table status register (MEMU_PERIPH_RAM_UNCERR_STS) ... 3116
73.7.13 Peripheral RAM uncorrectable error reporting table address register (MEMU_PERIPH_RAM_UNCERR_ADDR) ... 3117

73.7.14 Peripheral RAM concurrent overflow register (MEMU_PERIPH_RAM_OFLW*n*)..... 3117
73.7.15 Flash memory correctable error reporting table status register (MEMU_FLASH_CERR_STS*n*)..... 3118
73.7.16 Flash memory correctable error reporting table address register (MEMU_FLASH_CERR_ADDR*n*)..... 3119
73.7.17 Flash memory uncorrectable error reporting table status register (MEMU_FLASH_UNCERR_STS).....3119
73.7.18 Flash memory uncorrectable error reporting table address register (MEMU_FLASH_UNCERR_ADDR)..... 3120
73.7.19 Flash memory concurrent overflow register (MEMU_FLASH_OFLW*n*)..... 3120
73.8 Functional description.....3121
73.8.1 Initializing MEMU.....3121
73.8.2 Reading the reporting table..... 3122
73.8.3 Handling overflows (Multiple error reporting).....3122

Chapter 74
Fault Collection and Control Unit (FCCU)

74.1 Chip-specific FCCU information.....3125
74.1.1 FCCU configuration.....3125
74.1.2 FCCU register reset values 3125
74.1.3 FCCU_CFG register event bit values by source (N and C).....3126
74.1.4 Fault inputs.....3128
74.1.5 Error signal flow diagram..... 3133
74.2 Introduction.....3134
74.2.1 Acronyms and abbreviations.....3135
74.3 Main features..... 3135
74.4 Block diagram.....3136
74.5 Signal description.....3137
74.5.1 Signals.....3137
74.6 Put FCCU in Configuration or Normal state..... 3138
74.6.1 Introduction.....3138
74.6.2 About changing states..... 3139
74.6.3 Put FCCU in Configuration state..... 3139

74.6.4 Put FCCU in Normal state ... 3140
74.7 Run operations ... 3140
74.7.1 Introduction ... 3140
74.7.2 About running operations ... 3140
74.7.3 Run an operation ... 3141
74.8 Lock and unlock the configuration ... 3141
74.8.1 Introduction ... 3141
74.8.2 About locking the configuration ... 3141
74.8.3 Temporarily lock the configuration ... 3141
74.8.4 Temporarily unlock the configuration ... 3142
74.8.5 Permanently lock the configuration ... 3142
74.9 Functional description ... 3142
74.9.1 Definitions ... 3142
74.9.2 FSM description ... 3143
74.9.3 Fault priority scheme and nesting ... 3145
74.9.4 Fault recovery ... 3146
74.9.5 NMI/WKPU interface ... 3148
74.9.6 STCU interface ... 3149
74.9.7 Nonvolatile memory interface ... 3150
74.9.8 EOUT interface ... 3151
74.9.9 Error signal flow ... 3160
74.10 Register descriptions ... 3160
74.10.1 Control (FCCU_CTRL) ... 3164
74.10.2 Control Key (FCCU_CTRLK) ... 3166
74.10.3 Configuration (FCCU_CFG) ... 3167
74.10.4 Noncritical Fault Configuration (FCCU_NCF_CFG*n*) ... 3171
74.10.5 Noncritical Fault State Configuration (FCCU_NCFS_CFG*n*) ... 3172
74.10.6 Noncritical Fault Status (FCCU_NCF_S*n*) ... 3173
74.10.7 Noncritical Fault Key (FCCU_NCFK) ... 3175

74.10.8 Noncritical Fault Enable (FCCU_NCF_E*n*)....3175
74.10.9 Noncritical Fault Timeout Enable (FCCU_NCF_TOE*n*)....3176
74.10.10 Noncritical Fault Timeout (FCCU_NCF_TO)....3177
74.10.11 Configuration-State Timer Interval (FCCU_CFG_TO)....3178
74.10.12 IO Control (FCCU_EINOUT)....3179
74.10.13 Status (FCCU_STAT)....3180
74.10.14 NA Freeze Status (FCCU_N2AF_STATUS)....3182
74.10.15 AF Freeze Status (FCCU_A2FF_STATUS)....3183
74.10.16 NF Freeze Status (FCCU_N2FF_STATUS)....3184
74.10.17 FA Freeze Status (FCCU_F2A_STATUS)....3185
74.10.18 Noncritical Fault Fake (FCCU_NCFF)....3186
74.10.19 IRQ Status (FCCU_IRQ_STAT)....3187
74.10.20 IRQ Enable (FCCU_IRQ_EN)....3189
74.10.21 XTMR (FCCU_XTMR)....3190
74.10.22 Mode Controller Status (FCCU_MCS)....3191
74.10.23 Transient Configuration Lock (FCCU_TRANS_LOCK)....3193
74.10.24 Permanent Configuration Lock (FCCU_PERMNT_LOCK)....3194
74.10.25 Delta T (FCCU_DELTA_T)....3194
74.10.26 IRQ Alarm Enable (FCCU_IRQ_ALARM_EN*n*)....3195
74.10.27 NMI Enable (FCCU_NMI_EN*n*)....3196
74.10.28 Bistable Fault-Output (EOUT) Mode Signaling Enable (FCCU_EOUT_SIG_EN*n*)....3197
74.10.29 Configuration registers....3198
74.10.30 FCCU_CFG register bit value sources (N and C) by event....3199
74.11 Use cases and limitations....3200
74.11.1 Configuration guidelines....3200
74.11.2 Recommendations to configure FCCU....3201

Chapter 75
Self-Test Control Unit (STCU2)

75.1 Chip-specific STCU2 information....3203

75.1.1 STCU configuration....3203
75.1.2 Supported BIST sequence....3204
75.1.3 Device specific STCU Registers....3204
75.1.4 STCU register reset values....3204
75.1.5 Partition overview....3205
75.1.6 STCU On-Line and Off-Line Self-Test sequence preparation....3207
75.1.7 AUTOLOCK_VALUE for register write access and DCF_COMPLETION value for DCF write completion....3207
75.1.8 Wait time for writing to the online registers....3207
75.1.9 On-Line reset generation (only MBIST)....3207
75.2 Introduction....3208
75.3 Main features....3209
75.4 Block diagram....3210
75.5 IPS bus interface....3211
75.6 BISTs and BIST partitions....3213
75.6.1 Definition: BIST....3213
75.6.2 Definition: BIST partition....3213
75.6.3 Example: BIST partitions on a chip....3213
75.6.4 Types of BIST partitions....3213
75.7 BIST sequences....3214
75.7.1 Definition: BIST sequence....3214
75.7.2 Example: Single-phase BIST sequence....3214
75.7.3 Example: Multiphase BIST sequence....3214
75.7.4 Types of BIST sequences....3214
75.7.5 Supported BIST sequences....3215
75.7.6 Definition: Default offline BIST sequence....3215
75.8 Functional description....3215
75.8.1 FSM description....3215
75.8.2 Reset management....3216

75.8.3 Built-in self-test scheduling ... 3216
75.8.4 ABORT management ... 3217
75.8.5 PLL interface ... 3217
75.8.6 FCCU interface ... 3217
75.8.7 Watchdogs ... 3218
75.8.8 SSCM interface ... 3219

75.9.9 STCU2 Off-Line MBIST Status Medium Register (STCU2_MBSM) ... 3240
75.9.10 STCU2 Off-Line MBIST Status High Register (STCU2_MBSH) ... 3242
75.9.11 STCU2 Off-Line MBIST End Flag Low Register (STCU2_MBEL) ... 3243
75.9.12 STCU2 Off-Line MBIST End Flag Medium Register (STCU2_MBEM) ... 3246
75.9.13 STCU2 Off-Line MBIST End Flag High Register (STCU2_MBEH) ... 3248
75.9.14 STCU2 On-Line MBIST Status Low Register (STCU2_MBSLSW) ... 3249
75.9.15 STCU2 On-Line MBIST Status Medium Register (STCU2_MBSMSW) ... 3252
75.9.16 STCU2 On-Line MBIST Status High Register (STCU2_MBSHSW) ... 3254
75.9.17 STCU2 On-Line MBIST End Flag Low Register (STCU2_MBELSW) ... 3255
75.9.18 STCU2 On-Line MBIST End Flag Medium Register (STCU2_MBEMSW) ... 3259
75.9.19 STCU2 On-Line MBIST End Flag High Register (STCU2_MBEHSW) ... 3261
75.9.20 STCU2 MBIST Unrecoverable FM Low Register (STCU2_MBUFML) ... 3261
75.9.21 STCU2 MBIST Unrecoverable FM Medium Register (STCU2_MBUFMM) ... 3265
75.9.22 STCU2 MBIST Unrecoverable FM High Register (STCU2_MBUFMH) ... 3267

75.9.23 STCU2 MBIST Control Register (STCU2_MB_CTRL*n*)..... 3268
75.10 Use cases and limitations..... 3269
75.10.1 Offline self-test sequence..... 3269
75.10.2 Online self test sequence..... 3270
75.10.3 Bypass USER Mode..... 3272
75.10.4 Design implementation information..... 3272

Chapter 76
Cyclic Redundancy Check (CRC) Unit

76.1 Introduction..... 3273
76.2 Main features..... 3273
76.2.1 Standard features..... 3273
76.3 Block diagram..... 3274
76.4 External signal description..... 3274
76.4.1 Peripheral bus interface..... 3274
76.5 CRC memory map and registers..... 3275
76.5.1 Configuration Register (CRC_CFG)..... 3276
76.5.2 Input Register (CRC_INP)..... 3277
76.5.3 Current Status Register (CRC_CSTAT)..... 3278
76.5.4 Output Register (CRC_OUTP)..... 3278
76.6 Functional description..... 3279
76.7 Use cases..... 3281
76.7.1 Programming example..... 3281
76.7.2 Register programming..... 3282

Chapter 77
Register Protection

77.1 Chip-specific Register Protection information..... 3285
77.1.1 Register protection configuration..... 3285
77.1.2 Clock Monitor Unit (CMU) protected registers..... 3286
77.1.3 Fast Oscillator Digital Interface (FXOSC) protected registers..... 3286

77.1.4 Clock Generation Module (MC_CGM) protected registers ... 3287
77.1.5 Mode Entry (MC_ME) protected registers ... 3287
77.1.6 Reset Generation Module (MC_RGM) protected registers ... 3288
77.1.7 Memory Error Management Unit (MEMU) protected registers ... 3289
77.1.8 PLL Digital Interface (PLL_DIG) protected registers ... 3289
77.1.9 Power Management Controller digital interface (PMCDIG) protected registers ... 3289
77.1.10 SIUL2 protected registers ... 3290
77.1.11 Slow Oscillator Digital Interface (SXOSC) protected registers ... 3290
77.1.12 LPU Controller (LPU_CTL) protected registers ... 3291
77.2 Overview ... 3291
77.3 Features ... 3292
77.4 Modes of operation ... 3292
77.5 External signal description ... 3293
77.6 Memory map and register definition ... 3293
77.6.1 Memory map ... 3294
77.6.2 Register descriptions ... 3295
77.7 Memory map and registers ... 3295
77.7.1 Soft Lock Bit Register *n* (REG_PROT_SLBRn) ... 3296
77.7.2 Global Configuration Register (REG_PROT_GCR) ... 3298
77.8 Functional description ... 3298
77.8.1 General ... 3299
77.8.2 Change lock settings ... 3299
77.8.3 Access errors ... 3302

Chapter 78
Password and Device Security Module (PASS)

78.1 Chip-specific PASS information ... 3305
78.1.1 Password and Device Security Module (PASS) configuration ... 3305
78.2 Introduction ... 3310
78.2.1 Overview ... 3310

78.2.2 Features ... 3311
78.2.3 Modes of operation ... 3311
78.3 Memory map and register definition ... 3311
78.3.1 Life Cycle Status Register (PASS_LCSTAT) ... 3313
78.3.2 Challenge Selector Register (PASS_CHSEL) ... 3315
78.3.3 Challenge Status Register (PASS_CSTAT) ... 3315
78.3.4 Challenge Input Register (PASS_CIN*n*) ... 3316
78.3.5 Password Group *n* - Lock 0 Status Register (PASS_LOCK0_PG*n*) ... 3316
78.3.6 Password Group *n* - Lock 1 Status Register (PASS_LOCK1_PG*n*) ... 3318
78.3.7 Password Group *n* - Lock 2 Status Register (PASS_LOCK2_PG*n*) ... 3319
78.3.8 Password Group *n* - Lock 3 Status Register (PASS_LOCK3_PG*n*) ... 3320
78.4 DCF clients ... 3324
78.4.1 Censorship ... 3324
78.4.2 Test mode enable DCF Client ... 3325
78.5 Functional description ... 3326
78.5.1 Censorship ... 3326
78.5.2 Debug Interface Access ... 3326
78.5.3 Flash Memory Read Protection ... 3327
78.5.4 Flash Memory Write and Erase Protection ... 3328
78.5.5 Test mode enable ... 3328
78.5.6 Test mode enable password ... 3329
78.6 Initialization/application information ... 3330
78.6.1 Reset ... 3330
78.6.2 Setting lock bits in a password group ... 3330

Chapter 79
Tamper Detect Module (TDM)

79.1 Chip-specific TDM information ... 3333
79.1.1 Tamper Detection Module (TDM) configuration ... 3333
79.1.2 Diary Base Address (DBA) DCF client ... 3333

79.1.3 Tamper Region Override (TO) DCF client....3334
79.1.4 OTPENn DCF clients....3334
79.1.5 TDRx_LOCKn DCF clients....3334
79.1.6 TDM register reset value....3335
79.2 Overview....3335
79.3 Features....3337
79.4 External signal description....3337
79.5 DCF clients....3337
79.5.1 Diary Base Address (DBA) DCF client....3338
79.5.2 Tamper Region Override (TO) DCF client....3339
79.5.3 Software Tamper Region Override Disable (STO_DIS) DCF client....3339
79.5.4 One Time Programmable Enable (OTPEN0) DCF client....3340
79.5.5 One Time Programmable Enable (OTPEN1) DCF client....3341
79.5.6 One Time Programmable Enable (OTPEN2) DCF client....3342
79.5.7 One Time Programmable Enable (OTPEN3) DCF client....3343
79.5.8 Tamper Region Assignment DCF client (TDRn_LOCK0)....3343
79.5.9 Tamper Region Assignment DCF client (TDRn_LOCK1)....3344
79.5.10 Tamper Region Assignment DCF client (TDRn_LOCK2)....3345
79.5.11 Tamper Region Assignment DCF client (TDRn_LOCK3)....3346
79.6 Memory Map/Register Definition....3347
79.6.1 TDR Status Register (TDM_TDRSR)....3347
79.6.2 Last Flash Programmed Address Register (TDM_LFPAR)....3350
79.6.3 Diary Base Address (TDM_DBA)....3350
79.6.4 Software Tamper Override Key Region (TDM_STO_KEY*n*)....3351
79.7 Functional description....3351
79.7.1 Flash erase counter and tamper detection....3351
79.7.2 Assigning blocks to Tamper Detect Regions (TDR)....3353
79.7.3 Diary....3354
79.7.4 Specifying the diary base address....3354

79.7.5 TDR lock status....3355
79.7.6 TDR override....3356
79.7.7 One time programmable (OTP)....3356

Chapter 80
Flash Memory Programming and Configuration

80.1 Introduction....3359
80.2 Selection of flash memory blocks for erase....3361
80.3 Non-secure write protection....3364
80.4 Secure write protection....3366
80.4.1 Implementing secure write protection....3367
80.4.2 Overriding secure write protection....3371
80.5 Secure read protection....3373
80.5.1 Implementing secure read protection....3375
80.5.2 Overriding secure read protection....3379
80.6 Debug port enable/disable....3380
80.7 Tamper detection....3380
80.7.1 Implementing tamper detection....3380
80.7.2 Creating the tamper detect diary....3381
80.7.3 Assigning blocks to Tamper Detection Regions (TDRs)....3383
80.7.4 Overriding tamper detection....3384
80.8 Implementing OTP....3385
80.9 Implementing test mode disable....3385
80.9.1 Unconditional test mode disable seal....3386
80.9.2 Passcode-protected test mode disable seal....3387
80.9.3 Selecting flash memory blocks for test mode disable seal....3387
80.10 Security configuration planning....3391
80.10.1 Hardware Security Module (HSM)....3391
80.10.2 Creating password groups....3392
80.10.3 Planning secure write protection....3392

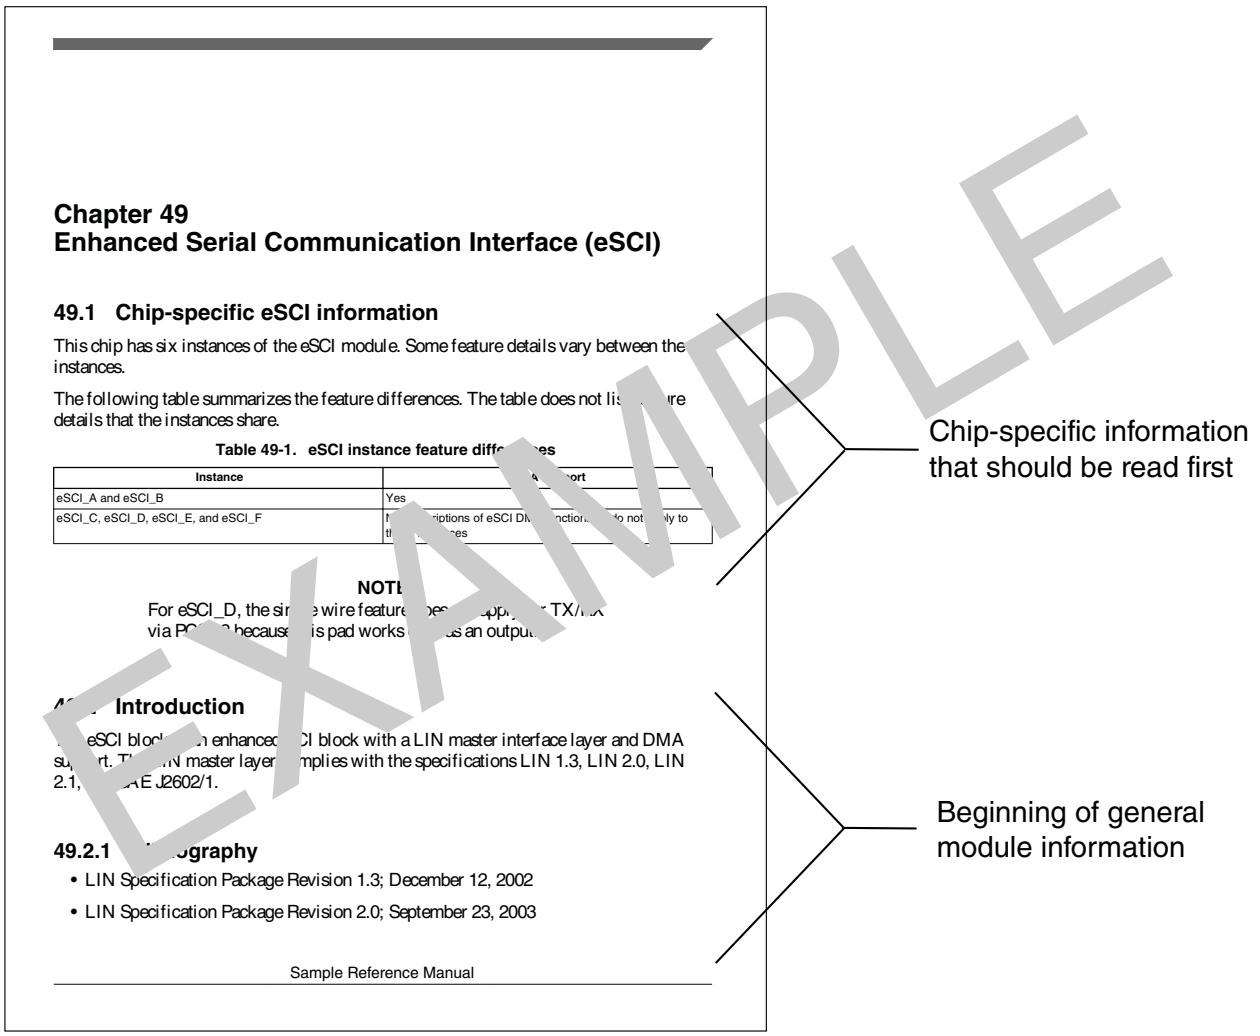
80.10.4 Planning secure read protection..... 3393
80.10.5 Planning debug port enable/disable..... 3393
80.10.6 Planning OTP flash memory block assignment..... 3393
80.10.7 Planning factory test mode disable..... 3393

Chapter 1
About This Manual

1.1 Audience

This reference manual is intended for system software and hardware developers and applications programmers who want to develop products with this device. It assumes that the reader understands operating systems, microprocessor system design, and basic principles of software and hardware.

1.2 Organization



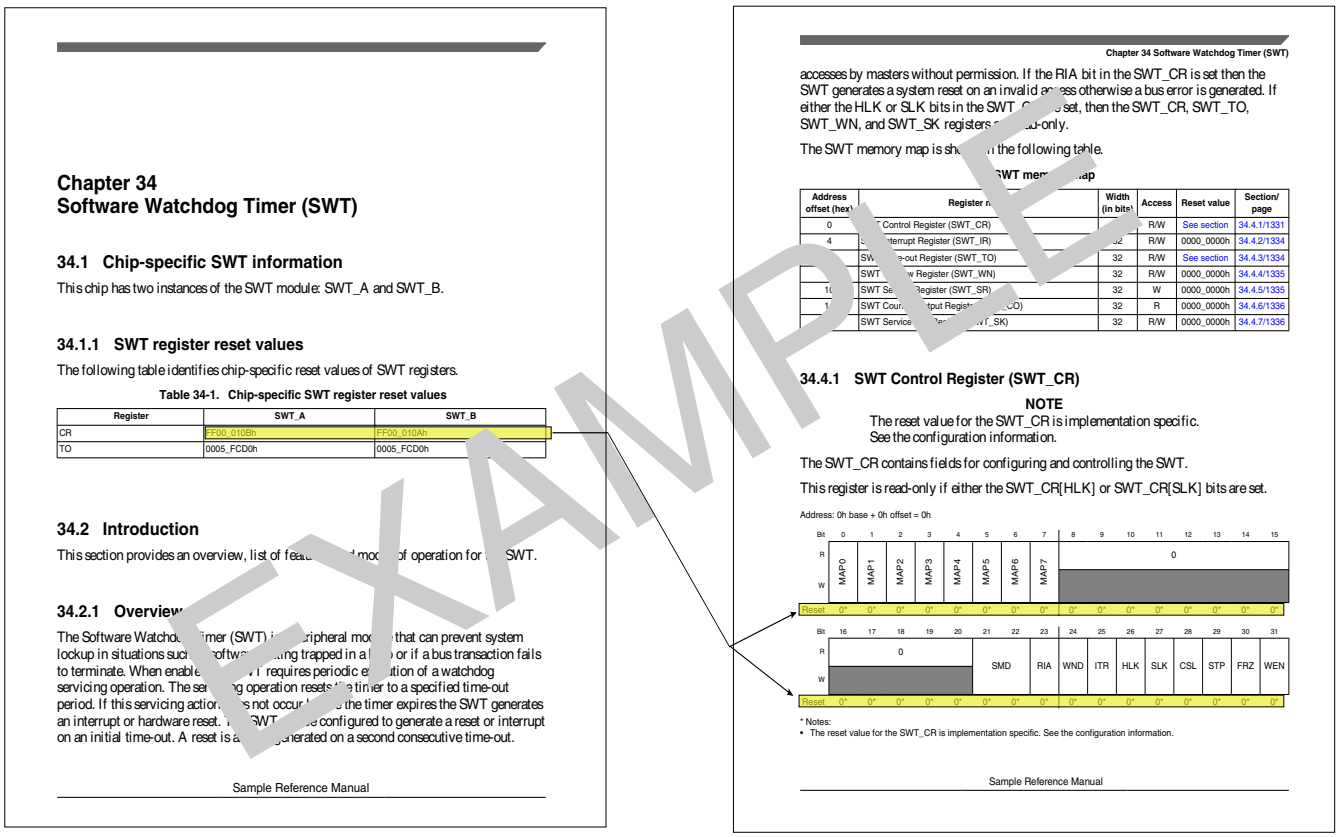
This manual has two main sets of chapters.

1. Chapters in the first set contain information that applies to all components on the chip.
2. Chapters in the second set are organized into functional groupings that detail particular areas of functionality.
   - Examples of these groupings are clocking, timers, and communication interfaces.
   - Each grouping includes chapters that provide a technical description of individual modules.

1.3 Module descriptions

Each module chapter has two main parts:

- The first section, *Chip-specific [module name] information*, provides details such as the number of module instances on the chip and connections between the module and other modules. Read this section *first* because its content is crucial to understanding the information in other sections of the chapter.
- The subsequent sections provide general information about the module, including its signals, registers, and functional description.



EXAMPLE

Figure 1-1. Example: chapter chip-specific information and general module information

1.3.1 Example: chip-specific information that clarifies content in the same chapter

The example below shows chip-specific information that clarifies general module information presented later in the chapter. In this case, the chip-specific register reset values supercede the reset values that appear in the register diagram.

Chapter 34
Software Watchdog Timer (SWT)

34.1 Chip-specific SWT information

This chip has two instances of the SWT module: SWT_A and SWT_B.

34.1.1 SWT register reset values

The following table identifies chip-specific reset values of SWT registers.

Table 34-1. Chip-specific SWT register reset values

Register	SWT_A	SWT_B
CR	FF00_010Bh	FF00_010Ah
TO	0005_FCD0h	0005_FCD0h

34.2 Introduction

This section provides an overview, list of feat... mod... of operation for ... SWT.

34.2.1 Overview

The Software Watchdo... imer (SWT) i... ripheral mo... that can prevent system lockup in situations suc... softw... ting trapped in a l... or if a bus transaction fails to terminate. When enable... T requires periodic e... ution of a watchdog servicing operation. The ser... g operation resets ... timer to a specified time-out period. If this servicing actio... s not occur ... the timer expires the SWT generates an interrupt or hardware reset. ... SWT ... be configured to generate a reset or interrupt on an initial time-out. A reset is a... generated on a second consecutive time-out.

Sample Reference Manual

Chapter 34 Software Watchdog Timer (SWT)

accesses by masters without permission. If the RIA bit in the SWT_CR is set then the SWT generates a system reset on an invalid a... ss otherwise a bus error is generated. If either the HLK or SLK bits in the SWT_C... set, then the SWT_CR, SWT_TO, SWT_WN, and SWT_SK registers ... -only.

The SWT memory map is sh... n the following table.

SWT mem... ap

Address offset (hex)	Register n...	Width (in bits)	Access	Reset value	Section/ page
0	... Control Register (SWT_CR)		R/W	See section	34.4.1/1331
4	... terrupt Register (SWT_IR)	32	R/W	0000_0000h	34.4.2/1334
	SW... e-out Register (SWT_TO)	32	R/W	See section	34.4.3/1334
	SWT ... w Register (SWT_WN)	32	R/W	0000_0000h	34.4.4/1335
10	SWT Se... Register (SWT_SR)	32	W	0000_0000h	34.4.5/1335
1	SWT Cour... tput Regist... CO)	32	R	0000_0000h	34.4.6/1336
	SWT Service ... (SWT_SK)	32	R/W	0000_0000h	34.4.7/1336

34.4.1 SWT Control Register (SWT_CR)

NOTE
The reset value for the SWT_CR is implementation specific.
See the configuration information.

The SWT_CR contains fields for configuring and controlling the SWT.

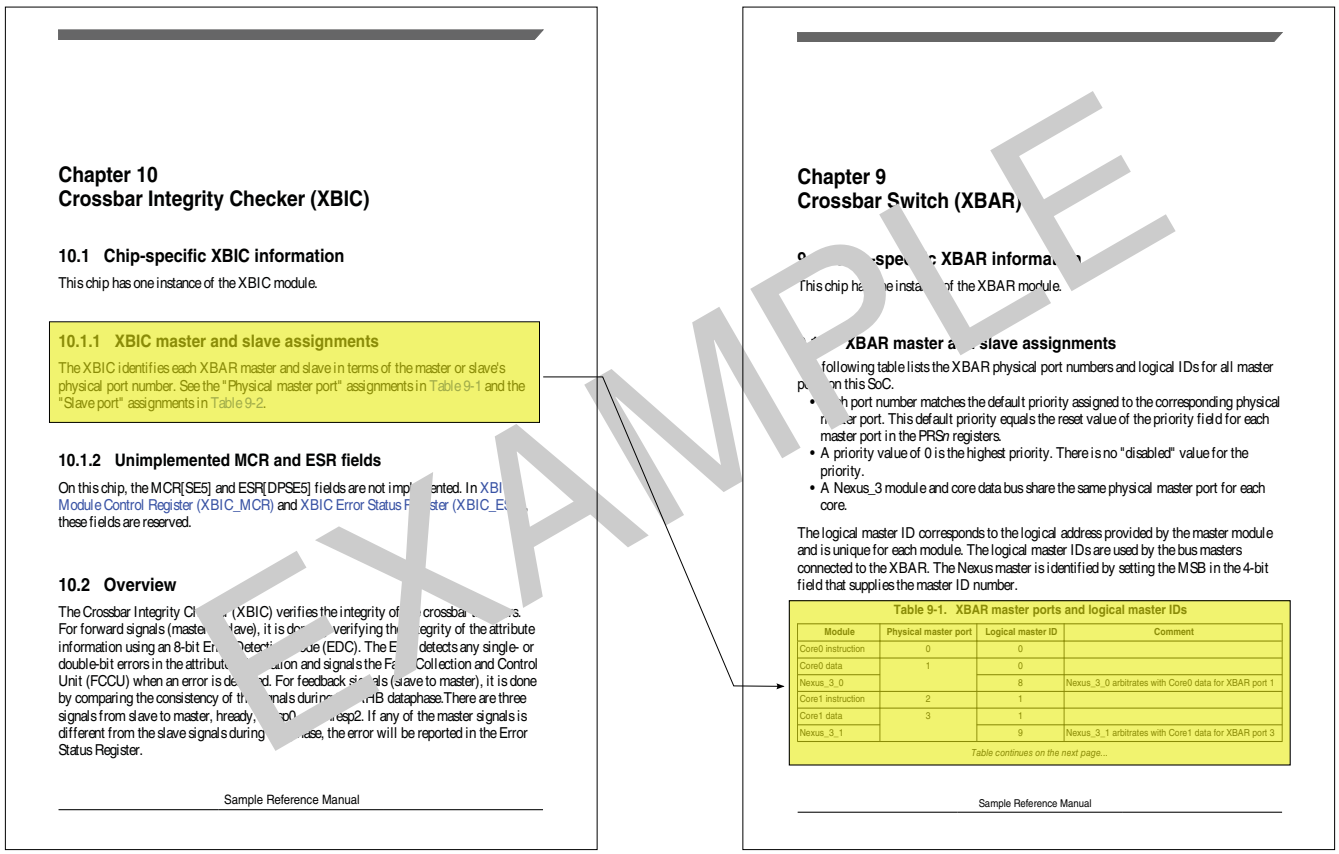
This register is read-only if either the SWT_CR[HLK] or SWT_CR[SLK] bits are set.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	MAP0	MAP1	MAP2	MAP3	MAP4	MAP5	MAP6	MAP7	0							
W																
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0					SMD	RIA	WND	ITR	HLK	SLK	CSL	STP	FRZ	WEN	
W																
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- The reset value for the SWT_CR is implementation specific. See the configuration information.



Sample Reference Manual

EXAMPLE

Figure 1-2. Example: chip-specific information that clarifies content in the same chapter

1.3.2 Example: chip-specific information that refers to a different chapter

The chip-specific information below refers to another chapter's chip-specific information. In this case, read both sets of chip-specific information before reading further in the chapter.

Chapter 10
Crossbar Integrity Checker (XBIC)

10.1 Chip-specific XBIC information

This chip has one instance of the XBIC module.

10.1.1 XBIC master and slave assignments

The XBIC identifies each XBAR master and slave in terms of the master or slave's physical port number. See the "Physical master port" assignments in Table 9-1 and the "Slave port" assignments in Table 9-2.

10.1.2 Unimplemented MCR and ESR fields

On this chip, the MCR[SE5] and ESR[DPSE5] fields are not implemented. In XBIC Module Control Register (XBIC_MCR) and XBIC Error Status Register (XBIC_ES... these fields are reserved.

10.2 Overview

The Crossbar Integrity Ch... (XBIC) verifies the integrity of ... crossbar ... For forward signals (maste... lave), it is do... verifying th... egrity of the attribute information using an 8-bit Er... Detecti... ue (EDC). The E... detects any single- or double-bit errors in the attribut... ation and signals the Fa... Collection and Control Unit (FCCU) when an error is de... d. For feedback si... ls (slave to master), it is done by comparing the consistency of th... nals during ... hB dataphase.There are three signals from slave to master, hready, ... so0, ... esp2. If any of the master signals is different from the slave signals during ... ase, the error will be reported in the Error Status Register.

Sample Reference Manual

Chapter 9
Crossbar Switch (XBAR)

9 ... -spe... : XBAR informa...

This chip ha... e insta... of the XBAR module.

... XBAR master a... slave assignments

... following table lists the XBAR physical port numbers and logical IDs for all master p... on this SoC.

- ... h port number matches the default priority assigned to the corresponding physical m... er port. This default priority equals the reset value of the priority field for each master port in the PRSn registers.
- A priority value of 0 is the highest priority. There is no "disabled" value for the priority.
- A Nexus_3 module and core data bus share the same physical master port for each core.

The logical master ID corresponds to the logical address provided by the master module and is unique for each module. The logical master IDs are used by the bus masters connected to the XBAR. The Nexus master is identified by setting the MSB in the 4-bit field that supplies the master ID number.

Table 9-1. XBAR master ports and logical master IDs

Module	Physical master port	Logical master ID	Comment
Core0 instruction	0	0	
Core0 data	1	0	
Nexus_3_0		8	Nexus_3_0 arbitrates with Core0 data for XBAR port 1
Core1 instruction	2	1	
Core1 data	3	1	
Nexus_3_1		9	Nexus_3_1 arbitrates with Core1 data for XBAR port 3

Table continues on the next page...

Sample Reference Manual

EXAMPLE

Figure 1-3. Example: chip-specific information that refers to a different chapter

1.4 Register descriptions

Module chapters present register information in:

- Memory maps containing:
  - An offset from the module's base address
  - The name and acronym/abbreviation of each register
  - The width of each register (in bits)
  - Each register's reset value
  - The page number on which each register is described
- Register figures
- Field-description tables
- Associated text

The register figures show the field structure using the conventions in the following figure.

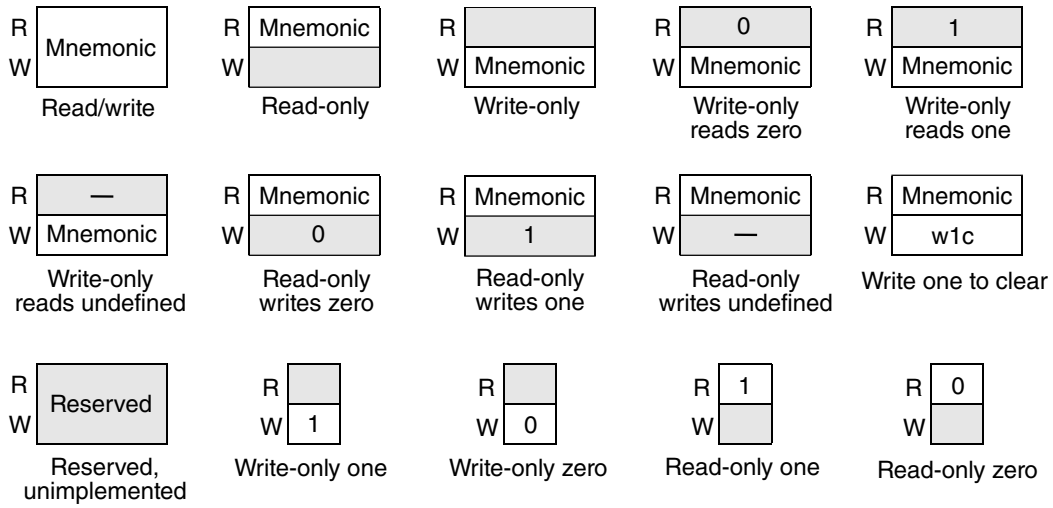


Figure 1-4. Register figure conventions

1.5 Conventions

1.5.1 Notes, Cautions, and Warnings

Note, Caution, and Warning notices appear throughout this manual. Each notice type alerts readers to a specific kind of information.

NOTE

Notes convey information that may be tangential to a topic or that may not apply to all readers.

CAUTION

Caution notices call out information that readers should know before taking further action. Cautions frequently point to trouble spots that may damage the chip or board.

WARNING

Warning notices inform readers about actions that could result in unwanted consequences, especially those that may cause bodily injury.

1.5.2 Numbering systems

The following suffixes identify different numbering systems:

This suffix	Identifies a
b	Binary number. For example, the binary equivalent of the number 5 is written 101b. In some cases, binary numbers are shown with the prefix *0b*.
d	Decimal number. Decimal numbers are followed by this suffix only when the possibility of confusion exists. In general, decimal numbers are shown without a suffix.
h	Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is written 3Ch. In some cases, hexadecimal numbers are shown with the prefix *0x*.

1.5.3 Typographic notation

The following typographic notation is used throughout this document:

Example	Description
placeholder, x	Items in italics are placeholders for information that you provide. Italicized text is also used for the titles of publications and for emphasis. Plain lowercase letters are also used as placeholders for single letters and numbers.
`code`	Fixed-width type indicates text that must be typed exactly as shown. It is used for instruction mnemonics, directives, symbols, subcommands, parameters, and operators. Fixed-width type is also used for example code. Instruction mnemonics and directives in text and tables are shown in all caps; for example, BSR.
SR[SCM]	A mnemonic in brackets represents a named field in a register. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).
REVNO[6:4], XAD[7:0]	Numbers in brackets and separated by a colon represent either: • A subset of a register's named field For example, REVNO[6:4] refers to bits 6–4 that are part of the COREREV field that occupies bits 6–0 of the REVNO register. • A continuous range of individual signals of a bus For example, XAD[7:0] refers to signals 7–0 of the XAD bus.

1.5.4 Special terms

The following terms have special meanings:

Term	Meaning
asserted	Refers to the state of a signal as follows: • An active-high signal is asserted when high (1). • An active-low signal is asserted when low (0).
deasserted	Refers to the state of a signal as follows: • An active-high signal is deasserted when low (0). • An active-low signal is deasserted when high (1). In some cases, deasserted signals are described as *negated*.

Table continues on the next page...

Term	Meaning
reserved	Refers to a memory space, register, field, or programming setting. Writes to a reserved location can result in unpredictable functionality or behavior. • Do not modify the default value of a reserved programming setting, such as the reset value of a reserved register field. • Consider undefined locations in memory to be reserved.
w1c	Write 1 to clear: Refers to a register bitfield that must be written as 1 to be "cleared."

Chapter 2
Introduction

2.1 Introduction

The MPC5746C is a 32-bit Power Architecture based microcontroller unit (MCU) for automotive applications and builds on the successful legacy of the MPC56xx family of microcontrollers.

There are two application processor cores on this device.

Table 2-1. Processor cores

Computational Shell		
Core0	Main Core 0	e200z420n3
Core1	Peripheral Core	e200z210n3

2.1.1 Target Applications

The family of devices are designed to address a wide variety of automotive applications including but not limited to the door modules, seat modules, central body, vehicle body controllers, smart junction box, front module applications, high end gateway or combined body controller and gateway applications.

2.2 Block diagram

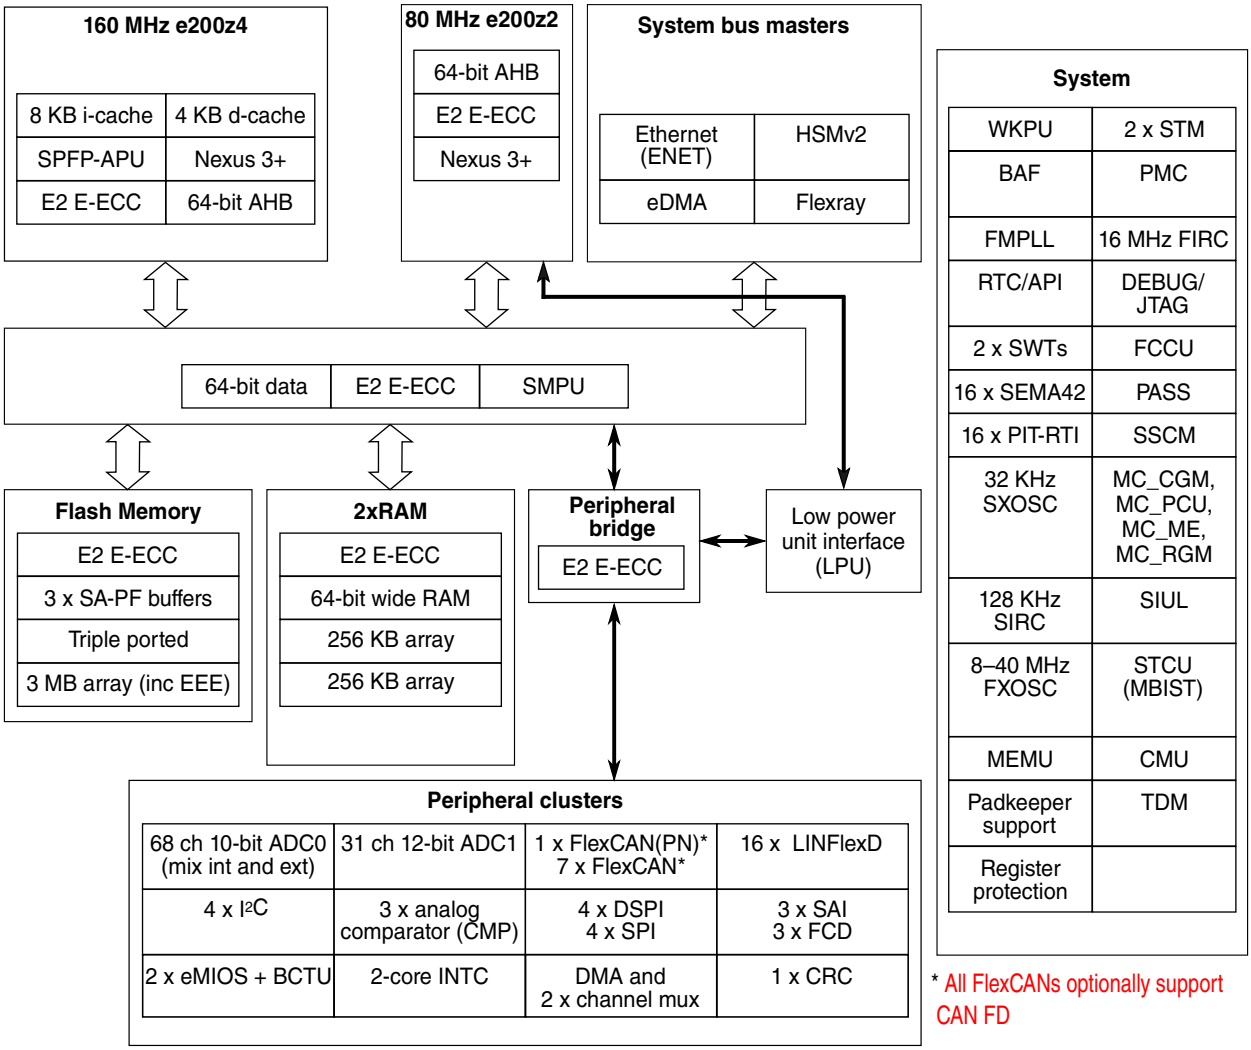

Figure 2-1. MPC5746C block diagram

2.3 Family comparison

The following table provides a summary of the different members of the MPC5746C family and their proposed features. This information is intended to provide an understanding of the range of functionality offered by this family. For full details of all of the family derivatives please contact your marketing representative.

NOTE

All optional features (Flash memory, RAM, Peripherals) start with lowest number or address (e.g., FlexCAN0) and end at highest available number or address (e.g., MPC574xB/C have 6 CAN, ending with FlexCAN5).

Table 2-2. MPC5746C Family Comparison[1]

2.4 Feature list

On-chip modules available within the device include the following features:

Table 2-6. Feature List

Cores	• 1 x 160 MHz Power Architecture® e200Z4 Dual issue, 32-bit CPU
	  • Single precision floating point operations
	  • 8 KB instruction cache and 4 KB data cache
	  • Only variable length encoding (VLE) for significant code density improvements
	• 1 x 80 MHz Power Architecture® e200Z2 Single issue, 32-bit CPU
	  • Using variable length encoding (VLE) for significant code size footprint reduction
	• End-to-End ECC ensuring full protection of all data accesses throughout the system, from each of the core through the crossbar and into the memories and peripheral bridge

Supported memories	• 3 MB on-chip flash supported with the flash controller • 3 x flash page buffers (3 port flash controller) to improve access time to code and data held in flash • 512 KB on-chip SRAM across two RAM ports
Clocks	• 8-40 MHz Fast External Crystal Oscillator (FXOSC) • 16 MHz Fast Internal RC Oscillator (FIRC) • 128 KHz Slow Internal RC Oscillator(SIRC) • 32 KHz Slow External Crystal Oscillator (SXOSC) • Clock Monitor Unit (CMU) to support monitoring of critical clocks • Frequency modulated phase-locked loop (FMPLL) • Sophisticated clocking architecture allowing core and peripheral clocks to be scaled independently of the peripheral operation (some restrictions may apply)
System	• Two System Memory Protection Unit (SMPU) with up to 32 region descriptors and 16-byte region granularity • 16 Semaphores to manage access to shared resource • Interrupt controller (INTC) capable of routing interrupts to any CPU • Single crossbar switch architecture for concurrent access to peripherals, flash, and RAM from multiple bus masters • 32-channels eDMA controller with multiple transfer request sources using DMAMUX • Body Cross Trigger Unit (BCTU) to enable synchronization of ADC conversions with a timer event from the eMIOS or from the PIT • Capable of triggering groups of channels • Supports wake-up from low power modes via the wakeup unit (WKPU)
Communications	• Four Deserial Peripheral Interface (DSPI) • Four Serial Peripheral interface (SPI) • 16 serial communication interface (LIN) • Eight enhanced FlexCAN modules with configurable buffers • Each instance supports DMA on RxFIFO

Table continues on the next page...

Table 2-6. Feature List (continued)

	• Low power mode with Pretended Networking support on a single FlexCAN (FlexCAN0) • CAN FD support • Four inter-IC communication interface (I2C) • One dual-channel FlexRay Controller with 128 Message buffers and stopwatch function for synchronisation to OS • One ENET complex (10/100 Ethernet) that supports 1588 and MII/RMII • Enhanced ENET complex supporting multiple queues • Mutiple queue AVB support • Three Synchronous Audio Interface (SAI) capable of supporting six stereo audio channels • Three Fractional clock dividers (FCD) operating in conjunction with the SAIs
Analog	• Two analog-to-digital converters (ADC), one 10-bit and one 12-bit • 12-bit ADC has independent reference on larger packages • Each ADC can be independently 3.3 V or 5 V • Three analogue comparators (CMP) providing up to 24 compare inputs • Supports analog input comparison without any software supervision during STANDBY mode • Supports four instances of IGF, one for each HF interface
Timers	• Real Time Counter (RTC) with clock source from internal 128 KHz SIRC, 32 KHz SXOSC, 16 MHz FIRC or the 8-40 MHz FXOSC • Two System Timer Module (STM), each with 4 compare registers. • Two Software WatchDog Timers (SWT) clocked by the SIRC, one additional in HSM • 16 Periodic Interrupt Timers (PIT) channels with 32-bit counter resolution • Channels can be concatenated together to produce a 64-bit resolution • RTI also supported and clocked by FXOSC • 64 Configurable Enhanced Modular Input Output Subsystem (eMIOS) channels • Provides a range of 16-bit input capture, output compare, and pulse width modulation functions • Improved flexibility by addition of second global counter bus and second global pre-scaler
Boot support	• Boot Assist Flash (BAF) supports internal flash programming via a serial link (LIN/SCI and FlexCAN) • BAF runs initialization routines at the device boot • Device always boot on e200Z4 • Device can boot from any core on exit from STANDBY or LPU_RUN
Input output pin configuration	• Maximum amount of general purpose pins supporting input and output operations (Number supported is package dependent) • General purpose I/O support state retention in all low power modes. State retention controlled by pad keeper logic. Limted I/O supports state retention in Power Domain 0 (PD0) and Power Domain 1 (PD1) • Configurable I/O domains supporting Ethernet and general I/O (package dependent)
Power management	• On-chip power management controller (PMC-Dig) • External regulation mode where low voltage input supply of ~1.25 V (+/- 4 %) is regulated and supplied through on board power supply • Internal regulation mode where low voltage input supply of ~1.25 V (+/- 4 %) is regulated by on-chip PMC and supplied via external ballast transistor • Internal regulation mode where low voltage input supply of ~1.25 V (+/- 4 %) is regulated by on-chip PMC and supplied via internal ballast transistor
Debug	• e200Z2 core: Nexus development interface (NDI) per IEEE-ISTO 5001-2012 Class 3+ • Only class 1 debug interface supported during LPU mode • e200Z4 core: Nexus development interface (NDI) per IEEE-ISTO 5001-2012 Class 3+

Table continues on the next page...

Table 2-6. Feature List (continued)

	• Device/board boundary Scan testing supported with per JTAG (IEEE 1149.1) and cJTAG (1149.7) • Possible to trace SRAM accesses via nexus auxiliary interface
Safety	• One hardware Cyclic Redundancy Check (CRC) module • Two Memory Error Management Unit (MEMU) • One Fault Collection and Control Unit (FCCU) • One Self-Test Control Unit (STCU) • Targeted for specific device functions being ASIL-B certifiable
Security	• One Password and Device Security Module (PASS) implementing password-based read and write protection for flash blocks • Tamper Detection Module (TDM) provides flash memory write protection mechanism • Register protection supported on key registers • Hardware Security Module (HSM) enabling advanced security management

2.5 Package Options

The following package options are available in the device:

- 100-pin BGA, 1mm ball pitch, 11mm x 11mm outline
- 176-pin LQFP, 0.5mm pitch, 24mm x 24mm outline
- 256-pin BGA, 1mm ball pitch, 17mm x 17mm outline
- 324-pin BGA, 1mm ball pitch, 19mm x 19mm outline (development only)

2.6 Modes of Operation

This family of devices will have two types of modes, SYSTEM modes and USER modes.

SYSTEM Modes

SYSTEM modes are entered automatically on system events or on application request. There are three SYSTEM modes: RESET, SAFE, and DRUN as described in the table below.

Table 2-7. System Modes

Mode	Description	Entry	Exit
RESET	System remains in this mode until all resources are available for S/W to take device control. This mode manages hardware	System reset assertion from RGM	System reset deassertion from RGM

Table continues on the next page...

Table 2-7. System Modes (continued)

Mode	Description	Entry	Exit
	initialization of flash and various chip configuration registers		
SAFE	May be entered on detection of an error, reaction of which has been pre-configured via MC_RGM and FCCU. Forces system into pre-defined safe configuration such as the system clock source switches to internal fast RC oscillator and output pins are forced into high impedance (Hi-z) from which the system may try to recover.	Hardware fail, Software request from DRUN, RUNx	System reset assertion, DRUN via Software
DRUN	Default entry mode for the embedded software. Provides full system accessibility & enables system configuration. BAF is executed in DRUN mode if exiting from RESET mode or STANDBY mode provided its is configured to execute BAF on standby exit	Reset removed, from any of the mode SAFE and RUNx via software configuration, from LPU_RUN via software configuration, STANDBY/ LPU_STANDBY on wakeup	It is possible to transition to all the modes from DRUN

USER Modes

USER modes are used to control the device performance and consumption during normal application operation. The modes are organized according to the performance provided by the device in each mode. There are various USER modes as described in the table below, depending on the specific device: RUNx, STOP, STANDBY, LPU_RUN, LPU_STOP and LPU_STANDBY.

Table 2-8. User Modes

Mode	Description	Entry	Exit
RUN0, RUN1, RUN2, RUN3	These are software running modes where most processing activity is done. These various run modes allow to enable different clock & power configurations of the system with respect to each other	software request from DRUN, interrupt event from wakeup request from STOP	Device can enter in all modes SAFE, RUNx, STOP, RESET, LPU_RUN via software
STOP0	Advanced low-power modes during which the clock to the core is disabled. STOP0 may be configured to switch off most of the peripherals including oscillator for efficient	Software request from RUNx	Reset asserted, SAFE on hardware failure, RUNx on wakeup event

Table continues on the next page...

Table 2-8. User Modes (continued)

Mode	Description	Entry	Exit
	power management at the cost of higher wakeup latency		
STANDBY/LPU_STANDBY	Reduced-leakage low-power mode during which power is cut off from most of device and content is lost and must be restored from backup	Software request from RUNx, DRUN, LPU_RUN modes	Device will enter in DRUN mode on STANDBY exit and LPU_RUN on LPU_STANDBY exit. It is possible to exit from LPU_STANDBY to DRUN if LPU_MCR[DIRECT_DRUN] is configured.

Advanced Low Power USER modes: Advanced Low Power USER modes are used to control the device performance and consumption during advanced low power operation. The modes are organized according to the performance provided by the device in each mode.

There are three modes on this device: LPU_RUN, LPU_STOP, and LPU_SLEEP.

Table 2-9. Advanced Low Power USER modes

Mode	Description	Entry	Exit
LPU_RUN	In LPU_RUN mode only small subsystem with Z2 core and some communication peripheral is powered. Other cores and majority of modules are power gated. Only FIRC and FXOSC can be source of system clock as PLL is power gated.	Software request from RUNx, DRUN, from LPU_STANDBY and LPU_STOP on wakeup	Device will enter into DRUN mode on LPU_RUN exit
LPU_STOP	In LPU_STOP mode, Z2 core enters the low-power state and its clock is gated. FlexCAN pretended network feature is available but all peripherals are stopped, clocks are gated to all modules in LPU domain. LPU_STOP may be configured to switch off oscillators for efficient power management at the cost of higher wakeup latency	On software request from LPU_RUN	Device will enter into LPU_RUN mode on interrupt from FlexCAN, WKPU or SWT timeout
LPU_SLEEP	Z2 core is stopped and clock gated by hardware. LPU_SLEEP may be configured to clock gated module clocks by configuring LPU_MDIS	On software request from LPU_RUN	The device can exit to LPU_RUN mode on any peripheral interrupt, external interrupt or WKPU source.

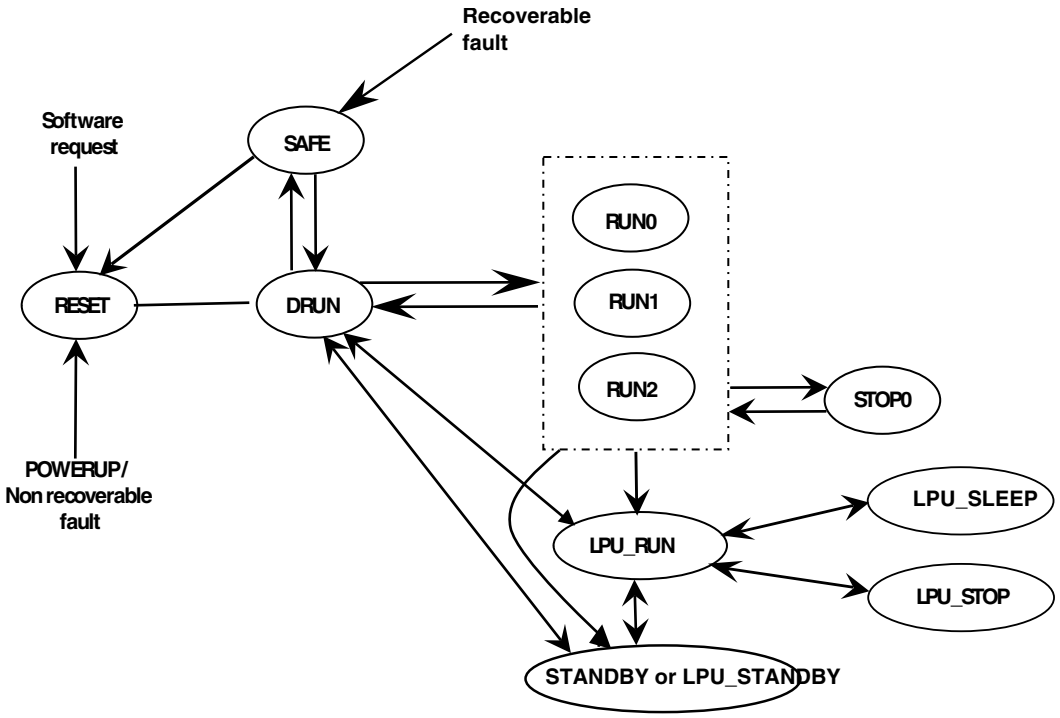

Figure 2-2. Mode relationship

NOTE

If we are entering into complete power gated mode via LPU_RUN mode, it is called LPU_STANDBY else it is referred as STANDBY. Only difference in two modes is that user can select clock sources to be ON/OFF by configuring ME_STANDBY0_MC for STANDBY mode and LPU_STANDBY_CF for LPU_STANDBY mode

When exiting STANDBY or LPU_RUN, the user will determine which core(s) are active. This will be optionally the Z2 or Z4.

Brief Description of Power Domains

The Power Control Unit (MC_PCU) and Low Power Subsystem LPU are used to manage all mode transition. Power can be saved by gating the power supply via a power switching device. The device is grouped into 3 parts which are called “power domains”. When a power domain is disconnected from the supply, the power consumption is reduced to zero in that domain. Any status information of such a power domain is lost.

Power Domain0 (PD0): It is an always alive domain, which consists of modules required for mode transitions and some timers.

Power Domain1 (PD1): It consists of modules required to be operational in LPU modes. z2 core is present in PD1. This domain is power gated off in STANDBY/ LPU_STANDBY mode.

Power Domain2 (PD2): It is the biggest domain with most of the modules, many XBAR masters. z4 core is present in PD2. This domain is power gated off in any of the LPU modes as well as STANDBY mode.

Powered with External Regulator

If the application is using an external 1.25 V supply, then that 1.25 V supply will continue to be connected to the PD2 domain unless the customer application takes steps to remove it. Hence depending on the application configuration there may be leakage from the PD2 area in STANDBY or LPU modes. This can be avoided by disconnecting the external supply when the device has entered the low power states, although it must be re-applied to enable exit from the low power states. For details, see Applications and Low Power Modes.

Maximum power saving is reached by entering the STANDBY modes. On each mode change request, the power and mode controllers in the chip i.e. MC_ME, MC_PCU, LPU_CTL and PMC evaluates the power domain settings in the power domain configuration registers and initiates a power-down or a power-up sequence for each individual power domain. The power-up/down sequences are handled by finite state machines to ensure a smooth and safe transition from one power state to the other.

Low Power Mode Exit

Exiting STANDBY modes can only be done via a system wakeup event or reset as all power domains other than PD0 are in the power-down state. Refer the wakeup sources for the wakeup event triggers details. See the device I/O Signal Description and Input Multiplexing tables attached to this document as an Excel file. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click the Excel file to open it and select the I/O Signal Description table tab.

NOTE

For interrupt handling during mode transitions, refer to section: Interrupts handling during mode transitions.

Chapter 3
Memory Map

3.1 Introduction

This chapter describes the memory and peripheral locations within the specified memory space. The addresses represent the physical addresses assigned to each region or module. An access to the reserved locations may produce undesirable results.

3.2 System memory map

The following table shows the system memory map.

Table 3-1. System memory map

Start Address	End Address	Size	Description
0x00000000	0x003FFFFF	16 KB	Reserved
0x00400000	0x00403FFF	16 KB	UTEST
0x00404000	0x00407FFF	16 KB	BAF

0x00400348	0x00400FFF	3256	DCF Records
0x00401000	0x00403FFF	12288	Reserved for customer OTP data

1. When device is in CUST_DEL (or later) life cycle and prefetching is enabled in the platform flash controller (PFLASH_C55FM), it reads of the HSM 'ROM' key locations (0x0400308 - 0x0400347) and return dummy DCF records. However, accesses to these locations may cause result in anomalous operation. Reading the HSM 'ROM' key locations can result in a false ECC event, specifically either a false single-bit correction or a false multi-bit error detection. Reading the HSM 'ROM' key locations can also interfere with an unrelated, but coincident, loading of the PFLASH_C55FM prefetch buffers. As a result a subsequent request to flash, may result in a false ECC event, specifically either a false single-bit correction or a false multi-bit error detection.
2. Program MPU to prevent accesses to 0x0400308 - 0x0400347. Avoid accessing the HSM ROM key locations in the flash UTEST region (0x0400308 - 0x0400347). Prior to accessing this region; disable flash buffer prefetches.

3.5 RAM memory map

Table 3-4. RAM memory map

Start Address	End Address	Allocated Size [KB]	Description

Chapter 4
Signal Description

4.1 Generic pins/balls

The I/O Signal Description Table contains information on generic pins/balls. See the device I/O Signal Description and Input Multiplexing tables attached to this document as an Excel file. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click the Excel file to open it and select the I/O Signal Description table tab.

NOTE

On 176LQFP-EP package, expose pad must be connected to VSS_LV on board.

4.1.1 MSCR assignments

The I/O Signal Description table provides the port pin, SIUL Multiplexed Signal Configuration Register (MSCR) number, MSCR Source Signal Select (SSS) function, module, signal description, direction, pad type, and package pin/ball numbers for each I/O pin on the device.

The Implemented SIUL2 Multiplexed Single Configuration Register details is provided in the I/O Signal Description Table attached as excel.

NOTE

Implemented SIUL2 Multiplexed Single Configuration Register are from SIUL2_MSCR0 to SIUL2_MSCR263 and SIUL2_IMCR0 to SIUL2_IMCR511. Please note that MSCR 513 in this column corresponds to IMCR 0 and so on.

Example:

If user wants to configure CAN0RX and CAN0TX, then the following configuration can be used in SIUL2 registers:

```
SIUL2.MSCR[16].R  = 0x03000001; /* PB[0] -&gt OBE = 1, ODE = 1 and MSCR16_SSS = 1 */
SIUL2.MSCR[17].R  = 0x00080000; /* PB[1] -&gt IBE = 1 */
SIUL2.IMCR[188].R = 0x00080002; /* PB[1] -&gt MSCR17_SSS = 2, notice that
"IO_Signal_Description_and_Input_multiplexing_tables.xls" shows 700 for the MSCR/IMCR see
note above, thus 188 must be used to properly configure the pin signal connected to it */
```

MSCR bit fields corresponds to pin/pad basis, these are independent of muxing implemented on that specific pin/pad. As an example, PAD18/PB[2] has SRE, ODE, SMC, IBE, HYS, PUS, PUE, SSS and OBE are implemented with the reset value 0000_0000.

In the “IO_Signal_Description_and_Input_multiplexing_tables.xls" spreadsheet, in "IO Signal Table" worksheet, the MSCR register bits shows ‘0’, ‘1’, and ‘-’ for state of all bits associated with different ports. ‘0’ or ’1’ represents the reset state and ‘-’ represents the bit is not supported on the respective port.

NOTE

IF HSM DO functionality is used on GPIO[28], GPIO[60] pads or GPIO[134], GPIO[135] pads using HSM_IO configurations for security, then all four GPIOs would get dedicated to HSM.

4.2 PAD keeping feature in LPU/STANDBY mode

The device is capable to retain the output value of some selected pads when device is power gated i.e. in LPU or STANDBY mode. These pads reside in always alive power domain(PD0).

To enable this feature, set PMCDIG_RDCR[PAD_KEEP_EN] to '1'. The PAD's output values are retained until software writes a '0' to this bit on exit from LPU or STANDBY mode . If the bit is not set, latched PAD values are automatically cleared on LPU or STANDBY exit and the PADS go to Hi-z

Table 4-1 lists the pads which support PAD Keeping feature. However, the pads in the following two tables combine to form the full list of pads available in LPU and STANDBY modes.

Table 4-1. PADS alive in LPU mode with pad keeping feature

GPIO[197]	STBY_LPU
GPIO[198]	STBY_LPU
GPIO[205]	STBY_LPU
GPIO[206]	STBY_LPU

NOTE

For pads 42 and 102, only if source signal select is configured for CMP0_O and CLKOUT1 respectively via SIUL2_MSCR registers, the analog comparator 0 CMP0_O and CLKOUT1 clock would be exposed during standby. If expose during standby is enabled for CMP0_O or CLKOUT1 on pad 42 and 102 respectively, then padkeeping on these pads would be disabled.

Chapter 5
Security Overview

5.1 Introduction

All MPC574xx family devices have a comprehensive set of customer-configurable security features designed to protect code and data from unauthorized access. Some security features are available in all device configurations. Other, more advanced security features are not available in all device configurations. These more advanced features require more than simply being turned on or off. They require significant involvement for implementation; consequently, they provide an important opportunity to define the security level of the device.

5.2 Basic security

All MPC574xx devices have the following basic set of security features.

- Device censorship based on life cycle model. Access to device code and data becomes progressively more restricted as the device matures through a defined set of life cycle steps.
- Memory security features
  - NVM censorship support, password protection, and one-time-programmable (OTP) flash memory areas, Flash erase counter and tamper detection.
- Unique ID for each device. Each MPC574xx device has a unique identification number stored in an OTP flash memory area. This unique ID can be read by any of the cores on the device.
- Basic debugger restrictions (on/off via censorship mode)

5.3 Advanced security

Depending on the device configuration, the following features are available:.

- Customer programmable Hardware Security Module (HSM). The HSM is a dedicated security subsystem that includes a processor core, dedicated SRAM, an encryption module, and exclusive access to secure areas of device flash memory. The HSM runs code independently from the main device processor cores and can be used to implement advanced security and monitoring functions.
- Secure debugger interface
- Boot modes
  - Trusted/secure boot support.
  - Handshake with Boot Assist Flash (BAF) supported.
- Monitoring of operating conditions
- Basic debugger restrictions (on/off via censorship mode)

5.4 Detailed security information

Details of most of the device security features will be published in a separate document, the *MPC574xx Microcontroller Security Reference Manual*. Please contact your NXP sales representative for details.

Chapter 6
Platform Overview

6.1 Introduction

All MPC574xx family devices supports multiple cores with Power PC Architecture. The MPC5746C Platform overview top level block diagram is shown below.

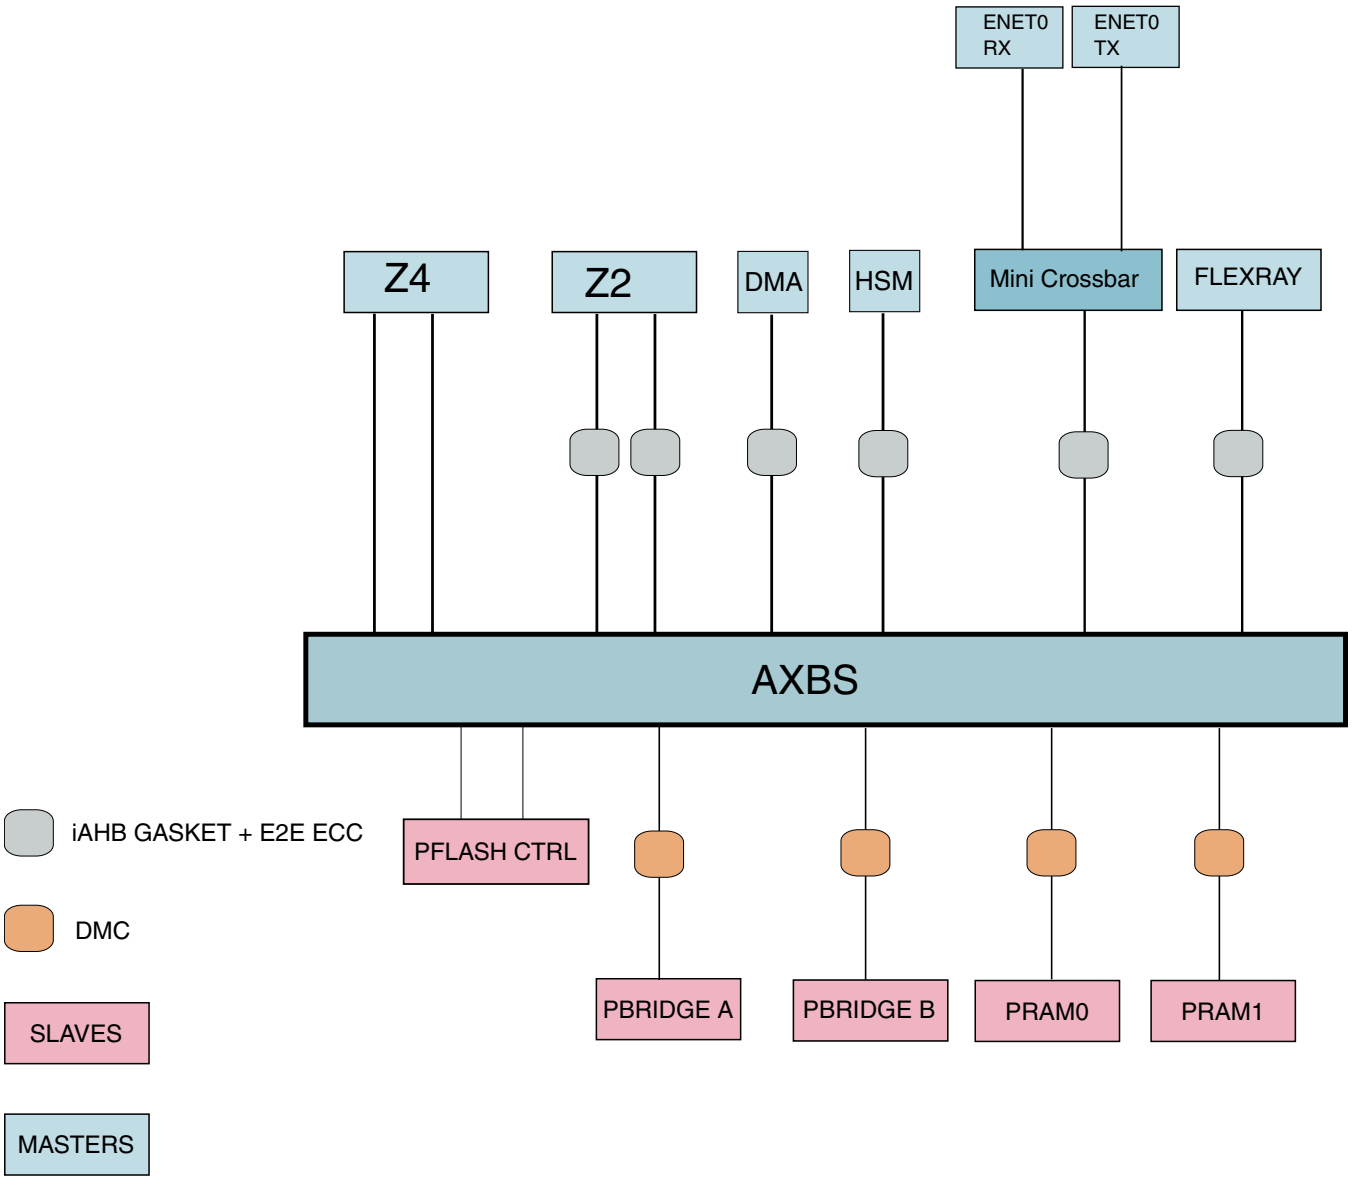

Figure 6-1. Platform Overview

6.2 User/Privilege Access

The non-core masters like ENET, Flexray etc can access the System RAM in either user or privileged mode. The kind of access per master is summarized in the below table.

Table 6-1. User/Privilege Access

Masters	Access
DMA	Master Configurable
HSM	Master Configurable

Table continues on the next page...

Table 6-1. User/Privilege Access (continued)

Masters	Access
ENET 0	Master Configurable
FlexRay	User mode only

NOTE

Bus error response will be generated when read or write access violation occurs for these Masters.

NOTE

Burst accesses via HSM IAHB gasket are not allowed.

Chapter 7
Power Management Overview

7.1 Introduction

The MPC5746C microcontroller's PMC generates, monitors and controls the power supply and related resets in the device. This chapter describes the analog PMC and its integration within the device, specifically detailing how the power supply to various modules is generated. It also explains different supply configurations for the MPC5746C.

The power management infrastructure comprises the following modules:

- Mode Entry Unit (MC_ME)
- LPU Control Unit (LPU_CTL)
- Power Control Unit (MC_PCU)
- Power Management Controller (PMC)

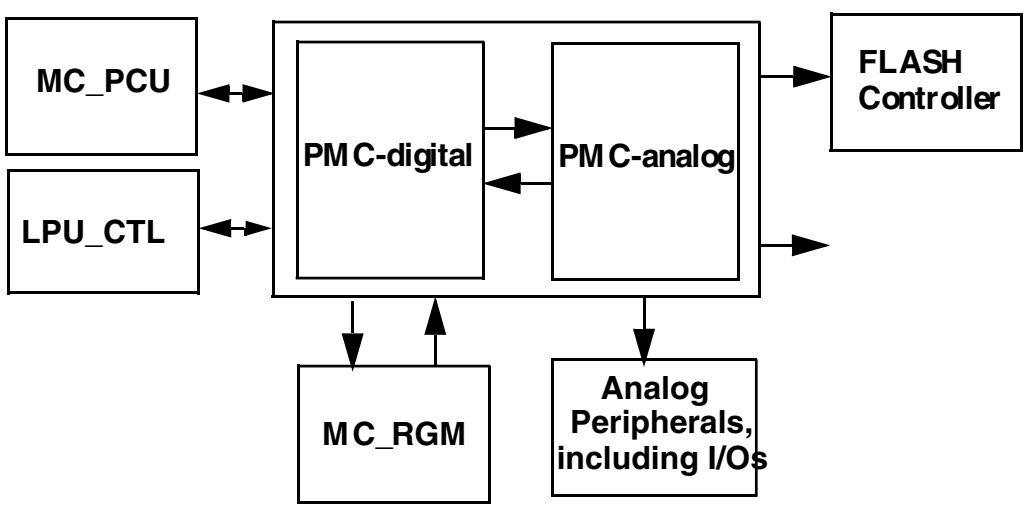

Figure 7-1. Power Management Overview

Finally, the chapter gives a brief introduction about power mode transitions, in conjunction with other sections of this reference manual.

NOTE

The PMC control registers are in the PMC Digital Interface (PMC-Dig) module. See that chapter for details on configuring the PMC.

Table 7-1 defines the abbreviations used throughout this chapter.

Table 7-1. Abbreviations used in this chapter

Abbreviation	Description
Voltage Supplies	
VDD_LV	Core logic low voltage supply
VSS_LV	Core logic ground supply
VDD_HV_A	Main I/O voltage supply
VDD_HV_B	Ethernet voltage supply
VDD_LP_DEC	Low power decoupling capacitor
VDD_HV_FLA	Flash memory high voltage supply
VRC_CTRL	PMC Voltage Regulator Control Output
Internal Regulators	
FLASHREG	Flash regulator. Regulates flash high voltage
FPREG	Full power regulator. Regulates core logic supply during full power operation
FPREG_init	Full power regulator with internal ballast.Regulates core logic supply during full power operation
LPREG	Low power regulator. Active in low power modes
ULPREG	Ultra-low power regulator. Active in STANDBY modes
Other	
LPU	Low Power Unit. An operational mode in which the main processor core and some associated peripherals and logic remain powered while the entire rest of the device is completely power gated off.

See Table 7-2 for links to related information.

Table 7-2. Related information

Link	Description
PMC Digital Interface (PMCDIG) chapter	PMC digital interface module chapter. Contains details on registers used to configure and control the PMC.
UTEST miscellaneous register [UTEST_MISC]	DCF UTEST miscellaneous register. The REG_TYPE bit referenced later in this chapter is used when bypassing the internal core logic power regulator and supplying the core logic voltage from an externally-regulated source.
Modes of Operation	Overview of device operational modes
Mode Entry (MC_ME) Module chapter	Mode Entry module chapter

7.1.1 Features

Features include:

- A linear regulator with an external NPN ballast to generate a regulated 1.25V(nominal) supply (VDD_LV) for the core logic, using external 5V/3.3V supply(VDD_HV_A), with an option to bypass the regulator and provide the core supply externally.
- A linear regulator with an internal ballast(PMOS FET) to generate a regulated 1.25V(nominal) supply (VDD12) for the core logic, using external 5V/3.3V supply(VDDE_A), with an option to bypass the regulator and provide the core supply externally.
- Two low power linear regulators (with internal ballasts) to power the core logic during low power modes (supply VDD_LP_DEC and an internal supply powering the IOP domain).
- Power switches to isolate voltage islands and configure the device in low power modes.
- A linear regulator to generate a regulated 3.3V supply for flash memory (VDD_HV_FLA) when the chip is configured in 5V mode.
- Voltage monitors to ensure the device transitions to a safe state (Power on RESET) when a supply is out of valid range.
- Controls power mode transitions through the interaction with digital interface.

7.2 Power domains

The MPC5746C microcontroller features multiple power domains to provide performance configurations with varying power consumption. The power domains are illustrated in Figure 7-2.

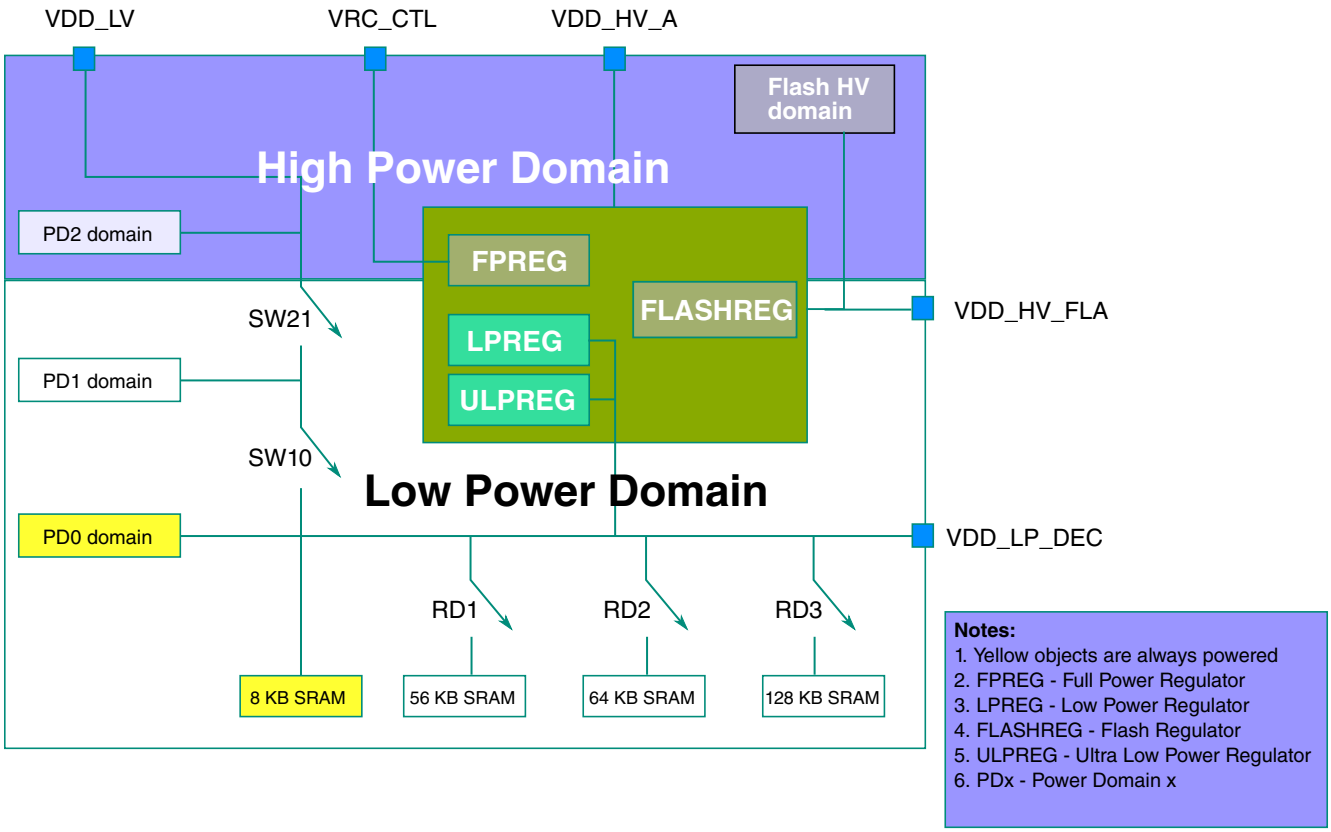

Figure 7-2. Power block diagram

The following sections describe the power domains in detail.

7.2.1 Power Domain0 (PD0)

PD0 is the ‘always ON’ power domain on the device. This domain plays an important role in maintaining device configuration as well as providing basic autonomous functionality with very low power.

7.2.2 Power Domain1 (PD1)

PD1 contains the computational blocks that comprise the LPU domain. This domain is power gated OFF in STANDBY and LPU_STANDBY modes.

7.2.3 Power Domain2 (PD2)

PD2 consists of various high performance blocks. This domain is power gated off in STANDBY mode and all LPU modes.

7.2.4 Flash HV power domain

The Flash HV power domain consists of high voltage devices inside the flash memory module. This domain must be kept powered at all times while the chip is out of 'power on reset'. The domain is supplied by Flash Regulator, as described later in this chapter.

7.2.5 SRAM domains

The MPC5746C microcontroller has a total of 512 KB SRAM, which is divided among the SRAM domains (known as RDx, where x is from 0 to 3) as follows:

- The *RD0* domain contains 8KB SRAM that is always available, and resides in the PD0 power domain.
- The *RD1*, *RD2*, and *RD3* SRAM domains, can be configured to be available during STANDBY.
- The remaining 256 KB SRAM resides in the PD2 power domain. This SRAM is completely powered off in STANDBY and LPU modes, but is always powered on (available) in other modes.

NOTE

All SRAM is available in RUN modes.

7.2.6 SRAM Configuration

256K RAM is available in LPU modes for code execution or data storage. Following guidelines should be considered.

1. RAM Domain Configuration Register (PMCDIG_ RDCR) must be configured to 256K retention mode before enabling LPU subsystem.
2. There is no option to power gate RAM domains in LPU_STOP.
3. RAM Domain Configuration Register (PMCDIG_ RDCR) can be configured to enable desired retention for enhanced power saving in LPU_STANDBY mode.

Table 7-3. RAM retention

RET_RD256	RET_RD128	RET_RD64	Comments
0	0	0	8K RAM retained
0	0	1	64K RAM retained
0	1	x	128K RAM retained
1	x	x	256K RAM retained

7.3 User operating modes, power domains, and clock gating

User operating modes, power domains, and clock gating in the MPC5746C microcontroller are as follows:

- Power domains are logical divisions within the microcontroller that can be power-gated to put the microcontroller in a reduced-power configuration. In other words, a power domain is a group of modules that can all be shutdown by gating the power to that domain.
- A user operating mode is a pre-defined group of power- and/or clock settings that can be applied to the microcontroller while in its normal operational state (DRUN). The settings control power consumption by controlling the availability of device functions.
- Within a given user operating mode, clocks can be configured or gated to achieve desired power targets.

NOTE

- For a full list of the operational modes, see Modes of Operation.

The table below shows the general settings and options available for user operating modes.

Table 7-4. User Operating mode settings and options

Operating Mode	Powered Domains[1],[2]	Chip Features[3],[4],[5]						Clock Sources					Wake up Options
		Z2 core (PD1)	Z4 cores (PD2)	Powered SRAM Domains[6],[7],[8]	Flash (PD2)	LPU Peripherals (PD1)	Main Peripherals (PD2)	16 MHz FIRC	8MHz-40MHz FXOSC	Phase Locked Loop (PLL)	128 kHz SIRC	32 kHz SXOSC	
RUN	PD0 PD1 PD2	OPT	OPT	All	OPT	OPT	OPT	Always ON	OPT	OPT	OPT	OPT	N/A
STOP	PD0 PD1 PD2	CG	CG	All	CG	OPT	OPT	OPT	OPT	CG	OPT	OPT	All peripheral interrupts, refer Wakeup Sources for various modes

Table continues on the next page...

Table 7-4. User Operating mode settings and options (continued)

Operating Mode	Powered Domains[1],[2]	Chip Features[3],[4],[5]						Clock Sources					Wake up Options
		Z2 core (PD1)	Z4 cores (PD2)	Powered SRAM Domains[6],[7],[8]	Flash (PD2)	LPU Peripherals (PD1)	Main Peripherals (PD2)	16 MHz FIRC	8MHz-40MHz FXOSC	Phase Locked Loop (PLL)	128 kHz SIRC	32 kHz SXOSC	
LPU_RUN	PD0 PD1	OPT	Off	RD0 RD1 RD2 RD3	Off	OPT	Off	Always ON	OPT	Off	OPT	OPT	All peripheral interrupts, refer Wakeup Sources for various modes
LPU_STOP	PD0 PD1	CG	Off	RD0 RD1 RD2 RD3	Off	CG	Off	OPT	OPT	Off	OPT	OPT	FLexCAN_0 (PN), no other peripheral interrupts, refer Wakeup Sources for various modes
STANDBY/ LPU_STANDBY	PD0	Off	Off	RD0 RD1[9] RD2 RD3	Off	Off	Off	OPT	OPT	Off	OPT	OPT	WKPU RTC/API Anal Comp, refer Wakeup Sources for various modes

1. *All* means all power domains, i.e., PD0, PD1, and PD2
2. PD0 is always powered during normal device operation
3. *OPT* means optionally configurable to be enabled or disabled
4. *CG* means clock gated, powered but clock stopped
5. *Off* means powered off and clock gated off
6. Depending on the specific device within the microcontroller famly, there are from 1 to 3 on-chip RAM arrays. RAM array 0 contains multiple blocks of RAM of varying sizes and each is defined by an "SRAM domain", RD0-RD3. See SRAM domains for details.
7. On-chip RAM not assigned to an SRAM domain is part of the PD2 power domain and is available only when PD2 is powered.
8. *All* means all RAM including all SRAM domains plus all additional on-chip RAM.
9. RD1, RD2, and RD3 can be independently configured to be available or not during STANDBY/LPU_STANDBY

7.4 Voltage regulators

The MPC5746C microcontroller has a sophisticated Power Management Unit (PMU) comprised of four separate voltage regulators.[1]

7.4.1 FPREG voltage regulator

The FPREG (Full Power Regulator) is a linear regulator that uses an off-chip NPN transistor as a pass device. This regulator is used during internal regulation mode of the microcontroller to generate a regulated 1.25V supply (VDD_LV). The VRC_CTRL pin controls the base of the pass device, while the VDD_LV pins of the device connect to the emitter of the pass device, as shown in diagram below. Note that VDD_HV_BALLAST is just for representation – it can be shorted to the source of VDD_HV_A supply on the application hardware.

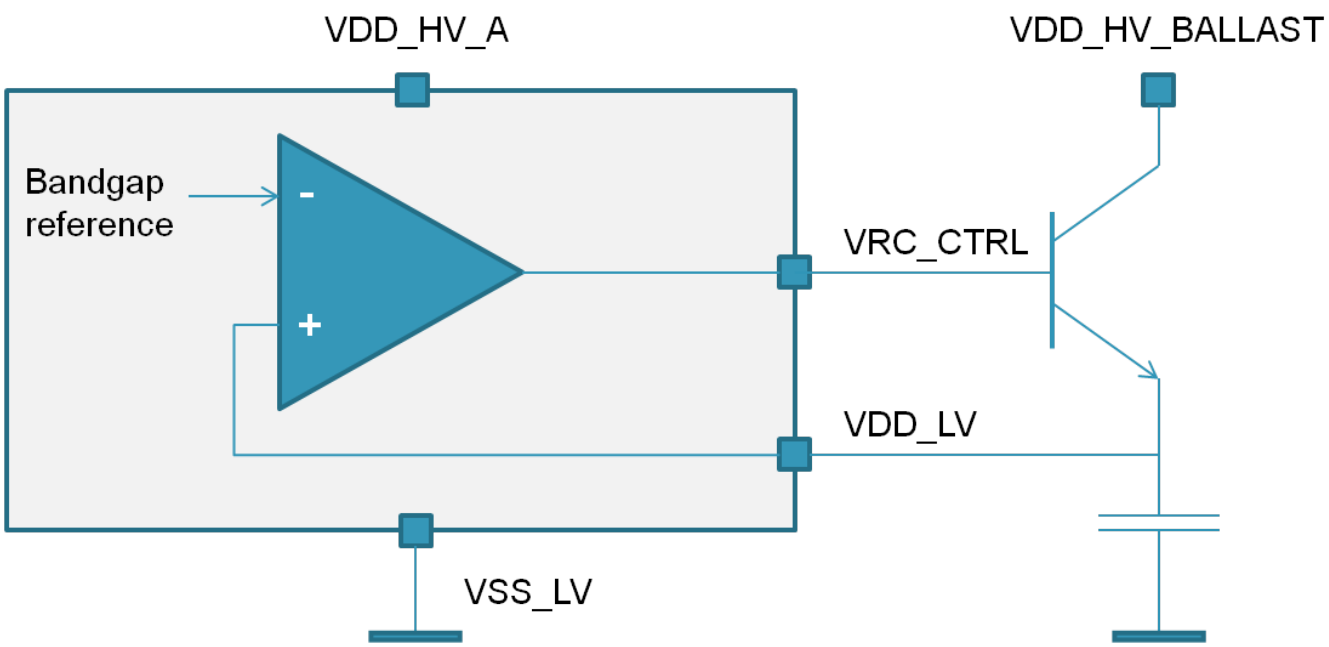

Figure 7-3. FPREG voltage regulator

NOTE

VDD_HV_BALLAST can be an independent supply from VDD_HV_A. Alternatively, these two can be shorted. The minimum voltage for VDD_HV_BALLAST must be 2.5V-10% (2.25V) in order to avoid NPN transistor saturation issues.

1. Refer to datasheet for electrical specifications of these voltage regulators.

Resistor should not be placed at the collector of NPN. Refer Table, Voltage regulator electrical specifications, from DS for related specifications.

If the core logic voltage (VDD_LV) needs to be supplied using an external on board regulator, the FPREG regulator is bypassed by not connecting the NPN pass device (leave the VRC_CTRL pin unconnected).

NOTE

Since the default configuration at boot-up is internal regulation mode, a user option bit UTEST_MISC[REG_TYPE] must be programmed to disable the FPREG regulator when it is not needed.

Disabling of the FPREG regulator is applied during RGM phase 3 when SSCM reads device configuration. Additionally, when using an external VDD_LV supply, the PORST pin must be driven until the supplies are stable. This can be accomplished by driving PORST pin such that when external VDD_LV is not stable, PORST is driven LOW externally, and once VDD_LV is stable, PORST is driven HIGH. Alternatively, another equally robust solution is to connect PORST pin to VDD_HV_A supply. In this latter case, multiple voltage monitor resets may be seen during power-up / power-down in presence of a non-monotonic VDD_LV supply.

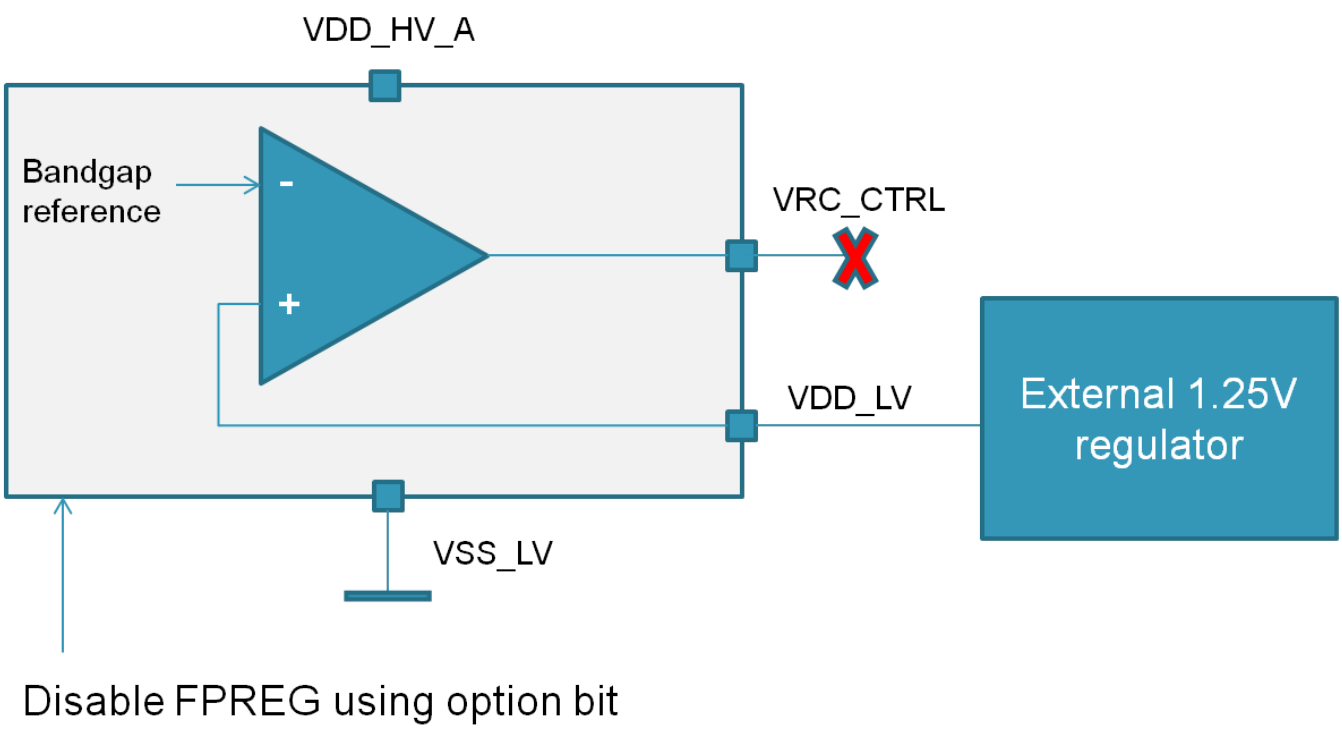

Figure 7-4. Using an externally supplied core logic power supply

NOTE

When using an externally supplied core logic power supply it is acceptable to leave the VRC_CTRL pin floating.

7.4.2 Internal regulation (Internal ballast)

The FPREG has it's ballast sitting on chip. This regulation mode is applicable to only those use cases where the RunIDD numbers are below 160mA, due to thermal limitation of the package.

7.4.3 LPREG voltage regulator

The LPREG (Low Power Regulator) is a linear regulator with an on-chip PMOS pass device. This regulator is active during LPU modes. It powers both PD1 and PD0 domains (and SW10 is closed). During these modes, power domain PD2 is powered off since SW21 is open.

NOTE

- LPREG regulator require an off-chip decoupling capacitor, which must be connected to the VDD_LP_DEC pin. Refer to the data sheet for the electrical specifications of this decoupling capacitor.
- The VDD_LP_DEC supply ramps up sometime after the VDD_LV supply has powered, regardless of whether the FPREG regulator is used.

7.4.4 ULPREG voltage regulator

The ULPREG (Ultra Low Power Regulator) is a very low power linear regulator with an on-chip NMOS pass device. This regulator is active during STANDBY modes and powers the PD0 domain. During this mode, power domains PD2 and PD1 are power gated OFF since SW21 and SW10 are both open.

NOTE

- ULPREG regulator require an off-chip decoupling capacitor, which must be connected to the VDD_LP_DEC pin. Refer to the data sheet for the electrical specifications of this decoupling capacitor.
- The VDD_LP_DEC supply ramps up sometime after the VDD_LV supply has powered, regardless of whether the FPREG regulator is used.

7.4.5 Flash voltage regulator

The Flash regulator is an on-chip linear regulator that generates 3.3 V supply for Flash memory, when the device is configured in 5 V mode (UTEST_MISC[5V_3p3V] in default state). This regulator is bypassed when device is configured in 3.3 V mode, in which VDD_HV_FLA is connected to VDD_HV_A and both are supplied by the same external 3.3V source.

NOTE

The Flash regulator always require an off-chip decoupling capacitor, which must be connected to VDD_HV_FLA pin. Refer to data sheet for electrical specification of this capacitor.

7.4.6 Regulation mode decoding scheme

Internal regulation (internal ballast) Vs internal regulation (external ballast)

INT_BAL_SELECT pin is a dedicated pin , which is used to select regulation mode between internal ballast mode Vs external ballast mode.

INT_BAL_SELECT pin tied to VDD_HV_A on board - Internal regulation (internal ballast).

INT_BAL_SELECT pin tied to ground on board - Internal regulation (external ballast).

Internal regulation Vs external regulation

The ballast is disconnected (un-mounted on board). The customer can apply the core supply externally. Selection of regulation modes between internal and external regulation mode is done by reading a bit in DCF record. In external regulation mode as soon as the DCF is read the internal regulators would be switched OFF.

Table 7-5. Configuration for regulation mode selection

INT_BAL_SELECT (PIN)	REG_TYPE (DCF bit)	FPREG (external ballast regulator)	FPREG_int (internal ballast regulator)	External regulation mode
1	x	No	Yes	No
0	0	No	No	Yes
0	1	Yes	No	No

NOTE

Last row of the table is the default configuration of the device, in which the device works in internal regulation mode with external ballast.

7.4.7 Voltage monitoring

The microcontroller features internal voltage monitoring to ensure supplies are within their correct operating ranges. If any ‘essential’ supply falls outside of its correct operating range, the voltage monitors take the device into a ‘safe, power on reset’ state. The following diagram describes the various voltage monitors and what supplies (and what point on supply) they monitor. Refer to the data sheet for details on electrical specifications for these voltage monitors.

NOTE

- The non essential supplies that are NOT shown in the diagram (VDD_HV_IO_B, VDD_HV_IO_C, VDD_HV_ADC0, VDD_HV_ADC1 and reference voltages VDD_HV_ADC1_REF and VIN1_CMP_REF) below are NOT monitored internally; it is recommended to implement external voltage monitoring on these supplies, if required.
- As shown in the followng figure, hot sense point refers to the point of maximum internal voltage drop due to routing grid. Hot point has the lowest voltage on that supply domain. Conversely, cold sense point refers to the source point for supply, which is the device supply pins.

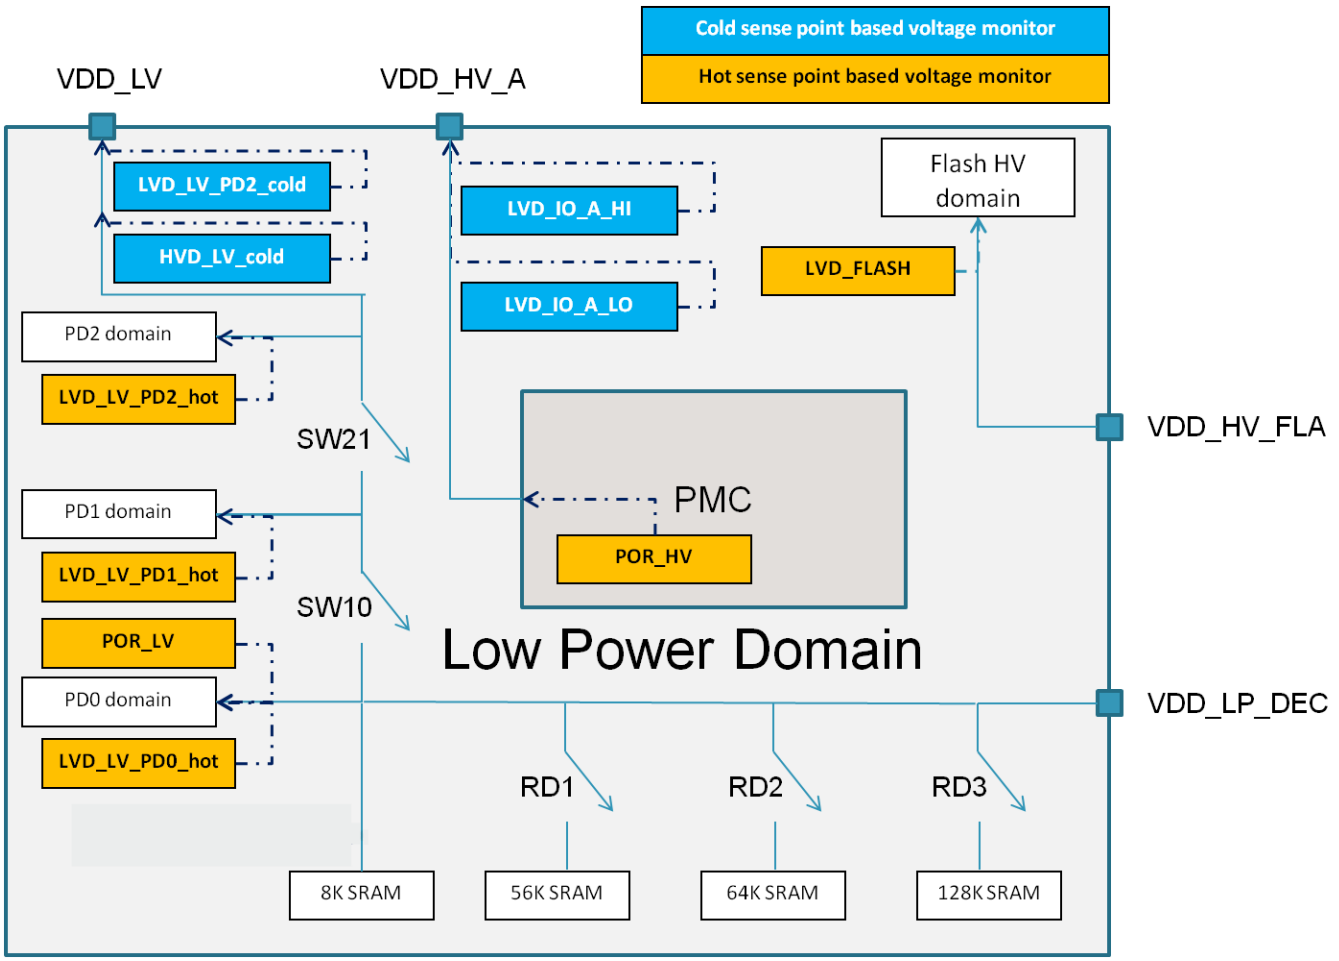

Figure 7-5. Voltage monitoring

The below table provides the complete list of voltage detect signals and their configuration in various modes. For checking there status, refer Supply Gauge Status Register (PMCDIG_SGSR)

Table 7-6. Voltage detect signals

Voltage detect signals	ULP	LP	RUN
POR_LV	ON	ON	ON
POR_HV	ON	ON	ON
LVD_LV_PD0_hot	ON	ON	ON
LVD_LV_PD1_hot	OFF	ON	ON
LVD_LV_PD2_hot	OFF	OFF	ON
LVD_LV_PD2_cold	OFF	OFF	ON
LVD_IO_A_LO	ON	ON	ON
LVD_IO_A_HI	ON	ON	ON
LVD_FLASH	ON	ON	ON
HVD_LV_cold	OFF	OFF	ON

NOTE

When the device is configured in 5V mode, the user should configure LVD_IO_A_HI as a source of functional reset before transitioning to any of the power gated low power modes (STANDBY, LPU etc.). If this configuration is not done, the device may encounter a destructive reset if VDD_HV_IO_A supply drops below 4.5V.

7.4.8 Applications and Low Power Modes

Depending on application profile, a combination of one or more power modes will be useful to optimize power dissipation and overall execution speed. For example, powering off the PD1 and PD2 power domains helps reduce power, particularly at higher temperatures.

NOTE

- When determining the optimum trade-off between fully powered and partially powered modes, consideration should be given to the energy required to recharge the system capacitances (VDD_LV pin decoupling capacitance, see the datasheet for specification).
- It is essential to perform power budgeting calculations to determine which low power mode would be more efficient. In general, the longer the time spent in a low power mode, the more efficient it is to use the advanced power gating features.

7.5 External Regulation

7.5.1 PORST in EXTERNAL REGULATION

It is recommended to drive PORST pin when using external regulation mode, such that when external VDD_LV is not stable, PORST is driven LOW externally, and once VDD_LV is stable, PORST is driven HIGH. Alternatively, another equally robust solution is to connect PORST pin to VDD_HV_A supply. In this latter case, multiple voltage monitor resets may be seen during power-up/power-down in presence of a non-monotonic VDD_LV supply.

During Low Power Modes i.e. all LPU Modes and STANDBY mode, if UTEST_MISC[PORST_MASK] is set to 0 then PORST must be kept high even if VDD_LV is supplied externally or not. Pulling PORST pin low in low power modes will result in chip getting into RESET.

In case UTEST_MISC[PORST_MASK] is set to 1 then PORST pin can be pulled low in low power modes to indicate externally supplied VDD_LV is not present. Also PORST pin can be pulled high if externally supplied VDD_LV is within operating range on low power mode exit.

The device will not exit a low power mode as long as the PORST pin is kept low.

7.5.2 External regulator contol

External regulator control functionality is provided on Pin PG[6]. It indicates if external regulator can be disabled or VDD_LV can be isolated if device is in one of the power gated mode i.e. STANDBY or LPU modes.

- External regulator control functionality on Pin PG[6] can be enabled by configuring UTEST_MISC[EXT_REG_CTRL].
- Polarity of PG[6] can be further controlled by appropriately configuring UTEST_MISC[EXT_REG_POL].
- This indication can be used to control external circuitry and either disable external regulator, or isolate VDD_LV pins from the external regulator as shown in Figure 7-6.

The circuit should be designed in such a way that electrical specs stated in the device datasheet are respected.

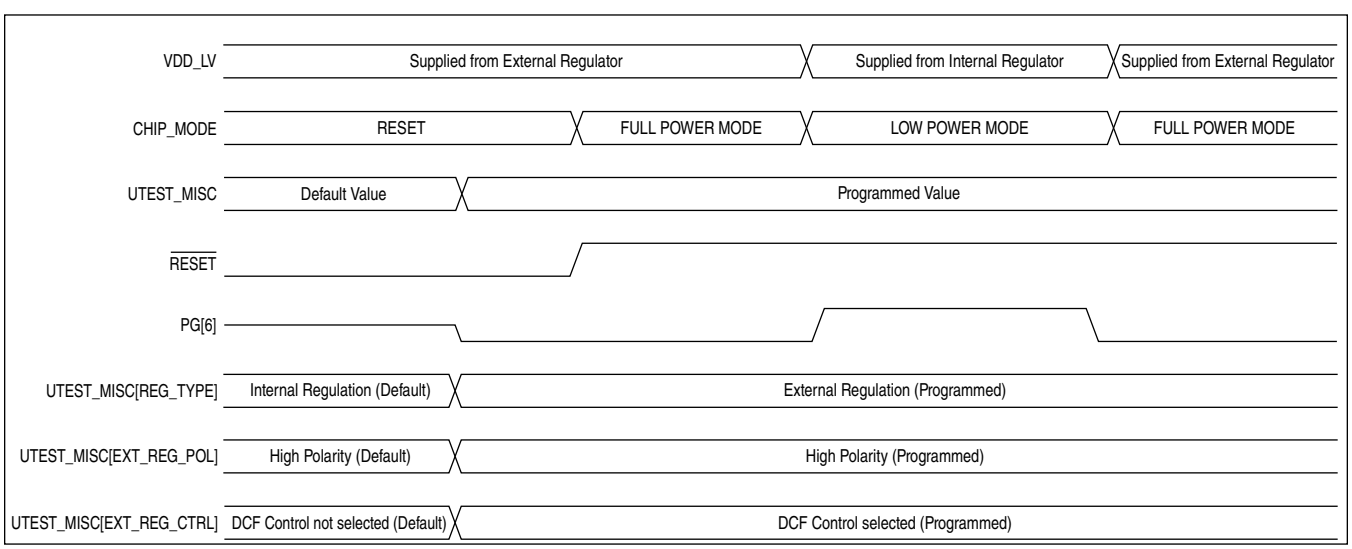

Figure 7-6. External regulator control handshake protocol

NOTE

The circuit is based upon default high polarity of EXT_REG_CTRL control signal. The pass device needs to change (NMOS to PMOS) or an inverter needs to be implemented to modify the required polarity. Refer to UTEST_MISC register for polarity details.

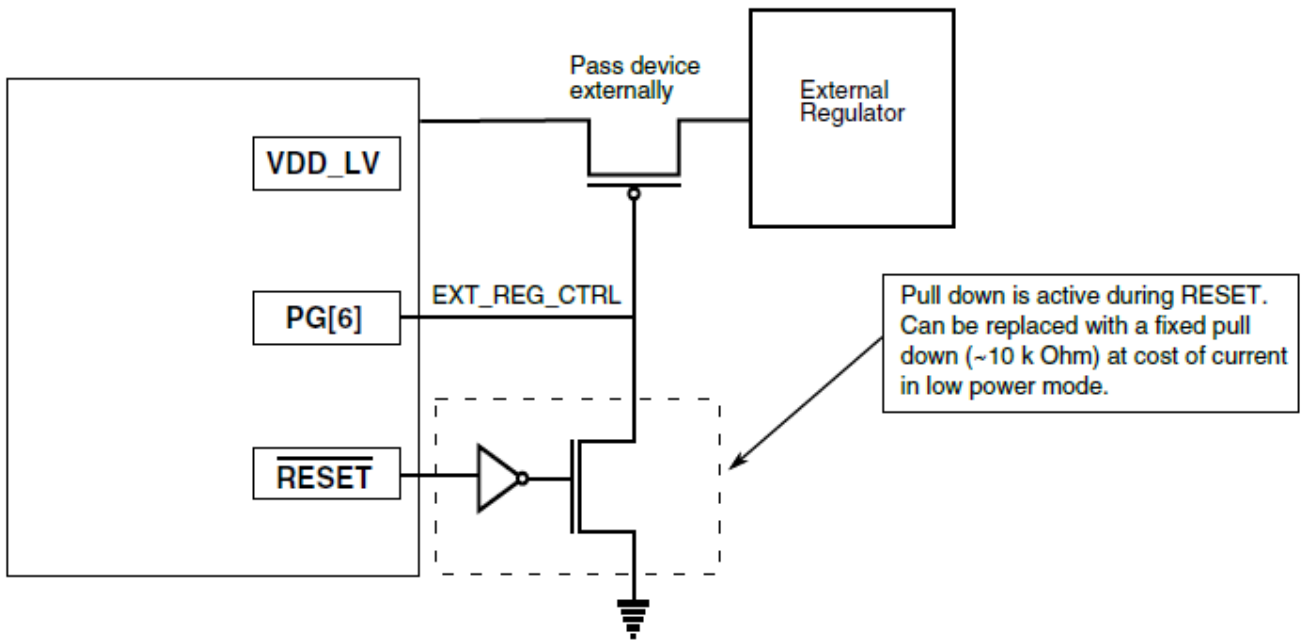

Figure 7-7. External regulator control

Alternatively, if the user is switching off the external regulator in low power mode, it is recommended to pull down the VDD_LV to at least 1.08 V.

In this case, user can program EXT_REG_EXIT_TRIM_WAIT DCF counter to indicate the external regulator stabilization time needed on low power mode exit. See External Regulation Exit Trim Wait (PMCDIG_ERETW) for details.

7.6 Accelerated Low Power Exit

Device supports reduced wakeup time on low power exit LPU or STANDBY, if executing from FLASH. The device can automatically select PLL as system clock source if MC_ME is configured prior to low power mode. This feature allows considerable improvement in low power exit time where HSM is enabled and requires RAM initialization as configured through HSM DCF options.

NOTE

If booting core is z4 and executing from SRAM, this feature cannot be used as Read Wait State needs to be configured to 1 before making read access to SRAM at PLL frequency.

PLL reference clock source is selected by MC_CGM_AC6_SC before low power mode is selected. In case FXOSC is turned off in low power mode then wakeup time will include the stabilization time of FXOSC as configured in FXOSC_CTL[EOCV].

Wakeup time is reduced because of the following enhancements:

- PLL fast lock mechanism is achieved by automatically restoring all the previous programmed PLL Configurations on low power mode exit thus saving calibration time and achieving lock faster.

NOTE

Only Last Programmed PLL configuration gets restored which was used to attain PLL Lock

.

- Automatic selection of PLL as System clock source on low power exits, thus flash and core initialization and mode transition to desired RUN can happen at faster clock frequency than FIRC.

Required Software Configurations

- ME_DRUN_MC[SYSCLK] = 0x0002 and ME_DRUN_MC[PLLON] is SET.
- ME_DRUN_MC[FXOSCON] should also be set before entering low power mode,if FXOSC is selected as the reference clock or FXOSC is available while exiting low power mode. See DRUN Mode. GPR_CTL[0] should be programmed to 1 before entering low power mode, if HSM is enabled.
- ME_DRUN_MC[SIRCON] is recommended to be set before entering low power mode,if SIRC is available while exiting low power mode.
- ME_DRUN_MC[SXOSCON] is recommended to be set before entering low power mode,if SXOSC is available while exiting low power mode. See DRUN Mode.
- PLL_DIG configured for bypass of calibration to achieve fast PLL lock. Refer PLL Wakeup from low power mode for further details.

Chapter 8
Low Power Subsystem (LPU)

8.1 Introduction

The low-power unit (LPU) is a subsystem that enables the chip to perform simple tasks with minimal power consumption. When LPU subsystem is active majority of the chip can remain power gated, thus achieving the minimal power consumption. Power Domain 1 (PD1) and Power Domain 0 (PD0) are together referred to as the LPU domain. Power Domain2 is power gated when the LPU subsystem is active. Refer to Modes of Operation for more information.

Operating modes in LPU subsystem are referred to as LPU modes. Z2 core executes from the 256 KB system RAM in LPU RUN modes. Maximum operating frequency in LPU modes is 40 MHz. Tasks performed in LPU modes can include:

- Reacting to incoming messages on the FlexCAN or LINFlexD buses.
- Performing ADC conversions and processing the results.

The chip can enter into LPU mode from any of the RUN modes by configuring the MC_ME register definition and the LPU Controller (LPU_CTL). Refer to Transition to LPU mode. LPU_CTL controls all the mode transitions and clock source configurations in the LPU subsystem independent of the mode entry module.

8.2 Block diagram

The e200z2 core has access to all the peripherals in the LPU subsystem and executes from the 256 KB RAM.

Modules in power domain 0 (PD0) are always powered. Modules in power domain1 (PD1) will be power gated in LPU_STANDBY mode. Refer to Modes of Operation for more details.

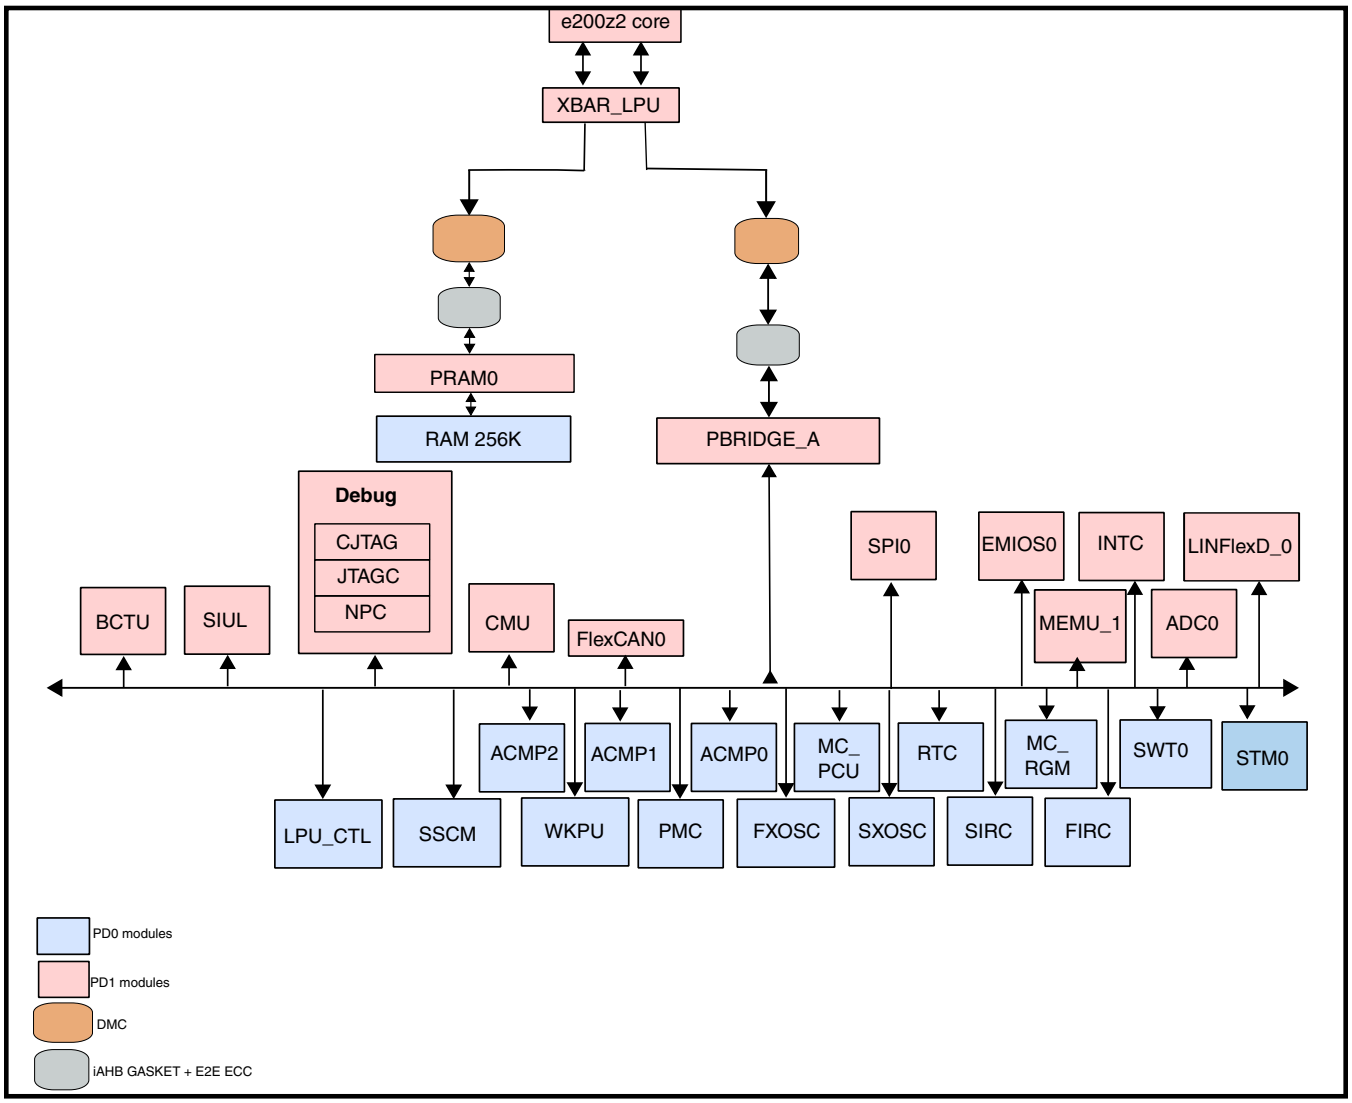

Figure 8-1. LPU subsystem diagram

8.3 Features

- The LPU subsystem can enter into three low-power modes:
  - LPU_SLEEP
  - LPU_STOP
  - LPU_STANDBY
- Nexus class one seamlessly through RUN and LPU mode
- Debug through LPU_STOP and LPU_STANDBY is supported
- Full interrupt support from LPU domain peripherals
- Clock sources available:
  - FIRC
  - FXOSC

    - SIRC
    - SXOSC
- A divided FIRC or FXOSC are available as a system clock source.
- Clock monitoring unit available for measurement of frequency for all clock sources and frequency range check for FXOSC.
- The MEMU module captures faults from the following four sources and raises an interrupt or NMI to the z2 core:
    - AHB_E2E_ECC error from PBRIDGE A
    - z2 intstruction bus error
    - z2 data bus error
    - PRAM_E2E_ECC error from PRAM_CTL0
- Pretended Networking supported on FlexCAN0. It is also possible to wake up from LPU_STOP to LPU_RUN with only the protocol engine clock of FlexCAN0 working when a valid match is found on received message buffer. For details, refer FlexCAN configuration.
- Configurable FlexCAN0 wakeup events:
    - Wakeup on “bus off”
    - Matching message: Receives a pre-configured message
    - Matching message and data: Pre-configured message and RX data matches value
    - Matching range of messages: RX a range of pre-configured messages
    - Matching message range and data
    - Matching data received n times
    - Pre-configured data missing over specific time
    - Pre-configured network management message missing over a specific time
    - Payload length error if a pre-configured message

- Configurable FlexCAN0 Transmit Messages
    - Transmit network management message
    - Transmit pre-configured static message

NOTE

LPU_STANDBY mode is the mode when power domain 1 is power-gated. This mode is entered from LPU_RUN mode. If the chip enters power-gated mode from normal RUN mode, it is referred as STANDBY mode. The only difference between the two modes is how the clock sources are configured. Select the clock sources to be on or off by configuring:

- ME_STANDBY0_MC for STANDBY mode
- LPU_STANDBY_CF for LPU_STANDBY mode

8.4 Modes of operation

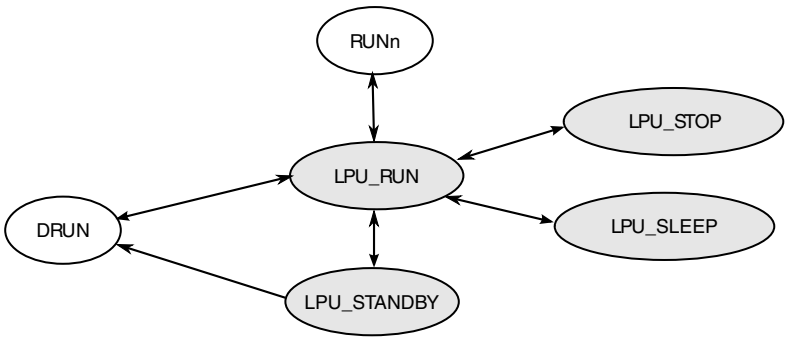

Figure 8-2. LPU modes

- **LPU_RUN**
  - All modules in the LPU domain have their clocks enabled.
  - The chip can enter into LPU_RUN mode under the following conditions:
    - From any of the RUN modes by configuring the ME_MCTL and LPU_MCTL registers.
    - On exit from LPU_STOP,LPU_SLEEP
    - On exit from LPU_STANDBY, if LPU_MCTL[DIRECT_DRUN] is not set.
  - The chip can exit to DRUN, LPU_STOP, or LPU_STANDBY only via configuring the LPU_MCTL register.
  - FIRC is always ON during either LPU_RUN or LPU_SLEEP mode. All other clock sources can be disabled. LPU domain modules can be configured via LPU_MDIS to be clock gated. To change clock source configuration or clock gate modules, an LPU_RUN-to-LPU_RUN mode transition is required.
- **LPU_SLEEP**
  - In this mode, the z2 core enters low-power state and its clock is gated. All other modules in the LPU domain have their clocks enabled by default and can be disabled by configuring LPU_MDIS.
  - The device can enter into LPU_SLEEP mode from LPU_RUN mode.
  - The device can exit to LPU_RUN mode on any peripheral interrupt or external interrupt, or WKPU source.
  - All the LPU peripheral interrupts can cause exit from LPU SLEEP.
- **LPU_STOP**
  - In this mode, the z2 core enters the low-power state and its clock is gated. FLexCAN pretended network feature is available but all peripherals are stopped, clocks are gated to all modules in LPU domain. Clock sources are enabled or disabled by configuring the LPU_STOP_CF register.

- The chip can enter LPU_STOP mode from LPU_RUN mode.
- The chip can exit to LPU_RUN mode when a wakeup event comes from WKPU, SWT timeout, RTC/API, or FlexCAN pretended network interrupt.

NOTE

There should be no pending interrupts or outstanding transactions as it may not allow entry in LPU_STOP. To centrally ensure this, all modules can be disabled by configuring LPU_MDIS in LPU_RUN to LPU_RUN mode transition followed by LPU_STOP mode entry. To bypass STOP acknowledge handshake with LPU domain modules, refer GPR_CTL[LPU_STOP_ACK_BYPASS].

- **LPU_STANDBY**
  - This mode is entered when the chip enters STANDBY mode from LPU_RUN mode.
  - All modules in the PD1 domain are power gated.
  - Device can exit to LPU_RUN mode or DRUN mode when a wakeup event comes from the WKPU, SWT timeout interrupt, or RTC/API timeout interrupt. An Analog comparator can also provide wakeup functionally, if enabled.To exit to DRUN mode, LPU_RUN_CF[DIRECT_DRUN] should be set to 1 before requesting for LPU_STANDBY mode transition.

The following guidelines should be observed when preparing to enter an LPU mode before initiating further low power mode request in LPU:

- LPU_SR[PD2_PWR_STAT] should be polled to be 0 to ensure PD2 is power gated.
- FIRC_CTL[FIRCDIV] should be configured to 0x0 before initiating LPU_STANDBY mode request. It should be reconfigured appropriately on exit to LPU_RUN or DRUN from LPU_STANDBY exit
- PMC_RDCR[PAD_KEEP_EN] should be configured appropriately.
- PMC_RDCR[RD*_RETN] should be configured appropriately

8.5 Transition to LPU mode

The following flowchart shows the hardware state transition from user RUNx/DRUN mode to LPU subsystem RUN mode, that is, LPU_RUN.

Care should be taken that there are no active ongoing transactions on power domain 2 peripherals. Clocks to the processor are gated after the acknowledgement of the low-power stop request from the MC_ME.

The LPU subsystem is enabled after gating the main XBAR clock, while the power gating mechanism is ongoing. Enabling the LPU subsystem before power gating PD2 will allow the z2 core to be available as early as possible to service power domain 1 peripherals, if required.

Clock source enabling and disabling is controlled by the LPU_RUN_CF register as soon as TARGET LPU_RUN mode is requested.

NOTE

The device can enter LPU_STOP or LPU_STANDBY mode from LPU_RUN mode only. The following mode transitions are illegal and if attempted will result the chip to go into STANDBY mode:

- Any RUN/DRUN to LPU_STOP
- Any RUN/DRUN to LPU_STANDBY

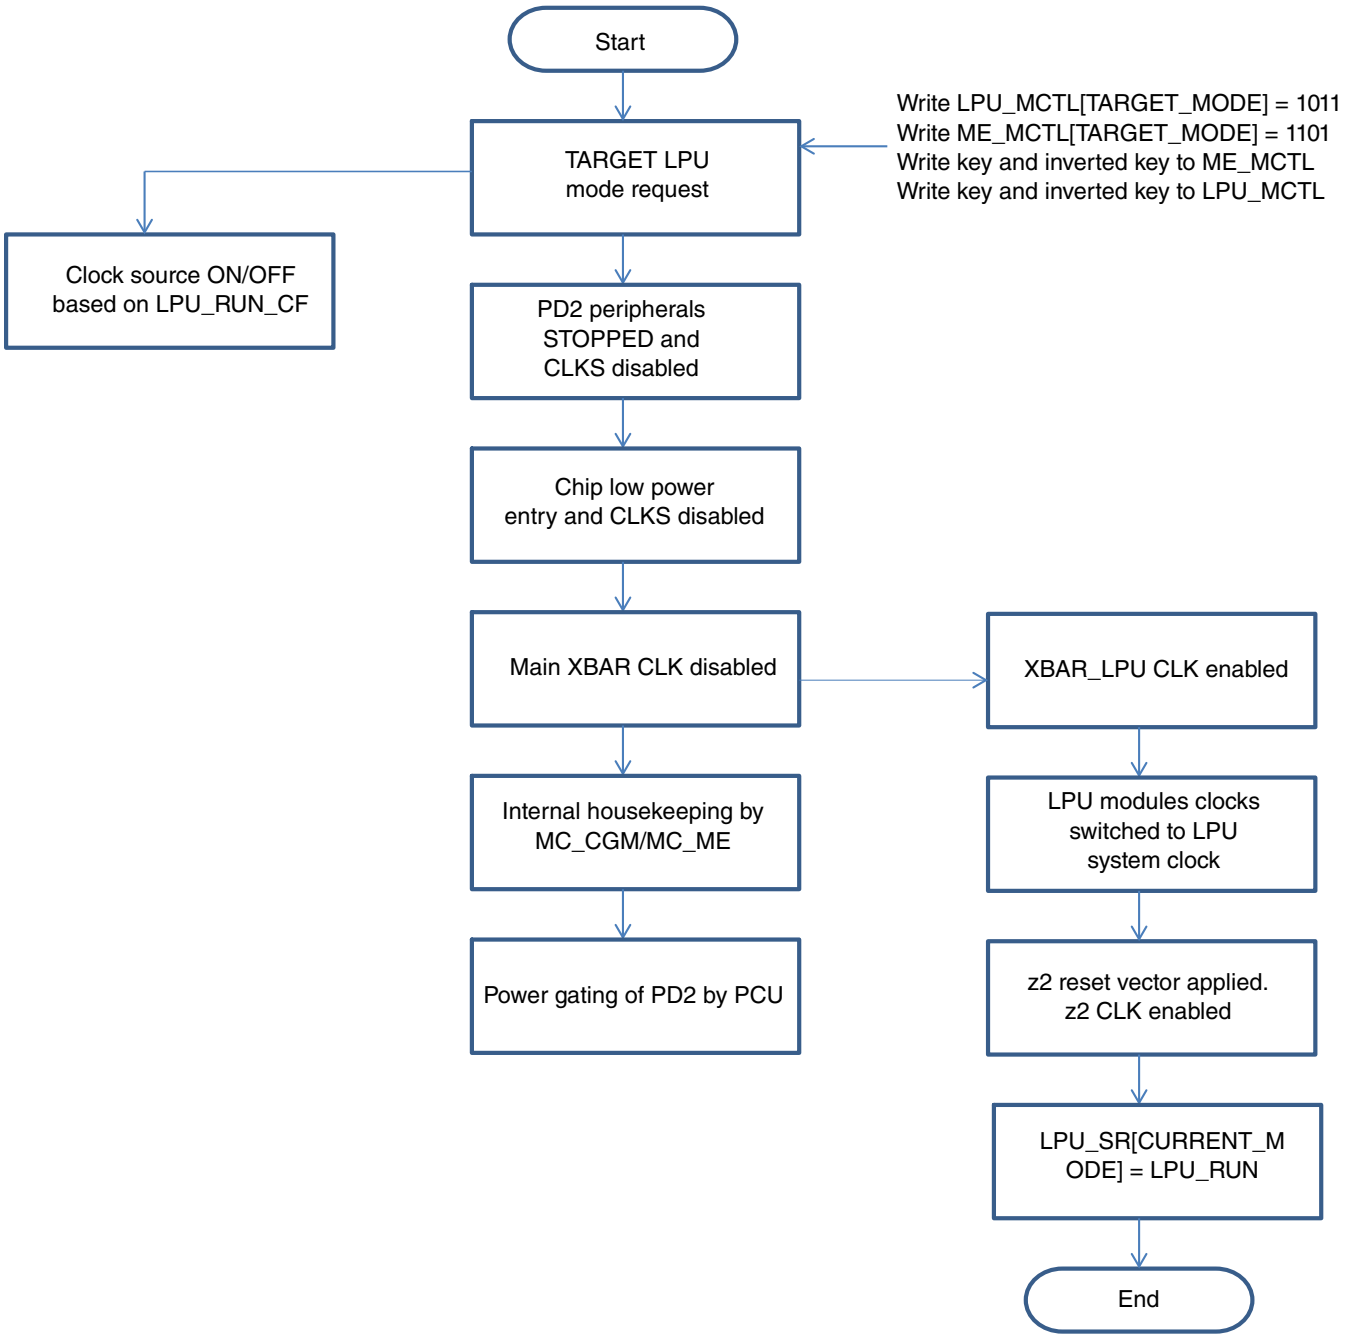

Figure 8-3. Mode transition to LPU mode

NOTE

The transition to LPU mode will not complete if any of the cores are in debug mode.

The following basic code snippet demonstrates how the registers and bit fields are programmed to transition from DRUN to LPU_RUN mode. LPU entry can be carried out on any of the cores: z4 or z2.

```
void LPU_RUN_init ()
```

Transition to LPU mode

```
{
LPU.LPU_RUN_CF.B.CRSxON = 1;           /* Enabled clock sources for LPU_RUN mode. */

/* LPU_RUN init */
LPU.LPU_MCTL.B.TARGET_MODE = 0b1011;   /* Request for LPU_RUN mode */
LPU.LPU_MCTL.B.KEY = 0x5AF0;           /* Write the key to initiate mode change. */
LPU.LPU_MCTL.B.KEY = 0xA50F;           /* Write the inverted key to finalise the */
                                       /*  mode change. */

/* Mode Entry - Standby0 mode init */
/* In order to enter into LPU_RUN mode, Standby0 must be */
/* initialized to disable non-required functionality. */
MC_ME.MC_ME_MCTL.B.TARGET_MODE = 0b1101;   /* Configure ME for standby0 entry. */
MC_ME.MC_ME_MCTL.B.KEY = 0x5AF0;           /* Write the key to initiate mode change. */
MC_ME.MC_ME_MCTL.B.KEY = 0xA50F;          /* Write the inverted key to finalise the mode
change. */
                                                                    /* Loop here until the
Standby0 mode */
                                                                   /*  transition has
occurred by reading */
                                                                 /*  back the current
operating mode. */

/* Loop here until the LPU mode transition has occurred */
/* and also read back the current operating mode. */
while((LPU.LPU_SR.B.MTRANS != 1) && (LPU.LPU_SR.B.CURRENT_MODE = 0b1011));
}
```

The following guidelines should be observed when preparing to enter an LPU mode:

- Ensure steps have been taken to initialize the appropriate core via the Mode Entry registers MC_ME_CADRR*n* and MC_ME_CCTL*n*.
- LPU clock source configuration must be done prior to an LPU mode transition request because the new configuration is selected only after a valid mode transition.
- Prepare to enter LPU modes by writing appropriate LPU target mode and keys to the LPU Mode Control Register, LPU_MCTL.
- To complete the transition, enable STANDBY mode via the Mode Entry registers, which provides the necessary preparation of disabling functionality not required within the LPU modes.Please ensure all software guidelines mentioned for STANDBY mode in MC_ME chapter are followed here.
- LPU mode transition status, LPU_SR[MTRANS], is asserted only after the mode entry target mode is configured to be Standby0.
- Complete the transition by reading the LPU status register, LPU_SR, for transition complete and current mode as expected.
- Register protection configuration should follow the guideline mentioned in section: Register protection configuration

NOTE

SWT_0 enabling or disabling is prohibited in LPU modes. It should be configured prior to entry in LPU.

NOTE

After initiating any mode transition, the software should poll for LPU_SR[MTRANS] before initiating any other mode transition.

For the DRUN -> (LPU modes) -> DRUN transition, any one of the following two conditions should be satisfied by the software:

- If FXOSC is to be used in LPU modes as LPU_SYS_CLK, then FXOSC should be kept ON in DRUN before/after LPU mode is entered/exit.
- If LPU RUN is entered with FXOSC off in DRUN mode, then LPU_SYS_CLK should be made as IRC before entering into LPU STANDBY.

8.6 Exit from LPU Modes

The following flowchart shows the hardware state transition from user LPU_RUN to DRUN mode.

Exit from LPU_RUN to DRUN

This can be initiated by software by configuring LPU_MCTL. LPU_CTL requests PMCDIG to initiate power up of Power Domain 2. Glitch free clock switching occurs from LPU_SYS_CLK to CGM_CLK on LPU mode exit. LPU peripherals will be clock gated. Care should be taken that there are no active ongoing transactions on LPU peripherals before requesting exit to DRUN mode. Clocks to the processor are gated after the acknowledgement that Power Domain 2 is powered. Power Domain 2 goes through reset sequence and z2 core is enabled if it was configured via ME_CADDR and ME_CCTL prior to entry in LPU modes.

Clock source enabling and disabling and mode transition controls are now transferred back to ME from LPU_CTL.

Exit from LPU_STANDBY to DRUN

Any wakeup source can take the chip back to DRUN mode, if LPU_RUN_CF[DIRECT_DRUN] was configured to 1 before LPU_STANDBY mode transition request was initiated. Exit sequence is identical to exit from DRUN except that LPU peripherals and processors were already power gated in LPU_STANDBY, so no housekeeping is required by software

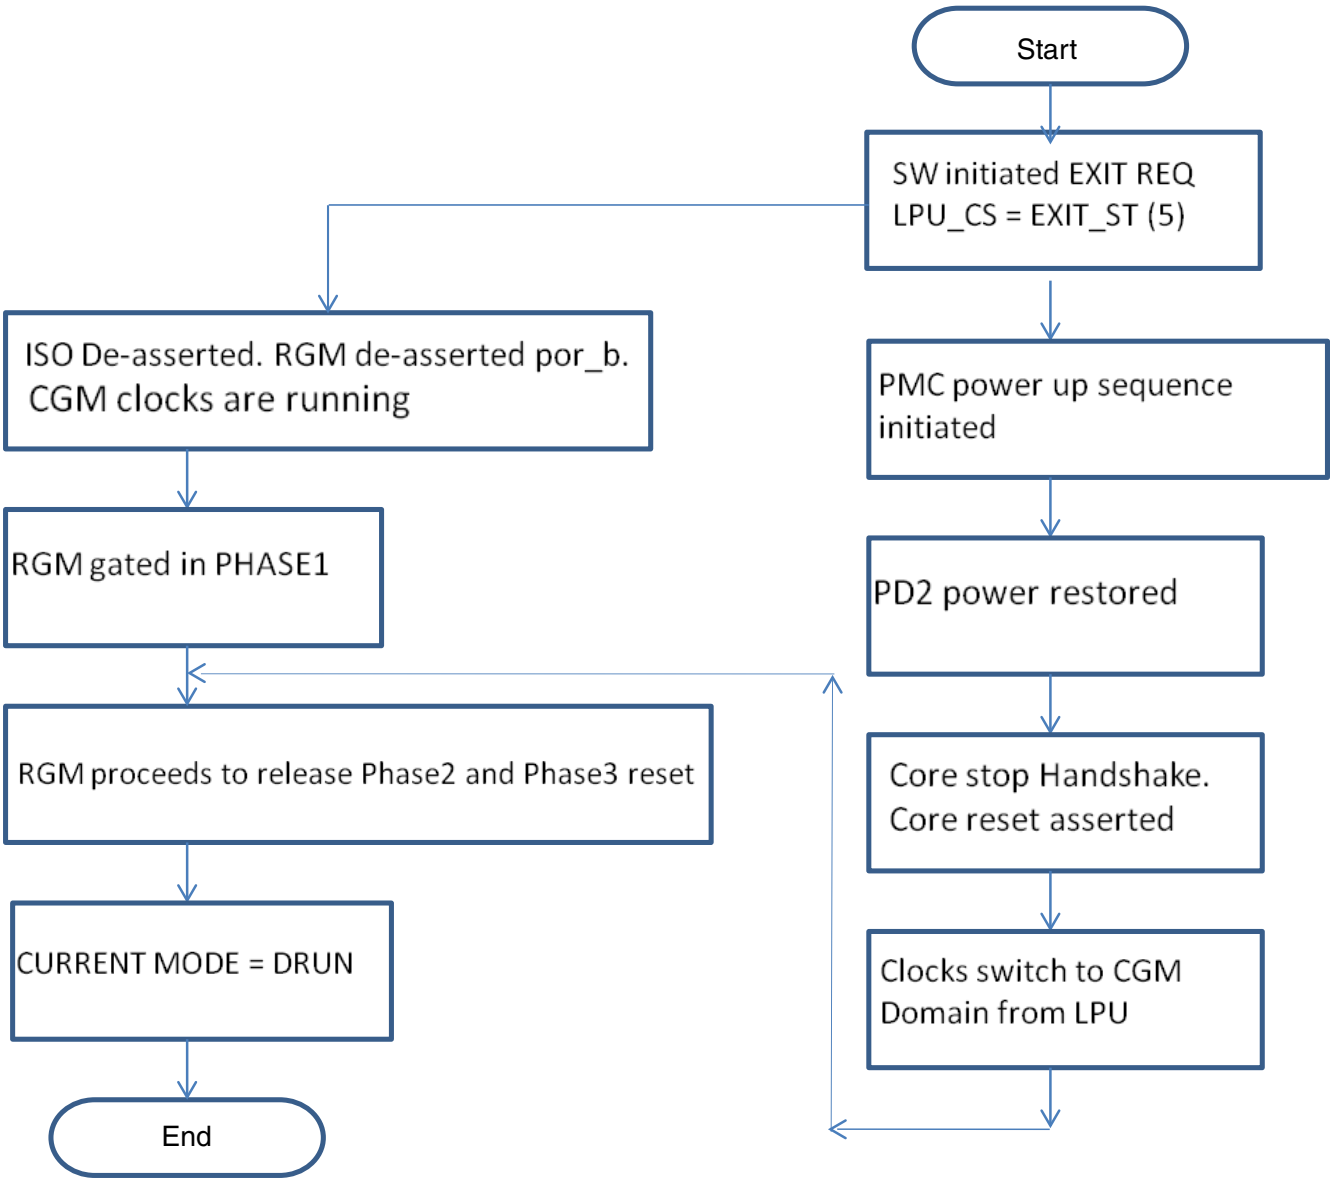

Figure 8-4. Exit from LPU_RUN to DRUN

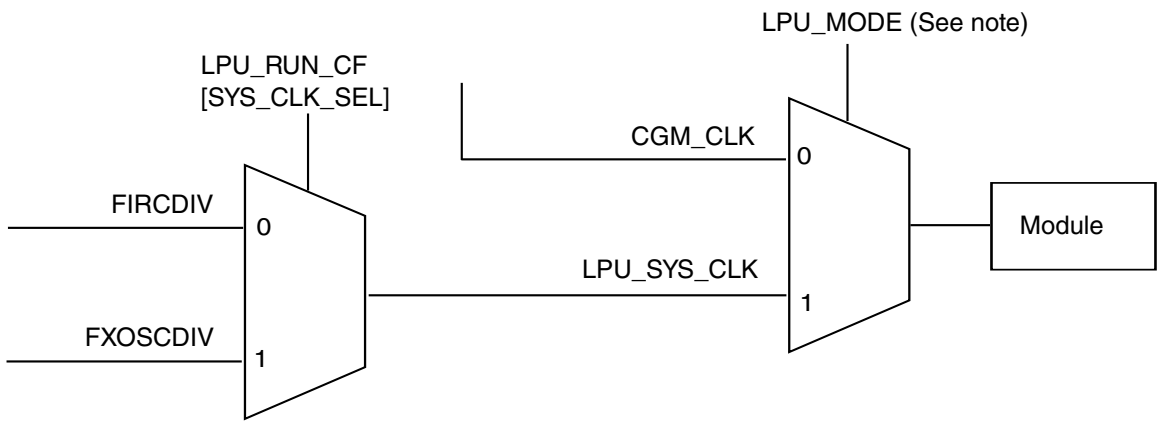
8.7 Clocking

8.7.1 LPU System Clock Generation



The two primary clock sources, FIRC and FXOSC, are the source of the system clock network in the LPU domain (see Clocking chapter for details). The 16 MHz FIRC clock is the default clock source in LPU_RUN mode. The frequency of the LPU system clock

can be scaled down by configuring the FIRC and FXOSC dividers via the FIRC_CTL and FXOSC_CTL registers, respectively. SIRC and SXOSC are also available for timers, for example, SWT and RTC (see SWT and RTC).

In LPU modes, the LPU system clock is the multiplexed output of either the FIRC divider or the FXOSC divider as shown below. The maximum operating frequency is 40 MHz.

All the module clocks switch from MC_CGM (CGM_CLK) to LPU_SYS_CLK. For example, the z2 clock is sourced from the S80 group, but in LPU mode it will be sourced from the LPU_SYS_CLK. There is a multiplexer between CGM_CLK and LPU_SYS_CLK for each clock frequency node in frequency groups, that is, F160, S160, S80, F80, F40, S40, FS80, and F20. Refer to Clock Generation Module (MC_CGM) for clocking details.

All the module clocks will be gated for period less than or equal to 2 clock cycle of current clock plus 2 clock cycle of next clock period to allow glitch free switching of clocks to LPU_SYS_CLK.

Note: LPU_MODE implies any of the three LPU modes - LPU_RUN, LPU_STOP, LPU_SLEEP, and LPU_STANDBY. There is no software control for this mux. Switching is handled during RUN to LPU_RUN transition protocol.

Figure 8-5. LPU clocking

NOTE

If the CGM mapped peripherals registers of module FIRC, FXOSC, SIRC, SXOSC, CMU are protected under Register protection scheme before transitioning to LPU mode then the protected registers will not be accessible during LPU mode for further write operation. Protected register would be available for read operation. Hence if any register is required to be modified during LPU mode then software should ensure that these registers should remain unlocked under register protection scheme.

NOTE

FIRC, FXOSC, SIRC, SXOSC, CMU registers cannot be locked under register protection scheme during LPU mode.

8.7.2 FlexCAN0 Clocking

CAN0 Clocking

During an LPU mode, working clock of all modules except CAN0 will be the same as the LPU system clock.

Device can be configured to support seamless operation of CAN0 during LPU_RUN mode entry and exit. This can be ensured by providing continuously running clock through an independent mux. This configuration should be done before CAN0 is enabled in device DRUN/RUNx modes. CAN0 CHI and PE interfaces would be synchronously operating with frequency ratio 1:1 and corresponding CAN network configurations should be done based on max CHI frequency equal to FXOSC frequency.

- MC_CGM_AC9_SC should be configured to select FXOSC. Refer FlexCAN clocking
- LPU_RUN_CF[CAN0_CONT] should be SET to ensure seamless operation on LPU_RUN to DRUN. Refer LPU Memory map and register definition

8.7.3 LinFlexD Clocking

LINFlexD[0] requires 2 clocks for operation : BUS_CLK and BAUD_CLK. Frequency of these clocks should satisfy the equation freq(BAUD_CLK)/3 is less than freq(BUS_CLK) and freq(BUS_CLK) is less than BAUD_CLK.

- **BAUD CLK:** Baud clock is generated from F40 node It is recommended to select FXOSC as source of baud clock. The baud clock may disappear for few cycles while switching from CGM_CLK to LPU_SYS_CLK.
- **BUS CLK:** While entering LPU modes, F20 node which is the BUS_CLK of LINFlexD[0] is same as LPU_SYS_CLK. A divider is automatically enabled to scale F20 node by 2 in LPU modes. Refer LINFlexD clocking

8.7.4 SPI_0 Clocking

SPI requires 2 clocks for operation : BUS_CLK and BAUD_CLK. BAUD_CLK is absolutely asynchronous to BUS_CLK. Baud clock is generated from a mux which is controlled by MC_CGM_AC8_SC. It is recommended to select FXOSC as source of

baud clock. If F40 is selected as source of baud clock than this clock may disappear for few cycles while switching from CGM_CLK to LPU_SYS_CLK. Refer DSPI/SPI clocking

8.7.5 LPU clock source control

For all LPU modes, clock source enabling and disabling is controlled by the LPU mode configuration registers.

FIRC cannot be disabled in LPU_RUN mode or LPU_SLEEP mode. All the module clocks, that is, clocks that are operating from the LPU system clock, will be gated in the LPU_STOP mode and the LPU_STANDBY mode. For more information, see the Table 7-4.

All clock sources can be disabled in any of the low-power modes, that is, LPU_STOP and LPU_STANDBY.

8.8 Reset

Reset generation and control is supported through the MC_RGM module. Both destructive and functional resets are supported.

The only reactions possible via functional reset sources is Long Reset or Short Reset. It is not possible to generate a SAFE mode request or interrupt via the MC_RGM while in LPU mode.

On reset, the chip will exit to DRUN mode from any of the LPU modes.

NOTE

During Low Power Modes i.e. all LPU Modes and STANDBY in external regulation mode PORST must be kept high even if VDD_LV is supplied externally or not. Pulling PORST pin low in case VDD_LV is not driven externally in low power modes will result in chip getting into RESET.

Following are the active reset sources in the LPU mode.

Table 8-1. Destructive reset sources

Reset Source Mapping	Destructive Reset Source	Reactions Possible	Bidirectional External reset generation/Software control
7	SWT0 (flash initialization error)	Destructive	Yes/Read_only

Table 8-2. Functional reset sources

Reset Source Mapping	Functional Reset Source	Reactions Possible	Bidirectional External reset generation/Software control
4	NMI from wakeup unit	Long/Short	No/Read_Write
5	JTAG Reset	Long/Short	No/Read_Write
7	FXOSC frequency out of range from CMU	Long/Short	No/Read_Write
12	z2 Debug Reset	Long/Short	No/Read_Write
13	LVD_IO_A_HI Reset	Long/Short	No/Read_Write

NOTE

If the application software is required to trigger a software reset in LPU_RUN this can be achieved via z2 core register DBCR0[RST]. This reset will be flagged at RGM_FES[F_Z2_DBG].

The LPU_CTL can enter, gate, or control the reset process as listed in the following table together with their type of contribution.

Table 8-3. Reset Process Modules

Module	Contribution Type		
	event	gating	control
LPU_CTL	Yes	Yes	Yes

The types of contribution are described in the following table.

Table 8-4. Module contribution type

Contribution Type	Description
event	The module may generate events which may trigger the entry into a reset state, if the event configuration in the MC_RGM allows this.
gating	The module can prevent the exit of a reset state if it has not reached a certain internal state.
control	The module controls the sequence of the reset process.

8.9 Interrupts

Interrupts from modules in the LPU domain are supported. Interrupt mapping is consistent across full modes to LPU modes. Refer to INTC interrupt sources for details.

NOTE

If any interrupt is pending before requesting mode transition to LPU_STOP and LPU_STANDBY, the mode transition request would be ignored.

8.10 Boot

On entry into LPU_RUN mode, the z2 is reset and starts executing from SRAM0 at 0x4000_0000 on reset de-assertion. On LPU_STANDBY exit to LPU_RUN mode, the z2 starts executing from SRAM0 at 0x4000_0000. The device can boot from any core on exit from LPU_RUN/LPU_STANDBY mode.

Upon LPU_STANDBY exit to DRUN mode, which can happen if the exit occurs due to a reset event or LPU_RUN_CF[DIRECT_DRUN] bit is set before entering in LPU_STANDBY, the z2 will start executing from the address configured in MC_ME[CADDR3] if it is enabled in MC_ME[CCTL3]. For more information see, Table 13-18.

NOTE

Configure MC_ME[CADDR*n*] and MC_ME[CCTL*n*] prior to entering LPU_RUN mode.

8.11 LPU Controller (LPU_CTL)

The LPU controller module controls the mode transition sequences for LPU modes. It also contains configuration, control, and status registers accessible to the application. The LPU controller takes ownership to control the mode from the MC_ME module whenever the chip enters LPU_RUN mode. The LPU controller generates the necessary control signals during various LPU modes for the following:

- clock gating and clock source control
- reset control
- debug handshake across RUN to LPU_RUN and within LPU_MODES

8.11.1 Memory map and register definition

LPU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	LPU Mode Control Register (LPU_MCTL)	32	R/W	3000_A50Fh	8.11.2/172
4	LPU Run Configuration Register (LPU_RUN_CF)	32	R/W	0000_0001h	8.11.3/174
8	LPU Stop Configuration Register (LPU_STOP_CF)	32	R/W	0000_0001h	8.11.4/176
C	LPU Standby Configuration Register (LPU_STANDBY_CF)	32	R/W	0000_0001h	8.11.5/177
10	LPU Status Register (LPU_SR)	32	R	0001_8003h	8.11.6/178
14	LPU Interrupt control register (LPU_ICR)	32	w1c	0000_0000h	8.11.7/181
18	Module Disable (LPU_MDIS)	32	R/W	0000_0000h	8.11.8/183

8.11.2 LPU Mode Control Register (LPU_MCTL)

This register is used to trigger software-controlled LPU mode changes. Software can configure LPU_MCTL[TARGET_MODE] to DRUN, LPU_STOP, or LPU_STANDBY only when the current mode is LPU_RUN.

Byte and half-word write accesses are not allowed to this register because a predefined key is required to change its value.

NOTE

Further low power mode transitions i.e. LPU_STANDBY and LPU_STOP should not be requested if LPU_SR[PD2_PWR_STAT] is 1. Software should wait for PD2 to be power gated before requesting further low power modes.

NOTE

Software should always check PMCDIG_MCR[LP_ST_CHG_IN_PRGRS] is 0 before a new mode transition request is initiated.

Address: 0h base + 0h offset = 0h

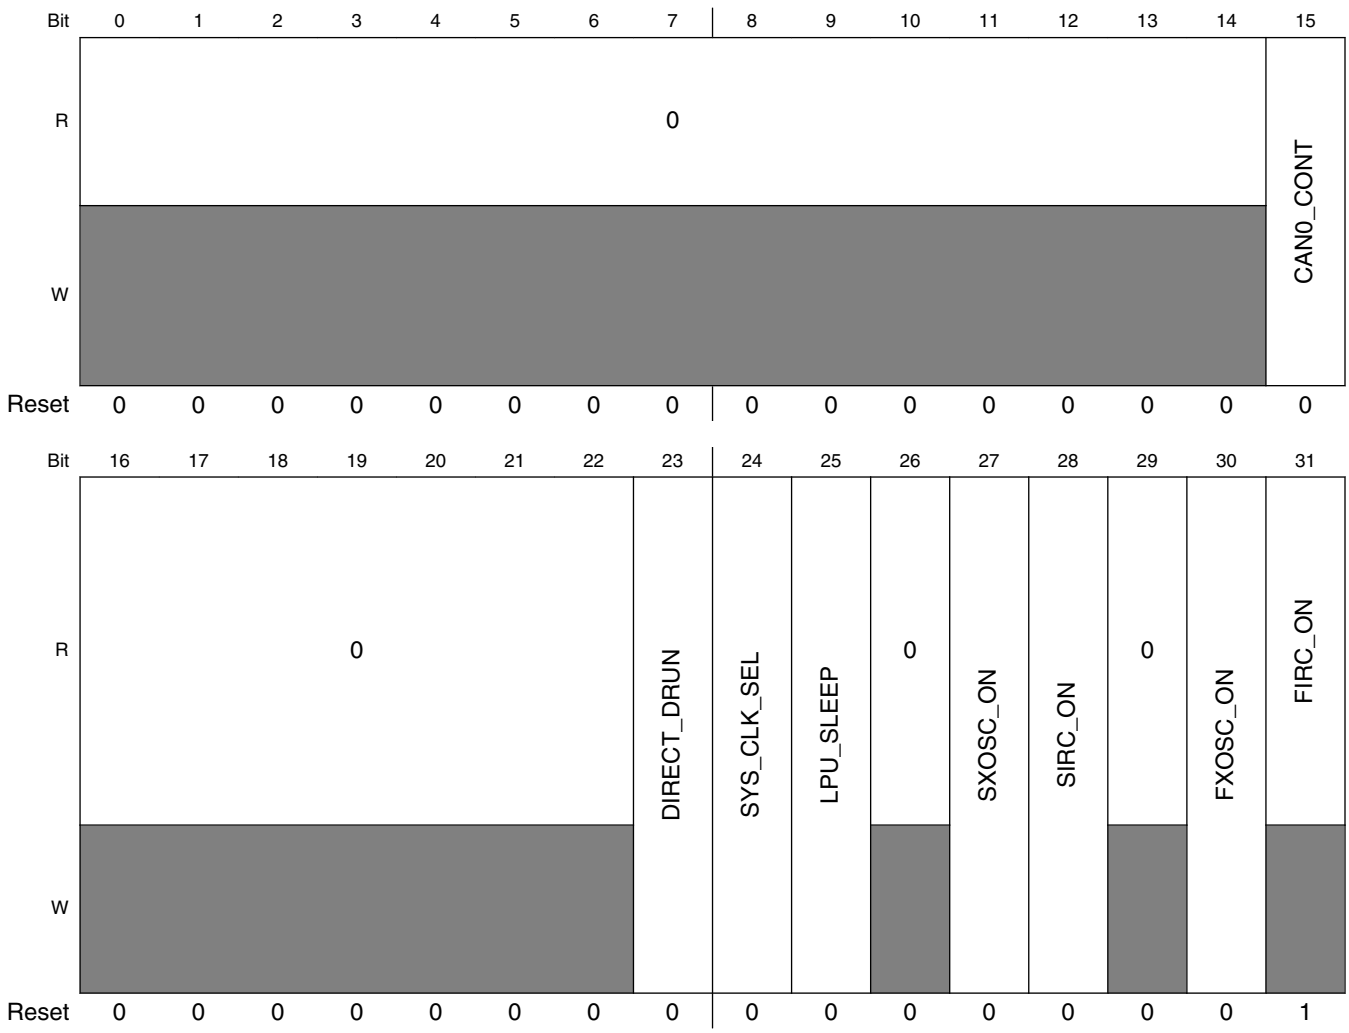
	1. Write key. 2. Write inverted key. **NOTE:** LPU_SLEEP is entered by configuration of LPU_RUN_CF[LPU_SLEEP]. 0011 DRUN 1011 LPU_RUN 1100 LPU_STOP 1110 LPU_STANDBY
4–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 KEY	This field provides the key to change the target mode. Any write access to the register with a value different from the keys is always ignored. Read access will always return the inverted key KEY: 0101_1010_1111_0000 (0x5AF0) INVERTED KEY: 1010_0101_0000_1111 (0xA50F)



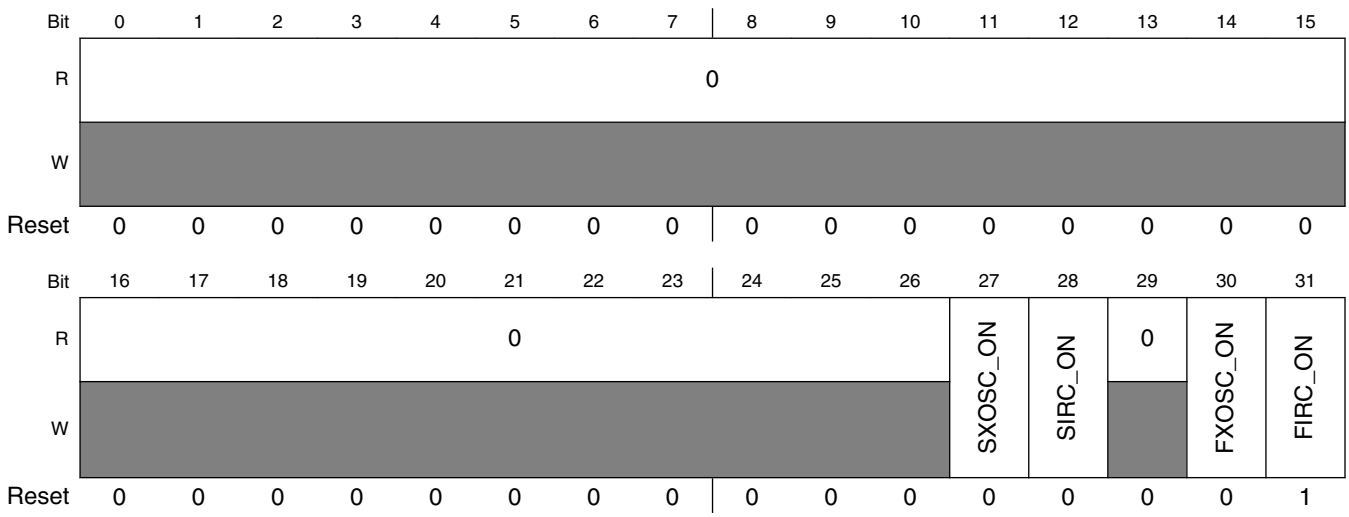
8.11.3 LPU Run Configuration Register (LPU_RUN_CF)

This register configures system behavior during LPU_RUN.

NOTE

LPU_RUN_CF[SYS_CLK_SEL] should never be changed from 1 to 0 in DRUN/RUNx modes. Also, if LPU_RUN_CF[SYS_CLK_SEL] is selecting FXOSC then LPU_RUN_CF[FXOSC_ON] should also be SET.

Address: 0h base + 4h offset = 4h



LPU_RUN_CF field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 CAN0_CONT	CAN0 continuous operation across LPU modes. CAN CHI frequency will switch from FS80 to LPU_SYS_CLK which will require reconfiguration thus inhibiting continuous operation across LPU modes. 0 Continuous CAN0 operation is not supported 1 Continuous CAN0 operation is supported. CAN0 needs to be operated by selected FXOSC as the source of its CHI clock by configuring MC_CGM_ACx
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

LPU_ICR field descriptions (continued)

Field	Description
14 Reserved	This field is reserved.
15 Reserved	This field is reserved.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 LPU_MRIG	LPU mode request ignored This field is set if during LPU_RUN the core tries to enter a low-power mode, that is, LPU_STOP or LPU_STANDBY, while the interrupt is pending. The core is still able to go to DRUN mode, however. 0 Mode request ignored interrupt is not pending 1 Mode request ignored interrupt is pending
29 LPU_NEM	LPU non-exist mode interrupt This field is set if the mode transition request through the LPU_MCTL register is to a nonexistent mode, that is, not one of the four valid modes: DRUN, LPU_RUN, LPU_STOP, or LPU_STANDBY. The field is cleared by writing 1 to it. 0 Non-exist mode interrupt is not pending 1 Non-exist mode interrupt is pending
30 Reserved	This field is reserved.
31 Reserved	This field is reserved.

8.11.8 Module Disable (LPU_MDIS)

If a module is disabled in RUN mode using ME_PCTL, it is suggested to configure MDIS to 1 in LPU modes as by default the clock to that module will be enabled while transitioning to LPU mode.

NOTE

Module system bus clocks are gated in LPU_STOP mode without any option of keeping them ON.

NOTE

During transition from RUNx mode to LPU_RUN mode, peripherals clock gated with LPU_MDIS will observe few clock cycles. Hence it is recommended to check and clear any pending interrupts in LPU_RUN mode. For example, it is possible to have a MEMU interrupt flag set due to some free running clock cycles during RUNx to LPU transition.

Address: 0h base + 18h offset = 18h

22 eMIOS_0	eMIOS_0 is disabled in RUN mode using ME_PCTL, it is suggested to configure MDIS to 1 in LPU modes as by default the clock to that eMIOS_0 will be enabled while transitioning to LPU mode. 0 Module clock is enabled in LPU_RUN or LPU_SLEEP mode. 1 Module clock is disabled in LPU_RUN or LPU_SLEEP mode.

Table continues on the next page...

LPU_MDIS field descriptions (continued)

Field	Description
23 CMP_2	CMP_2 is disabled in RUN mode using ME_PCTL, it is suggested to configure MDIS to 1 in LPU modes as by default the clock to that CMP_2 will be enabled while transitioning to LPU mode. 0 Module clock is enabled in LPU_RUN or LPU_SLEEP mode. 1 Module clock is disabled in LPU_RUN or LPU_SLEEP mode.
24 CMP_1	CMP_1 is disabled in RUN mode using ME_PCTL, it is suggested to configure MDIS to 1 in LPU modes as by default the clock to that CMP_1 will be enabled while transitioning to LPU mode. 0 Module clock is enabled in LPU_RUN or LPU_SLEEP mode. 1 Module clock is disabled in LPU_RUN or LPU_SLEEP mode.
25 CMP_0	CMP_0 is disabled in RUN mode using ME_PCTL, it is suggested to configure MDIS to 1 in LPU modes as by default the clock to that CMP_0 will be enabled while transitioning to LPU mode. 0 Module clock is enabled in LPU_RUN or LPU_SLEEP mode. 1 Module clock is disabled in LPU_RUN or LPU_SLEEP mode.
26 MEMU_1	MEMU_1 is disabled in RUN mode using ME_PCTL, it is suggested to configure MDIS to 1 in LPU modes as by default the clock to that MEMU_1 will be enabled while transitioning to LPU mode. 0 Module clock is enabled in LPU_RUN or LPU_SLEEP mode. 1 Module clock is disabled in LPU_RUN or LPU_SLEEP mode.
27 BCTU	BCTU is disabled in RUN mode using ME_PCTL, it is suggested to configure MDIS to 1 in LPU modes as by default the clock to that BCTU will be enabled while transitioning to LPU mode. 0 Module clock is enabled in LPU_RUN or LPU_SLEEP mode. 1 Module clock is disabled in LPU_RUN or LPU_SLEEP mode.
28 CAN0	CAN0 is disabled in RUN mode using ME_PCTL, it is suggested to configure MDIS to 1 in LPU modes as by default the clock to that CAN0 will be enabled while transitioning to LPU mode. 0 Module clock is enabled in LPU_RUN or LPU_SLEEP mode. 1 Module clock is disabled in LPU_RUN or LPU_SLEEP mode.
29 LIN_0	LIN_0 is disabled in RUN mode using ME_PCTL, it is suggested to configure MDIS to 1 in LPU modes as by default the clock to that LIN_0 will be enabled while transitioning to LPU mode. 0 Module clock is enabled in LPU_RUN or LPU_SLEEP mode. 1 Module clock is disabled in LPU_RUN or LPU_SLEEP mode.
30 SPI_0	SPI_0 is disabled in RUN mode using ME_PCTL, it is suggested to configure MDIS to 1 in LPU modes as by default the clock to that SPI_0 will be enabled while transitioning to LPU mode. 0 Module clock is enabled in LPU_RUN or LPU_SLEEP mode. 1 Module clock is disabled in LPU_RUN or LPU_SLEEP mode.
31 ADC_0	ADC_0 is disabled in RUN mode using ME_PCTL, it is suggested to configure MDIS to 1 in LPU modes as by default the clock to that ADC_0 will be enabled while transitioning to LPU mode. 0 Module clock is enabled in LPU_RUN or LPU_SLEEP mode. 1 Module clock is disabled in LPU_RUN or LPU_SLEEP mode.

Chapter 9
Clocking Overview

9.1 Introduction

This chapter describes the architecture for the system level clocks and includes the following information:

- Dynamic frequency scaling
- System clock specifics
- Clock architecture
- Clock sources
- Clock monitoring
- Programmable clock dividers
- Clock control registers
- Progressive clock switching

NOTE

This chapter covers only clocks that are generated on the device. Protocol clocks that are provided by external devices are covered in the respective chapters where they are used.

The system clock can be configured as frequency modulated clock to reduce electromagnetic emissions, while having a precise clock for timers and communication functions[1]. There is also the ability of the chip to enter a low power mode and utilize the low power clocks.

The device boots from the internal 16 MHz RC oscillator (FIRC), and uses this as a backup clock in the event of a PLL or oscillator failure. The backup clock is enabled in the Mode Entry Module (MC_ME) (see the "Mode Entry Module (MC_ME) Overview chapter for details).

System clocks can be generated from the three sources:

1. Using the frequency modulated clock is not recommended for LINFlexD.

- Fast external crystal oscillator 8 – 40 MHz (FXOSC)
- Fast internal RC oscillator 16 MHz (FIRC)
- Frequency-modulated phase-locked loop (FMPLL)

Additionally, there are two low power oscillators:

- Slow internal RC oscillator 128 KHz (SIRC)
- Slow external crystal oscillator 32 KHz (SXOSC)

Internal system clocks are generated from either PLL_PHI_0, FIRC, or FXOSC. There is one clock selector which is used exclusively for system clock source selection. The system clocks along with PLL_PHI_0, FIRC, FXOSC, SIRC, SXOSC, can be selected to drive system peripherals depending on the configuration of the Auxillary Clock Selectors in the Clock Generation Module (MC_CGM), and selectors based locally in the modules. There are six Auxillary Clock Selectors which allow developers to drive peripherals with a specific clock source (see Figure 9-1).

The MPC5746C has a Clock Monitor Unit (CMU) that is used to check the integrity of the clocks making sure that their frequencies stay within necessary operating limits. If the CMU detects an issue with the monitored clocks, an interrupt or system reset could be generated (depending on FCCU configuration).

NOTE

The auxilary clock multiplexers (for example, MC_CGM_AC*n*_SC[SELCTL]) should be programmed to select the clock source before the corresponding module is enabled.

9.2 System clock generation

The MPC5746C supports seven synchronous clock nodes to support Dynamic Frequency Scaling (DFS). These groups can be classified into 3 categories:

- Fixed Frequency Group (F160, F80, F40, F20): This group will not scale down during DFS operation. It implies all the modules will continue receiving the same frequency (for example, PIT timers are operating at F40MHz and would not scale down).
- Scalable Frequency Group (S160, S80, S40): This group will scale down during DFS operation (for example, Z4 core is operating at S160 and would scale down as per configuration in MC_CGM_SC_DC*n* registers.
- Flexible Group (FS80): This group should be configured to scale down along with the Scalable group during Linear DFS and should be kept at a fixed frequency during Non-Linear DFS.

Each module can have clocks coming from different groups. See Table 9-6 for peripheral clocking.

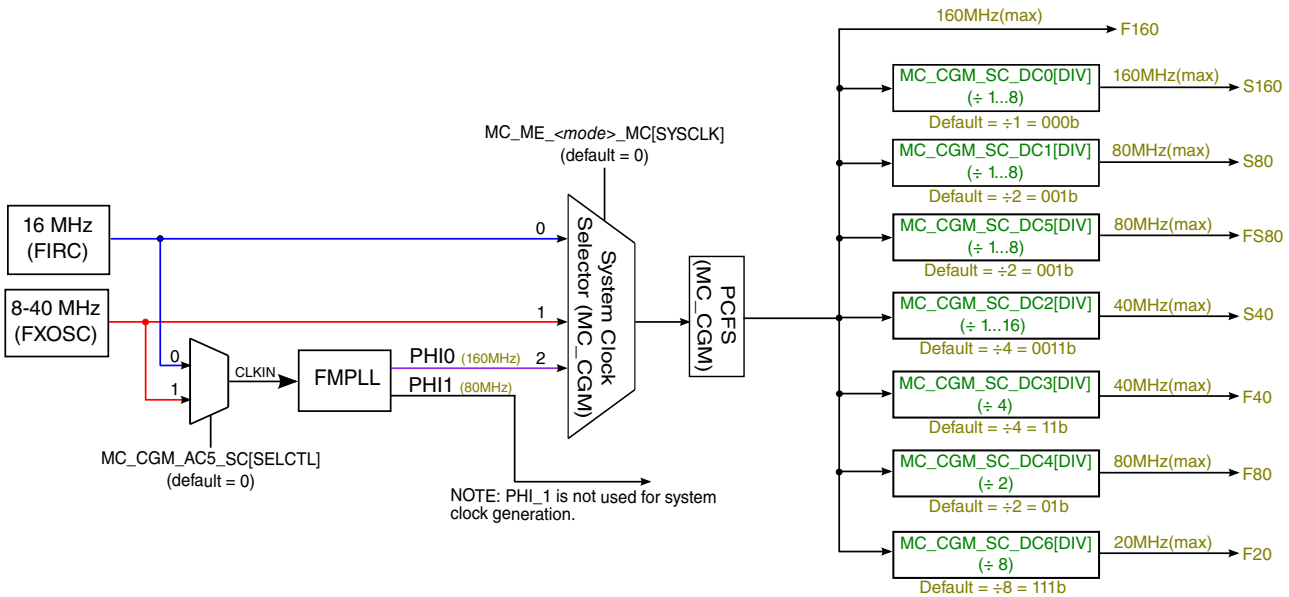

Figure 9-1. System clock generation

9.3 Dynamic Frequency Scaling

9.3.1 Overview

Dynamic Frequency Scaling (DFS) enables the core and system frequency to be reduced during RUN mode, while keeping frequency of key peripherals constant. This enables the power consumption of the device to be temporarily reduced when processing needs are low.

There is a considerable amount of power savings as frequency is reduced for all three cores, AXBS, flash memory, SRAM, PBRIDGE and bus interface unit of modules. During this mode, the frequency for timers like PIT, SWT, eMIOS, and baud rates for modules like LIN, DSPI, are kept constant.

The clocks scaled during DFS are the following:

- S40
- S80
- S160
- FS80

NOTE

All frequencies in this chapter are based on assumption that PLL PHI0 is 160MHz. If PLL PHI0 is at a different clock frequency the system clock nodes will vary based on divider configurations in MC_CGM_SC_DCn

There are two DFS modes supported:

- Linear DFS (LDFS)
  - This mode is entered by writing MC _CGM_SC_DIV_RC[SYS_DIV_RATIO_CHNG] = 0. In LDFS, the system clock divider ratios will not change when the next system clock divider configuration is updated.
- Non_Linear DFS (NLDFS)
  - This mode is entered by writing MC _CGM_SC_DIV_RC[SYS_DIV_RATIO_CHNG] = 1. In NLDFS, the system clock divider ratios will change when the next system clock divider configuration is updated.

The below table gives frequency scaling during all DFS modes.

NOTE

FS80 must not be configured to any frequency less than that of F40 group.

Table 9-1. Dynamic Frequency scaling

Clock nodes	RUN - Full Power	Linear DFS	NLDFS80	NLDFS40	NLDFS20
F160	160	160	160	160	160
S160	160	80	80	40	20
S80	80	40	80	40	20
S40	40	20	20	20	10
F40	40	40	40	40	40
F80	80	80	80	80	80
FS80	80	40	80	80	80
F20	20	20	20	20	20

All the modules which are clocked from a scalable frequency group will scale down in both the modes (see System clock generation).

9.3.2 Linear DFS Configuration

In this mode, frequency is scaled down while keeping the ratio between master (for example, FlexRay, DMA) and AXBS as same. For example, in full run mode Z2 is at 80 MHz and AXBS is at 160 MHz, thus ratio is 1:2. In Linear DFS mode Z2 can be scaled down to 40 MHz and AXBS to 80 MHz, thus maintaining a 1:2 ratio. Transitioning between frequencies occurs seamlessly, such that transactions can continue without halting AXBS.

Following is the frequency configurations supported in Linear DFS (all frequencies are in MHz).

Table 9-2. Linear DFS supported frequencies

	System (Z4 core, AXBS, SRAM, flash memory)	Z2	eDMA	HSM	ENET	FlexRay	PBRIDGE
Case 1: Full RUN	160	80	80	80	80	80	80
Case 2: Linear DFS	80	40	40	40	—[1]	—[2]	40

1. Linear DFS feature not supported.
2. The Flexray can be used in the Linear DFS mode only when the FXOSC is selected as the Flexray PE clock source.

Suggested configuration sequence for Linear DFS

1. Configure MC_CGM_SC_DC0[DIV] = 01b, to scale down S160 group to generate 80 MHz
2. Configure MC_CGM_SC_DC1[DIV] = 0011b, to scale down S80 group to generate 40 MHz
3. Configure MC_CGM_SC_DC2[DIV] = 0111b, to scale down S40 group to generate 20 MHz
4. Configure MC_CGM_SC_DC5[DIV] = 011b, to scale down FS80 group to generate 40 MHz
5. Configure MC_CGM_SC_DIV_RC[SYS_DIV_RATIO_CHNG] = 0 to disable HALT/ACK handshake with AXBS.
6. Configure MC_ME_PCTL*n* to disable ENET (MC_ME_PCTL15) to save dynamic power.
7. Configure MC_CGM_DIV_UPD_TRIG any non-zero value.

9.3.3 Non-Linear DFS Configuration

In this mode frequency is scaled down and also the ratio between master and AXBS can be varied. For example, in full run mode ENET is at 80 MHz and AXBS is at 160 MHz, thus ratio is 1:2. In Non-Linear DFS mode ENET can be maintained at 80 MHz and AXBS scaled to 80 MHz, thus changing ratio to 1:1. It is required to put the AXBS into a quiescent state such that on a DFS request all ongoing transactions at the AXBS slave are completed and an acknowledgement is issued to the MC_CGM to change frequencies.

Following is the frequency configurations supported in Non-Linear DFS.

Table 9-3. Non-Linear DFS supported frequencies

	System (Z4 core, AXBS, SRAM, flash memory)	Z2	eDMA	HSM	ENET	FlexRay	PBRIDGE
Case 1:Full RUN	160	80	80	80	80	80	80
Case 3: NLDFS80	80	80	80	40	80	80	80
Case 4: NLDFS40	40	40	80	20	80	80	80
Case 5: NLDFS20	20	20	80	10	80	80	80

Suggested configuration sequence for Non-Linear DFS

- Configure MC_CGM_SC_DC0[DIV] = 01b, to scale down S160 group to generate 80 MHz
- Configure MC_CGM_SC_DC2[DIV] = 0111b, to scale down S40 group to generate 20 MHz
- Configure AXBS*x*_PRS*n* to set the priorities as per application requirement. It is suggested to provide highest priority for FlexRay.
- Configure MC_CGM_SC_DIV_RC[SYS_DIV_RATIO_CHNG] = 1 to enable HALT/ACK handshake with AXBS. Configure MC_CGM_DIV_UPD_TRIG any non-zero value.

If lowest frequency Non-Linear DFS is chosen, the restrictions are same as that of lowest frequency DFS case.

NOTE

The modules working on FS80 group will not be scaled down in all NLDFS modes.

9.3.4 DFS Limitations

There are some frequency requirements mandated by the protocol which should be considered while selecting DFS mode for an application.

Refer Peripheral Clock Restrictions for more details

Table 9-4. DFS Limitations

Mode	Limitation
NLDFS80	No restriction. All modules can operate well.
LDFS	Refer Peripheral Clock Restrictions

9.3.5 NLDFS Abort on Interrupt

When the software initiates NLDFS, the crossbar including the masters are halted before the system frequency is dynamically switched. It may take a while for all masters to halt together. However, the NLDFS can be aborted in between using following critical interrupts.

- NMI to Z4 and Z2
- Critical interrupts to Z4 and Z2
- Machine check request to Z4 and Z2
- SWT0 Interrupt
- SWT1 Interrupt
- HSM_SWT interrupt
- Flexray FIFO interrupts such as, *FR_GIFER[FAFAIF]* or *FR_GIFER[FAFBIF]*
- MAC0 underrun interrupt, *MAC 0 Transmit FIFO Underrun*

The enabling and disabling of HALT abort feature can be controlled by MC_CGM_SC_DIV_RC[HALT_ABORT_DIS], System Clock Divider Ratio Change Register (MC_CGM_SC_DIV_RC)

9.4 Peripheral clock generation

9.4.1 Overview

Each module requires the following clocks to operate (see Figure 9-2):

- HCLK – This is the AHB interface clock of modules which are master or slaves on AXBS. This clock is gated in low power modes, or if the module is disabled and is supported by MC_ME_PCTL configuration.
- Peripheral CLK – This clock is required by modules for internal state machines and processing of data.
- BIU CLK – Bus interface unit clock. This clock is required for register read write configurations. It is available only when a module is accessed for configurations and else it is disabled. Some modules operate its bus interface unit on peripheral clock and corresponding column is marked as '—' for these modules (see System Clock Distribution for details).
- Memory CLK - Memory of the modules operate on this clock.
- Baud_CLK/Auxiliary CLK - This clock is provided to generate external interface clock or if there is any special clock requirement

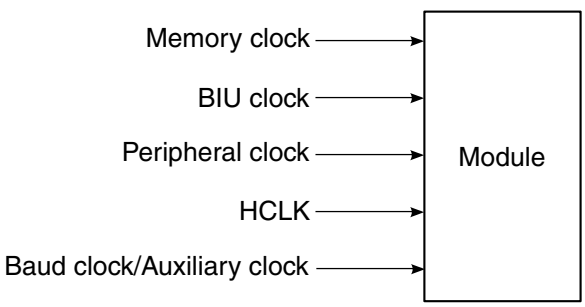

Figure 9-2. General module clocking

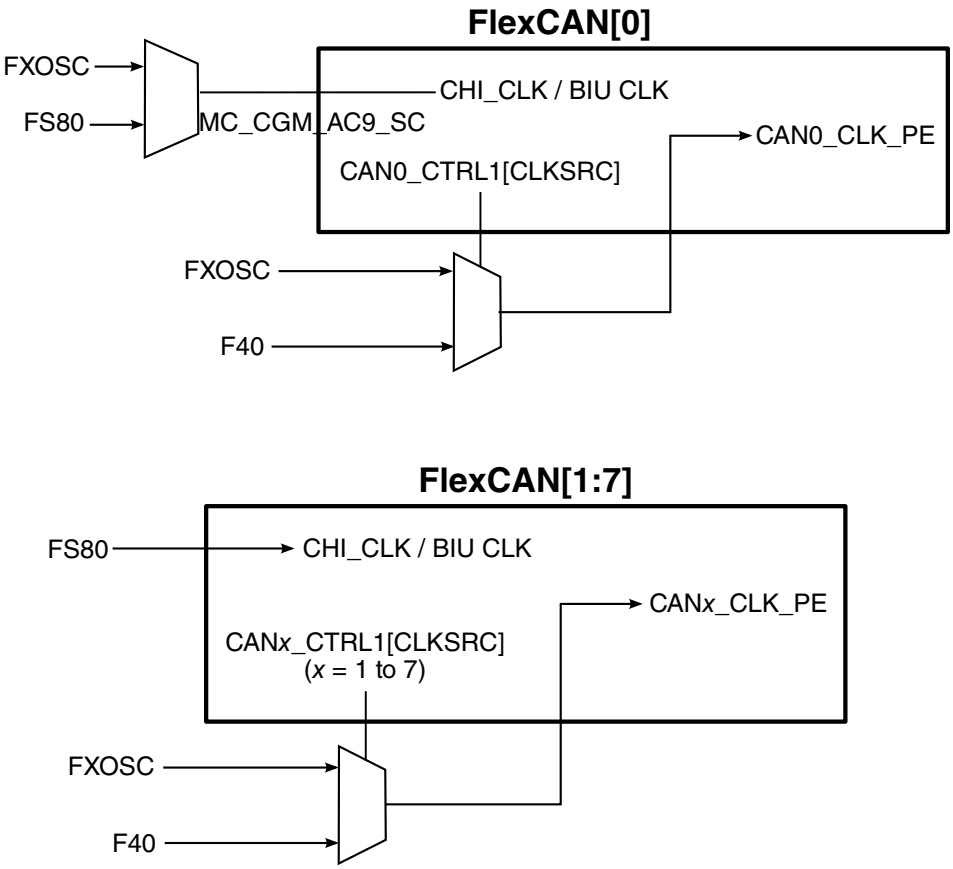
9.4.2 Enabling/Disabling of peripherals and clock sources

Disabling of peripherals and clock sources: Software should take care that secondary (auxiliary) clock sources selected for a peripheral are not disabled during any mode transition preceding a mode transition to disable the peripheral. For Example: In FlexCAN when FXOSC is selected for the CAN Engine Clock Source (CAN_CTRL1[CLKSRC]), before disabling FlexCAN Peripheral Clock the user must ensure FXOSC is enabled in the current mode prior to the target mode transition that will disable the FlexCAN.

Enabling of peripherals and clock sources: Software should take care that secondary (auxiliary) clock sources are enabled for the target mode before initiating the target mode transition to enable the peripheral.

9.4.3 Communication interfaces

9.4.3.1 FlexCAN clocking



The FlexCAN Protocol Engine clock (PE clock) has an option to be sourced from either the F40 or the external oscillator (FXOSC). Clock selection is controlled by CAN*x*_CTRL1[CLKSRC]. Control host interface(CHI) clock of CAN1 to CAN7 is sourced from FS80 group whereas, CAN0 has an option to be sourced from either FXOSC or FS80 group.

NOTE

FlexCAN_1-7 CHI clock frequency should not be lower than the PE clock when the system clock is dynamically updated.

FlexCAN0 CHI clock and PE clock can operate in 1:1 frequency ratio. There is an auxiliary mux selector added to ensure seamless operation while entry-exit from LPU subsystem. ReferFlexCAN0 Clocking

Software Guideline: If FXOSC is selected as the FlexCAN_*n* clock source, MC_ME_PCTL[70:77] (corresponding to FlexCAN_0 through FlexCAN_7, respectively) should be configured after MC_ME_GS[S_FXOSC] = 1. For example, if FXOSC is the source for FlexCAN_0, then MC_ME_PCTL70 should be configured after MC_ME_GS[S_FXOSC] = 1. This is required to ensure clock source is available before module is enabled.

NOTE: The multiplexers for all FlexCAN modules are located outside of the module, but are controlled by registers inside the FlexCAN modules.

Figure 9-3. FlexCAN Clock generation

9.4.3.2 FlexRay clocking

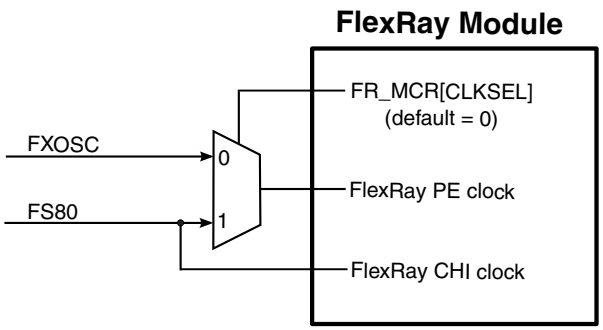
The FlexRay protocol clock can be sourced from either FS80 (non-FM PLL) or the external oscillator (FXOSC). Clock selection is controlled by configuring the FlexRay Module Configuration register FR_MCR[CLKSEL] field. Control host interface (CHI) clock of FlexRay is sourced from FS80 group.

- When using the external oscillator clock, a 40 MHz crystal is required for proper operation.
- When using FS80, the MC_CGM_SC_DC5 register must be configured to provide 80 MHz on FS80 for proper operation.
- The frequency of the FS80 source must be double the frequency of the XOSC source (40 MHz) because the PLL has a less stable duty cycle.

- The FlexRay module itself divides the FS80 frequency to provide a steady, 50% duty cycle, 40 MHz clock internally.
- This internal FlexRay divider is driven automatically when FR_MCR[CLKSEL] is 1. The user cannot change this internal divider or select it for the XOSC source.

NOTE

The FlexRay module used in the device has the StopWatch functionality. The OS_tick is the input into the FlexRay module and the source is from the STM and PIT channels.



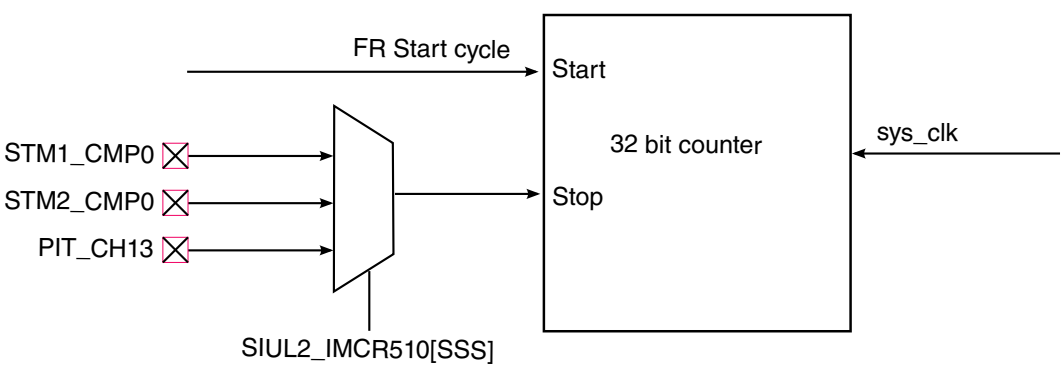


Figure 9-4. FlexRay clock generation

9.4.3.2.1 FlexRay OS tick selection

The following figure shows the OS tick selection configuration which is implemented at the device level outside the FlexRay StopWatch interface (see the StopWatch function section in the "FlexRay" chapter for details).

For detailed description, see I/O Signal Description and Input Multiplexing Tables (excel file) attached to this document.

NOTE

Software Guideline: If FXOSC is selected as the FlexRay clock source, MC_ME_PCTL28 needs to be configured after MC_ME_GS[S_FXOSC] = 1.

9.4.3.3 LINFlexD clocking

LINFlexD requires bus interface unit clock for configurations and a baud clock. LINFlexD belongs to fixed frequency group such that its baud rate remains constant during DFS.

LINFlexD[0] BIU clock is from F20 group. It cannot belong to F80 group as maximum frequency supported in LPU subsytem is 40 MHz. Refer LinFlexD Clocking

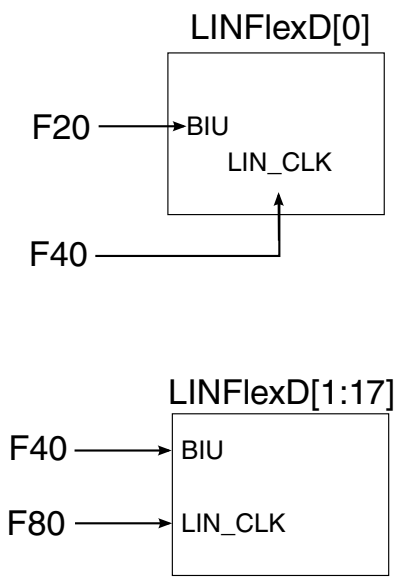

Figure 9-5. LINFLexD Clock generation

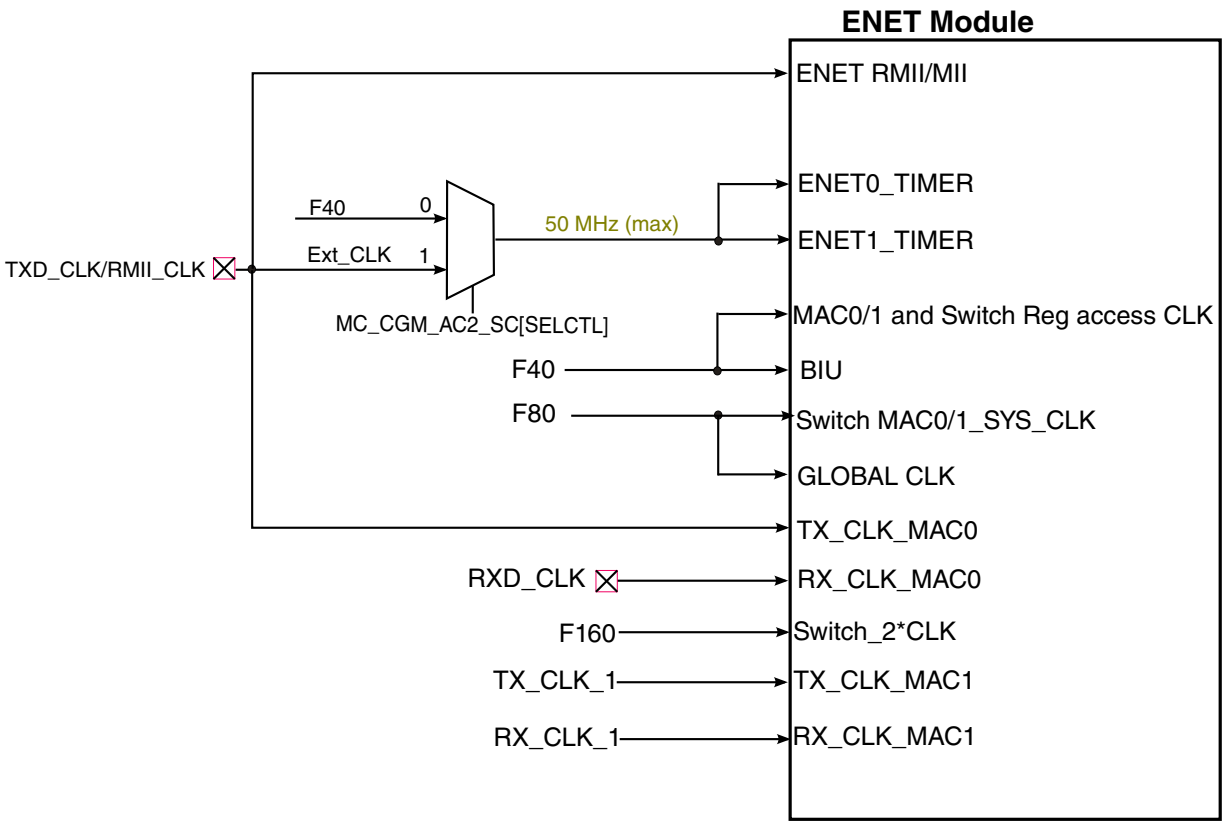
9.4.3.4 ENET clocking

ENET HCLK cannot be below 50 MHz to support MII and RMII modes. Either F40 or the Ext_CLK clocks can be selected as the timer clock. The period of this clock should be an integer value (for example, 25 ns if 40 MHz clock frequency is used).

NOTE

Ext_CLK is sourced from the TXD_CLK/RMII_CLK external pad which is TXD_CLK in MII mode.



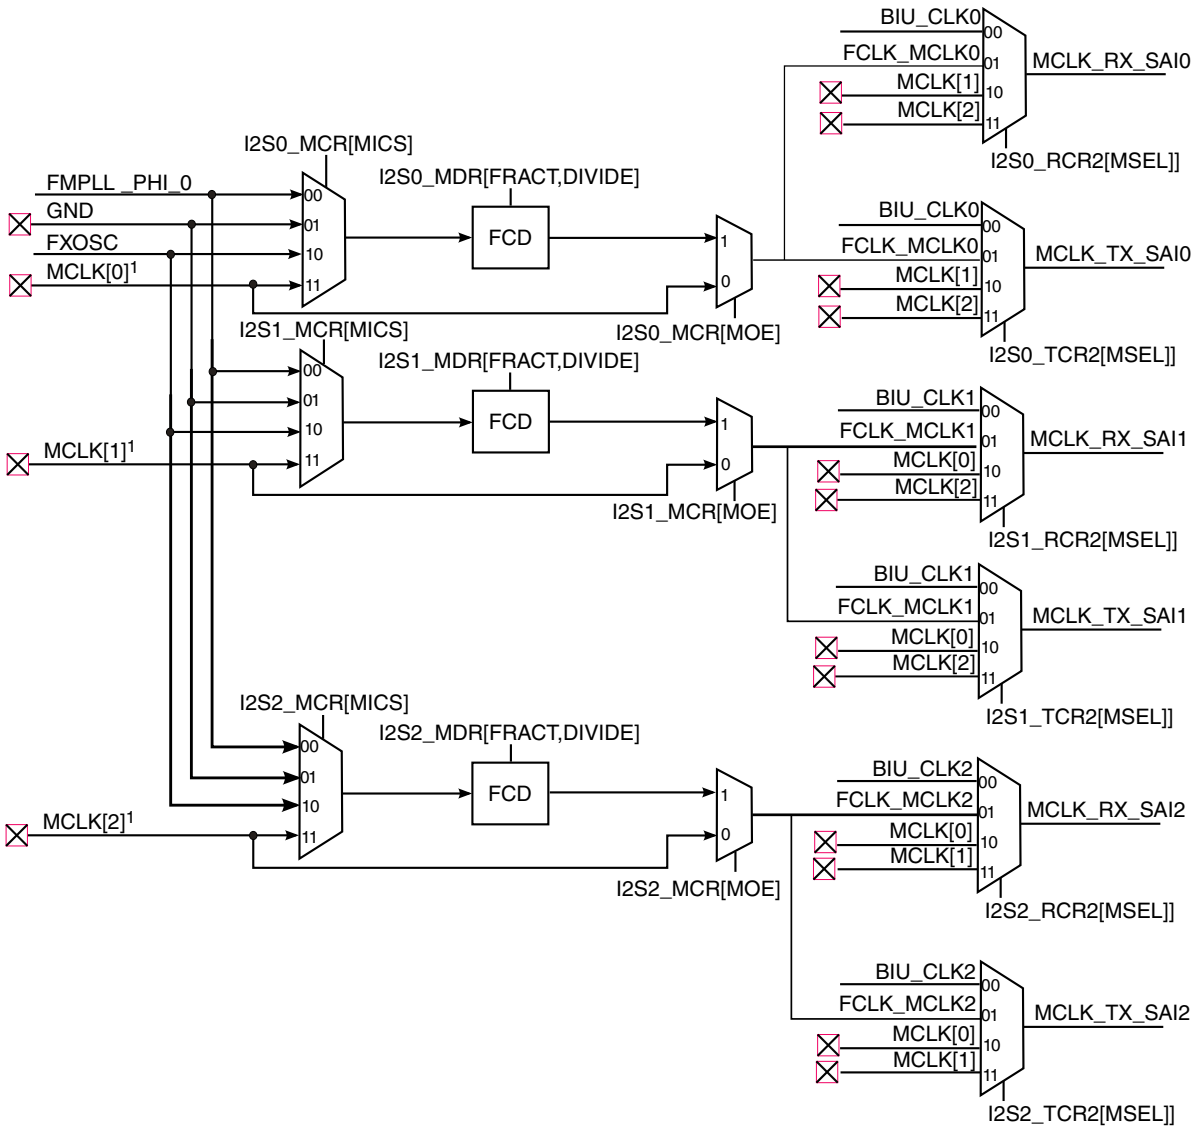


Figure 9-6. ENET Clock generation

9.4.3.5 SAI clocking

Figure 9-7 shows how the SAI master clock (MCLK) is generated via fractional clock divider (FCD) . The input clock to the FCD is limited to 160 MHz. MCLK[2:0] can also come as an input via external pins. Bit clock (BCLK) is half of MCLK and can be generated internally by dividing MCLK or they can be input via external pin. BIU operates at S40.

NOTE

BCLK should never be greater than BIU clock which is S40 as it will lead to underrun or overflow of FIFO inside SAI.

[1]Driven by signals external to the MPC5746C

Figure 9-7. SAI clock generation

9.4.3.6 DSPI/SPI clocking

There are four DSPI (DSPI_[0:3]) and four SPI (SPI_[0:3]) modules on the MPC5746C. DSPI_[0:1] and SPI_[0,3] uses F40 for its baud rate clock, and DSPI_[2:3] and SPI_[1:2] uses F80 for its baud rate clock as given in the following figure.

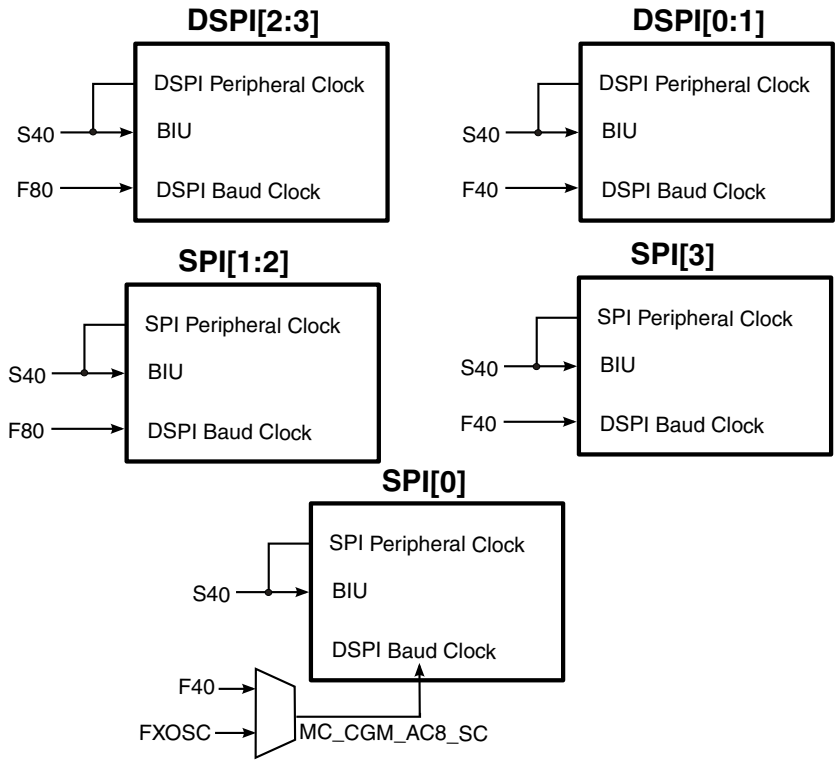

Figure 9-8. DSPI/SPI clock generation

9.4.4 Timers Clock

9.4.4.1 RTC clocking

The RTC_CLK for the RTC-API is generated by selecting one of four clocks as shown in Figure 9-9. If needed, the RTC_CLK can be divided for finer granularity (see RTC Block Diagram).

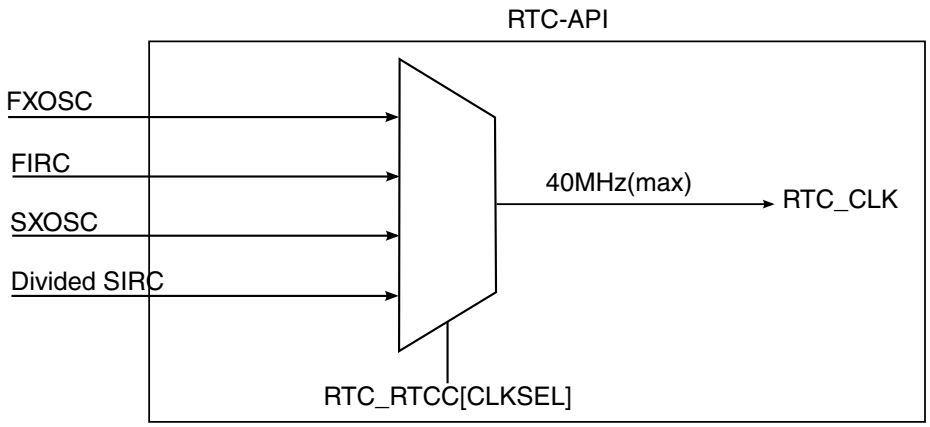

Figure 9-9. RTC Clock generation

NOTE

SIRC_DIV if configured for non zero value, will get reset on any chip reset thus generating 128kHz clock frequency.

9.4.4.2 PIT-RTI clocking

The PIT_RTI contains 16 PIT channels and a single RTI channel. The PIT channels are clocked from the system clock (F40). The clock source for the RTI is the FXOSC.

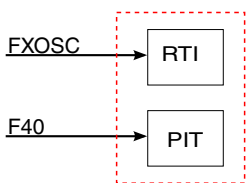

Figure 9-10. PIT Clock generation

NOTE

Software Guideline: If FXOSC is selected as the RTI clock source, MC_ME_PCTL91 needs to be configured after MC_ME_GS[S_FXOSC] = 1. Also, the clock for RTI timers needs to be enabled (PIT_MCR[MDIS_RTI] = 1) after MC_ME_GS[S_FXOSC] = 1.

9.4.4.3 STM clocking

FS80 is selected as the source clock for all STM to allow a constant frequency of 80 MHz while core frequency scales down from 160 MHz to 80 MHz during NLDFS.

NOTE

STM counter should be enabled only after selecting STM_2CLK_CR[CSL].

NOTE

If STM is configured in STOP/STANDBY/LPU modes, FXOSC should be kept ON in target modes (RUNx/DRUN) also, to exit properly

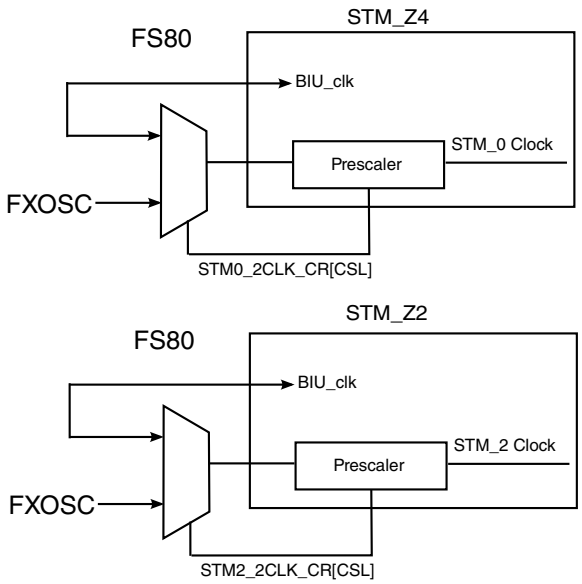

Figure 9-11. STM Clock generation

9.4.4.4 SWT clocking

SIRC is always enabled after reset such that the SWT receives the clock during the reset sequence and avoids a timeout. If a timeout occurs, a destructive reset will be initiated indicating flash memory initialization fails.

NOTE

SWT must be configured only if ME_GS[S_SIRCON] is 1.

NOTE

SIRC should always be kept ON (in DRUN/RUNx modes) if at least one SWT is enabled to allow proper mode transitions.

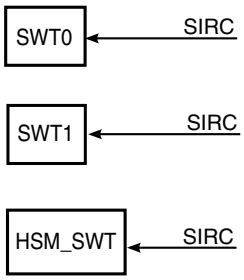

Figure 9-12. SWT clock generation

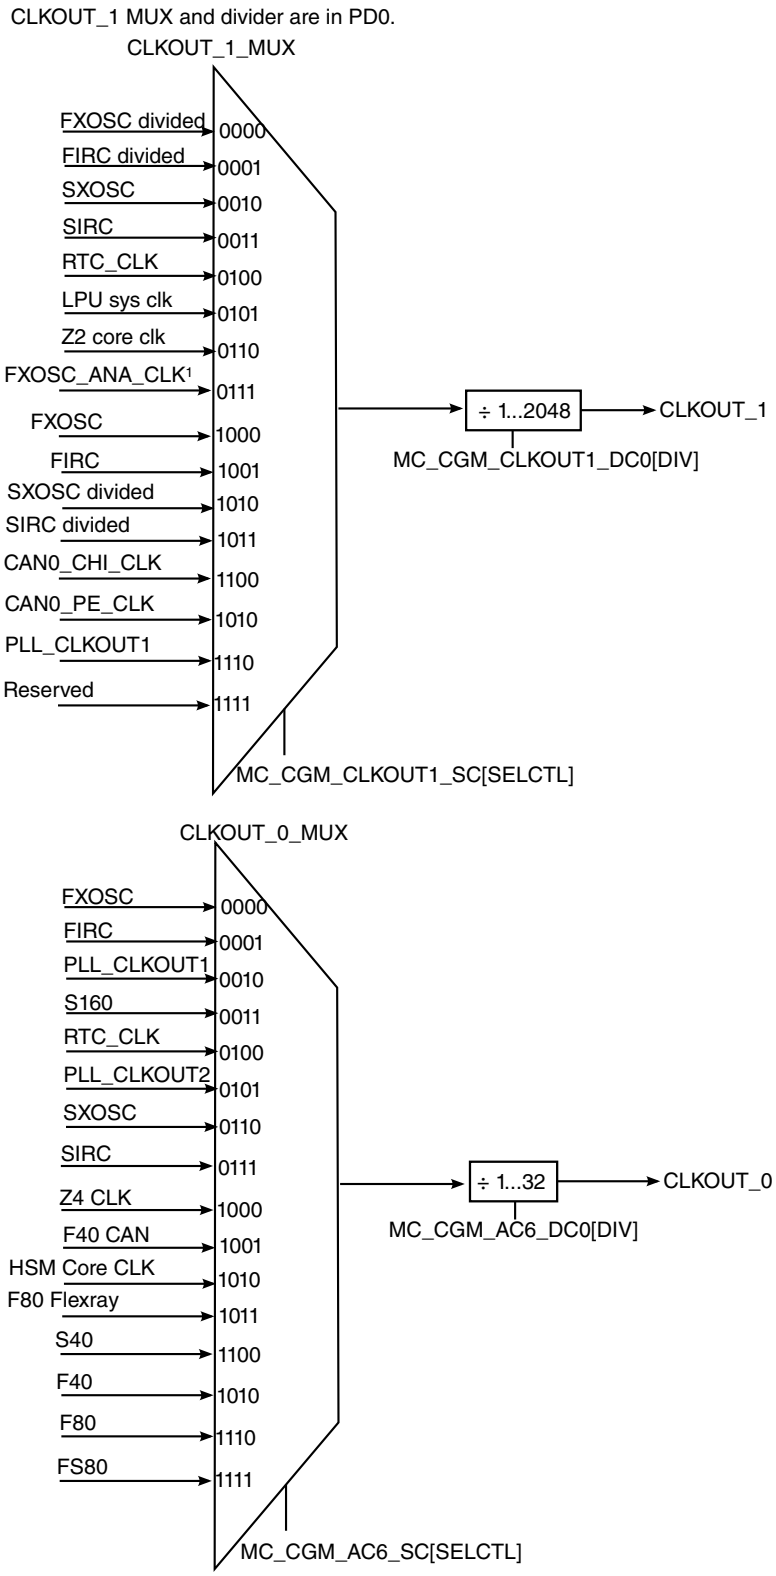
9.4.5 ADC/BCTU/eMIOS clocking

The ADC clock source is FS80. The ADC can reduce the source clock to generate a 40 MHz clock of the correct tolerance. The ADC, BCTU, and eMIOS are in the same 80 MHz peripheral set to avoid clock domain crossing delays. These modules will not be scaled down across NLDFS modes.

NOTE

The ADC meets the 1 μS conversion time with an 80 MHz clock source. If the clock frequency is higher than 80 MHz, the conversion accuracy is reduced. If a lower frequency is used, conversion time will be longer, but accuracy is not affected. The minimum ADC clock frequency is 1 MHz (see the MPC5746C Data Sheet for timing details).



9.4.6 CLKOUT clocking

There are two external clock output pins on the device:

- CLKOUT_0
- CLKOUT_1

CLKOUT_0 clock is available only in RUN, DRUN and STOP modes. However, CLKOUT_0 pin is available in all modes, including STANDBY and LPU modes.

Both CLKOUT_1 clock and CLKOUT_1 pin are available in all modes, including STANDBY and LPU modes.

1. FXOSC_ANA_CLK is an output of analog fast oscillator which is actually fed from XTAL on board. This has same frequency as FXOSC.

Figure 9-13. CLKOUT clock generation

9.4.7 HSM clocking

The HSM Core works at a set frequency of half the system clock (S160). The clock divider for random number generator (TRNG) is located outside the HSM in the CGL, is controlled by the HSM. The HSM contains an internal PIT/RTI block, which uses the FIRC as its clock source. The HSM also contains an internal clock monitor on its input clock.

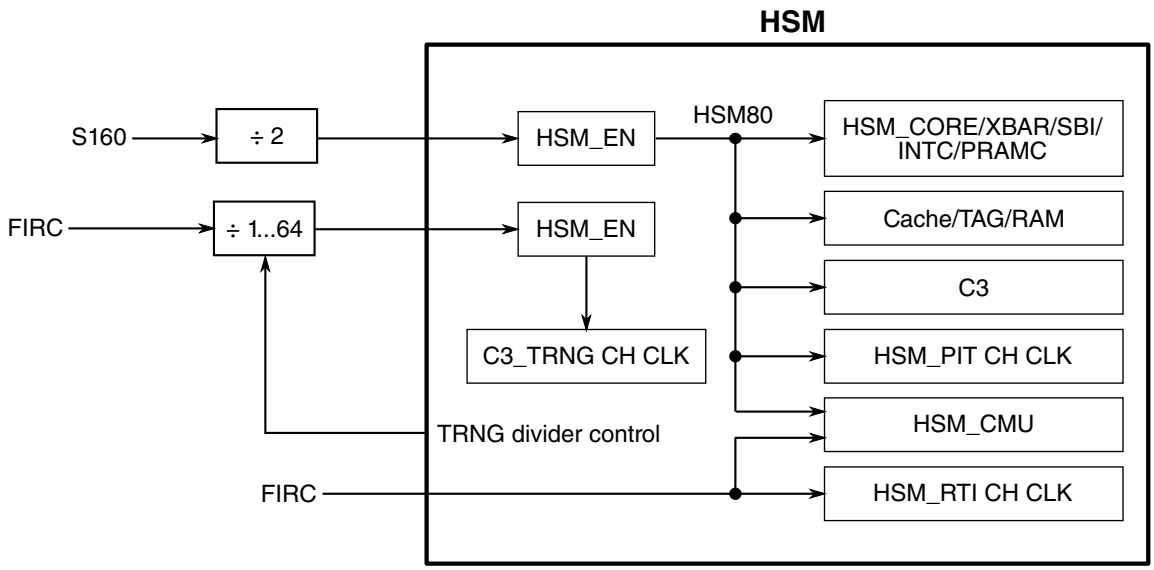


Figure 9-14. HSM clocking

9.4.8 LPU clocking

It is possible to run the Low Power Unit (LPU) from either the FXOSC or FIRC. These frequencies can be reduced using dividers before they are routed to the peripherals in the low power domain (for example, LINFlexD, SPI, ADC, and so on).

NOTE

See the Clocking section in the LPU chapter for clocking details during low power operation.

9.5 MC_CGM registers

The relationship between the output clocks and the MC_CGM registers is shown in Figure 9-1.

NOTE

See Clock Generation Module (MC_CGM) for specifics on register implementation.

9.6 Built-In Self-Test clocking

The device supports user Built-In Self-Test (MBIST) as part of the functional safety concept. The configuration is controlled via the STCU2 module. MBIST can run at start up (before cores exit reset), or initiated by application during run time. It is possible to run Built-In Self-Test from the FIRC or PLL_PHI1 clock (limited to 40 MHz). At start up, the selection of the BIST clock is configured in the DCF record, STCU_PLL_CFG (default is the FIRC). As cores are not running during MBIST, the PLL setup is controlled with hardware. During Run time, the BIST clock selection is done by the application by writing in STCU2_RUNSW Register.

NOTE

The STCU2 registers read/write is done on S40 clock.

9.7 System Clock Distribution

The maximum frequency of operation for the device system level clocks is shown in Table 9-5 and Table 9-6.

The AXBS are clocked from the S160 group. There is no mode where any of the masters or slaves can work at a frequency higher than the AXBS frequency.

The PBRIDGE clock cannot be scaled below 40 MHz. It is clocked from FS80 group, there is no mode where any of the slaves can work at a frequency higher than the PBRIDGE frequency. As there are modules which have their BIU clocked from F40 group (except for PIT and LINFlexD), this limits PBRIDGE to 40 MHz.

Dividers corresponding to fixed frequency groups (for example, F20, F40, F80, F160) should not be modified in any DFS mode.

NOTE

The user is responsible to verify that these values are not exceeded.

In Table 9-5 and Table 9-6 the Peripheral clock will also serve the purpose of BIU clock for the modules in which BIU clock is not defined

Table 9-5. Maximum clock frequencies - AXBS master/slave

Module	HCLK	Peripheral CLK	BIU	Memory CLK	BAUD_CLK/Auxiliary CLK

9.7.1 JTAG Frequencies

The following table shows the maximum frequencies of the JTAG interface.

Table 9-7. JTAG Frequencies

Configuration	e200z4 Max Internal JTAG Frequency	e200z2 Max Internal JTAG Frequency	Maximum External JTAG Frequency (TCK/TCK_ALT)	Notes
System Clock configured to 160 MHz	40 MHz	40 MHz	16 MHz	JTAG usable at 1/4 CPU frequency

9.7.2 Peripheral Clock Restrictions

There are some frequency requirements mandated by the protocol which should be considered while selecting DFS mode for an application.

- ENET AHB master clock interface should be greater than 50 MHz to support MII and RMII mode. ENET is sourced from clock node F80.
- ENET timer clock period should always be an integer. It is sourced from clock node F40 or FXOSC.
- BCLK which is bit clock of SAI and half of audio master clock should never be greater than BIU clock which is S40 as it will lead to underrun or overflow of FIFO inside SAI
- ADC conversion rate will drop as its frequency scales down. It is sourced from clock node FS80.
- FlexCAN protocol engine clock should always be less than its control host interface clock if MC_CGM_AC9_SC[SELCTL] is 0x0
- Flexray PE clock always need 80 Mhz clock (if FMPLL is clock source) or 40 Mhz clock (if FXOSC is clock source) to support 10/8/5/2.5 Mbit/s flexray data rates.

9.8 Default clock configuration

- **POWER UP:**After power is applied to the MPC5746C, the FIRC is the default clock for the system clock, and all clock sources and clock control blocks are reset to their default state. See clocking diagrams for default settings of dividers.
- **STANDBY/LPU EXIT:** System clock is based on configuration done in ME_DRUN_MC before LPU or STANDBY mode is requested. PLL can be selected as system source clock for faster low power exit time. Refer Accelerated Low Power Exit

9.9 Clock sources

This section provides the overview of the various clock sources.

9.9.1 PLL

The chip has a frequency modulated PLL with two outputs (PHI_0 and PHI_1). The separate system and peripheral clocks are provided with external dividers (see Figure 9-1 and Figure 9-15).

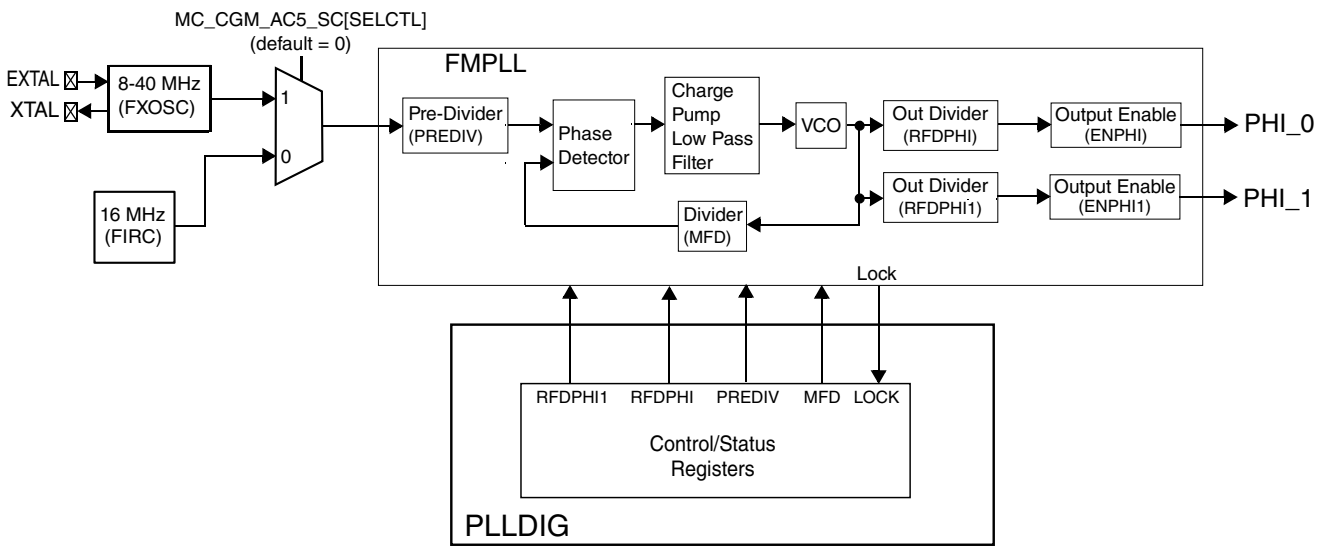

Figure 9-15. PLL block diagram

9.9.1.1 PLL input clocks

The clock source for the PLL can be either the external oscillator (FXOSC) or the 16 MHz internal oscillator (FIRC). The clock source is selected by configuring the MC_CGM_AC5_SC[SELCTL]. The input frequency range of the PLL is 8 – 40 MHz. The default input source for the PLL is the FIRC (MC_CGM_AC5_SC[SELCTL] = 0), but the FXOSC should be selected for best system clock accuracy (MC_CGM_AC5_SC[SELCTL] = 1).

9.9.1.2 PLL output clocks

The PLL has two output clocks:

- PHI_0
- PHI_1

PHI_0 is the primary output and is used to drive the system clock. It has a maximum frequency of 160 MHz. PHI_1 is the secondary output clock and has a maximum output frequency of 80 MHz.

NOTE

The PLL multiplication factor and output divider is software programmable.

9.9.1.3 PLL register interface

This device has a single digital interface for the PLL. The digital interface provides register control of all features of the PLL. Details are provided in the PLLDIG memory map and register definition section.

9.9.1.4 PLLDIG register reset values

All reset values for the PLLDIG registers that are device specific are shown in the following table. All other register reset values are shown in the PLL Digital Interface chapter.

Table 9-8. PLLDIG reset values

Register	Reset Value
PLL Calibration Register 3 (PLLDIG_PLLCAL3)	0000_0062h
PLLDIG PLL Control Register (PLLDIG_PLLCR)	0000_0400h
PLLDIG PLL Status Register (PLLDIG_PLLSR)	0000_0000h
PLLDIG PLL Divide Register (PLLDIG_PLLDV)	0C06_0018h

9.9.1.5 PLLDIG initialization information

Coming out of reset the PLL is disabled per the DRUN mode configuration register, MC_ME_DRUN_MC.

1. Configure PLL and related modules.

a. With PLL disabled, program PLL clock source in MC_CGM_AC5_SC[SELCTL]. Default is MC_CGM_AC5_SC[SELCTL] = 0 which selects the FIRC.

b. Program PLLDV[MFD] and PLLDV[RFDPHI].

c. If required, program the PLLFM register with the desired frequency modulation parameters and enable FM modulation, PLLFM[SSCGBYP] = 0. The PLLFM register must not be written after PLL enabled and operating in normal mode.

2. Turn on PLL.

a. Configure a mode configuration for turning on PLL, and keeping XOSC on. In a mode configuration register (for example, MC_ME_DRUN_MC), initialize MC_ME_<*mode*>_MC[XOSCON] = 1, MC_ME_<*mode*>_MC_PLLON] = 1. If desired, also set MC_ME_<*mode*>_MC[SYSCLK] needs to be initialized accordingly for this new mode configuration to use PLL as the sysclk (for example, MC_ME_RUN0_MC[SYSCLK] = 2 for PLL_PH0).

b. Enter that mode by two writes to MC_ME_MCTL register. First write should include the new mode and the key (use a single 32-bit write). The second write should include the same target mode but with the key inverted (again using a single 32-bit write). This is required even if entering the same mode.

3. Wait for the mode transition to complete.

a. Wait for the mode transition to complete by polling MC_MC_GS[MTRANS] or enabling an interrupt for flag MC_ME_IS[I_MTC]. A timer, even if it is the watchdog, should be used to make sure the mode transition completes. Mode transition will NOT complete until:

- XOSC counter expires (if the new mode configuration changes XOSCON to 1), and
- PLL is locked (if the new mode configuration changes MC_ME_<*mode*>_MC[PLLON] = 1)

b. Confirm the desired target mode was entered by checking the status of MC_ME_GS[S_CURRENT_MODE].

NOTE

See the "Mode Entry Module (MC_ME)" chapter in this *Reference Manual* more details.

9.9.2 Fast External Oscillator (FXOSC)

The external oscillator allows a crystal, or external clock, to be used as the reference for the MPC5746C. The input frequency range for the FXOSC is 8 – 40 MHz. The FXOSC clock source can be selected as the clock source for any operating mode (for example, DRUN, SAFE, and RUN[0:3]). The current operating mode is selected by configuring MC_ME_MCTL[TARGET_MODE]. Each of these operating modes can have the FXOSC as the clock source as selected in MC_ME_<*mode*>_MC for the corresponding operating mode. The FXOSC is the clock source for the RTI.

See Fast OSC Digital Interface chapter for details.

The Figure 9-16 shows the block diagram for FXOSC clock configuration.

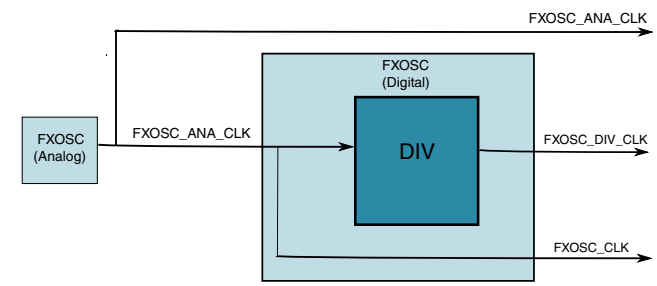

Figure 9-16. FXOSC Clock Configuration

9.9.2.1 FXOSC register reset values

All reset values for the FXOSC registers that are device specific are shown in the following table.

Table 9-9. FXOSC reset values

Register	Reset Value
FXOSC Control Register (FXOSC_CTL)	4030_0000h

NOTE

Reset value for I_OSC field depends on the DCF record for this field.

9.9.3 Slow external oscillator (SXOSC)

The SXOSC oscillator provides a 32 KHz clock with control and status registers accessible for application use (see Slow external oscillator for details).

The Figure 9-17 shows the block diagram for SXOSC clock configuration.

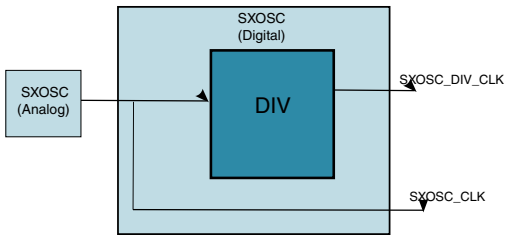

Figure 9-17. SXOSC Clock Configuration

9.9.3.1 SXOSC register reset values

All reset values for the SXOSC registers that are device specific are shown in the following table. All other register reset values are shown in the SXOSC chapter.

Table 9-10. FXOSC reset values

Register	Reset Value
SXOSC Control Register (SXOSC_CTL)	0040_0000h

9.9.4 16 MHz internal RC oscillator (FIRC)

The MPC5746C has a 16 MHz internal RC oscillator (FIRC) that is always enabled in RUN modes, and can be used as the clock source for the PLL. It is the clock source for the MC_RGM, FCCU, RTC, and SIUL input filters, and can also be used as a clock source for the ADCs and system clock. The FIRC is the default system clock after reset. The register interface is used for user trimming of the oscillator (see Internal 16 MHz RC Oscillator for details).

The Figure 9-18 shows the block diagram for FIRC clock configuration.

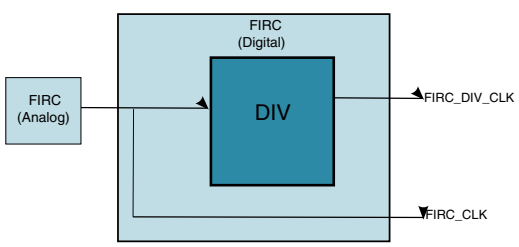

Figure 9-18. FIRC Clock Configuration

9.9.4.1 FIRC register reset values

The reset value of the FIRC Control register (FIRC_CTL) is device-specific and is shown in the following table.

Table 9-11. FIRC reset values

Register	Reset Value
FIRC Control Register (FIRC_CTL)	00*nn*_0011h

NOTE

Bits 10-15 are trim bits, with values determined during factory test to ensure the most accurate clock timing. To maintain accurate timing, these bits should never be written by application software.

9.9.5 128 kHz internal RC (SIRC)

This internal RC oscillator provides the 128 kHz clock with high accuracy, low power, fast stabilization, and fast recovery (see Internal 128 kHz RC oscillator chapter for details).

The Figure 9-19 shows the block diagram for SIRC clock configuration.

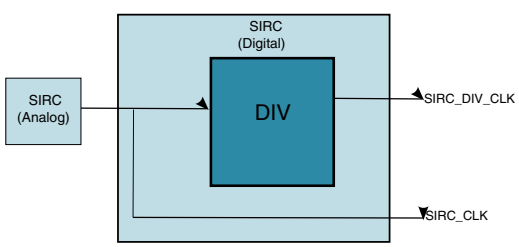

Figure 9-19. SIRC Clock Configuration

9.9.5.1 SIRC register reset values

The reset value of the SIRC Control register (SIRC_CTL) is device-specific and is shown in the following table.

Table 9-12. SIRC reset values

Register	Reset Value
SIRC Control Register (SIRC_CTL)	00*nn*_0011h

NOTE

Bits 8-15 are trim bits, with values determined during factory test to ensure the most accurate clock timing. To maintain accurate timing, these bits should never be written by application software.

9.10 Clock monitoring

The device supports clock monitoring of PLL and FXOSC clock. FIRC is used as reference clock (see Clock Monitor Unit (CMU) and CMU configuration for details).

9.10.1 CMU configuration

This section explains the CMU configuration.

Figure 9-20 shows the block diagram for the CMU on the MPC5746C.

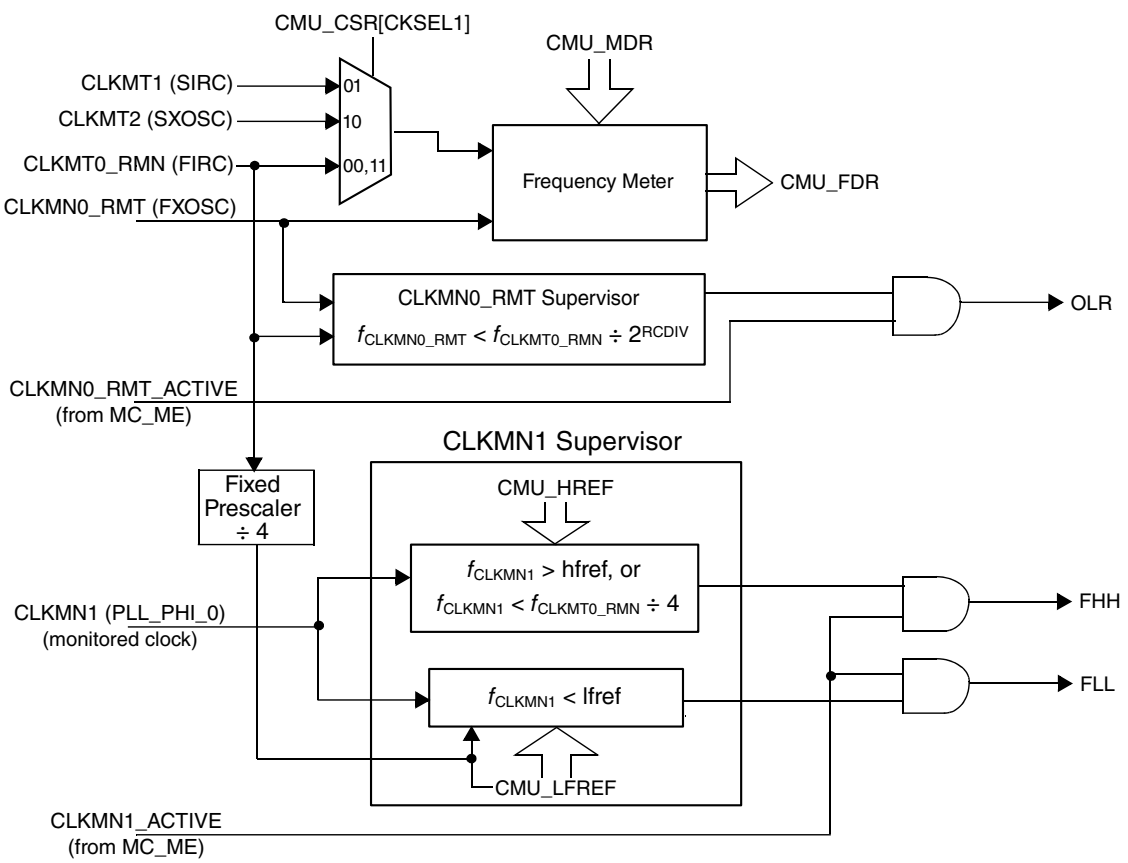

Figure 9-20. CMU block diagram

9.10.1.1 Clock input sources

The following table shows the clocks that are monitored by the CMU. These signals are connected internally on the chip, but are not accessible via pins on the boundary of the device. FIRC is the reference clock for clock monitor.

Table 9-13. Clock input sources

Clock module	Monitored clock
CMU	FXOSC, FIRC

9.10.1.2 PLL Monitor

Software can program an upper and lower limit for the expected PLL PHI_0 output clock frequency. If the monitor is enabled, and the measured frequency is above or below the limits, a flag bit is set in a status register. This will lead to FCCU_NCF[32] fault being set when the flag bit is set. The default condition of the clock monitor is disabled (CMU_CSR[CME] = 0). The FIRC is used as the reference clock for the monitor (CLKMT0_RMN, and CMU_CSR[CKSEL1] = 00b or CMU_CSR[CKSEL1] = 11b).

9.10.1.3 FXOSC monitor

The frequency of the FXOSC is compared to a minimum limit as configured in the CMU. If the measured FXOSC frequency is below the limit, a flag bit is set in a status register (CMU_ISR[OLRI]). The OLR signal from the CMU is one of the functional reset sources of MC_RGM, and an interrupt could be generated (depending on MC_RGM configuration, see 'Functional' Event Reset DisableAlternate Request Status Register (MC_RGM_FEAR)). It is not recommended to configure OLR signal from CMU as interrupt if FXOSC is selected as system clock.

If CMU_ISR[OLRI] is set, then status in CMU_ISR and in RGM_FES would be cleared by the software routine. However on such a condition, till the time FXOSC is not corrected, the CMU_ISR[OLRI] would not recur again. Hence the software should ensure that FXOSC is corrected by polling of MC_ME_GS[FXOSC_ON]. Also, the software should not attempt any mode transition until ME_GS[FXOSC_ON] is set. Otherwise the mode transition would hang.

OLR will not be captured in STANDBY mode as CMU is power gated. When MCU is in Standby mode and counters are working on FXOSC clock and FXOSC is running slow then expected wake-up can be delayed or prevented without notification. For example, if

crystal clock dies during STANDBY mode and crystal clock is configured to be ON in target DRUN mode, then mode transition to DRUN will not complete. However SWT can be kept running on SIRC and can generate wake-up on timeout to protect against such cases when FXOSC is not functioning correctly. Additionally, external wakeups can also always cause a low power exit.

NOTE

The FXOSC monitor is always enabled when the FXOSC and FIRC are valid (see field descriptions MC_ME_GS[S_FXOSC] and MC_ME_GS[S_FIRCON] in the Global Status Register (MC_ME_GS)).

9.10.1.4 FIRC monitor

The frequency of the 16 MHz FIRC (as well as SIRC and SXOSC) can be calibrated with the CMU using the FXOSC as a reference (CLKMN0_RMT (FXOSC)). This allows application trimming of the FIRC frequency. The application specifies the duration of the measurement period in units of FIRC clock periods. The clock monitor provides in a register the number of references clocks counted during the measurement period, which can be used to calculate the actual FIRC frequency (see Frequency meter for details).

9.10.1.5 System Clock Monitors

Clock monitoring at the device level is not required for the HSM, as it contains its own internal monitor.

9.10.1.6 CMU register reset values

All reset values for the CMU registers that are device specific are shown in the following table. All other register reset values are shown in the CMUchapter.

Table 9-14. CMU reset values

Register	Reset Value
CMU Control Status Register (CMU_CSR)	0000_0006h
CMU Interrupt Status Register (CMU_ISR)	0000_0000h

9.11 Loss of system clock behavior

This device has built-in mechanisms for detecting loss of the oscillator or PLL clocks, and provides several options for reaction to a loss of clock in the application. See Figure 9-21.

9.11.1 Loss of PLL lock/FXOSC clock

As shown in Figure 9-21, each loss of lock signal from the PLL and the FXOSC failure signals are monitored by the FCCU. The FCCU can be programmed to generate a short or long reset sequence when a clock failure occurs, or simply to generate an interrupt. By default, FCCU is configured to generate Long reset sequence when a clock failure occurs.There is no automatic system clock switch, and the user is required to program the switch through the Mode Entry module (MC_ME).

If a long reset is selected the PLL, FXOSC, MC_ME, and MC_CGM are reset to their default states, and the system clock is switched to the FIRC. If a short reset is selected, the clock configuration is maintained, but again, the PLL backup clock is the only available clock to clock the system through an MC_ME mode switch.

NOTE

If PLL lock is lost and PLL clock dies immediately, FCCU will generate reset but status will not be captured as its BIU_CLK was not available. This can be debugged if MC_RGM_FES indicates FCCU as source of reset and no status reported in FCCU.

NOTE

If FXOSC failure happens, FXOSC registers will reset to its default state. It is recommended to check S_FXOSC bit of Global Status Register (MC_ME_GS) before using FXOSC clock source again.

9.11.2 Loss of FIRC clock

The frequency of the FIRC clock is monitored by the frequency meter in CMU. There is no automated trigger of an FCCU error condition if the FIRC fails. Since the FIRC is the boot and backup clock, a failure is a catastrophic failure.

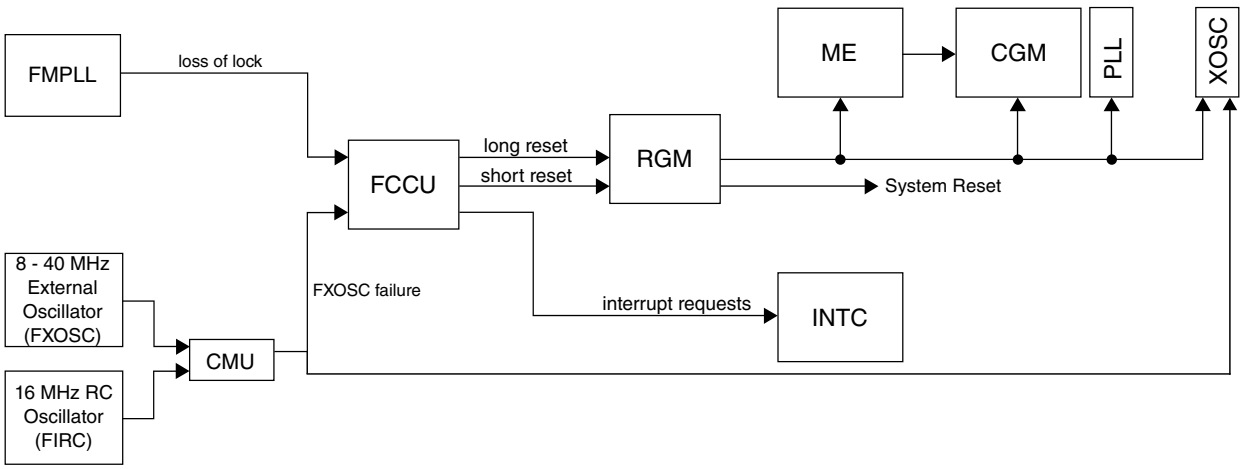

Figure 9-21. Loss of clock logic

Chapter 10
Embedded Memories

10.1 Overview

The embedded memory architecture for devices includes:

- Onboard SRAM, including system SRAM
- Onboard system error correction code (ECC) flash memory
- End-to-end ECC (e2eECC) error detection and correction
- Built-in flash memory security features including censorship and a programmable Hardware Security Module (HSM)
- Embedded memories in the peripherals[1] such as, FlexCAN, eDMA, FlexRay, and ENET.

10.2 System SRAM

MPC5746C devices include 512 KB of general-purpose on-chip ECC SRAM, configurable for either zero- or one-wait state read operation latency.

For power-sensitive applications it is important to note which ranges of SRAM are available in each device run mode. See Table 10-1 for overview of SRAM run mode availability. See the Power Management chapter Introduction for details.

Table 10-1. SRAM run modes

Start Address	End Address	Allocated Size [KB]	Run Mode(s)
0x40000000	0x40001FFF	8 (STANDBY)	All
0x40002000	0x4000FFFF	56	RUN, STOP. Optionally STANDBY, LPU [1]
0x40010000	0x4001FFFF	64	RUN, STOP. Optionally STANDBY, LPU[1]

Table continues on the next page...

1. Refer to the respective module chapter for details.

Table 10-1. SRAM run modes (continued)

Start Address	End Address	Allocated Size [KB]	Run Mode(s)
0x40020000	0x4003FFFF	128	RUN, STOP. Optionally STANDBY, LPU[1]
0x40040000	0x4007FFFF	256	RUN, STOP

1. Can be independently configured to be available during STANDBY or LPU modes.

NOTE

It is recommended to use SMPU to protect the SRAM cuts which one intends to put in SLEEP mode using the GPR Sleep Memory register.

10.2.1 SRAM Controller (PRAMC)

Each of the microcontroller's 2 banks of system SRAM has a dedicated Platform RAM Controller (PRAMC) module. The modules appear in the Peripheral Bridge A memory map as:

- PRAMC_0
- PRAMC_1

Each PRAMC module controls access to its associated SRAM by bus masters.

- PRAMC_0 corresponds to SRAM address space 0x4000_0000 to 0x4003_FFFF.
- PRAMC_1 corresponds to SRAM address space 0x4004_0000 to 0x4007_FFFF.

Additionally, the PRAMC_0 module is integrated with the flash controller (PFLASH) module to provide overlay SRAM support.

NOTE

1. PRAMC configuration settings are not global, i.e., each PRAMC module's settings affect only the SRAM array associated with that module.
2. Each SRAM array can be configured for either zero- or one-wait state read operation latency via settings in its associated PRAMC module's PFCR1 register.
3. If the system frequency is set to 160 MHz, then the PRAMCx_PRCR1[FT_DIS] field should be set to 1.
4. See the RAM controller chapter for details on configuring the SRAM controller.
6. See System memory map for the MPC5746C SRAM map.

10.2.1.1 SRAM controller (PRAMC) registers

Not all of the PRAMC register fields shown in the RAM Controller (PRAMC) chapter are applicable to all PRAMC modules. The following sections show the applicable register fields for each PRAMC module.

10.2.1.1.1 PRAMC_0 valid control register bits

Figure 10-1. PRAMC_0 register definitions

	W																

10.2.2 Overlay SRAM

The MPC5746C includes the capability of mapping a portion of system SRAM over specific regions of on-chip flash memory so that any access to an overlaid flash address is routed to the overlay SRAM instead. This enables the calibration of constant data without requiring additional external RAMs and calibration memory interfaces.

Note

Overlay SRAM is normally used for system development purposes only. Execution from overlay RAM remapped over Flash can be enabled or disabled by use of PFCRCR[IRMEM].

The overlay function is implemented using registers in the flash memory controller.

1. Using PFlash Calibration Region Descriptors (PFCRDn) define one or more (up to 8) overlay regions.
2. Enable individual regions using the appropriate bits in the PFLASH Remap Descriptor Enable Register (PFDCRDE).
3. Enable overlay using the PFCRCR[GRMEN] field.

NOTE

On the microcontroller, the only overlay RAM target available is system RAM array0 (0x40000000 – 0x4003FFFF). There are no restrictions within that range.

See PFlash calibration remap support for details on memory overlay (remapping).

10.3 Flash memory

Flash memory on MPC5746C devices consists of a flash memory controller and a flash memory array module. The flash controller provides flash configuration and control functions and manages the interface between the flash memory array and the device crossbar switch. The following figure shows the memory architecture.

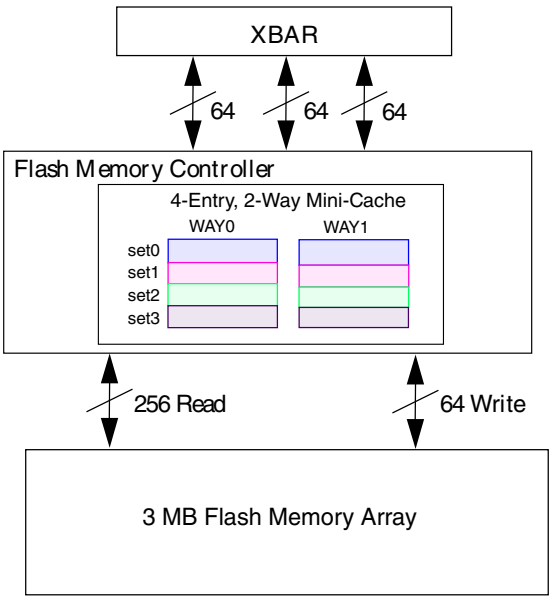

Figure 10-3. MPC5746C flash memory block diagram

The remaining sections give the functional details of the flash controller and flash array, followed by the memory maps.

10.3.1 Flash memory controller

The MPC5746C flash memory controller acts as an interface between the system bus and the flash memory array and serves as the interface to the on-chip system SRAM for calibration remapping.

The flash memory controller contains a four-entry, two-way set-associative mini-cache that delivers flash read data with a zero-wait state response on lines that reside in the cache. Each entry contains one flash page, a 32-byte memory value. Read requests that miss the cache generate the needed flash memory array access.

The flash memory controller contains configuration registers that manage flash functionality such as read buffering in the mini-cache, access control, calibration RAM overlay remapping, and read wait state management of the flash memory.

See Flash memory controller for details.

NOTE

PFLASH_PFCR1[APC] and PFLASH_PFCR1[RWSC] field values needs to be updated while read accesses to flash are stopped, that is, the software code which updates the PFLASH_PFCR1[APC] and PFLASH_PFCR1[RWSC] fields must be executed from RAM.

High clock speeds require the PFLASH_PFCR1[RWSC] field setting to a non-zero value to insert one or more wait states into flash accesses. For more information, refer MPC5746C data sheet. Operating with RWSC and APC settings outside of those specified in the data sheet is not supported and may result in corrupted read data.

10.3.2 Flash memory array

MPC5746C devices include a single 3 MB flash memory array, referred to as "main space," plus an independent 16 KB block of one-time-programmable (OTP) flash memory included to support systems that require non-volatile memory for security features or system initialization information. The independent 16 KB block is referred to as "UTEST space."

Reads of the embedded flash memory return a 256-bit page of data that may be buffered in the mini-cache in the flash memory controller. Programming of the flash may be done by double word (64-bits), page (256-bits), or quad-page (1024-bits). Flash memory is erased on a block by block basis.

NOTE

Entry to FLASH low power mode while a program/erase operation is ongoing should be prohibited, or this can result in unpredictable behavior.

10.3.2.1 Features

- Flash segmentation
  - Two 16 KB, four 32 KB, and two 64 KB, and ten 256 KB blocks provided for third party code
  - Eight 16 KB provided for boot code EEPROM emulation
  - Two 64 KB and one 16 KB blocks provided for secure code

    - Two 16 KB blocks provided for secure data
    - Support for reading-while-writing when the accesses are to different partitions
- Flash memory protection: write protection and OTP function available for each block
- Test and initialization data stored in a non-volatile 16 KB OTP UTest block
- ECC with double bit detection, single bit correction
- Erase suspend, program suspend, and erase-suspended program all supported

10.3.3 Flash organization

The embedded flash memory consists of blocks from 16 KB to 256 KB, divided into partitions that determine locations for valid read-while-write (RWW) operations. While the embedded flash memory is performing a "write" (program or erase) to a given partition, it can simultaneously read from any other partition.

- For program operations, only the address specified by an interlock write determines the partition being written (block locking and block select registers do not determine the RWW partitions being written).
- For erase operations, only blocks that are selected and unlocked determine the RWW partitions being written.

The following figure shows the flash block segmentation and read-while-write partitioning for devices.

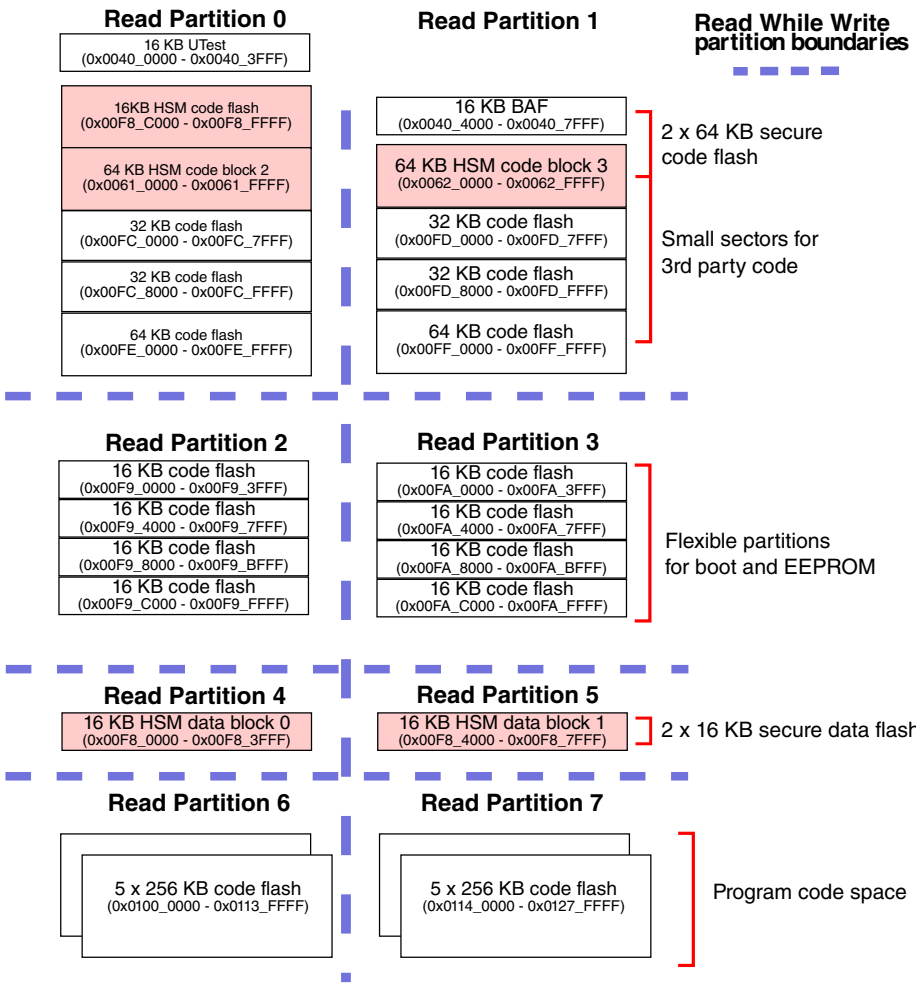

Figure 10-4. Flash memory segmentation and read-while-write partitioning

Note

See Table 1 for the flash memory map.

10.3.4 UTest NVM memory space

Devices in the family contain a 16KB area of One-Time Programmable (OTP) flash memory for storing test information and device configuration data. Most of the device configuration data is in the form of Device Configuration Format (DCF) records.

- See Introduction for details on DCF record structure, function, and contents.
- See Table 1 for the UTest flash memory map.

10.3.5 Overlay flash memory

In addition to the ability to use on-chip system RAM for overlay, the microcontroller can also reroute accesses to on-chip flash memory to other addresses within on-chip flash memory. The mechanism and controls are similar, with the following exceptions:

- Accesses to special-purpose flash blocks, i.e., UTEST flash, EEPROM, secure flash, and BAF cannot be rerouted, nor can accesses to other blocks be rerouted to the UTEST flash, EEPROM, secure flash, or BAF blocks.
- When specifying addresses for overlay flash, i.e., the flash memory addresses that accesses are to be rerouted to, the *mirrored* flash address must be used. The mirrored address range refers to the normal range (0x00F8C000 – 0x127FFFF), with address field bit[27][2] is set, giving a range of 0x08F8C0000 - 0x0927FFFF.

See PFlash calibration remap support, for details on memory overlay (remapping).

10.4 End-to-end Error Correction Code (e2eECC)

To support market requirements related to improved functional and transient fault detection capabilities, this family of automotive microcontrollers includes end-to-end ECC (e2eECC) support. This e2eECC is structurally different to traditional "ECC at memory" functionality because it provides robust error detection capabilities from one endpoint of an information transfer to another endpoint, with temporary information storage in one or more intermediate components.

Memory protected by ECC/EDC traditionally generates and checks additional error parity information local to the memory unit to detect and/or correct errors that have occurred on data stored in the memory. On the other hand, e2eECC generates error protection codes at the source of data generation. It sends the encoded data and error protection codes to intermediate storage when a memory write is initiated by a bus master and performs a data integrity check using the previously stored error protection codes at a data memory when a read of stored information is requested by a bus master. The intermediate storage may transform the generated error protection codes into another format for storage and then regenerate the codes for provision when a request is made to read the stored information or it may simply store the original protection codes unaltered, depending on the particular unit.

2. where the least significant bit of the address field is numbered '0'

Additionally, the error protection codes are generated on the basis of more than just the data associated with a storage location to protect additional information associated with an access. In particular, address information corresponding to the access location of the stored information is combined with the stored data at the data source to generate error protection codes that cover certain types of addressing errors in the system interconnect or in the memory unit. The error protection codes may be checked at the memory unit on a store to ensure that no address information or data has been corrupted while the request has transitioned through the device from the bus master source. The error protection codes may also be checked to ensure that address decoding within the storage memory was performed properly (although not all address decoding errors can be detected this way) or it may simply store the received data and protection codes at the address it receives.

On a read request from a bus master, the memory unit retrieves the data information and error protection codes corresponding to the received address from the storage location or locations and supplies the data along with the error protection codes to the requesting device. The requesting device uses a locally stored address value corresponding to the read request to check the returning data and error protection codes to ensure that no errors have occurred in either addressing the memory or in the retrieved data. This ensures that the address sent for the request was not corrupted, the addressed location was actually accessed (to the extent it is possible to ensure) and the stored data was error free, to the extent the ECC coding scheme is able to detect. As a result, the fault coverage provided by the end-to-end check is considerably more robust than the previous implementation of locally generated and checked/corrected error protection at each memory unit.

A comparison of the traditional and e2eECC approaches is shown in the following table.

Table 10-2. ECC comparison of data write-then-read sequence

Traditional ECC	End-to-End ECC (e2eECC)
Bus master initiates data write	Bus master initiates data write and generates ECC checkbits based on 29-bit address and 64-bit data fields for the computational shell or 32-bit data field for the peripheral shell
Data write transfer routed from bus master to appropriate bus slave	Data write transfer (including checkbits) routed from bus master to appropriate bus slave
For a bus memory slave, generate the ECC checkbits based on the data value and store data + checkbits into the memory	For a bus memory slave, store data and checkbits into the memory
Bus master initiates data read of previously written memory location	Bus master initiates data read of previously written memory location
Data read transfer routed from bus master to appropriate bus slave	Data read transfer routed from bus master to appropriate bus slave
For a bus memory slave, the memory array is accessed, the controller performs the ECC checkbit decode and syndrome generation, performs any needed single-bit correction and drives the read data onto the system bus interconnect	For a bus memory slave, the memory array is accessed, and the controller passes the read data and associated checkbits onto the system bus interconnection

Table continues on the next page...

Table 10-2. ECC comparison of data write-then-read sequence (continued)

Traditional ECC	End-to-End ECC (e2eECC)
The bus master captures the read data and continues	The bus master captures the read data and associated checkbits, performs the ECC checkbit decode and syndrome generation, performs any needed single-bit correction and continues

The scope of differences in the operations "covered" by the ECC checks is readily apparent with the e2eECC concept providing improved fault detection capabilities in two important aspects:

- The entire data transaction; from the initiating bus master, through the entire platform crossbar steering mechanism, to the destination slave target is covered during write accesses. Likewise, a read is checked from the initiating bus master, through the crossbar steering mechanism, through the actual memory read and transmission of the data plus checkbits back to the bus master, where the integrity and correctness of the entire transaction is checked.
- The selected ECC provides protection of both the address field as well as the data field, again for improved fault coverage.

Additionally, this particular structure also provides a significant implementation improvement. The traditional ECC at the memory approach places the checkbit decode and error syndrome generation with the error/no_error state, affecting whether the system bus transfer must be stalled (to correct a single bit error or report a noncorrectable event) or is allowed to complete (for error-free transfers) in a critical timing arc which often sets the upper limit of the operating frequency of the microcontroller. With the e2eECC scheme, the checkbit decode and error syndrome logic is located in the requesting bus master where there are generally more degrees of implementation freedom and the error/no_error state determination is removed from the system bus cycle termination logic; producing an improved timing arc and generally higher operating speeds.

Errors that occur within the system interconnect are typically manifested as an incorrect address, incorrect write data, or incorrect read data to be presented to the slave or back to the master. Errors occurring within the storage typically manifest themselves eventually in corrupted read data or checkbits being returned to a requester. While not all possible errors can be detected this way, this approach provides a substantial improvement versus traditional methods. Additional on-line diagnostics, or additional hardware, or both should be able to catch a majority of the errors not covered directly by the e2eECC scheme.

10.5 Security features

The MPC5746C architecture uses a combination of device life cycle monitoring and password protection to limit the conditions under which debugging interfaces can access certain areas of flash memory. For more information, refer, Security Reference Manual.

Chapter 11
Device Configuration Format (DCF) records

11.1 Introduction

Device Configuration Format (DCF) records are used to configure certain registers in the device during system boot while the reset signal is asserted. An individual DCF record consists of a pointer to the location of a register internal to the device and the data to be written to that register.

There are two broad categories of DCF records, TEST DCF Records and UTEST DCF Records. TEST DCF records are developed by the factory and are used mainly to program registers involved in trimming trip points for voltage comparators, adjusting analog to digital voltage supplies, trimming oscillator frequencies, and enabling RAM repair. However these records can also be used to write any DCF client. The TEST DCF Records are programmed into TEST flash during production and cannot be modified. TEST flash is not visible to the user.

The second set of DCF records are UTEST DCF records. Some UTEST DCF records are written by the factory and programmed during production testing (see DCF_Clients spreadsheet attached to this document). Others are written by the end user and programmed at the same time application code is programmed into the flash memory. User-supplied UTEST DCF records start at the next location in the UTEST memory map following the UTEST DCF records programmed into the flash memory during factory production. The user-defined DCF records set up the initial memory map, define which tests the Self-Test Control Unit (STCU2) will run during the boot sequence, enable the HSM, assign memory blocks as OTP, assign flash blocks to be associated with specific password groups and assign flash memory blocks to specific tamper detect regions.

System boot is a complex process requiring a considerable amount of initialization to take place before releasing reset. Before the device can be used in an application, the user application code, reset vectors for all of the CPUs and the DCF records must be properly programmed into their respective flash memories.

When power is applied to a properly programmed device, the Power Management Controller (PMC) takes control of the device. After the system power supplies have reached predefined levels, the Power Management Controller signals the Reset Generation Module (RGM) to begin the boot sequence. During the boot sequence, the RGM enables another internal module, the System Status and Control Module (SSCM), to read the device configuration records and then write the configuration information to the specified registers. After registers are initialized, the SSCM starts the Self-Test Control Unit (STCU2), which begins running the tasks enabled by the DCF record information.

11.2 DCF clients

DCF clients are 32-bit wide hardware registers inside a module, that receive and store the data from a DCF record. This stored data is used to initialize registers and to configure features. DCF Clients have a default value before any DCF Records are written, and may have special writing constraints, such as, ‘Write Once’ or allowing bits to be written from ‘1’ to ‘0’ only or vice versa. DCF clients need not implement all 32 bits. DCF clients maybe designated ‘TEST DCF record only’, which means that only DCF Records stored in TEST flash can write to the DCF Client. The DCF Records select the ‘target’ DCF client by a 30-bit field in the DCF Record consisting of a 15-bit ‘Chip Select’ field and a 15-bit Address field. Each module that includes DCF clients is assigned a Chip Select during chip definition. The address field is only relevant to the address decoding within that module and may not necessarily relate to the address of a register visible to software.

11.2.1 Safety features of DCF clients

Depending on its role in the device a client may be equipped with a safety feature or a combination of safety features.

11.2.1.1 Parity

If a DCF client implements parity checking, then it will receive a parity bit additionally to it's data in the DCF record. During device operation it will continuously monitor whether the data it stores matches the parity and report errors to the SSCM.

11.2.1.2 Triple voting

DCF clients that use the triple voting have three copies of the register. The SSCM will write to all three registers in a single write cycle. During device operation the DCF client continuously monitors whether all three copies match and reports errors to the SSCM. The device will use the majority result, so single errors will not affect device operation.

11.2.1.3 Spreaded triple voting

DCF clients that use spreaded triple voting have three copies of the register which are individually addressed and where the data is stored in three different formats. The SSCM will fetch these records independently. During device operation the DCF client continuously monitors whether all three copies can be resolved from the stored format to the value and reports errors to the SSCM. The device will use the majority result, so single errors will not affect device operation.

11.2.1.4 Second write check

This feature is used by DCF clients which receive their records twice - e.g. once before and once after BIST for clients which retain their value during self test. They will monitor whether the second write matches the first and report deviations to the SSCM.

11.2.2 DCF client modification rules

Depending on its role in the device a client may implement one or a combination of modification rules. If a modification rule is in effect, the order in which DCF records are placed in the record list may be important.

11.2.2.1 Write Once

A DCF client using the Write Once rule can only be written with a single DCF record. Records appended later in the list will be ignored and not change the value of the client.

11.2.2.2 Write 0 only

A bit in a DCF client can only be written from a 1 to a 0. So, if an earlier DCF record has set a bit to 0, then an attempt by a later record to set this bit to a 1 will be ignored.

11.2.2.3 Write 1 only

A bit in a DCF client can only be written from a 0 to a 1. So, if an earlier DCF record has set a bit to 1, then an attempt by a later record to set this bit to a 0 will be ignored.

11.3 DCF record structure

A DCF record is a double-word (64-bit) entry consisting of the following:

- Control word: Information to locate the corresponding DCF client internal to the device (pointer to the location of a register internal to the device)
- Data word: Data to be written to that client

DCF Records select the target DCF client by a 30-bit field in the DCF Record consisting of a 15-bit ‘Chip Select’ field and a 15-bit Address field. Each module that includes DCF clients is assigned a Chip Select during chip definition. The address field is only relevant to the address decoding within that module and may not necessarily relate to the address of a register visible to software.

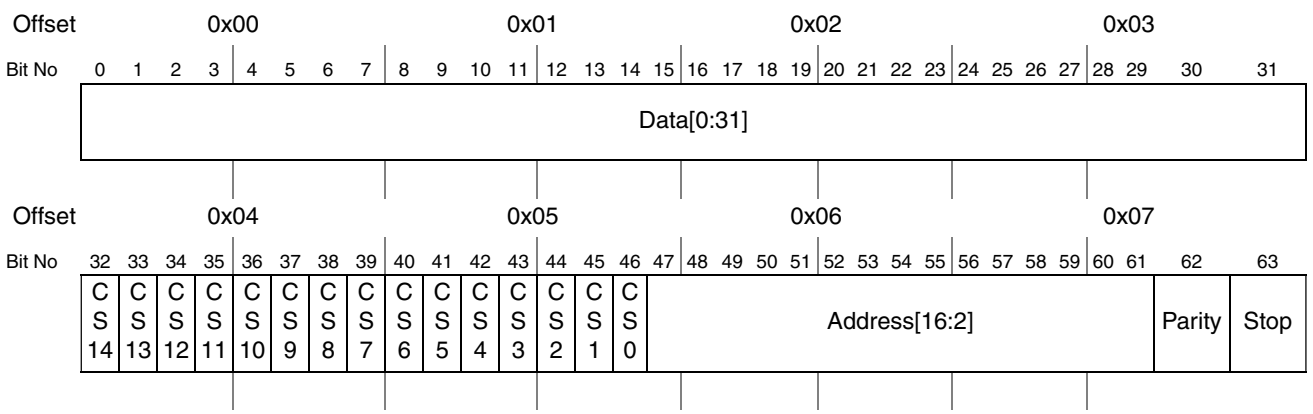

Figure 11-1. DCF Record Structure

Table 11-1. DCF Record Field Description

Field	Name	Description
0-31	Data[0:31]	32 bits of data that is to be written to the DCF Client
32-46	CS*n*	Chip Select *n* One Chip select is asserted (‘1’) per DCF record to select the target module for the DCF client. All other Chip Selects should be negated (‘0’).
47-61	Address[16:2]	Address of the DCF client within the selected module.

Table continues on the next page...

Table 11-1. DCF Record Field Description (continued)

Field	Name	Description
		Note: Address decoding for DCF clients may not match the standard software address map decoding. Details of DCF Client addresses are defined in each module chapter.
62	Parity	Parity Bit for the DCF Record. Note: This bit is NOT implemented for DCF Client written from UTEST.
63	Stop	Stop bit. Indicates the end of the list of DCF Records. Stop = ‘0’ - NOT the end of the list Stop = ‘1’ - End of the list Note: The Erased state of flash is 0xFFFF_FFFF_FFFF_FFFF. Therefore the list ends with the first unprogrammed double word. This location can be programmed with a new record to extend the list.

11.4 DCF records sequence

An individual DCF record consists of information to locate the corresponding DCF client internal to the device (control word) and the data to be written to that client (data word).

DCF records appear as contiguous series of entries programmed at a specific address within flash memory. The following structure must be present:

- The first DCF record must be a start record. This record must be placed at the beginning of a DCF area in flash memory to indicate to the device that the following records must be processed.
- DCF records containing configuration data must immediately follow the start record with no blank records between-an unprogrammed record is interpreted as a stop record and no DCF records following that record are processed. This allows one to program the records in several sessions, each time appending new records at the end of the list.
- The end of the configuration records are indicated by the presence of a stop record; indicated by the stop bit being set. Normally, the stop bit is never set in a valid UTEST DCF record programmed during production, since this would prevent appending additional UTEST records. The flash memory location following the last UTEST DCF record programmed at the factory is an unprogrammed location. Therefore, that location's contents will be 0xFFFF_FFFF. Thus, the stop bit location in this unprogrammed flash memory location will be a logic 1, signifying that this is the last DCF record and it is not to be acted upon.

SSCM recognizes the following record as a start record.

Table 11-2. DCF start record

0x00 (0:31)	0x04 (32:63)
0x05AA_55AF	0x0000_0000

The start bit is set by the factory at the beginning of the UTEST flash memory area.

SSCM recognizes the following record as a stop record.

Table 11-3. DCF stop record

0:31	32:62	63
Ignored	Ignored	1

User-supplied DCF records may be added in a contiguous manner immediately following the factory-written DCF records. There must never be an unprogrammed record in the series of DCF records as it will be interpreted as a stop record.

The following table shows the series of DCF records when *n* data records are stored in the UTEST flash.

Table 11-4. Series of DCF records in UTEST flash memory

Record type	ADDR offset	DATA			
Start record	0x00	0x05AA_55AF			
	0x04	0x0000_0000			STOP=0
Data records	0x08	WDATA[31:0]			
	0x0C	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
	0x10	WDATA[31:0]			
	0x14	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
	...	...			
Stop record	8(*n*-1) + 0x0	Reserved			
	8(*n*-1) + 0x4	Reserved			1
	8*n* + 0x0				
	8*n* + 0x4				

It is possible for more than one DCF Record to write to the same DCF client. In this case the later record usually overrides a DCF client value set by a previous record. However, not all DCF clients allow overwrites; this depends on the DCF client implementation.

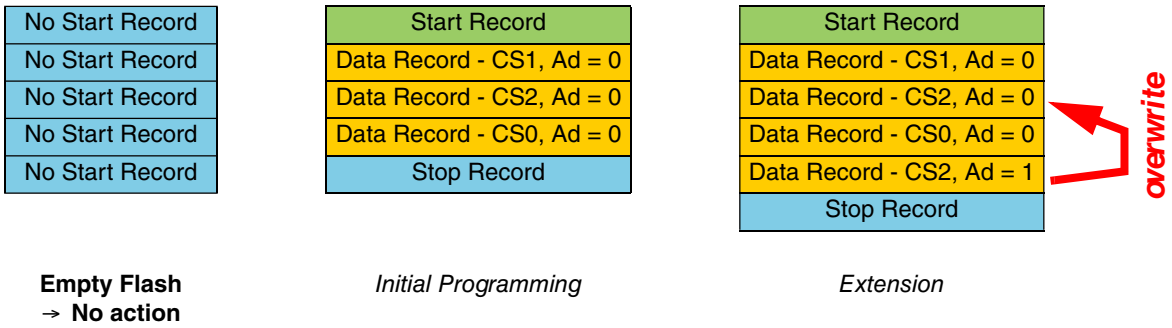

Figure 11-2. Appending DCF records

11.5 Chip configuration records

The DCF Clients Table contains information on DCF clients available in the chip. See the UTEST-FULL DCF excel attached to this document.

11.5.1 External Regulation Exit Trim Wait (PMCDIG_ERETW)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0		DELAY_VAL[2:15]													
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	DELAY_VAL[16:31]															
W																
Reset	0	0	1	1	1	1	1	0	1	0	0	0	0	0	0	0

The following table describes the register functions.

Table 11-5. PMCDIG_ERETW register field descriptions

Field	Description
0-1 Reserved	This field is reserved. This read-only field is reserved and always has the value zero.
2-15 DELAY_VAL[2:15]	Programmable External Regulation Trim Delay Value This can be programmed according to the external regulator stablization delay time. This value will hold no significance where external regulator startup time is fast or external regulator is turned off during low power modes.

Table continues on the next page...

Table 11-5. PMCDIG_ERETW register field descriptions (continued)

Field	Description
16-31 DELAY_VAL[16:31]	Programmable External Regulation Trim Delay Value This can be programmed according to the external regulator stablization delay time. This value will hold no significance where external regulator startup time is fast or external regulator is turned off during low power modes.

11.5.2 Security and serial boot mode records

For a description for the Flash backdoor password, serial boot mode and security records, please refer to the SSCM chapter.

11.5.3 STCU configuration records

The STCU provides a large number of configuration records. Please see, Self-Test Control Unit (STCU2) for more details.

Chapter 12
Debug Overview

12.1 Introduction

The device contains multiple Nexus clients (Nexus class 3+) that communicate over an auxiliary port interface compliant to IEEE-ISTO 5001-2012 standard and two sets of JTAG ports compliant with IEEE 1149.1 standard and 1149.7 cJTAG standard.

Nexus class 3+ module provides real-time development capabilities for e200z2 and e200z4 core processor in compliance with Class 3 of the IEEE-ISTO 5001-2012 standard, with additional Class 4 features available.

The debug requirements covers instruction and data trace across the 2 host cores, instruction trace from the instruction trace of Z0 core inside the HSM and data trace of accesses to system RAM. In addition, compact CJTAG is supported alongside standard JTAGC.

NOTE

Throughout this manual, the e200Z4204n3 core is referred as Z4 or e200Z4.

Similarly, the e200z210n3 core is referred as Z2 or e200Z2.

The debug solution is created by the following modules:

- JTAGC - IEEE-1149.1 operations
- CJTAGC for IEEE 1149.7 operations (note full 4-pin JTAG operation is the default mode of operation)
- JDC - required to support the Challenge Response password authentication protocol via the HSM module
- e200z43 nexus class 3 module
- e200z2 nexus class 3 module
- Nexus Data Trace client (NXMC) for the SRAM.
- Nexus 2 trace client for Z0 core of HSM
- Nexus Port Controller, capable of supporting 16xMDO full port mode and 12xMDO reduced port mode

The communication with Nexus Debug Interface (NDI) is handled via the auxiliary port and the JTAG port.

- The auxiliary port comprises 20 output pins and one input pin. The output pins include one message clock out (MCKO) pin, 16 message data out (MDO) pins, two message start/end out (MSEO0, MSEO1) pins, and one event out (EVTO) pin. Event in (EVTI) is the only input pin for the auxiliary port.
- There are two sets of JTAG ports, each consists of three inputs and one output. Only BGA324 supports two sets of JTAG ports.These pins include test data input (TDI), test data output (TDO), test mode select (TMS), and test clock input (TCK). TDI, TDO, TMS, and TCK are compliant with the IEEE 1149.1-2001 standard and are shared with the NDI through the test access port (TAP) interface. Ownership of the TAP is achieved by loading the appropriate enable instruction for the desired Nexus client in the JTAG controller (JTAGC). See Memory map and registers section for the JTAGC opcodes to access the different Nexus clients.

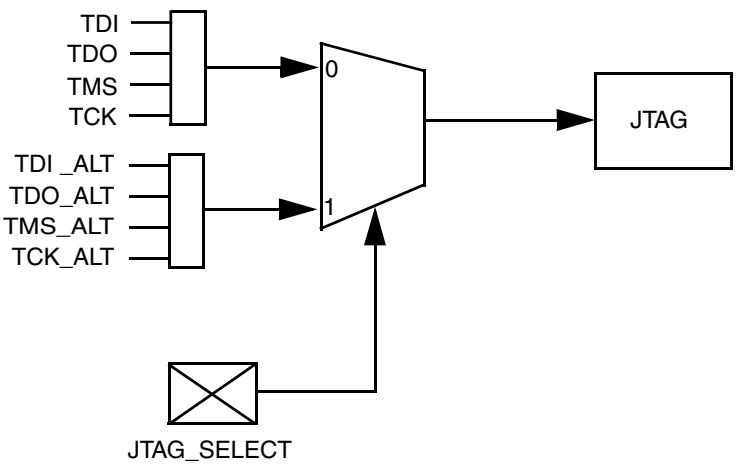

Figure 12-1. JTAG Ports

NOTE

For details on JTAG pads, see the device I/O Signal Description and Input Multiplexing tables attached to this document as an excel file.

The following peripherals support debug features:

- STM_0, STM_1
- SWT_0, SWT_1, and HSM_SWT
- FCCU
- eMIOS_0, eMIOS_1
- SAI0, SAI1, and SAI2
- ENET
- IIC_0, IIC_1, IIC_2, and IIC_3
- DSPI[3:0]

- FLEXCAN[7:0]
- eDMA controller
- SPI[3:0]
- PIT-RTI
- RTC-API
- SSCM

NOTE

Debugger connection would break after STANDBY exit if Pad Keeper functionality is enabled in STANDBY modes.

12.2 Features

The debug module of the device compliant with the IEEE-ISTO 5001-2012 standard. The following features are implemented:

- 29-bit pin interface for high throughput, including two sets of four JTAG pins
  - Two modes are supported: full port mode (FPM) and reduced port mode (RPM). FPM comprises 16 MDO pins. RPM comprises 12 MDO pins, and can be used to increase the number of GPIOs. Care must be taken as bandwidth will be limited.
  - At ambient temperature, the Nexus Aux port MCKO supports the maximum frequency of 80 MHz both at FPM and RPM. Otherwise, the maximum supported frequency is reduced to 40 MHz.
  - Auxiliary output port
    - One MCKO (Message clock out) pin
    - 16 MDO (Message data out) pins
    - Two MSEO (Message start/end out) pins
    - One EVTO (Event out) pin
  - Auxiliary input port uses one EVTI (Event in) pin.
  - Two sets of JTAG ports each uses four pins (TDI, TDO, TMS, TCK, TDI_ALT, TDO_ALT, TMS_ALT, and TCK_ALT)
- The NPC block performs the following functions:
  - Control arbitration for ownership of Nexus Auxiliary Output Port between all the nexus clients
  - Nexus Device Identification Register and Messaging
  - Generates MCKO enable and frequency division control signals
  - Controls sharing of EVTO between different nexus clients.
  - Generates an MCKO clock gating control signal to enable gating of MCKO when the auxiliary output port is idle.
  - Control of the device-wide debug mode
  - Generates asynchronous reset signal for Nexus blocks

- Host processor (e200z4) and secondary processor (e200z2) development support features:
  - IEEE-ISTO 5001-2012 standard class 3+ compliant.
    - Program trace via Branch Trace Messaging (BTM), with the option of using Branch history messaging to enhance message throughput.
    - Data trace via data write messaging (DWM) and data read messaging (DRM). This allows the development tool to trace reads and/or writes to selected internal memory resources.
    - Ownership trace via ownership trace messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated. An ownership trace message is transmitted when a new process/task is activated, allowing development tools to trace ownership flow.
    - Run-time access to the on-chip memory map via the JTAG port.
    - Watchpoint messaging (WPM) via the auxiliary port. This allows a watchpoint to be set, which then sends a watchpoint message each time the watchpoint is hit. Unlike watchpoint triggering, WPM does not stop the core or start trace.
    - Registers for Program Trace, Data Trace, Ownership Trace and Watchpoint messaging.
  - Additional class 4 features
    - Watchpoint trigger enable of program and/or data trace messaging. This is an extension of WPM to allow a watchpoint to stop or start program or data trace.
    - Processor overrun control
- Cross triggering — The capability for an EVTO (event out) signal from either the e200z4 or e200z2 Nexus3+ to generate a debug request to the other core, thus allowing both cores to enter debug mode within a short period of each other.

12.3 Debug scheme

The debug scheme and connectivity is shown in the following figure:

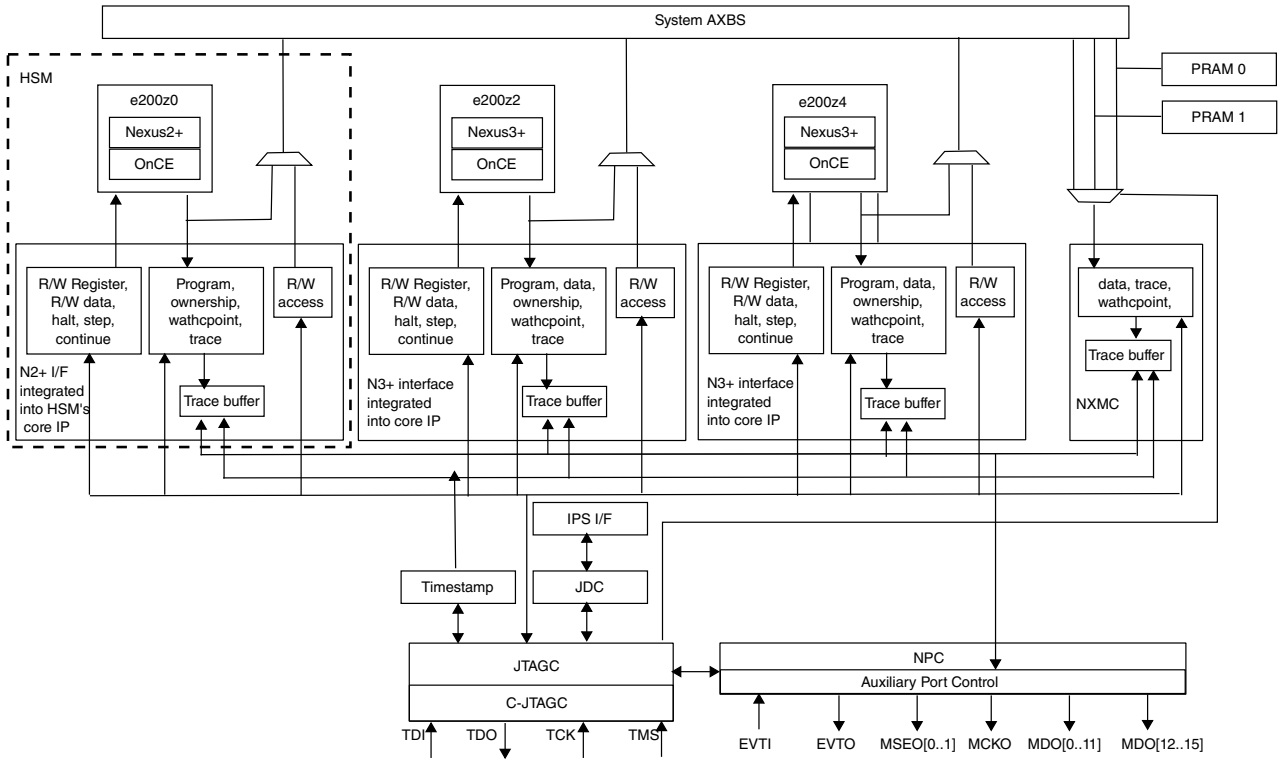

Figure 12-2. Debug scheme

12.4 Modes of operation

The Nexug debug interface (NDI) block is in reset when the TAP controller state machine is in the TEST-LOGIC-RESET state. The TEST-LOGIC-RESET state is entered on the assertion of the power-on reset signal, or through state machine transitions controlled by TMS. Ownership of the TAP is achieved by loading the appropriate enable instruction for the desired Nexus client in the JTAG controller (JTAGC) block. The NPC transitions out of the reset state immediately following negation of power-on reset.

12.4.1 Nexus Reset Mode

In Nexus reset mode, the following actions occur:

- Register values default back to their reset values.
- The message queues are marked as empty.
- The auxiliary output port pins are negated if the NDI controls the pads.
- The TDO output buffer is disabled if the NDI has control of the TAP.

- The TDI, TMS, and TCK inputs are ignored.
- The NDI block indicates to the MCU that it is not using the auxiliary output port. This indication can be used to three-state the output pins or use them for another function.

12.4.2 Full-port Mode

In the full-port mode (FPM), 16 MDO pins (MDO[0..15]) pins are used to transmit Nexus messages. All trace features are available by writing to the configuration registers via the JTAG port. FPM is entered by asserting the MCKO_EN and FPM bits in the Port Configuration Register (PCR).

12.4.3 Reduced-port Mode

In the reduced-port mode (RPM), the number of MDO pins is reduced from 16 to 12 (MDO[0..11]). All trace features are available by writing to the configuration registers via JTAG. However, the FIFO overflow errors are more likely to occur in this mode, especially if the data trace is enabled. RPM is entered by asserting the MCKO_EN bit and negating the FPM bit in the Port Configuration Register (PCR).

12.4.4 Disabled-Port Mode

In the disabled-port mode, auxiliary output pin port enable signals are negated, thereby disabling the message transmission. Any debug feature that generates messages cannot be used. The primary features available are class 1 features and read/write access to the registers. Class 1 features include the ability to trigger a breakpoint event indication through EVTO. The NDI is placed in disabled mode upon exit of power-on reset.

12.4.5 Multi mode nexus TAP

In this mode, Nexus Debug interface of e200Z4 and e200Z2 gets connected in a daisy fashion. This allows the tools to treat each core individually and then start (or stop) all cores together with a longer scan chain. Note that the HSM is not included in this daisy chain.

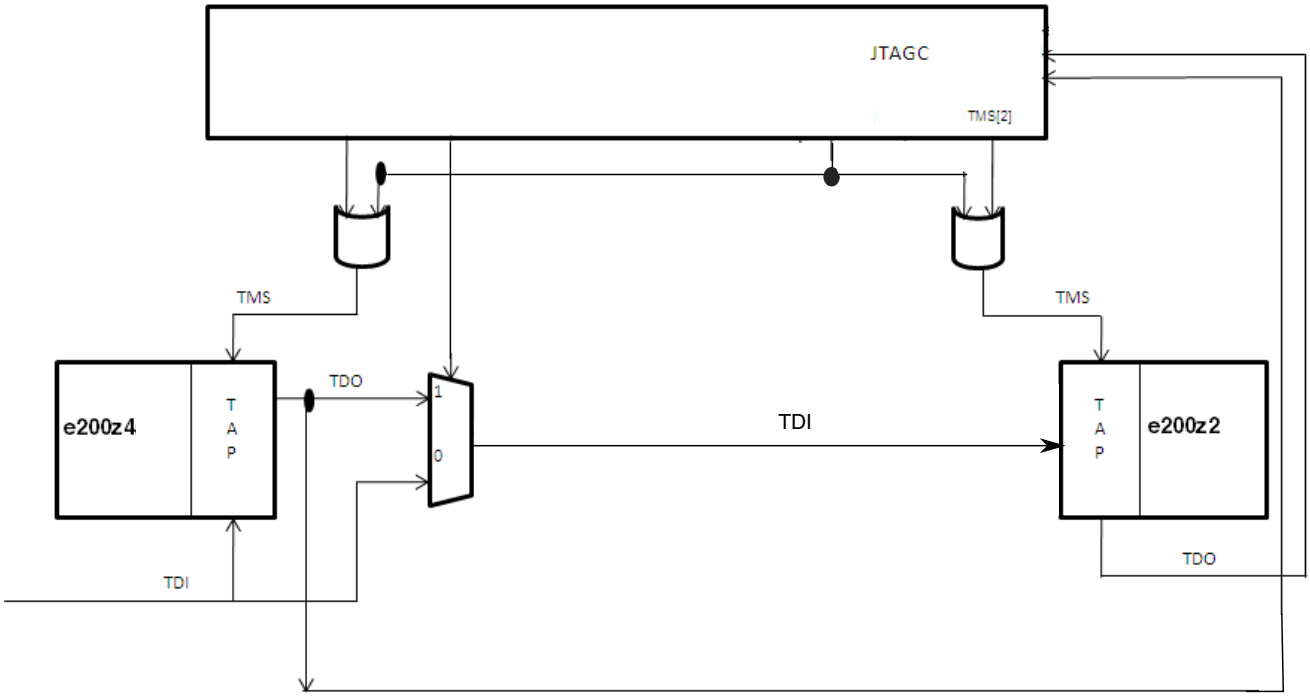

Figure 12-3. Multi mode nexus TAP

12.5 External signal description

The auxiliary and JTAG pin interfaces provide for the transmission of messages from Nexus modules to the external development tools and for access to Nexus client registers. The auxiliary/JTAG pin definitions are outlined in the following table:

Table 12-1. Auxiliary/JTAG pin definitions

Name	Port	Function
EVTO	Auxiliary	Event Out pin
EVTI	Auxiliary	Event In pin
MCKO	Auxiliary	Message Clock Out pin (from NPC)
MDO[0:15]	Auxiliary	Message Data Out pins
MSEO[0:1]	Auxiliary	Message Start/End Out pins
TCK	JTAG	Test Clock Input
TDI	JTAG	Test Data Input
TDO	JTAG	Test Data Output
TMS	JTAG	Test Mode Select Input

12.6 Memory Map and Registers

The NDI block contains no memory mapped registers. Nexus registers are accessed by the development tool via the JTAG port using a client select and a register index. The client select is controlled by loading the correct access instruction into the JTAG controller. After the desired client TAP is selected, OnCE registers for that core client are accessible by loading the appropriate value in the RS[0:6] field of the OnCE command register (OCMD). Other Nexus clients (data trace client on SRAM) use a Nexus access command to access the Nexus registers of the clients. Nexus is enabled, and the associated Nexus registers become accessible, by loading the NEXUS_ENABLE instruction into the RS[0:6] field of the OCMD. When Nexus register access is enabled, the desired Nexus registers are accessible.

12.7 Functional Description

The block is implemented by integrating the following blocks:

- Nexus Port Controller Block
- Dual Nexus e200z4 Development Interface (OnCE and Nexus3+ subblocks)
- Nexus e200z2 Development Interface (OnCE and Nexus3+ subblocks)
- NPC_HNDSHK module
- NXMC module

NOTE

The TAP controller logic, reset logic, and some miscellaneous logic are duplicated in all these blocks.

12.7.1 Enabling Nexus Clients for TAP Access

Once the NDI is out of the reset state, the loading of a specific instruction in the JTAG controller (JTAGC) block is required to grant the NDI ownership of the TAP. Each Nexus client has its own JTAGC instruction opcode for ownership of the TAP, granting that client the means to read/write its registers. Once the JTAGC opcode for a client has been loaded, the client is enabled by loading its NEXUS-ENABLE instruction. Opcodes for all other instructions supported by Nexus clients can be found in the relevant sections of this chapter.

12.7.2 TAP Sharing

Each of the individual Nexus blocks on the MCU implements a TAP controller for accessing its registers. The JTAGC controls the ownership of the TAP so that the interface to all of these individual TAP controllers appears to be a single port from outside the device. Once a Nexus client has been granted ownership of the TAP, any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive.

12.7.3 Configuring the NDI for Nexus Messaging

The NDI is placed in disabled mode upon exit of power-on reset. If message transmission via the auxiliary port is desired, a write to the port configuration register (PCR) located in the NPC is then required to enable the NDI and select the mode of operation. Asserting MCKO_EN in the PCR places the NDI in enabled mode and enables MCKO. The frequency of MCKO is selected by writing the MCKO_DIV field. Asserting the FPM bit selects full-port mode.

When writing to the PCR, the PCR LSB must be written to a logic 0. Setting the LSB of the PCR enables factory debug mode and prevents the transmission of Nexus messages.

The following table describes the NDI configuration options:

Table 12-2. NDI Configuration Options

MCKO_EN bit of PCR	FPM bit of PCR	Configuration
0	X	Disabled
1	1	Full-Port Mode
1	0	Reduced Port Mode

12.7.4 TCK clock relation with NPC clock

The TCK frequency should always be less than or equal to half of the NPC clock frequency.

12.7.5 Programmable MCKO frequency

MCKO is an output clock to the development tools used for the timing of MSEO and MDO pin functions. MCKO is derived from the system clock, and its frequency is determined by the value of the MCKO_DIV field in the port configuration register (PCR) located in the NPC. Possible operating frequencies include NPC_CLK, one-half, one-quarter, and one-eighth NPC_CLK speed.

The following table shows the MCKO_DIV encodings. In this table, NPC_CLK represents the system clock frequency of 80 MHz.

Table 12-3. MCKO_DIV values

MCKO_DIV[2:0]	MCKO Frequency
0b000[1]	NPC_CLK
0b001	NPC_CLK/2
0b010	Reserved
0b011	NPC_CLK/4
0b100	Reserved
0b101	Reserved
0b110	Reserved
0b111	NPC_CLK/8

1. The NPC_CLK setting for MCKO frequency should only be used if this setting does not violate the maximum operating frequency of the auxiliary port pins (80 MHz).

NOTE

The Nexus Port Controller Port Configuration Register MCKO Divider bits (NPC_PCR[MCKO_DIV]) can be set to 0b000 to select a 1X clock rate as the Nexus Auxiliary output port frequency for the MCKO and MDO pins. Depending on the system frequency, this may force the MCKO and MDO pins to switch at a frequency higher than can be supported by the pins. This maximum frequency is specified in the device electrical specification of the Nexus MCKO and MDO pins. Insure that the maximum operating frequency of the MDO and MCKO pins is not violated when setting the NPC_PCR[MCKO_DIV] values.

The following table shows the NPC clock frequencies across DFS modes.

Table 12-4. NPC clock frequencies

Use cases	when HSM is enabled	when HSM is disabled
Full Run	80	80

Table continues on the next page...

Table 12-4. NPC clock frequencies (continued)

Use cases	when HSM is enabled	when HSM is disabled
LDFS80	40	40
NLDFS80	40	80
NLDFS40	20	40
NLDFS20	10	20

12.7.6 Cross Triggering Control

To enable a debug event in one core to cause a debug event in the other core at approximately the same time, the EVTO signal from the e200z2 Nexus3+ or e200z4 Nexus3+ is connected to the other core's DEVT1 input. When enabled in each core's Nexus1 DBCR0 register, a pulse of the DEVT1 signal causes a debug event to occur. In this case, only one external EVTO signal is generated and each core controls whether or not EVTO causes a debug event to occur.

Cross triggering of breakpoints between cores is supported. As a minimum this should include the ability to stop and start cores synchronously. i.e., break on one core can stop other cores immediately and run on one core can trigger other cores to run. Cross triggering with the HSM is NOT to be supported since it is to be completely independent.

Interconnection of debug mode control signals are shown in the following figure.

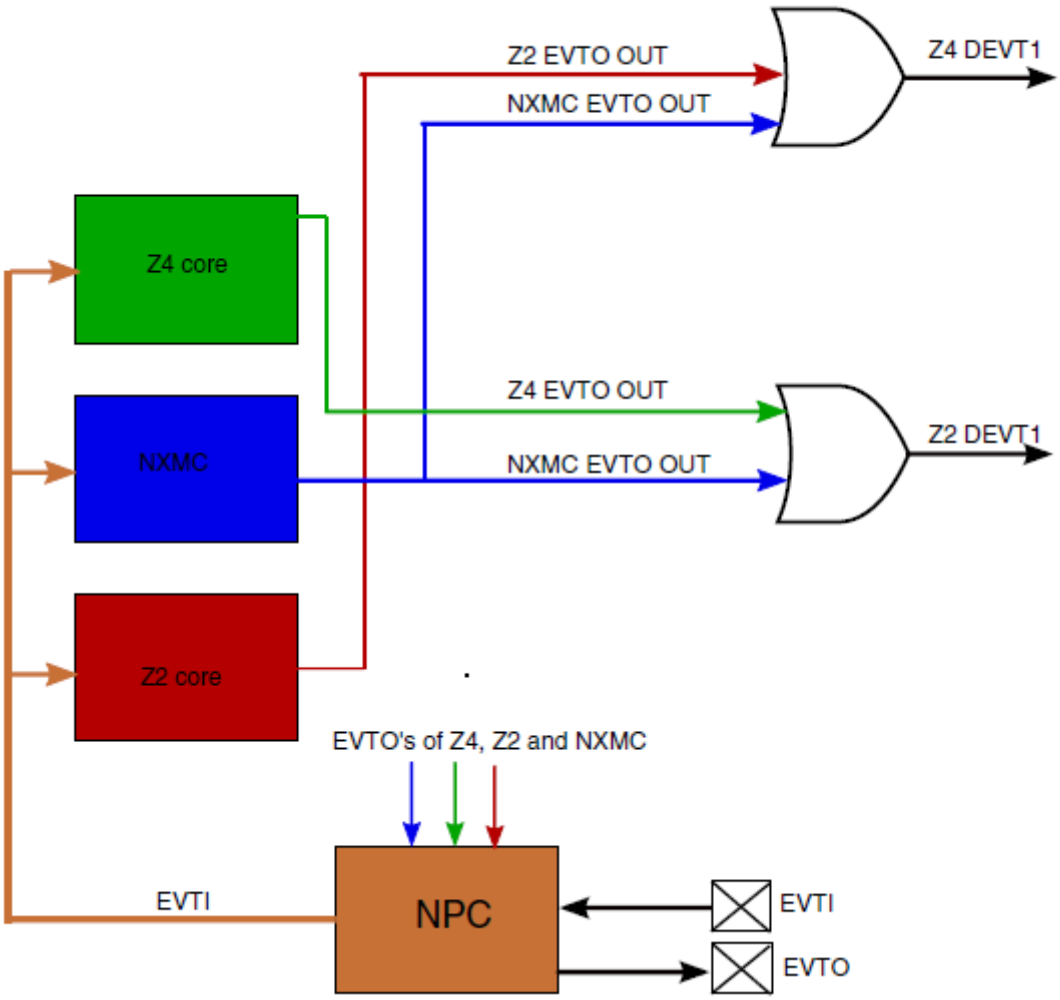

Figure 12-4. Debug Mode Control Interconnections

12.7.7 Time Stamping

The device implements Nexus trace time-stamping support logic module. This provides a mechanism to insert time-stamping data into the trace stream from each nexus client. Enable and disable controls of this time-stamping feature is included in the JTAGC, using some of the available auxiliary data bits of DATA1 register.

The time-stamping should run on the fastest core clock frequency.

- The time-stamping is based upon the full 30-bit time-stamp.
- The time-stamp is required to be reset only upon a power on reset.

12.8 Nexus Port Controller (NPC)

The Nexus Port Controller (NPC) is that part of the NDI that controls access and arbitration of the device's internal Nexus modules. The NPC contains the port configuration register (PCR) and the device identification register (DID).

The device has two instances of NPC. NPC_0 is responsible for the traces and interaction with pads and remains in full power domain. NPC_1 exists in always on domain and interacts with NPC Handshake (NPC HNDSHK). When the system enters into the low power mode, the NPC_1 and the NPC HNDSHK together follow a protocol handshaking with the debugger. The handshake enables the load and store of the context appropriately by the debugger.

NOTE

NPC_0 TAP should be reset on LPU_RUN to DRUN transition if nexus tracing is required to be enabled in DRUN mode.

The protocol to be followed by the debugger for each low power mode is described in the following section.

For details, see the NPC chapter.

12.8.1 NPC Handshake module

This module together with the NPC_1 enables debug entry/exit across the low power modes. The NPC Handshake supports:

- setting and clearing of the PCR sync bit in NPC_1 on low-power mode entry and exit
- putting the core into debug mode on low-power mode exit
- generating a falling edge on the JTAG TDO pad on low-power mode exit

Entry into STOP/STANDBY from RUN modes or Entry into LPU_STOP/ LPU_STANDBY from LPU_RUN mode:

- For the device to be in debug mode on low power exit, the debugger should set the LP_DBG and LP1_SYNC bit in the NPC_1 PCR register.
- On STOP, STANDBY, LPU_STOP or LPU_STANDBY mode entry, the LPU controller asserts the LP mode entry request input after it gets an indication from MC_ME that the clock disable process has completed and before the processor enters its stopped state. The mode transition will then not proceed until the LP mode entry acknowledge output has been asserted to the LPU controller.
- The notification to the debugger of a low-power mode entry consists of setting the NPC_1 PCR [LP1_SYNC] bit by the NPC Handshake module.

- The debugger acknowledges that the transition into a low-power mode may proceed by clearing NPC_1 PCR [LP1_SYNC] bit.
- The device enters into the low power modes. In anticipation of the low-power mode exit notification, the TDO pad is driven to '1'.

Exit from STOP/STANDBY into RUN modes or Exit from LPU_STOP/ LPU_STANDBY into LPU_RUN mode:

- On STOP or LPU_STOP mode exit, the LPU controller asserts the LP mode exit request input after ensuring that the regulator and memories are in normal mode and before the processor exits its stopped state. The mode transition will then not proceed until the LP mode exit request has been acknowledged. The MC_RGM asserts the exit from standby input when executing a reset sequence due to a STANDBY or LPU_STANDBY exit. The reset sequence will then not complete until the LP mode exit request has been acknowledged.
- The notification to the debugger of a low-power mode exit consists of driving the TDO pad to '0'.
- The debugger acknowledges that the transition from a low-power mode can continue by setting the NPC_1 PCR [LP1_SYNC] bit.
- Further, the NPC_1 PCR[LP1_sync] bit is de-asserted by the hardware and the LP mode exit acknowledge output is sent to the LPU controller. The chip comes out of low power mode with the core in the debug mode.

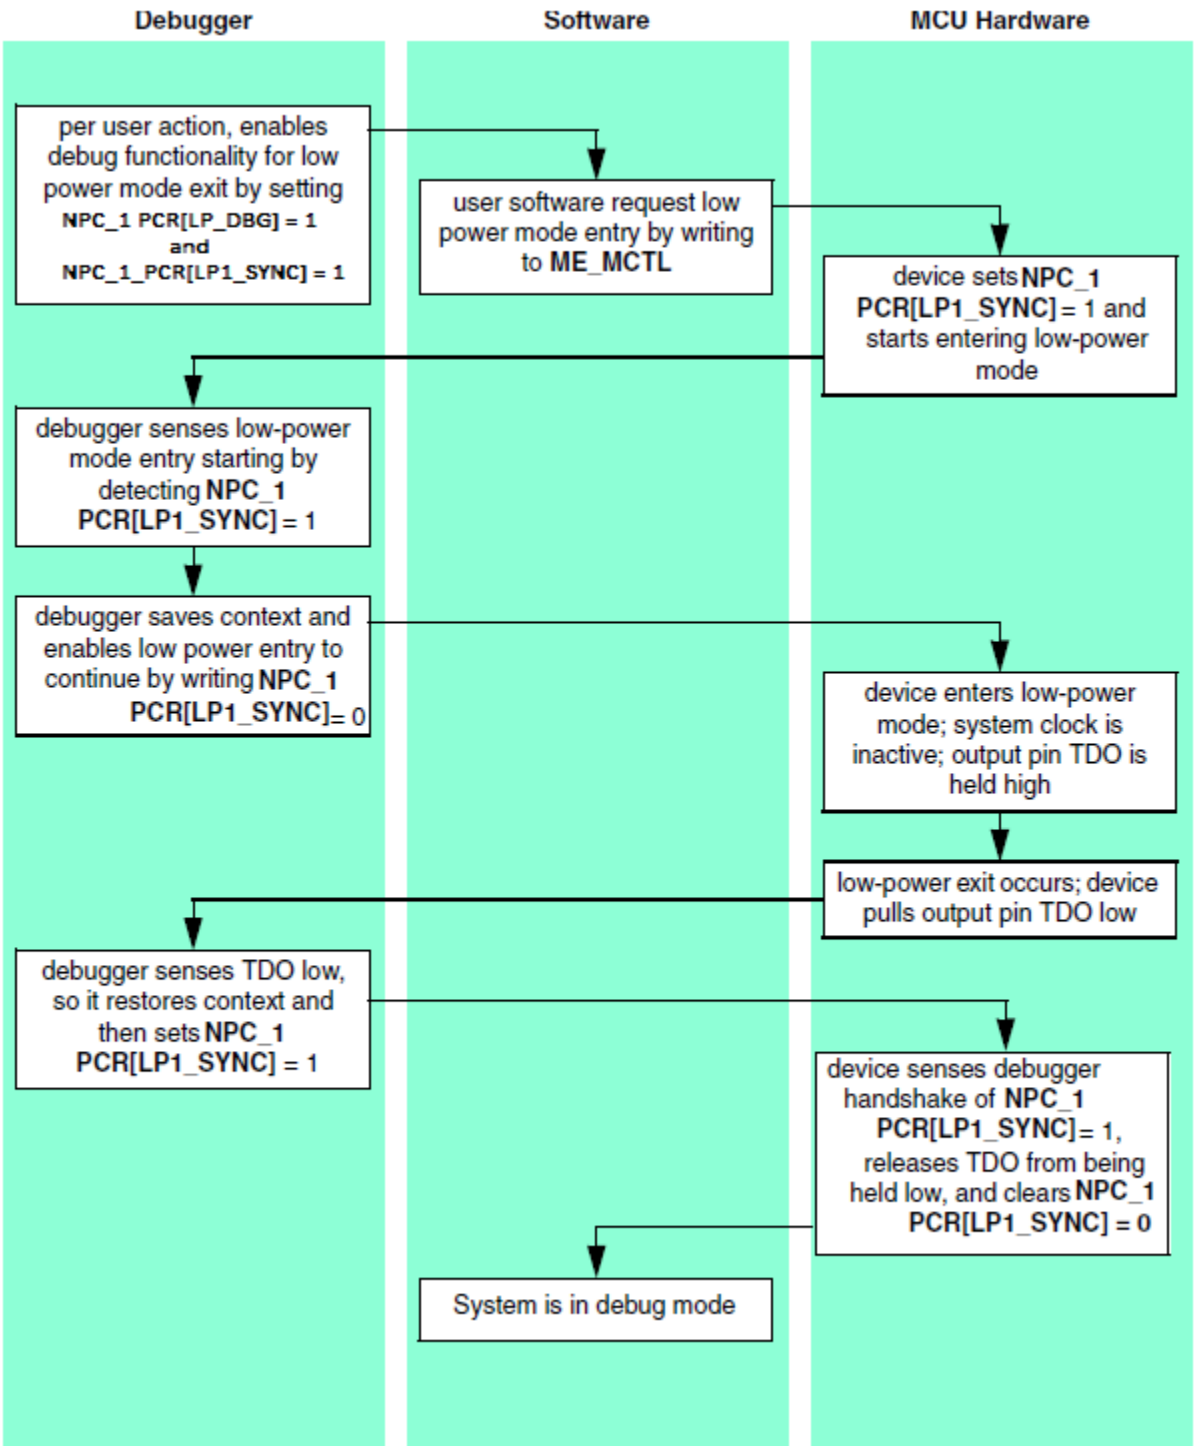

Figure 12-5. Low-Power mode debug handshake flow Ddiagram for STOP, STANDBY, LPU_STOP, LPU_STANDBY

Entry into LPU_RUN mode from RUN modes:

- For the device to be in debug mode on LPU_RUN mode entry, the debugger should set the NPC_1 PCR [LP_DBG] and NPC_1_PCR[LP1_SYNC].

- On LPU_RUN mode entry, the LPU controller asserts the LP mode entry request input after it gets an indication from MC_ME that the clock disable process has completed and before the processor enters its stopped state. The mode transition will then not proceed until the LP mode entry acknowledgement has been asserted to the LPU controller.
- The notification to the debugger of a low-power mode entry consists of setting the NPC_1 PCR[LP1_SYNC] bit.
- The debugger acknowledges that the transition into a low-power mode may proceed by clearing the NPC_1 PCR[LP1_SYNC].
- If the target mode is LPU_RUN and not the stop/standby modes, the debugger should observe '0' on TDO pad and acknowledge that the transition into LPU_RUN mode can continue by setting the NPC_1 PCR[LP1_SYNC].
- Further, the NPC_1 PCR[LP1_sync] bit is de-asserted by the hardware and the LPU RUN entry acknowledgement is sent to the LPU controller. The device comes into LPU_RUN mode with the Z2 core in the debug mode.

For getting Z2 core out of debug mode, see the Core debug support chapter.

Exit from LPU_RUN mode into RUN modes:

- For the device to be in debug mode on RUN mode entry, the debugger should set the NPC_1 PCR[LP_DBG] and NPC_1_PCR[LP1_SYNC].
- On LPU_RUN mode exit, the LPU controller asserts the LP mode entry request after it gets an indication from MC_ME that the clock disable process has completed and before the processor enters its stopped state. The mode transition will then not proceed until the LP mode entry acknowledgement has been asserted to the LPU controller.
- The notification to the debugger consists of setting the low-power mode handshake bit in the NPC_1 PCR[LP1_SYNC].
- The debugger acknowledges by clearing the NPC_1 PCR[LP1_SYNC].
- If the target mode is RUN and not the LPU stop/standby modes, the debugger should observe '0' on TDO pad and further acknowledge that the transition into RUN mode can continue by setting the NPC_1 PCR[LP1_sync] bit.
- Further, the NPC_1 PCR[LP1_sync] bit is de-asserted by the hardware and the LP mode exit acknowledgement is sent to the LPU controller. The device comes into RUN mode with the Z4 core in the debug mode.

For getting Z4 core out of debug mode, see the Z4 core debug support chapter.

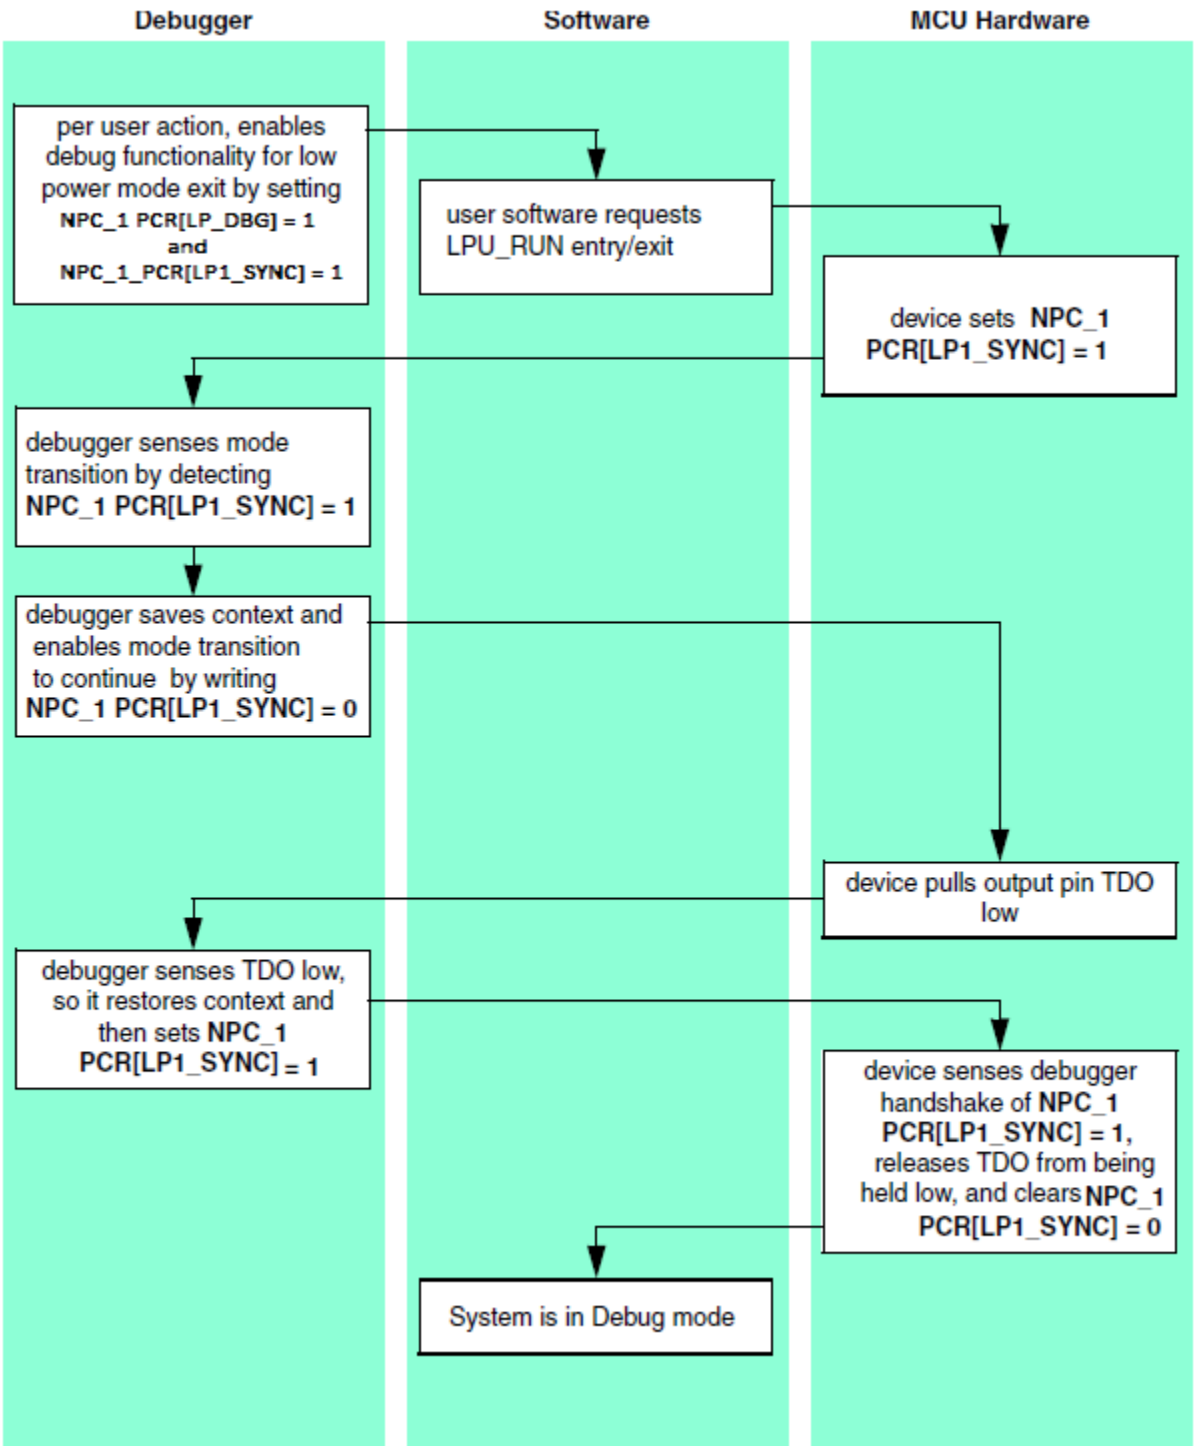

Figure 12-6. Low-Power mode debug handshake flow diagram for LPU_RUN entry and exit

12.9 e200z4 core and e200z2 core debug support

Internal debug support in the e200z4 core and e200z2 core allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes.

For details, see the e200z4 Core Debug Support chapter and e200z2 Core Debug Support chapter.

12.10 JTAG Controller (JTAGC)

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format. All Nexus debug registers are accessed and configured via the JTAG controller.

Sharing of TAP with other TAP controllers via ACCESS_AUX_x instruction (nexus clients/ other TAPs for debug placed as aux TAPs).

AUX port selection: When ACCESS_AUX_x instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive.

DATA 1 register: It is used for SRAM_MUX support, timestamping support and for disabling port enables from NPC to aux pads. See JTAGC Control 1 register.

For details, see the JTAGC chapter.

12.11 JTAG ID

The JTAG ID of the device is dependent on SIUL2_MIDR1[MAJOR_MASK] and SIUL2_MIDR1[MINOR_MASK] register field value.

SIUL2_MIDR 1[MAJOR_MASK]	SIUL2_MIDR 1[MINOR_MASK]	Version Number	Design Center	PIN	Manufacturer ID	Constant	JTAG_ID
		4 bit	6 bit	10 bit	11 bit	1 bit	32 bit
0x0	0x1	0x1	0x26	0x84	0xE	0x1	1988401D
0x1	0x1	0x1	0x26	0x85	0xE	0x1	1988501D

12.12 CJTAGC

The CJTAG is based on IEEE 1149.7. It has two wire interface (TCK and TMS) with default mode as 4-wire interface. Switches to 2-wire with standard switching sequence. For details, see Switching from Standard Protocol to Advanced Protocol.

Unused ports can be assigned for other purposes once switching is done. No special configuration required for the device. For details, see CJTAG chapter.

12.13 JDC

The JDC allows movement of data from IPS to JTAG domain registers (and back), but it does not perform the top level JTAG functions such as aux port sharing or boundary scan register control. It is currently used to allow communication between CPU and external tools for things such as security password challenge/response.

For details, see JDC chapter.

12.14 Debug implementation

This section describes the practical implementation of the debug port, its management, and the multiplexing strategy of its pads. It is required on the device to support the Class 3+ (2012) debug features on the e200Z4 and minimum Class 3 (2012) on the e200Z2.

12.14.1 Debug Capabilities

The device supports the Class 3 and Class 3+ debug features listed in the following table.

Table 12-5. Nexus3 Debug Requirements

Feature	Class 1	Class 2	Class 3	Class 4
Static debug	X	X	X	X
Set breakpoints/watchpoints	X	X	X	X
Watchpoint messaging	X	X	X	X
Ownership trace	-	X	X	X
Program trace (BTM)	-	X	X	X
Port replacement	-	-	-	-
Data trace (write only)	-	-	X	X
Dynamic memory read/write	-	-	X	X
Data trace (read/write)	-	-	X	X

The JTAG and Nexus port will work both at 3.3 V and 5 V, according to the device power supply.

Boundary scan test is supported.

12.14.2 Debug port

The debug port is composed of a total number of 25 pads. For Nexus 3+ pin description, see Signal Description chapter.

The reset and ready pins that are often present as extensions to the JTAG port are not implemented.

12.15 Nexus Class 3+ Auxiliary Port

The Nexus Auxiliary Port provides real-time development class 3+ capabilities in compliance with the IEEE-ISTO 5001-2012 standard. This development support is supplied without requiring external address and data pins for internal visibility.

By default, after power-on reset, Nexus Auxiliary Port circuitry (controller) and the dedicated pad are disabled to avoid power consumption. It can only be enabled via a certain sequence given by the debugger. As soon as the Nexus Auxiliary Port is enabled, the Nexus pads are enabled.

NOTE

A full-port (16 MDOs) and reduced-port mode (12 MDOs) is supported and controlled via the Port Configuration Register (PCR) register.

Table 12-6. AUX Port Assignments

Instruction	Codes[5:0]	Instruction Summary
AUX_TAP_NPC_0	100001	Enables access to the NPC controller
AUX_TAP_NPC_1	100010	Enables access to the NPC controller used for low power handshake
AUX_TAP_MBIST	100100	Enables access to the MBIST TAP controller
AUX_TAP_JDC	100110	Enables access to the JDC TAP controller
AUX_TAP_HSM	100111	Enables access to the HSM TAP controller
AUX_TAP_Z4	101000	Enables access to the Z4 TAP controller
AUX_TAP_Z2	101010	Enables access to the Z2 TAP controller
AUX_TAP_NXMC	110100	Enables access to the NXMC TAP controller
AUX_TAP_PARALLEL	111100	Enables access to all the cores in daisy chain manner. For details, see Multi mode nexus TAP.

12.16 e200z2 Nexus 3

The e200z2 Nexus 3 module provides real-time development capabilities for corresponding core processors in compliance with the IEEE-ISTO 5001-2012 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility

A portion of the pin interface (the JTAG port) is also shared with the OnCE / Nexus 1 unit. The IEEE-ISTO 5001-2012 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port in these processors

For details, see the e200z2 Nexus 3 chapter.

12.17 e200z4 Nexus 3

The e200z4 modules provide real-time development capabilities for e200z4d processors in compliance with the IEEE-ISTO 5001-2012 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering and Processor Overrun Control.

For details, see the Z4 Nexus Module chapter.

12.18 Nexus Crossbar Multi-master Client (NXMC)

The Nexus Crossbar Multi-master Client (NXMC) module provides real-time trace capabilities in compliance with the IEEE-ISTO Nexus 5001-2011 standard. This module provides development support capabilities for SoCs without requiring address and data pins for internal visibility. A portion of the pin interface is also compliant with the IEEE 1149.1 JTAG standard.

To provide Nexus data trace messaging from bus masters on the master ports of the crossbar (XBAR) that do not inherently have a trace client, a Nexus Crossbar Multi-Master Client (NXMC) monitors traffic into the master port of the XBAR. Trace messages transmitted over the Nexus interface (or stored in trace memory) include which master generated the message as well as an identifier for the pre-concentrator source of the message.

- Data Trace Message Formats supported: Data write/ read/ write sync/ read sync/ error messages.
- HSM master accesses filtering feature
- Watchpoint trigger input based messaging
- Watchpoint trigger out
- EVTO EVTI initiates sync message (message with complete address)
- All nexus trace control features just like any other client.
- No peripheral interface supported.
- It is an acceptable restriction that the user can not dynamically switch the input mux during run-time
- Watchpoints are to be implemented to permit enable/disable of trace

- The pin list specifies an EVTO pin for watch point signalling, which can be shared among all core nexus clients and the NXMC
- EVTO from the NXMC should be used for driving cross trigger, just like EVTO from other cores. NXMC is included in the cross triggering scheme for example, a watchpoint on a specified data access can trigger system (all other cores) to stop

For details, see the NXMC chapter.

Chapter 13
Reset and Boot Overview

13.1 Introduction

The chapter describes the global and local reset behavior of the device.

13.1.1 Global Reset

The global reset behavior refers to device reset behavior controlled by the MC_RGM which affects several modules of the device at the same time. The global reset is linked to the reset process described in Global Reset Process.

13.1.2 Local Reset

The local reset behavior refers to module reset behavior controlled by the MC_RGM or dedicated modules which affects only one module at a time. Local resets are described in the modules chapter.

13.1.3 Reset sources

As long as critical supply voltages are not reliable, the PMC provides the below mentioned signals to put the whole device into a POWERUP state. For more information, refer section, Reset Process Sequences

- LVD_FLASH
- LVD_IO_A_LO
- LVD_LV_PD0_hot
- LVD_LV_PD1_hot
- LVD_LV_PD2_hot

- POR_HV
- POR_LV

NOTE

On any of the above events, MC_RGM_DES[F_POR] will be set. Refer to PMCDIG_SGSR to detect the exact source of POWERUP for RGM. PMCDIG_SGSR[POR] indicates the POWERUP condition for the voltage regulator and MC_RGM_DES[F_POR] indicates the POWERUP for digital logic of the chip.

The following table lists the destructive and functional reset sources of the device.

Table 13-1. Destructive reset sources

Reset Source Mapping	Destructive Reset Source	Status	Reactions Possible	Bidirectional External reset generation/ Software control	Destructive Reset escalation enabled
1	Reserved				
2	HSM destructive reset	OK	Destructive	Yes/Read_only	Yes
3	Software generated destructive reset	OK	Destructive	Yes/Read_only	Yes
4	SSCM Secure reset request	OK	Destructive	Yes/Read_only	Yes
5	func_reset_escalation	OK	Destructive	Yes/Read_only	Yes
6	STCU unrecoverable fault	OK	Destructive	Yes/Read_only	Yes
7	SWT0 (flash initialization error)	OK	Destructive	Yes/Read_only	Yes
8	SWT1 reset request	OK	Destructive	Yes/Read_only	Yes

NOTE

Destructive reset escalation due to selective destructive reset sources can be disabled by configuring GPR_CTL[DEST_ESC_CTRL2], GPR_CTL[DEST_ESC_CTRL1], and GPR_CTL[DEST_ESC_CTRL0]. For more details see, GPR Chapter.

NOTE

STCU unrecoverable fault as source of destructive reset can be disabled from UTEST_MISC[SUF_DIS].

NOTE

No functional reset source can be demoted to Safe mode or interrupt in the LPU mode.

Table 13-2. Functional Reset Sources

Reset Source Mapping	Functional Reset Sources	Status	Reactions Possible	Bidirectional External reset generation/ Software control	Functional Reset escalation enabled
1	Reserved				
2	HSM generated functional reset	OK	Short Functional	No/Read_Write	Yes
3	Software generated functional reset	OK	Long/Short/ Functional	No/Read_Write	Yes
4	NMI from WKPU	OK	Long/Short Functional/Safe Request	No/Read_Write	Yes
5	JTAG_RST	OK	Long/Short Functional/Safe Request/Interrupt	No/Read_Write	Yes
6	Reset generated after self test is complete	OK	Long Functional	Yes/Read_only	Yes
7	FXOSC frequency out of range from CMU [1]	OK	Long/Short Functional/Safe Request/Interrupt	No/Read_Write	Yes
8	Long functional reset source by fault correction unit	OK	Long Functional	No/Read_Write	Yes
9	Short functional reset source by fault correction unit	OK	Short Functional	No/Read_Write	Yes
10	Z4 DBRST	OK	Long/Short Functional/Safe Request/Interrupt	No/Read_Write	Yes
11	Reserved				
12	Z2 DBRST	OK	Long/Short Functional/Safe Request/Interrupt	No/Read_Write	Yes
13	LVD_IO_A_HI	OK	Long/Short Functional/Safe Request/Interrupt	No/Read_Write	Yes
14	HVD_LV_cold	OK	Long/Short Functional/Safe Request/Interrupt	No/Read_Write	Yes
15	Reserved				
16	Reserved				
17	LVD_LV_PD2_cold	OK	Long/Short Functional/Safe Request/Interrupt	No/Read_Write	Yes

1. Reaction for this reset source should never be configured as interrupt or safe mode.

NOTE

HVD_LV_cold, LVD_LV_PD2_cold, and LVD_IO_A_HI as source of functional reset can be disabled from PMC_MISC[REE] bits. Also HVD feature can be disabled/ enabled from UTEST_MISC[HVD_EN]

During power-up, all functional terminal are maintained into a known state as described within Table 13-3

Table 13-3. Functional terminal state during power-up and reset

TERMINAL TYPE[1]	POWERUP pad state[2]	RESET pad state	DEFAULT pad state[3]	Comments
RESET	strong pull-down	strong pull-down	weak pull-up	functional reset pad.
PORST[4]	Weak pull down	Weak pull up	weak pull-up	power on reset pad.
GPIO	high impedance	high impedance	high impedance	by default, but configurable for STANDBY exit
ANALOG	high impedance	high impedance	high impedance	-
EOUT0, EOUT1	high impedance	high impedance	high impedance	
TCK	high impedance	weak pull-up	weak pull-up	-
TMS	high impedance	weak pull-up	weak pull-up	-
TDI	high impedance	weak pull-up	weak pull-up	-
TDO	high impedance	high impedance	high impedance	-
TCK_ALT	high impedance	weak pull-up	weak pull-up	-
TMS_ALT	high impedance	weak pull-up	weak pull-up	-
TDI_ALT	high impedance	weak pull-up	weak pull-up	-
TDO_ALT	high impedance	high impedance	high impedance	-

1. refer to pinout information for terminal type
2. POWERUP state is maintained until supply cross the power-on reset threshold: POR_LV for LV supply, POR_HV for high voltage supply.
3. before software configuration
4. PORST is not driven internally, so the state needs to be maintained externally on board

13.2 Global Reset Process

This section describes the global reset process.

13.2.1 Overview

The global reset process is a sequence of several reset phases. Each reset phase has a specific entry condition, a specific exit condition, and a specific device reset behavior, which is different among the reset phases. The reset phases are executed in a specific

order, thus building the actual global reset process. There are several modules contributing to the global reset process. All modules of the device can be affected by the global reset process.

13.2.2 Reset Process Modules

All modules which can enter, gate, or control the reset process are listed in Table 13-4 together with their type of contribution. The types of contribution are described in Table 13-5.

Table 13-4. Reset Process Modules

Module	Contribution Type		
	event	gating	control
Reset Generation Module (MC_RGM)	Yes	Yes	Yes
Power Management Digital Controller (PMC-Dig)	Yes	Yes	Yes
Mode Entry Module (MC_ME)	Yes	—	—
System Status and Configuration Module (SSCM)	—	Yes	—
Self-Test Control Unit	Yes	—	—
Flash Memory	—	Yes	—
MC_CGM	—	Yes	—
Software Watchdog Timeout (SWT0)	Yes	—	—

Table 13-5. Module Contribution Type

Contribution Type	Description
event	The module may generate events which may trigger the entry into a reset state, if the event configuration in the MC_RGM allows this.
gating	The module can prevent the exit of a reset state if it has not reached a certain internal state.
control	The module controls the sequence of the reset process.

13.2.2.1 Reset Generation Module (MC_RGM)

The MC_RGM is one of the two controlling module for the reset process. The MC_RGM can receive events from other modules and starts the reset process based on the configuration for these events. The event configuration defines the reset phase at which start the reset process starts. The MC_RGM controls the reset process sequence based on the gating information it receives from the gating modules.

13.2.2.2 Power Management Controller (PMC)

The PMC provides different voltage detect signals for the reset process control.

As long as the supply voltages are not reliable, the PMC provides following signals to allow the device to enter the various phases of reset process. For details, refer Reset sources

13.2.2.3 Mode Entry Module (MC_ME)

The MC_ME can generate events to enter the reset process. These events can be triggered only by application software.

13.2.2.4 System Status and Configuration Module (SSCM)

The SSCM is started automatically during a specific phase of the reset process. The SSCM fetches DCF records from the flash memory and distributes the read values via an internal DCF bus to the related modules. As long as the SSCM is still fetching DCF records, this specific reset phases can not be exited.

13.2.2.5 Self-Test Control Unit (STCU)

The STCU controls the execution of the start-up and shut-down self-test. Depending on its configuration the STCU is started when PHASE3[DEST] is left or when software triggers the self-test. The STCU generates a functional event when the self-testing has been completed.

STCU can also generate a STCU unrecoverable fault (SUF). If this fault occurs during start-up self test, it is intended to cause the start-up self test to be executed again. This is done via a ‘destructive’ reset request , if it is not disabled through UTEST_MISC[SUF_DIS]. If this fault occurs repeatedly, the ‘destructive’ reset escalator

in the MC_RGM will increment until it finally keeps the chip in reset until the next power-on reset. This is to prevent a start-up self-test pass that occurs after numerous failures to allow an unreliable chip to start execution and thus become a safety risk.

If this fault occurs during on-line or shut-down self-test , the handling is done by the FCCU. In this case, no ‘destructive’ reset request is generated.

13.2.2.6 Fault Collection and Control Unit (FCCU)

The FCCU generates reset events. Refer to Fault inputs for sources of fault. These can be configured through FCCU register interface for generating reset event.

13.2.2.7 MC_CGM

PHASE3 RESET will not exit if all system dividers are not aligned. This is internally checked by MC_CGM module.

13.2.2.8 Software Watchdog Timeout (SWT0)

SWT0 becomes active during PHASE2[FUNC]/PHASE2[DEST] RESET to monitor flash initialization failure. During normal operation, the flash indicates that it has completed its initialization process and exits PHASE2[FUNC]/PHASE2[DEST] RESET in reset sequence process.

In order to ensure that this happens within a reasonable time, the SWT is brought out of reset for PHASE2[FUNC]/PHASE2[DEST] RESET. So, if the SWT times out during this time, the flash’s initialization sequence was not able to complete. This is also referred as SWT0 (flash initialization error).

In order to trigger another attempt at initializing the flash, a ‘destructive’ reset is generated. If it occurs repeatedly, the ‘destructive’ reset escalator in the MC_RGM will increment until it finally keeps the chip in reset until the next power-on reset. This is to prevent unnecessary power consumption due to reset cycling.

13.2.3 Reset Process Sequences

This section specifies the reset processes sequences. An overview of the reset process sequences is given in the following figure. When the reset process has reached the IDLE state, the device is operational.

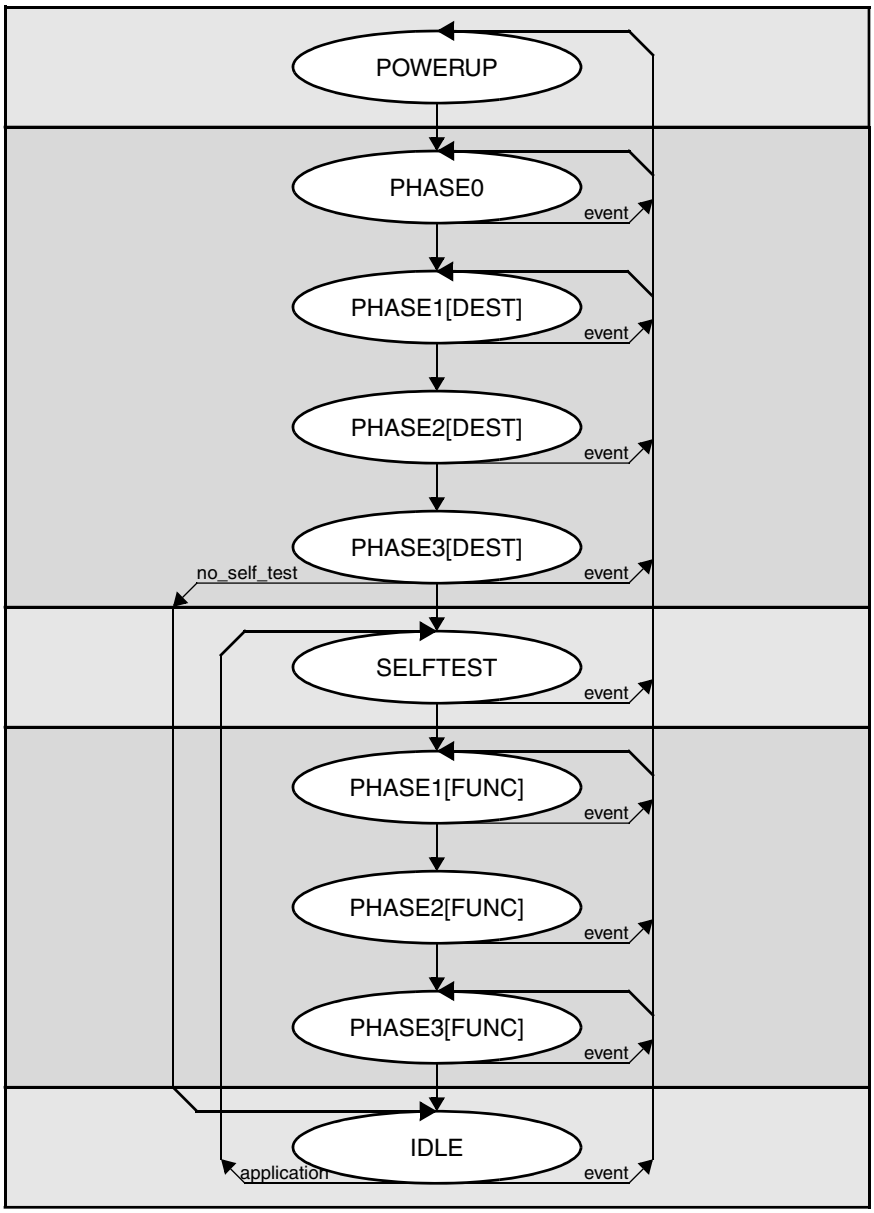

Figure 13-1. Reset Process Sequences

13.2.4 Reset Process State Transitions

This sections specifies the transitions between the reset states in the reset process. For each state, the state entry, the state execution, and the state exit is described.

13.2.4.1 POWERUP

13.2.4.1.1 POWERUP State Entry

This state is entered from any state if at least one of the following events appear

- Power is applied to the unpowered device.
- PMC has detected a low power condition that is lower than the minimum operating voltage

13.2.4.1.2 POWERUP State Execution

During this state, the PMC is waiting for stable power supply.

PMC will check that all logic domains are above min threshold voltage, referred as LVD, and then release power up for MC_RGM

Output pins are undriven and inputs are at default value. For details on state of each pad on reset, refer the device I/O Signal Description and Input Multiplexing tables attached to this document as an Excel file.

13.2.4.1.3 POWERUP State Duration

There are no bounds on the duration of this state.

13.2.4.1.4 POWERUP State Exit

Table 13-6. POWERUP Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE0	(1) The PORST pin is high in internal regulation mode and transitions from low to high when external supply is stable. Refer to the device datasheet for specifications. and (2) the PMC module indicates all supplies are in the operational range	FIRC MC_RGM PMC-Dig MC_CGM

NOTE

It is recommended to drive PORST pin when using external regulation mode, such that when external VDD_LV is not stable, PORST is driven LOW externally, and once VDD_LV is stable, PORST is driven HIGH. Alternatively, another equally robust solution is to connect PORST pin to VDD_HV_A supply. In this latter case, multiple voltage monitor resets may be seen during power-up/power-down in presence of a non-monotonic VDD_LV supply.

13.2.4.2 PHASE0

13.2.4.2.1 PHASE0 State Entry

This state can be entered whenever a destructive reset source is active. See Reset Sources section of the Reset Generation Module (MC_RGM) chapter.

13.2.4.2.2 PHASE0 State Execution

All trimming bits are reset to their default values.

13.2.4.2.3 PHASE0 State Duration

The maximum state of this duration depends on when the gates of this phase are released. Following are the gates which are required to be released

- FIRC stabilization counter should expire. Maximum count is 16 cycles of FIRC untrimmed clock

13.2.4.2.4 PHASE0 State Exit

Table 13-7. PHASE0 Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE1[DEST]	(1) The MC_RGM indicates that all sources of enabled destructive reset events are deasserted, and (2) the FIRC module indicates the generation of a stable clock,	STCU

13.2.4.3 PHASE1[DEST]

13.2.4.3.1 PHASE1[DEST] State Entry

This state can be entered from state

- PHASE0,
- PHASE1[FUNC],
- PHASE2[FUNC],

- PHASE3[FUNC],
- IDLE.

13.2.4.3.2 PHASE1[DEST] State Execution

There are no state changes in any module, only a counter in the MC_RGM is running.

13.2.4.3.3 PHASE1[DEST] State Duration

The duration of this state is 8 FIRC clock cycles.

13.2.4.3.4 PHASE1[DEST] State Exit

Table 13-8. PHASE1[DEST] Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE0	The MC_RGM has detected that the source of an enabled destructive reset event is asserted.	
PHASE2[DEST]	8 FIRC clocks passed by after state entry.	FLASH - starts initialization sequence FCCU - enters configuration state

13.2.4.4 PHASE2[DEST]

13.2.4.4.1 PHASE2[DEST] State Entry

This state can be entered from state

- PHASE1[DEST].

13.2.4.4.2 PHASE2[DEST] State Execution

FLASH executes initialization and confirms that it is ready for access. This information is used to gate phase2.

13.2.4.4.3 PHASE2[DEST] State Duration

There is no counter in MC_RGM, it is completely gate dependent.

13.2.4.4.4 PHASE2[DEST] State Exit

Table 13-9. PHASE2[DEST] Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE0	The MC_RGM has detected that the source of an enabled destructive reset event is asserted.	
PHASE3[DEST]	The FLASH module indicates that it is ready for access.	SSCM - starts device configuration and boot location search

13.2.4.5 PHASE3[DEST]

13.2.4.5.1 PHASE3[DEST] State Entry

This state can be entered only from state

- PHASE2[DEST].

13.2.4.5.2 PHASE3[DEST] State Execution

SSCM runs device configuration and boot location search.

The PMC adjusts its LVD and HVD levels according to the DCF record content after SSCM confirms that the DCF records are read from Flash.

Gates of phase3

- SSCM confirm DCF records are read from flash.
- HSM's RAM initialization is done.
- MC_CGM confirms that all system clock dividers are aligned.
- Flash is ready for access. This is again a gate for phase3 to ensure that flash is available when a short functional reset occurs.

13.2.4.5.3 PHASE3[DEST] State Duration

Maximum duration of this phase is determined by the gates. Its duration can be extended if external reset pin is kept asserted. Minimum phase duration is 40 FIRC clock cycles.

13.2.4.5.4 PHASE3[DEST] State Exit

Table 13-10. PHASE3[DEST] Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE0	The MC_RGM has detected that the source of an enabled destructive reset event is asserted.	
SELFTEST	(1) The FLASH module indicates availability of full speed array access, and (2) the SSCM module indicates device configuration is done, and (3) the HSM module indicates that HSM RAM initialization is done, and (4) the CGM module indicates that all system clock dividers are aligned, and (5) the STCU module is configured to execute a start-up self test.	BIST on - FCCU - CORES - PERIPHERALS
IDLE	(1) The FLASH module indicates availability of array access, and (2) the SSCM module indicates device configuration is done, and (3) the HSM module indicates that HSM RAM initialization is done, and (4) the CGM module indicates that all system clock dividers are aligned.	Z4A CORE ALL OTHER PERIPHERALS

13.2.4.6 SELFTEST

13.2.4.6.1 SELFTEST State Entry

This state can be entered only from state

- PHASE3[DEST],
- IDLE.

13.2.4.6.2 SELFTEST State Execution

The start-up self test is executed as configured in the STCU by the DCF record content.

13.2.4.6.3 SELFTEST State Duration

The SELFTEST runtimes with respect to PLL and IRC can be calculated as below:

SELFTEST state duration = reset phases + SELFTEST RUN (mbist) + reset phases

The minimum SELFTEST state duration (@PLL 40 Mhz)= 6.4795ms (0.194ms + 6.1047ms + 0.182ms), where

mbist all memories parallel= 4.299ms

Maximum selftest state duration (@IRC 16Mhz)= 14.30279ms (0.194ms + 13.9323ms + 0.182ms), where

mbist all memories parallel= 10.748ms

13.2.4.6.4 SELFTEST State Exit

Table 13-11. SELFTEST Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE0	The MC_RGM has detected that the source of an enabled destructive reset event is asserted.	
PHASE1[FUNC]	STCU module indicates end of self test.	

13.2.4.7 PHASE1[FUNC]

13.2.4.7.1 PHASE1[FUNC] State Entry

This state can be entered from states

- SELFTEST,
- PHASE3[FUNC],
- IDLE.

13.2.4.7.2 PHASE1[FUNC] State Execution

There are no state changes in any module, only a counter in the MC_RGM is running.

13.2.4.7.3 PHASE1[FUNC] State Duration

The duration of this state is 8 FIRC clock cycles.

13.2.4.7.4 PHASE1[FUNC] State Exit

Table 13-12. PHASE1[FUNC] Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE0	The MC_RGM has detected that the source of an enabled destructive reset event is asserted.	
PHASE1[DEST]	The MC_RGM has detected that the source of the enabled long functional external reset event is asserted.	
PHASE2[FUNC]	(1) The MC_RGM indicates that all sources of enabled long functional reset events are deasserted, and (2) 8 FIRC clocks passed by after state entry.	FLASH - starts initialization sequence FCCU -enters configuration state

13.2.4.8 PHASE2[FUNC]

13.2.4.8.1 PHASE2[FUNC] State Entry

This state can be entered from state

- PHASE1[FUNC].

13.2.4.8.2 PHASE2[FUNC] State Execution

Flash executes initialization for array access.

13.2.4.8.3 PHASE2[FUNC] State Duration

There is no counter in MC_RGM, it is completely gate dependent.

13.2.4.8.4 PHASE2[FUNC] State Exit

Table 13-13. PHASE2[FUNC] Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE0	The MC_RGM has detected that the source of an enabled destructive reset event is asserted.	
PHASE1[DEST]	The MC_RGM has detected that the source of the enabled long functional external reset event is asserted.	
PHASE1[FUNC]	The MC_RGM has detected that the sources of an enabled long functional reset event is asserted.	
PHASE3[FUNC]	The FLASH module indicates that it is ready for access.	SSCM - starts device configuration

13.2.4.9 PHASE3[FUNC]

13.2.4.9.1 PHASE3[FUNC] State Entry

This state can be entered from states

- PHASE2[FUNC]
- IDLE

13.2.4.9.2 PHASE3[FUNC] State Execution

SSCM runs device configuration, if state was entered from PHASE2[FUNC].

The FCCU executes its configuration sequence if PHASE3[FUNC] was entered via the SELFTEST state.

The FLASH indicates that it is ready for access.

13.2.4.9.3 PHASE3[FUNC] State Duration

Duration of this phase is determined by the gates. Its duration can be extended if external reset pin is kept asserted.

13.2.4.9.4 PHASE3[FUNC] State Exit

Table 13-14. PHASE3[FUNC] Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE0	The MC_RGM has detected that the source of an enabled destructive reset event is asserted.	
PHASE1[DEST]	The MC_RGM has detected that the source of the enabled long functional external reset event is asserted.	
PHASE1[FUNC]	The MC_RGM has detected that the sources of an enabled long functional reset event is asserted.	
IDLE	(1) The FLASH module indicates availability of array access, and (2) the SSCM module indicates device configuration is done, and (3) the HSM module indicates that HSM RAM initialization is done and (4) the CGM module indicates that all system clock dividers are aligned.	Z4A CORE ALL OTHER PERIPHERALS

13.2.4.10 IDLE

13.2.4.10.1 IDLE State Entry

The IDLE state can be entered only from states

- PHASE3[DEST]
- PHASE3[FUNC]

13.2.4.10.2 IDLE State Execution

During the IDLE state, the device is fully operational.

13.2.4.10.3 IDLE State Duration

There are no bounds on the duration of this state.

13.2.4.10.4 IDLE State Exit

The IDLE state next state table is shown in Table 13-15 the following table.

Table 13-15. IDLE Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE0	The MC_RGM has detected that the source of an enabled destructive reset event is asserted.	
PHASE1[DEST]	The MC_RGM has detected that the source of the enabled long functional external reset event is asserted.	
PHASE1[FUNC]	The MC_RGM has detected that the source of an enabled long functional reset event is asserted.	
PHASE3[FUNC]	The MC_RGM has detected that the source of an enabled short functional reset event is asserted.	
SELFTEST	The application has triggered the start of the shut-down selftest.	

13.2.5 Module Status During Reset Process

This section specifies in Table 13-16 the status of the device modules during the reset process. The status abbreviation explained in Table 13-17.

Table 13-16. Module Status during reset states

	Global Reset State									
Module	POWER UP	PHASE0	PHASE 1[DEST]	PHASE 2[DEST]	PHASE 3[DEST]	SELFTEST	PHASE 1[FUNC]	PHASE 2[FUNC]	PHASE 3[FUNC]	IDLE

Z4A CORE	RST	RST	RST	RST	RST	BIST	RST	RST	RST	ON
OTHERS	RST	RST	RST	RST	RST	BIST	RST	RST	RST	ON
SWT0	RST	RST	RST	ON	RST	ON	RST	ON	RST	ON

Table 13-17. Module Status Glossary

Module Status	Status Description
RST	Module is held in reset by the global reset process
BIST	Module is being tested or held in a non-functional state during self test execution as controlled by the STCU.
ON	Module is functional.

For information on impact of different phases of reset on individual modules, See *MPC5746C_Module_Reset_Status* spreadsheet attached to this document.

13.3 Boot

This following table lists the various conditions for booting the device.

Table 13-18. Booting conditions

Boot Condition	Booting Core	Boot vector
Power Up	Only Z4a	BAF code entry point - 0040_4100h
Exit from STANDBY/LPU_STANDBY to DRUN	Any core based on configuration of MC_ME_CCTLn	MC_ME_CADDRn
Exit from LPU STANDBY to LPU_RUN	Only Z2	SRAM_0 base address - 0x40000000
Entry from RUNx/DRUN to LPU_RUN	Only Z2	SRAM_0 base address - 0x40000000

13.3.1 Power Up

Refer BAF for details.

13.3.2 Exit from STANDBY/LPU_STANDBY to DRUN

MC_ME_CADDRn should be configured prior to entry into STANDBY or LPU modes.

13.3.2.1 Boot from RAM

SRAM location to be loaded in MC_ME_CADDRn. Standby exit to DRUN is faster if Flash is kept power down by configuring MC_ME_DRUN_MC[FLAON] to 2'b01 prior to entry into STANDBY or LPU modes.

13.3.2.2 Boot with BAF

Device can boot from BAF location, if the same is configured in MC_ME_CADDRn. Flash should be powered ON in DRUN if booting vector resides in flash address range.

NOTE

While configuring the device to boot from BAF after standby exit, it needs to be taken care of that UTEST_MISC[BAF_DIS] is not set.

13.3.3 Exit from LPU STANDBY to LPU_RUN

Refer Boot section.

13.3.4 Entry from RUNx/DRUN to LPU_RUN

Refer Boot section.

13.3.5 Interrupt Vector Prefix retention during STANDBY

In the Cores, the Interrupt Vector Prefix Register is used during interrupt processing for determining the starting address of a software handler used to handle an interrupt. However to use this IVPR feature on exit from STANDBY modes, the prefix value can be programmed in GPR_CTL1[IVPR] before STANDBY entry.

This register defines the base location of the interrupt vector table to the two cores z4 and z2.

When exiting Standby mode with boot vector pointing to RAM location, IVPR of the cores can be directed to RAM address location.

Chapter 14
Functional Safety

14.1 Introduction

The MPC5746C is developed according to ISO 26262 and has an integrated safety concept targeting safety-related systems requiring high safety integrity levels. In order to support the integration of the MPC5746C into safety-related systems, the following documentation is available:

- Reference Manual (MPC5746CRM) - Describes the MPC5746C functionality
- Data Sheet (MPC5746CDS) - Describes the operating conditions
- Safety Manual (MPC5746CSM) - Describes the MPC5746C safety concept and possible safety mechanisms (integrated in MPC5746C, system level hardware or system level software), as well as measures to reduce dependent failures.
- Dynamic FMEDA - Inductive analysis enabling customization of system level safety mechanisms, including the resulting safety metrics for ISO 26262 (SPFM, LFM and PMHF) and IEC 61508 (SFF and Beta IC Factor)
- FMEDA Report - Describes the FMEDA methodology and safety mechanisms supported in the FMEDA, including source of failure rates, failure modes and assumptions made during the analysis.

The Dynamic FMEDA and FMEDA report are available upon request. The MPC5746C is a SafeAssure solution; for further information regarding functional safety, visit www.nxp.com/safeassure.

Chapter 15
System Integration Unit Lite2 (SIUL2)

15.1 Introduction

15.1.1 Overview

The SIUL2 provides control over all the electrical pin controls and up to 32 ports with 16 bits of bidirectional, general-purpose input and output signals. One of the most important functions of the SIUL2 is that it enables the user to select the functions and electrical characteristics that appear on external device pins. It also controls the multiplexing of internal signals from one module to another and controls device I/O. It supports up to 32 external interrupts with trigger event configuration.

The module provides dedicated pad control to general-purpose pads that can be configured as either inputs or outputs. The SIUL2 module provides registers that enable user software to read values from GPIO pads configured as inputs, and write values to GPIO pads configured as outputs

- When configured as output, you can write to an internal register to control the state driven on the associated output pad.
- When configured as input, you can detect the state of the associated pad by reading the value from an internal register.
- When configured as input and output, the pad value can be read back, which can be used as a method of checking if the written value appeared on the pad.

To assist software development, GPIO data registers can be accessed using various mechanisms. These differing mechanisms allow support for port access or for bit manipulation without the need to use read-modify-write operations or access with Power Architecture reservation.

- Access to two 16 bit ports in one access

- Read/write access to a single bit
- A 16-bit Port write with a bit mask, using single 32-bit access.

NOTE

For any unavailable MSCR, transfer error for peripheral access will not be generated. However, 8- or 16- bit access to any valid MSCR will result in a transfer error.

The external interrupt sources can be configured at the MCU level to be used with any chip pad. From 0 to 31 of the interrupt sources can be configured to have a digital filter to reject short glitches on the inputs. The external interrupt requests map to the REQ pins in the device packages.

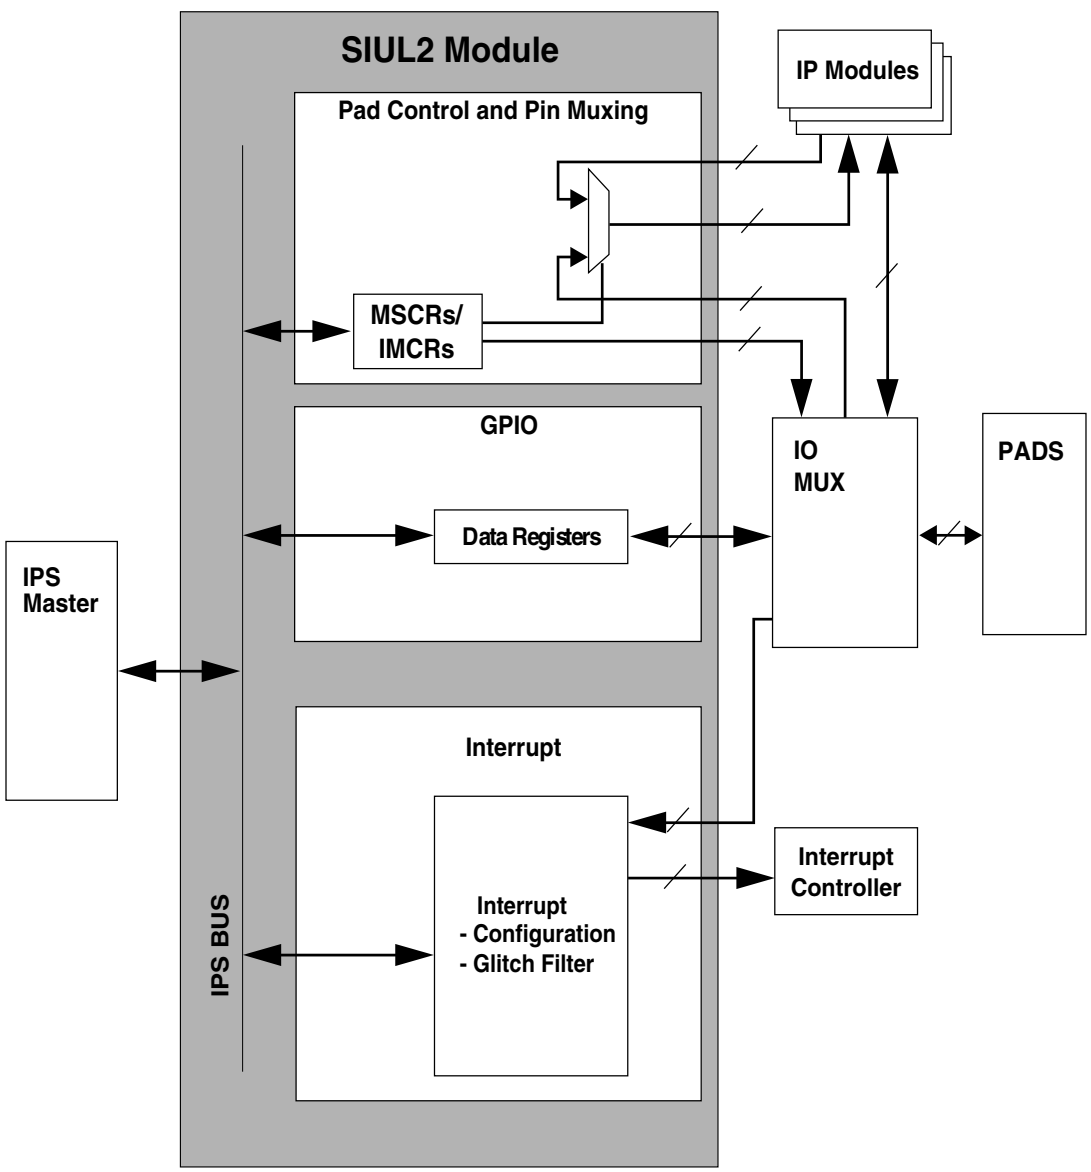

Figure 15-1. SIUL2 block diagram

15.1.2 Features

The SIUL2 supports these distinctive features:

- 1 to 32 GPIO ports with data control
  - Drive data to up to 16 independent I/O channels
  - Sample data from up to 16 independent I/O channels

Two 16-bit registers can be read/written with one access for a 32-bit port, if needed.

External interrupt request support with:

- 0 to 3 system interrupt vectors for 0 to 31 interrupt sources with independent interrupt masks. For 32 external interrupt sources (REQ pins), four groups have eight interrupt sources each, and each of the four groups is assigned one system interrupt vector.
- 0 to 31 programmable digital glitch filters, one for each REQ pin
- Edge detection

Additionally the SIUL2 contains the Multiplexed Signal Configuration Registers that configure the electrical parameters and settings of up to 264 functional pads. The number of these registers that is actually implemented varies by device. These registers configure the following pad features:

- Drive strength
- Open drain/source output enable
- Slew rate control
- Hysteresis control
- Internal pull control and pull selection
- Pin function assignment
- Control of analog path switches
- Safe mode behavior configuration

15.1.3 Register protection

The System Integration Unit Lite2 uses the Register Protection Scheme to protect the individual registers from accidental writes. The following registers can be protected:

- SIUL2 Interrupt Request Enable Register 0 (SIUL2_IRER0)
- SIUL2 Interrupt Request Select Register 0 (SIUL2_IRSR0)
- SIUL2 Interrupt Rising-Edge Event Enable Register 0 (SIUL2_IREER0)
- SIUL2 Interrupt Falling-Edge Event Enable Register 0 (SIUL2_IFEER0)
- SIUL2 Interrupt Filter Enable Register 0 (SIUL2_IFER0)
- SIUL2 Interrupt Filter Maximum Counter Register (SIUL2_IFMCR0 to SIUL2_IFMCR31)
- SIUL2 Interrupt Filter Clock Prescaler Register (SIUL2_IFCPR)
- SIUL2 Multiplexed Single Configuration Register (SIUL2_MSCR0 to SIUL2_MSCR263 and SIUL2_IMCR0 to SIUL2_IMCR511): Only the specific MSCRs and IMCRs that are actually implemented on a device are protected.
- SIUL2 GPIO Pad Data Output Register (SIUL2_GPDOn)
- SIUL2 Parallel GPIO Pad Data Out Register (SIUL2_PGPDOn)
- SIUL2 Masked Parallel GPIO Pad Data Out Register (SIUL2_MPGPDOn)

A compiled list identifies the protected registers at specific addresses for this device. Please refer the Register protection configuration.

15.2 Memory map and register description

This section provides a detailed description of all registers accessible in the SIUL module in address order. Each description includes a standard register diagram. Details of register bit and field function follow the register diagrams, in bit order. MIDRn, IFMCRn, MSCRn, IFCP, MPGPDOn(writes) are 32-bit accessible only registers.

The following table gives an overview on the SIUL2 registers implemented.

NOTE

Undocumented register spaces in the SIUL2 memory map, including addresses shown as "blank," are reserved. Reserved registers read as 0, and writes to these registers have no effect. A transfer error is issued for attempts to access a completely reserved register space. A write to reserved register bit has no effect.

SIUL2_MIDR2 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–4 FLASH_SIZE_1	Maximum Flash size of the MCU family (part1) Total flash memory size = FLASH_SIZE_1 + FLASH_SIZE_2: 0111 2M Value is set at factory and cannot be changed. All other bit combinations are reserved.
5–8 FLASH_SIZE_2	Maximum Flash size of the MCU family (part2) Total flash memory size = FLASH_SIZE_1 + FLASH_SIZE_2: 0100 1M Value is set at factory and cannot be changed. All other bit combinations are reserved.
9–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–23 PARTNUM	ASCII character in MCU Family

Table continues on the next page...

SIUL2_MIDR2 field descriptions (continued)

Field	Description
	This field specifies the part number suffix, and needs to be combined with MIDR1[PARTNUM] to indicate the MCU Family. All other values reserved for future use. Value is set at factory and cannot be changed. 01000011 Character "C"
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

15.2.3 SIUL2 Interrupt Status Flag Register0 (SIUL2_ISR0)

The Interrupt Status Register contains flag bits that record an event on the external IRQ pins. When an event as defined in IRQ Rising-Edge Event Enable Register (SIUL2_IREER0) and IRQ Falling-Edge Event Enable Register (SIUL2_IFEER0) occurs, the corresponding flag bit is set. The IRQ Flag bit is set regardless of the state of the corresponding Interrupt Request Enable bit in Interrupt Request Enable Register (SIUL2_IRER0) - Standard. The IRQ Flag bit remains set until cleared by software. The IRQ Flag bits are cleared by writing a '1' to the bits. A write of '0' has no effect. The number of bits implemented is specified by the parameter that defines the number external IRQ pins.

This register holds the interrupt flags and supports 8-bit, 16-bit, and 32-bit accesses.

Address: 0h base + 10h offset = 10h

15.2.4 SIUL2 Interrupt Request Enable Register0 (SIUL2_IRER0)

The Interrupt Request Enable Register enables the interrupt request if the corresponding External IRQ Flag bit is set in Interrupt Status Flag Register0. The type of request enabled is determined by the corresponding Interrupt Request Select bit in Interrupt Request Select Register0. The number of bits implemented is specified by the parameter that defines the number of external IRQ pins. This register is used to enable the interrupt messaging to the interrupt controller.

15.2.7 SIUL2 Interrupt Falling-Edge Event Enable Register 0 (SIUL2_IFEER0)

This register is used to enable falling-edge triggered events on the corresponding interrupt pads.

NOTE

If both IREE bit and IFEE bit is cleared for the same interrupt source, the interrupt status flag for the corresponding external interrupt will never be set.

Address: 0h base + 30h offset = 30h

15.2.8 SIUL2 Interrupt Filter Enable Register 0 (SIUL2_IFER0)

This register is used to enable a digital filter counter on the corresponding interrupt pads to filter out glitches on the inputs. The number of interrupts supporting this feature is MCU dependent and can be configured between 0 and 31.

Address: 0h base + 38h offset = 38h

SIUL2_IFMCR*n* field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 MAXCNT	Maximum Interrupt Filter Counter setting Filter Period = TCK*MAXCNTx + n*TCK where (n can be 0 to 4) MAXCNTx can be 0 to 15 (for MAXCNT<3 filter will behave as all PASS filter) TCK Prescaled Filter Clock Period, which is IRC clock prescaled to IFCP value T(IRC) Basic Filter Clock Period: 62.5 ns (F=16 MHz) Also note that Filter delay is 2 TCK clock cycles more than Filter period

15.2.10 SIUL2 Interrupt Filter Clock Prescaler Register (SIUL2_IFCPR)

This register is used to configure a clock prescaler which is used to select the clock for all digital filter. Prescaler is applied to the input clock to the SIUL2, which is the system AIPS clock counters in the SIUL2.

NOTE

The glitch filters need a running internal oscillator clock to work. If no such clock is available, external interrupts will be effectively disabled when the glitch filter is enabled on a interrupt line.

Address: 0h base + C0h offset = C0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SIUL2_IFCPR field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 IFCP	Interrupt Filter Clock Prescaler setting Prescaled Filter Clock Period = T(IRC) x (IFCP + 1) T(IRC) is the internal oscillator period. IFCP can be 0 to 15

15.2.11 SIUL2 Multiplexed Signal Configuration Register (SIUL2_MSCR*n*)

Selects which source signal is connected to the register's associated destination, which is a chip pin that is or can be configured as an output.

For the associated chip-pin destination, the register also specifies the pin's electrical properties.

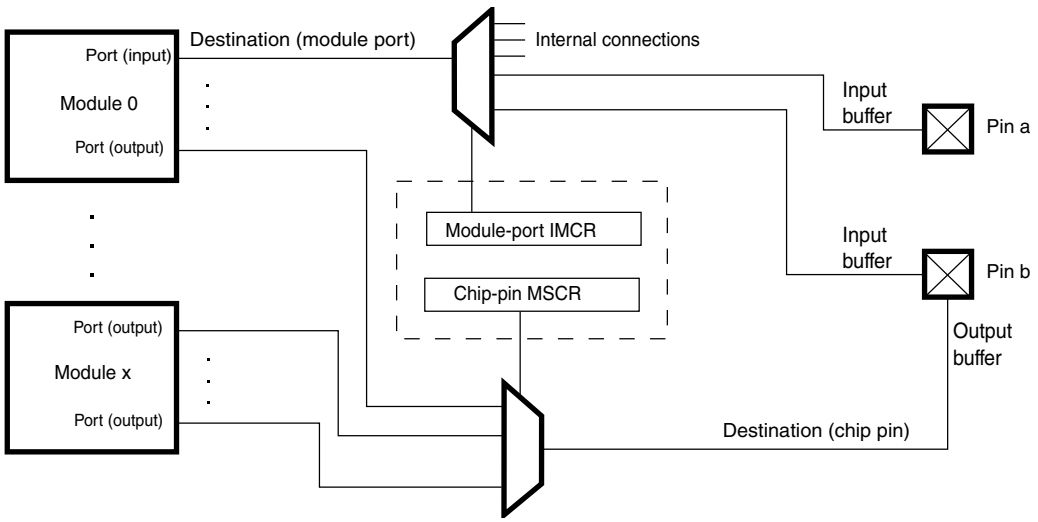

Figure 15-2. MSCR pin connection

The fields in an MSCR vary depending on its associated destination (chip pin).

For available chip-pin MSCR assignments, pin types, bit availability on each MSCR, APC support, and SSS values etc. see the I/O Signal Description and Input Multiplexing Tables (excel file) attached to this document.

This register only supports 32-bit access. Byte and half-word write accesses are not supported.

Address: 0h base + 240h offset + (4d × i), where i=0d to 263d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

* Notes:

- See the Signal Description details for the reset values and the availability of pad setting bits in MSCRs.

SIUL2_MSCR*n* field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–3 SRC[1:0]	Slew Rate Control Used only when the associated destination is a chip pin. 00 Half drive strength with slew rate control 01 Full drive strength with slew rate control 10 Half drive strength without slew rate control 11 Full drive strength without slew rate control
4–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 OBE	GPIO Output Buffer Enable Applies only to digital pins. Otherwise this bit is reserved. 0 Output driver disabled 1 Output driver enabled
7 ODE	Open Drain Enable 0 Open drain function disabled 1 Open drain function enabled, when OBE is also 1.
8 SMC	Safe Mode Control Used only when the associated destination is a chip pin. Specifies whether the chip disables the pin's output buffer when the chip enters Safe mode. 0 Disable (the output buffer returns to its previous state when the chip leaves Safe mode) 1 Don't disable
9 APC	Analog Pad Control Used only when the associated destination is a chip pin that supports analog I/O. Enables the pin's analog-input-path switch. 0 Disable (the switch is off) 1 Enable (another module can control the state of the switch)
10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 IBE	Input Buffer Enable Used only when the associated destination is a chip pin. Enables the associated pin's input buffer. 0 Disabled 1 Enabled
13 HYS	Input Hysteresis Used only when the associated destination is a chip pin. Enables input hysteresis for the associated pin.

Table continues on the next page...

SIUL2_MSCR*n* field descriptions (continued)

Field	Description
	0 Disabled 1 Enabled
14 PUS	Pull Select Determines whether the pull function is a pullup or pulldown when the pull function is enabled by the PUE field. Used only when the associated destination is a chip pin. 0 Pulldown 1 Pullup
15 PUE	Pull Enable Enables the pull function. Used only when the associated destination is a chip pin. 0 Disabled 1 Enabled
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 SSS	Source Signal Select Selects which source signal is connected to the associated destination (chip pin or module port). This field has a variable width depending on the number of alternate functions available for that pin/port. For a chip pin, the source signals are outputs from module ports. For a module port, the source signals are either outputs from module ports or inputs from chip pins. See the device I/O Signal Description and Input Multiplexing Tables (excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the excel file to open it and select the I/O Signal Description Table tab.

15.2.12 SIUL2 Input Multiplexed Signal Configuration Register (SIUL2_IMCR*n*)

Selects which source signal is connected to the register's associated destination, which is an internal module port that is or can be configured as an input.

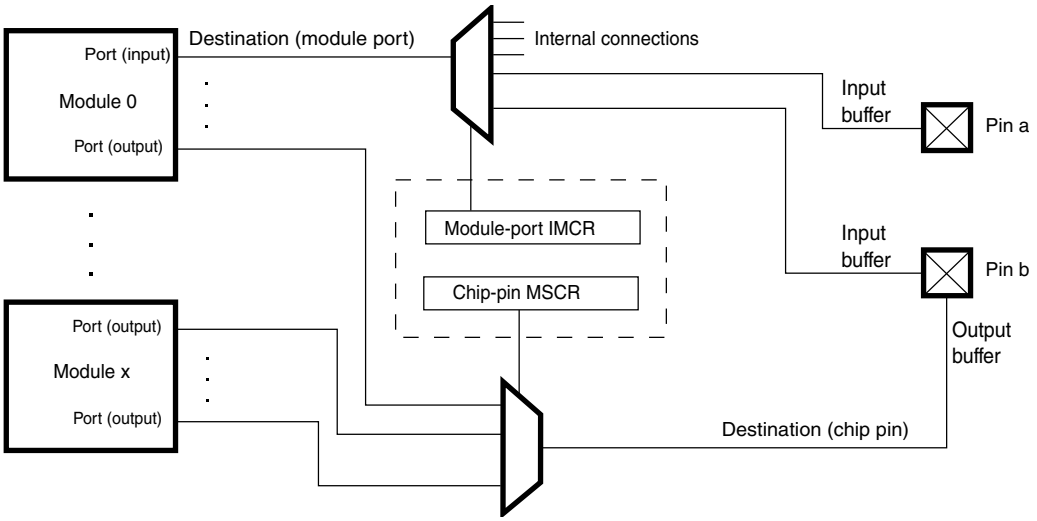

Figure 15-3. IMCR module-port connection(For IMCR0 to IMCR27, IMCR32 to IMCR63, IMCR68 to IMCR511)

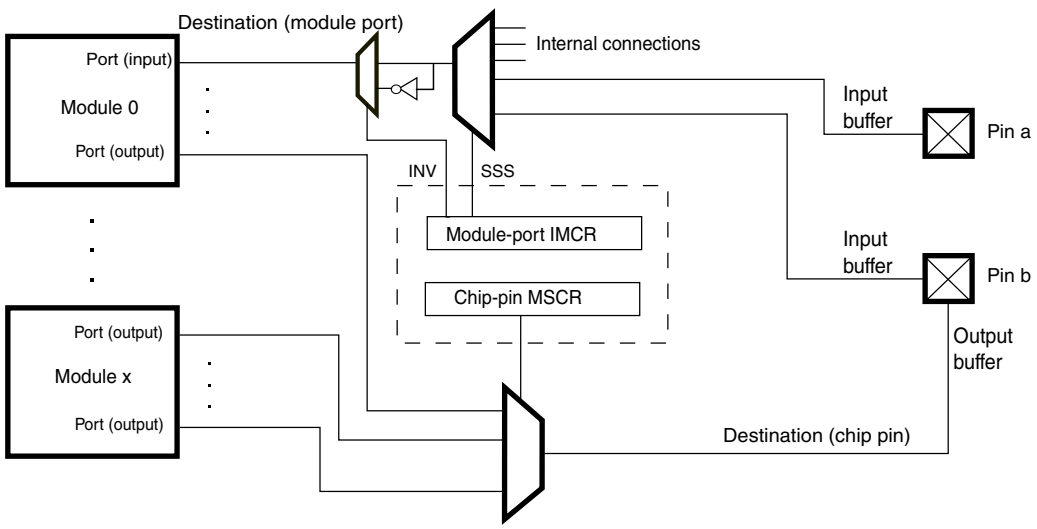

Figure 15-4. IMCR module-port connection (For IMCR28 to IMCR31 and IMCR64 to IMCR67)

The fields in an IMCR vary depending on its associated destination (module port).

For IMCR assignments and SSS values, see the I/O Signal Description and Input Multiplexing Tables (excel file) attached to this document.

Address: 0h base + A40h offset + (4d × i), where i=0d to 511d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

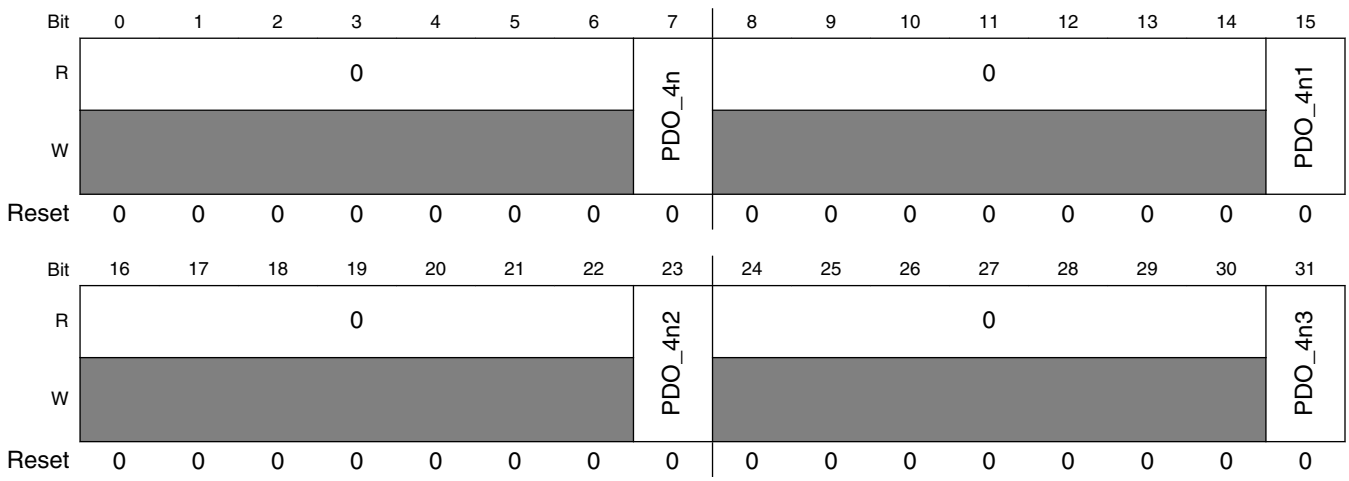
* Notes:

- INV field: INV bit exist only for IMCR28, IMCR29, IMCR30, IMCR31, IMCR64, IMCR65, IMCR66, and IMCR67. For rest of the IMCRs this field is reserved.



SIUL2_IMCR*n* field descriptions

Field	Description
0 INV	Invert This bit is used to invert the source signal. 0 Source signal is connected to the associated destination directly either from chip pin or module port. 1 Source signal is inverted before it is connected to the associated destination directly either from chip pin or module port.
1–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 SSS	Source Signal Select Selects which source signal is connected to the associated destination (chip pin or module port). This field has a variable width depending on the number of alternate functions available for that pin/port. For a chip pin, the source signals are outputs from module ports. For a module port, the source signals are either outputs from module ports or inputs from chip pins. See the device I/O Signal Description and Input Multiplexing Tables (excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the excel file to open it and select the I/O Signal Description Table tab.

15.2.13 SIUL2 GPIO Pad Data Output Register (SIUL2_GPDO*n*)

These registers can be used to set or clear a single GPIO pad with a byte access.

Address: 0h base + 1300h offset + (4d × i), where i=0d to 65d

SIUL2_GPDO*n* field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 PDO_4n	Pad Data Out This bit stores the data to be driven out on the external GPIO pad controlled by this register. PDO_4n represents PDO[4n], where n is the instance of the register. For example, for the GPDO3 register, PDO_4n represents PDO12. 0 Logic low value is driven on the corresponding GPIO pad when the pad is configured as an output 1 Logic high value is driven on the corresponding GPIO pad when the pad is configured as an output
8–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 PDO_4n1	Pad Data Out This bit stores the data to be driven out on the external GPIO pad controlled by this register. PDO_4n1 represents PDO[4n+1], where n is the instance of the register. For example, for the GPDO3 register, PDO_4n1 represents PDO13. 0 Logic low value is driven on the corresponding GPIO pad when the pad is configured as an output 1 Logic high value is driven on the corresponding GPIO pad when the pad is configured as an output
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 PDO_4n2	Pad Data Out This bit stores the data to be driven out on the external GPIO pad controlled by this register.

Table continues on the next page...

SIUL2_GPDO*n* field descriptions (continued)

Field	Description
	PDO_4n2 represents PDO[4n+2], where n is the instance of the register. For example, for the GPDO3 register, PDO_4n2 represents PDO14. 0 Logic low value is driven on the corresponding GPIO pad when the pad is configured as an output 1 Logic high value is driven on the corresponding GPIO pad when the pad is configured as an output
24–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 PDO_4n3	Pad Data Out This bit stores the data to be driven out on the external GPIO pad controlled by this register. PDO_4n3 represents PDO[4n+3], where n is the instance of the register. For example, for the GPDO3 register, PDO_4n3 represents PDO15. 0 Logic low value is driven on the corresponding GPIO pad when the pad is configured as an output 1 Logic high value is driven on the corresponding GPIO pad when the pad is configured as an output

15.2.14 SIUL2 GPIO Pad Data Input Register (SIUL2_GPDI*n*)

These registers can be used to read the GPIO pad data with a byte access.

Address: 0h base + 1500h offset + (4d × i), where i=0d to 65d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SIUL2_GPDI*n* field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 PDI_4n	Pad Data In This bit stores the value of the external GPIO pad associated with this register. PDI_4n represents PDI[4n], where n is the instance of the register. For example, for the GPDI3 register, PDI_4n represents PDI12. 0 The value of the data in signal for the corresponding GPIO pad is logic low 1 The value of the data in signal for the corresponding GPIO pad is logic high
8–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 PDI_4n1	Pad Data In This bit stores the value of the external GPIO pad associated with this register. PDI_4n1 represents PDI[4n+1], where n is the instance of the register. For example, for the GPDI3 register, PDI_4n1 represents PDI13. 0 The value of the data in signal for the corresponding GPIO pad is logic low 1 The value of the data in signal for the corresponding GPIO pad is logic high
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 PDI_4n2	Pad Data In This bit stores the value of the external GPIO pad associated with this register. PDI_4n2 represents PDI[4n+2], where n is the instance of the register. For example, for the GPDI3 register, PDI_4n2 represents PDI14. 0 The value of the data in signal for the corresponding GPIO pad is logic low 1 The value of the data in signal for the corresponding GPIO pad is logic high
24–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 PDI_4n3	Pad Data In This bit stores the value of the external GPIO pad associated with this register. PDI_4n3 represents PDI[4n+3], where n is the instance of the register. For example, for the GPDI3 register, PDI_4n3 represents PDI15. 0 The value of the data in signal for the corresponding GPIO pad is logic low 1 The value of the data in signal for the corresponding GPIO pad is logic high

15.2.15 SIUL2 Parallel GPIO Pad Data Out Register (SIUL2_PGPDO*n*)

These registers are used to set or clear the respective pads of the device. Parallel port registers for input (PGPDI) and output (PGPDO) are provided to allow a complete port to be written or read in one operation, dependent on the individual pad configuration. The difference between PGPDO and GPDO is that PGPDO registers can be used to set the values of all output pins assigned to a device port with a single 16-bit register write vs. the GPDO registers, which are used to set the value on a specific pin with a byte write.

The SIUL2_PGPDO registers access the same physical resource as the SIUL2_PDO and SIUL2_MPGPDO address locations. Some examples of the mapping:

- PPDO[0][0] = PDO[0]
- PPDO[2][0] = PDO[32]
- PPDO[31][15] = PDO[511]

Address: 0h base + 1700h offset + (2d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	PPDO															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIUL2_PGPDO*n* field descriptions

Field	Description
0–15 PPDO	Parallel Pad Data Out Write or read the data register that stores the value to be driven on the pad in output mode. Access to this register location are coherent with access to the bit-wise GPIO Pad Data Output Registers (SIUL2_GPDO).The x and bit index define which PPDO register bit is equivalent to which PDO register bit according to the following equation: PPDO[x][y] = PDO[(x*16)+y]

15.2.16 SIUL2 Parallel GPIO Pad Data In Register (SIUL2_PGPDI*n*)

These registers hold the synchronized input value from the pads. Parallel port registers for input (PGPDI) and output (PGPDO) are provided to allow a complete port to be written or read in one operation, dependent on the individual pad configuration.The difference between PGPDI and GPDI registers is that PGPDI registers can be used to read the values of all input pins assigned to a device port with a single 16-bit register read vs. the GPDI registers, which are used to read the value on a specific pin with a byte read.

Address: 0h base + 1740h offset + (2d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SIUL2_MPGPDO*n* field descriptions

Field	Description
0–15 MASK	Mask Field Each bit corresponds to one data bit in the MPPDO[x] register at the same bit location. 0b The associated bit value in the MPPDO[x] field is ignored 1b The associated bit value in the MPPDO[x] field is written
16–31 MPPDO	Masked Parallel Pad Data Out Write the data register that stores the value to be driven on the pad in output mode. Access to this register location are coherent with access to the bit-wise GPIO Pad Data Output Registers (PDO).The x and bit index define which MPPDO register bit is equivalent to which PDO register bit according to the following equation: MPPDO[x][y] = PDO[(x*16)+y]

15.3 Functional description

15.3.1 General

This section provides a complete functional description of the System Integration Unit Lite2.

15.3.2 Pad Control

The SIUL2 is capable of controlling the electrical characteristic of up to 264 pads. It provides a consistent interface for all pads, both on a by-port and a by-bit basis. The following describes the pad characteristics that can be supported by the SIUL2. Not all of these features will be supported on all devices or on all pads as this is dependent on the specific application needs an the pads implemented on the device.

The required controls are:

- Slew rate control
  - Offers improved EMC performance.
  - Support for a fast and a slow slew rate.
- Drive strength control

    - Offers improved EMC performance.
    - Up to 4 different drive strength levels can be supported.
- Pull capability
    - Offers flexibility in the device configuration and the elimination of external hardware in some cases.
    - The configuration of the pull on any pad should be independently controlled to be either pull-up, pull-down or no-pull enabled.
- Input and Out Buffer control
- Hysteresis
- Open drain
    - Needed to support different pads muxed (e.g. mux I2C, with non open drain pads)
- Pad Output Assignment
    - This setting defines which chip function has control over the output of the pad.

The setting of each pad out of reset is fixed per MCU, but can be configured individually. In this way it is possible to select special pull settings or peripheral pad ownership per design.

It is possible for the user software to configure each pad independently of all other pads on the device or other pads grouped within a single port. This allows different pad types to be grouped together in ports and allows the necessary flexibility needed for the pads individual operation. This is achieved by grouping all of the above functions into a single register for each pad on the device, and allows each pad to be configured with a single write to one register and allowing simplified duplication of software for each pad with indexed changes for each pad.

15.3.3 General Purpose Input and Output Pads (GPIO)

The SIUL2 allows each pad to be configured as either a General Purpose Input or Output pad (GPIO), and as one or more alternate functions (input or output), the function of which is determined by the peripheral that will use the pad.

GPIO pads can also optionally be implemented without any alternate function.

The SIUL2 is designed to manage up to 264 GPIO pads organized as ports that can be accessed for data reads and writes as 32-bit.

All port access are identical with each read or write being performed only at a different location to access a different port width.

This requires that the registers are arranged in such a way as to support this range of port widths without having to split reads or writes into multiple accesses.

The module has separate data input and data output registers for all pads, allowing the possibility of reading back an input or output value of a pad directly. This supports the ability to validate what is present on the pad rather than simply confirming the value that was written to the data register by accessing the data input registers.

The data output registers support both read and write operations to be performed.

The data input registers support read access only.

When the pad is configured to use one of its alternate functions, the data input value reflect the respective value of the pad. If a write operation is performed to the data output register for a pad configured as an alternate function (non GPIO), this write will not be reflected by the pad value until re-configured to GPIO. All general purpose pads are implemented as bidirectional.

Note

In case the bi-directional operation impacts some performances (e.g. ADC accuracy), or is not required for a specific pad function it is acceptable to limit the functionality of some pads to "Input Only"

15.3.4 External Interrupts Requests (REQ Pins)

The SIUL2 supports 0 to 31 external interrupts, which can be allocated to any pad necessary at the MCU level. This allocation is fixed per MCU.

For the assignments of the external interrupts, see the Signal Description details.

The SIUL2 supports up to 4 interrupt vectors to the interrupt controller of the MCU. Each interrupt vector can support up to 8 external interrupt sources from the device pads.

For devices with a number of interrupt sources that is smaller than the maximum number, the MCU can implement either all four interrupt vectors with fewer sources or reduce the number of vectors as the number of sources are reduced. The following figure shows two sample scenarios.

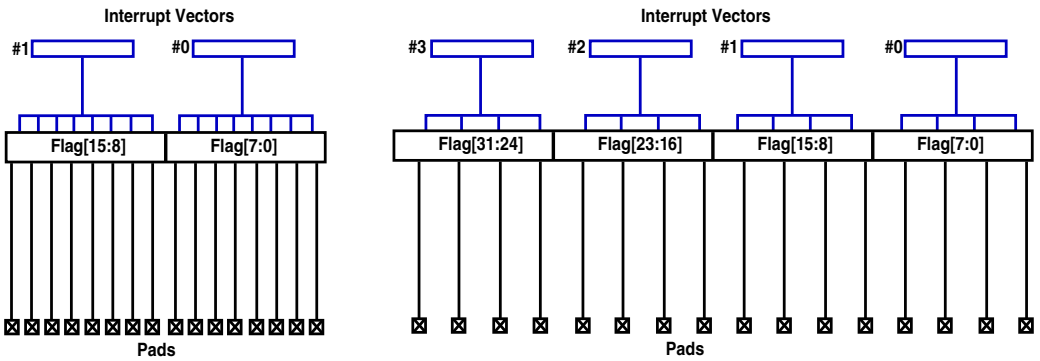

Figure 15-5. Example of different interrupt to vector mapping at MCU level

All the external interrupt pads within a single group (maximum 8 pads) have equal priority. It is the responsibility of the user software to search through the group of sources in the most appropriate way for their application.

The priority of the vectors used by the external interrupt pads is fixed based on the platform and the interrupt controller and its priority levels, but the allocation of pads to each group of interrupts can be independently configured by the MCU.

An MCU-specific number of external interrupt lines can have a digital glitch filters applied to them. The supported range is up to 32.

15.3.4.1 External interrupt initialization

When an external interrupt pin is first enabled, it is possible to get a false interrupt flag. To prevent a false interrupt request, during pin interrupt initialization, the user must do the following:

1. Mask interrupts by clearing the EIREn bits in IRER0.
2. Select the pin polarity by setting the appropriate IREEn bits in IREER0 and the appropriate IFEEn bits in IFEER0 as desired.
3. Configure the appropriate bits in the MSCR[0:511] register for the external interrupt pin(s) desired as follows:
   - Clear the OBE and ODE bits to disable output.
   - Set the IBE bit to enable the pin's input buffer.
   - If using the internal pullup/pulldown, configure the appropriate PUE and PUS fields.

Note

MSCR[SSS] bits do not need to be changed for either MSCR[0:511] or IMCR[0:511] because the external interrupt pin input is directly connected to the SIUL for EIRQ pins.

External interrupt pins should never be configured as outputs (MSCR[ODC] bits are not zeros) when external interrupt inputs are desired because false interrupts could be detected (such as from a GPIO configuration).

4. Select the request desired Interrupt by writing the appropriate IRSn bits in IRSR0.
5. Select the desired glitch filter setup for the pins by writing the following:
   - Write the Filter Counter setting to the desired value by writing the MAXCNT[3:0] bits in the IFMCn register for the respective external interrupt that is being used.
   - Set the Filter Clock Prescaler setting from 0 to 15 to the desired value by writing the IFCP[3:0] bits in the IFCPR register.
   - Enable the glitch filter for the desired external interrupt pins by setting the appropriate IFEn bits in IFER0.

NOTE

The glitch filter clock runs on the internal RC oscillator clock whereas the SIUL logic runs off of the PBRIDGEx clock. The IRC clock is at a fixed frequency of 16 MHz. The PBRIDGEx clock can run as high as 40 MHZ when core clock is at 160 MHz. The glitch filter is enabled on IRC clock, so make sure at least one IRC clock occurs after enabling it before trying to detect glitchless events.

6. Write to EIFn bits in ISR0 to as desired to clear any flags.
7. Enable the interrupt pins by setting the appropriate EIREn bits in IRER0.

15.3.4.2 External interrupt management

The user can enable or disable each interrupt independently using a single rolled up register, SIUL2_IRER0.

A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge, or both edges being active. A setting of having both edge events disabled is reserved and should not be configured. The user controls the active IRQ edge through the registers SIUL2_IREER and SIUL2_IFEER.

Each external interrupt supports an individual flag which is held in the Flag register (ISR0). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

Refer to the following figure for an overview of the external interrupt implementation.

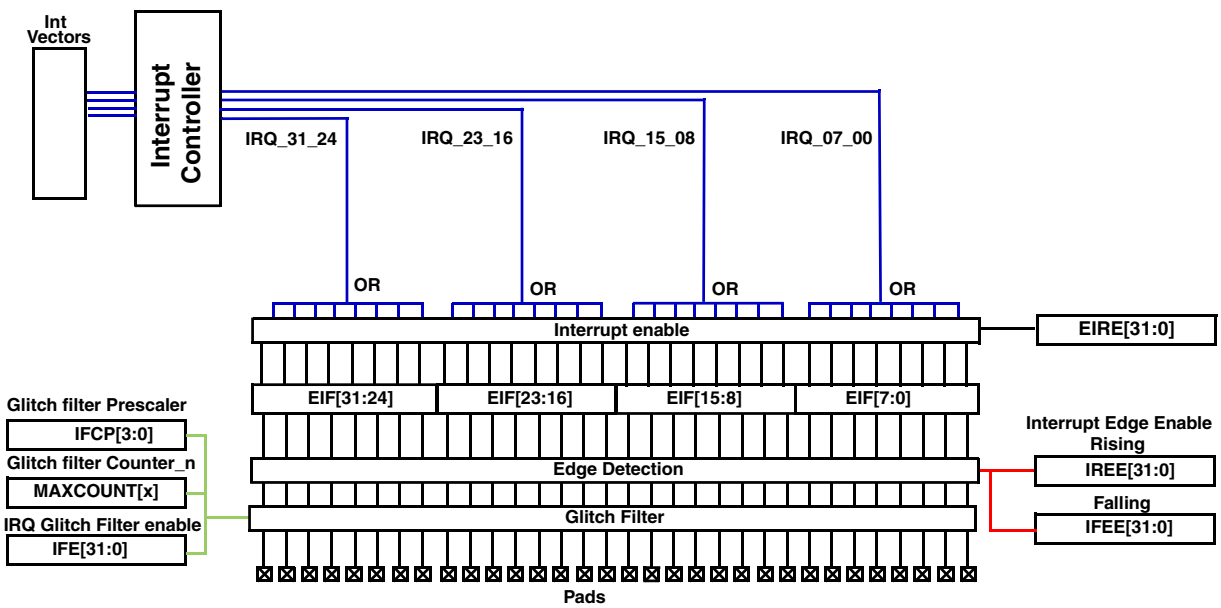

Figure 15-6. External interrupt pad diagram

15.3.4.3 External Interrupt request

The EIRQ input pins on the device are sources for interrupt requests. The system has four possible interrupt vectors available for the EIRQ pins in the SIUL2. The mapping of 32 interrupt request sources to vectors and channels appears in the following table.

Table 15-1. Interrupt source mapping to SIUL2 Interrupt request output for 32 interrupt sources

Vector/Channel #	Interrupt Vector Source
0	EIRQ[07] | EIRQ[06] | EIRQ[05] | EIRQ[04] | EIRQ[03] | EIRQ[02] | EIRQ[01] | EIRQ[00]
1	EIRQ[15] | EIRQ[14] | EIRQ[13] | EIRQ[12] | EIRQ[11] | EIRQ[10] | EIRQ[09] | EIRQ[08]
2	EIRQ[23] | EIRQ[22] | EIRQ[21] | EIRQ[20] | EIRQ[19] | EIRQ[18] | EIRQ[17] | EIRQ[16]
3	EIRQ[31] | EIRQ[30] | EIRQ[29] | EIRQ[28] | EIRQ[27] | EIRQ[26] | EIRQ[25] | EIRQ[24]

Chapter 16
Crossbar Switch (AXBS)

16.1 Chip-specific AXBS information

16.1.1 Crossbar Switch configuration

This section summarizes how the AXBS_0 is configured in the chip.

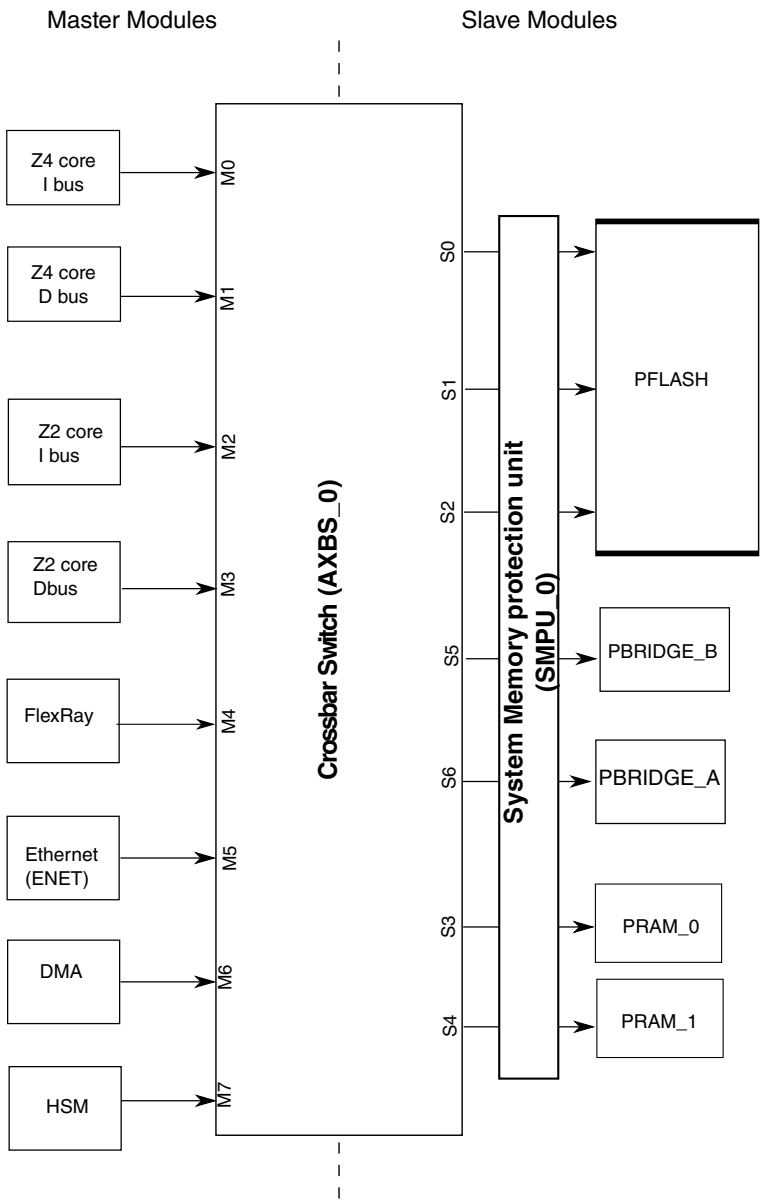

Figure 16-1. AXBS 0 integration

16.1.2 AXBS 0 Master and Slave assignments

This device contains 8 masters connected to the crossbar switch 0 (AXBS_0).

The master and slave assignments are as follows:

Table 16-1. AXBS_0 (Key: x = available connection)

Master Ports	Slave Ports							
Master	Master Port No.	0	1	2	3	4	5	6
		(PFLASH__ 0)	(PFLASH_1)	(PFLASH_2)	(PBRIDGE_ A)	(PBRIDGE_ B)	PRAM_0	PRAM_1
Z4 I bus	0	**x**[1]			**x**	x	x	x
Z4 D bus	1		x		x	x	x[2]	x
FlexRay	2						x	x[3]
ENET	3						x	x
Z2 I bus	4		x[4]		x	x	x	x
Z2 D bus	5	x			x[5]	x[6]	x	x
DMA	6			x	x	x	x	x
HSM	7			x[7]	x	x	x	x

1. Slave Port No. 0 should be set to “park on last”. Arbitration mode should be set to fixed priority and Master Port No. 0 (Z4_I) should be given highest priority when accessing Slave Port No. 0 by default.
2. Slave Port No. 5 should be set to “park on last”. Arbitration mode should be set to fixed priority and Master Port No. 1(Z4_D) should be given highest priority when accessing Slave Port No. 5 by default
3. Slave Port No. 6 should be set to “park on last”. Arbitration mode should be set to fixed priority and Master Port No. 2(FlexRay) should be given highest priority when accessing Slave Port No. 6 by default
4. Slave Port No. 1 should be set to “park on last”. Arbitration mode should be set to fixed priority and Master Port No. 4(Z2_I) should be given highest priority when accessing Slave Port No. 1 by default.
5. Slave Port No. 3 should be set to “park on last”. Arbitration mode should be set to fixed priority and Master Port No. 5(Z2_D) should be given highest priority when accessing Slave Port No. 3 by default
6. Slave Port No. 4 should be set to “park on last”. Arbitration mode should be set to fixed priority and Master Port No. 5(Z2_D) should be given highest priority when accessing Slave Port No. 4 by default
7. Slave Port No. 2 should be set to “park on last”. Arbitration mode should be set to fixed priority and Master Port No. 7(HSM) should be given highest priority when accessing Slave Port No. 2 by default.

16.1.3 PRS register reset values

The AXBS0_PRS*n* registers reset to 7654_3210h.

16.1.4 CRS register reset values

The AXBS0_CRS*n* registers reset to 00FF_0010h.

NOTE

To enable DMA master HPE mode, DMA_TCDn_CSR[BWC] field must be set to 0x01.

16.2 Introduction

The information found here provides information on the layout, configuration, and programming of the crossbar switch.

The crossbar switch connects bus masters and bus slaves using a crossbar switch structure. This structure allows all bus masters to access different bus slaves simultaneously, while providing arbitration among the bus masters when they access the same slave. A variety of bus arbitration methods and attributes may be programmed on a slave-by-slave basis.

16.2.1 Features

The crossbar switch includes these features:

- Symmetric crossbar bus switch implementation
  - Allows concurrent accesses from different masters to different slaves
  - Slave arbitration attributes configured on a slave-by-slave basis
- Up to single-clock 64-bit transfer
- Support for burst transfers of up to 16 beats of data
- Low-Power Park mode support
- Dynamic master priority elevation

16.3 Memory Map / Register Definition

Each slave port of the crossbar switch contains configuration registers. Read- and write-transfers require two bus clock cycles. The registers can be read from and written to only in supervisor mode. Additionally, these registers can be read from or written to only by 32-bit accesses.

A bus error response is returned if an unimplemented location is accessed within the crossbar switch.

The CRS*n* and PRS*n* registers can be programmed to be read-only to prevent changes to their configuration. After being read-only protected, future writes to them will terminate with an error.

NOTE

This section shows the registers for all eight master and slave ports. If a master or slave is not used on this particular device, then unexpected results occur when writing to its registers. See the chip configuration details for the exact master/slave assignments for your device.

All references to the crossbar switch registers are based on the physical port connections.

16.3.1 Priority Registers Slave (AXBS_PRS*n*)

The priority registers (PRSn) set the priority of each master port on a per slave port basis and reside in each slave port. The priority register can be accessed only with 32-bit accesses. After the CRSn[RO] bit is set, the PRSn register can only be read; attempts to write to it have no effect on PRSn and result in a bus-error response to the master initiating the write.

Two available masters must not be programmed with the same priority level. Attempts to program two or more masters with the same priority level result in a bus-error response and the PRSn is not updated.

NOTE

Valid values for the M*n* priority fields depend on which masters are available on the chip. This information can be found in the chip-specific information for the crossbar.

- If the chip contains less than five masters, values 0 to 3 are valid. Writing other values will result in an error.
- If the chip contains five or more masters, valid values are 0 to n-1, where n is the number of masters attached to the Crossbar Switch. Other values will result in an error.

NOTE

See the chip-specific crossbar information for the reset value of this register.

Sets the arbitration priority for this port on the associated slave port. 000 This master has level 1, or highest, priority when accessing the slave port. 001 This master has level 2 priority when accessing the slave port. 010 This master has level 3 priority when accessing the slave port. 011 This master has level 4 priority when accessing the slave port. 100 This master has level 5 priority when accessing the slave port. 101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8, or lowest, priority when accessing the slave port.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 M0	Master 0 Priority. Sets the arbitration priority for this port on the associated slave port. 000 This master has level 1, or highest, priority when accessing the slave port. 001 This master has level 2 priority when accessing the slave port. 010 This master has level 3 priority when accessing the slave port. 011 This master has level 4 priority when accessing the slave port. 100 This master has level 5 priority when accessing the slave port. 101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8, or lowest, priority when accessing the slave port.

16.3.2 Control Register (AXBS_CRS*n*)

These registers control several features of each slave port and must be accessed using 32-bit accesses. After CRSn[RO] is set, the PRSn can only be read; attempts to write to it have no effect and result in an error response.

NOTE

See the chip-specific crossbar information for the reset value of this register.

Not all HPE*n* fields may be active. See the chip-specific crossbar information for which masters support high priority elevation. Setting a field corresponding to a master that does not support high-priority elevation has no effect.

26–27 PCTL	Parking Control Determines the slave port's parking control. The low-power park feature results in an overall power savings if the slave port is not saturated; however, this forces an extra latency clock when any master tries to access the slave port while not in use because it is not parked on any master. 00 When no master makes a request, the arbiter parks the slave port on the master port defined by the PARK bit field 01 When no master makes a request, the arbiter parks the slave port on the last master to be in control of the slave port 10 Low-power park. When no master makes a request, the slave port is not parked on a master and the arbiter drives all outputs to a constant safe state 11 Reserved
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 PARK	Park Determines which master port the current slave port parks on when no masters are actively making requests and the PCTL bits are cleared. **NOTE:** Select only master ports that are present on the chip. Otherwise, undefined behavior might occur. 000 Park on master port M0 001 Park on master port M1 010 Park on master port M2 011 Park on master port M3 100 Park on master port M4 101 Park on master port M5 110 Park on master port M6 111 Park on master port M7

16.3.3 Master General Purpose Control Register (AXBS_MGPCR*n*)

The MGPCR controls only whether the master's undefined length burst accesses are allowed to complete uninterrupted or whether they can be broken by requests from higher priority masters. The MGPCR can be accessed only in Supervisor mode with 32-bit accesses.

NOTE

If there are fewer than eight master ports, only the registers associated with those masters are present. Register addresses associated with master ports that are not present are reserved.

Please see this module's chip-specific information for which master ports are present on this module.

16.4 Functional Description

16.4.1 General operation

When a master accesses the crossbar switch, the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. Single-clock or zero-wait-state accesses are possible through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the requesting master simply sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Because the crossbar switch appears to be just another slave to the master device, the master device has no knowledge of whether it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it simply waits.

After the master has control of the slave port it is targeting, the master remains in control of the slave port until it relinquishes the slave port by running an IDLE cycle or by targeting a different slave port for its next access.

The master can also lose control of the slave port if another higher-priority master makes a request to the slave port. However, if the master is running a fixed- or undefined-length burst transfer it retains control of the slave port until that transfer completes. Based on MGPCR[AULB], the master either retains control of the slave port when doing undefined-length, incrementing burst transfers or loses the bus to a higher-priority master.

The crossbar terminates all master IDLE transfers, as opposed to allowing the termination to come from one of the slave buses. Additionally, when no master is requesting access to a slave port, the crossbar drives IDLE transfers onto the slave bus, even though a default master may be granted access to the slave port.

When a slave bus is being idled by the crossbar, it can park the slave port on the master port indicated by CRS*n*[PARK] . This is done to save the initial clock of arbitration delay that otherwise would be seen if the same master had to arbitrate to gain control of the slave port. The slave port can also be put into Low Power Park mode to save power, by using CRS*n*[PCTL].

16.4.2 Register coherency

The operation of the crossbar is affected as soon as a register is written. The values of the registers do not track with slave-port-related master accesses, but instead track only with slave accesses.

The MGPCRx[AULB] bits are the exception to this rule. The update of these bits is only recognized when the master on that master port runs an IDLE cycle, even though the slave bus cycle to write them will have already terminated successfully. If the MGPCRx[AULB] bits are written between two burst accesses, the new AULB encodings do not take effect until an IDLE cycle is initiated by the master on that master port.

16.4.3 Arbitration

The crossbar switch supports two arbitration algorithms:

- Fixed priority
- Round-robin

The arbitration scheme is independently programmable for each slave port.

16.4.3.1 Arbitration during undefined length bursts

Arbitration points during an undefined length burst are defined by the current master's MGPCR[AULB] field setting. When a defined length is imposed on the burst via the AULB bits, the undefined length burst is treated as a single or series of single back-to-back fixed-length burst accesses.

The following figure illustrates an example:

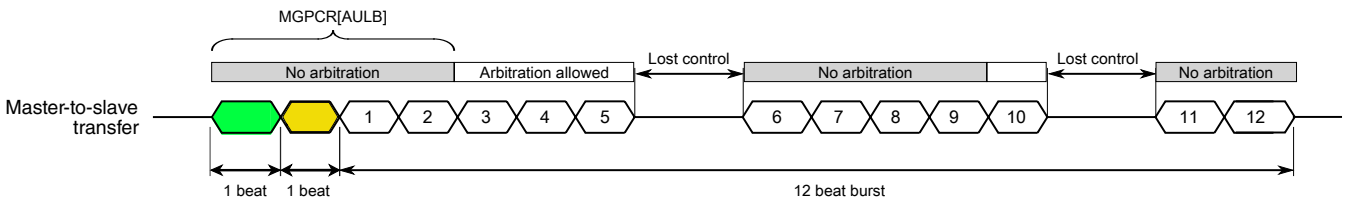

Figure 16-2. Undefined length burst example

In this example, a master runs an undefined length burst and the MGPCR[AULB] bits indicate arbitration occurs after the fourth beat of the burst. The master runs two sequential beats and then starts what will be a 12-beat undefined length burst access to a new address within the same slave port region as the previous access. The crossbar does not allow an arbitration point until the fourth overall access, or the second beat of the second burst. At that point, all remaining accesses are open for arbitration until the master loses control of the slave port.

Assume the master loses control of the slave port after the fifth beat of the second burst. After the master regains control of the slave port no arbitration point is available until after the master has run four more beats of its burst. After the fourth beat of the now continued burst, or the ninth beat of the second burst from the master's perspective, is taken, all beats of the burst are once again open for arbitration until the master loses control of the slave port.

Assume the master again loses control of the slave port on the fifth beat of the third now continued burst, or the 10th beat of the second burst from the master's perspective. After the master regains control of the slave port, it is allowed to complete its final two beats of its burst without facing arbitration.

Note

Fixed-length burst accesses are not affected by the AULB bits. All fixed-length burst accesses lock out arbitration until the last beat of the fixed-length burst.

16.4.3.2 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the priority registers (PRS*n*). If two masters request access to the same slave port, the master with the highest priority in the selected priority register gains control over the slave port.

NOTE

In this arbitration mode, a higher-priority master can monopolize a slave port, preventing accesses from any lower-priority master to the port.

When a master makes a request to a slave port, the slave port checks whether the new requesting master's priority level is higher than that of the master that currently has control over the slave port, unless the slave port is in a parked state. The slave port performs an arbitration check at every clock edge to ensure that the proper master, if any, has control of the slave port.

The following table describes possible scenarios based on the requesting master port:

Table 16-2. How the Crossbar Switch grants control of a slave port to a master

When	Then the Crossbar Switch grants control to the requesting master
Both of the following are true: • The current master is not running a transfer. • The new requesting master's priority level is higher than that of the current master.	At the next clock edge
Both of the following are true: • The current master is running a fixed length burst transfer or a locked transfer. • The requesting master's priority level is higher than that of the current master.	At the end of the burst transfer or locked transfer
Both of the following are true: • The current master is running an undefined length burst transfer. • The requesting master's priority level is higher than that of the current master.	At the next arbitration point for the undefined length burst transfer **NOTE:** Arbitration points for an undefined length burst are defined in the MGPCR for each master.
The requesting master's priority level is lower than the current master.	At the conclusion of one of the following cycles: • An IDLE cycle • A non-IDLE cycle to a location other than the current slave port

16.4.3.3 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the master port number. This relative priority is compared to the master port number (ID) of the last master to perform a transfer on the slave bus. The highest priority requesting master becomes owner of the slave bus at the next transfer boundary, accounting for locked and fixed-length burst transfers. Priority is based on how far ahead the ID of the requesting master is to the ID of the last master.

After granted access to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and master 0, 4, and 5 make simultaneous requests, they are serviced in the order: 4 then 5 then 0.

Parking may continue to be used in a round-robin mode, but does not affect the round-robin pointer unless the parked master actually performs a transfer. Handoff occurs to the next master in line after one cycle of arbitration. If the slave port is put into low-power park mode, the round-robin pointer is reset to point at master port 0, giving it the highest priority.

16.4.3.4 Priority assignment

Each master port must be assigned a unique 3-bit priority level. If an attempt is made to program multiple master ports with the same priority level within the priority registers (PRS*n*), the crossbar switch responds with a bus error and the registers are not updated.

16.5 Initialization/application information

No initialization is required for the crossbar switch.

Hardware reset ensures that all the register bits used by the crossbar switch are properly initialized to a valid state. However, settings and priorities may be programmed to achieve maximum system performance.

NOTE

- During configuration of the crossbar switch, all other masters must be idle.
- To prevent reconfiguration of the crossbar switch, write 1 to CRS*n*[RO].

Chapter 17
Peripheral Bridge

17.1 Chip-specific PBridge information

17.1.1 PBRIDGE Configuration

The peripheral bridge converts the crossbar switch interface to an interface that can access a majority of peripherals on the device.

This device contains two identical peripheral bridges: PBRIDGE_A (or AIPS_0) and PBRIDGE_B (or AIPS_1).

For SMPU Logical Bus Master Number, see table Table 20-1.

17.1.2 Register reset values

The following table shows the device-specific register reset values.

Table 17-1. AIPS0 register reset values

17.2 Introduction

The peripheral bridge converts the crossbar switch interface to an interface that can access most of the slave peripherals on this chip.

The peripheral bridge occupies 64 MB of the address space, which is divided into peripheral slots of 16 KB. (It might be possible that all the peripheral slots are not used. See the memory map chapter for details on slot assignments.) The bridge includes separate clock enable inputs for each of the slots to accommodate slower peripherals.

17.2.1 Features

Key features of the peripheral bridge are:

- Supports peripheral slots with 8-, 16-, and 32-bit datapath width
- Supports a pair of 32-bit transactions for selected 64-bit memory accesses
- Programming model provides memory protection functionality

17.2.2 General operation

The slave devices connected to the peripheral bridge are modules which contain a programming model of control and status registers. The system masters read and write these registers through the peripheral bridge.

The register maps of the peripherals are located on 16 KB boundaries. Each peripheral is allocated one or more 16-KB block(s) of the memory map.

17.3 Memory map/register definition

The 32-bit peripheral bridge registers can be accessed only in supervisor mode by trusted bus masters. Additionally, these registers must be read from or written to only by a 32-bit aligned access. The peripheral bridge registers are mapped into the Peripheral Access Control Register A PACRA[PACR0] address space.

AIPS memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

17.3.1 Master Privilege Register A (AIPS_MPRA)

This register specifies eight identical 4-bit fields defining the access-privilege level associated with a bus master in the device to various peripherals. The register provides one field per bus master. Each master is assigned a logical master number. See the device configuration information for details.

Address: 0h base + 0h offset = 0h

17.3.3 Peripheral Access Control Register (AIPS_PACR*n*)

Each of the on-platform peripherals has a 4-bit PACR*n* field, which defines the access levels supported by the given module. Eight PACR fields are grouped together to form a 32-bit PACR*x* register.

The peripheral assignment for each PACR field is defined by the memory map slot that the peripheral is assigned to. See the device's memory map details for the assignments for a particular device.

If a peripheral is absent, the corresponding PACR field is not implemented. Reads or writes to the location of an unimplemented PACR register (because all eight of its peripherals are absent) should be avoided to prevent undesired behavior.

The following table shows the top-level structure of PACRs.

Offset	Register	[0:3]	[4:7]	[8:11]	[12:15]	[16:19]	[20:23]	[24:27]	[28:31]
0x100	PACRA	PACR0	PACR1	PACR2	PACR3	PACR4	PACR5	PACR6	PACR7

17.3.4 Off-Platform Peripheral Access Control Register (AIPS_OPACR*n*)

Each of the on-platform peripherals has a 4-bit OPACR*n* field, which defines the access levels supported by the given module. Eight OPACR fields are grouped together to form a 32-bit OPACR*x* register.

The peripheral assignment for each OPACR field is defined by the memory map slot that the peripheral is assigned to. See the device's memory map details for the assignments for a particular device.

If a peripheral is absent, the corresponding OPACR field is not implemented. Reads or writes to the location of an unimplemented OPACR register (because all eight of its peripherals are absent) should be avoided to prevent undesired behavior.

The following table shows the top-level structure of OPACRs.

Offset	Register	[0:3]	[4:7]	[8:11]	[12:15]	[16:19]	[20:23]	[24:27]	[28:31]
0x140	OPACRA	OPACR0	OPACR1	OPACR2	OPACR3	OPACR4	OPACR5	OPACR6	OPACR7
0x144	OPACRB	OPACR8	OPACR9	OPACR10	OPACR11	OPACR12	OPACR13	OPACR14	OPACR15

AIPS_OPACR*n* field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 SP0	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for accesses. When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPR *x* [MPL *n*] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
2 WP0	Write Protect Determines whether the peripheral allows write accesses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
3 TP0	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this bit is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 SP1	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for access. When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPR *x* [MPL *n*] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
6 WP1	Write Protect Determines whether the peripheral allows write accesses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
7 TP1	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this field is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates.

17.4 Functional description

The peripheral bridge functions as a bus protocol translator between the crossbar switch and the slave peripheral bus.

Support is provided for generating a pair of 32-bit slave accesses when performing certain 64-bit peripheral accesses.

The peripheral bridge manages all transactions destined for the attached slave devices and generates select signals for modules on the peripheral bus by decoding accesses within the attached address space.

17.4.1 Access support

All combinations of access size and peripheral data port width are supported. An access that is larger than the target peripheral's data width will be decomposed to multiple, smaller accesses. Bus decomposition is terminated by a transfer error caused by an access to an empty register area.

Chapter 18
Decorated Storage Memory Controller (DSMC)

18.1 Introduction

This section details the hardware support for atomic read-modify-write memory operations. In the Power Architecture, these capabilities are called "*decorated storage*". It is supported by capabilities in the processor cores plus instantiations of a Decorated Storage Memory Controller (DSMC).

The Decorated Storage APU defines instructions for providing load and store operations to memory addresses that require *additional semantics* beyond just the reading and writing of data values to the addressed memory locations. Decorated storage operations are intended to be used for specific devices or memory targets that require these additional semantics. A "decoration" is the additional semantic information to be applied to the decorated storage operation by the DSMC.

Consider the basic mnemonics, syntax and formats for the decorated load instructions.

For loads, the syntax is `l[b,h,w]d{cb}x rT,rB,rA` where the data size specifier is defined as 8-bit (`b` = byte), 16-bit (`h` = halfword) or 32-bit (`w` = word), and the three register specifiers include `rT` as the destination target register, `rB` as the effective address and `rA` as the decoration. The optional `{cb}` specifier defines a version of the instruction which is treated as a cache bypass operation.

The syntax for store instruction is `st[b,h,w]d{cb}x rS,rB,rA` where the same data size specifiers are used, and the three register specifiers are `rS` as the source data register, `rB` as the effective address and `rA` as the decoration. The cache bypass attribute is again specified with the use of the optional `{cb}` in the instruction mnemonic.

For all decorated loads and stores, the memory effective address is simply defined by the rB register (hence the `"x"` mnemonic suffix, signaling an "indexed" addressing mode) and the decoration is specified by the rA register. The core transmits the contents of the rA register as the decoration value along with the access address (register rB) to the DSMC.

The decorated load and store instruction formats are shown in the following figure.

Table 18-1. Power Architecture decorated load and store instruction formats

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

stbdx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1	0	0	0	0	0	0	1	1	/
sthdx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1	0	1	0	0	0	0	1	1	/
stwdx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1	1	0	0	0	0	0	1	1	/
stbdcbx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1	0	0	0	0	0	0	1	0	/
sthdcbx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1	0	1	0	0	0	0	1	0	/
stwdcbx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1	1	0	0	0	0	0	1	0	/

The basic decorated load or store memory reference supplements the access address and attribute information with a 32-bit "decoration". The DSMC decoration defines the special memory operation to be performed and optionally includes bit specifiers and/or operand data for the command.

The default format for the 32-bit decoration field defines a 4-bit command in the most significant bits (decoration[0:3]).

The cache bypass decoration load (`l[b,h,w]dcbx`) and store (`st[b,h,w]dcbx`) instructions do not distinguish between cacheable and cache-inhibited storage attributes, and instead have semantics to effectively emulate a cache-inhibited operation to storage regardless of the actual storage attributes. This is desired in order to allow a small portion of an otherwise cacheable storage area to be treated as non-cacheable using instruction supplied semantics, regardless of storage attributes provided by a memory management, protection or other memory control scheme. This allows decoration or other accesses to be applied to a portion of memory that is normally treated as cacheable according to its storage attributes, as well as to ensure that any stale copies of storage locations present in the cache are not used.

The combination of the decorated load and store instruction support in the e200zX cores plus the decorated storage memory controller in the core platform adds a robust atomic read-modify-write capability to the Power Architecture. The architecture capability defined by these core and platform functions is targeted at manipulation of *n*-bit fields in peripheral registers (and is consistent with I/O hardware addressing in the Embedded C standard) as well as software synchronization data structures needed in multi-core systems (mutexes, semaphores, test-and-set and compare-and-swap structures).

For additional information on the decorated load and store instructions from the core's perspective, refer to the appropriate e200zX core reference manual.

18.2 Decorated stores: `st[b,h,w]d{cb}x rS,rA,rB`

The next sections present descriptions of the specific operations, based on the 4-bit command field defined in decoration[0:3]. These descriptions include the bit pattern definitions for the 32-bit decoration value and include pseudo-code detailing the sequence of operations. The decoration formats are defined using a `<command>.<size>` syntax where the operand size specifier is b (byte, 8-bit), h (halfword, 16-bit) or w (word, 32-bit). The operand size is specified directly in the decorated instruction executed in the core, and this attribute is driven to the system bus as part of the decorated data transfer. Additionally, the write data is taken from the right-justified 8, 16 or 32 bits of the rS register, that is:

```
 8-bit wdata = rS[24:31]
16-bit wdata = rS[16:31]
32-bit wdata = rS[ 0:31]
```

Likewise, read data is loaded into the right-justified 8, 16 or 32 bits of the rT register:

```
 8-bit rdata = rT[24:31]
16-bit rdata = rT[16:31]
32-bit rdata = rT[ 0:31]
```

For the byte and halfword decorated load instructions, the upper bits of the rT register are zero filled.

The starting bit (SRTBIT) position follows the Power Architecture convention where the MSB is bit 0 and the LSB is bit 31. The bit field width (BFW) value defines the width and BFW = 0 specifies the maximum width, that is, the container size.

The basic decorated store includes three data transfer fields sourced from the core: the access address (rB), the decoration (rA) and the write data (wdata) operand (rS). There are five operations defined and most of these transactions convert a single core AHB write bus cycle into an atomic read-modify-write, that is, an indivisible read followed by write sequence. Support for three basic boolean logic functions (AND, OR, XOR) is provided along with a compare-and-store operation plus a bit field insert operation. These operations do not support any type of bit field wrapping.

In the next sections detailing the decorated store operations, the following associations between the pseudocode variables and the core registers apply.

- decoration = rA

- accessAddress = rB
- wdata = rS

18.2.1 Bit Field Insert (BFINS) into an 8, 16 or 32-bit memory container

Table 18-2. Decoration format: BFINS

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
bfins.b	0	0	0	0	0	0	0	SRTBIT			0	0	0	BFW			-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
bfins.h	0	0	0	0	0	0	SRTBIT				0	0	BFW				-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
bfins.w	0	0	0	0	0	SRTBIT					0	BFW					-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command inserts a bit field defined by SRTBIT and BFW into the memory "container" defined by the access size associated with the decorated store instruction using an atomic read-modify-write sequence.

```
tmp = mem[accessAddress, size] // memory read
if bfw == 0
         then bfw = container

if ((srtbit + bfw) <= container) // generate bit mask
    mask = ((1 << bfw) - 1) << (container - (srtbit + bfw))
else
    mask = ((1 << bfw) - 1) >> ((srtbit + bfw) - container)

tmp = tmp  & ~mask// modify
    | wdata &  mask

mem[accessAddress, size] = tmp // memory write
```

The write data operand (wdata) associated with the decorated store instruction contains the bit field to be inserted. *It must be properly aligned within a right-justified container in the source register (rS)*, that is, within the lower 8 bits for a byte operation, the lower 16 bits for a halfword or the entire 32 bits for a word operation.

To illustrate, consider the following example of the insertion of the 3-bit field "xyz" into an 8-bit memory container, initially set to "abcd_efgh". For all cases, the bit field width (BFW) is 3.

```
if SRTBIT = 0 and the decorated store rS register[24:31] = xyz-_----,
   then destination is "xyzd_efgh"
if SRTBIT = 1 and the decorated store rS register[24:31] = -xyz_----,
   then destination is "axyz_efgh"
if SRTBIT = 2 and the decorated store rS register[24:31] = --xy_z---,
   then destination is "abxy_zfgh"
if SRTBIT = 3 and the decorated store rS register[24:31] = ---x_yz--,
   then destination is "abcx_yzgh"
if SRTBIT = 4 and the decorated store rS register[24:31] = ---_xyz-,
```

```
   then destination is "abcd_xyzh"
if SRTBIT = 5 and the decorated store rS register[24:31] = ---_-xyz,
   then destination is "abcd_exyz"
if SRTBIT = 6 and the decorated store rS register[24:31] = ---_--xy,
   then destination is "abcd_efxy"
if SRTBIT = 7 and the decorated store rS register[24:31] = ---_---x,
   then destination is "abcd_efgx"
```

If the bit field insert operation specifies SRTBIT as 0 and BFW as 0 (indicating the width matches the container width), then the operation is logically equivalent to a simple register store operation.

18.2.1.1 Compare-and-Store (CAST)

Table 18-3. Decoration format: CAST

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24 25 26 27	28 29 30 31
cast.b	1	0	0	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	CD8	
cast.h	1	0	0	1	-	-	-	-	-	-	-	-	-	-	-	-	CD16									
cast.w	1	0	0	1	CD28																					

This command begins by performing a read of the referenced memory address and comparing that data with the operand included in the decoration word. If the read data is equal to the compare operand, the write data associated with the decorated store instruction is placed into the memory location, else the original read data is rewritten into the memory location. The write operand is selected from the appropriate data byte lanes in the same manner as any memory store operation; this implies the write data operand is right justified in the rS source register.

```
tmp = mem[accessAddress, size]  // memory read

if (size == 8)             // define compare_operand
    compare_operand = CD8
else if (size == 16)
         compare_operand = CD16
     else compare_operand = {0x0, CD28}// zero-filled data

if (tmp == compare_operand) // compare - "modify"
     mem[accessAddress, size] = wdata// memory write
else mem[accessAddress, size] = tmp
```

Note for the word size operation (cast.w), the data value specified in the low-order 28 bits of the decoration is zero filled in the most significant bits to create the required 32 bit compare operand.

18.2.1.1.1 Logical AND (AND)

Table 18-4. Decoration format: AND

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24 25 26 27	28 29 30 31

Table continues on the next page...

Table 18-4. Decoration format: AND (continued)

and.{b,h,w}	1	0	1	0	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical AND operation using the write operand defined by the rS register; finally, the result of the AND operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp & wdata      // modify
mem[accessAddress, size] = tmp// memory write
```

18.2.1.1.2 Logical OR (OR)

Table 18-5. Decoration format: OR

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
or.{b,h,w}	1	1	0	0	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical OR operation using the write operand defined by the rS register; finally, the result of the OR operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp | wdata          // modify
mem[accessAddress, size] = tmp// memory write
```

18.2.1.1.3 Logical Exclusive-OR (XOR)

Table 18-6. Decoration format: XOR

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
xor.{b,h,w}	1	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical XOR operation using the write operand defined by the rS register; finally, the result of the XOR operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp ^ wdata          // modify
mem[accessAddress, size] = tmp// memory write
```

18.2.1.2 Decorated Loads: `l[b,h,w]d{cb}x rT,rA,rB`

The basic decorated load includes two data transfer fields sourced from the core: the access address (rB), the decoration (rA) plus the read data (rdata) operand returned from DSMC to the core and loaded into the destination register (rT). There are 3 operations defined and two of these transactions convert a single core AHB read bus cycle into an atomic read-modify-write. Support for a swap function, a load-and-set-1-bit functions are provided along with a simple load (aka an "extract") operation.

In the next sections detailing the decorated load operations, the following associations between the pseudocode variables and the core registers apply.

- decoration = rA
- accessAddress = rB
- rdata = rT

18.2.1.2.1 Simple Load (SLD)

Table 18-7. Decoration format: SLD

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
sld. {b,h,w}	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs a simple memory load of the reference size from the access address. For this operation, the 12-bit field defined in decoration[4:15] must be zeroes else the transfer is not performed and error terminated.

```
rdata = mem[accessAddress, size] // memory read
```

Support for generic bit field extract operations is best handled using existing core and compiler capabilities involving standard load instructions followed by left and right shift operations to emulate these functions.

18.2.1.2.2 Registers-and-memory exchange (SWAP)

Table 18-8. Decoration format: SWAP

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
swap.b	0	1	0	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	WD8							
swap.h	0	1	0	1	-	-	-	-	-	-	-	-	-	-	-	-	**WD16**															
swap.w	0	1	0	1	WD28																											

This command loads the contents of the referenced memory location into the core's rT register and stores the source operand from the core's rA register (the decoration) into the memory location.

```
tmp   = mem[accessAddress, size] // memory read
rdata = tmp// rT = rdata = tmp

if (size == 8)             // store_operand - "modify"
    store_operand = WD8
else if (size == 16)
           store_operand = WD16
    else store_operand = {0x0, WD28} // zero-filled write data

mem[accessAddress, size] = store_operand// memory write
```

Note for the word size operation (swap.w), the data value specified in the low-order 28 bits of the decoration is zero filled in the most significant bits to create the required 32 bit store operand.

18.2.1.2.3 Load-and-Set-1(Bit) (LAS1)

Table 18-9. Decoration format: LAS1

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
las1.b	0	1	1	0	0	0	0	BIT			-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
las1.h	0	1	1	0	0	0	BIT				-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
las1.w	0	1	1	0	0	BIT					-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command first reads the referenced memory location; it then modifies the read operand by setting the single bit position defined in the decoration (BIT); the modified data is then written back to the referenced memory location and the original read data returned to the initiating processor core.

```
tmp   = mem[accessAddress, size] // memory read
rdata = tmp // rT = rdata = tmp
mask  = 1 << (container - bit - 1) // generate bit mask
tmp   = tmp | mask// modify
mem[accessAddress, size] = tmp// memory write
```

18.3 DSMC instantiations

The decorated storage memory controller which performs these operations is instantiated multiple times within the core platform and physically resides between the slave ports of the crossbar and the targeted memory controllers.

The module includes error checking logic that validates the decoration field is properly defined (all illegal commands are rejected and the transfer error terminated). Additionally, the decorated memory controller only operates on aligned, single data transfers (misalignment and/or bursts are not supported and error terminated if attempted).

As the DSMC generates the atomic read-modify-write bus transactions to the attached slave memory controller, the two transactions (read, write) are fully pipelined with no idle cycles introduced. During these transactions, the AHB hlock control signal is asserted to the slave during the entire read-modify-write.

Chapter 19
Intelligent AHB Gasket (IAHBG)

19.1 Chip-specific IAHBG information

19.1.1 IAHBG configuration

Table 19-1 shows the operating modes implemented in the IAHBG on this chip.

Table 19-1. IAHBG implemented operation modes

Operating mode (Master:Slave)	Comments
1:1	Master and slave at same operating frequency; gasket performance optimizations on by default
2:1	Master at twice frequency of slave; gasket performance optimizations on by default
1:2	Slave at twice frequency of master; gasket performance optimizations on by default
4:1	Master at four times frequency of slave; gasket performance optimizations disabled at this time
1:4	Slave at four times frequency of master; gasket performance optimizations disabled at this time

19.1.2 IAHBG clock selection ratios

The IAHBG is used as a bus gasket to connect buses running at different bus clock speeds. Internal signals generated by the MC_CGL are connected to the IAHBG module that determine the clock ratio selection. Clock ratio setting for the IAHBG is controlled using DFS configurations. Refer Dynamic Frequency Scaling for details.

19.1.3 IAHBG features enabled by Platform Configuration Module (PCM)

The Platform Configuration Module (PCM) is used to enable/disable features of the IAHBG module. In general, the default setting in the PCM enables IAHBG features for the highest performance case.

19.2 Introduction

This section details the intelligent bridging gasket between the fast and slow clock domains. The intelligent operation of the gasket initiates pending reads early and optimizes bursts to recover some of the performance that is lost on a registered interface between different clock domains. Pending reads begin even if there is not an hready to the master. Non-bursted writes only begin when the slave is IDLE, pending writes wait until IDLE.

The IAHBG complies with the AHBV6lite protocol, including an extension to support masters that do address retraction during the error termination sequence or abort a burst read due to an error termination or another non-error termination like cache inhibit termination.

Table 19-2 lists the available operation modes.

Table 19-2. Operation modes available

Operating mode (Master:Slave)	Comments
0:0	Flowthru (no register wall)
1:1	Master and slave at same operating frequency; gasket performance optimizations on by default
2:1	Master at twice frequency of slave; gasket performance optimizations on by default
1:2	Slave at twice frequency of master; gasket performance optimizations on by default
4:1	Master at four times frequency of slave; gasket performance optimizations disabled at this time
1:4	Slave at four times frequency of master; gasket performance optimizations disabled at this time

19.3 Timing modes

19.3.1 1:1

In the 1:1 timing mode the master is running at the same clock frequency as the slave. The pending read can either be a single or burst transaction.

19.3.2 2:1

In the 2:1 timing mode the master is running at twice the clock frequency of the slave. The 4:1 mode is not shown because it is very similar to the 2:1 mode. The pending read can either be a single or burst transaction.

19.3.3 1:2

In the 1:2 timing mode, the slave is running at twice the clock frequency of the master. The 1:4 mode is not shown because it is very similar to the 1:2 mode. The pending read can either be a single or burst transaction.

Because the slave is operating at a faster clock frequency than the master, the transactions from the master must be stored into a queue of data and response attribute registers. At a certain point during the master burst transactions, the queue is either emptied into the master for a burst read or it is emptied into the slave for a burst write..

Chapter 20
System Memory Protection Unit (SMPU)

20.1 Chip-specific SMPU information

20.1.1 System Memory Protection Unit (SMPU) configuration

This chip contains one instance of the System Memory Protection Unit (SMPU):

- SMPU_0 protects flash, peripherals and RAM.

The following figure explains how SMPU is configured on this chip.

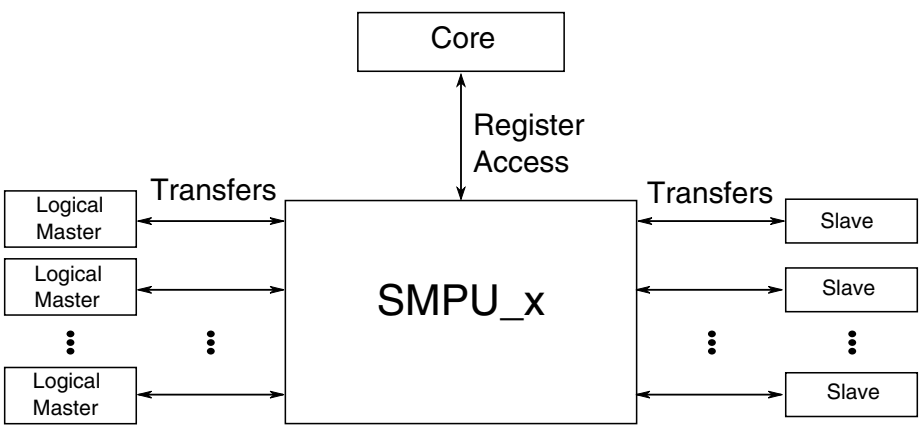

Figure 20-1. SMPU configuration

Table 20-1. SMPU Logical Bus Master Number

Master Name	Master ID
e200Z4	0
e200Z2	1
HSM	3
eDMA	4
Ethernet	5
FlexRAY	6

Table continues on the next page...

Table 20-1. SMPU Logical Bus Master Number (continued)

Master Name	Master ID
Debug e200Z4	8
Debug e200Z2	9

NOTE

Only Z4, Z2, and HSM core provide process identifier to SMPU.

NOTE

PID miss error does not occur for Debug e200Z4 and Debug e200Z2.

20.1.1.1 SMPU core exceptions

The core interrupt handling for a SMPU protected access is summarized in the following table:

SMPU Protected Access	Z4	Z2
Read	Data Storage Exception	Data Storage Exception
Write	See below	Data Storage Exception
Execute	Instruction Storage exception	Instruction Storage exception

The Z4 core interrupt handling for a SMPU protected write access is summarized in the following table:

MSR[ME]	HDBCR0[DSB]	Exception
0	0	No exception
0	1	Data Storage
1	0	Machine Check
1	1	Data Storage

The Z4 core has a store buffer and when enabled any core store to a SMPU protected region will be imprecise. For this scenario an imprecise data access will result in a machine check interrupt, when the machine check interrupt is enabled at Machine State Register (MSR). For the case when the data storage buffer is disabled the Z4 core will issue a data storage exception.

HDBCR0 is the hardware debug cache control register. This register would not normally be used by a normal user. It is intended to be used only by debugger vendors. Please refer to the e200z4 Core Reference manual for details.

20.2 Overview

The System Memory Protection Unit (SMPU) provides hardware access control for system bus memory references. The SMPU concurrently monitors system bus transactions and evaluates their appropriateness using preprogrammed region descriptors that define memory spaces and their access rights. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with an access error response.

20.2.1 Block diagram

A simplified block diagram of the SMPU module is shown in the following figure. The access signals coming from the crossbar switch slave ports are shown on the left. The access evaluation macros and region descriptors are in the middle, and the peripheral bus interface is on the right side.

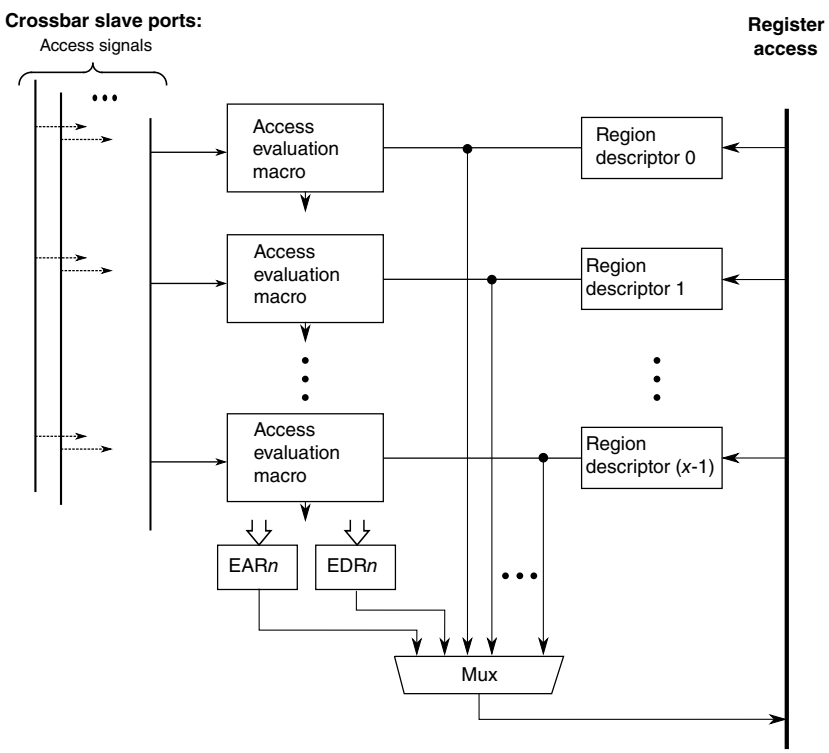

Figure 20-2. SMPU block diagram

The access evaluation macros determine hits to memory regions and detect violations to access protections. If a violation is detected, the macros update the appropriate master's error registers. For details of the access evaluation macro, see Access evaluation macro.

20.2.2 Features

The SMPU feature set includes:

- Support for a maximum of 16 program-visible 192-bit region descriptors, accessible as six 32-bit words each.
  - Each region descriptor defines an arbitrarily-sized space, aligned anywhere in memory.
    - Region sizes can vary from a minimum of 16 bytes to a maximum of (4 GB – 16 bytes).
  - Read/write access control permissions are defined in the region descriptor.
  - Global cache-inhibit attribute indicator.
  - Hardware-assisted maintenance of the descriptor valid bit minimizes coherency issues.
  - Priority given to granting permission over denying access for overlapping region descriptors.
- Detection of access errors if a memory reference does not hit in any memory region, or if the reference is illegal in all hit memory regions. If an access error occurs, the reference is terminated with an error response, and the SMPU inhibits the bus cycle being sent to the targeted slave device.
- Instruction storage (ISI) or data storage (DSI) interrupts generated by aborted core accesses.
- Error registers (per bus master ID) capture the last faulting address, attributes, and other information.
- Global SMPU enable/disable control bit.

20.3 Memory map/register definition

The programming model is partitioned into three groups:

- Control registers

- Error capture registers
- Data structure containing the region descriptors

The programming model can be referenced only in supervisor mode using 32-bit accesses. Attempted references with a different access size, to an undefined (reserved) address, with a non-supported access type (a write to a read-only register, or a read of a write-only register), or in user mode generate an error termination.

NOTE

See the chip configuration details for any chip-specific register information for this module. For example, a specific instance of the module may support only eight or fewer region descriptors.

SMPU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Control/Error Status Register 0 (SMPU_CES0)	32	R/W	0000_8008h	20.3.1/442

20.3.1 Control/Error Status Register 0 (SMPU_CES0)

CESR0 provides error status plus configuration information. A global SMPU enable/ disable bit is also included in this register.

Address: 0h base + 0h offset = 0h

SMPU_CES0 field descriptions

Field	Description
0–15 MERR	Master n error, where the bus master number matches the bit number Indicates a captured error in EARn and EDRn. A bit is set when the hardware detects an error and records the faulting address and attributes. It is cleared by writing one to it. If another error is captured at the exact same cycle as the write, the flag remains set. A find-first-one instruction (or equivalent) can detect the presence of a captured error. 0 No error has occurred for bus master n. 1 An error has occurred for bus master n.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–30 HRL	Hardware revision level Specifies the SMPU's hardware and definition revision level. It can be read by software to determine the functional definition of the module.
31 GVLD	Global Valid (global enable/disable for the SMPU)

Table continues on the next page...

SMPU_CES0 field descriptions (continued)

Field	Description
	0 SMPU is disabled. All accesses from all bus masters are allowed. 1 SMPU is enabled.

20.3.2 Control/Error Status Register 1 (SMPU_CES1)

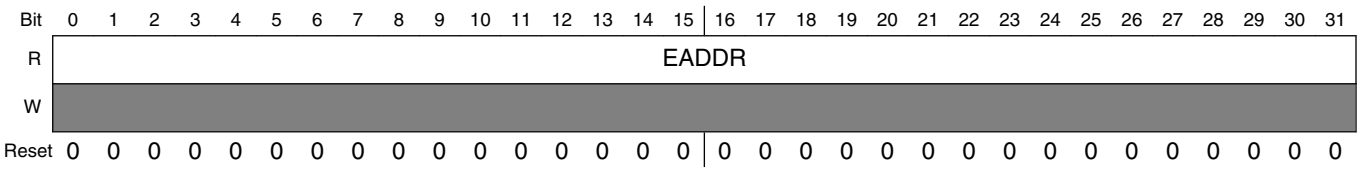
CESR1 provides additional error status plus configuration information.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	MEOVR																0												NRGD			
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

SMPU_CES1 field descriptions

Field	Description
0–15 MEOVR	Master n error overrun, where the bus master number matches the bit number Each bit in this field signals that another SMPU error for bus master n has occurred before the previous error was processed. The details of the first error are recorded in the EARn and EDRn registers and no information on subsequent errors is recorded until the associated CESR0[MERR] flag is cleared. 0 No error overrun condition has been detected for bus master n. 1 An error overrun condition has been detected for bus master n.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 NRGD	Number of region descriptors Indicates the number of region descriptors implemented in the SMPU. The number of region descriptors is (4 x NRGD). 0001 4 region descriptors 0010 8 region descriptors 0011 12 region descriptors 0100 16 region descriptors 0101 20 region descriptors 0110 24 region descriptors



20.3.3 Error Address Register, Bus Master (SMPU_ERR_ADR*n*)

When the SMPU detects an access error on bus master n, the 32-bit reference address is captured in this read-only register and the corresponding bit in CESR0[MERR] set. Additional information about the faulting access is captured in the corresponding EDRn at the same time.

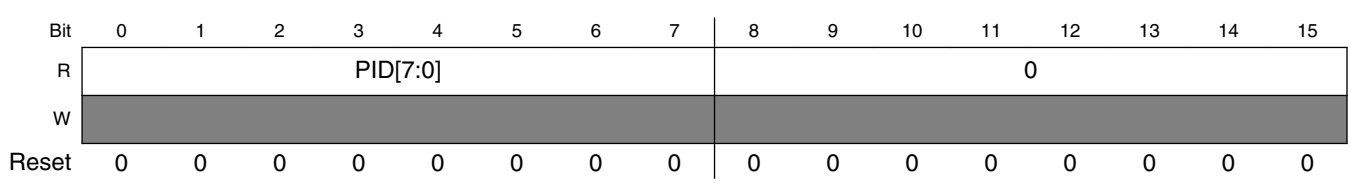
NOTE

The corresponding EARn and EDRn registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the CESR1[MEOVR] field until the CESR0[MERR] flag associated with the original error is cleared (by writing a 1).

Address: 0h base + 100h offset + (16d × i), where i=0d to 15d

SMPU_ERR_ADR*n* field descriptions

Field	Description
0–31 EADDR	Error address Indicates the reference address from bus master n that generated the access error.



20.3.4 Error Attribute Detail Register, Bus Master (SMPU_ERR_ADTL*n*)

When the SMPU detects an access error associated with bus master n, 32 bits of error detail are captured in this read-only register and the corresponding bit in CESR0[MERR] isset. Information on the faulting address is captured in the corresponding EARn register at the same time.

NOTE

The corresponding EARn, EADRn, and EACDRn registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the CESR1[MEOVR] Þeld until the original error is processed.

Address: 0h base + 104h offset + (16d × i), where i=0d to 15d

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0						EATTR		ERW	EMN						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SMPU_ERR_ADTL*n* field descriptions

Field	Description
0–7 PID[7:0]	PID of offending access.
8–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 EATTR	Error attributes Indicates attribute information about the faulting reference. 00 User mode, instruction access 01 User mode, data access 10 Supervisor mode, instruction access 11 Supervisor mode, data access
24 ERW	Error read/write Indicates the access type of the faulting reference. 0 Read 1 Write
25–31 EMN	Error master number Indicates the logical bus master number of the faulting reference. This field is used to determine the bus master that generated the access error.

20.3.5 Error Attribute Control Detail Register, Bus Master (SMPU_ERR_ACDL*n*)

When the SMPU detects an access error associated with bus master n, 32 bits of error detail are captured in this read-only register and the corresponding bit in CESR0[MERR] is set. Information on the faulting address is captured in the corresponding EARn register at the same time.

NOTE

The corresponding EARn, EADRn, and EACDRn registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the CESR1[MEOVR] field until the original error is processed.

Address: 0h base + 108h offset + (16d × i), where i=0d to 15d

Bit	0–15	16–23	24–31
R	EACD	0	
W			
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	1 0 0 0 0 0 0 0

SMPU_ERR_ACDL*n* field descriptions

Field	Description
0–23 EACD	Error access control detail Indicates the region descriptor with the access error, where the region descriptor number matches the bit number. If EDRn contains a captured error and EACD is all zeroes, an access did not hit in any region descriptor. If only a single EACD bit is set, the access error was caused by a single non-overlapping region descriptor. If two or more EACD bits are set, the access error was caused by an overlapping set of region descriptors. **NOTE:** When the address hits in a region but there is a PID miss (the PID is reflected in the Error Attribute Detail register), the field EACD = 0, if there is no other error. If there is another error, the EACD will reflect the region of the error (i.e., when it is hit in two regions)
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

20.3.6 Region Descriptor n, Word 0 (SMPU_RGD*n*_WRD0)

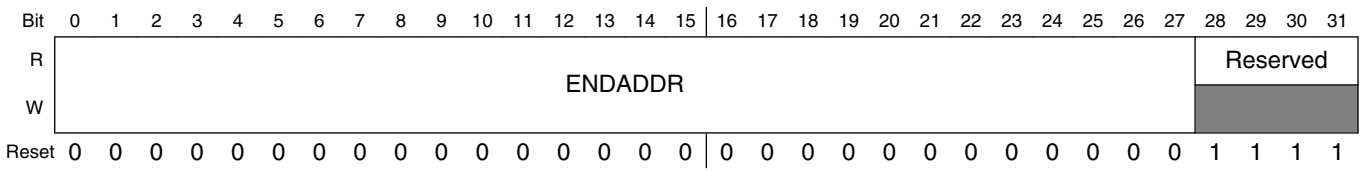
The first word of the region descriptor defines the byte start address of the memory region. Writes to this register clear the region descriptor's valid bit (RGDn_WORD5[VLD]).

Writes to ANY word of the descriptor clears the valid bit.

Address: 0h base + 400h offset + (64d × i), where i=0d to 15d

Bit	0–15	16–27	28–31
R	SRTADDR		Reserved
W			
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0

SMPU_RGD*n*_WRD0 field descriptions



Field	Description
0–27 SRTADDR	Start address Defines the start address of the memory region.
28–31 Reserved	This field is reserved.

20.3.7 Region Descriptor n, Word 1 (SMPU_RGD*n*_WRD1)

The second word of the region descriptor defines the end address of the memory region. (RGDn_WORD5[VLD]).

Writes to ANY word of the descriptor clears the valid bit.

Address: 0h base + 404h offset + (64d × i), where i=0d to 15d

SMPU_RGD*n*_WRD1 field descriptions

Field	Description
0–27 ENDADDR	End address Defines the end address of the memory region. **NOTE:** 1. The SMPU module does not verify that a region's starting address (SMPU_RGDn_WRD0[SRTADDR]) is less than its ending address (SMPU_RGDn_WRD1[ENDADDR]). When a region's ending address is a lower address than the starting address, no error is generated and no hits can be generated for that region. 2. Both the starting address and the ending address are contained within a defined region. For example, the SRTADDR and ENDADDR default values (0000_0000h and 0000_000Fh, respectively) define a 16-byte region starting at address 0000_0000h and containing all bytes through address 0000_000Fh.
28–31 Reserved	This field is reserved.

20.3.8 Region Descriptor n, Word 2 (SMPU_RD_*n*W2)

RGD_WORD2 defines the access control rights of the memory region. The access control rights are defined by separate read and write permissions. For these fields, the bus master number refers to the *logical* bus master number.

For the access control rights, there are two flags:

- Read (r) permission refers to the ability to access the referenced memory address using an operand (data) fetch or an instruction fetch.
- Write (w) permission refers to the ability to update the referenced memory address using a store (data) operation.

Each field consists of the two flags, with (r) being in the more significant position. For example, M0P has (r) as bit 0 and (w) as bit 1.

- 00 - No Write or Read
- 01 - Write allowed, no Read
- 10 - Read allowed, no Write
- 11 - Both Read and Write allowed

Writes to this word clear the region descriptor's valid bit.

Address: 0h base + 408h offset + (64d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

20.3.9 Region Descriptor n, Word 3 (SMPU_RGD*n*_WRD3)

The third word of the SMPU region descriptor contains the format select (FMT), three sets of access permissions flags used when FMT = 1, and the cache inhibit bit.

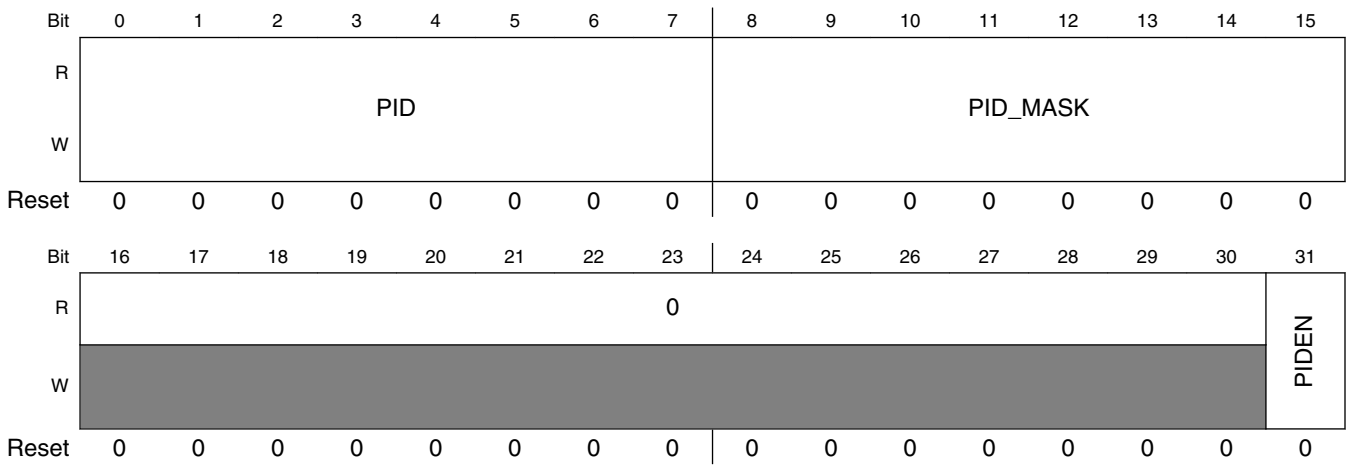
Writes to ANY word of the descriptor clears the valid bit.

Address: 0h base + 40Ch offset + (64d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0												0		CI	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SMPU_RGD*n*_WRD3 field descriptions



Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 CI	Cache Inhibit Defines the cacheability attribute of the memory region. This bit is returned to the bus master that initiated the memory reference. **NOTE:** An address range specified in an SMPU region descriptor for a cacheable space (that is, CI = 0) must be defined with a starting address aligned on a 0-modulo-32 byte address and with a multiple of the 32 byte cache line size factoring into the end address. For details on operation of CI attribute, please refer to CI note in Putting it all together and error terminations 0 References to this region can be cached. 1 References to this region cannot be cached.
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

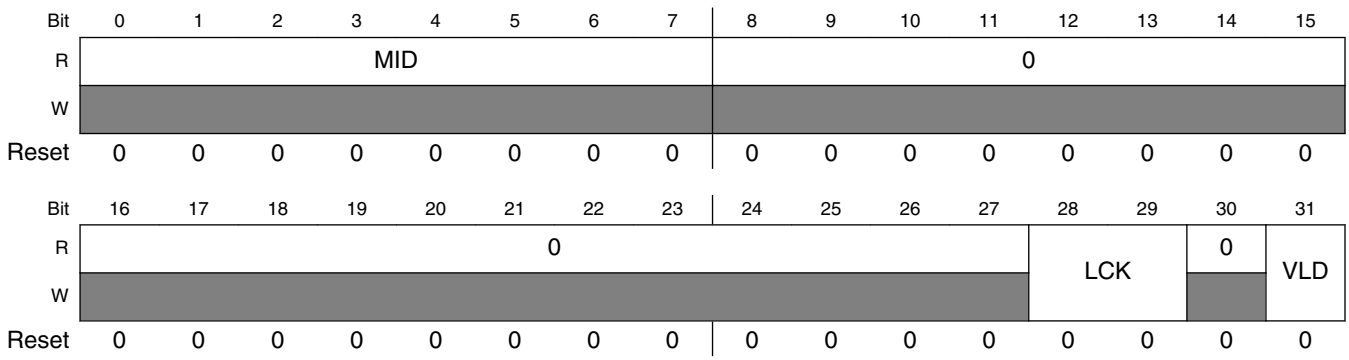
20.3.10 Region Descriptor n, Word 4 (SMPU_RGD*n*_WRD4)

The fifth word of the MPU region descriptor contains the optional process identifier and mask. If PIDEN is set, the PID and PID MASK of will be included in the hit evaluation calculation.

Writes to ANY word of the descriptor clears the valid bit.

Address: 0h base + 410h offset + (64d × i), where i=0d to 15d

SMPU_RGD*n*_WRD4 field descriptions



Field	Description
0–7 PID	Process Identifier This field specifies that the optional process identifier is to be included in the determination of whether the current access hits in the region descriptor. This field is combined with the PIDMASK and included in the region hit determination if SMPUx_RGDn_WORD3[PIDEN] is set.
8–15 PID_MASK	Process Identifier Mask This field provides a masking capability so that multiple process identifiers can be included as part of the region hit determination. If a bit in the PID_MASK is set, then the corresponding bit of the PID is ignored in the comparison. This field is combined with the PID and included in the region hit determination if SMPUx_RGDn_WORD3[PIDEN] is set. For more information on the handling of the PID and PID_MASK.
16–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 PIDEN	Region Descriptor PID Enable This flag specifies if the process identifier and mask (defined in MPU_RGDn_Word4) are to be included in the region hit evaluation 0 Do not include PID in the region hit evaluation 1 Include PID in the region hit evaluation

20.3.11 Region Descriptor n, Word 5 (SMPU_RGD*n*_WRD5)

The sixth word of the MPU region descriptor contains the master ID of the master who has locked the RGD as well as the Lock function and Valid bit. If LCK is set, the master ID of the master who has locked it will be stored here.

Writes to ANY word of the descriptor clears the valid bit.

Address: 0h base + 414h offset + (64d × i), where i=0d to 15d

SMPU_RGD*n*_WRD5 field descriptions

Field	Description
0–7 MID	Master ID of RGDn owner If this RGDn is locked through the setting of SMPUx_RGDn_WORD5[LCK], the MID field will reflect the Master ID of the current RGDn owner.
8–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–29 LCK	Region Descriptor Lock This bit allows a master to Lock a region descriptor. Once locked, only that master can modify the Region descriptor's contents. This includes all words of the RGD. **NOTE:** Setting LCK to 1x in an RGD locks all words of the RGD until system reset, the Valid bit of the RGD and the Global Valid bit of the SMPU have no effect. 00 Unlocked 01 Locked by the master wrote this register and LCK bit. Attempted writes by other masters are ignored with an error-free data transfer termination 10 This value is reserved for future enhancements and should not be used. 11 Attempted writes to any location in the region descriptor are ignored with an error-free data transfer termination.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 VLD	Valid Signals the region descriptor is valid. Any write to RGDn_WORD0–4 clears this bit. 0 Region descriptor is invalid 1 Region descriptor is valid

SMPU_RGD*n*_WRD5 field descriptions (continued)

Field	Description

20.4 Functional description

In this section, the functional operation of the SMPU is detailed, including the operation of the access evaluation macro and the handling of error-terminated bus cycles.

20.4.1 Access evaluation macro

The basic operation of the SMPU is performed in the access evaluation macro, a hardware structure replicated in the connection matrix. The following block diagram represents an individual macro.

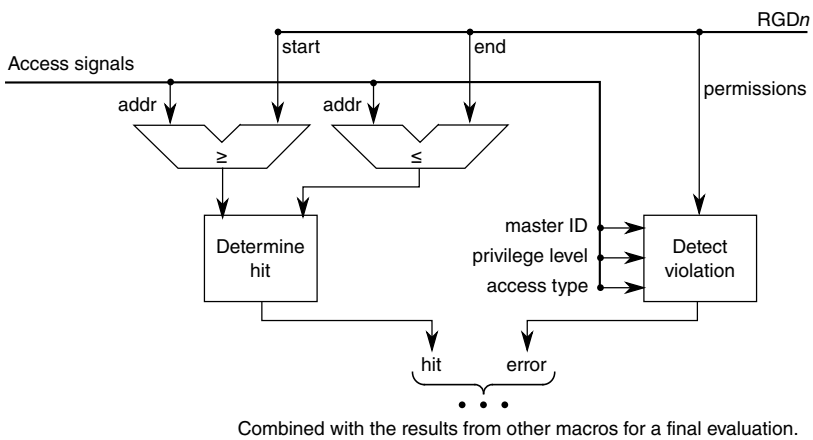


Figure 20-3. SMPU access evaluation macro

Each macro uses the information contained in the access signals (the address, the access type, and the master's ID and privilege level) and the contents of its corresponding region descriptor (RGD*n*) to perform two major functions: Hit determination and Violation determination. The individual hit and error results from each macro are then combined for a final evaluation; see Putting it all together and error terminations.

20.4.1.1 Hit determination

To determine if the current reference hits in the given region, two magnitude comparators are used with the region's start and end addresses. The boolean equation for this portion of the hit determination is:

```
region_hit = ((addr[0:31] >= RGDn_Word0[SRTADDR]) & (addr[0:31] <= RGDn_Word1[ENDADDR])) &
RGDn_Word5[VLD]
```

where addr is the current reference address, RGD*n*_Word0[SRTADDR] and RGD*n*_Word1[ENDADDR] are the start and end addresses, and RGD*n*_Word5[VLD] is the valid bit.

NOTE

The SMPU does not verify that ENDADDR > SRTADDR.

NOTE

Region hit determination is based only on an address comparison of the first byte being accessed; that is, the SMPU does not check the size of the access to make sure it fits within an allowed region.

In addition to the algebraic comparison of the reference address versus the region descriptor's start and end addresses, the optional process identifier is examined against the region descriptor's PID and PIDMASK fields. Using the hmaster[*] number to select the appropriate MxPE field from the region descriptor, a process identifier hit term is formed as:

```
pid_hit = ~rgdn.mxpe | ((current_pid[0:7] | rgdn.pidmask[0:7]) ==
(rgdn.pid[0:7] | rgdn.pidmask[0:7]))
```

where rgdn.mxpe is the PID Enable of the RGD, the current_pid[*] is the selected process identifier from the current bus master, and rgdn.pid[*] and rgdn.pidmask[*] are the appropriate process identifier fields from the region descriptor n. For bus masters that do not output a process identifier, the SMPU forces the pid_hit term to be asserted. As shown in Figure 20-2, the access evaluation macro actually forms the logical complement (hit_b) of the combined region_hit and pid_hit boolean equations.

20.4.1.2 Violation determination

While the access evaluation macro is determining region hit, the logic is also evaluating if the current access is allowed by the permissions defined in the region descriptor. Using the master ID, a set of effective permissions is generated from the appropriate fields in the region descriptor. The protection violation logic then evaluates the access against the effective permissions using the specification shown below.

Table 20-2. Protection violation definition

Access type	Access permissions		Protection violation?
	r	w	
Instruction fetch read	0	—	Yes, no execute permission
	1	—	No, access is allowed
Data read	0	—	Yes, no read permission
	1	—	No, access is allowed
Data write	—	0	Yes, no write permission
	—	1	No, access is allowed

20.4.2 Putting it all together and error terminations

For each slave port monitored, the SMPU performs a reduction-AND of all the individual terms from each access evaluation macro. This expression then terminates the bus cycle with an error and reports an access error for three conditions:

1. The access does not hit in any region descriptor.
2. The access hits in a single region descriptor and that region has a protection violation.
3. The access hits in multiple (overlapping) regions and all regions have protection violations.

As shown in the third condition, granting permission is a higher priority than denying access for overlapping regions. This approach is more flexible to system software in region descriptor assignments. For an example of the use of overlapping region descriptors, see Application information.

NOTE

For Cache-Inhibit (CI), it continues with least restrictive being higher priority. If there are overlapping regions, and at least one hitting region has CI=0, then it will not be Cache inhibited. It should be noted that CI only considers whether or not there is a hit, not whether there is a hit and permissions. For example, if two regions hit, one hit has permissions and has CI=1. Another region hit does not allow permissions, but has CI=0. This access would be granted, and it would not be cache inhibited.

NOTE

Aborted core accesses generate instruction storage (ISI) or data storage (DSI) interrupts (see the documentation related to the core for details).

20.5 Initialization information

At system startup, load the appropriate number of region descriptors, including setting RGD*n*_Word5[VLD]. Setting CESR0[GVLD] enables the module.

If the system requires that all the loaded region descriptors be enabled simultaneously, first ensure that the entire SMPU is disabled (CESR0[GVLD]=0). Next, load the appropriate region descriptors (RGDn), including the setting of the RGDn_Word5[VLD] bits. Finally, set CESR0[GVLD] to enable the entire module.

Note

A region descriptor must be set to allow access to the SMPU registers if further changes are needed.

20.6 Application information

In an operational system, interfacing with the SMPU is generally classified into the following activities:

- Creating a new memory region

  Load the appropriate region descriptor into an available RGD*n*, using four sequential 32-bit writes. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes.

- Modifying a region descriptor

  Load the updates into the region descriptor using sequential 32-bit writes. Writing 1 to RGD*n*_WRD5[VLD] re-enables the region descriptor. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes.

- Removing a region descriptor

  Clearing RGD*n*_WRD5[VLD] deletes an existing region descriptor.

- Accessing the SMPU

Allocate a region descriptor to restrict SMPU access to supervisor mode from specific masters as appropriate.

- Detecting an access error

  The current bus cycle is terminated with an error response and EAR*n* and EDR*n* capture information on the faulting reference. The error-terminated bus cycle typically initiates an error response in the originating bus master. For example, a processor core may respond with a bus error exception, while a data movement bus master may respond with an error interrupt. The processor can retrieve the captured error address and detail information simply by reading E{A,D}R*n*. CESR0[MERR] signals which error registers contain captured fault data. Once the error information is retrieved, write a 1 to the appropriate CESR0[MERR] bit to clear it, thereby rearming the error capture logic associated with the EAR*n* and EDR*n* registers.

- Overlapping region descriptors

  Applying overlapping regions often reduces the number of descriptors required for a given set of access controls. In the overlapping memory space, the protection rights of the corresponding region descriptors are logically summed together (the boolean OR operator).

Chapter 21
Semaphores2 (SEMA42)

21.1 Introduction

The SEMA42 is a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve "lock and unlock" operations via a single write access. The hardware semaphore module provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

21.1.1 Features

- Supports 16 hardware-enforced gates in a multi-processor configuration
  - Gates appear as an 16-entry byte-size array with read and write accesses.
    - Processors lock gates by writing "processor_number+1" to the appropriate gate and must read back the gate value to verify the lock operation was successful.
    - Once locked, the gate is unlocked by a write of zeroes from the locking processor.
    - The number of implemented gates is specified by a hardware configuration define.
  - Each hardware gate appears as a 16-state, 4-bit state machine.
    - 16-state implementation

      if gate = 0x0, then state = unlocked
      if gate = 0x1, then state = locked by processor (master) 0
      if gate = 0x2, then state = locked by processor (master) 1
      …
      if gate = 0xF, then state = locked by processor (master) 14

- Uses the logical bus master number as a reference attribute plus the specified data patterns to validate all write operations.
- Once locked, the gate can (and must) be unlocked by a write of zeroes from the locking processor.

- Secure reset mechanisms are supported to clear the contents of individual gates, as well as a clear_all capability.

A simplified block diagram of the Semaphores module is shown in the following figure. In the diagram, the register blocks named gate0, gate1,…, gate (n-2), gate (n-1) include the finite state machines implementing the semaphore gates.

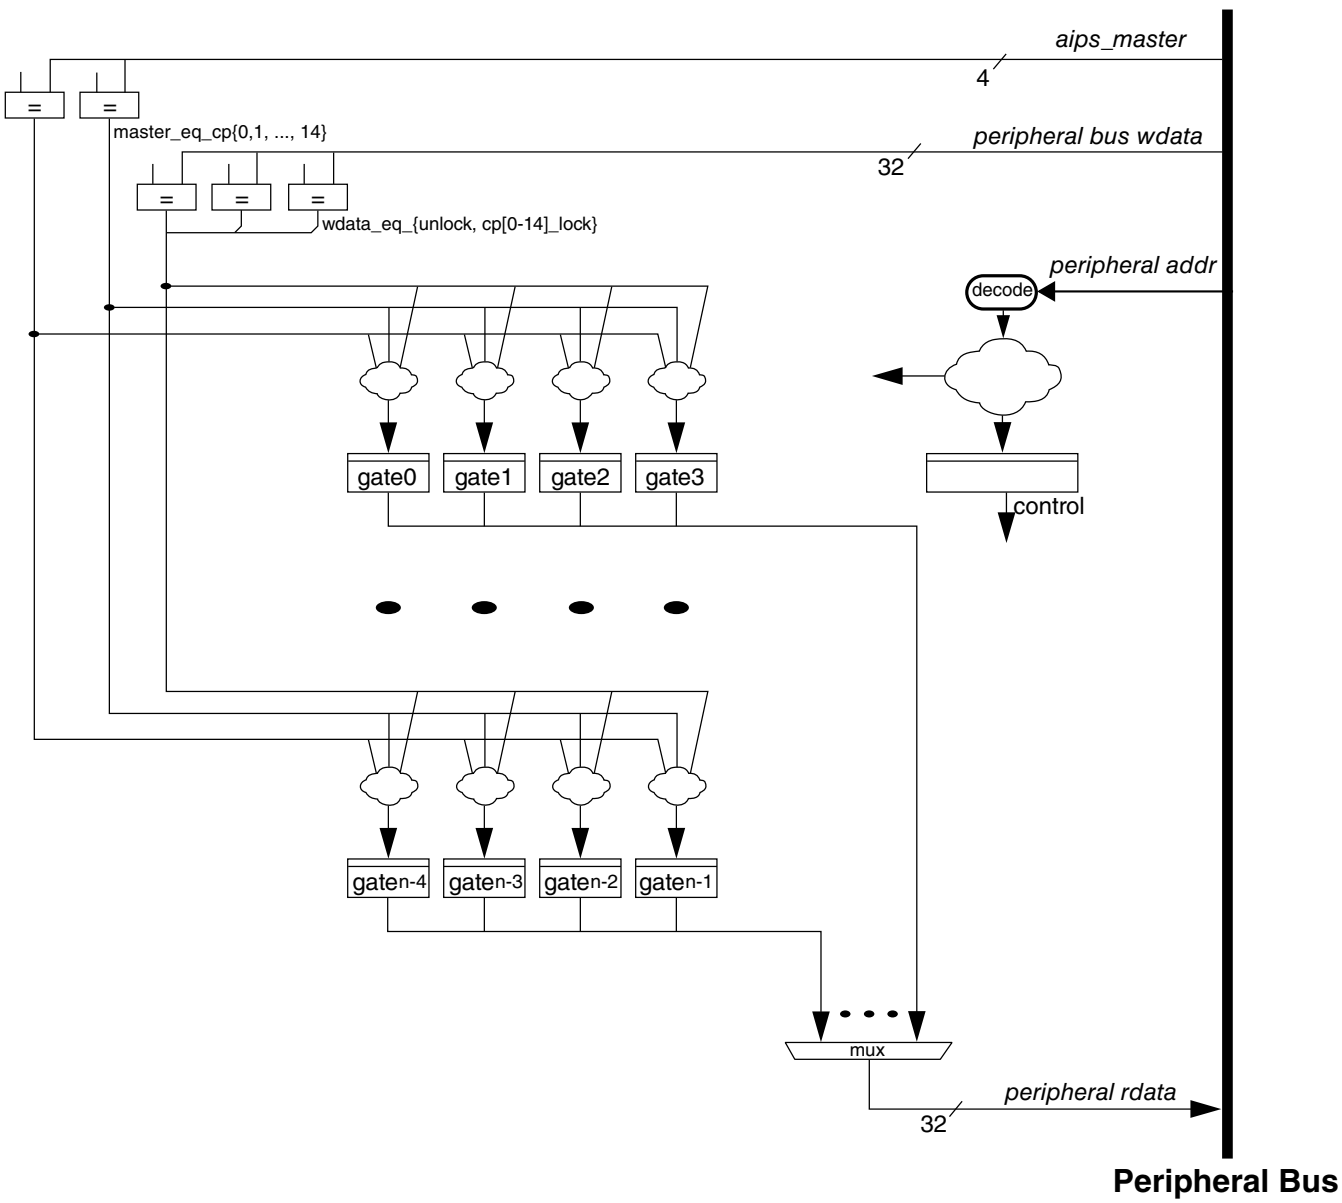

Figure 21-1. Semaphores2 block diagram

21.2 Memory map/register definition

Only Supervisor Mode accesses are allowed on these registers. User accesses will be terminated with an error.

SEMA42 memory map

21.2.1 Gate Register (SEMA42_GATE*n*)

Each semaphore gate is implemented in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical bus master number in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. Attempted writes with a data value that is neither the unlock value (0x00) nor the appropriate lock value (processor_number + 1) are simply

treated as "no operation" and do not affect any gate state. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes.

Address: 0h base + 0h offset + (1d × i), where i=0d to 15d

SEMA42_GATE*n* field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 GTFSM	Gate Finite State Machine. The state of the gate reflects the last processor that locked it, which can be useful during system debug. The hardware gate is maintained in a 16-state implementation, defined as: 0000 The gate is unlocked (free). 0001 The gate has been locked by processor 0. 0010 The gate has been locked by processor 1. 0011 The gate has been locked by processor 2. 0100 The gate has been locked by processor 3. 0101 The gate has been locked by processor 4. 0110 The gate has been locked by processor 5. 0111 The gate has been locked by processor 6. 1000 The gate has been locked by processor 7. 1001 The gate has been locked by processor 8. 1010 The gate has been locked by processor 9. 1011 The gate has been locked by processor 10. 1100 The gate has been locked by processor 11. 1101 The gate has been locked by processor 12. 1110 The gate has been locked by processor 13. 1111 The gate has been locked by processor 14.

21.2.2 Reset Gate Write (SEMA42_RSTGT_W)

NOTE

This section and the following section, Reset Gate Read (SEMA42_RSTGT_R), describe the same register. This section describes the general operation of the register and also shows how the register fields appear when the register is written. Reset Gate Read (SEMA42_RSTGT_R) shows how the register fields appear when the register is read.

Although the intent of the hardware gate implementation specifies a protocol where the locking domain must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the Semaphores module implements a "secure" reset mechanism that allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same domain to force the clearing of the specified gate(s). The required access pattern is:

1. A domain performs a 16-bit write to the SEMA42_RSTGT memory location. The most significant byte (SEMA42_RSTGT[RSTGDP]) must be E2h; the least significant byte is a "don't_care" for this reference.
2. The same domain then performs a second 16-bit write to the SEMA42_RSTGT location. For this write, the upper byte (SEMA42_RSTGT[RSTGDP]) is the logical complement of the first data pattern (1Dh) and the lower byte (SEMA42_RSTGT[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate be cleared, or that all gates are to be cleared. If the same domain writes incorrect data on the second access or another domain performs the second write access, the special gate reset sequence is aborted and no error signal is asserted.
3. Reads of the SEMA42_RSTGT location return information on the 2-bit state machine (SEMA42_RSTGT[RSTGSM]) that implements this function, the domain performing the reset (SEMA42_RSTGT[RSTGMS]), and the gate number(s) last cleared (SEMA42_RSTGT[RSTGTN]). Reads of the SEMA42_RSTGT register do not affect the secure reset finite state machine in any manner.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Write	RSTGDP								RSTGTN							
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- Reset value is not applicable for writes.

SEMA42_RSTGT_W field descriptions

Field	Description
0–7 RSTGDP	Reset Gate Data Pattern. This write-only field is accessed with the specified data patterns on the two consecutive writes to enable the gate reset mechanism. For the first write, RSTGDP = E2h while the second write requires RSTGDP = 1Dh.

Table continues on the next page...

SEMA42_RSTGT_W field descriptions (continued)

Field	Description
8–15 RSTGTN	Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write. If RSTGTN < 64, then reset the single gate defined by RSTGTN, else reset all the gates.

21.2.3 Reset Gate Read (SEMA42_RSTGT_R)

This section describes how the Reset Gate register fields appear when the register is read. See Reset Gate Write (SEMA42_RSTGT_W) for the description of the register's overall operation and how the register fields appear when the register is written.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	ROZ		RSTGSM		RSTGMS				RSTGTN							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SEMA42_RSTGT_R field descriptions

Field	Description
0–1 ROZ	This field always returns the value 0 when read.
2–3 RSTGSM	Reset Gate Finite State Machine. Reads of the SEMA42_RSTGT register return the encoded state machine value. Note the RSTGSM = 10 state is valid for only a single machine cycle, so it is impossible for a read to return this value. The reset state machine is maintained in a 2-bit, 3-state implementation, defined as: 00 Idle, waiting for the first data pattern write. 01 Waiting for the second data pattern write. 10 The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. The "01" state persists for only one clock cycle. Software cannot observe this state. 11 This state encoding is never used and therefore reserved.
4–7 RSTGMS	Reset Gate Bus Master. This 4-bit read-only field records the logical number of the bus master performing the gate reset function. The reset function requires that the two consecutive writes to this register must be initiated by the same bus master to succeed. This field is updated each time a write to this register occurs. The association between system bus master port numbers, the associated bus master device, and the logical processor number is SoC-specific. Consult the device reference manual for this information.
8–15 RSTGTN	Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write. If RSTGTN < 64, then reset the single gate defined by RSTGTN, else reset all the gates.

21.3 Functional description

Functional operation of the Semaphores module and specific details of the state machines of the SEMA42_GATEn registers are provided as follows.

As described previously, each of the SEMA42_GATEn registers implements a 4-bit, 16-state machine. A *simplified* diagram of the state transitions for each gate is shown in Figure 21-2.

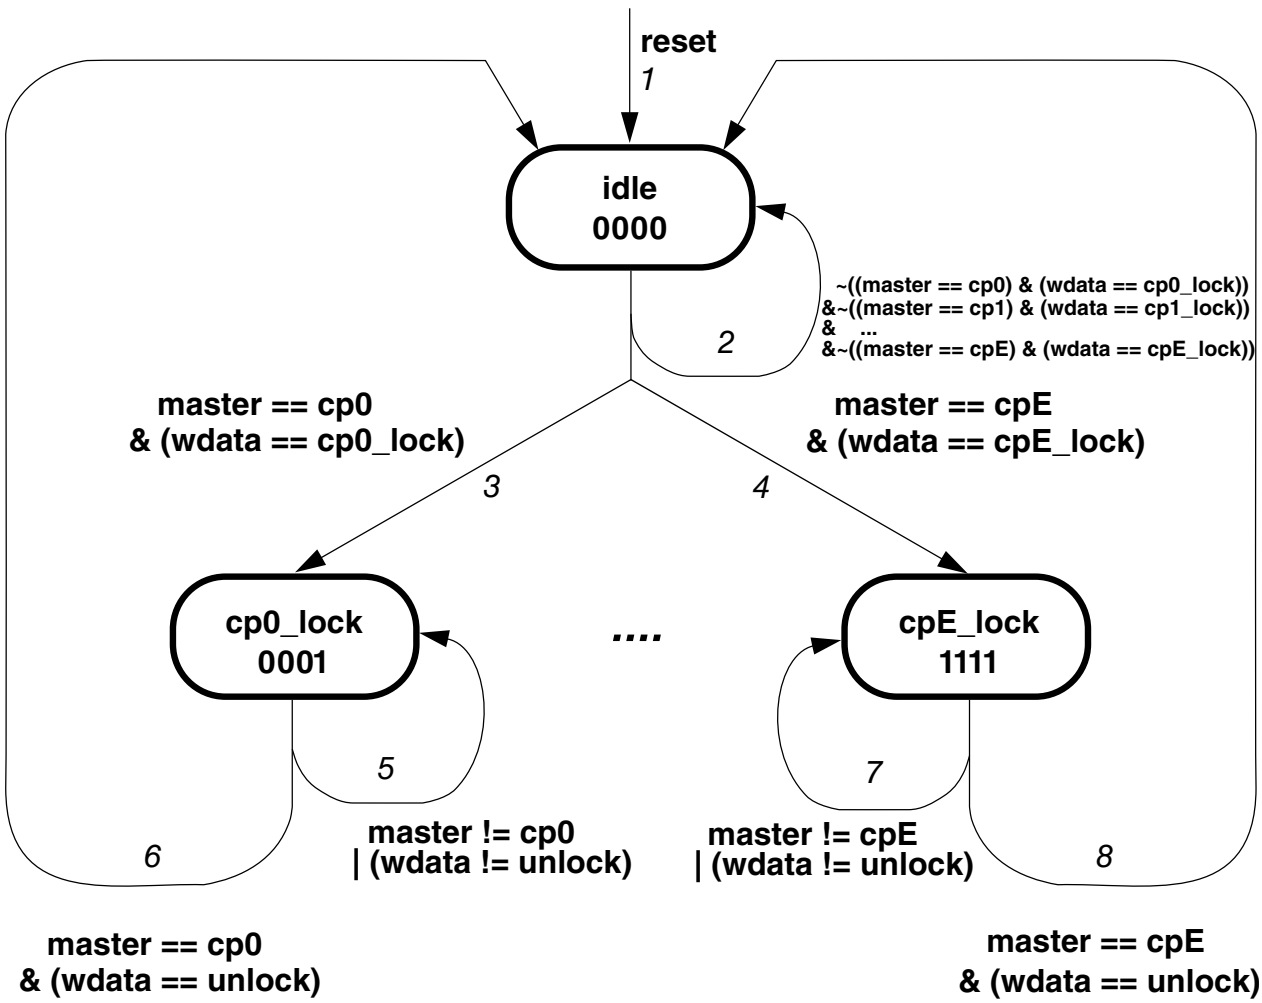

Figure 21-2. SEMA42_GATEn state machine

The bus master number is used to identify core processor *X* (cp*X*) where the notation cpE is used to represent core processor 14 (= 0xE). The platform passes the AHB bus master number through the peripheral bridge controller and drives a signal to the Semaphores module.

The state transitions for SEMA42_GATEn are defined in Table 21-1.

Table 21-1. SEMA42_GATEn state transitions

Current State	Next State	Transition	Description
–	idle	1	Any reset, whether a system reset or a software-initiated gate reset, unconditionally forces the gate into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding processor occurs, the gate remains in the idle state.
idle	cp0_lock	3	When a write of the "cp0_lock" data value is initiated by processor 0, the gate transitions into the cp0_lock state.
idle	cpE_lock	4	When a write of the "cpE_lock" value is initiated by processor 0xE, the gate transitions into the cpE_lock state.
cp0_lock	cp0_lock	5	Once in this state, the gate remains here if any attempted write is not from cp0 with the unlock data value.
cp0_lock	idle	6	The gate returns to the idle (unlocked) state once a write from cp0 with the unlock data value occurs.
cpE_lock	cpE_lock	7	Once in this state, the gate remains here if any attempted write is not from cpE with the unlock data value.
cpE_lock	idle	8	The gate returns to the idle (unlocked) state once a write from cpE with the unlock data value occurs.

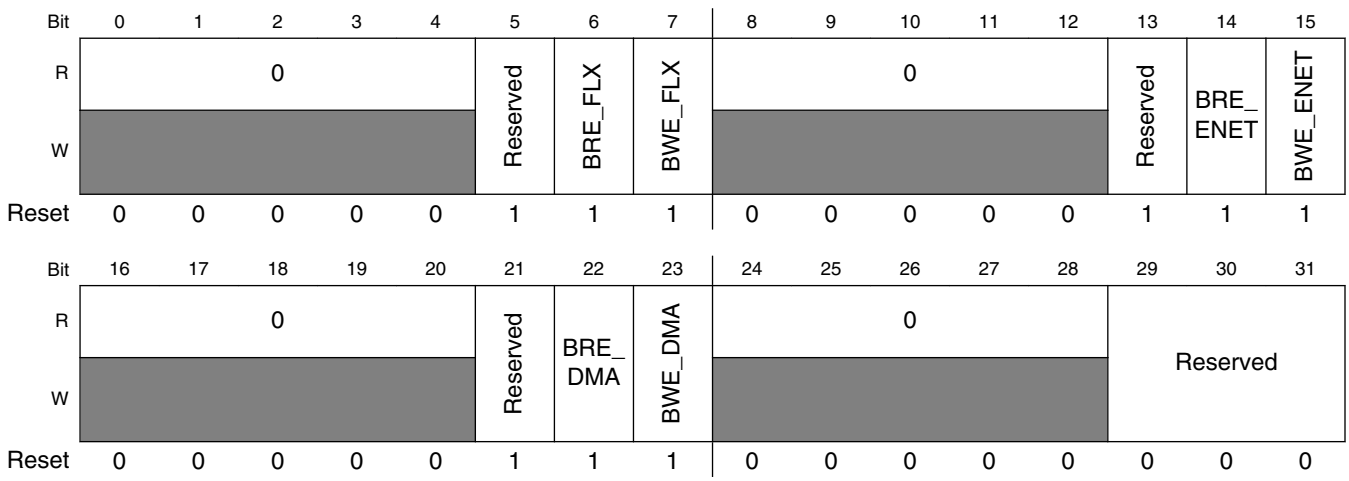
The following gate data values are used:

- The lock data value is (processor number + 1) where the processor number and the platform bus master number are the same.
- The unlock data value is 0x00.

Chapter 22
Platform Configuration Module (PCM)

22.1 Memory map and register definition

The Platform Configuration Module (PCM) contains miscellaneous configuration registers for the device. Currently, the configuration registers are related to the operation of the intelligent bus bridging gasket. The module is mapped to PBRIDGE on-platform slot 10 with a base address of 0xFC02_8000. This PCM drives ports on the intelligent bridging gaskets and Clock Gating Module



PCM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Bus Bridge Configuration Register 0 (PCM_IAHB_BE0)	32	R/W	0707_0700h	22.1.1/466
4	Bus Bridge Configuration Register 1 (PCM_IAHB_BE1)	32	R/W	0707_0707h	22.1.2/468

PCM_IAHB_BE0 field descriptions (continued)

Field	Description
	0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
15 BWE_ENET	Burst Write Enable ENET This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat.
16–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 Reserved	This field is reserved.
22 BRE_DMA	Burst read enable (BRE) DMA This bit controls the bus gasket's handling of burst read transactions 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance
23 BWE_DMA	Burst write enable (BWE) DMA This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as “imprecise” such that an error response on any beat of the burst is reported on the last beat.
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 Reserved	This field is reserved.

22.1.2 Bus Bridge Configuration Register 1 (PCM_IAHB_BE1)

This register must be accessed in supervisor mode.

Address: 0h base + 4h offset = 4h

PCM_IAHB_BE1 field descriptions

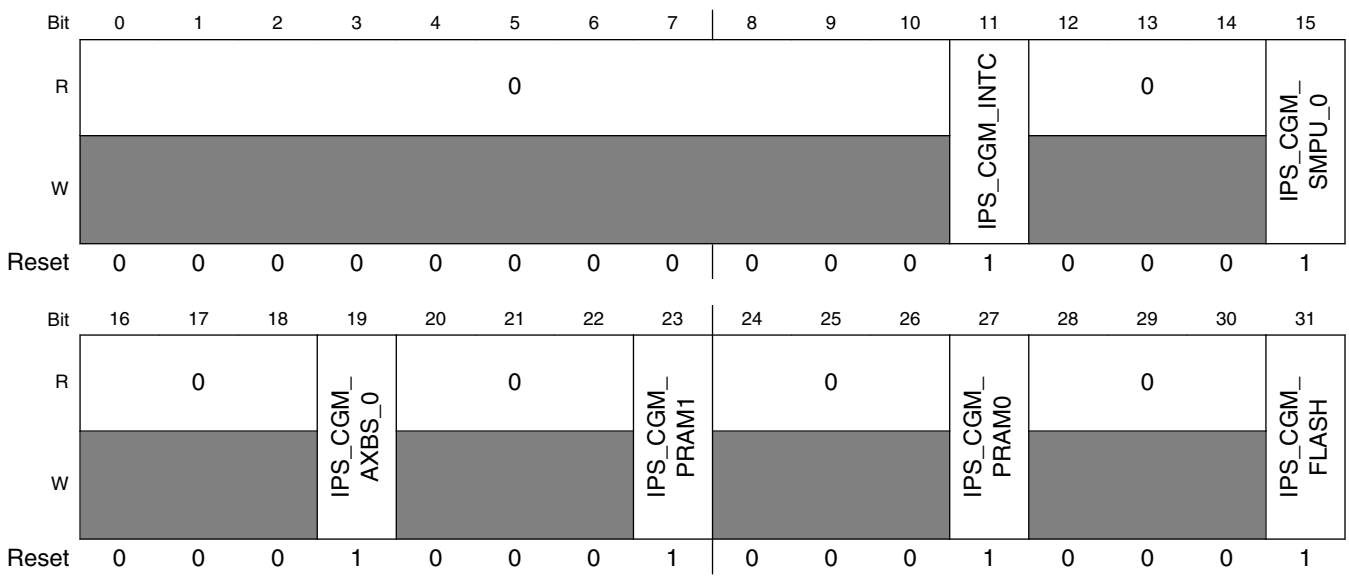
Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 PRE_PBRIDGE_A	Pending read enable (PRE) PBRIDGE_A This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled 1 Pending reads are enabled
6 BRE_PBRIDGE_A	Burst read enable (BRE) PBRIDGE_A This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket 1 Burst reads are optimized for best system performance
7 BWE_PBRIDGE_A	Burst Write Enable PBRIDGE_A This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat.

Table continues on the next page...

PCM_IAHB_BE1 field descriptions (continued)

Field	Description
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 PRE_PBRIDGE_B	Pending Read Enable PBRIDGE_B This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
14 BRE_PBRIDGE_B	Burst read enable (BRE) PBRIDGE_B This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
15 BWE_PBRIDGE_B	Burst Write Enable PBRIDGE_B This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat.
16–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 PRE_Z2_DATA	Pending read enable (PRE) Z2_DATA This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled 1 Pending reads are enabled
22 BRE_Z2_DATA	Burst read enable (BRE) Z2_DATA This bit controls the bus gasket's handling of burst read transactions 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance
23 BWE_Z2_DATA	Burst write enable (BWE) Z2_DATA This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat.
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 PRE_Z2_INST	Pending read enable (PRE) Z2_INST This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled 1 Pending reads are enabled

Table continues on the next page...



PCM_IAHB_BE1 field descriptions (continued)

Field	Description
30 BRE_Z2_INST	Burst read enable (BRE) Z2_INST This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance
31 BWE_Z2_INST	Burst write enable (BWE) Z2_INST This bit controls the bus gasket's handling of burst write transactions 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat

22.1.3 IPS Clock Gating Module Enable 0 Register (PCM_IPS_CGM_EN0)

This register must be accessed in supervisor mode.

Address: 0h base + 8h offset = 8h

PCM_IPS_CGM_EN0 field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PCM_IPS_CGM_EN0 field descriptions (continued)

Field	Description
11 IPS_CGM_INTC	IPS clock gating enable for INTC 1 Enable clock gating, one IPS clock delay is introduced between master and slave. 0 Disable clock gating
12–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 IPS_CGM_ SMPU_0	IPS clock gating enable for SMPU_0 1 Enable clock gating, one IPS clock delay is introduced between master and slave 0 Disable clock gating
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 IPS_CGM_ AXBS_0	IPS clock gating enable for AXBS_0 1 Enable clock gating, one IPS clock delay is introduced between master and slave 0 Disable clock gating
20–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 IPS_CGM_ PRAM1	IPS clock gating enable for PRAM1 1 Enable clock gating, one IPS clock delay is introduced between master and slave 0 Disable clock gating
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 IPS_CGM_ PRAM0	IPS clock gating enable for PRAM0 1 Enable clock gating, one IPS clock delay is introduced between master and slave 0 Disable clock gating
28–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 IPS_CGM_ FLASH	IPS clock gating enable for PFlash Controller 1 Enable clock gating, one IPS clock delay is introduced between master and slave 0 Disable clock gating

Chapter 23
Interrupt Controller (INTC)

23.1 Chip-specific INTC information

23.1.1 INTC configuration

23.1.1.1 INTC configurable parameters

The INTC on this chip supports 2 processors (0, 1) and 16 level priorities of each interrupt.

23.1.2 INTC interrupt sources

The following table defines the interrupt sources for the INTC on this chip. All IRQ numbers not specifically listed are not used.

NOTE

All interrupts which are masked in INTC should also be marked as disabled in the respective modules.

Table 23-1. INTC Vector Table

Vector number	Vector offset	Source module	Source description
0	1000	Software setable flag 0	SSCIR0[CLR0]
1	1004	Software setable flag 1	SSCIR0[CLR1]
2	1008	Software setable flag 2	SSCIR0[CLR2]
3	100C	Software setable flag 3	SSCIR0[CLR3]
4	1010	Software setable flag 4	SSCIR0[CLR4]
5	1014	Software setable flag 5	SSCIR0[CLR5]
6	1018	Software setable flag 6	SSCIR0[CLR6]

Table continues on the next page...

NOTE

- Transfer error would not be generated if 477 and 484 slot is accessed.
- Interrupts are not serviced during self-test.

23.1.3 INTC implemented registers

The following table shows the registers implemented on the INTC on this chip. All offsets not specifically listed are reserved. In this chapter, z4and z2 cores are represented as processor 0, processor 1respectively.

Table 23-2. INTC implemented registers

Address offset	Register
000h	INTC Block Configuration Register (INTC_BCR)
010h	INTC Current Priority Register for Processor 0 (INTC_CPR0)
014h	INTC Current Priority Register for Processor 1 (INTC_CPR1)
018h	Reserved
020h	INTC Interrupt Acknowledge Register for Processor 0 (INTC_IACKR0)
024h	INTC Interrupt Acknowledge Register for Processor 1 (INTC_IACKR1)
028h	Reserved
030h	INTC End Of Interrupt Register for Processor 0 (INTC_EOIR0)
034h	INTC End Of Interrupt Register for Processor 1 (INTC_EOIR1)
038h	Reserved

Table continues on the next page...

Table 23-2. INTC implemented registers (continued)

Address offset	Register
040h–057h	INTC Software Set/Clear Interrupt Register 0 (INTC_SSCIR0) – INTC Software Set/Clear Interrupt Register 23 (INTC_SSCIR23)
060h-5FAh	INTC Priority Select Register 24 (INTC_PSR24) – INTC Priority Select Register 765 (INTC_PSR765)

23.1.4 Interrupts handling during mode transitions

1. All interrupts which are masked in INTC should also be marked as disabled in the respective modules.
2. All the modules, which do not support STOP-ACK handshake in hardware preferably should have the interrupt routines to poll for MC_ME_GS[S_MTRANS] to be 0 or for such modules the interrupts should be disabled before initiating mode transition request.
3. Modules which support STOP-ACK handshake (ADC, FlexCAN, DSPI, i2c, LINFlexD, SAI, RTC, BCTU, ENET and PIT-RTI) should have the interrupt service routine such that the interrupt flag in the module (i.e Program SSCIRn[CLR] to 1) is cleared and then before accessing any other module it waits for MC_ME_GS[S_MTRANS] to go to 0.

23.2 Introduction

The INTC:

- Provides priority-based preemptive scheduling of interrupt requests
- Schedules interrupt requests (IRQs) from software and internal peripherals to one or more processors (PRCs)
- Provides interrupt prioritization and preemption, interrupt masking, interrupt priority elevation, and protocol support

This scheduling scheme is suitable for statically scheduled hard real-time systems.

The INTC is targeted to work with a Power Architecture processor and is capable of processing high-demand interrupt sources where the Interrupt Service Routines (ISRs) nest to multiple levels, but it also can be used with other processors and applications.

For high-priority interrupt requests in these target applications, it is necessary to minimize the interval between the assertion of the interrupt request from the peripheral and the point at which the processor is performing useful work to service the interrupt request. The INTC supports this goal by providing a unique vector for each interrupt request source. It also provides 16 priorities so that lower priority ISRs do not delay the execution of higher priority ISRs. Since each individual application will have different priorities for each source of interrupt request, the priority of each interrupt request is configurable.

When multiple tasks share a resource, coherent accesses to that resource need to be supported. The INTC supports the Priority Ceiling Protocol for coherent accesses. By providing a modifiable priority mask, the priority can be raised temporarily so that all tasks which share the resource are unable to preempt each other.

Multiple processors can assert interrupt requests to each other through software-settable interrupt requests. These same software-settable interrupt requests can also be used to separate the work involved in servicing an interrupt request into two parts, a high-priority portion and a low-priority portion. The high-priority portion is initiated by a peripheral interrupt request, but then the ISR can assert a software-settable interrupt request to finish the servicing in a lower priority ISR. Therefore these software-settable interrupt requests can be used instead of having the peripheral ISR schedule a task through the RTOS.

23.3 Block diagram

The following figure shows the block diagram of an INTC with four processors (PRC0...PRC3). The actual number of processors is described in the chip-specific INTC information. The structure of the INTC remains the same for each implemented processor.

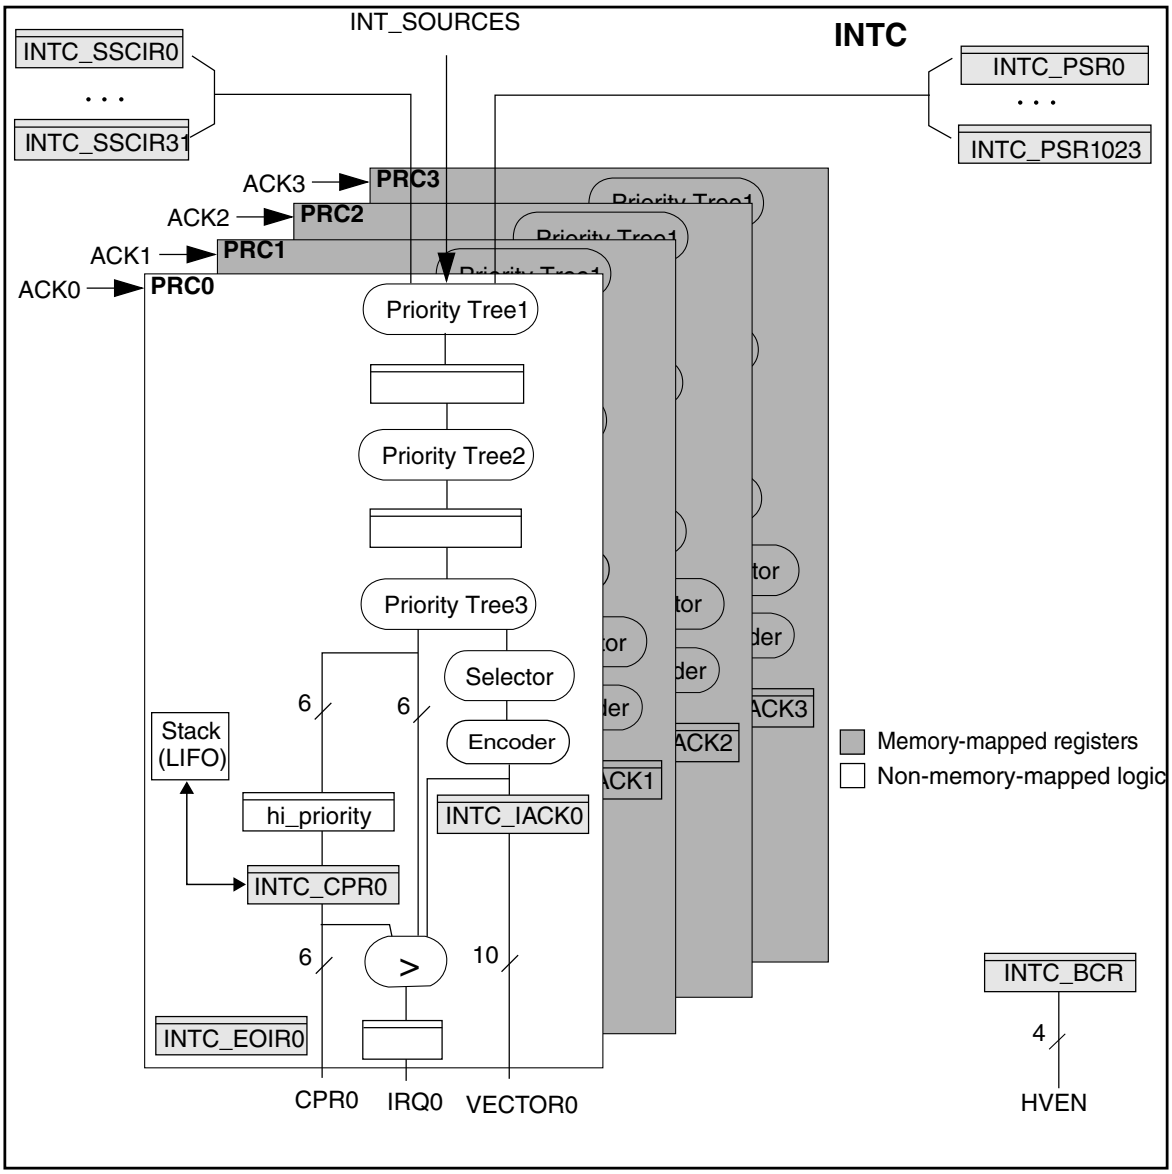

Figure 23-1. Block diagram for an INTC with four processors

23.4 Features

- Each peripheral interrupt source is software-steerable to any combination of interrupt request outputs to the following:
  - Processor 0
  - Processor 1
- 24 software-settable interrupt request sources
- 10-bit vector

    - Unique vector for each interrupt request source
    - Hardware connection to processor or read from register
- Each interrupt source can be programmed to one of 16 priorities
- Each interrupt source can be triggered by software
- Preemption
    - Preemptive prioritized interrupt requests to processor
    - ISR with higher priority preempts ISRs or tasks with lower priorities
    - Automatic pushing or popping of preempted priority to or from a LIFO
    - Ability to modify the ISR or task priority; modifying the priority can be used to implement the Priority Ceiling Protocol for accessing shared resources
    - 3 INTC clock cycles from interrupt request into interrupt request to CPU
- Low latency
    - Two INTC clock cycles from receipt of interrupt request from peripheral to interrupt request to processor; three clock cycles from receipt of software request

23.5 Modes of operation

The interrupt controller has two handshaking modes with the processor: software vector mode and hardware vector mode. The state of the hardware vector enable bit, INTC_BCR[HVEN], determines which mode is used. In Power Architecture devices, software vector mode uses the autovector mode of the Processor for a single entry point for the ISR (16 bytes of vector space available), whereas the hardware vector mode uses the non-autovector mode where the vector offset from the INTC is provided to the Processor (4 bytes for each IRQ).

In debug mode the interrupt controller operation is identical to its normal operation of software vector mode or hardware vector mode.

23.5.1 Software vector mode

In software vector mode, software (that is, the interrupt exception handler) must read a register in the INTC to obtain the vector associated with the interrupt request to the processor. The INTC will use software vector mode for a given processor when its

associated HVEN_PRCn bit in the INTC_BCR is negated. The hardware vector enable signal to any processor is driven as negated when its associated HVEN_PRC*n* bit is negated. The vector is read from the INTC_IACKRn registers. Reading the INTC_IACKR*n* negates the interrupt request to the associated processor. Even if a higher priority interrupt request has arrived while waiting for this interrupt acknowledge, the interrupt request to the processor will negate for at least one clock. The reading also pushes the PRI value in the INTC_CPRn onto the associated LIFO, and updates PRI in the associated INTC_CPR_PRC*n* with the new priority.

23.5.2 Hardware vector mode

In hardware vector mode, the hardware causes the first instruction that will be executed (when handling the interrupt request to the processor) to be an instruction that is specific to that vector. Therefore the interrupt exception handler is specific to a peripheral or software-settable interrupt request, rather than being common to all of them. The INTC will use hardware vector mode for a given processor when its associated HVENn bit in the INTC_BCR is asserted. The hardware vector enable signal to the associated processor is driven as asserted.

When the interrupt request to the associated processor asserts, the interrupt vector signal is updated. The value of that interrupt vector is the unique vector associated with the preempting peripheral or software-settable interrupt request. The vector value matches the value of the INTVEC field in the INTC_IACKRn, depending on which processor was assigned to handle a given interrupt source.

The assertion of the interrupt acknowledge signal for a given processor pushes the associated PRI value in the associated INTC_CPR*n* register onto the associated LIFO and updates the associated PRI in the associated INTC_CPR*n* register with the new priority. This pushing of the PRI value onto the associated LIFO and updating PRI in the associated INTC_CPR*n* does not occur when the associated interrupt acknowledge signal asserts and the INTC_SSCIRs is written at a time such that the PRI value in the associated INTC_CPR*n* register would need to be pushed and the previously last pushed PRI value would need to be popped simultaneously. In this case, PRI in the associated INTC_CPR*n* is updated with the new priority, and the associated LIFO is neither pushed or popped.

23.6 Memory map and register definition

A transfer error will be asserted if an access is attempted outside of the memory map or for any unimplemented registers. For example, if the design has only 512 interrupt sources and a source > 512 is accessed, a transfer error is asserted.

With the exception of the INTC_SSCIR *n* and INTC_PSR *n* registers, all of the registers are 32-bit. Any combination of accessing the four bytes of a register with a single access is supported, provided that the access does not cross a register boundary. These supported accesses include types and sizes of 8 bits, aligned 16 bits, misaligned 16 bits to the middle two bytes, and aligned 32 bits.

Although INTC_SSCIR*n* are 8 bits wide and INTC_PSR*n* are 16 bits wide, they can be accessed with a single 16-bit or 32-bit access, provided that the access does not cross a 32-bit boundary.

Some registers have specific exceptions to these rules, as outlined in their definitions.

When writing to INTC_PSRs or INTC_SSCIRs, the following restrictions (illustrated in Figure 23-2) apply:

- For PSRs, write accesses must not span 16-bit boundaries where one register is implemented and one is unimplemented (unimplemented interrupt source).
- For SSCIRs, write accesses must not span 8-bit boundaries where one register is implemented and one is unimplemented (unimplemented interrupt source).

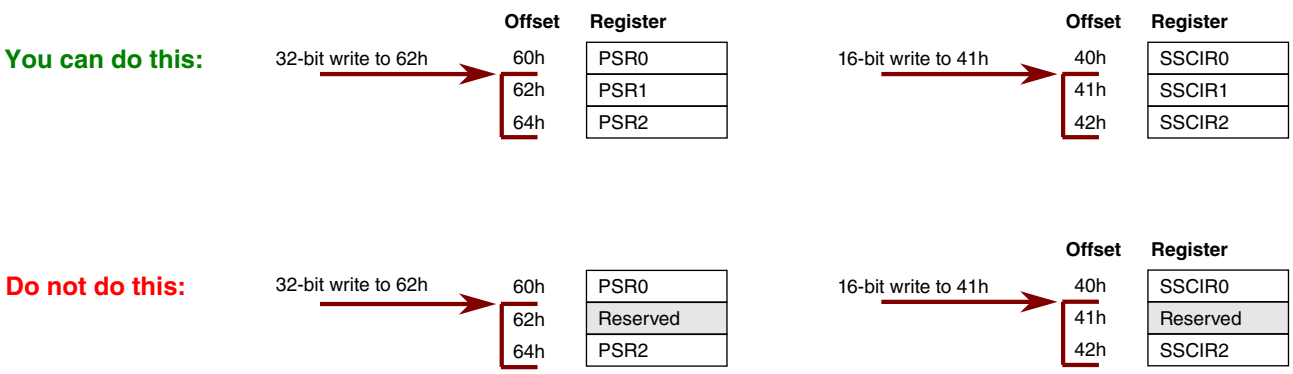

Figure 23-2. INTC_PSR*n* and INTC_SSCIR*n* write restrictions

In software vector mode, the effects of a read of the INTC Interrupt Acknowledge register (INTC_IACKR *n*) are the same regardless of the size of the read. In either software or hardware vector mode, the size of a write to the INTC end-of-interrupt register (INTC_EOIR *n*) does not affect the operation of the write.

23.6.1 INTC Block Configuration Register (INTC_BCR)

The Block Configuration Register is used to configure options of the INTC.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] has write access, otherwise, a termination error is asserted.

Address: 0h base + 0h offset = 0h

INTC_BCR field descriptions

Field	Description
0–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 HVEN1	Hardware vector enable for processor 1. Controls whether the INTC is in hardware vector mode or software vector mode. See Modes of operation for the details of the handshaking with the processor in each mode. 0 Software vector mode 1 Hardware vector mode
28–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 HVEN0	Hardware vector enable for processor 0. Controls whether the INTC is in hardware vector mode or software vector mode. See Modes of operation for the details of the handshaking with the processor in each mode. 0 Software vector mode 1 Hardware vector mode

23.6.2 INTC Master Protection Register (INTC_MPROT)

The Master Protection Register is used to protect cores from writing to other cores INTC registers.

Address: 0h base + 4h offset = 4h

INTC_MPROT field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–27 ID	ID This register can only be updated if MPROT=0 or if processor master ID=ID. When MPROT is set, the ID should also be updated to indicate which master can write to any register in the INTC memory map. Only the field values related to core bus masters can be selected. Non-core bus masters cannot be selected and would result in a bus access error. 00 master0 (reset default) 01 master1 10 master2 11 master3
28–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 MPROT	Master Protection Controls what programming space a given master can write to. If MPROT is disabled, then all masters can write to any valid entry of the INTC memory map. If MPROT is enabled, INTC_MPROT[ID] can write to any valid entry of the INTC memory map but other masters can only write to their assigned resources. Once MPROT is enabled by a master, only that master may modify INTC_MPROT. 0 Master programming space protection disabled 1 Master programming space protection enabled

23.6.3 INTC Current Priority Register for Processor 0 (INTC_CPR0)

The INTC_CPRn masks any peripheral or software-settable interrupt request that is set at the same or lower priority as the current value of the INTC_CPR*n*[PRI] field from generating an interrupt request to the processor. When the INTC Interrupt Acknowledge register (INTC_IACKR*n*) is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode, the value of PRI is pushed onto the LIFO, and PRI is updated with the priority of the preempting interrupt request. When the INTC end-of-interrupt register (INTC_EOIR*n*) is written, the LIFO is popped into the INTC_CPR*n* PRI field. An exception case in hardware vector mode to this behavior is described in Hardware vector mode.

The masking priority can be raised or lowered by writing to the PRI field, supporting the priority ceiling protocol. See Priority ceiling protocol.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

NOTE

A store to modify the PRI field that closely precedes or follows an access to a shared resource may result in a non-coherent access to that resource. See Ensuring coherency for example code to ensure coherency.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

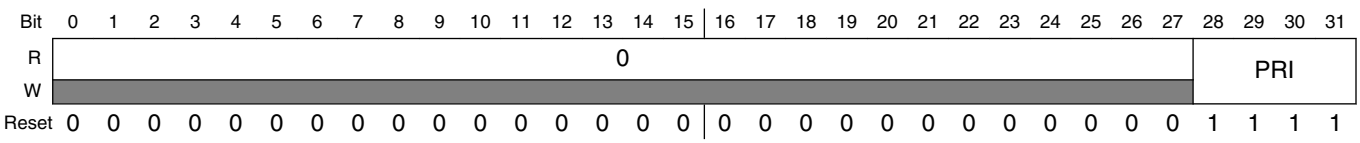
INTC_CPR0 field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 PRI	Priority of the currently executing ISR, according to the field values 15 (highest priority) down to 0 (lowest priority).

23.6.4 INTC Current Priority Register for Processor 1 (INTC_CPR1)

The INTC_CPRn masks any peripheral or software-settable interrupt request that is set at the same or lower priority as the current value of the INTC_CPR*n*[PRI] field from generating an interrupt request to the processor. When the INTC Interrupt Acknowledge register (INTC_IACKR*n*) is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode, the value of PRI is pushed onto the LIFO, and PRI is updated with the priority of the preempting interrupt request. When the INTC end-of-interrupt register (INTC_EOIR*n*) is written, the LIFO is popped into the INTC_CPR*n* PRI field. An exception case in hardware vector mode to this behavior is described in Hardware vector mode.

The masking priority can be raised or lowered by writing to the PRI field, supporting the priority ceiling protocol. See Priority ceiling protocol.



If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

NOTE

A store to modify the PRI field that closely precedes or follows an access to a shared resource may result in a non-coherent access to that resource. See Ensuring coherency for example code to ensure coherency.

Address: 0h base + 14h offset = 14h

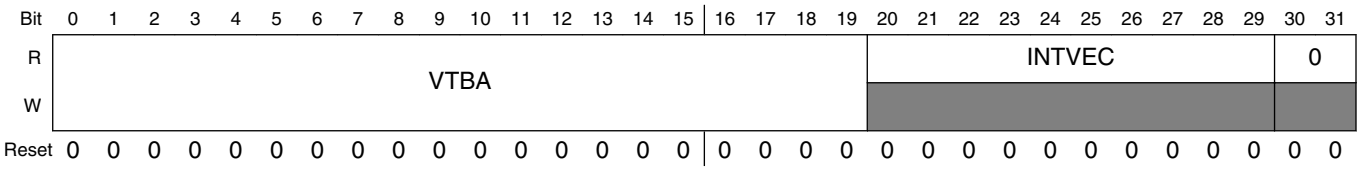
INTC_CPR1 field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 PRI	Priority of the currently executing ISR, according to the field values 15 (highest priority) down to 0 (lowest priority).

23.6.5 INTC Interrupt Acknowledge Register for Processor 0 (INTC_IACKR0)

The Interrupt Acknowledge Register for Processor *n* provides a value which can be used to load the address of an ISR from a vector table. The vector table can be composed of addresses of the ISRs specific to their respective interrupt vectors.

Also, in software vector mode, the INTC_IACKR*n* has side effects from reads unless INTC_MPROT[MPROT]=1 and processor with master ID (0-3) != INTC_MPROT[ID]. Therefore, it must not be read speculatively while in this mode. The side effects are the same regardless of the size of the read. Reading the INTC_IACKRn does not have side effects in hardware vector mode.



If INTC_MPROT[MPROT]=0 (disabled), all processors have read and write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has read and write access, otherwise, a termination error is asserted.

NOTE

When the corresponding INTC_BCR[HVENn] = 1, a read of the INTC_IACKR has no side effects.

Address: 0h base + 20h offset = 20h

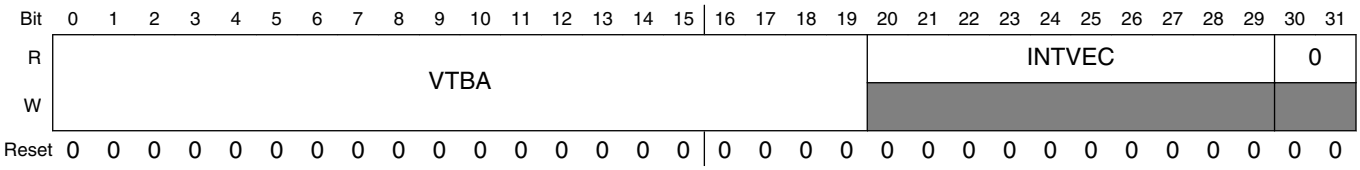
INTC_IACKR0 field descriptions

Field	Description
0–19 VTBA	Vector table base address. Can be the base address of a vector table of addresses of ISRs.
20–29 INTVEC	Interrupt vector. Vector of the peripheral or software-settable interrupt request that caused the interrupt request to the processor. When the interrupt request to the processor asserts, the INTVEC is updated, whether the INTC is in software or hardware vector mode.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

23.6.6 INTC Interrupt Acknowledge Register for Processor 1 (INTC_IACKR1)

The Interrupt Acknowledge Register for Processor *n* provides a value which can be used to load the address of an ISR from a vector table. The vector table can be composed of addresses of the ISRs specific to their respective interrupt vectors.

Also, in software vector mode, the INTC_IACKR*n* has side effects from reads unless INTC_MPROT[MPROT]=1 and processor with master ID (0-3) != INTC_MPROT[ID]. Therefore, it must not be read speculatively while in this mode. The side effects are the same regardless of the size of the read. Reading the INTC_IACKRn does not have side effects in hardware vector mode.



If INTC_MPROT[MPROT]=0 (disabled), all processors have read and write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has read and write access, otherwise, a termination error is asserted.

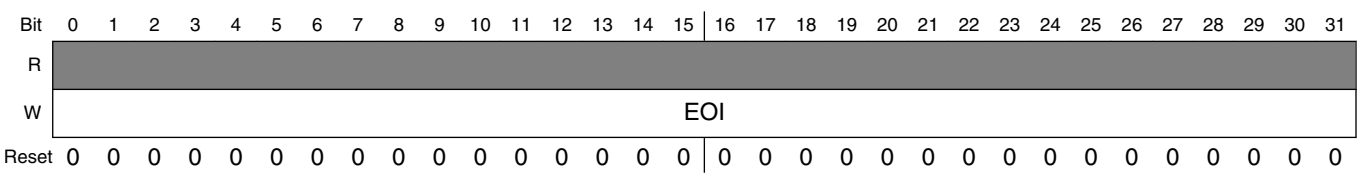
NOTE

When the corresponding INTC_BCR[HVENn] = 1, a read of the INTC_IACKR has no side effects.

Address: 0h base + 24h offset = 24h

INTC_IACKR1 field descriptions

Field	Description
0–19 VTBA	Vector table base address. Can be the base address of a vector table of addresses of ISRs.
20–29 INTVEC	Interrupt vector. Vector of the peripheral or software-settable interrupt request that caused the interrupt request to the processor. When the interrupt request to the processor asserts, the INTVEC is updated, whether the INTC is in software or hardware vector mode.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.



23.6.7 INTC End Of Interrupt Register for Processor 0 (INTC_EOIR0)

Writing to the INTC_EOIR*n* signals the end of the servicing of the interrupt request. When the INTC_EOIR*n* is written, the priority last pushed on the LIFO is popped into INTC_CPR*n*. The values and size of data written to the INTC_EOIR*n* are ignored. Those values and sizes written to this register neither update the INTC_EOIR*n* contents nor affect whether the LIFO pops. Typically, when you write to this register, write four all-zero bytes.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

Address: 0h base + 30h offset = 30h

INTC_EOIR0 field descriptions

Field	Description
0–31 EOI	End of Interrupt. Write four all-zero bytes to this field to signal the end of the servicing of an interrupt request.

23.6.8 INTC End Of Interrupt Register for Processor 1 (INTC_EOIR1)

Writing to the INTC_EOIR*n* signals the end of the servicing of the interrupt request. When the INTC_EOIR*n* is written, the priority last pushed on the LIFO is popped into INTC_CPR*n*. The values and size of data written to the INTC_EOIR*n* are ignored. Those values and sizes written to this register neither update the INTC_EOIR*n* contents nor affect whether the LIFO pops. Typically, when you write to this register, write four all-zero bytes.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

Address: 0h base + 34h offset = 34h

INTC_EOIR1 field descriptions

Field	Description
0–31 EOI	End of Interrupt. Write four all-zero bytes to this field to signal the end of the servicing of an interrupt request.

23.6.9 INTC Software Set/Clear Interrupt Register (INTC_SSCIR*n*)

The INTC_SSCIR registers support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. Unlike the SWT bit in the PSRs, the INTC_SSCIR registers do not require a read-modify-write. With the exception of being set by software, this flag bit behaves the same as a flag bit set within a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a 1 to SET will leave SET unchanged at 0 but will set CLR. Writing a 0 to SET will have no effect. CLR is the flag bit. Writing a 1 to CLR will clear it. Writing a 0 to CLR will have no effect. If a 1 is written to a pair of SET and CLR bits at the same time, CLR is asserted, regardless of whether CLR was asserted before the write.

See Figure 23-2 for limitations on writing to this register.

Any processor will be allowed to write to any of the SET bits in the INTC_SSCIRn registers.

If INTC_MPROT[MPROT]=0 (disabled), all processors can write to the CLR bit.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor can write to the CLR bit, otherwise, a termination error is asserted.

NOTE

If INTC_MPROT[MPROT] is enabled, processors with master ID != INTC_MPROT[ID] must only write the INTC_SSCIRn registers using a byte operation. A write of any other size will result in a termination error.

Address: 0h base + 40h offset + (1d × i), where i=0d to 23d

Bit	0	1	2	3	4	5	6	7
Read	0						0	CLR
Write							SET	w1c
Reset	0	0	0	0	0	0	0	0

INTC_SSCIR*n* field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 SET	Set flag bits. Writing a 1 will set the corresponding CLR bit. Writing a 0 will have no effect. Each SET is read as a 0.
7 CLR	Clear flag bits. CLR is the flag bit. Writing a 1 to CLR will clear it provided that a 1 is not written simultaneously to its corresponding SET bit. Writing a 0 to CLR will have no effect. 0 Interrupt request not pending within INTC. 1 Interrupt request pending within INTC.

23.6.10 INTC Priority Select Register (INTC_PSR*n*)

The Priority Select Registers support the selection of an individual priority for each source of interrupt request, and the routing of the request to one or more processors. The unique vector of each peripheral or software-settable interrupt request determines which INTC_PSRn is assigned to that interrupt request. The software-settable interrupt requests are assigned the lowest numbered vectors, and their priorities are configured in the lowest numbered INTC_PSR registers. The peripheral interrupt requests are assigned to vectors immediately following the software-settable interrupt requests, and their priorities are configured in the immediately following INTC_PSR registers. The peripheral interrupt requests are assigned vectors 32-1023, and their priorities are configured in INTC_PSR32-1023, respectively.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access to INTC_PSRn[PRC_SEL,SWT], otherwise, a termination error is asserted. When writing the INTC_PSRn[PRI], only the processor with master ID (0-3) = INTC_MPROT[ID] and the processor whose master ID (0-3) matches the setting of the INTC_PSRn[PRC_SEL] will be allowed to write the INTC_PSRn[PRI]. An attempt by any other processor to write the INTC_PSRn[PRI] will result in a termination error.

See Figure 23-2 for limitations on writing to this register.

NOTE

Unlike the peripheral interrupt request PSRs, there is no SWT bit in the PSRs corresponding to the software-settable interrupt requests.

NOTE

Interrupts are not detected while the PSRs are being written.

NOTE

If INTC_MPROT[MPROT] is enabled, the core with master ID (0-3) = INTC_MPROT[ID] will be able to write the INTC_PSRn with either byte, half-word or word operations. All other master IDs are restricted to byte operations to the INTC_PSRn[PRI] bits (i.e the odd addresses). Any other sized write operation, or a byte operation to the INTC_PSRn[PRC_SEL] (i.e. the even byte) will result in a termination error.

Address: 0h base + 60h offset + (2d × i), where i=0d to 1023d

INTC_PSR*n* field descriptions

Field	Description
0 PRC_SELN0	Processor select 0. If an interrupt source is enabled, this field selects whether the interrupt request is to be sent to processor 0. 0 Interrupt request not sent to processor 0 1 Interrupt request sent to processor 0
1 PRC_SELN1	Processor select 1. If an interrupt source is enabled, this field selects whether the interrupt request is to be sent to processor 1. 0 Interrupt request not sent to processor 1 1 Interrupt request sent to processor 1
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 SWTN	This bit is only available in PSRs that do not correspond to the SSCIRs. The SWT bit supports triggering an interrupt by software rather than hardware. This is an alternative to setting a flag bit in a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a '1' to SWT*n* sets the bit. On the interrupt acknowledge cycle, the SWT*n* bit is cleared. The SWT function works both in hardware and software vector mode. It is only cleared by the enabled Processor(s) defined in the PRC_SEL*n* field of the PSR.
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 PRIN	Priority select. Selects the priority for the interrupt requests. PRI has values 15 (highest priority) down to 0 (lowest priority).

23.7 Functional description

The functional description involves the areas of interrupt request sources, priority management, and handshaking with the processor. In addition, spaces in the memory map have been reserved for other possible implementations of the INTC.

23.7.1 Interrupt request sources

The INTC has two types of interrupt requests, peripheral and software-settable. These interrupt requests can assert on any clock cycle.

The INTC has no spurious vector support. Therefore, if an asserted peripheral or software-settable interrupt request, whose PRI*n* value in INTC_PSR*n* is higher than the PRI value in INTC_CPR*n*, negates before the interrupt request to the processor for that peripheral or software-settable interrupt request is acknowledged, then the interrupt request to the processor still can assert (or will remain asserted) for that peripheral or software-settable interrupt request. In this case, the interrupt vector will correspond to that peripheral or software-settable interrupt request. Also, the PRI value in the associated INTC_CPR*n* is updated with the corresponding PRI*n* value in INTC_PSR*n*.

Furthermore, clearing the peripheral interrupt request's enable bit in the peripheral, or (alternatively) setting its mask bit, has the same consequences as clearing its flag bit. Setting its enable bit or clearing its mask bit while its flag bit is asserted has the same effect on the INTC as an interrupt event setting the flag bit.

23.7.1.1 Peripheral interrupt requests

An interrupt event in a peripheral's hardware sets a flag bit which resides in that peripheral. The interrupt request from the peripheral is driven by that flag bit.

The time from when the peripheral starts to drive its peripheral interrupt request to the INTC, to the time that the INTC starts to drive the interrupt request to the processor, is three clocks.

23.7.1.2 Software-settable interrupt requests

The software set/clear interrupt registers (INTC_SSCIR*n*) support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. An interrupt request is triggered by software by writing a 1 to a SET bit in INTC_SSCIR*n*. This write sets the corresponding CLR bit, which is a flag bit, resulting in the interrupt request. The interrupt request is cleared by writing a 1 to the CLR bit. Specific behavior includes the following:

- Writing a 1 to SET leaves SET unchanged at 0 but sets the flag bit (which is the CLR bit).
- Writing a 0 to SET has no effect.

- Writing a 1 to CLR clears the flag (CLR) bit.
- Writing a 0 to CLR has no effect.
- If a 1 is written to a pair of SET and CLR bits at the same time, the flag (CLR) is set, regardless of whether CLR was asserted before the write.

The time from the write to the SET bit, to the time that the INTC starts to drive the interrupt request to the processor, is four clocks.

Any Processor n will be allowed to write to any of the SET bits in the Software Set/Clear Interrupt registers. The CLR bit will only be writable by the Processor n which has been assigned to handle that interrupt request, as determined by the setting of the INTC_PSRn[PRC_SELn] bits.

23.7.1.3 Unique vector for each interrupt request source

Each peripheral and software-settable interrupt request is assigned a hardwired unique 10-bit vector. Software-settable interrupts 0–23 are assigned vectors 0–23, respectively. The peripheral interrupt requests are assigned vectors from 24 to a number as high as needed to cover all peripheral interrupt requests.

23.7.2 Priority management

The asserted interrupt requests are compared to each other based on their PRI*n* and PRC_SEL*n* values set in INTC_PSR*n*. The result of that comparison also is compared to PRI in the associated INTC_CPR*n*. The results of those comparisons are used to manage the priority of the ISR being executed by the associated processor. The associated LIFO also assists in managing that priority.

23.7.2.1 Current priority and preemption

The priority arbitrator, selector, encoder, and comparator logic shown in Figure 23-1 are used to compare the priority of the asserted interrupt requests to the current priority. If the priority of any asserted peripheral or software-settable interrupt request is higher than the current priority for a given processor, then the interrupt request to the processor is asserted. Also, a unique vector for the preempting peripheral or software-settable interrupt request is generated for the associated INTC_IACKR*n*, and if in hardware vector mode, for the interrupt vector provided to the processor.

23.7.2.1.1 Priority tree

The priority tree for each processor compares all the priorities of all of the asserted interrupt requests assigned to that processor, both peripheral and software-settable. The output of the priority tree is the highest of those priorities assigned to a given processor. Also, any interrupt requests which have this highest priority are output as asserted interrupt requests to the associated selector logic.

23.7.2.1.2 Selector

If only one interrupt request from the associated priority tree is asserted, then it is passed as asserted to the associated encoder logic. If multiple interrupt requests from the associated priority tree are asserted, then only the one with the lowest vector is passed as asserted to the associated encoder logic. The lower vector is chosen regardless of the time order of the assertions of the peripheral or software-settable interrupt requests.

23.7.2.1.3 Encoder

The encoder logic generates the unique 10-bit vector for the asserted interrupt request from the request selector subblock for the associated processor.

23.7.2.1.4 Comparator

The comparator logic compares the highest priority output from the associated priority arbitrator subblock with PRI in the associated INTC_CPR*n*. If the comparator detects that this highest priority is higher than the current priority, then it asserts the interrupt request to the associated processor. This interrupt request to the processor asserts whether this highest priority is raised above the value of PRI in the associated INTC_CPR*n*, or the PRI value in the associated INTC_CPR*n* is lowered below this highest priority. This highest priority then becomes the new priority which is written to PRI in the associated INTC_CPR*n* when the interrupt request to the processor is acknowledged. Interrupt requests whose PRI*n* in INTC_PSR*n* are zero will not cause a preemption because their PRI*n* will not be higher than PRI in the associated INTC_CPR*n*.

Another function of the comparator is to signal an update of the INTC_IACKR*n* with the vector number of the first interrupt that arrives that has a priority higher than the current priority. Once the vector number and priority are captured, they cannot be superseded by a higher priority interrupt until an update of the INTC_CPR*n* occurs. In software vector mode, higher priority interrupts can supersede the previously captured interrupt vector number and priority until the time a hardware or software interrupt acknowledge is processed.

23.7.2.2 Stack (LIFO)

The LIFO stores the preempted PRI values from the associated INTC_CPR*n*. Therefore, because these priorities are stacked within the INTC, if interrupts need to be enabled during the ISR, at the beginning of the interrupt exception handler the PRI value in the associated INTC_CPR*n* does not need to be loaded from the associated INTC_CPR*n* and stored onto the context stack. Likewise at the end of the interrupt exception handler, the priority does not need to be loaded from the context stack and stored into the associated INTC_CPR*n*.

The PRI value in the associated INTC_CPR*n* is pushed onto the LIFO when the associated INTC_IACKR*n* is read in software vector mode or the interrupt acknowledge signal from the associated processor is asserted in hardware vector mode. The priority is popped into PRI in the associated INTC_CPR*n* whenever the associated INTC_EOIR*n* is written. An exception case in hardware vector mode to this behavior is described in Hardware vector mode.

Although the INTC supports up to 16 priorities, an ISR executing with PRI in the INTC_CPR*n* equal to 15 will not be preempted. Therefore, the LIFO supports the stacking of 15 priorities. However, the LIFO is only 14 entries deep. An entry for a priority of 0 is not needed because of the ways that pushing onto a full LIFO and popping an empty LIFO are treated. If the LIFO is pushed 15 or more times than it is popped, the priorities first pushed are overwritten. A priority of 0 would be an overwritten priority. However, the LIFO will pop zeroes if it is popped more times than it is pushed. Therefore, although a priority of 0 was overwritten, it is regenerated with the popping of an empty LIFO.

23.7.3 Handshaking with processor

This section describes handshaking with the processor.

23.7.3.1 Software vector mode handshaking

This section describes the software vector mode handshaking.

23.7.3.1.1 Acknowledging interrupt request to processor

The software vector mode handshaking can be used with processors that only support an interrupt request to them, or processors that support both an interrupt request by itself as well as an interrupt request with an interrupt vector. The software vector mode handshaking even supports processors that always expect an interrupt vector with the interrupt request to them. Refer to Figure 23-3.

A timing diagram of the interrupt request and acknowledge handshaking in software vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in Figure 23-3. The INTC examines the peripheral and software-settable interrupt requests. When it finds an asserted peripheral or software-settable interrupt request with a higher priority than PRI in the associated INTC_CPR*n*, it asserts the interrupt request to the associated processor. The INTVEC field in the associated INTC_IACKR*n* is updated with the preempting interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the processor is asserted. The rest of the handshaking is described in Software vector mode.

23.7.3.1.2 End of interrupt exception handler

Before the interrupt exception handling completes, INTC_EOIR*n* must be written. When it is written, the associated LIFO is popped so that the preempted priority is restored into PRI of the associated INTC_CPR*n*. Before it is written, the peripheral or software-settable flag bit must be cleared so that the peripheral or software-settable interrupt request is negated.

When returning from the preemption, the INTC does not search for the peripheral or software-settable interrupt request whose ISR was preempted. Depending on how much the ISR has progressed, that interrupt request may no longer even be asserted. When PRI in the associated INTC_CPR*n* is lowered to the priority of the preempted ISR, the interrupt request for the preempted ISR or any other asserted peripheral or software-settable interrupt request at or below that priority will not cause a preemption. Instead, after the restoration of the preempted context, the processor will return to the instruction address that it had been going to execute next, before it was preempted. This next instruction is part of the preempted ISR or the interrupt exception handler's prolog or epilog.

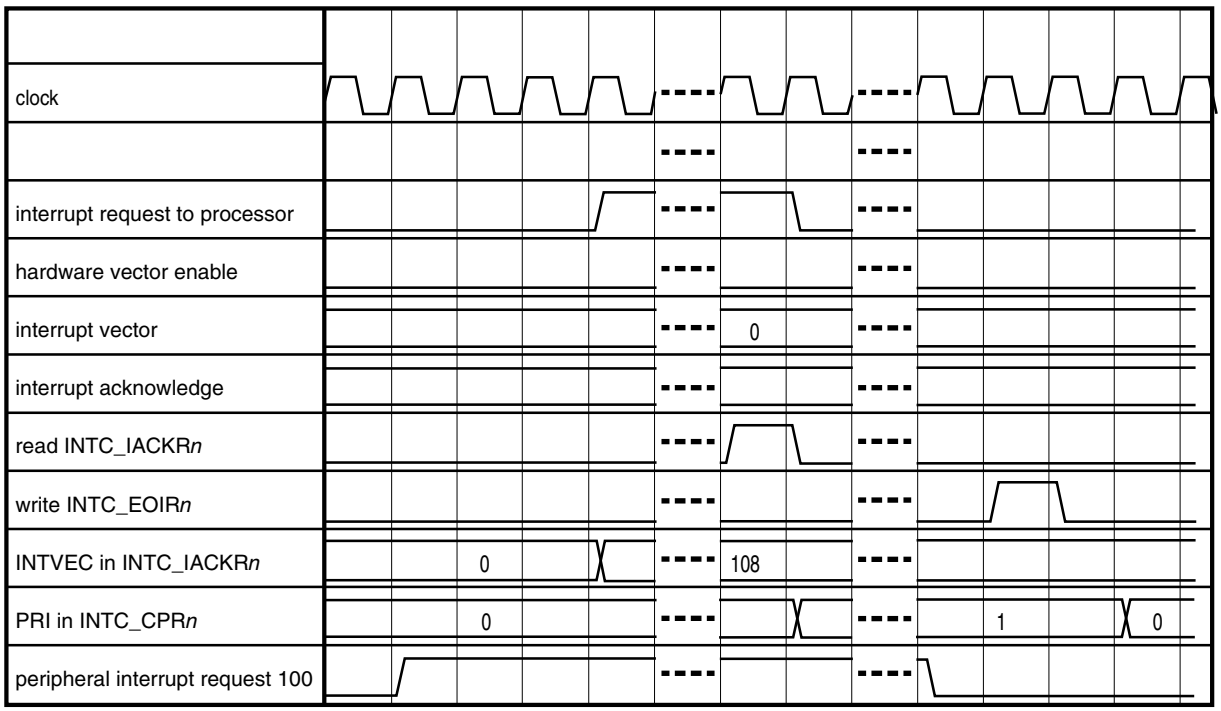

Figure 23-3. Timing diagram of software vector mode handshaking

23.7.3.2 Hardware vector mode handshaking

A timing diagram of the interrupt request and acknowledge handshaking in hardware vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in Figure 23-4. As in software vector mode, the INTC examines the peripheral and software-settable interrupt requests, and when it finds an asserted interrupt request with a higher priority than PRI in the associated INTC_CPR*n*, it asserts the interrupt request to the associated processor. The INTVEC field in the associated INTC_IACKR*n* is updated with the preempting peripheral or software-settable interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the associated processor is asserted. In addition, the value of the interrupt vector to the associated processor matches the value of the INTVEC field in the associated INTC_IACKR*n*. The rest of the handshaking is described in Hardware vector mode.

The handshaking near the end of the interrupt exception handler, that is the writing to the associated INTC_EOIR*n*, is the same as in software vector mode. See End of interrupt exception handler.

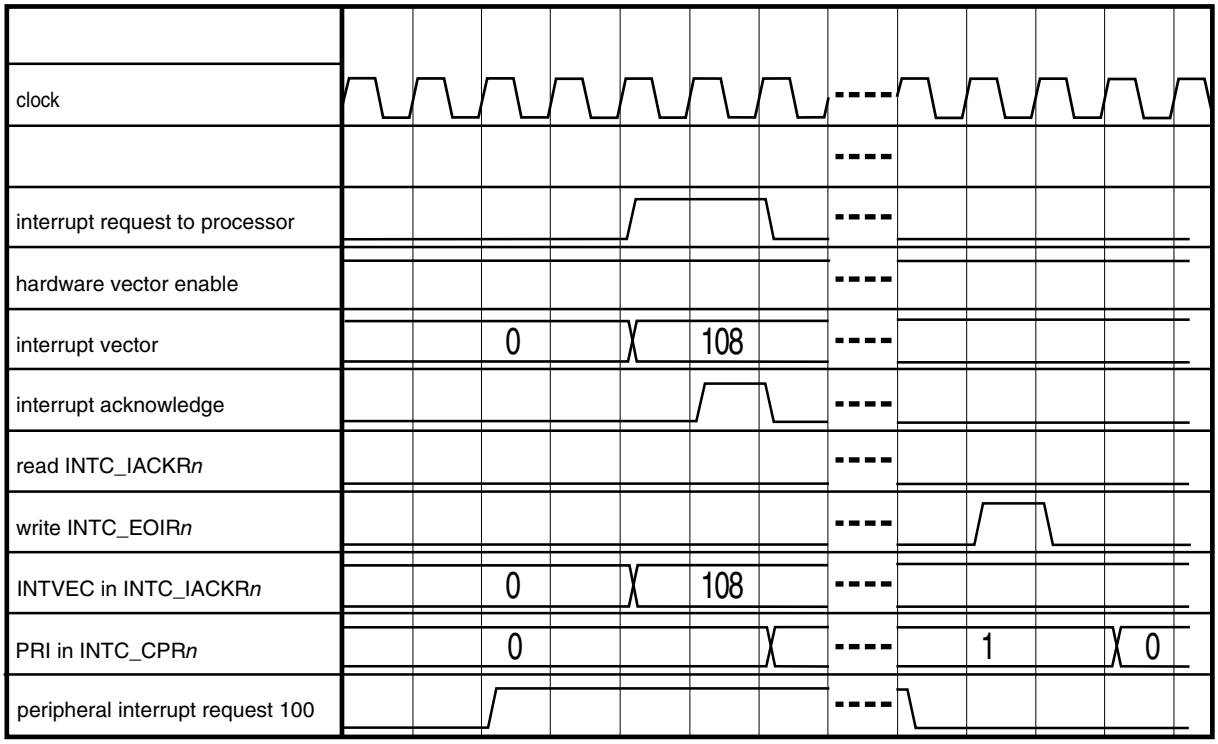

Figure 23-4. Timing diagram for hardware vector mode handshaking

23.8 Initialization/application information

This section contains initialization/application information.

23.8.1 Initialization flow

After exiting reset, all of the PRI*n* and PRC_SEL*n* fields in INTC_PSR*n* are zero, and PRI in the INTC_CPRn registers is 15. These reset values will prevent the INTC from asserting the interrupt request to the processors. The enable or mask bits in the peripherals are reset such that the peripheral interrupt requests are negated. An initialization sequence for allowing the peripheral and software-settable interrupt requests to cause an interrupt request to the processor is:

- interrupt_request_initialization:
  - Configure HVENn in INTC_BCR.
  - Configure VTBAn in INTC_IACKRn.
  - Raise the PRIn fields and set the PRC_SELn fields to the desired processor in INTC_PSRn.
  - Set the enable bits or clear the mask bits for the peripheral interrupt requests.

- Lower PRI in INTC_CPRn to zero.
- Enable processor(s) recognition of interrupts.

23.8.2 Interrupt exception handler

These example interrupt exception handlers excerpts use Power Architecture assembly code.

23.8.2.1 Software vector mode

In software vector mode for Power Architecture, there are 16 bytes of vector space available at the single ISR entry point.

23.8.3 ISR, RTOS, and task hierarchy

The RTOS and all of the tasks under its control typically execute with PRI in INTC_CPR*n* having a value of 0. The RTOS will execute the tasks according to whatever priority scheme it may have, but that priority scheme is independent and has a lower priority of execution than the priority scheme of the INTC. In other words, the ISRs execute above INTC_CPR*n* priority 0 and outside the control of the RTOS, the RTOS executes at INTC_CPR*n* priority 0, and while the tasks execute at different priorities under the control of the RTOS, they also execute at INTC_CPRn priority 0.

If a task shares a resource with an ISR and the Priority Ceiling Protocol (PCP) is being used to manage that shared resource, then the task's priority can be elevated in the INTC_CPR*n* while the shared resource is being accessed.

An ISR whose PRI*n* in INTC_PSR*n* has a value of 0 will not cause an interrupt request to the selected processor, even if its peripheral or software-settable interrupt request is asserted. For a peripheral interrupt request, not setting its enable bit or disabling the mask bit will cause it to remain negated, which consequently also will not cause an interrupt request to the processor. Since the ISRs are outside the control of the RTOS, this ISR will not run unless called by another ISR or the interrupt exception handler, perhaps after executing another ISR.

23.8.4 Order of execution

An ISR with a higher priority can preempt an ISR with a lower priority, regardless of the unique vectors associated with each of their peripheral or software-settable interrupt requests. However, if multiple peripheral or software-settable interrupt requests are asserted, more than one of these interrupt requests has the highest priority and that priority is high enough to cause preemption, the INTC selects the one with the lowest unique vector regardless of the order in time that they asserted. However, the ability to meet deadlines with this scheduling scheme is no less than if the ISRs execute in the time order that their peripheral or software-settable interrupt requests asserted.

The example in the following table shows the order of execution of both cases, ISRs with different priorities and ISRs with the same priority.

Table 23-3. Order of ISR execution example

Step #	Step Description	Code executing at end of step						PRI in INTC_CPR at end of step
		RTOS	ISR108 [1]	ISR208	ISR308	ISR408	interrupt exception handler	
1	RTOS at priority 0 is executing.	X						0
2	Peripheral interrupt request 100 at priority 1 asserts. Interrupt taken.		X					1
3	Peripheral interrupt request 400 at priority 4 asserts. Interrupt taken.					X		4
4	Peripheral interrupt request 300 at priority 3 asserts.					X		4
5	Peripheral interrupt request 200 at priority 3 asserts.					X		4
6	ISR408 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	1

Table continues on the next page...

Table 23-3. Order of ISR execution example (continued)

Step #	Step Description	Code executing at end of step						PRI in INTC_CPR at end of step
		RTOS	ISR108 [1]	ISR208	ISR308	ISR408	interrupt exception handler	
7	Interrupt taken. ISR208 starts to execute, even though peripheral interrupt request 300 asserted first.			X				3
8	ISR208 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	1
9	Interrupt taken. ISR308 starts to execute.				X			3
10	ISR308 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	1
11	ISR108 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	0
12	RTOS continues execution.	X						0

1. ISR108 executes for peripheral interrupt request 100 because the first eight ISRs are for software-settable interrupt requests.

23.8.5 Priority ceiling protocol

This section describes the priority ceiling protocol.

23.8.5.1 Elevating priority

The PRI field in INTC current priority register (INTC_CPR*n*) is elevated in the OSEK PCP to the ceiling of all of the priorities of the ISRs that share a resource. This protocol therefore allows coherent accesses of the ISRs to that shared resource.

For example, ISR1 has a priority of 1, ISR2 has a priority of 2, and ISR3 has a priority of 3. They all share the same resource. Before ISR1 or ISR2 can access that resource, they must raise the PRI value in INTC_CPR*n* to 3, the ceiling of all of the ISR priorities. After they release the resource, they must lower the PRI value in INTC_CPR*n* to prevent further priority inversion. If they do not raise their priority, then ISR2 can preempt ISR1, and ISR3 can preempt ISR1 or ISR2, possibly corrupting the shared resource. Another possible failure mechanism is deadlock if the higher priority ISR needs the lower priority ISR to release the resource before it can continue, but the lower priority ISR cannot release the resource until the higher priority ISR completes and execution returns to the lower priority ISR.

Using the PCP instead of disabling processor recognition of all interrupts eliminates the time when accessing a shared resource that all higher priority interrupts are blocked. For example, while ISR3 cannot preempt ISR1 while it is accessing the shared resource, all of the ISRs with a priority higher than 3 can preempt ISR1.

23.8.5.2 Ensuring coherency

This section discusses how to ensure coherency.

23.8.5.2.1 Interrupt with blocked priority

A scenario can exist that can cause non-coherent accesses to the shared resource. As an example, ISR1 and ISR2 both share a resource. ISR1 has a lower priority than ISR2. ISR1 is executing, and it writes to the INTC_CPR*n*. The instruction following this store is a store to a value in a shared coherent data block. Either just before or at the same time as the first store, the INTC asserts the interrupt request to the processor because the peripheral interrupt request for ISR2 has asserted. As the processor is responding to the interrupt request from the INTC, and as it is aborting transactions and flushing its pipeline, it is possible (in some implementations) that both of these stores are executed. ISR2 thereby assumes that it can access the data block coherently, but the data block has been corrupted.

OSEK uses the GetResource and ReleaseResource system services to manage access to a shared resource. To prevent this corruption of a coherent data block, modifications to PRI in INTC_CPR*n* can be made by those system services with the code sequence:

```
GetResource:
        wrteei 0                # disable external interrupts to the Processor
        raise PRI                # Write to CPR, cache inhibit, guarded
        mbar                    # flush out writes from store buffer
        wrteei 1                # enable external interrupts to the Processor
        isync                    # re-fetch Processor pipeline

ReleaseResource:
        mbar                    # flush out writes from store buffer
        wrteei 0                # disable external interrupts to the Processor
        lower PRI                # Write to CPR, cache inhibit, guarded
        wrteei 1                # enable external interrupts to the Processor
```

23.8.5.2.1.1 Interrupt request to processor

Referencing Figure 23-1, the interrupt request logic to the processor is shown in the following figure.

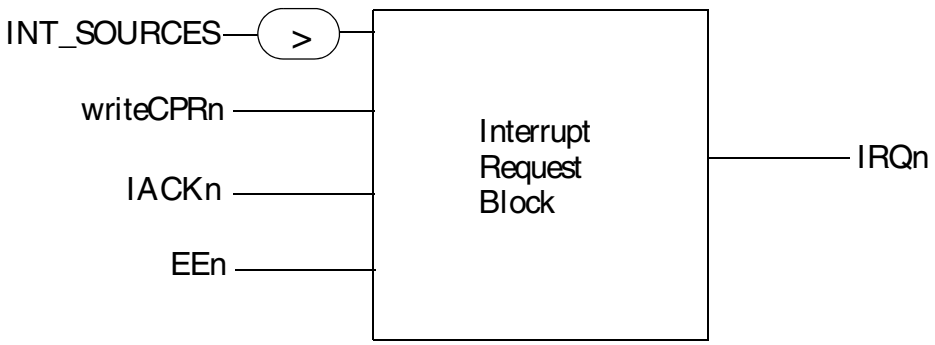

Figure 23-5. Interrupt Request Block Diagram

Assuming that there are no IRQn deasserted (no pending interrupt requests to processor n), if one of the external interrupt sources (INT_SOURCES) has a priority higher than the INTC_CPRn, then interrupt request to the processor (IRQn) is asserted. It will stay asserted until one of the following conditions is true:

- Interrupt acknowledge (IACK) is asserted
- If the EEn bit has been cleared by the wrteei instruction (see the code sequence in Interrupt with blocked priority), IRQn will be re-evaluated when processor n writes to the INTC_CPRn while processor n ignores IRQn

This provides a safe way to guarantee that no interrupts will be recognized by processor n while updating the INTC_CPRn.

23.8.5.2.2 Raised priority preserved

Before the instruction after the GetResource system service executes, all pending transactions have completed. These pending transactions can include an ISR for a peripheral or software-settable interrupt request whose priority was equal to or lower than the raised priority. The shared coherent data block now can be accessed coherently. The following figure shows the timing diagram for this scenario, and the following table explains the events. The example is for software vector mode. Except for the method of retrieving the vector and acknowledging the interrupt request to the processor, hardware vector mode is identical.

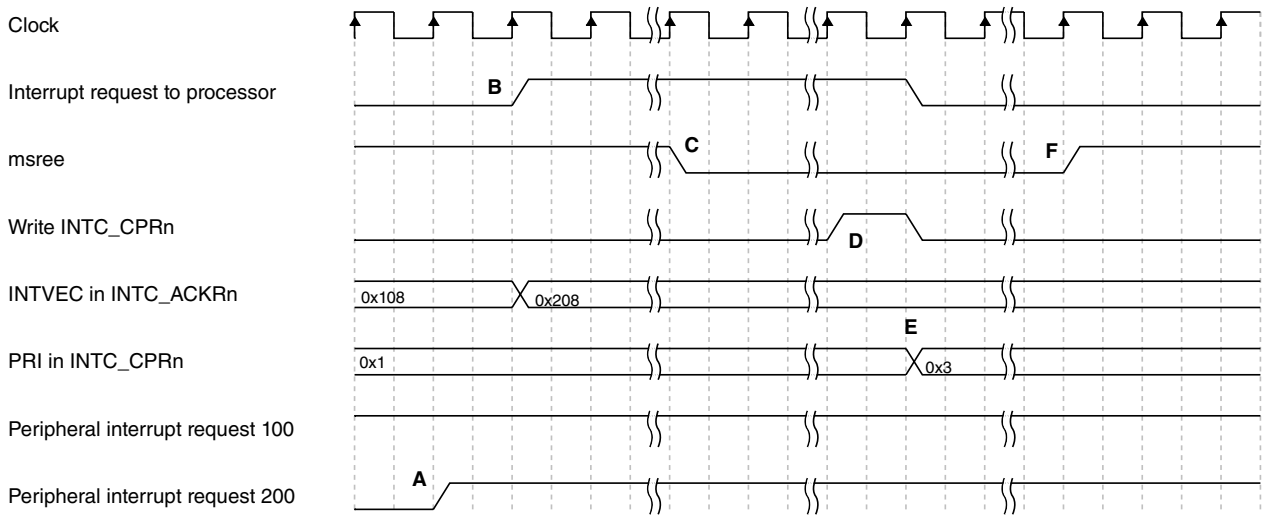

Figure 23-6. Timing diagram of raised priority preserved

Table 23-4. Raised priority preserved events

Event	Description
A	Peripheral interrupt request 200 of priority 2 asserts during execution of ISR108 running at priority 1.
B	Interrupt request to processor asserts. INTVEC in INTC_IACKRn updates with vector for that peripheral interrupt request.
C	Write to msree bit to disable external interrupts
D	ISR108 writes to INTC_CPRn to raise priority to 3 before accessing shared coherent data block.
E	PRI in INTC_CPRn now at 3, reflecting the write. This write, just before accessing data block, is the last instruction the processor executes before being interrupted.
F	Write to msree bit to enable external interrupts

23.8.6 Selecting priorities according to request rates and deadlines

The selection of the priorities for the ISRs can be made using Rate Monotonic Scheduling (RMS) or a superset of it, Deadline Monotonic Scheduling (DMS). In RMS, the ISRs which have higher request rates have higher priorities. In DMS, if the deadline is before the next time the ISR is requested, then the ISR is assigned a priority according to the time from the request for the ISR to the deadline, not from the time of the request for the ISR to the next request for it.

For example, ISR1 executes every 100 µs, ISR2 executes every 200 µs, and ISR3 executes every 300 µs. ISR1 has a higher priority than ISR2 which has a higher priority than ISR3. However, if ISR3 has a deadline of 150 µs, then it has a higher priority than ISR2.

The INTC supports 16 priorities, which may be many fewer than the number of ISRs. In this case, the ISRs should be grouped with other ISRs that have similar deadlines. For example, a priority could be allocated for every time the request rate doubles. ISRs with request rates around 1 ms would share a priority, ISRs with request rates around 500 µs would share a priority, ISRs with request rates around 250 µs would share a priority, and so on. With this approach, a range of ISR request rates of 2^{16} could be covered, regardless of the number of ISRs.

Reducing the number of priorities does cause some priority inversion, which reduces the processor's ability to meet its deadlines. However, reducing the number of priorities can reduce the size and latency through the interrupt controller. It also allows easier management of ISRs with similar deadlines that share a resource. They can be placed at the same priority without any further priority inversion, and they do not need to use the PCP to access the shared resource.

23.8.7 Software-settable interrupt requests

The software-settable interrupt requests can be used in two ways. They can be used to schedule a lower priority portion of an ISR and for processors to interrupt other processors in a multiple processor system.

23.8.7.1 Scheduling a lower priority portion of an ISR

A portion of an ISR needs to be executed at the PRIn value in INTC_PSR*n*, which becomes the PRI value in INTC_CPR*n* with the interrupt acknowledge. The ISR, however, can have a portion of it which does not need to be executed at this higher priority. Therefore, executing this later portion which does not need to be executed at this higher priority can prevent the execution of ISRs which do not have a higher priority than the earlier portion of the ISR but do have a higher priority than the later portion of the ISR needs. This preemptive scheduling inefficiency reduces the processor's ability to meet its deadlines.

One option is for the ISR to complete the earlier higher priority portion, but then schedule through the RTOS a task to execute the later lower priority portion. However, some RTOSs can require a large amount of time for an ISR to schedule a task. Therefore, a second option is for the ISR, after completing the higher priority portion, to set a SET bit

in INTC_SSCIR*n*. Writing a '1' to SET causes a software-settable interrupt request. This software-settable interrupt request, which usually will have a lower PRI*n* value in the INTC_PSR*n*, therefore will not cause preemptive scheduling inefficiencies.

23.8.7.2 Scheduling an ISR on another processor

Since the SET bits in the INTC_SSCIR*n* are memory mapped, processors in multiple processor systems can schedule ISRs on the other processors. One possible application is if one processor simply wants to command another processor to perform a piece of work, and the initiating processor does not need to use the results of that work. If the initiating processor needs to know if the processor executing the software-settable ISR has not completed the work before asking it to again execute that ISR, it can check if the corresponding CLR bit in INTC_SSCIR*n* is asserted before again writing a 1 to the SET bit.

Another application is the sharing of a block of data. For example, a first processor has completed accessing a block of data and wants a second processor to then access it. Furthermore, after the second processor has completed accessing the block of data, the first processor again wants to access it. The accesses to the block of data must be done coherently. The procedure is that the first processor writes a 1 to a SET bit on the second processor. The second processor, after accessing the block of data, clears the corresponding CLR bit and then writes 1 to a SET bit on the first processor, informing it that it now can access the block of data.

23.8.8 Lowering priority within an ISR

In implementations without the software-settable interrupt requests in INTC_SSCIR*n*, one way (besides scheduling a task through an RTOS) to prevent preemptive scheduling inefficiencies with an ISR whose work spans multiple priorities (as described in Scheduling a lower priority portion of an ISR) is to lower the current priority. However, the INTC has a LIFO whose depth is determined by the number of priorities.

Note

Lowering the PRI value in INTC_CPR*n* within an ISR to below the ISR's corresponding PRI value in INTC_PSR*n* allows more preemptions than the depth of the LIFO can support.

Therefore, through its use of the LIFO the INTC does not support lowering the current priority within an ISR as a way to avoid preemptive scheduling inefficiencies.

23.8.9 Negating an interrupt request outside of its ISR

This section discusses the negation of an interrupt service request outside of its ISR.

23.8.9.1 Negating an interrupt request as a side effect of an ISR

Some peripherals have flag bits which can be cleared as a side effect of servicing a peripheral interrupt request. For example, reading a specific register can clear the flag bits, and consequently their corresponding interrupt requests too. This clearing as a side effect of servicing a peripheral interrupt request can cause the negation of other peripheral interrupt requests besides the peripheral interrupt request whose ISR presently is executing. This negating of a peripheral interrupt request outside of its ISR can be a desired effect.

23.8.9.2 Negating multiple interrupt requests in one ISR

An ISR can clear other flag bits besides its own flag bit. One reason that an ISR clears multiple flag bits is because it serviced those other flag bits, and therefore the ISRs for these other flag bits do not need to be executed.

23.8.9.3 Proper setting of interrupt request priority

Whether an interrupt request negates outside of its own ISR due to the side effect of an ISR execution or the intentional clearing of a flag bit, the priorities of the peripheral or software-settable interrupt requests for these other flag bits must be selected properly. Their PRI*n* values in INTC_PSR*n* must be selected to be at or lower than the priority of the ISR that cleared their flag bits. Otherwise, those flag bits still can cause the interrupt request to the processor to assert. Furthermore, the clearing of these other flag bits also has the same timing relationship to the writing to INTC_SSCIR*n* as the clearing of the flag bit that caused the present ISR to be executed. Refer to End of interrupt exception handler for more information.

A flag bit whose enable bit or mask bit is negating its peripheral interrupt request can be cleared at any time, regardless of the peripheral interrupt request's PRI*n* value in INTC_PSR*n*.

23.8.10 Examining LIFO contents

There are multiple methods for tracking interrupts in a system, one of which is described here using existing hardware (LIFO) within the INTC. Although the LIFO contents are not memory-mapped, the user can read the contents by popping the LIFO and reading the PRI field in the INTC current priority register (INTC_CPR*n*). To avoid a lower-level interrupt being serviced because the popping of the LIFO updates the INTC_CPR*n*, the processor recognition of interrupts should be disabled when examining LIFO contents. The pseudo-code is as follows:

```
      wrteei 0                # disable processor recognition of external interrupts
      oldCPRn = INTC_CPRn;    # save INTC_CPRn
      (branch to the pop_lifo)

pop_lifo:
      store INTC_EIORn        # pop INTC_CPR from LIFO, examine PRI, etc...
      examine INTC_CPRn[PRI], and store onto stack
      if PRI is not zero or value when interrupts were enabled, branch to pop_lifo
      branch to push_lifo
```

When the examination is complete, the LIFO can be restored using this code sequence:

```
push_lifo:
      load stacked PRI value and store to INTC_CPRn
      load INTC_IACKn         # IACK; push INTC_CPRn into LIFO
      if stacked PRI values are not depleted, branch to push_lifo

      INTC_CPRn    = oldCPRn; # restore original INTC_CPRn and re-evaluate pending external
interrupts
      wrteei 1                # enable processor recognition of interrupts
```

NOTE

Disabling the processor recognition of interrupts during LIFO examination will introduce latency, but none of the interrupt requests will be missed.

23.9 Interrupt sources

The list of interrupt sources is chip-specific. For this list, see the chip-specific INTC information.

Chapter 24
Wakeup Unit (WKPU)

24.1 Chip-specific WKPU information

24.1.1 Wakeup configuration

The Wakeup Unit supports 2 internal sources and 30 external sources that can generate interrupts or wakeup events. it also supports a non-maskable interrupt input. The following table shows the WKPU configuration in the device.

Feature	Value
Number of NMI sources	1
Number of interrupt sources	2 - internal, 30 - external
Number of glitch filters for external interrupts	30
Number of external interrupt vectors	4

24.1.2 NMI configuration

The following figure shows the WKUP NMI configuration implemented on the device. The Wakeup Unit (WKPU) supports one external source that can cause non-maskable interrupts to on-chip cores and wakeup events to the system. This NMI external source can also generate a functional reset event to the MC_RGM.

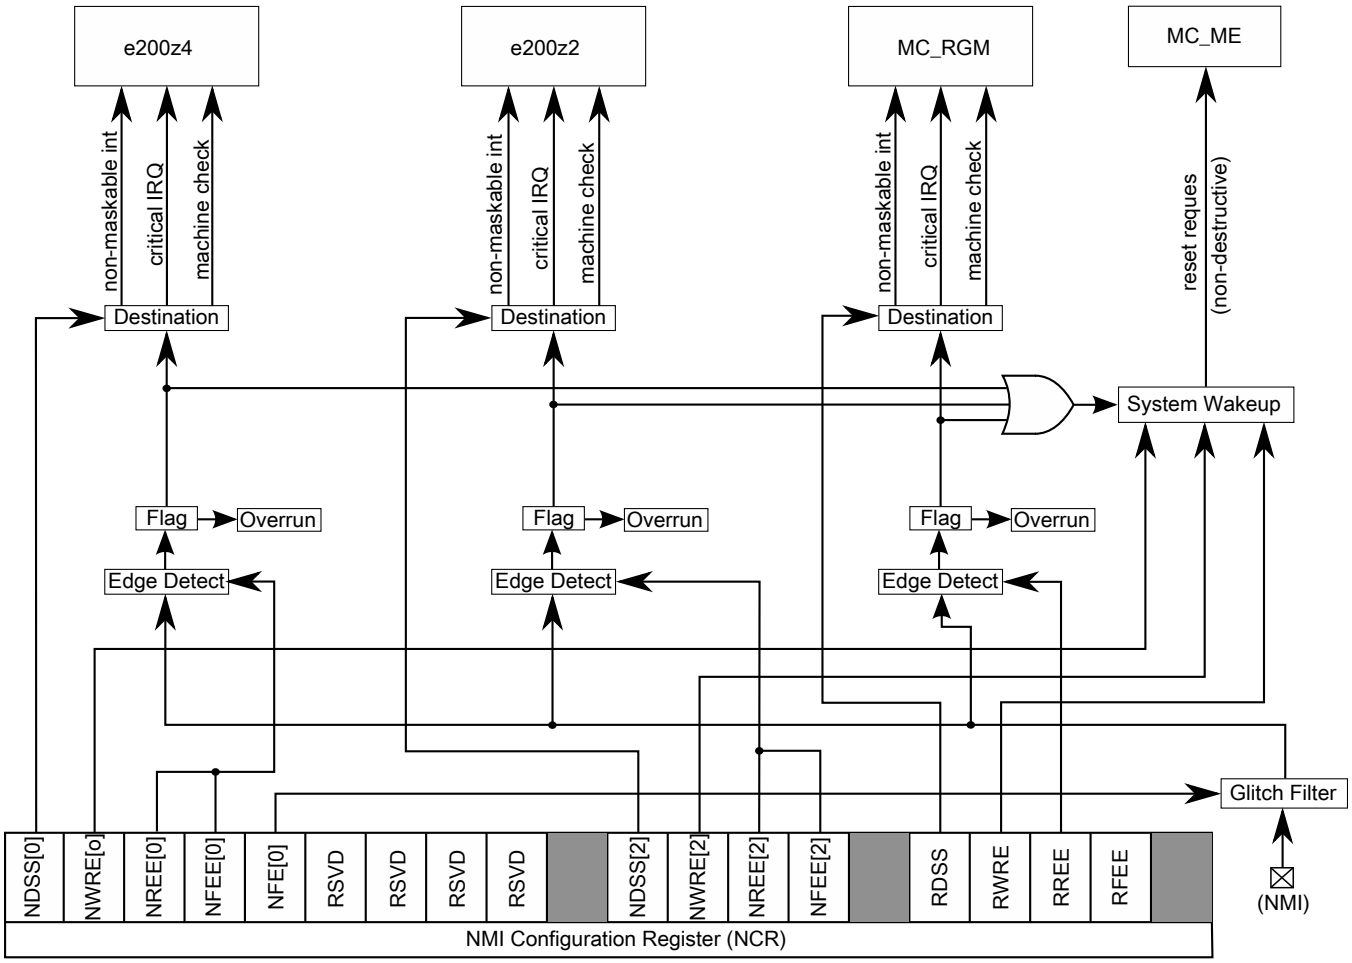

Figure 24-1. Wakeup NMI configuration

24.1.3 Interrupts

The WKPU allows the external NMI pin to assert the non-maskable interrupts of the cores on the device. These interrupts include non-maskable interrupts, critical interrupts, or machine check requests to any of the cores (excluding HSM).

- The NMI destination interrupt is controlled by the user through the configuration of the NDSS bits.
- The enabling of rising edge, falling edge, or either edge reaction to the NMI pin is independent for each core, and is controlled by NFEE[2:0] and NREE[2:0] bits in the NCR register.
- The WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event.
- The NMI supports a status flag and an overrun flag which are located in the NSR register.

The routing of External wakeup/interrupts with the WKPU and system interrupt controller is shown below.

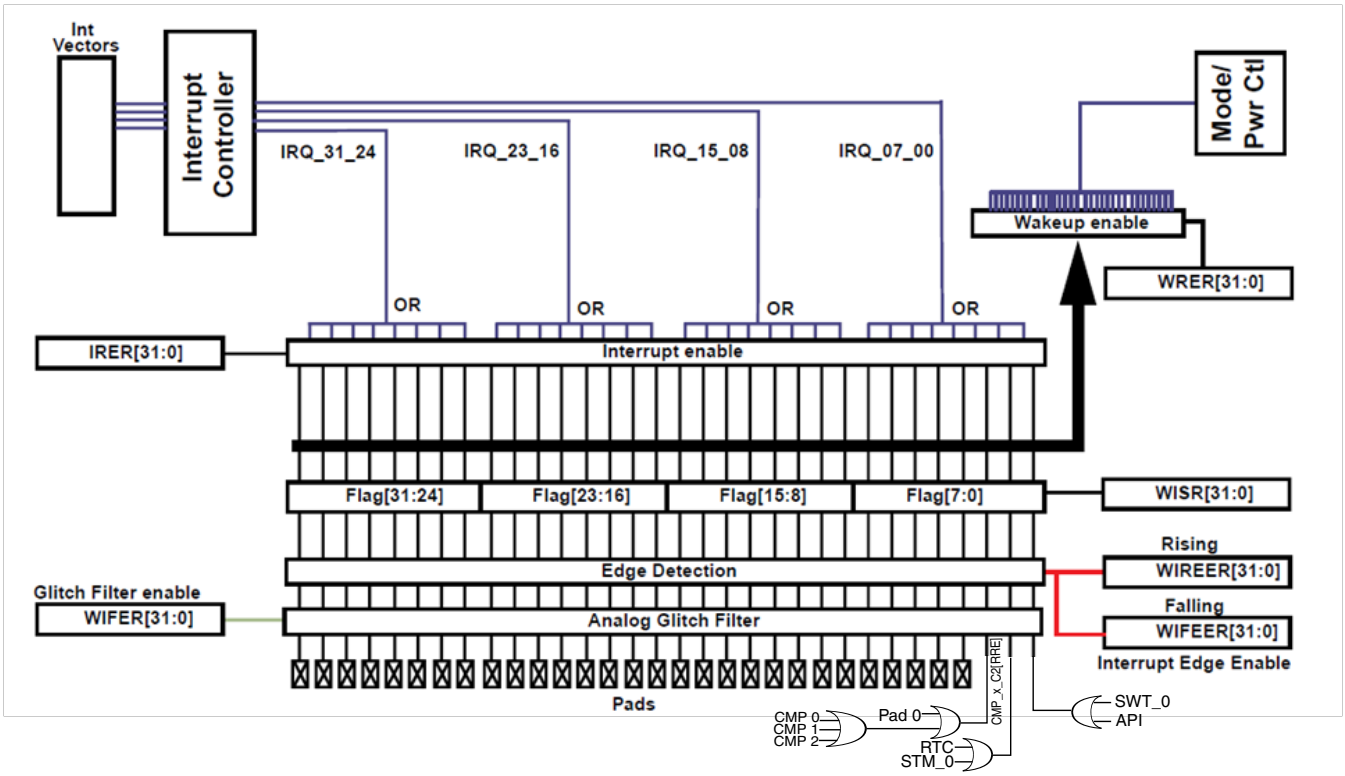

Figure 24-2. WKPU External interrupts connectivity

- The SWT0 and API inputs provides a wakeup trigger to WKPU interrupt source 0. API wakeup is supported only when all the CMP_x_C2 [RRE] fields are disabled.
- The RTC and STM_0 provides a wakeup trigger to WKPU interrupt source 1.

If the user configures any or all of the CMP_x_C2 [RRE] fields to be active then WKPU interrupt source 3 should be dedicated to interrupt (generated in STANDBY/STOP or LPU_STANDBY/LPU_STOP) from any of the CMP_x_C2 [RRE] fields. If the user is not using any of the CMP then it is desirable that the pad may still operate as a digital WKPU input signal. Thus, users not taking advantage of the CMP do not lose a digital wakeup source.

NOTE

Software must enable the WKPU (by using the appropriate MC_ME_PCTLx register for the WKPU) before entering any low-power mode of the device.

24.1.4 Wakeup Sources for various modes

All peripheral interrupts can cause wakeup from STOP mode if they support STOP mode and are enabled via ME_PCTL and system clock is available. LPU Peripheral interrupts can cause wakeup from LPU SLEEP mode if they are enabled via LPU MDIS. The peripherals which can cause wakeup from LPU mode are covered in the table below. The asynchronous interrupts can cause wake up from low power modes when system clock is gated.

The below table lists the asynchronous wakeup sources in low power modes.

Table 24-1. Asynchronous wakeup sources in low power modes

Sources	STOP	LPU_STOP	STANDBY	LPU_STANDBY
SWT_0	√	√	√[1]	√[1]
SWT_1	√	.	.	.
SWT_HSM	√	.	.	.
STM_0	√	√	√[1]	√[1]
STM_1	√	.	.	.
CMP 0, CMP 1 and CMP 2 (Continuous mode comparisons)	√	√	.	.
CMP 0, CMP 1 and CMP 2 (round robin mode comparisons)	√	√	√[1]	√[1]
FlexCAN_0 (Pretended Networking)	√	√	.	.
ENET 0 (magic packet detection)	√	.	.	.
RTI (timeout)	√	.	.	.
NMI	√[1]	√[1]	√[1]	√[1]
WKPU	√[1]	√[1]	√[1]	√[1]
RTC	√[1]	√[1]	√[1]	√[1]

1. This requires prior configuration in WKPU to generate asynchronous wakeup when SYSCLK is disabled.

24.1.5 NMI on standby exit

The NMI configuration register (NCR) would be:

1. Always reset in STANDBY mode
2. Reset along with Z2 core in LPU modes

Hence NMI from WKPU would never be generated on STANDBY exit until the SW is ready and has initialized the NCR register.

24.1.6 Register reset values

Some of the registers in this module have chip-specific reset values. They are listed below.

Register	Reset value
WKPU_NCR	0x6060_6060

24.1.7 Pull control of wakeup pads

The following table mentions how the PULL value of the WKPU pads are controlled by SIUL and WKPU configuration.

Table 24-2. Pull control of wakeup pads

Device Mode	SIUL2_MSCRn[PUE]	SIUL2_MSCRn[PUS]	WKPU_WIPUER[IPUE]	Affect on WKPU PAD
All except STANDBY modes	1	0	x	Pull down
	1	1	x	Pull up
	0	x	0	Highz
	0	0	1	Pull down
	0	1	1	Pull up

Table 24-3. Pull control of wakeup pads

Device Mode	State of SIUL2_MSCRn[PUS] before entering Standby	WKPU_WIPUER[IPUE]	Affect on WKPU PAD
STANDBY/LPU_STANDBY mode	x	0	Highz
	0	1	Pull down
	1	1	Pull up

The pull up/down voltage level for unconnected wakeup/interrupt input is VDD_HV_A supply level.

Recommended WKPU Configuration before entering into STANDBY/LPU_STANDBY mode

- Disable IBE of all EIRQ pads in SIUL2 Multiplexed Signal Configuration Register (SIUL2_MSCR*n*).
- CLEAR the Wakeup/Interrupt Status Flag Register (WKPU_WISR) by writing W1C to all bits.

- ENABLE wakeup for desired sources in Wakeup Request Enable Register (WKPU_WRER).
- ENABLE edge selection in Wakeup/Interrupt Rising-Edge Event Enable Register (WKPU_WIREER) or Wakeup/Interrupt Falling-Edge Event Enable Register (WKPU_WIFEER) as per the wakeup sources enabled in Wakeup Request Enable Register (WKPU_WRER) configuation.

24.2 Introduction

The WKPU supports external sources that can generate interrupts or wakeup events and external source(s) that can cause non-maskable interrupt request(s) or wakeup event(s). In addition, it combines its wakeup events with those generated from other wakeup sources to supply a single wakeup to the system. The block diagram of the WKPU and its interfaces to other system components is shown below.

NOTE

The signal widths in the following diagram might not depict this device's particular configuration. See the Chip-specific WKPU information for more information.

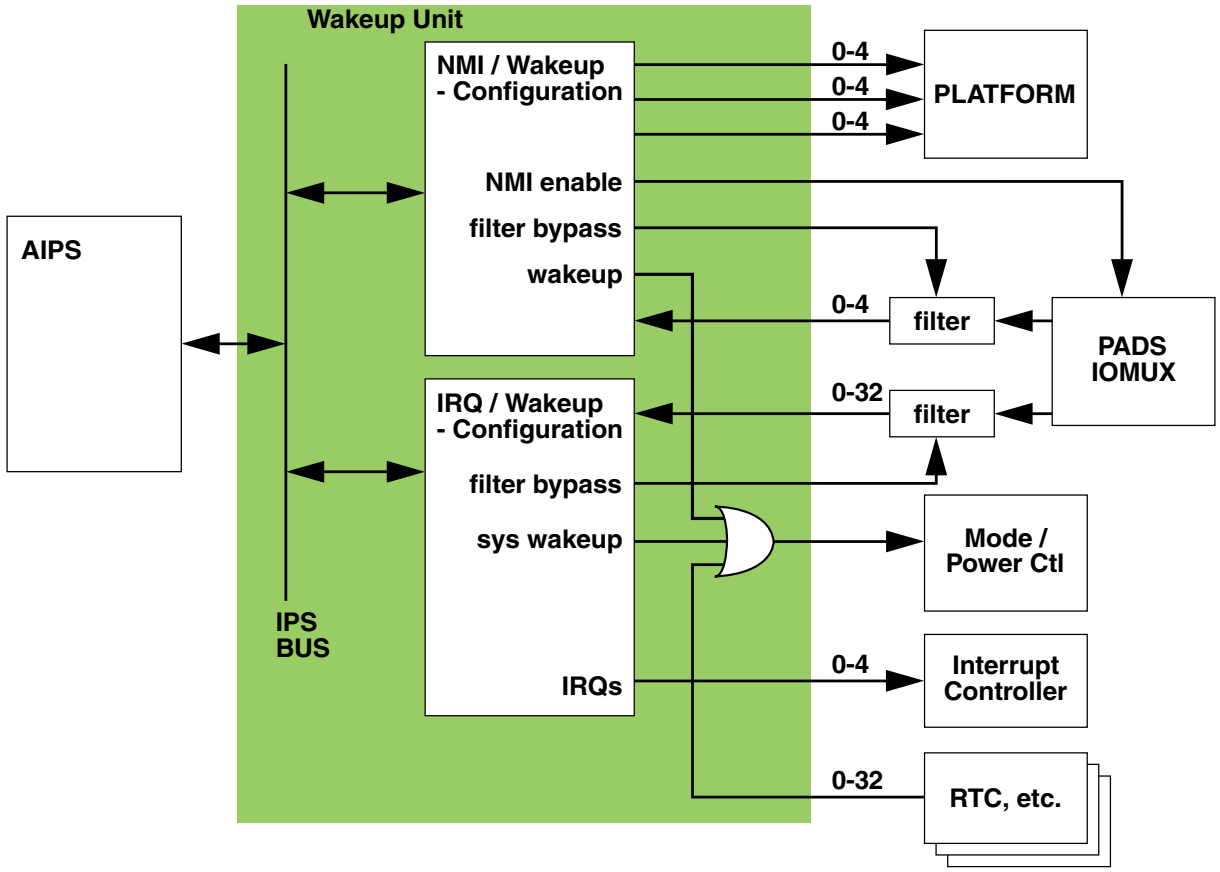

Figure 24-3. WKPU and connected system components

24.3 Features

The WKPU supports these features:

- Non-maskable Interrupt support with:
  - External NMI sources
  - Analog glitch filters
- Independent interrupt destination for each core:
  - Non-maskable interrupt
  - Critical interrupt
  - Machine check request
- Active edge selection control for events to each core
- Configurable system wakeup triggering from NMI source(s)

24.4 External signal description

The WKPU has signal inputs that can be used as external interrupt sources in normal run mode or as system wakeup sources in certain power down modes.

24.5 WKPU memory map and register definition

This section provides a detailed description of all registers accessible in the WKPU module.

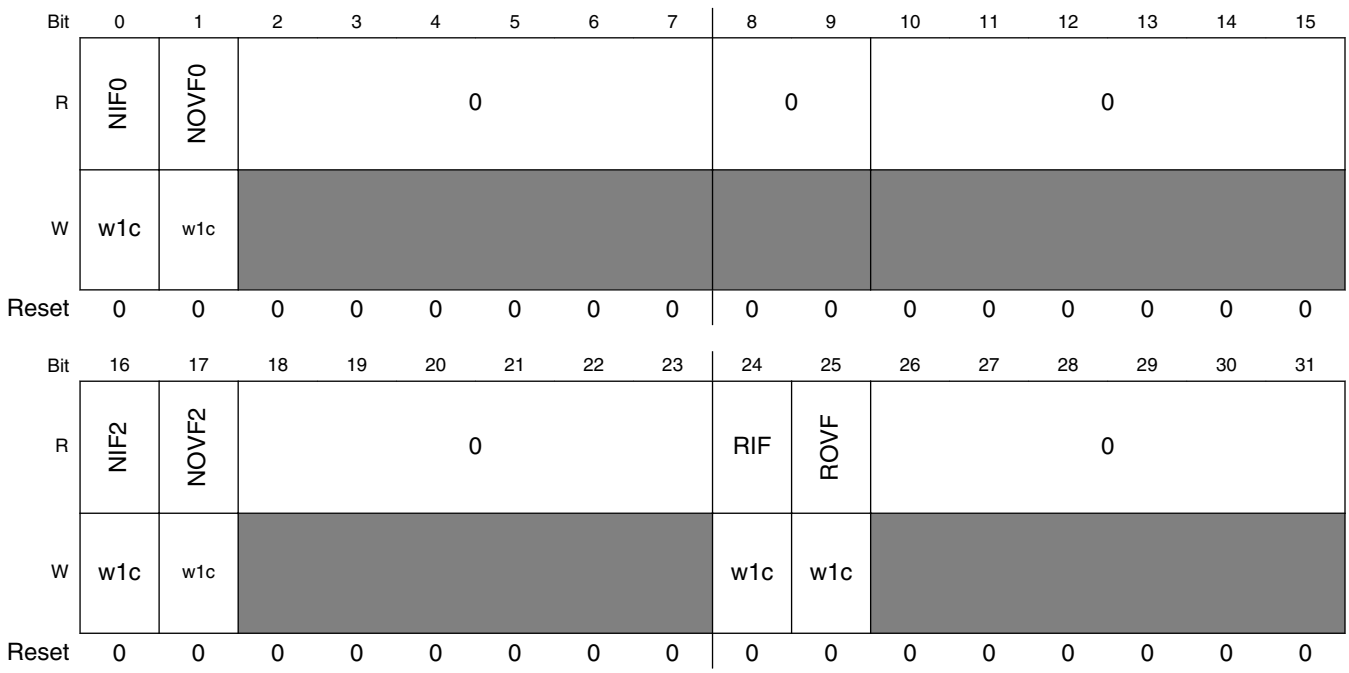
NOTE

Reserved registers will read as 0, writes will have no effect. Transfer error will be generated when trying to access completely reserved register space. The field length in external pad control registers depends on the number of WKPU channels implemented in a chip.

WKPU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	NMI Status Flag Register (WKPU_NSR)	32	w1c	0000_0000h	24.5.1/570
8	NMI Configuration Register (WKPU_NCR)	32	R/W	See section	24.5.2/572
14	Wakeup/Interrupt Status Flag Register (WKPU_WISR)	32	R/W	0000_0000h	24.5.3/575
18	Interrupt Request Enable Register (WKPU_IRER)	32	R/W	0000_0000h	24.5.4/576
1C	Wakeup Request Enable Register (WKPU_WRER)	32	R/W	0000_0000h	24.5.5/577
28	Wakeup/Interrupt Rising-Edge Event Enable Register (WKPU_WIREER)	32	R/W	0000_0000h	24.5.6/577
2C	Wakeup/Interrupt Falling-Edge Event Enable Register (WKPU_WIFEER)	32	R/W	0000_0000h	24.5.7/578
30	Wakeup/Interrupt Filter Enable Register (WKPU_WIFER)	32	R/W	0000_0000h	24.5.8/578
34	Wakeup/Interrupt Pull Enable Register (WKPU_WIPER)	32	R/W	0000_0000h	24.5.9/579

24.5.1 NMI Status Flag Register (WKPU_NSR)



This register holds the non-maskable interrupt status flags.

NOTE

This register is accessible by 8-, 16-, and 32-bit read/write operations.

Access: User read/write

Address: 0h base + 0h offset = 0h

WKPU_NSR field descriptions

Field	Description
0 NIF0	NMI Status Flag 0. This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE0 or NFEE0 set), NIF0 causes an interrupt request. 0 No event has occurred on the pad 1 An event as defined by NREE0 and NFEE0 has occurred
1 NOVF0	NMI Overrun Status Flag 0. This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF0 value whenever a NMI event occurs, thereby indicating to the software that a NMI occurred while the last one was not yet serviced. If enabled (NREE0 or NFEE0 set), NOVF0 causes an interrupt request. 0 No overrun has occurred on NMI input 0 1 An overrun has occurred on NMI input 0
2–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 NIF2	NMI Status Flag 2. This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE2 or NFEE2 set), NIF2 causes an interrupt request.

Table continues on the next page...

WKPU_NSR field descriptions (continued)

Field	Description
	0 No event has occurred on the pad 1 An event as defined by NREE2 and NFEE2 has occurred
17 NOVF2	NMI Overrun Status Flag 2. This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF2 value whenever a NMI event occurs, thereby indicating to the software that a NMI occurred while the last one was not yet serviced. If enabled (NREE2 or NFEE2 set), NOVF2 causes an interrupt request. 0 No overrun has occurred on NMI input 2 1 An overrun has occurred on NMI input 2
18–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 RIF	Reset Status Flag If enabled (i.e., if NCR[RREE] or NCR[RFEE] is set), this status bit is set and will cause a functional reset request to the RGM if NCR[RDSS] 0b00. This bit is automatically cleared if the ESR1 reset request is configured in the MC_RGM to generate a long or short “functional” reset. 0 No event has occurred on the pad 1 An event as defined by NCR[RREE] and NCR[RFEE] has occurred
25 ROVF	Reset Overrun Status Flag This field is a copy of the current RIF value whenever a NMI event occurs, thereby indicating to the software that an NMI occurred while the last one was not yet serviced. If enabled (i.e., NCR[RREE] or NCR[RFEE] is set), this field can cause a reset request to MC_RGM if NCR[RDSS] 0b00. This bit is automatically cleared if the ESR1 reset request is configured in the MC_RGM to generate a long or short “functional” reset. 0 No overrun has occurred on the NMI reset request input 1 An overrun has occurred on the NMI reset request input
26–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

24.5.2 NMI Configuration Register (WKPU_NCR)

This register holds the configuration bits for the non-maskable interrupt settings.

NOTE

- This register is accessible by 8-, 16-, and 32-bit read/write operations.
- Writing a 0 to both NREE[*n*] and NFEE[*n*] disables the NMI functionality completely (i.e., no system wakeup or interrupt will be generated on any pad activity).

Access: User read/write

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	NLOCK0	NDSS0		NWRE0	0	NREE0	NFEE0	NFE0	0	0		0	0	0	0	Reserved
W																
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

R	NLOCK2	NDSS2		NWRE2	0	NREE2	NFEE2	Reserved	RLOCK	RDSS		RWRE	0	RREE	RFEE	Reserved
W																
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- See the chip-specific WKPU information for the reset value of this register.

WKPU_NCR field descriptions

Field	Description
0 NLOCK0	NMI Configuration Lock Register 0. Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset . Writing a 0 has no effect.
1–2 NDSS0	NMI Destination Source Select 0. **NOTE:** If this field is configured for machine check exception, the following steps must be performed in order to receive the exception on the NMI Pad: 1. Set MSR[ME], Machine Check Enable field of the core's Machine State Register, to 1. 2. Set HID0[EMCP] to 1. 00 Non-maskable interrupt 01 Critical interrupt 10 Machine check request 11 No NMI, critical Interrupt, or machine check request generated.
3 NWRE0	NMI Wakeup Request Enable 0 **NOTE:** If wakeup requests are disabled, the corresponding NDSS field must be set to 11 to disable wakeups from an NMI, critical interrupt, or machine check. 0 System wakeup requests from the corresponding NIF0 bit are disabled. 1 A set NIF0 bit or set NOVF0 bit causes a system wakeup request.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 NREE0	NMI Rising-edge Events Enable 0. 0 Rising-edge event is disabled 1 Rising-edge event is enabled
6 NFEE0	NMI Falling-edge Events Enable 0. 0 Falling-edge event is disabled 1 Falling-edge event is enabled

Table continues on the next page...

WKPU_NCR field descriptions (continued)

Field	Description
7 NFE0	NMI Filter Enable 0. Enable analog glitch filter on the NMI pad input. 0 Filter is disabled 1 Filter is enabled
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

31 Reserved	This field is reserved.

24.5.3 Wakeup/Interrupt Status Flag Register (WKPU_WISR)

This register holds the wakeup/interrupt flags.

NOTE

- This register is accessible only by 32-bit read/write operations.
- Status bits associated with on-chip wakeup sources are located to the left of the external wakeup/interrupt status bits and are read only. The wakeup for these sources must be configured and cleared at the on-chip wakeup source.

Also, the configuration registers for the external interrupts/ wakeups do not have corresponding bits.

Access: User read/write

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W	w1c																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

WKPU_WISR field descriptions

Field	Description
0–31 EIF	External Wakeup/Interrupt Status Flag x. This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER[x]), EIF[x] causes an interrupt request. 0 No event has occurred on the pad 1 An event as defined by WIREER and WIFEER has occurred

24.5.4 Interrupt Request Enable Register (WKPU_IRER)

This register is used to enable the interrupt messaging from the wakeup/interrupt pads to the interrupt controller.

NOTE

This register is accessible only by 32-bit read/write operations.

Access: User read/write

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

WKPU_IRER field descriptions

Field	Description
0–31 EIRE	External Interrupt Request Enable x. 0 Interrupt requests from the corresponding EIF[x] bit are disabled 1 A set EIF[x] bit causes an interrupt request

24.5.5 Wakeup Request Enable Register (WKPU_WRER)

This register is used to enable the system wakeup messaging from the wakeup/interrupt pads to the mode entry and power control modules.

NOTE

This register is accessible only by 32-bit read/write operations.

If a pin is disabled through this register, the corresponding bits in the WIFEER and WIREER registers must be written to 0 to ensure that the pin does not respond to any change.

Access: User read/write

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

WKPU_WIFEER field descriptions

Field	Description
0–31 IFEEx	External Interrupt Falling-edge Events Enable x. 1 Falling-edge event is enabled 0 Falling-edge event is disabled

24.5.8 Wakeup/Interrupt Filter Enable Register (WKPU_WIFER)

This register is used to enable an analog filter on the corresponding interrupt pads to filter out glitches on the inputs. The number of wakeups/interrupts supporting this feature is SoC dependent and can be configured to be between 1 and 32.

NOTE

This register is accessible only by 32-bit read/write operations.

Access: User read/write

Address: 0h base + 30h offset = 30h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Field	Description
0–31 IPUE	External Interrupt Pull Enable x. 0 Pull is disabled 1 Pull is enabled

24.6 Functional description

This section provides a functional description of the WKPU.

24.6.1 Non-maskable interrupts

The WKPU supports the generation of 3 types of interrupts per NMI input to the SoC. The WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event, though it creates an overrun condition.

Each NMI passes through a bypassable analog glitch filter.

NOTE

Glitch filter control and pad configuration should be done while the NMI is disabled in order to avoid erroneous triggering by glitches caused by the configuration process itself.

24.6.1.1 NMI management

Each NMI can be enabled or disabled independently. This can be performed using the single NCR register laid out to contain all configuration bits for a given NMI in a single byte (see NMI Configuration Register (WKPU_NCR)). A pad defined as an NMI can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active. A setting of having both edge events disabled results in no interrupt being detected and should not be configured.

The active NMI edge is controlled by the user through the configuration of the NREE and NFEE bits.

Note

After reset, NREE and NFEE are set to '0', therefore the NMI functionality is disabled after reset and must be enabled explicitly by software.

Once a pad's NMI functionality has been enabled, the pad cannot be reconfigured in the IOMUX to override or disable the NMI. Please see chip specific section for details on NMI implementation.

The NMI destination interrupt is controlled by the user through the configuration of the NDSS bits. See NMI Configuration Register (WKPU_NCR) for details.

Each NMI supports a status flag and an overrun flag which are located in the NSR register (see NMI Status Flag Register (WKPU_NSR)). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register. The status flag is set whenever an NMI event is detected. The overrun flag is set whenever an NMI event is detected and the status flag is set (i.e. has not yet been cleared).

Note

The overrun flag is cleared by writing a '1' to the appropriate overrun bit in the NSR register. If the status bit is cleared and the overrun bit is still set, the pending interrupt will not be cleared.

During an NMI ISR, on wakeup of the SoC from an NMI, any writes to ECC-protected memory must have the correct ECC.

24.7 Initialization Information

This section discusses initialization for the following features:

- Glitch Filter and Pad Configuration
- Non-Maskable Interrupts
- Reset Request

24.7.1 Glitch Filter and Pad Configuration

Glitch filter control and pad configuration should be performed while the NMI is disabled in order to avoid erroneous triggering by glitches caused by the configuration process itself.

When enabling the glitch filter, do not enable the rising-/falling-edge events bits, i.e., the NREE, NFEE, RREE, and RFEE, bits in the same register write.

24.7.2 Non-Maskable Interrupts

When an NMI interrupt pin is first enabled, it is possible to get a false interrupt flag. To prevent a false interrupt request during pin interrupt initialization the user must do the following:

1. Mask interrupts by clearing NSR[NIF*n*] and NSR[NOVF*n*].
2. Clear NCR[NFEE*n*] and NCR[NREE*n*], preferably by writing 0 to all bits in the register.
3. Configure the analog glitch filter using NCR[NFE0].

4. Write appropriate bit values to the NCR register to configure:
    - NMI source (NDSS*n*).
    - Wakeup request (NWRE*n*).
    - Glitch filter (NFE0)
    - Rising/falling edge events enable (NFEE*n* and NREE*n*).
    - NMI configuration lock (NLOCK*n*).

24.7.3 Reset Request

When an NMI reset request pin is first enabled, it is possible to get a false reset request. To prevent a false reset request during pin reset request initialization, the user must do the following:

1. Mask reset requests by clearing NSR[RIF] and NSR[ROVF].
2. Clear NCR[RFEE] and NCR[RREE], preferably by writing 0 to all bits in this register.
3. Configure the analog glitch filter, as desired, using NCR[NFE0].
4. Write appropriate bit values to the NCR register to configure:
    - Reset destination source (RDSS]).
    - Reset wakeup request (RWRE).
    - Glitch filter (NFE0)
    - Rising/falling edge events enable (RFEE and RREE).
    - Reset configuration lock (RLOCK).

Chapter 25
PLL Digital Interface (PLLDIG)

25.1 Introduction

The PLL system is composed of a single analog PLL block and the digital interface (PLLDIG).

For low power operation, the chip provides an option to work with the PLL in either disabled or powered down modes.

25.2 Block Diagram

Please refer to the “Clocking chapter” of this *Reference Manual* to see the block diagram.

25.3 Features

The PLLDIG module has the following features:

- Reference clock pre-divider for finer frequency synthesis resolution.
- Reduced frequency divider for decreasing the PLL output clock frequency without causing the PLL to lose lock.
- Programmable frequency modulation.
- Lock detect circuitry reports when the PLL has achieved frequency lock, and continuously monitors lock status to report loss of lock conditions.
    - The loss of lock indication is sent to the FCCU via the system glue logic.
- Loss-of-clock detection for the reference and output clocks.

25.4 Modes of operation

PLLDIG operates in normal mode with a reference clock and PLL enabled.

NOTE

Mode changes are controlled by configuring the MC_ME Mode Configuration registers (MC_ME_<*mode*>_MC).

Normal mode is defined as the mode where the clocks are driven by the PLL. When using a crystal for the reference clock, reset should remain asserted until the oscillator has stabilized.

25.4.1 Normal mode with reference, PLL enabled

In normal mode, the PLL receives an input clock from a reference which can be prescaled by the pre-divider. The PLL multiplies the reference to create the output clock. The user must supply a crystal that is within the appropriate frequency range with the crystal manufacturers recommended external support circuitry, and a short signal route from the crystal to the MCU.

The PLL can generate either a frequency modulated clock or a non-modulated clock (for example, locked on a single frequency). The modulation rate, modulation depth, and modulation enable are programmed by configuring the PLLFM register.

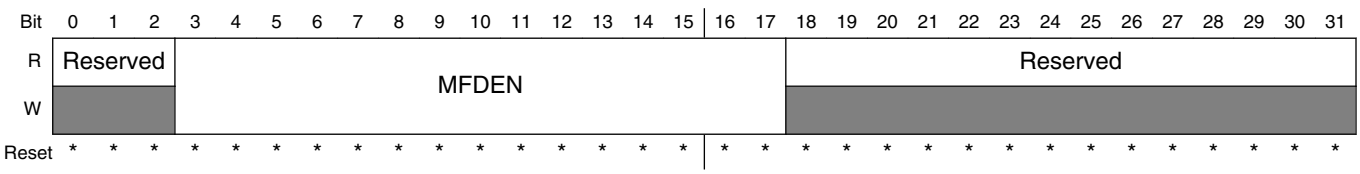
25.5 Memory map and register definition

This section provides the memory map and detailed descriptions of all registers for configuring the PLL. The table below shows the memory map. Addresses are given as offsets from the module base address. All registers can be accessed using 8-bit, 16-bit or 32-bit addressing.

PLLDIG memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
18	PLL Calibration Register 3 (PLLDIG_PLLCAL3)	32	R/W	See section	25.5.1/585
20	PLLDIG PLL Control Register (PLLDIG_PLLCR)	32	R/W	See section	25.5.2/586

Table continues on the next page...



PLLDIG memory map (continued)

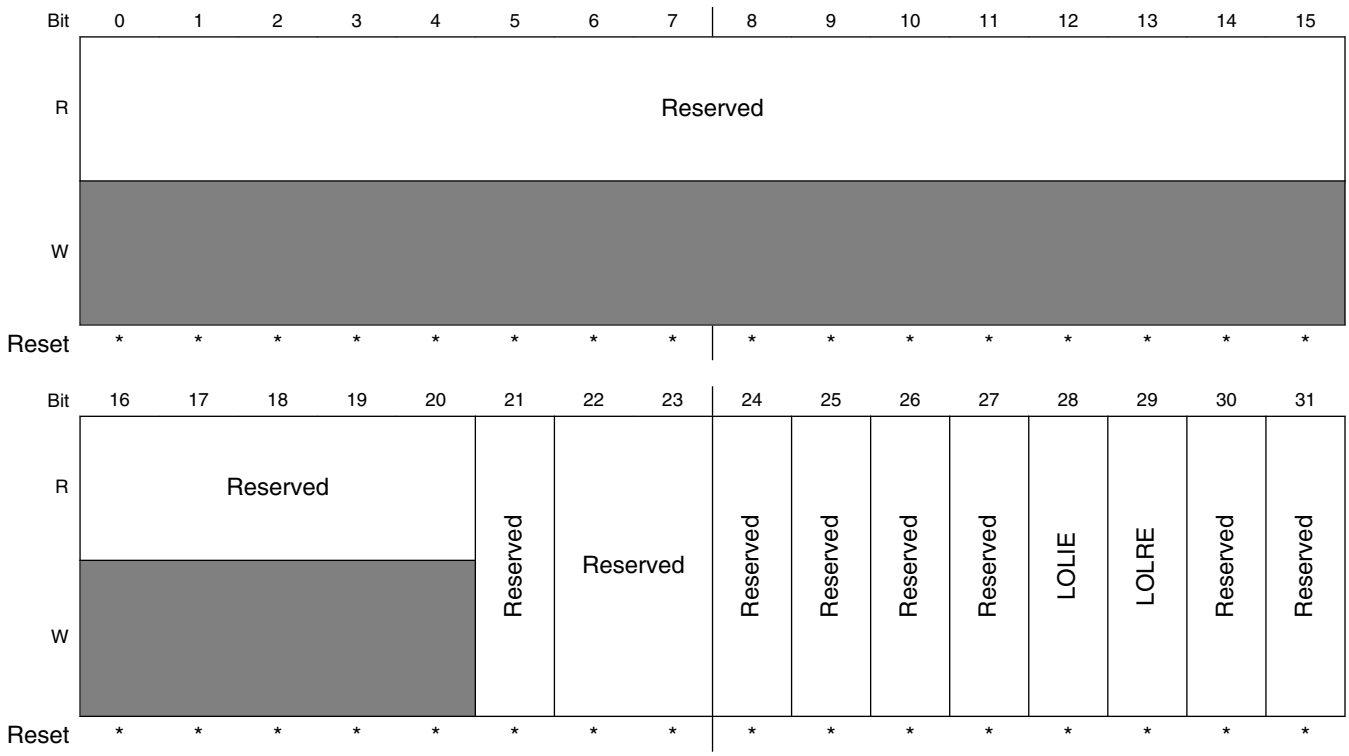
Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
24	PLLDIG PLL Status Register (PLLDIG_PLLSR)	32	R/W	See section	25.5.3/588
28	PLLDIG PLL Divider Register (PLLDIG_PLLDV)	32	R/W	See section	25.5.4/590
2C	PLLDIG PLL Frequency Modulation Register (PLLDIG_PLLFM)	32	R/W	See section	25.5.5/592
30	PLLDIG PLL Fractional Divide Register (PLLDIG_PLLFD)	32	R/W	See section	25.5.6/594

25.5.1 PLL Calibration Register 3 (PLLDIG_PLLCAL3)

PLLCAL3 contains the denominator of the fractional loop division factor.

Address: 0h base + 18h offset = 18h

* Notes:
- See "Clocking" chapter for reset value.



PLLDIG_PLLCAL3 field descriptions

Field	Description
0–2 Reserved	This field is reserved.
3–17 MFDEN	Denominator of fractional loop division factor. The value for this field must be greater than PLLFD[MFN] (see Clock configuration for details).
18–31 Reserved	This field is reserved.

25.5.2 PLLDIG PLL Control Register (PLLDIG_PLLCR)

The PLLCR is shown in the following table. It contains the operational state of the PLL, and is used to enable/disable PLL specific interrupts.

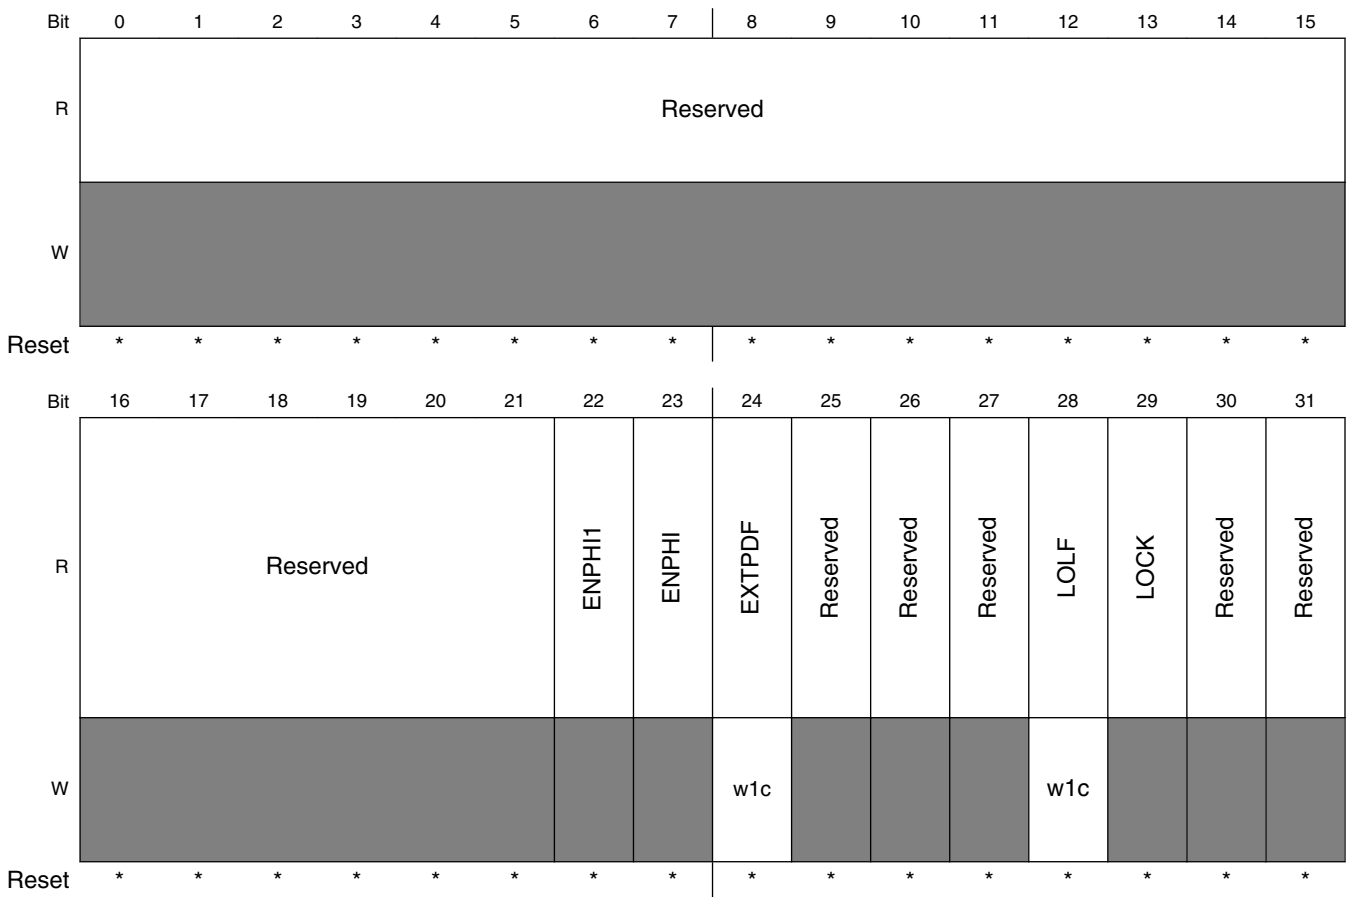
Address: 0h base + 20h offset = 20h

* Notes:
- See "Clocking" chapter for reset value.
- LOLIE field: Please refer to device "Clocking" chapter for details on configuring this field.

PLLDIG_PLLCR field descriptions

Field	Description
0–20 Reserved	This field is reserved.
21 Reserved	This field is reserved.
22–23 Reserved	This field is reserved.
24 Reserved	This field is reserved.
25 Reserved	This field is reserved.

Table continues on the next page...



PLLDIG_PLLCR field descriptions (continued)

Field	Description
26 Reserved	This field is reserved.
27 Reserved	This field is reserved.
28 LOLIE	Loss-of-lock interrupt enable. The LOLIE bit enables a loss-of-lock interrupt request when PLLSR[LOLF] = 1. If PLLSR[LOLF] = 0 or PLLCR[LOLIE] = 0, the interrupt request is ignored. The interrupt request only occurs in normal mode. 0 Ignore loss-of-lock. Interrupt not requested. 1 Enable interrupt request upon loss-of-lock.
29 LOLRE	Loss-of-lock reset enable. The PLLCR[LOLRE] bit determines whether system reset is asserted or not upon a loss-of-lock indication from PLL. If both PLLCR[LOLRE] = 1 and PLLCR[LOLIE] = 1, PLLCR[LOLRE] has precedence and the device asserts reset with the interrupt not being taken. 0 Ignore loss-of-lock. Reset not asserted. 1 Assert reset on loss-of-lock when operating in normal mode.
30 Reserved	This field is reserved.
31 Reserved	This field is reserved.

25.5.3 PLLDIG PLL Status Register (PLLDIG_PLLSR)

PLLSR contains status flags showing the current state of the PLL.

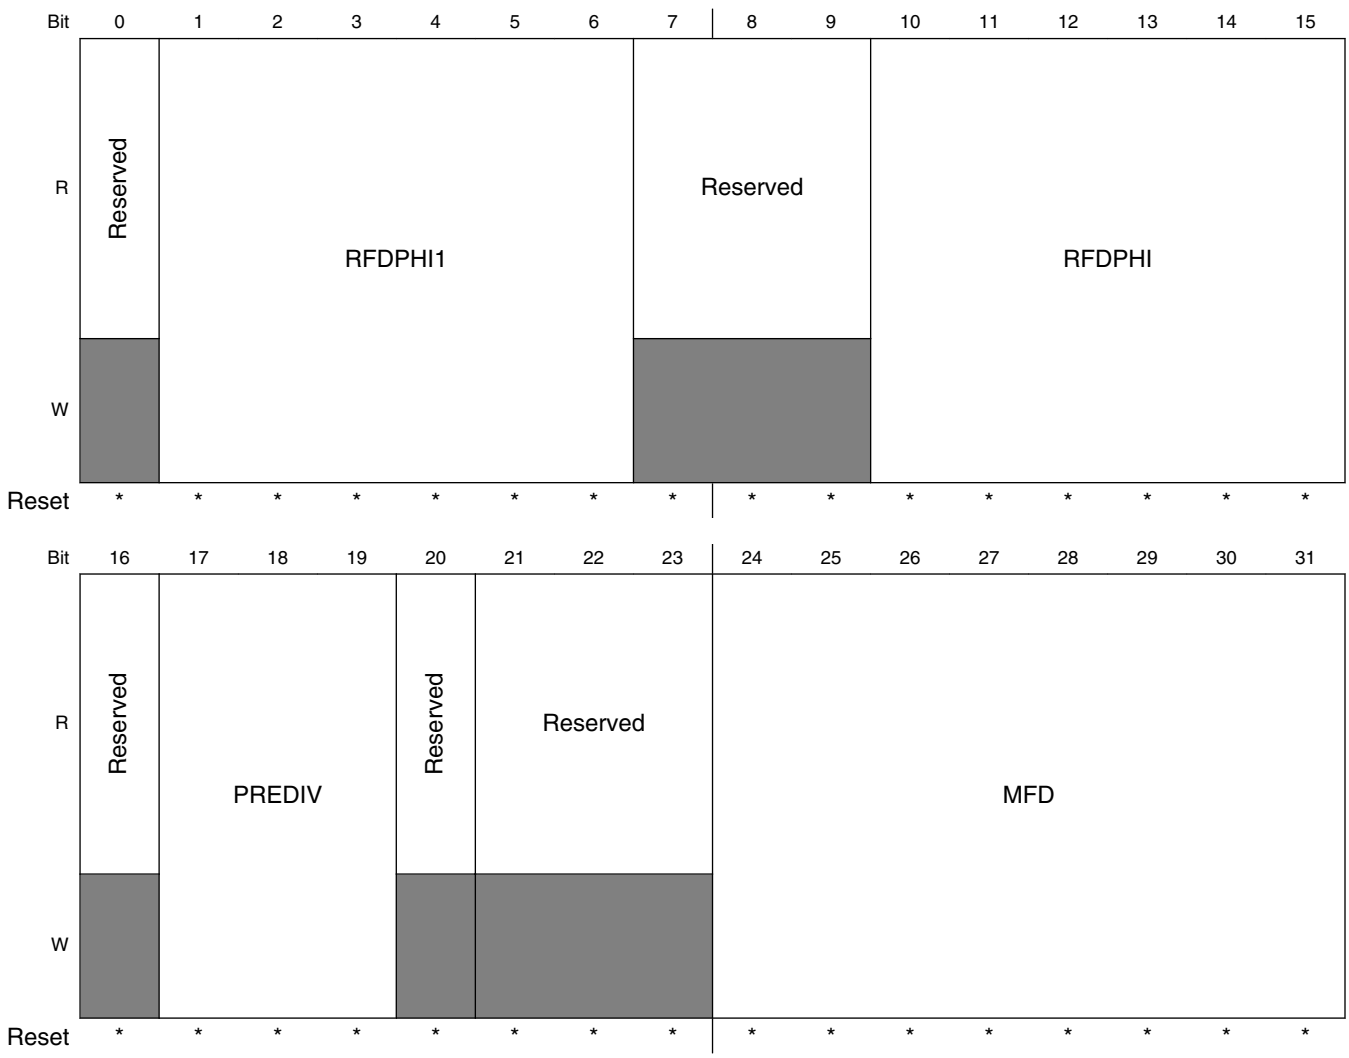
Address: 0h base + 24h offset = 24h

* Notes:
- See "Clocking" chapter for reset value.

PLLDIG_PLLSR field descriptions

Field	Description
0–21 Reserved	This field is reserved.
22 ENPHI1	PLL PHI1 Output Enable 0 PLL_PHI1 output is disabled 1 PLL_PHI1 output is enabled
23 ENPHI	PLL PHI Output Enable

Table continues on the next page...



PLLDIG_PLLSR field descriptions (continued)

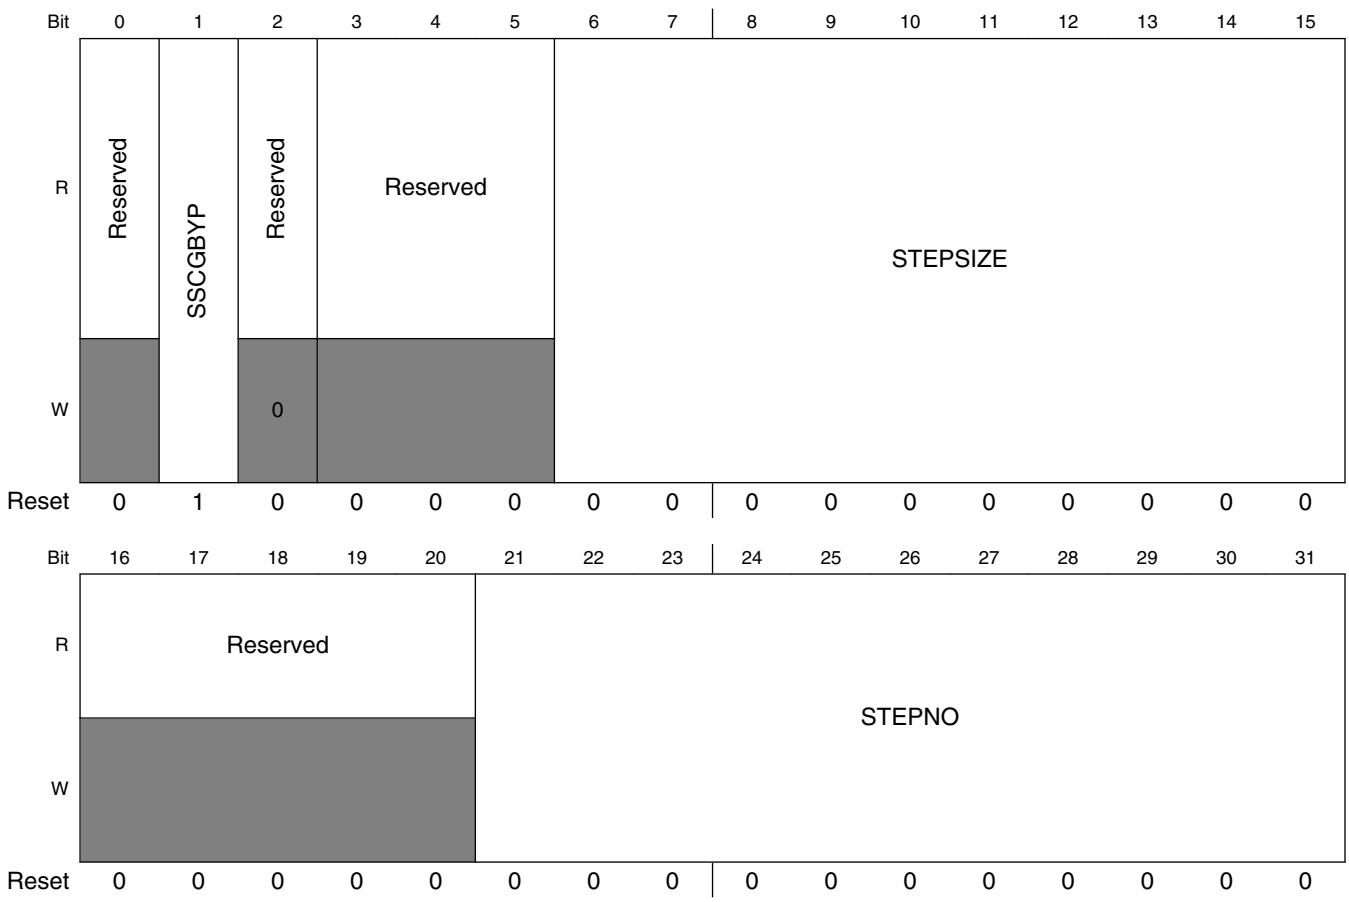
Field	Description
	0 PLL_PHI output is disabled 1 PLL_PHI output is enabled
24 EXTPDF	External Power Down Cycle Complete indication interrupt flag. This bit indicates that the external power down of the PLL is complete (for example, PLLs are powered down and then powered up). 0 PLLs not power cycled. 1 PLLs power down cycle is complete.
25 Reserved	This field is reserved.
26 Reserved	This field is reserved.
27 Reserved	This field is reserved.
28 LOLF	Loss-of-lock flag. This bit provides the interrupt request flag for the loss-of-lock condition. Software must write 1 to LOLF to clear it, writing 0 has no effect. This flag bit is sticky in the sense that if lock is reacquired, the bit will remain set until cleared by either writing 1 or asserting reset. Clearing this bit does not clear the interrupt request since this is handled by the MC_RGM. 0 No loss of lock detected. Interrupt service not requested. 1 Loss of lock detected. Interrupt service requested.
29 LOCK	Lock status bit. Indicates whether PLL has acquired lock. 0 PLL is unlocked. 1 PLL is locked.
30 Reserved	This field is reserved.
31 Reserved	This field is reserved.

25.5.4 PLLDIG PLL Divider Register (PLLDIG_PLLDV)

The values of the reduced frequency divider (RFDPHI) and loop multiplication factor divider (MFD) can be modified at anytime, but the new values only become effective after the PLL is disabled, then reenabled.

Address: 0h base + 28h offset = 28h

* Notes:
- See "Clocking" chapter for reset value.



PLLDIG_PLLDV field descriptions

Field	Description
0 Reserved	This field is reserved.
1–6 RFDPHI1	PHI1 reduced frequency divider. This field determines the VCO clock post divider for driving the PHI1 output clock. The settings for RFDPHI1 are: 000000 Divide by 2 000001 Divide by 4 000010 Divide by 8 000011 Divide by 16 0001xx Divide by 32 All other values are reserved.
7–9 Reserved	This field is reserved.
10–15 RFDPHI	PHI reduced frequency divider. This 6-bit field determines the VCO clock post divider for driving the PHI output clock. The settings for RFDPHI are as follows: 000000 Divide by 2 000001 Divide by 4 000010 Divide by 8 000011 Divide by 16 0001xx Divide by 32 All other values are reserved.
16 Reserved	This field is reserved.
17–19 PREDIV	Input clock predivider. This field controls the value of the divider on the input clock. The output of the predivider circuit generates the reference clock to the PLL analog loop. 000 Divide by 1 001 Divide by 1 010 Divide by 2 011 Divide by 3 100 Divide by 4 101 Divide by 5 110 Divide by 6 111 Reserved
20 Reserved	This field is reserved.
21–23 Reserved	This field is reserved.
24–31 MFD	Loop multiplication factor divider. This field controls the value of the divider in the feedback loop. The value specified by the MFD bits establishes the multiplication factor applied to the reference frequency. Divider value = MFD, where MFD has the range 10...150 (Ah...96h). All other values are reserved.

25.5.5 PLLDIG PLL Frequency Modulation Register (PLLDIG_PLLFM)

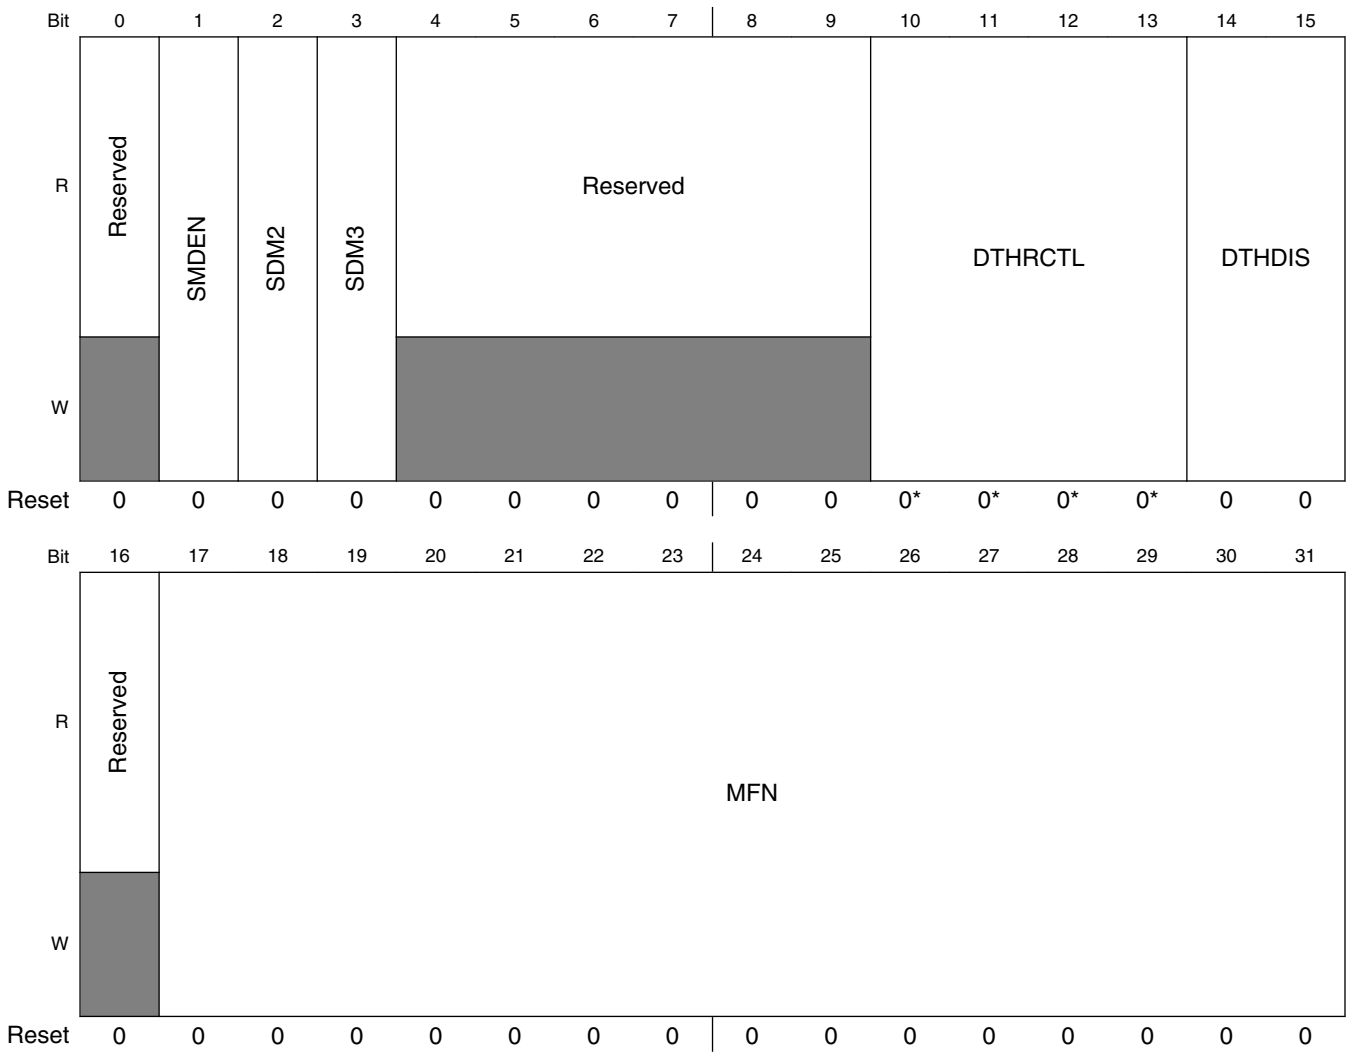
The PLLFM register controls enables frequency modulation, and provides controls for modulation mode selection, modulation depth and modulation rate. The PLL would then be required to be power cycled to regain normal functionality.

Address: 0h base + 2Ch offset = 2Ch

PLLDIG_PLLFM field descriptions

Field	Description
0 Reserved	This field is reserved.
1 SSCGBYP	Modulation enable. This bit enables spectrum modulation. 0 Spread spectrum modulation is not bypassed. 1 Spread spectrum modulation is bypassed.

Table continues on the next page...



PLLDIG_PLLFM field descriptions (continued)

Field	Description
2 Reserved	This field is reserved.
3–5 Reserved	This field is reserved.
6–15 STEPSIZE	Modulation period. STEPSIZE is the modulation period variable derived from the formulas shown in Frequency modulation.
16–20 Reserved	This field is reserved.
21–31 STEPNO	Increment step. This field is the STEPNO variable derived from the formulas shown in Frequency modulation.

25.5.6 PLLDIG PLL Fractional Divide Register (PLLDIG_PLLFD)

The PLLFD register provides the enable and fractional divide factor for the loop divider. The PLL would then require power cycling to regain normal functionality.

Address: 0h base + 30h offset = 30h

* Notes:
- DTHRCTL field: See field description for details.

PLLDIG_PLLFD field descriptions

Field	Description
0 Reserved	This field is reserved.

Table continues on the next page...

PLLDIG_PLLFD field descriptions (continued)

Field	Description
1 SMDEN	Sigma Delta Modulation Enable 0 Sigma delta modulation disabled 1 Sigma delta modulation enabled
2 SDM2	Second Order Sigma Delta Modulation Select See Table 25-1 for proper SDM2 and SDM3 field configuration. 0 2nd order sigma delta modulation disabled. 1 2nd order sigma delta modulation enabled.
3 SDM3	Third Order Sigma Delta Modulation Select Table 25-1 shows how to configure the SDM3 and SDM2 fields for proper operation. **Table 25-1. SDM2/SDM3 field configuration** SDM2 | SDM3 | Order of modulation 0 | 0 | Not applicable 0 | 1 | Not applicable 1 | 0 | 2nd order sigma delta modulation 1 | 1 | 3rd order sigma delta modlation **NOTE:** For SSCG mode, PLLDIG must be configured for 3rd order sigma delta modulation. 0 3rd order sigma delta modulation disabled. 1 3rd order sigma delta modulation enabled.
4–9 Reserved	This field is reserved.
10–13 DTHRCTL	Dither Control. **NOTE:** DTHRCTL may be written, but for normal operation this field must be 0000b. All other values are reserved.
14–15 DTHDIS	Dither Disable. 00 Dither enabled 01 Dither disabled 10 Dither enabled 11 Dither disabled
16 Reserved	This field is reserved.
17–31 MFN	Numerator for fractional loop division factor (see Clock configuration).

25.6 Functional description

This section explains the operation and configuration of the PLLDIG module.

25.6.1 Input clock frequency

The PLL is designed to operate over an input clock frequency range. The operating ranges for the PLL is discussed in detail in the *Data Sheet*.

25.6.2 Clock configuration

The relationship between input and output frequency is determined by programming the PLLDV, PLLCAL3, and PLLFD registers, and calculated according to the following equation:

$$f_{\text{pll_phi}} = f_{\text{pll_ref}} \times \left(\frac{\text{PLLDV[MFD]} + \frac{\text{PLLFD[MFN]}}{(\text{PLLCAL3[MFDEN]} + 1)}}{\text{PLLDV[PREDIV]} \times 2 \times \left(2^{\text{PLLDV[RFDPHI]}}\right)} \right)$$

Equation 1. PLL PHI Output Frequency

The relationship between the VCO frequency (f_{VCO}) and the output frequency of the PLL is determined by the PLLDV, PLLCAL3 and PLLFD registers, according to the following equation:

$$f_{\text{pll_VCO}} = \frac{f_{\text{pll_ref}}}{\text{PLLDV[PREDIV]}} \times \left(\text{PLLDV[MFD]} + \frac{\text{PLLFD[MFN]}}{(\text{PLLCAL3[MFDEN]} + 1)} \right)$$

Equation 2. PLL VCO Frequency

When programming the PLL, user software must not violate the maximum system clock frequency or max/min VCO frequency specification of the PLL.

The lock signal and PLLSR[LOCK] flag are immediately negated if the fields of the PLLDV register are changed without powering down the analog PLL.

When any of these events occur, an internal timer is initialized to count 64 cycles of the PLL input clock. During this period (64 cycles and a few extra clock cycles for synchronization, for example, 64 to 72 cycles), the PLLSR[LOCK] flag is held negated. After the timer expires, the PLLSR[LOCK] flag reflects the value coming from the PLL lock detection circuitry. To prevent an immediate reset, the PLLCR[LOLRE] bit of the PLL must be cleared before doing any of the above operations.

Note

The PLL must be powered down and powered up by configuring, then executing, a mode change in the MC_ME_<*mode*>_MC before PLLDV[PREDIV], PLLDV[MFD], or the input clocks are modified.

The recommended procedure to program the PLL and engage normal mode is shown in Initialization information.

25.6.3 Fault Collection and Control Unit (FCCU)

When a loss of lock condition is detected, a signal is sent to the INTC as well as the FCCU. The FCCU then uses this signal to determine an appropriate action.

25.6.4 Frequency modulation

Frequency modulation uses a triangular profile as shown in Figure 25-1. The modulation frequency and depth are controlled using PLLFM[STEPSIZE] and PLLFM[STEPNO].

NOTE

Frequency Modulation is only possible if,

$$\text{PLLFM[STEPSIZE]} \times \text{PLLFM[STEPNO]} < (\text{PLLCAL3[MFDEN]} + 1).$$

PLLFM[SSCGBYP] must be cleared and PLLFD[SMDEN] must be set for the frequency modulation mechanism to be enabled.

Maximum peak-to-peak Modulation Depth (MD) = (PLL reference clock ÷ VCO frequency) × 100.

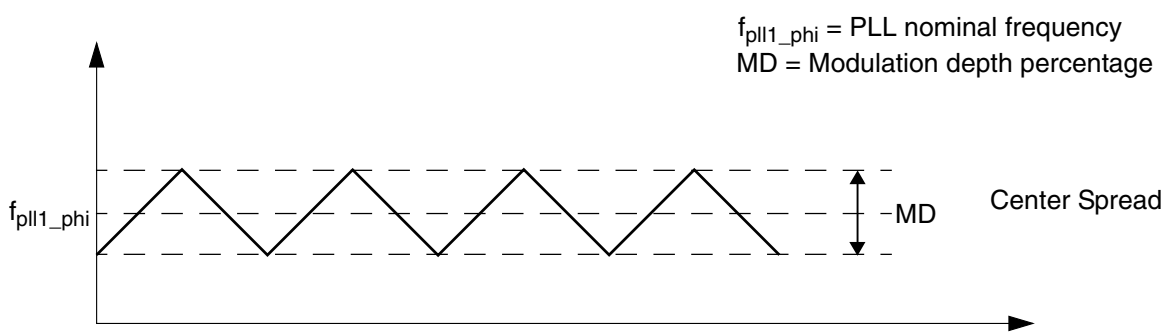


Figure 25-1. Triangular frequency modulation

NOTE

The device maximum operating frequency includes the frequency modulation. If center modulation is used, the f_{sys} must be below f_{max} by MD percentage such that $f_{max} = f_{sys} \times (1 + (MD\% / 100))$.

The following equations define how to calculate PLLFM[STEPSIZE] and PLLFM[STEPNO] based on the output frequency of the feedback divider (f_{ref}), the modulation frequency (f_{mod}) and the modulation depth percentage (MD).

$$PLLFM[STEPSIZE] = \text{round}\left(\frac{MD\% \times N \times PLLCAL3[MFDEN] + 1}{PLLFM[STEPNO] \times 100}\right)$$

Equation 3. PLLFM[STEPSIZE] Calculation

Where MD is the % Modulation Depth, and N is shown in Equation 4 on page 598.

$$N = PLLDV[MFD] + \frac{PLLFD[MFN]}{PLLCAL3[MFDEN] + 1}$$

Equation 4. Calculation of N

The equation to determine PLLFM[STEPNO] is shown in Equation 5 on page 598.

$$PLLFM[STEPNO] = \text{round}\left(\frac{f_{ref}}{PLLDV[PREDIV] \times 2 \times f_{mod}}\right)$$

Equation 5. PLLFM[STEPNO] Calculation

25.6.5 PLL Wakeup from low power mode

When the PLL is running normally and locked, the PLL operating point is sampled and stored.

On entering low power state, register configurations will not be maintained. However, the PLL register configurations are saved. On wake-up from a low power mode, the stored values of the PLL are written back to the registers. This process allows the PLL to acquire a faster lock.

25.6.6 Calibration feature

The PLL has a mechanism to calibrate the VCO. After the PLL exits reset, the PLL undergoes an automatic tuning of the VCO. The automatic tuning of the VCO will assist the VCO to oscillate close to the locking frequency. During the automatic tuning the main loop of PLL will not be working. Upon completion of calibration, the main loop of the PLL is closed which fine tunes the VCO to lock at the desired frequency.

25.7 Initialization information

Coming out of reset the PLL is disabled per the DRUN mode configuration register, MC_ME_DRUN_MC. The PLLDIG initialization procedure is described in the "Clocking" chapter.

NOTE

See the "Mode Entry Module (MC_ME)" chapter in this *Reference Manual* more details.

Chapter 26
Slow Internal 128 kHz Oscillator (SIRC)

26.1 Introduction

This internal RC oscillator provides the 128 kHz clock with high accuracy, low power consumption, fast stabilization, and fast recovery.

26.2 Features

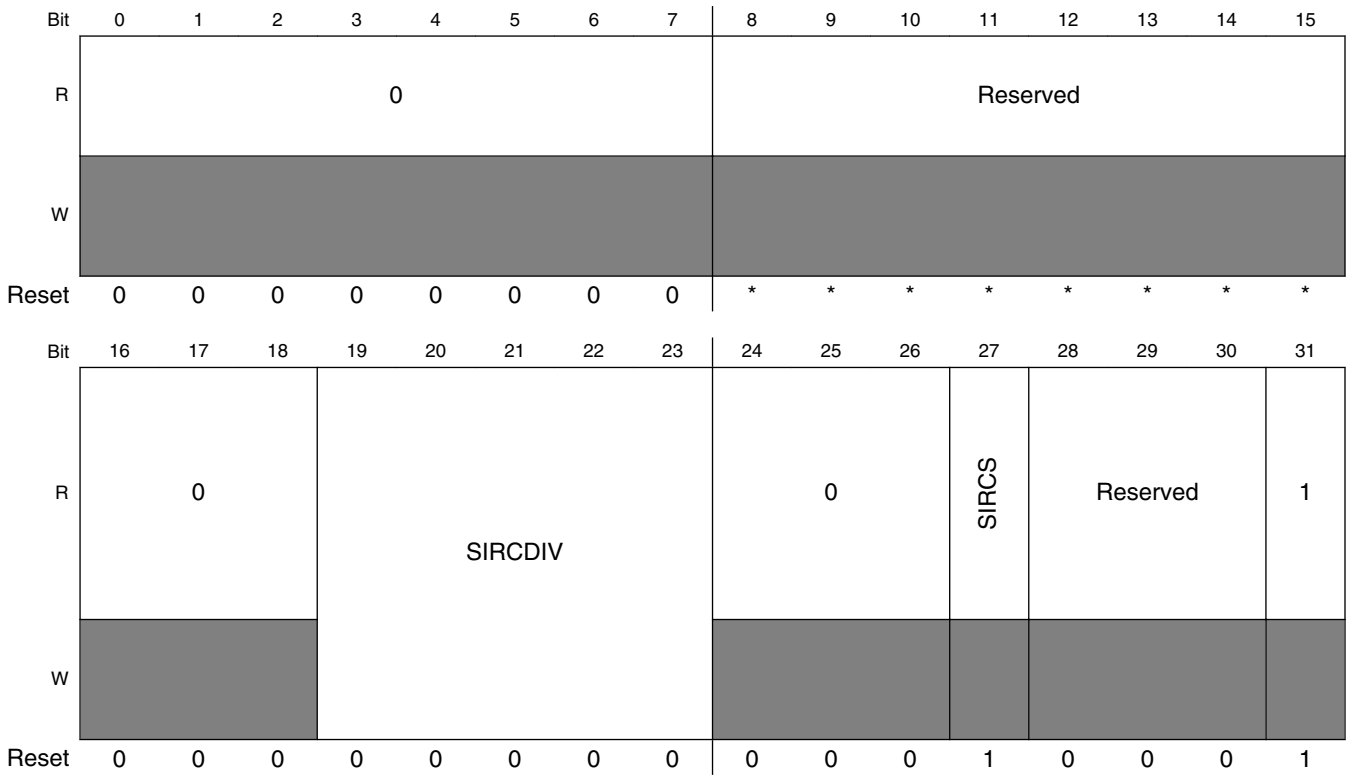
Key features of the 128 kHz SIRC module are as follows:

- Operating voltage generated internally from V_{DD_LV}
- Nominal frequency (F_{nom}) of 128 kHz
- Frequency accuracy
- Low current consumption

26.3 Memory map and register definition

The following section shows the memory map and explains the register.

SIRC memory map



Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Control register (SIRC_CTL)	32	R/W	See section	26.3.1/601

26.3.1 Control register (SIRC_CTL)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 0h offset = 0h

* Notes:

- Reserved field: These fields may be written during reset, and their values will be change. Please consult the "Clocking Overview" chapter in this document for more information on field values after reset.

SIRC_CTL field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 Reserved	This field is reserved.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 SIRCDIV	The SIRC Divider bits select the clock divider . factor 00000 1 00001 2 00010 3 11111 32
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

SIRC_CTL field descriptions (continued)

Field	Description
27 SIRCS	Describes the SIRC clock status. 0 IRC is not providing a stable clock. 1 IRC is providing a stable clock.
28–30 Reserved	This field is reserved.
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.

26.4 Functional description

The clock provided by SIRC is always on in the normal mode after startup. The stabilization time from startup is shorter than 16 clock cycles. The SIRC_CTL[SIRCS] bit is set once the clock is stable.

The clock can be further divided by a configurable division factor in the range 1 to 32 to generate the divided clock to match system requirements. This division factor is specified by SIRC_CTL[SIRCDIV]. The on-off in standby mode is configurable by writing to ME_STANDBY0_MC[SIRCON].

Chapter 27
Fast Internal 16 MHz RC Oscillator (FIRC)

27.1 Introduction

This internal RC oscillator provides the 16 MHz clock with high accuracy, low-power, fast stabilization, and fast recovery.

27.2 Features

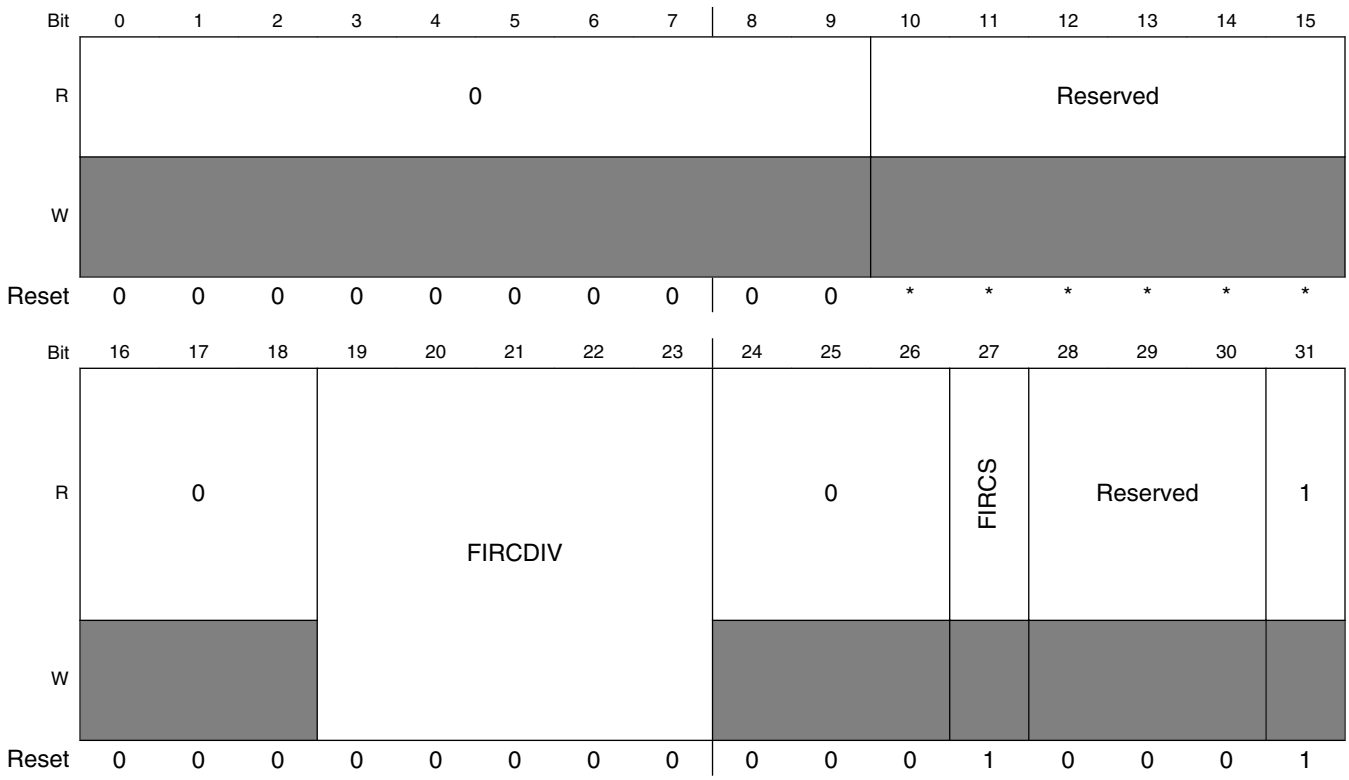
Key features of the 16 MHz FIRC module include:

- Operation from internally generated power supply (3 V or 5 V, with support down to 2.7 V)
- Nominal frequency (F_{nom}) of 16 MHz
- Frequency accuracy
- Low current consumption
- Ultra fast stabilization, enabling fast recovery in less than 16 cycles

27.3 Memory map and register definition

The following section shows the memory map and explains the register.

FIRC memory map



Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Control register (FIRC_CTL)	32	R/W	See section	27.3.1/606

27.3.1 Control register (FIRC_CTL)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 0h offset = 0h

* Notes:

- Reserved field: These reserved fields may be written during reset, and their values will be change. Please consult the "Clocking Overview" chapter in this document for more information on field values after reset.

Field	Description
	00001 2 00010 3 11111 32
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 FIRCS	Describes the FIRC clock status. 0 FIRC is not providing a stable clock. 1 FIRC is providing a stable clock.
28–30 Reserved	This field is reserved.
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.

27.4 Functional description

The clock provided by FIRC is always on in the normal mode after startup. The stabilization time from startup is less than 16 clock cycles. Once the clock is stable, the FIRC_CTL[FIRCS] bit is set.

The clock can be further divided by a configurable division factor in the range 1 to 32 to generate the divided clock to match system requirements. This division factor is specified by FIRC_CTL[FIRCDIV]. The on-off in Standby mode is configurable by writing to ME_STANDBY0_MC[FIRCON].

Chapter 28
Slow External 32 KHz Oscillator (SXOSC)

28.1 Introduction

The slow external 32 KHz oscillator (SXOSC) provides a 32 KHz clock with control and status registers accessible for use by applications.

28.2 Features

Key features of the 32 KHz SXOSC module include:

- Operation from internally generated power supply (3 V or 5 V)
- Frequency (F_{nom}) — 32 KHz crystal
- Voltage and Frequency filtering to guarantee clock frequency and stability
- Power Consumption target: 5 µA
- Startup time lower than 2 sec

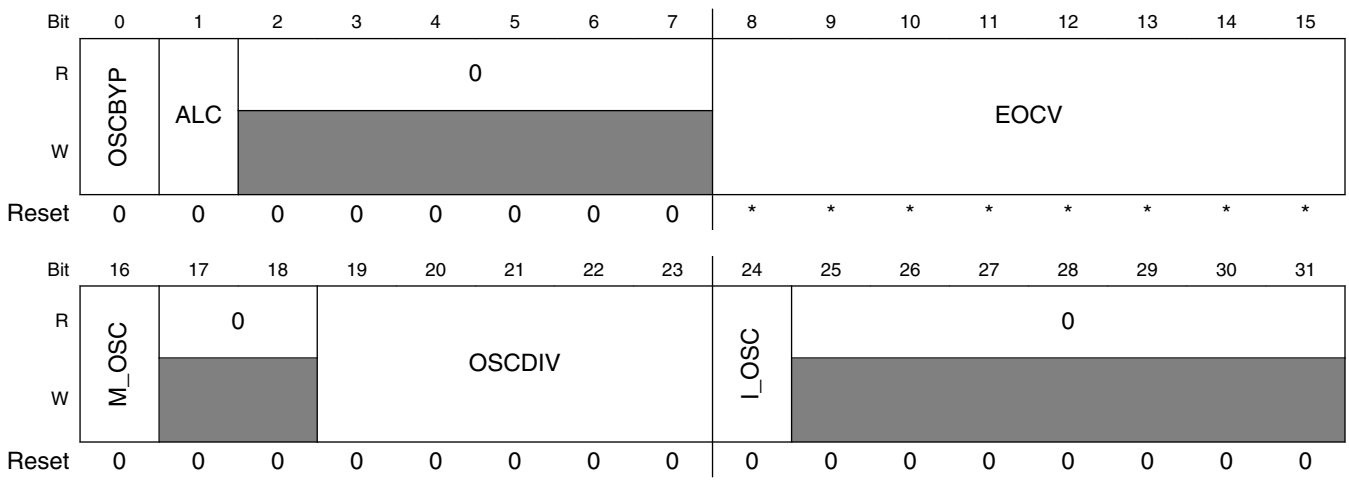
28.3 Memory map and register definition

The following section shows the memory map and explains the register.

SXOSC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	SXOSC_CTL	32	R/W	See section	28.3.1/610

28.3.1 SXOSC_CTL



Access:

- Supervisor read/write
- User read/write

NOTE

"Write should be restricted to SXOSC when not being used as a clock".

Address: 0h base + 0h offset = 0h

* Notes:
- EOCV field: See Clocking chapter for reset value.

SXOSC_CTL field descriptions

Field	Description
0 OSCBYP	Oscillator start-up delay bypass This bit specifies whether to bypass the EOCV counter, which provides startup stabilization time for the crystal oscillator. When this bit is set, the oscillator starts immediately when the SXOSC is selected, instead of waiting for the stabilization time to elapse. The user can only set this bit. System reset is needed to clear this bit. 0 The EOCV counter is not bypassed, and the oscillator starts after the stabilization period has elapsed.. 1 The EOCV counter is bypassed, and the oscillator starts immediately.
1 ALC	Auto Level Control The ALC bit controls the current provided to the crystal. When set, the amplitude of the crystal is reduced by approximately one-third to one-half. This helps limit noise, limits power consumption, and may improve crystal life. When cleared, the amplitude of the crystal is at its maximum, which may help to prevent erratic clock generation in a very noisy environment.The customer should initially set this bit to see whether their system will maintain good clock generation at the lower power level.

Table continues on the next page...

SXOSC_CTL field descriptions (continued)

Field	Description
	0 Auto level control is disabled. 1 Auto level control is enabled.
2–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 EOCV	End of Counter Value These bits specify the end of the count value to be used for comparison by the SXOSC stabilization counter OSCCNT after reset or whenever it is switched on from the off state. This counting period ensures that the external oscillator clock signal is stable before it can be selected by the system. When the oscillator counter reaches the value EOCV*512, the oscillator available interrupt request is generated. The reset vaule of this field depends on the device specification. The OSCCNT counter is kept under reset if oscillator bypass mode is selected.
16 M_OSC	SXOSC clock interrupt mask 0 SXOSC clock interrupt is masked. 1 SXOSC clock interrupt is enabled.
17–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 OSCDIV	The SXOSC Divider bits select the clock divider factor. 00000 1 00001 2 00010 3 .. --- 11111 32
24 I_OSC	SXOSC clock interrupt This bit is set by hardware when the OSCCNT counter reaches the count value of EOCV × 512. It is cleared by software. 0 No SXOSC interrupt has occurred. 1 SXOSC interrupt is pending.
25–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

28.4 Functional description

The SXOSC frequency oscillator includes an internal oscillator driver, a controller, and external crystal circuitry. It provides an output clock that can be used to clock a PLL or as a reference clock to specific modules, depending on system needs. The SXOSC can be powered down and then restarted by the user whenever required.

Whenever the SXOSC is switched on, the OSCCNT counter starts. When it reaches the value of EOCV × 512, the SXOSC clock is made available to the system. The availability status is provided. Depending on the setting of the SXOSC_CTL[I_OSC] bit, an interrupt will be generated if the SXOSC_CTL[M_OSC] is set.

The SXOSC can be bypassed by setting the SXOSC_CTL[OSCBYP] bit. This can only be set by the user. It is disabled in default. In this bypass mode (OSCBYP is set), the output clock has the same polarity as the external clock applied on the EXTAL pin. The oscillator status is forced to 1, and the bypass configuration is independent of the power-down mode of the oscillator.

The SXOSC output can be further divided by a configurable factor in the range 1 to 32 to generated the divided clock to match system requirements. This factor is specified by SXOSC_CTL[OSCDIV].

Chapter 29
Fast OSC Digital Interface (FXOSC)

29.1 Introduction

The FXOSC digital interface is used to control the on-chip oscillator (FXOSC) and provide the register interface for the programmable features. Selection of the FXOSC as a source clock is controlled by the Clock Generation Module (MC_CGM). The FXOSC is enabled and disabled by configuring the Mode Entry Module (MC_ME).

The programmable features of the FXOSC digital interface are as follows:

- Oscillator power-down control and status
- Oscillator startup delay
- Oscillator clock available interrupt
- Oscillator bypass mode control
- Output clock division factors ranging from 1, 2, 3…32
- Crystal oscillator mode selection
    - Loop Controlled Pierce Mode (LCP)
    - Full Swing Pierce Mode (FSP)

29.2 Functional description

The FXOSC digital interface provides control of the on-chip oscillator and the register interface for the mode, internal divider, and startup delay control. The oscillator provides an output clock that is used as an input to the PLL and can be selected as the reference clock for many of the peripherals on the device.

The table below shows the possible configurations of the FXOSC.

Table 29-1. FXOSC configurations

OSC EN (from MC_ME)	FXOSC_CTL[OSCBYP]	XTAL	EXTAL	FXOSC Output	FXOSC MODE
0	0	Crystal, or left opened	Crystal, or left opened	0	Power down, IDDQ
0	1	x	external clock	Undefined	Reserved, OSC Disabled
1	1	x	external clock	XTALOUT	Bypass, OSC Enabled
1	0	crystal	crystal	XTALOUT	Normal, OSC Enabled

29.2.1 Oscillator power-down control and status

Enabling and disabling of the oscillator is done in the Mode Entry (MC_ME) module (see "Mode Entry Module (MC_ME)" chapter). The ME_<*mode*>_MC[XOSCON] controls the power down of oscillator based on the current device mode (see "MC_ME Memory Map" table for available *modes*). The status of the FXOSC is shown in the MC_ME_GS[S_XOSC].

29.2.2 Oscillator startup delay

In order to allow the oscillator to reach full amplitude before use, the internal counter (OSCCNT) is started when the device exits reset. The counter is driven by the oscillator output clock. When the counter reaches FXOSC_CTL[EOCV] × 512, a signal is sent to the MC_ME module, allowing a mode switch to the oscillator (when used as a system clock or an input to the PLL).

The default value for this field after reset depends on implementation and can be found in the FXOSC Device Configuration. After reset, software can clear or change the EOCV field in order to shorten or lengthen the delay until the oscillator is ready.

Note

It is advised that if the EOCV value is modified it should be done as early as possible in user code. This will ensure that the new value will be used before OSCCNT reaches the count value.

29.2.3 Oscillator clock available interrupt

An interrupt can be generated when the count value is reached (OSCCNT = FXOSC_CTL[EOCV] × 512). The FXOSC_CTL[I_OSC] will be set and an interrupt will be generated if the interrupt mask is set (FXOSC_CTL[M_OSC] = 1).

29.2.4 Oscillator bypass mode

The oscillator circuit can be bypassed by setting FXOSC_CTL[OSCBYP]. This field can only be set by software and is only cleared by a system reset. In bypass mode, the oscillator is disabled and the input clock on the EXTAL pins is level-shifted and driven to the logic on the device. The power-down mode has priority over the bypass configuration for FXOSC.

NOTE

The external oscillator must be running before the FXOSC is turned off. If FXOSC is being turned on, the status will be updated only after the clock starts toggling.

NOTE

The FXOSC will automatically be enabled until RTC auto calibration is active. Once RTC auto calibration is complete, the FXOSC will transition to power-down.

NOTE

Power down from the MC_ME will have no effect on the oscillator. The bypass clock will continue running in the device. It is ensured that mode transitions from the MC_ME complete successfully by providing bypass information to the MC_ME.

29.2.5 Crystal oscillator mode selection

There are two oscillator mode selections possible, Full Swing Pierce mode and Loop Controlled Pierce mode. The operating mode is selected by configuring the FXOSC_CTL[OSCM].

29.2.5.1 Loop Controlled Pierce mode

Loop Controlled Pierce mode (LCP) is the default oscillator mode. LCP has the following attributes:

- Provides a smaller frequency range
- Limits the amplitude of the crystal oscillation utilizing Amplitude Loop Control (ALC)
- Reduced EMI
- Reduced power consumption
- Shorter settling time
- Crystal is exposed to reduced stress since the amplitude is reduced
- Reduced number of external components, feedback resistor already integrated

29.2.5.2 Full Swing Pierce mode

Full Swing Pierce mode (FSP) has the following attributes when compared with LCP:

- Provides a wider frequency range
- Less susceptible to noise
- The crystal amplitude is rail-to-rail
  - Distorted oscilation with several harmonics
  - Increased EMI
- Slower settling time
- Feedback resistor and 300 ohms of current limitation are already integrated.

NOTE

Consult with crystal supplier to determine the need of extra resistance in XTAL to avoid crystal overdrive.

29.2.6 Oscillator divider

The oscillator output can be divided down if needed by the user. The CTL[OSCDIV] allows for the output of the FXOSC to be divided by values from 1…32 in increments of 1.

29.3 Memory map and register definition

FXOSC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	FXOSC Control Register (FXOSC_CTL)	32	R/W	See section	29.3.1/617

29.3.1 FXOSC Control Register (FXOSC_CTL)

NOTE

After reset, writing the FXOSC_CTL register would override the fuse values with the IPS write or reset value (depending upon the type of register access).

NOTE

The FXOSC_CTL is only writable in supervisor mode.

Address: 0h base + 0h offset = 0h

FXOSC_CTL field descriptions

Field	Description
0 OSCBYP	Crystal Oscillator bypass This bit specifies whether the oscillator should be bypassed or not. Software can only set this bit. System reset is needed to reset this bit. 0 Oscillator output is used as root clock. 1 EXTAL is used as root clock.
1 OSCM	Crystal Oscillator Mode. This bit selects the oscillator mode when not in bypass. **NOTE:** User should not change the OSCM bit while crystal is being used. 0 FSP mode (full swing pierce mode) 1 LCP mode (loop controlled pierce mode)
2 Reserved	This field is reserved.
3–7 Reserved	This field is reserved.
8–15 EOCV	End of Count Value These bits specify the end of count value to be used for comparison by the oscillator stabilization counter OSCCNT after reset or whenever it is switched on from the off state. This counting period ensures that external oscillator clock signal is stable before it can be selected by the system. When oscillator counter reaches the value EOCV × 512, oscillator available interrupt request is generated. The OSCCNT counter is kept under reset if oscillator bypass mode is selected. **NOTE:** In order to find the appropriate EOCV value, it should be ensured that the internal counter be run for at least the stabilization time of the crystal as given in the Data Sheet.
16 M_OSC	Crystal oscillator clock interrupt mask This bit masks the I_OSC interrupt bit. 0 Crystal oscillator clock interrupt is masked. 1 Crystal oscillator clock interrupt is enabled.
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 OSCDIV	Crystal oscillator clock division factor These bits specify the crystal oscillator output clock division factor. The output clock is divided by the factor OSCDIV+1.
24 I_OSC	Crystal oscillator clock interrupt This bit is set by hardware when OSCCNT counter reaches the count value EOCV × 512. It is cleared by software by writing 1.

31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Chapter 30
Clock Monitor Unit (CMU)

30.1 Introduction

The Clock Monitor Unit (CMU), also referred to as Clock Quality Checker or Clock Fault Detector, serves three purposes:

- Measures the frequency of clock sources CLKMT0_RMN/CLKMT1/CLKMT2 with CLKMN0_RMT as the reference clock
- Monitors CLKMN0_RMT frequency with CLKMT0_RMN as reference clock
- Monitors CLKMN1 frequency with CLKMT0_RMN as reference clock and detects if the monitored clock frequency leaves an upper or lower frequency boundary

NOTE

See the "Clocking" chapter for chip-specific sources used by the CMU.

One of the tasks is to supervise the integrity of the various clock sources on the chip, for example CLKMN0_RMT or CLKMN1. If the monitored clock frequency is less than the reference clock, or it violates an upper or lower frequency boundary, the CMU detects and reports this event. These events signal the FCCU, which can take the necessary corrective actions as its configuration dictates.

The CMU can monitor CLKMN0_RMT, which must have a frequency higher than that of CLKMT0_RMN divided by the factor shown in CMU_CSR[RCDIV], and reports this event. The CMU can also monitor CLKMN1 and generate an event if CLKMN1 is greater than a high frequency boundary or less than a low frequency boundary. The upper and lower frequency boundaries are defined by the CMU High Frequency Reference Register (CMU_HFREFR) and CMU Low Frequency Reference Register (CMU_LFREFR).

The second task of the CMU is to provide a frequency meter, which allows measuring the frequency of a clock source against a reference clock. This is useful to allow the calibration of the metered clocks (such as CLKMT0_RMN, CLKMT1, CLKMT2), as well as to be able to correct/calculate the time deviation of a counter that is clocked by the metered clocks.

NOTE

See the "Clocking" chapter for the number of CMU instances on this chip.

30.1.1 Main features

- CLKMT0_RMN, CLKMT1, CLKMT2 frequency measurement with CLKMN0_RMT as reference clock.
- CLKMN0_RMT monitoring with respect to CLKMT0_RMN ÷ $2^{CSR[RCDIV]}$ clock.
- Upper or lower frequency boundary monitoring of CLKMN1 with respect to CLKMT0_RMN ÷ 4.
- Event generation for various failures detected inside monitoring unit.

30.2 Block diagram

The block diagram of the CMU module(s) is shown in the “Clocking" chapter of this Reference Manual.

30.3 Signals

The table below describes the signals on the boundary of the CMU (in alphabetical order).

Table 30-1. Signal description

Signal	I/O	Description
CLKMN0_RMT	I	Monitored Clock Signal 0/Metered Clock Signal Reference — Receives a clock signal that the CMU compares to a specified low-limit frequency to determine whether the frequency of the clock signal is greater than the specified limit. Also provides a reference clock signal for all metered clock signals.
CLKMN1	I	Monitored Clock Signal 1 — Receives a clock signal that the CMU compares to specified low-limit and high-limit frequencies to determine whether the frequency of the clock signal is between the specified limits.

Table continues on the next page...

Table 30-1. Signal description (continued)

Signal	I/O	Description
CLKMT0_RMN	I	Metered Clock Signal 0/Monitored Clock Signal Reference — Receives a clock signal that the CMU measures against a reference clock frequency. Also provides a reference clock signal for all monitored clock signals.
CLKMT1	I	Metered Clock Signal 1 — Receives a clock signal that the CMU measures against a reference clock frequency.
CLKMT2	I	Metered Clock Signal 2 — Receives a clock signal that the CMU measures against a reference clock frequency.

NOTE

See the "Clocking" chapter for device specific clock sources of each CMU.

30.4 Register description and memory map

This section describes in address order all the CMU registers. Each description includes a standard register diagram with an associated figure number. The CMU memory map is listed in the following table.

NOTE

See "Clocking" chapter for register and field availability details.

CMU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	CMU Control Status Register (CMU_CSR)	32	R/W	See section	30.4.1/624

- RCDIV field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.
- CKSEL1 field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.
- SFM field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.

CMU_CSR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 SFM	Start frequency measure. The software can only set this bit to start a clock frequency measure. It is reset by hardware when the measure is ready in the CMU_FDR. **NOTE:** MSR[MD] must be written before enabling frequency measurement (CSR[SFM] = 1). Do not write MDR[MD] while CSR[SFM] = 1. 0 Frequency measurement is completed or not yet started 1 Frequency measurement is not completed
9–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 CKSEL1	Frequency measure clock selection bit. CKSEL1 selects the clock to be measured by the frequency meter. This only affects CMU instances that utilizes clock metering. Not all CMU blocks will utilize this feature. See the “Clocking” chapter for device specific CMU implementation details. 00 CLKMT0_RMN is selected 01 CLKMT1 is selected 10 CLKMT2 is selected 11 CLKMT0_RMN is selected
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

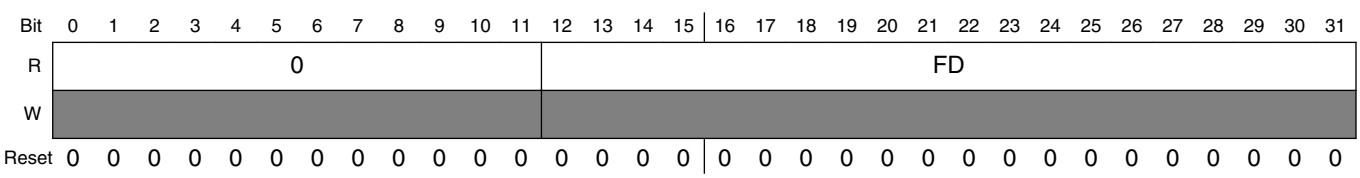
Table continues on the next page...

CMU_CSR field descriptions (continued)

Field	Description
29–30 RCDIV	CLKMT0_RMN division factor. These bits specify the CLKMT0_RMN division factor. The output clock frequency is $f_{CLKMT0_RMN} \div 2^{CMU_CSR[RCDIV]}$. This output clock is used as reference clock to compare with CLKMN0_RMT for crystal clock monitor feature. 00 CLKMT0_RMN ÷ 1 (No division) 01 CLKMT0_RMN ÷ 2 10 CLKMT0_RMN ÷ 4 11 CLKMT0_RMN ÷ 8
31 CME	CLKMN1 monitor enable. 0 CLKMN1 monitor is disabled 1 CLKMN1 monitor is enabled

30.4.2 CMU Frequency Display Register (CMU_FDR)

The CMU_FDR is used to determine the measured frequency of:



- CLKMT0_RMN
- CLKMT2
- CLKMT1

with respect to the reference clock CLKMN0_RMT.

NOTE

The CMU_FDR should be read only when CMU_CSR[SFM] = 0.

Address: 0h base + 4h offset = 4h

CMU_FDR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 FD	Measured frequency bits. This register displays the measured frequency (f_{sel}) with respect to the reference clock (f_{CLKMN0_RMT}). The measured value is given by the following formula: $f_{sel} = (f_{CLKMN0_RMT} \times CMU_MDR[MD]) \div CMU_FDR[FD]$

30.4.3 CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)

The HFREFR is configured for the high frequency reference that the CMU will use for comparing against the monitored clock. The figure and table below show the CMU_HFREFR register.

NOTE

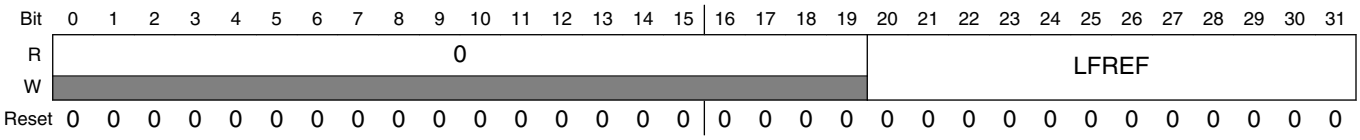
For correct synchronization of CMU_HFREFR write data, the user must ensure that a time interval of 10 peripheral bus clock cycles + 40 CLKMT0_RMN clock cycles elapses before attempting subsequent writes to the same register.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																0				HFREF											
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1

CMU_HFREFR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 HFREF	High Frequency reference value. These bits determine the high reference value for the CLKMN1 frequency. The reference value is given by: (HFREF ÷ 16) × (f_{CLKMT0_RMN} ÷ 4).



30.4.4 CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)

The LFREFR is configured for the low frequency reference that the CMU will use for comparing against the monitored clock. The figure and table below show the CMU_LFREFR register.

NOTE

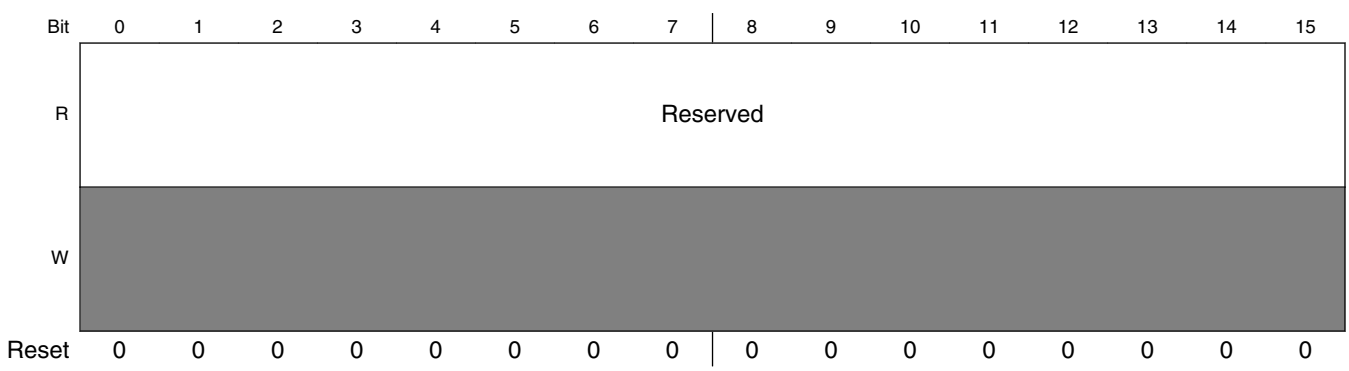
For correct synchronization of CMU_LFREFR write data, the user must ensure that a time interval of 10 peripheral bus clock cycles + 40 CLKMT0_RMN clock cycles elapses before attempting subsequent writes to the same register.

Address: 0h base + Ch offset = Ch

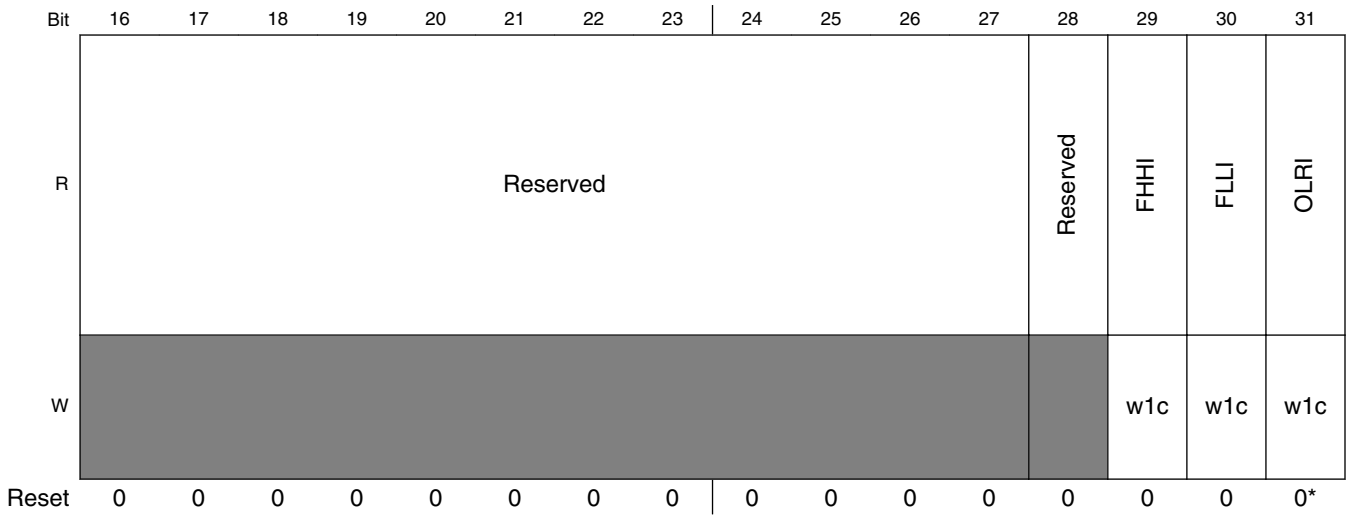
CMU_LFREFR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 LFREF	Low Frequency reference value. These bits determine the low reference value for the CLKMN1 frequency. The reference value is given by: (LFREF ÷ 16) × (f_{CLKMT0_RMN} ÷ 4).

30.4.5 CMU Interrupt Status Register (CMU_ISR)



NOTE



All flags in the CMU_ISR are set asynchronously. This register must be read only after a CMU event is triggered. Otherwise, a read access on this register may fetch an incorrect value (see "Clocking" chapter for interrupt operation) .

NOTE

Before entering low-power stop modes, all clock frequency measurements in the CMU should be disabled. Failing to do so may result in ISR flags being spuriously set.

Address: 0h base + 10h offset = 10h

* Notes:
- OLRI field: Not all CMU blocks will utilize this feature. See the "Clocking" chapter for specific CMU implementation details.

CMU_ISR field descriptions

Field	Description
0–27 Reserved	This field is reserved.
28 Reserved	This field is reserved. **NOTE:** This bit will show indeterministic behavior if the clock monitored by the CMU is not enabled .
29 FHHI	CLKMN1 frequency higher than high reference event status. This bit is set by hardware when CLKMN1 frequency becomes higher than the high frequency reference value determined by CMU_HFREFR[HFREF] and CLKMN1 is 'ON' as signaled by the MC_ME. It can be cleared by software by writing '1'. 0 No FHH event 1 FHH event occurred
30 FLLI	CLKMN1 frequency less than low reference event status. This bit is set by hardware when CLKMN1 frequency becomes lower than the low frequency reference value determined by CMU_LFREFR[LFREF], and CLKMN1 is 'ON' as signaled by the MC_ME. Software clears this field by writing a '1'. **NOTE:** This bit will show indeterministic behavior if the clock monitored by the CMU is not enabled . 0 No FLL event 1 FLL event occurred
31 OLRI	Oscillator frequency less than $f_{CLKMT0_RMN} \div 2^{CMU_CSR[RCDIV]}$event status. This bit is set by hardware when the f_{CLKMN0_RMT} is less than $f_{CLKMT0_RMN} \div 2^{CMU_CSR[RCDIV]}$frequency and CLKMN0_RMT is 'ON' as signaled by the MC_ME. It can be cleared by software by writing '1'. **NOTE:** While entering STOP mode, OLRI may be triggered due to stoppage of XOSC. To avoid this, disable the XOSC before entering STOP mode.

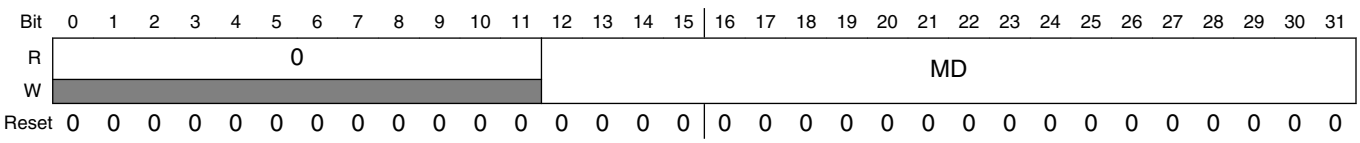


Table continues on the next page...

CMU_ISR field descriptions (continued)

Field	Description
	0 No OLR event 1 OLR event occurred

30.4.6 CMU Measurement Duration Register (CMU_MDR)

Address: 0h base + 18h offset = 18h

CMU_MDR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 MD	Measurement duration bits This field displays the measurement duration in terms of selected clock (CLKMT0_RMN, CLKMT1, CLKMT2) cycles. This value is loaded in the frequency meter down-counter. The down-counter starts counting when CMU_CSR [SFM] = 1. **NOTE:** Only values that do not cause a CMU_FDR[FD] overflow shall be written to CMU_MDR[MD]. There is no internal status of a CMU_FDR[FD] overflow.

30.5 Functional description

30.5.1 Frequency meter

The purpose of the frequency meter is to evaluate the deviation from the nominal metered source (such as CLKMT0_RMN, CLKMT2, CLKMT1) frequencies. This in turn allows either recalibration of these clocks or other timing corrections. Programming of the CMU_CSR[CKSEL1] field is used to select one of the metered clocks from a multiplexer that drives a simple Frequency Meter (see the CMU Block Diagram in the "Clocking" chapter). The reference clock for the Frequency Meter is the CLKMN0_RMT signal. The measurement starts when CMU_CSR[SFM] = 1. The measurement duration is given by the contents of CMU_MDR[MD] in terms of number of clock cycles of the selected metered clock. The CMU_CSR[SFM] bit is cleared by hardware once the frequency

measurement is complete and the count is loaded in CMU_FDR[FD]. The frequency of the selected clock (f_{sel}) can be derived from the value loaded in the CMU_FDR[FD] as shown in the following equation:

$$f_{sel} = f_{CLKMN0_RMT} \times \frac{CMU_MDR[MD]}{CMU_FDR[FD]}$$

30.5.2 CLKMN0_RMT supervisor

If frequency of CLKMN0_RMT is smaller than the frequency of CLKMT0_RMN $\div 2^{CMU_CSR[RCDIV]}$ and CLKMN0_RMT is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[OLRI].
- The CMU asserts the OLR signal.

Note

f_{CLKMN0_RMT} must be greater than $f_{CLKMT0_RMN} \div 2^{CMU_CSR[RCDIV]}$ by at least 0.5 MHz in order to guarantee correct f_{CLKMN0_RMT} monitoring.

30.5.3 CLKMN1 supervisor

The frequency of CLKMN1(f_{CLKMN1}) can be monitored by programming CMU_CSR[CME] = 1. CLKMN1 monitoring starts as soon as CMU_CSR[CME] = 1. This monitor can be disabled at any time by programming CMU_CSR[CME] = 0.

If f_{CLKMN1} is greater than the reference value determined by fields CMU_HFREFR[HFREF] and CLKMN1 is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[FHHI].
- The CMU asserts the FHH signal.

If f_{CLKMN1} is less than a reference value determined by the bits CMU_LFREFR[LFREF] and the CLKMN1 is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[FLLI].
- The CMU asserts the FLL signal.

Note

An example of determining the $HFREF_{Actual}$ is as follows. Assume a f_{CLKMT0_RMN} = 16 MHz with a accuracy of +/-5% (see *Data Sheet* for actual value). In order to monitor a f_{CLKMN1} = 200 MHz, the ideal $HFREF_{Ideal}$ = 800. The actual HFREF value will be 842 when the accuracy is taken into consideration ($HFREF_{Actual}$ = ($HFREF_{Ideal}$ ÷ 0.95). The actual LFREF value will be 762 when accuracy is taken into consideration ($LFREF_{Actual}$ = $LFREF_{Ideal}$ ÷ 1.05).

Chapter 31
Clock Generation Module (MC_CGM)

31.1 Introduction

31.1.1 Overview

The clock generation module (MC_CGM) generates reference clocks for all the chip blocks. The MC_CGM selects one of the system clock sources to supply the system clock. The MC_ME controls the system clock selection (see the MC_ME chapter for more details). The memory spaces of system and peripheral clock sources which have addressable memory spaces are accessed through the MC_CGM memory space.

The following figure shows the MC_CGM block diagram.

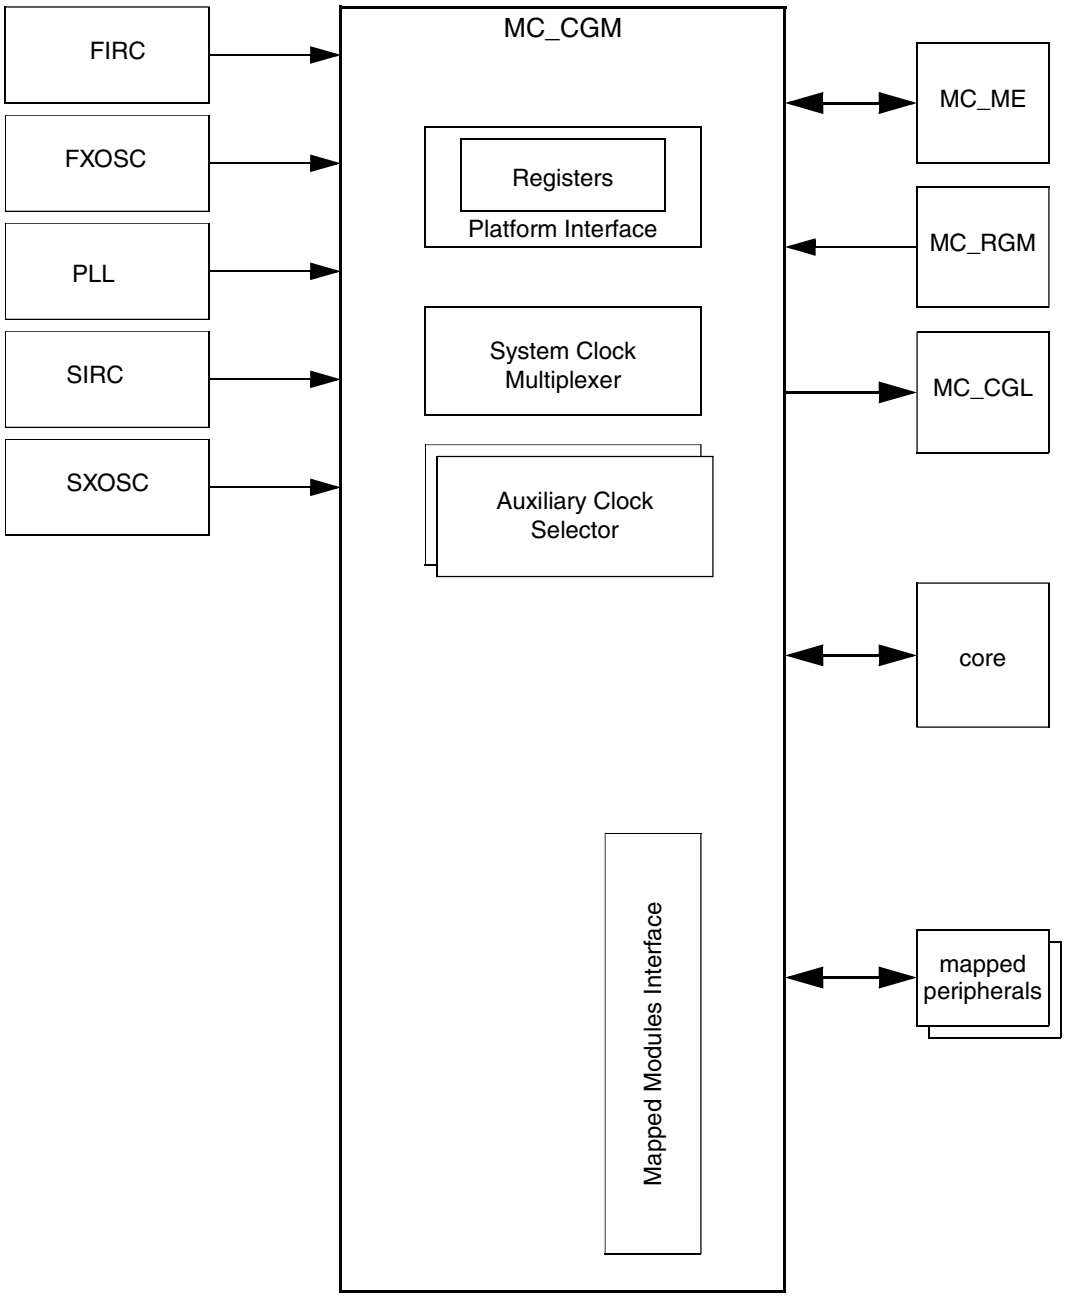

Figure 31-1. MC_CGM Block Diagram

31.1.2 Features

The MC_CGM includes the following features:

- generates system and peripheral clocks
- selects and enables/disables the system clock supply from system clock sources according to MC_ME control

- performs progressive system clock frequency change depending on MC_ME mode configuration
- contains a set of registers to control clock dividers for divided clock generation
- contains a set of registers to control peripheral clock selection
- contains IPS interface for mapped clock source modules
- supports multiple clock sources and maps their address spaces to its memory map
- supports 8, 16, and 32-bit wide read/write accesses

31.2 External Signal Description

The MC_CGM delivers output clocks to the CLKOUT0 and CLKOUT1 pins for off-chip use and/or observation.

31.3 Memory Map and Register Definition

Any access to unused registers as well as write accesses to read-only registers will:

- not change register content
- cause a transfer error

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the CGM_PCS_DIVC1 register RATE bits may be accessed as a word at address offset 0x0704, as a half-word at address offset 0x0706, or as a byte at address offset 0x0707.

MC_CGM_AC9_SS field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 SELSTAT	Auxiliary Clock 9 Source Selection Status — This value indicates the current source for auxiliary clock 9. 0 FS80 1 FXOSC
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

31.3.10 PCS Switch Duration Register (MC_CGM_PCS_SDUR)

This register contains the progressive system clock switching duration for each step. See Progressive System Clock Switching for details on how to set this value.

This register is reset only on POR reset.

Address: 0h base + 700h offset = 700h

Bit	0	1	2	3	4	5	6	7
Read Write	SDUR							
Reset	0	0	0	0	0	0	0	0

MC_CGM_PCS_SDUR field descriptions

Field	Description
0–7 SDUR	Switch Duration This value defines the duration of one PCS clock switch step in terms of 16 MHz int. RC osc. cycles.

31.3.11 PCS Divider Change Register 1 (MC_CGM_PCS_DIVC1)

This register defines the rate of frequency change and initial change value for the progressive system clock switching when switching the system clock source to or from the fast external crystal oscillator. See Progressive System Clock Switching for details on how to set these values.

This register is reset only on POR reset.

Address: 0h base + 704h offset = 704h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

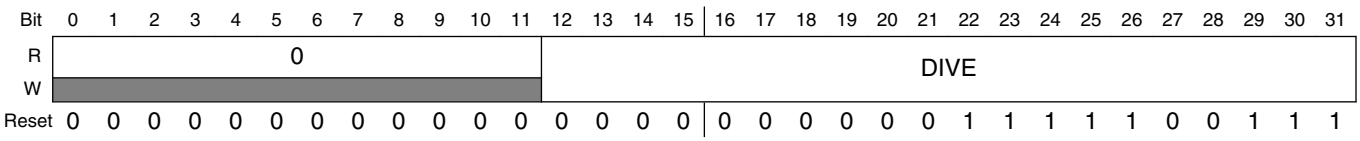
MC_CGM_PCS_DIVC1 field descriptions

Field	Description
0–15 INIT	Divider Change Initial Value This is initial change value of the clock divider for the clock ramp-up phase when switching to fast external crystal oscillator
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 RATE	Divider Change Rate This value controls the change value of the clock divider for the clock ramp-up and ramp-down phase when switching from the fast external crystal oscillator

31.3.12 PCS Divider End Register 1 (MC_CGM_PCS_DIVE1)



This register defines the final division value for the progressive system clock switching when switching from or to fast external crystal oscillator on ramp up and ramp down. See Progressive System Clock Switching for details on how to set this value.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

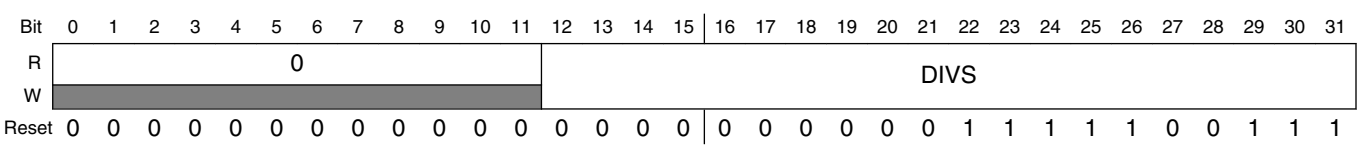
This register is reset only onPOR reset.

Address: 0h base + 708h offset = 708h

MC_CGM_PCS_DIVE1 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 DIVE	Divider End Value - This is the clock divider end value for the clock ramp-down phase when switching from the fast external crystal oscillator.

31.3.13 PCS Divider Start Register 1 (MC_CGM_PCS_DIVS1)



These registers define the initial division value on frequency ramp-up for the progressive system clock switching when switching the system clock from or to the fast external crystal oscillator on ramp up and ramp down. *n* . See Progressive System Clock Switching for details on how to set these values.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

This register is reset only on POR reset.

Address: 0h base + 70Ch offset = 70Ch

MC_CGM_PCS_DIVS1 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

MC_CGM_PCS_DIVS1 field descriptions (continued)

Field	Description
12–31 DIVS	Divider Start Value This is the start value of the clock divider for the clock ramp-up phase when switching to the fast external crystal oscillator

31.3.14 PCS Divider Change Register 2 (MC_CGM_PCS_DIVC2)

These registers define the rate of frequency change and initial change value on frequency ramp-up for the progressive system clock switching when switching to or from the PLL PHI0. See Progressive System Clock Switching for details on how to set these values.

NOTE

Byte write accesses are not allowed for the INIT field of this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

This register is reset only on POR reset.

Address: 0h base + 710h offset = 710h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

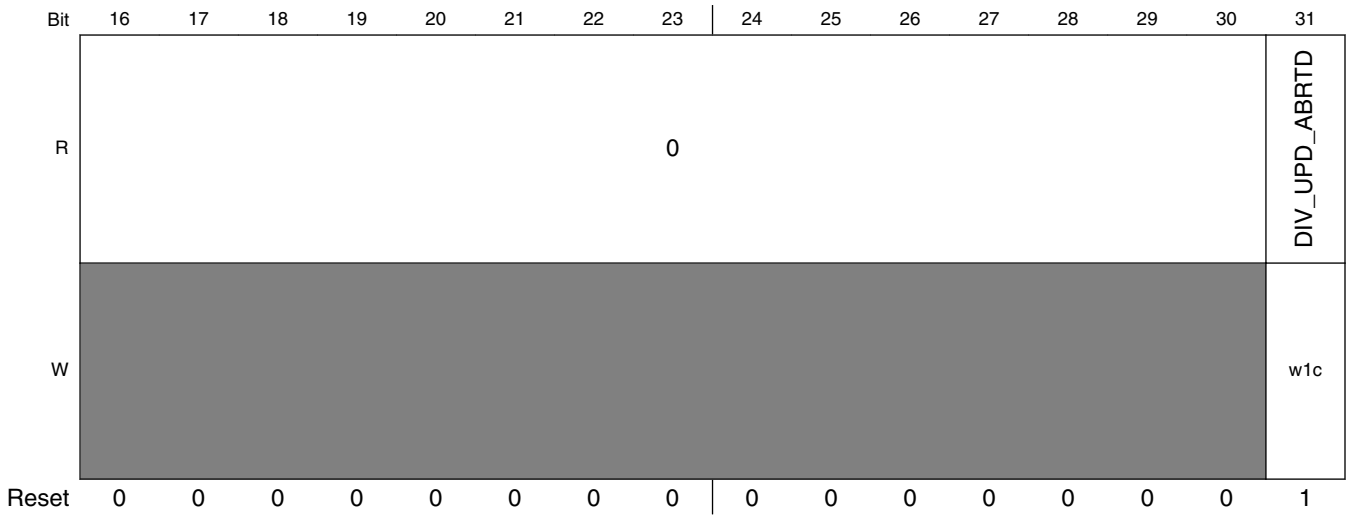
Table continues on the next page...

MC_CGM_PCS_DIVS2 field descriptions (continued)

Field	Description
12–31 DIVS	Divider Start Value - This is the start value of the clock divider for the clock ramp-up phase when switching to the PLL PHI0.



31.3.17 Divider Update Abort Register (MC_CGM_DIV_UPD_ABRTD)

This register provides the status of the halt handshake abort request, if any, from the system. Depending on when the halt abort request was received, the halt handshake may or may not be aborted. If the abort is successful and the dividers were not updated, the value of DIV_UPD_ABRTD is set as 1. In case the DIV_UPD_ABRTD bit is set, the software should clear the status by writing a 1 to bit 0 of this register and should initiate the divider update trigger at some later point. Till such a time that the dividers are updated again, the current division value of the dividers would not match the divider configuration.

This register is reset only on PHASE3 reset.

Address: 0h base + 7CCh offset = 7CCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MC_CGM_DIV_UPD_ABRTD field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 DIV_UPD_ ABRTD	Divider Update Aborted **NOTE:** At power-on reset or before initiating the divider update with Halt-protocol, the DIV_UPD_ABRTD register bit should be cleared by writing 1 to it. 1 The abort is successful and the dividers were not updated, the value of DIV_UPD_ABRTD is set to 1.

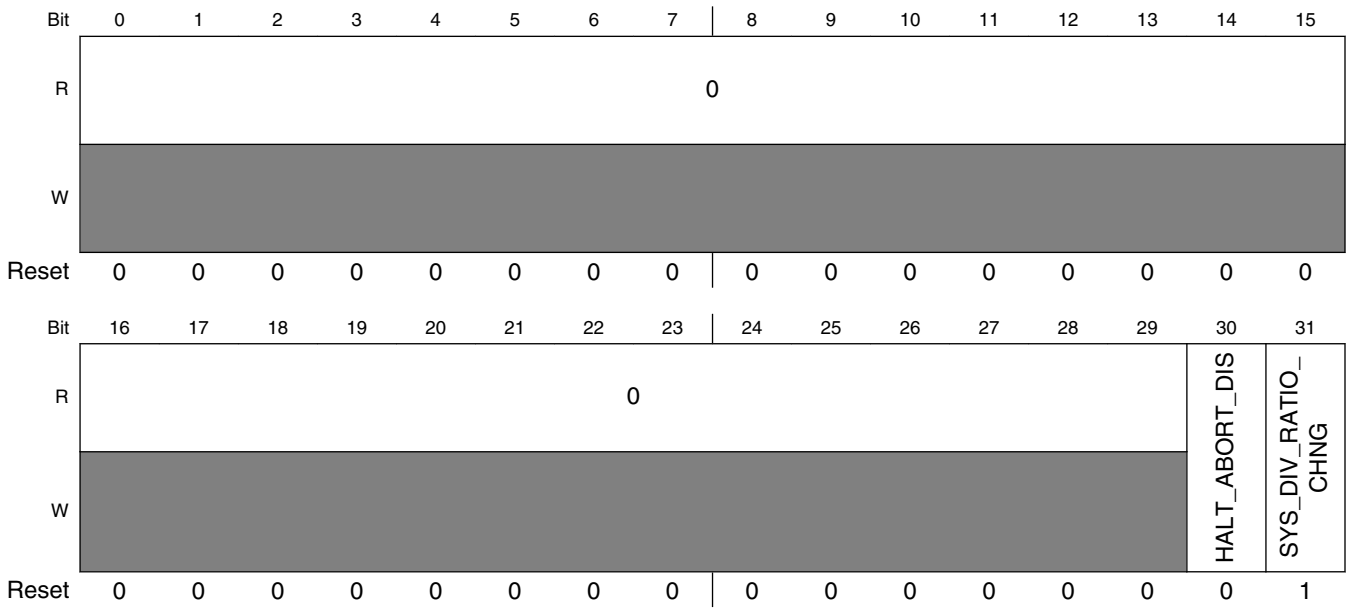
31.3.18 System Clock Divider Ratio Change Register (MC_CGM_SC_DIV_RC)

This register selects whether the system clock divider ratios will change from the current configuration to the configuration in the next update. If the value of SYS_DIV_RATIO_CHNG is ‘1’ at the time of a write to the CGM_DIV_UPD_TRIG register and a pre-loaded system clock divider update is pending, the crossbar is halted while the system clock divider update takes place. If the value of SYS_DIV_RATIO_CHNG is ‘0’, the crossbar switch is not halted. This register has no effect if the system clock divider update is configured in the CGM_DIV_UPD_TYPE register to be immediate.

An example of a divider ratio not changing is divider 0 changes from divide by 1 to divide by 2, and divider 1 changes from divide by 2 to divide by 4. The ratio is 1:2 in both configurations.

An example of a divider ratio changing is divider 0 changes from divide by 1 to divide by 2, and divider 1 changes from divide by 2 to divide by 6. The ratio changes from 1:2 to 1:3.

The value of SYS_DIV_RATIO_CHNG is returned to ‘1’ automatically on each write to the CGM_DIV_UPD_TRIG register.



Software must never write a ‘0’ to the SYS_DIV_RATIO_CHNG bit if the system clock divider ratios change from the current configuration to the next configuration. This can potentially cause errors in the crossbar which lead to lost data.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception (i.e., ips_xfr_err is not asserted), however the value will not be loaded with the new value.

This register is reset only on PHASE3 reset.

Address: 0h base + 7D0h offset = 7D0h

MC_CGM_SC_DIV_RC field descriptions

Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 HALT_ABORT_DIS	Halt Abort Disable Software can disable the abort of crossbar halt handshake by setting the HALT_ABORT_DIS bit as 1. 0 Halt handshake abort is enabled 1 Halt handshake abort is disabled
31 SYS_DIV_RATIO_CHNG	System Clock Divider Ratio Change For details see, Dynamic Frequency Scaling section 0 For linear DFS, the system clock divider ratios will not change with the next system clock divider configuration update. 1 For non-linear DFS, the system clock divider ratios will change with the next system clock divider configuration update.

31.3.19 Divider Update Type Register (MC_CGM_DIV_UPD_TYPE)

This register selects whether the dividers associated with a clock are updated immediately on writing to the corresponding divider configuration register or only on writing to the divider update trigger register CGM_DIV_UPD_TRIG, after which the pre-loaded configuration in the divider configuration registers will take effect.
For usage information, see section, “Divider Update Triggering”.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

This register is reset only on PHASE3 reset.

Address: 0h base + 7D4h offset = 7D4h

MC_CGM_DIV_UPD_TYPE field descriptions

Field	Description
0 SYS_UPD_TYPE	System Clock Divider Update Type 0 The configuration for each system clock divider is updated immediately on writing to the corersponding CGM_SC_DCi register 1 The configuration for each system clock divider is preloaded on writing to the corersponding CGM_SC_DCi register, and the pre-loaded configurations of all the system clock dividers are updated on writing to the CGM_DIV_UPD_TRIG register
1–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 Reserved	This field is reserved.
26–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

31.3.20 Divider Update Trigger Register (MC_CGM_DIV_UPD_TRIG)

This register selects whether the system clock divider ratios will change from the current configuration to the configuration in the next update. If the value of SYS_DIV_RATIO_CHNG is ‘1’ at the time of a write to the CGM_DIV_UPD_TRIG register and a pre-loaded system clock divider update is pending, the crossbar is halted while the system clock divider update takes place. If the value of SYS_DIV_RATIO_CHNG is ‘0’, the crossbar switch is not halted. This register has no effect if the system clock divider update is configured in the CGM_DIV_UPD_TYPE register to be immediate.

An example of a divider ratio not changing is divider 0 changes from divide by 1 to divide by 2, and divider 1 changes from divide by 2 to divide by 4. The ratio is 1:2 in both configurations.

An example of a divider ratio changing is divider 0 changes from divide by 1 to divide by 2, and divider 1 changes from divide by 2 to divide by 6. The ratio changes from 1:2 to 1:3.

The value of SYS_DIV_RATIO_CHNG is returned to ‘1’ automatically on each write to the CGM_DIV_UPD_TRIG register.

Software must never write a ‘0’ to the SYS_DIV_RATIO_CHNG bit if the system clock divider ratios change from the current configuration to the next configuration. This can potentially cause errors in the crossbar which lead to lost data.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

This register is reset only on PHASE3 reset.

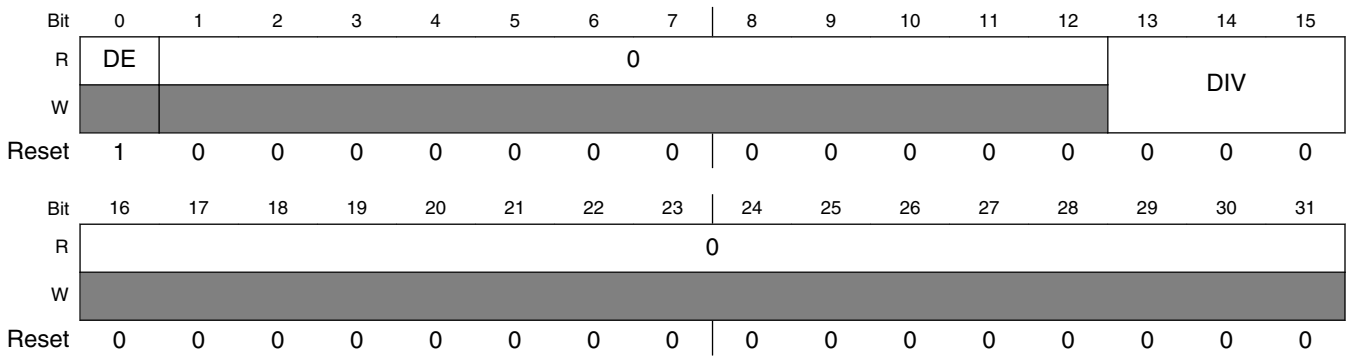
1. In such a case the system clock is switched to system clock source 0.

31.3.23 System Clock Divider 0 Configuration Register (MC_CGM_SC_DC0)



This register controls system clock divider 0 - S160 clock.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

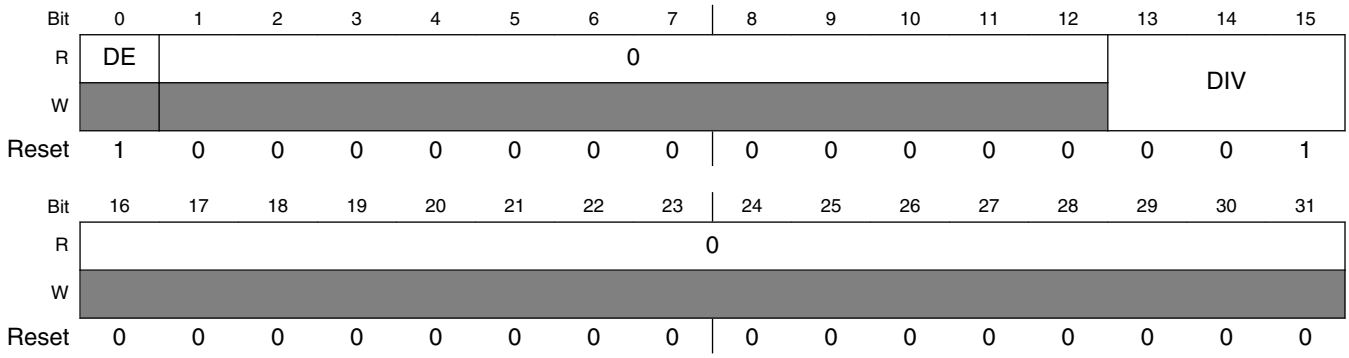
This register is reset only on POR reset, while on PHASE3 reset the clock divider loads the default reset value at the completion of division cycle corresponding to programmed value.

Address: 0h base + 7E8h offset = 7E8h

MC_CGM_SC_DC0 field descriptions

Field	Description
0 DE	Divider 0 Enable 1 Enable system clock divider 0
1–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 DIV	Divide 0 Division Value — The resultant S160 clock will have a period ‘DIV + 1’ times that of the system clock.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

31.3.24 System Clock Divider 1 Configuration Register (MC_CGM_SC_DC1)



DC1 register control selected modules working on system clock divider 1 - S80 clock.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

This register is reset only on POR reset, while on PHASE3 reset the clock divider loads the default reset value at the completion of division cycle corresponding to programmed value.

Address: 0h base + 7ECh offset = 7ECh

MC_CGM_SC_DC1 field descriptions

Field	Description
0 DE	Divider 0 Enable 1 Enable system clock divider 0
1–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 DIV	Divide 1 Division Value — The resultant S80 clock will have a period ‘DIV + 1’ times that of the system clock.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

31.3.25 System Clock Divider 2 Configuration Register (MC_CGM_SC_DC2)

This register controls system clock divider 2 - S40 clock.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

This register is reset only on POR reset, while on PHASE3 reset the clock divider loads the default reset value at the completion of division cycle corresponding to programmed value.

Address: 0h base + 7F0h offset = 7F0h

31.3.34 Aux Clock 6 Divider Configuration 0 for CLKOUT_0 (MC_CGM_AC6_DC0)

This register controls auxiliary clock 6 divider 0.

Access: User read, Supervisor read/write

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access does not result in an exception, however the value is not loaded with the new value.

This register is reset only on POR reset, while on PHASE3 reset the clock divider loads the default reset value at the completion of division cycle corresponding to programmed value.

Address: 0h base + 8C8h offset = 8C8h

31.4 Functional Description

31.4.1 System Clock Generation

The following figure shows the block diagram of the system clock generation logic. The MC_ME provides the system clock select and switch mask (see MC_ME chapter for more details), and the MC_RGM provides the safe clock request (see MC_RGM chapter for more details). The safe clock request forces the selector to select the 16 MHz internal RC oscillator as the system clock and to ignore the system clock select.

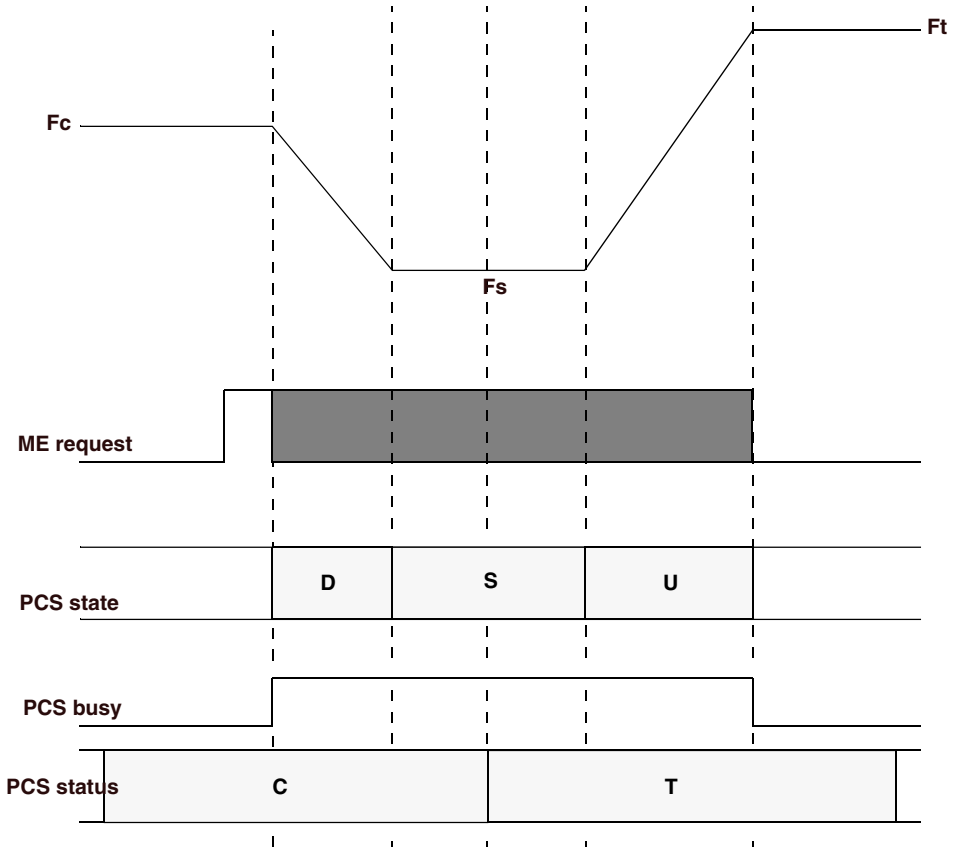
Note: MC_CGM_SC_DC1[DIV] and MC_CGM_SC_DC5[DIV] must be equal at all times.

Figure 31-2. MC_CGM System Clock Generation Overview

31.4.1.1 System Clock Source Selection

During normal operation, the system clock selection is controlled

- on a SAFE mode or reset event, by the MC_RGM via the safe_clock_req input
- otherwise, by the MC_ME via the clk_sys_src_sel input



31.4.1.2 Progressive System Clock Switching

Progressive clock switching (PCS) is an option which simplifies the load changes when transitioning between modes by first going to a lower frequency, of the 16 MHz IRC, and then ramping the frequency with the new clock source selected.

The diagram below shows the frequency change in a device using PCS when the system moves from Fc to Ft. The current clock or Fc is gradually divided using the PCS configuration registers to reach 16 MHz which is the safe clock freq (Fs). Once the current clock frequency comes down to Fs, a clock switch to IRC is made. At this point all the peripherals and cores are switched on/off to match the target configuration of the MC_ME registers. Then the clock is switched from IRC to the target clock with dividers configured such that the target clock is running at 16 MHz (Fs). After that the dividers are changed to get a gradual ramp up to the target frequency(Ft), at this point, the PCS divider is dividing the target clock by 1.

NOTE

PCS configuration should not be done if some communication peripherals e.g., FlexCAN, LinFlex which are required to be working in a seamless manner during mode transition.

Note:
C: Current clock, T: Target clock, D: Clock Ramp down, S: Safe clock, U: Clock Ramp up

Figure 31-3. Progressive System Clock Switching

Based on the power level values of the current and target modes, the MC_ME requests the MC_CGM to ramp the system clock frequency down and/or up. During ramp-down, the rate of the frequency change is based on the CGM_PCS_SDUR, CGM_PCS_DIVCn, and CGM_PCS_DIVEn registers, where n corresponds to the current system clock source selection. During ramp-up, the rate of the frequency change is based on the CGM_PCS_SDUR, CGM_PCS_DIVCn, and CGM_PCS_DIVSn registers, where n corresponds to the target system clock source selection.

It is recommended to program the PCS configuration registers (i.e. MC_CGM_PCS_SDUR, MC_CGM_PCS_DIVCn, MC_CGM_PCS_DIVEn and MC_CGM_DIVSn) with FIRC selected as the system clock. This ensures reliable progressive clock operation during the PCS register programming in case of a SAFE mode or RESET event.

31.4.1.2.1 Generic Clock Change Requirements

For a maximum allowed change of the frequency (f_{chg}) and for a given source clock frequency f_{src} (current or target clock source), the maximum allowed frequency change rate a_{max} is given in the following equation.

$$a_{max} = \frac{f_{chg}}{f_{src}}$$

Equation 6

31.4.1.2.2 Configuration of CGM_PCS_SDUR

The switch duration field CGM_PCS_SDUR[SDUR] defines the duration of one system clock switch step in terms of 16 MHz internal RC oscillator. After the expiration of this time, the module changes the clock divider value which chnages the frequency of the system clock.

31.4.1.2.3 Configuration of CGM_PCS_DIVC*n*[RATE]

For a given maximum allowed frequency change rate a_{max} the value d to be programmed into the PCS_DIVCn[RATE] register is given in the following table.

Table 31-1. MC_CGM CGM_PCS_DIVC*n*[RATE] Values

a_{max}	d = CGM_PCS_DIVC*n*[RATE]	CGM_PCS_DIVC*n*[RATE] in decimal	CGM_PCS_DIVC*n*[RATE] in hex
0.05	0.012	12	0x0C
0.10	0.048	48	0x30
0.15	0.112	112	0x70
0.20	0.184	184	0xB8

31.4.1.2.4 Generic Clock Change Properties

The number *k* of required steps to reach or leave the divided system clock with frequency f_{safe} from the source clock with frequency f_{src} is given in the following equation.

$$k = \left\lceil 0.5 + \sqrt{0.25 - \frac{2\left(1 - \frac{f_{src}}{16MHz}\right)}{d}} \right\rceil$$

Equation 7

31.4.1.2.5 Clock Ramp-Down

The clock ramp-down starts with the divider value 1 and with the given divider increment value PCD_DIVCn[RATE] and ends with the given divider value PCS_DIVEn[DIVE].

The divider end value for clock ramp-down is given in the following equation.

$$\text{PCS_DIVEn[DIVE]} = \frac{f_{curr}}{f_{safe}} \times 1000 - 1$$

Equation 8

Where f_{curr} is the frequency of the currently selected system clock source.

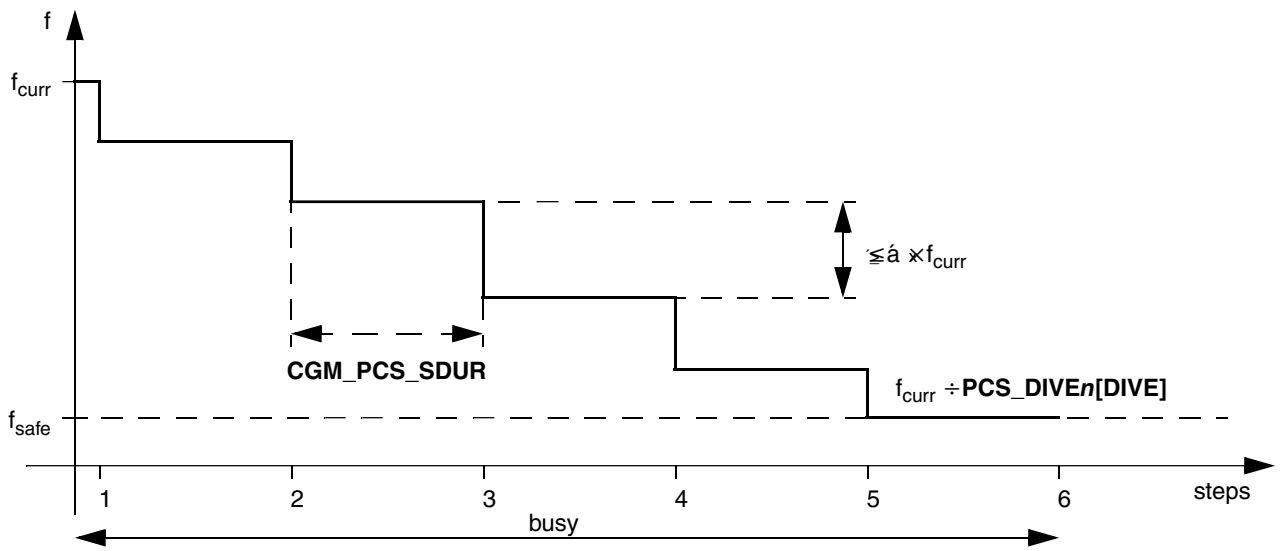


Figure 31-4. MC_CGM System Clock Ramp-Down Timing (k = 6 example)

31.4.1.2.6 Clock Ramp-Up

The clock ramp-up starts with the given divider value PCS_DIVSn[DIVS] and with the given divider decrement value PCD_DIVCn[INIT] and ends with the divider value 1.

The initial divider change start value PCS_DIVCn[INIT] for system clock ramp-up is given in the following equation.

$$\text{PCS_DIVCn[INIT]} = d \times k \times 1000$$

Where k is calculated as shown in the sectionGeneric Clock Change Properties using the target system clock source frequency f_{targ}. The divider start value for clock ramp-up is given in the following equation.

$$\text{PCS_DIVSn[DIVS]} = \left(1 + d\frac{k(k+1)}{2}\right) \times 1000 - 1$$

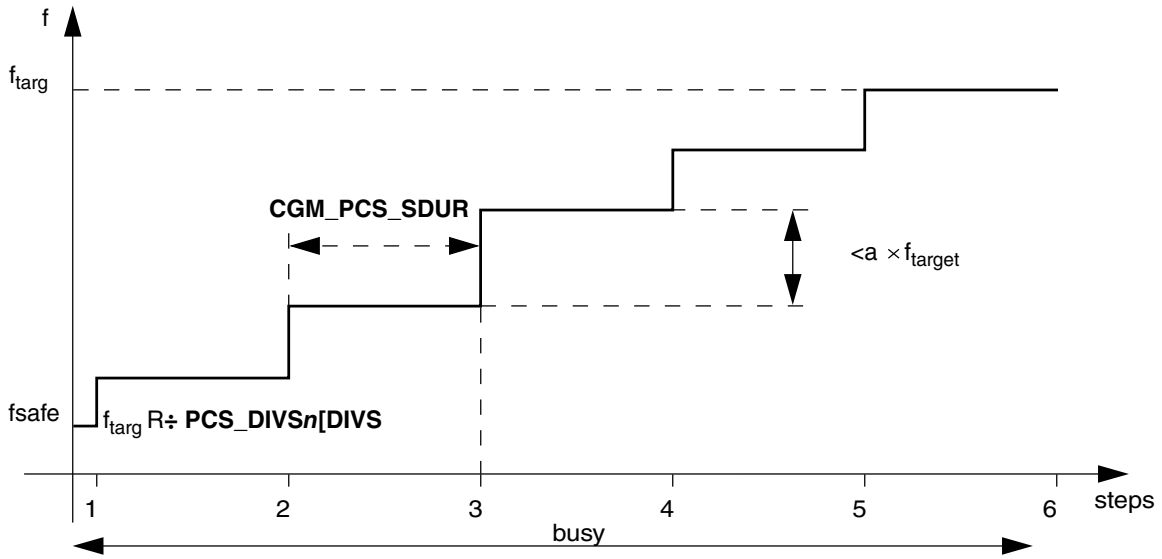

Figure 31-5. MC_CGM System Clock Ramp-Up Timing (k = 6 example)

31.4.1.3 System Clock Disable

During the TEST mode, the system clock can be disabled by the MC_ME.

31.4.1.4 System Clock Dividers

The MC_CGM generates the following derived clocks from the system clock:

- S160 clock - controlled by the CGM_SC_DC0 register
- S80 clock - controlled by the CGM_SC_DC1 register (selected modules - Flexray RAM and DMA_RAM).
- S40 clock - controlled by the CGM_SC_DC2 register
- F40 peripheral clock - controlled by the CGM_SC_DC3 register
- F80 peripheral clock - controlled by the CGM_SC_DC4 register
- FS80 clock - controlled by the CGM_SC_DC5 register
- F20 clock - controlled by the CGM_SC_DC6 register

31.4.2 Auxiliary Clock Generation

The following figures show the block diagrams of the generation logic for the various auxiliary clocks. See the following sections for auxiliary clock selection control:

- Auxiliary Clock 2 Select Control Register (MC_CGM_AC2_SC)

-
-
- Auxiliary Clock 5 Select Control Register (MC_CGM_AC5_SC)
- Auxiliary Clock 6 Select Control Register (MC_CGM_AC6_SC)

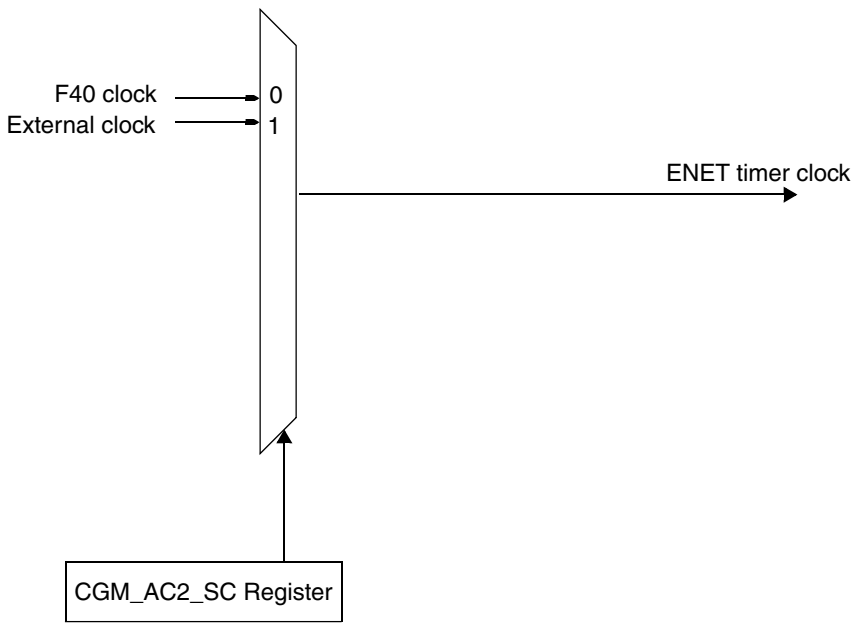

Figure 31-6. MC_CGM Auxiliary Clock 2 Generation Overview

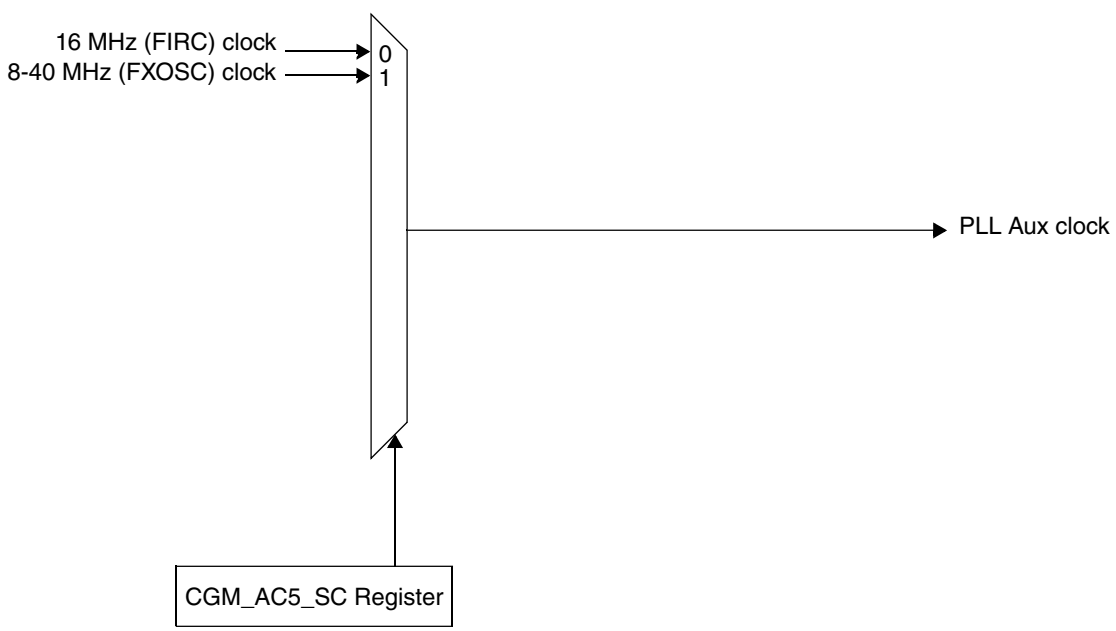

Figure 31-7. MC_CGM Auxiliary Clock 5 Generation Overview

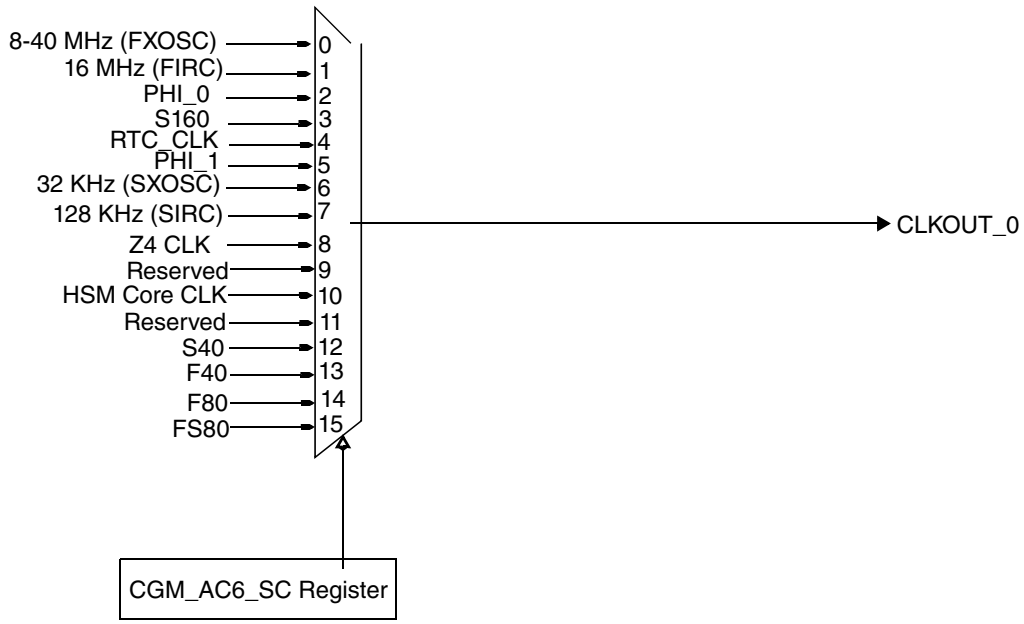

Figure 31-8. MC_CGM Auxiliary Clock 6 Generation Overview

31.4.3 Dividers Functional Description

Dividers are used for the generation of divided system and peripheral clocks. The MC_CGM has the following control registers for built-in dividers:

- System Clock Divider 0 Configuration Register (MC_CGM_SC_DC0)
- System Clock Divider 2 Configuration Register (MC_CGM_SC_DC2)
- System Clock Divider 3 Configuration Register (MC_CGM_SC_DC3)
- System Clock Divider 4 Configuration Register (MC_CGM_SC_DC4)
- System Clock Divider 5 Configuration Register (MC_CGM_SC_DC5)

The reset value of all counters is '1'. If a divider has its DE bit in the respective configuration register set to '0' (the divider is disabled), any value in its DIV field is ignored.

31.4.4 Halt Abort

A divider update trigger with SYS_DIV_RATIO_CHNG bit set will assert a request to the crossbar switch to halt the ongoing transactions. The dividers are updated once the crossbar switch acknowledges the request for halt. This protocol maybe aborted by urgent

system interrupts. The time instant at which the abort is asserted determines if the crossbar halt is aborted or the abort is ignored. If the abort request comes before the halt is acknowledged form the crossbar, the halt handshake is aborted.

The CGM_DIV_UPD_ABRT.DIV_UPD_ABRTD bit is set after a successful abort and must be read by software to take necessary steps. In case the CGM_DIV_UPD_ABRT.DIV_UPD_ABRTD bit is set, the software should initiate the divider update trigger at some later point. Till such a time that the dividers are updated again, the current division value of the dividers would not match the divider configuration. The CGM_DIV_UPD_STAT bit is de asserted after the abort is successfully completed signalling that no divider update is ongoing.

The halt abort feature may be disabled by software by setting the CGM_SC_DIV_RC.HALT_ABORT_DIS CGM_HALT_ABORT_DIS.

Chapter 32
Input Glitch Filter

32.1 Introduction

The Input Glitch Filter provides programmable glitch rejection filtering of digital input signals.

32.2 Block Diagram

The figure below is the block diagram for the Input Glitch Filter module.

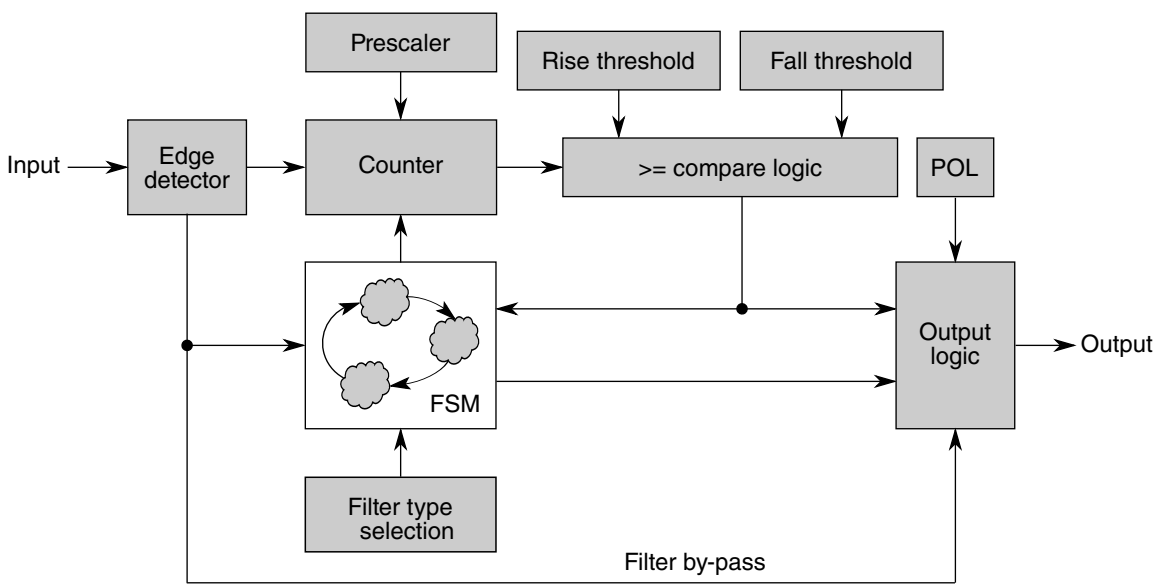

Figure 32-1. Input Glitch Filter block diagram

32.3 Input Glitch Filter overview

The Input Glitch Filter receives an input signal usually from a device PAD. Signals generated externally to the device are affected by environmental noise or glitches. The signal level has to be evaluated with some criteria in order to remove the noise which could affect the measurements done over this signal, such as transition time, period and level.

In a typical application, the Input Glitch Filter interfaces with one or more timer peripherals.

The strategy to remove glitches from an input signal is to monitor the level of the signal during a wide time window thus the glitches can be evaluated and removed.

32.3.1 Interaction with other peripherals

The figure below shows an example of how the Input Glitch Filter interacts with on-chip peripherals.

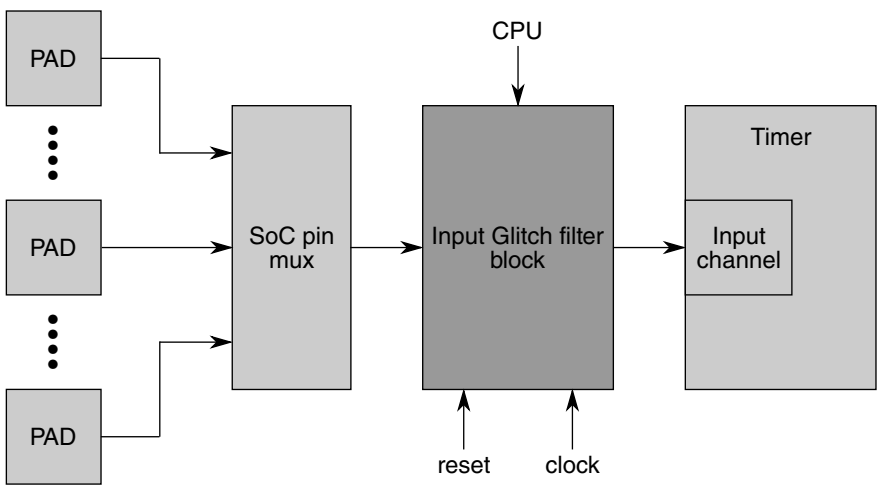

Figure 32-2. Input Glitch Filter application example

32.3.2 Mode of operation

The Input Glitch Filter has the following modes of operation:

- Configuration mode
- Normal mode

- Debug mode
- Low power mode

32.3.2.1 Configuration mode

The configuration mode is the initial mode of the Input Glitch filter after system reset is applied. The configuration mode is selected when FGEN = ‘0’ in the MCR register. The filter parameters such as rising and falling thresholds can be programmed when the filter is in configuration mode without disturbing the internal device logic since the filter output is kept at logic '0' state. Once FGEN is programmed with logic ‘1’ the filter enters the normal operating mode and is able to initiate the filtering process.

NOTE

The MDIS bit in the MCR register, if set to logic '1', makes the filter transition to low power mode independent of FGEN bit settings. Thus, in order to enter the configuration mode MDIS bit needs to be at logic '0'.

32.3.2.2 Normal mode

The normal mode of operation is entered when MCR register FGEN = ‘1’. In this mode the filter implements one of the filter types:

- Bypass filter
- Windowing filter
- Windowing filter with post-sample
- Integrating filter
- Integrating-hold filter

These filter types are described in the following sections. Before entering the normal mode, the filter parameters, such as rise and fall thresholds, need to be programmed in the appropriate registers, as well as the type needs to be defined in the corresponding register.

NOTE

In the normal mode it is still possible to change the filter parameters, such as rise and fall thresholds. See section On-the-fly filter reconfiguration for more details.

32.3.2.3 Debug mode

The debug mode is entered when the MCR FRZ bit is set and a system level debug request occurs. Once the debug mode is entered, the internal filter counter is halted and the debug functions controlled by the FBP, FOH, and FOL bits are enabled. The filter output is frozen and remains at the state it was immediately before the debug mode was entered. The FOH and FOL MCR bits can be used to force the filter output to logic '1' or '0', respectively. These bits are self-negating, thus they always read as zero.

By setting the MCR FBP bit, the filter input state is copied to the filter output, thus allowing to control the filter output based on the filter input state. The output is forced during one clock cycle. After that the filter output remains at the new forced state until it is changed again by using a debug control bit or if the filter returns to the normal mode of operation.

NOTE

The system level debug request occurs when a specific event, or a series of events, occurs in one of the device sub-modules and is interpreted by the device debug logic as a debug request. The Input Glitch Filter is not capable of generating an event that causes the assertion of the system level debug request.

32.3.2.4 Low power mode

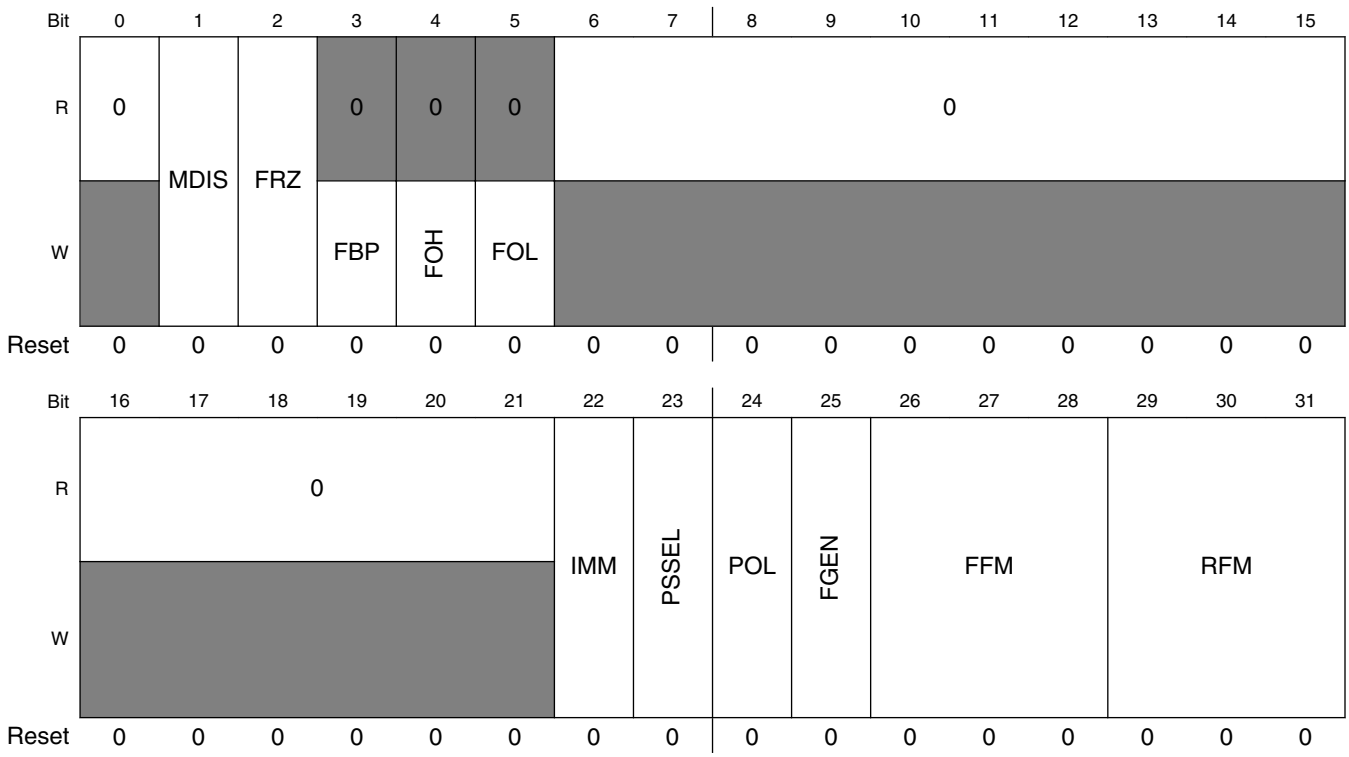
The low power mode is controlled by the MDIS bit in the MCR register or by the STOP signal which is the system level low power control signal. When entering low power mode the filter output remains unchanged at the state it was just before the low power mode was entered. Since the Input Glitch Filter clocks are stopped in this mode, the internal counter remains inactive. The description of this mode is covered in the Low Power Mode section of this document.

32.4 Memory map

The Input Glitch Filter registers are implemented in 32-bit. 8-bit write operations are allowed. The coherency in case of 8-bit access must be provided by the application software since there is no coherence mechanism built into the hardware.

NOTE

RESERVED bit registers, when available for write operations, should be written always with logic '0'. Read access does not return meaningful data from RESERVED bit registers.



IGF memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Module Configuration Register (IGF_MCR0)	32	R/W	0000_0000h	32.4.1/684

20	Falling edge Threshold Register (IGF_FTHR)	32	R/W	0000_0000h	32.4.5/689

32.4.1 Module Configuration Register (IGF_MCR*n*)

The Module Configuration register (MCR) provides access to low power, debug, and filter control bits.

Address: 0h base + 0h offset + (0d × i), where i=0d to 0d

IGF_MCR*n* field descriptions

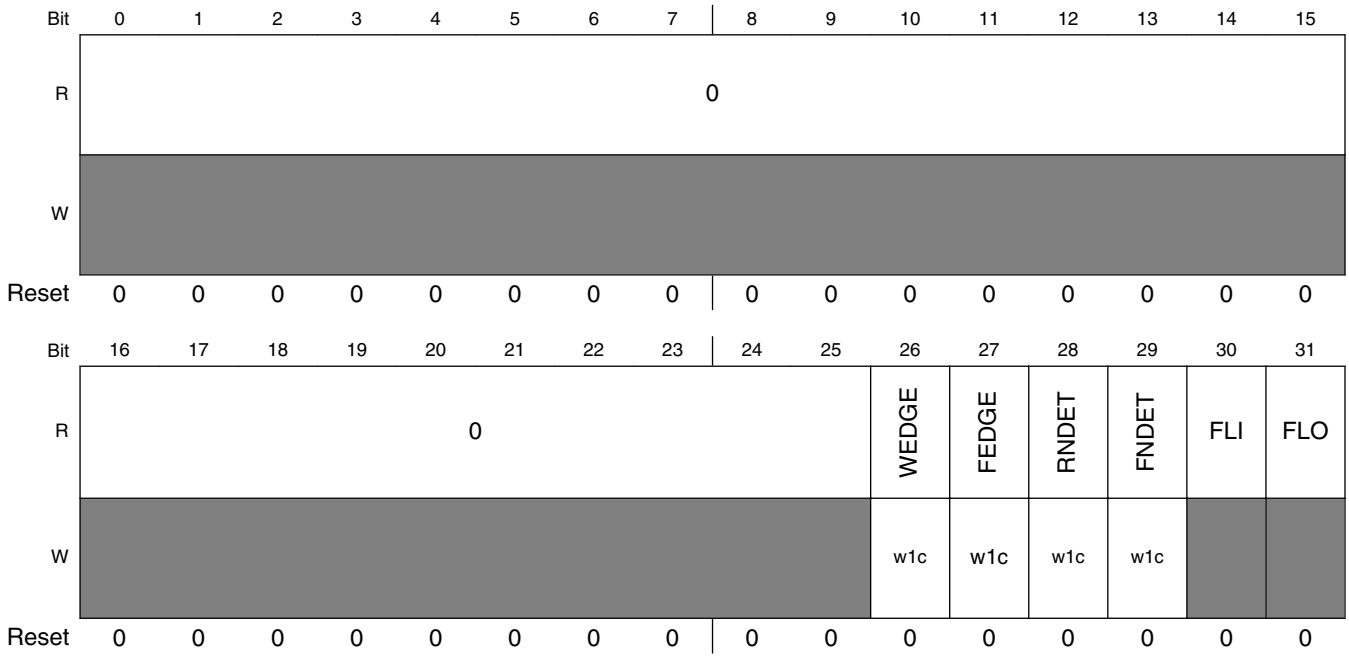
Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 MDIS	Module Disable The MDIS bit forces the filter to enter a low power state. After this bit is asserted the clock for the module is removed thus filter operation is not possible. The access to filter registers is allowed. 0 Input Glitch Filter is not in low power mode due to MDIS bit 1 Input Glitch Filter is in low power mode
2 FRZ	Freeze bit for debug operation The FRZ bit enables the Input Glitch Filter to enter freeze mode (debug mode) when a system level signal request the module enters freeze (debug) mode. Once in freeze mode the filter operation is disabled meaning that transitions on the input signal will not propagate through the filter output. The bypass FBP bit can be used by the software to force the filter output to be the same as the filter input. In this mode FOH and FOL also can be used to define the filter output state.

Table continues on the next page...

IGF_MCR*n* field descriptions (continued)

Field	Description
	0 Freeze mode disabled 1 Freeze mode enabled
3 FBP	Force Bypass This bit is self-negated thus is only read as zero. Writing 1 to this bit while in freeze mode forces the filter to bypass the value in the input to the filter output, thus allowing a software control on the filter. This bit is functional only in freeze mode. 0 no filter bypass 1 transfer input signal value to the filter output
4 FOH	Force filter output high If set, this bit forces the Input Glitch Filter output to '1'. This bit is functional only in debug mode. It is self-negated thus always read as zero. 0 no action 1 forces the filter output to '1'
5 FOL	Force filter output low If set this bit forces the Input Glitch Filter output to '0'. This bit is functional only in debug mode. It is self-negated thus always read as zero. 0 no action 1 forces the filter output to '0'
6–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 IMM	Immediate edge propagation control bit The IMM bit controls the propagation of an edge through the filter. If asserted, this bit defines that an edge at the filter input propagates through the filter output independent of the prescaler settings. In bypass mode the propagation delay is three system clock cycles. If negated, the signal propagation depends upon the prescaler settings. The filter hardware will only allow chages to this bit if the filter is disabled, FGEN = 0 0 edge propagation depends on prescaler 1 edge propagation within three system clock cycles
23 PSSEL	Prescaler selection bit The PSSEL selects if the prescaler used by the Input Glitch Filter is from internal source (internal prescaler counter) or from external source. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN=0. 0 internal prescaler selected 1 external prescaler selected
24 POL	Output polarity bit This bit sets the polarity of the filter output to inverted or not inverted. The polarity control implemented by the POL bit is applied at the filter output stage thus also changing the reset state of the output, even if the filter is disabled by the FGEN bit. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN=0.

Table continues on the next page...



IGF_MCR*n* field descriptions (continued)

Field	Description
	0 not inverted output 1 inverted output
25 FGEN	Filter global enable This control bit enables the filter operation, meaning that if the filter is enabled the filtering selected types are applied to the rising and falling edges of the input signal. If the filter is not enabled, then the filter output remains unchanged independent of the filter input signal. Note that the filter output state is affected by the POL bit when the filter is disabled. 0 filter is disabled: filter output keeps current state. 1 filter is enabled: filtering is applied to selected edges.
26–28 FFM	Falling edge filter type selection This bit field selects the filter type for the filter input signal falling edge. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN=0. 000 bypass: edge is propagated to filter output without any filtering in three system clock cycles 001 windowing: windowing filter is selected for the falling edge 010 integrating: integrating filter is selected for the falling edge 011 integrating-hold: integrating-hold filter is selected for the falling edge 100 windowing with post sample: windowing filter with post sample is selected for the falling edge
29–31 RFM	Rising edge filter type selection This bit field selects the filter type for the input signal rising edge. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN=0. 000 bypass: edge is propagated to filter output without any filtering in three system clock cycles 001 windowing: windowing filter is selected for the rising edge 010 integrating: integrating filter is selected for the rising edge 011 integrating-hold: integrating-hold filter is selected for the rising edge 100 windowing with post sample: windowing filter with post sample is selected for the rising edge

32.4.2 Module Status Register (IGF_MSR*n*)

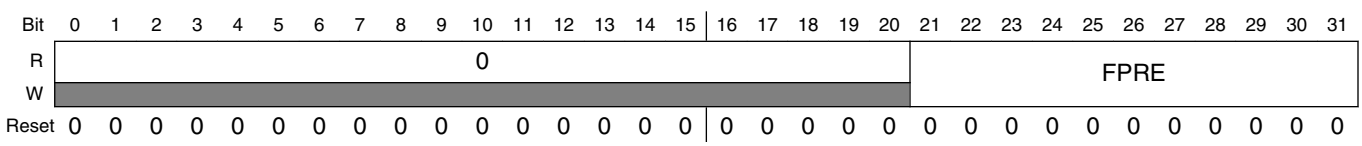
The Module status register (MSR) provides access to filter status bits and corresponding clear bits as well as access to the state of filter input and output signals.

Address: 0h base + 4h offset + (64d × i), where i=0d to 0d

IGF_MSR*n* field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 WEDGE	Filter is active waiting for an edge This bit is set when the filter is enabled but the internal counter is not active. It indicates that the filter is waiting for an edge to occur at the filter input. It is set by the Input Glitch Filter hardware and cleared by the software by writing 1 to the bit. Since the intention of this bit is to capture the dynamic of the filter hardware, it should be cleared after the read thus being able to capture a new event. 0 Input Glitch Filter is disabled or the internal counter is active 1 Input Glitch Filter is waiting for an edge
27 FEDGE	Filter is active processing an edge This bit is set during the filter active state thus when the filter internal counter is counting, processing an edge in a filtering mode. It is cleared by the software by writing 1 to the bit. Since the intention of this bit is to capture the dynamic of the filter hardware, it should be cleared after the read thus being able to capture a new event. 0 Input Glitch Filter internal counter is not active 1 Input Glitch Filter internal counter is active

Table continues on the next page...



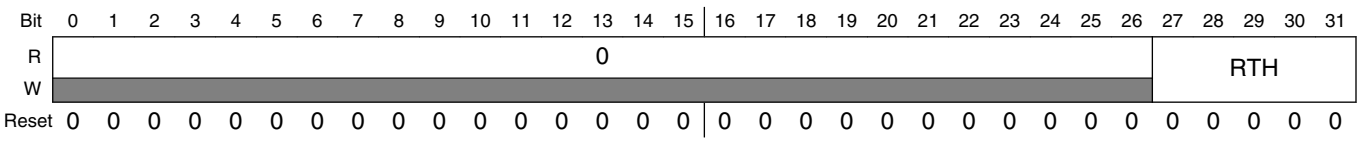
IGF_MSR*n* field descriptions (continued)

Field	Description
28 RNDET	Rise noise detected bit This bit indicates that the filter filtered out noise in the input signal after a rising edge was detected. The criteria to set this bit is when a rising edge is detected thus starting the filter counter and before this edge pass through the filter (if filter is in integrating filter types) or during a window (if filter is in windowing filter types) another edge occurs in the input signal. This bit is set by a noise detection and cleared by the software by writing 1 to this bit. 0 noise was not detected 1 noise was detected after a rising edge
29 FNDET	Fall noise detected bit This bit indicates that the filter filtered out noise in the input signal after a falling edge was detected. The criteria to set this bit is when a falling edge is detected, thus starting the filter counter, and, if the filter is in integrating types, before this edge passes through the filter, or, in windowing types, when another edge occurs in the input signal during a window. This bit is set by a noise detection and cleared by the software by writing 1 to this bit. 0 noise was not detected 1 noise was detected after a falling edge
30 FLI	Filter input The FLI bit follows the state of the filter input value as captured by the filter input logic, which is affected by the IMM bit and prescaler settings.
31 FLO	Filter output The FLO bit follows the state of the filter output value considering the POL bit state.

32.4.3 Prescaler Register (IGF_PRESR*n*)

The prescaler register (PRESR) provides access to the prescaler bits.

Address: 0h base + 10h offset + (64d × i), where i=0d to 0d



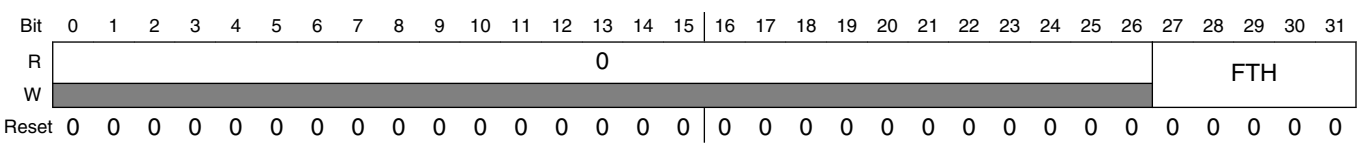
IGF_PRESR*n* field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–31 FPRE	Filter prescaler The prescaler defines the rate of the filter counter FCOUNT. The filter counter clock rate is defined by the formula: Filter counter clock = module clock / (FPRE + 1).

32.4.4 Rising edge Threshold Register (IGF_RTHR*n*)

The Rising edge Threshold register (RTHR) provides access to the rising edge threshold bits.

Address: 0h base + 1Ch offset + (64d × i), where i=0d to 0d



IGF_RTHR*n* field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 RTH	Rising edge threshold This bit field defines the filter counter threshold when a rising edge occurs is being filtered.

32.4.5 Falling edge Threshold Register (IGF_FTHR)

The Falling edge Threshold register (FTHR) provides access to the falling edge threshold bits.

Address: 0h base + 20h offset = 20h

IGF_FTHR field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 FTH	Falling edge threshold This bit field defines the filter counter threshold when a falling edge is being filtered.

32.5 Functional description

The following sections describe the Input Glitch Filter module functionality.

32.5.1 Input double sampling

The filter input is double sampled for clock domain translation thus avoiding asynchronous signals to propagate through the filter internal logic. This stage is composed by two flip-flops connected back to back. The delay caused by this logic is therefore two clock cycles.

Note that due to the synchronous nature of the Input Glitch Filter design, if a glitch smaller than one clock cycle occurs at the filter input it will not propagate to the filter internal logic and thus will not propagate to the filter output. Also, if clock is not applied to the filter (i.e. in low power mode) any transition at the filter input will not propagate to the filter output.

32.5.2 Filter types

The Input Glitch Filter implements four main filter types:

- Windowing
- Windowing with post sample
- Integrating
- Integrating hold

These filter types can be selected for the rising and falling edges independently, thus allowing different filter types to be selected for different edges (i.e. rising edge filtered with windowing filter and falling edge filtered with integrating).

32.5.2.1 Windowing filter

This filter type detects an edge (positive or negative edge) at the filter input and then mask out detection of subsequent edges over a period of time, which is defined as the blanking period, thus effectively behaving as a high pass filter. After an edge is detected the level at the filter input is propagated to the filter output within three clock cycles. The delay is caused by the synchronization stage at the input and by the filter output register stage. During the blanking period any transition at the filter input is disregarded. After the blanking period has elapsed, the filter compares the input level state with the filter output state. In case they are different a transition is inferred and re-evaluate according to the filter type assigned to that transition (positive or negative edges). Since, in this example,

the windowing filter type is programed for both edges, the inferred negative edge is propagated to the filter output and another blanking period is initiated. The figure below describes the windowing filter type behavior.

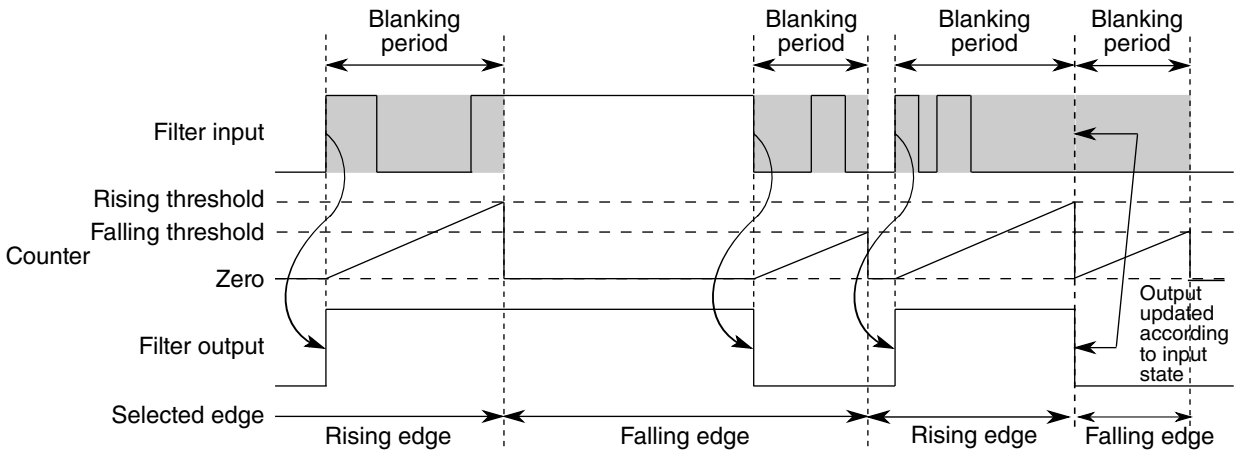


Figure 32-3. Windowing filter type

32.5.2.2 Windowing filter with post sample

This filter type detects an edge (positive or negative edge) at the filter input and then masks out detection of subsequent edges over a period of time, which is defined as the blanking period. During the blanking period, any transition at the filter input is disregarded.

When the blanking period finishes, the filter input level is propagated to the filter output. If the filter input is equal to the filter output when the blanking period finishes, then the filter output is not changed at the end of blanking period.

The figure below describes the windowing filter with post sample.

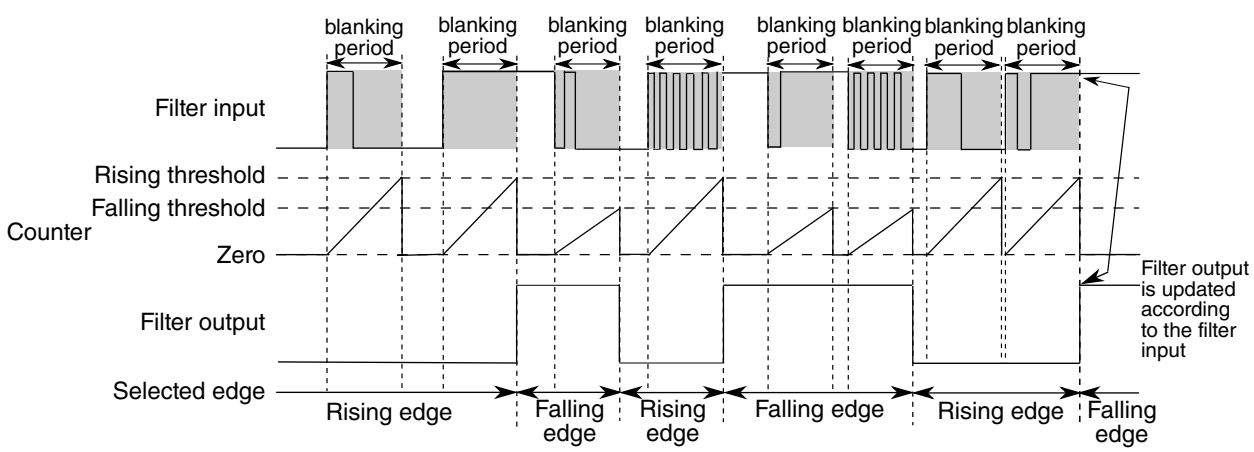

Figure 32-4. Windowing filter with post sample type

The windowing filter with post sample type is used to remove glitches and sparks around an edge.

32.5.2.3 Integrating filter

The integrating filter behaves like a low-pass filter, thus removing high frequency bursts from the input signal. The input and output signals are compared and if they are at different states an internal filter counter is enabled.

The direction of the counter (up or down counting) is defined by the states of the input and output filter signals as follows:

- Filter output is at the same state as the filter input: down-counting
- Filter output is at different state as the filter input: up-counting

The counter is compared with the rising or falling threshold register according to:

- Rising threshold register is selected if the rising edge is being filtered.
- Falling threshold register is selected if the falling edge is being filtered.

The filter output changes state to the same state as the filter input:

- If filter counter reaches the selected threshold for the edge being filtered.

The internal counter is disabled and cleared:

- If filter counter reaches the selected threshold for the edge being filtered.

The figure below describes an example of the Integrating filter type operation.

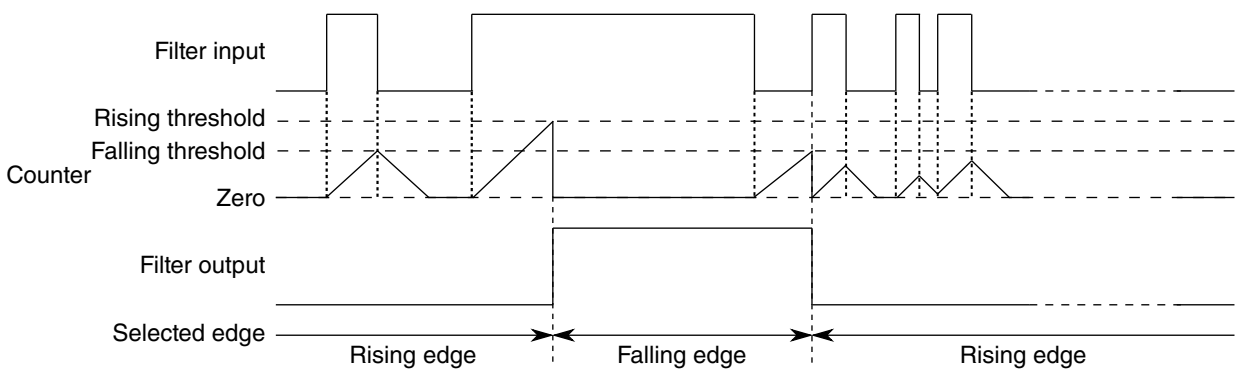

Figure 32-5. Integrating filter type

32.5.2.4 Integrating-hold filter

The integrating-hold filter type is similar to the integrating filter. The difference is the counter, which only counts in up direction instead of up-down in the integrating mode. In this filter configuration the input and output signals are compared and if they are at different states the filter counter is enabled. This counter is controlled by the state of the filter input and filter output signals as follows:

- Filter output is at the same state as the filter input: counter is in hold state (no-counting).
- Filter output is at different state as the filter input: counter is counting up.

The counter is compared with the rising or falling threshold register according to:

- Rising threshold register is selected if the rising edge is being filtered.
- Falling threshold register is selected if the falling edge is being filtered.

The filter output changes state to the same state as the filter input:

- If the filter counter reaches the selected threshold for the edge being filtered.

The internal counter is disabled and cleared:

- If the filter counter reaches the selected threshold for the edge being filtered.

The figure below shows an example of the Integrating-hold filter type operation.

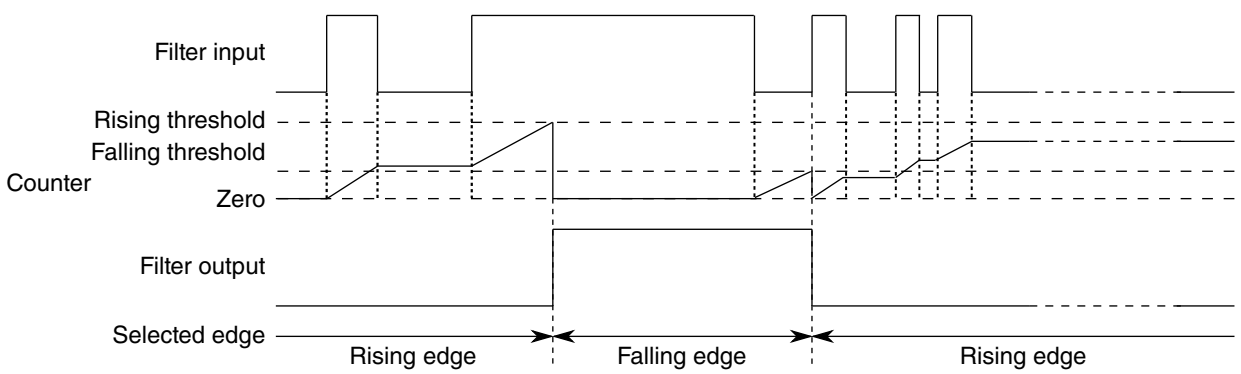

Figure 32-6. Integrating-hold filter type

32.5.2.5 Bypass filter

In the bypass filter type, the Input Glitch Filter immediately propagates any transition on the filter input to the filter output. This filter type does not provide any protection against glitches in the input signal. It is intended to be used in situations where the input signal is already filtered, or it is a glitch free signal, or the filter output is connected to a module that already has filtering capabilities. The bypass filter type is independently selected for rising or falling edges. Thus rising edges may be not filtered by the bypass filter type while the falling edges are filtered by any of the available filter types.

The bypass filter presents a delay in the edge propagation through the filter that is caused by the double sampling at the filter input and by the output filter register. Therefore, the total delay is three clock cycles.

32.5.2.6 Combined filter

The Input Glitch Filter allows the combination of filter types for different edges, positive and negative. As an example, the rising edges may be filtered using the windowing filter while the falling edges are filtered with an integrating filter. This configuration of the Input Glitch Filter is provided for situations where the noise present in the rising edges is different from the noise in the falling edges. Another use case is when the delay requirements of the input signal is different for rising and falling edges.

The figure below shows the combined filter operation. The windowing filter type is applied to the rising edges. The integrating filter is used for the falling edges.

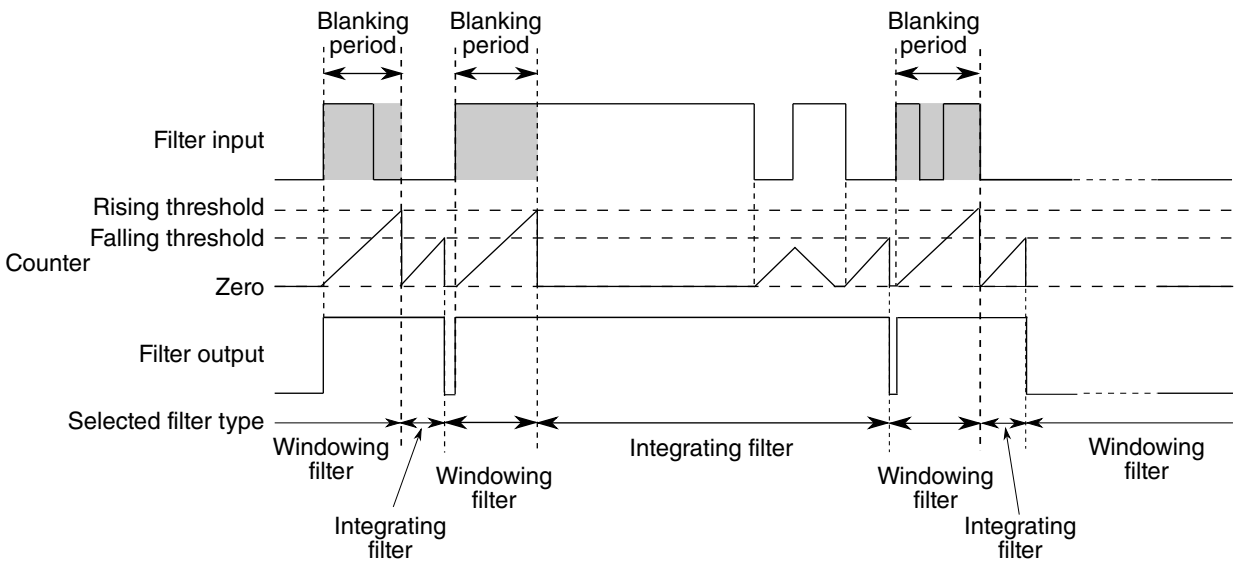

Figure 32-7. Combined filter type (windowing + integrating)

32.5.3 Application

This section describes several applications for the Input Glitch filter module.

32.5.3.1 Application use case 1: integrating filter

The integrating filter type is particularly useful in applications where glitches occur spuriously while the signal is expected to be in a steady state (either 1 or 0). Choosing correct up and down filter clock rates can ensure that the effects of spurious glitches can be completely eliminated, whilst minimizing propagation delays.

The application must be able to tolerate delays between the actual edge occurrence and the time that the signal is propagated through the filter logic. Because the delays are constants defined by the detection thresholds, application software may compensate for them, provided little or no noise occurs on the detected edge.

32.5.3.2 Application use case 2: windowing filter

The windowing filter type is particularly useful for removing noise bounce produced by a switch or sensor when its signal changes state. In this case, there is no propagation delay (except for the filter input synchronization logic and output register) between the filter input and filter output signals. This type of filter would not necessarily provide much immunity to spurious noise that occurred during the steady state portion of the signal. In order to optimize the characteristics of this filter, the blanking period should be of the same magnitude as the expected input signal rate. Signals that change frequency can be accommodated by software by dynamically updating the blanking period.

32.5.3.3 Application use case 3: windowing filter

Safety applications may need to compare the inputs obtained from different input pins, but derived from a single external source. This form of redundancy may detect non-common mode faults that may occur in the portions of the SoC that route and process the incoming signal. Having two different instances of windowing filter used on each input pin will ensure that the signal edge timing for both input paths is equal. Applying different filter characteristics for each input path can enhance the ability to detect SoC fault conditions.

32.5.3.4 Application use case 4: combined filter

Some applications may have rising edge signals that exhibit different characteristics to falling edge signals which might require different filtering to optimize the filtering effect. For example the “first” rising edge may represent a true real time event with a fast slew rate that must be captured without delay, while the falling edge signal may have a slow slew rate with many noisy transitions. The Input Glitch Filter can apply, for example, a

windowing filter on the rising edge to ensure no loss of real time information and an integrating filter on the falling edge to eliminate noise from being detected as a new rising transition.

32.5.3.5 Application use case 5: prescaler settings in windowing filter

The prescaler settings influence the timing for an edge to propagate through the filter. In windowing filter the IMM bit in the MCR register controls the way an edge is propagated through the filter. The figure below describes the windowing filter operation with regard to the IMM bit settings.

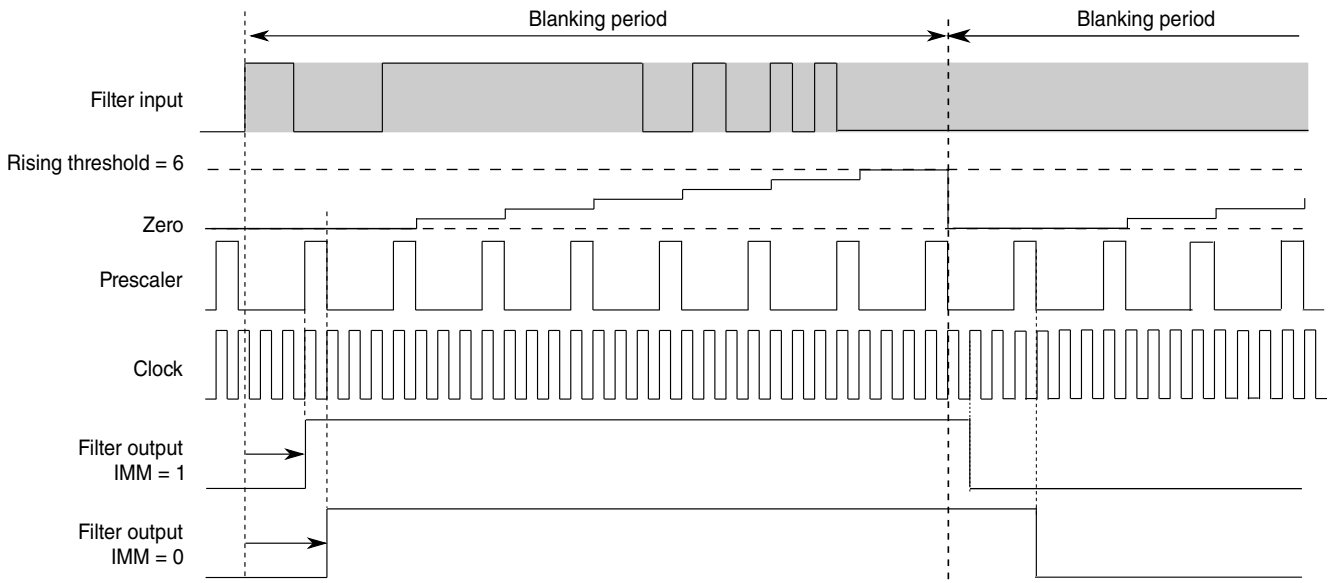

Figure 32-8. Input signal propagation through the filter in windowing filter type

If IMM = 0 then the input signal edges are propagated according to the prescaler ticks. If IMM = 1 then the input edges are propagated immediately (within 3 clock cycles) to the filter output.

32.5.3.6 Application use case 6: prescaler settings in bypass

The prescaler settings influence the timing for an input signal edge to propagate through the filter. In bypass, the IMM bit in the MCR register controls the way an edge is propagated through the filter. If IMM= 0, the prescaled clock is used to sample the input filter signal. The resolution the input signal is sampled is therefore related to the prescaler frequency. Glitches narrower than the prescaler period that are not aligned with the

prescaler clock are not captured by the filter. If IMM = 1, the system clock is used to sample the filter input signal instead of the prescaled clock. In this case, the resolution of the sampled input signal is the system clock.

The figure below describes the filter input signal sampling behavior for IMM = 0 and IMM = 1.

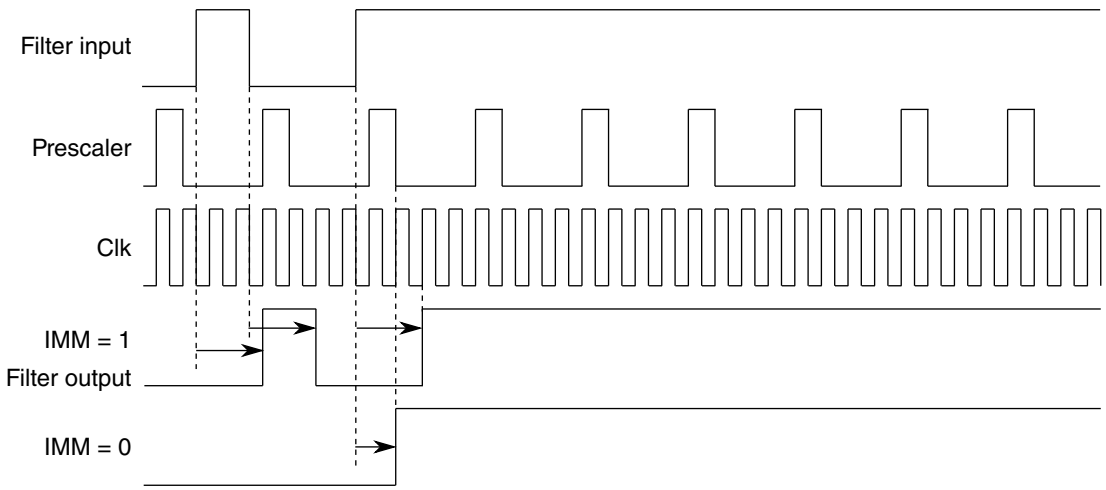

Figure 32-9. Input signal propagation through the filter in bypass

32.5.4 Programming guidelines

The following generalized procedure may be used to configure the Input Glitch Filter Block:

1. Program the SoC pin mux logic to route an external signal to the input of the selected glitch filter.
2. Enable the destination module to receive the Input Glitch filter output.
3. Enable the clock source at the SoC level.
4. Program the Glitch Filter counter prescaler(s) to the desired rate.
5. Select the filter type for each edge using MCR[FFM] and MCR[RFM].
6. Clear any status bits if necessary.
7. Enable the filter using MCR[FGEN]

32.5.5 On-the-fly filter reconfiguration

The architecture of the Input Glitch Filter allows for on the fly reconfiguration of filter parameters such as rise and fall threshold values.

If a parameter is changed it influences the filter operation immediately after the new parameter value was written. The main problem when changing parameters, such as a threshold value, when the filter is enabled is that the filter counter could lose a match due to the parameter change. A great or equal comparator is used in the threshold match logic which allows correct filter operation when the threshold parameters are changed. The figure below shows an example of changing the rising edge parameter value. Note that in this case the match occurs immediately after the parameter is changed since the new parameter value is below the current counter value.

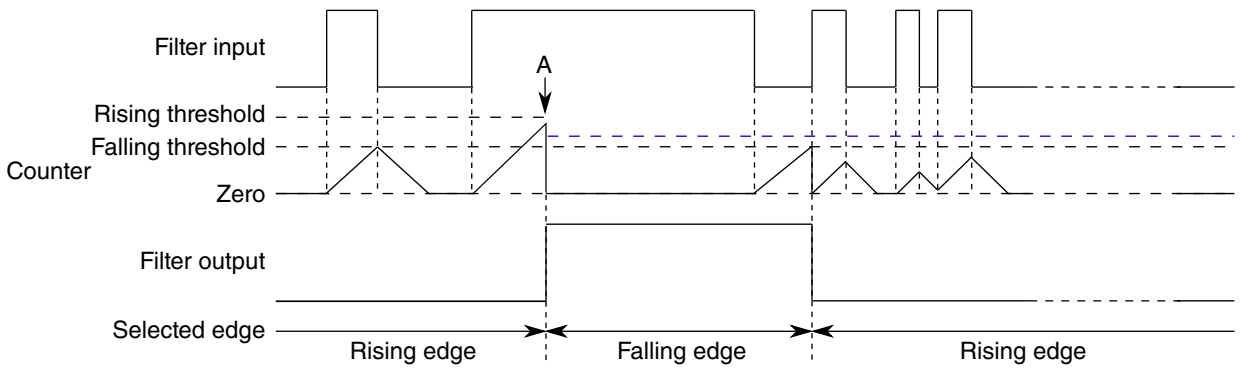

Figure 32-10. On-the-fly rising threshold parameter change

In the case shown in the figure above the match occurs immediately after the new rising threshold is programmed at ‘A’.

NOTE

Note that when changing the threshold values the match may not occur when the counter is equal to the threshold value (the old or the new programmed value). Instead, the match may occur in between the old and new programmed thresholds when the threshold re-programming instant A is done when the counter is greater than the new value. This is a transitory effect which may occur when the threshold value is changed and should be considered by the application.

32.6 Power saving mode

The Input Glitch Filter implements power saving mode thus allowing to reduce power consumption when device inputs connected to the filter are not used or the filter is not necessary to be functioning in a specific SoC mode of operation.

32.6.1 STOP mode

There are two ways for the Input Glitch filter to enter low power mode:

- MDIS bit
- STOP mode system request

The MDIS control bit in the MCR register, when set, disables the filter logic by stopping the module clock signals and thus halting the internal filter counter which reduces the dynamic power consumption of the module. The MDIS bit provides a selective control of the low power operation of each one of the Input Glitch Filter instances in the device.

The STOP mode system request is similar to MDIS operation with exception that it applies to all Input Glitch Filter instances in the device. It does not need to be enabled by any control bit in the Input Glitch filter module. The low power mode in this case is controlled by the assertion of the STOP signal which is a system wide low power control signal.

Chapter 33
HF - Interface

33.1 Chip specific HFIF information

33.1.1 Module Interconnect

This MCU supports **four** HF-interfaces.

The figure below shows an example of how the Input Glitch Filter interacts with on chip peripherals in the HF-Interface use-case. The connecting of the filter output signal to the eMIOS channel is individually connect-able.

The eMIOS channels C28-31 are used for HF-interface usage, because these channels are only from CH type Y (channel type with least supported modes, but high number of available channels on both eMIOS blocks).

To increase the system flexibility several pads are multiplexed to the glitch/symbol filter.

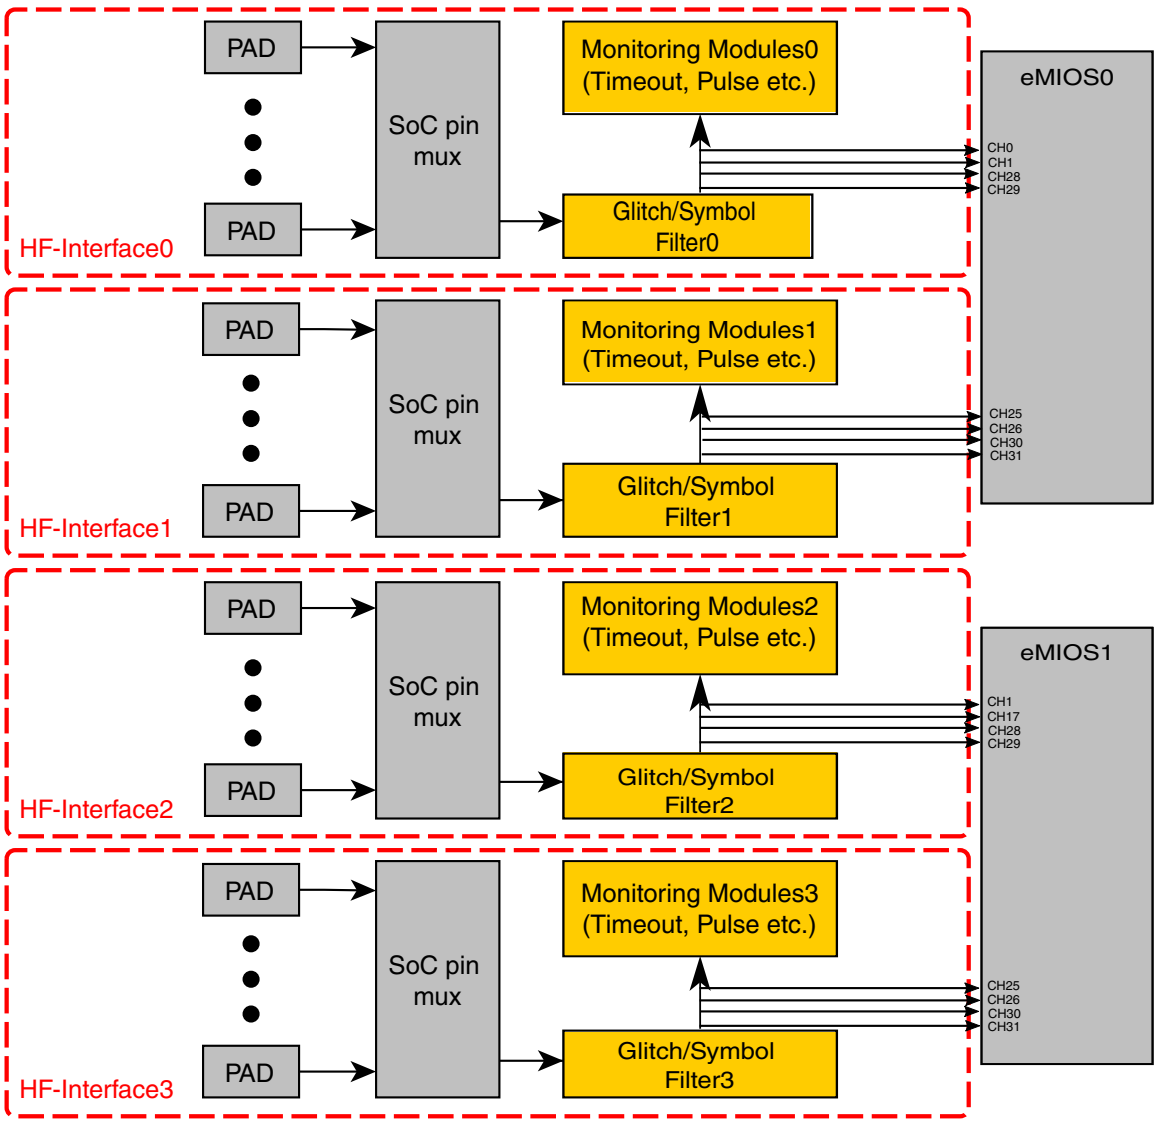

Figure 33-1. Interaction of IGF, HFIF, and eMIOS

The pin muxing implementation for Glitch-Filter0 and eMIOS0 channels 28 and 29 is shown in the diagram below. The input for Glitch-Filter0 is muxed using SIUL-MSCR 1018. The output of the Glicth-Filter0 is directly given as input to the HF-interface0, and is given to eMIOS0 channels 28 and 29 via SIUL MSCRs 540 and 541. When using these channels for HF-interface functionality, the Glitch Filter's outputs must be selected to go to these channels, otherwise normal eMIOS pads can be used. Similar to the muxing below, HF-interface 1, 2 and 3 also have simlar input-muxes using SIUL MSCR registers. This information can be derived using the "IO_Signal_Description_and_Input_multiplexing_tables.xls" attached with the RM.

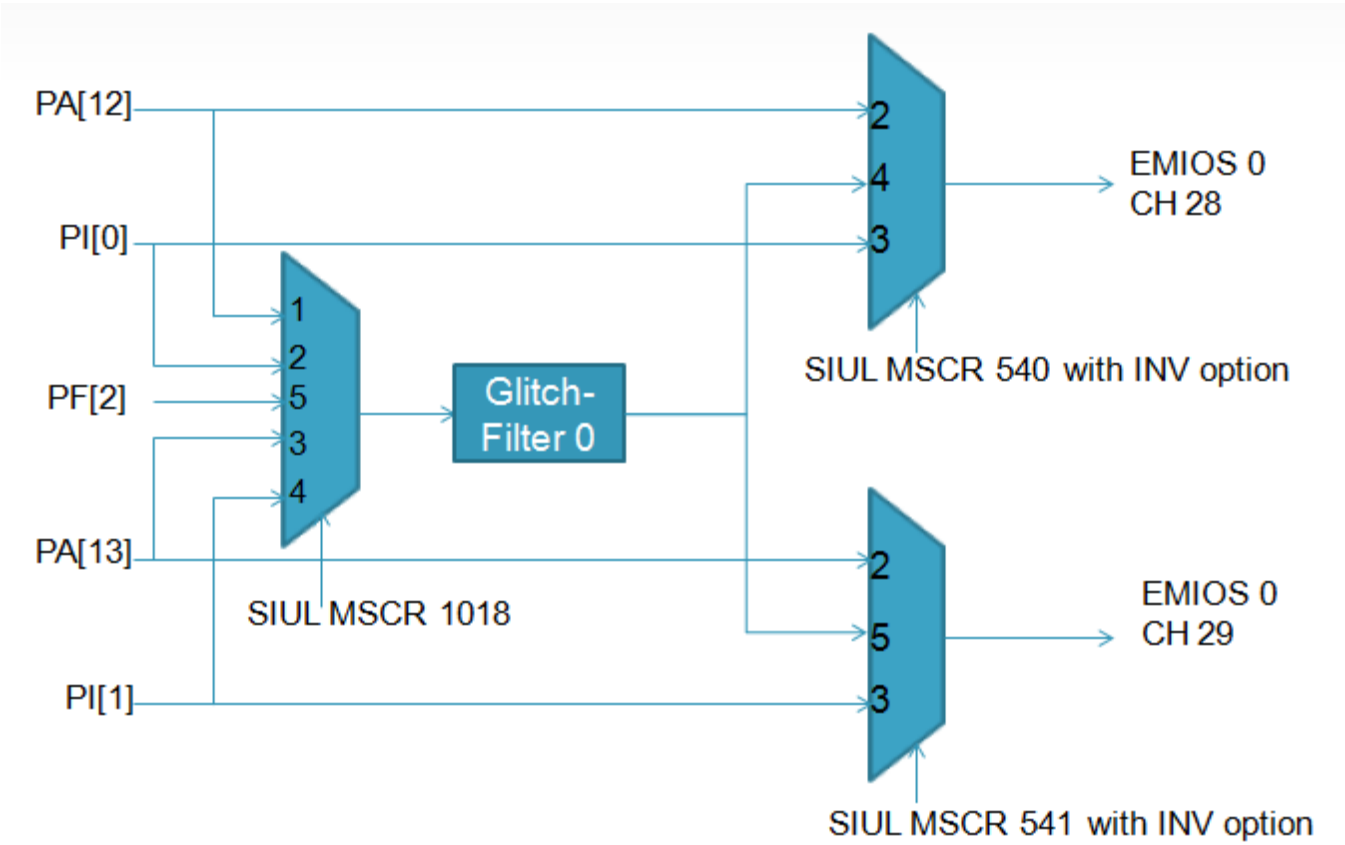

Figure 33-2. Pin muxing implementation for Glitch-Filter0 and eMIOS0 channel 28 and 29

33.2 Introduction

The HF-Interface is used to establish a cost-effective internal vehicle communication between MCU(s) and antenna modules. The HF interface is a single wire bus and offers a bi-directional communication with a maximum bandwidth of 20kBaud. Antenna modules could be: Keyless-go, Remote control, Key fob, Tire pressure. The antenna modules are responsible for the high-frequency wireless communication and HFIF offers a custom specific communication interface inside the vehicle.

The goal is to support the HF-interface in this MCU and reduce the load on Core significantly. Active communication happens before and while the vehicle is moving.

33.3 Block Diagram

The figure below is the block diagram for the HFIF module.

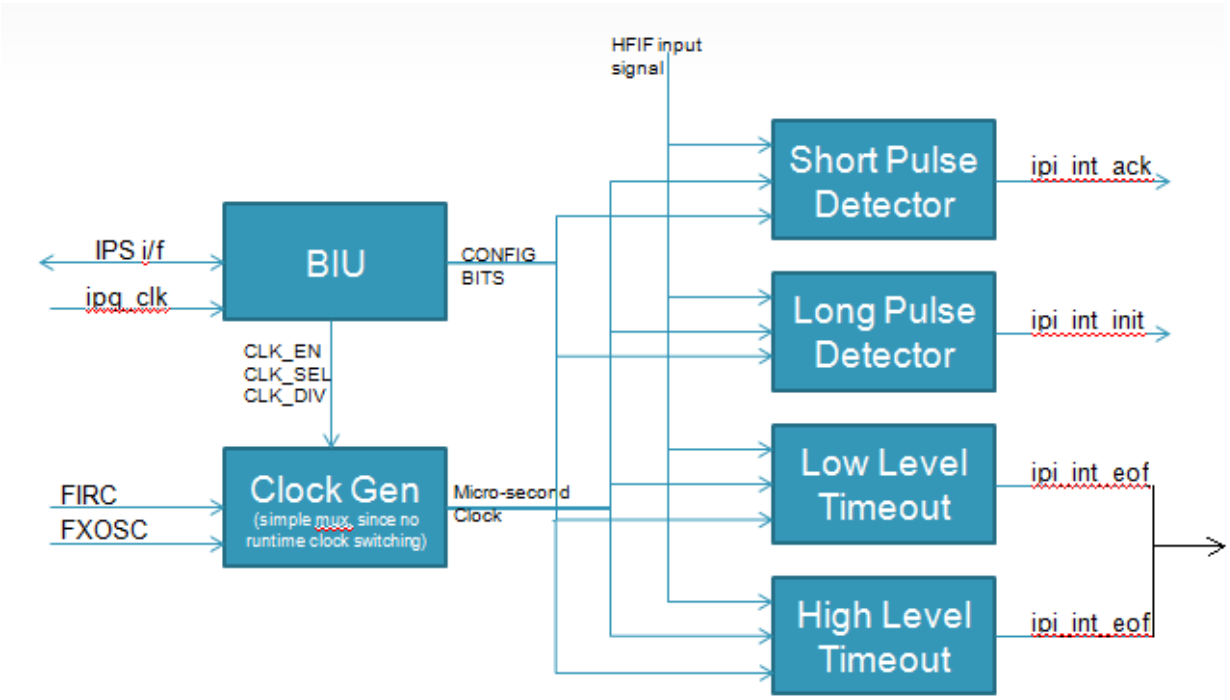

Figure 33-3. HFIF Block Diagram.

The following modules form the part of HFIF IP.

- Long Pulse Detection.
- Short Pulse Detection.
- Low Level Timeout.
- High Level Timeout.
- Clock Generation.

These modules are used in combination with the following IPs to provide the complete HF-interface support:

- Input Glitch Filter.
- eMIOS (for Rx-edge sampling and Tx handling).
- DMA channels/task to transfer the data to and fro.
- INTC (for interrupt handling).

The following diagram shows how the HF-Interface could be supported by these resources when used along with the HFIF timer and pulse-detector modules.

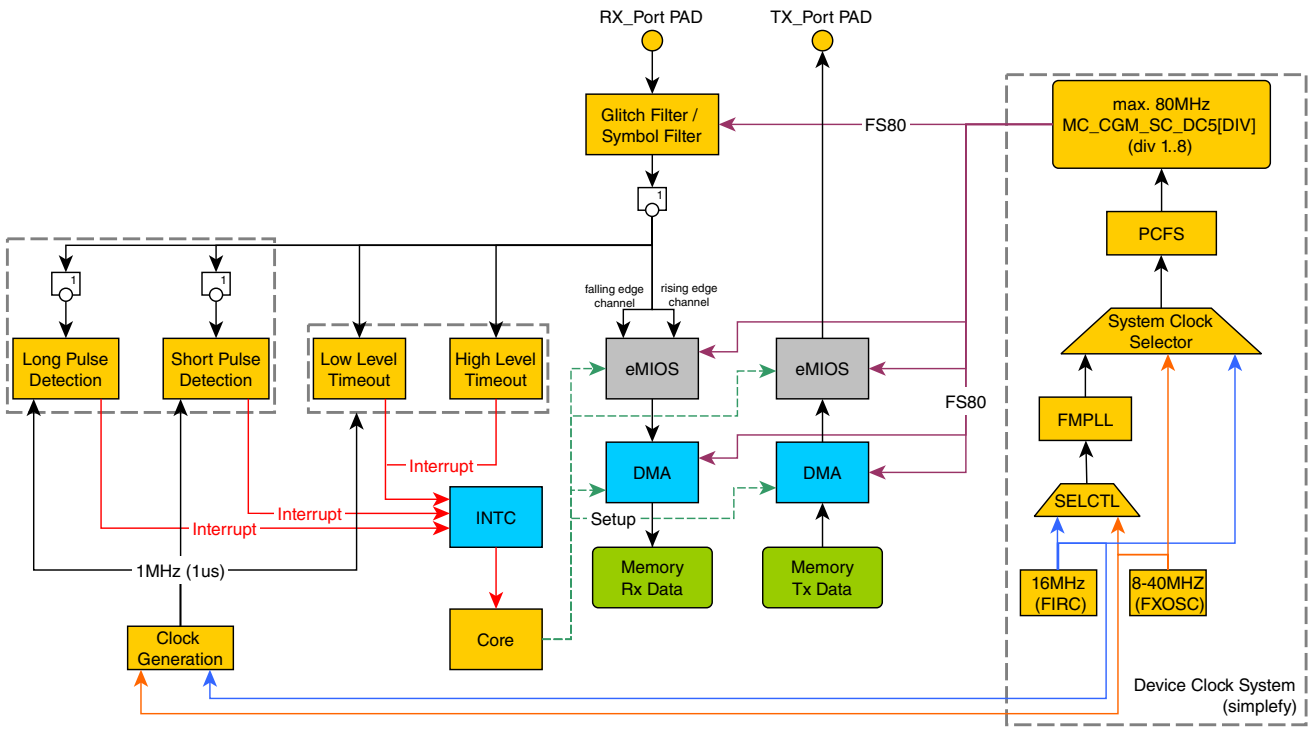

Figure 33-4. Modules used in the MCU to support HF-interface.

The next section describes the various tasks performed by these modules to acheive the functionality of HF-interface.

33.4 Overview

33.4.1 Receiving Data

The following tasks are needed to perform the Rx Function of HF-interface.

Init Tasks:

- Setup glitch/symbol filter
- Setup timeout modules
- Setup pulse detection modules
- Setup DMA to transfer the capture values from the eMIOS register to memory
- Setup 2x eMIOS channels in the "single action input capture" (SAIC) mode, one for the falling and the other one for the rising edge

Main Tasks:

- Glitch/symbol filter output signal is routed to two eMIOS channels, one channel will capture the time of rising and the other the falling edge. Together with the timing the signal polarity will be captured and published in the register interface.
- The DMA task is triggered when one of the eMIOS channels capture a new time. The DMA moves the timing values to the memory. The DMA can trigger an interrupt to the core when the maximum number of transfers is reached.
- The monitor modules (timeout and pulse detection) could be enabled/disabled (depending of the protocol status) by the core and trigger an interrupt in case one of the monitoring events occurs.

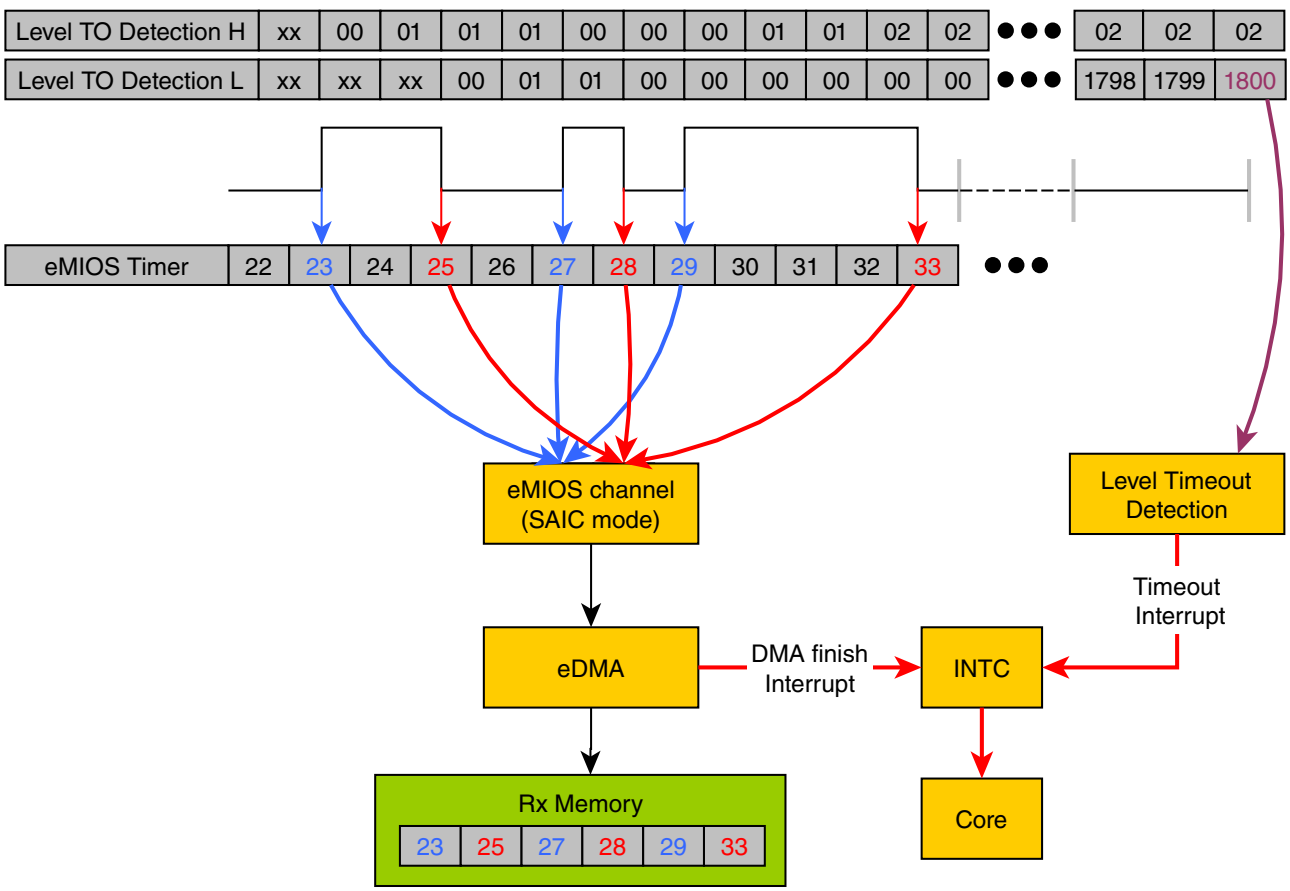

Figure 33-5. Data Flow for HFIF Rx function.

The Glitch Filter filters out any signal noise on its input port during a specific time and publishes the filtered signal to its output port. Various filtering schemes are supported by the Glitch Filter. One of them is "Windowing filter with post sample". In case the input signal pass the decision level (high or low) the timer will start to count. During this filtering time, the output port will still be at the previous signal level. If the filter time expires the output port will follow the actual input port level. In case the signal level goes

back to the previous one before the filter time expires, no signal level change is visible on the output port. The following waveform shows the behavior of the glitch filter in "Windowing filter with post sample" mode.

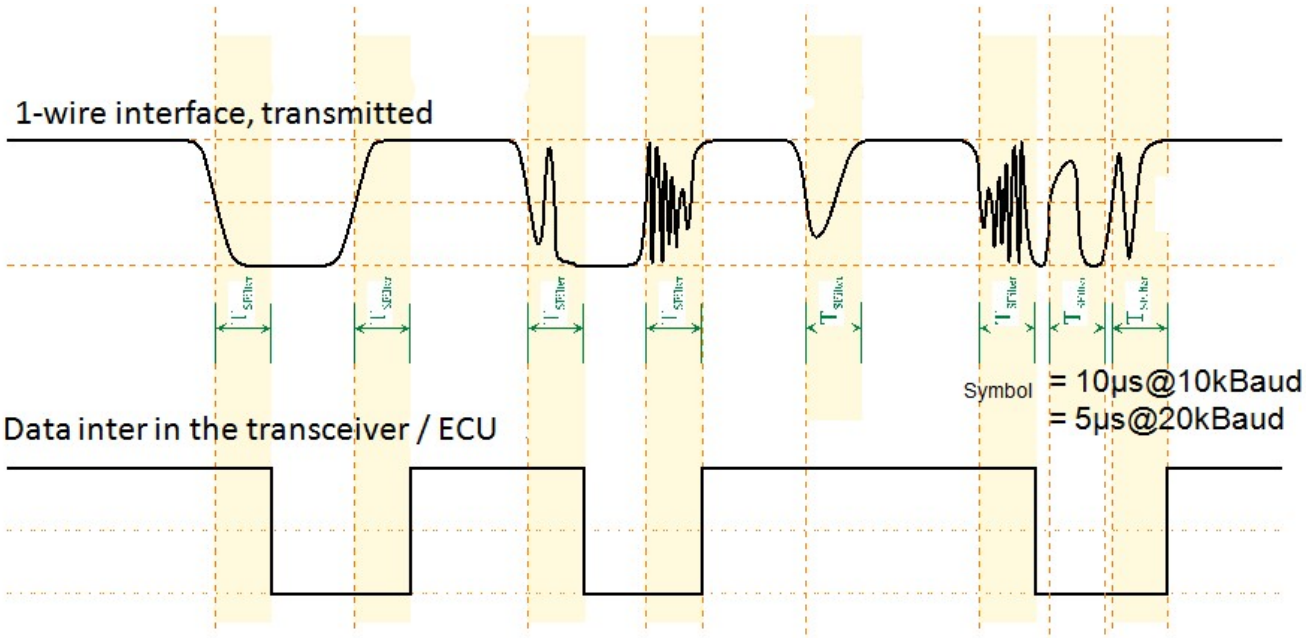

Figure 33-6. Windowing Filter with Post Sample.

33.4.2 Transmitting Data

The following tasks are needed to perform the Tx Function of HF-interface.

Init Tasks:

- Setup eMIOS for Single Action Output Compare (SAOC) mode, setup signal polarity (EDPOL register)
- Setup DMA to copy Tx-data from memory into the eMIOS register A1

Main Tasks:

- Core: WritesTx message data into the memory
- Core: Write the first Tx message data to eMIOS registers
- eMIOS: Triggers the DMA task to copy the next values to eMIOS registers
- DMA: send " end-of-transfer" via interrupt to the core when the complete data set (Tx message) is copied

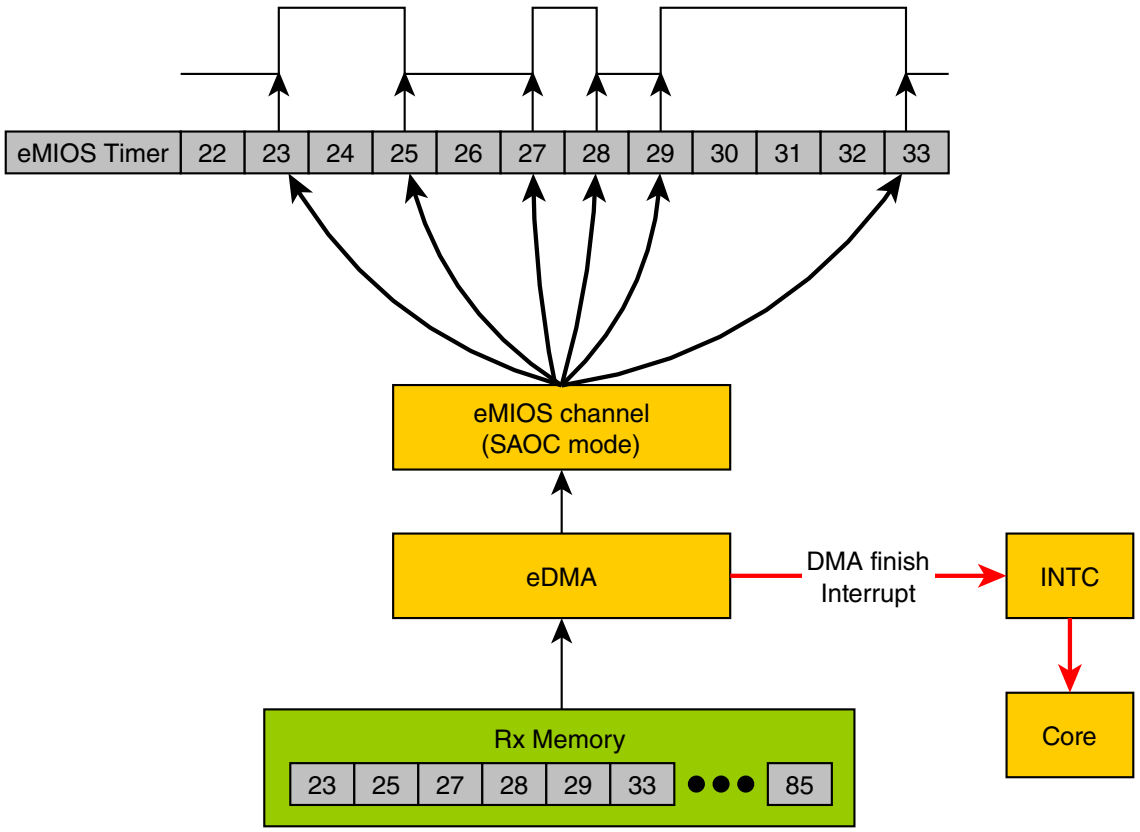

Figure 33-7. Data Flow for HFIF Tx function.

33.5 Functional Description

33.5.1 Clock Generation

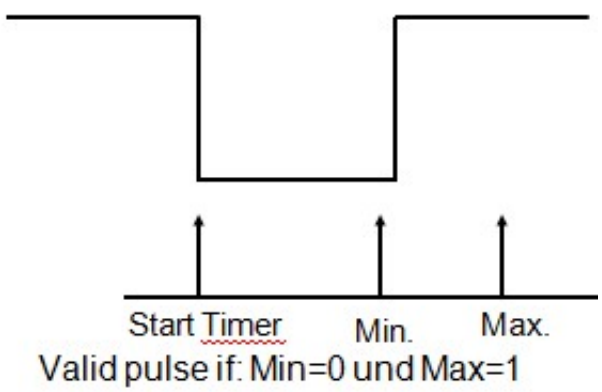
The clock generation module is used to generate an clock for the pulse and timeout sub-modules of the HF interface. The customer can choose between the internal FIRC (16MHz) or the external FXOSC (8-40MHz) as clock source.

The clock generation module has a clock pre-scaler to reduce the input clock to a lower level (e.g 1MHz/1usec cycle time). To control the module function, the Clock Configuration Register (CCR) is used.

33.5.2 Signal Level Timeout Detection

The timeout detection is based on two timer modules one for the low-level and one for the high-level detection. The counter counts as long as the level is stable on the signal input. A falling edge resets the timer to measure the low level and a rising edge resets the timer for the high signal level. If one of both timer reach the maximum/timeout value the module triggers an interrupt. Both modules share the same interrupt line.

To control these modules, the following configuration registers are used :



- Low-level Timeout Detector Configuration Register (LTDCR)
- High-level Timeout Detector Configuration Register (HTDCR)

33.5.3 Pulse Detection

The HF-Interface protocol defines two signal pulses of a specific length. A short ACK pulse and a long INIT pulse (sent two times in a sequence).

The pulse are only valid in case the length fits in the specified timing window. For this the customer can specify a minimum and a maximum value as the following graphic shows. When the signal fits the timing window (min-max-window) an interrupt will be triggered to the core.

In case the pulse length is outside of the min-max-window (before and after) the pulse is ignored and no interrupt event is triggered.

Due to the fact that two different pulse length must be supported, two instances of the same module are used. The typical working timing ranges for the ACK (typical range of 90-110 usec) and the INIT (typical range of 3.9 - 4.1 msec) pulse are different.

NOTE

The modules are not able to detect a sequence of two or more pulses (e.g. INIT), for this each single INIT pulse will trigger an interrupt.

To control these modules, the following configuration registers are used :

- Short Pulse Detector Configuration Register (SPDCR)
- Long Pulse Detector Configuration Register (LPDCR)

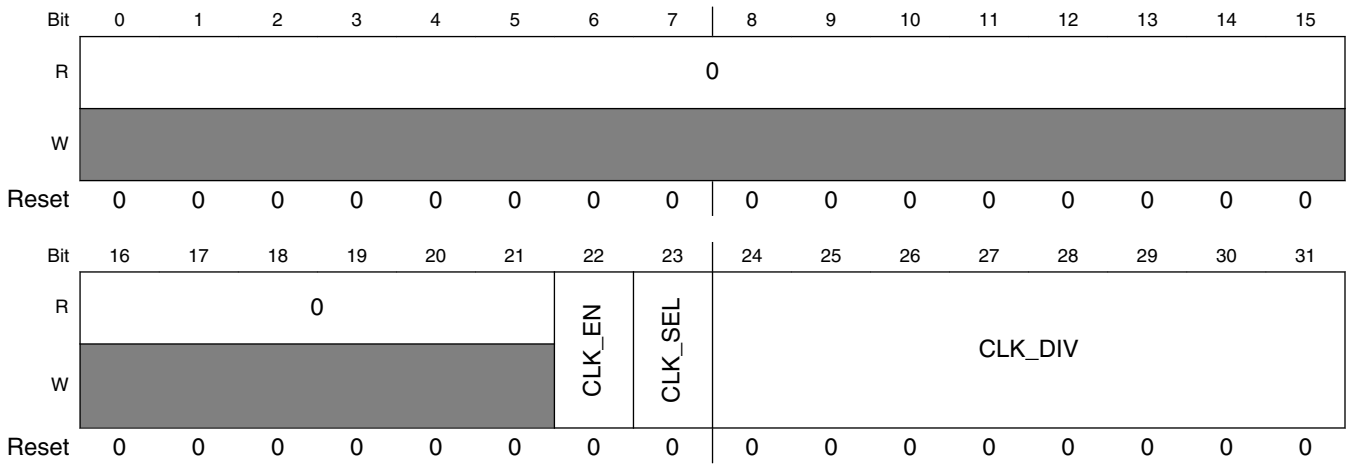
33.5.4 Interrupts

Timeout (1x) and Pulse (2x) detection modules offers three new interrupt signals. They are managed via these two registers.

- Interrupt Enable Register (IER)
- Interrupt Status Register (ISR)

By disabling the interrupt will have similar effect like to disable the modules.

33.6 Memory Map and Registers



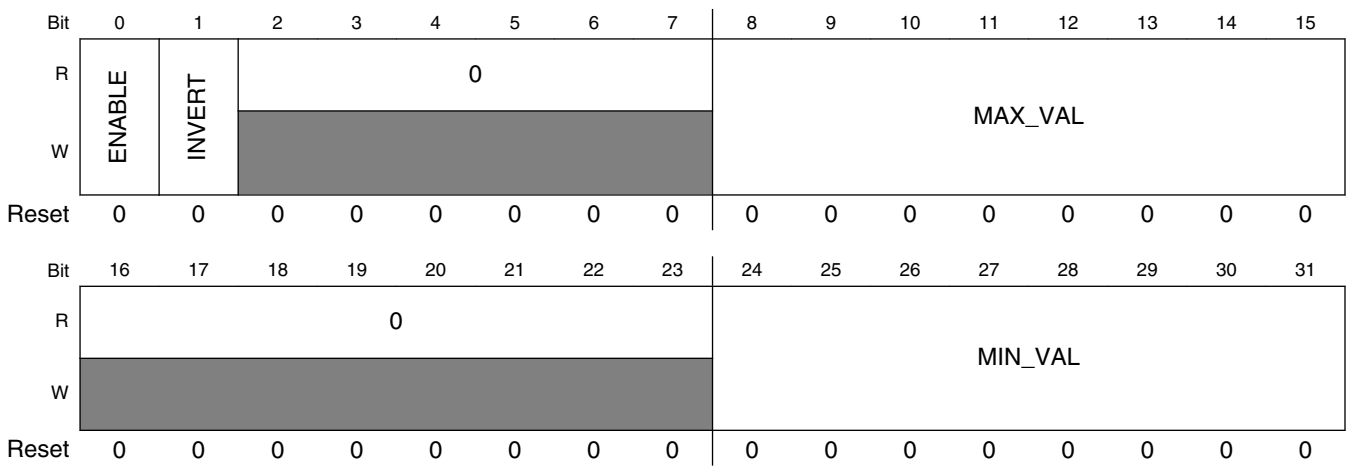
HFInterface memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Clock Configuration Register (HFInterface_CCR)	32	R/W	0000_0000h	33.6.1/711
4	Short Pulse Detector Configuration Register (HFInterface_SPDCR)	32	R/W	0000_0000h	33.6.2/712
8	Long Pulse Detector Configuration Register (HFInterface_LPDCR)	32	R/W	0000_0000h	33.6.3/713
C	Low-level Timeout Detector Configuration Register (HFInterface_LTDCR)	32	R/W	0000_0000h	33.6.4/714
10	High-level Timeout Detector Configuration Register (HFInterface_HTDCR)	32	R/W	0000_0000h	33.6.5/715
14	Interrupt Enable Register (HFInterface_IER)	32	R/W	0000_0000h	33.6.6/716
18	Interrupt Status Register (HFInterface_ISR)	32	R/W	0000_0000h	33.6.7/717

33.6.1 Clock Configuration Register (HFInterface_CCR)

This register is used for generating clock for the pulse and time out sub modules of the HF interface. Internal FIRC (16MHz) or the external FXOSC (8-40MHz) can be used as clock source.

Address: 0h base + 0h offset = 0h



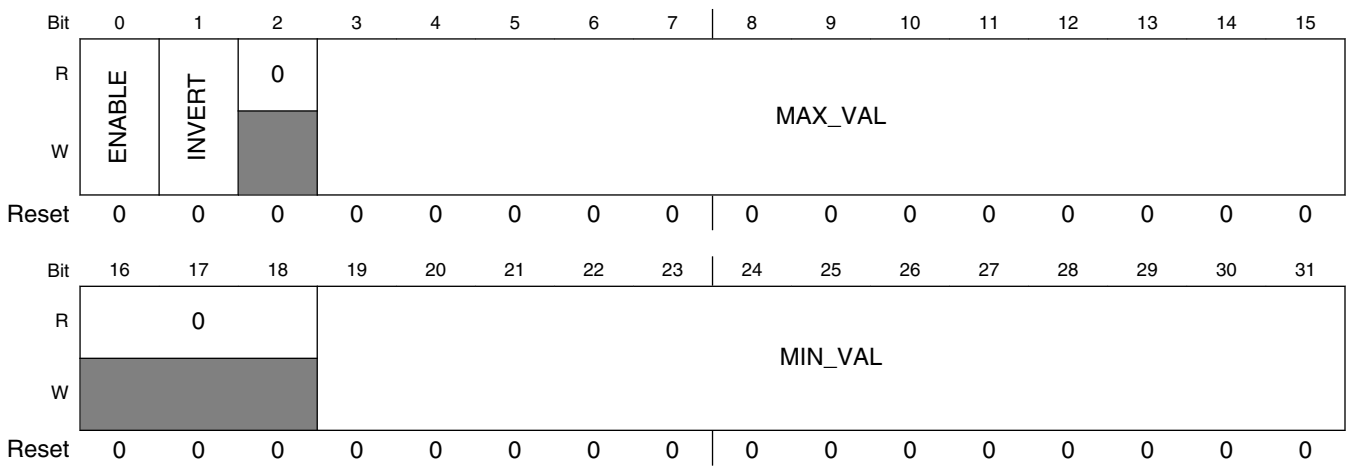
HFInterface_CCR field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 CLK_EN	Clock Enable This bit controls the output us_clk which will be enabled only after this bit is made 1.
23 CLK_SEL	Clock Select This bit selects the clock source. 0 FXOSC 1 FIRC
24–31 CLK_DIV	Clock Divider An M MHz clock will be needed to be divided by M to get 1us clock.

33.6.2 Short Pulse Detector Configuration Register (HFInterface_SPDCR)

This register defines a short ACK pulse. The pulse are only valid in case the length fits in the specified timing window. When the signal fits the timing window (min-max-window) an interrupt will be triggered to the core. In case the pulse length in outside of the minmax- window (before and after) the pulse is ignored an no interrupt event is triggered.

Address: 0h base + 4h offset = 4h



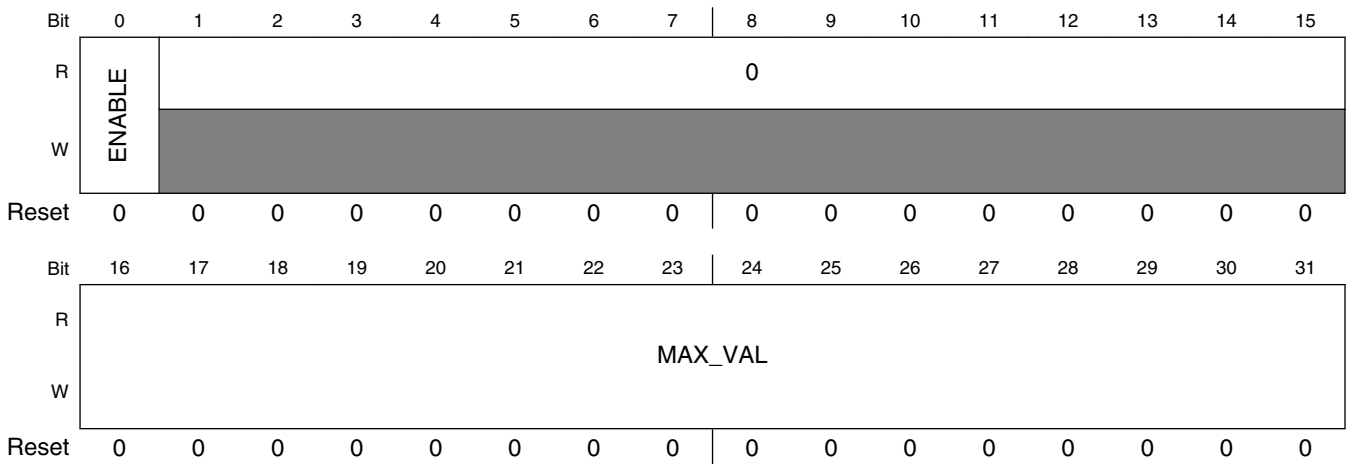
HFInterface_SPDCR field descriptions

Field	Description
0 ENABLE	This bit enables the input signal.
1 INVERT	This bit inverts the input signal
2–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 MAX_VAL	Maximum clock cycles Specify the maximum number of clock cycles after the the edge for a valid pulse.
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 MIN_VAL	Minimum clock cycles Specify the minimum number of clock cycles after the the edge for a valid pulse.

33.6.3 Long Pulse Detector Configuration Register (HFInterface_LPDCR)

This register defines a long INIT pulse. The pulse are only valid in case the length fits in the specified timing window. When the signal fits the timing window (min-max-window) an interrupt will be triggered to the core. In case the pulse length in outside of the minmax- window (before and after) the pulse is ignored an no interrupt event is triggered.

Address: 0h base + 8h offset = 8h



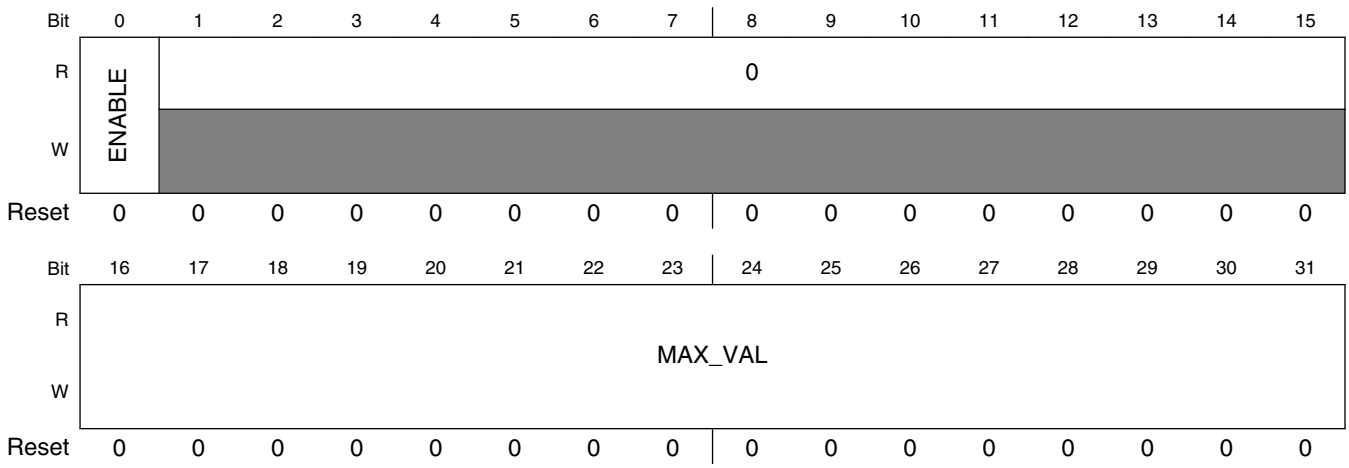
HFInterface_LPDCR field descriptions

Field	Description
0 ENABLE	This bit enables the input signal.
1 INVERT	This bit inverts the input signal
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–15 MAX_VAL	Maximum high level value Gives the maximum number of clock cycles for a high level time out.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–31 MIN_VAL	Minimum high level value Gives the minimum number of clock cycles for a high level time out.

33.6.4 Low-level Timeout Detector Configuration Register (HFInterface_LTDCR)

This register controls the low level time out detection. The counter counts as long as the level is stable on the signal input and a falling edge resets the timer to measure the low level time out.

Address: 0h base + Ch offset = Ch



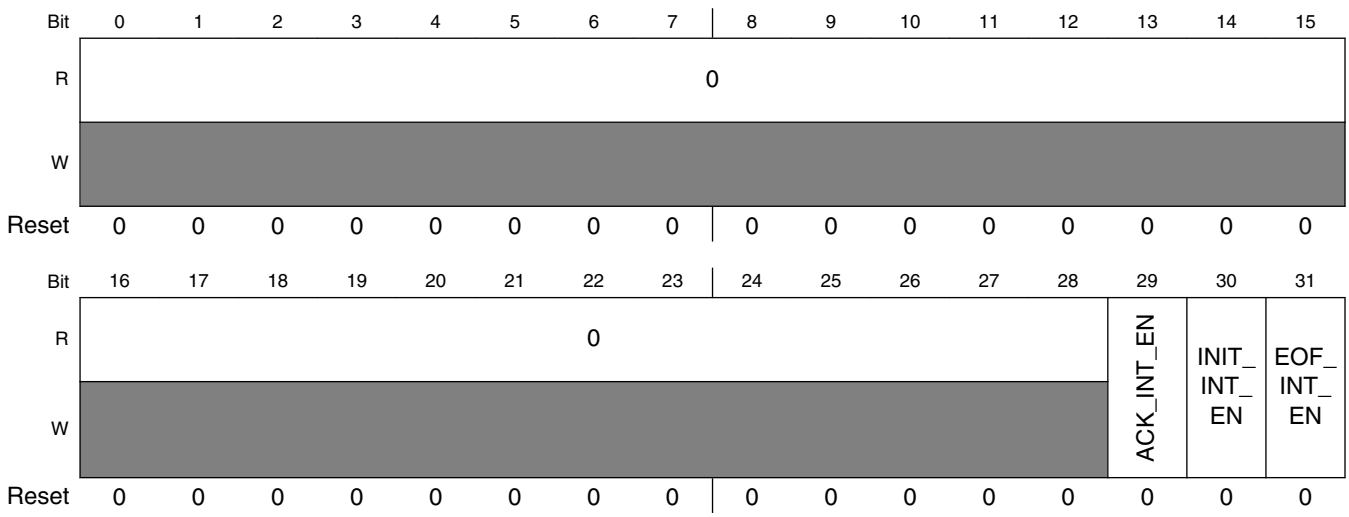
HFInterface_LTDCR field descriptions

Field	Description
0 ENABLE	This bit enables the input signal.
1–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 MAX_VAL	Maximum value Gives the maximum number of clock cycles for a low level time out.

33.6.5 High-level Timeout Detector Configuration Register (HFInterface_HTDCR)

This register controls the high level time out detection. The counter counts as long as the level is stable on the signal input and a rising edge resets the timer for the high signal level.

Address: 0h base + 10h offset = 10h



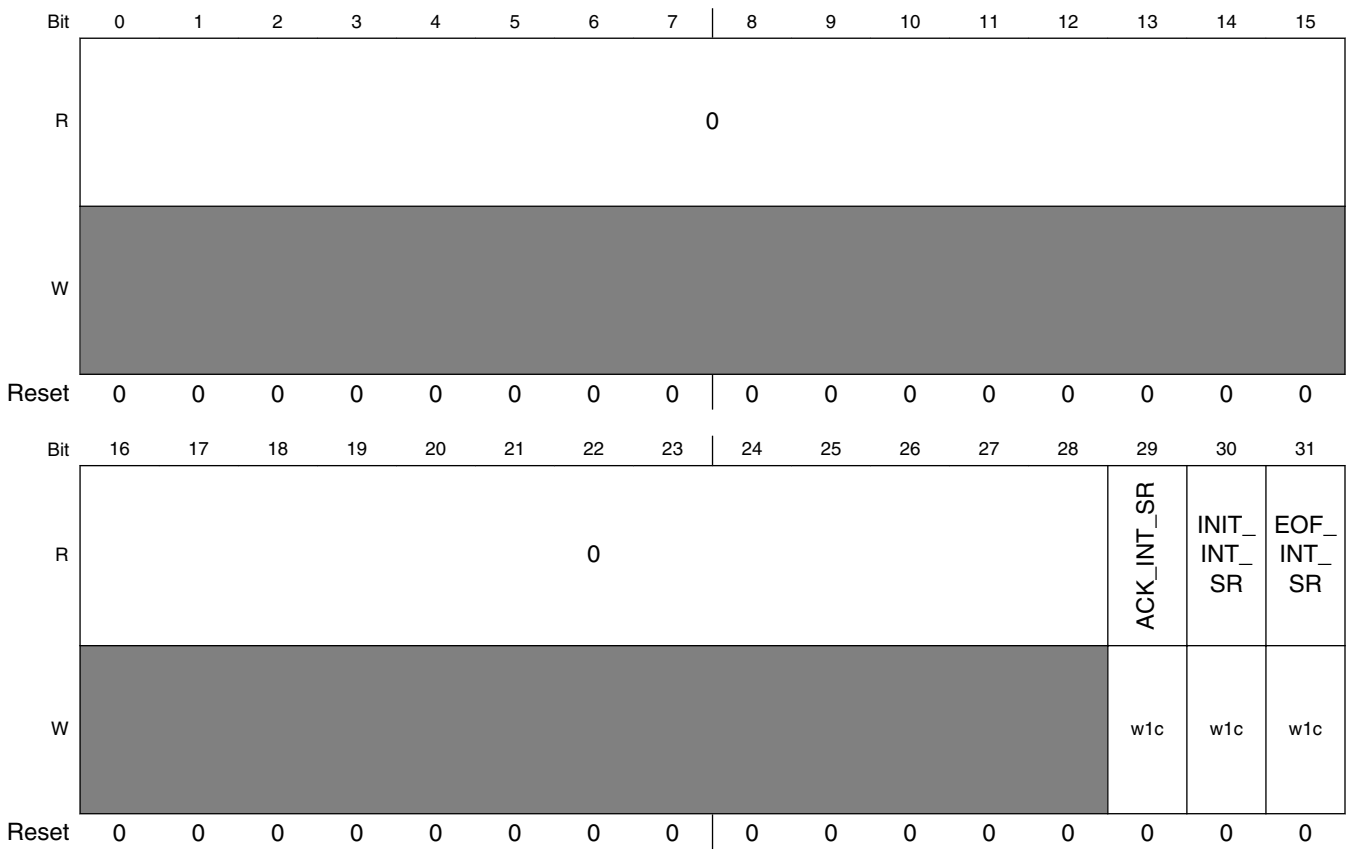
HFInterface_HTDCR field descriptions

Field	Description
0 ENABLE	This bit enables the input signal.
1–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 MAX_VAL	Maximum value Gives the maximum number of clock cycles for a high level time out.

33.6.6 Interrupt Enable Register (HFInterface_IER)

This register enables the interrupt signal.

Address: 0h base + 14h offset = 14h



HFInterface_IER field descriptions

Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 ACK_INT_EN	Interrupt enable for ACK pulse interrupt.
30 INIT_INT_EN	Interrupt enable for INIT pulse interrupt.
31 EOF_INT_EN	Interrupt enable for level-timeout interrupt (low or high).

33.6.7 Interrupt Status Register (HFInterface_ISR)

This register gives the status of interrupt signals.

Address: 0h base + 18h offset = 18h

HFInterface_ISR field descriptions

Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 ACK_INT_SR	Interrupt status for ACK pulse interrupt.
30 INIT_INT_SR	Interrupt status for INIT pulse interrupt.
31 EOF_INT_SR	Interrupt status for level-timeout interrupt (low or high).

Chapter 34
Analog-to-Digital Converter (ADC)

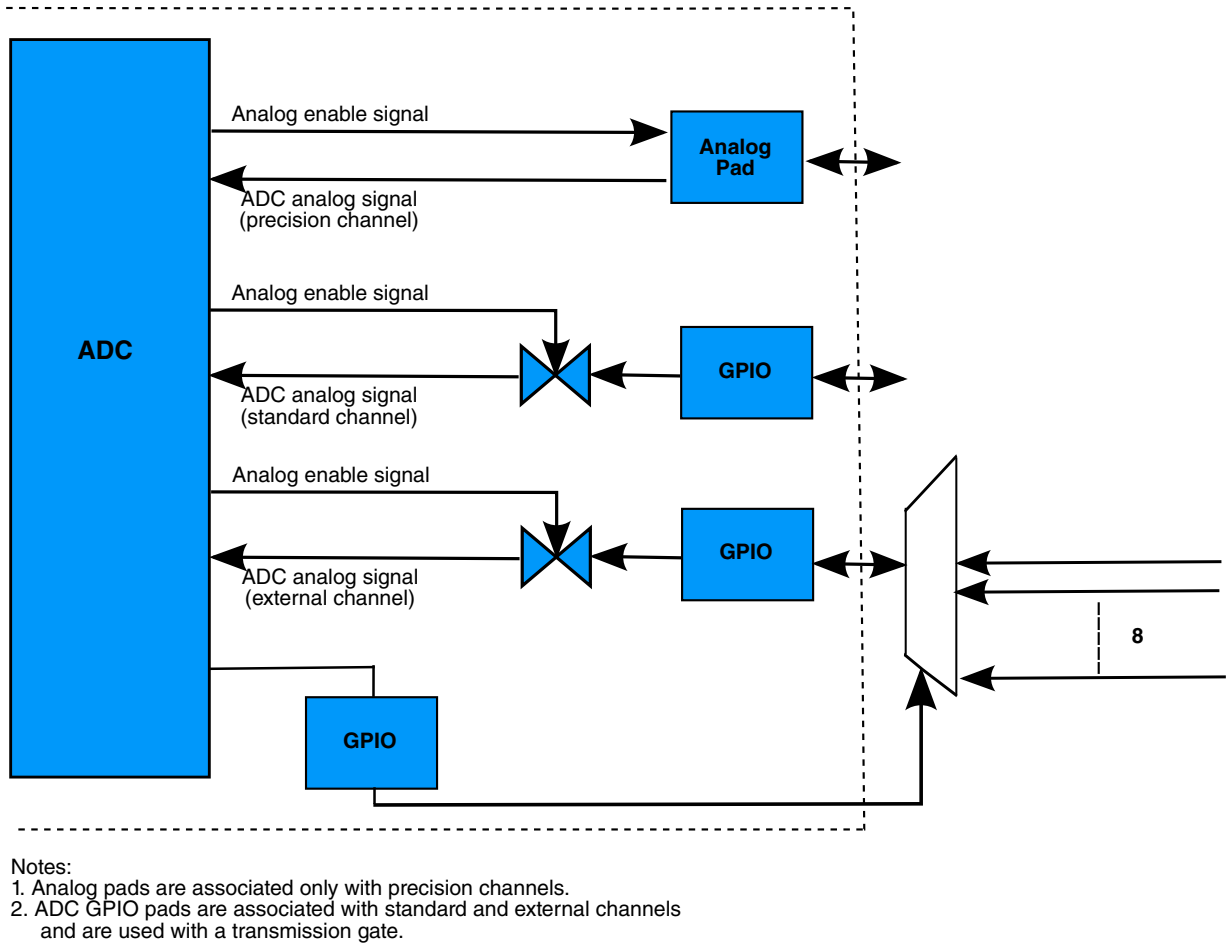
34.1 Chip-specific ADC information

34.1.1 ADC configuration

The MPC5746C supports two independent SAR ADCs: one 10-bit ADC (ADC0) and one 12-bit ADC (ADC1).

NOTE

- ADC0 and ADC1 have differences in their features and control registers. See the following sections for details.
- See the *MPC5746C Microcontroller Data Sheet* for performance specifications.



34.1.2 Feature comparison

The following table lists the features for each of the on-chip SAR ADC modules. Refer Figure 34-1 for ADC channel mapping details with various pads.

Table 34-1. ADC features

Feature	ADC_0 (10-bit)	ADC_1 (12-bit)
Resolution	10-bit	12-bit
No. of precision channels	0	16
No. of standard internal channels	36	16
No. of special internal channels	5	5
No. of external channels	32	32
BCTU trigger support	yes	yes
DMA support	yes	yes
Presampling support	yes	yes
No. of watchogs	6	3

Figure 34-1 shows the difference between standard, precision and external channels.

Notes:
1. Analog pads are associated only with precision channels.
2. ADC GPIO pads are associated with standard and external channels and are used with a transmission gate.

Figure 34-1. ADC channel types

34.1.3 ADC register reset values

Reset values for the following ADC registers varies per the ADC instance. This value overrides the reset value that is shown in the body of this chapter.

Table 34-2. ADC register reset values[1]

Register	ADC_0 Reset Value (10-bit ADC)	ADC_1 Reset Value (12-bit ADC)
Threshold Register 0 (THRHLR0)	03FF_0000h	0FFF_0000h
Threshold Register 1 (THRHLR1)	03FF_0000h	0FFF_0000h
Threshold Register 2 (THRHLR2)	03FF_0000h	0FFF_0000h
Threshold Register 3 (THRHLR3)	03FF_0000h	—[1]
Threshold Register 4 (THRHLR4)	03FF_0000h	—[1]

Table continues on the next page...

Table 34-2. ADC register reset values[1] (continued)

Register	ADC_0 Reset Value (10-bit ADC)	ADC_1 Reset Value (12-bit ADC)
Threshold Register 5 (THRHLR5)	03FF_0000h	—[1]
Calibration, BIST Control and status register (CALBISTREG)	4137_06F6h	C73706F6h
Conversion Timing Register 0 (CTR0)	0000_0014h	0000_0014h
Conversion Timing Register 1 (CTR1)	0000_0014h	0000_0014h
Conversion Timing Register 2 (CTR2)	0000_0014h	0000_0014h

1. ADC_1 does not include the THRHLR3,THRHLR4, and THRHLR5 registers.

34.1.4 SARADC control registers

Not all control registers are applicable to every ADC instance. The following table shows the registers applicable to each.

Table 34-3. SAR ADC control register applicability

Register	ADC_0	ADC_1
Main Configuration Register (ADC_MCR)	yes	yes
Main Status register (ADC_MSR)	yes	yes
Interrupt Status Register (ADC_ISR)	yes	yes
Channel Pending register 0 (ADC_CEOCFR0)	yes	yes
Channel Pending register 1 (ADC_CEOCFR1)	yes	yes
Channel Pending register 2 (ADC_CEOCFR2)	yes	yes
Interrupt Mask Register (ADC_IMR)	yes	yes
Channel Interrup Mask Register 0 (ADC_CIMR0)	yes	yes
Channel Interrup Mask Register 1 (ADC_CIMR1)	yes	yes
Channel Interrup Mask Register 2 (ADC_CIMR2)	yes	yes
Watchdog Threshold Interrupt Status Register (ADC_WTISR)	yes	yes
Watchdog Threshold Interrupt Mask Register (ADC_WTIMR)	yes	yes

34.1.5 ADC channel mapping

The following table shows the ADC channel mapping with respect to Precision[P], Standard[S] and External[X] channels. Please refer to the device IO Signal Description Input Multiplexing Tables workbook for input signal descriptions and the mapping of signals to device pins.

Table 34-4. ADC channel mapping

Channel Number	Source of Inputs	
	ADC_0 (10-bit)	ADC_1 (12-bit)
0	—	ADC1_P[4]
1	—	ADC1_P[5]
2	—	ADC1_P[6]
3	ADC0_S[1]	ADC1_P[7]
4	ADC0_S[0]	ADC1_P[8]
5	—	ADC1_P[9]
6	—	ADC1_P[10]
7	ADC0_S[2]	ADC1_P[11]
8	ADC0_S[8]	ADC1_P[12]
9	—	ADC1_P[0]
10	—	ADC1_P[1]
11	ADC0_S[9]	ADC1_P[2]
12	ADC0_S[10]	ADC1_P[3]

Table continues on the next page...

Table 34-4. ADC channel mapping (continued)

Channel Number	Source of Inputs	
	ADC_0 (10-bit)	ADC_1 (12-bit)
13	—	ADC1_P[13]
14	—	ADC1_P[14]

34.1.8 BCTU Interface

Both ADCs are triggered from the BCTU. The BCTU provides channel conversion commands to the ADC (includes channel number information). In addition, the ADC provides the conversion result back to the BCTU.

34.1.9 DMA interface

Each ADC supports a single DMA request that can be requested after the conversion of every channel

NOTE

The last ongoing conversion will be aborted as soon as ADC gets STOP request from the software and it will move to STOP mode.

34.1.10 ADC's stop-stop ack protocol

The software must ensure to poll ADC_MSR[ADCSTATUS] to be "idle" before asserting the stop request to the ADC module.

34.2 Introduction

The analog-to-digital converter (ADC) uses Successive Approximation Register (SAR) architecture and provides accurate and fast conversions for a wide range of applications.

34.3 Overview

34.3.1 Parts of the ADC

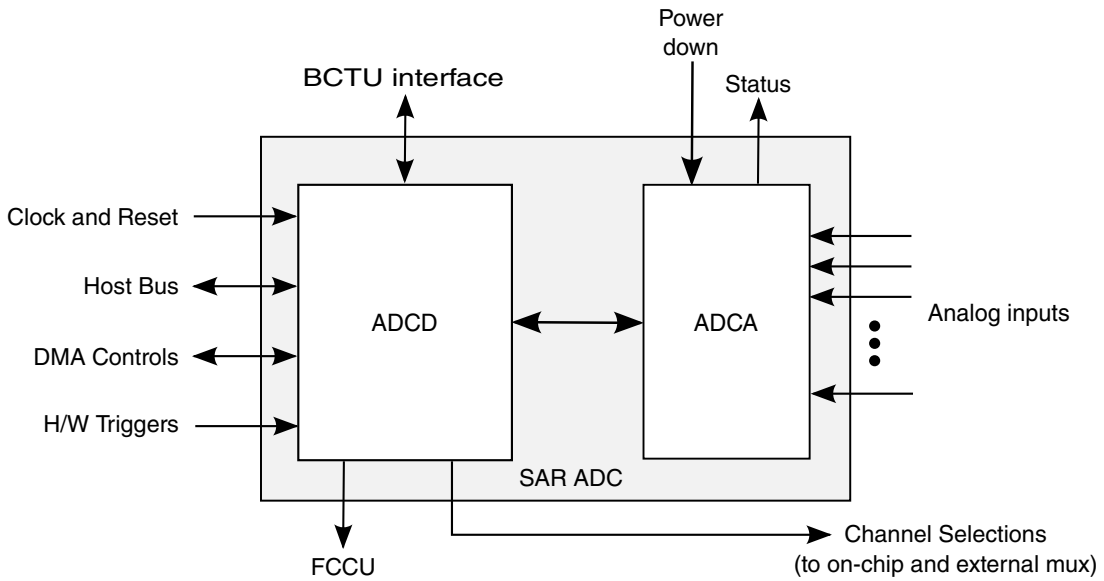

Figure 34-2. ADC high-level block diagram

The ADC is comprised of:

- An ADC digital interface (ADCD). The ADCD holds the configuration, control, and status registers accessible to software via the host bus. The converted value is stored in a register and then transferred through the DMA or host access.
- An ADC analog hard macrocell (ADCA). The analog channel inputs are fed to the inputs of the ADCA. Each channel is sampled for a specific duration and compared with an analog voltage generated with digital code via a digital-to-analog converter (DAC) in the ADCA. The comparison result is given to the ADCD to generate the converted digital value.

34.3.2 ADC clock signals

The ADC uses the following clock signals:

- Bus clock—bus clock at ADCD. Used to access the registers and the operating clock of inter-module interfaces.
- AD_clk—derived from *bus clock*, this signal serves as the operating clock for the ADCA and the SAR controller inside the ADCD.

The relation between the two clocks is determined by the setting of the ADC_MCR[ADCLKSEL] field.

- If ADC_MCR[ADCLKSEL] is 1, the clock signals are the same
- If ADC_MCR[ADCLKSEL] is 0, AD_clk is half of the bus clock.

NOTE

1. Regardless of the setting of the ADC_MCR[ADCLKSEL] field, the maximum clock speed for the ADC clock (AD_clk) is 80 MHz.
2. Depending on your chip's configuration and timing needs, MCR[ADCLKSEL] may always need to be 1.

If the bus clock for the microcontroller is 80 MHz and ADC_MCR[ADCLKSEL] is 1, the ADC clock (AD_clk) is 80 MHz.

If the bus clock for the microcontroller is 80 MHz and ADC_MCR[ADCLKSEL] is 0, the ADC clock (AD_clk) is 40 MHz.

See ADCLKSEL for details on the ADC_MCR register fields.

34.3.3 About ADC channels

ADC channels are divided into 3 groups, each with independent configuration settings. Each group may have different accuracy/performance levels depending on system need (check device configuration for details).

The groups are:

- Group 1, referred to as *precision* channels:
  - 0 - 23 (ADC0—10 bit)
  - 0 - 15 (ADC1—12 bit)
- Group 2, referred to as *internal* channels:
  - 32 - 63 (ADC0—10 bit)
  - 32 - 57 (ADC1—12 bit)
- Group 3, referred to as *external* channels[1] :
  - 64 to 95 (ADC0—10 bit)
  - 64 to 95 (ADC1—12 bit)

NOTE

Accuracy of *external* channels can be increased by increasing the sampling duration, i.e., by increasing the value in the ADC_CTR*n*[INPSAMP] register field. This should be done with caution, though, because increasing sampling duration also

1. This group has an 8 x 1 external multiplexing option. A 3-bit output control is provided for shared use by 4 multiplexers.

increases total conversion time, resulting in a *decrease* in the number of samples per second.

34.3.3.1 Channel configuration

ADC channels can be configured in the following ways:

- The sampling duration of each channel type, i.e., *precision* channels, *internal* channels, *external* channels, is controlled independently, through programming the respective Conversion Timing Register (CTR).
- Separate mask registers for each channel type can be programmed to configure the channels to be converted (each bit in these registers represents one channel).
- External channel selection is provided through external decode signals and is available at the port. Each set of eight external channels can be mapped to an analog input. (See the chip-specific configuration for availability.)
- Analog watchdogs allow continuous hardware monitoring of the converted value from input channels. (See the chip-specific configuration for availability.)
- Presampling

NOTE

Each type of channel is converted in the same way.

34.3.3.2 Initiating conversions

Conversions can be initiated by either software or hardware.

The ADCD has an on-chip Cross-Triggering Unit (BCTU) interface that can also initiate conversions. The BCTU interface supports BCTU Trigger mode and BCTU Control mode (mode is selected via setting the ADC_MCR[CTU_MODE] field).

An example of an application for which BCTU triggering is suitable is a current control loop for lamps or LEDs. Using an on-chip timer module as trigger source, a BCTU can initiate periodic conversions.

34.3.3.3 Interrupt/DMA support

The ADCD provides interrupt/DMA support for each type of channel for various end-of-channel conversion conditions. Data can be transferred via DMA.

34.4 Features

The following general features are implemented in the ADC. (See the chip-specific section for availability of features, as each instance of an ADC within a chip may support different features.)

- Resolution: 10- or 12-bit
- Maximum speed: 1 Mega samples/second at 80 MHz
- Up to 88 channels
- Separate sampling time register for each available range of channels:
  - *precision* channels:
    - 0 - 23 (ADC0—10 bit)
    - 0 - 15 (ADC1—12 bit)
  - *internal* channels:
    - 32 - 63 (ADC0—10 bit)
    - 32 - 57 (ADC1—12 bit)
  - *external* channels:
    - 64 to 95 (ADC0—10 bit)
    - 64 to 95 (ADC1—12 bit)
- External decode signals available for (8 × 1) configuration (external channels only)
- Modes of operation:
  - Normal
  - Injected
  - BCTU
- Normal mode supports One-Shot/Scan (continuous)
- Injected mode supports One-Shot
- Presampling
- Power-Down mode
- Two abort features that allow you to abort either a single channel in a chain or the full chain in normal and injected mode
- Each channel has a dedicated register for conversion results and mode of operation (normal, injected, or BCTU)
- Analog watchdog support:
  - Up to 6 analog watchdogs
  - Configurable for different channels
- Auto clock-off feature
- Programmable clock prescaler (bus clock divided by 2)
- Two BCTU modes: Control and Trigger
- DMA support for each channel
- Interrupts for the following conditions:

    - End of conversion for a single channel for both normal and injected conversions
    - End of conversion for a chain for both normal and injected conversions
    - End of BCTU conversion
    - Watchdog thresholds crossover
- Software-initiated calibration

34.5 Memory Map/Register Definition

The following tables describe the registers and bit meanings for this module.

NOTE

There will be an Access Error for Reserved and out-of-range addresses. Special exceptions are the Reserved spaces at 039Ch and 03A4h: Do not write or change any value in these locations, or the ADC might malfunction.

NOTE

See the chip-specific configuration information because not all registers are available in all ADC instances.

Control logic registers:

- Main Configuration Register (ADC_MCR)
- Main Status register (ADC_MSR)
- Interrupt Status Register (ADC_ISR)
- Channel Pending register 0 (ADC_CEOCFR0)
- Channel Pending register 1 (ADC_CEOCFR1)
- Channel Pending register 2 (ADC_CEOCFR2)
- Interrupt Mask Register (ADC_IMR)
- Channel Interrupt Mask Register 0 (ADC_CIMR0)
- Channel Interrupt Mask Register 1 (ADC_CIMR1)
- Channel Interrupt Mask Register 2 (ADC_CIMR2)
- Watchdog Threshold Interrupt Status Register (ADC_WTISR)
- Watchdog Threshold Interrupt Mask Register (ADC_WTIMR)
- Analog Watchdog Out of Range Register 0 (ADC_AWORR0)
- Analog Watchdog Out of Range Register 1 (ADC_AWORR1)
- Analog Watchdog Out of Range Register 2 (ADC_AWORR2)

DMA registers:

- DMA Enable register (ADC_DMAE)
- DMA Channel Select Register 0 (ADC_DMAR0)

- DMA Channel Select Register 1 (ADC_DMAR1)
- DMA Channel Select Register 2 (ADC_DMAR2)

Threshold registers:

These registers are used to store the user programmable lower and upper thresholds 12-bit values. These registers include:

- Threshold Register (ADC_THRHLR*n*)

Presampling registers:

- Presampling Control Register (ADC_PSCR)
- Presampling register 0 (ADC_PSR0)
- Presampling register 1 (ADC_PSR1)
- Presampling register 2 (ADC_PSR2)

Conversion timing registers:

- Conversion Timing Register 0 (ADC_CTR0)
- Conversion Timing Register 1 (ADC_CTR1)
- Conversion Timing Register 2 (ADC_CTR2)

Mask register: These registers are used to program which input channels must be converted during Normal and Injected conversion. These registers include:

- Normal Conversion Mask Register 0 (ADC_NCMR0)
- Normal Conversion Mask Register 1 (ADC_NCMR1)
- Normal Conversion Mask Register 2 (ADC_NCMR2)
- Injected Conversion Mask Register 0 (ADC_JCMR0)
- Injected Conversion Mask Register 1 (ADC_JCMR1)
- Injected Conversion Mask Register 2 (ADC_JCMR2)

Delay registers:

- Power Down Exit Delay Register (ADC_PDEDR)
- Decode Signals Delay Register (ADC_DSDR)

Data registers:

The conversion results for the internal channels are loaded into data registers. Each data register also gives information regarding the corresponding result. These registers start with CDR0:

- Channel Data Register *n* (Precision Channels) (ADC_CDR*n*)

Other registers include:

- Calibration, BIST Control and status Register (ADC_CALBISTREG)
- Offset and Gain User Register (ADC_OFSGNUSR)

ADC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Main Configuration Register (ADC_MCR)	32	R/W	0000_0101h	34.5.1/760
4	Main Status register (ADC_MSR)	32	R	0000_0001h	34.5.2/763
10	Interrupt Status Register (ADC_ISR)	32	R/W	0000_0000h	34.5.3/765
14	Channel Pending register 0 (ADC_CEOCFR0)	32	R/W	0000_0000h	34.5.4/766
18	Channel Pending register 1 (ADC_CEOCFR1)	32	R/W	0000_0000h	34.5.5/769
1C	Channel Pending register 2 (ADC_CEOCFR2)	32	R/W	0000_0000h	34.5.6/772
20	Interrupt Mask Register (ADC_IMR)	32	R/W	0000_0000h	34.5.7/775
24	Channel Interrupt Mask Register 0 (ADC_CIMR0)	32	R/W	0000_0000h	34.5.8/775
28	Channel Interrupt Mask Register 1 (ADC_CIMR1)	32	R/W	0000_0000h	34.5.9/778
2C	Channel Interrupt Mask Register 2 (ADC_CIMR2)	32	R/W	0000_0000h	34.5.10/ 780
30	Watchdog Threshold Interrupt Status Register (ADC_WTISR)	32	R/W	0000_0000h	34.5.11/ 783
34	Watchdog Threshold Interrupt Mask Register (ADC_WTIMR)	32	R/W	0000_0000h	34.5.12/ 785
40	DMA Enable register (ADC_DMAE)	32	R/W	0000_0000h	34.5.13/ 786
44	DMA Channel Select Register 0 (ADC_DMAR0)	32	R/W	0000_0000h	34.5.14/ 787
48	DMA Channel Select Register 1 (ADC_DMAR1)	32	R/W	0000_0000h	34.5.15/ 789
4C	DMA Channel Select Register 2 (ADC_DMAR2)	32	R/W	0000_0000h	34.5.16/ 792
60	Threshold Register (ADC_THRHLR0)	32	R/W	0FFF_0000h	34.5.17/ 794
64	Threshold Register (ADC_THRHLR1)	32	R/W	0FFF_0000h	34.5.17/ 794
68	Threshold Register (ADC_THRHLR2)	32	R/W	0FFF_0000h	34.5.17/ 794
6C	Threshold Register (ADC_THRHLR3)	32	R/W	0FFF_0000h	34.5.17/ 794
80	Presampling Control Register (ADC_PSCR)	32	R/W	0000_0000h	34.5.18/ 795
84	Presampling register 0 (ADC_PSR0)	32	R/W	0000_0000h	34.5.19/ 796
88	Presampling register 1 (ADC_PSR1)	32	R/W	0000_0000h	34.5.20/ 798
8C	Presampling register 2 (ADC_PSR2)	32	R/W	0000_0000h	34.5.21/ 801
94	Conversion Timing Register 0 (ADC_CTR0)	32	R/W	0000_0014h	34.5.22/ 803
98	Conversion Timing Register 1 (ADC_CTR1)	32	R/W	0000_0014h	34.5.23/ 804

Table continues on the next page...

ADC memory map (continued)

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
9C	Conversion Timing Register 2 (ADC_CTR2)	32	R/W	0000_0016h	34.5.24/ 804
A4	Normal Conversion Mask Register 0 (ADC_NCMR0)	32	R/W	0000_0000h	34.5.25/ 805
A8	Normal Conversion Mask Register 1 (ADC_NCMR1)	32	R/W	0000_0000h	34.5.26/ 807
AC	Normal Conversion Mask Register 2 (ADC_NCMR2)	32	R/W	0000_0000h	34.5.27/ 810
B4	Injected Conversion Mask Register 0 (ADC_JCMR0)	32	R/W	0000_0000h	34.5.28/ 812
B8	Injected Conversion Mask Register 1 (ADC_JCMR1)	32	R/W	0000_0000h	34.5.29/ 814
BC	Injected Conversion Mask Register 2 (ADC_JCMR2)	32	R/W	0000_0000h	34.5.30/ 817
C4	Decode Signals Delay Register (ADC_DSDR)	32	R/W	0000_0000h	34.5.31/ 820
C8	Power Down Exit Delay Register (ADC_PDEDR)	32	R/W	0000_0000h	34.5.32/ 820
100	Channel Data Register n (Precision Channels) (ADC_CDR0)	32	R	0000_0000h	34.5.33/ 821
104	Channel Data Register n (Precision Channels) (ADC_CDR1)	32	R	0000_0000h	34.5.33/ 821
108	Channel Data Register n (Precision Channels) (ADC_CDR2)	32	R	0000_0000h	34.5.33/ 821
10C	Channel Data Register n (Precision Channels) (ADC_CDR3)	32	R	0000_0000h	34.5.33/ 821
110	Channel Data Register n (Precision Channels) (ADC_CDR4)	32	R	0000_0000h	34.5.33/ 821
114	Channel Data Register n (Precision Channels) (ADC_CDR5)	32	R	0000_0000h	34.5.33/ 821
118	Channel Data Register n (Precision Channels) (ADC_CDR6)	32	R	0000_0000h	34.5.33/ 821
11C	Channel Data Register n (Precision Channels) (ADC_CDR7)	32	R	0000_0000h	34.5.33/ 821
120	Channel Data Register n (Precision Channels) (ADC_CDR8)	32	R	0000_0000h	34.5.33/ 821
124	Channel Data Register n (Precision Channels) (ADC_CDR9)	32	R	0000_0000h	34.5.33/ 821
128	Channel Data Register n (Precision Channels) (ADC_CDR10)	32	R	0000_0000h	34.5.33/ 821
12C	Channel Data Register n (Precision Channels) (ADC_CDR11)	32	R	0000_0000h	34.5.33/ 821
130	Channel Data Register n (Precision Channels) (ADC_CDR12)	32	R	0000_0000h	34.5.33/ 821

3A0	Calibration, BIST Control and status Register (ADC_CALBISTREG)	32	R/W	C737_06F6h	34.5.54/ 853
3A8	Offset and Gain User Register (ADC_OFSGNUSR)	32	R/W	0000_0000h	34.5.55/ 855

34.5.1 Main Configuration Register (ADC_MCR)

Address: 0h base + 0h offset = 0h

ADC_MCR field descriptions

Field	Description
0 OWREN	Overwrite enable. 0 Older valid conversion data is not overwritten by newer conversion data. 1 Newer conversion result is always overwritten, irrespective of the validity of older conversion data.
1 WLSIDE	Write Left/Right aligned. 0 The conversion data is written right aligned from (32-resolution) to 31). 1 Data is left aligned (from 16 to (16 + resolution - 1).
2 MODE	One_Shot/Scan. 0 One_Shot Mode: configure the Normal conversion of one chain. 1 Scan Mode: configure continuous chain conversion mode; when the programmed chain conversion is finished it restarts immediately.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 Reserved	This field is reserved. Writing a value to this field has no effect.
5 Reserved	This field is reserved. Writing a value to this field has no effect.
6 Reserved	This field is reserved. **NOTE:** User must not overwrite default value of this field.
7 NSTART	Start of Normal conversion. Setting this field starts a normal conversion. In One shot mode: This field is cleared as soon as conversion is started. Setting this field during any ongoing conversion keeps this bit high until the requested conversion is started.

Table continues on the next page...

ADC_MCR field descriptions (continued)

Field	Description
	NOTE: This bit cannot be set (1) when PWDN = 1. This bit is always cleared when PWDN = 1.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 JTRGEN	Injection external trigger enable. When set, enables the external trigger to start a injected conversion; if the external trigger feature is needed for injected conversion then this field must be set.
10 JEDGE	Injection trigger edge selection. Edge selection for external trigger; if JTRGEN is one this bit selects the falling (JEDGE = zero) or rising (JEDGE = one) edge for the external trigger.
11 JSTART	Injection start. Setting this field will start the configured injected conversion chain. Resetting this field has no effect, as the injected chain conversion cannot be interrupted. Setting this field during ongoing Injected conversion keeps this field high value until the requested conversion is started.
12–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 CTUEN	Crosstrigger Unit Enable. Enables the crosstriggering unit (BCTU). 0 The crosstriggering unit is disabled and the BCTU-triggered injected conversion cannot take place. 1 The crosstriggering unit is enabled and the BCTUtriggered injected conversion can take place.
15 CTU_MODE	Crosstrigger Unit MODE bit When both modes are present in an ADC instance, this bit sets the operating mode of the ADC with respect to the BCTU. Please see the chip-specific ADC section for whether a specific ADC instance has both modes. Otherwise, treat this bit as Reserved. 0 BCTU control mode is selected. 1 BCTU trigger mode is selected.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 ADCLKSEL	Analog Clock frequency Selector. This field can be written in Power Down mode only. Please check device specific additional restriction on programming of this field. 0 ADC clock frequency is half of bus clock 1 ADC clock frequency is equal to bus clock
24 ABORT_CHAIN	Abort Chain. If this bit is set the ongoing Chain Conversion is aborted. This bit gets reset by hardware as soon as a new conversion is requested. **NOTE:** Setting this bit in idle state (no normal/injected conversion is ongoing) has no effect. In this case it is reset immediately. During ongoing BCTU conversion this bit also cannot be programmed.

Table continues on the next page...

ADC_MCR field descriptions (continued)

Field	Description
25 ABORT	Abort Conversion. If this bit is set, the ongoing channel conversion is aborted and the next channel conversion is invoked. This bit gets reset by hardware as soon as the new conversion is invoked. **NOTE:** Setting this bit in idle state (No Normal/injected conversion is ongoing) has no effect. In this case it is reset immediately. During ongoing BCTU conversion this bit cannot be programmed
26 ACKO	Auto clock off enable. If set, enables the Auto clock off feature.
27–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 REFSEL	Reference voltage selection for ADC analog part. 00 Select VREFH as reference voltage [1] 01 Reserved 10 Reserved 11 Reserved
31 PWDN	Power-down enable. When this bit is set, the analog module is requested to enter Power-Down mode. When the ADC's status is PWDN, resetting this bit will start the ADC's transition to IDLE mode. In BCTU control mode MCR[CTUEN] must be reset before entering into power-down mode.

1. For ADC0, VREFH corresponds to VDD_HV_ADC0
   For ADC1, VREFH corresponds to VDD_HV_ADC1_REF

34.5.2 Main Status register (ADC_MSR)

Address: 0h base + 4h offset = 4h

ADC_MSR field descriptions

Field	Description
0 CALIBRTD	This bit indicates the ADC calibration status. This bit gets updated after running the High Accuracy Calibration mode. 0 Uncalibrated or calibration unsuccessful 1 Calibration was run and it was successful

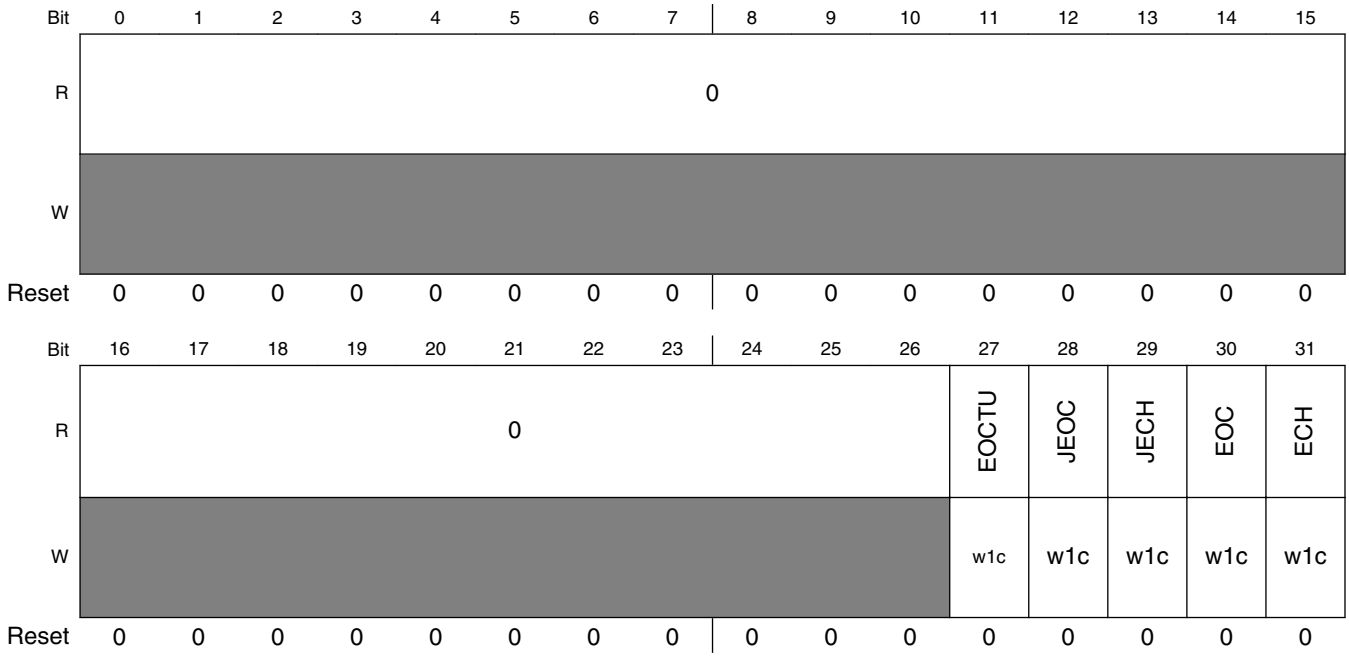

Table continues on the next page...

ADC_MSR field descriptions (continued)

Field	Description
1–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 NSTART	This status bit is used to signal that a Normal conversion is ongoing.
8 JABORT	This status bit is used to signal that an Injected conversion has been aborted by BCTU. That bit is reset when a new injected conversion starts.
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 JSTART	This status bit is used to signal that an Injected conversion is ongoing.
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 CTUSTART	This status bit is used to signal that a BCTU conversion is ongoing. This bit is set when a BCTU trigger pulse is received and the BCTU conversion starts.When BCTU trigger mode is enabled this bit is automatically reset when the conversion is completed.When Control Mode is enabled this bit is reset when the BCTU is disabled (CTUEN set to 0).
16–22 CHADDR	Channel under measure address. Status bits are used to signal which channel is under measure. MSR[CHADDR] is only valid when the SARADC is in the sample phase of the conversion (MSR[ADCSTATUS] = 100b).
23–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 ACKO	Auto clock off enable. This status bit is used to signal if the Auto clock off feature is on.
27–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 ADCSTATUS	Status of the ADC. 000 Idle 001 Power Down 100 Sample 110 Conversion 010 Wait state (waiting to start conversion [external trigger]) The start of ADC conversion can be delayed (after a programmed duration in "DSDR" register) for a time after the application of trigger for External channels. During this wait period the ADCSTATUS is shown as "wait state". 011 Busy in Calibration

34.5.3 Interrupt Status Register (ADC_ISR)

Address: 0h base + 10h offset = 10h

ADC_ISR field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 EOCTU	End of BCTU conversion. This bit is set for a digital end of conversion on a the BCTU Channel; active when set.
28 JEOC	End of injected channel conversion. This bit is set for a digital end of conversion on an injected channel; active when set.
29 JECH	End of injected chain conversion. This bit is set for a digital end of chain conversion on an injected channel; active when set. **NOTE:** If there is no channel selected in the ADC_JCMR*n* register(s) and there is a start of conversion trigger, then ADC_ISR[JECH] is set and a JECH interrupt is immediately issued (if enabled). Similarly, if no channel is selected in the ADC_NCMR*n* register and a normal conversion is triggered, ADC_ISR[ECH] is set and an ECH interrupt is immediately issued, if enabled.
30 EOC	End of channel conversion. This bit is set for a digital end of conversion on a Normal Channel; active when set.
31 ECH	End of chain conversion. This bit is set for a digital end of chain conversion on a Normal Channel; active when set. **NOTE:** If there is no channel selected in the ADC_NCMR*n* register(s) and there is a start of conversion trigger, then ADC_ISR[ECH] is set and an ECH interrupt is immediately issued (if enabled).

Table continues on the next page...

ADC_ISR field descriptions (continued)

Field	Description
	Similarly, if no channel is selected in the ADC_JCMR*n* register and an injected conversion is triggered, ADC_ISR[JECH] is set and a JECH interrupt is immediately issued, if enabled.

34.5.4 Channel Pending register 0 (ADC_CEOCFR0)

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

34.5.7 Interrupt Mask Register (ADC_IMR)

Address: 0h base + 20h offset = 20h

ADC_IMR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 MSKEOCTU	Mask bit for EOCTU. When set, the interrupt is enabled.
28 MSKJEOC	Mask bit for JEOC. When set, the interrupt is enabled.
29 MSKJECH	Mask bit for JECH. When set, the interrupt is enabled.
30 MSKEOC	Mask bit for EOC. When set, the interrupt is enabled.
31 MSKECH	Mask bit for ECH. When set, the interrupt is enabled.

34.5.8 Channel Interrupt Mask Register 0 (ADC_CIMR0)

The fields in this register globally enable or disable end of conversion interrupts by channels within the range of Channel 0 through 31.

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific details to find which channels are applicable.

Address: 0h base + 24h offset = 24h

ADC_CIMR0 field descriptions

Field	Description
0 CIM31	Channel 31 interrupt enable. When this field is set, the interrupt for channel 31 is enabled.
1 CIM30	Channel 30 interrupt enable. When this field is set, the interrupt for channel 30 is enabled.
2 CIM29	Channel 29 interrupt enable. When this field is set, the interrupt for channel 29 is enabled.
3 CIM28	Channel 28 interrupt enable. When this field is set, the interrupt for channel 28 is enabled.
4 CIM27	Channel 27 interrupt enable. When this field is set, the interrupt for channel 27 is enabled.
5 CIM26	Channel 26 interrupt enable. When this field is set, the interrupt for channel 26 is enabled.
6 CIM25	Channel 25 interrupt enable. When this field is set, the interrupt for channel 25 is enabled.
7 CIM24	Channel 24 interrupt enable. When this field is set, the interrupt for channel 24 is enabled.
8 CIM23	Channel 23 interrupt enable. When this field is set, the interrupt for channel 23 is enabled.

Table continues on the next page...

ADC_CIMR0 field descriptions (continued)

Field	Description
9 CIM22	Channel 22 interrupt enable. When this field is set, the interrupt for channel 22 is enabled.
10 CIM21	Channel 21 interrupt enable. When this field is set, the interrupt for channel 21 is enabled.
11 CIM20	Channel 20 interrupt enable. When this field is set, the interrupt for channel 20 is enabled.
12 CIM19	Channel 19 interrupt enable. When this field is set, the interrupt for channel 19 is enabled.
13 CIM18	Channel 18 interrupt enable. When this field is set, the interrupt for channel 18 is enabled.
14 CIM17	Channel 17 interrupt enable. When this field is set, the interrupt for channel 17 is enabled.
15 CIM16	Channel 16 interrupt enable. When this field is set, the interrupt for channel 16 is enabled.
16 CIM15	Channel 15 interrupt enable. When this field is set, the interrupt for channel 15 is enabled.
17 CIM14	Channel 14 interrupt enable. When this field is set, the interrupt for channel 14 is enabled.
18 CIM13	Channel 13 interrupt enable. When this field is set, the interrupt for channel 13 is enabled.
19 CIM12	Channel 12 interrupt enable. When this field is set, the interrupt for channel 12 is enabled.
20 CIM11	Channel 11 interrupt enable. When this field is set, the interrupt for channel 11 is enabled.
21 CIM10	Channel 10 interrupt enable. When this field is set, the interrupt for channel 10 is enabled.
22 CIM9	Channel 9 interrupt enable. When this field is set, the interrupt for channel 9 is enabled.
23 CIM8	Channel 8 interrupt enable. When this field is set, the interrupt for channel 8 is enabled.
24 CIM7	Channel 7 interrupt enable. When this field is set, the interrupt for channel 7 is enabled.
25 CIM6	Channel 6 interrupt enable. When this field is set, the interrupt for channel 6 is enabled.
26 CIM5	Channel 5 interrupt enable.

Table continues on the next page...

ADC_CIMR0 field descriptions (continued)

Field	Description
	When this field is set, the interrupt for channel 5 is enabled.
27 CIM4	Channel 4 interrupt enable. When this field is set, the interrupt for channel 4 is enabled.
28 CIM3	Channel 3 interrupt enable. When this field is set, the interrupt for channel 3 is enabled.
29 CIM2	Channel 2 interrupt enable. When this field is set, the interrupt for channel 2 is enabled.
30 CIM1	Channel 1 interrupt enable. When this field is set, the interrupt for channel 1 is enabled.
31 CIM0	Channel 0 interrupt enable. When this field is set, the interrupt for channel 0 is enabled.

34.5.9 Channel Interrupt Mask Register 1 (ADC_CIMR1)

The fields in this register globally enable or disable end of conversion interrupts by channels within the range of Channel 32 through 63.

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific details to find which channels are applicable.

ADC_CIMR1 field descriptions

Field	Description
0 CIM63	Channel 63 interrupt enable. When this field is set, the interrupt for channel 63 is enabled.
1 CIM62	Channel 62 interrupt enable. When this field is set, the interrupt for channel 62 is enabled.
2 CIM61	Channel 61 interrupt enable. When this field is set, the interrupt for channel 61 is enabled.
3 CIM60	Channel 60 interrupt enable. When this field is set, the interrupt for channel 60 is enabled.
4 CIM59	Channel 59 interrupt enable. When this field is set, the interrupt for channel 59 is enabled.
5 CIM58	Channel 58 interrupt enable. When this field is set, the interrupt for channel 58 is enabled.
6 CIM57	Channel 57 interrupt enable. When this field is set, the interrupt for channel 57 is enabled.
7 CIM56	Channel 56 interrupt enable. When this field is set, the interrupt for channel 56 is enabled.
8 CIM55	Channel 55 interrupt enable. When this field is set, the interrupt for channel 55 is enabled.
9 CIM54	Channel 54 interrupt enable. When this field is set, the interrupt for channel 54 is enabled.
10 CIM53	Channel 53 interrupt enable. When this field is set, the interrupt for channel 53 is enabled.
11 CIM52	Channel 52 interrupt enable. When this field is set, the interrupt for channel 52 is enabled.
12 CIM51	Channel 51 interrupt enable. When this field is set, the interrupt for channel 51 is enabled.
13 CIM50	Channel 50 interrupt enable. When this field is set, the interrupt for channel 50 is enabled.
14 CIM49	Channel 49 interrupt enable. When this field is set, the interrupt for channel 49 is enabled.
15 CIM48	Channel 48 interrupt enable. When this field is set, the interrupt for channel 48 is enabled.
16 CIM47	Channel 47 interrupt enable. When this field is set, the interrupt for channel 47 is enabled.
17 CIM46	Channel 46 interrupt enable.

Table continues on the next page...

ADC_CIMR1 field descriptions (continued)

Field	Description
	When this field is set, the interrupt for channel 46 is enabled.
18 CIM45	Channel 45 interrupt enable. When this field is set, the interrupt for channel 45 is enabled.
19 CIM44	Channel 44 interrupt enable. When this field is set, the interrupt for channel 44 is enabled.
20 CIM43	Channel 43 interrupt enable. When this field is set, the interrupt for channel 43 is enabled.
21 CIM42	Channel 42 interrupt enable. When this field is set, the interrupt for channel 42 is enabled.
22 CIM41	Channel 41 interrupt enable. When this field is set, the interrupt for channel 41 is enabled.
23 CIM40	Channel 40 interrupt enable. When this field is set, the interrupt for channel 40 is enabled.
24 CIM39	Channel 39 interrupt enable. When this field is set, the interrupt for channel 39 is enabled.
25 CIM38	Channel 38 interrupt enable. When this field is set, the interrupt for channel 38 is enabled.
26 CIM37	Channel 37 interrupt enable. When this field is set, the interrupt for channel 37 is enabled.
27 CIM36	Channel 36 interrupt enable. When this field is set, the interrupt for channel 36 is enabled.
28 CIM35	Channel 35 interrupt enable. When this field is set, the interrupt for channel 35 is enabled.
29 CIM34	Channel 34 interrupt enable. When this field is set, the interrupt for channel 34 is enabled.
30 CIM33	Channel 33 interrupt enable. When this field is set, the interrupt for channel 33 is enabled.
31 CIM32	Channel 32 interrupt enable. When this field is set, the interrupt for channel 32 is enabled.

34.5.10 Channel Interrupt Mask Register 2 (ADC_CIMR2)

The fields in this register globally enable or disable end of conversion interrupts by channels within the range of Channel 64 through 95.

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific details to find which channels are applicable.

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ADC_WTISR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 WDG5H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 5 (WD5). **NOTE:** Write a '1' to this field to clear it.
21 WDG5L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 5 (WD5). **NOTE:** Write a '1' to this field to clear it.
22 WDG4H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 4 (WD4). **NOTE:** Write a '1' to this field to clear it.
23 WDG4L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 4 (WD4). **NOTE:** Write a '1' to this field to clear it.
24 WDG3H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 3 (WD3). **NOTE:** Write a '1' to this field to clear it.
25 WDG3L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 3 (WD3). **NOTE:** Write a '1' to this field to clear it.
26 WDG2H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 2 (WD2). **NOTE:** Write a '1' to this field to clear it.
27 WDG2L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 2 (WD2). **NOTE:** Write a '1' to this field to clear it.
28 WDG1H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 1 (WD1). **NOTE:** Write a '1' to this field to clear it.
29 WDG1L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 1 (WD1). **NOTE:** Write a '1' to this field to clear it.
30 WDG0H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 0 (WD0). **NOTE:** Write a '1' to this field to clear it.
31 WDG0L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 0 (WD0). **NOTE:** Write a '1' to this field to clear it.

34.5.12 Watchdog Threshold Interrupt Mask Register (ADC_WTIMR)

Address: 0h base + 34h offset = 34h

ADC_WTIMR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 MSKWDG5H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 5 (WD5) being higher than the programmed higher threshold. When set, the interrupt is enabled.
21 MSKWDG5L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 5 (WD5) being lower than the programmed lower threshold. When set, the interrupt is enabled.
22 MSKWDG4H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 4 (WD4) being higher than the programmed higher threshold. When set, the interrupt is enabled.
23 MSKWDG4L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 4 (WD4) being lower than the programmed lower threshold. When set, the interrupt is enabled.
24 MSKWDG3H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 3 (WD3) being higher than the programmed higher threshold. When set, the interrupt is enabled.
25 MSKWDG3L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 3 (WD3) being lower than the programmed lower threshold. When set, the interrupt is enabled.
26 MSKWDG2H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 2 (WD2) being higher than the programmed higher threshold. When set, the interrupt is enabled.
27 MSKWDG2L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 2 (WD2) being lower than the programmed lower threshold. When set, the interrupt is enabled.

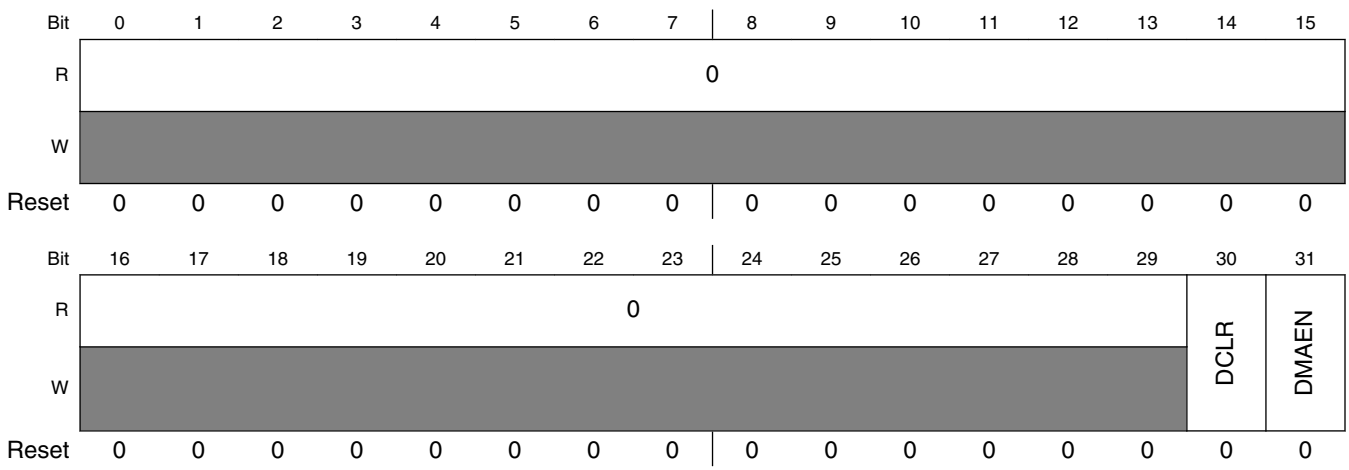

Table continues on the next page...

ADC_WTIMR field descriptions (continued)

Field	Description
28 MSKWDG1H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 1 (WD1) being higher than the programmed higher threshold. When set, the interrupt is enabled.
29 MSKWDG1L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 1 (WD1) being lower than the programmed lower threshold. When set, the interrupt is enabled.
30 MSKWDG0H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 0 (WD0) being higher than the programmed higher threshold. When set, the interrupt is enabled.
31 MSKWDG0L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 0 (WD0) being lower than the programmed lower threshold. When set, the interrupt is enabled.

34.5.13 DMA Enable register (ADC_DMAE)

Address: 0h base + 40h offset = 40h

ADC_DMAE field descriptions

Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 DCLR	DMA Clear sequence enable. 0 DMA request cleared by Acknowledge from DMA controller 1 DMA request cleared on read of data registers
31 DMAEN	DMA global enable. When this bit is set, the DMA feature is enabled.

34.5.14 DMA Channel Select Register 0 (ADC_DMAR0)

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + 44h offset = 44h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

ADC_DMAR1 field descriptions

Field	Description
0 DMA63	DMA enable for channel 63. When set, transferring data in DMA mode is enabled for channel 63.
1 DMA62	DMA enable for channel 62. When set, transferring data in DMA mode is enabled for channel 62.
2 DMA61	DMA enable for channel 61. When set, transferring data in DMA mode is enabled for channel 61.
3 DMA60	DMA enable for channel 60. When set, transferring data in DMA mode is enabled for channel 60.
4 DMA59	DMA enable for channel 59. When set, transferring data in DMA mode is enabled for channel 59.
5 DMA58	DMA enable for channel 58. When set, transferring data in DMA mode is enabled for channel 58.
6 DMA57	DMA enable for channel 57. When set, transferring data in DMA mode is enabled for channel 57.
7 DMA56	DMA enable for channel 56. When set, transferring data in DMA mode is enabled for channel 56.
8 DMA55	DMA enable for channel 55. When set, transferring data in DMA mode is enabled for channel 55.
9 DMA54	DMA enable for channel 54. When set, transferring data in DMA mode is enabled for channel 54.
10 DMA53	DMA enable for channel 53. When set, transferring data in DMA mode is enabled for channel 53.
11 DMA52	DMA enable for channel 52. When set, transferring data in DMA mode is enabled for channel 52.
12 DMA51	DMA enable for channel 51. When set, transferring data in DMA mode is enabled for channel 51.
13 DMA50	DMA enable for channel 50. When set, transferring data in DMA mode is enabled for channel 50.
14 DMA49	DMA enable for channel 49. When set, transferring data in DMA mode is enabled for channel 49.
15 DMA48	DMA enable for channel 48. When set, transferring data in DMA mode is enabled for channel 48.
16 DMA47	DMA enable for channel 47. When set, transferring data in DMA mode is enabled for channel 47.
17 DMA46	DMA enable for channel 46.

Table continues on the next page...

ADC_DMAR1 field descriptions (continued)

Field	Description
	When set, transferring data in DMA mode is enabled for channel 46.
18 DMA45	DMA enable for channel 45. When set, transferring data in DMA mode is enabled for channel 45.
19 DMA44	DMA enable for channel 44. When set, transferring data in DMA mode is enabled for channel 44.
20 DMA43	DMA enable for channel 43. When set, transferring data in DMA mode is enabled for channel 43.
21 DMA42	DMA enable for channel 42. When set, transferring data in DMA mode is enabled for channel 42.
22 DMA41	DMA enable for channel 41. When set, transferring data in DMA mode is enabled for channel 41.
23 DMA40	DMA enable for channel 40. When set, transferring data in DMA mode is enabled for channel 40.
24 DMA39	DMA enable for channel 39. When set, transferring data in DMA mode is enabled for channel 39.
25 DMA38	DMA enable for channel 38. When set, transferring data in DMA mode is enabled for channel 38.
26 DMA37	DMA enable for channel 37. When set, transferring data in DMA mode is enabled for channel 37.
27 DMA36	DMA enable for channel 36. When set, transferring data in DMA mode is enabled for channel 36.
28 DMA35	DMA enable for channel 35. When set, transferring data in DMA mode is enabled for channel 35.
29 DMA34	DMA enable for channel 34. When set, transferring data in DMA mode is enabled for channel 34.
30 DMA33	DMA enable for channel 33. When set, transferring data in DMA mode is enabled for channel 33.
31 DMA32	DMA enable for channel 32. When set, transferring data in DMA mode is enabled for channel 32.

34.5.16 DMA Channel Select Register 2 (ADC_DMAR2)

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + 4Ch offset = 4Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	DMA95	DMA94	DMA93	DMA92	DMA91	DMA90	DMA89	DMA88	DMA87	DMA86	DMA85	DMA84	DMA83	DMA82	DMA81	DMA80
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ADC_DMAR2 field descriptions

Field	Description
0 DMA95	DMA enable for channel 95. When set, transferring data in DMA mode is enabled for channel 95.
1 DMA94	DMA enable for channel 94. When set, transferring data in DMA mode is enabled for channel 94.
2 DMA93	DMA enable for channel 93. When set, transferring data in DMA mode is enabled for channel 93.
3 DMA92	DMA enable for channel 92. When set, transferring data in DMA mode is enabled for channel 92.
4 DMA91	DMA enable for channel 91. When set, transferring data in DMA mode is enabled for channel 91.
5 DMA90	DMA enable for channel 90. When set, transferring data in DMA mode is enabled for channel 90.
6 DMA89	DMA enable for channel 89. When set, transferring data in DMA mode is enabled for channel 89.

Table continues on the next page...

ADC_DMAR2 field descriptions (continued)

Field	Description
7 DMA88	DMA enable for channel 88. When set, transferring data in DMA mode is enabled for channel 88.
8 DMA87	DMA enable for channel 87. When set, transferring data in DMA mode is enabled for channel 87.
9 DMA86	DMA enable for channel 86. When set, transferring data in DMA mode is enabled for channel 86.
10 DMA85	DMA enable for channel 85. When set, transferring data in DMA mode is enabled for channel 85.
11 DMA84	DMA enable for channel 84. When set, transferring data in DMA mode is enabled for channel 84.
12 DMA83	DMA enable for channel 83. When set, transferring data in DMA mode is enabled for channel 83.
13 DMA82	DMA enable for channel 82. When set, transferring data in DMA mode is enabled for channel 82.
14 DMA81	DMA enable for channel 81. When set, transferring data in DMA mode is enabled for channel 81.
15 DMA80	DMA enable for channel 80. When set, transferring data in DMA mode is enabled for channel 80.
16 DMA79	DMA enable for channel 79. When set, transferring data in DMA mode is enabled for channel 79.
17 DMA78	DMA enable for channel 78. When set, transferring data in DMA mode is enabled for channel 78.
18 DMA77	DMA enable for channel 77. When set, transferring data in DMA mode is enabled for channel 77.
19 DMA76	DMA enable for channel 76. When set, transferring data in DMA mode is enabled for channel 76.
20 DMA75	DMA enable for channel 75. When set, transferring data in DMA mode is enabled for channel 75.
21 DMA74	DMA enable for channel 74. When set, transferring data in DMA mode is enabled for channel 74.
22 DMA73	DMA enable for channel 73. When set, transferring data in DMA mode is enabled for channel 73.
23 DMA72	DMA enable for channel 72. When set, transferring data in DMA mode is enabled for channel 72.
24 DMA71	DMA enable for channel 71.

Table continues on the next page...

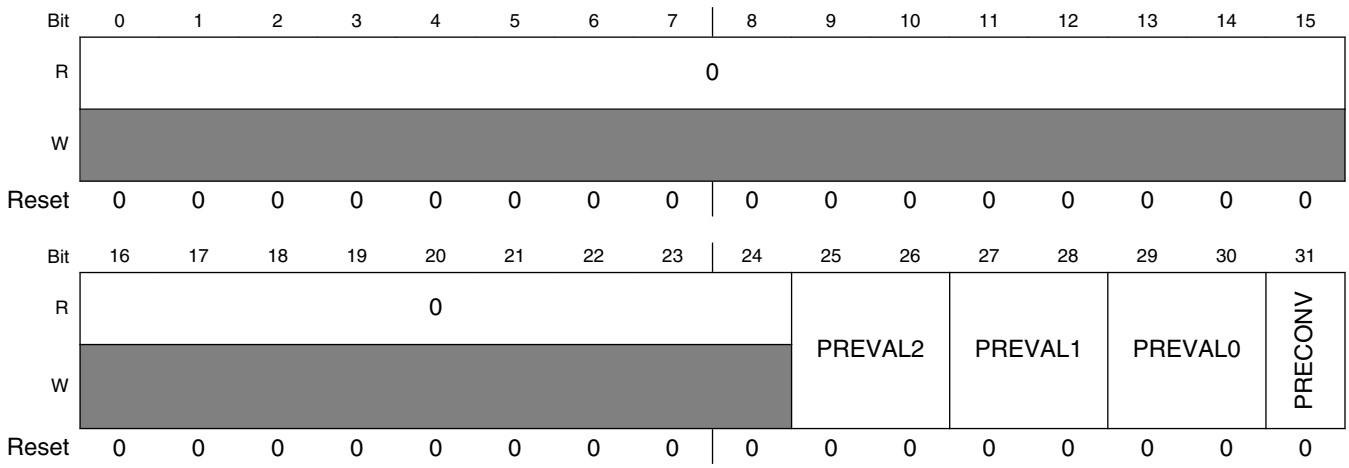
ADC_DMAR2 field descriptions (continued)

Field	Description
	When set, transferring data in DMA mode is enabled for channel 71.
25 DMA70	DMA enable for channel 70. When set, transferring data in DMA mode is enabled for channel 70.
26 DMA69	DMA enable for channel 69. When set, transferring data in DMA mode is enabled for channel 69.
27 DMA68	DMA enable for channel 68. When set, transferring data in DMA mode is enabled for channel 68.
28 DMA67	DMA enable for channel 67. When set, transferring data in DMA mode is enabled for channel 67.
29 DMA66	DMA enable for channel 66. When set, transferring data in DMA mode is enabled for channel 66.
30 DMA65	DMA enable for channel 65. When set, transferring data in DMA mode is enabled for channel 65.
31 DMA64	DMA enable for channel 64. When set, transferring data in DMA mode is enabled for channel 64.

34.5.17 Threshold Register (ADC_THRHLR*n*)

Address: 0h base + 60h offset + (4d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0				THRH												0				THRL											
W																																
Reset	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



ADC_THRHLR*n* field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 THRH	High threshold value for watchdog n.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value for watchdog n.

34.5.18 Presampling Control Register (ADC_PSCR)

See the chip configuration details for the availability of this register.

Address: 0h base + 80h offset = 80h

ADC_PSCR field descriptions

Field	Description
0–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–26 PREVAL2	Internal voltage selection for Presampling Selects analog input voltage for presampling from the available four internal voltages for External channels (channel 64 to 95). Refer to Presampling channel enable.
27–28 PREVAL1	Internal voltage selection for Presampling. These two bits select analog input voltage for presampling from the available internal voltages using internal extended channels (channel 32 to 63). Refer to Presampling channel enable.
29–30 PREVAL0	Internal voltage selection for Presampling. These two bits select analog input voltage for presampling from the available four internal voltages for Internal precision channels (Channel 0 to 31). Refer to Presampling channel enable.
31 PRECONV	Convert Presampled value If bit PRECONV is set, presampling is followed by the conversion. Sampling will be bypassed and conversion of presampled data will be done. This bit has no effect on conversion of a channel when presampling on that channel is disabled (for example, PSR*x*[PRES*y*] = 0 , where *x* = register index and *y* = channel number).

34.5.19 Presampling register 0 (ADC_PSR0)

See the chip configuration details for the availability of this register.

Address: 0h base + 84h offset = 84h

ADC_PSR2 field descriptions (continued)

Field	Description
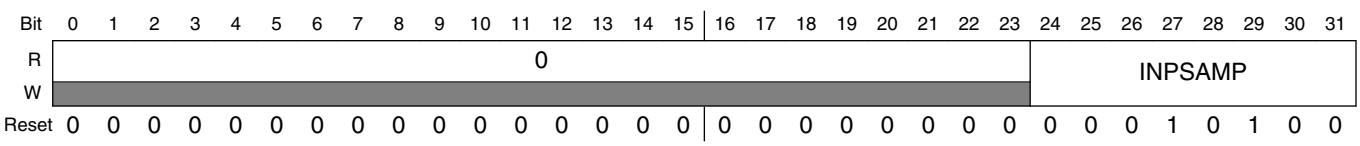
	When set, presampling is enabled for channel 68.
28 PRES67	Presampling enable for channel 67. When set, presampling is enabled for channel 67.
29 PRES66	Presampling enable for channel 66. When set, presampling is enabled for channel 66.
30 PRES65	Presampling enable for channel 65. When set, presampling is enabled for channel 65.
31 PRES64	Presampling enable for channel 64. When set, presampling is enabled for channel 64.



34.5.22 Conversion Timing Register 0 (ADC_CTR0)

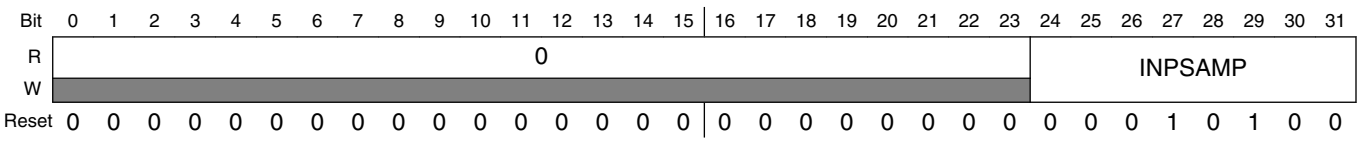
Conversion timing register. CTR0 is associated with channels 0 to 31.

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + 94h offset = 94h

ADC_CTR0 field descriptions



Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 INPSAMP	Configuration of sampling phase duration. This value tells the sample period duration in terms of the SAR Controller operating clock. The minimum acceptable value is 8. Setting a lower value automatically takes 8 cycles. **NOTE:** The Bandgap voltage sampling time is controlled by CTR0[INPSAMP]. CTR0[INPSAMP] is also used for the external channel sample time. When the user software needs to sample the Bandgap voltage, it must change the CTR0[INPSAMP] value to allow for a longer time while the Bandgap is being sampled, then change its value back to the normal value for sampling external channels.

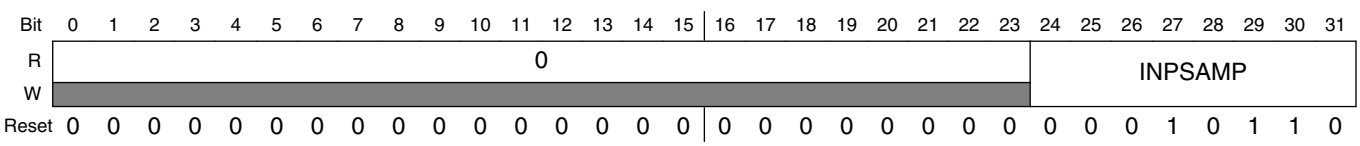
34.5.23 Conversion Timing Register 1 (ADC_CTR1)

CTR1 is associated with channels 32 to 63.

Please see the chip-specific configuration information as all channels may not be available in all ADC instances.

Address: 0h base + 98h offset = 98h

ADC_CTR1 field descriptions



Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 INPSAMP	Configuration of sampling phase duration. This value tells the sample period duration in terms of the SAR Controller operating clock. The minimum acceptable value is 8. Setting a lower value automatically takes 8 cycles.

34.5.24 Conversion Timing Register 2 (ADC_CTR2)

CTR2 is associated to channels 64 to 95.

Please see the chip-specific configuration information as all channels may not be available in all ADC instances.

Address: 0h base + 9Ch offset = 9Ch

ADC_CTR2 field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 INPSAMP	Configuration of sampling phase duration. This value tells the sample period duration in terms of the SAR Controller operating clock. The minimum acceptable value is 8. Setting a lower value automatically takes 8 cycles.

34.5.25 Normal Conversion Mask Register 0 (ADC_NCMR0)

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + A4h offset = A4h

16 CH79	Injected sampling enable for channel 79. When set, injected sampling is enabled for channel 79.
17 CH78	Injected sampling enable for channel 78.

Table continues on the next page...

ADC_JCMR2 field descriptions (continued)

Field	Description
	When set, injected sampling is enabled for channel 78.
18 CH77	Injected sampling enable for channel 77. When set, injected sampling is enabled for channel 77.
19 CH76	Injected sampling enable for channel 76. When set, injected sampling is enabled for channel 76.
20 CH75	Injected sampling enable for channel 75. When set, injected sampling is enabled for channel 75.
21 CH74	Injected sampling enable for channel 74. When set, injected sampling is enabled for channel 74.
22 CH73	Injected sampling enable for channel 73. When set, injected sampling is enabled for channel 73.
23 CH72	Injected sampling enable for channel 72. When set, injected sampling is enabled for channel 72.
24 CH71	Injected sampling enable for channel 71. When set, injected sampling is enabled for channel 71.
25 CH70	Injected sampling enable for channel 70. When set, injected sampling is enabled for channel 70.
26 CH69	Injected sampling enable for channel 69. When set, injected sampling is enabled for channel 69.
27 CH68	Injected sampling enable for channel 68. When set, injected sampling is enabled for channel 68.
28 CH67	Injected sampling enable for channel 67. When set, injected sampling is enabled for channel 67.
29 CH66	Injected sampling enable for channel 66. When set, injected sampling is enabled for channel 66.
30 CH65	Injected sampling enable for channel 65. When set, injected sampling is enabled for channel 65.
31 CH64	Injected sampling enable for channel 64. When set, injected sampling is enabled for channel 64.

34.5.31 Decode Signals Delay Register (ADC_DSDR)

Address: 0h base + C4h offset = C4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																DSD															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ADC_DSDR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 DSD	The delay between the external decode signals and the beginning of the sampling phase. It is used to take into account the settling time of the external mux. The decode signal delay is calculated as (DSD x 1/ Frequency of System Clock).

34.5.32 Power Down Exit Delay Register (ADC_PDEDR)

Address: 0h base + C8h offset = C8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ADC_PDEDR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 PDED	The delay between the power down bit reset and the start of conversion. The power down delay is calculated as (PDED x 1/[ADC_clock_frequency]).

34.5.33 Channel Data Register *n* (Precision Channels) (ADC_CDR*n*)

Note

It is important to note that the content of the CDATA field is affected by the setting of the ADC_MCR[WLSIDE] field, which controls whether the data is left aligned or right aligned. When ADC_MCR[WLSIDE]=1 (data to be left aligned), the CDATA field is left aligned from bit 16 to bit (16 + resolution - 1). When ADC_MCR[WLSIDE]=0 (data to be right aligned), the CDATA field is right aligned from bit (32-resolution) to bit 31. All other fields are unaffected.

Address: 0h base + 100h offset + (4d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

ADC_CDR*n* field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 VALID	Used to notify when the data is valid (a new value has been written). It is automatically cleared when data is read.

Table continues on the next page...

ADC_CDR*n* field descriptions (continued)

Field	Description
13 OVERW	Overwrite data Used to notify when a conversion data is overwritten by a newer result. The new data is written or discarded according to the OWREN bit of MCR register.
14–15 RESULT	These two bits reflect the mode of conversion for the corresponding channel. 00 Data is a result of Normal conversion mode 01 Data is a result of Injected conversion mode 10 Data is a result of BCTU conversion mode 11 Reserved
16–31 CDATA	Converted Data 11:0. **Note:** It is important to note that the content of the CDATA field is affected by the setting of the ADC_MCR[WLSIDE] field, which controls whether the data is left aligned or right aligned. When ADC_MCR[WLSIDE]=1 (data to be left aligned), the CDATA field is left aligned from bit 16 to bit (16 + resolution - 1). When ADC_MCR[WLSIDE]=0 (data to be right aligned), the CDATA field is right aligned from bit (32-resolution) to bit 31. All other fields are unaffected.

34.5.34 Channel Data Register *n* (Internal Channels) (ADC_CDR*n*)

Note

It is important to note that the content of the CDATA field is affected by the setting of the ADC_MCR[WLSIDE] field, which controls whether the data is left aligned or right aligned. When ADC_MCR[WLSIDE]=1 (data to be left aligned), the CDATA field is left aligned from bit 16 to bit (16 + resolution - 1). When ADC_MCR[WLSIDE]=0 (data to be right aligned), the CDATA field is right aligned from bit (32-resolution) to bit 31. All other fields are unaffected.

Address: 0h base + 180h offset + (4d × i), where i=0d to 31d

ADC_AWORR0 field descriptions

Field	Description
0 AWOR_CH31	Analog watchdog out of range for channel 31. When set, indicates the converted data is out of range for channel 31.
1 AWOR_CH30	Analog watchdog out of range for channel 30. When set, indicates the converted data is out of range for channel 30.
2 AWOR_CH29	Analog watchdog out of range for channel 29. When set, indicates the converted data is out of range for channel 29.
3 AWOR_CH28	Analog watchdog out of range for channel 28. When set, indicates the converted data is out of range for channel 28.
4 AWOR_CH27	Analog watchdog out of range for channel 27. When set, indicates the converted data is out of range for channel 27.
5 AWOR_CH26	Analog watchdog out of range for channel 26. When set, indicates the converted data is out of range for channel 26.
6 AWOR_CH25	Analog watchdog out of range for channel 25. When set, indicates the converted data is out of range for channel 25.
7 AWOR_CH24	Analog watchdog out of range for channel 24. When set, indicates the converted data is out of range for channel 24.
8 AWOR_CH23	Analog watchdog out of range for channel 23. When set, indicates the converted data is out of range for channel 23.
9 AWOR_CH22	Analog watchdog out of range for channel 22. When set, indicates the converted data is out of range for channel 22.
10 AWOR_CH21	Analog watchdog out of range for channel 21. When set, indicates the converted data is out of range for channel 21.
11 AWOR_CH20	Analog watchdog out of range for channel 20. When set, indicates the converted data is out of range for channel 20.
12 AWOR_CH19	Analog watchdog out of range for channel 19.

ADC_AWORR0 field descriptions (continued)

Field	Description
	When set, indicates the converted data is out of range for channel 19.
13 AWOR_CH18	Analog watchdog out of range for channel 18. When set, indicates the converted data is out of range for channel 18.
14 AWOR_CH17	Analog watchdog out of range for channel 17. When set, indicates the converted data is out of range for channel 17.
15 AWOR_CH16	Analog watchdog out of range for channel 16. When set, indicates the converted data is out of range for channel 16.
16 AWOR_CH15	Analog watchdog out of range for channel 15. When set, indicates the converted data is out of range for channel 15.
17 AWOR_CH14	Analog watchdog out of range for channel 14. When set, indicates the converted data is out of range for channel 14.
18 AWOR_CH13	Analog watchdog out of range for channel 13. When set, indicates the converted data is out of range for channel 13.
19 AWOR_CH12	Analog watchdog out of range for channel 12. When set, indicates the converted data is out of range for channel 12.
20 AWOR_CH11	Analog watchdog out of range for channel 11. When set, indicates the converted data is out of range for channel 11.
21 AWOR_CH10	Analog watchdog out of range for channel 10. When set, indicates the converted data is out of range for channel 10.
22 AWOR_CH9	Analog watchdog out of range for channel 9. When set, indicates the converted data is out of range for channel 9.
23 AWOR_CH8	Analog watchdog out of range for channel 8. When set, indicates the converted data is out of range for channel 8.
24 AWOR_CH7	Analog watchdog out of range for channel 7. When set, indicates the converted data is out of range for channel 7.
25 AWOR_CH6	Analog watchdog out of range for channel 6. When set, indicates the converted data is out of range for channel 6.
26 AWOR_CH5	Analog watchdog out of range for channel 5. When set, indicates the converted data is out of range for channel 5.
27 AWOR_CH4	Analog watchdog out of range for channel 4. When set, indicates the converted data is out of range for channel 4.
28 AWOR_CH3	Analog watchdog out of range for channel 3. When set, indicates the converted data is out of range for channel 3.
29 AWOR_CH2	Analog watchdog out of range for channel 2. When set, indicates the converted data is out of range for channel 2.

Table continues on the next page...

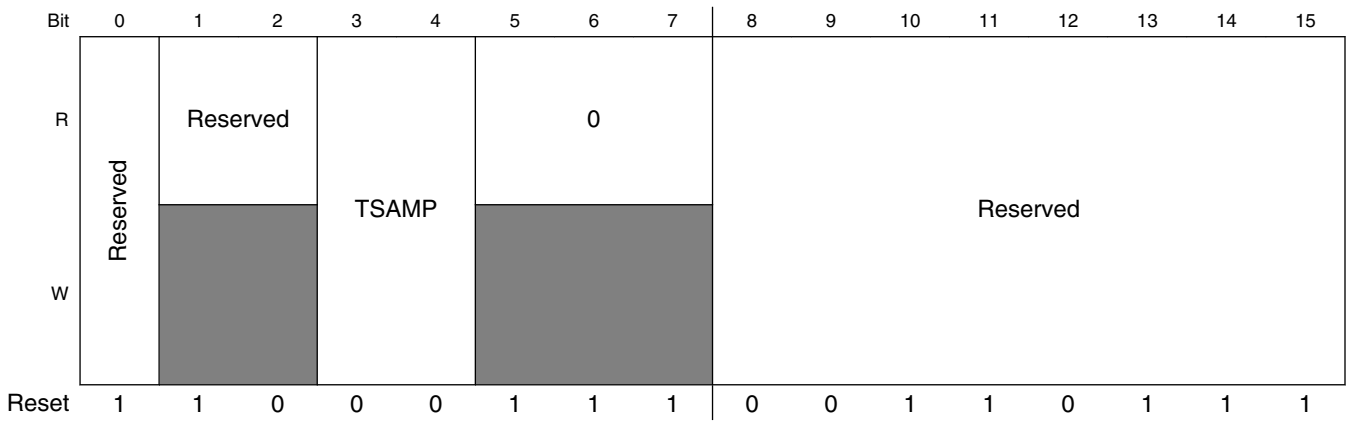
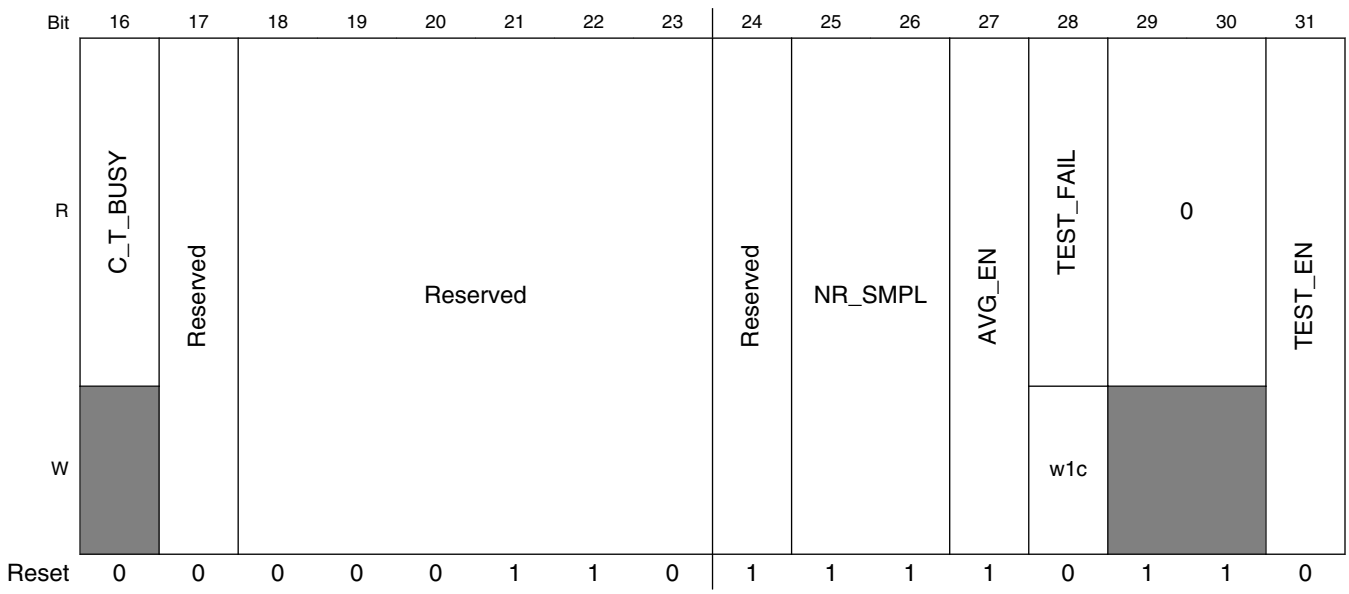
29 AWOR_CH66	Analog watchdog out of range for channel 66. When set, indicates the converted data is out of range for channel 66.
30 AWOR_CH65	Analog watchdog out of range for channel 65. When set, indicates the converted data is out of range for channel 65.
31 AWOR_CH64	Analog watchdog out of range for channel 64. When set, indicates the converted data is out of range for channel 64.



34.5.54 Calibration, BIST Control and status Register (ADC_CALBISTREG)



This register controls the Offset calculation, Calibration and BIST functionality with Averaging option. The averaging function has no effect in other conversion modes.

NOTE

The reset value shown for this register is for a 12-bit resolution ADC. The 10-bit ADC reset value is 4137_06F6h.

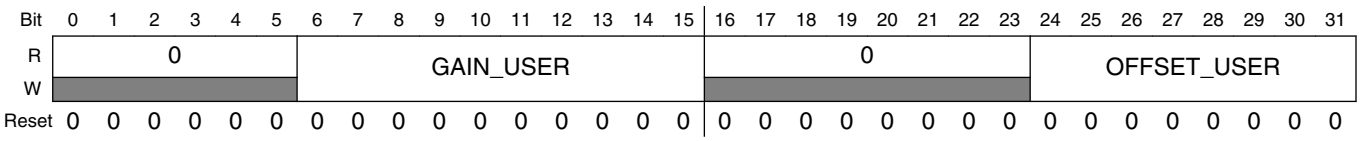
Address: 0h base + 3A0h offset = 3A0h

ADC_CALBISTREG field descriptions

Field	Description
0 Reserved	This field is reserved. When writing to this register, do not change the default value of this field.
1–2 Reserved	This field is reserved. When writing to this register, do not change the default value of this field. **NOTE:** The reset value of this field depends on the resolution of the ADC instance. • Reset value is 01b for 12-bit ADC instances • Reset value is 10b for 10-bit ADC instances
3–4 TSAMP	Test Sample period in Calibration, BIST and Offset calculation process. 00 22 cycles of ADC clk 01 8 cycles of ADC clk 10 16 cycle of ADC clk 11 32 cycle of ADC clk
5–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ADC_CALBISTREG field descriptions (continued)



Field	Description
8–15 Reserved	This field is reserved. When writing to this register, do not change the default value of this field.
16 C_T_BUSY	This bit indicates that ADC is doing internal operations for BIST or Calibration. This is set when the TEST_EN bit is set. 0 ADC is ready for use 1 ADC is busy in calibration or test operation
17 Reserved	This field is reserved.
18–23 Reserved	This field is reserved. When writing to this register, do not change the default value of this field.
24 Reserved	This field is reserved. The default value must not change. Always write the default value to this field.
25–26 NR_SMPL	Number of Samples for averaging. **NOTE:** The sample setting is providing a trade-off between calibration time and accuracy. For best accuracy 512 samples are recommended. The 16 sample setting shall only be used for applications which require very fast calibration time at the expense of accuracy. 00 16 samples 01 32 samples 10 128 samples 11 512 samples
27 AVG_EN	Average Enable (for Calibration only). 0 Disable 1 Enable
28 TEST_FAIL	Test Fail. This bit indicates the status of Calibration output. This bit sets automatically if tests are aborted prematurely by any normal conversion or tests complete but one of them fails. This bit is cleared by writing 1 to it or on restarting of test by writing 1 to TEST_EN 0 Test passed 1 Test failed
29–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 TEST_EN	Enable the test. 0 Disable the test 1 Enable the test (self clearing) (once set it cannot be overwritten till it resets)

34.5.55 Offset and Gain User Register (ADC_OFSGNUSR)

This register contains the user configured offset and Gain values used by ADC for data processing and have all the bits valid (MSB through LSB).

OFFSET and Gain Calibration values can be either positive or negative, so they need to be in 2's complement format with MSB as sign bit.

Address: 0h base + 3A8h offset = 3A8h

ADC_OFSGNUSR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 GAIN_USER	Gain User (2's complement format)
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 OFFSET_USER	Offset User (2's complement format)

34.6 Functional description

The following sections detail the ADCD interfaces as well as the functionality of this module.

34.6.1 Conversion

After power-up or reset, the ADC is in power-down mode until the MCR[PWDN] field is written. There are some configurations, listed below, available only in power-down mode, that must be handled before exiting power down.

- Clock selection for SAR Controller (AD_clk): MCR [ADCLKSEL]
- Operating mode of ADC for BCTU (Trigger / Control): MCR [CTU_MODE] (if available)

After the above configurations, ADC need to be taken out from power-down mode by writing '0' into MCR [PWDN], Conversions can be initiated now in the following modes:

- Normal
- Injected
- BCTU Triggered

34.6.1.1 Normal conversion

The conversion mode generally used to convert channels is called normal conversion. Programming the available Normal Conversion Mask Register(s) (ADC_NCMR*n*) selects the channel(s). Each channel can be individually enabled by setting a bit in the corresponding field of the appropriate NCMR*n* register.

- NCMR0 serves *precision* channels:
  - 0 - 23 (ADC0—10 bit)
  - 0 - 15 (ADC1—12 bit)
- NCMR1 serves *internal* channels:
  - 32 - 63 (ADC0—10 bit)
  - 32 - 57 (ADC1—12 bit)
- NCMR2 serves *external* channels:
  - 64 to 95 (ADC0—10 bit)
  - 64 to 95 (ADC1—12 bit)

The mask register(s) must be programmed before starting the conversion and cannot be changed until the conversion of all the selected channels ends. Conversion always starts from the lowest channel number selected and sequentially goes to the highest number.

34.6.1.1.1 Starting a normal conversion

After programming the MCR and NCMR0*n* register(s), a normal conversion is started via *software* by setting the MCR[NSTART] bit.

34.6.1.2 Normal conversion operating modes

Two operating modes are available for normal conversion:

- One-Shot mode
- Scan mode

The MCR[MODE] bit determines which mode is used during a normal conversion. The first phase of the conversion process involves sampling the analog channel. The next phase is the conversion phase, during which the sampled analog value is converted to digital as shown in the figure below.

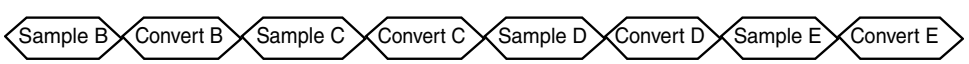


Figure 34-3. Normal conversion flow

34.6.1.2.1 One shot mode

In one shot mode (MCR[MODE] = 0) a sequential conversion specified in the following mask register(s) is performed only once:

- NCMR0
- NCMR1
- NCMR2

At the end of each conversion, the digital result of the conversion is stored into the corresponding data register(CDRx, x = channel number).

For example: Channels A-B-C-D-E-F-G-H are present in the device where channels B-D-E are to be converted in One-Shot mode. Conversion starts with channel B, followed by the conversion of channels D and E. At the end of conversion of channel E, the scanning of channels will stop.

The MSR[NSTART] status bit is automatically set when the normal conversion starts. At the same time, MCR[NSTART]is reset by hardware, allowing the software to program a new start of conversion in advance. In this case, the newly requested conversion starts after completing the running/current conversion. However, for the sake of simplicity and straightforwardness, it is advisable to program the NSTART bit for the new conversion only after the completion of the running conversion. To know the end of conversion of running chain, application will either wait for an End of Chain (ECH) Interrupt or check the status of MSR[NSTART] prior to setting MCR[NSTART] again.

34.6.1.2.2 Scan mode

In scan mode (MCR[MODE] = 1), a sequential conversion of *n* channels specified in the NCMR*n* register(s) is continuously performed. At the end of each conversion, the converted result is stored into the corresponding data registers, as in One-Shot mode.

The MSR[NSTART] status bit is automatically set when the normal conversion starts. Unlike One-Shot mode, the MCR[NSTART] bit is not reset automatically in Scan mode. It can be reset by software when you need to stop Scan mode. In that case, the ADC completes the current chain and, after the last conversion, resets MSR[NSTART].

For example: Channels A-B-C-D-E-F-G-H are present in the device where channels B-D-E are to be converted in Scan mode. MCR[MODE] = 1 is set for Scan mode. Conversion starts from channel B, followed by the conversion of channels D and E. At the end of the conversion of channel E, the conversion of channel B starts again, followed by the conversion of channels D and E. This sequence repeats itself until MCR[NSTART] is reset by software.

This scan chain can be stopped by writing 0 to MCR[NSTART]. The conversion stops when the ongoing chain is finished.

34.6.1.2.3 End of conversion

In both modes, at the end of each conversion an end-of-conversion (EOC) interrupt is issued if enabled by the corresponding mask bit in the following register(s):

- CIMR0
- CIMR1
- CIMR2

Additionally, the EOC interrupt must enabled in the IMR register. After the conversion of all the channels selected in the NCMR*n* register(s) is completed and the conversion operation is considered finished, ISR[ECH] is set and an end-of-chain (ECH) interrupt is issued (if enabled in IMR[MSKECH]). The corresponding channel bit within the appropriate CEOCFR*n* register is updated to indicate that data is available on the data register (CDR*n*) of the respective channel. If there is no channel selected in the NCMR*n* register(s) and there is a start of conversion trigger, then ISR[ECH] is set and an ECH interrupt is immediately issued (if enabled).

NOTE

To add or remove channels to/from the ongoing chain:

1. Clear the MCR[NSTART] bit
2. Set/clear mask bit for the needed channels in NCMR*n*
3. Set the MCR[NSTART] bit

34.6.1.3 Injected conversion

An injected conversion is a conversion chain that can be injected at any time, including into an ongoing normal conversion chain. To do so, configure the injected mask register(s):

- JCMR0
- JCMR1
- JCMR2

As in a normal conversion, each internal or external channel can be individually selected for injected conversion.

- JCMR0 controls *precision* channels:
  - 0 - 23 (ADC0—10 bit)
  - 0 - 15 (ADC1—12 bit)

- JCMR1 controls *internal* channels:
  - 32 - 63 (ADC0—10 bit)
  - 32 - 57 (ADC1—12 bit)
- JCMR2 controls *external* channels:
  - 64 to 95 (ADC0—10 bit)
  - 64 to 95 (ADC1—12 bit)

Injected conversion can only be run in One-Shot mode, and can only interrupt a normal conversion. Please note, that a BCTU conversion cannot be interrupted by an injected conversion. In this case, the injected conversion is discarded. When an injected chain is inserted into an ongoing normal chain, the ongoing normal channel is suspended and the injected channel request is processed. After completing the last channel in the injected chain, normal conversion resumes from the channel at which it was suspended as shown in the following figure.

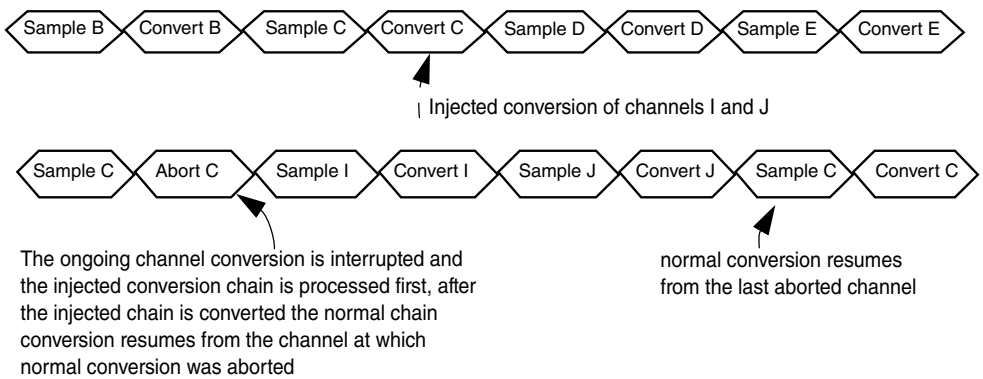

Figure 34-4. Injected sample/conversion sequence

34.6.1.3.1 Starting injected conversion

The injected conversion can be started via *software* by setting the MCR[JSTART] bit to start an injected conversion; the current normal conversion is suspended and the injected chain is converted.

To start an injected conversion via *external trigger*, enable external triggering by setting MCR[JTRGEN]=1. A programmed event (rising/falling edge depending on MCR[JEDGE] bit) on the injection trigger input starts the injected conversion.

The MSR[JSTART] status bit is automatically set when the injected conversion starts. At the same time, the MCR[JSTART] bit is reset, allowing software to program a new start of conversion in advance. In that case, the new requested conversion starts after the running conversion is completed.

At the end of each conversion, an End Of Injected Conversion (JEOC) interrupt is issued (if enabled by the corresponding mask bit in IMR) and at the end of the chain an End Of Injected Chain (JECH) interrupt is issued (if enabled by the corresponding mask bit in IMR). The status bit ISR[JECH] is also set.

If the content of all the injected conversion mask registers (JCMRn) is zero (i.e., no channel is selected) the interrupt JECH is immediately issued to resume normal operation or conversion mode.

The corresponding channel bit in the appropriate CEOCFR*n* register is updated to indicate that data is available in the data register (CDR) of the respective channel.

Once started, injected chain conversion cannot be interrupted by Normal or another Injected conversion. A BCTU trigger has the higher priority; injected conversion has a lower priority. Therefore, only a BCTU trigger can interrupt an ongoing injected conversion. In this case, the injected conversion will be discarded.

34.6.1.4 Aborting conversions

Two different abort functions are provided:

- A single channel abort
- A chain abort

You can abort the ongoing conversion by setting the MCR[ABORT] bit. The current conversion is aborted and the conversion of the next channel of the chain is immediately started. The abort action may take 1 to 4 cycles of the bus clock to abort the current conversion depending on the state of the conversion. At the start of any conversion and at the end of a particular conversion, when internal state counters are changing, then abort is delayed by a maximum of 3 cycles to take all states in stable condition. Abort also should not be programmed along with and within 3 cycles of programming the MCR[NSTART] or MCR[JSTART]. This may not have a significant impact from software point of view since on any SoC the next write access comes only after a minimum of 3 clock cycles.

NOTE

Programming Abort or Abort chain with NSTART or JSTART in idle condition has no effect.

For a Normal conversion chain having only one channel:

1. Abort re-runs the conversion again from the Abort point
2. If Interrupted by BCTU (in Trigger mode) Normal conversion runs twice instead of just once

In the case of an abort operation, the MSR[NSTART/JSTART] bit remains set, if not in last channel of chain, and the MCR[ABORT] bit is reset as soon as the channel is aborted. The EOC corresponding to the aborted channel is not generated. This behavior is true for Normal or Injected conversion modes. If the last channel of a chain is aborted, the end of chain is reported by generating an ECH interrupt.

It is also possible to abort the current chain of conversions by setting the MCR[ABORTCHAIN] bit. In that case, the behavior of the ADC depends on the MCR[MODE] bit (One-Shot/Scan) for Normal conversion. In One-Shot mode, MSR[NSTART] is automatically reset together with the MCR[ABORTCHAIN]. Otherwise, in Scan mode, a new chain is started, and the current chain is aborted. The EOC of the current aborted conversion is not generated, but an ECH interrupt is generated to signal the end of the chain. For Injected conversion, the behavior of ABORTCHAIN is same as for One-shot Normal conversion. In this case, MSR[JSTART] is automatically reset together with the MCR[ABORTCHAIN].

When an ABORTCHAIN is requested while an injected chain is running over a suspended normal chain, both injected and normal chains are aborted; both MSR[NSTART] and MSR[JSTART] are reset. ABORT and ABORTCHAIN requests are ignored during BCTU conversion.

34.6.2 Crosstriggering Unit interface

The Crosstriggering Unit (BCTU) interface enhances the injected conversion capability of the ADC. The BCTU contains multiple event inputs that can be used to select the channels to be converted from the appropriate event configuration register. The BCTU/ADC interface is shown in the figure below. The BCTU generates a trigger and a channel number to be converted. A single channel is converted for each request. After performing the conversion, the ADC returns the result.

The conversion result is also saved in the corresponding data register and it is compared with watchdog thresholds if requested. DMA and interrupt feature of ADC can also be used during CTU conversion.

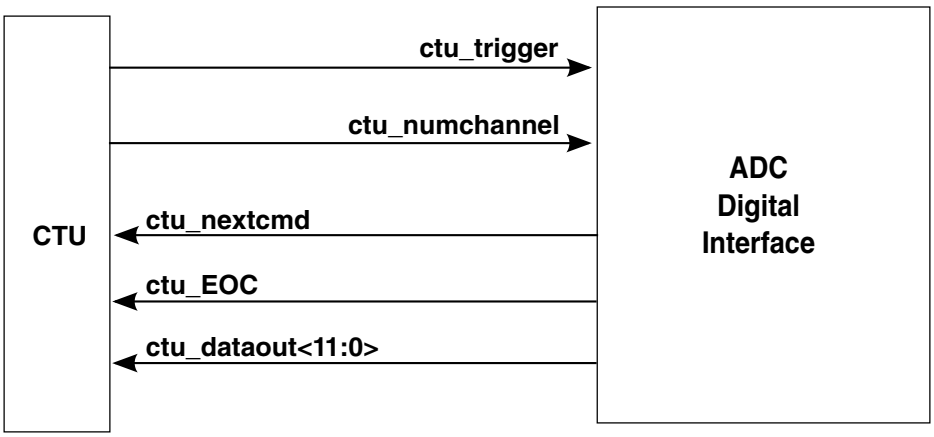

Figure 34-5. ADC Crosstriggering Unit

The BCTU interface has two modes of operation: Trigger and Control.

The BCTU interface is enabled by programming the MCR[CTUEN] bit. The BCTU interface operating mode is programmed by MCR[CTU_MODE] bit.

34.6.2.1 BCTU Trigger mode

In trigger mode, normal and injected conversions are enabled along with BCTU conversion, allowing all kinds of conversions to run.

When a trigger is received, the channel number is taken as the channel value and the BCTU conversion starts. The MSR[CTUSTART] bit is set automatically at this point and it is also automatically reset when the BCTU conversion is completed.

BCTU conversions should be requested after calibration is over. If a BCTU trigger is received during calibration, the calibration fails and BCTU conversion is started.

If a BCTU trigger is received during an ongoing injected conversion, then the injected chain is aborted immediately and only the BCTU conversion proceeds. The MSR[JSTART] bit is reset. Aborting of the injected conversion is indicated through the status bit of MSR[JABORT].

If a BCTU trigger is received during a ongoing normal conversion, the ongoing normal channel is suspended and the BCTU conversion is processed. Normal conversion resumes from the suspended channel after completion of BCTU triggered conversion.

If another BCTU trigger is received before ctu_nextcmd signal, that triggered conversion request is discarded.

If a Normal conversion is requested during BCTU conversion (MSR[CTUSTART] bit equal to ‘1’), the Normal conversion starts after the BCTU conversion is completed (MSR[CTUSTART] bit reset).

Injected conversion requests are discarded during a BCTU conversion, and the MCR[JSTART] bit is immediately reset.

34.6.2.2 BCTU Control mode

In BCTU Control mode, if enabled via MCR[CTUEN], the CPU is able to write in the ADC registers, but it cannot start a conversion. Conversion requests can be generated only by a BCTU trigger. If a normal or injected conversion is requested when the BCTU is enabled (MCR[CTUEN]), it will be automatically discarded.

Along with BCTU trigger the ctu_numchannel is taken as channel and BCTU conversion starts. MSR[CTUSTART]is set automatically at this point and it remains set unless the BCTU is disabled by resetting MCR[CTUEN].

BCTU conversions must be requested when calibration is over. If a BCTU trigger is received during calibration, the calibration stops immediately in order to satisfy the BCTU request. Calibration will fail in this case.

34.6.3 ADC clock prescaler and sample time settings

The clock (AD_clk) provided to the ADC's SAR controller, which controls the ADCA, must satisfy particular conditions of frequency and duty cycle. The maximum acceptable frequency is 80 MHz with a duty cycle equal to 50% (±5%).

The AD_clk frequency can be scaled by programming the MCR[ADCLKSEL] bit. If this bit is set, AD_clk frequency is the same as the bus clock. Otherwise, AD_clk frequency is half of the bus clock. MCR[ADCLKSEL] can only be written in power-down, when MCR[PWDN] = 1.

Sampling times are controlled by settings in the Conversion Timing Register (CTR*n*). A CTR register is provided for each channel type.

- CTR0 controls sampling time for *precision* channels:
  - 0 - 23 (ADC0—10 bit)
  - 0 - 15 (ADC1—12 bit)
- CTR1 controls sampling time for *internal* channels:

- 32 - 63 (ADC0—10 bit)
- 32 - 57 (ADC1—12 bit)

- CTR2 controls sampling time for *external* channels:
  - 64 to 95 (ADC0—10 bit)
  - 64 to 95 (ADC1—12 bit)

34.6.4 Presampling

Presampling allows the ADC internal capacitor to precharge or discharge to a defined level before it starts the actual sampling/conversion of the analog input coming from the pads. This is useful for resetting information (history effect/offset) regarding the last converted data. During presampling, the ADC samples the internally generated voltage while, during sampling, the ADC samples the analog input coming from the pads.

Presampling can be enabled/disabled on an individual channel by setting the corresponding bit in the applicable PSR*n* register.

- PSR0 controls precision channels
- PSR1 controls internal channels
- PSR2 controls external channels

After enabling the presampling for a channel, the normal sequence of operation is presampling + sampling + evaluation for that channel. Sampling of the channel can be bypassed by setting PSCR[PRECONV]. When sampling of a channel is bypassed, the presampled voltage will be converted.

See Conversion time for the conversion's timing equation.

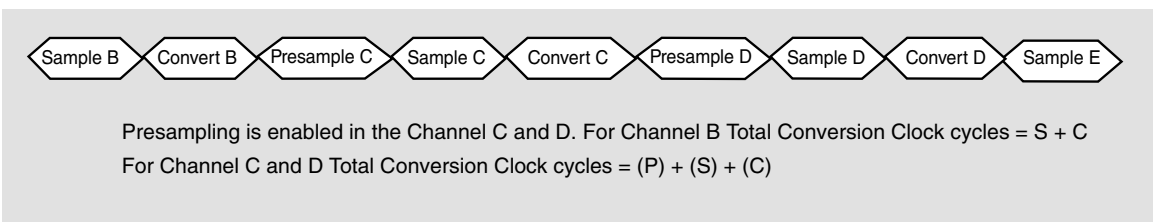

Figure 34-6. Presampling sequence

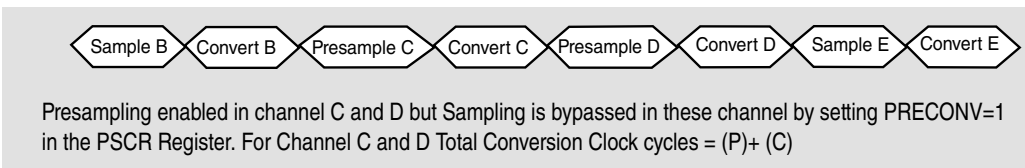

Figure 34-7. Presampling sequence with PRECONV = 1

34.6.4.1 Presampling channel enable

The presampling channels are selected by programming the presampling register (Presampling Control Register (ADC_PSCR)). These are used to enable analog switches that samples an internally generated voltage. It is possible to select presample voltage from four internally available voltages depending on the value of PREVAL*x* [*x* = 0,1,2] fields in the PSCR register as given in Table 34-7.

Table 34-7. Presample voltage selection

PREVAL*n*	Presampling voltage
00b	Presample voltage 1: VSS_HV_ADC0 (SAR ADC 0 ground), VSS_HV_ADC1 (SAR ADC 1 ground)
01b[1]	Presample voltage 2: VDD_HV_ADC0/8 (SAR ADC 0 supply divided by 8), VDD_HV_ADC1/8 (SAR ADC 1 supply divided by 8)
10b	Presample voltage 3: V_{REFL}
11b	Presample voltage 4: VDD_HV_ADC1_REF ADC1 (SAR ADC 1 reference high)

1. The voltage sampled inside ADCA is always (analog supply) / 8 for PSCR[PREVAL*n*] = 01b. However, when sampling is bypassed (PSCR[PRECONV] = 1), ADCD multiplies the conversion result by 8 to make the conversion result equal to the analog supply, or maximum value possible during saturation.

   So, for an open or short circuit test on any channel with presampling feature and PSCR[PRECONV] = 0b, user should expect conversion results as shown below:
   - Equal to Vin of the channel (if there is no open or short defect)
   - Close to (analog supply) / 8 if the channel is open (not connected to any voltage source, internally or externally)
   - Close to 0 V if the channel has a short to ground (analog ground, either internally or externally).
   - Close to the analog supply if the channel has a short to supply (analog supply, either internally or externally).

The PREVAL*n* fields are associated with specific channels, as shown in Table 34-8.

Table 34-8. PREVAL*n* channel association

Field	Channels
PREVAL0	• 0 - 23 (ADC0—10 bit) • 0 - 15 (ADC1—12 bit)
PREVAL1	• 32 - 63 (ADC0—10 bit) • 32 - 57 (ADC1—12 bit)
PREVAL2	• 64 to 95 (ADC0—10 bit) • 64 to 95 (ADC1—12 bit)

34.6.5 Programmable analog watchdog

NOTE

The number of analog watchdogs and channels may vary depending on the ADC instance on your chip. Please see the chip-specific section for how many are available on each instance.

The analog watchdogs are used for determining whether the result of a conversion lies within a given guard area (as shown in Figure 34-8) specified by an upper and a lower threshold value named THRH and THRL, respectively.

After the conversion of the selected channel, a comparison is performed between the converted value and the threshold values. If the converted value lies outside the guard area, then the corresponding threshold violation interrupt is generated.

The comparison result is stored as WTISR[WDGxH] and WTISR[WDGxL], as explained in the following table. Depending on the WTIMR[MSKWDGxL] and WTIMR[MSKWDGxH] mask bits, an interrupt is generated upon threshold violation.

Table 34-9. Values of WDGxH and WDGxL fields

WDGxH	WDGxL	Converted data
1	0	converted data > THRH
0	1	converted data < THRL
0	0	THRH ≤ converted data ≤ THRL

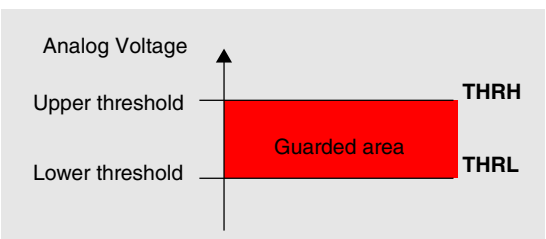

Figure 34-8. Guarded Area

34.6.5.1 Analog watchdog setting

For each watchdog there is one Threshold value (Low and High) Register (THRHLR).

The analog watchdog for each channel can be enabled independently by programming CWENR*n* register bits.

- CWENR0 controls *precision* channels:

    - 0 - 23 (ADC0—10 bit)
    - 0 - 15 (ADC1—12 bit)
- CWENR1 controls *internal* channels:
    - 32 - 63 (ADC0—10 bit)
    - 32 - 57 (ADC1—12 bit)
- CWENR2 controls *external* channels:
    - 64 to 95 (ADC0—10 bit)
    - 64 to 95 (ADC1—12 bit)

The availability of these registers depends on device configuration.

Threshold values for each channel can be selected independently from a maximum of 16 threshold registers (THRHLRx,(x=0..15)) by the WSEL_CHx field of CWSELRx (x=0..11) register.

Each CWSELRx register holds selection for 8 consecutive channels. CWSELR0 holds 8 WSEL_CH fields for channel 0 to 7. Likewise CWSELR1 is for channel 8 to 15 and so on. The availability of fields and registers depends on device configuration.

If the converted value for a particular channel lies outside the range specified by threshold values, then the corresponding bit is set in the Analog Watchdog Out of Range Register (AWORR).

For example, if channel number 12 is to be monitored with the threshold values in register THRHLR3, then CWSELR1[WSEL_CH4] needs to be programmed with 3. The enabling will be done by setting the bit corresponding to channel 12 in the CWENR0 register.

A set of threshold values (THRHLRx) can be linked to several ADC channels. The threshold values to be selected for a channel needs be programmed only once in the CWSELRx register.

34.6.6 DMA functionality

Conversion data of any channel can be transferred from register to system memory via Direct Memory Access (DMA). The DMA transfers can be enabled by setting ADC_DMAE[DMAEN]. Once enabled, the on chip DMA controller can get DMA requests after the conversion of every channel by setting the respective masking bit in the DMAR*n* registers. The DMA masking registers must be programmed before starting any conversion.

The DMA request to DMA controller can be cleared at different times in two modes:

MODE-1: Clearing of DMA request on Acknowledgement from DMA controller (ADC_DMAE [DCLR] = 0)

MODE-2: Clearing of DMA request on Read to data registers (ADC_DMAE [DCLR] = 1)

The figures below shows DMA operation in two modes (cycle counts are typical values).

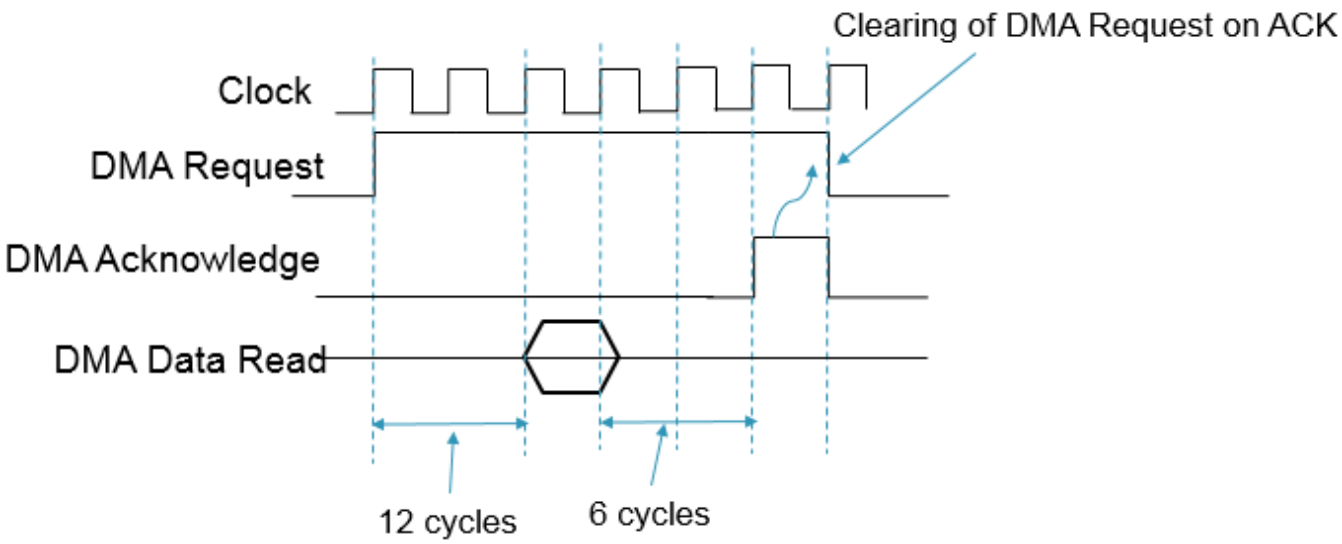

Figure 34-9. DMA operation MODE – 1 (DMAE [DCLR] = 0)

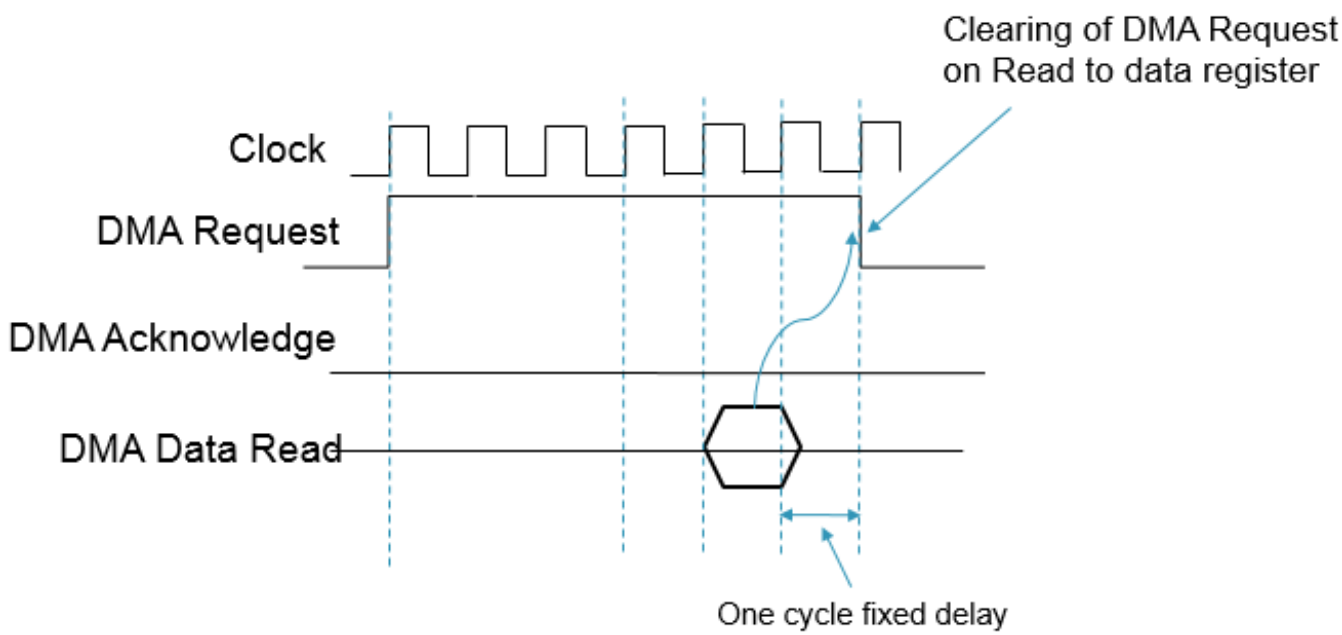

Figure 34-10. DMA operation MODE – 2 (DMAE [DCLR] = 1)

34.6.7 Interrupts

ADC generates the following maskable interrupt signals:

- End-of-conversion interrupt (EOC) request
- End-of-chain interrupt (ECH) request
- End-of-injected conversion interrupt (JEOC) request
- End-of-injected chain interrupt (JECH) request
- End-of-CTU conversion interrupt (EOCTU) request
- Watchdog threshold interrupt (WDGxL and WDGxH) requests

Interrupts are generated during the conversion process to signal events, like the end of a conversion, as explained in the register description for the Interrupt Status Register (ISR). The ISR and the Interrupt Mask Register (IMR) allow you to check and enable the interrupt request.

Interrupts can be individually enabled on a channel-by-channel basis by programming the Channel Interrupt Mask Register (CIMR).

Three Channel Pending Registers (CEOCFR*n*) are also provided in order to signal which of the channels' measurement has been completed.

Analog Watchdog interrupts are enabled by Watchdog Threshold Interrupt Mask Register (WTIMR) and the status can be checked at Watchdog Threshold Interrupt Status Register (WTISR). The watchdog interrupt source sets two fields, WDGxH and WDGxL, for each channel monitored in the WTISR.

In particular, the EOC, ECH, EOCTU, JEOC, and JECH interrupt lines are combined (OR-ed) on the same line. The EOC interrupt request is cleared by clearing either ISR[EOC] or all bits of CEOCFR. The JEOC interrupt request is cleared by clearing either ISR[JEOC] or all bits of CEOCFR. The EOCTU interrupt request is cleared by clearing either ISR[EOCTU] or all bits of CEOCFR.

All WDGxH and WDGxL requests are combined on the second line.

Another interrupt on the third line is a combination of WDSERR, WDTERR, ERR_S0, ERR_S1, and ERR_S2.

The ISR register contains the interrupt pending request status. If you want to clear a particular interrupt event status, then writing a 1 to the corresponding status bit will clear the pending interrupt flag. (At this write operation, all the other bits of the ISR register must be programmed to 0.)

34.6.8 External Decode signals Delay

The ADC provides three external decode signals to be used to select one channel out of eight channels in external Analog multiplexers. There can be a maximum of four such multiplexers that are used for the 32 external channels to be converted. In order to take into account the control of switching time of the external analog mux, a Decode Signals Delay (DSD) register is provided. This register allows you to program the delay between the decoding signal selection and the actual start of conversion.

If presampling is enabled then the DSD delay starts after the presample phase (presampling time is same as sample time).

34.6.9 Power-Down mode

The analog part of the ADC can be put in Power-Down mode by setting the MCR[PWDN] bit, which shuts off the ADCA and stops the clock in the SAR controller. After power-on or device reset, the ADCA is kept in Power-Down mode by default, so this state must be exited before starting any operation by resetting the MCR[PWDN] bit. In Power-Down mode, no conversion and calibration can be started. Trigger from BCTU during power down is discarded. In the ADC power-down mode, the BCTU must not start any conversion.

The MCR[PWDN] bit may be programmed high at any time. However, if a conversion is ongoing, then the ADCA cannot be sent immediately into Power-down mode. In fact, the ADC enters Power-down mode only after completing the ongoing conversion. Otherwise, the ongoing operation should be aborted manually by resetting the NSTART bit and using the ABORTCHAIN function.

The ADC status in MSR[ADCSTATUS] field shows Power-down status only when ADC enters in Power-down mode.

If BCTU is enabled and MSR[CTUSTART] is 1, then the MCR[PWDN] bit cannot be set. When BCTU Control mode is enabled, the application needs to reset the CTUEN bit before entering Power-Down mode.

After the power-down phase is complete, the process ongoing before the power-down phase must be restarted manually .

NOTE

Resetting the MCR[PWDN] bit and setting the MCR[NSTART] or MCR[JSTART] bit during the same cycle is forbidden.

34.6.10 Auto-Clock-Off mode

To reduce power consumption in Idle mode (without going into Power-Down mode), an auto-clock-off feature can be enabled by setting MCR[ACKO]. When enabled, the analog clock is automatically switched off when no operation is ongoing (that is, when no conversion has been programmed).

NOTE

This feature must remain off during calibration.

34.6.11 Calibration

The ADC is calibrated at runtime. The test result is used for computation and is stored during the calibration process.

Calibration test mode is referred to as *High-Accuracy* or *Calibration* mode, and needs to be run after power-on reset and whenever required in runtime operation. This mode calibrates the ADC and updates calibration-related registers.

The following section describes the steps for executing calibration.

34.6.11.1 Calibration (High Accuracy mode)

The functioning of the analog block of ADC depends on the accuracy of values of its various parts and parameters, such as the value of capacitors, the gain of the amplifier, and so on. Due to variations in manufacturing and various runtime environmental effects, the actual values may differ from the ideal values for which the ADC is targeted.

Because of these deviations, the ADC's converted values contain errors. To eliminate these errors, the ADC must be calibrated prior to any conversion.

In the calibration process, a fixed known reference voltage (VrefH) is sampled many times and converted under various controlled conditions to check for deviations between these converted values and predefined values.

The deviations, known as offsets or modified values, are used to eliminate errors during the data processing of normal conversions.

Note

The ADC must be recalibrated if the operating conditions (particularly VrefH) change significantly.

Recommended settings:

- Clock frequency = 40 MHz
- Averging – Maximum (512)

The calibration process will take ~12ms of time with the above recommended settings.

NOTE

If the ADC clock frequency is > 40MHz during calibration, the accuracy of the calibration process will be compromised, hence the performance of the ADC. Thus, it is strongly recommended to run the calibration with 40 MHz clock.

As calibration is a time consuming process, it can be performed after a long interval – probably several hours of operation – but it is not necessary to recalibrate frequently. The goal is to maximize the possible accuracy delivered from conversion and to catch any structural fault to flag the error.

The calibration routine sets the fail flag (CALBISTREG[TEST_FAIL]) to indicate:

- A fault in ADC
- A premature abort of the calibration

Calibration is aborted if a normal conversion is initiated during calibration; this is called *premature termination*. The terminating conversion and the immediate next one to it will have invalid result in this case.

CALBISTREG[TEST_FAIL] = 1 indicates that the ADC health is not good and that it will not meet specifications.

To execute this routine, follow these steps:

1. Configure the ADC to 40 MHz.
   - Put the ADC in power down mode: set MCR[PWDN]
   - Configure clock divider selection: reset MCR[ADCLKSEL]
   - Power-up the ADC: reset MCR[PWDN]
2. Configure the Calibration, BIST Control, and Status Register (CALBISTREG). The default values are set for maximum accuracy (recommended).
3. Start calibration: set CALBISTREG[TEST_EN].
4. Wait for calibration to complete. Check MSR[ADCSTATUS] or till CALBISTREG[C_T_BUSY] becomes 0.
5. Check the value of MSR[CALIBRTD] to determine whether calibration was successful.
6. If MSR[CALIBRTD] = 1, calibration was successful; otherwise, it failed, and CALBISTREG[TEST_FAIL] = 1.
7. If required, reconfigure the ADC clock frequency for normal operation.

34.6.12 Conversion time

Total conversion time depends on ADC-SAR controller's operating clock. This clock can be prescaled to bus clock ÷ 2. The ADC-SAR operating clock (AD_clk) is always synchronous with bus clock. The frequency of AD_clk is dependent on settings of ADC_MCR[ADCLKSEL].

If ADC_MCR[ADCLKSEL] = 0, then AD_clk = (bus clock ÷ 2)

If ADC_MCR[ADCLKSEL] = 1, then AD_clk = bus clock

The various components of conversion time and affecting configurations are shown and described in Figure 34-11.

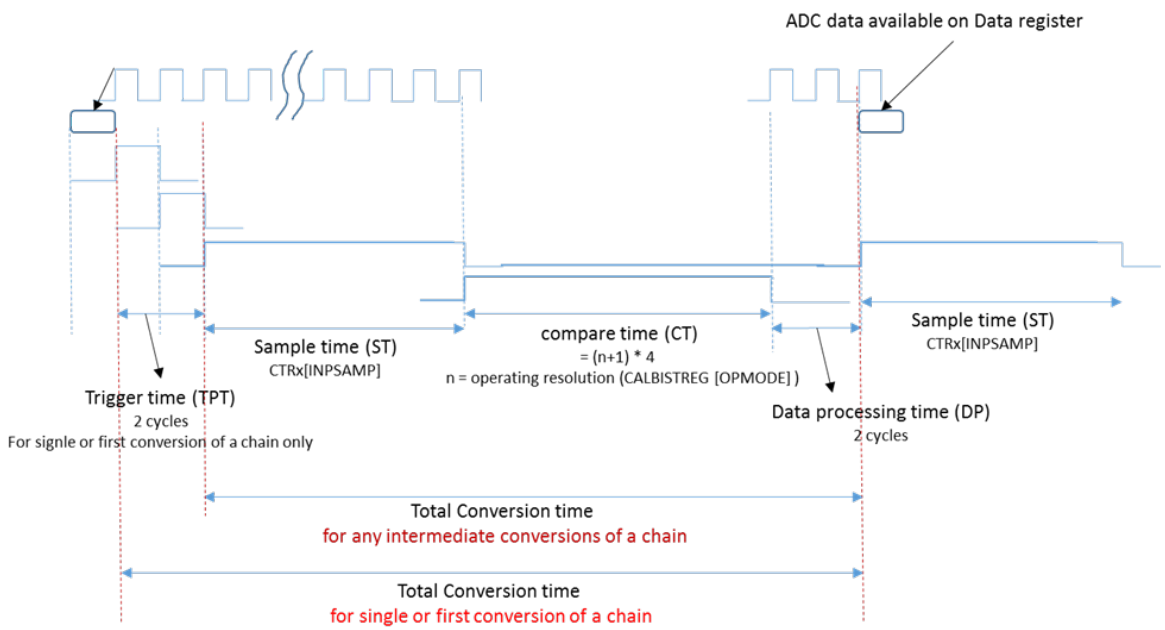

Figure 34-11. Conversion time

- Trigger processing time (TPT):
  To prepare the channel and start the operation, two clock cycles of bus clock is required by the ADC for the first conversion and for subsequent conversions in a chain, or for a continuous conversion, this time is not required as it is hidden in the pipeline operation. Triggers from Synchronous CTU interface requires two cycle of bus clock for first conversion and for back-to-back CTU conversions it takes only one cycle for trigger processing as the other cycle is hidden in pipeline operation. Triggers from Asynchronous CTU interface requires three cycles of bus clock for synchronization and processing.
- Sample phase time (ST):

Sample time duration is controlled by the INPSAMP[7:0] field of Conversion timing Registers ADC_CTR*x* (*x* = 0...2) for different types of channels. Value in each register affects the sample time in similar way. The value in the register represents units of cycle of the AD_clk. The minimum value of sample time is 8. If the value programmed is less than 8, then it has no effect on sample time duration and in this case sample time will be 8 AD_clk cycles.

- Compare phase time (CT):

  The compare phase of the ADC dependends on the resolution setting (which is 13 for this chip), and takes ((13 + 1) × 4) cycles of AD_clk.

- Data processing time (DP):

  The ADC takes 2 cycles of AD_clk to post process and load the data int registers.

- Total Conversion Time:

  The total time required for single or first conversion is [TPT+ST+CT+DP] cycles of AD_clk and for subsequent conversion is a chain or continuous conversion is [ST+CT+DP] cycles of AD_clk.

  Examples:

  - CTR*x*[INPSAMP] = 20d; software/hardware triggered (NSTART):
    - Single/First Conversion: 2 + 20 + ((13 + 1) × 4) + 2 = 2 + 20 + 56 + 2 = 80 cycles of AD_clk
    - Subsequent/continuous conversion: 20 + ((13 + 1) × 4) + 2 = 20 + 56 + 2 = 78 cycles of AD_clk
  - CTR*x*[INPSAMP] = 20d; CTU triggered:
    - Single/First Conversion: 2 + 20 + ((13 + 1) × 4) + 2 = 2 + 20 + 56 + 2 = 80 cycles of AD_clk
    - Subsequent/continuous conversion: 1 + 20 + ((13 + 1) × 4) + 2 = 1 + 20 + 56 + 2 = 79 cycles of AD_clk

- Pre-Sampling:

  When pre-sampling is enabled, the ADC does pre-sampling prior to starting the actual channel sampling as described in pre-sampling section. This phase takes CTR*x*[INPSAMP] cycles of AD_clk. Additionally, to switch from pre-sample phase to actual channel sampling phase, it takes another two cycles of AD_clk. So, total CTR*x*[INPSAMP] + 2 cycles additionally required for a conversion to be completed. Thus, in case of pre-sample, all the equations and examples above are valid with the addition of (CTR*x*[INPSAMP] + 2) cycles.

34.6.12.1 Conversion time for BCTU interface

The BCTU can work in a different clock domain, and for this there is an asynchronous domain crossing that occurs before the CTU trigger is processed. Data is also processed after domain crossing. These times need to be considered in the conversion time calculation. The synchronization may take a maximum of two additional ADC clock cycles and three BCTU clock cycles over normal conversion time.

The total conversion time taking BCTU timing into consideration is as follows:

Total conversion time = Synchronization time + TPT + ST + CT + DP + Reverse synchronization time in BCTU

The figure below shows the different components of total conversion time.

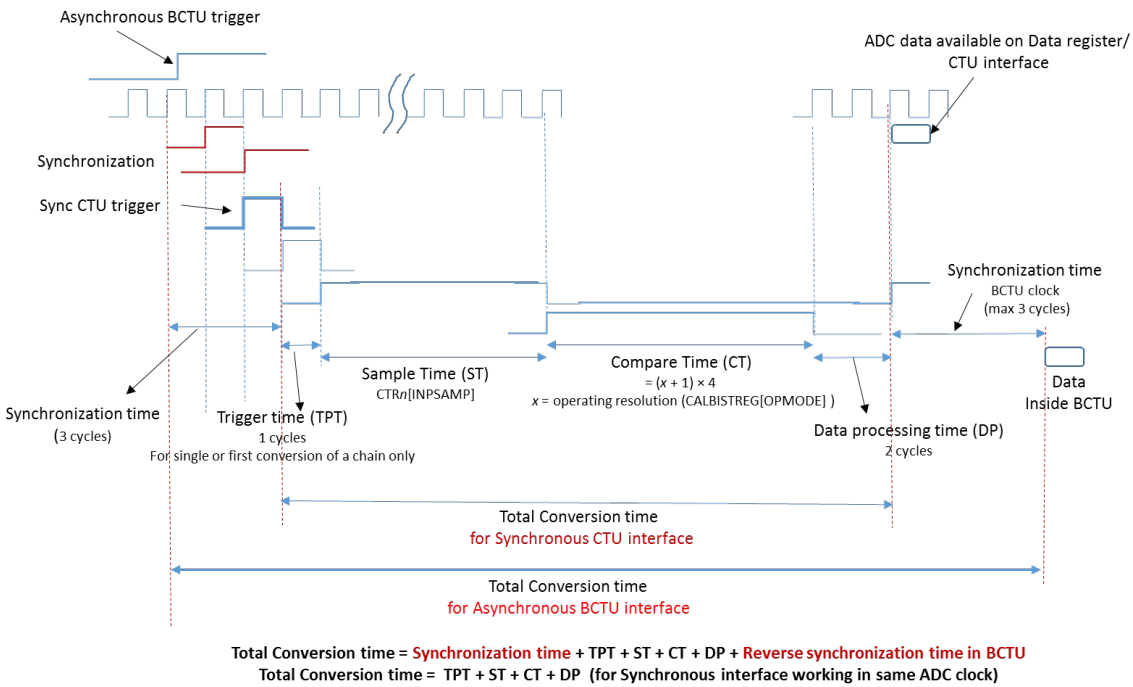

Figure 34-12. Normal Conversion time from BCTU (asynchronous, not working in ADC clock)

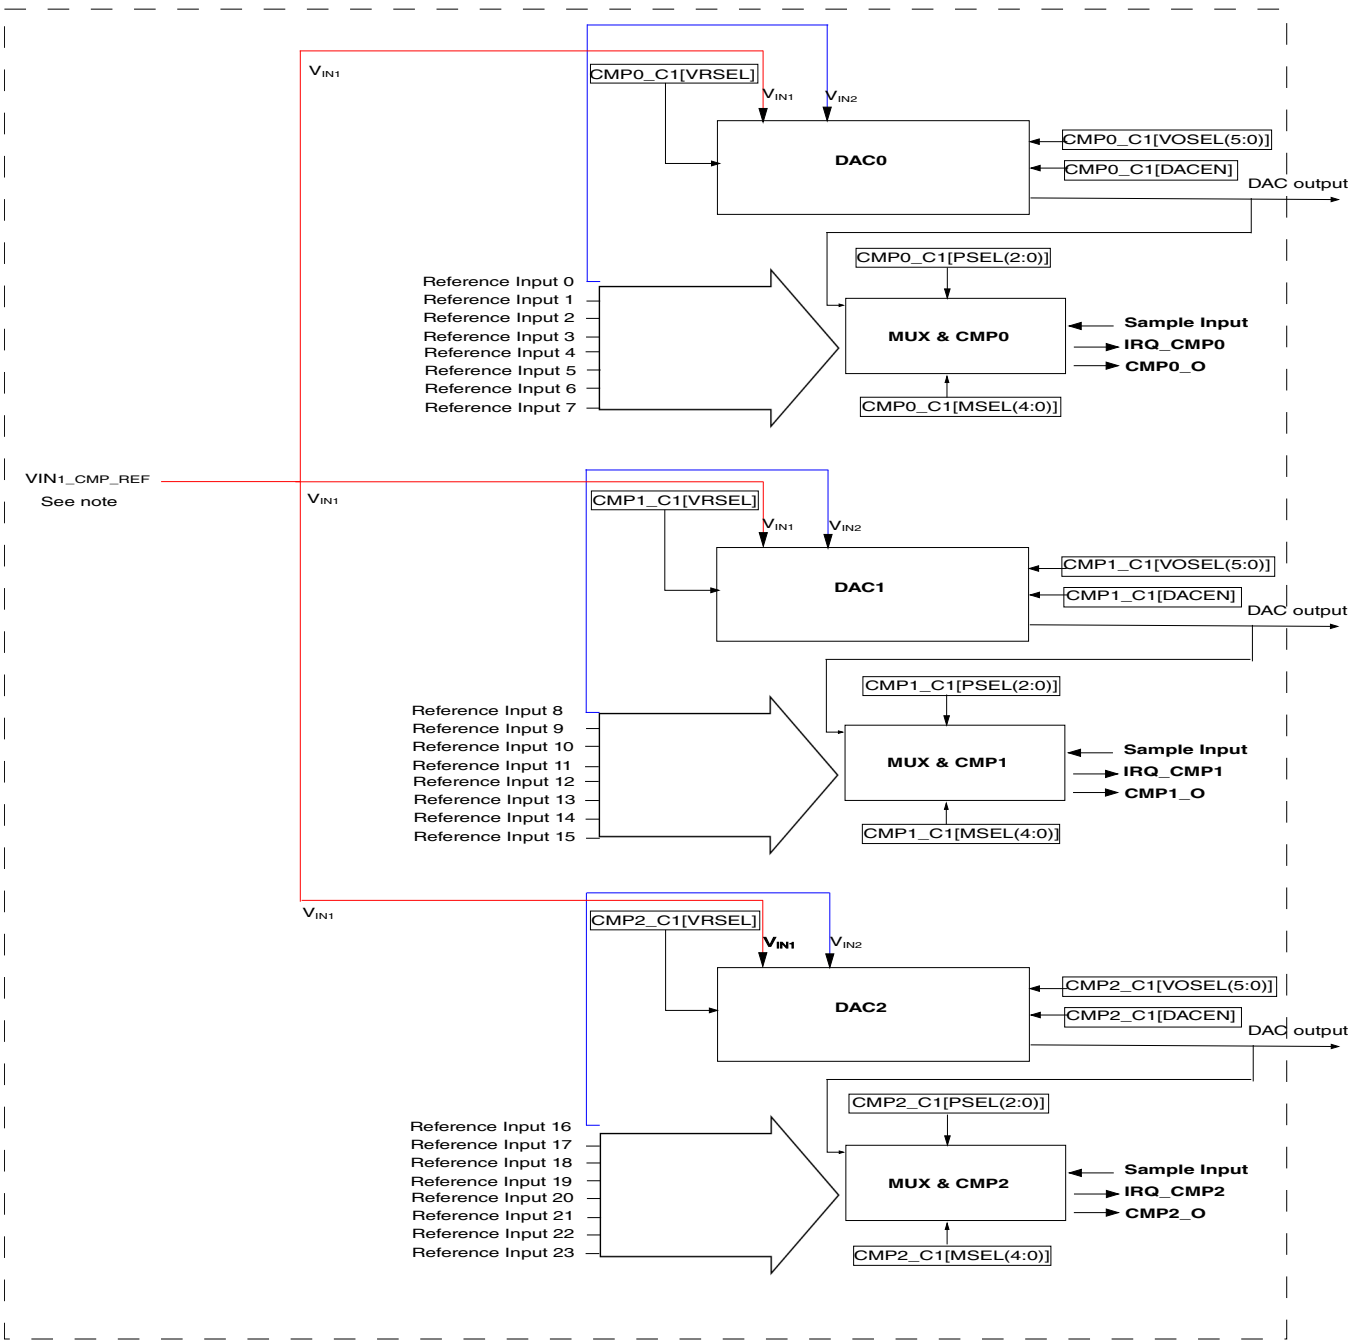
34.6.13 Conversion data processing

The raw converted ADC data contains many types of errors such as offset, gain, DC bias, and so on. Thus, to generate error-free results, raw converted data is processed before it is written to a result register. The process of error correction goes bit-by-bit during conversion with the values generated during the offset calculation and calibration process. This helps in reducing final data processing time as only one addition/addition (2's complement) is performed simultaneously with conversion.

34.7 Clock frequency

The ADC internal blocks are designed to work with an 80 MHz clock. Thus, the specified speed can be met with this clock frequency. If the clock is faster than this, ADCA cannot work properly and the ADC may malfunction. If the clock is slower, then the ADC speed will be lower, but it will work properly. It should be noted that there is an absolute maximum value of the sampling time that the analog portion of the ADC can support. For slower clocks, the sampling clock count will need to be programmed accordingly.

Chapter 35
Analog Comparator (CMP)



35.1 Chip-specific CMP information

35.1.1 CMP configuration

This device supports three instances of this module: CMP0, CMP1, and CMP2. This gives a total of 24 external inputs. In addition, each comparator has its own unique DAC reference. Thus, each comparator has a total of nine inputs.

The DAC in each comparator is a 6-bit comparator, yielding 64 reference points.

The MDIS/PCTL control bits will control the ACMP bus clock in various mode. The comparison will be active even when bus clock is disabled.

Note: $V_{IN1_CMP_REF}$ is not available in the LQFP176 SO V_{IN1} is connected to $V_{DD_HV_A}$ in LQFP176.

Figure 35-1. Comparator connectivity with 24 channel inputs

35.1.2 CMP input output connections

The following table shows the fixed connections to the CMP.

Table 35-1. CMP input output connections

Source	CMP0	CMP1	CMP2
IN0	CMP0_0	CMP1_8	CMP2_16
IN1	CMP0_1	CMP1_9	CMP2_17
IN2	CMP0_2	CMP1_10	CMP2_18
IN3	CMP0_3	CMP1_11	CMP2_19
IN4	CMP0_4	CMP1_12	CMP2_20
IN5	CMP0_5	CMP1_13	CMP2_21
IN6	CMP0_6	CMP1_14	CMP2_22
IN7	CMP0_7	CMP1_15	CMP2_23
OUT	CMP0_O	CMP1_O	CMP2_O

35.1.3 CMP "V_{IN1}" and "V_{IN2}" references

The 6-bit DAC sub-block supports selection of "V_{IN1}" and "V_{IN2}" references.

For each comparator, one of the references ("V_{IN1},V_{IN2}") for DAC has a dedicated pin $V_{IN1_CMP_REF}$ and the other source is shared with input channel 0. Therefore, in order to use the other reference, channel 0 of the corresponding comparator has to be sacrificed. The reference switching is based on the VRSEL signal. So the comparators have to work on the external reference $V_{IN1_CMP_REF}$ to utilize all the available input channels otherwise one less than total number of channels and use internal reference – that is channel 0.

The following tables list the package-wise V_{IN1} and V_{IN2} references.

Table 35-2. CMPx package-wise Vin2 references

Package	CMP0_Vin2	CMP1_Vin2	CMP2_Vin2
All	CMP0_0	CMP1_8	CMP2_16

Table 35-3. CMP package-wise Vin1 references

Package	CMPx_Vin1

35.1.4 Interaction with RTC API to cause wakeup

The CMP module is used in conjunction with the RTC/API module to cause wakeup in STOP, LPU_STOP, STANDBY and LPU_STANDBY modes. The API is configured to generate a trigger signal to inform the CMP module to enable the DAC. After a short interval, the RTC/API sends the CMP module a START signal that begins the round robin operation. Following the START, the CMP module performs a round robin on all eight inputs while comparing each input with the fixed DAC voltage. On completion of the round robin, the result is compared to the previous stored result. If any difference is detected, the CMP module sends an interrupt to the system. The device comes out of the low power state via the wakeup module. The following figure shows a flowchart describing the procedure.

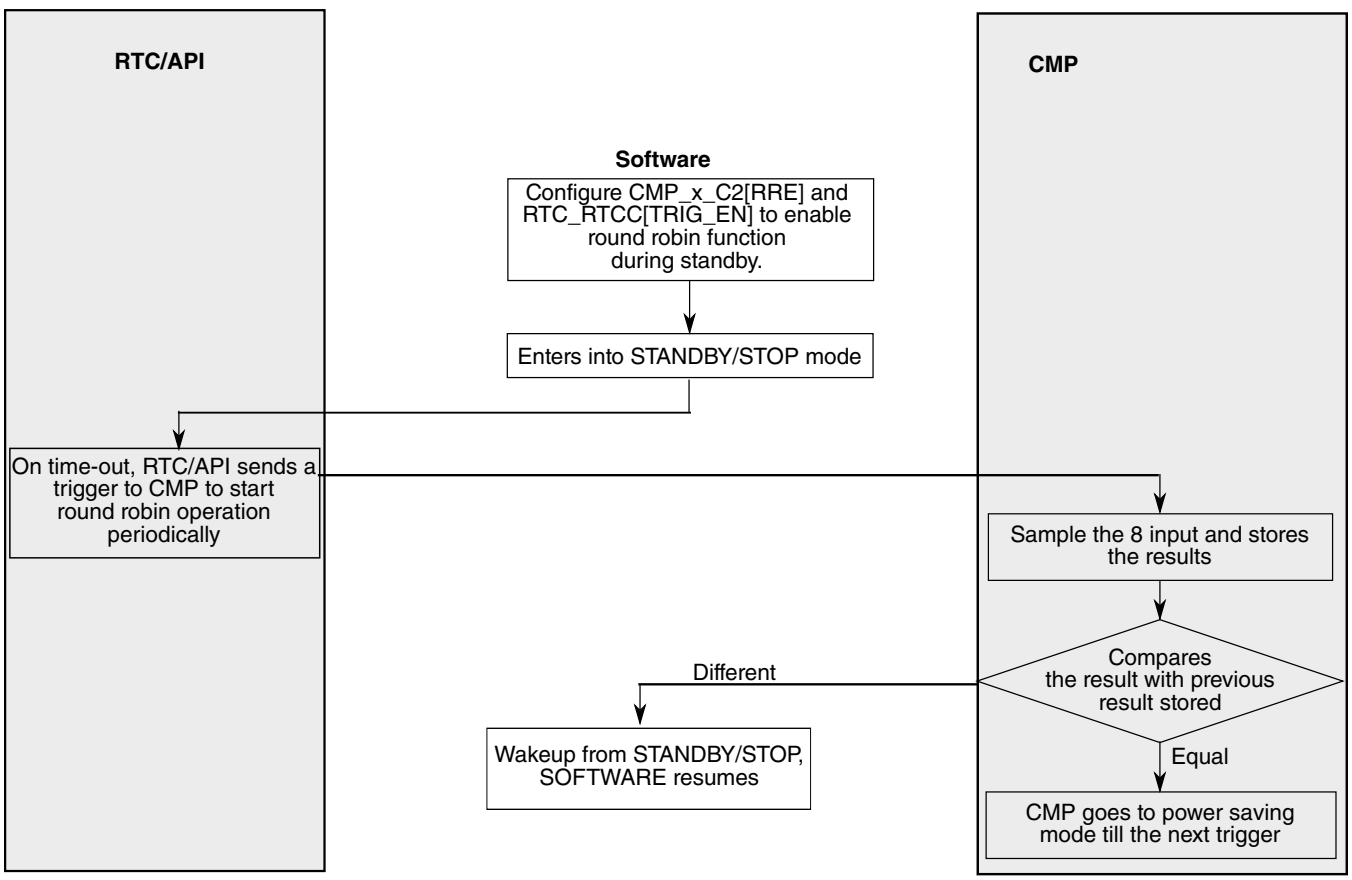

Figure 35-2. CMP-RTC interaction

In the round robin mode, only the continuous mode is supported. None of the window/ filter/sample functions should be used.

Summary of register configurations before entering STANDBY mode:

1. Configure CMP_x_C2[RRE] and RTC_RTCC[TRIG_EN] to enable round robin function during standby.
2. Enable the round robin interrupt by configuring RRIE in CMP_*x*_C2.
3. Enable the DAC to be used as the reference voltage on either plus or minus of the mux inside CMP.
4. Configure the NSAM field of the CMP_*x*_C2 register(s) to select the number of clock cycles for which a channel is selected for sampling.
5. Set ACO*n* for the predefined values of the state of the 8 bits corresponding to the eight inputs.
6. Configure RTC_APIVAL to set the period of the round robin operation.
7. Configure RTC_ANLCMP_CNT as the initialization time of the CMP module.

NOTE

This RTC API - CMP interaction for wakeup feature is available in STOP, LPU_STOP, STANDBY and LPU_STANDBY modes.

35.1.5 CMP Window control

The window in the window mode of the CMP is controlled via the GPR register bits in the device. If the filter is enabled and if the RTC clock is to be used as the clock to the filter block instead of the bus clock, the window mode should be disabled.

Whenever there is switching on bit GPR_CTL[CMP_SAMP_SEL], both the filter and window blocks needs to be disabled.

Refer to GPR_CTL[CMP_ACT_SAM] and GPR_CTL[CMP_SAMP_SEL] for details.

35.2 Introduction

The comparator (CMP) module provides a circuit for comparing two analog input voltages. The comparator circuit is designed to operate across the full range of the supply voltage, known as rail-to-rail operation.

The Analog MUX (ANMUX) provides a circuit for selecting an analog input signal from eight channels. One signal is provided by the 6-bit digital-to-analog converter (DAC). The mux circuit is designed to operate across the full range of the supply voltage.

The DAC is a 64-tap resistor ladder network that provides a selectable voltage reference for applications requiring a voltage reference. The 64-tap resistor ladder network divides the supply reference V_{in} into 64 voltage levels. A 6-bit digital signal input selects the

output voltage level, which varies from V_{in} to $V_{in}/64$. V_{in} can be selected from two voltage sources, V_{in1} and V_{in2}. The DAC from a comparator is available as an on-chip internal signal only and is not available externally to a pin.

35.3 Features

The following subsections list the features of the CMP, the DAC, and the ANMUX.

35.3.1 CMP features

The CMP has the following features:

- Operational over the entire supply range
- Inputs may range from rail to rail
- Programmable hysteresis control
- Selectable interrupt on rising-edge, falling-edge, or both rising or falling edges of the comparator output
- Selectable inversion on comparator output
- Capability to produce a wide range of outputs such as:
  - Sampled
  - Windowed, which is ideal for certain PWM zero-crossing-detection applications
  - Digitally filtered:
    - Filter can be bypassed
    - Can be clocked via external SAMPLE signal or scaled bus clock
- External hysteresis can be used at the same time that the output filter is used for internal functions
- Two software selectable performance levels:
  - Shorter propagation delay at the expense of higher power
  - Low power, with longer propagation delay
- DMA transfer support
  - A comparison event can be selected to trigger a DMA transfer

- Functional in all MCU power modes
- The window and filter functions are not available in STOP modes
- The comparator can be triggered by other peripherals to work for only a small fraction of the time

35.3.2 6-bit DAC key features

The 6-bit DAC has the following features:

- 6-bit resolution
- Selectable supply reference source
- Power Down mode to conserve power when not in use
- Option to route the output to internal comparator input

35.3.3 ANMUX key features

The ANMUX has the following features:

- Two 8-to-1 channel MUXes
- Operational over the entire supply range

35.4 CMP, DAC, and ANMUX diagram

The following figure shows the block diagram for the High-Speed Comparator, DAC, and ANMUX modules.

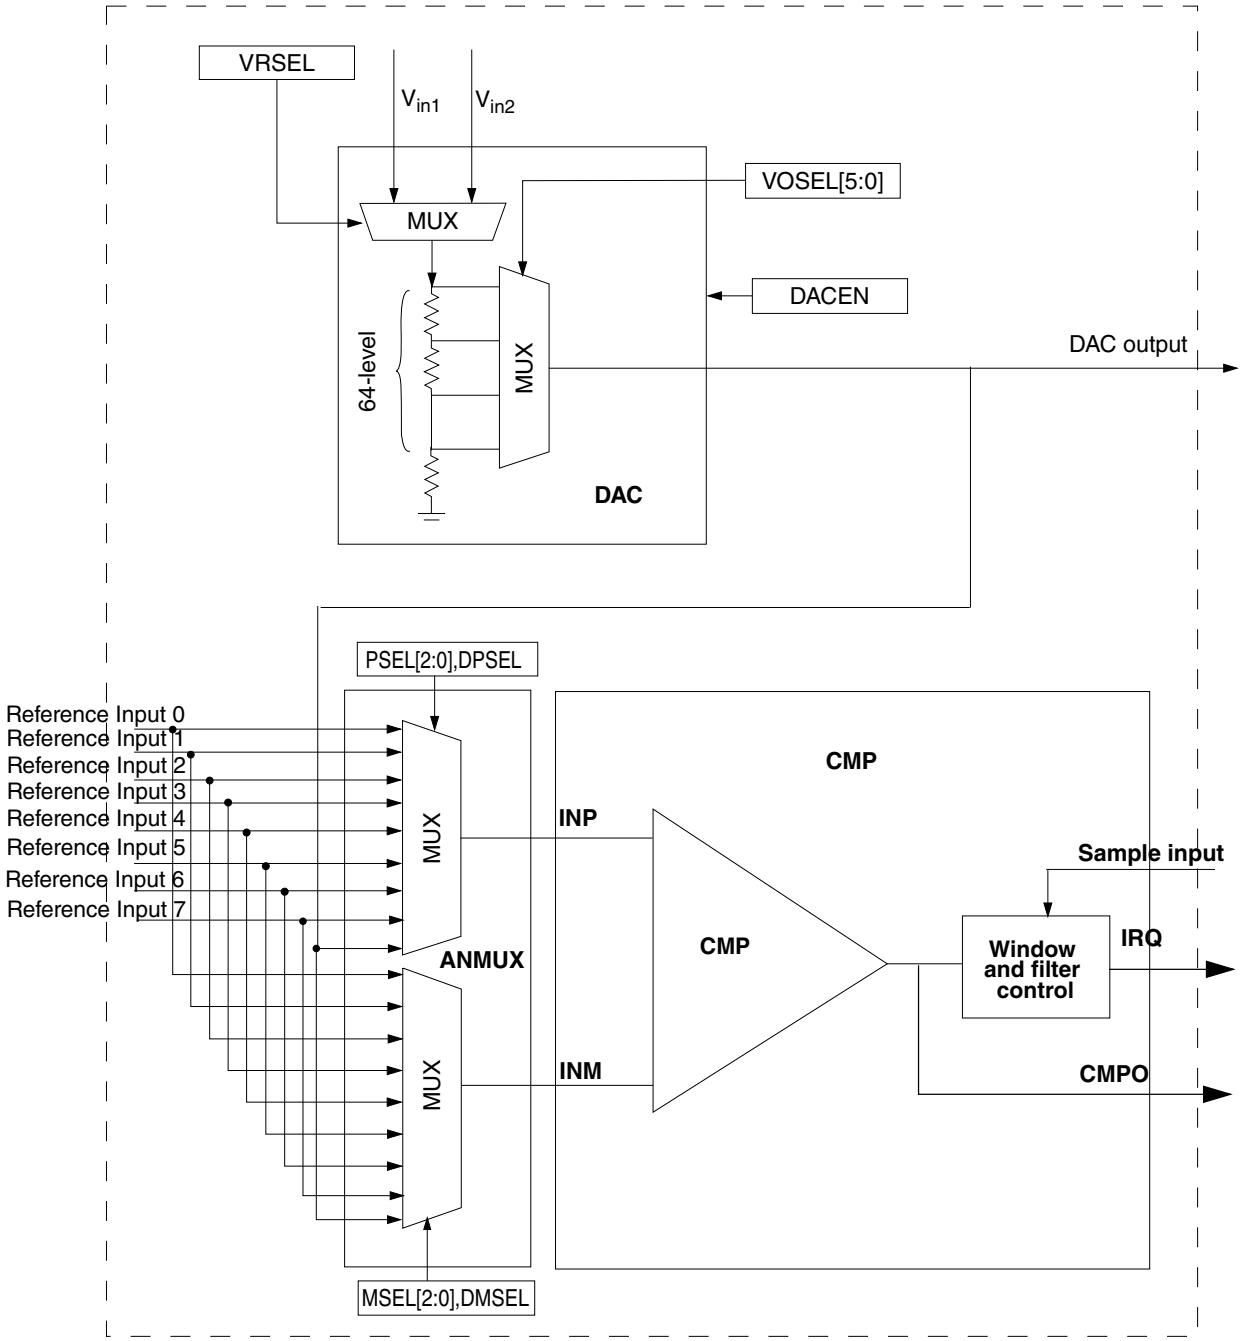

Figure 35-3. CMP high level diagram

35.5 CMP block diagram

The following figure shows the block diagram for the CMP module.

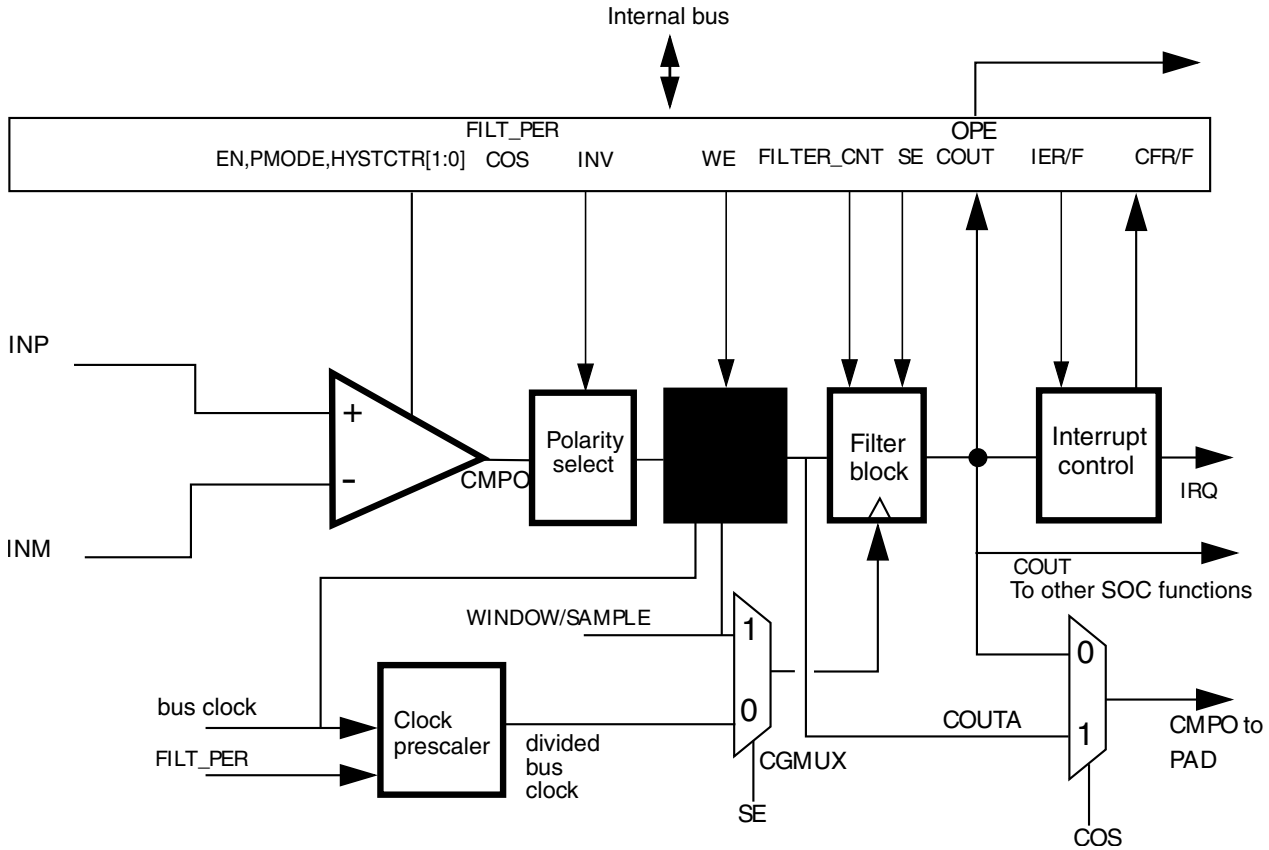

Figure 35-4. Comparator module block diagram

In the CMP block diagram:

- The Window Control block is bypassed when C0[WE] = 0.
- If C0[WE] = 1, the comparator output is sampled on every bus clock when WINDOW=1 to generate COUTA. Sampling does NOT occur when WINDOW = 0.
- The Filter block is bypassed when not in use.

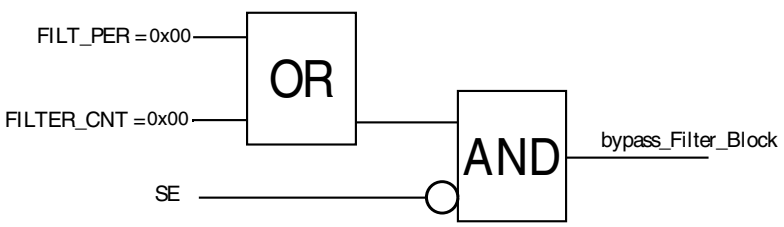

Figure 35-5. Filter block bypass logic

- The Filter block acts as a simple sampler if the filter is bypassed and C0[FILTER_CNT] is set to 0x01.
- The Filter block filters based on multiple samples when the filter is bypassed and C0[FILTER_CNT] is set greater than 0x01.

- If C0[SE] = 1, the external SAMPLE input is used as the sampling clock.
- IF C0[SE] = 0, the divided bus clock is used as the sampling clock.

- If enabled, the Filter block will incur up to one bus clock additional latency penalty on COUT due to the fact that COUT, which crosses clock domain boundaries, must be resynchronized to the bus clock.
- C0[WE] and C0[SE] are mutually exclusive.
- If enabled, the filter clock and the sample period must be at least 4 tims slower than the system clock to the comparator.

35.6 CMP pin descriptions

This section provides the comparator pin descriptions. The MSB input IN[7] is muxed with the DAC output on both the plus and minus sides by CMP_C1[DPSEL] and CMP_C1[DMSEL], respectively. When CMP_C1[DPSEL] is set, the DAC output is selected as the reference input for the plus MUX channel 7, regardless of the CMP_C1[PSEL] setting. Similarly, when CMP_C1[DMSEL] is set, the DAC output is selected as the reference input for the minus MUX channel 7, regardless of the CMP_C1[MSEL] setting.

Table 35-4. CMP signal descriptions

Signal	Description	I/O
IN[7:0]	Analog voltage inputs	I

35.6.1 External pins

The CMP has two analog inputs: INP and INM. Each of these pins can accept an input voltage that varies across the full operating range of the MCU. If the module is not enabled, each pin can be used as a digital input or output. Consult the specific MCU documentation to determine what functions are shared with these analog inputs.

The user can select either filtered or unfiltered comparator outputs for use on an external I/O pad.

35.7 CMP functional modes

There are three main sub-blocks to the CMP module:

- The comparator itself
- The window function
- The filter function

The filter, C0[FILTER_CNT], can be clocked from an internal or external clock source. The filter is programmable with respect to the number of samples that must agree before a change in the output is registered. In the simplest case, only one sample must agree. In this case, the filter acts as a simple sampler.

The external sample input is enabled using C0[SE]. When set, the output of the comparator is sampled only on rising edges of the sample input.

The "windowing mode" is enabled by setting C0[WE]. When set, the comparator output is sampled only when WINDOW=1. This feature can be used to ignore the comparator output during time periods in which the input voltages are not valid. This is especially useful when implementing zero-crossing-detection for certain PWM applications.

The comparator filter and sampling features can be combined as shown in the following table. Individual modes are discussed below.

Table 35-5. Comparator sample/filter controls

Mode #	C0[EN]	C0[WE]	C0[SE]	C0[FILTER_CNT]	C0[FPR]	Operation
1	0	X	X	X	X	**Disabled** See the Disabled mode (# 1).
2A	1	0	0	0x00	X	**Continuous Mode** See the Continuous mode (#s 2A & 2B).
2B	1	0	0	X	0x00	
3A	1	0	1	0x01	X	**Sampled, Non-Filtered mode** See the Sampled, Non-Filtered mode (#s 3A & 3B).
3B	1	0	0	0x01	> 0x00	
4A	1	0	1	> 0x01	X	**Sampled, Filtered mode** See the Sampled, Filtered mode (#s 4A & 4B).
4B	1	0	0	> 0x01	> 0x00	
5A	1	1	0	0x00	X	**Windowed mode**
5B	1	1	0	X	0x00	

Table continues on the next page...

Table 35-5. Comparator sample/filter controls (continued)

Mode #	C0[EN]	C0[WE]	C0[SE]	C0[FILTER_CNT]	C0[FPR]	Operation
						Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA. See the Windowed mode (#s 5A & 5B).
6	1	1	0	0x01	0x01–0xFF	**Windowed/Resampled mode** Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA, which is then resampled on an interval determined by C0[FPR] to generate COUT. See the Windowed/Resampled mode (# 6).
7	1	1	0	> 0x01	0x01–0xFF	**Windowed/Filtered mode** Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA, which is then resampled and filtered to generate COUT. See the Windowed/Filtered mode (#7).
All other combinations of C0[EN], C0[WE], C0[SE], C0[FILTER_CNT], and C0[FPR] are illegal.						

For cases where a comparator is used to drive a fault input, for example, for a motor-control module such as FTM, it must be configured to operate in Continuous mode so that an external fault can immediately pass through the comparator to the target fault circuitry.

Note

Filtering and sampling settings must be changed only after setting C0[SE]=0 and C0[FILTER_CNT]=0x00. This resets the filter to a known state.

35.7.1 Disabled mode (# 1)

In Disabled mode, the analog comparator is non-functional and consumes no power. CMPO is 0 in this mode.

35.7.2 Continuous mode (#s 2A & 2B)

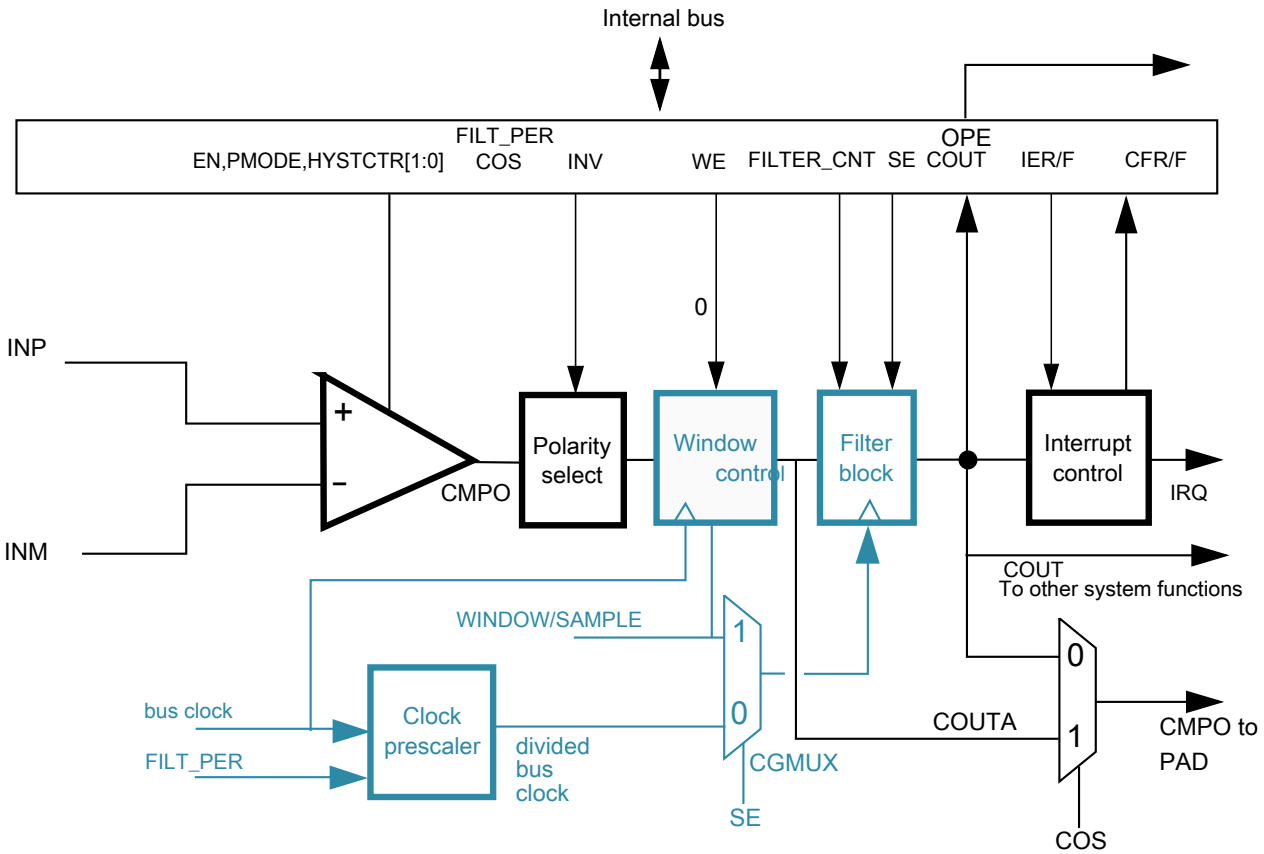

Figure 35-6. Comparator operation in Continuous mode

NOTE

See the chip configuration section for the source of sample/ window input.

The analog comparator block is powered and active. CMPO may be optionally inverted, but is not subject to external sampling or filtering. Both window control and filter blocks are completely bypassed. C0[COUT] is updated continuously. The path from comparator input pins to output pin is operating in combinational unclocked mode. COUT and COUTA are identical.

For control configurations that result in disabling the filter block, see Figure 35-5.

35.7.3 Sampled, Non-Filtered mode (#s 3A & 3B)

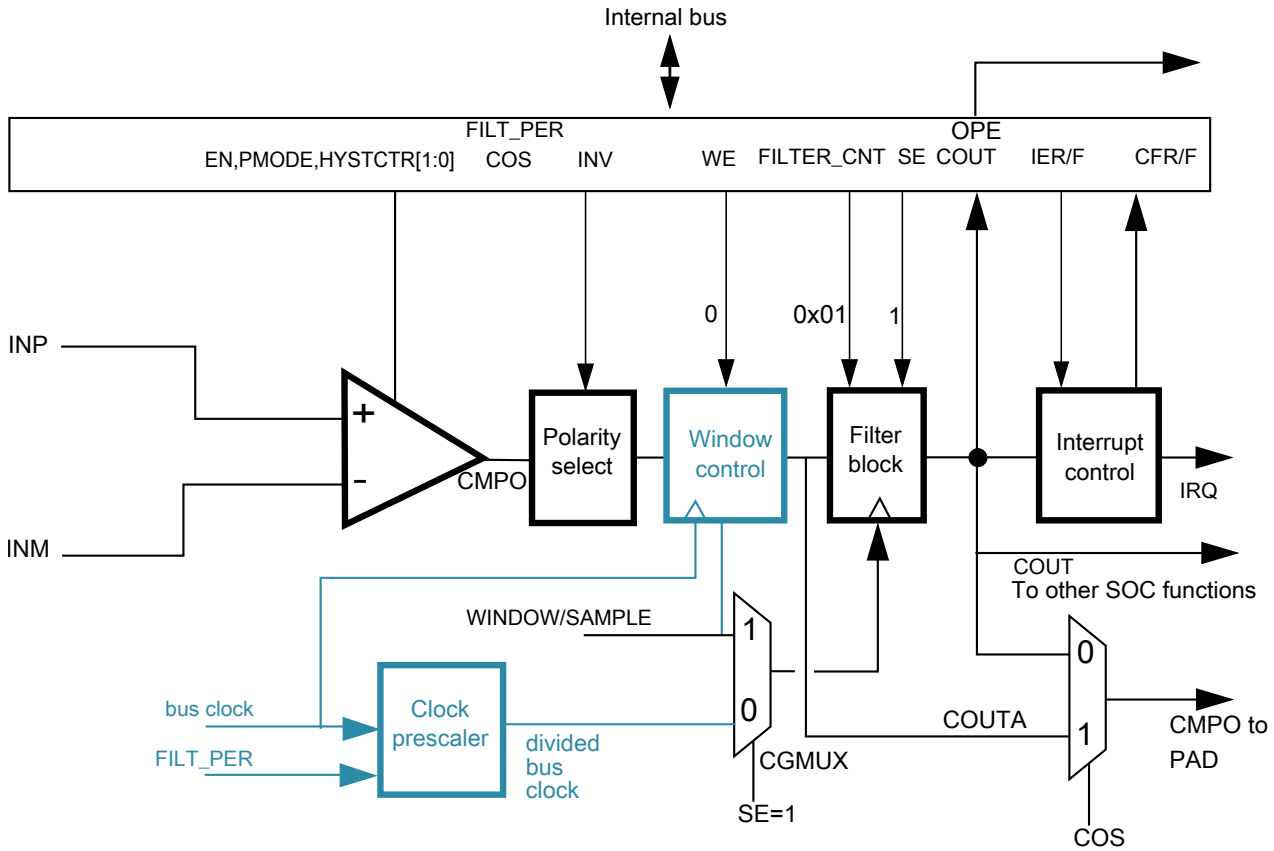

Figure 35-7. Sampled, Non-Filtered (# 3A): sampling point externally driven

In Sampled, Non-Filtered mode, the analog comparator block is powered and active. The path from analog inputs to COUTA is combinational unclocked. Windowing control is completely bypassed. COUTA is sampled whenever a rising edge is detected on the filter block clock input.

The only difference in operation between Sampled, Non-Filtered (# 3A) and Sampled, Non-Filtered (# 3B) is in how the clock to the filter block is derived. In #3A, the clock to filter block is externally derived while in #3B, the clock to filter block is internally derived.

The comparator filter has no other function than sample/hold of the comparator output in this mode (# 3B).

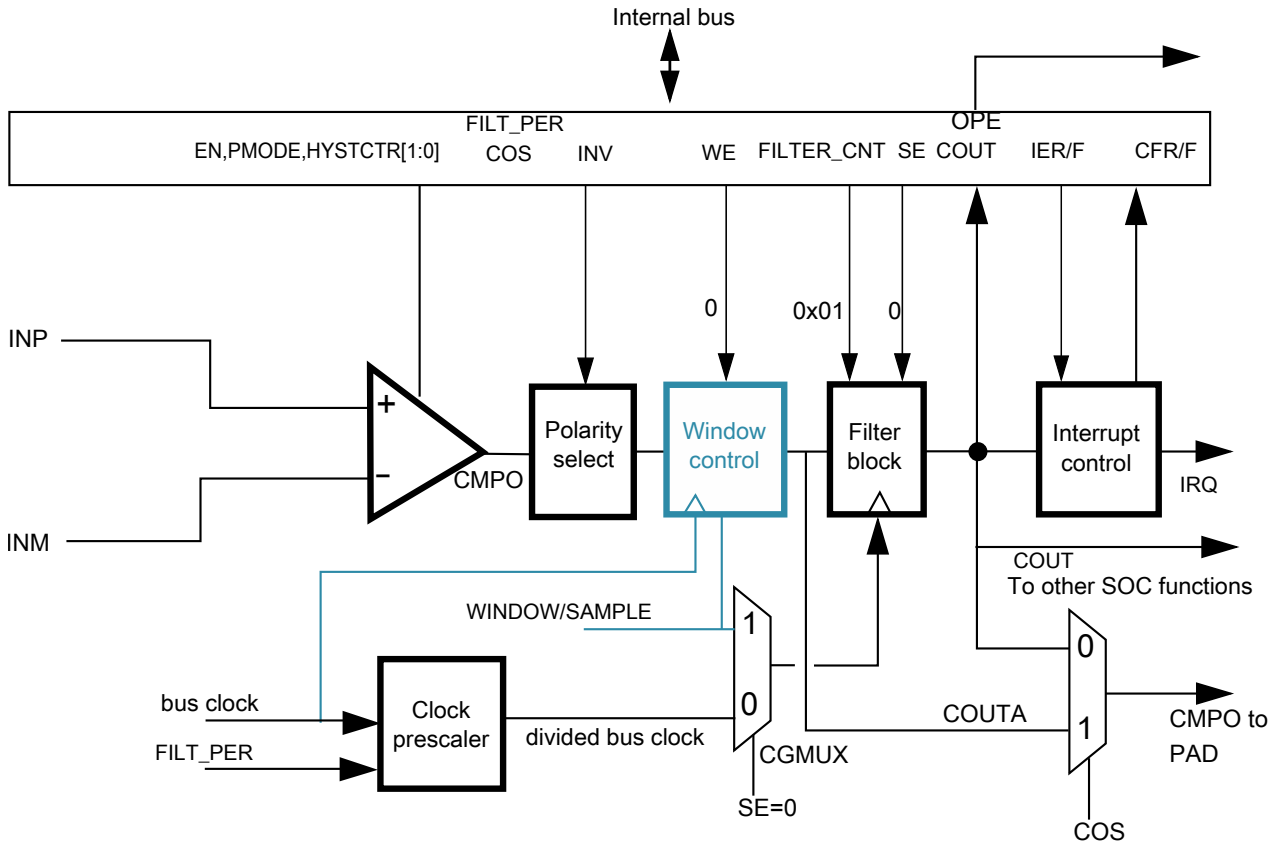

Figure 35-8. Sampled, Non-Filtered (# 3B): sampling interval internally derived

35.7.4 Sampled, Filtered mode (#s 4A & 4B)

In Sampled, Filtered mode, the analog comparator block is powered and active. The path from analog inputs to COUTA is combinational unclocked. Windowing control is completely bypassed. COUTA is sampled whenever a rising edge is detected on the filter block clock input.

The only difference in operation between Sampled, Non-Filtered (# 3A) and Sampled, Filtered (# 4A) is that, now, C0[FILTER_CNT]>1, which activates filter operation.

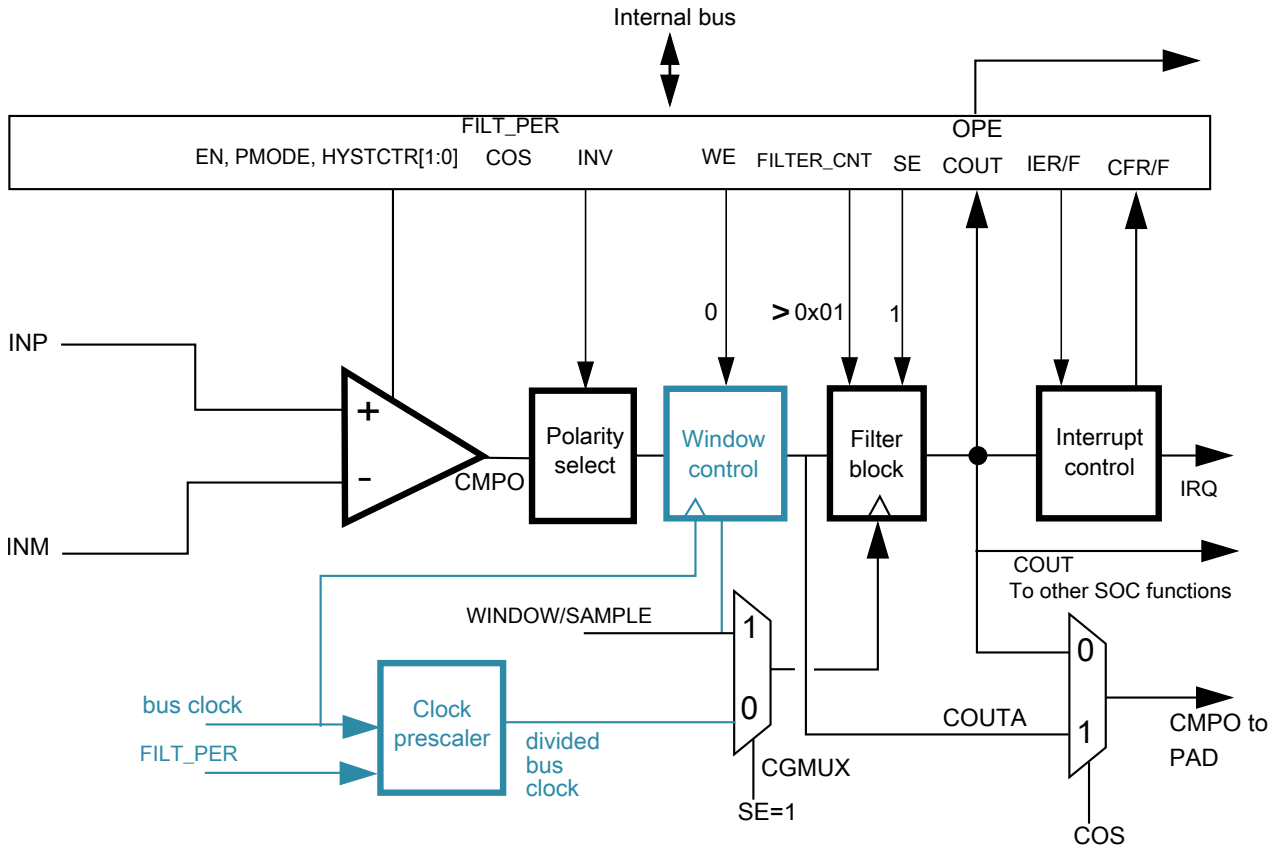

Figure 35-9. Sampled, Filtered (# 4A): sampling point externally driven

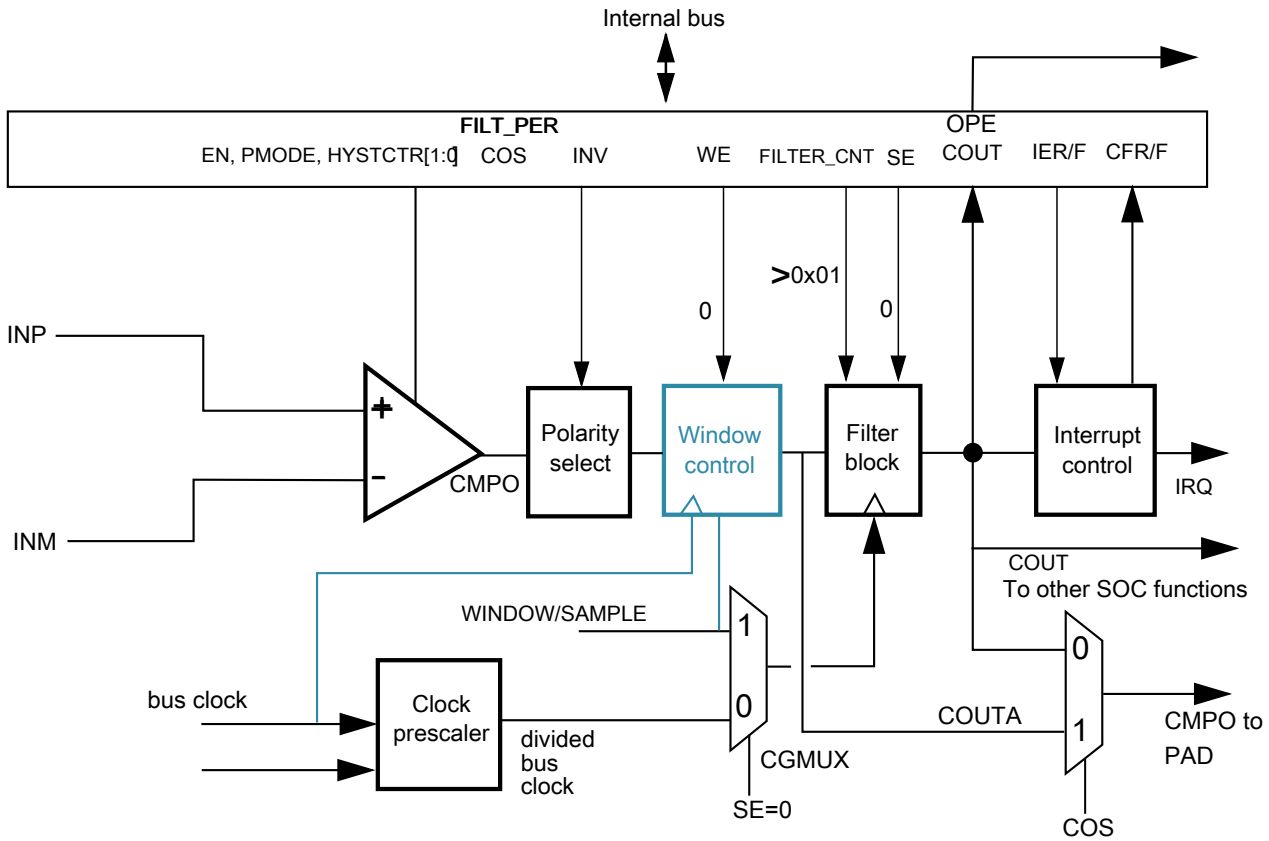

Figure 35-10. Sampled, Filtered (# 4B): sampling point internally derived

The only difference in operation between Sampled, Non-Filtered (# 3B) and Sampled, Filtered (# 4B) is that now, C0[FILTER_CNT]>1, which activates filter operation.

35.7.5 Windowed mode (#s 5A & 5B)

The following figure illustrates comparator operation in the Windowed mode, ignoring latency of the analog comparator, polarity select, and window control block. It also assumes that the polarity select is set to non-inverting state.

NOTE

The analog comparator output is passed to COUTA only when the WINDOW signal is high.

In actual operation, COUTA may lag the analog inputs by up to one bus clock cycle plus the combinational path delay through the comparator and polarity select logic.

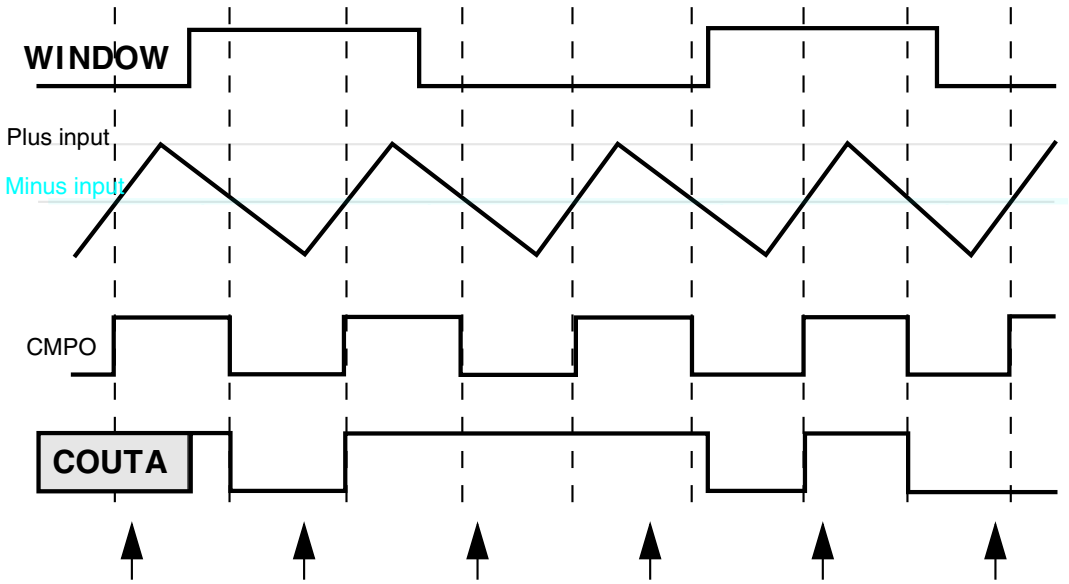

Figure 35-11. Windowed mode timing diagram

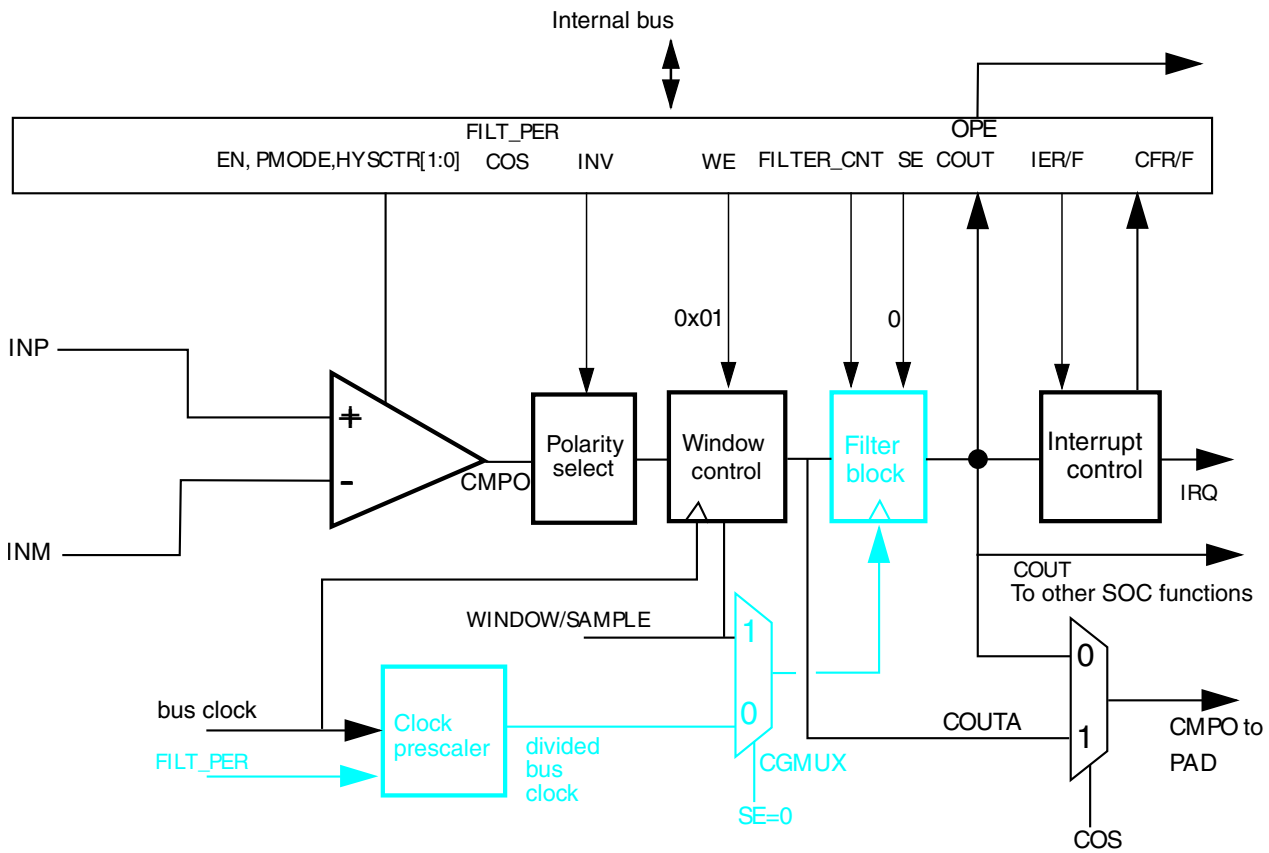

Figure 35-12. Windowed mode

For control configurations which result in disabling the filter block, see Figure 35-5.

When any windowed mode is active, COUTA is clocked by the bus clock whenever WINDOW = 1. The last latched value is held when WINDOW = 0.

35.7.6 Windowed/Resampled mode (# 6)

The following figure uses the same input stimulus shown in Figure 35-11, and adds resampling of COUTA to generate COUT. Samples are taken at the time points indicated by the arrows in the figure. Again, prop delays and latency are ignored for the sake of clarity.

This example was generated solely to demonstrate operation of the comparator in windowed/resampled mode, and does not reflect any specific application. Depending upon the sampling rate and window placement, COUT may not see zero-crossing events detected by the analog comparator. Sampling period and/or window placement must be carefully considered for a given application.

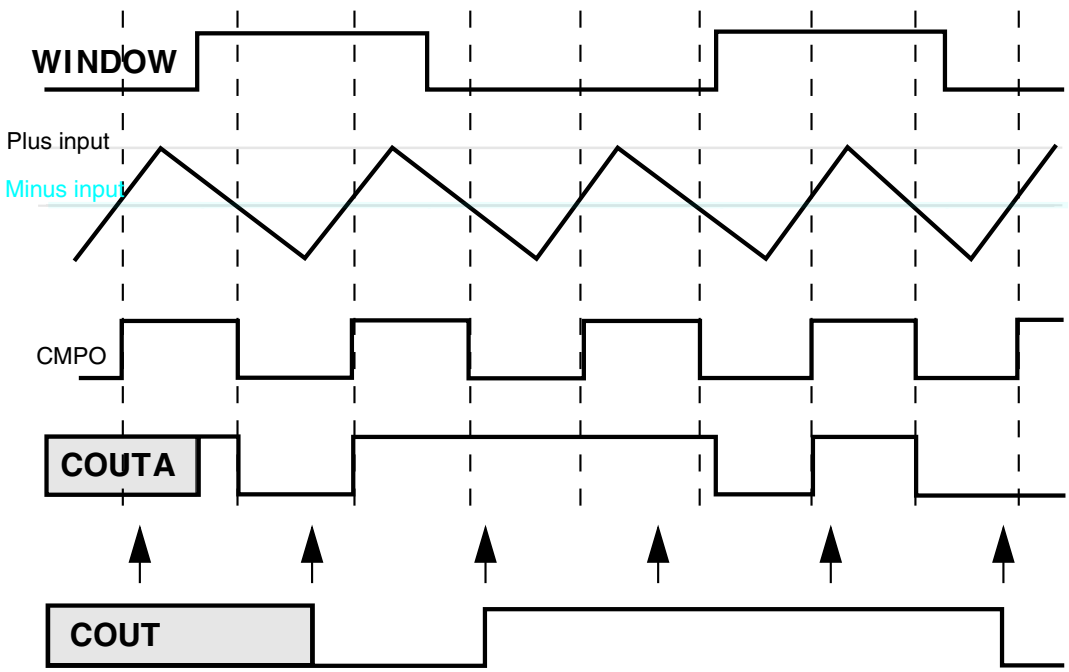

Figure 35-13. Windowed/resampled mode operation

This mode of operation results in an unfiltered string of comparator samples where the interval between the samples is determined by FPR[FILT_PER] and the bus clock rate. Configuration for this mode is virtually identical to that for the Windowed/Filtered Mode shown in the next section. The only difference is that the value of C0[FILTER_CNT] must be 1.

35.7.7 Windowed/Filtered mode (#7)

This is the most complex mode of operation for the comparator block, as it uses both windowing and filtering features. It also has the highest latency of any of the modes. This can be approximated: up to 1 bus clock synchronization in the window function + ((C0[FILTER_CNT] * C0[FPR]) + 1) * bus clock for the filter function.

When any windowed mode is active, COUTA is clocked by the bus clock whenever WINDOW = 1. The last latched value is held when WINDOW = 0.

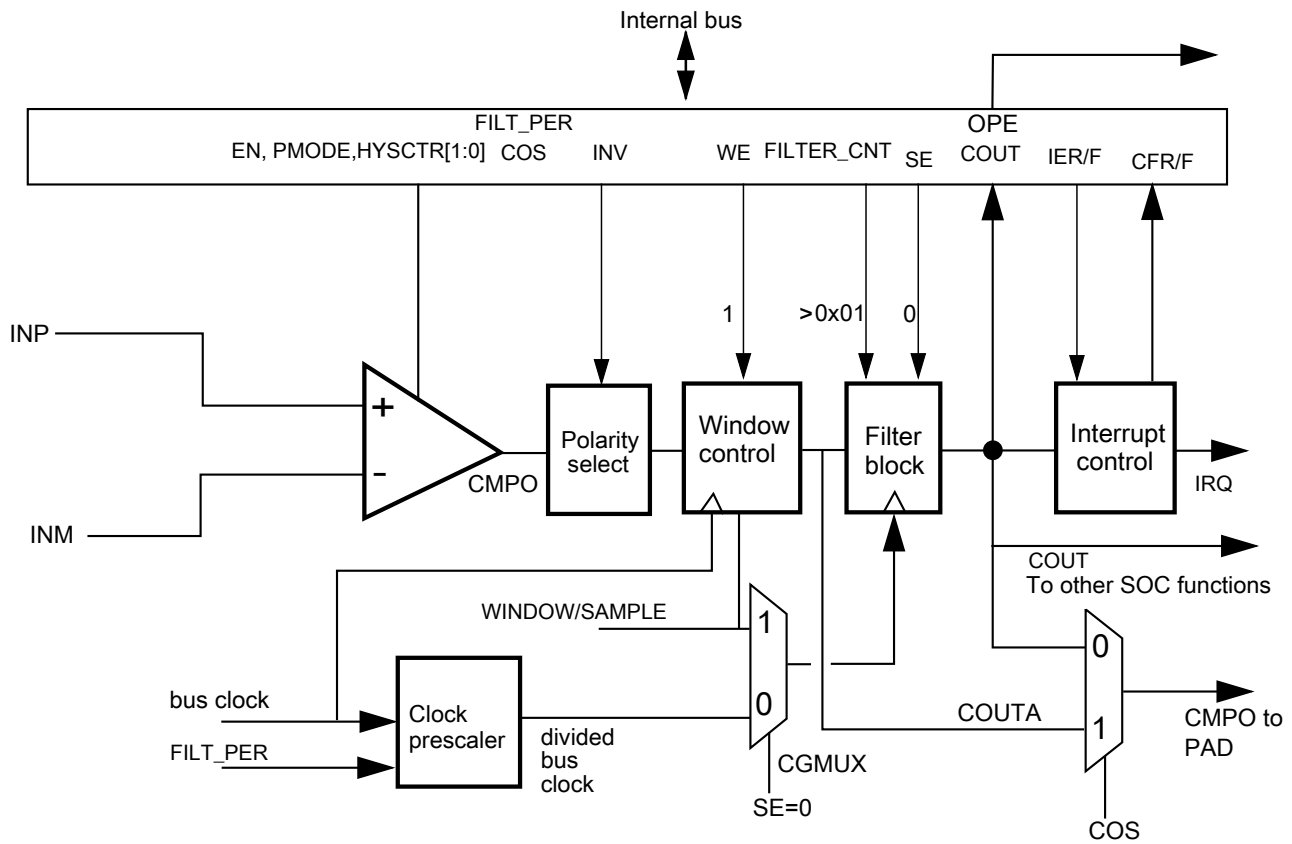

Figure 35-14. Windowed/Filtered mode

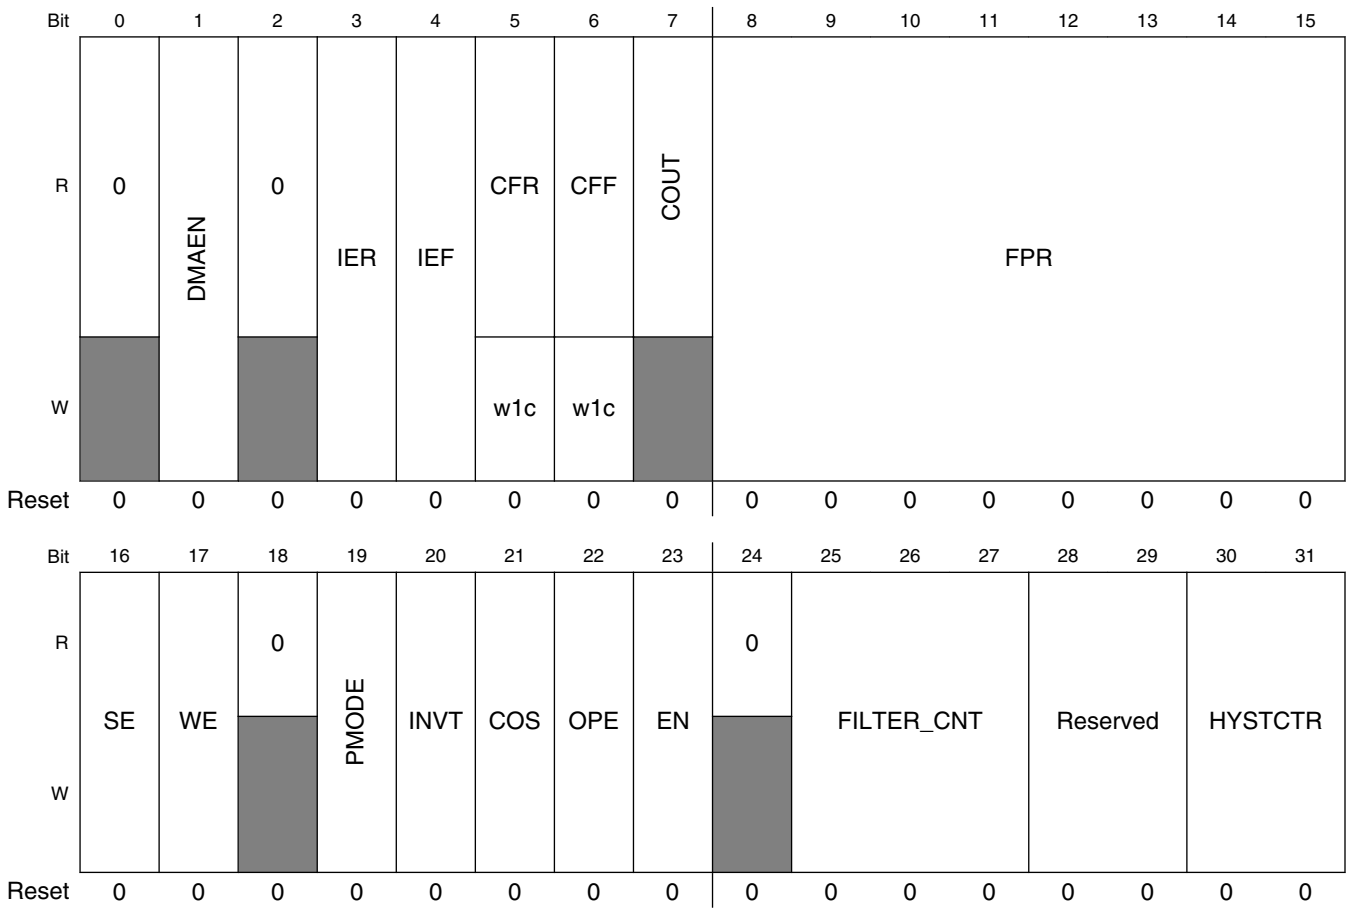
35.8 Memory map/register definitions

CMP memory map



Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

CMP_C0 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 DMAEN	DMA Enable Enables the DMA transfer triggered from the CMP module. When this field is set, a DMA request is asserted when CFR or CFF is set. 0 DMA is disabled. 1 DMA is enabled.

Table continues on the next page...

CMP_C0 field descriptions (continued)

Field	Description
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 IER	Comparator Interrupt Enable Rising Enables the CFR interrupt from the CMP. When this field is set, an interrupt will be asserted when CFR is set. 0 Interrupt is disabled. 1 Interrupt is enabled.
4 IEF	Comparator Interrupt Enable Falling Enables the CFF interrupt from the CMP. When this field is set, an interrupt will be asserted when CFF is set. 0 Interrupt is disabled. 1 Interrupt is enabled.
5 CFR	Analog Comparator Flag Rising Detects a rising-edge on COUT, when set, during normal operation. CFR is cleared by writing 1 to it. During Stop modes, CFR is level sensitive 0 A rising edge has not been detected on COUT. 1 A rising edge on COUT has occurred.
6 CFF	Analog Comparator Flag Falling Detects a falling-edge on COUT, when set, during normal operation. CFF is cleared by writing 1 to it. During Stop modes, CFF is level senstive . 0 A falling edge has not been detected on COUT. 1 A falling edge on COUT has occurred.
7 COUT	Analog Comparator Output Returns the current value of the Analog Comparator output, when read. The field is reset to 0 and will read as C0[INVT] when the Analog Comparator module is disabled, that is, when C0[EN] = 0. Writes to this field are ignored.
8–15 FPR	Filter Sample Period Specifies the sampling period, in bus clock cycles, of the comparator output filter, when C1[SE] = 0. Setting FPR to 0x0 disables the filter. Filter programming and latency details are provided in the CMP functional description. This field has no effect when C0[SE]= 1. In that case, the external SAMPLE signal is used to determine the sampling period.
16 SE	Sample Enable At any given time, either SE or WE can be set. If a write to this register attempts to set both, then SE is set and WE is cleared. However, avoid writing ones to both bit locations because this "11" case is reserved. 0 Sampling mode is not selected. 1 Sampling mode is selected.
17 WE	Windowing Enable At any given time, either SE or WE can be set. If a write to this register attempts to set both, then SE is set and WE is cleared. However, avoid writing ones to both bit locations because this "11" case is reserved.

Table continues on the next page...

CMP_C0 field descriptions (continued)

Field	Description
	0 Windowing mode is not selected. 1 Windowing mode is selected.
18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 PMODE	Power Mode Select 0 Low Speed (LS) comparison mode is selected. 1 High Speed (HS) comparison mode is selected.
20 INVT	Comparator invert This bit allows selecting the polarity of the analog comparator function. It is also driven to the COUT output (on both the device pin and as C0[COUT]) when CR1[OPE]=0. 0 Does not invert the comparator output. 1 Inverts the comparator output.
21 COS	Comparator Output Select 0 Set CMPO to equal COUT (filtered comparator output). 1 Set CMPO to equal COUTA (unfiltered comparator output).
22 OPE	Comparator Output Pin Enable The OPE bit enables the path from the comparator output to a selected pin. 0 When OPE is 0, the comparator output (after window/filter settings dependent on software configuration) is not available to a packaged pin. 1 When OPE is 1, and if the software has configured the comparator to own a packaged pin, the comparator is available in a packaged pin.
23 EN	Comparator Module Enable The EN bit enables the Analog Comparator Module. When the module is not enabled, the analog part remains in the off state, and consumes no power. When the same input is selected from analog mux to the positive and negative port, the comparator is disabled automatically. 0 Analog Comparator is disabled. 1 Analog Comparator is enabled.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–27 FILTER_CNT	Filter Sample Count This field specifies the number of consecutive samples that must agree prior to the comparator ouput filter accepting a new output state. For information regarding filter programming and latency, please see the Functional Description. 000 Filter is disabled. If SE = 1, then COUT is a logic zero (this is not a legal state, and is not recommended). If SE = 0, COUT = COUTA. 001 1 consecutive sample must agree (comparator output is simply sampled). 010 2 consecutive samples must agree. 011 3 consecutive samples must agree. 100 4 consecutive samples must agree. 101 5 consecutive samples must agree.

Table continues on the next page...

CMP_C0 field descriptions (continued)

Field	Description
	110 6 consecutive samples must agree. 111 7 consecutive samples must agree.
28–29 Reserved	This field is reserved.
30–31 HYSTCTR	Comparator hard block hysteresis control 00 The hard block output has no hysteresis internally. 01 The hard block output has 20 mv hysteresis internally. 10 The hard block output has 40 mv hysteresis internally. 11 The hard block output has 60 mv hysteresis internally.

8 CHN7	Channel 7 input enable

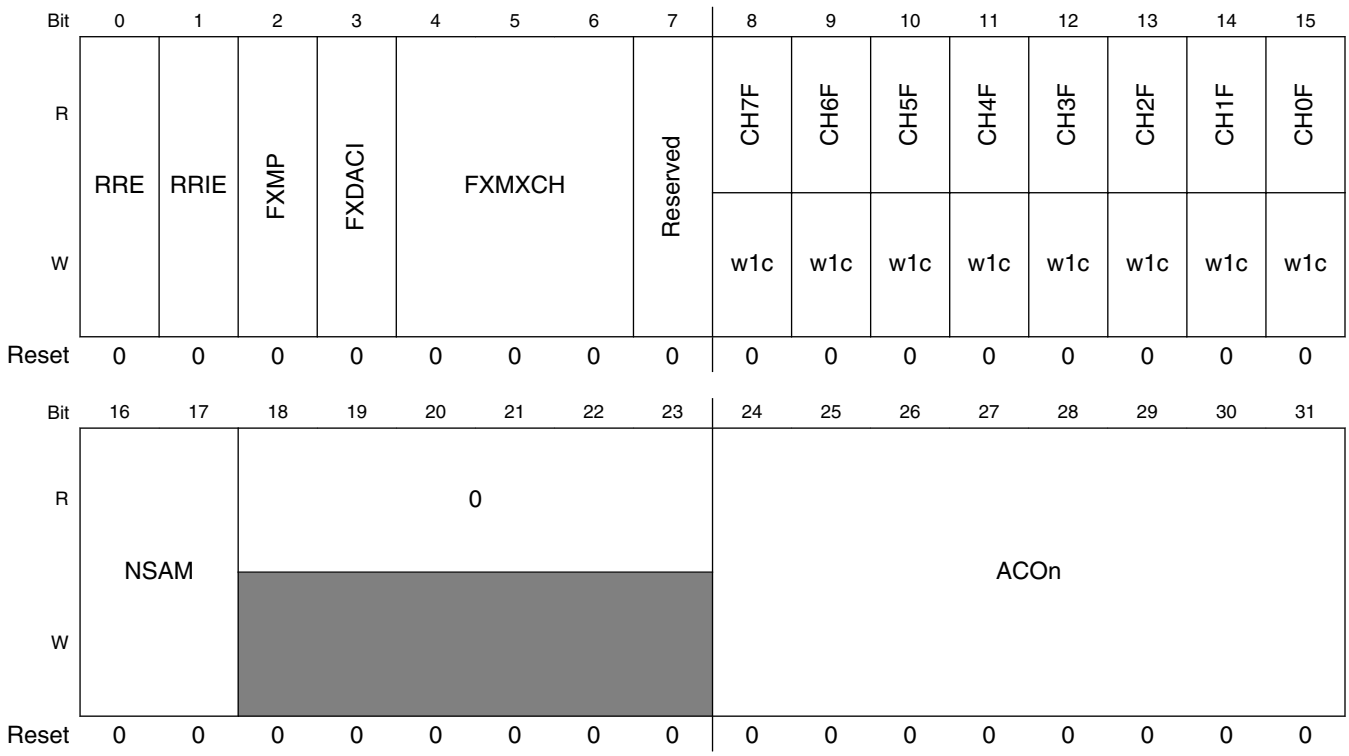
Table continues on the next page...

CMP_C1 field descriptions (continued)

Field	Description
	Channel 7 of the input enable for the round-robin checker. If CHN7 is set, then the corresponding channel to the non-fixed mux port is enabled to check its voltage value in the round-robin mode. If the same channel is selected as the reference voltage, this bit has no effect.
9 CHN6	Channel 6 input enable Channel 6 of the input enable for the round-robin checker. If CHN6 is set, then the corresponding channel to the non-fixed mux port is enabled to check its voltage value in the round-robin mode. If the same channel is selected as the reference voltage, this bit has no effect.
10 CHN5	Channel 5 input enable Channel 5 of the input enable for the round-robin checker. If CHN5 is set, then the corresponding channel to the non-fixed mux port is enabled to check its voltage value in the round-robin mode. If the same channel is selected as the reference voltage, this bit has no effect.
11 CHN4	Channel 4 input enable Channel 4 of the input enable for the round-robin checker. If CHN4 is set, then the corresponding channel to the non-fixed mux port is enabled to check its voltage value in the round-robin mode. If the same channel is selected as the reference voltage, this bit has no effect.
12 CHN3	Channel 3 input enable Channel 3 of the input enable for the round-robin checker. If CHN3 is set, then the corresponding channel to the non-fixed mux port is enabled to check its voltage value in the round-robin mode. If the same channel is selected as the reference voltage, this bit has no effect.
13 CHN2	Channel 2 input enable Channel 2 of the input enable for the round-robin checker. If CHN2 is set, then the corresponding channel to the non-fixed mux port is enabled to check its voltage value in the round-robin mode. If the same channel is selected as the reference voltage, this bit has no effect.
14 CHN1	Channel 1 input enable Channel 1 of the input enable for the round-robin checker. If CHN1 is set, then the corresponding channel to the non-fixed mux port is enabled to check its voltage value in the round-robin mode. If the same channel is selected as the reference voltage, this bit has no effect.
15 CHN0	Channel 0 input enable Channel 0 of the input enable for the round-robin checker. If CHN0 is set, then the corresponding channel to the non-fixed mux port is enabled to check its voltage value in the round-robin mode. If the same channel is selected as the reference voltage, this bit has no effect.
16 DPSEL	DAC output to Plus side ANMUX selection 0 The analog mux_out (selected from the external inputs) is selected as the comparator plus side input. 1 The DAC out is selected as the comparator plus side input.
17 DMSEL	DAC output to Minus side ANMUX selection 0 The analog mux_out (selected from the external input) is selected as the comparator minus side input. 1 The DAC out is selected as the comparator input.
18–20 PSEL	Plus Input MUX Control Determines which input is selected for the plus input of the comparator. NOTE: When an inappropriate operation selects the same input for both MUXes, the comparator automatically shuts down to prevent itself from becoming a noise generator.

Table continues on the next page...

CMP_C1 field descriptions (continued)



Field	Description
	Note: For the round robin mode of operation, the MSEL and PSEL bitfields in CMP*x*_C1 register must have different values. 000 IN0 001 IN1 010 IN2 011 IN3 100 IN4 101 IN5 110 IN6 111 IN7
21–23 MSEL	Minus Input MUX Control Determines which input is selected for the minus input of the comparator. NOTE: When an inappropriate operation selects the same input for both MUXes, the comparator automatically shuts down to prevent itself from becoming a noise generator. Note: For the round robin mode of operation, the MSEL and PSEL bitfields in CMP*x*_C1 register must have different values. 000 IN0 001 IN1 010 IN2 011 IN3 100 IN4 101 IN5 110 IN6 111 IN7
24 DACEN	DAC Enable This bit is used to enable the DAC. When the DAC is disabled, it is powered down to conserve power. 0 DAC is disabled. 1 DAC is enabled.
25 VRSEL	Supply Voltage Reference Source Select 0 Vin1 is selected as resistor ladder network supply reference Vin. 1 Vin2 is selected as resistor ladder network supply reference Vin.
26–31 VOSEL	DAC Output Voltage Select This bit selects an output voltage from one of 64 distinct levels. DACO = (Vin/64) * (VOSEL[5:0] + 1), so the DACO range is from Vin/64 to Vin.

35.8.3 CMP Control Register 2 (CMP_C2)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 8h offset = 8h

CMP_C2 field descriptions

Field	Description
0 RRE	Round-Robin Enable This bit enables the round-robin operation. 0 Round-robin operation is disabled. 1 Round-robin operation is enabled.
1 RRIE	Round-Robin interrupt enable This bit enables the interrupt/wake-up when the comparison result changes for a given channel. 0 The round-robin interrupt is disabled. 1 The round-robin interrupt is enabled when a comparison result changes from the last sample.
2 FXMP	Fixed MUX Port This bit is used to fix the analog mux port for the round-robin mode. 0 The Plus port is fixed. Only the inputs to the Minus port are swept in each round. 1 The Minus port is fixed. Only the inputs to the Plus port are swept in each round.
3 FXDACI	Fix DAC input to the fixed mux port side 0 The DAC output is not used as the reference input to the fixed mux port. 1 The DAC output is used as the reference input to the fixed mux port, regardless of the FXMXCH configuration.
4–6 FXMXCH	Fixed channel selection

Table continues on the next page...

CMP_C2 field descriptions (continued)

Field	Description
	This field indicates which channel in the mux port is fixed in a given round-robin mode. If FXDACI is set, FXMXCH has no effect. 000 Channel 0 is selected as the fixed reference input for the fixed mux port. 001 Channel 1 is selected as the fixed reference input for the fixed mux port. 010 Channel 2 is selected as the fixed reference input for the fixed mux port. 011 Channel 3 is selected as the fixed reference input for the fixed mux port. 100 Channel 4 is selected as the fixed reference input for the fixed mux port. 101 Channel 5 is selected as the fixed reference input for the fixed mux port. 110 Channel 6 is selected as the fixed reference input for the fixed mux port. 111 Channel 7 is selected as the fixed reference input for the fixed mux port.
7 Reserved	This field is reserved.
8 CH7F	Channel 7 input changed flag. This bit is set If the channel 7 input changed from the last comparison with the fixed mux port.
9 CH6F	Channel 6 input changed flag. This bit is set If the channel 6 input changed from the last comparison with the fixed mux port.
10 CH5F	Channel 5 input changed flag. This bit is set If the channel 5 input changed from the last comparison with the fixed mux port.
11 CH4F	Channel 4 input changed flag. This bit is set If the channel 4 input changed from the last comparison with the fixed mux port.
12 CH3F	Channel 3 input changed flag. This bit is set If the channel 3 input changed from the last comparison with the fixed mux port.
13 CH2F	Channel 2 input changed flag. This bit is set If the channel 2 input changed from the last comparison with the fixed mux port.
14 CH1F	Channel 1 input changed flag. This bit is set If the channel 1 input changed from the last comparison with the fixed mux port.
15 CH0F	Channel 0 input changed flag. This bit is set If the channel 0 input changed from the last comparison with the fixed mux port.
16–17 NSAM	Number of sample clocks For a given channel, this field specifies how many round-robin clock cycles later the sample takes place. 00 The comparison result is sampled in . 01 The sampling takes place 1 round-robin clock cycle after the next cycle of the round-robin clock. 10 The sampling takes place 2 round-robin clock cycles after the next cycle of the round-robin clock. 11 The sampling takes place 3 round-robin clock cycles after the next cycle of the round-robin clock.
18–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 ACOn	The result of the input comparison for channel *n* . This field stores the latest comparison result of the input channel *n* with the fixed mux port. Reading this bit returns the latest comparison result. Writing this field defines the pre-set state of channel *n*.

35.9 CMP functional description

The CMP module can be used to compare two analog input voltages applied to INP and INM. CMPO is high when the non-inverting input is greater than the inverting input, and is low when the non-inverting input is less than the inverting input. This signal can be selectively inverted by setting C0[INVT] = 1.

C0[IER] and C0[IEF] are used to select the condition that causes the CMP module to assert an interrupt to the processor. C0[CFF] is set on a falling edge, and C0[CFR] is set on a rising edge of the comparator output. The optionally filtered CMPO can be read directly through C0[COUT].

35.9.1 Initialization

A typical startup sequence is as follows.

The time required to stabilize COUT is the power-on delay of the comparators plus the largest propagation delay from a selected analog source through the analog comparator, windowing function, and filter. See the datasheet for power-on delays of the comparators. The windowing function has a maximum of one bus clock period delay. The filter delay is specified in the Low-pass filter section.

During operation, the propagation delay of the selected data paths must always be considered. It may take many bus clock cycles for COUT and C0[CFR]/C0[CFF] to reflect an input change or a configuration change to one of the components involved in the data path.

When programmed for filtering modes, COUT initially equals 0 until sufficient clock cycles have elapsed to fill all stages of the filter. This occurs even if COUTA is at a logic 1.

35.9.2 Low-pass filter

The low-pass filter operates on the unfiltered and unsynchronized and optionally inverted comparator output COUTA and generates the filtered and synchronized output COUT. Both COUTA and COUT can be configured as module outputs and are used for different purposes within the system.

Synchronization and edge detection are always used to determine status register bit values. They also apply to COUT for all sampling and windowed modes. Filtering can be performed using an internal timebase defined by FPR[FILT_PER], or using an external SAMPLE input to determine sample time.

The need for digital filtering and the amount of filtering is dependent on user requirements. Filtering can become more useful in the absence of an external hysteresis circuit. Without external hysteresis, high-frequency oscillations can be generated at COUTA when the selected INM and INP input voltages differ by less than the offset voltage of the differential comparator.

35.9.2.1 Enabling filter modes

Filter modes can be enabled by:

- Setting C0[FILTER_CNT] > 0x01 and
- Setting C0[FPR] to a nonzero value or setting C0[SE]=1

If using the divided bus clock to drive the filter, it samples COUTA every C0[FPR] bus clock cycles.

The filter output is at logic 0 when first initalized, and subsequently changes when all the consecutive C0[FILTER_CNT] samples agree that the output value has changed. In other words, C0[COUT] is 0 for some initial period, even when COUTA is at logic 1.

Setting both C0[SE] and C0[FPR] to 0 disables the filter and eliminates switching current associated with the filtering process.

Note

Always switch to this setting prior to making any changes in filter parameters. This resets the filter to a known state. Switching C0[FILTER_CNT] on the fly without this intermediate step can result in unexpected behavior.

If C0[SE]=1, the filter samples COUTA on each positive transition of the sample input. The output state of the filter changes when all the consecutive C0[FILTER_CNT] samples agree that the output value has changed.

35.9.2.2 Latency issues

The value of C0[FPR] or SAMPLE period must be set such that the sampling period is just longer than the period of the expected noise. This way a noise spike will corrupt only one sample. The value of C0[FILTER_CNT] must be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of C0[FILTER_CNT].

The values of C0[FPR] or SAMPLE period and C0[FILTER_CNT] must also be traded off against the desire for minimal latency in recognizing actual comparator output transitions. The probability of detecting an actual output change within the nominal latency is the probability of a correct sample raised to the power of C0[FILTER_CNT].

The following table summarizes maximum latency values for the various modes of operation *in the absence of noise*. Filtering latency is restarted each time an actual output transition is masked by noise.

Table 35-6. Comparator sample/filter maximum latencies

Mode #	C0[EN]	C0[WE]	C0[SE]	C0[FILTER_CNT]	Co[FPR]	Operation	Maximum latency[1]
1	0	X	X	X	X	Disabled	N/A
2A	1	0	0	0x00	X	Continuous Mode	T_{PD}
2B	1	0	0	X	0x00		
3A	1	0	1	0x01	X	Sampled, Non-Filtered mode	$T_{PD} + T_{SAMPLE} + T_{per}$
3B	1	0	0	0x01	> 0x00		$T_{PD} + (C0[FPR] * T_{per}) + T_{per}$
4A	1	0	1	> 0x01	X	Sampled, Filtered mode	$T_{PD} + (C0[FILTER_CNT] * T_{SAMPLE}) + T_{per}$
4B	1	0	0	> 0x01	> 0x00		$T_{PD} + (C0[FILTER_CNT] * C0[FPR] \times T_{per}) + T_{per}$
5A	1	1	0	0x00	X	Windowed mode	$T_{PD} + T_{per}$
5B	1	1	0	X	0x00		$T_{PD} + T_{per}$
6	1	1	0	0x01	0x01 - 0xFF	Windowed / Resampled mode	$T_{PD} + (C0[FPR] * T_{per}) + 2T_{per}$
7	1	1	0	> 0x01	0x01 - 0xFF	Windowed / Filtered mode	$T_{PD} + (C0[FILTER_CNT] * C0[FPR] \times T_{per}) + 2T_{per}$

1. T_{PD} represents the intrinsic delay of the analog component plus the polarity select logic. T_{SAMPLE} is the clock period of the external sample clock. T_{per} is the period of the bus clock.

35.10 Interrupts

The CMP module is capable of generating an interrupt on either the rising- or falling-edge of the comparator output, or both. Assuming the CMP DMA enable bit is not set, the following table gives the conditions in which the interrupt request is asserted and deasserted.

Table 35-7. CMP interrupt generations

When	Then
C0[IER] and C0[CFR] are set	The interrupt request is asserted
C0[IEF] and C0[CFF] are set	The interrupt request is asserted
C0[IER] and C0[CFR] are cleared for a rising-edge interrupt	The interrupt request is deasserted
C0[IEF] and C0[CFF] are cleared for a falling-edge interrupt	The interrupt request is deasserted

35.11 DMA support

Normally, the CMP generates a CPU interrupt if there is a change on the COUT. When DMA support is enabled by setting C0[DMAEN] and the interrupt is enabled by setting C0[IER], C0[IEF], or both, the corresponding change on COUT forces a DMA transfer request rather than a CPU interrupt instead. When the DMA has completed the transfer, it sends a transfer completing indicator signal that deasserts the DMA transfer request and clears the flag to allow a subsequent change on comparator output to occur and force another DMA request.

35.12 DAC functional description

This section provides DAC functional description.

35.12.1 Digital-to-analog converter block diagram

The following figure shows the block diagram of the DAC module. It contains a 64-tap resistor ladder network and a 64-to-1 multiplexer, which selects an output voltage from one of 64 distinct levels that outputs from DACO. It is controlled through the DAC

Control Register (DACCR). Its supply reference source can be selected from two sources V_{in1} and V_{in2}. The module can be powered down or disabled when not in use. When in Disabled mode, DACO is connected to the analog ground.

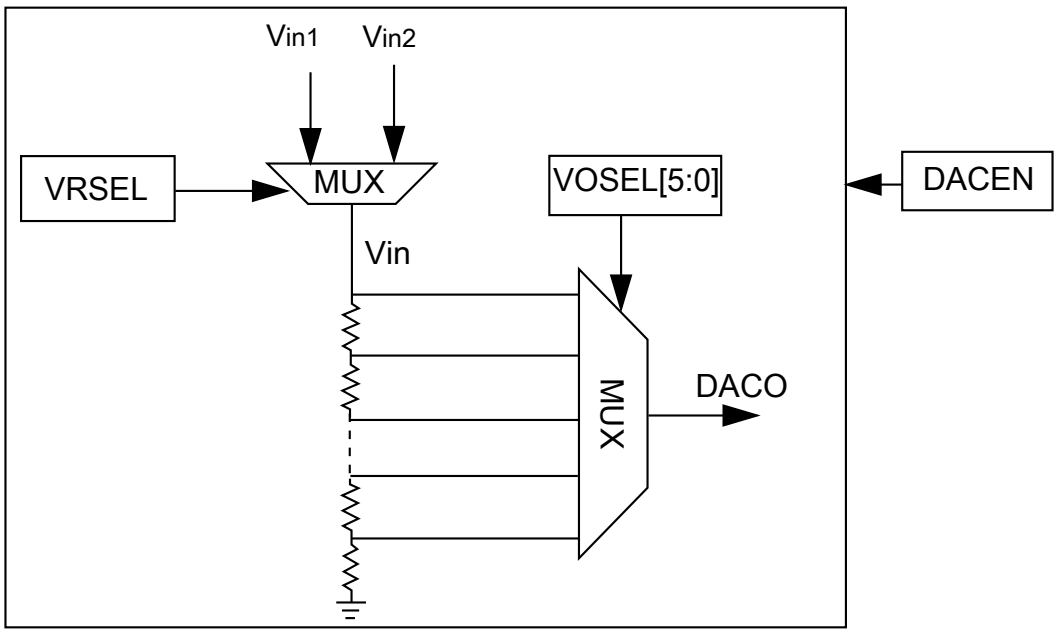


Figure 35-15. 6-bit DAC block diagram

35.12.2 Voltage reference source select

- V_{in1} must be used to connect to the primary voltage source as supply reference of 64 tap resistor ladder
- V_{in2} must be used to connect to an alternate voltage source, or primary source, if an alternate voltage source is not available

35.13 DAC resets

This module has a single reset input, corresponding to the chip-wide peripheral reset.

35.14 DAC clocks

This module has a single clock input, the bus clock.

35.15 DAC interrupts

This module has no interrupts.

35.16 Trigger mode

The CMP and the 6-bit DAC are designed to support the trigger mode operation, which is enabled when the MCU enters STOP modes with CMP_*x*_C2[RRE] set.

With this mode enabled, the trigger events that include the operation clock and a trigger start signal will initiate a compare sequence that must first enable the CMP and DAC prior to performing a CMP operation and capturing the output. A fixed channel for either the plus side mux or the minus side mux is selected by software with CMP_*x*_C2[FXMP] and CMP_*x*_C2[FXMXCH].

The active channels selected by CMP_*x*_C1[CHN*n*] are then routed to the non-fixed channel mux and compared with the reference input in a round-robin manner. In order to meet the comparator stabilization time, after the configurable number of operation clocks defined by CMP_*x*_C2[NSAM], the comparison result is sampled for the selected channel. A software pre-progammed state for each channel is configured by writing to CMP_*x*_C2[ACO*n*] field. After all the active channels are sampled, if the comparison result changes from its pre-programmed state, the corresponding flag in CMP_*x*_C2[CH*n*F] is set. If CMP_*x*_C2[RRIE] is set, an asynchronous reset is asserted to bring the MCU out of STOP mode.

Note that these flags do not support generating a DMA transfer event.

This mode is active when the MCU is in STOP mode, so none of the window/filter functions are available. A basic assumption of this mode is that the selected inputs are changing at a much slower rate than the operation clock. It is suggested to configure the comparator in low power comparison mode as well.

The following diagram shows the basic flow of this mode. In the diagram, CMP_*x*_C1[CHN1], CMP_*x*_C1[CHN3], and CMP_*x*_C1[CHN7] are set, so channels #1, #3, and #7 are selected for round robin. CMP_*x*_C2[NSAM] is set to 2'b01, so one clock later the comparison result of the selected channel is sampled. When channel #7 is compared, the result is sampled, and round robin ends. If any of the comparison results from channel #1, #3, or #7 changed from their programmed value (written to CMP_*x*_C2[ACO1], CMP_*x*_C2[ACO3], and CMP_*x*_C2[ACO7]), an interrupt is generated to wake up the MCU from the STOP mode. Software can then poll the CMP_*x*_C2[CH*n*F] to see which channel input(s) changed value during the STOP mode.

NOTE

In round robin mode, it should be ensured that the RTC_CLK period is greater than the comparison time corresponding to the value of CMPx_C0[PMODE].

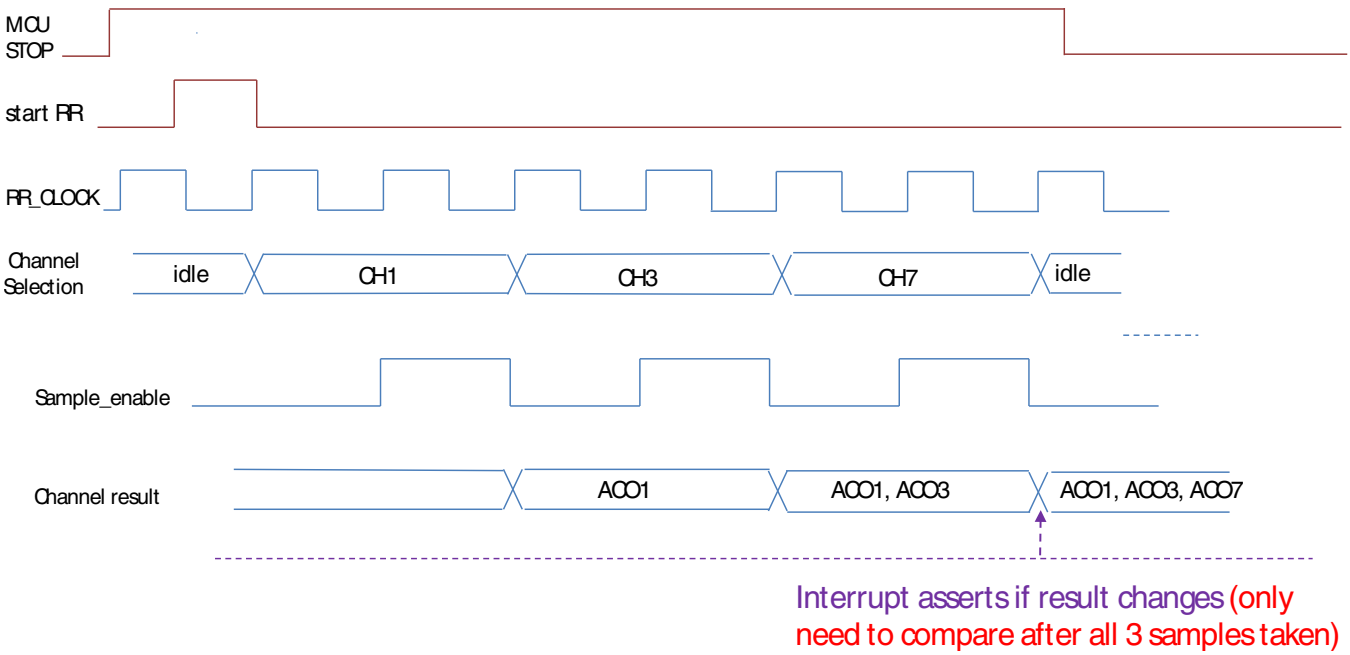

Figure 35-16. Trigger mode

Chapter 36
Body Cross triggering unit (BCTU)

36.1 Chip-specific BCTU information

36.1.1 BCTU configuration

The enhanced BCTU allows synchronization between an ADC conversion and a timer event. All channels from the 2x eMIOS modules, and 3 PIT channels can be used to trigger an ADC conversion. A single event (eMIOS channel or PIT) can trigger a group of ADC channels to be converted.

36.1.2 Trigger sources

The BCTU has input triggers from all eMIOS channels, a number of PIT channels. The BCTU can be triggered from the software also. The following table lists the BCTU trigger sources.

Table 36-1. BCTU Trigger sources

BCTU Trigger Number	Module	Source
0	eMIOS_0	Channel_0
1	eMIOS_0	Channel_1
2	eMIOS_0	Channel_2

36.1.3 BCTU's stop-stop ack protocol

The BCTU module provides the acknowledgement to the stop request:

- Immediately if there is no on-going ADC conversion requested by BCTU.
- After completion of ADC conversion, if there is any on-going ADC conversion requested by BCTU.
- The acknowledgement signal is provided as long as the request signal to the IP is asserted.

36.2 Introduction

The Body Cross-triggering Unit (BCTU) is a module that is used to trigger the on chip ADCs. The trigger sources are generated by on chip timer modules. Usually in Body domain of applications the timers used are the enhanced Modular IO Sub-system (eMIOS) and the Programmable Interrupt Timer (PIT). In addition to triggering ADC single conversions, the BCTU also implements a LIST—a set of registers programmed by software that stores ADC channel numbers—that triggers several conversions based on a single trigger occurrence. Up to 64 trigger inputs are available. The CPU can also be a source of conversion triggers, thus implementing a software trigger control. Up to 2 ADC modules are supported. The conversion results are stored in a register which is available for CPU read access. Figure below shows the BCTU top level diagram.

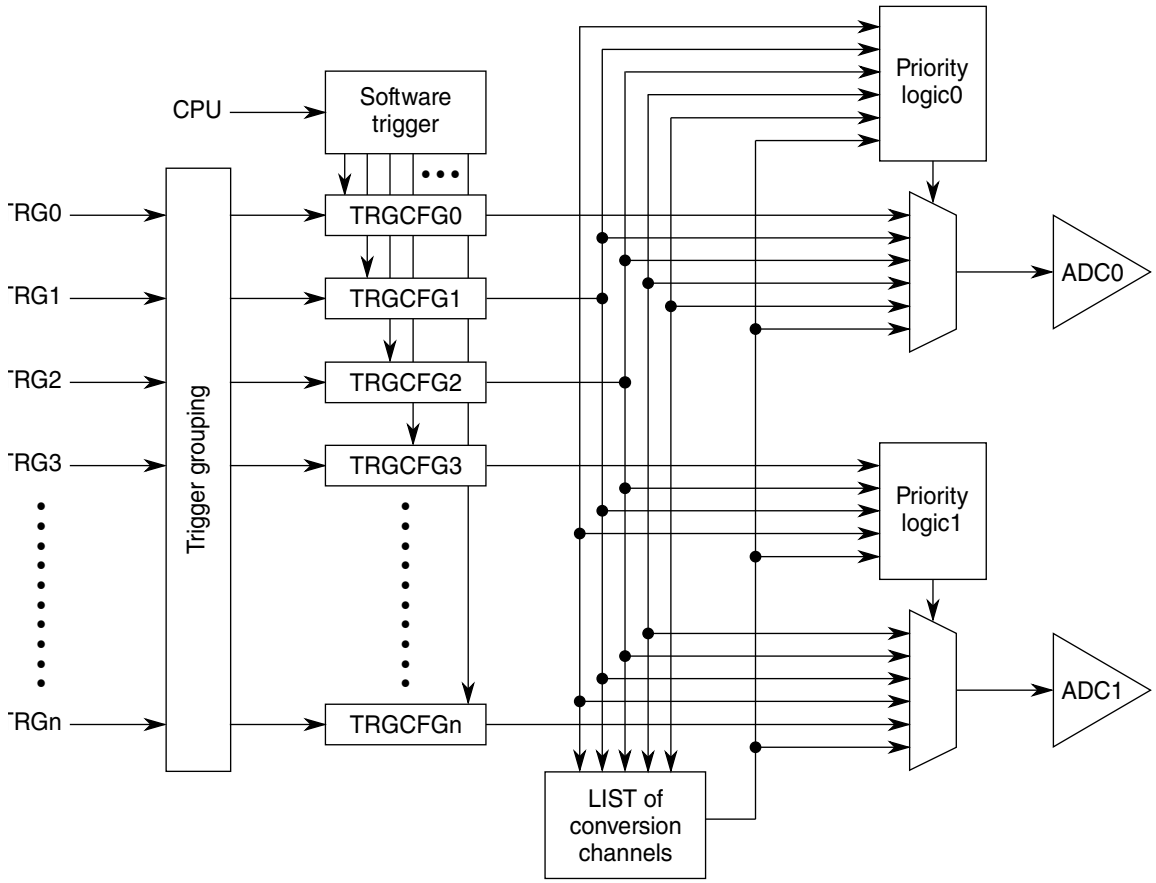

Figure 36-1. BCTU block diagram

36.3 BCTU overview

The BCTU receives several triggers from on chip timers and a software trigger controlled by the host CPU. These signals are used in order to generate the ADC trigger signals for up to 2 ADC modules. One trigger input selects one trigger configuration register. The trigger configuration register has the information about the target ADC and channel for the conversion. Alternatively a list of ADC channels can be associated with a trigger configuration register. In this case the target ADC converts a sequence of channels which are stored in the LIST.

The BCTU inputs are up to 64 trigger signals, which are level-sensitive; thus, if a logical level 1 is detected, an event is captured by the BCTU.

The figure above shows a high level BCTU block diagram. The BCTU hardware architecture consists of:

- Up to 64 conversion configuration registers TRGCFG
- One priority selection logic per ADC

- Up to 4 selection multiplexers to select one trigger at a time for each ADC
- A LIST of ADC channels

The priority logic is responsible for selecting among all active trigger inputs the one which is used to trigger an ADC conversion. The basic operation of the priority logic is to select the smallest trigger number as the higher priority. Thus if TRG[0] and TRG[1] are active TRG[0] is selected first and then TRG[1]. This priority scheme is used only if TRG[0] and TRG[1] target the same ADC. If a different ADC is selected by each trigger then there is no conflict and both triggers are selected at the same time. In addition to the trigger priority scheme the BCTU provides a LIST of channels that are used in a sequence of conversions. The LIST is a set of registers programmed by the software that stores ADC Channel numbers. The LIST also stores information of the last conversion to be executed in a sequence of conversions. A regular single conversion or a LIST of conversions are configured in the Trigger Configuration register. Since the ADC is selected by the ADC_SEL bit in the TRGCFG register for one single or a list of conversions, the LIST does not store the target ADC selection, thus all channels in the LIST refers to the ADCs specified in the TRGCFG register.

NOTE

Differently from the single command, the LIST can execute conversions on more than one ADC. Up to two ADCs can be addressed in a LIST.

36.4 BCTU Interacting with other peripherals

Figure below shows an example of how the BCTU interacts with on chip peripherals.

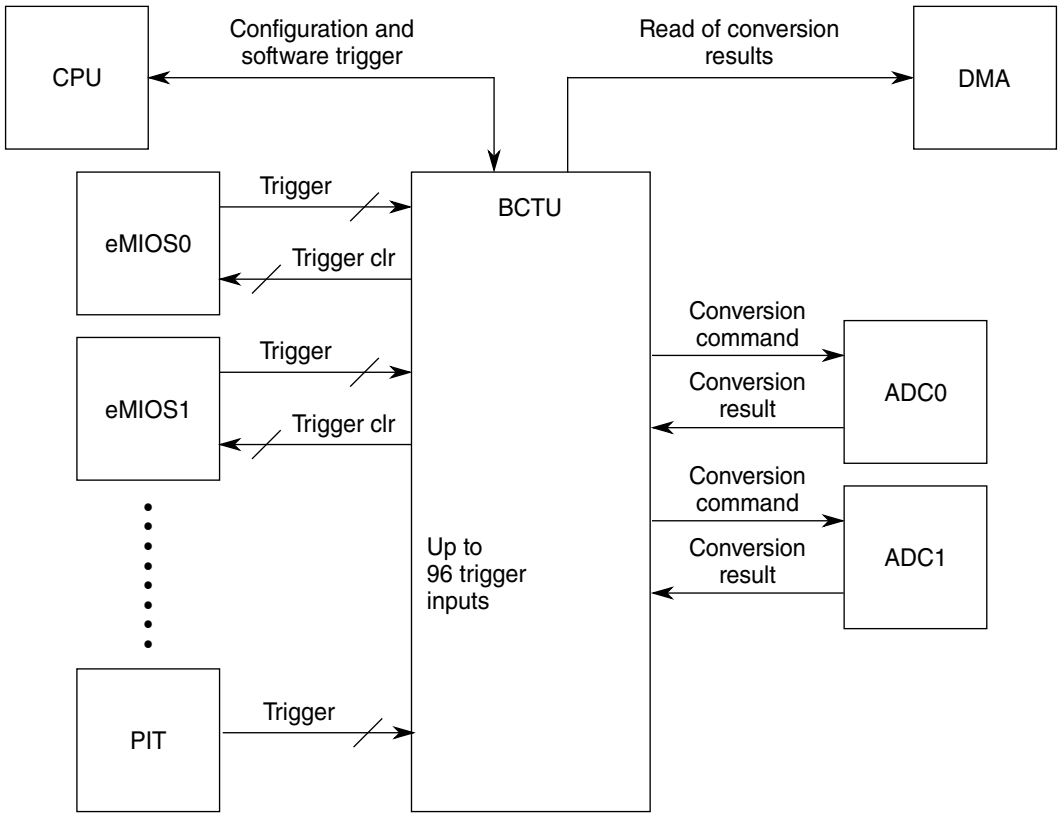

Figure 36-2. BCTU connections to other on chip modules

The timers (i.e. eMIOS and PIT) generate triggers which are asserted at a specific time when the ADC conversion should be done. The transition, from zero to one, of these signals is captured by the BCTU logic and stored until the corresponding ADC conversion starts. At this time the BCTU asserts a trigger clear signal which clears both this internal captured trigger signal and the external trigger source if they are still asserted.

NOTE

Since the timer trigger may remain active until the corresponding conversion has initiated, there could be a case where another match occurs in the timer (i.e. eMIOS or PIT). The detection of that condition is not done by the BCTU logic. It is up to the application software to evaluate such a trigger overrun.

36.5 BCTU Modes of operation

The BCTU has following modes of operation, which are described below.

- Configuration mode

- Normal mode
- Low power mode

36.5.1 Configuration Mode

In the configuration mode the BCTU does not issue triggers to the ADCs connected to it. This mode allows for the software to program the TRGCFG registers, freely, without generating any spurious trigger to the ADCs. All trigger inputs are disabled. The exit from the configuration mode is made by setting the global enable bit GTRGEN in the MCR register. This procedure allows to enable all trigger inputs, which are already individually enabled by the TRIGEN bit in the TRGCFG register, with a single software access.

NOTE

In order to reinitialize the trigger input interface registers, the application software should clear all triggers by writing 1 to the TRG_FLAG bit in all TRGCFG registers before asserting the GTRGEN bit . This procedure clears the BCTU trigger input registers as well as the trigger sources that are connected to BCTU trigger clear signals (i.e. eMIOS).

36.5.2 Normal Mode

In the normal mode of operation the BCTU generates triggers for the ADCs based on trigger inputs from the on-chip timer modules. Due to backward compatibility reasons this is the mode selected coming out of reset.

36.5.3 Low Power Mode

The low power mode is entered when the MDIS bit in the MCR register is set. In this mode the BCTU is disabled, meaning that all trigger inputs are disregarded.

No triggers are issued to the ADCs connected to it. If MDIS is set any on going conversion is finished before the low power mode is entered. The TRG and NDATAx flags are not set when the module enters in low power mode.

If there are pending active triggers, they remain active (no trigger clear signal is issued). In this case it is up for the application software to clear the pending triggers, if required.

In the low power mode, the clocks for the BCTU module may be stopped, thus allowing to reduce the dynamic power consumption of the module. The exit from low power mode is made by clearing the MDIS bit in the MCR register. The module becomes immediately active after the MDIS bit is cleared, meaning that if the GTRGEN bit is set any active trigger input is processed and the corresponding ADC is triggered in order to execute a new conversion. In low power mode the ADCDRx registers are available for software read operation.

36.6 Memory Map

BCTU registers are implemented in 32-bit. 8-bit write operations are allowed. The coherency in this case must be provided by the application software since there is no coherence mechanism built into the BCTU hardware.

NOTE

RESERVED bit registers, when available for write operations, should be written always with logic ‘0’. Read access does not return meaningful data from RESERVED bit registers.

NOTE

Registers with write protection, if protection mechanism is active and an attempt for writing to those registers is done, will not cause any change to the register content and a transfer error will be issued.

36.6.1 Module Configuration Register (BCTU_MCR)

The Module Configuration register (MCR) provides access to low power, debug, trigger control, DMA control and Interrupt control bits.

Access: User read/write

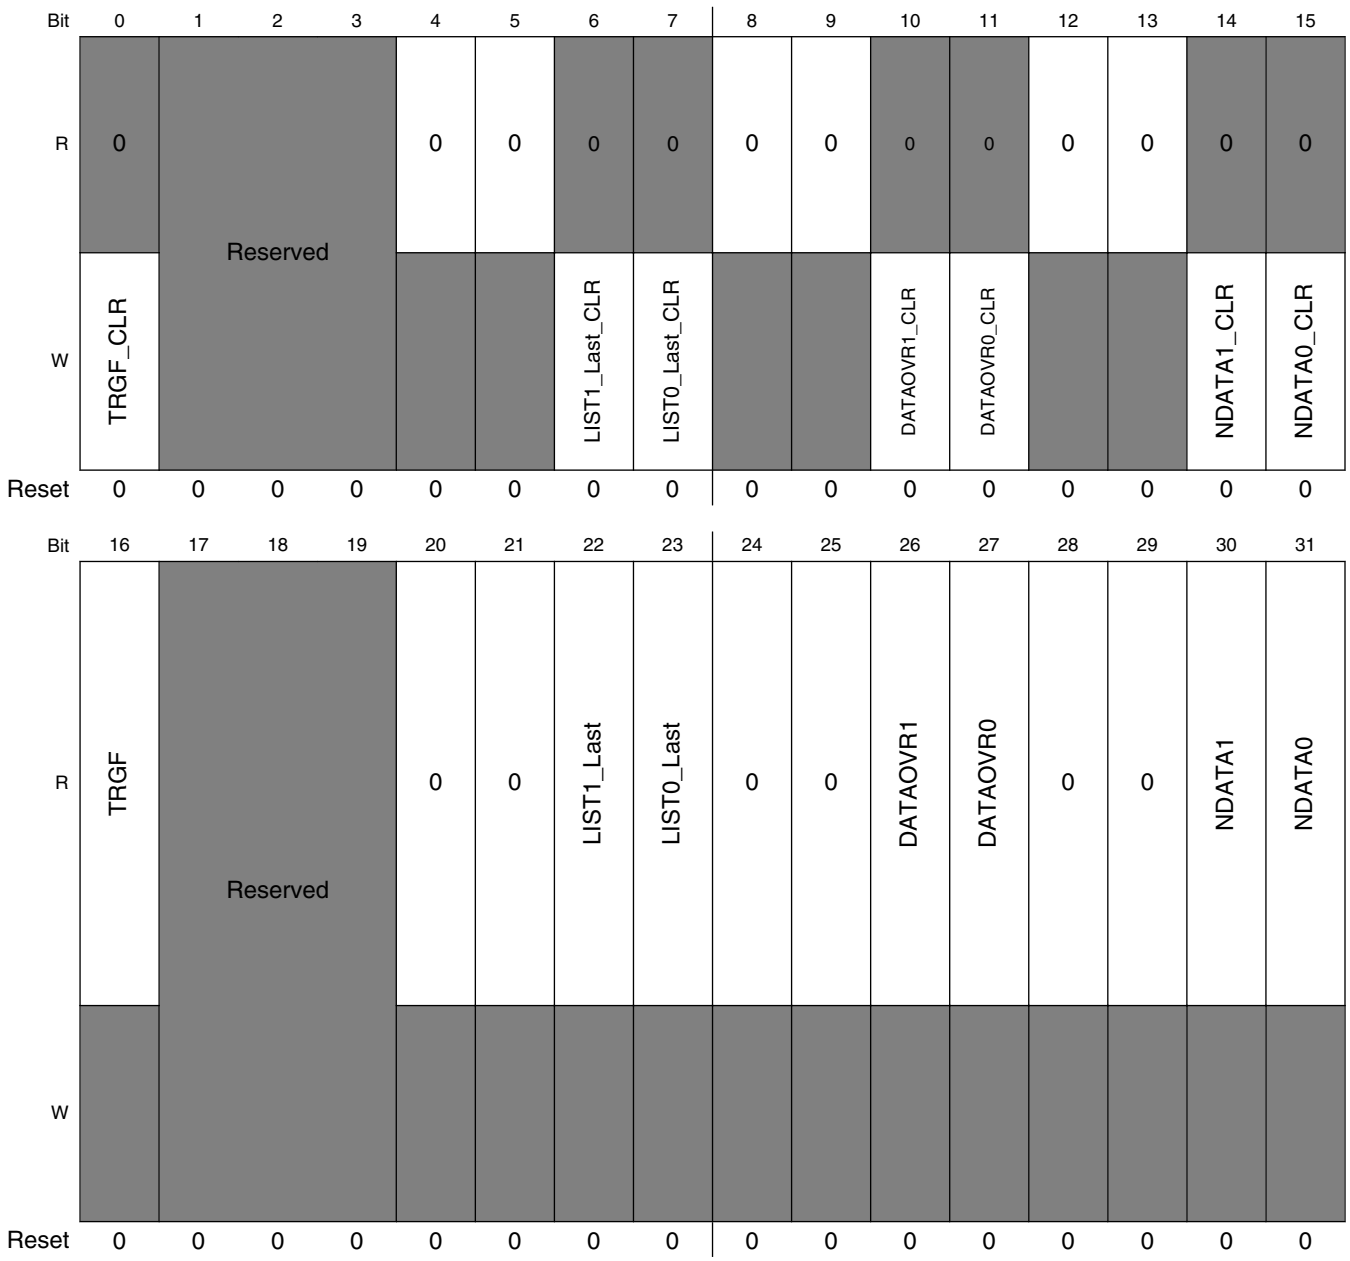
Address: 0h base + 0h offset = 0h

BCTU_MCR field descriptions

Field	Description
0 Reserved	This field is reserved.
1 MDIS	Module Disable 0 Module is in normal mode. 1 Module is in low power mode.
2 FRZ	Freeze mode - for debug operation. The freeze mode disables all trigger inputs from timers but leave the software trigger enabled, thus allowing the software to trigger a conversion and read the conversion result.
3–4 Reserved	This field is reserved.
5 GTRGEN	Global Trigger Enable. Enables all trigger inputs at the same time. The individual trigger enable must be set in order for that trigger to become active.
6–11 Reserved	This field is reserved.
12 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 DMA1	ADC1DR data transferring by DMA. Enables DMA operation on transferring ADC1DR data when there is new data available in this register. 0 Disable DMA operation. 1 Enable DMA operation.
15 DMA0	ADC0DR data transferring by DMA. Enables DMA operation on transferring ADC0DR data when there is new data available in this register. 0 Disable DMA operation. 1 Enable DMA operation.
16–23 Reserved	This field is reserved.
24 TRGEN	Trigger interrupt request enable. Enables TRGF flag set in MSR register to generate interrupt request 0 Trigger interrupt request disabled. 1 Trigger interrupt request enabled. A request is generated if the TRGF flag bit in MSR register is set.
25 Reserved	This field is reserved.
26 LIST_IEN	LIST interrupt enable. If a LIST last conversion is executed an interrupt request is issued to the CPU if LIST_IEN is set. For the interrupt to occur the LIST and LAST flags must be set.

Table continues on the next page...

BCTU_MCR field descriptions (continued)



Field	Description
	0 No interrupt request. 1 Interrupt request.
27 Reserved	This field is reserved.
28 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
29 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
30 IEN1	Interrupt enable bit for ADC1DR new data. This bit enables an interrupt request if the ADC1DR register is written by the hardware, meaning that there is new conversion data available. It also enables an interrupt request to be issued if there is an overrun in the ADC1DR register, meaning that the previous data in this register was overwritten by a new data. See also NDATA1 and DATAOVR1 in the MSR register. If DMA1 bit is set the interrupt for ADC1DR new data is disabled but the interrupt for ADC1DR data overrun remains enabled. In this case if an overrun condition occurs an interrupt request is generated. 0 Disable interrupt request. 1 Enable interrupt request.
31 IEN0	Interrupt enable bit for ADC0DR new data. This bit enables an interrupt request if the ADC0DR register is written by the hardware, meaning that there is new conversion data available. It also enables an interrupt request to be issued if there is an overrun in the ADC0DR register, meaning that the previous data in this register was overwritten by a new data. See also NDATA0 and DATAOVR0 in the MSR register. If DMA0 bit is set the interrupt for ADC0DR new data is disabled but the interrupt for ADC0DR data overrun remains enabled. In this case if an overrun condition occurs an interrupt request is generated. 0 Disable interrupt request. 1 Enable interrupt request.

36.6.2 Module Status register (BCTU_MSR)

The Status register provides software access to flags that indicate if conversion data is available for all ADCs. There are also indication of LIST status bits, such as last conversion command executed in a LIST.

Access: User read/write

Address: 0h base + 8h offset = 8h

BCTU_MSR field descriptions

Field	Description
0 TRGF_CLR	TRGF clear This bit is the clear for the TRGF flag bit 0 No action 1 Clears TRGF flag
1–3 Reserved	This field is reserved.

Table continues on the next page...

BCTU_MSR field descriptions (continued)

Field	Description
4 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
5 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
6 LIST1_Last_CLR	Clears LIST_Last flag for ADC1 0 no action 1 clears LIST1_Last flag
7 LIST0_Last_CLR	Clears LIST_Last flag for ADC0 0 no action 1 Clears LIST0_Last flag
8 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
9 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
10 DATAOVR1_ CLR	Clears DATAOVR1 flag 0 no action 1 Clears DATAOVR1 flag
11 DATAOVR0_ CLR	Clears DATAOVR0 flag 0 no action 1 Clears DATAOVR0 flag
12 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
13 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
14 NDATA1_CLR	Clears NDATA1 flag 0 no action 1 Clears NDATA1 flag
15 NDATA0_CLR	Clears NDATA0 flag 0 no action 1 Clears NDATA0 flag
16 TRGF	Trigger Flag

Table continues on the next page...

BCTU_MSR field descriptions (continued)

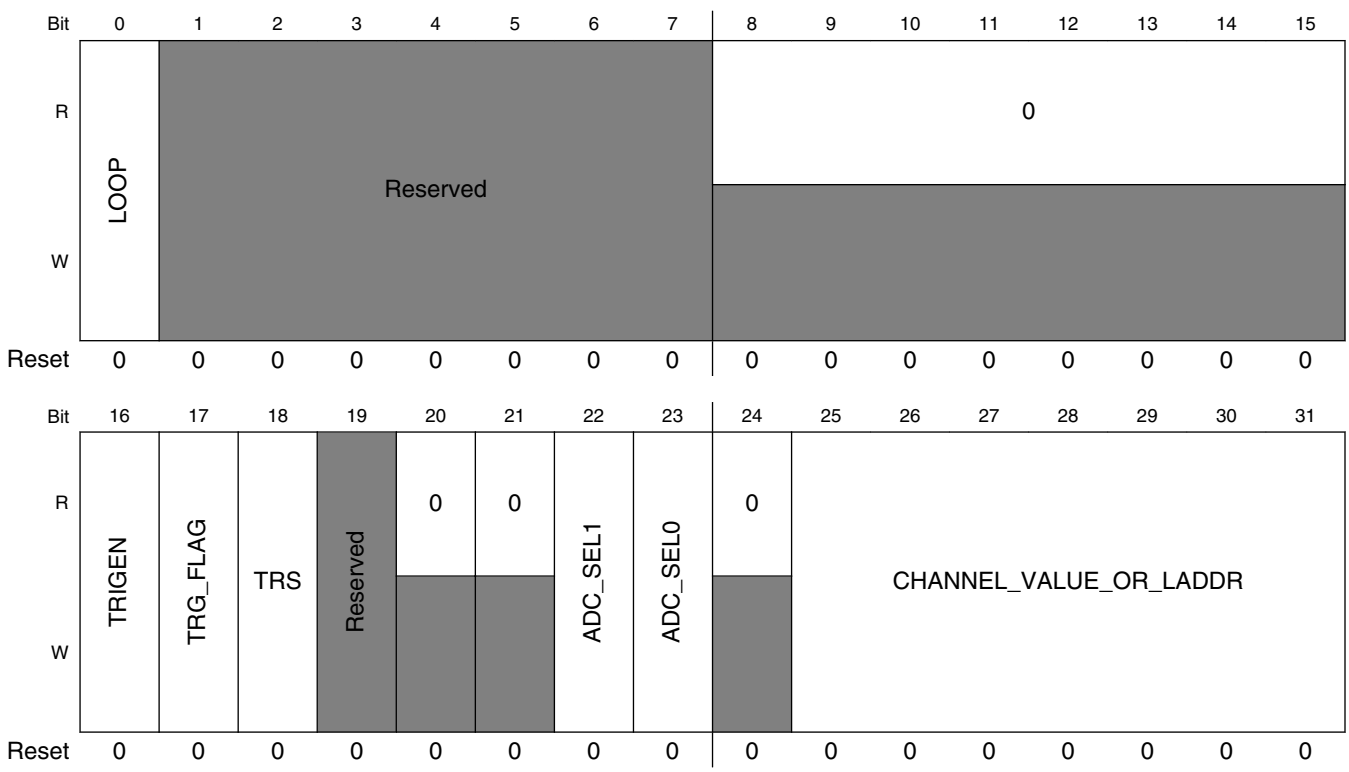
Field	Description
	Indicates that at least one ADC was triggered. 0 ADC was not triggered 1 An ADC was triggered
17–19 Reserved	This field is reserved.
20 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
21 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
22 LIST1_Last	Execution of the last conversion in a LIST of conversions for ADC1 0 not the last conversion 1 last conversion in a LIST
23 LIST0_Last	Execution of the last conversion in a LIST of conversions for ADC0 0 not the last conversion 1 last conversion in a LIST
24 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
25 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
26 DATAOVR1	Data overrun for ADC1. Old data in the ADCDR1 register was overwritten 0 data not overwritten 1 data overwritten
27 DATAOVR0	Data overrun for ADC0. Old data in the ADCDR0 register was overwritten 0 data not overwritten 1 data overwritten
28 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
29 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
30 NDATA1	New conversion data is available for ADC1 0 no new data available 1 new data available

Table continues on the next page...

BCTU_MSR field descriptions (continued)

Field	Description
31 NDATA0	New conversion data is available for ADC0 0 no new data available 1 new data available

36.6.3 Trigger Configuration Register (BCTU_TRGCFG_*n*)



The Trigger Configuration register is a set of registers, one register per input trigger. This register controls the target ADC and ADC channel to be used in a conversion. It also controls if a LIST is used instead of a single ADC conversion command.

NOTE

x varies from 0 up to the number of input triggers.

Access: User read/write

Address: 0h base + 18h offset + (4d × i), where i=0d to 63d

BCTU_TRGCFG_*n* field descriptions

Field	Description
0 LOOP	LOOP bit

Table continues on the next page...

BCTU_TRGCFG_*n* field descriptions (continued)

Field	Description
	The LOOP bit , defined if the current trigger should execute a loop, meaning that the conversion triggered by the input trigger is executed again until the LOOP bit is cleared. Each time the new conversion is triggered it should win the priority evaluation among all pending triggers. It is only executed if it is the highest priority triggered conversion at the moment the conversion starts.
1–7 Reserved	This field is reserved.
8–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16 TRIGEN	Trigger enable Enable/disable triggers from the input trigger (hardware) to initiate an ADC conversion. This bit does not disable software triggers. 0 disable hardware triggers 1 enable hardware triggers
17 TRG_FLAG	Clear timer flag through software 0 When written, indicates no action. When read, indicates that there is no ongoing ADC conversion initiated by this trigger. 1 When written, clears timer flag through software. Which means that any previous input trigger event is cleared, preventing a new ADC conversion to be initiated by this trigger source. When read, indicates that there is an ongoing ADC conversion initiated by this trigger.
18 TRS	Trigger resolution Selects single conversion or LIST of conversions 0 single conversion 1 List of conversions
19 Reserved	This field is reserved.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 ADC_SEL1	Selects ADC 0 for conversion 0 does not selected ADC1 1 selects ADC1
23 ADC_SEL0	Selects ADC 0 for conversion 0 does not selected ADC0 1 selects ADC0
24 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

BCTU_TRGCFG_*n* field descriptions (continued)

Field	Description
25–31 CHANNEL_ VALUE_OR_ LADDR	Channel Value or List Address Value. If TRS = 0. this field is the ADC Channel selected for the conversion. If TRS = 1, this field represents the address of the first LIST position to be executed.

36.6.4 Write Protection register (BCTU_WRPROT)

Coming out from reset state the protection is enabled. In order to allow writes to protected registers it is necessary to write a special code in a 4-bit field. There are two possible codes that allow writes thus removing the protection. One 4-bit code that permanently disables the protection mechanism and another code that disables the protection during one write cycle to a protected register. After that the state of the protection code returns to its initial (protected) state.

Access: User read/write

Address: 0h base + 228h offset = 228h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved																												PROTEC_ CODE			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

BCTU_WRPROT field descriptions

Field	Description
0–27 Reserved	This field is reserved.
28–31 PROTEC_CODE	The Protection code sets protection for the write protected registers There are two codes which disables the protection for the write protected registers. One code disables the write protection permanently and another code disables the protection for one write access only. **NOTE:** This field is writable only if the MCR[MDIS] bit is 0. 1010 This code defines that the protected registers are not in the protected mode, thus writes are enabled. 1001 Protection temporarily deactivated. This code disables the protection for writes on the protected registers for one write cycle operation. After that the protection code is reset to the initial state "0000" thus restoring the protection for the protected registers. Protection is active for other values

36.6.5 Software Trigger register 1 (BCTU_SFTRGR1)

The Software Trigger register allows the software to trigger any of the conversions associated with the Trigger Configuration registers. In order to avoid ambiguity in the conversion results regarding the source of trigger (if from hardware or from the software) the trigger enable (TRIGEN) bit in the Trigger Configuration register should be cleared when the software trigger is used thus the trigger for that configuration register is only issued by the SFTRGR register. This register is write protected by the WRPROT register. If protection is enabled writes to this register do not modify the register content and generates a transfer error.

All bits in this register are set by the software and cleared by the hardware.

Access: User read/write; this register is write protected by the BCTU_WRPROT register.

Address: 0h base + 22Ch offset = 22Ch

36.6.6 Software Trigger register 2 (BCTU_SFTRGR2)

The Software Trigger register allows the software to trigger any of the conversions associated with the Trigger Configuration registers. In order to avoid ambiguity in the conversion results regarding the source of trigger (if from hardware or from the software) the trigger enable (TRIGEN) bit in the Trigger Configuration register should be cleared when the software trigger is used thus the trigger for that configuration register is only issued by the SFTRGR register. This register is write protected by the WRPROT register. If protection is enabled writes to this register do not modify the register content and generates a transfer error.

All bits in this register are set by the software and cleared by the hardware.

Access: User read/write; this register is write protected by the BCTU_WRPROT register.

Address: 0h base + 230h offset = 230h

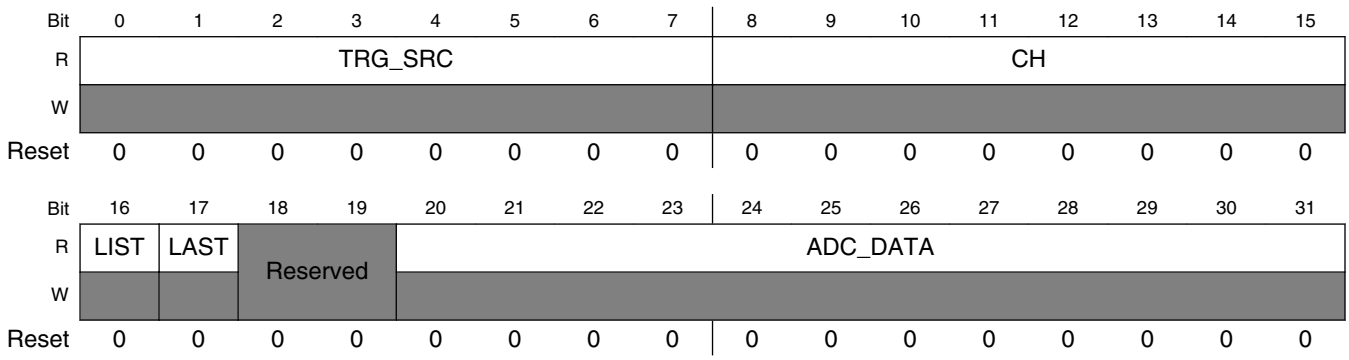
36.6.7 ADC0 Result Data register (BCTU_ADC0DR)

The ADC Result Data register allows software access to ADC conversion result data. It also indicates the ADC channel used in that conversion, the trigger source that initiated that conversion and LIST status indication in case the conversion was initiated from a LIST.

Access: User read

Address: 0h base + 23Ch offset = 23Ch

BCTU_ADC0DR field descriptions



Field	Description
0–7 TRG_SRC	Trigger number used to triggered the conversion
8–15 CH	ADC Channel used for the conversion
16 LIST	Indicates if the conversion was initiated by a LIST element or single conversion trigger 0: single conversion 0 single conversion 1 LIST
17 LAST	In case the conversion was done through a LIST, if set to 1, this bit indicates that the conversion result is the last conversion in the LIST. If the conversion was not controlled by a LIST this bit is always zero. 0 The conversion result is not the last coversion in a LIST 1 The conversion result is the last conversion in a LIST
18–19 Reserved	This field is reserved.
20–31 ADC_DATA	DATA from ADC conversion

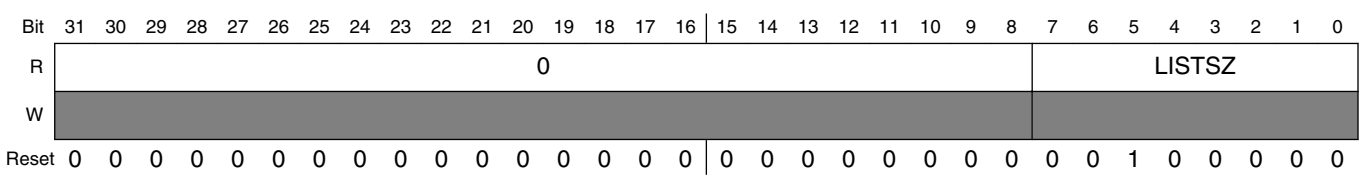
36.6.8 ADC1 result data register (BCTU_ADC1DR)

The ADC Result Data register allows software access to ADC conversion result data. It also indicates the ADC channel used in that conversion, the trigger source that initiated that conversion and LIST status indication in case the conversion was initiated from a LIST.

Access: User read

Address: 0h base + 240h offset = 240h

BCTU_ADC1DR field descriptions



Field	Description
0–7 TRG_SRC	Trigger number used to triggered the conversion
8–15 CH	ADC Channel used for the conversion
16 LIST	Indicates if the conversion was initiated by a LIST element or single conversion trigger 0 single conversion 1 LIST
17 LAST	In case the conversion was done through a LIST, if set to 1, this bit indicates that the conversion result is the last conversion in the LIST. If the conversion was not controlled by a LIST this bit is always zero. 0 The conversion result is not the last coversion in a LIST 1 The conversion result is the last conversion in a LIST
18–19 Reserved	This field is reserved.
20–31 ADC_DATA	DATA from ADC conversion

36.6.9 LIST Size Status register (BCTU_LISTSTAR)

Each element has the channel number used in one conversion.

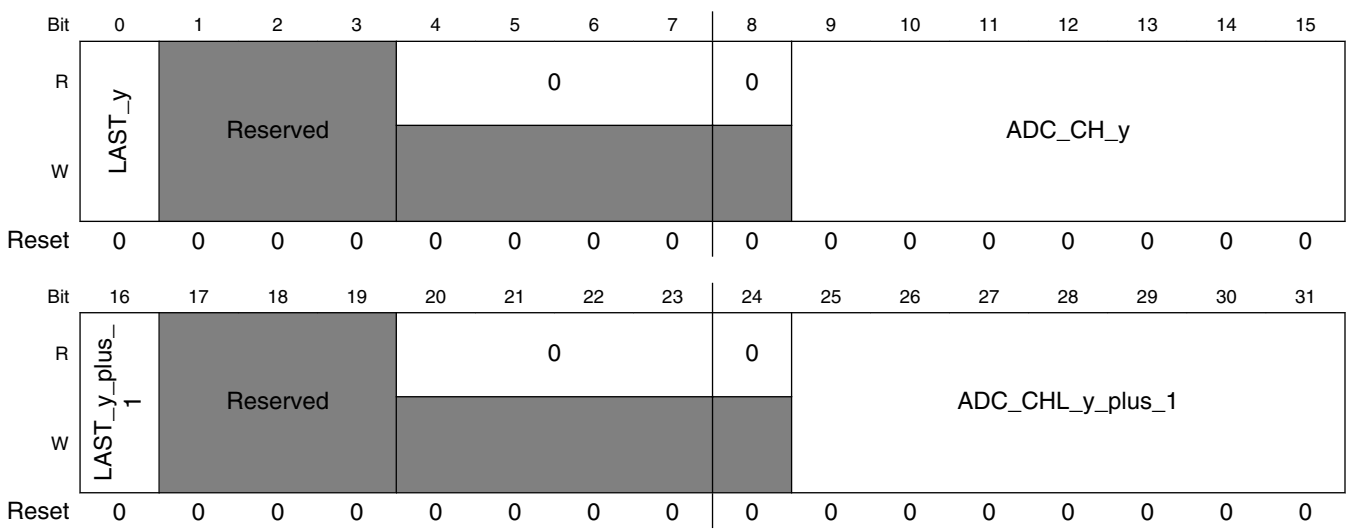
Access: User read

Address: 0h base + 24Ch offset = 24Ch

BCTU_LISTSTAR field descriptions

Field	Description
31–8 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
LISTSZ	Size of the LIST in number of elements. This field reflects the value of a hardware parameter.

36.6.10 LIST Channel Address Register (BCTU_LISTCHR_*n*)



The LIST channel address register corresponds to two LIST elements which stores the ADC channel number to be used in a conversion as well as the indication if that element corresponds to the last element of a LIST of conversion commands.

NOTE

y varies from 0 to 31.

Access: User read/write

Address: 0h base + 250h offset + (4d × i), where i=0d to 15d

BCTU_LISTCHR_*n* field descriptions

Field	Description
0 LAST_y	Last channel in the list of channels. 0 It is not the last channel in the list 1 This is the last channel in the List
1–3 Reserved	This field is reserved.

Table continues on the next page...

BCTU_LISTCHR_*n* field descriptions (continued)

Field	Description
4–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
9–15 ADC_CH_y	ADC channel selection. y indicates the position (address) of the ADC channel in the LIST of channels.
16 LAST_y_plus_1	Second to last channel in the list of channels.
17–19 Reserved	This field is reserved.
20–23 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
24 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
25–31 ADC_CHL_y_ plus_1	ADC channel selection. y indicates the position (address) of the ADC channel in the LIST of channels.

36.7 Functional description

The following sections describes the BCTU functionality.

36.7.1 Trigger Configuration

The triggers from on-chip timers and software are configured in the TRGCFG (Trigger Configuration Register). Each trigger can be individually enabled by the TRIGEN bit in the TRGCFG_n registers. The target ADC and channel are also defined in this register. The TRS (Trigger Resolution bit) sets if either a single conversion is executed for the corresponding trigger or if the LIST of conversions should be executed. In the case of a LIST the channel/LADDR field is used as a pointer for the LIST element. If the LIST is used, multiple conversions are executed due to the corresponding trigger assertion.

A protocol is implemented such that when an input trigger is selected to issue an ADC conversion, the BCTU clears the corresponding trigger source when the ADC conversion is initiated.

NOTE

If a LIST is triggered the corresponding trigger will be cleared when the last conversion in the LIST is started.

The software trigger is controlled by the SFTRGR (Software Trigger Registers). By writing to a bit in those registers, an ADC conversion is triggered similar to a conversion initiated by an input trigger. A software triggered conversion does not require to be enabled by the TRIGEN bit in the TRGCFG register. Thus if any bit in the SFTRGR register is set, the corresponding conversion is triggered independent of the TRIGEN bit state. This functionality is useful such that it avoids conflict between software and hardware triggers.

NOTE

The software triggered conversion is enabled by the GTRGEN bit in the MCR register meaning that this bit needs to be set in order to allow a software conversion. This enable bit does not prevent the SFTRGR bits to be set, it just disables the conversion start. As soon as the GTRGEN bit is set the software conversions already triggered are initiated following the predefined priority scheme, i.e. from the lowest to the highest SFTRG bit number.

36.7.2 Trigger priority and multiplexing

The ADC triggers are prioritized based on the trigger number. The lower the trigger input number the higher is the priority associated with it. Thus TRG[0] is the highest priority trigger and TRG[95], in case 96 triggers are used, is the lowest priority. The trigger input priority scheme applies when the triggers occur at the same time or when the ADC is busy in a conversion. Thus there are two possible scenarios for the trigger priority selection: when there are no on-going conversions and when the ADC is executing a conversion.

The figure below describes the BCTU input triggers related to the ADC trigger signal generation. There is four clock cycles from the input trigger to the ADC trigger. This figure also shows the CLR[n] (clear) signal generated by the BCTU which clears the input trigger signal.

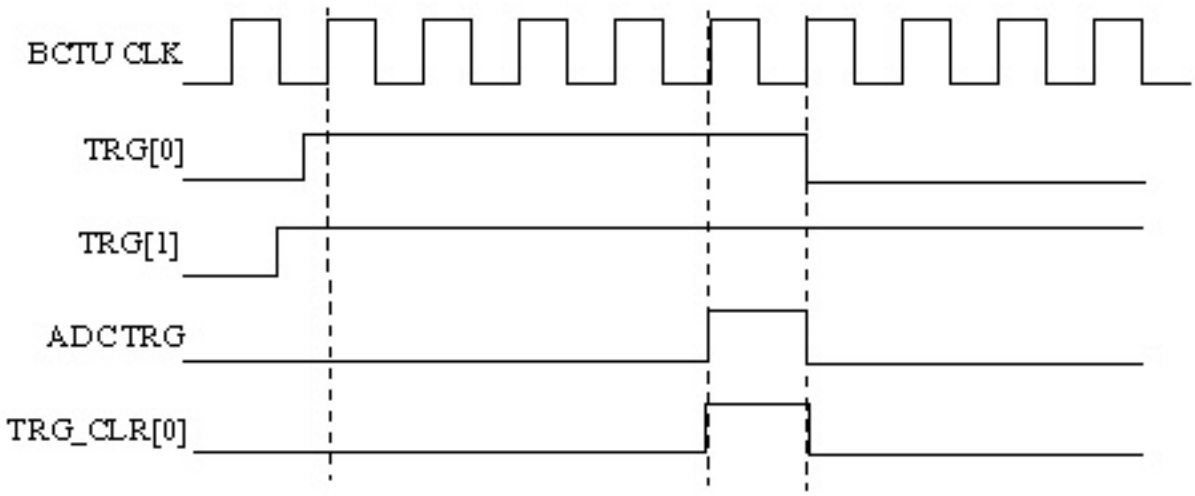


Figure 36-3. Input trigger to ADC trigger timing

The figure below describes the priority logic behavior in case TRG[0] and TRG[1] occur at the same time. Since TRG[0] has higher priority then it is selected for the ADC trigger generation. TRG[1] remains active (pending) until the conversion related to TRG[0] is executed. Note that if TRG[0] signal is asserted again, before the next trigger selection opportunity at the end of the current conversion, then it is selected one more time and TRG[1] remains asserted (pending) for more one ADC conversion time frame.

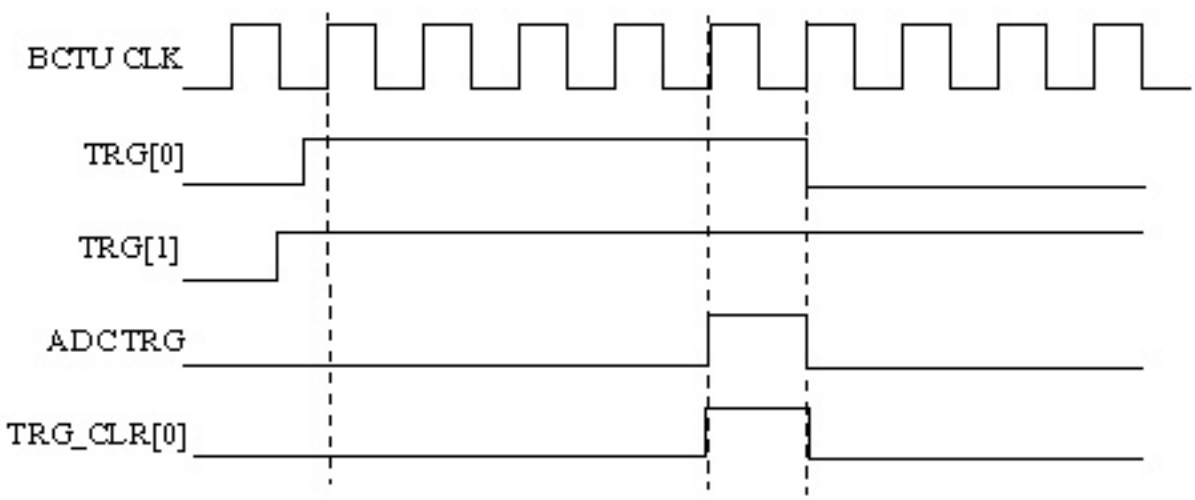

Figure 36-4. TRG[0] and TRG[1] priority example

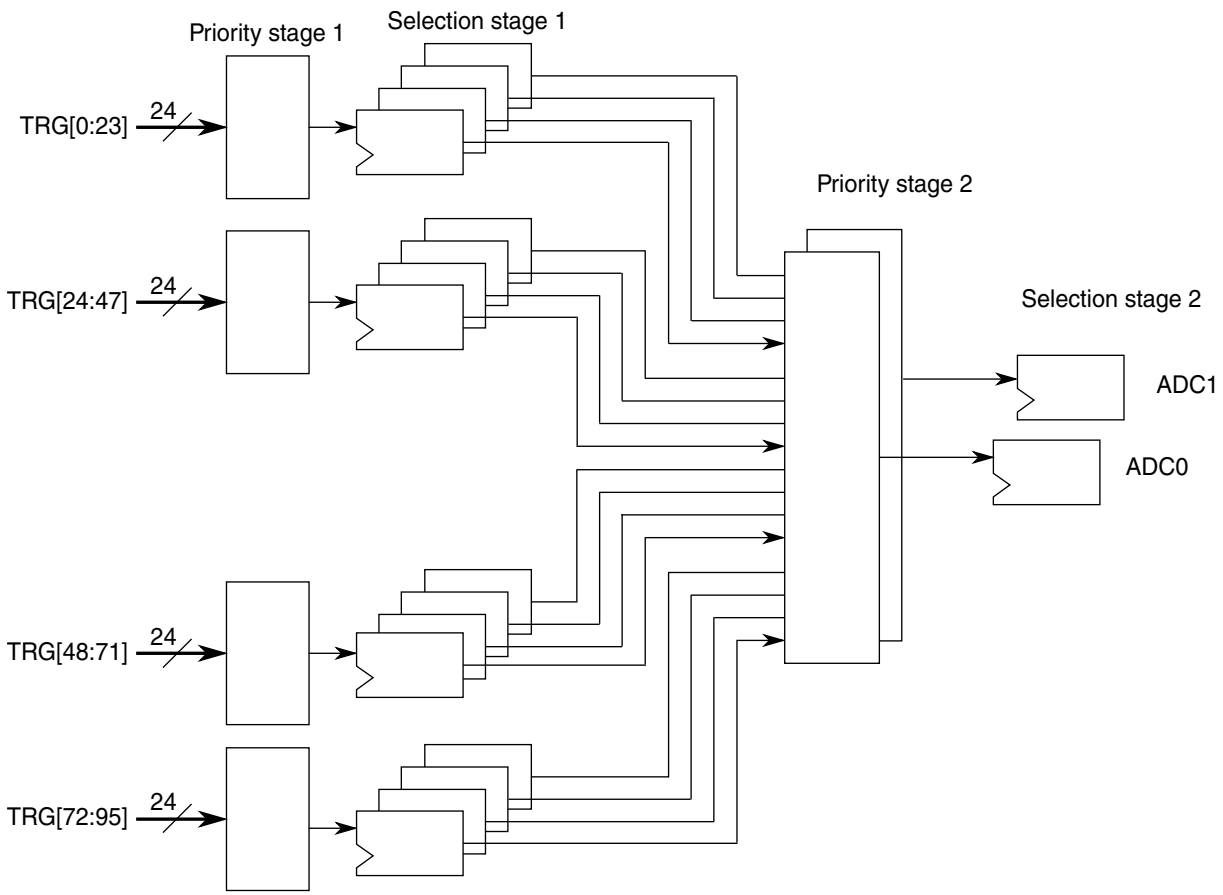
The figure below describes the pipeline and logic (combinational logic) stages architecture, which resolves the priority among trigger inputs into two pipeline stages. The sel logic 1 and 2,combinational logic, are responsible for selecting the priority among all 96 inputs. The pipeline stage 3 stores this result and connects to a pulse generator stage which generates the trigger for the ADCs. Another stage isolates any

combinational logic in the BCTU to the external modules, thus allowing a clean clock domain crossing to connected to the ADC clock domain. In this architecture the timing from input trigger to the ADC trigger is 4 BCTU clock cycles.

NOTE

Back to back conversions are executed with 3 BCTU clock delay since the trigger selection is done during the current conversion thus the next trigger is ready when the conversion ends. The 4 clock delays occurs only when there are no conversions being executed by the ADC and new trigger occurs at the BCTU input.



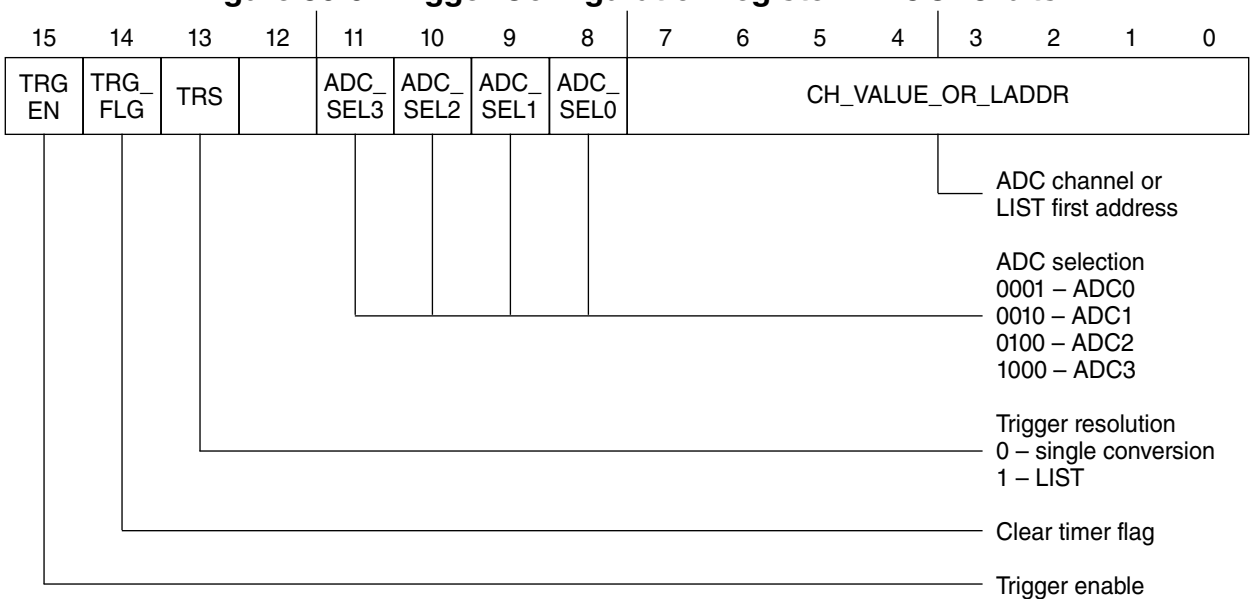


Figure 36-5. Priority stages architecture

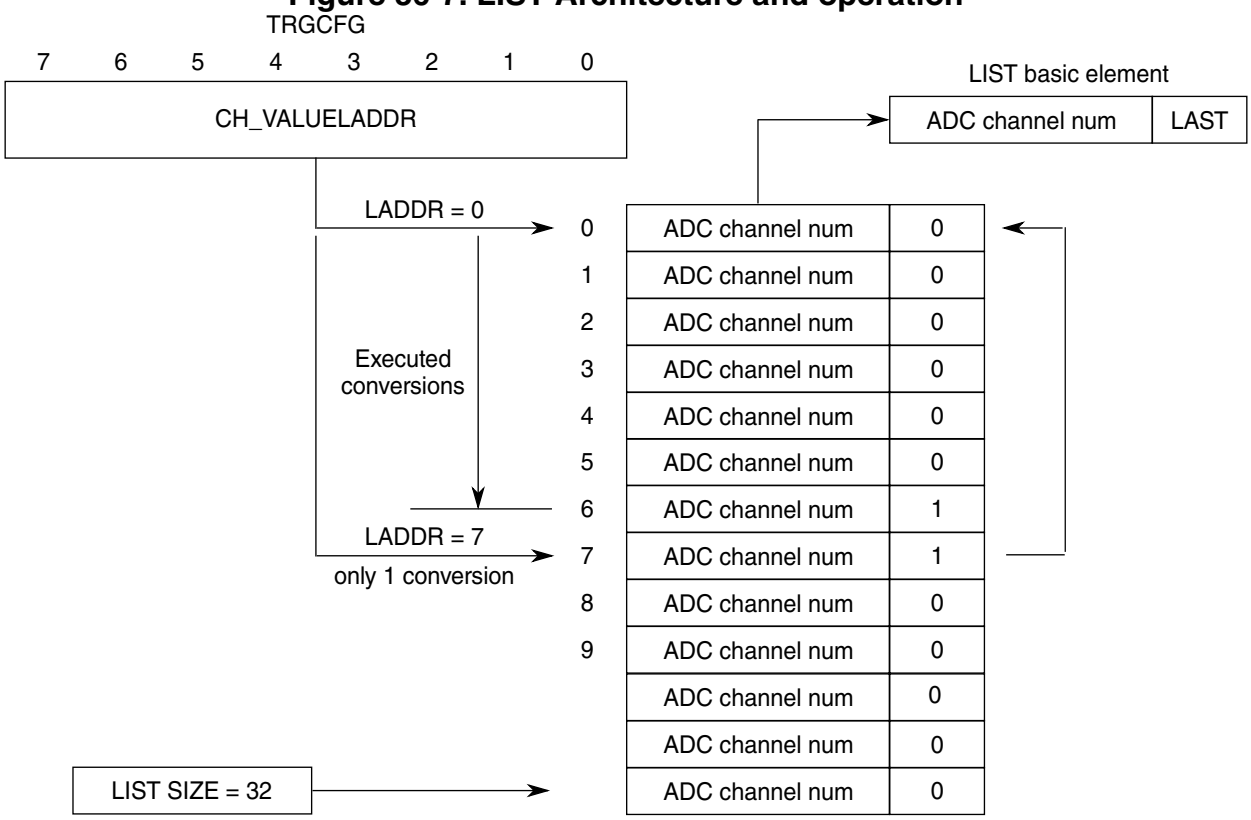
36.7.3 Conversion LIST

The figure below describes the bits of the Trigger Configuration register (TRGCFG). The TRS bit selects between a single conversion and a list of conversions. In case a list of conversions is selected the CH_VALUE/LADDR field is used as the list pointer. The TRG_EN and CLR_FLAG bits have similar functionality regardless of single or list of conversion.

Figure 36-6. Trigger Configuration register -TRGCFG bits



NOTE

ADC_SEL bits are one hot encoded, meaning that more than one ADC can be selected for a conversion. The multiple ADC selection is only valid for multiple parallel conversions LIST functionality. If more than one ADC is selected for a single conversion, instead of for a LIST, no conversion will be triggered by this register.

The figure below describes the LIST of channels architecture and operation. If the LADDR field in the TRGCFG register points to a LIST element then a sequence of conversions is initiated. The sequence of conversions are executed until the LAST field is set. The channel with the LAST field set is the last channel to be converted in a sequence of conversions.

Figure 36-7. LIST Architecture and operation

If LADDR points to a LIST element with the LAST field set, only one conversion is executed. In this case the LIST behaves such as a single conversion.

The LIST of channels has the following rules:

- A sequence of conversions is executed until the LAST field is evaluated as 1
- Conversions are executed in a sequence, thus other conversions for the same ADC are not allowed in parallel (the LIST is atomic)
- Two or more triggers for different ADCs may point to the LIST. In this case both LISTs are executed in parallel for the selected ADCs
- LADDR should point to a valid list address < LIST SIZE, otherwise address 0 is used
- After LIST SIZE -1 address is executed the list pointer wraps to address 0

36.7.4 ADC conversion results access

The access to ADC results can be done by the software using the flags and interrupt request or by the DMA interface. The interrupt request is based on the Status Register (MSR) flags. The results are available in the ADCxDR registers, one for each ADC. This register also indicates the channel used in the conversion and the trigger input that initiated that conversion. In order to give support for conversions from a LIST, two bits are available in the ADCxDR register, the LIST and LAST bits. The LIST bit indicates that the conversion was generated by a LIST element. The LAST bit indicates that the data is the last conversion of a LIST.

The software access to converted data can be based on interrupt request. An interrupt request is generated if the IENx bit in the MCR register is set and the corresponding DMAx bit is not set. In this case on each available conversion data in the ADCxDR register an interrupt request is asserted. The software can then check which is the source of the interrupt by reading the MSR register. Note that more then one conversion data may be available at the same time, since the conversions on different ADCs are executed in parallel. The NDATAx bit in the MSR register indicates which ADCxDR has a new conversion data available. The NDATAx flag can be cleared by using the NDATAx_CLR bit in the MSR register.

If DMA operation is selected by the DMA bit in the MCR register, a new data in the ADCxDR registers generates a DMA request. The NDATAx flag is also asserted in this case. A DMA DONE signal from the DMA controller de-asserts the DMA request and clears the NDATAx bit.

In order to allow DMA operation for all ADCxDR registers it is required one DMA channel per ADC, thus two DMA channels if two ADCs are used.

In case a new ADC conversion data is available before the old data had been read from the ADCxDR register then the DATAOVRx flag, new data overrun flag, is set indicating that the previous data in the ADCxDR register was overwritten by a new conversion result. The DATAOVRx flag also sets an interrupt request which is also enabled by the IENx bit. This interrupt request is asserted independently of the DMA bit settings. The DATAOVRx flag can only be cleared by the software writing 1 to the DATAOVRx_CLR bit.

36.7.5 Trigger clearing mechanism

There are two sources of ADC conversion triggers: hardware trigger, from the trigger inputs and software triggers, from SFTRGR register

A logical level 1 is detected in the input and captured into an input trigger register. This register remains set until the related conversion starts. At this time, the input trigger register is cleared. If another logical level 1 is detected while the trigger register is already set, the new level is not considered by the BCTU hardware. If a new logical level 1 occurs at the same time the trigger register is being cleared, then the register remains set and a new conversion is triggered by this input.

NOTE

The new triggered conversion will participate in the trigger priority selection thus may not trigger the next conversion.

The software trigger behaves similarly to the hardware trigger. The difference is that the trigger register is set by a CPU write operation. The trigger register is cleared by the BCTU hardware when the related conversion starts. If the CPU tries to set the trigger register by writing to the SFTRGR register corresponding bit, while the register is already set, the new attempt to set the register is not considered by the BCTU hardware. If a set occurs at the same time the hardware is attempting to clear the same trigger register, then the set has precedence and the register remains set. A new conversion will be triggered following the trigger priority criteria implemented in the hardware.

In case a LIST of conversions is triggered, instead of a single conversion, the trigger register is cleared at the start of the last conversion in the LIST.

36.7.6 On-the-fly reconfiguration of BCTU registers

The support for on-the-fly reconfiguration of triggers, specially for the Trigger Configuration register is done by the TRG_FLAG. If this bit field is read as 1, then the related trigger had started a conversion which is still ongoing. Therefore it is not safe to change the register bits.

The process of changing the Trigger Configuration register should start by clearing the TRIGEN bit. This will disable any new conversion be started by the corresponding trigger. After that the value of the TRG_FLAG bit should be evaluated. If this bit is set then it indicates that the current ongoing conversion or LIST execution was started by the trigger controlled by this register. The software should then read the TRGCFG register until the TRG_FLAG bit is cleared, which indicates that the on-going conversion had finished. After that the register can be modified safely. No conversions occur while the TRIGEN bit is cleared. In order to make sure that any trigger that occurred before the TRGCFG reconfiguration starts a new conversion, the application software should write 1 to the TRG_FLAG bit, thus clearing the trigger sources. Only triggers that occurred after this write operation was done are able to start a new conversion.

36.7.7 Multiple Parallel Conversions

The Multiple Parallel Conversions functionality is implemented using the LIST of channels. In order to execute this function more than one ADC should be selected in the TRGCFG register and the TRS bit must be set. In this case the TRGCFG CH_VALUE/ LADDR field points to an element in the LIST. The channels in the LIST are interpreted as referring to the ADCs selected in the TRGCFG register. The figure below describes the parallel conversion execution. Note that the channel numbers in the LIST are interpreted in pairs since two ADCs are selected, ADC0 and ADC1. If three ADC are selected, the LIST is interpreted in groups of three elements, being the order from ADC0 through ADC2.

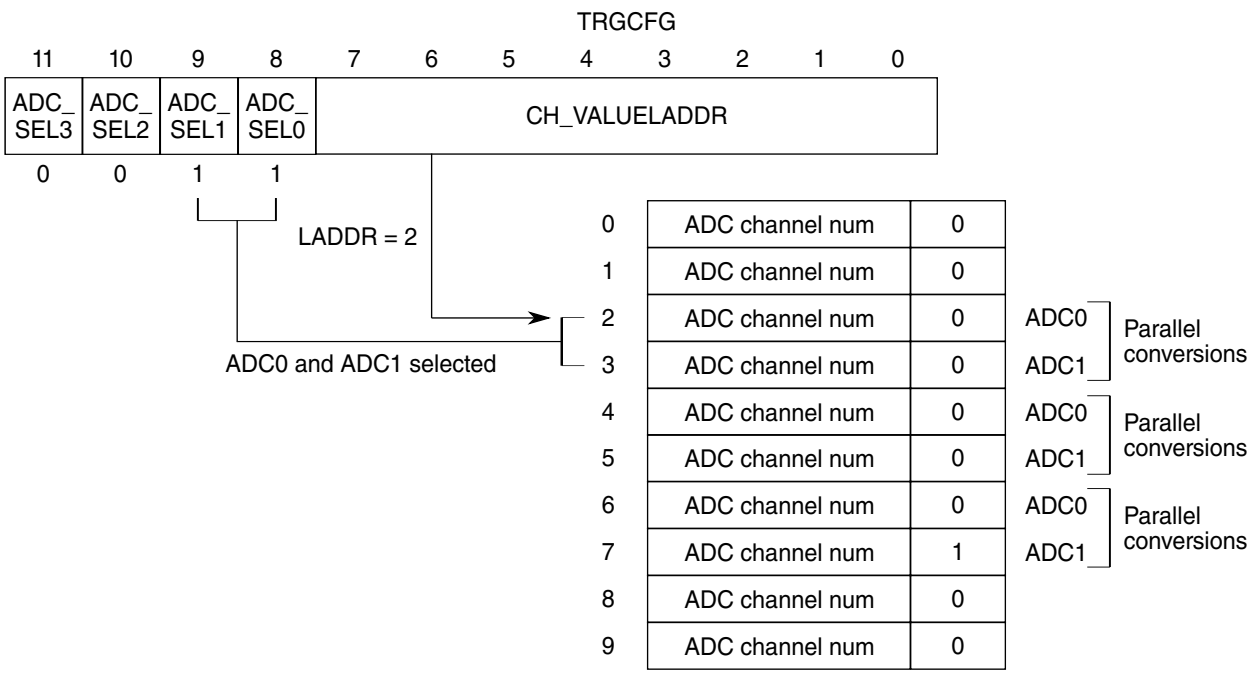


Figure 36-8. Multiple Parallel Conversions LIST operation

The Multiple Parallel Conversion (MPC) follows the same priority rules of a single conversion which is based on the trigger input number: the lower the trigger the higher the priority is. The difference is that a MPC cannot start until all the ADCs defined in the LIST are free. Thus if a MPC is triggered for ADC0 and ADC1, this LIST of conversions does not initiate until ADC0 and ADC1 are free. Note that if ADC0 is free but there is a higher priority trigger for ADC1 then the MPC does not start. If two MPC that have at least one ADC in common are triggered, the lower trigger number has higher priority. Note that the conflict in the priority only occurs if the triggered conversions are trying to use at least one ADC in common. If the MPCs are using different ADCs than there is no conflict and the MPCs are executed at the same time.

36.8 Interrupts and DMA requests

The BCTU module has several interrupts to signal input triggers and conversion results events. These interrupts can also be used as DMA requests.

Trigger interrupt : signals an ADC trigger event occurred, thus a conversion have started. This interrupt line is an or of all ADC triggers (up to two).

ADC data ready: these interrupts (up to two) signals when an ADC result is available. The software should read the BCTU_ADCx_DR register in order to access the ADC conversion result.

LIST interrupt: the LIST interrupt line signals when the LIST executed the last conversion. If the conversion from a LIST was transferred to the system memory then this interrupt signals to the software that all results, from a LIST, are ready to be processed. Note that this interrupt always occur along with the ADC data ready interrupt.

Chapter 37
Configurable Enhanced Modular IO Subsystem (eMIOS)

37.1 Chip-specific eMIOS information

37.1.1 eMIOS configuration

The device has 2 eMIOS modules that are each configured as shown in the following table.

Table 37-1. Configurations

Parameter	eMIOS_0	eMIOS_1
Timer width	16 bits	16 bits
Number of channels	32	32
Channels configuration	See EMIOS channel configuration figure below	
Channel pre-scaler width	4	4
Number of global counter buses	2	2
Number of global pre-scalers	1	1

37.1.2 Channel types

The eMIOS contain 4 different types of channel, which are listed below.

Table 37-2. eMIOS channel types

Mode Description	Name	Ch TypeX	Ch TypeY	Ch TypeG	Ch TypeH
General Purpose Input / Output	GPIO	X	X	X	X
Single Action Input Capture	SAIC	X	X	X	X

Table continues on the next page...

Table 37-2. eMIOS channel types (continued)

Mode Description	Name	Ch TypeX	Ch TypeY	Ch TypeG	Ch TypeH
Single Action Output Compare	SAOC	X	X	X	X
Modulus Counter	MC	X			
Modulus Counter Buffered (Up / Down)	MCB	X		X	
Input Pulse Width Measurement	IPWM			X	X
Input Period Measurement	IPM			X	X
Double Action Output Compare	DAOC			X	X
Output Pulse Width and Frequency Modulation Buffered	OPWFMB	X		X	
Center aligned Output PWM Buffered with dead time	OPWMCB			X	
Output Pulse Width Modulation Buffered	OPWMB	X	X	X	X
Output Pulse Width Modulation Trigger	OPWMT	X	X	X	X

NOTE

ChType X and G has internal counters.

Table 37-3. eMIOS channel configuration

Channel number	eMIOS0	eMIOS1
CH0	X	X
CH8	X	X

37.1.3 DMA channel configuration

Table 37-4. eMIOS DMA Channel configuration

Channel type	Channel number
eMIOSx_chA	Channel 0
eMIOSx_chB	Channel 1
eMIOSx_chC	Channel 9
eMIOSx_chD	Channel 10
eMIOSx_chE	Channel 17
eMIOSx_chF	Channel 18
eMIOSx_chG	Channel 25
eMIOSx_chH	Channel 26

37.1.4 Channel configuration

The eMIOS channel configuration is shown below. Please note that each channel and eMIOS are not identical.

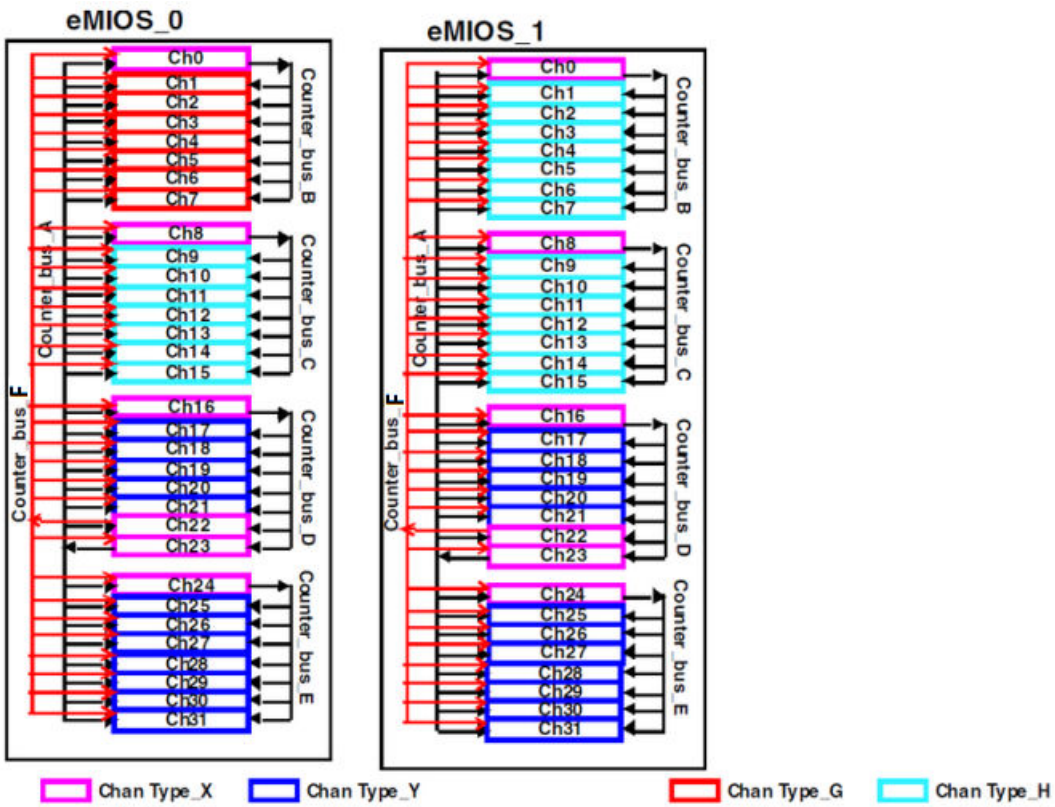

Figure 37-1. EMIOS channel types

37.1.5 eMIOS disabling

eMIOS can disable it's output using it's disable inputs. Disable inputs[3:0] are driven from the flag out bits[11:8].

Disable inputs	
eMIOS0 Output disable input[3:0]	eMIOS0 flag_out bits[11:8]
eMIOS1 Output disable input[3:0]	eMIOS1 flag_out bits[11:8]

37.1.6 Serialization

The channels from eMIOS_1 and eMIOS_0 are serialized with the DSPI[0:3] to allow control of external Lamp/LED drivers. PISR muxes are integrated into the DSPIs and also DSPI[0:1] supports DSI 64 bit mode. Hence routing between eMIOS and DSPIs are different. See diagram below for details

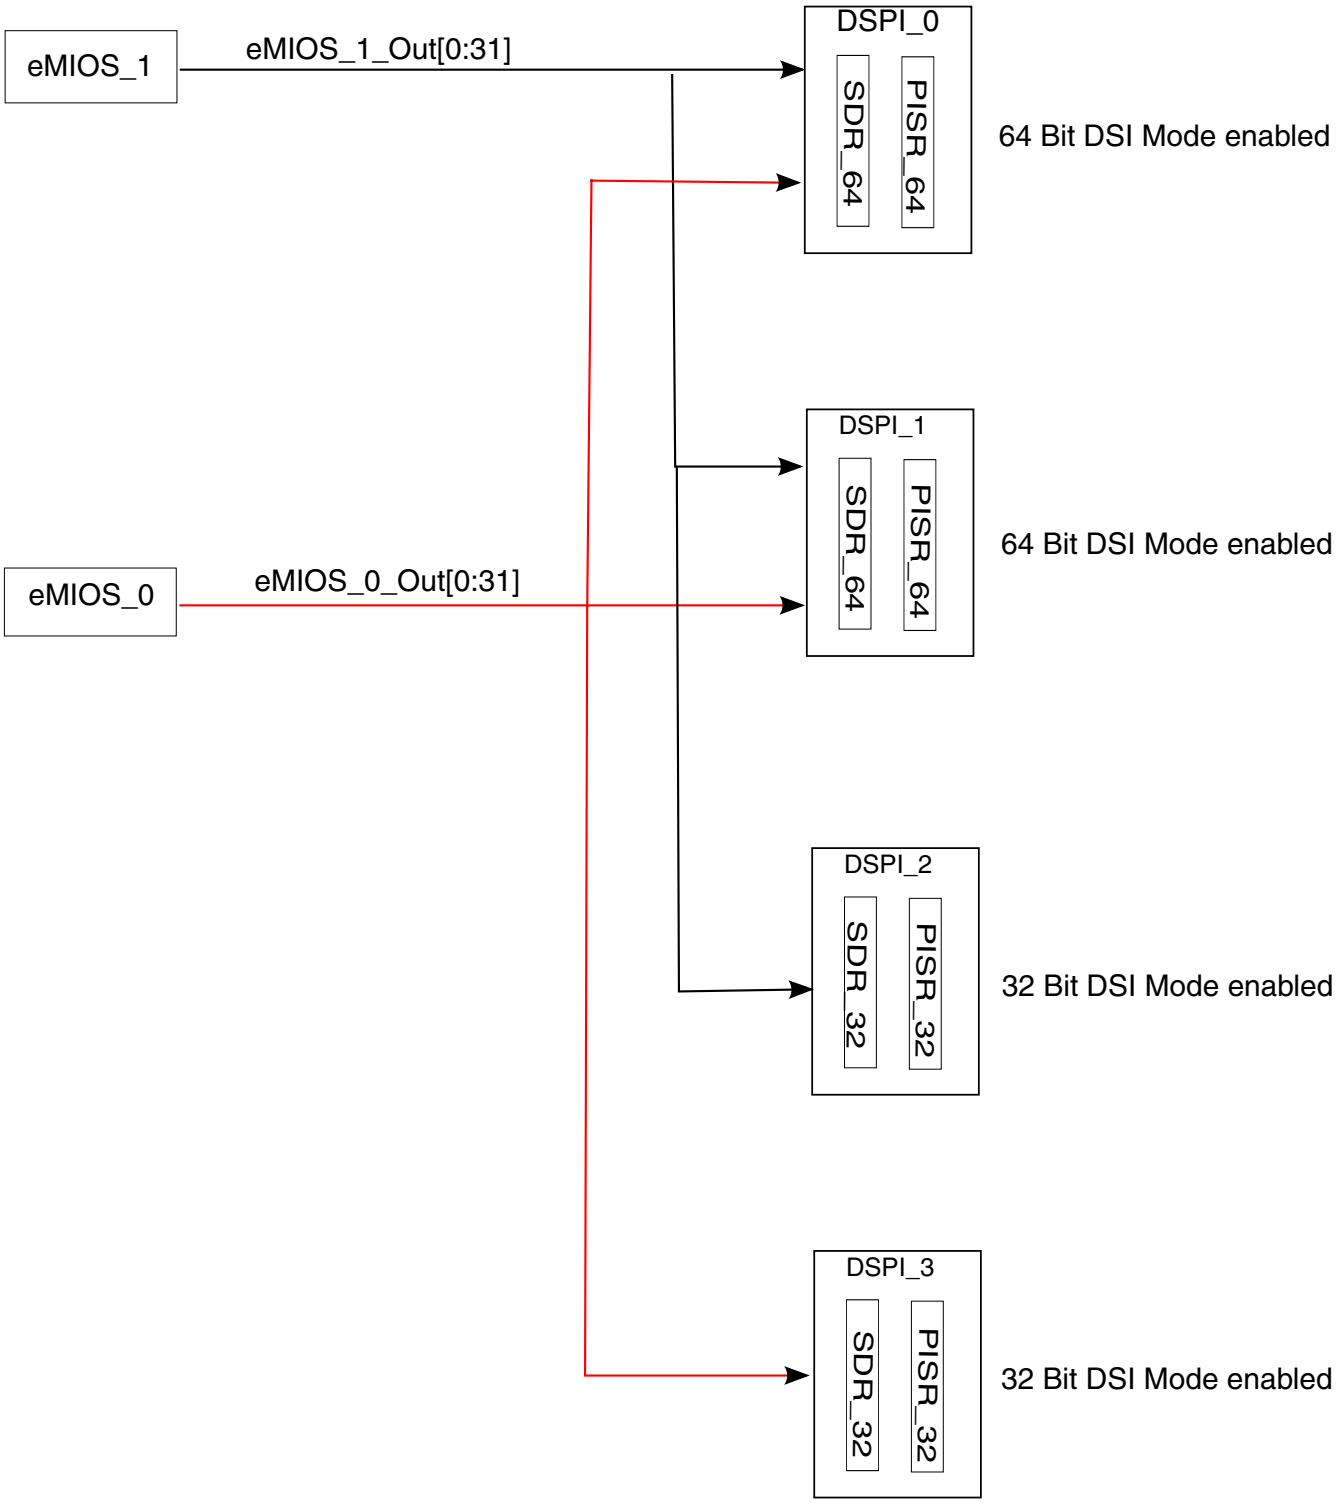

Figure 37-2. eMIOS serialisation

Non-Shaded Blocks Correspond to eMIOS2 Channels																	

1. x is 0 or 1

37.1.7 BCTU Interface

Each eMIOS channel, with the exception of the main counterbus channel (ch[23]) is capable of triggering the BCTU. See BCTU chapter for mapping. BCTU allows triggering from as many eMIOS modes as possible.

37.1.8 EMIOS register reset value

All register reset values for the EMIOS registers that are device specific are shown below. All other registers reset values are shown in the EMIOS Memory chapter

EMIOS 0 disable channel register (EMIOS_0_UCDIS) resets to 0000_0000h.

EMIOS 1 disable channel register (EMIOS_1_UCDIS) resets to 0000_0000h.

37.2 Introduction

37.2.1 Overview

The configurable enhanced Modular Input/Output Subsystem (eMIOS) provides functionality to generate or measure time events. Its overall architecture resembles that of the MIOS timer.

The predecessor MIOS timer block provides a framework in which a set of sublocks with different timer functions are assembled to attend to the specific needs of an SoC. The eMIOS builds on this concept by using a Unified Channel module that provides a superset of the functionality of all the individual MIOS channels, while also providing a consistent user interface. This allows more flexibility as each Unified Channel can be

programmed for different functions in different applications of the SoC. In addition, eMIOS architecture allows the use of Dedicated Channels which perform specific functions not included in MIOS inheritance.

The block diagram of the configurable eMIOS block is shown below.

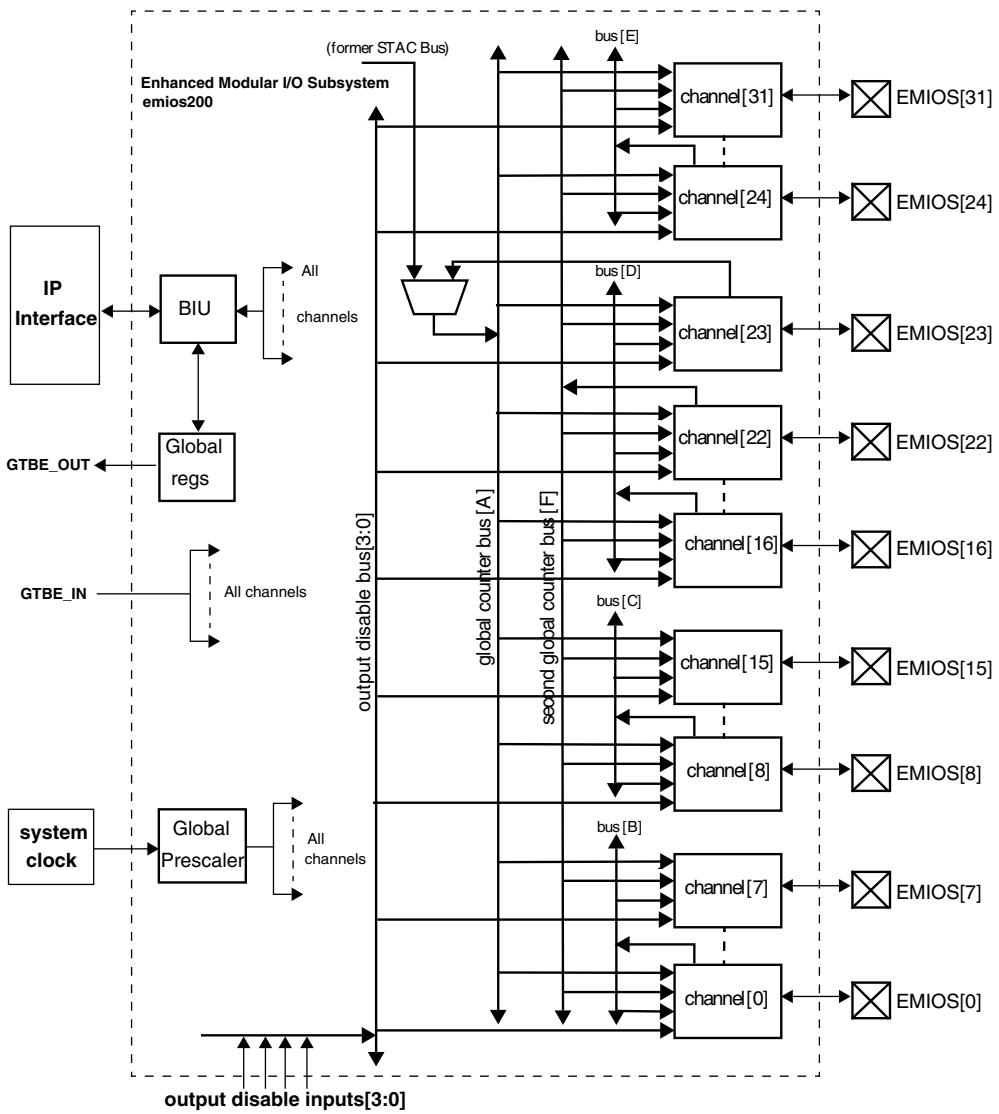

Figure 37-3. eMIOS block diagram with 2 global counter buses

37.2.2 Features

The eMIOS has the following features:

- Up to 32 channels chosen among Unified or Dedicated Channels, not necessarily numbered in a continuous sequence. (See Configuration information)
- Data registers of either 8-, 16-, 24-, or 32-bit width. (See Configuration information)
- Counter buses B, C, D, and E can be driven by Unified Channels 0, 8, 16, and 24, respectively. (See Configuration information)
- Counter bus A can be driven by Unified Channel 23 or by the external shared timer bus.
- Counter bus F can be driven by a specified Unified Channel, defined by the system configuration.
- Each channel has its own timebase, alternative to the counter buses.
- One global prescaler
- One prescaler per channel (CP)
- Timebases shared through the counter buses
- Control and status bits grouped in separated registers
- Synchronization among timebases
- Shadow FLAG register
- State of the Unified Channels can be frozen for debug purposes

37.2.3 Modes of operation

The Unified Channels can be configured to operate in the following modes:

- General-Purpose Input/Output (GPIO)
- Single-Action Input Capture (SAIC)
- Single-Action Output Compare (SAOC)
- Input Pulse-Width Measurement (IPWM)
- Input Period Measurement (IPM)

- Double-Action Output Compare (DAOC)
- Modulus Counter (MC)
- Modulus Counter Buffered (MCB)
- Output Pulse-Width and Frequency Modulation Buffered (OPWFMB)
- Center Aligned Output Pulse Width Modulation with Dead Time Insertion Buffered (OPWMCB)
- Output Pulse-Width Modulation Buffered (OPWMB)
- Output Pulse-Width Modulation with Trigger (OPWMT)

These modes are described in Unified Channel modes of operation.

Each channel can have a specific set of modes.

37.3 Memory map / register definition

37.3.1 Memory map

The overall address map organization is shown in the table below.

Whenever an access to either an absent register, absent channel, or reserved address space is performed, the transfer is terminated with an error.

Table 37-7. eMIOS Memory Map

eMIOS[n] Base Address	Description
0x000 0x003	Module Configuration register (EMIOSMCR)
0x004 0x007	Global FLAG register (EMIOSGFLAG)
0x008 0x00B	Output Update Disable (EMIOSOUDIS)
0x00C 0x00F	Disable Channel (EMIOSUCDIS)
0x01F	Reserved
0x020 0x11F	Channel 0 to Channel 7
0x120 0x21F	Channel 8 to Channel 15

Table continues on the next page...

Table 37-7. eMIOS Memory Map (continued)

eMIOS[n] Base Address	Description
0x220 0x31F	Channel 16 to Channel 23
0x320	Channel 24 to Channel 31
0x41F	
0x420	Reserved
0xFFF	

37.3.1.1 Unified channel memory map

Addresses of Unified Channel registers are specified as offsets from the channel's base address, otherwise the eMIOS base address is used as reference.

The following table describes the Unified Channel memory map.

Table 37-8. Unified channel memory map

UC[n] Base Address	Description
UC[n]_BASE + 0x000	A register (EMIOSA[n])
UC[n]_BASE + 0x004	B register (EMIOSB[n])
UC[n]_BASE + 0x008	Counter register (EMIOSCNT[n])
UC[n]_BASE + 0x00C	Control register (EMIOSC[n])
UC[n]_BASE + 0x010	Status register (EMIOSS[n])
UC[n]_BASE + 0x014	Alternate A register (EMIOSALTA[n])
UC[n]_BASE + 0x018	Control 2 register (EMIOSC2[n])
UC[n]_BASE + 0x01C to UC[n]_BASE + 0x01F	Reserved

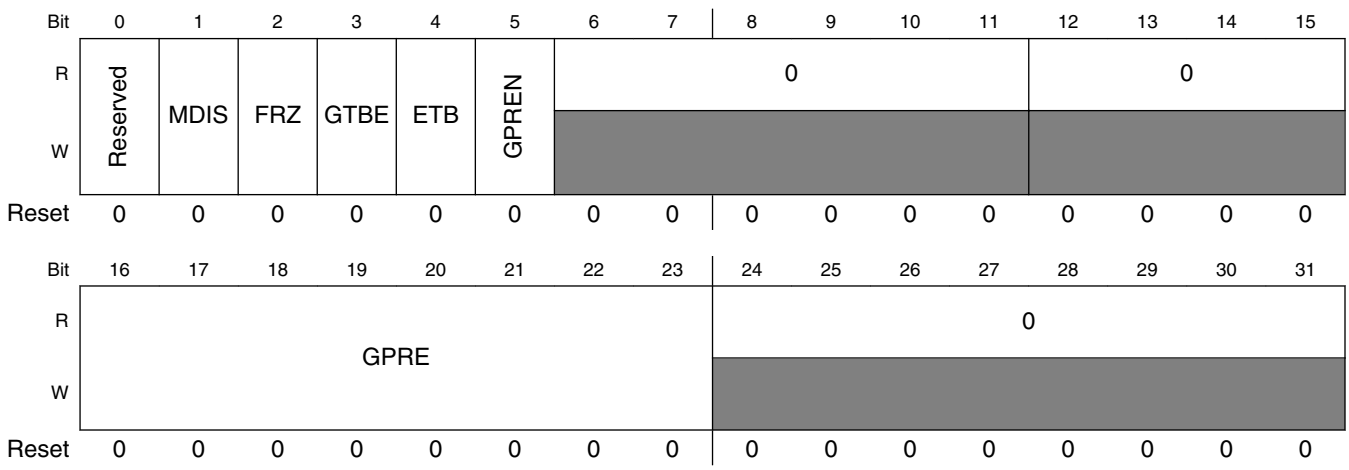
37.4 Control Memory Map and Registers

All control registers are 32 bits wide. This document illustrates the eMIOS with 24 Unified Channels and 24-bit wide data registers.

eMIOS memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	eMIOS Module Configuration Register (eMIOS_MCR)	32	R/W	0000_0000h	37.4.1/970

Table continues on the next page...



eMIOS memory map (continued)

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4	eMIOS Global FLAG Register (eMIOS_GFLAG)	32	R	0000_0000h	37.4.2/972
8	eMIOS Output Update Disable register (eMIOS_OUDIS)	32	R/W	0000_0000h	37.4.3/972
C	eMIOS Disable Channel register (eMIOS_UCDIS)	32	R/W	0000_0000h	37.4.4/973

37.4.1 eMIOS Module Configuration Register (eMIOS_MCR)

The MCR register contains Global Control bits for the eMIOS block.

Address: 0h base + 0h offset = 0h

eMIOS_MCR field descriptions

Field	Description
0 Reserved	Reserved. This field is reserved. Only write this field with the reset value.
1 MDIS	Module Disable bit. Puts the eMIOS into low power mode. The MDIS bit stops the clock of the block, except the access to registers EMIOSMCR, EMIOSOUDIS and EMIOSUCDIS. 0 Clock is running 1 Enter low power mode
2 FRZ	Freeze bit. This bit enables the eMIOS to freeze the registers of the Unified Channels when Debug Mode is requested at MCU level. Each Unified Channel should have FREN bit set in order to enter freeze state. While in Freeze state, the eMIOS continues to operate to allow the MCU access to the Unified Channels registers. The Unified Channel will remain frozen until the FRZ bit is written to zero or the MCU exits Debug mode or the Unified Channel FREN bit is cleared.

Table continues on the next page...

eMIOS_MCR field descriptions (continued)

Field	Description
	0 Exit freeze state 1 Stops Unified Channels operation when in Debug mode and the FREN bit is set in the EMIOSC[n] register
3 GTBE	Global Time Base Enable bit. The GTBE bit is used to export a Global Time Base Enable from the module and provide a method to start time bases of several blocks simultaneously. **NOTE:** The Global Time Base Enable input pin controls the internal counters. When asserted, Internal counters are enabled. When negated, Internal counters disabled. 0 Global Time Base Enable Out signal negated 1 Global Time Base Enable Out signal asserted
4 ETB	External Time Base bit The ETB bit selects the time base source that drives counter bus[A]. 0 Counter bus[A] assigned to Unified Channel. 1 Reserved
5 GPREN	Global Prescaler Enable bit. The GPREN bit enables the prescaler counter. 0 Prescaler disabled (no clock) and prescaler counter is cleared 1 Prescaler enabled
6–11 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
12–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16–23 GPRE	Global Prescaler bits. The GPRE[0:7] bits select the clock divider value for the global prescaler, as shown in the following table. GPRE values and corresponding divide ratio values are: 00000000 1 00000001 2 00000010 3 00000011 4 ------- - 11111110 255 11111111 256
24–31 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

37.4.2 eMIOS Global FLAG Register (eMIOS_GFLAG)

GFLAG is a read-only register that groups the FLAG bits from all channels. Each bit relates to one channel.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	F31_F0																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eMIOS_GFLAG field descriptions

Field	Description
0–31 F31_F0	Channel [n] mirrored FLAG bit. For Unified Channels these bits are mirrors of the FLAG bits in the EMIOSS[n] register.

37.4.3 eMIOS Output Update Disable register (eMIOS_OUDIS)

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	OU31_OU0																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eMIOS_OUDIS field descriptions

Field	Description
0–31 OU31_OU0	Channel [n] Output Update Disable bit. When running MC, MCB or an output mode, values are written to registers A2 and B2. OU[n] bits are used to disable transfers from registers A2 to A1 and B2 to B1. Each bit controls one channel.

37.4.4 eMIOS Disable Channel register (eMIOS_UCDIS)

NOTE

See the Configuration information for the reset value of this register.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	CHDIS31_CHDIS0																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eMIOS_UCDIS field descriptions

Field	Description
0–31 CHDIS31_ CHDIS0	Enable Channel n bit. The CHDISn bit is used to disable each of the channels by stopping its respective clock.

37.5 Unified Channels Memory Map and Registers

The Unified Channel registers are as follows:

eMIOS memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
20	eMIOS UC A register n (eMIOS_A0)	32	R/W	0000_0000h	37.5.1/979
24	eMIOS UC B register n (eMIOS_B0)	32	R/W	0000_0000h	37.5.2/980
28	eMIOS CNT register n (eMIOS_CNT0)	32	R/W	0000_0000h	37.5.3/981
2C	eMIOS UC Control register n (eMIOS_C0)	32	R/W	0000_0000h	37.5.4/982

37.5.1 eMIOS UC A register n (eMIOS_A*n*)

Address: 0h base + 20h offset + (32d × i), where i=0d to 31d

eMIOS_A*n* field descriptions

Field	Description
0–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8–31 A	Depending on the mode of operation, internal registers A1[0:23] or A2[0:23], used for matches and captures, can be assigned to address EMIOS_An. Both A1 and A2 are cleared by reset. The table in the EMIOS_Bn register description summarizes the EMIOS_An writing and reading accesses for all operation modes. Values not listed are reserved. For more information, see the “UC Modes of Operation” section.

37.5.2 eMIOS UC B register n (eMIOS_B*n*)

Depending on the mode of operation, internal registers B1[0:23] or B2[0:23] can be assigned to address EMIOS_Bn. Both B1 and B2 are cleared by reset. The table below summarizes the EMIOS_Bn writing and reading accesses for all operation modes. Values not listed are reserved. For more information see the “UC Modes of Operation” section.

Depending on the channel configuration, it may have an EMIOS_B register or not. EMIOS_B register is required for the following modes: DAOC, IPM, IPWM, OPWMB, OPWMT, OPWFMB, OPWMCB, MC, MCB.

The following table summarizes the EMIOS_An, EMIOS_Bn, and EMIOS_ALTAn writing and reading accesses for all operation modes. Values not listed are reserved. For more information, see the “UC Modes of Operation” section.

Table 37-9. EMIOS_An, EMIOS_Bn and EMIOS_ALTAn values assignment

Operation mode	Register access					
	Write	Read	Write	Read	Alt write	Alt read
GPIO	A1, A2	A1	B1, B2	B1	A2	A2
SAIC[1]	–	A2	B2	B2	–	–
SAOC[1]	A2	A1	B2	B2	–	–
IPWM	–	A2	–	B1	–	–
IPM	–	A2	–	B1	–	–
DAOC	A2	A1	B2	B1	–	–
PEA	A1	A2	–	B1	–	–
PEC[1]	A1	A1	B1	B1	–	A2
WPTA	A1	A1	B1	B1	–	A2
MC[1]	A2	A1	B2	B2	–	–
OPWFM	A2	A1	B2	B1	–	–
OPWMC	A2	A1	B2	B1	–	–
OPWM	A2	A1	B2	B1	–	–
OPWMT	A2	A1	B2	B1	A2	A2
MCB[1]	A2	A1	B2	B1	–	–
OPWFMB	A2	A1	B2	B1	–	–
OPWMCB	A2	A1	B2	B1	–	–
OPWMB	A2	A1	B2	B1	–	–

1. In these modes, the register EMIOS_Bn is not used, but B2 can be accessed.

Address: 0h base + 24h offset + (32d × i), where i=0d to 31d

eMIOS_B*n* field descriptions

Field	Description
0–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8–31 B	See text above register figure.

37.5.3 eMIOS CNT register n (eMIOS_CNT*n*)

When GPIO mode is selected or the channel is frozen, the EMIOS_CNTn register is read/write. For all others modes, the EMIOS_CNTn is a read-only register. When entering some operation modes, this register is automatically cleared (refer to the “UC Modes of Operation” section for details).

EMIOS_CNTn register is required for the following modes:

- OPWFMB
- OPWMCB
- MC
- MCB

For other modes, the internal counter is not used. Therefore, depending on the modes available in a channel, the internal counter may be absent.

Address: 0h base + 28h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

eMIOS_CNT*n* field descriptions

Field	Description
0–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16–31 C	The C field contains the value of the internal counter.

37.5.4 eMIOS UC Control register n (eMIOS_C*n*)

The UC Control register gathers several read/write control bits affecting the UC operation conditions.

NOTE

This register does not include a FORCMB bit for Channel Types A and C.

Address: 0h base + 2Ch offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R	0				0	BSL		EDSEL	EDPOL	MODE						
W			FORCMA	FORCMB												
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eMIOS_C*n* field descriptions

Field	Description
0 FREN	Freeze Enable bit. The FREN bit, if set and validated by FRZ bit in EMIOS_MCR register allows the channel to enter freeze state, freezing all registers values when in debug mode and allowing the MCU to perform debug functions. 0 Normal operation 1 Freeze UC registers values
1 ODIS	Output Disable bit. The ODIS bit allows disabling the output pin when running any of the output modes with the exception of GPIO mode.

Table continues on the next page...

eMIOS_C*n* field descriptions (continued)

Field	Description
	0 The output pin operates normally 1 If the selected Output Disable Input signal is asserted, the output pin goes to EDPOL for OPWFMB and OPWMB modes and to the complement of EDPOL for other output modes, but the Unified Channel continues to operate normally, i.e., it continues to produce FLAG and matches. When the selected Output Disable Input signal is negated, the output pin operates normally.
2–3 ODISSL	Output Disable select bits. The ODISSL[0:1] bits select one of the four output disable input signals, as shown in the following table. **Table 37-10. UC ODISSL selection** ODISSL[0:1] / input signal: 00 Output Disable Input 0; 01 Output Disable Input 1; 10 Output Disable Input 2; 11 Output Disable Input 3
4–5 UCPRE	Prescaler bits. The UCPRE[0:1] bits select the clock divider value for the internal prescaler of Unified Channel, as shown in the following table. **Table 37-11. UC Internal Prescaler clock divider** UCPRE[0:1] / Divide ratio: 00 1; 01 2; 10 3; 11 4 **NOTE:** The UCPRE bits are mirrored in the two LSBs of the UCEXTPRE field in register EMIOS_Cn. Any write operations to UCPRE bits will affect the respective bits at EMIOS_C2n register.
6 UCPREN	Prescaler Enable bit. The UCPREN bit enables the prescaler counter. 0 Prescaler disabled (no clock) 1 Prescaler enabled
7 DMA	Direct Memory Access bit. The DMA bit selects if FLAG generation will be used as an interrupt or as a DMA request. 0 Flag/overrun assigned to Interrupt request. 1 Flag/overrun assigned to DMA request.
8 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

eMIOS_C*n* field descriptions (continued)

Field	Description
9–12 IF	Input Filter bits. The IF[0:3] bits control the programmable input filter, selecting the minimum input pulse width that can pass through the filter, as shown in the following table. For output modes, these bits have no meaning. **Table 37-12. UC Input Filter bits** **IF[0:3]** [1] / **Minimum input Pulse width [filter clock periods]** 0000 — bypassed[2] 0001 — 02 0010 — 04 0100 — 08 1000 — 16 All others — Reserved
13 FCK	Filter Clock select bit. The FCK bit selects the clock source for the programmable input filter. 0 Prescaled clock 1 eMIOS module clock
14 FEN	FLAG Enable bit. The FEN bit allows the Unified Channel FLAG bit to generate an interrupt signal or a DMA request signal (the type of signal to be generated is defined by the DMA bit). 0 Disable (FLAG does not generate an interrupt request) 1 Enable (FLAG generates an interrupt request)
15–17 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
18 FORCMA	Force Match A bit. For output modes, the FORCMA bit is equivalent to a successful comparison on comparator A (except that the FLAG bit is not set). This bit is cleared by reset and is always read as zero. This bit is valid for every output operation mode which uses comparator A, otherwise it has no effect. For input modes, the FORCMA bit is not used and writing to it has no effect. 0 Has no effect. 1 Force a match at comparator A
19 FORCMB	Force Match B bit. For output modes, the FORCMB bit is equivalent to a successful comparison on comparator B (except that the FLAG bit is not set). This bit is cleared by reset and is always read as zero. This bit is valid for every output operation mode which uses comparator B, otherwise it has no effect. 0 Has not effect 1 Force a match at comparator B
20 Reserved	Reserved.

Table continues on the next page...

eMIOS_C*n* field descriptions (continued)

Field	Description
	This field is reserved. This read-only field is reserved and always has the value 0.
21–22 BSL	Bus Select bits. The BSL[0:1] bits are used to select either one of the counter buses or the internal counter to be used by the Unified Channel , as shown in the following tables.

Table 37-13. UC BSL bits

BSL[0:1]	Selected bus[3]
00	All channels: counter bus[A]
01	Channels 0 to 7: counter bus[B]
	Channels 8 to 15: counter bus[C]
	Channels 16 to 23: counter bus[D]
	Channels 24 to 31: counter bus[E]
10	A system specified channel: counter bus F
11	All channels: internal counter

23 EDSEL	Edge Selection bit. For input modes, the EDSEL bit selects whether the internal counter is triggered by both edges of a pulse or just by a single edge as defined by the EDPOL bit . When not shown in the mode of operation description, this bit has no effect. 0 – Single edge triggering defined by the EDPOL bit 1 – Both edges triggering{mts_ipi_slv_saic} For GPIO in mode, the EDSEL bit selects if a FLAG can be generated. 0 – A FLAG is generated as defined by the EDPOL bit 1 – No FLAG is generated For SAOC mode, the EDSEL bit selects the behavior of the output flip-flop at each match. 0 – The EDPOL value is transferred to the output flip-flop 1 – The output flip-flop is toggled
24 EDPOL	Edge Polarity bit. For input modes, the EDPOL bit asserts which edge triggers either the internal counter or an input capture or a FLAG . When not shown in the mode of operation description, this bit has no effect. 0 – Trigger on a falling edge 1 – Trigger on a rising edge For output modes, the EDPOL bit is used to select the logic level on the output pin . 0 – A match on comparator A clears the output flip-flop, while a match on comparator B sets it 1 – A match on comparator A sets the output flip-flop, while a match on comparator B clears it
25–31 MODE	Mode selection bits. The MODE bits select the mode of operation of the Unified Channel, as shown in the following table. Values not listed are reserved.

Table continues on the next page...

eMIOS_C*n* field descriptions

Field	Description

NOTE: If a reserved value is written to the mode bit field, the results are unpredictable.

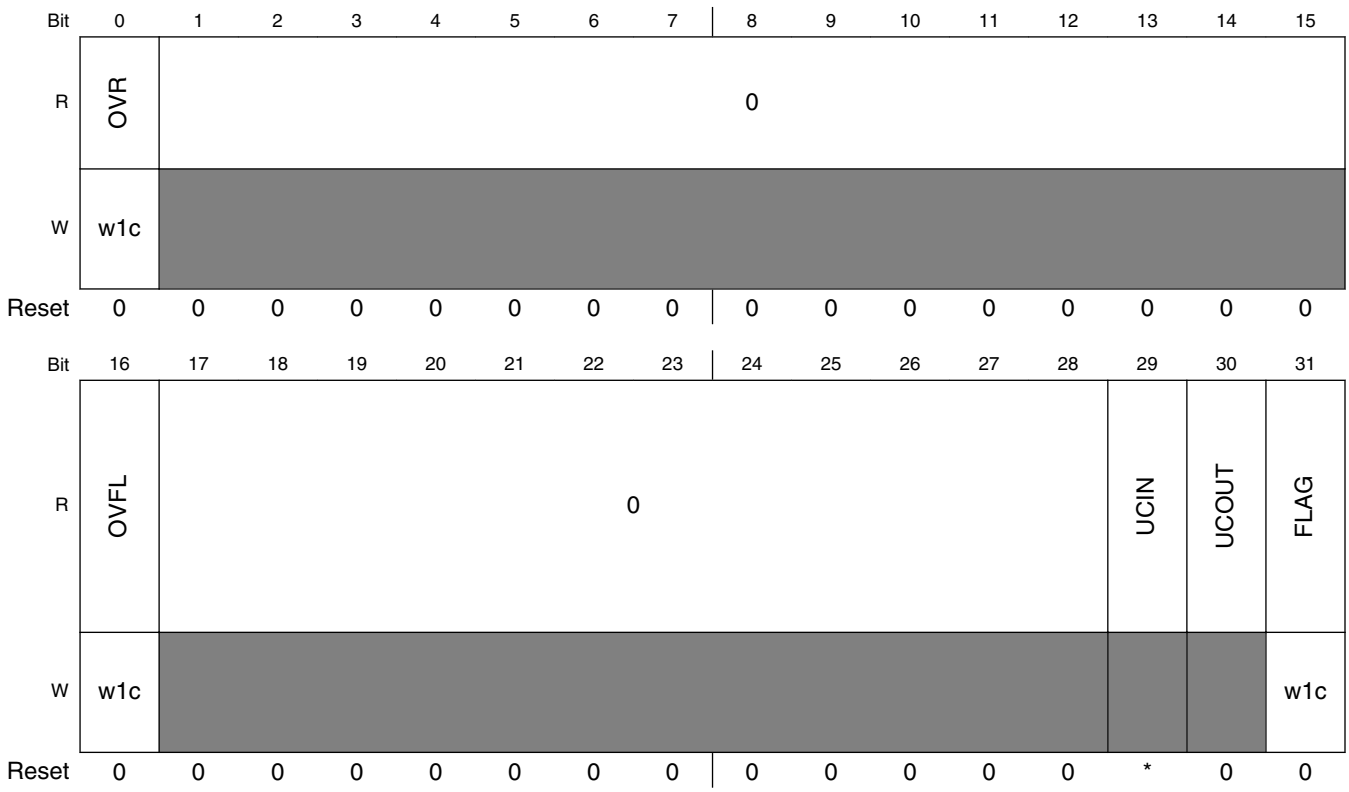
Table 37-14. UC MODE bits

MODE[0:6]	Mode of operation[4]
0000000	General purpose Input/Output mode (input)
0000001	General purpose Input/Output mode (output)
0000010	Single Action Input Capture
0000011	Single Action Output Compare
0000100	Input Pulse Width Measurement
0000101	Input Period Measurement
0000110	Double Action Output compare (with FLAG set on B match)
0000111	Double Action Output compare (with FLAG set on both match)
0001000	Pulse/Edge Accumulation (continuous)
0001001	Pulse/Edge Accumulation (single shot)
0001010	Pulse/Edge Counting (continuous)
0001011	Pulse/Edge Counting (single shot)
0001100	Quadrature Decode (for count and direction encoders type)
0001101	Quadrature Decode (for phase_A and phase_B encoders type)
0001110	Windowed Programmable Time Accumulation
0001111	Reserved
001000b[5]	Modulus Counter (Up counter with clear on match start)
001001b	Modulus Counter (Up counter with clear on match end)
00101bb[5]	Modulus Counter (Up/Down counter)
00110b0[5]	Output Pulse Width and Frequency Modulation (immediate update)
00110b1[5]	Output Pulse Width and Frequency Modulation (next period update)
00111b0[5]	Center Aligned Output Pulse Width Modulation (with trail edge dead-time)
00111b1[5]	Center Aligned Output Pulse Width Modulation (with lead edge dead-time)
01000b0[5]	Output Pulse Width Modulation (immediate update)
01000b1[5]	Output Pulse Width Modulation (next period update)
0100100 through 0100101	Reserved
0100110	Output Pulse Width Modulation with Trigger
0100111 through 1001111	Reserved
101000b[5]	Modulus Counter Buffered (Up counter)
101001b[5]	Reserved
10101bb[5]	Modulus Counter Buffered (Up/Down counter)
10110b0[5]	Output Pulse Width and Frequency Modulation Buffered

eMIOS_C*n* field descriptions (continued)

Field	Description

Table 37-14. UC MODE bits (continued)



MODE[0:6]	Mode of operation[4]
10110b1[5]	Reserved
10111b0[5]	Center Aligned Output Pulse Width Modulation Buffered (with trail edge dead-time)
10111b1[5]	Center Aligned Output Pulse Width Modulation Buffered (with lead edge dead-time)
11000b0[5]	Output Pulse Width Modulation Buffered
1100001 through 1111111	Reserved

1. Filter latency (the difference in time between the input and the response) is 3 clock edges.
2. The input signal is synchronized before arriving to the digital filter.
3. Not all devices support all counter buses. See the Device Configuration chapter for details.
4. Not all modes of operation are supported. See the configuration information for details.
5. b = adjust parameters for the mode of operation. Refer to “UC Modes of Operation” section for details.

37.5.5 eMIOS UC Status register n (eMIOS_S*n*)

The UC Status register EMIOS_Sn gathers bits reflecting the status of the UC input/ output signals and the overflow condition of the internal counter.

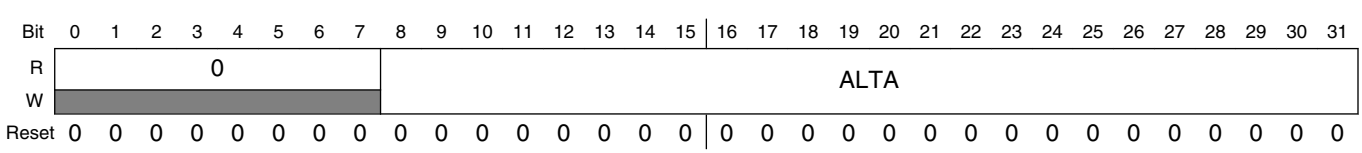
Address: 0h base + 30h offset + (32d × i), where i=0d to 31d

* Notes:
- UCIN field: Reset value is undefined.

eMIOS_S*n* field descriptions

Field	Description
0 OVR	Overrun bit. The OVR bit indicates that FLAG generation occurred when the FLAG bit was already set . The OVR bit can be cleared either by clearing the FLAG bit or by writing a 1 to the OVR bit. 0 Overrun has not occurred 1 Overrun has occurred
1–15 Reserved	Reserved. This field is reserved.

Table continues on the next page...



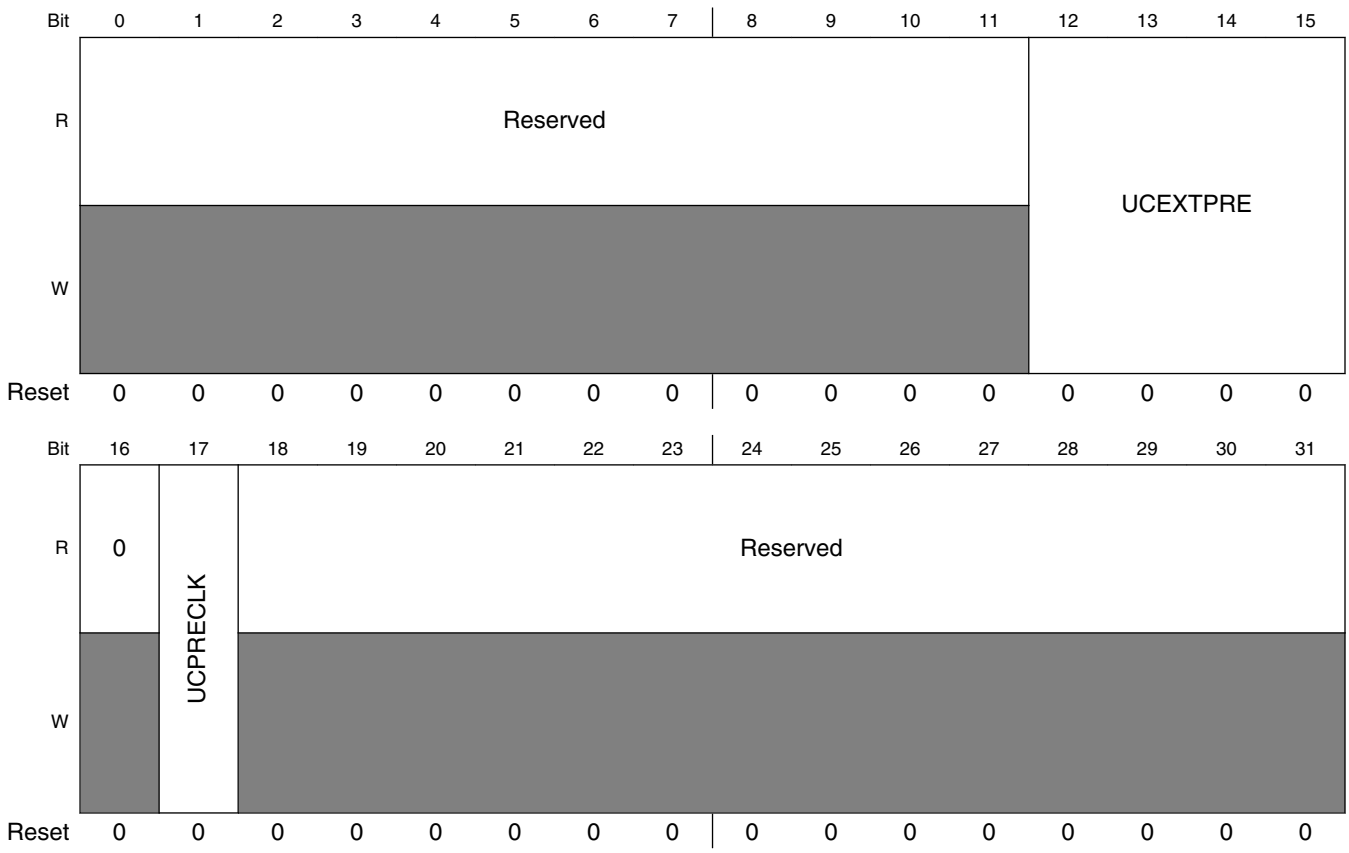
eMIOS_S*n* field descriptions (continued)

Field	Description
	This read-only field is reserved and always has the value 0.
16 OVFL	Overflow bit. The OVFL bit indicates that an overflow has occurred in the internal counter. The OVFL bit must be cleared by software writing a 1 to it. 0 No overflow 1 An overflow had occurred
17–28 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
29 UCIN	Unified Channel Input pin bit. The UCIN bit reflects the input pin state after being filtered and synchronized.
30 UCOUT	Unified Channel Output pin bit. The UCOUT bit reflects the output pin state .
31 FLAG	FLAG bit. The FLAG bit is set when an input capture or a match event in the comparators occurred. The FLAG bit must be cleared by writing a 1 to it. 0 FLAG cleared 1 FLAG set event has occurred

37.5.6 eMIOS Alternate Address register n (eMIOS_ALTA*n*)

The eMIOS_ALTAn register provides an alternate address to access A2 channel registers in restricted modes (GPIO, OPWMT)only. In modes where the function of eMIOS_ALTAn register is not specified, any write access is ignored and any read access returns unspecified data. If eMIOS_An register is used along with eMIOS_ALTAn, both A1 and A2 registers can be accessed in these modes. The table in the eMIOS_Bn register's description summarizes the EMIOS_ALTAn writing and reading accesses for all EMIOS_ALTAn operation modes. See the “General purpose Input/Output mode (GPIO) Mode” section, and the “Output Pulse Width Modulation with Trigger (OPWMT) Mode” section for a more detailed description of the use of eMIOS_ALTAn register.

Address: 0h base + 34h offset + (32d × i), where i=0d to 31d



eMIOS_ALTA*n* field descriptions

Field	Description
0–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8–31 ALTA	See text above register figure.

37.5.7 eMIOS UC Control 2 register n (eMIOS_C2_*n*)

Address: 0h base + 38h offset + (32d × i), where i=0d to 31d

eMIOS_C2_*n* field descriptions

Field	Description
	The UCEXTPRE bits allow the internal prescaler to be extended to 4 bits. The UCEXTPRE bits select the clock divider value for the internal prescaler of Unified Channel, as shown in the following table. **Table 37-15. UC Extended Internal Prescaler clock divider** UCEXTPRE[0:3] / Divide ratio 0000 / 1 0001 / 2 ------ / ------ 1110 / 15 1111 / 16 **NOTE:** The two LSBs of UCEXTPRE are mirrored in UCPRE bits (EMIOSC[4:5]). Any write operations to UCEXTPRE bits will affect the respective bits in the eMIOS_Cn register.

17 UCPRECLK	Prescaler Clock select bit. The UCPRECLK bit selects the clock source for the internal prescaler, 0 Prescaled Clock 1 eMIOS module clock
18–31 Reserved	Reserved. This field is reserved.

37.6 Functional Description

The eMIOS provides independent channels (Unified) that can be configured and accessed by a host MCU. Up to six time bases can be shared by the channels.

The eMIOS module is based on a multi-bus timer architecture in which several timer channels are used to drive counter buses that are shared among the channels. Up to five timebases can be shared by the channels through five counter buses (counter bus A or F, B, C, D and E) and each channel can generate its own timebase. There are six counter buses in the module: one global counter bus, shared by all channels and selectable among time bases A or F, and four local counter buses (B, C, D, and E), each one dedicated to a slice of 8 channels. Counter buses A and F are referred to as the global counter buses. Counter buses B, C, D, and E are the local counter buses.

The eMIOS counter buses are driven by channels in specific locations. Global counter bus A is driven by the channel in channel slot [23] and counter bus F is driven by the channel in channel slot [22].. Counter buses B, C, D, and E are driven by channels in slots 0, 8, 16, and 24, respectively. Counter bus A or F drives all channels. Counter bus B drives channels in slots from 0 through 7. Counter bus C drives channels in slots from 8 through 15. Counter bus D drives channels in slots from 16 through 23. Counter bus E drives channels from 24 through 31.

The eMIOS block is reset asynchronously. All registers are cleared on reset.

The following figure shows an eMIOS block configured with a mix of Unified Channels. In this configuration example, each one of the channels can be driven by the respective local bus—B for the [7:0] slice and D for the [23:16] slice—or by the global counter bus A. Note that there are Unified Channels with no external pin associated. These channels are used to trigger internal SoC signals such as interrupt requests or DMA transfer requests. Since the channel flags are also connected to the block top-level pins, they can be used as trigger signals for other blocks at chip level.

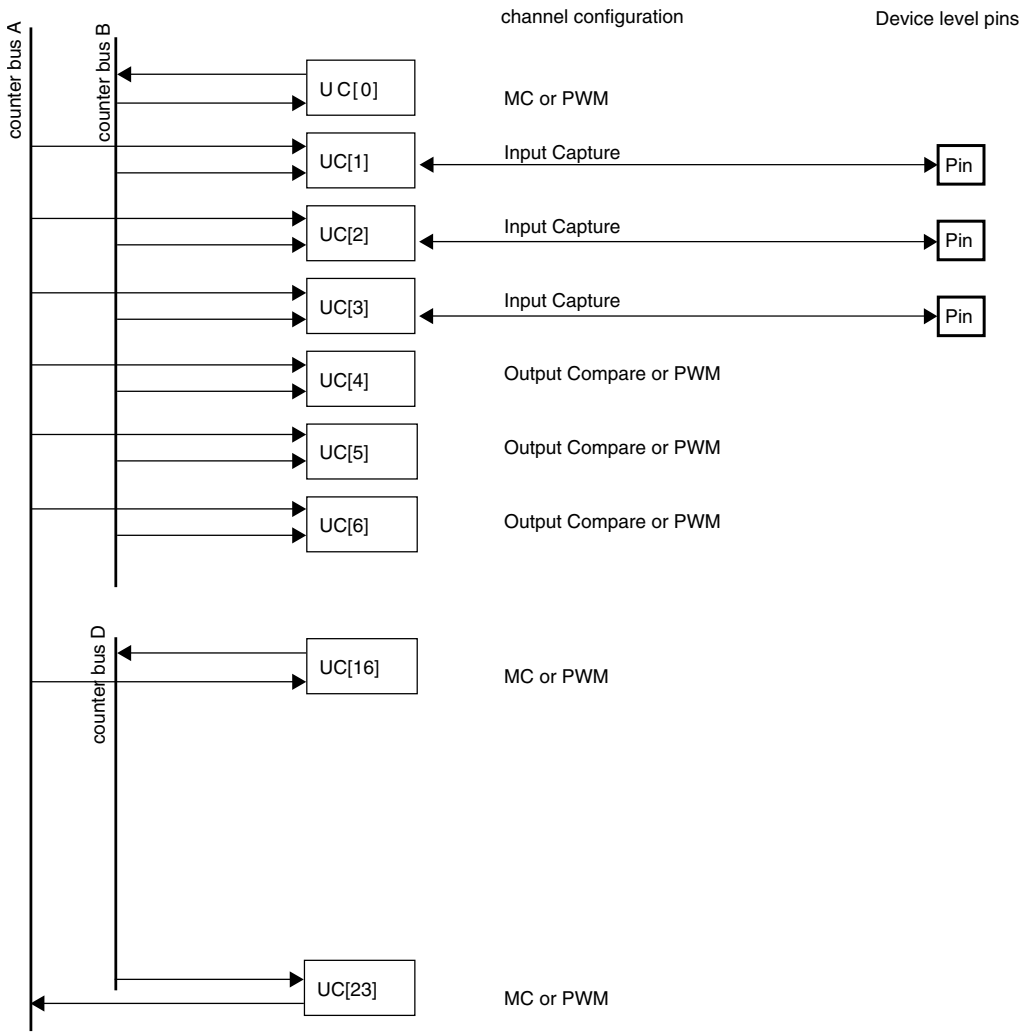

Figure 37-4. eMIOS example configuration using Unified Channels

37.6.1 Unified Channel (UC)

shows the Unified Channel block diagram. Each Unified Channel consists of the following:

- A counter bus selector, which selects the timebase to be used by the channel for all timing functions
- A programmable clock prescaler
- Two double-buffered data registers, A and B, that allow up to two input capture and/or output compare events to occur before software intervention is needed
- Two comparators (equal only), A and B, that compare the selected counter bus with the value in the data registers

- An internal counter, which can be used as a local time base or to count input events
- Programmable input filter, which ensures that only valid pin transitions are received by channel
- Programmable input edge detector, which detects the rising, falling, or either edge
- An output flip-flop, which holds the logic level to be applied to the output pin
- eMIOS Status and Control register
- An Output Disable Input selector, which selects the Output Disable Input signal that will be used as output disable

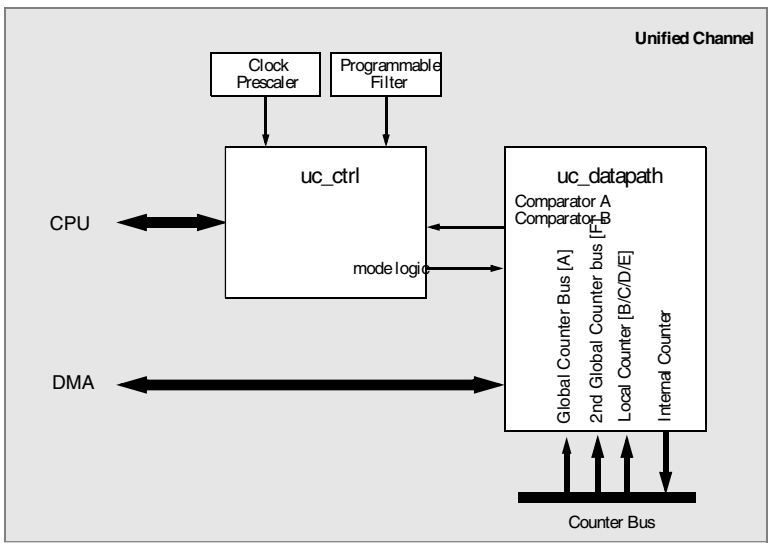

Figure 37-5. Unified Channel block diagram

shows both the Unified Channel control and datapath block diagrams. The control sub-block is responsible for the generation of signals to control the multiplexers in the datapath sub-block. Each mode is implemented by a dedicated logic independent from others modes, thus allowing to optimize the logic by disabling the mode and therefore its associated logic. Targeting the logic optimization, a set of registers is shared by the modes thus providing sequential events to be stored.

The datapath block provides the channel A and B registers, the internal timebase and comparators. Multiplexers select the input of comparators and data for the registers inputs, thus configuring the datapath to implement the channel modes. The outputs of the A and B comparators are connected to the uc_ctrl control block.

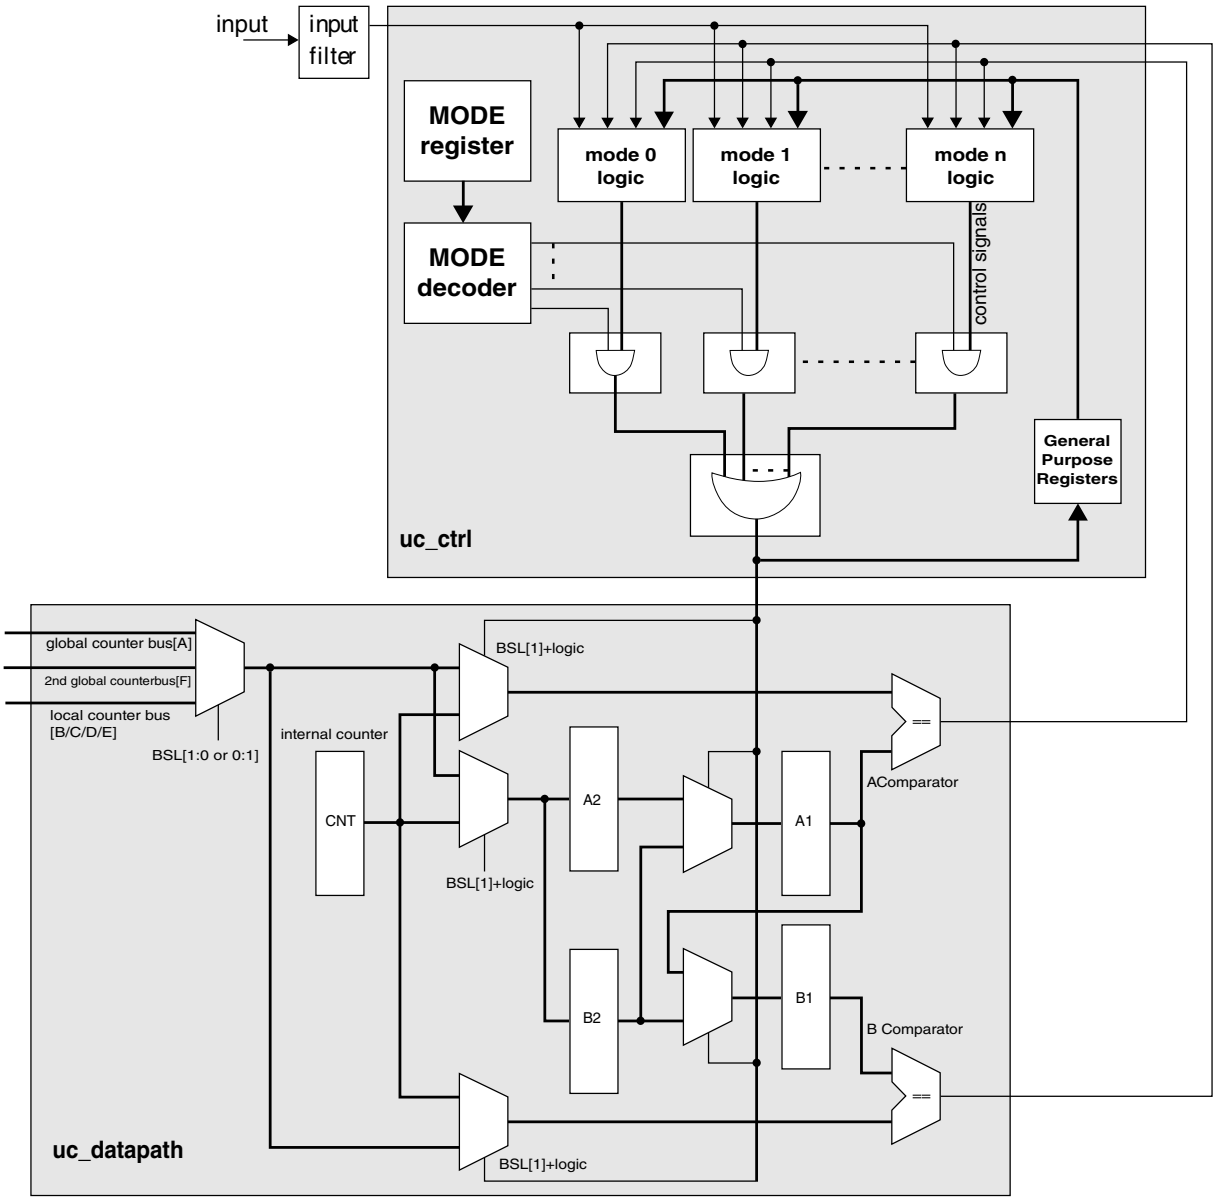

Figure 37-6. Unified Channel control and datapath block diagrams (BSL[0:1]

37.6.1.1 Unified Channel modes of operation

The mode of operation of the Unified Channel is determined by the mode select bits MODE[0:6] in the EMIOS_C_n register.

When entering an output mode (except for GPIO mode), the output flip-flop is set to the disabled state according to EMIOSCn[ODIS].

As the internal counter, EMIOSCNTn, runs in all modes (except for GPIO mode) and can be used as a timebase if the resource is not used in the current mode.

In order to provide smooth waveform generation even when A and B registers are immediately changed, it is available with the MCB, OPWFMB, OPWMB and OPWFMB modes. In these modes, A and B registers are double buffered. They are presented in separate sections because there are several basic differences between these and each corresponding nonbuffered mode.

37.6.1.1.1 General-Purpose Input/Output (GPIO) mode

In GPIO mode, all input capture and output compare functions of the Unified Channel are disabled, and the internal counter (EMIOSCNTn register) is cleared and disabled. All control bits remain accessible. In order to prepare the UC for a new operation mode, writing to registers EMIOSAn or EMIOSBn stores the same value in registers A1/A2 or B1/B2, respectively. Writing to the EMIOSALTAn register stores a value only in register A2.

MODE[6] bit selects between input (MODE[6] = 0) and output (MODE[6] = 1) modes.

When changing MODE[0:6], the application software must first enter GPIO mode to reset the Unified Channel's internal functions properly. Failure to do this could lead to invalid and unexpected output compare or input capture results or the FLAGs being set incorrectly.

In GPIO input mode (MODE[0:6] = 0000000), FLAG generation is determined according to EDPOL and EDSEL bits and the input pin status can be determined by reading the UCIN bit.

In GPIO output mode (MODE[0:6] = 0000001), the Unified Channel is used as a single output port pin and the value of the EDPOL bit is permanently transferred to the output flip-flop.

37.6.1.1.2 Single Action Input Capture (SAIC) Mode

In SAIC mode (MODE[0:6]=0000010), when a triggering event occurs on the input pin, the value on the selected time base is captured into register A2. The FLAG bit is set along with the capture event to indicate that an input capture has occurred. Register EMIOSA[n] returns the value of register A2. As soon as the SAIC mode is entered coming out from GPIO mode the channel is ready to capture events. The events are captured as soon as they occur thus reading register A always returns the value of the latest captured event. Subsequent captures are enabled with no need of further reads from EMIOSA[n] register. The FLAG is set at any time a new event is captured.

The input capture is triggered by a rising, falling or either edges in the input pin, as configured by EDPOL and EDSEL bits in EMIOSC[n] register.

Figure 37-7 and Figure 37-8 show how the Unified Channel can be used for input capture.

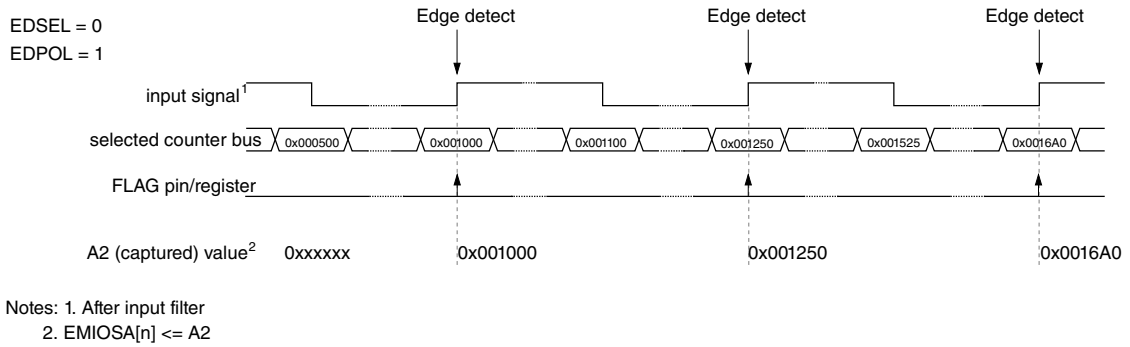

Figure 37-7. Single Action Input Capture with rising edge triggering example

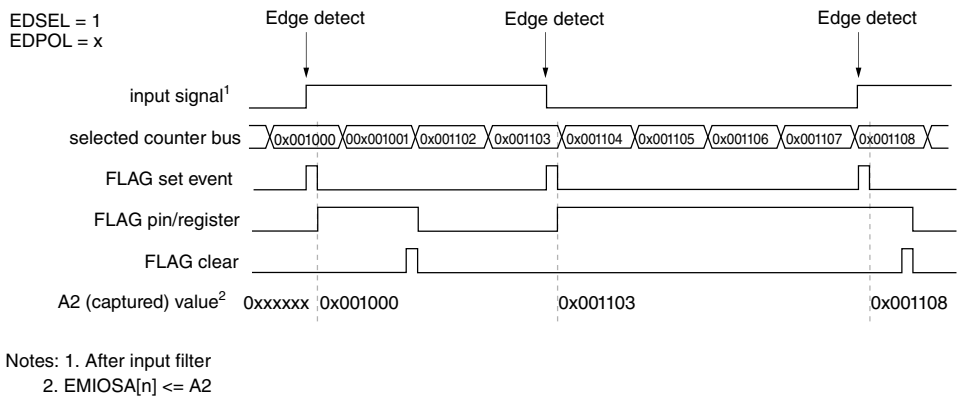

Figure 37-8. Single Action Input Capture with both edges triggering example

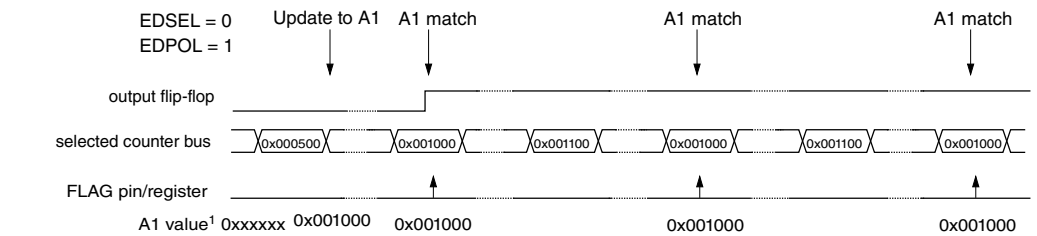
37.6.1.1.3 Single Action Output Compare (SAOC) Mode

In SAOC mode (MODE[0:6]=0000011) a match value is loaded in register A2 and then immediately transferred to register A1 to be compared with the selected time base. When a match occurs, the EDSEL bit selects whether the output flip-flop is toggled or the value in EDPOL is transferred to it. Along with the match the FLAG bit is set to indicate that the output compare match has occurred. Writing to register EMIOSA[n] stores the value in register A2 and reading to register EMIOSA[n] returns the value of register A1.

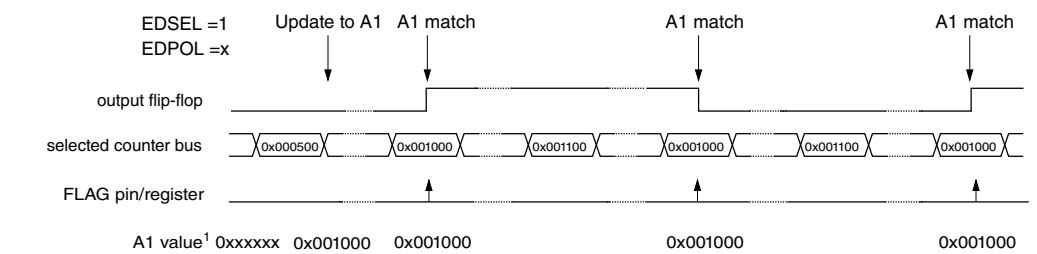
An output compare match can be simulated in software by setting the FORCMA bit in EMIOSC[n] register. In this case, the FLAG bit is not set.



When SAOC mode is entered coming out from GPIO mode, the output flip-flop is set to the complement of the EDPOL bit in the EMIOSC[n] register.

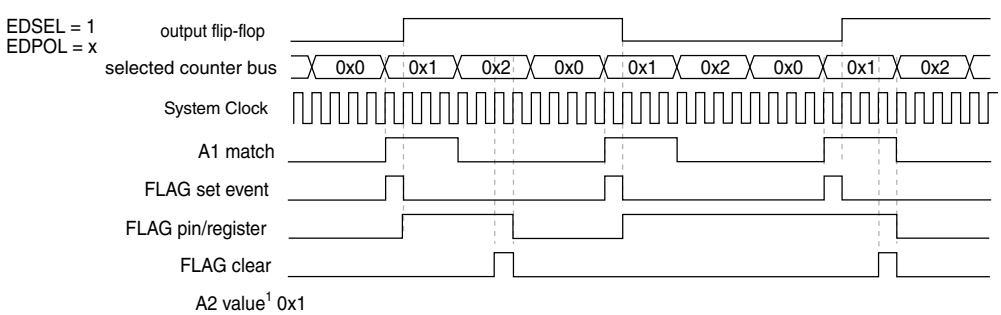
Counter bus can be either internal or external and is selected through BSL[0:1] bits.

Figure 37-9 and Figure 37-10 show how the Unified Channel can be used to perform a single output compare with EDPOL value being transferred to the output flip-flop and toggling the output flip-flop at each match, respectively. Note that once in SAOC mode the matches are enabled thus the desired match value on register A1 must be written before the mode is entered. A1 register can be updated at any time thus modifying the match value which will reflect in the output signal generated by the channel. Subsequent matches are enabled with no need of further writes to EMIOSA[n] register. The FLAG is set at the same time a match occurs (see Figure 37-11).



Note

The channel internal counter in SAOC mode is free-running. It starts counting as soon as the SAOC mode is entered.



Notes: 1. EMIOSA[n] = A2
A2 = A1 according to OU[n] bit

Note: 1. EMIOSA[n] <= A2

Figure 37-11. SAOC example with flag behavior

37.6.1.1.4 Input Pulse Width Measurement (IPWM) Mode

The IPWM mode (MODE[0:6]=0000100) allows the measurement of the width of a positive or negative pulse by capturing the leading edge on register B1 and the trailing edge on register A2. Successive captures are done on consecutive edges of opposite polarity. The leading edge sensitivity (i.e., pulse polarity) is selected by EDPOL bit in the EMIOSC[n] register. Registers EMIOSA[n] and EMIOSB[n] return the values in register A2 and B1, respectively.

The capture function of register A2 remains disabled until the first leading edge triggers the first input capture on register B2. When this leading edge is detected, the count value of the selected time base is latched into register B2; the FLAG bit is not set. When the trailing edge is detected, the count value of the selected time base is latched into register A2 and, at the same time, the FLAG bit is set and the content of register B2 is transferred to register B1 and to register A1.

If subsequent input capture events occur while the corresponding FLAG bit is set, registers A2, B1 and A1 will be updated with the latest captured values and the FLAG will remain set. Registers EMIOSA[n] and EMIOSB[n] return the value in registers A2 and B1, respectively.

In order to guarantee coherent access, reading EMIOSA[n] forces B1 be updated with the content of register A1. At the same time transfers between B2 and B1 are disabled until the next read of EMIOSB[n] register. Reading EMIOSB[n] register forces B1 be updated with A1 register content and re-enables transfers from B2 to B1, to take effect at the next trailing edge capture. Transfers from B2 to A1 are not blocked at any time.

The input pulse width is calculated by subtracting the value in B1 from A2.

The following figure shows how the Unified Channel can be used for input pulse width measurement.

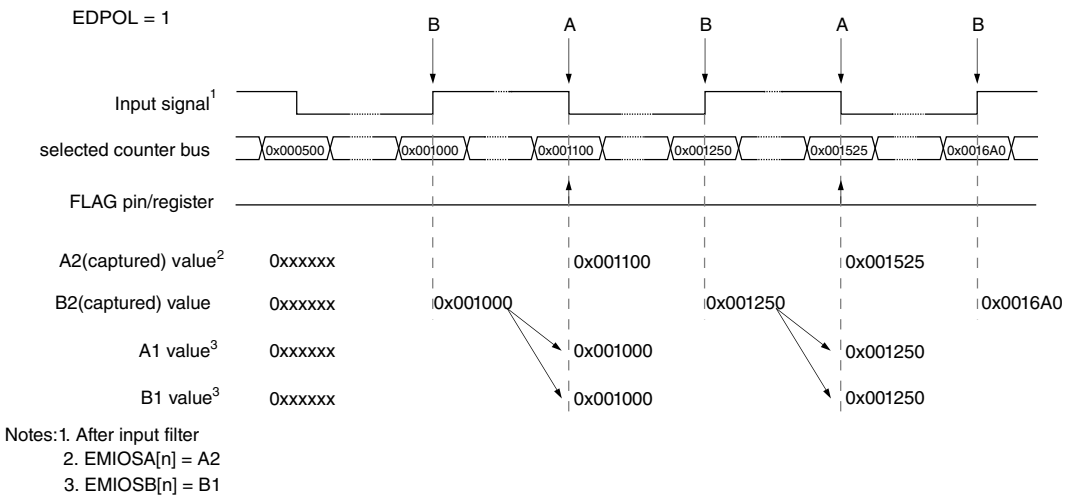

Figure 37-12. Input Pulse Width Measurement example

The following figure shows the A1 and B1 updates when EMIOSA[n] and EMIOSB[n] register reads occur. Note that A1 register has always coherent data related to A2 register. Note also that when EMIOSA[n] read is performed B1 register is loaded with A1 register content. This guarantee that the data in register B1 has always the coherent data related to the last EMIOSA[n] read. The B1 register updates remains locked until EMIOSB[n] read occurs. If EMIOSA[n] read is performed B1 is updated with A1 register content even if B1 update is locked by a previous EMIOSA[n] read operation.

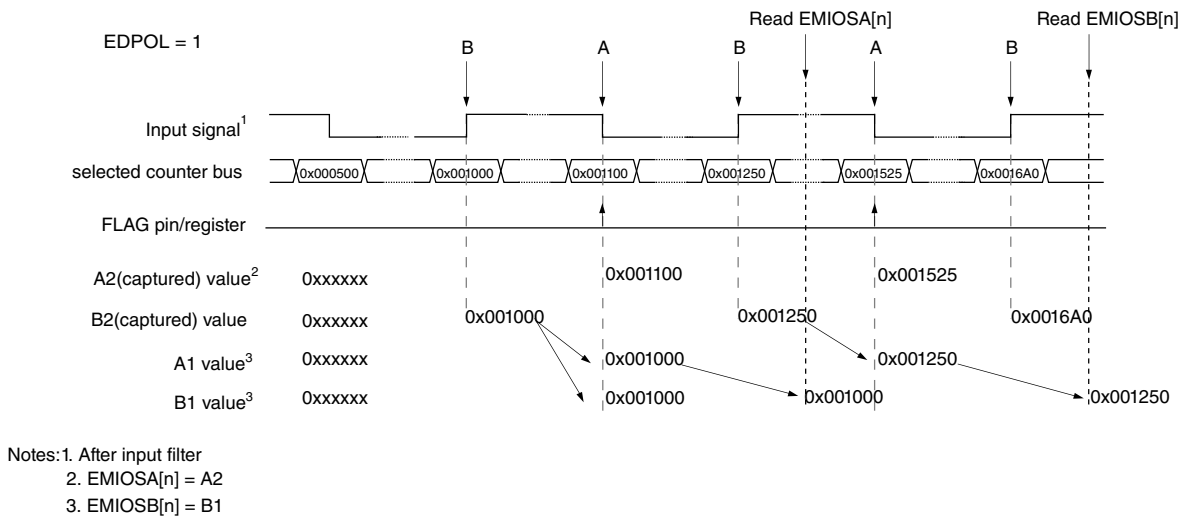

Figure 37-13. B1 and A1 updates at EMIOSA[n] and EMIOSB[n] reads

Reading EMIOS_A_n followed by EMIOS_B_n always provides coherent data. If coherent data is not required for any reason, the sequence of reads should be inverted, therefore EMIOSB[n] should be read prior to EMIOSA[n] register. Note that even in this case B1 register updates will be blocked after EMIOSA[n] read, thus a second EMIOSB[n] is required in order to release B1 register updates.

37.6.1.1.5 Input Period Measurement (IPM) Mode

The IPM mode (MODE[0:6]=0000101) allows the measurement of the period of an input signal by capturing two consecutive rising edges or two consecutive falling edges. Successive input captures are done on consecutive edges of the same polarity. The edge polarity is defined by the EDPOL bit in the EMIOSC[n] register.

Note

The input signal must have at least four system clock cycles period in order to be properly captured by the synchronization logic at the channel input even if the input filter is in by-pass mode.

When the first edge of selected polarity is detected, the selected time base is latched into the registers A2 and B2, and the data previously held in register B2 is transferred to register B1. On this first capture the FLAG line is not set, and the values in registers B1 is meaningless. On the second and subsequent captures, the FLAG line is set and data in register B2 is transferred to register B1.

When the second edge of the same polarity is detected, the counter bus value is latched into registers A2 and B2, the data previously held in register B2 is transferred to data register B1 and to register A1. The FLAG bit is set to indicate the start and end points of a complete period have been captured. This sequence of events is repeated for each subsequent capture. Registers EMIOSA[n] and EMIOSB[n] return the values in register A2 and B1, respectively.

In order to allow coherent data, reading EMIOSA[n] forces A1 content be transferred to B1 register and disables transfers between B2 and B1. These transfers are disabled until the next read of the EMIOSB[n] register. Reading EMIOSB[n] register forces A1 content to be transferred to B1 and re-enables transfers from B2 to B1, to take effect at the next edge capture.

The input pulse period is calculated by subtracting the value in B1 from A2.

The following figure shows how the Unified Channel can be used for input period measurement.

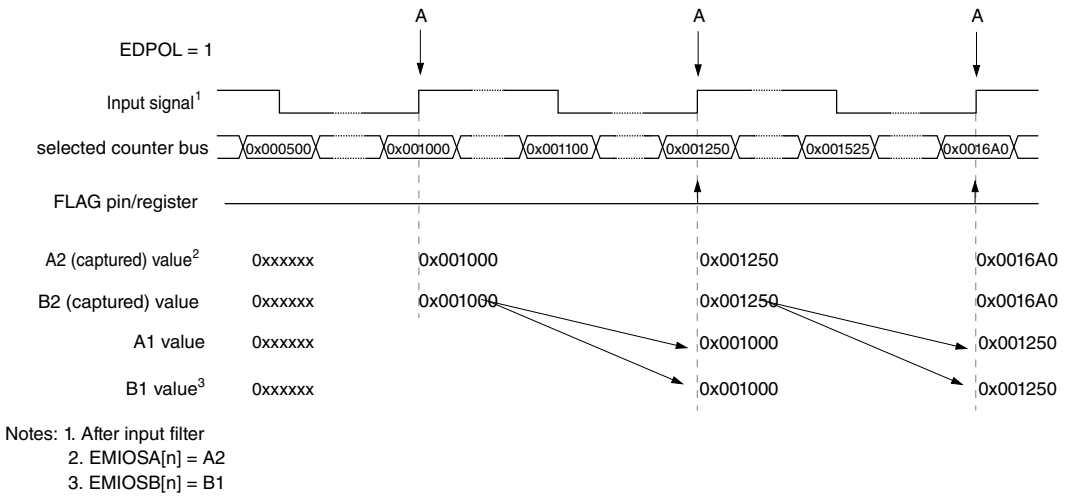

Figure 37-14. Input Period Measurement example

Figure 37-15 describes the A1 and B1 register updates when EMIOSA[n] and EMIOSB[n] read operations are performed. When EMIOSA[n] read occurs the content of A1 is transferred to B1 thus providing coherent data in A2 and B1 registers. Transfers from B2 to B1 are then blocked until EMIOSB[n] is read. After EMIOSB[n] is read, register A1 content is transferred to register B1 and the transfers from B2 to B1 are re-enabled to occur at the transfer edges, which is the leading edge in the following example figure.

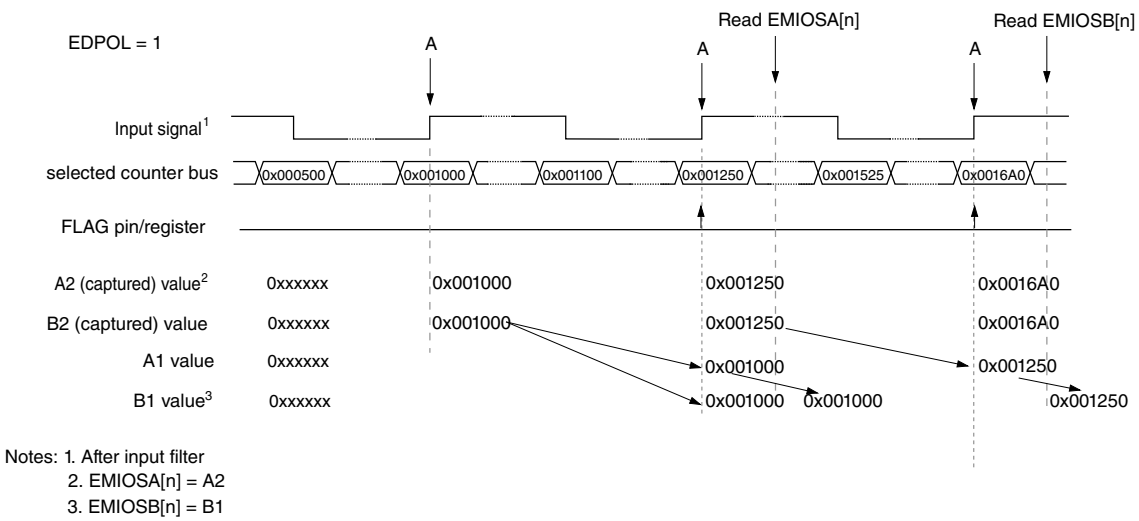

Figure 37-15. A1 and B1 updates at EMIOSA[n] and EMIOSB[n] reads

37.6.1.1.6 Double Action Output Compare (DAOC) Mode

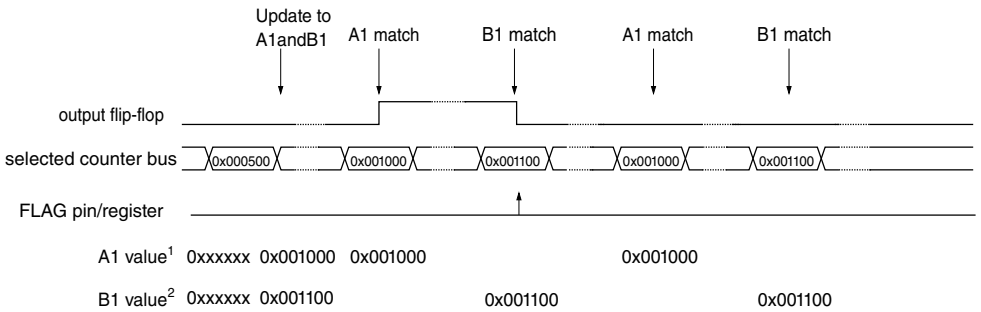
In the DAOC mode, the leading and trailing edges of the variable pulse width output are generated by matches occurring on comparators A and B. There is no restriction concerning the order in which A and B matches occur.

When the DAOC mode is entered, coming out from GPIO mode both comparators are disabled and the output flip-flop is set to the complement of the EDPOL bit in the EMIOSC[n] register.

Data written to A2 and B2 are transferred to A1 and B1, respectively, on the next system clock cycle if OU[n] bit of EMIOSOUDIS register is cleared (see Figure 37-31). The transfer is blocked if OU[n] bit is set. Comparator A is enabled only after the transfer to A1 register occurs and is disabled on the next A match. Comparator B is enabled only after the transfer to B1 register occurs and is disabled on the next B match. Comparators A and B are enabled and disabled independently.

The output flip-flop is set to the value of EDPOL when a match occurs on comparator A and to the complement of EDPOL when a match occurs on comparator B.

MODE[6] controls if the FLAG is set on both matches (MODE[0:6]=0000111) or just on the B match (MODE[0:6]=0000110). FLAG bit assertion depends on comparator enabling.

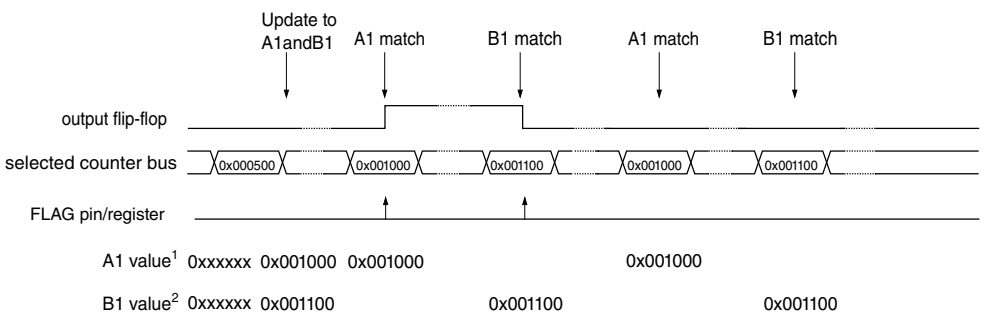


If subsequent enabled output compares occur on registers A1 and B1, pulses will continue to be generated, regardless of the state of the FLAG bit.

At any time, the FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a comparison event in comparator A or B, respectively. Note that the FLAG bit is not affected by these forced operations.

Note

If both registers (A1 and B1) are loaded with the same value, the B match prevails concerning the output pin state (output flip-flop is set to the complement of EDPOL), the FLAG bit is set and both comparators are disabled.



The following two tables show how the Unified Channel can be used to generate a single output pulse with FLAG bit being set on the second match or on both matches, respectively.

Notes:1. EMIOSA[n] = A1 (when reading)
2. EMIOSB[n] = B1 (when reading)

A2 = A1 according to OU[n] bit
B2 = B1 according to OU[n] bit

Figure 37-16. Double Action Output Compare with FLAG set on the second match, MODE[0] bit is 0

Notes:1. EMIOSA[n] = A1 (when reading)
2. EMIOSB[n] = B1 (when reading)

A2 = A1 according to OU[n] bit
B2 = B1 according to OU[n] bit

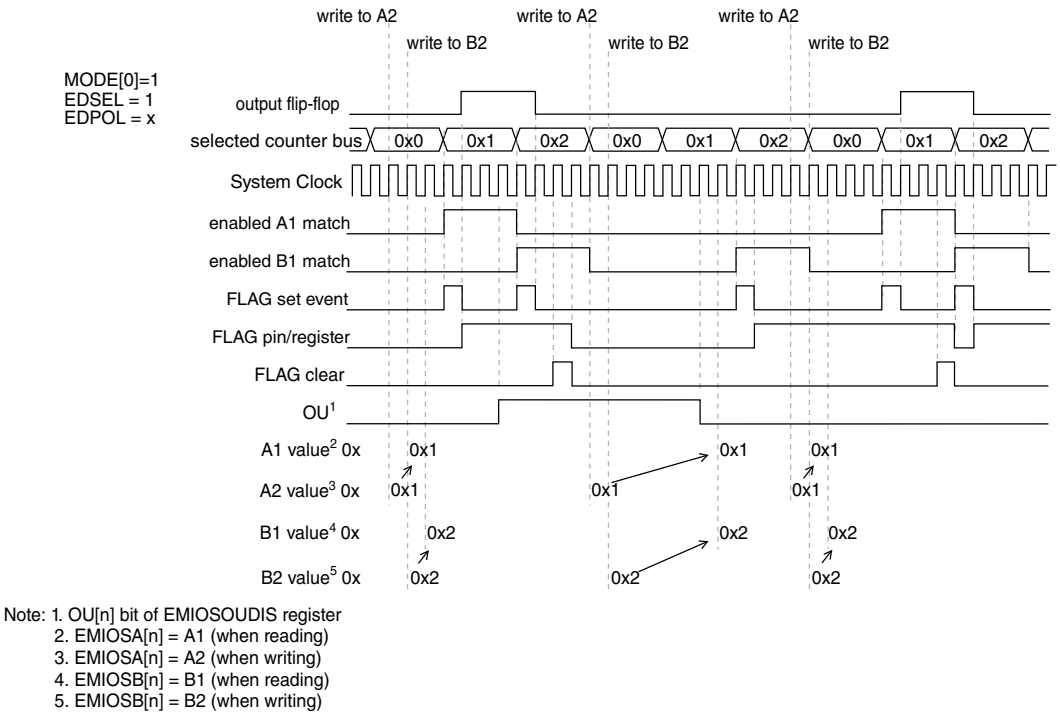

Figure 37-18. DAOC with transfer disabling example

37.6.1.1.7 Modulus Counter (MC) Mode

The MC mode can be used to provide a time base for a counter bus or as a general purpose timer.

MODE[6] bit selects internal or external clock source when cleared or set, respectively. When external clock is selected, the input signal pin is used as the source and the triggering polarity edge is selected by the EDPOL and EDSEL in the EMIOSC[n] register.

The internal counter counts up from the current value until it matches the value in register A1. Register B1 is cleared and is not accessible to the MCU. MODE[4] bit selects up mode or up/down mode, when cleared or set, respectively.

When in up count mode, a match between the internal counter and register A1 sets the FLAG and clears the internal counter. The timing of those events varies according to the MC mode setup as follows:

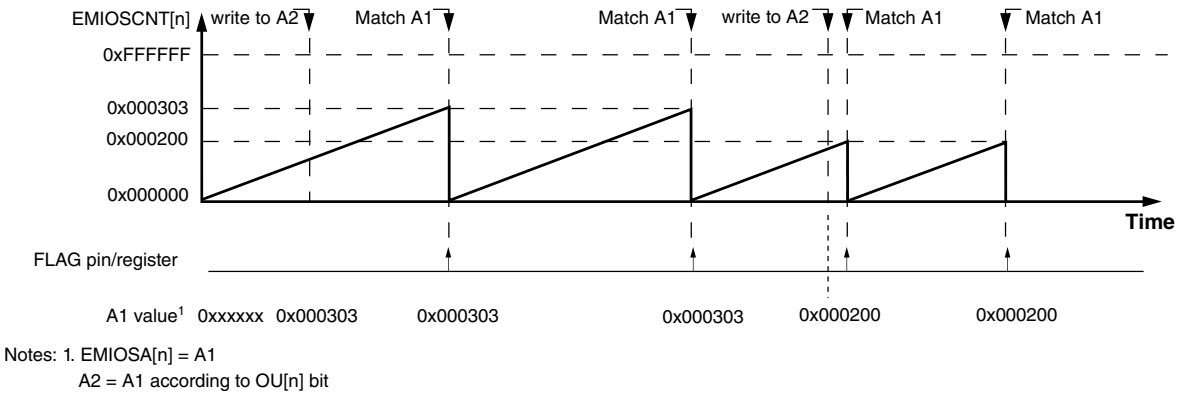
- Internal counter clearing on match start (MODE[0:6]=001000b)

- External clock is selected if MODE[0] is set. In this case the internal counter clears as soon as the match signal occurs. The channel FLAG is set at the same time the match occurs. Note that by having the internal counter cleared as soon as the match occurs and incremented at the next input event a shorter zero count is generated. See Figure 37-43 and Figure 37-44.
- Internal clock source is selected if MODE[0] is cleared. In this case the counter clears as soon as the match signal occurs. The channel FLAG is set at the same time the match occurs. At the next prescaler tick after the match the internal counter remains at zero and only resumes counting on the following tick. See Figure 37-43 and Figure 37-45.

- Internal counter clearing on match end (MODE[0:6]=001001b)
  - External clock is selected if MODE[0] is set. In this case the internal counter clears when the match signal is asserted and the input event occurs. The channel FLAG is set at the same time the counter is cleared. See Figure 37-43 and Figure 37-46.
  - Internal clock source is selected if MODE[0] is cleared. In this case the internal counter clears when the match signal is asserted and the prescaler tick occurs. The channel FLAG is set at the same time the counter is cleared. See Figure 37-43 and Figure 37-46.

Note

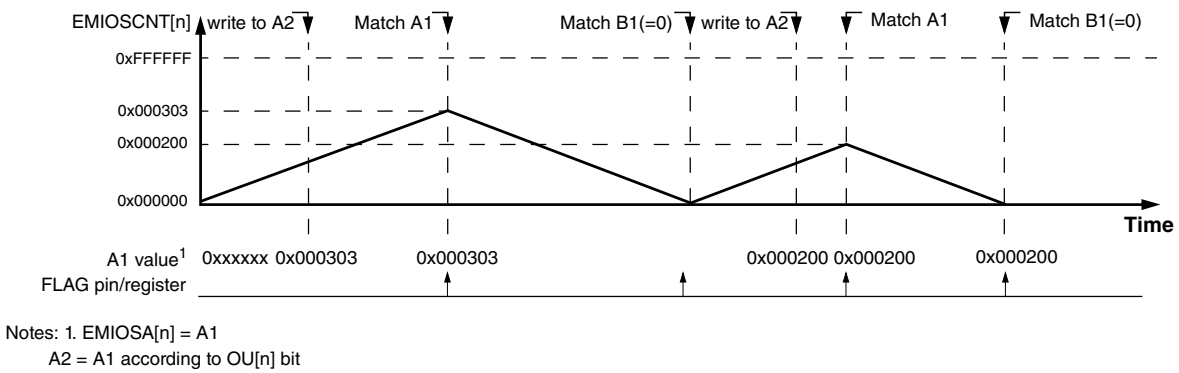
If internal clock source is selected and the prescaler of the internal counter is set to 1 the MC mode behaves the same way even in Clear on Match Start or Clear on Match End sub-modes.



When in up/down count mode (MODE[0:6]=00101bb), a match between the internal counter and register A1 sets the FLAG and changes the counter direction from increment to decrement. A match between register B1 and the internal counter changes the counter direction from decrement to increment and sets the FLAG only if MODE[5] bit is set.

Only values different than 0x0 must be written at A register. Loading 0x0 leads to unpredictable results.

Updates on register A or counter in MC mode may cause loss of match in the current cycle if the transfer occurs near the match. In this case, the counter may rollover and resume operation in the next cycle.



Register B2 has no effect in MC mode. Nevertheless, register B2 can be accessed for reads and writes by addressing EMIOSB.

The following two figures show how the Unified Channel can be used as modulus counter in up mode and up/down mode, respectively.

Notes: 1. EMIOSA[n] = A1
A2 = A1 according to OU[n] bit

Figure 37-19. Modulus Counter up mode example (MODE[4] bit is 0)

Notes: 1. EMIOSA[n] = A1
A2 = A1 according to OU[n] bit

Figure 37-20. Modulus Counter up/down mode example (MODE[4] bit is 1)

37.6.1.1.8 Modulus Counter Buffered (MCB) Mode

The MCB mode provides a time base which can be shared with other channels through the internal counter buses. Register A1 is double buffered thus allowing smooth transitions between cycles when changing A2 register value on the fly. Register A1 is updated at the cycle boundary, which is defined as when the internal counter transitions to 0x1.

The internal counter values operates within a range from 0x1 up to register A1 value. If when entering MCB mode coming out from GPIO mode the internal counter value is not within that range then the A match will not occur causing the channel internal counter to wrap at the maximum counter value which is 0xff_ffff for a 24-bit counter. After the counter wrap occurs it returns to 0x1 and resume normal MCB mode operation. Thus in order to avoid the counter wrap condition make sure its value is within the 0x1 to register A1 value range when the MCB mode is entered.

MODE[6] bit selects internal clock source if cleared or external if set. When external clock is selected the input channel pin is used as the channel clock source. The active edge of this clock is defined by EDPOL and EDSEL bits in the EMIOSC[n] channel register.

When entering in MCB mode, if up counter is selected by MODE[4]=0 (MODE[0:6]=101000b), the internal counter starts counting from its current value to up direction until A1 match occurs. The internal counter is set to 0x1 when its value matches A1 value and a clock tick occurs (either prescaled clock or input pin event).

If up/down counter is selected by setting MODE[4]=1, the counter changes direction at A1 match and counts down until it reaches the value 0x1. After it has reached 0x1 it is set to count in up direction again. Register B1 is used to generate a match in order to set the internal counter in up-count direction if up/down mode is selected. Register B1 cannot be changed while this mode is selected.

Note that differently from the MC mode, the MCB mode counts between 0x1 and A1 register value. Only values greater than 0x1 must be written at register A1. Loading values other than those leads to unpredictable results. The counter cycle period is equal to A1 value in up counter mode. If in up/down counter mode the period is defined by the expression: (2*A1)-2.

Figure 37-21 describes the counter cycle for several A1 values. Register A1 is loaded with A2 register value at the cycle boundary. Thus any value written to A2 register within cycle **n** will be updated to A1 at the next cycle boundary and therefore will be used on cycle **n+1**. The cycle boundary between cycle **n** and cycle **n+1** is defined as when the internal counter transitions from A1 value in cycle **n** to 0x1 in cycle **n+1** . Note that the FLAG is generated at the cycle boundary and has a synchronous operation, meaning that it is asserted one system clock cycle after the FLAG set event.

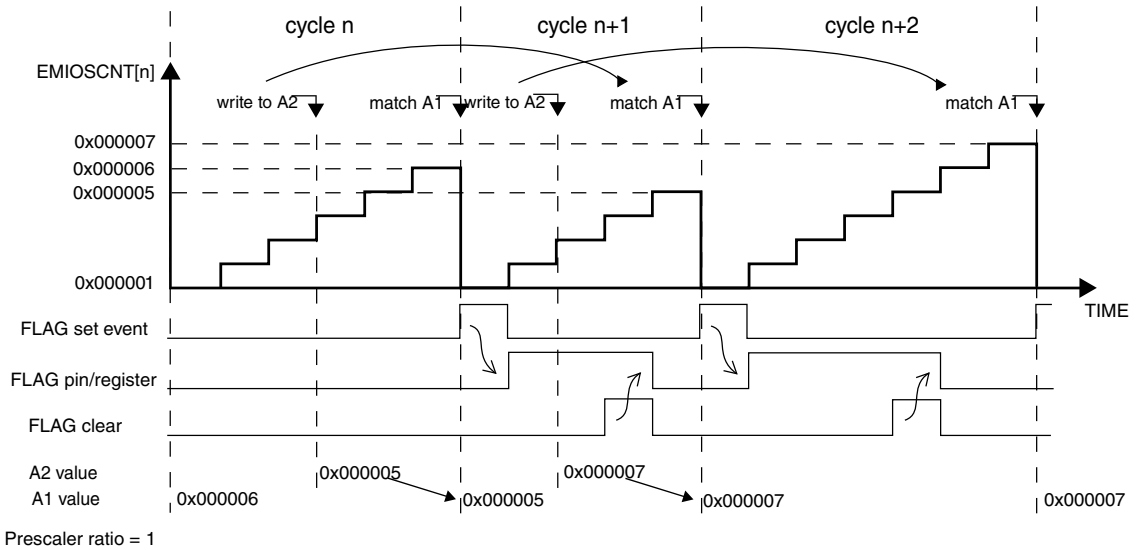


Figure 37-21. Modulus Counter Buffered (MCB) Up Count mode

Figure 37-22 describes the MCB in up/down counter mode (MODE[0:6]=10101bb). Register A1 is updated at the cycle boundary. If A2 is written in cycle **n**, this new value will be used in cycle **n+1** for A1 match. Flags are generated only at A1 match start if MODE[5] is 0. If MODE[5] is set to 1 flags are also generated at the cycle boundary.

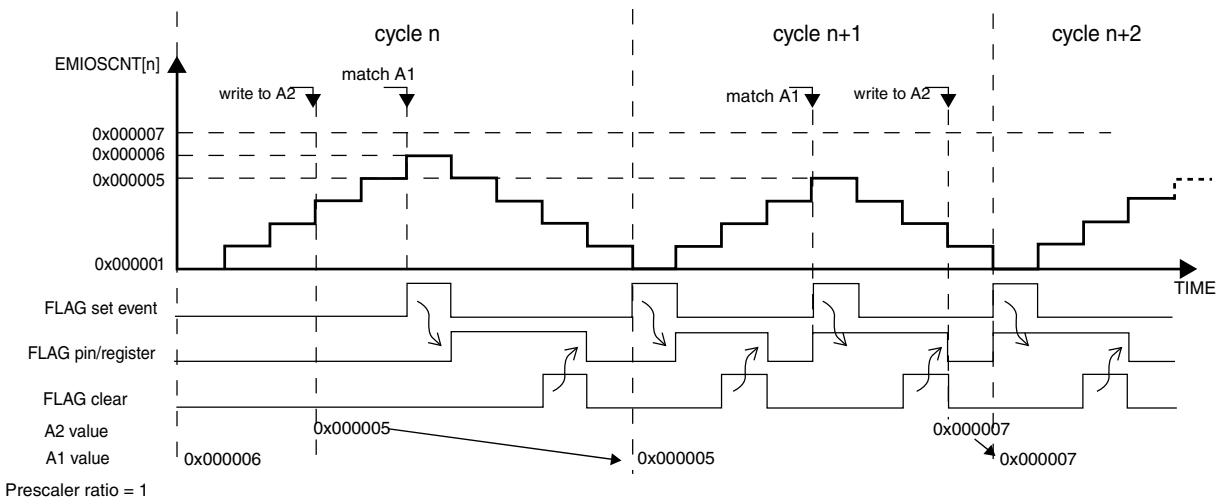

Figure 37-22. Modulus Counter Buffered (MCB) Up/Down Mode

The figure below describes in more detail, the register A1 update process in up counter mode. The A1 load signal is generated at the last system clock period of a counter cycle. Thus, A1 is updated with A2 value at the same time that the counter (EMIOSCNT[n]) is loaded with 0x1. The load signal pulse has the duration of one system clock period. If A2 is written within cycle **n** its value is available at A1 at the first clock of cycle **n+1** and the new value is used for match at cycle **n+1**. The update disable bits OU[n] of EMIOSOUDIS register can be used to control the update of this register, thus allowing to delay the A1 register update for synchronization purposes.

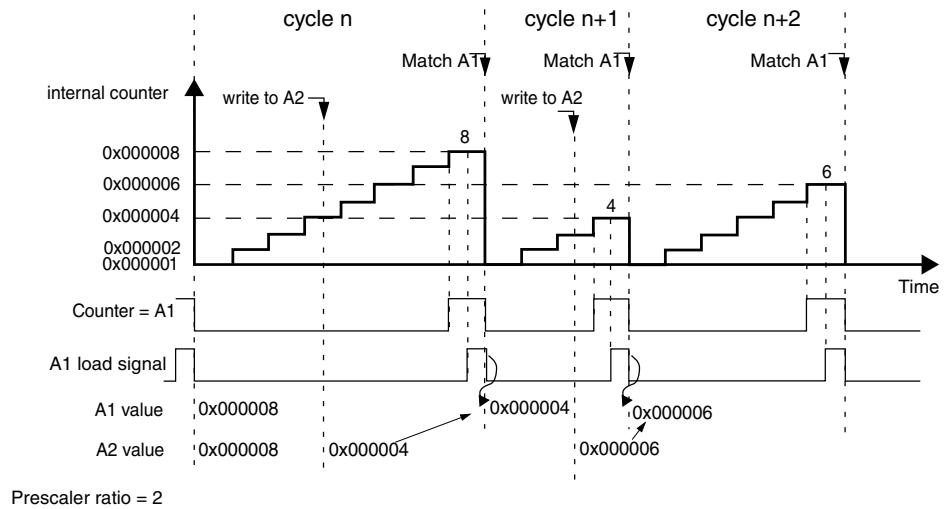

Figure 37-23. MCB Mode Register A1 Update in Up Counter Mode

The figure below describes the register A1 update in up/down counter mode. Note that A2 can be written at any time within cycle **n** in order to be used in cycle **n+1**. Thus A1 receives this new value at the next cycle boundary. Note that the update disable bits OU[n] of EMIOSOUDIS register can be used to disable the update of register A1.

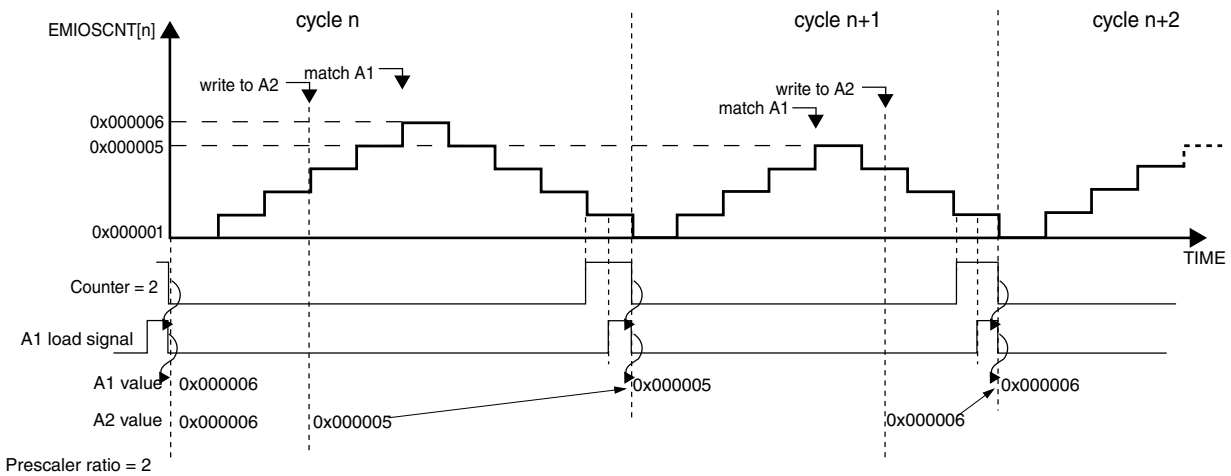

Figure 37-24. MCB Mode Register A1 Update in Up/Down Counter Mode

37.6.1.1.9 Output Pulse Width and Frequency Modulation Buffered (OPWFMB) Mode

This mode (MODE[0:6]=10110b0) provides waveforms with variable duty cycle and frequency. The internal channel counter is automatically selected as the time base when this mode is selected. Register A1 indicates the duty cycle and B1 register the frequency. Both registers A1 and B1 are double buffered to allow smooth signal generation when changing the registers values.. 0% and 100% duty cycles are supported.

At OPWFMB mode entry, the output flip-flop is set to the value of the EDPOL bit in the EMIOSC[n] register.

In order to provide smooth and consistent channel operation this mode differs substantially from the OPWFM mode. The main differences reside in the A1 and B1 registers update, on the delay from the A1 match to the output pin transition and on the range of the internal counter values which starts from 0x1 up to register B1 value.

When entering OPWFMB mode coming out of GPIO mode, the internal counter value is not within that range then the B match will not occur causing the channel internal counter to wrap at the maximum counter value which is 0xff_ffff for a 24-bit counter. After the counter wrap occurs it returns to 0x1 and resume normal OPWFMB mode operation. Thus in order to avoid the counter wrap condition make sure its value is within the 0x1 to B1 register value range when the OPWFMB mode is entered.

When a match on comparator A occurs the output register is set to the value of EDPOL. When a match on comparator B occurs the output register is set to the complement of EDPOL. B1 match also causes the internal counter to transition to 0x1, thus restarting the counter cycle.

Only values greater than 0x1 are allowed to be written to register B1. Loading values other than those leads to unpredictable results.

Figure 37-25 describes the operation of the OPWFMB mode regarding output pin transitions and A1/B1 registers match events. Note that the output pin transition occurs when the A1 or B1 match signal is deasserted which is indicated by the A1 match negedge detection signal. If register A1 is set to 0x4 the output pin transitions 4 counter periods after the cycle had started, plus one system clock cycle. Note that in the example shown in Figure 37-25 the internal counter prescaler has a ratio of two.

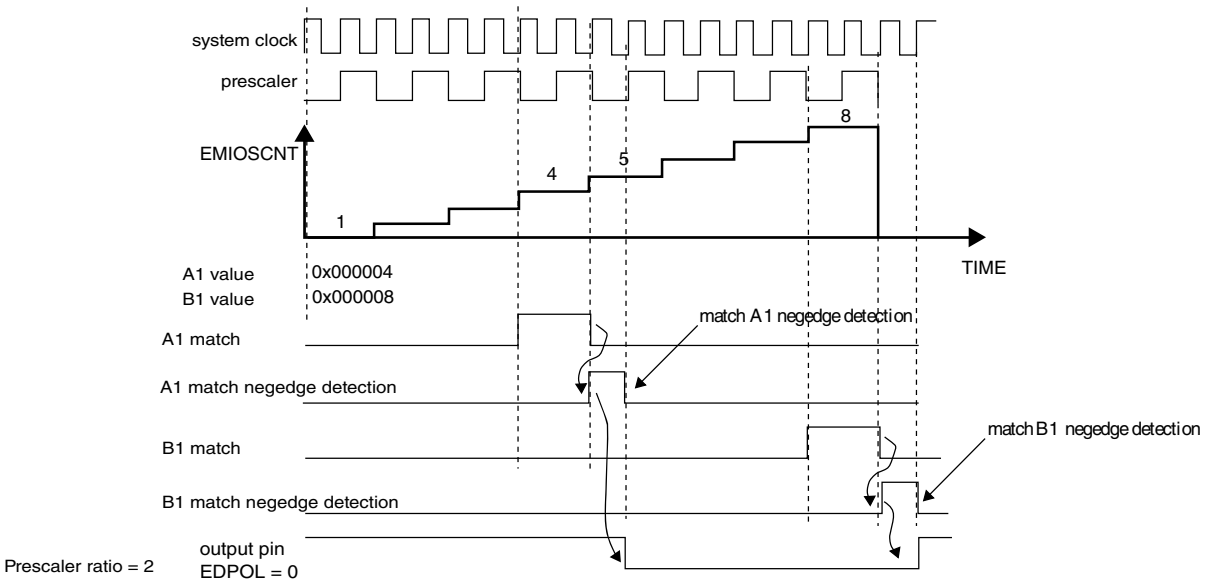

Figure 37-25. OPWFMB A1 and B1 match to Output Register Delay

Figure 37-26 describes the generated output signal if A1 is set to 0x0. Since the counter does not reach zero in this mode, the channel internal logic infers a match as if A1=0x1 with the difference that in this case, the posedge of the match signal is used to trigger the output pin transition instead of the negedge used when A1=0x1. Note that A1 posedge match signal from cycle **n+1** occurs at the same time as B1 negedge match signal from cycle **n** . This allows to use the A1 posedge match to mask the B1 negedge match when they occur at the same time. The result is that no transition occurs on the output flip-flop and a 0% duty cycle is generated.

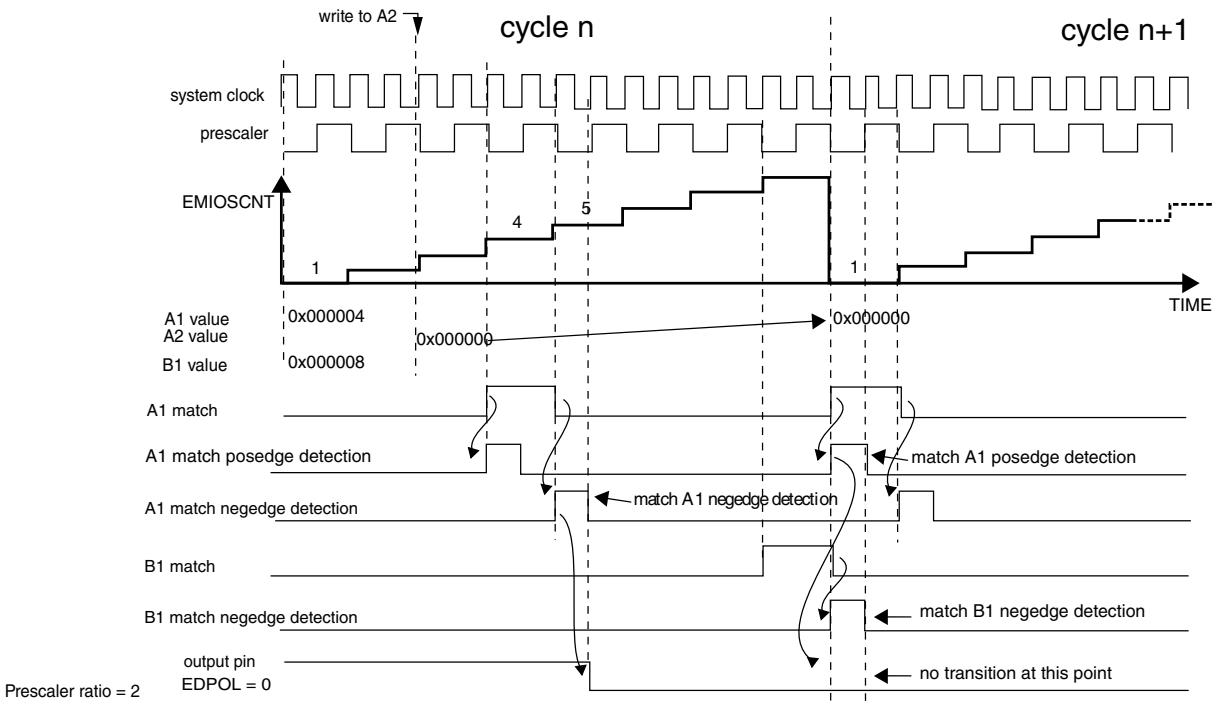

Figure 37-26. OPWFMB Mode with A1 = 0 (0% duty cycle)

Figure 37-27 describes the timing for the A1 and B1 registers load. The A1 and B1 load use the same signal which is generated at the last system clock period of a counter cycle. Thus, A1 and B1 are updated respectively with A2 and B2 values at the same time that the counter (EMIOSCNT[n]) is loaded with 0x1. This event is defined as the cycle boundary. The load signal pulse has the duration of one system clock period. If A2 and B2 are written within cycle **n** their values are available at A1 and B1, respectively, at the first clock of cycle **n+1** and the new values are used for matches at cycle **n+1**. The update disable bits OU[n] of EMIOSOUDIS register can be used to control the update of these registers, thus allowing to delay the A1 and B1 registers update for synchronization purposes.

In Figure 37-27, it is assumed that both the channel and global prescalers are set to 0x1 (each divide ratio is two), meaning that the channel internal counter transitions at every four system clock cycles. FLAGs can be generated only on B1 matches when MODE[5] is cleared, or on both A1 and B1 matches when MODE[5] is set. Since B1 flag occurs at the cycle boundary, this flag can be used to indicate that A2 or B2 data written on cycle **n** were loaded to A1 or B1, respectively, thus generating matches in cycle **n+1**. Note that the FLAG has a synchronous operation, meaning that it is asserted one system clock cycle after the FLAG set event.

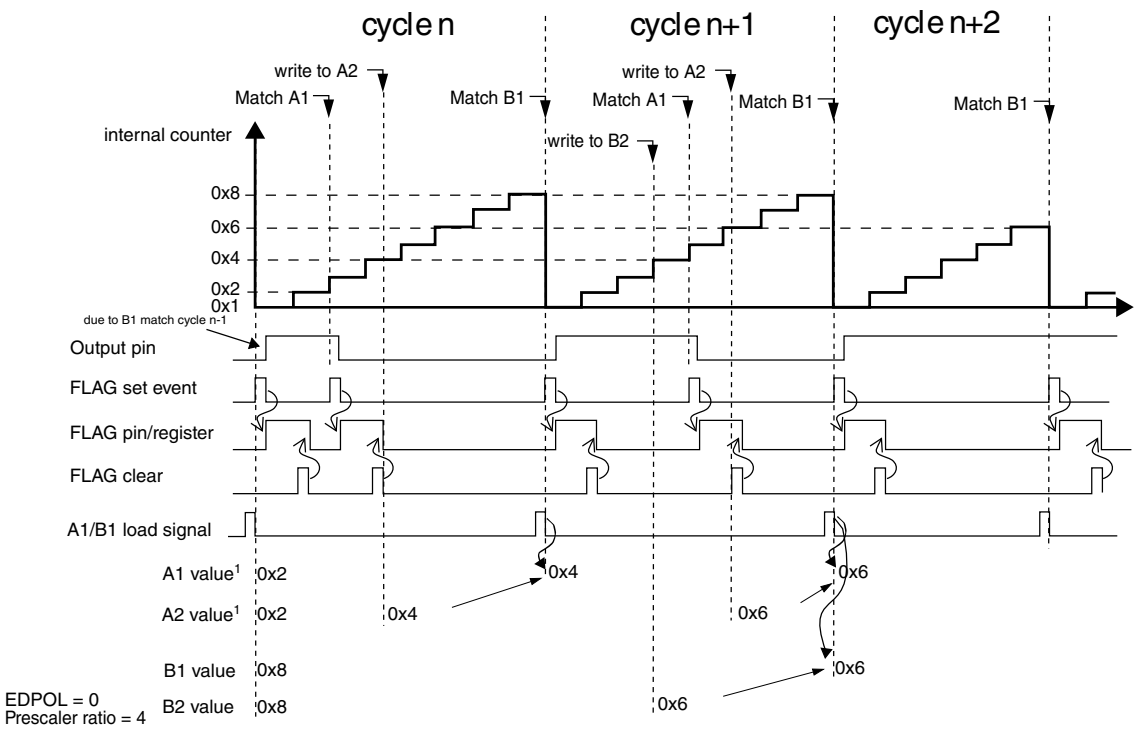

Figure 37-27. OPWFMB A1 and B1 Registers Update and Flags (MODE6] bit is 0b)

Figure 37-28 describes the operation of the Output Disable feature in OPWFMB mode. Differently from the OPWFM mode, the output disable forces the channel output flip-flop to EDPOL bit value. This functionality targets applications that use active high signals and a high to low transition at A1 match. In this case EDPOL should be set to 0. Note that both the channel and global prescalers are set to 0x0 (each divide ratio is one), meaning that the channel internal counter transitions at every system clock cycle.

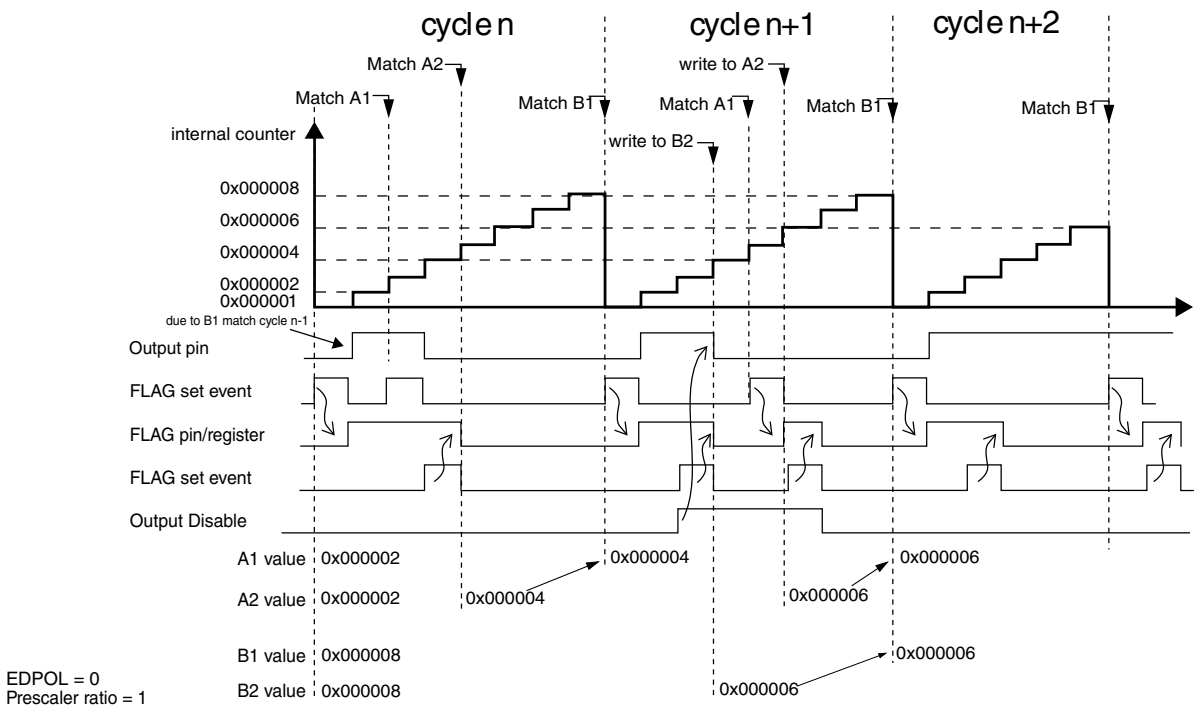

Figure 37-28. OPWFMB Mode with Active Output Disable (MODE[6] bit is 1b)

Note that the output disable has a synchronous operation, meaning that the assertion of the Output Disable input pin causes the channel output flip-flop to transition to EDPOL at the next system clock cycle. If the Output Disable input is deasserted the output pin transition at the following A1 or B1 match.

In Figure 37-28, it is assumed that the Output Disable input is enabled and selected for the Channel. Please, refer to UC Control Register (EMIOSCn) for a detailed description about the ODIS and ODISSL bits, respectively enable and selection of the Output Disable inputs.

The FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a match on comparators A or B respectively. Similarly to a B1 match FORCMB sets the internal counter to 0x1. The FLAG bit is not set by the FORCMA or FORCMB bits being asserted.

Figure 37-29 describes the generation of 100% and 0% duty cycle signals. It is assumed EDPOL =0 and the resultant prescaler value is 1. Initially, A1=0x8 and B1=0x8. In this case, B1 match has precedence over A1 match, thus the output flip-flop is set to the complement of EDPOL bit. This cycle corresponds to a 100% duty cycle signal. The same output signal can be generated for any A1 value greater or equal to B1.

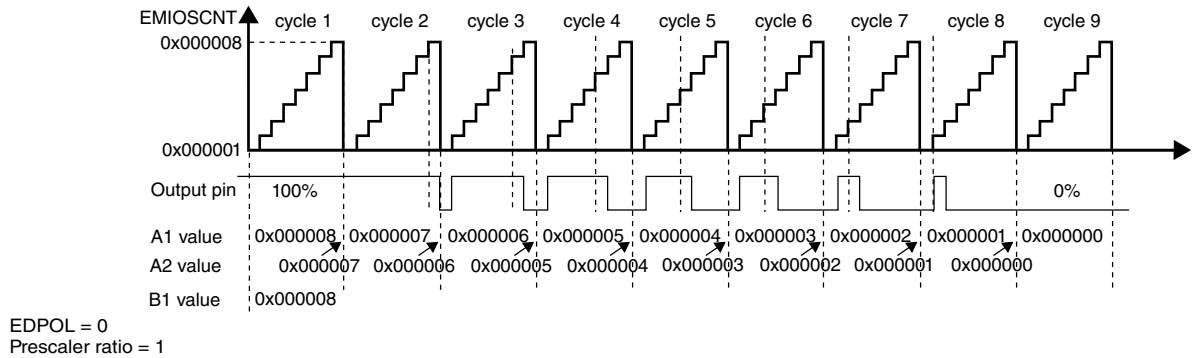

Figure 37-29. OPWFMB Mode from 100% to 0% Duty Cycle

A 0% duty cycle signal is generated if A1=0x0 as shown in Figure 37-29 cycle 9. In this case B1=0x8 match from cycle 8 occurs at the same time as the A1=0x0 match from cycle 9. Please, refer to Figure 37-26 for a description of the A1 and B1 match generation. In this case A1 match has precedence over B1 match and the output signal transitions to EDPOL.

37.6.1.1.10 Center Aligned Output Pulse Width Modulation with Dead Time Insertion Buffered (OPWMCB) Mode

This operation mode generates a center aligned PWM with dead time insertion to the leading (MODE[0:6]=10111b1) or trailing edge (MODE[0:6]=10111b0). A1 and B1 registers are double buffered to allow smooth output signal generation when changing A2 or B2 registers values.

BSL[0:1] bits select the time base. The time base selected for a channel configured to OPWMCB mode should be a channel configured to MCB Up/Down mode, as shown in Figure 37-22 . It is recommended to start the MCB channel time base after the OPWMCB mode is entered in order to avoid missing A matches at the very first duty cycle.

Register A1 contains the ideal duty cycle for the PWM signal and is compared with the selected time base.

Register B1 contains the dead time value and is compared against the internal counter. For a leading edge dead time insertion, the output PWM duty cycle is equal to the difference between register A1 and register B1, and for a trailing edge dead time insertion, the output PWM duty cycle is equal to the sum of register A1 and register B1. Mode[6] bit selects between trailing and leading dead time insertion, respectively.

Note

The internal counter runs in the internal prescaler ratio, while the selected time base may be running in a different prescaler ratio.

When OPWMCB mode is entered, coming out from GPIO mode, the output flip-flop is set to the complement of the EDPOL bit in the EMIOSC[n] register.

The following basic steps summarize proper OPWMCB startup, assuming the channels are initially in GPIO mode:

1. *[global]* Disable Global Prescaler.
2. *[MCB channel]* Disable Channel Prescaler.
3. *[MCB channel]* Write 0x1 at internal counter.
4. *[MCB channel]* Set A register.
5. *[MCB channel]* Set channel to MCB Up mode.
6. *[MCB channel]* Set prescaler ratio.
7. *[MCB channel]* Enable Channel Prescaler.
8. *[OPWMCB channel]* Disable Channel Prescaler.
9. *[OPWMCB channel]* Set A register.
10. *[OPWMCB channel]* Set B register.
11. *[OPWMCB channel]* Select time base input through BSL[1:0] bits.
12. *[OPWMCB channel]* Enter OPWMCB mode.
13. *[OPWMCB channel]* Set prescaler ratio.
14. *[OPWMCB channel]* Enable Channel Prescaler.
15. *[global]* Enable Global Prescaler.

The following figure describes the load of A1 and B1 registers which occurs when the selected counter bus transitions from 0x2 to 0x1 . This event defines the cycle boundary. Note that values written to A2 or B2 within cycle **n** are loaded into A1 or B1 registers, respectively, and used to generate matches in cycle **n+1** .

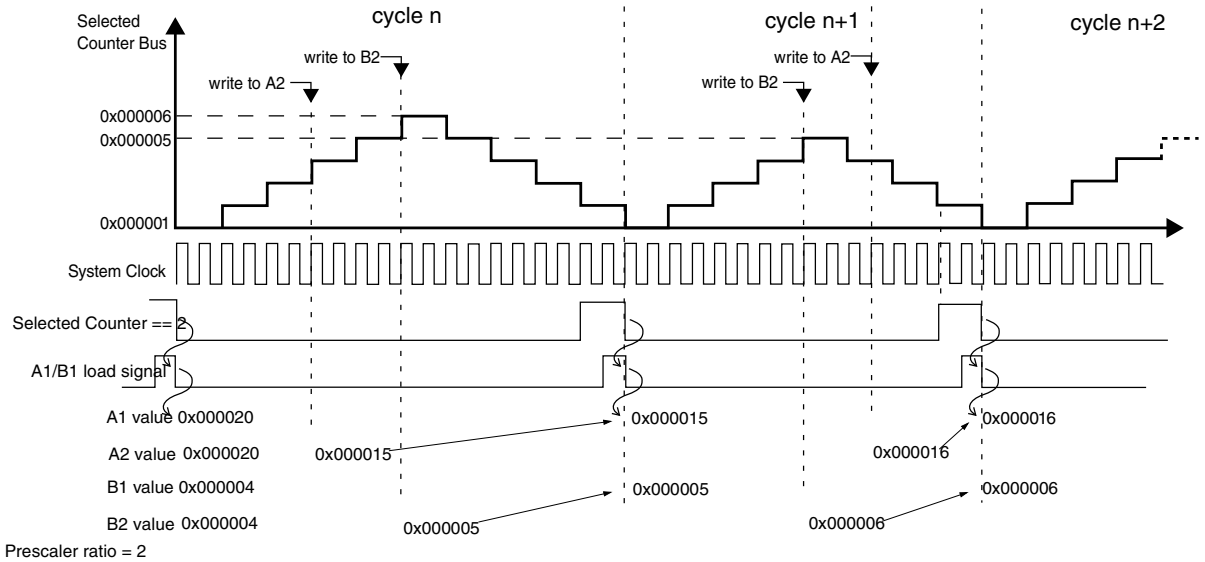

Figure 37-30. OPWMCB A1 and B1 registers load

The OU[n] bit of EMIOSOUDIS register can be used to disable the A1 and B1 updates, thus allowing to synchronize the load on these registers with the load of A1 or B1 registers in others channels. Note that using the update disable bit A1 and B1 registers can be updated at the same counter cycle thus allowing to change both registers at the same time.

In this mode, A1 matches always sets the internal counter to 0x1 . When operating with leading edge dead time insertion the first A1 match sets the internal counter to 0x1. When a match occurs between register B1 and the internal time base, the output flip-flop is set to the value of the EDPOL bit. In the following match between register A1 and the selected time base, the output flip-flop is set to the complement of the EDPOL bit. This sequence repeats continuously. The internal counter should not reach 0x0 as consequence of a rollover. In order to avoid it, the user should not write to EMIOSB register a value greater than twice the difference between external count up limit and EMIOSA value.

The following figure shows two cycles of a Center Aligned PWM signal. Note that both A1 and B1 register values are changing within the same cycle which allows to vary at the same time the duty cycle and dead time values.

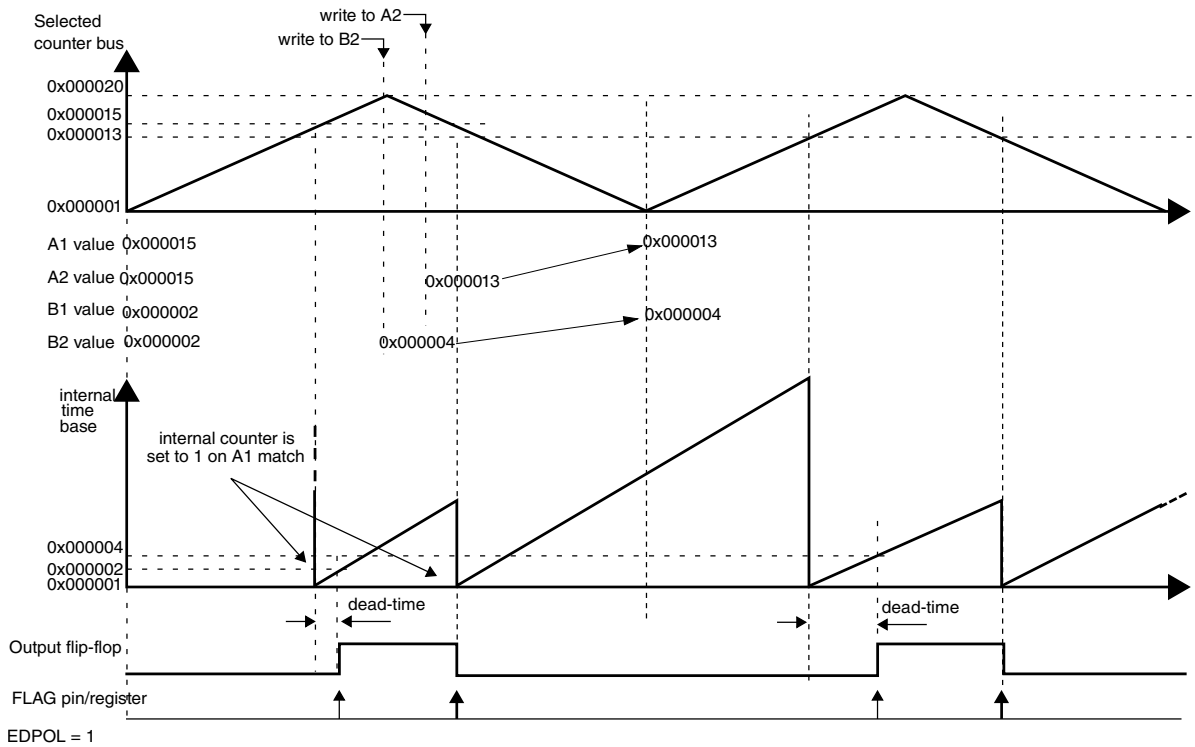

Figure 37-31. OPWMCB with Lead Dead Time Insertion

When operating with trailing edge dead time insertion, the first match between A1 and the selected time base sets the output flip-flop to the value of the EDPOL bit and sets the internal counter to 0x1. In the second match between register A1 and the selected time base, the internal counter is set to 0x1 and B1 matches are enabled. When the match between register B1 and the selected time base occurs the output flip-flop is set to the complement of the EDPOL bit. This sequence repeats continuously.

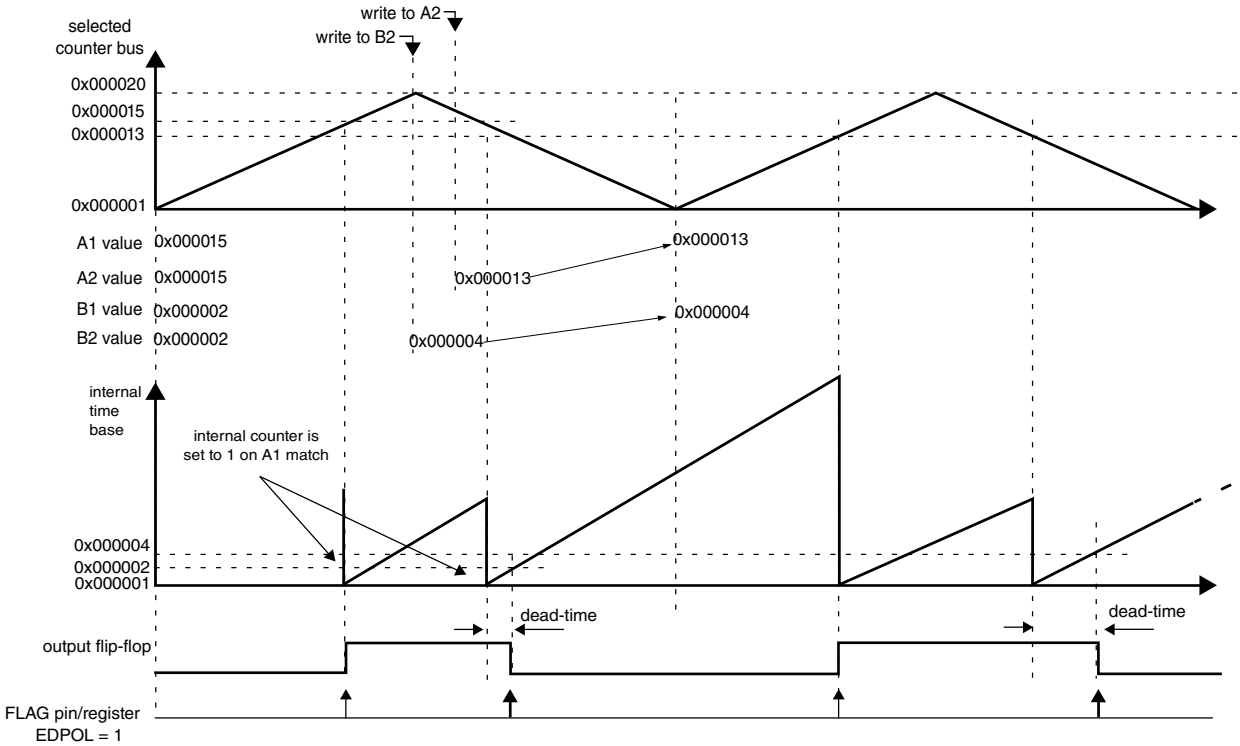

Figure 37-32. OPWMCB with Trail Dead Time Insertion

A FLAG can be generated in the trailing edge of the output PWM signal when MODE[5] is cleared, or in both edges, when MODE[5] is set. If subsequent matches occur on comparators A and B, the PWM pulses continue to be generated, regardless of the state of the FLAG bit.

Note

In OPWMCB mode FORCMA and FORCMB do not have the same behavior as a regular match. Instead they force the output flip-flop to constant value which depends upon the selected dead time insertion mode, lead or trail and the value of the EDPOL bit.

FORCMA has different behaviors depending upon the selected dead time insertion mode, lead or trail. In lead dead time insertion FORCMA force a transition in the output flip-flop to the opposite of EDPOL. In trail dead time insertion the output flip-flop is forced to the value of EDPOL bit.

If FORCMB bit is set, the output flip-flop value depends upon the selected dead time insertion mode. In lead dead time insertion FORCMB forces the output flip-flop to transition to EDPOL bit value. In trail dead time insertion the output flip-flop is forced to the opposite of EDPOL bit value.

Note

FORCMA bit set does not set the internal time-base to 0x1 as a regular A1 match.

The FLAG bit is not set either in case of a FORCMA or FORCMB or even if both forces are issued at the same time.

Note

FORCMA and FORCMB have the same behavior even in Freeze or normal mode regarding the output pin transition.

When *FORCMA* is issued along with *FORCMB* the output flip-flop is set to the opposite of EDPOL bit value. This is equivalent of saying that *FORCMA* has precedence over *FORCMB* when lead dead time insertion is selected and *FORCMB* has precedence over *FORCMA* when trail dead time insertion is selected.

A duty cycle from 0% to 100% can be generated by setting appropriate values to A1 and B1 registers relatively to the period of the external time base. Setting A1=0x1 generates a 100% duty cycle waveform. Assuming EDPOL is set to one and OPWMCB mode with trail dead time insertion, 100% duty cycle signals can be generated if B1 occurs at or after the cycle boundary (external counter = 1). If A1 is greater than the maximum value of the selected counter bus period, then a 0% duty cycle is produced, only if the pin starts the current cycle in the opposite of EDPOL value. In case of 100% duty cycle, the transition from EDPOL to the opposite of EDPOL may be obtained by forcing pin, using FORCMA and/or FORCMB.

Note

If A1 is set to 0x1 at OPWMCB entry the 100% duty cycle may not be obtained in the very first PWM cycle due to the pin condition at mode entry.

Only values different than 0x0 are allowed to be written to A1 register. If 0x0 is loaded to A1, the results are unpredictable.

Note

A special case occurs when A1 is set to (external counter bus period)/2, which is the maximum value of the external counter. In this case the output flip-flop is constantly set to the EDPOL bit value.

The internal channel logic prevents matches from one cycle to propagate to the next cycle. In trail dead time insertion B1 match from cycle **n** could eventually cross the cycle boundary and occur in cycle **n+1.** In this case B1 match is masked out and does not cause the output flip-flop to transition. Therefore matches in cycle **n+1** are not affected by the late B1 matches from cycle **n**.

The following figure shows a 100% duty cycle output signal generated by setting A1=0x4 and B1=0x3. In this case, the trailing edge is positioned at the boundary of cycle **n+1**, which is actually considered to belong to cycle **n+2** and therefore does not cause the output flip-flip to transition.

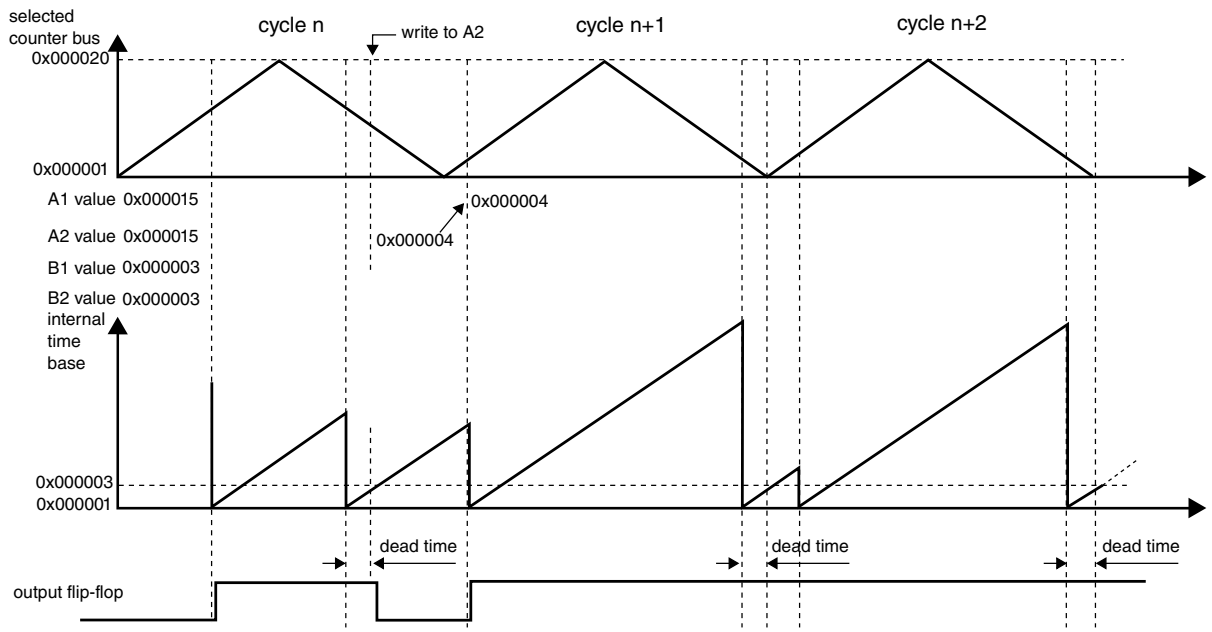

Figure 37-33. OPWMCB with 100% Duty Cycle (A1=4 and B1=3)

The output disable feature, if enabled, causes the output flip-flop to transition to the EDPOL inverted state. This feature allows an application to force the channel output pin to a "safe" state. The internal channel matches continue to occur even in this case, thus generating Flags. As soon as the output disable is deasserted, the channel output pin is again controlled by A1 and B1 matches. Note that this process is synchronous, meaning that the output channel pin transitions only on system clock edges.

It is important to notice that, such as in OPWMB and OPWFMB modes, the match signal used to set or clear the channel output flip-flop is generated on the deassertion of the channel combinational comparator output signal which compares the selected time base with A1 or B1 register values. Please refer to Figure 37-25, which describes the delay from matches to output flip-flop transition in OPWFMB mode. The operation of OPWMCB mode is similar to OPWFMB regarding matches and output pin transition.

37.6.1.1.11 Output Pulse Width Modulation Buffered (OPWMB) Mode

OPWMB mode (MODE[0:6]=11000b0) is used to generate pulses with programmable leading and trailing edge placement. An external counter driven in MCB Up mode must be selected from one of the counter buses. A1 register value defines the first edge and B1

the second edge. The output signal polarity is defined by the EDPOL bit. If EDPOL is zero, a negative edge occurs when A1 matches the selected counter bus and a positive edge occurs when B1 matches the selected counter bus.

The A1 and B1 registers are double buffered and updated from A2 and B2, respectively, at the cycle boundary. The load operation is similar to the OPWFMB mode. Please refer to Figure 37-27 for more information about A1 and B1 registers update.

FLAG can be generated at B1 matches, when MODE[5] is cleared, or in both A1 and B1 matches, when MODE[5] is set. If subsequent matches occur on comparators A and B, the PWM pulses continue to be generated, regardless of the state of the FLAG bit.

FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a match on A1 or B1 respectively. The FLAG bit is not set by the FORCMA and FORCMB operations.

At OPWMB mode entry the output flip-flop is set to the value of the EDPOL bit in the EMIOSC[n] register.

Some rules applicable to the OPWMB mode are:

- B1 matches have precedence over A1 matches if they occur at the same time within the same counter cycle
- A1=0 match from cycle **n** has precedence over B1 match from cycle **n-1**
- A1 matches are masked out if they occur after B1 match within the same cycle
- Any value written to A2 or B2 on cycle **n** is loaded to A1 and B1 registers at the following cycle boundary (assuming OU[n] bit of EMIOSOUDIS register is not asserted). Thus the new values will be used for A1 and B1 matches in cycle **n+1**

The following figure describes the operation of the OPWMB mode regarding A1 and B1 matches and the transition of the channel output pin. In this example EDPOL is set to zero.

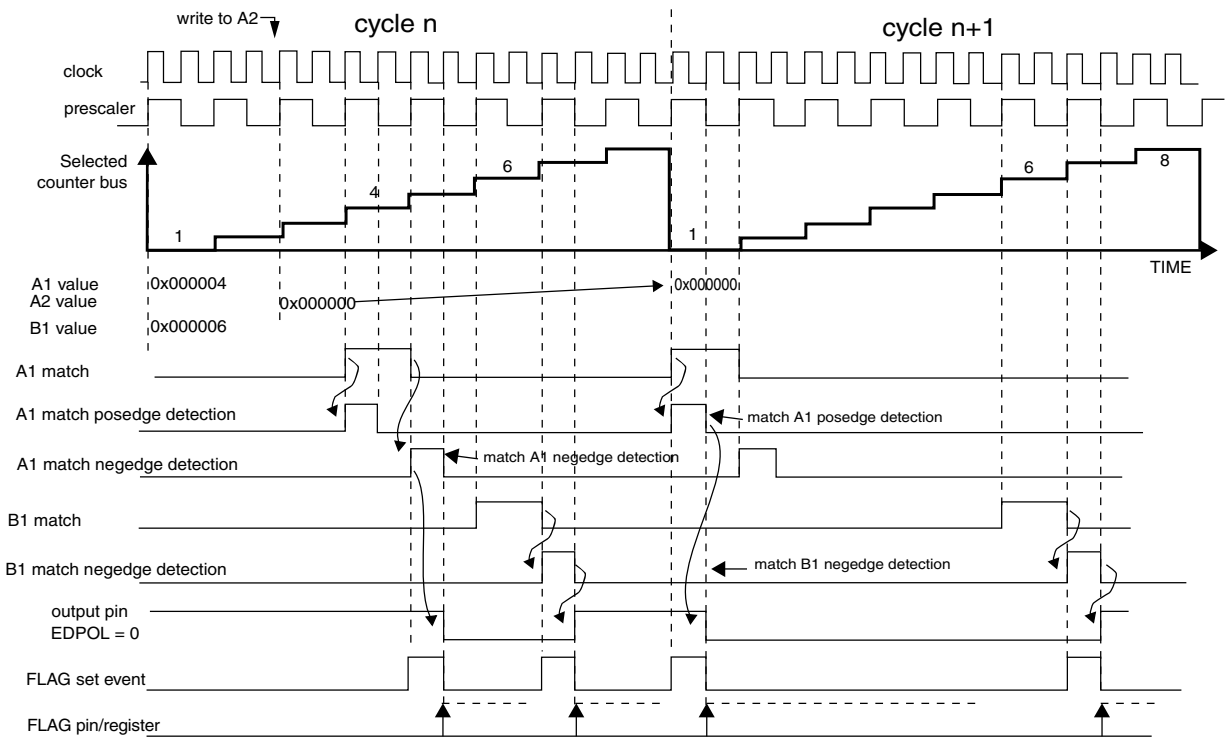

Figure 37-34. OPWMB Mode Matches and Flags

Note that the output pin transitions are based on the negedges of the A1 and B1 match signals. The figure above shows in cycle **n+1** the value of A1 register being set to zero. In this case the match posedge is used instead of the negedge to transition the output flip-flop.

The figure below describes the channel operation for 0% duty cycle. Note that the A1 match posedge signal occurs at the same time as the B1=0x8 negedge signal. In this case A1 match has precedence over B1 match, causing the output pin to remain at EDPOL bit value, thus generating a 0% duty cycle signal.

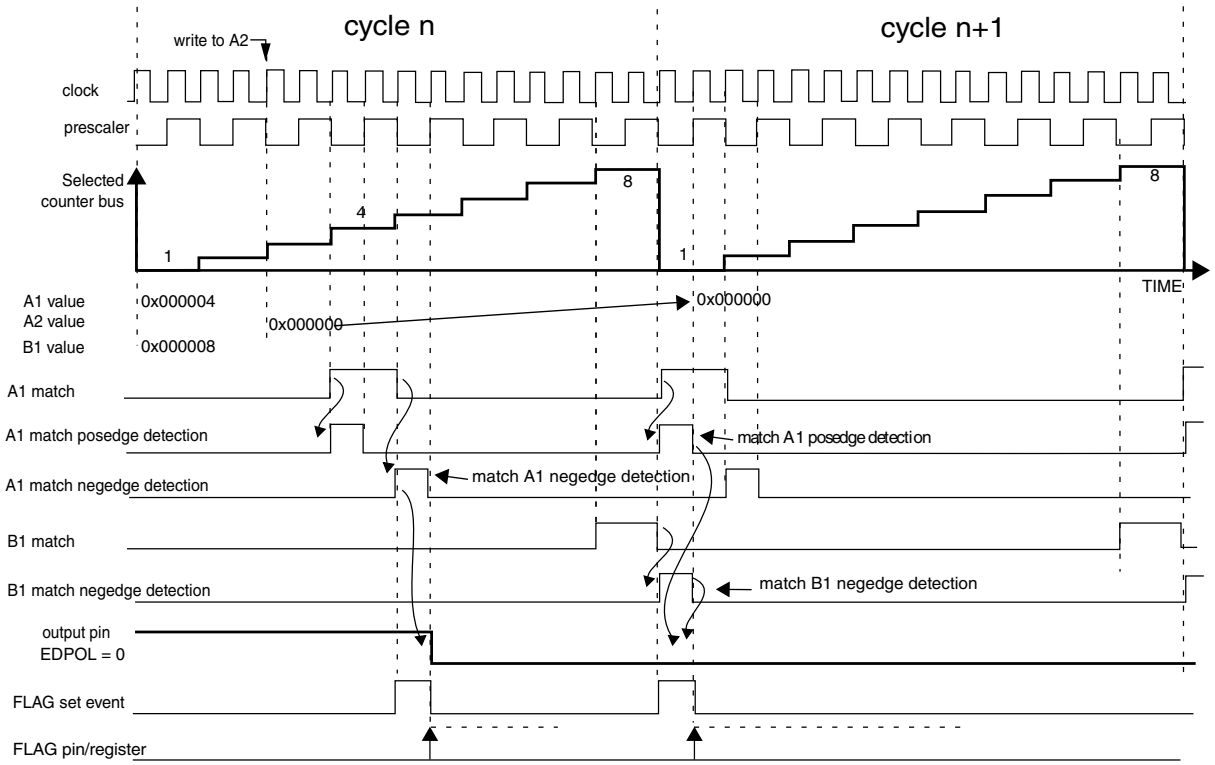

Figure 37-35. OPWMB Mode with 0% Duty Cycle

Figure 37-36 describes the operation of the OPWMB mode with the Output Disable signal being asserted. The Output Disable forces a transition in the output pin to the EDPOL bit value. After deasserted, the output disable allows the output pin to transition at the following A1 or B1 match. Note that the Output Disable does not modify the Flag bit behavior. Note that there is one system clock delay between the assertion of the output disable signal and the transition of the output pin to EDPOL.

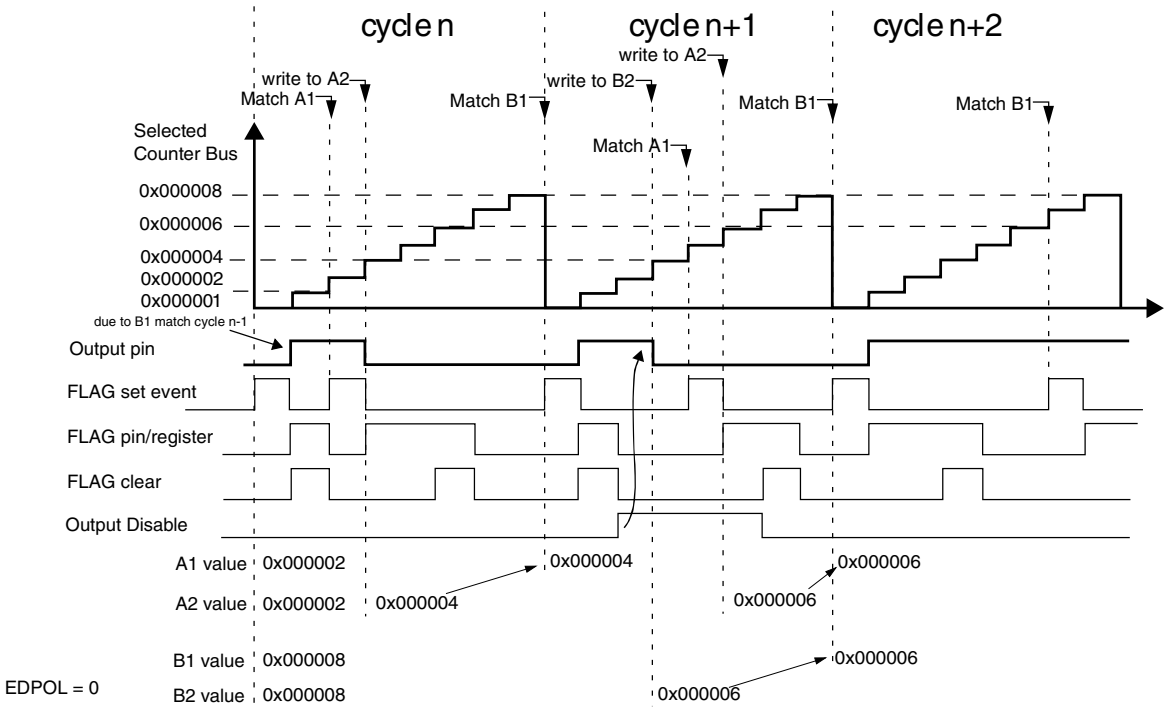

Figure 37-36. OPWMB Mode with Active Output Disable (MODE[6] bit is 1b)

Figure 37-37 shows a waveform changing from 100% to 0% duty cycle. EDPOL in this case is zero. In this example, B1 is programmed to the same value as the period of the external selected time base.

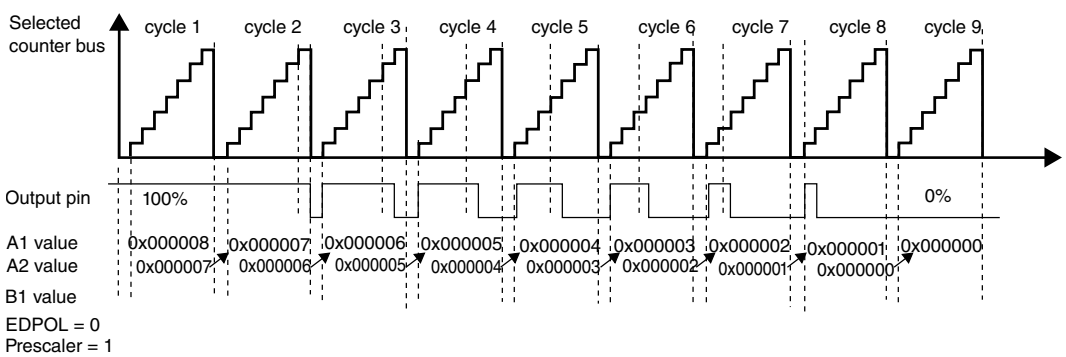

Figure 37-37. OPWMB Mode from 100% to 0% Duty Cycle

In Figure 37-37, if B1 is set to a value lower than 0x8, it is not possible to achieve 0% duty cycle by only changing A1 register value. Since B1 matches have precedence over A1 matches the output pin transitions to the opposite of EDPOL bit at B1 match. Note also that if B1 is set to 0x9, for instance, B1 match does not occur, thus a 0% duty cycle signal is generated.

37.6.1.1.12 Output Pulse Width Modulation with Trigger (OPWMT) Mode

OPWMT mode (MODE[0:6]=0100110) is intended to support the generation of Pulse Width Modulation signals where the period is not modified while the signal is being output, but where the duty cycle will be varied and must not create glitches. The mode is intended to be used in conjunction with other channels executing in the same mode and sharing a common timebase. It will support each channel with a fixed PWM leading edge position with respect to the other channels and the ability to generate a trigger signal at any point in the period that can be output from the module to initiate activity in other parts of the SoC such as starting ADC conversions.

An external counter driven in either MC Up or MCB Up mode must be selected from one of the counter buses.

Register A1 defines the leading edge of the PWM output pulse and as such the beginning of the PWM's period. This makes it possible to insure that the leading edge of multiple channels in OPWMT mode can occur at a specific time with respect to the other channels when using a shared timebase. This can allow the introduction of a fixed offset for each channel which can be particularly useful in the generation of lighting PWM control signals where it is desirable that edges are not coincident with each other to help eliminate noise generation. The value of register A1 represents the shift of the PWM channel with respect to the selected timebase. A1 can be configured with any value within the range of the selected time base. Note that registers loaded with 0x0 will not produce matches if the timebase is driven by a channel in MCB mode.

A1 is not buffered as the shift of a PWM channel must not be modified while the PWM signal is being generated. In case A1 is modified it is immediately updated and one PWM pulse could be lost.

EMIOSB[n] address gives access to B2 register for write and B1 register for read. Register B1 defines the trailing edge of the PWM output pulse and as such the duty cycle of the PWM signal. To synchronize B1 update with the PWM signal and so ensure a correct output pulse generation the transfer from B2 to B1 is done at every match of register A1. This behavior is the same as the OPWM mode with next period update.

EMIOSOUDIS register affects transfers between B2 and B1 only.

In order to account for the shift in the leading edge of the waveform defined by register A1 it will be necessary that the trailing edge, held in register B1, can roll over into the next period. This means that a match against the B1 register should not have to be qualified by a match in the A1 register. The impact of this would mean that incorrectly setting register B1 to a value less that register A1 will result in the output being held over a cycle boundary until the B1 value is encountered.

This mode provides a buffered update of the trailing edge by updating register B1 with register B2 contents only at a match of register A1.

The value loaded in register A1 is compared with the value on the selected time base. When a match on comparator A1 occurs, the output flip-flop is set to the value of the EDPOL bit. When a match occurs on comparator B, the output flip-flop is set to the complement of the EDPOL bit.

Note that the output pin and flag transitions are based on the posedges of the A1, B1 and A2 match signals. Please refer to Figure 37-34 in Output Pulse Width Modulation Buffered (OPWMB) Mode for details on match posedge.

Register A2 defines the generation of a trigger event within the PWM period and A2 should be configured with any value within the range of the selected time base, otherwise no trigger will be generated. A match on the comparator will generate the FLAG signal but it has no effect on the PWM output signal generation. The typical setup to obtain a trigger with FLAG is enabling DMA and driving the channel's ipd_done input high.

A2 is not buffered and therefore its update is immediate. If the channel is running when a change is made this could cause either the loss of one trigger event or the generation of two trigger events within the same period. Register A2 can be accessed by reading or writing the eMIOS UC Alternate A Register (eMIOS_ALTA) at UC[n] base address +0x14.

The FLAG signal is set only at match on the comparator with A2. A match on the comparator with A1 or B1 or B2 has no effect on FLAG.

At any time, the FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a match on A or B respectively. Any FORCMA and/or FORCMB has priority over any simultaneous match regarding to output pin transitions. Note that the load of B2 content on B1 register at an A match is not inhibited due to a simultaneous FORCMA/FORCMB assertion. If both FORCMA and FORCMB are asserted simultaneously the output pin goes to the opposite of EDPOL value such as if A1 and B1 registers had the same value. FORCMA assertion causes the transfer from register B2 to B1 such as a regular A match, regardless of FORCMB assertion.

If subsequent matches occur on comparators A1 and B, the PWM pulses continue to be generated, regardless of the state of the FLAG bit.

At OPWMT mode entry the output flip-flop is set to the complement of the EDPOL bit in the EMIOSC[n] register.

In order to achieve 0% duty cycle both registers A1 and B must be set to the same value. When a simultaneous match on comparators A and B occur, the output flip-flop is set at every period to the complement value of EDPOL.

In order to achieve 100% duty cycle the register B1 must be set to a value greater than maximum value of the selected time base. As a consequence if 100% duty cycle must be implemented the maximum counter value for the time base is 0xFFFFFE for a 24-bit counter and 0xFFFE for a 16-bit counter, respectively. When a match on comparator A1 occurs the output flip-flop is set at every period to the value of EDPOL bit. The transfer from register B2 to B1 is still triggered by the match at comparator A.

As with other eMIOS mode, the OPWMT mode will implement the Output Disable function. Setting the ODIS bit in the eMIOS UC Control Register (EMIOSC[n]) will enable the Output Disable function. If the selected Output Disable input signal is asserted for the channel, the output pin will go to the inverse of the EDPOL. The channel will continue to operate normally, although the output will be fixed. When the Output Disable input signal is negated, the output pin will return to operate as normal.

Figure 37-38 shows the Unified Channel running in OPWMT mode with Trigger Event Generation and duty cycle update on next period update.

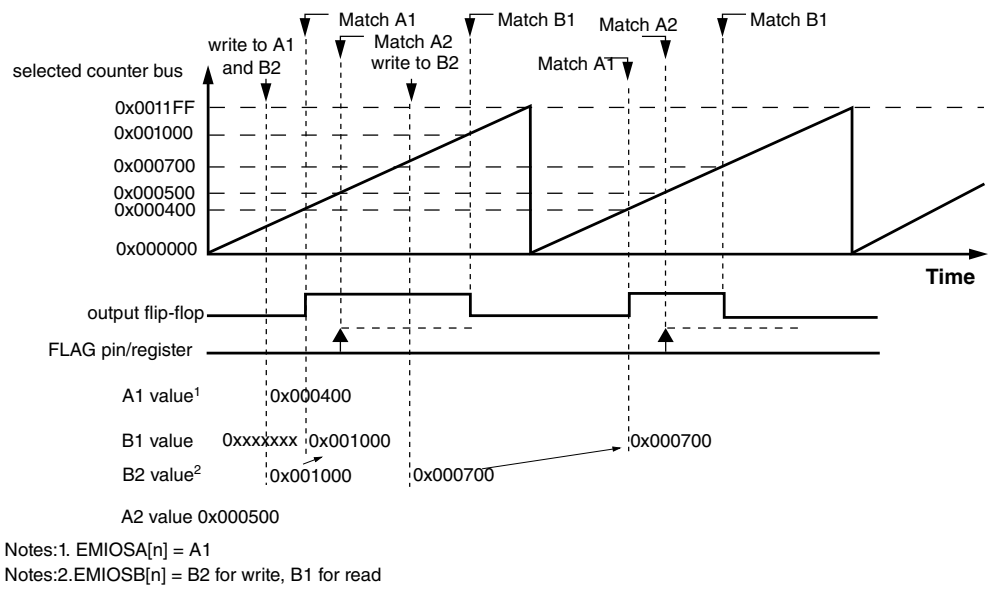

Figure 37-38. OPWMT example

Figure 37-39 shows the Unified Channel running in OPWMT mode with Trigger Event Generation and 0% duty.

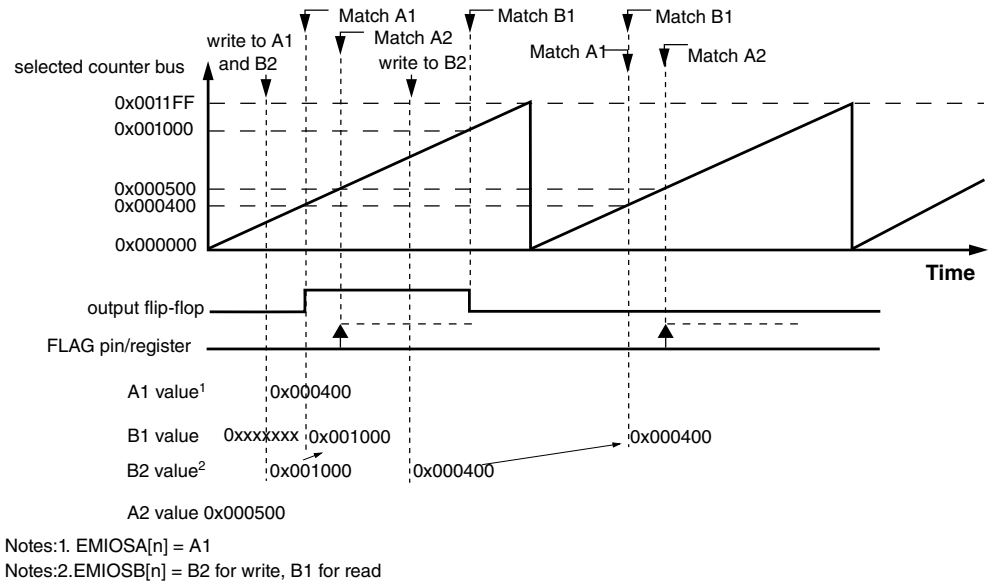

Figure 37-39. OPWMT with 0% Duty Cycle

Figure 37-40 shows the Unified Channel running in OPWMT mode with Trigger Event Generation and 100% duty cycle.

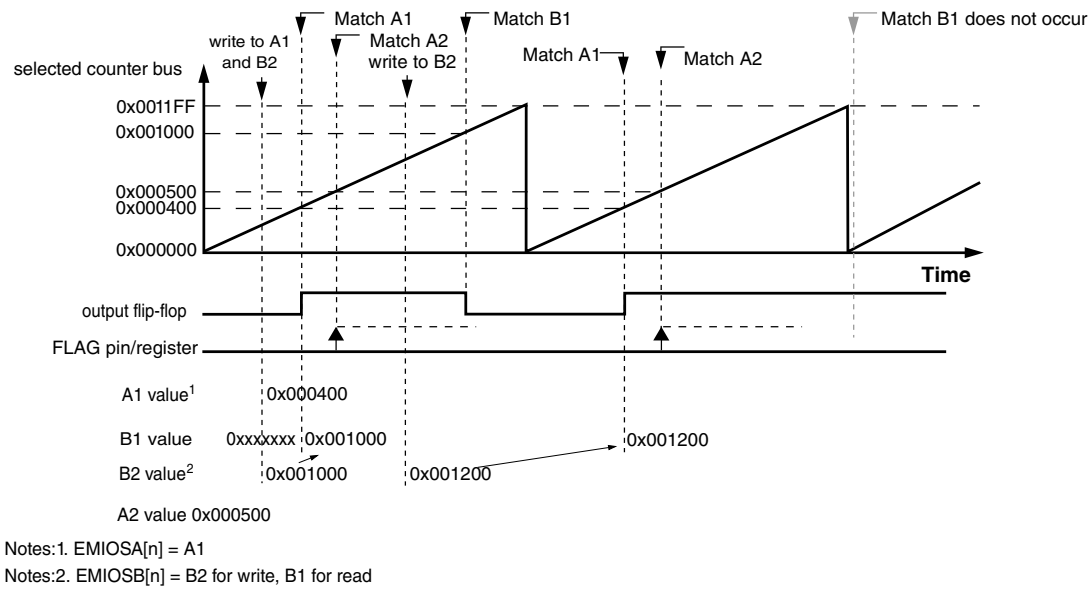

Figure 37-40. OPWMT with 100% Duty Cycle

37.6.1.2 Input Programmable Filter (IPF)

The IPF ensures that only valid input pin transitions are received by the Unified Channel edge detector. A block diagram of the IPF is shown in Figure 37-41.

The IPF is a 5-bit programmable up counter that is incremented by the selected clock source, according to bits IF[0:3] in EMIOSC[n] register.

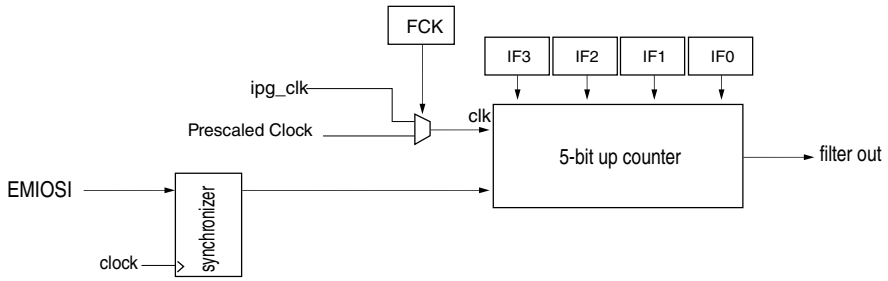

Figure 37-41. Input Programmable Filter Submodule Diagram

The input signal is synchronized by system clock . When a state change occurs in this signal, the 5-bit counter starts counting up. As long as the new state is stable on the pin, the counter remains incrementing. If a counter overflow occurs, the new pin value is validated. In this case, it is transmitted as a pulse edge to the edge detector. If the opposite edge appears on the pin before validation (overflow), the counter is reset. At the next pin transition, the counter starts counting again. Any pulse that is shorter than a full range of the masked counter is regarded as a glitch and it is not passed on to the edge detector. A timing diagram of the input filter is shown in Figure 37-42.

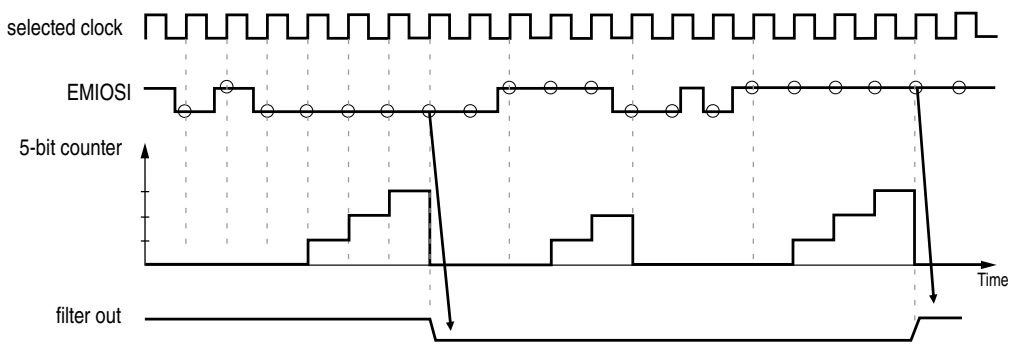

Figure 37-42. Input Programmable Filter Example (IF[0:3] is 0010b)

The filter is not disabled during either freeze state or negated GTBE input

37.6.1.3 Clock Prescaler (CP)

The CP divides the GCP output signal to generate a clock enable for the internal counter of the Unified Channels. The GCP output signal is prescaled by the value defined in the UCPRE[0:1] field description in the EMIOSC[n] register. The prescaler is enabled by setting the UCPREN bit in the EMIOSC[n] and can be stopped at any time by clearing this bit, thereby stopping the internal counter in the Unified Channel.

In order to ensure safe working and avoid glitches the following steps must be performed whenever any update in the prescaling rate is desired:

1. Write 0 at both GPREN bit in EMIOSMCR register and UCPREN bit in EMIOSC[n] register, thus disabling prescalers;
2. Write the desired value for prescaling rate at UCPRE[0:1] bits in EMIOSC[n] register;
3. Enable channel prescaler by writing 1 at UCPREN bit in EMIOSC[n] register;
4. Enable global prescaler by writing 1 at GPREN bit in EMIOSMCR register.

The prescaler is not disabled during either freeze state or negated GTBE input.

37.6.1.4 Effect of Freeze on the Unified Channel

When in debug mode, FRZ bit in the EMIOSMCR register and the FREN bit in the EMIOSC[n] are both set, the internal counter and Unified Channel capture and compare functions are halted. The UC is frozen in its current state.

During freeze, all registers are accessible. When the Unified Channel is operating in an output mode, the force match functions remain available, allowing the software to force the output to the desired level.

Note that for input modes, any input events that may occur while the channel is frozen are ignored.

When exiting debug mode or freeze enable bit is cleared (FRZ in the EMIOSMCR or FREN in the EMIOSC[n] register) the channel actions resume, but may be inconsistent until channel enters GPIO mode again.

37.6.2 IP Bus Interface Unit (BIU)

The BIU provides the interface between the Internal Interface Bus (IIB) and the Peripheral Bus, allowing communication among all submodules and this IP interface.

The BIU allows 8, 16 and 32 bits access. They are performed over a 32-bit data bus in a single cycle clock.

37.6.2.1 Effect of Freeze on the BIU

When the FRZ bit in the EMIOSMCR register is set and the module is in debug mode, the operation of BIU is not affected.

37.6.3 Global Clock Prescaler Submodule (GCP)

The GCP divides the system clock to generate a clock for the CPs of the channels. The main clock signal is prescaled by the value defined in the Global Prescaler clock divider table within the eMIOS Module Configuration Register (EMIOSMCR) description according to the GPRE[0:7] bits in EMIOSMCR register. The global prescaler is enabled by setting the GPREN bit in the EMIOSMCR register and can be stopped at any time by clearing this bit, thereby stopping the internal counters in all the channels.

In order to ensure safe working and avoid glitches the following steps must be performed whenever any update in the prescaling rate is desired:

1. Write 0 at GPREN bit in EMIOSMCR register, thus disabling global prescaler;
2. Write the desired value for prescaling rate at GPRE[0:7] bits in EMIOSMCR register;
3. Enable global prescaler by writing 1 at GPREN bit in EMIOSMCR register.

The prescaler is not disabled during either freeze state or negated GTBE input.

37.6.3.1 Effect of Freeze on the GCP

When the FRZ bit in the EMIOSMCR register is set and the module is in debug mode, the operation of GCP submodule is not affected, i.e., there is no freeze function in this submodule.

37.7 Initialization/Application Information

On resetting the eMIOS, the Unified Channels enter GPIO input mode.

37.7.1 Considerations

Before changing an operating mode, the UC must be programmed to GPIO mode and EMIOSA[n] and EMIOSB[n] registers must be updated with the correct values for the next operating mode. Then the EMIOSC[n] register can be written with the new operating mode. If a UC is changed from one mode to another without performing this procedure, the first operation cycle of the selected time base can be random, i.e., matches

can occur in random time if the contents of EMIOSA[n] or EMIOSB[n] were not updated with the correct value before the time base matches the previous contents of EMIOSA[n] or EMIOSB[n].

When interrupts are enabled, the software must clear the FLAG bits before exiting the interrupt service routine.

37.7.2 Application Information

Correlated output signals can be generated by all output operation modes. Bits OU[n] of eMIOS_OUDIS register can be used to control the update of these output signals.

In order to guarantee that the internal counters of correlated channels are incremented in the same clock cycle, the internal prescalers must be set up before enabling the global prescaler. If the internal prescalers are set after enabling the global prescaler, the internal counters may increment in the same ratio, but at a different clock cycle.

It is recommended to drive Output Disable Input signals with the emios_flag_out signals of some UCs running in SAIC mode. When an output disable condition happens, the software interrupt routine must service the output channels before servicing the channels running SAIC. This procedure avoid glitches in the output pins.

37.7.2.1 Time Base Generation

For MC and OPWFM with internal clock source operation modes, the internal counter rate can be modified by configuring the clock prescaler ratio. Figure 37-43 shows an example of a time base with prescaler ratio equal to one.

Note

MCB and OPWFMB modes have a different behavior.

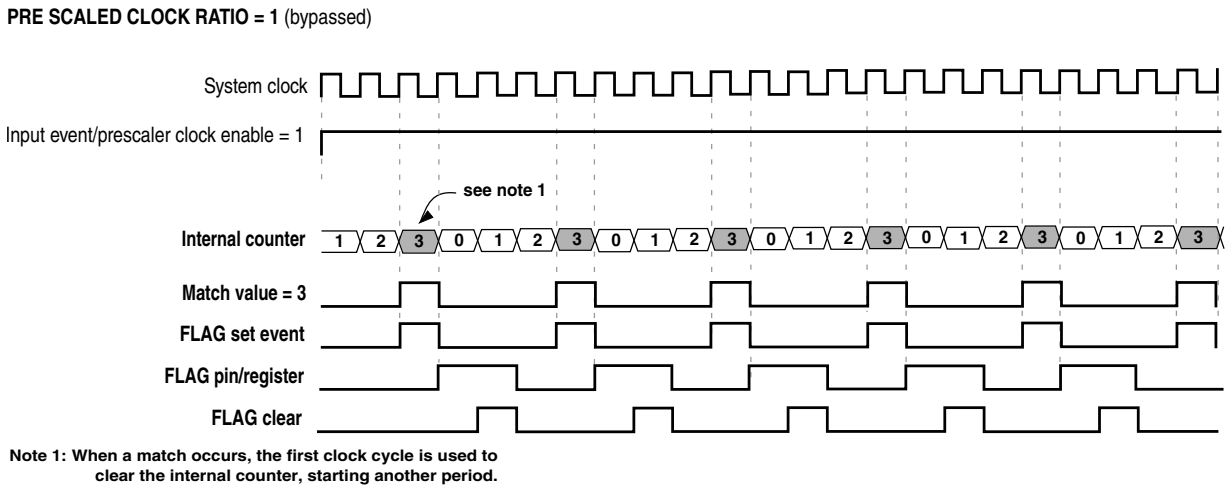

Figure 37-43. Time base period when running in the fastest prescaler ratio

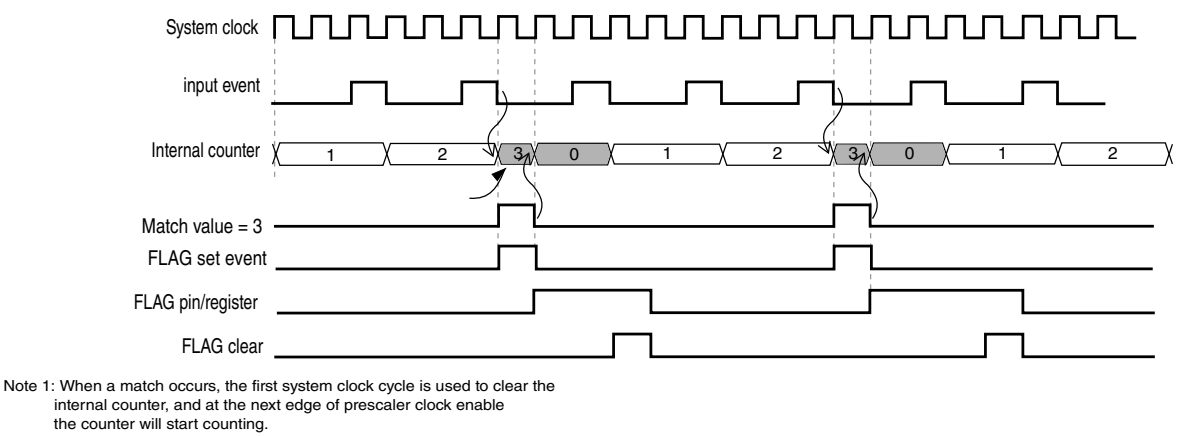
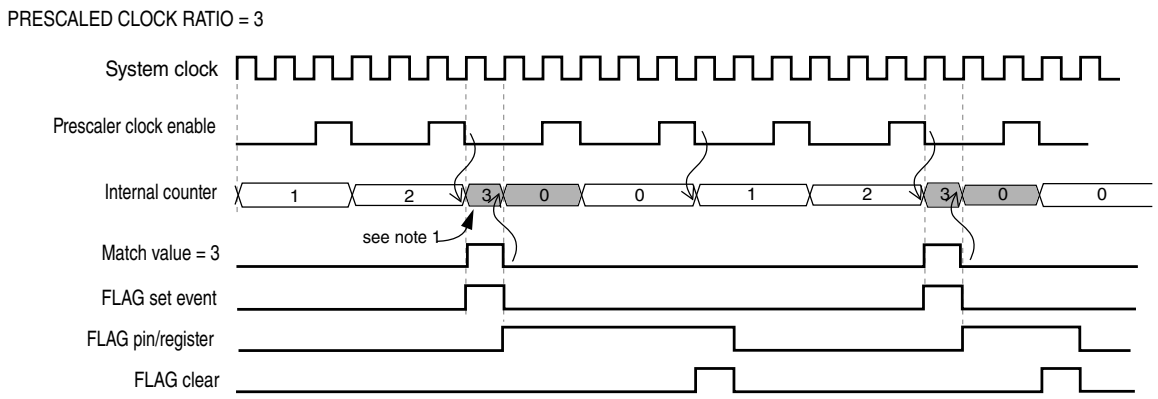
If the prescaler ratio is greater than one or external clock is selected, the counter may behave in one of four different ways depending on the channel mode:

- If MC mode and Clear on Match Start and External Clock source are selected the internal counter behaves as described in Figure 37-44 .
- If MC mode and Clear on Match Start and Internal Clock source are selected the internal counter behaves as described in Figure 37-45.
- If MC mode and Clear on Match End are selected the internal counter behaves as described in Figure 37-46.
- If OPWFM mode is selected the internal counter behaves as described in Figure 37-45. The internal counter clears at the start of the match signal, skips the next prescaled clock edge and then increments in the subsequent prescaled clock edge.

Note

MCB and OPWFMB modes have a different behavior.





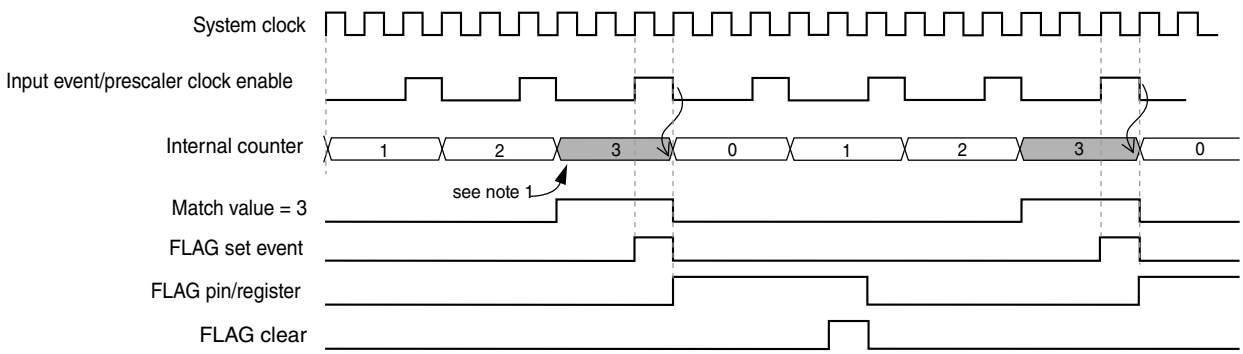


Figure 37-44. Time base generation with external clock and clear on match start

Note 1: When a match occurs, the first clock cycle is used to clear the internal counter, and only after a second edge of pre scaled clock the counter will start counting.

Figure 37-45. Time base generation with internal clock and clear on match start

Note 1: The match occurs only when the input event/prescaler clock enable is active. Then, the internal counter is immediately cleared.

Figure 37-46. Time base generation with clear on match end

37.7.2.2 Coherent Accesses

Reading the EMIOSA[n] register again in the same period of the last read of EMIOSB[n] register may lead to incoherent results. This will occur if the last read of EMIOSB[n] register occurred after a disabled B2 to B1 transfer.

37.7.2.3 Channel/Modes Initialization

The following basic steps summarize basic output mode startup, assuming the channels are initially in GPIO mode:

1. *[global]* Disable Global Prescaler.
2. *[timebase channel]* Disable Channel Prescaler.

3. *[timebase channel]* Write initial value at internal counter.
4. *[timebase channel]* Set A/B register.
5. *[timebase channel]* Set channel to MC(B) Up mode.
6. *[timebase channel]* Set prescaler ratio.
7. *[timebase channel]* Enable Channel Prescaler.
8. *[output channel]* Disable Channel Prescaler.
9. *[output channel]* Set A/B register.
10. *[output channel]* Select timebase input through BSL[1:0] bits.
11. *[output channel]* Enter output mode.
12. *[output channel]* Set prescaler ratio (same ratio as timebase channel).
13. *[output channel]* Enable Channel Prescaler.
14. *[global]* Enable Global Prescaler.
15. *[global]* Enable Global Time Base.

The timebase channel and the output channel may be the same for some applications such as in OPWFM(B) mode or whenever the output channel is intended to run the timebase itself.

At any time the flags can be configured.

Chapter 38
Power Control Unit (MC_PCU)

38.1 Introduction

38.1.1 Overview

The power control unit (MC_PCU) in conjunction with LPU_CTL and MC_ME, is used to reduce the overall chip power consumption. Power can be saved by disconnecting parts of the chip from the power supply via a power switching chip. The chip is grouped into multiple parts having this capability which are called “power domains”.

When a power domain is disconnected from the supply, the power consumption is reduced to zero in that domain. Any status information of such a power domain is lost. When re-connecting a power domain to the supply voltage, the domain draws an increased current until the power domain reaches its operational voltage.

Power domains are controlled on a chip mode basis. For each mode, software can configure whether a power domain is connected to the supply voltage (power-up state) or disconnected (power-down state). Maximum power saving is reached by entering the STANDBY0 mode.

The power-up/down sequences are handled by finite state machines to ensure a smooth and safe transition from one power state to the other.

Exiting the STANDBY0 mode can only be done via a system wakeup event as all power domains other than power domain #0 are in the power-down state.

In addition, the MC_PCU acts as a bridge for mapping the mapped peripheral peripheral to the MC_PCU address space.

The following figure depicts the MC_PCU block diagram.

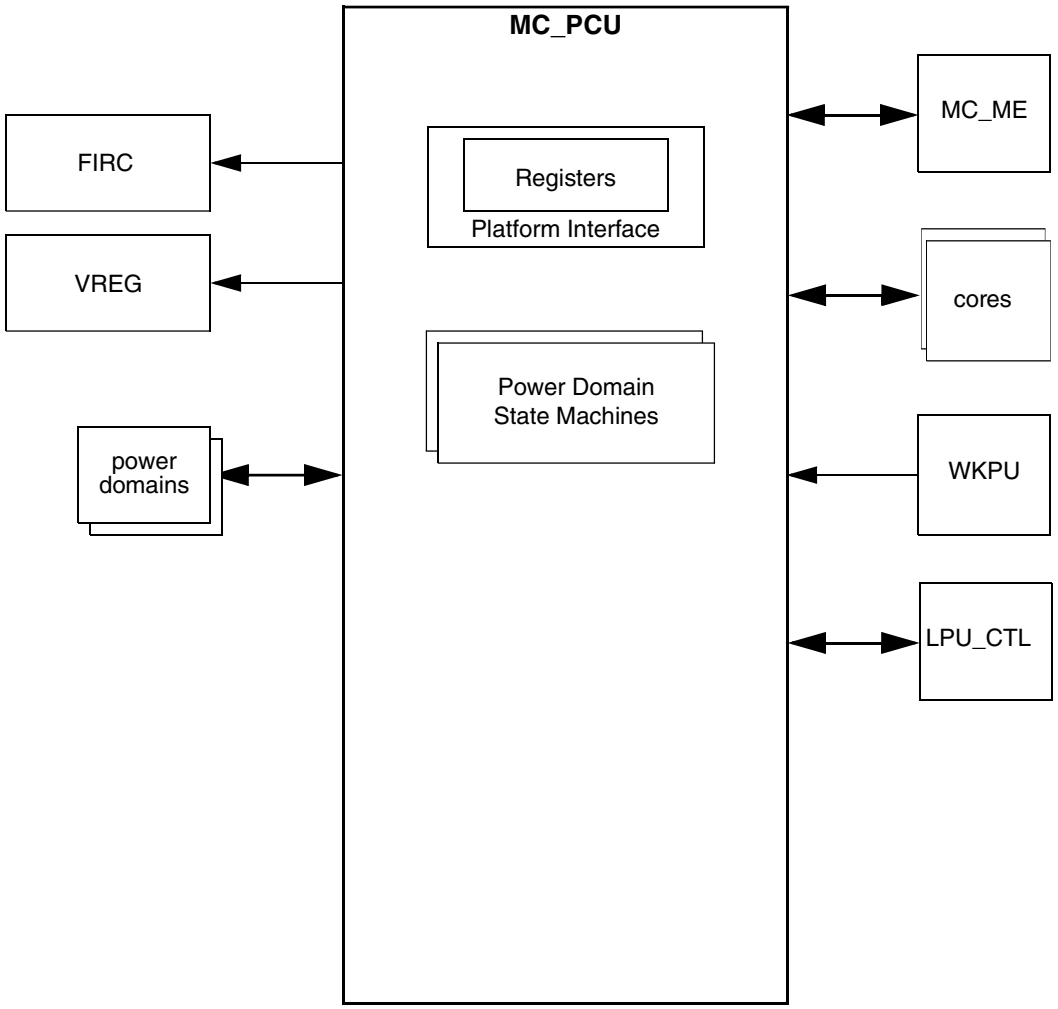

Figure 38-1. MC_PCU Block Diagram

38.1.2 Features

The MC_PCU includes the following features:

- PMCDIG registers are mapped to its address range.
- Bridge between MC_ME, LPU_CTL and PMCDIG to handle mode transitions from RUN to LPU mode, LPU_RUN to LPU_STANDBY and RUN to STANDBY0 mode.
- A handshake mechanism for power state changes thus guaranteeing operable voltage.

Chapter 39
Power Management Controller digital interface (PMCDIG)

39.1 Overview

The PMC has main linear voltage regulator that generates the internal 1.25 V digital supply from an external 3.3 V or 5 V supply. It also contains an option to bypass this main regulator and instead use an externally supplied 1.25 V inputIn addition, there are low power (LP) and ultra-low power (ULP) regulators that can be active, regardless of how the main 1.25 V is being supplied. Also, there is a linear regulator to power 3.3 V to the Flash HV domain (FLASHREG). Here, there is also an option to bypass and use an externally supplied 3.3 V input when device is in 3.3 V mode.

The PMC digital block generates a transfer error event to the system if the selected address is greater than the highest address in the PMC digital memory map. A transfer error is also generated if an unused address within the PMC digital memory space is accessed.

39.2 Features

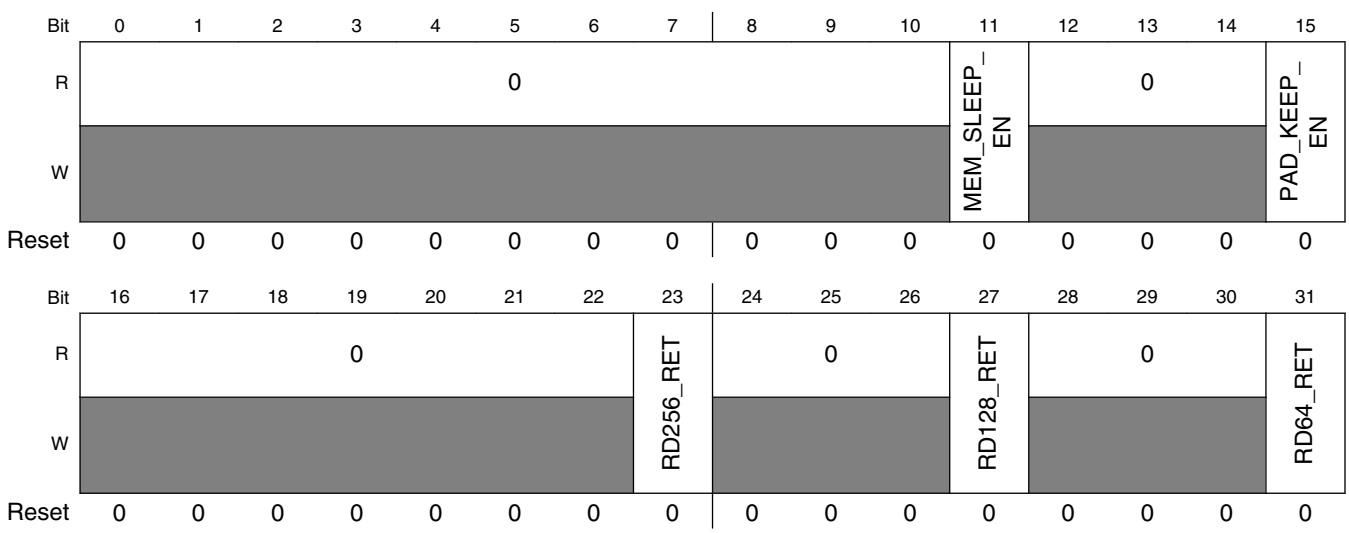
The PMC provides the following main features:

- Compatible with 3.3 V and 5 V operation.
- No specific power sequencing required and all power domains guaranteed safe-state during power-up, power-down.
- POR circuitry
  - Guarantees safe initialization of MC.
- Precision voltage monitors
  - PMC voltage supply - POR (Power on Reset).
  - VDD core voltage supply - POR, HVD (high voltage detector), LVD (low voltage detector).

- Flash memory voltage supply - LVD.
- VDD_HV_A voltage supply - LVD.

- Bandgap voltage reference for
  - Voltage monitors and regulators.
  - ADC voltage reference channel.

39.3 Memory Map and Registers



The following table shows the PMC memory map.

PMCDIG memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	RAM Domain Configuration Register (PMCDIG_RDCR)	32	R/W	0000_0000h	39.3.1/1042
4	Supply Gauge Status Register (PMCDIG_SGSR)	32	w1c	0000_0000h	39.3.2/1043
10	MISC Control Register (PMCDIG_MCR)	32	R/W	0000_0000h	39.3.3/1047

39.3.1 RAM Domain Configuration Register (PMCDIG_RDCR)

Address: 0h base + 0h offset = 0h

PMCDIG_RDCR field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PMCDIG_RDCR field descriptions (continued)

Field	Description
11 MEM_SLEEP_EN	Memory Sleep Enable When set, will enable the Sleep state for memories. Program this bit in STOP/LPU_STOP to take advantage of memory sleep state.
12–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 PAD_KEEP_EN	PAD Keeper Enable Enables the PAD keeping functionality where some Standby PADs can retain their configuration while in Power gated Modes (Standby). 0 Disable PAD Keeping functionality 1 Enabled Pad Keeping Functionality.
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 RD256_RET	RAM Domain 256K Retention Retains the whole 256K RAM while in Standby Mode. 0 Switch to RAM supplies Opened (RAM cut is shut off)(default reset value). 1 Switch to RAM supplies Closed .
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 RD128_RET	RAM Domain 128K Retention Retains 128K RAM while in Standby Mode. 0 Switch to RAM supplies Opened (RAM cut is shut off) (default reset value). 1 Switch to RAM supplies Closed.
28–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 RD64_RET	RAM Domain 64K Retention Retains 64K RAM while in Standby Mode. **NOTE:** If 8k of RAM is to be retained, it is implicitly achieved by disabling all bits here. 0 Switch to RAM supplies Opened (RAM cut is shut off) (default reset value). 1 Switch to RAM supplies Closed.

39.3.2 Supply Gauge Status Register (PMCDIG_SGSR)

This register is Reset only on a POR event.

On reading the flag indicating that a POR occured as 1 (after a POR event), the user should ideally ignore the rest of the bits in this register until a clear operation and read back is performed.

NOTE

On first Power up, bits from 19-31 may be set. It is suggested to read these bits and then write 1 to clear accordingly. In low power mode, if any of the LVD occurs then the behavior of this register will be similar to first power up.

NOTE

Bits 24-30 will remain set and will not get cleared if respective supply is below voltage monitor threshold. Please refer device datasheet for voltage monitor threshold levels.

Address: 0h base + 4h offset = 4h

PMCDIG_SGSR field descriptions

Field	Description
0–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–20 LP_STATUS	Low Power Status Indicates the last Low Power Mode entered. Software needs to ensure that to effectively use these bits, the field should be cleared before making a low power transition and then read back once the read is possible again (RUN/LPU_RUN). 00 No LP Mode Transition Triggered OR cleared by user for new status to be captured. 01 Invalid state (will not occur and user should ensure that the registers are not cleared in a manner that results in the bits reflecting this value, USER should ALWAYS clear both bits together or just bit LP_STATUS[0]). 10 LPU mode 11 STANDBY mode
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 LVD_FLASH	LVD VDD_HV_ FLA Flag 0 Indicates that a Flash LVD event has not occured since last clear of the Flag. 1 Indicates that a Flash LVD event had occured in the past after the time instance when Flag was cleared.
25 LVD_IO_A_HI	LVD IO Segment A High Flag 0 Indicates that an IO_A_HI LVD event has not occured since last clear of the Flag. 1 Indicates that an IO_A_HI LVD event had occured in the past after the time instance when Flag was cleared.
26 LVD_IO_A_LO	LVD IO Segment A Low Flag 0 Indicates that an IO_A_LO LVD event has not occured since last clear of the Flag. 1 Indicates that an IO_A_LO LVD event had occured in the past after the time instance when Flag was cleared.
27 LVD_LV_PD0_ hot	LVD VDD_LV PD0 hot point Flag 0 Indicates that an LVD event on PD0 has not occured since last clear of the Flag. 1 Indicates that an LVD event on PD0 had occured in the past after the time instance when Flag was cleared.
28 LVD_LV_PD1_ hot	LVD VDD_LV PD1 hot point Flag 0 Indicates that an LVD event on PD1 has not occured since last clear of the Flag. 1 Indicates that an LVD event on PD1 had occured in the past after the time instance when Flag was cleared.
29 LVD_LV_PD2_ COLD	LVD_LV_PD2 Cold Point Flag 0 Indicates that an LVD event on PD2 COLD Point has not occured since last clear of the Flag. 1 Indicates that an LVD event on PD2 COLD Point had occured in the past after the time instance when Flag was cleared.

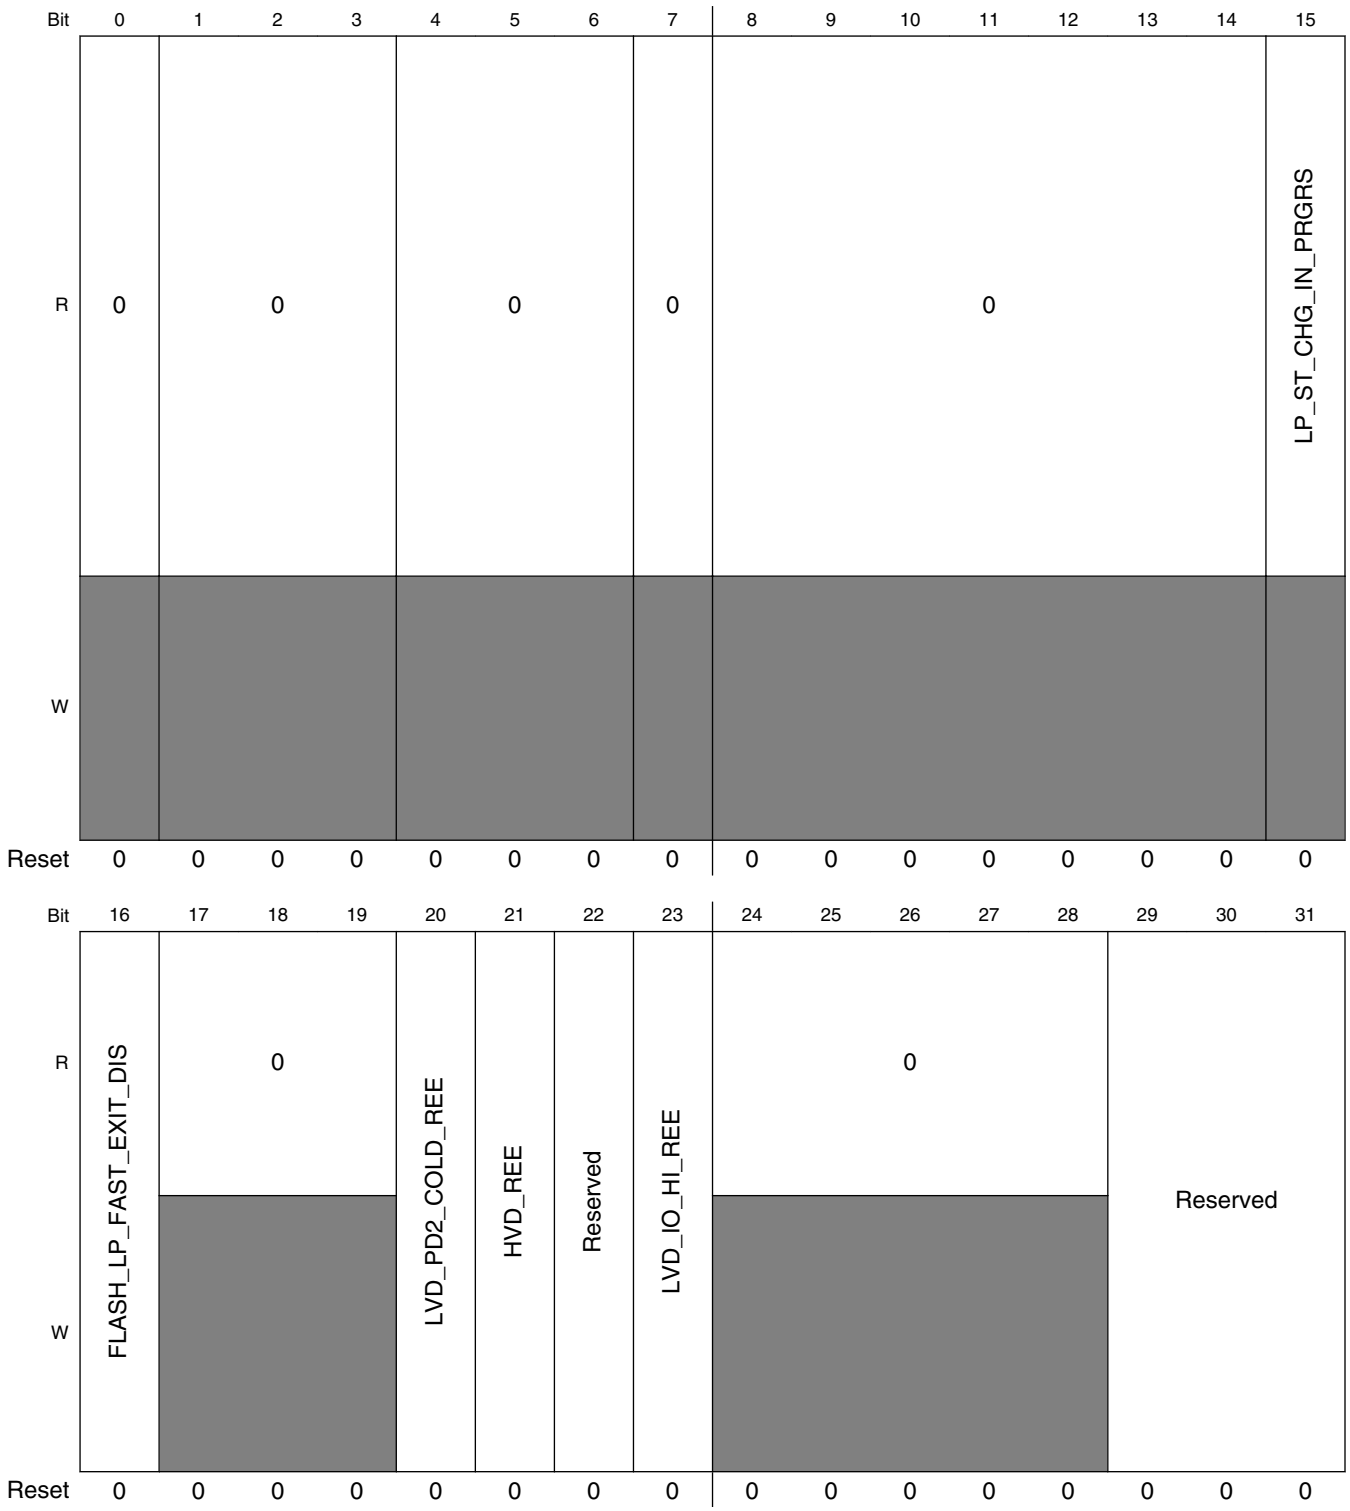

Table continues on the next page...

PMCDIG_SGSR field descriptions (continued)

Field	Description
30 LVD_LV_PD2_ HOT	LVD LV_PD2 hot Point Flag 0 Indicates that an LVD event on PD2 HOT Point has not occured since last clear of the Flag. 1 Indicates that an LVD event on PD2 HOT Point had occured in the past after the time instance when Flag was cleared.
31 POR_LV	Power On Reset Flag Flag Indicating that a Power On Reset occured. **NOTE:** To determine if the source of a power on destructive reset is por_lv, PORST or an essential LVD read PMC flags after reading the VOR bit. If none is set, it is PORST, else, the corresponding voltage reset. 0 Indicates that a POR event has not occured since last clear of the Flag. 1 Indicates that a POR event had occured in the past after the time instance when flag was cleared.

39.3.3 MISC Control Register (PMCDIG_MCR)

Address: 0h base + 10h offset = 10h

PMCDIG_MCR field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 LP_ST_CHG_IN_PRGRS	Low Power State Change in Progress This flag indicates that the PMC is currently undergoing a low power mode state transition, if set. This bit should always be set to '0' before a low power mode transition request is initiated.
16 FLASH_LP_FAST_EXIT_DIS	Flash Low Power Fast Exit Disable When set, the Flash will not be enabled for fast wakeup sequences. While fast wakeup provides around 4% of wakeup time reduction from low power modes, this mode can generate Flash Low Voltage Detection (LVD) events due to Flash load transients and therefore it is recommended to disable it. **NOTE:** It is recommended to set this field to prevent false Flash LVD detections. 0 Flash Low Power Fast Exit Enabled 1 Flash Low Power Fast Exit Disabled
17–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 LVD_PD2_COLD_REE	LVD_PD2 Cold Point Flag Reset Event Enable Enables the LVD_PD2 Cold Point Flag functional reset source to RGM if set.
21 HVD_REE	HVD Reset Event Enable Enables the HVD functional reset source to RGM if set.
22 Reserved	This field is reserved. **NOTE:** These bits should not be written by the user. Writes to a reserved location can result in unpredictable functionality or behavior.
23 LVD_IO_HI_REE	LVD_IO_HI Reset Event Enable Enables the LVD_IO_HI functional reset source to RGM if set.
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 Reserved	This field is reserved. **NOTE:** These bits should not be written by the user. Writes to a reserved location can result in unpredictable functionality or behavior.

39.4 Functional description

39.4.1 Analog PMC interface

The outputs from the PMC digital to the PMC analog circuit consists of enables for LVDs and the controls of the FPREG,FPREG_int LPREG, ULPREG , and FLASHREG, based on the power modes programmed in MC_ME and LPU_CTL.

The signals from the PMC analog to the PMC digital logic consists of simply POR and LVD event indication signals (both active high and active low, but only active low are used). These signals are used by the PMC digital logic to create the appropriate resets for the rest of the system.

39.4.2 Power-up Sequence

The following section describe the power sequence and the relation between the different supply during power-up and power-down.

NOTE

Refer to the device Datasheet for specific points on power sequence requirements relating to some of the supplies, if any.

Chapter 40
Mode Entry Module (MC_ME)

40.1 Introduction

40.1.1 Overview

The MC_ME controls the chip mode and mode transition sequences in all functional states. It also contains configuration, control and status registers accessible for the application.

The purpose of the MC_ME is to minimize the current consumption of device modules by:

- switching clocks on/off
- switching clock sources on/off
- switching power on/off to most of the device
- enabling system clock progressive switching when changing to a different power level configuration

The following figure shows the MC_ME block diagram.

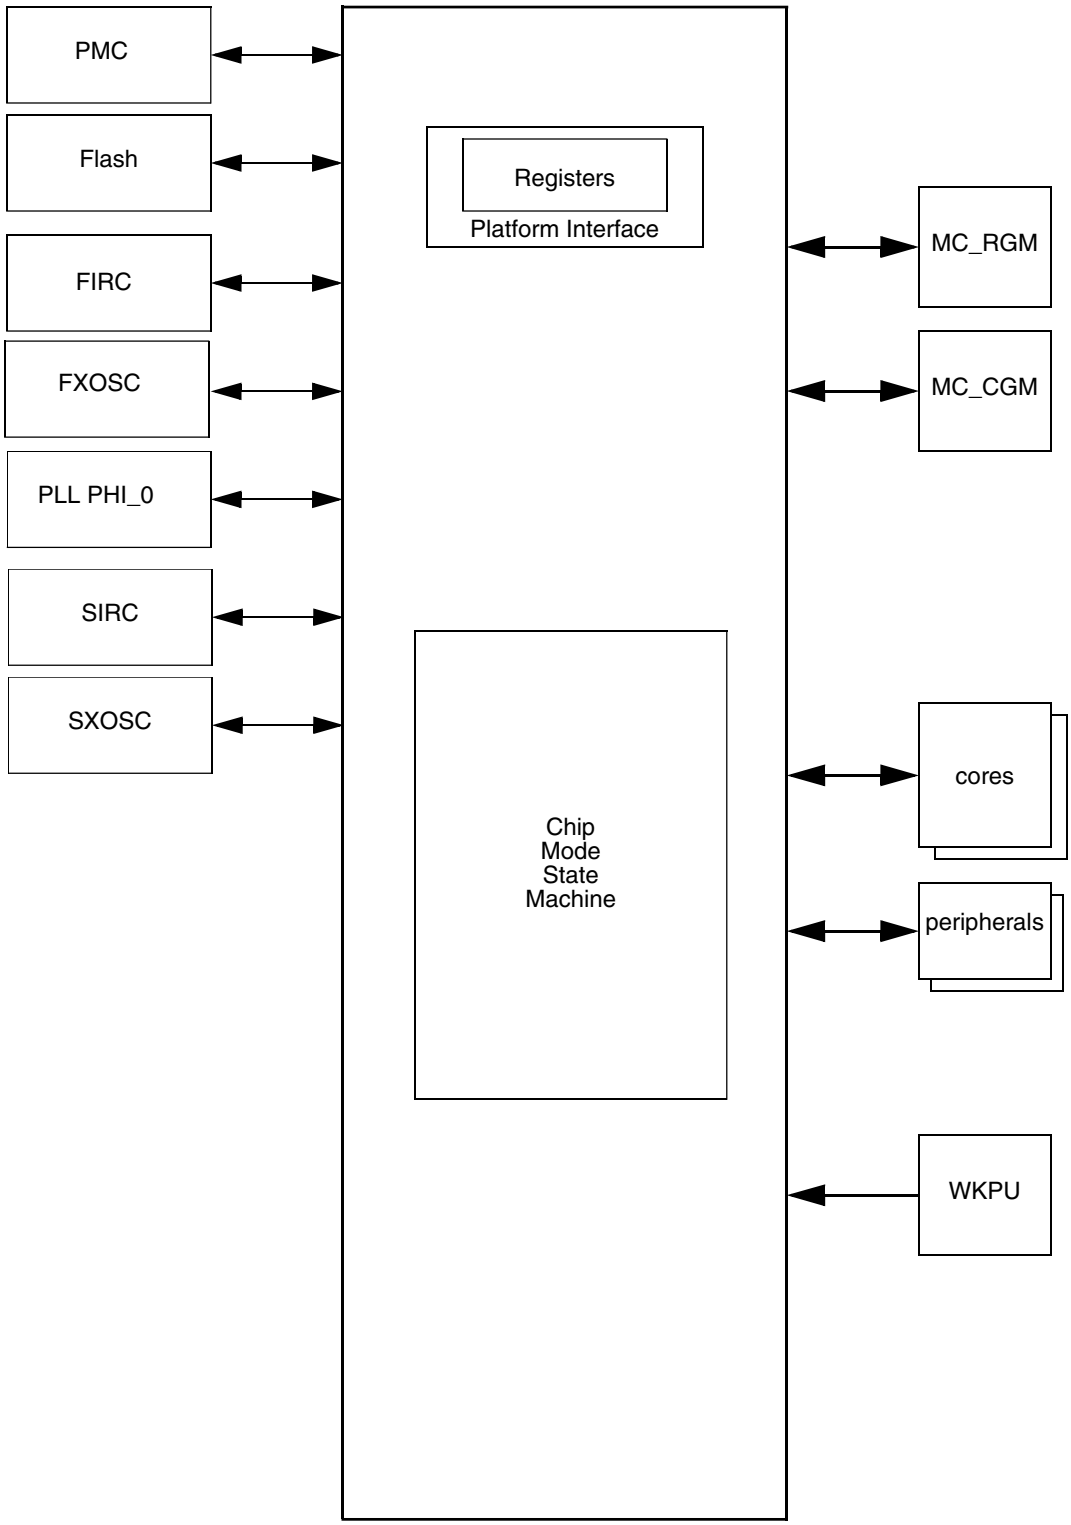

Figure 40-1. MC_ME Block Diagram

40.1.2 Features

The MC_ME includes the following features:

- control of the available modes by the ME_ME register
- definition of various chip mode configurations by the ME_<mode>_MC registers
- control of the actual chip mode by the ME_MCTL register for

  -switching between software-running modes

  -switching from software-running modes to low-power modes

  -switching to a mode to run diagnostics after a failure has been detected

  -triggering a device ‘functional’ reset which does not cause a start-up self test to run

  -triggering a device ‘destructive’ reset which may cause a start-up self test to run
- capture of the current mode and various resource status within the contents of the ME_GS register
- optional generation of various mode transition interrupts
- status bits for each cause of invalid mode transitions
- peripheral clock gating control based on the ME_RUN_PC0…7, ME_LP_PC0…7, and ME_PCTLn registers
- capture of current peripheral and additional core clock gated/enabled status
- core clock gating and boot control based on the ME_CCTLn and ME_CADDRn registers
- progressive system clock switching when transitioning from a lower power consumption mode to a higher power consumption mode, and vice versa
- capture of current core clock gated/enabled status

40.1.3 Use Cases

The following simplified use cases illustrate how the MC_ME module implements power saving mechanisms

40.1.3.1 Use Case 1: Software Tasks with Different Clock Requirements

Software runs one of the following three tasks at a time:

- Analog Monitor task

  — peripherals required: analog-to-digital converter

  — clock sources required: only 16 MHz internal RC oscillator, used for system clock and peripheral clocking

  — software: reads analog input; if the voltage meets a criteria, the Communications task is called

- Communication task

  — peripherals required: two CAN modules

  — clock sources required: only 8-40 MHz crystal oscillator, used for system clock and peripheral clocking

  — software: transmits analog data; if the response is positive, the Whole Chip task is activated

- Whole Chip task

  — peripherals required: all peripherals will be needed

  — clock sources required: PLL_PHI_0 will be used (requires 8-40 MHz crystal oscillator) for system clock and peripheral clocking

  — software: processes messages and information, then returns to Analog Monitor task

NOTE

All ME_PCTLx controlled peripherals should be accessed only after its clocks are enabled through ME_PCTLx and ME_RUN_PCx register configuration.

The three tasks are summarized in Table 40-1. Typically, many functions will execute (run) in a mode. The parameters for these modes are called Mode Configuration. The MC_ME implements a mode configuration register for each mode that specifies which clock sources are enabled, the system clock source, and other parameters.

After reset, code executes in a default run mode, called DRUN. Software can reconfigure DRUN and/or configure up to four RUNx modes, three of which are used here.

Each peripheral needs a clock for some modes, but not others. The combination of modes that have a clock enabled to a particular peripheral is called the Peripheral Configuration.

Table 40-1. MC_ME Use Case 1 Requirement Summary

Run Mode (tasks using that mode)	System Clock Selection	Clock Sources Required			Peripheral(s) Requiring Enabled Clock
		FIRC	FXOSC	PLL PHI_0	
	<------Mode Configuration---->				<--Peripheral Configuration--->
RUN0 (Analog Monitor)	FIRC	X			ADC_1
RUN1 (Communication)	FXOSC		X		FLEXCAN1, FLEXCAN2
RUN2 (Whole Chip)	PLL PHI_0		X	X	all peripherals

The table below reorganizes Table 40-1 for peripheral configuration to illustrate how the MC_ME implements controlling clocks to peripherals

Table 40-2. MC_ME Use Case 1 Peripheral Clocking Requirement Summary

Peripheral(s)	Modes with Enabled Peripheral Clock					Run Mode Peripheral Configuration	Peripheral's Control Register (specifies a run mode peripheral configuration)
	DRUN	RUN0	RUN1	RUN2	RUN3		
ADC_1		X		X		ME_RUN_PC1	ME_PCTL25[RUN_CFG] = 1
FLEXCAN 1, FLEXCAN 2			X	X		ME_RUN_PC2	ME_PCTL71[RUN_CFG] = 2, ME_PCTL72[RUN_CFG] = 2,
all other peripherals (with ME_PCTLx registers)				X		ME_RUN_PC3	all other ME_PCTLx[RUN_CFG] = 3

Each module that can be turned on or off by the MC_ME has its own perpheral control register (ME_PCTLx) which selects a run mode peripheral configuration register (ME_RUN_PCx). These peripheral configuration registers have bit fields for each mode to indicate whether a clock is enabled in each mode for peripherals selecting that peripheral configuration register. A complete list of ME_PCTLx registers is shown in Table "MC_ME Register Description".

NOTE

ME_RUN_PC0 is the default configuration for all peripherals during run modes. Therefore, changing its content may inadvertently turn on all peripherals whose ME_PCTLx content has not yet been changed to use another run mode peripheral configuration.

40.1.3.2 Use Case 2: Software Runs and Invokes Multiple Low-Power Modes

Software runs continuously while the machine (for example, automobile) has the ignition turned on. When the ignition is turned off, software stops executing code and enters the low-power STOP0 mode where all the I/O pads are kept in the same state, but PLL, FXOSC, the flash, and most of the peripheral clocks are configured to be turned off.

If the ignition needs to remain off for longer duration,then there is also a option to enter the low power STANDBY0 mode where most of the I/O pads,PLL,FXOSC,FIRC,the flash and most of the peripherals are configured to power-down.

The ignition state is an input to the chip. If the ignition is turned back on at any time, the input transition wakes up the device from either low-power mode. Since more of the chip is “off” in STANDBY0 mode than in STOP0 mode, STANDBY0 mode will take longer to recover.

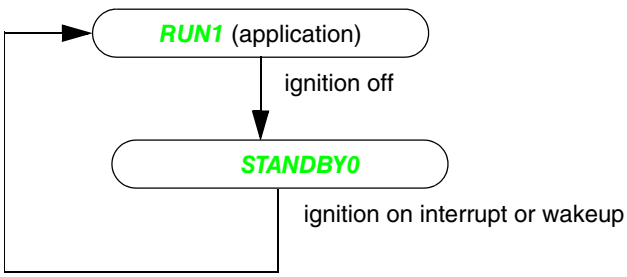

Figure 40-2. MC_ME Use Case 2: Low-Power Mode Flow Chart 1

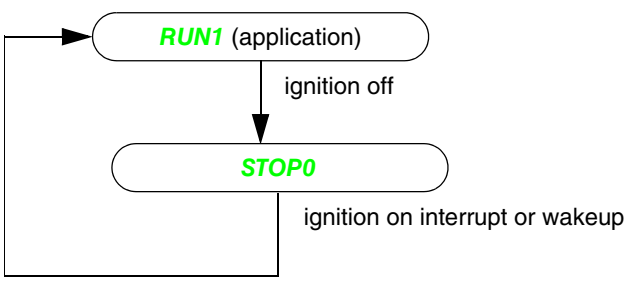

Figure 40-3. MC_ME Use Case 2: Low-Power Mode Flow Chart 2

After reset, software configures the chip to enter a run mode and two low-power modes:

- RUN1 mode
  - software runs continuously
  - if the ignition switch (a chip input) is switched off, software enters either STOP0 mode or STANDBY0 mode depending on Power Saving requirement.
- STOP0 mode
  - code does not run (no core clock)
  - all of the chip remains powered (no memory or register values lost)
  - STOP0 mode configuration:

        - pads are configured to maintain their state
        - PLL, FXOSC, the flash, and the main voltage regulator are configured to be off
    - STOP0 mode exits when
        - the ignition is detected via a wakeup input pin transition
- STANDBY0 mode
    - code does not run (core is power down)
    - Most of the chip remains power-down (memory or register values lost)
    - STANDBY0 mode configuration:
        - Selective pads are configured to maintain their state via padkeeping functionality.Most of the pads are powerdown.
        - PLL, FXOSC, the flash, and the main voltage regulator are configured to be powerdown.
    - STANDBY0 mode exits when
        - the ignition is detected via a wakeup input pin transition

The requirements for these modes are summarized in the following table:.

Table 40-3. MC_ME Use Case 2 Requirement Summary

Mode	System Clock Selection	Clock Sources			Memory Power Mode	Main Voltage Reg.	I/O Power Down Control	Peripherals Requiring Enabled Clock
		IRC	FXOSC	PLL	Flash			
Mode Configuration								
RUN1	PLL PHI_0	on	on	on	normal	on	off	all peripherals
STOP0	disabled	off	(off)	off	power-down	off	on	none
STANDBY0	disabled	off	(off)	disabled	power-down	off	off	none

The tables below summarize the modes where peripherals have a clock.

Table 40-4. MC_ME Use Case 2 Run Modes Peripheral Clocking Requirement

Peripheral	Run Modes with Enabled Peripheral Clock					Run Mode Peripheral Configuration	Peripheral's Control Register (specifies a run mode peripheral configuration)
	DRUN	RUN0	RUN1	RUN2	RUN3		
all peripherals (with ME_PCTLx registers)			X			ME_RUN_PC1	all ME_PCTLx[RUN_CFG] = 1

Table 40-5. MC_ME Use Case 2 Low-Power Modes Peripheral Clocking Requirement Summary

Peripheral	Low-Power Modes with Enabled Peripheral Clock		Low-Power Mode Peripheral Configuration	Peripheral's Control Register (specifies a run mode peripheral configuration)
	STOP0	STANDBY0		
all peripherals (with ME_PCTLx registers)			ME_LP_PC1	all ME_PCTLx[LP_CFG] = 1

40.1.3.3 Use Case 3: Mode Transitions Controlling Clocks to Multiple Cores

After initial boot, cores run or are disabled according to settings in their Core Control Register (ME_CCTLx).

Their boot address is contained in their Core Address Register (ME_CADDRx).The Core Address Register also has a configuration bit to reset the corresponding core on the next mode change where that core is configured to run (as defined in the Core Control Register), regardless of whether the core is currently running or is off.

NOTE

The fact that a core does not need to be on in the current mode for it to be reset using the ME_CADDRx[RMC] bit in the next mode transition allows the boot core, for example, to cause itself to re-boot from a new location when all other cores are off without needing to turn on one of the other cores to handle the mode transition.

These two registers are initialized by either

- the Boot Header (see the "BAF" chapter for details), or
- software with a mode transition to the configured mode

In the case of a transition between two RUNx modes where one or more cores will have their clocks gated off, software on a dedicated core whose clock will not be turned off must handle any necessary handshaking with the core(s) that will be losing their clock in the target mode.

An example of where multiple cores do not execute in all modes is shown in the following table. In this case, Z4 is the ‘master’ core that will handle the handshaking with the other cores.

Table 40-6. MC_ME Use Case 3 Run Modes Peripheral Clocking Requirement

Peripheral	Run Modes with Core Enabled Clock					Core's Control Register (specifies during which run mode the core run modes
	DRUN	RUN0	RUN1	RUN2	RUN3	
Z4 Core	X	X	X	X	X	ME_CCTL1
Z2 Core					X	ME_CCTL3

It is the responsibility of software to implement any needed handshaking when changing modes where a core loses a clock.

A high-level possible sequence is shown in the following figure for changing modes from RUN3 to RUN2. In this case, Z2 core, which is running in RUN3 mode, is turned off in RUN2 mode.

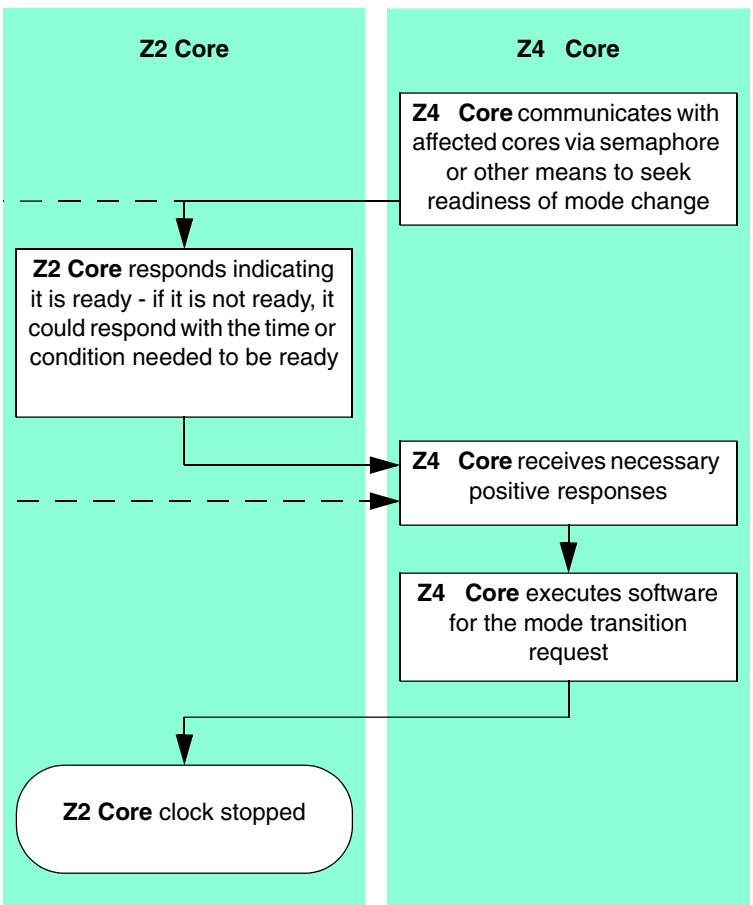

Figure 40-4. MC_ME Use Case 3: Possible mode Change sequence for turning off a core that is currently running (RUN3 to RUN2 in this case)

A high-level possible sequence is shown in the following figure for changing modes from DRUN to RUN3. In this case, Z4 Core, Z2 Core, all of which are off in DRUN mode, are turned on in RUN3 mode.

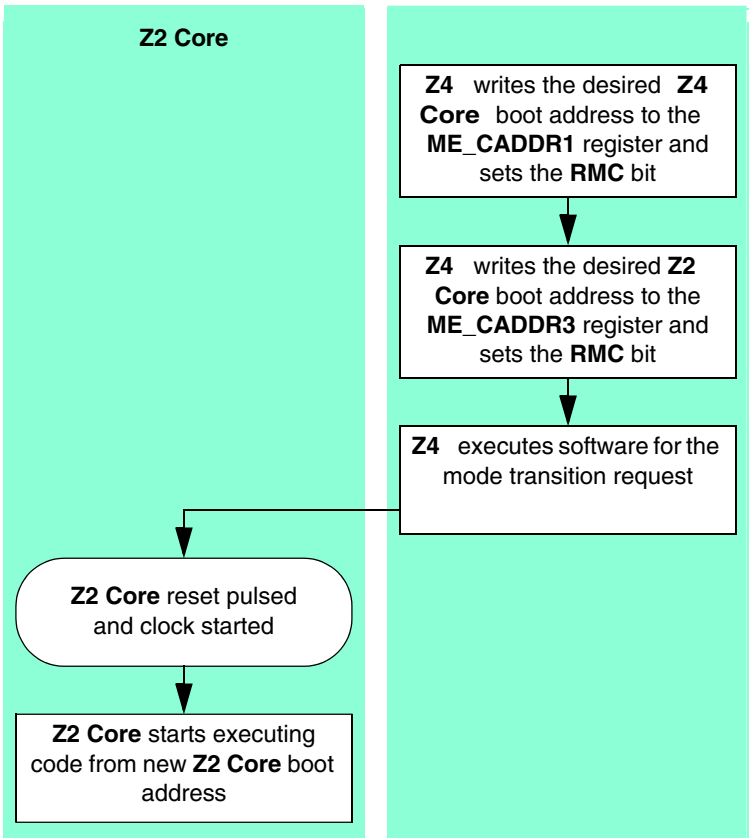

Figure 40-5. MC_ME Use Case 3: Possible mode change sequence for turning on one or more cores that are currently off (DRUN to RUN3 in this case)

40.1.4 Modes of Operation

The MC_ME is based on several chip modes corresponding to different usage models of the chip. Each mode is configurable and can define a policy for energy and processing power management to fit particular system requirements. An application can easily switch from one mode to another depending on the current needs of the system. The operating modes controlled by the MC_ME are divided into system and user modes. The system modes are modes such as RESET, DRUN, andSAFE. These modes aim to ease the configuration and monitoring of the system. The user modes are modes such as RUN0…3, and STOP0 which can be configured to meet the application requirements in terms of energy management and available processing power. The modes DRUN, SAFE, and RUN0…3 are the chip software running modes.

NOTE

AXBS masters cannot operate in SYSTEM STOP modes as system resources such as, DMA, SRAM, AXBS are clock gated. Also, NPC should be enabled if mode transition is initiated while debugger is connected.

The following table describes the MC_ME modes.

Table 40-7. MC_ME Mode Descriptions

Name	Description	Entry	Exit
RESET	This is a chip-wide virtual mode during which the application is not active. The system remains in this mode until all resources are available for the embedded software to take control of the chip. It manages hardware initialization of chip configuration, voltage regulators, clock sources, and flash modules.	system reset assertion from MC_RGM	system reset deassertion from MC_RGM
DRUN	This is the entry mode for the embedded software. It provides full accessibility to the system and enables the configuration of the system at startup. It provides the unique gate to enter user modes. BAM when present is executed in DRUN mode.	system reset deassertion from MC_RGM, software request from SAFE and RUN0…3	system reset assertion, RUN0…3, SAFE via software or hardware failure.
SAFE	This is a chip-wide service mode which may be entered on the detection of a recoverable error. It forces the system into a pre-defined safe configuration from which the system may try to recover.	hardware failure, software request from DRUN and RUN0…3	system reset assertion, DRUN via software
RUN0…3	These are software running modes where most processing activity is done. These various run modes allow to enable different clock & power configurations of the system with respect to each other.	software request from DRUN or other RUN0…3, interrupt event from interrupt or wakeup event from STOP0	system reset assertion, SAFE via software or hardware failure, DRUN and other RUN0…3 modes, STOP0 via software
STOP0	This is an advanced low-power mode during which the clock to the core is disabled. It may be configured to switch off most of the peripherals including clock sources for efficient power management at the cost of higher wakeup latency.	software request from RUN0…3	system reset assertion, SAFE on hardware failure, RUN0…3 on interrupt event or wakeup event
STANDBY0	This is a reduced-leakage low-power mode during which power supply is cut off from most of the chip. Wakeup from this mode takes a relatively long time, and content is lost or must be restored from backup	software request from RUN0…3, DRUN modes	system reset assertion, DRUN on wakeup event

40.1.4.1 Interrupts handling during mode transitions

All peripherals that will be disabled in the target mode must have their interrupt flags cleared prior to target mode entry. Before entering the target mode, software must ensure that all interrupt flags are cleared for those peripheral that are programmed to be disabled in the target mode. A pending interrupt from these peripherals at target mode entry will block the mode transition or possibly lead to unspecified behavior.

40.1.4.2 Advanced Low power user modes

The device adds two further advanced low power user modes, which are described in detail within LPU, Modes of operation : LPU_RUN and LPU_STOP modes.

For more information see table,Table 2-9

40.2 External Signal Description

The MC_ME has no connections to any external pins.

40.3 Memory Map and Register Definition

The MC_ME contains registers for:

- mode selection and status reporting
- mode configuration
- mode transition interrupts status and mask control
- scalable number of peripheral sub-mode selection and status reporting
- scalable number of additional core enabling and disabling control and status reporting

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the ME_RUN_PC0 register may be accessed as a word at address 0x080, as a half-word at address 0x082, or as a byte at address 0x083.

Some fields may be read-only, and their reset value of '1' or '0' and the corresponding behavior cannot be changed.

NOTE

All registers are read only in user mode.

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

MC_ME_GS field descriptions

Field	Description
0–3 S_CURRENT_MODE	Current chip mode status 0000 RESET 0001 Reserved 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 Reserved 1001 reserved 1010 STOP0 1011 reserved 1100 reserved 1101 STANDBY0 1110 reserved 1111 reserved
4 S_MTRANS	Mode transition status 0 Mode transition process is not active 1 Mode transition is ongoing
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
6–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 S_PDO	Output power-down status — This bit specifies output power-down status of I/Os. This bit is asserted whenever outputs of pads are forced to high impedance state or the pads power sequence driver is switched off. 0 No automatic safe gating of I/Os used and pads power sequence driver is enabled 1 In SAFE mode, outputs of pads are forced to high impedance state and the pads power sequence driver is disabled. The inputs are level unchanged. In STOP0 mode, only the pad power sequence driver is disabled, but the state of the output remains functional. In STANDBY0 mode, the power sequence driver and all pads except those mapped on wakeup lines are not powered and therefore high impedance. Wakeup lines configuration remains unchanged
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 S_MVR	Main voltage regulator status 0 Main voltage regulator is not ready 1 Main voltage regulator is ready for use
12–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 S_FLA	Flash availability status 00 Flash is not available 01 Flash is in power-down mode

Table continues on the next page...

MC_ME_GS field descriptions (continued)

Field	Description
	10 Flash is in power-down mode 11 Flash is in normal mode and available for use
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 S_SXOSC	32 KHz external oscillator status 0 32 KHz external oscillator is not stable 1 32 KHz external oscillator is providing a stable clock
24 S_SIRCON	128 KHz internal RC oscillator status 0 128 KHz internal RC oscillator is not stable 1 128 KHz internal RC oscillator is providing a stable clock
25 S_PLLON	PLL status 0 PLL is not stable 1 PLL is providing a stable clock
26 S_FXOSC	8-40 MHz crystal oscillator status **NOTE** S_XOSC alone should not be relied on. To get the current status of XOSC also check CMU0_ISR[OLRI] flag. XOSC is stable when MC_ME_GS[S_XOSC] is 1 and OLRI flag = 0 0 8-40 MHz crystal oscillator is not stable 1 8-40 MHz crystal oscillator is providing a stable clock
27 S_FIRCON	16 MHz internal RC oscillator status 0 16 MHz internal RC oscillator is not stable 1 16 MHz internal RC oscillator is providing a stable clock
28–31 S_SYSCLK	System clock switch status — These bits specify the system clock currently used by the system. 0000 16 MHz int. RC osc. 0001 FXOSC 0010 PLL PHI_0 0011 reserved 0110 reserved 0111 reserved 1000 reserved 1001 reserved 1010 reserved 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 system clock is disabled

40.3.2 Mode Control Register (MC_ME_MCTL)

This register is used to trigger software-controlled mode changes. Depending on the modes as enabled by ME_ME register bits, configurations corresponding to unavailable modes are reserved and access to ME_<mode>_MC registers must respect this for successful mode requests.

NOTE

Byte and half-word write accesses are not allowed for this register as a predefined key is required to change its value.

NOTE

Software should always check PMCDIG_MCR[LP_ST_CHG_IN_PRGRS] is 0 before a new mode transition request is initiated.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	TARGET_MODE				0																											
W																	KEY

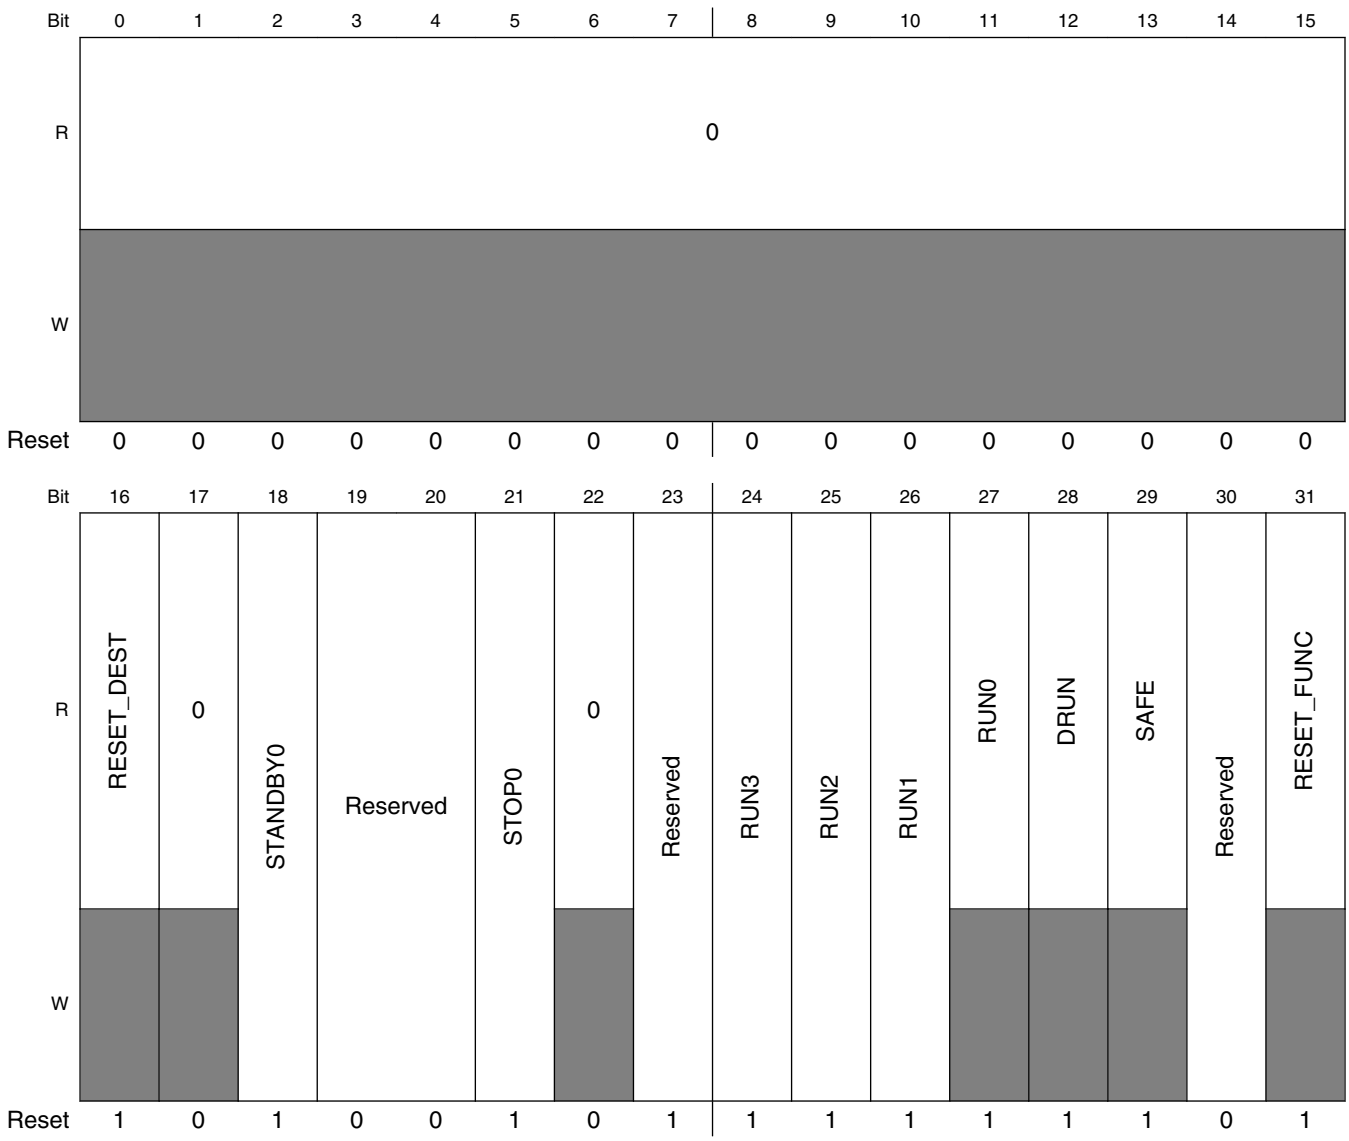
MC_ME_MCTL field descriptions

Field	Description
0–3 TARGET_MODE	Target chip mode These bits provide the target chip mode to be entered by software programming. The mechanism to enter into any mode by software requires the write operation twice: first time with key, and second time with inverted key. These bits are automatically updated by hardware while entering SAFE on hardware request. Also, while exiting from the STOP0 modes on hardware exit events, these are updated with the appropriate RUN0…3 mode value. 0000 RESET (triggers a 'functional' reset event) 0001 Reserved 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 Reserved 1001 reserved 1010 STOP0 1011 reserved 1100 reserved 1101 STANDBY0

Table continues on the next page...



MC_ME_MCTL field descriptions (continued)

Field	Description
	1110 reserved 1111 RESET (triggers a ‘destructive’ reset event)
4–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 KEY	Control key — These bits enable write access to this register. Any write access to the register with a value different from the keys is ignored. Read access will always return inverted key. KEY: 0101101011110000 (0x5AF0) INVERTED KEY: 1010010100001111 (0xA50F)

40.3.3 Mode Enable Register (MC_ME_ME)

This register allows a way to disable the chip modes which are not required for a given chip. RESET_FUNC, SAFE, DRUN, RESET_DEST, and RUN0 modes are always enabled.

Address: 0h base + 8h offset = 8h

MC_ME_ME field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

MC_ME_ME field descriptions (continued)

Field	Description
16 RESET_DEST	‘destructive’ RESET mode enable 1 ‘destructive’ RESET mode is enabled
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 STANDBY0	STANDBY0 mode enable 0 STANDBY0 mode is disabled 1 STANDBY0 mode is enabled
19–20 Reserved	This field is reserved.
21 STOP0	STOP0 mode enable 0 STOP0 mode is disabled 1 STOP0 mode is enabled
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 Reserved	This field is reserved.
24 RUN3	RUN3 mode enable 0 RUN3 mode is disabled 1 RUN3 mode is enabled
25 RUN2	RUN2 mode enable 0 RUN2 mode is disabled 1 RUN2 mode is enabled
26 RUN1	RUN1 mode enable 0 RUN1 mode is disabled 1 RUN1 mode is enabled
27 RUN0	RUN0 mode enable 1 RUN0 mode is enabled
28 DRUN	DRUN mode enable 1 DRUN mode is enabled
29 SAFE	SAFE mode enable 1 SAFE mode is enabled
30 Reserved	This field is reserved.
31 RESET_FUNC	‘functional’ RESET mode enable 1 ‘functional’ RESET mode is enabled 0 ‘functional’ RESET mode is disabled

40.3.4 Interrupt Status Register (MC_ME_IS)

This register provides the current interrupt status.

NOTE

After BAF exits, and the control moves to application code, IS register is not in Default Reset State. It shows 0x1 which implies 'Mode transition complete interrupt is pending'.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

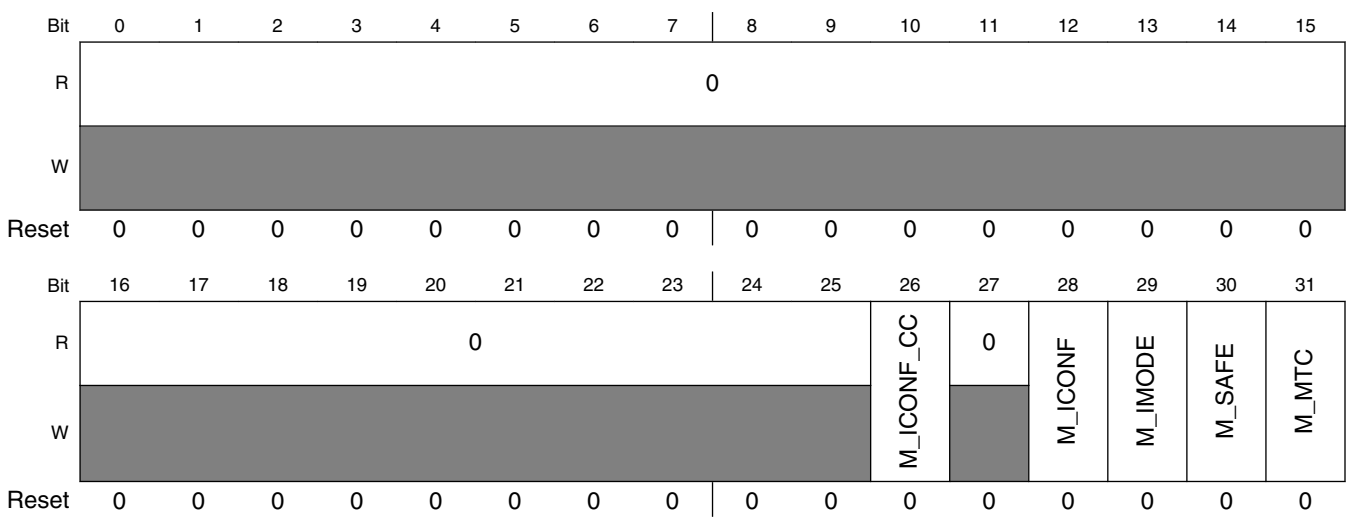
MC_ME_IS field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 I_ICONF_CC	Invalid mode configuration interrupt (core configuration) — This bit is set if a write access to one of the ME_CADDRn registers is attempted while a mode transition is in progress. 0 No write to an ME_CADDRn register was attempted during an ongoing mode transition 1 A write to an ME_CADDRn register was attempted during an ongoing mode transition

Table continues on the next page...



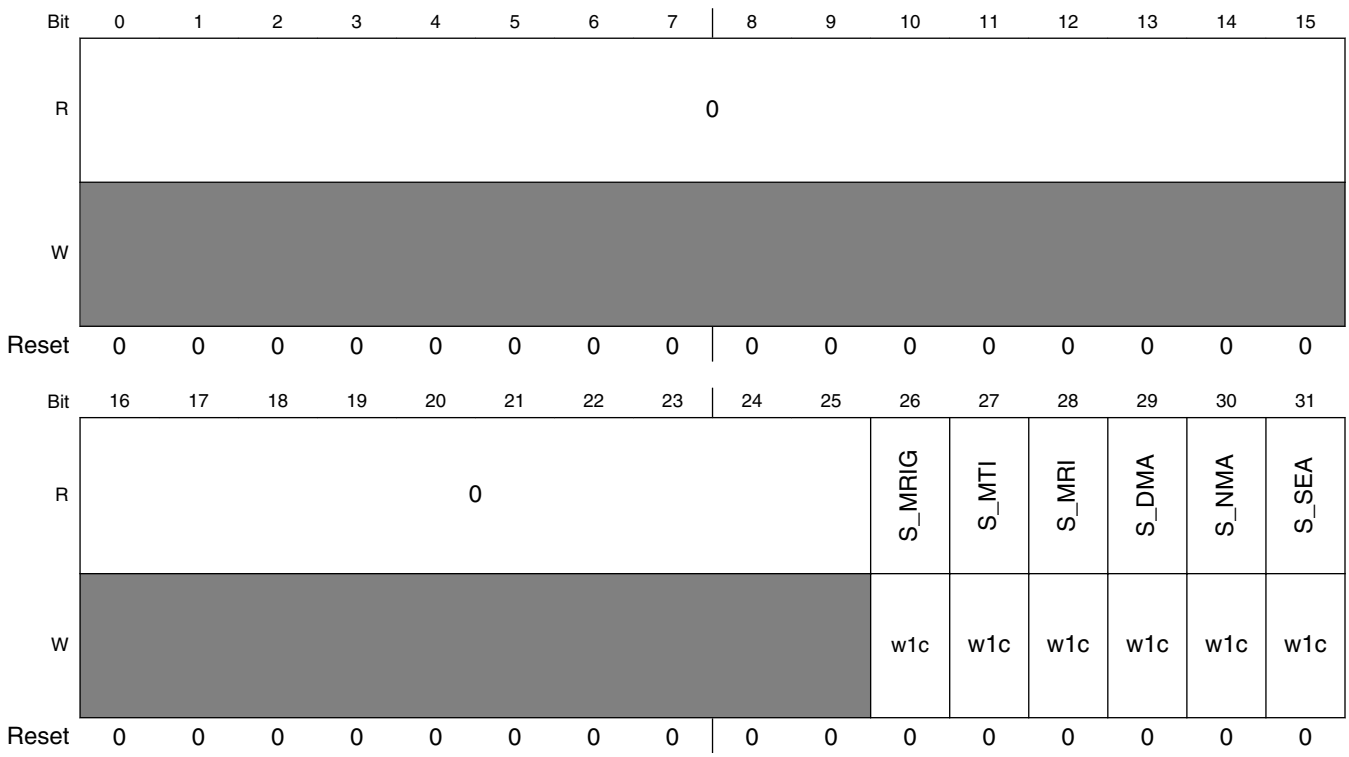
MC_ME_IS field descriptions (continued)

Field	Description
27 Reserved	This field is reserved and can be set to 1 by hardware during some mode transitions. The setting of this bit has no impact on the device. This field is reserved.
28 I_ICONF	Invalid mode configuration interrupt — This bit is set whenever a write operation to ME_<mode>_MC registers with invalid mode configuration is attempted. It is cleared by writing a '1' to this bit. 0 No invalid mode configuration interrupt occurred 1 Invalid mode configuration interrupt is pending
29 I_IMODE	Invalid mode interrupt — This bit is set whenever an invalid mode transition is requested. It is cleared by writing a '1' to this bit. 0 No invalid mode interrupt occurred 1 Invalid mode interrupt is pending
30 I_SAFE	SAFE mode interrupt — This bit is set whenever the chip enters SAFE mode on hardware requests generated in the system. It is cleared by writing a '1' to this bit. 0 No SAFE mode interrupt occurred 1 SAFE mode interrupt is pending
31 I_MTC	Mode transition complete interrupt — This bit is set whenever the mode transition process completes (S_MTRANS transits from 1 to 0). It is cleared by writing a '1' to this bit. This mode transition interrupt bit will not be set while entering low-power modes STOP0, or STANDBY0. 0 No mode transition complete interrupt occurred 1 Mode transition complete interrupt is pending

40.3.5 Interrupt Mask Register (MC_ME_IM)

This register controls whether an event generates an interrupt or not.

Address: 0h base + 10h offset = 10h



MC_ME_IM field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 M_ICONF_CC	Invalid mode configuration (core configuration) interrupt mask 0 Invalid mode configuration (core configuration) interrupt is masked 1 Invalid mode configuration (core configuration) interrupt is enabled
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 M_ICONF	Invalid mode configuration interrupt mask 0 Invalid mode configuration (core configuration) interrupt is masked 1 Invalid mode configuration (core configuration) interrupt is enabled
29 M_IMODE	Invalid mode interrupt mask 0 Invalid mode interrupt is masked 1 Invalid mode interrupt is enabled
30 M_SAFE	SAFE mode interrupt mask 0 SAFE mode interrupt is masked 1 SAFE mode interrupt is enabled
31 M_MTC	Mode transition complete interrupt mask 0 Mode transition complete interrupt is masked 1 Mode transition complete interrupt is enabled

40.3.6 Invalid Mode Transition Status Register (MC_ME_IMTS)

This register provides the status bits for the possible causes of an invalid mode interrupt.

Address: 0h base + 14h offset = 14h

MC_ME_IMTS field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 S_MRIG	Mode Request Ignored status — This bit is set whenever a new mode is requested while a transition to the SAFE mode is in progress. It is cleared by writing a ‘1’ to this bit. This bit is also set when a transition to STANDBY0/STOP0 mode is requested while a wakeup event is active. 0 Mode transition requested is not illegal 1 Mode transition requested is illegal
27 S_MTI	Mode Transition Illegal status — This bit is set whenever a new mode is requested while some other non-SAFE mode transition process is active (S_MTRANS is ‘1’). Please refer to Mode Transition Interrupts for the exceptions to this behavior. It is cleared by writing a ‘1’ to this bit. 0 Mode transition requested is not illegal 1 Mode transition requested is illegal

Table continues on the next page...

MC_ME_IMTS field descriptions (continued)

Field	Description
28 S_MRI	Mode Request Illegal status — This bit is set whenever the target mode requested is not a valid mode with respect to current mode. It is cleared by writing a ‘1’ to this bit. 0 Target mode requested is not illegal with respect to current mode 1 Target mode requested is illegal with respect to current mode
29 S_DMA	Disabled Mode Access status — This bit is set whenever the target mode requested is one of those disabled modes determined by ME_ME register. It is cleared by writing a ‘1’ to this bit. 0 Target mode requested is not a disabled mode 1 Target mode requested is a disabled mode
30 S_NMA	Non-existing Mode Access status — This bit is set whenever the target mode requested is one of those non existing modes determined by ME_ME register. It is cleared by writing a ‘1’ to this bit. 0 Target mode requested is an existing mode 1 Target mode requested is a non-existing mode
31 S_SEA	SAFE Event Active status — This bit is set whenever the chip is in SAFE mode, SAFE event bit is pending and a new mode requested other than RESET/SAFE modes. It is cleared by writing a ‘1’ to this bit. 0 No new mode requested other than RESET/SAFE while SAFE event is pending 1 New mode requested other than RESET/SAFE while SAFE event is pending

40.3.7 Debug Mode Transition Status Register (MC_ME_DMTS)

This register provides the status of different factors which influence mode transitions. It is used to give an indication of why a mode transition indicated by ME_GS.S_MTRANS may be taking longer than expected. NOTE The ME_DMTS register does not indicate whether a mode transition is ongoing. Therefore, some ME_DMTS bits may still be asserted after the mode transition has completed.

NOTE

After BAF exits, and the control moves to application code, DMTS register is not in Default Reset State. It shows 0x30000000 which implies previous mode was DRUN.

Address: 0h base + 18h offset = 18h

MC_ME_DMTS field descriptions

Field	Description
0–3 PREVIOUS_ MODE	Previous chip mode — These bits show the mode in which the chip was prior to the latest change to the current mode. **NOTE:** Mode codes “1001”, “1011”, “1100”, “1110”, and “1111” are reserved and should never appear. 0000 RESET 0001 Reserved 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 Reserved 1001 reserved 1010 STOP0 1011 reserved 1100 reserved 1101 STANDBY0[1] 1110 reserved 1111 reserved
4–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

MC_ME_DMTS field descriptions (continued)

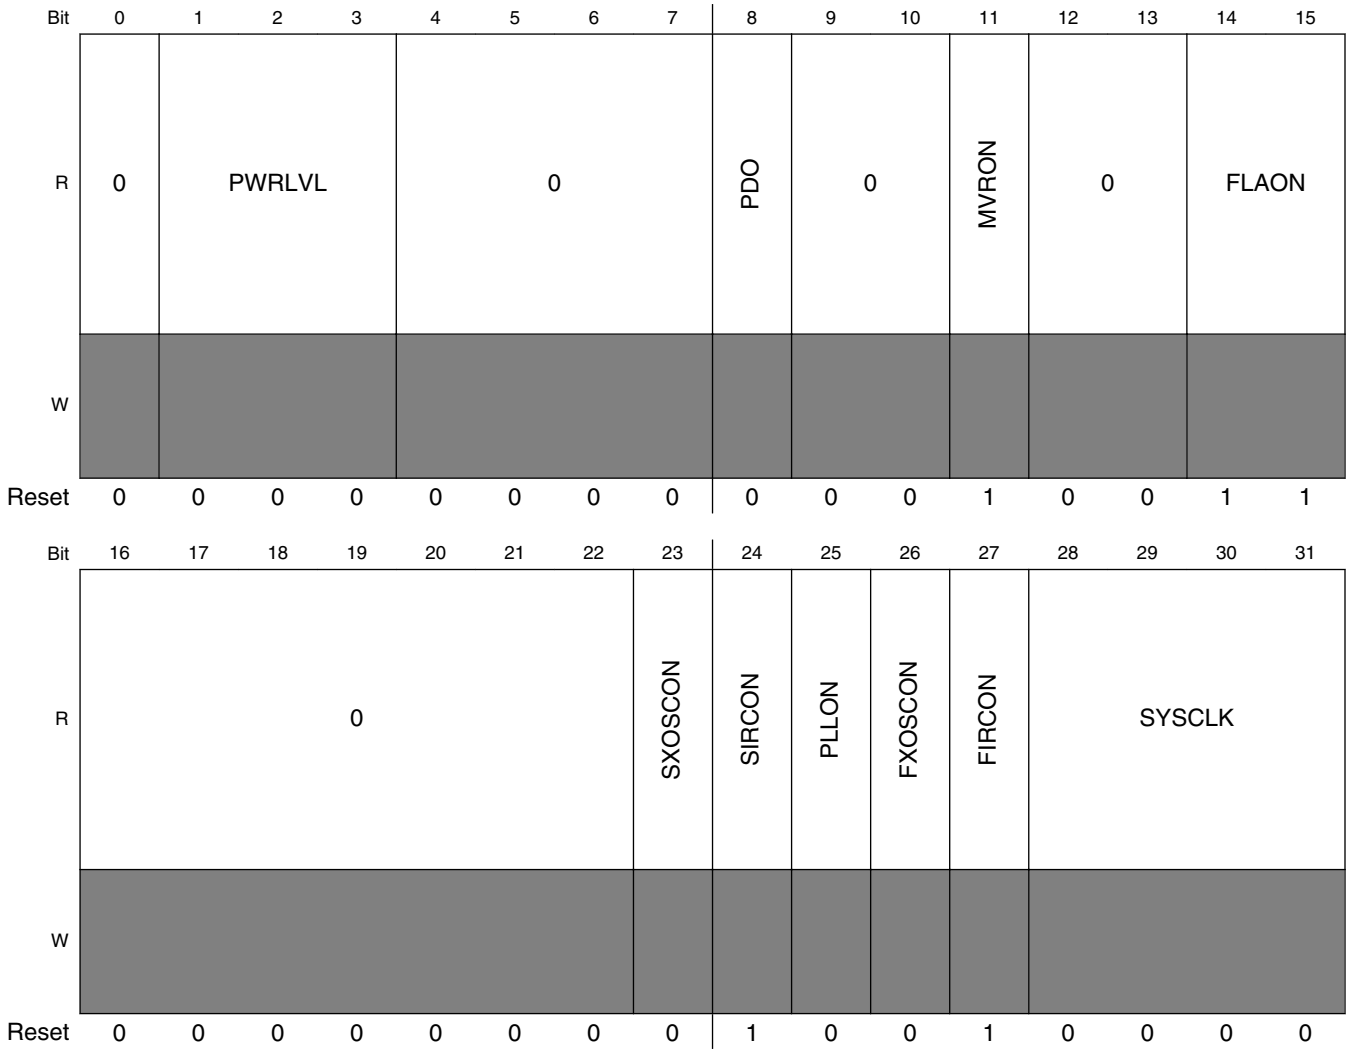
Field	Description
8 MPH_BUSY	MC_ME/MC_PCU Handshake Busy indicator — This bit is set if the MC_ME has requested a mode change from the MC_PCU and the MC_PCU has not yet completed its power-up/down sequencing. It is cleared when the MC_PCU has power-up/down sequencing. 0 Handshake is not busy 1 Handshake is busy
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 PMC_PROG	MC_PCU Mode Change in Progress indicator — This bit is set if the MC_PCU is in the process of powering up or down power domains. It is cleared when all power-up/down processes have completed. 0 Power-up/down transition is not in progress 1 Power-up/down transition is in progress
12 DBG_MODE	Debug mode indicator — This bit is set while the chip is in debug mode. 0 The chip is not in debug mode 1 The chip is in debug mode
13 CCKL_PROG	Core Clock Enable/Disable in Progress — This bit is set while any core's clock is in the process of being enabled or disabled. 0 No core clock is being enabled or disabled 1 A core clock is being enabled or disabled
14 PCS_PROG	Progressive System Clock Switching in Progress — This bit is set while the progressive system clock switching process is in progress. The PCS_PROG bit is set when the • PCS is in progress or • Peripheral clock switching is ongoing or • Core clock switching is ongoing or • Power sequence process is ongoing (provided the target mode is not STANDBY) 0 PCS is not in progress 1 PCS is in progress
15 SMR	SAFE mode request from MC_RGM is active indicator — This bit is set if a hardware SAFE mode request has been triggered. It is cleared when the hardware SAFE mode request has been cleared. 0 A SAFE mode request is not active 1 A SAFE mode request is active
16 Reserved	Clock Disable Process Pending status for Peripherals 0…255 This read-only field is reserved and always has the value 0. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
17 VREG_CSRC_SC	Main VREG dependent Clock Source State Change during mode transition indicator — This bit is set when a clock source which depends on the main voltage regulator to be powered-up is requested to change its power up/down state. It is cleared when the clock source has completed its state change. 0 No state change is taking place 1 A state change is taking place

Table continues on the next page...

MC_ME_DMTS field descriptions (continued)

Field	Description
18 CSRC_CSRC_SC	(Other) Clock Source dependent Clock Source State Change during mode transition indicator — This bit is set when a clock source which depends on another clock source to be powered-up is requested to change its power up/down state. It is cleared when the clock source has completed its state change. 0 No state change is taking place 1 A state change is taking place
19 IRC_SC	IRC State Change during mode transition indicator — This bit is set when the 16 MHz internal RC oscillator is requested to change its power up/down state. It is cleared when the 16 MHz internal RC oscillator has completed its state change. 0 No state change is taking place 1 A state change is taking place
20 SCSRC_SC	Secondary Clock Sources State Change during mode transition indicator — This bit is set when a secondary clock source is requested to change its power up/down state. It is cleared when all secondary system clock sources have completed their state changes. (A 'secondary clock source' is a clock source other than IRC.) 0 No state change is taking place 1 A state change is taking place
21 SYSCLK_SW	System Clock Switching pending status — 0 No system clock source switching is pending 1 A system clock source switching is pending
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 FLASH_SC	FLASH State Change during mode transition indicator — This bit is set when the FLASH is requested to change its power up/down state. It is cleared when the DFLASH has completed its state change. 0 No state change is taking place 1 A state change is taking place
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 CDP_PRPH_96_127	Clock Disable Process Pending status for Peripherals 96…127 — This bit is set when any peripheral appearing in ME_PS3 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. Peripheral n corresponds to the ME_PCTLn register. Please refer to memeory map table for the ME_PCTLn locations actually occupied, which in turn indicates which peripherals are reported in the ME_DMTS register. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
29 CDP_PRPH_64_95	Clock Disable Process Pending status for Peripherals 64…95 — This bit is set when any peripheral appearing in ME_PS2 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral

Table continues on the next page...



MC_ME_DMTS field descriptions (continued)

Field	Description
30 CDP_PRPH_32_63	Clock Disable Process Pending status for Peripherals 32…63 — This bit is set when any peripheral appearing in ME_PS1 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. Peripheral n corresponds to the ME_PCTLn register. Please refer to memeory map table for the ME_PCTLn locations actually occupied, which in turn indicates which peripherals are reported in the ME_DMTS register. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
31 CDP_PRPH_0_31	Clock Disable Process Pending status for Peripherals 0…31 — This bit is set when any peripheral appearing in ME_PS0 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. Peripheral n corresponds to the ME_PCTLn register. Please refer to memeory map table for the ME_PCTLn locations actually occupied, which in turn indicates which peripherals are reported in the ME_DMTS register. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral

1. This register/bitfield does not give a valid indication for the previous_mode after wakeup from STANDBY because MC_ME registers are power gated during STANDBY mode. See PMCDIG_SGSR[LP_STATUS] for STANDBY status.

40.3.8 RESET Mode Configuration Register (MC_ME_RESET_MC)

Address: 0h base + 20h offset = 20h

MC_ME_RESET_MC field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–3 PWRLVL	Power level — These bits indicate the relative power consumption level of this mode with respect to that of other modes. When switching between two modes with differing power levels, system clock progressive switching is enabled.
4–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 PDO	I/O output power-down control — This bit controls the output power-down of I/Os.

Table continues on the next page...

MC_ME_RESET_MC field descriptions (continued)

Field	Description
	0 No automatic safe gating of I/Os used and pads power sequence driver is enabled 1 In SAFE mode, outputs of pads are forced to high impedance state and pads power sequence driver is disabled. The inputs are level unchanged. In STOP0 mode, only the pad power sequence driver is disabled, but the state of the output remains functional.
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 MVRON	Main voltage regulator control — This bit specifies whether main voltage regulator is switched off or not while entering this mode. 1 Main voltage regulator is switched on
12–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 FLAON	Flash power-down control — This bit specifies the operating mode of the code flash after entering this mode. 00 reserved 01 Flash is in power-down mode 10 reserved 11 Flash is in RUN mode
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–3 PWRLVL	Power level — These bits indicate the relative power consumption level of this mode with respect to that of other modes. When switching between two modes with differing power levels, system clock progressive switching is enabled.
4–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 PDO	I/O output power-down control — This bit controls the output power-down of I/Os. 0 No automatic safe gating of I/Os used and pads power sequence driver is enabled 1 In SAFE mode, outputs of pads are forced to high impedance state and pads power sequence driver is disabled. The inputs are level unchanged. In STOP0 mode, only the pad power sequence driver is disabled, but the state of the output remains functional.
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 MVRON	Main voltage regulator control — This bit specifies whether main voltage regulator is switched off or not while entering this mode. 1 Main voltage regulator is switched on
12–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 FLAON	Flash power-down control — This bit specifies the operating mode of the code flash after entering this mode. 00 reserved 01 Flash is in power-down mode 10 reserved 11 Flash is in RUN mode
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 SXOSCON	32 KHz external oscillator control 0 32 KHz external oscillator control is off 1 32 KHz external oscillator control is on
24 SIRCON	128 KHz internal RC oscillator control 0 128 KHz internal RC oscillator control is switched off 1 128 KHz internal RC oscillator control is switched on
25 PLLON	PLL control 0 PLL is switched off 1 PLL is switched on
26 FXOSCON	8-40 MHz crystal oscillator control 0 8-40 MHz crystal oscillator is switched off 1 8-40 MHz crystal oscillator is switched on
27 FIRCON	16 MHz internal RC oscillator control

Table continues on the next page...

40.3.17 Peripheral Status Register 0 (MC_ME_PS0)

This register provides the status of the peripherals.

NOTE

Peripheral Status for ENET and PIT will be 1 when both ME_PCTL is enabled and the clock gating control bits within IP are also enabled. For other modules, Peripheral Status will depend on direct control through ME_PCTL.

Address: 0h base + 60h offset = 60h

MC_ME_PS0 field descriptions

Field	Description
0 S_IIC_1	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
1 S_IIC_0	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active

Table continues on the next page...

MC_ME_PS0 field descriptions (continued)

Field	Description
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 S_FlexRay	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
4–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 S_ADC_1	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0: Peripheral is frozen 1: Peripheral is active .
7 S_ADC_0	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0: Peripheral is frozen 1: Peripheral is active
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 S_ACMP_2	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0: Peripheral is frozen 1: Peripheral is active
10 S_ACMP_1	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0: Peripheral is frozen 1: Peripheral is active
11 S_ACMP_0	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0: Peripheral is frozen 1: Peripheral is active
12–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 S_ENET	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0: Peripheral is frozen 1: Peripheral is active
17–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 S_SAI_2	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0: Peripheral is frozen

Table continues on the next page...

MC_ME_PS0 field descriptions (continued)

Field	Description

MC_ME_PS1 field descriptions

Field	Description
0–13 S_LIN[13:0]	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0: Peripheral is frozen 1: Peripheral is active
14–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 S_DSPI[3:0]	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0: Peripheral is frozen 1: Peripheral is active
24–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 S_IIC[3:2]	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0: Peripheral is frozen 1: Peripheral is active

40.3.19 Peripheral Status Register 2 (MC_ME_PS2)

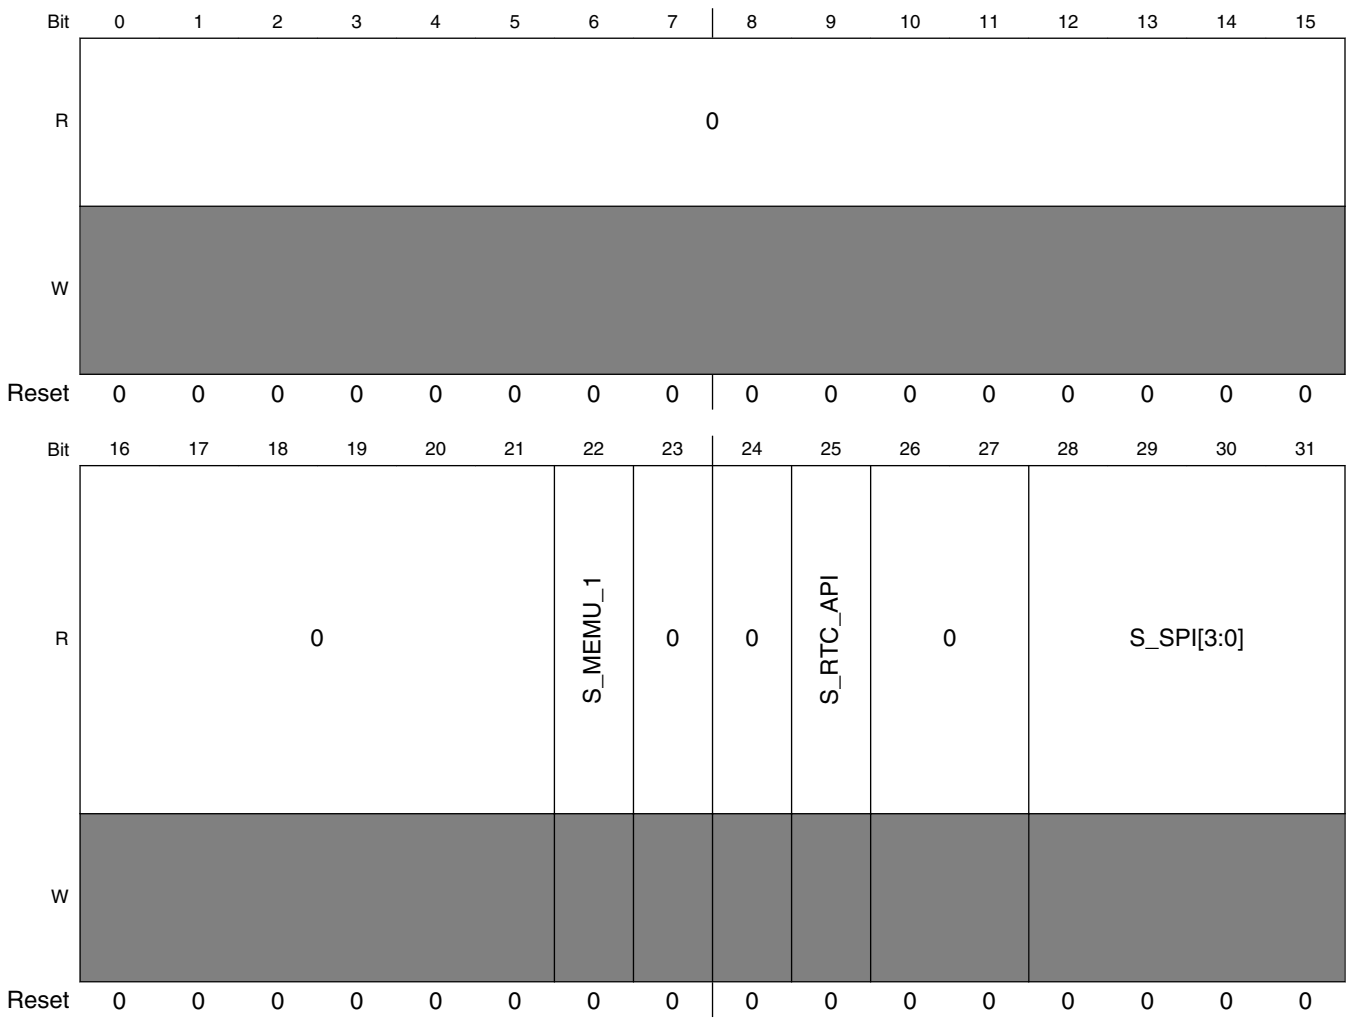
This register provides the status of the peripherals.

Address: 0h base + 68h offset = 68h

MC_ME_PS2 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 S_WKPU	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0: Peripheral is frozen

Table continues on the next page...



MC_ME_PS2 field descriptions (continued)

Field	Description
	1: Peripheral is active
3 S_LPU_CTL	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0: Peripheral is frozen 1: Peripheral is active
4 S_PIT_RTI_0	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0: Peripheral is frozen 1: Peripheral is active
5 S_DMAMUX	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
6–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 S_CRC	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME.
12 S_MEMU_0	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME.
13 S_JDC	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME.
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–25 S_FLEXCAN[7:0]	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0: Peripheral is frozen 1: Peripheral is active
26–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 S_LIN[15:14]	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0: Peripheral is frozen 1: Peripheral is active

40.3.20 Peripheral Status Register 3 (MC_ME_PS3)

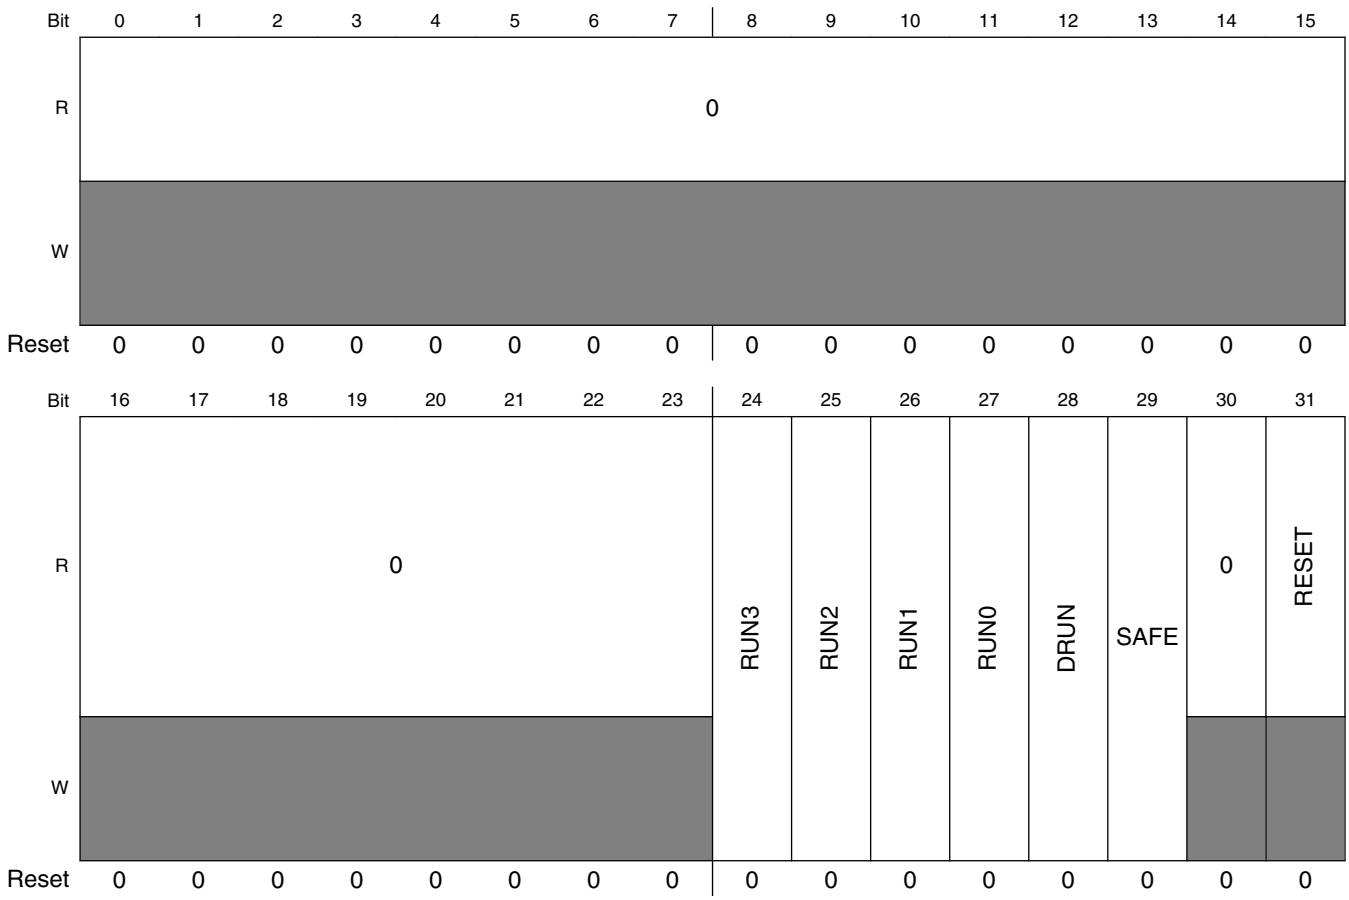
This register provides the status of the peripherals.

Address: 0h base + 6Ch offset = 6Ch

MC_ME_PS3 field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 S_MEMU_1	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0: Peripheral is frozen 1: Peripheral is active

Table continues on the next page...



MC_ME_PS3 field descriptions (continued)

Field	Description
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 S_RTC_API	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0: Peripheral is frozen 1: Peripheral is active
26–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 S_SPI[3:0]	Peripheral status — These bits specify the current status of each peripheral which is controlled by the MC_ME. 0: Peripheral is frozen 1: Peripheral is active

40.3.21 Run Peripheral Configuration Register (MC_ME_RUN_PC*n*)

The ME_RUN_PC0..7 registers configure eight different types of peripheral behavior during run modes.

Address: 0h base + 80h offset + (4d × i), where i=0d to 7d

MC_ME_RUN_PC*n* field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 RUN3	Peripheral control during RUN3 0 Peripheral is frozen with clock gated 1 Peripheral is active
25 RUN2	Peripheral control during RUN2 0 Peripheral is frozen with clock gated 1 Peripheral is active

Table continues on the next page...

MC_ME_RUN_PC*n* field descriptions (continued)

Field	Description
26 RUN1	Peripheral control during RUN1 0 Peripheral is frozen with clock gated 1 Peripheral is active
27 RUN0	Peripheral control during RUN0 0 Peripheral is frozen with clock gated 1 Peripheral is active
28 DRUN	Peripheral control during DRUN 0 Peripheral is frozen with clock gated 1 Peripheral is active
29 SAFE	Peripheral control during SAFE 0 Peripheral is frozen with clock gated 1 Peripheral is active
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 RESET	Peripheral control during RESET 0 Peripheral is frozen with clock gated 1 Peripheral is active

40.3.22 Low-Power Peripheral Configuration Register (MC_ME_LP_PC*n*)

The MC_LP_PC registers configure eight different types of peripheral behavior during non-run modes.

Address: 0h base + A0h offset + (4d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 DBG_F	Peripheral control in debug mode — This bit controls the state of the peripheral in debug mode **NOTE:** This feature is useful to freeze the peripheral state while entering debug. For example, this may be used to prevent a reference timer from running while making a debug accesses. 0 Peripheral state depends on RUN_CFG/LP_CFG bits and the chip mode 1 Peripheral is frozen if not already frozen in chip modes.
2–4 LP_CFG	Peripheral configuration select for non-run modes — These bits associate a configuration as defined in the ME_LP_PC0…7 registers to the peripheral. 000 Selects ME_LP_PC0 configuration 001 Selects ME_LP_PC1 configuration 010 Selects ME_LP_PC2 configuration 011 Selects ME_LP_PC3 configuration 100 Selects ME_LP_PC4 configuration 101 Selects ME_LP_PC5 configuration 110 Selects ME_LP_PC6 configuration 111 Selects ME_LP_PC7 configuration
5–7 RUN_CFG	Peripheral configuration select for run modes — These bits associate a configuration as defined in the ME_RUN_PC0…7 registers to the peripheral. 000 Selects ME_RUN_PC0 configuration 001 Selects ME_RUN_PC1 configuration 010 Selects ME_RUN_PC2 configuration 011 Selects ME_RUN_PC3 configuration 100 Selects ME_RUN_PC4 configuration 101 Selects ME_RUN_PC5 configuration 110 Selects ME_RUN_PC6 configuration 111 Selects ME_RUN_PC7 configuration

40.3.40 DSPI_0 Peripheral Control Register (MC_ME_PCTL40)

This register selects the configurations during run and non-run modes for the associated peripheral.

Address: 0h base + E8h offset = E8h

Bit	0	1	2	3	4	5	6	7
Read	0	DBG_F	LP_CFG			RUN_CFG		
Write								
Reset	0	0	0	0	0	0	0	0

MC_ME_PCTL40 field descriptions

Field	Description

MC_ME_PCTL60 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 DBG_F	Peripheral control in debug mode — This bit controls the state of the peripheral in debug mode **NOTE:** This feature is useful to freeze the peripheral state while entering debug. For example, this may be used to prevent a reference timer from running while making a debug accesses. 0 Peripheral state depends on RUN_CFG/LP_CFG bits and the chip mode 1 Peripheral is frozen if not already frozen in chip modes.
2–4 LP_CFG	Peripheral configuration select for non-run modes — These bits associate a configuration as defined in the ME_LP_PC0…7 registers to the peripheral. 000 Selects ME_LP_PC0 configuration 001 Selects ME_LP_PC1 configuration 010 Selects ME_LP_PC2 configuration 011 Selects ME_LP_PC3 configuration 100 Selects ME_LP_PC4 configuration 101 Selects ME_LP_PC5 configuration 110 Selects ME_LP_PC6 configuration 111 Selects ME_LP_PC7 configuration
5–7 RUN_CFG	Peripheral configuration select for run modes — These bits associate a configuration as defined in the ME_RUN_PC0…7 registers to the peripheral. 000 Selects ME_RUN_PC0 configuration 001 Selects ME_RUN_PC1 configuration 010 Selects ME_RUN_PC2 configuration 011 Selects ME_RUN_PC3 configuration 100 Selects ME_RUN_PC4 configuration 101 Selects ME_RUN_PC5 configuration 110 Selects ME_RUN_PC6 configuration 111 Selects ME_RUN_PC7 configuration

40.3.55 LIN_11 Peripheral Control Register (MC_ME_PCTL61)

This register selects the configurations during run and non-run modes for the associated peripheral.

Address: 0h base + FDh offset = FDh

Bit	0	1	2	3	4	5	6	7
Read	0	DBG_F	LP_CFG			RUN_CFG		
Write								
Reset	0	0	0	0	0	0	0	0

MC_ME_PCTL61 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

5–7 RUN_CFG	Peripheral configuration select for run modes — These bits associate a configuration as defined in the ME_RUN_PC0…7 registers to the peripheral. 000 Selects ME_RUN_PC0 configuration 001 Selects ME_RUN_PC1 configuration 010 Selects ME_RUN_PC2 configuration 011 Selects ME_RUN_PC3 configuration 100 Selects ME_RUN_PC4 configuration 101 Selects ME_RUN_PC5 configuration 110 Selects ME_RUN_PC6 configuration 111 Selects ME_RUN_PC7 configuration

40.3.69 MEMU_0 Control Register (MC_ME_PCTL83)

This register selects the configurations during run and non-run modes for the associated peripheral.

Address: 0h base + 113h offset = 113h

Bit	0	1	2	3	4	5	6	7
Read	0	DBG_F	LP_CFG			RUN_CFG		
Write								
Reset	0	0	0	0	0	0	0	0

MC_ME_PCTL83 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 DBG_F	Peripheral control in debug mode — This bit controls the state of the peripheral in debug mode **NOTE:** This feature is useful to freeze the peripheral state while entering debug. For example, this may be used to prevent a reference timer from running while making a debug accesses. 0 Peripheral state depends on RUN_CFG/LP_CFG bits and the chip mode 1 Peripheral is frozen if not already frozen in chip modes.
2–4 LP_CFG	Peripheral configuration select for non-run modes — These bits associate a configuration as defined in the ME_LP_PC0…7 registers to the peripheral. 000 Selects ME_LP_PC0 configuration 001 Selects ME_LP_PC1 configuration 010 Selects ME_LP_PC2 configuration 011 Selects ME_LP_PC3 configuration 100 Selects ME_LP_PC4 configuration 101 Selects ME_LP_PC5 configuration 110 Selects ME_LP_PC6 configuration 111 Selects ME_LP_PC7 configuration
5–7 RUN_CFG	Peripheral configuration select for run modes — These bits associate a configuration as defined in the ME_RUN_PC0…7 registers to the peripheral. 000 Selects ME_RUN_PC0 configuration 001 Selects ME_RUN_PC1 configuration 010 Selects ME_RUN_PC2 configuration 011 Selects ME_RUN_PC3 configuration 100 Selects ME_RUN_PC4 configuration 101 Selects ME_RUN_PC5 configuration 110 Selects ME_RUN_PC6 configuration 111 Selects ME_RUN_PC7 configuration

40.3.70 CRC Control Register (MC_ME_PCTL84)

This register selects the configurations during run and non-run modes for the associated peripheral.

Address: 0h base + 114h offset = 114h

Bit	0	1	2	3	4	5	6	7
Read	0	DBG_F	LP_CFG			RUN_CFG		
Write								
Reset	0	0	0	0	0	0	0	0

MC_ME_PCTL84 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 DBG_F	Peripheral control in debug mode — This bit controls the state of the peripheral in debug mode **NOTE:** This feature is useful to freeze the peripheral state while entering debug. For example, this may be used to prevent a reference timer from running while making a debug accesses. 0 Peripheral state depends on RUN_CFG/LP_CFG bits and the chip mode 1 Peripheral is frozen if not already frozen in chip modes.
2–4 LP_CFG	Peripheral configuration select for non-run modes — These bits associate a configuration as defined in the ME_LP_PC0…7 registers to the peripheral. 000 Selects ME_LP_PC0 configuration 001 Selects ME_LP_PC1 configuration 010 Selects ME_LP_PC2 configuration 011 Selects ME_LP_PC3 configuration 100 Selects ME_LP_PC4 configuration 101 Selects ME_LP_PC5 configuration 110 Selects ME_LP_PC6 configuration 111 Selects ME_LP_PC7 configuration
5–7 RUN_CFG	Peripheral configuration select for run modes — These bits associate a configuration as defined in the ME_RUN_PC0…7 registers to the peripheral. 000 Selects ME_RUN_PC0 configuration 001 Selects ME_RUN_PC1 configuration 010 Selects ME_RUN_PC2 configuration 011 Selects ME_RUN_PC3 configuration 100 Selects ME_RUN_PC4 configuration 101 Selects ME_RUN_PC5 configuration 110 Selects ME_RUN_PC6 configuration 111 Selects ME_RUN_PC7 configuration

40.3.71 DMAMUX Control Register (MC_ME_PCTL90)

This register selects the configurations during run mode for the associated peripheral. There is no affect in low power modes.

Address: 0h base + 11Ah offset = 11Ah

Bit	0	1	2	3	4	5	6	7
Read	0	DBG_F	LP_CFG			RUN_CFG		
Write								
Reset	0	0	0	0	0	0	0	0

MC_ME_PCTL90 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 DBG_F	Peripheral control in debug mode — This bit controls the state of the peripheral in debug mode **NOTE:** This feature is useful to freeze the peripheral state while entering debug. For example, this may be used to prevent a reference timer from running while making a debug accesses. 0 Peripheral state depends on RUN_CFG/LP_CFG bits and the chip mode 1 Peripheral is frozen if not already frozen in chip modes.

40.3.80 Core Status Register (MC_ME_CS)

This register provides the status of each core.

Address: 0h base + 1C0h offset = 1C0h

MC_ME_CS field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 S_CORE3	Core3 Status These bits specify the current status of Z2 core which is controlled by the MC_ME. 0 Z2 is disabled 1 Z2 is running
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 S_CORE1	Core 1 status — These bits specify the current status of Z4A core which is controlled by the MC_ME.

Table continues on the next page...

MC_ME_CS field descriptions (continued)

Field	Description
	0 Z4A is disabled 1 Z4A is running
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

40.3.81 Core1 Control Register (MC_ME_CCTL1)

This register controls whether the Z4A is disabled or running during run modes. Please refer to memory map table for information on which ME_CCTL1 locations are actually occupied. The unoccupied locations contain a read-only half-word value of 0x0000.

The run mode bits (SAFE, DRUN, and RUNx) of the ME_CCTL1 register are pre-loaded with the value provided by the device configuration just before reset exist.

The value of the DRUN bit just before entering STANDBY0 mode is the value of all the run mode bits (SAFE, DRUN, and RUNx) on STANDBY0 exit. The values of the low-power mode bits (STOP0, and STANDBY0) revert to their reset values on STANDBY0 exit.

The low-power mode bits (STOP0, and STANDBY0) of the ME_CCTL1 register are reset with the default value shown and are not pre-loaded with another value.

Address: 0h base + 1C6h offset = 1C6h

Bit	0	1	2	3	4	5	6	7
Read	0	STANDBY0		0		STOP0	0	0
Write								
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	RUN3	RUN2	RUN1	RUN0	DRUN	SAFE	0	RESET
Write								
Reset	0	0	0	1	1	0	0	0

MC_ME_CCTL1 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–2 STANDBY0	Core control during STANDBY0 0 Z4A is disabled with clock gated

Table continues on the next page...

MC_ME_CCTL1 field descriptions (continued)

Field	Description
3–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 STOP0	Core control during STOP0 — Z4A is disabled with clock gated.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 RUN3	Core control during RUN3 0 Z4A is disabled with clock gated 1 Z4A is running
9 RUN2	Core control during RUN2 0 Z4A is disabled with clock gated 1 Z4A is running
10 RUN1	Core control during RUN1 0 Z4A is disabled with clock gated 1 Z4A is running
11 RUN0	Core control during RUN0 0 Z4A is frozen with clock gated 1 Z4A is running
12 DRUN	Core control during DRUN 0 Z4A is frozen with clock gated 1 Z4A is running
13 SAFE	Core control during SAFE 0 Z4A is frozen with clock gated 1 Z4A is running
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 RESET	Core control during RESET — The Z4A is always disabled during RESET.

40.3.82 Core3 Control Register (MC_ME_CCTL3)

This register controls whether the Z2 core is disabled or running during run modes.

The run mode bits (SAFE, DRUN, and RUNx) of the ME_CCTL3 register are pre-loaded with the value provided by the device configuration just before reset exist.

The value of the DRUN bit just before entering STANDBY0 mode is the value of all the run mode bits (SAFE, DRUN, and RUNx) on STANDBY0 exit. The values of the low-power mode bits (STOP0, and STANDBY0) revert to their reset values on STANDBY0 exit. The low-power mode bits (STOP0, and STANDBY0) of the ME_CCTL3 register are reset with the default value shown and are not pre-loaded with another value.

Address: 0h base + 1CAh offset = 1CAh

Bit	0	1	2	3	4	5	6	7
Read	0	STANDBY0			0	STOP0	0	0
Write								
Reset	0*	0*	0*	0*	0*	0*	0*	0*

Bit	8	9	10	11	12	13	14	15
Read	RUN3	RUN2	RUN1	RUN0	DRUN	SAFE	0	RESET
Write								
Reset	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- Reset value of RUN3, RUN2, RUN1, RUN0, DRUN, and SAFE are determined by the chip configuration and boot mode.

MC_ME_CCTL3 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–2 STANDBY0	Core control during STANDBY0 0 Z2 is disabled with clock gated
3–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 STOP0	Core control during STOP0 — Z2 is disabled with clock gated.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 RUN3	Core control during RUN3 0 Z2 is disabled with clock gated 1 Z2 is running
9 RUN2	Core control during RUN2 0 Z2 is disabled with clock gated 1 Z2 is running
10 RUN1	Core control during RUN1 0 Z2 is disabled with clock gated 1 Z2 is running

Table continues on the next page...

MC_ME_CCTL3 field descriptions (continued)

Field	Description
11 RUN0	Core control during RUN0 0 Z2 is frozen with clock gated 1 Z2 is running
12 DRUN	Core control during DRUN 0 Z2 is frozen with clock gated 1 Z2 is running
13 SAFE	Core control during SAFE 0 Z2 is frozen with clock gated 1 Z2 is running
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 RESET	Core control during RESET — The Z2 is always disabled during RESET.

40.3.83 CORE1 Address Register (MC_ME_CADDR1)

This register contain the boot address of each Z4A and a bit for controlling whether the Z4A core is to be reset on the next mode change that has the core configured to be running in the target mode.

This register can be written only as words and cannot be written after a mode change request has been made until the mode transition has completed (i.e., while the S_MTRANS bit of the ME_GS register = ‘1’). A write access to any of this register during this time will result in the ICONF_CC flag in the ME_IS register being asserted.

ME_CADDR1 is pre-loaded with the value provided by the device configuration just before reset exit in order to ensure that Z4A boots from the correct address after any chip reset if the DRUN bit in the ME_CCTL1 register has a default value of ‘1’.

The value of the ADDR field just before entering STANDBY0 mode is the value of the ADDR field on STANDBY0 exit.

Address: 0h base + 1E4h offset = 1E4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	ADDR															
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ADDR														0	RMC
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0

* Notes:

- Reset value of ADDR field is determined by the chip configuration and boot mode.

MC_ME_CADDR1 field descriptions

Field	Description
0–29 ADDR	Core Address — This field is used by Z4A cores as the boot address (32-bit word aligned) when Z4A next exits reset.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 RMC	Reset on Mode Change The Z4A will be reset on the next mode change that has the core configured to be running in the target mode. 0 Z4A will not be reset on the next mode change 1 Z4A will be reset on the next mode change that has the core configured to be running in the target mode. This field is automatically cleared when the core reset triggered by the RMC is executed.

40.3.84 CORE3 Address Register (MC_ME_CADDR3)

This register contain the boot address of Z2 core and a bit for controlling whether the corresponding core is to be reset on the next mode change that has the Z2 core configured to be running in the target mode.

This register can be written only as words and cannot be written after a mode change request has been made until the mode transition has completed (i.e., while the S_MTRANS bit of the ME_GS register = ‘1’). A write access to this register during this time will result in the ICONF_CC flag in the ME_IS register being asserted.

ME_CADDR3 is pre-loaded with the value provided by the device configuration just before reset exit in order to ensure that Z2 core boots from the correct address after any chip reset if the DRUN bit in the ME_CCTL3 register has a default value of ‘1’.

The value of the ADDR field just before entering STANDBY0 mode is the value of the ADDR field on STANDBY0 exit.

Address: 0h base + 1ECh offset = 1ECh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	ADDR															
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ADDR														0	RMC
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- Reset value is determined by the chip configuration and boot mode.

MC_ME_CADDR3 field descriptions

Field	Description
0–29 ADDR	Core Address — This field is used by Z2 as the boot address (32-bit word aligned) when next exits reset.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 RMC	Reset on Mode Change The Z2 will be reset on the next mode change that has the core configured to be running in the target mode. 0 Z2 will not be reset on the next mode change 1 Z2 will be reset on the next mode change that has the core configured to be running in the target mode. This field is automatically cleared when the core reset triggered by the RMC field is executed.

40.4 Functional Description

40.4.1 Mode Transition Request

The transition from one mode to another mode is normally handled by software by accessing the mode control register ME_MCTL. In case of special events, the mode transition can be automatically managed by hardware. In order to switch from one mode to another, the application should access the ME_MCTL register twice by writing

- the first time with the value of the key (0x5AF0) into the KEY bit field and the required target mode into the TARGET_MODE bit field,
- and the second time with the inverted value of the key (0xA50F) into the KEY bit field and the required target mode into the TARGET_MODE bit field.

Once a valid mode transition request is detected, the target mode configuration information is loaded from the corresponding ME_<mode>_MC register.The mode transition request may require a number of cycles depending on the programmed configuration, and software should check the S_CURRENT_MODE bit field and the S_MTRANS bit of the global status register ME_GS to verify when the mode has been correctly entered and the transition process has completed. For a description of valid mode requests, please refer to Mode Transition Interrupts.

Any modification of the mode configuration register of the currently selected mode will not be taken into account immediately but on the next request to enter this mode. This means that transition requests such as RUN0…3 → RUN0…3, DRUN → DRUN, SAFE

→ SAFE are considered valid mode transition requests. As soon as the mode request is accepted as valid, the S_MTRANS bit is set till the status in the ME_GS register matches the configuration programmed in the respective ME_<mode>_MC register.

Note

Software should poll the ME_GS[S_MTRANS] field after requesting a transition to STOP0 or STANDBY0 modes or after reset exit and should initiate any transaction once the mode transition to the target mode is completed.

All mode transitions shown in figure, Mode Transition Interrupts are initiated by software except for those from RESET and the low-power modes or to SAFE and RESET on a hardware failure. See Table "MC_ME Mode Descriptions" for a more detailed summary of mode entry and exit triggers.

40.4.2 Modes Details

40.4.2.1 RESET Mode

The chip enters this mode on the following events:

- from SAFE or DRUN, RUN0…3 when the TARGET_MODE bit field of the ME_MCTL register is written with either "0000" for a 'functional' reset or "1111" for a 'destructive' reset
- from any mode due to a system reset by the MC_RGM because of some non-recoverable hardware failure in the system (see the MC_RGM chapter for details)

Transition to this mode is instantaneous, and the system remains in this mode until the reset sequence is finished. The mode configuration information for this mode is provided by the ME_RESET_MC register. This mode has a pre-defined configuration, and the 16 MHz int. RC osc. is selected as the system clock.

40.4.2.2 DRUN Mode

The chip enters this mode on the following events:

- automatically from RESET mode after completion of the reset sequence
- from RUN0…3 or SAFE when the TARGET_MODE bit field of the ME_MCTL register is written with "0011"

As soon as any of the above events has occurred, a DRUN mode transition request is generated. The mode configuration information for this mode is provided by the ME_DRUN_MC register. In this mode, the flash, all clock sources, and the system clock configuration can be controlled by software as required. After system reset, the software execution starts with the default configuration selecting the 16 MHz int. RC osc. as the system clock. The clock source configuration except system clock source 0 can be chosen by preloaded information in flash memory. This information is loaded into the ME_DRUN_MC register during PHASE3 of the reset sequence.

This mode is intended to be used by software

- to initialize all registers as per the system needs
- to execute small routines in a ‘ping-pong’ with the STANDBY0 mode

When this mode is entered from STANDBY0 after a wakeup event, the ME_DRUN_MC register content is restored to its pre-STANDBY0 values, and the mode starts in that configuration.

Note

On exit from STANDBY0 after a wakeup event, the software must ensure that the code executes from RAM before changing to this mode if the flash is configured to be in the low-power or power-down state in this mode.

40.4.2.3 SAFE Mode

The chip enters this mode on the following events:

- from any mode except RESET when the TARGET_MODE bit field of the ME_MCTL register is written with "0010"
- from any mode except RESET due to a SAFE mode request generated by the MC_RGM because of some potentially recoverable hardware failure in the system (see the MC_RGM chapter for details)

Note

If a hardware SAFE mode request occurs during RESET, depending on the timing of the SAFE mode request, SAFE mode may be entered immediately after the normal completion

of the reset sequence or several system clock cycles after DRUN entry. The SAFE mode request does not have any influence on the execution of the reset sequence itself.

Note

Do not confuse Safe Mode with the Functional Safety description of 'A safe state'. A Safe State is determined by the application in accordance with ISO26262 and the mode entry module safe mode is an unrelated state which can be entered from software via the following descriptions.

As soon as any of the above events has occurred, a SAFE mode transition request is generated. The mode configuration information for this mode is provided by the ME_SAFE_MC register. This mode has a pre-defined configuration, and the 16 MHz int. RC osc. is selected as the system clock.

If the SAFE mode is requested by software while some other mode transition process is ongoing, the new target mode becomes the SAFE mode regardless of other pending requests or new requests during the mode transition. No new mode request made during a transition to the SAFE mode will cause an invalid mode interrupt.

Note

If software requests to change to the SAFE mode and then requests to change back to the parent mode before the mode transition is completed, the chip's final mode after mode transition will be the SAFE mode, and an invalid mode transition interrupt will be generated.

As long as a SAFE event is active, the system remains in the SAFE mode, and any software mode request during this time is ignored and lost.

This mode is intended to be used by software

- to assess the severity of the cause of failure and then to either
  - re-initialize the chip via the DRUN mode, or
  - completely reset the chip via the RESET mode.

If the outputs of the system I/Os need to be forced to a high impedance state upon entering this mode, the PDO bit of the ME_SAFE_MC register should be set. The input levels remain unchanged.

40.4.2.4 RUN0…3 Modes

The chip enters one of these modes on the following events:

- from the DRUN or another RUN0…3 mode when the TARGET_MODE bit field of the ME_MCTL register is written with "0100…0111"
- from the STOP0 mode due to an interrupt or wakeup event

As soon as any of the above events has occurred, a RUN0…3 mode transition request is generated. The mode configuration information for these modes is provided by the ME_RUN0…3_MC registers. In these modes, the flash, all clock sources, and the system clock configuration can be controlled by software as required.

These modes are intended to be used by software

- to execute application routines

Note

Software must ensure that the code executes from RAM before changing to this mode if the flash is configured to be in the low-power or power-down state in this mode.

40.4.2.5 STOP0 Mode

The chip enters this mode on the following events:

- from one of the RUN0…3 modes when the TARGET_MODE bit field of the ME_MCTL register is written with "1010".

As soon as any of the above events has occurred, a STOP0 mode transition request is generated. The mode configuration information for this mode is provided by the ME_STOP0_MC register. This mode is fully configurable, and the ME_STOP0_MC register should be programmed according to the system needs. The following clock sources are switched off in this mode:

- the PLL PHI0

The flash memories can be put in power-down mode as needed. If there is a STOP0 mode request when any interrupt or wakeup event is active, the transition to STOP0 is aborted with the resultant mode being the current mode, and an invalid mode transition interrupt

is generated and ME_IMTS.MRIG bit is set. If a transition to safe mode is in progress, a transition to STOP0 mode will also set the ME_IMTS.MRIG bit. If a transiton to STOP0 mode is interrupted by a transition to DRUN (on reset), an invalid mode interrupt is not generated.

This can be used as an advanced low-power mode with the core clock frozen and almost all peripherals stopped.

This mode is intended as an advanced low-power mode with

- the core clock frozen
- the additional core clocks frozen
- almost all peripherals stopped

and to be used by software

- to wait until it is required to do something with no need to react quickly (e.g., allow for system clock source to be re-started)

The normal exit from the STOP0 mode is by an interrupt or a wakeup event.

This mode can be used to stop all clock sources and thus preserve the chip status. When exiting the STOP0 mode, the 16 MHz internal RC oscillator clock is selected as the system clock until the target clock is available.

Note

It is good practice for software to ensure that the S_MTRANS bit in the ME_GS register has been cleared on STOP0 mode exit to ensure that the previous RUN0…3 mode configuration has been fully restored before executing critical code.

NOTE

If waking up from stop mode through module interrupt and module is configured to be OFF in RUN and ON in STOP mode, then on stop exit, ME_GS may not show MTRANS as low till the module interrupt is cleared in ISR and so to avoid code hanging on MTRANS poll, if added as first check on stop exit, the MTRANS polling has to be done after clearing module interrupt.

NOTE

All interrupts that are masked in INTC should be disabled in the modules as well. Otherwise a hang situation can occur as follows:

- Module issues an interrupt and STOP_ACK to MC_ME is gated.
- MC_ME does not retract and wait for STOP_ACK.
- This interrupt is not available at INTC so the core cannot service it, which causes a hang.

NOTE

A potential system hang scenario may occur if a stop mode request is generated when the interrupts are enabled in active modules and interrupts appears when the MC_ME is transitioning to stop mode. User needs to adhere to some software guidelines:

- Disable Interrupts before requesting a stop mode change.
- If the previous guideline is not possible ensure any interrupt are finished before stop mode change.

40.4.2.6 STANDBY0 Mode

The chip enters this mode on the following events:.

- from the DRUN or one of the RUN0…3 modes when the TARGET_MODE bit field of the ME_MCTL register is written with “1101”.

As soon as any of the above events occur, a STANDBY0 mode transition request is generated. The mode configuration information for this mode is provided by the ME_STANDBY0_MC register. In this mode, the power supply is turned off for most of the chip. The only parts of the chip that are still powered during this mode are pads mapped on wakeup lines and power domain #0 which contains the MC_RGM, MC_PCU, WKPU etc.. The IRC can be optionally switched off. This is the lowest power consumption mode possible on the chip.

NOTE

Please ensure before entering STANDBY0 Mode, PMCDIG_MCR[LVD_PD2_COLD_REE] bit is programmed to 0.This will ensure LVD_PD2_COLD as source of functional reset doesnt get triggered on STANDBY0 Mode entry.Please refer PMCDIG chapter for further details.

This mode is intended as an extreme low-power mode with

- the cores, the flashes, and almost all peripherals and memories powered down

and to be used by software

- to wait until it is required to do something with no need to react quickly (i.e., allow for system power-up and system clock source to be re-started)

The normal exit of the STANDBY0 mode is from a wakeup event. Interrupt events will not cause STANDBY0 mode exit.

The exit sequence of this mode is similar to the reset sequence, and the resets to all but power domain #0 are asserted with timing that is the same as reset PHASE1 through PHASE3. However, in addition to booting from the default location, the chip can also be configured to boot from the backup RAM. In the case of booting from backup RAM , it is also possible to keep the flashes disabled by writing “01” to the FLAON fields in the ME_DRUN_MC register prior to STANDBY0 entry.

If there is a STANDBY0 mode request while any wakeup event is active, the chip mode does not change.

All power domains except power domains #0 and #1 are configurable in this mode in order to reduce leakage consumption. Active power domains are determined by the power configuration registers of the MC_PCU.

40.4.3 Mode Transition Process

The process of mode transition follows the following steps in a pre-defined manner depending on the current chip mode and the requested target mode. In many cases of mode transition, not all steps need to be executed based on the mode control information, and some steps may not be applicable according to the mode definition itself.

Since the MC_ME ensures that all resources are in the proper state during the mode transition process, the following, for example, do not need to be checked by software.

- When the 8-40 MHz crystal oscillator is enabled in a mode configuration register, a mode transition to that mode will not complete until the End Of Count timeout occurs for the oscillator. Software does not need to interrogate the End Of Count timeout status bit.
- When a PLL is enabled in a mode configuration register, a mode transition to that mode will not complete until the PLL is locked. Software does not need to interrogate the PLL’s lock status bit.

40.4.3.1 Target Mode Request

The target mode is requested by accessing the ME_MCTL register with the required keys. This mode transition request by software must be a valid request satisfying a set of pre-defined rules to initiate the process. If the request fails to satisfy these rules, it is ignored, and the TARGET_MODE bit field is not updated. An optional interrupt can be generated for invalid mode requests. Refer to Mode Transition Interrupts for details.

In the case of mode transitions occurring because of hardware events such as a reset, a SAFE mode request, or interrupt requests and wakeup events to exit from low-power modes, the TARGET_MODE bit field of the ME_MCTL register is automatically updated with the appropriate target mode. The mode change process start is indicated by the setting of the mode transition status bit S_MTRANS of the ME_GS register.

A RESET mode requested via the ME_MCTL register is passed to the MC_RGM, which generates a global system reset and initiates the reset sequence. The RESET mode request has the highest priority, and the MC_ME is kept in the RESET mode during the entire reset sequence.

The SAFE mode request has the next highest priority after reset. It can be generated either by software via the ME_MCTL register from all software running modes or by the MC_RGM after the detection of system hardware failures, which may occur in any mode.

40.4.3.2 Target Mode Configuration Loading

On completion of the Target Mode Request step, the target mode configuration from the ME_<target mode>_MC register is loaded to start the resources (voltage sources, clock sources, flash, pads, etc.) control process.

An overview of resource control possibilities for each mode is shown in the following table. A '√' indicates that a given resource is configurable for a given mode.

Table 40-8. MC_ME Resource Control Overview

Resource	Mode					
	RESET	SAFE	DRUN	RUN0...3	STOP0	STANDBY0
IRC	on	on	on	on	√ on	√ on
FXOSC	off	off	√ off	√ off	√ off	√ off
PLL	off	off	√ off	√ off	off	off
SIRC			√	√	√	√

Table continues on the next page...

Table 40-8. MC_ME Resource Control Overview (continued)

Resource	Mode					
	RESET	SAFE	DRUN	RUN0…3	STOP0	STANDBY0
	off	off	on	off	off	off
SXOSC	off	off	√ off	√ off	√ off	√ off
FLASH	normal	normal	√ normal	√ normal	√ power-down	power-down
MVREG	on	on	on	on	on	off
PDO	off	√ on	off	off	√ off	on

40.4.3.3 Peripheral Clocks Disable

On completion of the Target Mode Request step and the system clock frequency ramp-down of the System Clock Switching step, the MC_ME requests each peripheral to enter its stop mode when:

- the peripheral is configured to be disabled via the target mode, the peripheral configuration registers ME_RUN_PC0…7 and ME_LP_PC0…7, and the peripheral control registers ME_PCTL***n***

Note

The MC_ME automatically requests peripherals to enter their stop modes if the power domains in which they are residing are to be turned off due to a mode change. However, it is good practice for software to ensure that those peripherals that are to be powered down are configured in the MC_ME to be frozen.

Each peripheral acknowledges its stop mode request after closing its internal activity. The MC_ME then disables the corresponding clock(s) to this peripheral.

In the case of a SAFE mode transition request, the MC_ME does not wait for the peripherals to acknowledge the stop requests. The SAFE mode clock gating configuration is applied immediately regardless of the status of the peripherals' stop acknowledges.

Please refer to Peripheral Clock Gating for more details.

Each peripheral that may block or disrupt a communication bus to which it is connected ensures that these outputs are forced to a safe or recessive state when the chip enters the SAFE mode.

40.4.3.4 Processor Low-Power Mode Entry

If, on completion of the Peripheral Clocks Disable step, the mode transition is to the STOP0 or STANDBY0 mode, the MC_ME requests all processors which are configured in ME_CCTL***n*** to be disabled to enter its stopped state. Each processor acknowledges its stop state request bit after completing all outstanding bus transactions.

If, on completion of the Peripheral Clocks Disable step, the mode transition is from a non-low-power mode to another non-low-power mode, the MC_ME requests each processor which is configured in the ME_CCTL***n*** registers to be disabled to enter its stopped state. The processor acknowledges its stop state request bit after completing all outstanding bus transactions.

40.4.3.5 Processor Clocks Disable

If, on completion of the Processor Low-Power Mode Entry step, and all processors which are configured in the ME_CCTL***n*** registers to be disabled are in their appropriate stopped state, the MC_ME disables the applicable processor clocks bits to achieve further power saving.

The clocks to processors which are configured to be running in both the current and target modes or disabled in both the current and target modes are unaffected while transitioning between non-low-power modes.

Warning

Clocks to the whole chip including the processor and system memory can be disabled in TEST mode.

40.4.3.6 System Clock Disable

If, on completion of the Processor Clocks Disable step, all processor clocks have been disabled, the system clock used for non-processor system functions and memory is disabled.

40.4.3.7 Clock Sources (Main Voltage Regulator Independent) Switch-On

On completion of the Processor Low-Power Mode Entry step, the MC_ME switches on all clock sources based on the <clock source>ON bits of the ME_<current mode>_MC and ME_<target mode>_MC registers. The following clock sources are switched on at this step:

- the 16 MHz internal RC oscillator
- the 8-40 MHz crystal oscillator

NOTE

Clock sources which need the main voltage regulator to be stable are not controlled by this step.

The clock sources that are required by the target mode are switched on. The duration required for the output clocks to be stable depends on the type of source, and all further steps of mode transition depending on one or more of these clocks waits for the stable status of the respective clocks. The availability status of these clocks is updated in the S_<clock source> bits of ME_GS register.

The clock sources which need to be switched off are unaffected during this process in order to not disturb the system clock which might require one of these clocks before switching to a different target clock.

40.4.3.8 Main Voltage Regulator Switch-On

On completion of the Target Mode Request step, step, if the main voltage regulator needs to be switched on from its off state based on the MVRON bit of the ME_CURRENT MODE_MC and ME_TARGET MODE_MC registers, the MC_ME requests the MC_PCU to power-up the regulator and waits for the output voltage stable status in order to update the S_MVR bit of the ME_GS register.

This step is required only during the exit of the low-power modes STOP0. In this step, the 16 MHz internal RC oscillator is switched on regardless of the target mode configuration, as the main voltage regulator requires the 16 MHz int. RC osc. during power-up in order to generate the voltage status.

During the STANDBY0 exit sequence, the MC_PCU alone manages the power-up of the main voltage regulator, and the MC_ME is kept in RESET or shut off (depending on the power domain #1 status).

40.4.3.9 Flash Module Switch-On

On completion of the step, if the flash needs to be switched to normal mode from its low-power or power-down mode based on the FLAON bit field of the ME_<current mode>_MC and ME_<target mode>_MC registers, the MC_ME requests the flash to exit from its low-power/power-down mode. When the flash is available for access, the S_FLA bit field of the ME_GS register is updated to "11" by hardware.

Warning

It is illegal to switch the FLASH from low-power mode to power-down mode and from power-down mode to low-power mode. The MC_ME, however, does not prevent this nor does it flag it.

40.4.3.10 Clock Sources (Main Voltage Regulator Dependent) Switch-On

On completion of the Clock Sources (Main Voltage Regulator Independent) Switch-On and Main Voltage Regulator Switch-On,the MC_ME controls all clock sources, which need the main voltage regulator to be on, based on the CLOCK SOURCES ON bits of the ME_CURRENT_MODE_MC and ME_TARGET_MODE_MC registers. The following clock sources are switched on at this step:

- the PLL PHI_0

40.4.3.11 Pad Outputs-On

On completion of the Main Voltage Regulator Switch-On step, if the PDO bit of the ME_<target mode>_MC register is cleared, then

- all pad outputs are enabled to return to their previous state
- the I/O pads power sequence driver is switched on

40.4.3.12 Peripheral Clocks Enable

Based on the current and target chip modes, the peripheral configuration registers ME_RUN_PC0…7, ME_LP_PC0…7, and the peripheral control registers ME_PCTLn, the MC_ME enables the clocks for selected modules as required. This step is executed only after the Main Voltage Regulator Switch-On process is completed, and if the value of the PWRLVL field of the ME_TARGET_MODE_MC register is different from that of the ME_current mode_MC register's, the peripheral clock enable/disable isn't updated until after the system clock frequency ramp-down step of the System Clock Switching process is completed.

Also, if a mode change translates to a power up of one or more power domains, the MC_PCU indicates the MC_ME after completing the power-up sequence upon which the MC_ME may assert the peripheral clock enables of the peripherals residing in those power domains.

40.4.3.13 System and Processor Clocks Enable

On completion of the Flash Module Switch-On step, the MC_ME enables the non-processor system clock and the clocks of all processors that are configured in the ME_CCTL***n*** registers to be disabled in the current mode and to be running in the target mode.

If the value of the PWRLVL field of the ME_<target mode>_MC register is different from that of the ME_<current mode>_MC register, the mode change handshake will not be initiated until after the system clock frequency ramp-down step of the System Clock Switching process is completed.

40.4.3.14 Processor Low-Power Mode Exit

On completion of the System and Processor Clocks Enable step, the MC_ME requests all processors which are configured in the ME_CCTL***n*** registers to be disabled in the current mode and to be running in the target mode.

40.4.3.15 System Clock Switching

Based on the SYSCLK bit field of the ME_<current mode>_MC and ME_<target mode>_MC registers, if the target and current system clock configurations differ, the following method is implemented for clock switching.

- The target clock configuration for the 16 MHz int. RC osc. takes effect only after the S_IRC bit of the ME_GS register is set by hardware (i.e., the 16 MHz internal RC oscillator has stabilized).
- The target clock configuration for the FXOSC takes effect only after the S_FXOSC bit of the ME_GS register is set by hardware (8-40 MHz crystal oscillator has been stabilized).
- If the clock is to be disabled, the SYSCLK bit field should be programmed with “1111”. In the STANDBY0 mode, the clock configuration is fixed, and the system clock is automatically forced to ‘0’.

If the value of the PWRLVL field of the ME_<target mode>_MC register not equal to that of the ME_<current mode>_MC register's, a progresive clock switching is performed in the power consumption of the device.

The current system clock configuration can be observed by reading the S_SYSCLK bit field of the ME_GS register, which is updated after every system clock switching. Until the target clock is available, the system uses the previous clock configuration.

System clock switching starts only after

- the Clock Sources (Main Voltage Regulator Independent) Switch-On process has completed if the target system clock source is one of the following:
  - the PLL PHI_0
- the Peripheral Clocks Disable process has completed in order not to change the system clock frequency before peripherals close their internal activitiesthe Peripheral Clocks Enable processe has completed

An overview of system clock source selection possibilities for each mode is shown in the following table. A '√' indicates that a given clock source is selectable for a given mode. A shaded cell indicates that the given clock source is not selectable for a given mode.

Table 40-9. MC_ME System Clock Selection Overview

System Clock Source	Mode					
	RESET	SAFE	DRUN	RUN0…3	STOP0	STANDBY0
16 MHz int. RC osc.	√ (default)	√ (default)	√ (default)	√ (default)	√ (default)	
FXOSC			√	√	√	
PLL PHI_0			√	√	√	
SIRC			√	√		
SXOSC			√	√		

Table continues on the next page...

Table 40-9. MC_ME System Clock Selection Overview (continued)

System Clock Source	Mode					
	RESET	SAFE	DRUN	RUN0...3	STOP0	STANDBY0
system clock is disabled					√	√ (default)

40.4.3.16 Pad Switch-Off

If the PDO bit of the ME_<target mode>_MC register is '1' then

- the outputs of the pads are forced to the high impedance state if the target mode is SAFE or TEST.

In STANDBY0 mode, the power sequence driver and all pads except the external reset and those mapped on wakeup lines are not powered and therefore high impedance. The wakeup line configuration remains unchanged.

This step is executed only after the Peripheral Clocks Disable process has completed.

40.4.3.17 Clock Sources Switch-Off

Based on the chip mode and the <clock source>ON bits of the ME_<mode>_MC registers, if a given clock source is to be switched off, the MC_ME requests the clock source to power down and updates its availability status bit S_<clock source> of the ME_GS register to '0'. The following clock sources are switched off at this step:

- the 16 MHz internal RC osc
- the FXOSC
- the PLL PHI_0

For the clock sources related to the system clock, this step is executed only after the System Clock Switching process has completed.

40.4.3.18 Flash Switch-Off

Based on the FLAON bit field of the ME_<current mode>_MC and ME_<target mode>_MC registers, if the flash is to be put in its low-power or power-down mode, the MC_ME requests the flash to enter the corresponding power mode and waits for the flash to acknowledge. The exact power mode status of the flash is updated in the S_FLA bit field of the ME_GS register. This step is executed only when the Processor Clocks Disable and System Clock Disable processes have completed.

40.4.3.19 Main Voltage Regulator Switch-Off

Based on the MVRON bit of the ME_current mode_MC and ME_target mode_MC registers, if the main voltage regulator is to be switched off, the MC_ME requests it to power down and clears the availability status bit S_MVR of the ME_GS register.

This step is required only during the entry of low-power modes like STOP0. This step is executed only after completing the following processes:

- Clock Sources Switch-Off
- Flash Switch-Off

If the target mode is STANDBY0, the main voltage regulator is not switched off by the MC_ME and the STANDBY0 request is asserted after the above processes have completed upon which the MC_PCU takes control of the main regulator. As the MC_PCU needs the 16 MHz int. RC osc., the 16 MHz internal RC oscillator remains active until all the STANDBY0 steps are executed by the MC_PCU after which it may be switched off depending on the IRCON bit of the ME_STANDBY0_MC register.

40.4.3.20 Current Mode Update

The current mode status bit field S_CURRENT_MODE of the ME_GS register is updated with the target mode bit field TARGET_MODE of the ME_MCTL register when :

- all the updated status bits in the ME_GS register match the configuration specified in the ME_<target mode>_MC register
- power sequences are done
- clock disable/enable process is finished
- processor low-power mode (stop) entry and exit processes are finished

Note

SAFE mode entry does not wait for the clock disable/enable process to finish. It only waits for the ME_GS.S_RC bit to be set. This is to ensure that the SAFE mode is entered as quickly as possible.

Software can monitor the mode transition status by reading the S_MTRANS bit of the ME_GS register. The mode transition latency can differ from one mode to another depending on the resources' availability before the new mode request and the target mode's requirements.

If a mode transition is taking longer to complete than is expected, the ME_DMTS register can indicate which process is still in progress.

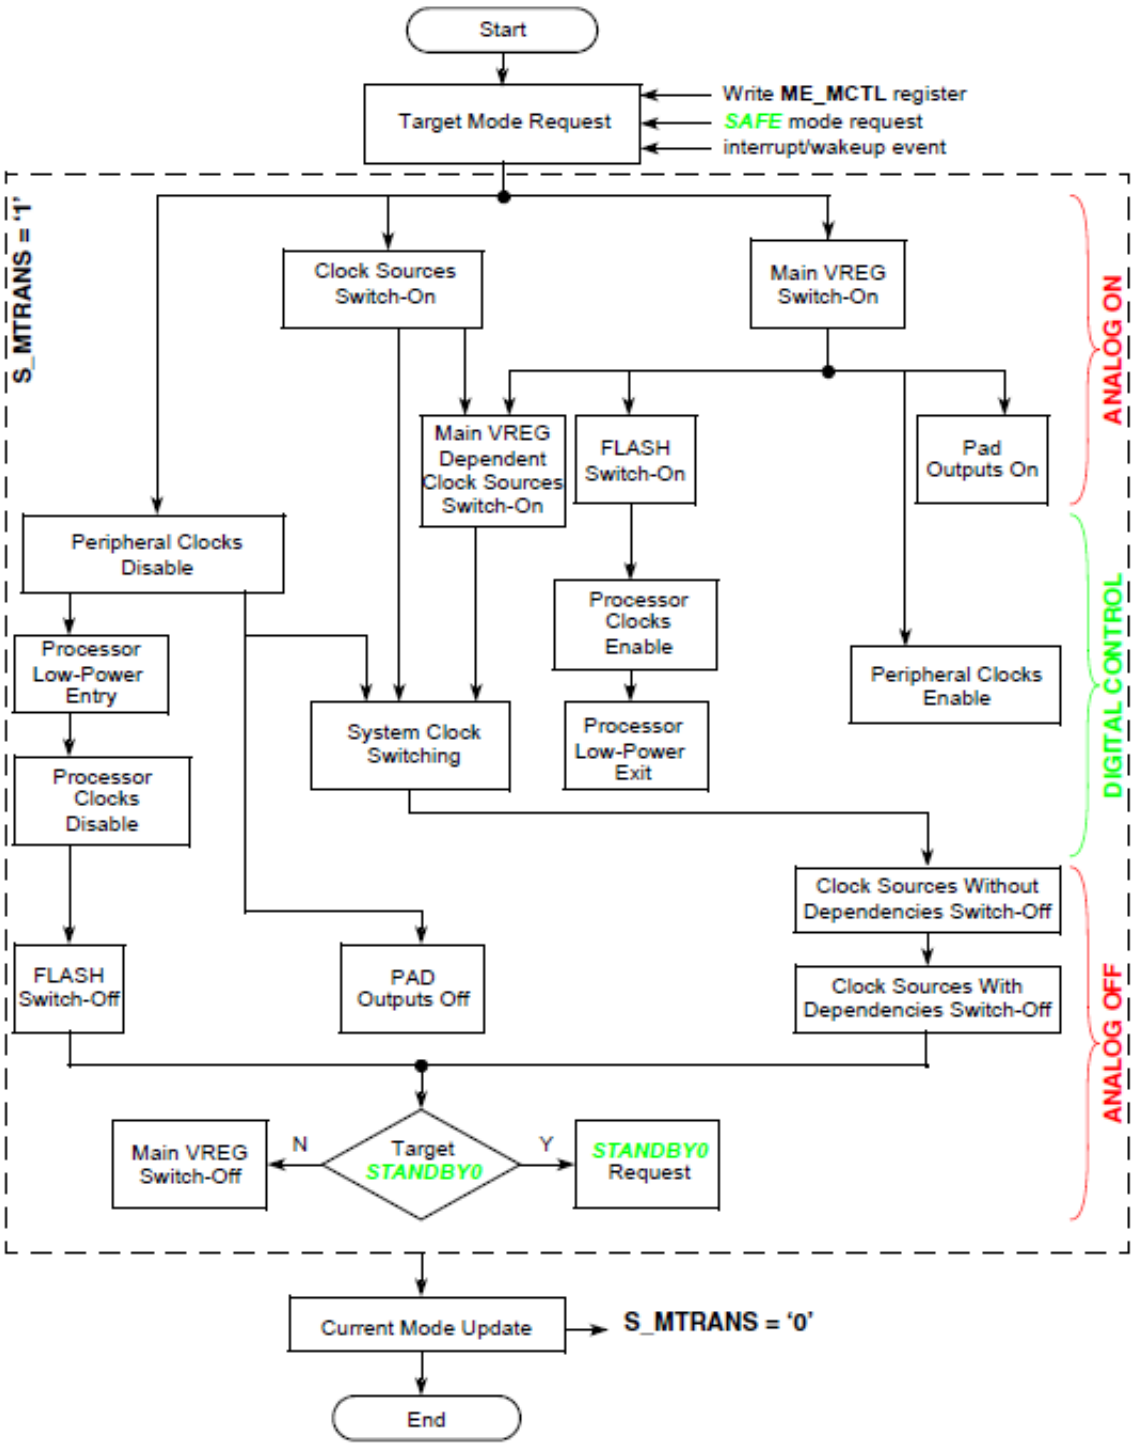

Figure 40-6. MC_ME Transition Diagram

40.4.3.21 Mode transition and progressive clock switching

The MC_ME initiates a progressive clock switching via MC_CGM whenever the **ME_<current mode>_MC.PWRLVL** field is different from **ME_<target mode>_MC.PWRLVL** bit field. Broadly, the mode transition process can be divided into three steps with respect to progressive cclock switching - RAMP DOWN, LOAD CHANGE and RAMP UP. One or more of these steps may not be needed based on the current and target mode configirations. The clock switching (from current system clock source to target system clock source) can happen before or after the LOAD CHANGE step.

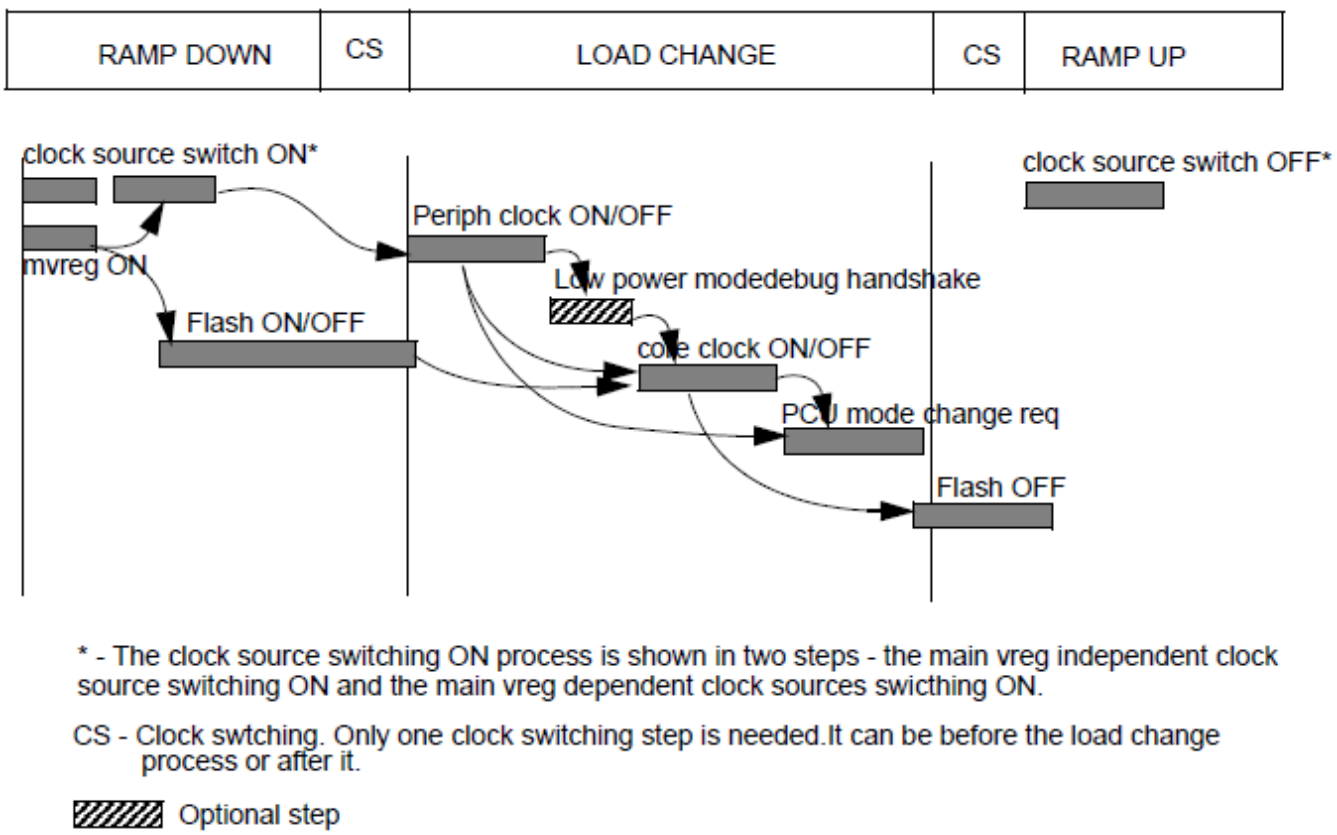

Figure 40-7. MC_ME mode transition process with PCS

The table below shows the different ways the mode transition process can complete.

Table 40-10. Mode transition steps

Pwrlvl	Source clock	Target clock	Mode transition steps
Same	IRC	Non-IRC	LoadChange -> ClockSwitch
	IRC	IRC	LoadChange
	Non-IRC	IRC	LoadChange -> ClockSwitch
	Non-IRC	Non-IRC	LoadChange -> ClockSwitch

Table continues on the next page...

Table 40-10. Mode transition steps (continued)

Pwrlvl	Source clock	Target clock	Mode transition steps
Different	IRC	Non-IRC	LoadChange -> ClockSwitch -> RampUp
	IRC	IRC	LoadChange
	Non-IRC	IRC	RampDown -> ClockSwitch -> LoadChange
	Non-IRC	Non-IRC	RampDown -> ClockSwitch -> LoadChange -> RampUp

40.4.4 Software Considerations for Preventing the Blocking of Mode Transitions

Mode transitions will not complete (i.e., mode transition is blocked) in certain conditions where

- resources are required in the target mode but are configured to be disabled in that target mode
- a low-power mode transition is attempted and there is a pending wakeup event
- a low-power mode transition is attempted and there is a pending interrupt

In these cases, ME_STATUS[S_MTRANS] never clears, ME_IS[I_MTC] never sets, and the invalid mode transition flags may not set.

While waiting for the mode transition to complete (e.g., polling ME_GS[S_MTRANS]), a timer can be used to detect if a mode transition takes too long. If the timer expires an error recovery function can be called.

To prevent mode transitions from being blocked, software must handle the following mode transition cases:

- **Enable required clock sources for the target mode's system clock selection.**

  Mode transitions can be blocked when a clock source to generate the system clock is not turned on in the target mode.

  Example for when FXOSC is the reference clock for PHI0:

  If the target mode is RUN1 and ME_RUN1_MC[SYSCLK] is PHI0, then both ME_RUN1_MC[FXOSCON] and ME_RUN1_MC[PHI0ON] must be set to '1'. If ME_RUN1_MC[FXOSCON] is '0', the mode transition is blocked.

  Software must ensure that all required clock sources for generating the target mode's system clock are turned on for that target mode configuration

- **Enable required clock sources for peripherals in the target mode.**

  Mode transitions can be blocked when an attempt is being made to stop a clock while one or more peripherals require this clock in the target mode.

  A given peripheral's clock is configured to be stopped in a target mode via peripheral configuration registers ME_RUN_PCx and ME_LP_PCx and the corresponding peripheral control register ME_PCTLx. In addition, some peripherals may require local disabling before stopping their clocks via the MC_ME. Local disabling is accomplished by setting the peripheral's MDIS bit to '1'.

  Modules requiring clocks being disabled before stopping them are:
  - CAN modules
  - display controllers (if included)

  Example:

  Assume a CAN module is using FXOSC. A mode transition to RUN1 is requested where MC_RUN1_MC[FXOSCON] is '0'. The mode transition will not complete.

  Software must disable the module whose clock source is to be turned off in the target mode.

- Disable or service any pending interrupts when transitioning to low-power modes.

  For transition into low power modes (STOP0, and STANDBY0), mode transitions can be blocked by a peripheral's pending interrupt.

  Pending interrupts are detected by the MC_ME when the peripheral's interrupt flag is set, and the peripheral's interrupt enable is set.

  NOTE

  The MSR[EE] and INTC_PSRx[PRI] registers have no effect on the MC_ME detecting a pending interrupt.

  Software must either
  - disable interrupt enable flags in peripherals that may have their flag set, or,
  - detect and process the interrupt by either
    - polling the peripheral flag and servicing it in software, or,
    - taking the interrupt vector (requires MSR[EE] = 1 and INTC_PSRx[PRI] >0 for that peripheral.

- **Service any pending wakeup events when transitioning to low power modes.**

  For transition into low-power modes (STOP0, and STANDBY0), mode transitions can be blocked by enabled wakeup events from the RTC, the API, or a wakeup pin transition.

  Example:

The API is set to a very short value and enabled as a wakeup event. After the first of two writes to the ME_MCTL register to request a mode transition, the API expires. The mode transition will not complete because the wakeup event requires servicing.

Software must either

- ensure wakeup events cannot occur before low-power mode entry completion, or,
- detect and process the wakeup events during mode transition by either
  - polling the flags of enabled wakeup events in the WISR register and servicing it in software, or,
  - enabling wakeup events to cause an interrupt and execute the interrupt service routine (ISR).

NOTE

If the ISR also invokes a mode transition on it's own, then any prior writes to the ME_MCTRL register for the low-power mode transition will not be valid.

40.4.5 Protection of Mode Configuration Registers

While programming the mode configuration registers ME_<mode>_MC, the following rules must be respected. Otherwise, the write operation is ignored and an invalid mode configuration interrupt may be generated.

- If the FIRC_CLK is selected as the system clock, FIRC must be on.
- If the FXOSC_CLK clock is selected as the system clock, FXOSC must be on.
- If the PLL_PHI0_CLK clock is selected as the system clock, PLL must be on.

Note

Software must ensure that clock sources with dependencies are switched on as needed. There is no automatic protection mechanism to check this in the MC_ME.

- Configuration "01" for the FLAON bit field is reserved.
- Configuration "10" for the FLAON bit field is reserved
- Configuration "00" for the FLAON bit field is reserved.
- MVREG must be on if any of the following is active:
  - the PLL PHI_0
  - FLASH
- System clock configurations marked as 'reserved' may not be selected.

40.4.6 Mode Transition Interrupts

The MC_ME provides interrupts for incorrectly configuring a mode, requesting an invalid mode transition, indicating a SAFE mode transition not due to a software request, and indicating when a mode transition has completed.

40.4.6.1 Invalid Mode Configuration Interrupt

Whenever a write operation is attempted to the ME_<mode>_MC registers violating the protection rules mentioned in the Protection of Mode Configuration Registers, the interrupt pending bit I_ICONF of the ME_IS register is set and an interrupt request is generated if the mask bit M_ICONF of the ME_IM register is '1'.

If an attempt to write to one of the ME_CADDRn registers is made after a mode change request has been made via the second write to the ME_MCTL register and before the completion of that mode transition as indicated by the S_MTRANS bit in the ME_GS register deasserting, the interrupt pending bit I_ICONF_CC of the ME_IS register is set and an iterrupt request is generated if the mask bit M_ICONF_CC of the ME_IM register is '1'.

40.4.6.2 Invalid Mode Transition Interrupt

The mode transition request is considered invalid under the following conditions:

- If the system is in the SAFE mode and the SAFE mode request from MC_RGM is active, and if the target mode requested is other than RESET or SAFE, then this new mode request is considered to be invalid, and the S_SEA bit of the ME_IMTS register is set.
- If the TARGET_MODE bit field of the ME_MCTL register is written with a value different from the specified mode values (i.e., a non-existing mode), an invalid mode transition event is generated. When such a non existing mode is requested, the S_NMA bit of the ME_IMTS register is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the ME_MCTL register. The following modes are defined as non-existing:
  - 1001
  - 1011
  - 1100
  - 1110

- If some of the chip modes are disabled as programmed in the ME_ME register, their respective configurations are considered reserved, and any access to the ME_MCTL register with those values results in an invalid mode transition request. When such a disabled mode is requested, the S_DMA bit of the ME_IMTS register is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the ME_MCTL register.
- If the target mode is not a valid mode with respect to the current mode, the mode request illegal status bit S_MRI of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.
- If further new mode requests occur while a mode transition to a mode other than SAFE mode is in progress (the S_MTRANS bit of the ME_GS register is '1'), the mode transition illegal status bit S_MTI of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.
- If a new mode request occur while a mode transition to the SAFE mode is in progress (the S_MTRANS bit of the ME_GS register is ‘1’), the mode request ignored status bit S_MRIG of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.

Note

As the causes of invalid mode transitions may overlap at the same time, the priority implemented for invalid mode transition status bits of the ME_IMTS register in the order from highest to lowest is S_SEA, S_NMA, S_DMA, S_MRI, S_MRIG, and S_MTI.

As an exception, the mode transition request is not considered as invalid under the following conditions:

- A new request is allowed to enter the RESET or SAFE mode irrespective of the mode transition status.

- As the exit of STOP0 modes depends on the interrupts of the system which can occur at any instant, these requests to return to RUN0…3 modes are always valid.
- In order to avoid any unwanted lockup of the chip modes, software can abort a mode transition by requesting the parent mode if, for example, the mode transition has not completed after a software determined 'reasonable' amount of time for whatever reason. The parent mode is the chip mode before a valid mode request was made.

Note

Depending on the cause of an incomplete mode transition, aborting by requesting the parent mode might not succeed. In this case, software must request a change to either SAFE or RESET mode, because the cause of the lockup is most likely a hardware fault.

- Self-transition requests (e.g., RUN0 → RUN0) are not considered as invalid even when the mode transition process is active (i.e., S_MTRANS is '1'). During the low-power mode exit process, if the system is not able to enter the respective RUN0…3 mode properly (i.e., all status bits of the ME_GS register match with configuration bits in the ME_<mode>_MC register), then software can only request the SAFE or RESET mode. It is not possible to request any other mode or to go back to the low-power mode again.

Whenever an invalid mode request is detected, the interrupt pending bit I_IMODE of the ME_IS register is set, and an interrupt request is generated if the mask bit M_IMODE of the ME_IM register is '1'.

40.4.6.3 SAFE Mode Transition Interrupt

Whenever the system enters the SAFE mode as a result of a SAFE mode request from the MC_RGM due to a hardware failure, the interrupt pending bit I_SAFE of the ME_IS register is set, and an interrupt is generated if the mask bit M_SAFE of ME_IM register is '1'.

The SAFE mode interrupt pending bit can be cleared only when the SAFE mode request is deasserted by the MC_RGM (see the MC_RGM chapter for details on how to clear a SAFE mode request). If the system is already in SAFE mode, any new SAFE mode request by the MC_RGM also sets the interrupt pending bit I_SAFE. However, the SAFE mode interrupt pending bit is not set when the SAFE mode is entered by a software request (i.e., programming of ME_MCTL register).

40.4.6.4 Mode Transition Complete interrupt

Whenever the system fully completes a mode transition (i.e., the S_MTRANS bit of ME_GS register transits from '1' to '0'), the interrupt pending bit I_MTC of the ME_IS register is set, and an interrupt request is generated if the mask bit M_MTC of the ME_IM register is '1'. The interrupt bit I_MTC is not set when entering low-power modes STOP0 in order to avoid the same event requesting the immediate exit of these low-power modes.

40.4.7 Peripheral Clock Gating

During all chip modes, each peripheral can be associated with a particular clock gating policy determined by two groups of peripheral configuration registers.

The run peripheral configuration registers ME_RUN_PC0…7 are chosen only during the software running modes DRUN, SAFE, and RUN0…3. All configurations are programmable by software according to the needs of the application. Each configuration register contains a mode bit which determines whether or not a peripheral clock is to be gated. Run configuration selection for each peripheral is done by the RUN_CFG bit field of the ME_PCTL***n*** registers.

The low-power peripheral configuration registers ME_LP_PC0…7 are chosen only during the low-power modes STOP0 and STANDBY0. All configurations are programmable by software according to the needs of the application. Each configuration register contains a mode bit which determines whether or not a peripheral clock is to be gated. Low-power configuration selection for each peripheral is done by the LP_CFG bit field of the ME_PCTL***n*** registers.

Any modifications to the ME_RUN_PC0…7, ME_LP_PC0…7, and ME_PCTL***n*** registers do not affect the clock gating behavior until a new mode transition request is generated.

Whenever the chip enters a debug session during any mode, the following occurs for each peripheral:

- The clock is gated if the DBG_F bit of the associated ME_PCTL***n*** register is set. Otherwise, the peripheral clock gating status depends on the RUN_CFG and LP_CFG bits.

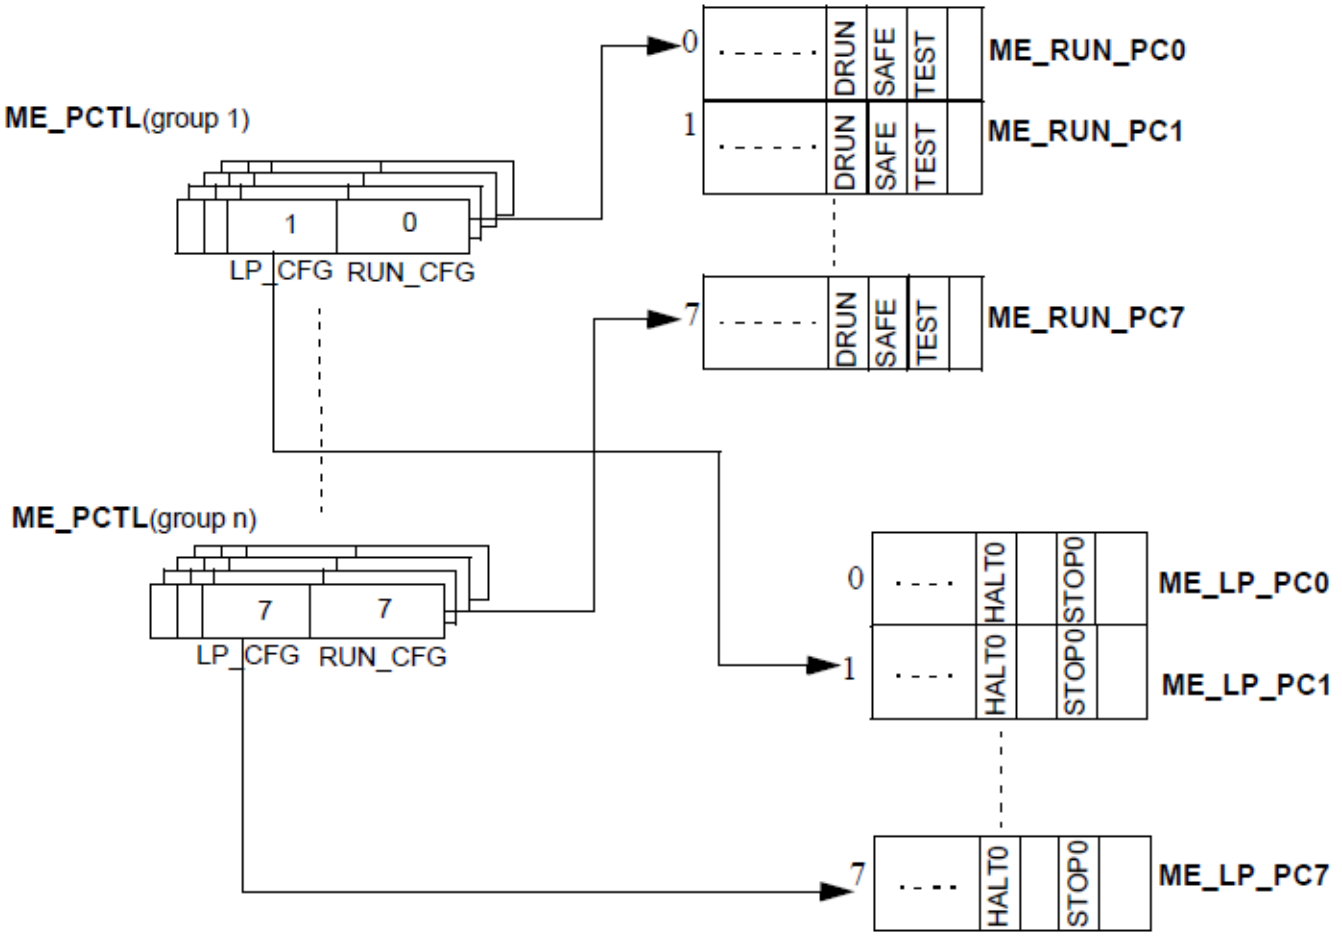

Figure 40-8. MC_ME Peripheral clock control

40.4.8 Initialization/Application Example

The following figure shows an example application flow for requesting a mode change and then waiting until the mode transition has completed.

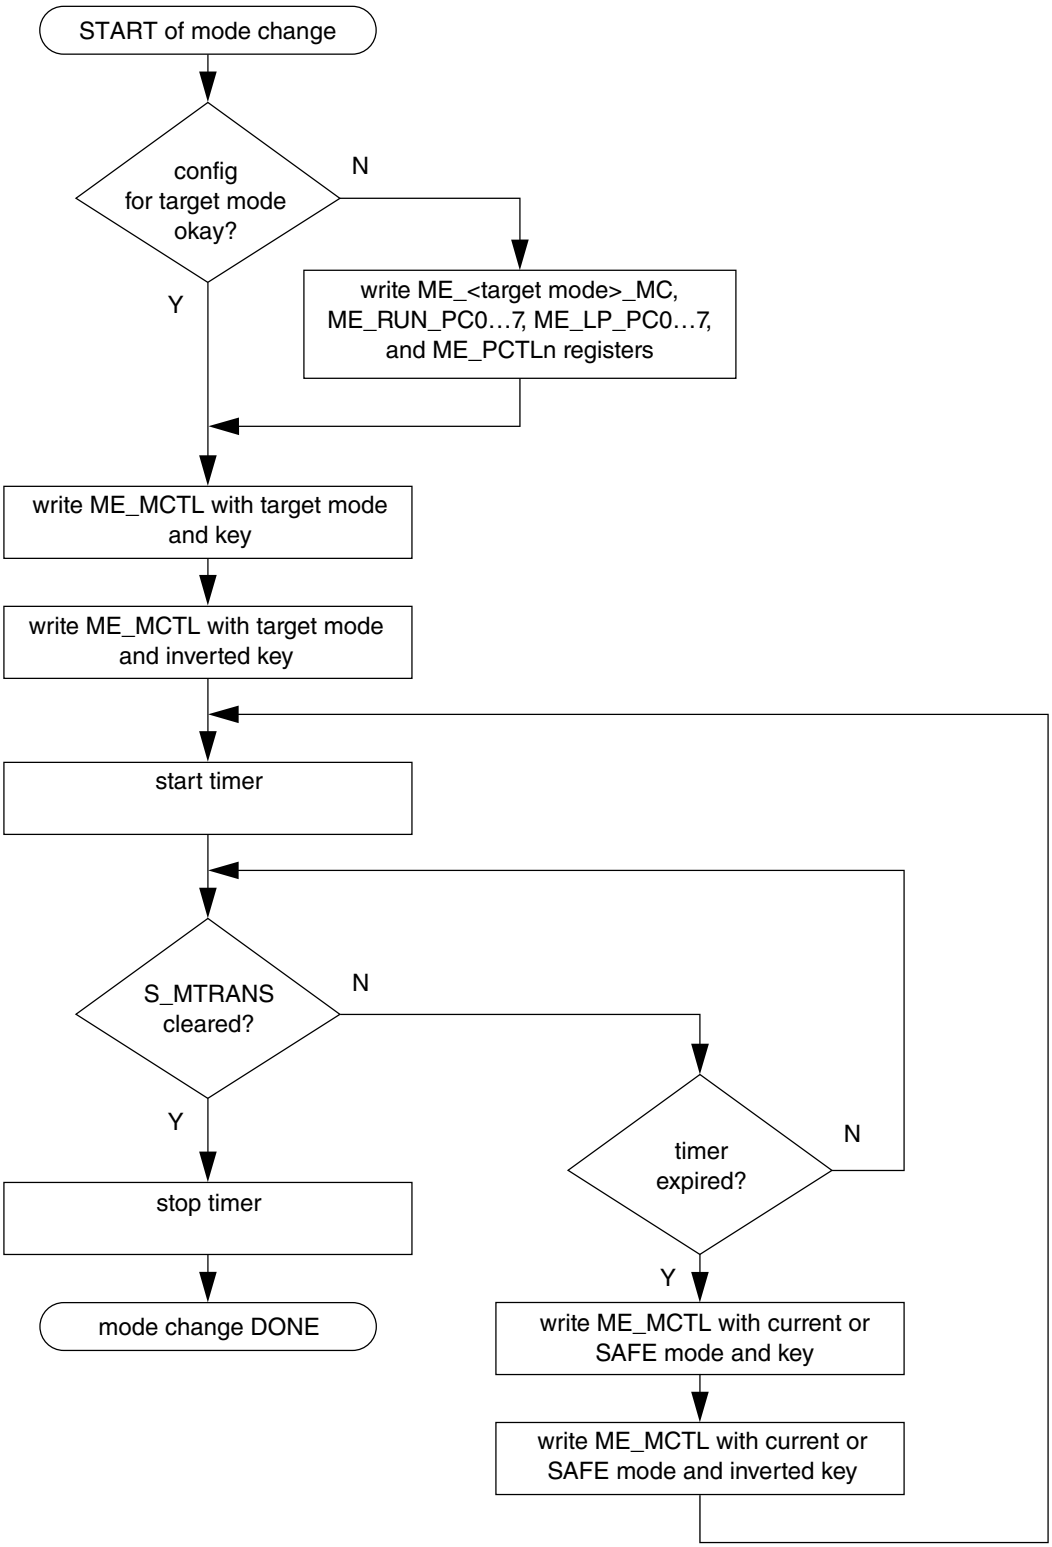

Figure 40-9. MC_ME Application Example Flow Diagram

40.4.8.1 Example 1: Minimal Code to Bring Up a PLL

The following minimal code brings up a PLL as the system clock and provides a clock to one peripheral (PIT-RTI). The peripheral itself would be initialized subsequently elsewhere. However, the peripherals registers cannot be written to for initialization unless there is a clock enabled to it. No additional cores are configured in this example.

Please note that the order of the code before the writes to the mode control register (MC_ME.MCTL) is not important.

```
void System_Clk_160mhz(void)
{
    /* F160 - max 160 MHz */
    MC_CGM.SC_DC0.B.DIV = 0;

    /* S80 - max 80 MHz */
    /* MC_CGM_SC_DC1[DIV] and MC_CGM_SC_DC5[DIV] must be equal at all times */
    MC_CGM.SC_DC1.B.DIV = 1;

    /* FS80 - max 80 MHz */
    /* MC_CGM_SC_DC1[DIV] and MC_CGM_SC_DC5[DIV] must be equal at all times */
    MC_CGM.SC_DC5.R = MC_CGM.SC_DC1.R;  /* 80 MHz max */

    /* S40 - max 40 MHz */
    MC_CGM.SC_DC2.B.DIV = 3;

    /* F40 - max 40 MHz */
    MC_CGM.SC_DC3.B.DIV = 3;

    /* F80 - max 80 MHz */
    MC_CGM.SC_DC4.B.DIV = 1;

    /* enable all modes, enable all peripherals */
    MC_ME.ME.R        = 0x000005FF;
    MC_ME.RUN_PC[0].R = 0x000000FE;

    /* Connect XOSC to PLL */
    MC_CGM.AC5_SC.B.SELCTL = 1;

    /* Configure PLL0 Dividers - 160MHz from 40Mhx XOSC */
    PLLDIG.PLLDV.B.PREDIV  = 2;
    PLLDIG.PLLDV.B.MFD     = 32;
    PLLDIG.PLLDV.B.RFDPHI  = 1;

    PLLDIG.PLLCAL3.R       = 0x09C3C000;
    PLLDIG.PLLFD.B.SMDEN   = 1;       /* Sigma delta modulation enabled*/
    /* switch to PLL */
    MC_ME.DRUN_MC.R  = 0x00130172;    /* FLASH in normal mode, PLLON, FXOSC ON, Use
PLL_PHI_0 */

    MC_ME.MCTL.R     = 0x30005AF0;    /* DRUN target mode + KEY */
    MC_ME.MCTL.R     = 0x3000A50F;    /* DRUN target mode + KEY Inverted */

    while(MC_ME.GS.B.S_MTRANS == 1); /* Wait for mode transition complete */
}
```

40.4.8.2 Example 2: Code to Enter Low-Power STOP0 Mode

The following code illustrates how STOP0 mode is entered. Upon STOP0 exit from a wakeup event, code simply continues to execute. If an interrupt caused STOP0 mode exit, the interrupt handler code would execute. Depending on the interrupt handler task, it may be necessary to ensure that the chip is not in SAFE mode with code in the interrupt handler itself.

```
ME.MCTL.R = 0xA0005AF0; /* Enter STOP0 mode and key */

ME.MCTL.R = 0xA000A50F; /* Enter STOP0 mode and inverted key */

while (ME.GS.B.S_MTRANS) {} /* Wait for STOP0 mode transition to complete */

/* STOP HERE FOR STOP0 MODE! ON STOP0 MODE EXIT, CODE CONTINUES HERE:*/

while(ME.GS.B.S_CURRENTMODE != x) {} /* Verify RUNx is the current mode */
```

Upon low-power mode exit, the current mode should be verified to make sure it is the RUNx mode that was in use during the low-power mode entry because a SAFE mode transition (caused by a hardware failure) may have occurred during the low-power mode exit.

If the low-power mode exit was caused by an interrupt, the interrupt handler may, depending on the application and handler, need to verify the current mode is not SAFE mode, since the check at the end of the code snippet above may not be executed before the jump to the interrupt vector.

Chapter 41
General Programmable Registers (GPR)

41.1 Overview

This module consists of registers which are used to control miscellaneous tasks in the device and capture the event status.

41.2 Memory map and register definition

GPR memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

GPR_CTL field descriptions

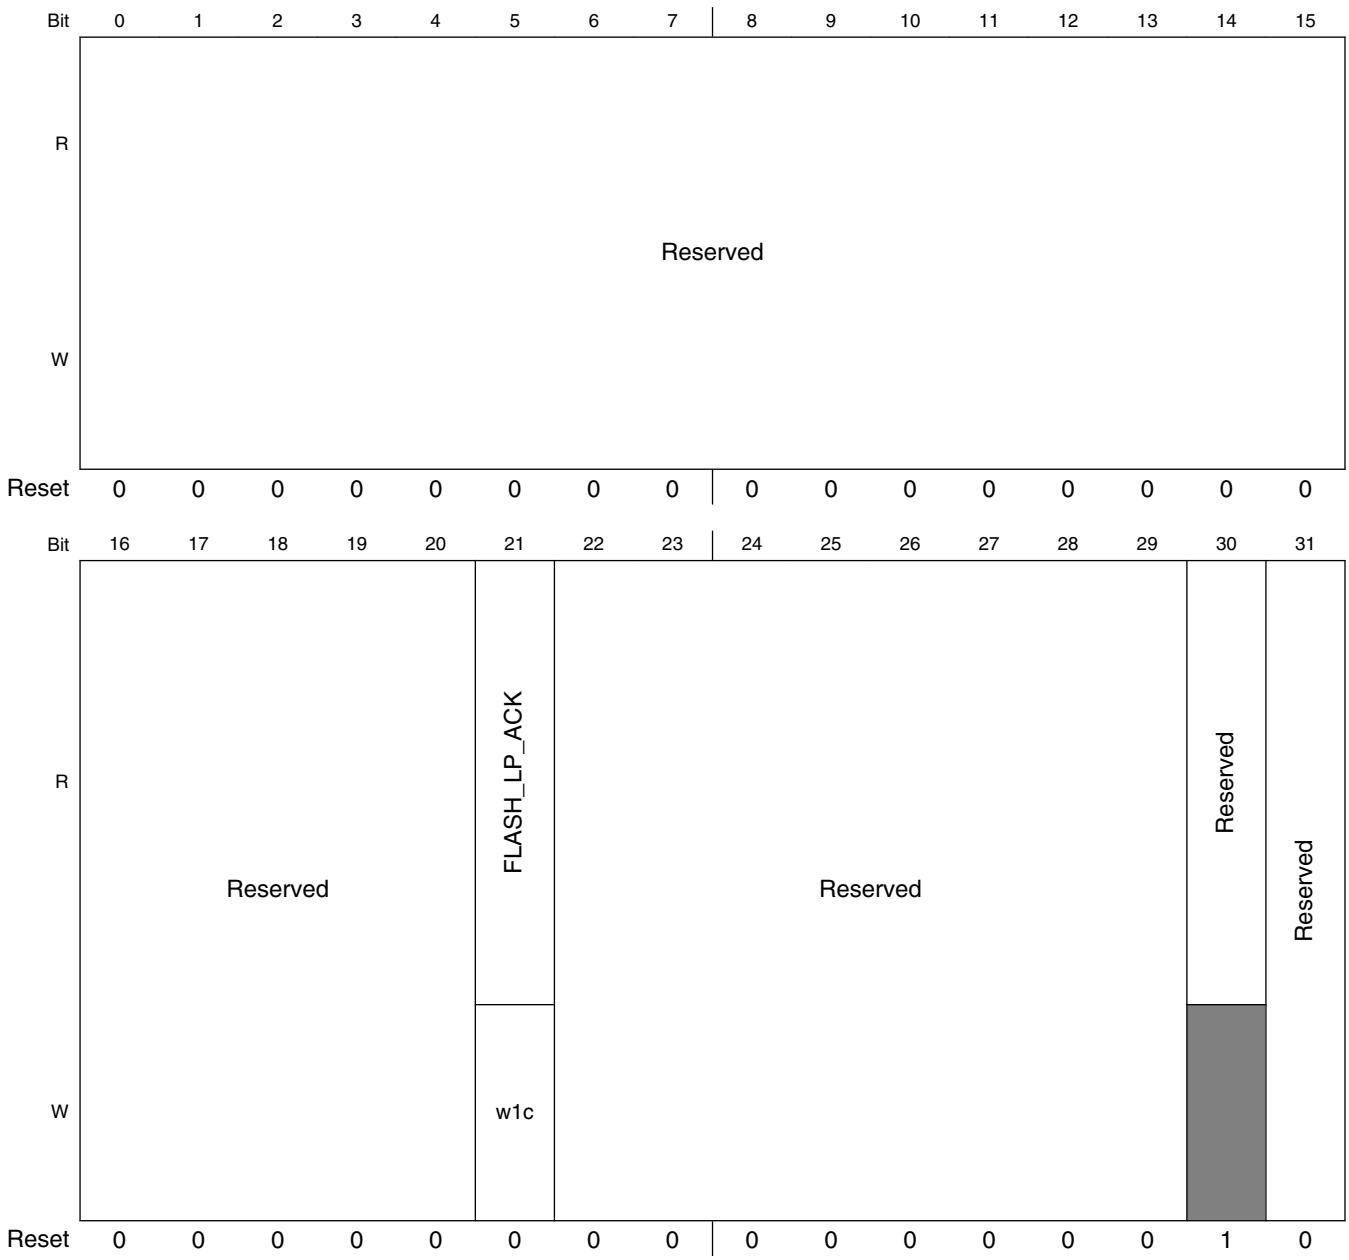
Field	Description
0 GPR_HSM_RAM_FAST_INIT_BYPASS	HSM RAM FAST initialization is bypassed on low power mode exit if this bit is set . 0 HSM RAM FAST initialization is not bypassed 1 HSM RAM FAST initialization is bypassed
1–2 Reserved	This field is reserved.
3 EXTREGC	This bit enables the external regulator control multiplexed function on PG[6] The PG[6] pin is configured as an output and is an indicator of a partial power-gated state of the SOC. The signal can be used to control and external regulator on the VDD_LV supply. This bit will reset only on PORST. 0 External regulator control functionality on PG[6] is disabled 1 External regulator control functionality on PG[6] is enabled

Table continues on the next page...

GPR_CTL field descriptions (continued)

Field	Description
4 DEST_ESC_ CTRL2	Enables the escalation of destructive reset source: SWT0 reset request. This bit will be reset on POR. 0 destructive reset escalation of SWT0 reset request is disabled 1 destructive reset escalation of SWT0 reset request is enabled (default)
5 DEST_ESC_ CTRL1	Enables the escalation of destructive reset source: functional reset escalation. This bit will be reset on POR. 0 destructive reset escalation of functional reset escalation is disabled 1 destructive reset escalation of functional reset escalation is enabled (default)
6 DEST_ESC_ CTRL0	Enables the escalation of destructive reset source: SSCM secured reset. This bit will be reset on POR. 0 destructive reset escalation of SSCM secured reset is disabled 1 destructive reset escalation of SSCM secured reset is enabled (default)
7–11 Reserved	This field is reserved.
12 CMP2_STDBY	To allow CMP2_O to be output to pad even after standby exit 0 The CMP2_O will not show the output after standby modes exit 1 The CMP2_O will show the the output after standby modes exit
13 CMP1_STDBY	To allow CMP1_O to be output to pad even after standby exit 0 The CMP1_O will not show the output after standby modes exit 1 The CMP1_O will show the the output after standby modes exit
14 CMP0_STDBY	To allow CMP0_O to be output to pad even after standby exit 0 The CMP0_O will not show the output after standby modes exit 1 The CMP0_O will show the the output after standby modes exit
15 CLKOUT1_ STDBY	To allow CLKOUT1 to be output to pads even during standby mode **NOTE:** If this bit is set before entering STANDBY/LPU_STANDBY mode, and SIUL MSCR is configured to enable CLKOUT1 on SIUL pad, then upon exit from STANDBY/LPU_STANDBY mode, CLKOUT1 remains selected even if SIUL MSCR configurations are cleared. In order to configure the CLKOUT1 pad for any other function via SIUL, this bit needs to be cleared first. 0 CLKOUT1 will not be output to pads during standby mode 1 CLKOUT1 will be output to pads even during standby mode
16 LPU_STOP_ ACK_BYPASS	Bypass STOP acknowledge handshake with LPU domain modules (which are present in LPU_MDIS register), during LPU_STOP and LPU_SLEEP. **NOTE:** Modules should be IDLE before entering LPU_STOP/SLEEP, that is, no outstanding transactions or interrupts should be pending. Bypassing STOP ACK will enable entry in LPU_STOP/SLEEP irrespective of interrupt generated during the mode transition and then the same interrupt will cause mode exit. If STOP Handshake is not bypassed, mode transition may hang as modules will not acknowledge stop due to outstanding interrupt during the mode transition. 0 Enable STOP ACK handshake(Default) 1 Bypass STOP ACK handshake
17 Reserved	This field is reserved.
18 Reserved	This field is reserved.

Table continues on the next page...



GPR_CTL field descriptions (continued)

Field	Description
19 RTC_SXOSC_ FREE_RUNNING	Enables seamless RTC operation across functional and destructive reset in the specific case when RTC is running on SXOSC. **NOTE** This Bit should be set after SXOSC is enabled by the software. 0 RTC will not work on SXOSC seamlessly across functional and destructive reset. 1 RTC will work on SXOSC seamlessly across functional and destructive reset.
20 CMP_ACT_SAM	Actual sample to the CMP 0 Sample of all three CMP = 0 when GPR_CTL [CMP_SAMP_SEL] = 1 1 Sample of all three CMP = 1 when GPR_CTL [CMP_SAMP_SEL] = 1
21 CMP_SAMP_ SEL	Sample select to the CMP 0 RTC.CLKOUT goes to "sample" of all three CMP 1 GPR_CTL [CMP_ACT_SAM] goes to "sample" of all three CMP

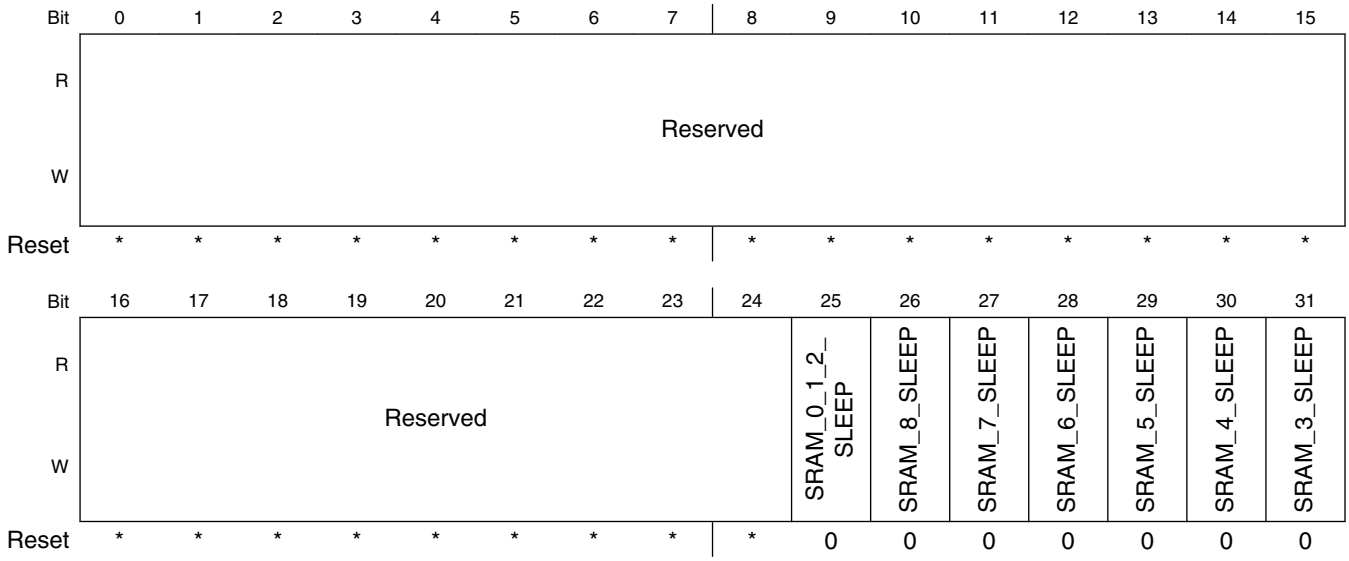
GPR_CTL1 field descriptions

Field	Description
0–7 Reserved	This field is reserved.
8–31 IVPR	Interrupt Vector Prefix Register Programming This field is used to define the base location of the interrupt vector table

41.2.4 GPR SLEEP Register (GPR_SLEEP)

This register defines the sleep status of SRAM memory blocks

NOTE



See RAM memory map for bit details.

NOTE

An attempt to SRAM Read with Sleep Bit set will result in incorrect read with ECC error, hence before attempting an

SRAM Read Sleep bit for the corresponding SRAM should be cleared.

Address: 0h base + 14h offset = 14h

* Notes:
- Reserved field: This bit should never be set.

GPR_SLEEP field descriptions

Field	Description
0–24 Reserved	This field is reserved.
25 SRAM_0_1_2_SLEEP	Enables the sleep mode for SRAM memory block 0, 1, 2. 0 Sleep mode disabled 1 Sleep mode enabled
26 SRAM_8_SLEEP	Enables the sleep mode for SRAM memory block 8. 0 Sleep mode disabled 1 Sleep mode enabled
27 SRAM_7_SLEEP	Enables the sleep mode for SRAM memory block 7. 0 Sleep mode disabled 1 Sleep mode enabled
28 SRAM_6_SLEEP	Enables the sleep mode for SRAM memory block 6. 0 Sleep mode disabled 1 Sleep mode enabled
29 SRAM_5_SLEEP	Enables the sleep mode for SRAM memory block 5. 0 Sleep mode disabled 1 Sleep mode enabled

Chapter 42
Deserial Serial Peripheral Interface (DSPI)

42.1 Chip-specific DSPI information

42.1.1 DSPI and SPI configuration

This section describes the configuration of these modules specific to the MPC5746C.

42.1.2 DSPI configuration

The device contains four DSPI[0:3] modules. DSPI_2 and DSPI_3 are targeted for faster frequency.

Table 42-1. Full Featured DSPI[1:0] configuration

Feature		Available
Extended (32-bit) SPI Mode Support		Yes
CSI and DSI mode support.		Yes
64 bit DSI Mode Support		Yes
TX FIFO		4
RX FIFO		4
CTAR registers (transfer attribute configuration)		6
TSB Mode		Yes
PCS Signals	DSPI0	DSPI0_PCS[0:5]
	DSPI1	DSPI1_PCS[0:4]

Table 42-2. Full Featured DSPI[3:2] configuration

Feature	Available
Extended (32-bit) SPI Mode Support	Yes
CSI and DSI mode support.	Yes

Table continues on the next page...

DSI Parallel Input Select Register 6 (PISR6)	
DSI Parallel Input Select Register 7 (PISR7)	
DSI Deserialized Data Interrupt Mask Register 1 (DIMR1)	
DSI Deserialized Data Polarity Interrupt Register 1 (DPIR1)	
Clock and Transfer Attributes Register Extended (CTAREn)	Clock and Transfer Attributes Register Extended (CTAREn)
Status Register Extended (SREX)	Status Register Extended (SREX)
Trigger Register (TRIG)	

NOTE

Before re-configuring DSPI, it should be disabled by setting its MDIS bit. Changing the configuration of DSPI while the module's clock is still running should be avoided.

42.1.5 DSPI's stop-stop ack protocol

1. If DSPI is disabled, it acknowledges the stop request immediately.
2. In master mode, DSPI asserts the acknowledgement for the stop request on frame boundary of the frame being transmitted/received. Additionally, if no frame is being transmitted/received DSPI immediately asserts the acknowledgement.
3. In slave mode, DSPI asserts the acknowledgement for stop request when it's slave select is high (inactive value).

NOTE

In both 2 and 3, DSPI checks for pending Interrupt/DMA requests before asserting the acknowledgement.

42.2 Introduction

The deserial serial peripheral interface (DSPI) module provides a synchronous serial bus for communication between a chip and an external peripheral device. The module supports chip pin count reduction through serialization and deserialization of chip internal signals transmitted over the DSPI serial link.

42.2.1 Block Diagram

The block diagram of this module is as follows:

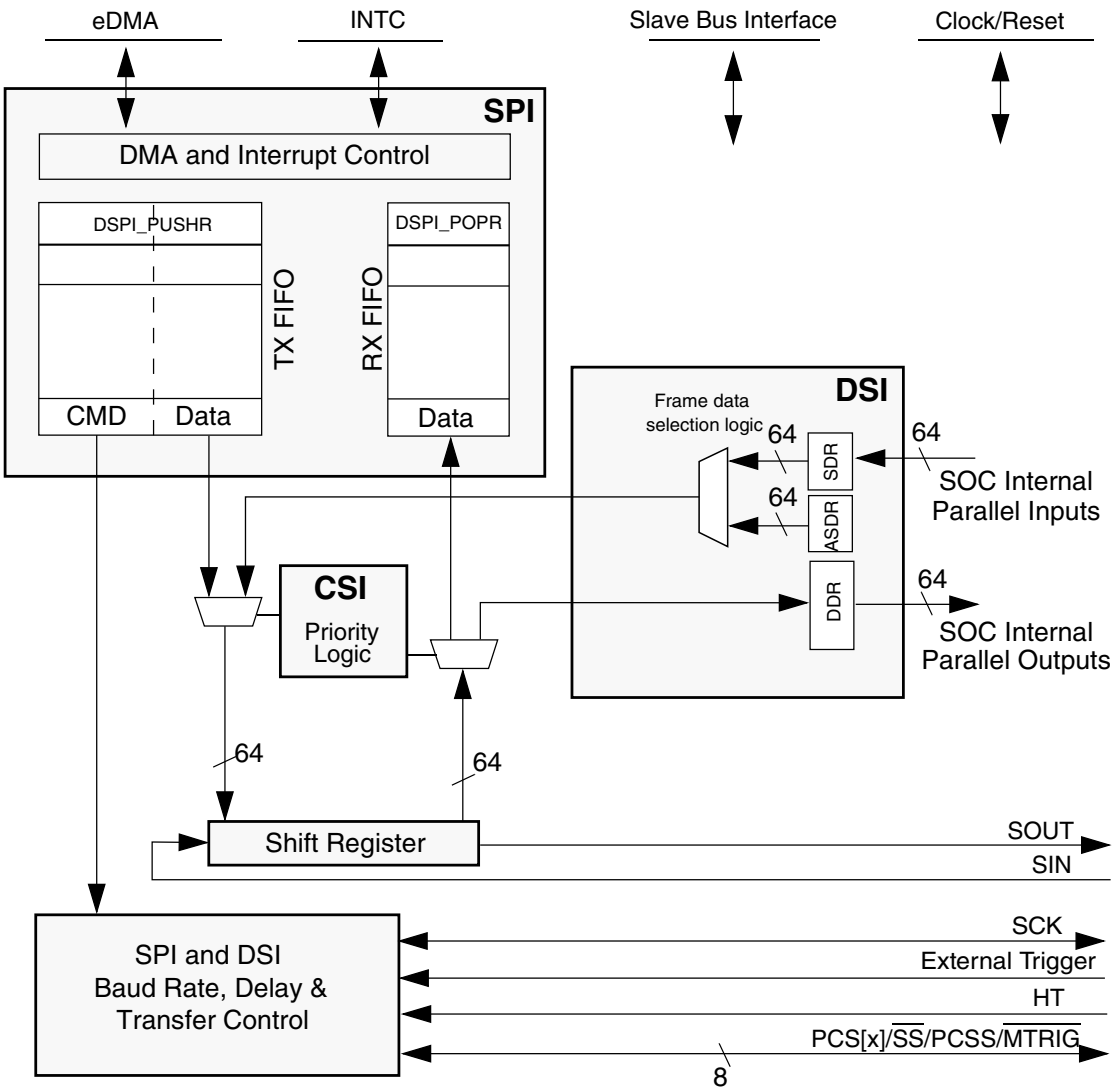

Figure 42-1. DSPI Block Diagram

42.2.2 Features

The module supports the following features:

- Full-duplex, three-wire synchronous transfers
- Master mode
- Slave mode
- Data streaming operation in Slave mode with continuous slave selection
- Buffered transmit operation using the transmit first in first out (TX FIFO) with depth of 4 entries

- Support for 8/16-bit accesses to the PUSH TX FIFO Register Data Field
- Buffered receive operation using the receive FIFO (RX FIFO) with depth of 4 entries
- Asynchronous clocking scheme for Register and Protocol Interfaces
- TX and RX FIFOs can be disabled individually for low-latency updates to SPI queues
- Visibility into TX and RX FIFOs for ease of debugging
- Programmable transfer attributes on a per-frame basis:
  - six transfer attribute registers
  - six extended transfer attribute registers
  - Serial clock (SCK) with programmable polarity and phase
  - Various programmable delays
  - Programmable serial frame size: 4 to 64 bits
    - SPI frames longer than 32 bits can be supported using the continuous selection format.
  - Continuously held chip select capability
  - Parity control
- 6 peripheral chip selects (PCSes), expandable to 64 with external demultiplexer
- Deglitching support for up to 32 peripheral chip selects (PCSes) with external demultiplexer
- DMA support for adding entries to TX FIFO and removing entries from RX FIFO:
  - TX FIFO is not full (TFFF)
  - RX FIFO is not empty (RFDF)
  - CMD FIFO is not full (CMDFFF)
- Interrupt conditions:
  - End of Queue reached (EOQF)
  - TX FIFO is not full (TFFF)
  - CMD FIFO is not full (CMDFFF)
  - Transfer of current frame complete (TCF)
  - Transfers due from current command frame complete (CMDTCF)

    - Transfer of current SPI frame complete (SPITCF)
    - Attempt to transmit with an empty Transmit FIFO (TFUF)
    - RX FIFO is not empty (RFDF)
    - Frame received while Receive FIFO is full (RFOF)
    - SPI Parity Error (SPEF)
    - Data present in TX FIFO while CMD FIFO is empty (TFIWF)
- Global interrupt request line
- Modified SPI transfer formats for communication with slower peripheral devices
- Power-saving architectural features:
    - Support for Stop mode

The DSPI also supports pin reduction through serialization and deserialization if enabled for the module.

- Two sources of serialized data:
    - The module memory-mapped register
    - Parallel Input signals
    - Programmable selection of source data on bit basis
- Deserialized data is provided as Parallel Output signals and as bits in a memory-mapped register
- Interrupt conditions:
    - Deserialized data matches pre-programmed pattern (DDIF)
    - Transfer of current DSI frame complete (DSITCF)
    - DSI Parity Error (DPEF)
- DMA Request support for following conditions:
    - Deserialized data matches pre-programmed pattern (DDIF)
- Transfer initiation conditions:
    - Continuous
    - Edge sensitive hardware trigger
    - Change in data

- Support for parallel and serial chaining of several modules inside the chip
- Pin serialization/deserialization with interleaved SPI frames for control and diagnostics
- Continuous serial communications clock

DSPI supports a combined SPI and DSI modes of operation known as the Combined Serial Interface (CSI). It also supports the downstream Micro Second Channel in the Timed Serial Bus (TSB) configuration or Interleaved Frames Configuration; configurable by software.

Both TSB and Interleaved TSB modes have the following common features:

- Transmission of frames is done at frame boundaries
- Frames from SPI and DSI are identifiable by a bit transmitted at the start of each frame
- Separate interrupts for frame completion from SPI and DSI

42.2.3 Interface configurations

42.2.3.1 SPI configuration

The Serial Peripheral Interface (SPI) configuration allows the module to send and receive serial data. This configuration allows the module to operate as a basic SPI block with internal FIFOs supporting external queue operation. Transmitted data and received data reside in separate FIFOs. The host CPU or a DMA controller read the received data from the Receive FIFO and write transmit data to the Transmit FIFO.

For queued operations, the SPI queues can reside in system RAM, external to the module. Data transfers between the queues and the module FIFOs are accomplished by a DMA controller or host CPU. The following figure shows a system example with DMA, DSPI, and external queues in system RAM.

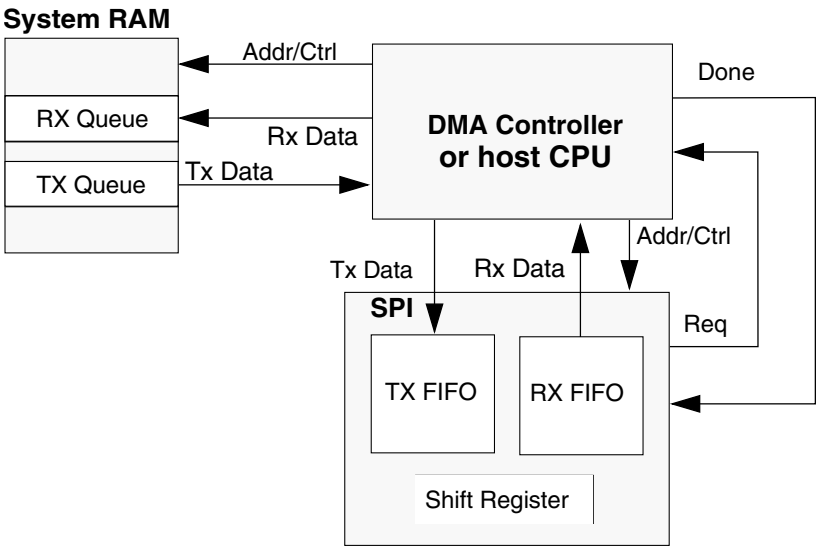

Figure 42-2. SPI with queues and DMA

42.2.3.2 DSI configuration

In the Deserial Serial Interface (DSI) configuration, DSPI serializes up to 64 parallel input signals or register bits. DSPI also deserializes the received data to parallel output signals or to a memory-mapped register. DSPI transfers the data using an SPI-like protocol.

Timed Serial Bus (TSB) mode provides the MicroSecond Channel (MSC) downstream support, serializing from 4 to 64 parallel input signals or register bits. For more information on TSB mode, see Timed Serial Bus (TSB).

42.2.3.3 CSI configuration

The Combined Serial Interface (CSI) configuration supports further configuration as follows:

- Normal: A combination of the SPI and DSI configurations. The DSPI interleaves DSI data frames with SPI data frames. Interleaving is done on the frame boundaries.
- TSB: Transmission of SPI data has higher priority than DSI data.
- Interleaved TSB (ITSB): The frames from SPI and DSI are interleaved without priority. On every trigger, frames from DSI are sent when there are no frames in the SPI or the previous transmission was a frame from SPI. For more information, see Interleaved TSB (ITSB) Mode.

42.2.4 Modes of Operation

The module supports the following modes of operation that can be divided into two categories:

- Module-specific modes:
  - Master mode
  - Slave mode
  - Module Disable mode
- Chip-specific modes:
  - External Stop mode
  - Debug mode

The module enters module-specific modes when the host writes a module register. The chip-specific modes are controlled by signals external to the module. The chip-specific modes are modes that a chip may enter in parallel to the block-specific modes.

42.2.4.1 Master Mode

Master mode allows the module to initiate and control serial communication. In this mode, these signals are controlled by the module and configured as outputs:

- SCK
- PCS[*x*]

42.2.4.2 Slave Mode

Slave mode allows the module to communicate with SPI/DSI bus masters. In this mode, the module responds to externally controlled serial transfers. The SCK signal and the PCS[0]/$\overline{SS}$ signals are configured as inputs and driven by an SPI bus master.

42.2.4.3 Module Disable Mode

The Module Disable mode can be used for chip power management. The clock to the non-memory mapped logic in the module can be stopped while in the Module Disable mode.

42.2.4.4 External Stop Mode

External Stop mode is used for chip power management. The module supports the Peripheral Bus Stop mode mechanism. When a request is made to enter External Stop mode, it acknowledges the request and completes the transfer that is in progress. When the module reaches the frame boundary, it signals that the protocol clock to the module may be shut off.

42.2.4.5 Debug Mode

Debug mode is used for system development and debugging. The MCR[FRZ] bit controls module behavior in the Debug mode:

- If the bit is set, the module stops all serial transfers, when the chip is in debug mode.
- If the bit is cleared, the chip debug mode has no effect on the module.

42.3 Module signal descriptions

This table describes the signals on the boundary of the module that may connect off chip (in alphabetical order).

Table 42-4. Module signal descriptions

Signal	Master mode	Slave mode	I/O
HT	Hardware Trigger	Hardware Trigger	I
PCS0/$\overline{SS}$	Peripheral Chip Select 0 (O)	Slave Select (I)	I/O
PCS[1:3]	Peripheral Chip Selects 1–3	(Unused)	O
PCS4/ $\overline{MTRIG}$	Peripheral Chip Select 4	Master Trigger	O
PCS5/ $\overline{PCSS}$	Peripheral Chip Select 5 /Peripheral Chip Select Strobe	(Unused)	O
SCK	Serial Clock (O)	Serial Clock (I)	I/O
SIN	Serial Data In	Serial Data In	I
SOUT	Serial Data Out	Serial Data Out	O

42.3.1 HT—Hardware Trigger

Master mode: Hardware Trigger (I)—Honored only when the module is configured for the DSI or CSI configuration (MCR[DCONF]), the multiple transfer operation is enabled (DSICR0[MTOE]), hardware-trigger reception is enabled (DSICR0[TRRE] or

TRIG[TRRE]), and the module is in the Running state (SR[TXRXS]). Receives hardware triggers that initiate data transfers. DSICR0[TPOL] specifies whether the module uses rising or falling edges of HT as hardware triggers.

Slave mode: Hardware Trigger (I)—Honored only when the module is configured for the DSI or CSI configuration (MCR[DCONF]), the multiple transfer operation is enabled (DSICR0[MTOE]), hardware-trigger reception is enabled (DSICR0[TRRE] or TRIG[TRRE]), and the module is in the Running state (SR[TXRXS]). Receives hardware triggers that initiate the assertion of $\overline{\text{MTRIG}}$. DSICR0[TPOL] specifies whether the module uses rising or falling edges of HT as hardware triggers.

42.3.2 PCS0/$\overline{\text{SS}}$—Peripheral Chip Select/Slave Select

Master mode: Peripheral Chip Select 0 (O)—Selects an SPI slave to receive data transmitted from the module.

Slave mode: Slave Select (I)—Selects the module to receive data transmitted from an SPI master.

NOTE

Do not tie the DSPI slave select pin to ground. Otherwise, DSPI cannot function properly.

42.3.3 PCS1–PCS3—Peripheral Chip Selects 1–3

Master mode: Peripheral Chip Selects 1–3 (O)—Select an SPI slave to receive data transmitted by the module.

Slave mode: Unused

42.3.4 PCS4/$\overline{\text{MTRIG}}$—Peripheral Chip Select 4/Master Trigger

Master mode: Peripheral Chip Select 4 (O)—Selects an SPI slave to receive data transmitted by the module.

Slave mode: Master Trigger (O)—Used only when the multiple transfer operation is enabled (DSICR0[MTOE]). Indicates via a pulse that a change in data to be serialized has occurred. The pulse is 4 protocol clock cycles in duration.

42.3.5 PCS5/$\overline{\text{PCSS}}$—Peripheral Chip Select 5/Peripheral Chip Select Strobe

Master mode:

- Peripheral Chip Select 5 (O)—Used only when the peripheral-chip-select strobe is disabled (MCR[PCSSE]). Selects an SPI slave to receive data transmitted by the module.
- Peripheral Chip Select Strobe (O)—Used only when the peripheral-chip-select strobe is enabled (MCR[PCSSE]). Strobes an off-module peripheral-chip-select demultiplexer, which decodes the module's PCS signals other than PCS5, preventing glitches on the demultiplexer outputs.

Slave mode: Unused

42.3.6 SCK—Serial Clock

Master mode: Serial Clock (O)—Supplies a clock signal from the module to SPI slaves.

Slave mode: Serial Clock (I)—Supplies a clock signal to the module from an SPI master.

42.3.7 SIN—Serial Input

Master mode: Serial Input (I)—Receives serial data.

Slave mode: Serial Input (I)—Receives serial data.

42.3.8 SOUT—Serial Output

Master mode: Serial Output (O)—Transmits serial data.

Slave mode: Serial Output (O)—Transmits serial data.

42.4 Memory Map/Register Definition

Register accesses to memory addresses that are reserved or undefined result in a transfer error. Any Write access to the POPR and RXFRn also results in a transfer error.

NOTE

While the module is in the running state, do not write to these registers:

- PISRn
- DIMRn, DPIRn, and SSRn
- CTAREn
- TRIG
- TSL and TS_CONF

42.4.1 Module Configuration Register (DSPI_MCR)

Contains bits to configure various attributes associated with the module operations. The HALT and MDIS bits can be changed at any time, but the effect takes place only on the next frame boundary. Only the HALT and MDIS bits in the MCR can be changed, while the module is in the Running state.

Address: 0h base + 0h offset = 0h

DSPI_MCR field descriptions

Field	Description
0 MSTR	Master/Slave Mode Select Enables either Master mode (if supported) or Slave mode (if supported) operation. 0 Enables Slave mode 1 Enables Master mode
1 CONT_SCKE	Continuous SCK Enable Enables the Serial Communication Clock (SCK) to run continuously.

Table continues on the next page...

DSPI_MCR field descriptions (continued)

Field	Description
	0 Continuous SCK disabled. 1 Continuous SCK enabled.
2–3 DCONF	Interface Configuration Selects among the different interface configurations of the module. 00 SPI 01 DSI 10 CSI 11 Reserved
4 FRZ	Freeze Enables transfers to be stopped on the next frame boundary when the device enters Debug mode. 0 Do not halt serial transfers in Debug mode. 1 Halt serial transfers in Debug mode.
5 MTFE	Modified Transfer Format Enable Enables a modified transfer format to be used. 0 Modified SPI transfer format disabled. 1 Modified SPI transfer format enabled.
6 PCSSE	Peripheral Chip Select Strobe Enable Enables the PCS5/ $\overline{\text{PCSS}}$ to operate as a PCS Strobe output signal. 0 PCS5/ $\overline{\text{PCSS}}$ is used as the Peripheral Chip Select[5] signal. 1 PCS5/ $\overline{\text{PCSS}}$ is used as an active-low PCS Strobe signal.
7 ROOE	Receive FIFO Overflow Overwrite Enable In the RX FIFO overflow condition, configures the module to ignore the incoming serial data or overwrite existing data. If the RX FIFO is full and new data is received, the data from the transfer, generating the overflow, is ignored or shifted into the shift register. 0 Incoming data is ignored. 1 Incoming data is shifted into the shift register.
8–9 Reserved	Always write the reset value to this field. This field is reserved.
10–15 PCSIS	Peripheral Chip Select x Inactive State Determines the inactive state of PCSx. Refer to the chip-specific D SPI information for the number of PCS signals used in this chip. **NOTE:** The effect of this bit only takes place when module is enabled. Ensure that this bit is configured correctly before enabling the DSPI interface. 0 The inactive state of PCSx is low. 1 The inactive state of PCSx is high.
16 Reserved	This field is reserved.

Table continues on the next page...

DSPI_MCR field descriptions (continued)

Field	Description
17 MDIS	Module Disable Allows the clock to be stopped to the non-memory mapped logic in the module effectively putting it in a software-controlled power-saving state. The reset value of the MDIS bit is parameterized, with a default reset value of 1. When the module is used in Slave Mode, it is recommended to leave this bit 0, because a slave doesn't have control over master transactions. 0 Enables the module clocks. 1 Allows external logic to disable the module clocks.
18 DIS_TXF	Disable Transmit FIFO When the TX FIFO is disabled, the transmit part of the module operates as a simplified double-buffered SPI. This bit can be written only when the MDIS bit is cleared. 0 TX FIFO is enabled. 1 TX FIFO is disabled.
19 DIS_RXF	Disable Receive FIFO When the RX FIFO is disabled, the receive part of the module operates as a simplified double-buffered SPI. This bit can only be written when the MDIS bit is cleared. 0 RX FIFO is enabled. 1 RX FIFO is disabled.
20 CLR_TXF	Clear TX FIFO Flushes the TX FIFO. Writing a 1 to CLR_TXF clears the TX FIFO Counter. The CLR_TXF bit is always read as zero. 0 Do not clear the TX FIFO counter. 1 Clear the TX FIFO counter.
21 CLR_RXF	CLR_RXF Flushes the RX FIFO. Writing a 1 to CLR_RXF clears the RX Counter. The CLR_RXF bit is always read as zero. **NOTE:** After every RX FIFO clear operation (MCR [CLR_RXF] = 0b1) following a RX FIFO overflow (SR [RFOF] = 0b1) scenario, immediately perform a single POP from the RX FIFO and discard the read data. The POP and discard operation should be completed before the reception of new incoming frame. 0 Do not clear the RX FIFO counter. 1 Clear the RX FIFO counter.
22–23 SMPL_PT	Sample Point Controls when the module master samples SIN in Modified Transfer Format. This field is valid only when CPHA bit in CTARn[CPHA] is 0. 00 0 protocol clock cycles between SCK edge and SIN sample 01 1 protocol clock cycle between SCK edge and SIN sample 10 2 protocol clock cycles between SCK edge and SIN sample 11 Reserved
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DSPI_MCR field descriptions (continued)

Field	Description
28 XSPI	Extended SPI Mode This bit enables usage of CTARE (Command and Transfer Attribute Register Extended) Registers. CTARE registers allow the user to send up to 32 bit SPI frames. Command Cycling is also enabled which allows the user to send multiple Data Frames using a single Command Frame. When MCR[DIS_TXF] is asserted, the Extended SPI Mode cannot be used to transmit SPI frames which are more than 16 bits in size. 0 Normal SPI Mode. Frame size can be up to 16 bits. Command Cycling is not available in this mode. 1 Extended SPI Mode. Up to 32 bit SPI Frames along with Command Cycling is Enabled.
29 FCPCS	Fast Continuous PCS Mode. This bit enables the masking of “After SCK (t_{ASC})” and “PCS to SCK (t_{CSC})” delays when operating in Continuous PCS mode. This masking is not available if Continuous SCK mode is enabled. The individual delay masks are selected via bits MASC and MCSC of the PUSHR register. The firmware should select appropriate masks when providing continuous frames via the PUSHR register. 0 Normal or Slow Continuous PCS mode. Masking of delays is disabled. 1 Fast Continuous PCS mode. Delays masked via control bits in PUSHR register.
30 PES	Parity Error Stop Controls SPI operation when a parity error is detected in a received SPI frame. 0 SPI frame transmission continues. 1 SPI frame transmission stops.
31 HALT	Halt The HALT bit starts and stops frame transfers. See Start and Stop of Module transfers 0 Start transfers. 1 Stop transfers.

42.4.2 Transfer Count Register (DSPI_TCR)

TCR contains a counter that indicates the number of SPI transfers made. The transfer counter is intended to assist in queue management. Do not write the TCR when the module is in the Running state.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DSPI_TCR field descriptions

Field	Description
0–15 SPI_TCNT	SPI Transfer Counter Counts the number of SPI transfers the module makes. The SPI_TCNT field increments every time the last bit of an SPI frame is transmitted. A value written to SPI_TCNT presets the counter to that value. SPI_TCNT is reset to zero at the beginning of the frame when the CTCNT field is set in the executing SPI command. The Transfer Counter wraps around; incrementing the counter past 65535 resets the counter to zero.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

42.4.3 Clock and Transfer Attributes Register (In Master Mode) (DSPI_CTAR*n*)

CTAR registers are used to define different transfer attributes. Do not write to the CTAR registers while the module is in the Running state.

In Master mode, the CTAR registers define combinations of transfer attributes such as frame size, clock phase and polarity, data bit ordering, baud rate, and various delays. In slave mode, a subset of the bitfields in CTAR0 and CTAR1 are used to set the slave transfer attributes.

When the module is configured as a SPI master, the CTAS field in the command portion of the TX FIFO entry selects which of the CTAR registers is used. When the module is configured as an SPI bus slave, it uses the CTAR0 register.

When the module is configured as a DSI master, the DSICTAS field in the DSI Configuration Register 0 (DSICR0), selects which of the CTAR register is used. When the module is configured as a DSI bus slave, the CTAR1 register is used.

In CSI Configuration, the transfer attributes are selected based on whether the current frame is SPI data or DSI data. SPI transfers in CSI Configuration follow the protocol described for SPI Configuration, and DSI transfers in CSI Configuration follow the protocol described for DSI Configuration.CSI Configuration is valid only in conjunction with master mode.

TSB mode sets some limitations on transfer attributes:

- Clock phase is forced to be CPHA = 1 and the CPHA bit setting has no effect.
- PCS lines are driven at the driving edge of the SCK clock together with SOUT, so PCS assertion and negation delays control is unavailable and PCSSCK, PASC, CSSCK and ASC fields have no effect.
- Delay after transfer can be set from 1 to 64 serial clocks with help of PDT and DT fields

Address: 0h base + Ch offset + (4d × i), where i=0d to 5d

DSPI_CTAR*n* field descriptions

Field	Description
0 DBR	Double Baud Rate Doubles the effective baud rate of the Serial Communications Clock (SCK). This field is used only in master mode. It effectively halves the Baud Rate division ratio, supporting faster frequencies, and odd division ratios for the Serial Communications Clock (SCK). When the DBR bit is set, the duty cycle of the Serial Communications Clock (SCK) depends on the value in the Baud Rate Prescaler and the Clock Phase bit as listed in the following table. See the BR field description for details on how to compute the baud rate.
1–4 FMSZ	Frame Size The number of bits transferred per frame is equal to the FMSZ value plus 1. Regardless of the transmission mode, the minimum valid frame size value is 4. There is a constraint on the minimum allowable Frame size, which depends on the ratio of the Register Read/Write clock to the Protocol clock. The minimum Frame size (FMSZ + 1) is determined by the following equation. Upper Ceiling must be applied for non-integer values.

Table 42-5. DSPI SCK Duty Cycle

DBR	CPHA	PBR	SCK Duty Cycle
0	any	any	50/50
1	0	00	50/50
1	0	01	33/66
1	0	10	40/60
1	0	11	43/57
1	1	00	50/50
1	1	01	66/33
1	1	10	60/40
1	1	11	57/43

0 The baud rate is computed normally with a 50/50 duty cycle.
1 The baud rate is doubled with the duty cycle depending on the Baud Rate Prescaler.

Table continues on the next page...

DSPI_CTAR*n* field descriptions (continued)

Field	Description
	Minimum Frame Size = ((4 x f_p) + (3 x f_r)) / (n x f_r) f_p = Protocol clock frequency f_r = Register interface clock frequency n = (PBR x BR) / (1 + DBR) = Multiple of protocol clock required to get Baud (SCK) Clock However, the minimum frame size can never be less than 4. There is no constraint on the maximum programmable frame size. Also note that `fp' can be equal to, less than or greater than `fr' purely based on user requirement. When the DSPI operates in TSB mode, the FMSZ field value plus 1 is equal to the data frame bit number, where control of the PCS assertion switches from the DSICR0 to the DSICR1 register. If TSB Mode is operated when DSI is in 64-bit mode, then DSICR0[FMSZ4] also affects the switching of PCS assertion control.
5 CPOL	Clock Polarity Selects the inactive state of the Serial Communications Clock (SCK). This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock polarities. When the Continuous Selection Format is selected, switching between clock polarities without stopping the module can cause errors in the transfer due to the peripheral device interpreting the switch of clock polarity as a valid clock edge. **NOTE:** In case of Continuous SCK mode, when the module goes in low power mode(disabled), inactive state of SCK is not guaranteed. 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
6 CPHA	Clock Phase Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode or TSB mode, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
7 LSBFE	LSB First Specifies whether the LSB or MSB of the frame is transferred first. When the DSPI operates in TSB configuration, this bit should be set to be compliant to the MSC specification. 0 Data is transferred MSB first. 1 Data is transferred LSB first.
8–9 PCSSCK	PCS to SCK Delay Prescaler Selects the prescaler value for the delay between assertion of PCS and the first edge of the SCK. See the CSSCK field description for information on how to compute the PCS to SCK Delay. Refer PCS to SCK Delay (t_{CSC}) for more details. In the TSB mode, the PCSSCK field has no effect. 00 PCS to SCK Prescaler value is 1. 01 PCS to SCK Prescaler value is 3. 10 PCS to SCK Prescaler value is 5. 11 PCS to SCK Prescaler value is 7.

Table continues on the next page...

DSPI_CTAR*n* field descriptions (continued)

Field	Description
10–11 PASC	After SCK Delay Prescaler Selects the prescaler value for the delay between the last edge of SCK and the negation of PCS. See the ASC field description for information on how to compute the After SCK Delay. In the TSB mode, the PASC field has no effect. Refer After SCK Delay (t_{ASC}) for more details. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.
12–13 PDT	Delay after Transfer Prescaler Selects the prescaler value for the delay between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. The PDT field is only used in master mode. In the TSB mode the PDT field defines two most-signficant bits of the Delay after Transfer. See the DT field description for details on how to compute the Delay after Transfer. Refer Delay after Transfer (t_{DT}) for more details. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.
14–15 PBR	Baud Rate Prescaler Selects the prescaler value for the baud rate. This field is used only in master mode. The baud rate is the frequency of the SCK. The protocol clock is divided by the prescaler value before the baud rate selection takes place. See the BR field description for details on how to compute the baud rate. 00 Baud Rate Prescaler value is 2. 01 Baud Rate Prescaler value is 3. 10 Baud Rate Prescaler value is 5. 11 Baud Rate Prescaler value is 7.
16–19 CSSCK	PCS to SCK Delay Scaler Selects the scaler value for the PCS to SCK delay. This field is used only in master mode. In the TSB mode the field has no effect. The PCS to SCK Delay is the delay between the assertion of PCS and the first edge of the SCK. The delay is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{CSC} = (1/f_P) \times PCSSCK \times CSSCK$. The following table lists the delay scaler values.

Table 42-6. Delay Scaler Encoding

Field Value	Delay Scaler Value
0000	2
0001	4
0010	8
0011	16
0100	32

Refer PCS to SCK Delay (t_{CSC}) for more details.
</td></tr>
<tr><td>20–23
ASC</td><td>After SCK Delay Scaler

Selects the scaler value for the After SCK Delay. This field is used only in master mode. The After SCK Delay is the delay between the last edge of SCK and the negation of PCS. The delay is a multiple of the protocol clock period, and it is computed according to the following equation:

$t_{ASC} = (1/f_P) \times PASC \times ASC$

See Delay Scaler Encoding table in CTARn[CSSCK] bit field description for scaler values. Refer After SCK Delay (t_{ASC}) for more details.</td></tr>
<tr><td>24–27
DT</td><td>Delay After Transfer Scaler

Selects the Delay after Transfer Scaler. This field is used only in master mode. The Delay after Transfer is the time between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame.

In the Continuous Serial Communications Clock operation, the DT value is fixed to one SCK clock period, The Delay after Transfer is a multiple of the protocol clock period, and it is computed according to the following equation:

$t_{DT} = (1/f_P) \times PDT \times DT$

See Delay Scaler Encoding table in CTARn[CSSCK] bit field description for scaler values.

In the TSB mode, the Delay after Transfer is equal to a number formed by concatenation of the PDT and DT fields plus 1 of the SCK clock periods. Refer Delay after Transfer (t_{DT}) for more details.</td></tr>
<tr><td>28–31
BR</td><td>Baud Rate Scaler

Selects the scaler value for the baud rate. This field is used only in master mode. The prescaled protocol clock is divided by the Baud Rate Scaler to generate the frequency of the SCK. The baud rate is computed according to the following equation:

SCK baud rate = (f_P /PBR) x [(1+DBR)/BR]

The following table lists the baud rate scaler values.</td></tr>
</table>

42.4.4 Clock and Transfer Attributes Register (In Slave Mode) (DSPI_CTAR*n*_SLAVE)

When the module is configured as an SPI bus slave, the CTAR0 register is used.

When the module is configured as a DSI master, the DSICTAS field in the DSI Configuration Register 0 (DSICR0), selects which of the CTAR register is used. When the module is configured as a DSI bus slave, the CTAR1 register is used.

Address: 0h base + Ch offset + (4d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

DSPI_CTAR*n*_SLAVE field descriptions

Field	Description
0–4 FMSZ	Frame Size The number of bits transferred per frame is equal to the concatenated field {CTARn_SLAVE[FMSZ5], CTARn_SLAVE[FMSZ]} value plus 1. Note that the minimum valid value of frame size is 4.
5 CPOL	Clock Polarity Selects the inactive state of the Serial Communications Clock (SCK). **NOTE:** In case of Continuous SCK mode, when the module goes in low power mode(disabled), inactive state of SCK is not guaranteed. 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
6 CPHA	Clock Phase Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode or TSB mode, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
7 PE	Parity Enable Enables parity bit transmission and reception for the frame. 0 No parity bit included/checked. 1 Parity bit is transmitted instead of last data bit in frame, parity checked for received frame.
8 PP	Parity Polarity Controls polarity of the parity bit transmitted and checked. 0 Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame.
9 FMSZ5	MSB of Frame Size when DSI is used in 64-bit Mode The number of bits transferred per frame is equal to the concatenated field {CTARn_SLAVE[FMSZ[5]], CTARn_SLAVE[FMSZ]} value plus 1.
10–31 Reserved	This field is reserved.

42.4.5 Status Register (DSPI_SR)

SR contains status and flag bits. The bits reflect the status of the module and indicate the occurrence of events that can generate interrupt or DMA requests. Software can clear flag bits in the SR by writing a 1 to them. Writing a 0 to a flag bit has no effect. This register may not be writable in Module Disable mode due to the use of power saving mechanisms.

Address: 0h base + 2Ch offset = 2Ch

DSPI_SR field descriptions

Field	Description
0 TCF	Transfer Complete Flag Indicates that all bits in a frame have been shifted out. TCF remains set until it is cleared by writing a 1 to it. 0 Transfer not complete. 1 Transfer complete.

Table continues on the next page...

DSPI_SR field descriptions (continued)

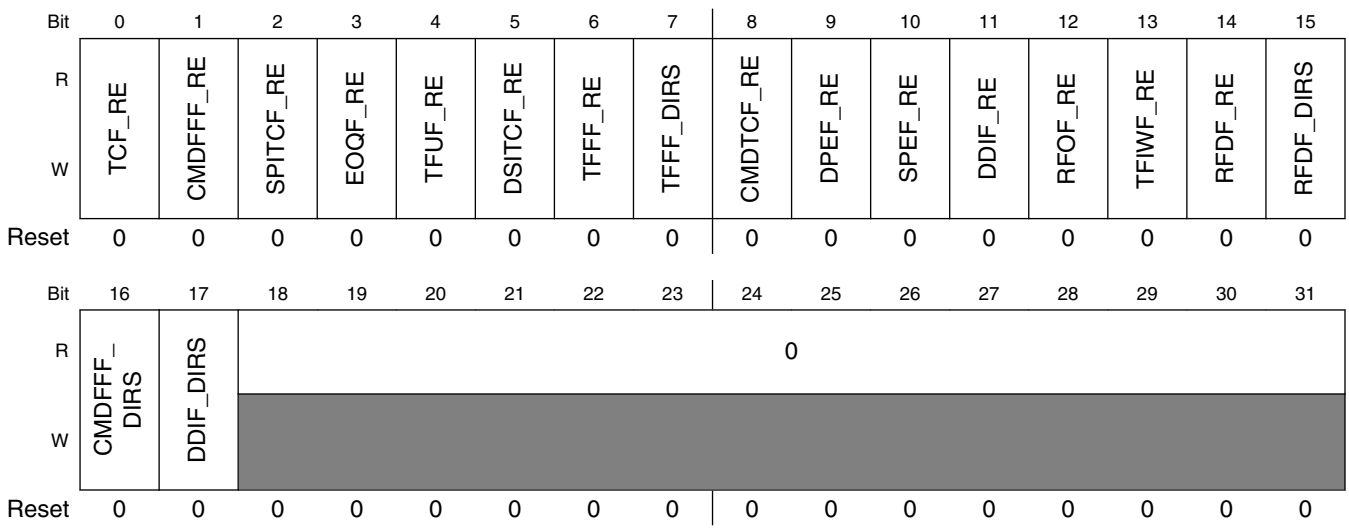
Field	Description
1 TXRXS	TX and RX Status Reflects the run status of the module. 0 Transmit and receive operations are disabled (The module is in Stopped state). 1 Transmit and receive operations are enabled (The module is in Running state).
2 SPITCF	SPI Frame Transfer Complete Flag. This bit functions similar to TCF except that this bit is asserted only on SPI frame transmission completion in the following modes: • CSI • TSB in CSI • ITSB This flag will not be asserted when the module is used in SPI or DSI Modes. 0 SPI frame transfer is not complete. 1 SPI frame transfer is complete.
3 EOQF	End of Queue Flag Indicates that the last entry in a queue has been transmitted when the module is in Master mode. The EOQF bit is set when the TX FIFO entry has the EOQ bit set in the command halfword and the end of the transfer is reached. The EOQF bit remains set until cleared by writing a 1 to it. When the EOQF bit is set, the TXRXS bit is automatically cleared. 0 EOQ is not set in the executing command. 1 EOQ is set in the executing SPI command.
4 TFUF	Transmit FIFO Underflow Flag Indicates an underflow condition in the TX FIFO. The transmit underflow condition is detected only for DSPI blocks operating in Slave mode and SPI configuration. TFUF is set when the TX FIFO of the module operating in SPI Slave mode is empty and an external SPI master initiates a transfer. The TFUF bit remains set until cleared by writing 1 to it. 0 No TX FIFO underflow. 1 TX FIFO underflow has occurred.
5 DSITCF	DSI Frame Transfer Complete Flag. This bit functions similar to TCF except that this bit is asserted only on DSI frame transmission completion in the following modes: • CSI • TSB in CSI • ITSB This flag will not be asserted when the module is in SPI or DSI mode. 0 DSI frame transfer is not complete. 1 DSI frame transfer is complete.
6 TFFF	Transmit FIFO Fill Flag Indicates whether there is an available location to be filled in the FIFO. Either a DMA request or an interrupt indication can be used to add another entry to the FIFO. Note that this bit is set if at least one location is free in the FIFO. The TFFF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller to the TX FIFO full request.

Table continues on the next page...

DSPI_SR field descriptions (continued)

Field	Description
	NOTE: The reset value of this bit is 0 when the module is disabled,(MCR[MDIS]=1). 0 TX FIFO is full. 1 TX FIFO is not full.
7 BSYF	Busy Flag. This bit is valid only when DSPI_MCR[XSPI] is enabled. Indicates that the current Command Frame is being used for transmiting multiple data frames. This bit is not set for the last Data Frame of a Cyclic command Transfer or when DSPI_CTARE[DTCP] = 1. Refer Command First In First Out (CMD FIFO) Buffering Mechanism for more details. 0 No Cyclic Command Transfer in Progress. 1 Cyclic Command Transfer is in progress. Current Data Frame is not the last data frame for on-going cyclic command transfer..
8 CMDTCF	Command Transfer Complete Flag. Indicates that the last Data frame for the current Cyclic Command has been transmitted. Hence this bit is set only for the last Data Frame of a Cyclic Command Transfer or when DSPI_CTARE[DTCP] = 1. The bit remains set until it is cleared by writing a ‘1’ to it. 0 Data Transfer by current Command not complete. 1 Data Transfer by current Command is complete.
9 DPEF	DSI Parity Error Flag Indicates that a DSI frame with parity error had been received. The bit remains set until it is cleared by writing a 1 to it. 0 No parity error. 1 Parity error has occurred.
10 SPEF	SPI Parity Error Flag Indicates that a SPI frame with parity error had been received. The bit remains set until it is cleared by writing a 1 to it. 0 No parity error. 1 Parity error has occurred.
11 DDIF	DSI Data Received with Active Bits Indicates that a DSI frame had been received with bits selected by DIMR with active polarity, defined by the DPIR register. The bit remains set until it is cleared by writing a 1 to it. 0 No DSI data with active bits was received. 1 DSI data with active bits was received.
12 RFOF	Receive FIFO Overflow Flag Indicates an overflow condition in the RX FIFO. The field is set when the RX FIFO and shift register are full and a transfer is initiated. The bit remains set until it is cleared by writing a 1 to it. 0 No Rx FIFO overflow. 1 Rx FIFO overflow has occurred.
13 TFIWF	Tranmit FIFO Invalid Write Flag

Table continues on the next page...



DSPI_SR field descriptions (continued)

Field	Description
	Indicates Data Write on TX FIFO while CMD FIFO is empty. Without a Command, the Data entries present in TXFIFO are invalid. This bit remains set until it is cleared by writing a '1' to it. 0 No Invalid Data present in TX FIFO. 1 Invalid Data present in TX FIFO since CMD FIFO is empty.
14 RFDF	Receive FIFO Drain Flag Indicates whether there is an available location to be drained from the FIFO. Either a DMA request or an interrupt indication can be used to read from the FIFO. Note that this bit is set if at least one location can be read from the FIFO. The RFDF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller when the RX FIFO is empty. 0 RX FIFO is empty. 1 RX FIFO is not empty.
15 CMDFFF	Command FIFO Fill Flag Indicates whether there is an available location to be filled in the FIFO. Either a DMA request or an interrupt indication can be used to add another entry to the FIFO. Note that this bit is set if at least one location is free in the FIFO. The CMDFFF is cleared by writing a '1' to it or by acknowledgement from the DMA controller to the CMD FIFO full request. 0 CMD FIFO is full. 1 CMD FIFO is not full.
16–19 TXCTR	TX FIFO Counter Indicates the number of valid entries in the TX FIFO. The TXCTR is incremented every time the PUSHR is written. The TXCTR is decremented every time an SPI command is executed and the SPI data is transferred to the shift register.
20–23 TXNXTPTR	Transmit Next Pointer Indicates which TX FIFO entry is transmitted during the next transfer. The TXNXTPTR field is updated every time SPI data is transferred from the TX FIFO to the shift register.
24–27 RXCTR	RX FIFO Counter Indicates the number of entries in the RX FIFO. The RXCTR is decremented every time the POPR is read. The RXCTR is incremented every time data is transferred from the shift register to the RX FIFO.
28–31 POPNXTPTR	Pop Next Pointer Contains a pointer to the RX FIFO entry to be returned when the POPR is read. The POPNXTPTR is updated when the POPR is read.

42.4.6 DMA/Interrupt Request Select and Enable Register (DSPI_RSER)

RSER controls DMA and interrupt requests. Do not write to the RSER while the module is in the Running state.

Address: 0h base + 30h offset = 30h

DSPI_RSER field descriptions

Field	Description
0 TCF_RE	Transmission Complete Request Enable Enables TCF flag in the SR to generate an interrupt request. 0 TCF interrupt requests are disabled. 1 TCF interrupt requests are enabled.
1 CMDFFF_RE	Command FIFO Fill Flag Request Enable. Enables the CMDFFF flag in the SR to generate a request. The CMDFFF_DIRS bit selects between generating an interrupt request or a DMA request. 0 CMDFFF interrupts or DMA requests are disabled. 1 CMDFFF interrupts or DMA requests are enabled.
2 SPITCF_RE	SPI Frame Transmission Complete Request Enable. The SPITCF_RE bit enables SPITCF flag in the SR to generate an interrupt request. 0 SPITCF interrupt requests are disabled. 1 SPITCF interrupt requests are enabled.
3 EOQF_RE	Finished Request Enable

Table continues on the next page...

DSPI_RSER field descriptions (continued)

Field	Description
	Enables the EOQF flag in the SR to generate an interrupt request. 0 EOQF interrupt requests are disabled. 1 EOQF interrupt requests are enabled.
4 TFUF_RE	Transmit FIFO Underflow Request Enable Enables the TFUF flag in the SR to generate an interrupt request. 0 TFUF interrupt requests are disabled. 1 TFUF interrupt requests are enabled.
5 DSITCF_RE	DSI Frame Transmission Complete Request Enable. The DSITCF_RE bit enables DSITCF flag in the SR to generate an interrupt request. 0 DSITCF interrupt requests are disabled. 1 DSITCF interrupt requests are enabled.
6 TFFF_RE	Transmit FIFO Fill Request Enable Enables the TFFF flag in the SR to generate a request. The TFFF_DIRS bit selects between generating an interrupt request or a DMA request. 0 TFFF interrupts or DMA requests are disabled. 1 TFFF interrupts or DMA requests are enabled.
7 TFFF_DIRS	Transmit FIFO Fill DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. When SR[TFFF] and RSER[TFFF_RE] are set, this field selects between generating an interrupt request or a DMA request. 0 TFFF flag generates interrupt requests. 1 TFFF flag generates DMA requests.
8 CMDTCF_RE	Command Transmission Complete Request Enable. The CMDTCF_RE bit enables CMDTCF flag in the SR to generate an interrupt request. 0 CMDTCF interrupt requests are disabled. 1 CMDTCF interrupt requests are enabled.
9 DPEF_RE	DSI Parity Error Request Enable Enables the DPEF flag in the SR to generate an interrupt request. 0 DPEF interrupt requests are disabled. 1 DPEF interrupt requests are enabled.
10 SPEF_RE	SPI Parity Error Request Enable Enables the SPEF flag in the SR to generate an interrupt request. 0 SPEF interrupt requests are disabled. 1 SPEF interrupt requests are enabled.
11 DDIF_RE	DSI data received with active bits Request Enable Enables the SR[DDIF] flag to generate an interrupt or DMA request.

Table continues on the next page...

DSPI_RSER field descriptions (continued)

Field	Description
	0 Disabled 1 Enabled
12 RFOF_RE	Receive FIFO Overflow Request Enable Enables the RFOF flag in the SR to generate an interrupt request. 0 RFOF interrupt requests are disabled. 1 RFOF interrupt requests are enabled.
13 TFIWF_RE	Transmit FIFO Invalid Write Request Enable. Enables the TFIWF flag in the SR to generate an interrupt request. 0 TFIWF interrupt requests are disabled. 1 TFIWF interrupt requests are enabled.
14 RFDF_RE	Receive FIFO Drain Request Enable Enables the RFDF flag in the SR to generate a request. The RFDF_DIRS bit selects between generating an interrupt request or a DMA request. 0 RFDF interrupt or DMA requests are disabled. 1 RFDF interrupt or DMA requests are enabled.
15 RFDF_DIRS	Receive FIFO Drain DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. When the RFDF flag bit in the SR is set, and the RFDF_RE bit in the RSER is set, the RFDF_DIRS bit selects between generating an interrupt request or a DMA request. 0 Interrupt request. 1 DMA request.
16 CMDFFF_DIRS	Command FIFO Fill DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. When the CMDFFF flag bit in the SR is set, and the CMDFFF_RE bit in the RSER is set, the CMDFFF_DIRS bit selects between generating an interrupt indication or a DMA request. 0 CMDFFF flag generates interrupt requests. 1 CMDFFF flag generates DMA requests.
17 DDIF_DIRS	DSI data received with active bits - DMA or Interrupt Request Select. Selects between generating a DMA request or an interrupt request. When the DDIF flag bit in the SR is set, and the DDIF_RE bit in the RSER is set, the DDIF_DIRS bit selects between generating an interrupt request or a DMA request. 0 Interrupt request. 1 DMA request.
18–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

42.4.7 PUSH TX FIFO Register In Master Mode (DSPI_PUSHR)

Specifies data to be transferred to the TX FIFO and CMD FIFO. User must write 16-bits data into TXDATA field. An 8- or 16-bit write access to the TXDATA field transfers 16 bits of data bus to the TX FIFO. A write access to the command fields transfers the 16 bits of command information to the CMD FIFO. In Master mode, the register transfers 16 bits of data to the TX FIFO and 16 bits of command information to the CMD FIFO.

If Extended SPI Mode is disabled (MCR[XSPI]), the TX FIFO and CMD FIFO must be filled simultaneously. In other words, you must perform write accesses to both the data and command fields for every PUSHR operation. With Extended SPI Mode disabled and both the TX FIFO and CMD FIFO are written to and read from simultaneously, they behave as a single 32 bit FIFO. When Extended SPI mode is enabled (MCR[XSPI]), the TX FIFO and CMD FIFO can be written to independently.

A read access of PUSHR returns the topmost TX FIFO and CMD FIFO entries concatenated.

When the module is disabled, writing to this register does not update the FIFO. Therefore, any reads performed while the module is disabled return the last PUSHR write performed while the module was still enabled.

Address: 0h base + 34h offset = 34h

DSPI_PUSHR field descriptions

Field	Description
0 CONT	Continuous Peripheral Chip Select Enable Selects a continuous selection format. The bit is used in SPI Master mode. The bit enables the selected PCS signals to remain asserted between transfers.

Table continues on the next page...

DSPI_PUSHR field descriptions (continued)

Field	Description
	0 Return PCSn signals to their inactive state between transfers. 1 Keep PCSn signals asserted between transfers.
1–3 CTAS	Clock and Transfer Attributes Select Selects which CTAR to use in master mode to specify the transfer attributes for the associated SPI frame. In SPI Slave mode, CTAR0 is used. See the chip specific section for details to determine how many CTARs this device has. You should not program a value in this field for a register that is not present. 000 CTAR0 001 CTAR1 010 CTAR2 011 CTAR3 100 CTAR4 101 CTAR5 110 Reserved 111 Reserved
4 EOQ	End Of Queue Host software uses this bit to signal to the module that the current SPI transfer is the last in a queue. At the end of the transfer, the EOQF bit in the SR is set. 0 The SPI data is not the last data to transfer. 1 The SPI data is the last data to transfer.
5 CTCNT	Clear Transfer Counter Clears the TCNT field in the TCR register. The TCNT field is cleared before the module starts transmitting the current SPI frame. 0 Do not clear the TCR[TCNT] field. 1 Clear the TCR[TCNT] field.
6 PE_MASC	Parity Enable or Mask T_{ASC} delay in the current frame PE – This bit enables parity bit transmission and parity reception check for the SPI frame. MASC - The current frame has the “after SCK” delay masked if this bit is asserted. See Fast Continuous Selection Format for more details. **NOTE:** This bit is used as Mask T_{ASC} in the Fast Continuous PCS mode when MCR[FCPCS] is set. 0 PE - No parity bit included/checked. MASC - T_{ASC} delay is not masked and the current frame has the after SCK delay. 1 PE - Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame. MASC - T_{ASC} delay is masked in the current frame.
7 PP_MCSC	Parity Polarity or Mask T_{CSC} delay in the next frame PP - It controls the polarity of the parity bit transmitted and checked. MCSC - The next frame has the “PCS to SCK” delay masked if this bit is asserted. See Fast Continuous Selection Format for more details. **NOTE:** This bit is used as Mask T_{CSC} in the Fast Continuous PCS mode when MCR[FCPCS] is set.

Table continues on the next page...

DSPI_PUSHR field descriptions (continued)

Field	Description
	0 PP - Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. MCSC - T_{CSC} delay is not masked and the next frame has the PCS to SCK delay. 1 PP - Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame. MCSC - T_{CSC} delay is masked in the next frame.
8–9 Reserved	Always write the reset value to this field. This field is reserved.
10–15 PCS	Select which PCS signals are to be asserted for the transfer. Refer to the chip-specific DSPI information for the number of PCS signals used in this chip. 0 Negate the PCS[x] signal. 1 Assert the PCS[x] signal.
16–31 TXDATA	Transmit Data Holds SPI data to be transferred according to the associated SPI command.

42.4.8 PUSH TX FIFO Register In Slave Mode (DSPI_PUSHR_SLAVE)

Specifies data to be transferred to the TX FIFO in slave mode. An 8- or 16-bit write access to PUSHR transfers the 16-bit TXDATA field to the TX FIFO.

When Extended SPI mode is enabled (MCR[XSPI]), up to 32-bit SPI frames may be queued for transmission or reception.

Address: 0h base + 34h offset = 34h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

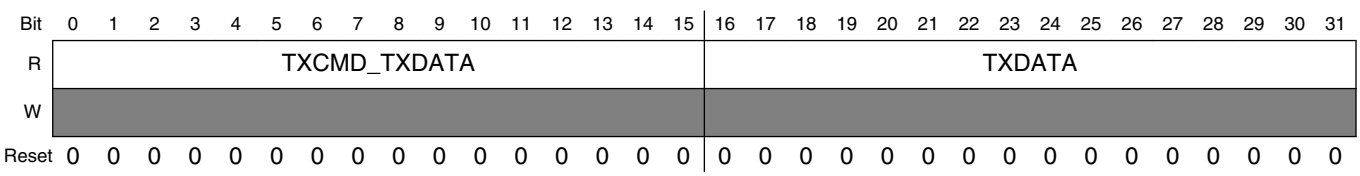
DSPI_PUSHR_SLAVE field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TXDATA	Transmit Data Holds SPI data to be transferred according to the associated SPI command.

42.4.9 POP RX FIFO Register (DSPI_POPR)

POPR is used to read the RX FIFO. Eight- or sixteen-bit read accesses to the POPR have the same effect on the RX FIFO as 32-bit read accesses. A write to this register will generate a Transfer Error.

Address: 0h base + 38h offset = 38h



DSPI_POPR field descriptions

Field	Description
0–31 RXDATA	Received Data Contains the SPI data from the RX FIFO entry to which the Pop Next Data Pointer points.

42.4.10 Transmit FIFO Registers (DSPI_TXFR*n*)

TXFRn registers provide visibility into the TX FIFO for debugging purposes. Each register is an entry in the TX FIFO. The registers are read-only and cannot be modified. Reading the TXFRx registers does not alter the state of the TX FIFO. When the module is operating in Extended SPI mode, reading TXFRn registers is invalid.

Address: 0h base + 3Ch offset + (4d × i), where i=0d to 3d

DSPI_TXFR*n* field descriptions

Field	Description
0–15 TXCMD_ TXDATA	Transmit Command or Transmit Data In Master mode the TXCMD field contains the command that sets the transfer attributes for the SPI data. In Slave mode, this field is reserved.

Table continues on the next page...

DSPI_TXFR*n* field descriptions (continued)

Field	Description
16–31 TXDATA	Transmit Data Contains the SPI data to be shifted out.

42.4.11 Receive FIFO Registers (DSPI_RXFR*n*)

RXFRn provide visibility into the RX FIFO for debugging purposes. Each register is an entry in the RX FIFO. The RXFR registers are read-only. Reading the RXFRx registers does not alter the state of the RX FIFO. The field MCR[MDIS] must be 0 when RXFR is read.

Address: 0h base + 7Ch offset + (4d × i), where i=0d to 3d

DSPI_RXFR*n* field descriptions

Field	Description
0–31 RXDATA	Receive Data Contains the received SPI data.

42.4.12 DSI Configuration Register 0 (DSPI_DSICR0)

Selects various attributes associated with the following configurations:

- DSI
- TSB
- ITSB

Do not write to the DSICR0 while the module is in the Running state.

Address: 0h base + BCh offset = BCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

DSPI_DSICR0 field descriptions

Field	Description
0 MTOE	Multiple Transfer Operation Enable Enables multiple DSPIs to be connected in a parallel or serial configuration. The MTOE and TSB bits should not be set simulteneously. 0 Multiple transfer operation disabled. 1 Multiple transfer operation enabled.
1 FMSZ4	MSB of the frame size in master mode. If the bit is set, 16 is added to the frame size, as defined by the CTARn[FMSZ] field. The CTARx register is selected by the DSICTAS field.
2–7 MTOCNT	Multiple Transfer Operation Count Selects the number of bits to be shifted out during a transfer in Multiple Transfer Operation. The field sets the number of SCK cycles that the bus master must generate to complete the transfer. The number of SCK cycles used is one more than the value in the MTOCNT field. The number of SCK cycles defined by MTOCNT must be equal to or greater than the frame size. When TSBC is set, MTOCNT has no effect.
8 FMSZ5	MSB of the frame size in master mode when DSI is used in 64-bit mode.

Table continues on the next page...

DSPI_DSICR0 field descriptions (continued)

Field	Description
	If the bit is set, 32 is added to the frame size, as defined by the concatenation of {DSICR0[FMSZ[4]] , CTARn[FMSZ]} fields. The CTARn register is selected by the DSICTAS field. Hence the final concatenated frame size using this bit would be {DSICR0[FMSZ[5]], DSICR0[FMSZ[4]] , CTARn[FMSZ]}. This field is only valid when DSICR1[DSI64E] is enabled.
9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 ITSB	Interleaved TSB mode. This bit enables the Interleaved TSB mode of operation. When enabled, there is no priority among frames from the SPI/DSI. DSI frames are always sent when either the previous transmission was a SPI frame or if the TX_FIFO is empty. Frames are transmitted on every trigger whose source is selected by the TRG bit setting. The ITSB mode requires the DSICR0[TSBC] bit to be set and should be written only when MCR[HALT] bit is asserted. If ITSB bit is set without setting DSICR0[TSBC], then the module operates in the Normal Mode depending on MCR[DCONF] bit. See Interleaved TSB (ITSB) Mode for more details. 0 Interleaved mode is disabled. 1 Interleaved mode is enabled.
11 TSBC	Timed Serial Bus Configuration. Enables the Timed Serial Bus interface configuration and allows t_{DT} to be programmable. 0 Timed Serial Bus Configuration disabled. 1 Timed Serial Bus Configuration enabled.
12 TXSS	Transmit Data Source Select. Selects the source of data to be serialized. The source can be either data from host software written to the DSI Alternate Serialization Data Register (ASDR0/1) or Parallel Input pin states latched into the DSI Serialization Data Register (SDR0/1). 0 Source of serialized data is the SDR. 1 Source of serialized data is the ASDR.
13 TPOL	Trigger Polarity Selects the active edge of the hardware trigger input signal (HT), initiating DSI frames transfer. 0 Falling edge initiates a transfer. 1 Rising edge initiates a transfer.
14 TRRE	Trigger Reception Enable Enables the module to initiate a DSI frames transfer with an external trigger signal. **NOTE:** When TRIG[ENABLE] is set, the TRRE bit is given by TRIG[TRRE] which overrides DSICR0[TRRE]. 0 Trigger signal reception disabled. 1 Trigger signal reception enabled.
15 CID	Change In Data Transfer Enable Enables a change in serialization data to initiate a DSI frames transfer in DSI and CSI configurations. When the CID bit is set, DSI frames are initiated when the current DSI data differs from the previous DSI data shifted out.

Table continues on the next page...

DSPI_DSICR0 field descriptions (continued)

Field	Description
	NOTE: When TRIG[ENABLE] is set, the CID bit is given by TRIG[CID] which overrides DSICR0[CID].
16 DCONT	DSI Continuous Peripheral Chip Select Enable Enables the PCS signals to remain asserted between transfers. The DCONT bit affects the PCS signals only in DSI master mode. When the TSBC bit is set, DCONT has no effect. 0 Return Peripheral Chip Select signals to their inactive state after the transfer is complete. 1 Keep Peripheral Chip Select signals asserted after transfer is complete.
17–19 DSICTAS	DSI Clock and Transfer Attributes Select Selects the CTAR register to use to provide transfer attributes for DSI frames. The DSICTAS field is used in DSI master mode. In DSI slave mode, CTAR1 is always selected.
20 DMS	Data Match Stop If set, stops DSI frame transmissions if DDIF flag is set in the SR register. 0 DDIF flag does not have an effect on DSI frame transmissions. 1 DDIF flag stops DSI frame transmissions.
21 PES	Parity Error Stop If set, stops DSI operation if the parity error happened in the received DSI frame. 0 Parity error does not stop DSI frame transmissions. 1 Parity error stops all DSI frame transmissions.
22 PE	Parity Enable Enables parity bit transmission and parity reception check for the DSI frames. 0 No parity bit included/checked. 1 Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame.
23 PP	Parity Polarity Controls the polarity of the parity bit transmitted and checked. 0 Even Parity: the number of 1 bits in the transmitted frame is even. The SR[DPEF] bit is set if in the received frame number of 1 bits is odd. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[DPEF] bit is set if in the received frame number of 1 bits is even.
24–31 DPCSx	DSI Peripheral Chip Select 0–7 Selects which of the PCS signals to assert during a DSI master mode transfer. 0 Negate PCS[x]. 1 Assert PCS[x].

42.4.13 DSI Serialization Data Register 0 (DSPI_SDR0)

SDR0 contains the states of the 32 LSB Parallel Input signals. The states of the Parallel Input signals are latched into the SDR0 on the rising edge of every bus clock. The SDR0 is read-only. When the TXSS bit in the DSICR0 is cleared, the data in the SDR0 is used as the source of the DSI frames. When DSI 64-bit mode is enabled (DSICR1[DSI64E]), the concatenation of {SDR1, SDR0} provides the 64-bit Serialization Data value.

Address: 0h base + C0h offset = C0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DSPI_SDR0 field descriptions

Field	Description
0–31 SER_DATA	Serialized Data Contains the signal states of the 32 LSB Parallel Input signals.

42.4.14 DSI Alternate Serialization Data Register 0 (DSPI_ASDR0)

ASDR0 is used by host software to write the 32 LSB of the data to be serialized. When the TXSS bit in the DSICR0 is set, the data in the ASDR0 is the source of the DSI frames. Writes to the ASDR0 take effect on the next frame boundary. When DSI 64-bit mode is enabled (DSICR1[DSI64E]), the concatenation of {ASDR1, ASDR0} provides the 64-bit Alternate Serialization Data value.

Address: 0h base + C4h offset = C4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DSPI_ASDR0 field descriptions

Field	Description
0–31 ASER_DATA	Alternate Serialized Data Holds the alternate 32 LSB of the data to be serialized.

42.4.15 DSI Transmit Comparison Register 0 (DSPI_COMPR0)

COMPR0 holds a copy of the 32 LSB of the last transmitted DSI data. COMPR0 is read-only. DSI data is transferred to this register as it is loaded into the TX Shift Register. When DSI 64-bit mode is enabled (DSICR1[DSI64E]), the concatenation of {COMPR1, COMPR0} provides the 64-bit Transmit Comparison value.

Address: 0h base + C8h offset = C8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

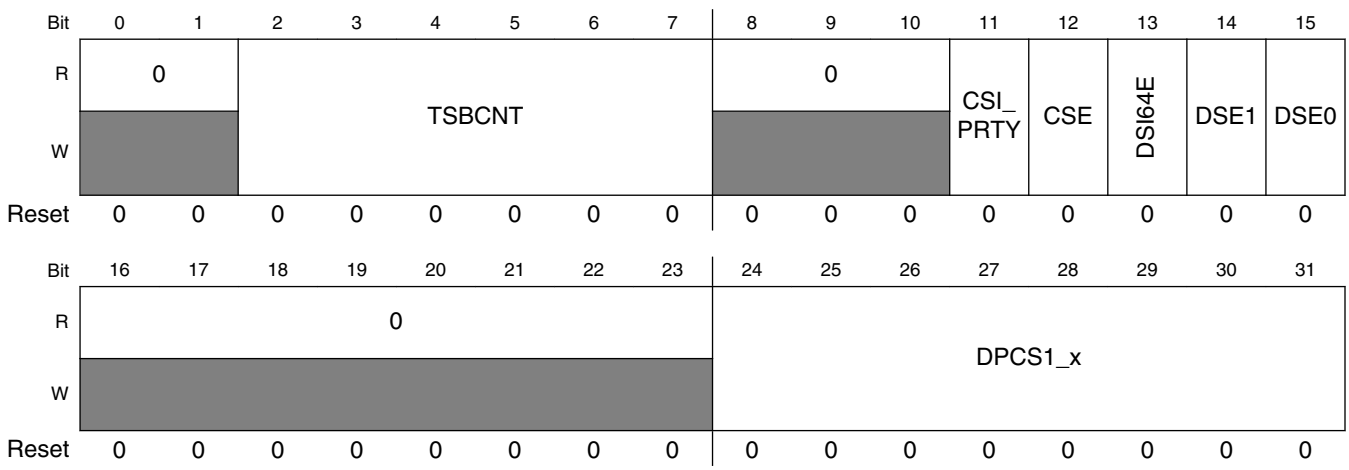
DSPI_DDR0 field descriptions

Field	Description
0–31 DESER_DATA	Deserialized Data Holds 32 LSB of deserialized data that is presented as signal states to the Parallel Output signals.



42.4.17 DSI Configuration Register 1 (DSPI_DSICR1)

Selects various attributes associated with the following configurations:

- DSI
- TSB
- ITSB

The user must not write to the DSICR1 while the module is in the Running state.

Address: 0h base + D0h offset = D0h

DSPI_DSICR1 field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 TSBCNT	Timed Serial Bus Operation Count When TSB is enabled (DSICR0[TSBC]), TSBCNT defines the length of the data frame. When DSI 64-bit mode is enabled (DSI64E), the length value can vary from 3 to 63 (000011b to 111111b); otherwise, it can vary from 3 to 31 (000011b to 011111b). The length value specifies the number of data bits to be shifted out during a transfer in TSB mode. The number of data bits in the data frame is one more than the value in the TSBCNT field.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 CSI_PRTY	CSI Priority This field allows the user to configure the priority of SPI and DSI frames when module is operating in CSI Mode. This is not applicable when DSICR0[ITSB] is enabled. 0 SPI frames has priority over DSI frames. 1 DSI frames have priority over SPI frames.
12 CSE	Command Select Enable

Table continues on the next page...

DSPI_DSICR1 field descriptions (continued)

Field	Description
	When the DSICR0[ITSB] is set, the CSE bit controls insertion of command selection bit (Logic 1) in the beginning of the SPI (command) frame. 0 No selection bit is inserted in the beginning of the command frame. 1 Command selection bit is inserted at the beginning of the command frame. Total number of bits in the command frame is increased by 1.
13 DSI64E	DSI 64-bit Mode Enable Enables DSI 64-bit mode, which allows the serialization and deserialization of data frames up to 64 bits in size. The following extended registers are valid only when this mode is enabled: SDR1, ASDR1, COMPR1, DDR1, SSR1, DIMR1, DPIR1, PISR4-7. 0 DSI 64-bit Mode Disabled. DSI Mode operates in the default 32 bit configuration. 1 DSI 64-bit Mode Enabled. DSI Mode operates in 64-bit configuration.
14 DSE1	Data Select Enable 1 When the TBSC bit is set, the DSE1 bit controls insertion of the zero bit (Data Select) in the middle of the data frame. The insertion bit position is defined by the FMSZ field of CTARn register, selected by the DSICR0[DSICTAS] field. If DSI 64-bit mode is enabled (DSICR1[DSI64]), then the insertion bit position is defined by the concatenation of {DSICR0[FMSZ4], CTAR[FMSZ]}. The TSBCNT field value must be greater than the position of insertion for proper operation of DSE1. 0 No Zero bit is inserted in the middle of the data frame. 1 Zero bit is inserted at the middle of the data frame. Total number of bits in the data frame is increased by 1.
15 DSE0	Data Select Enable 0 When the TBSC bit is set, the DSE1 bit controls insertion of the zero bit (Data Select) in the beginning of the DSI frame. 0 No Zero bit is inserted in the beginning of the frame. 1 Zero bit is inserted at the beginning of the data frame. Total number of bits in the data frame is increased by 1.
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 DPCS1_x	DSI Peripheral Chip Select 0–7 Specifies the PCSs to assert for the second part of the DSI frame when operating in TSB or ITSB configuration with dual receiver. DPCS1 selects the PCS signals to assert during the second part of the DSI frame. DPCS1 controls the assertions of PCS signals only in TSB and ITSB mode. 0 Negate PCS[x]. 1 Assert PCS[x].

42.4.18 DSI Serialization Source Select Register 0 (DSPI_SSR0)

SSR0 is used to create a combined frame for transmission that contains bits from ASDR0 and SDR0. Each bit in the SSR0 register selects a corresponding bit to be serialized. When DSICR0[TXSS] is set, the SSR0 register value has no effect. When DSI 64-bit mode is enabled (DSICR1[DSI64E]), the concatenation of {SSR1, SSR0} provides the 64-bit Serialization Source Select Value.

Address: 0h base + D4h offset = D4h

DSPI_SSR0 field descriptions

Field	Description
0–31 SS	Source Select Select the serialization source for the 32 LSB of the DSI frame. Each SS bit selects data for a corresponded bit in the transmitted frame. 0 The bit in the transmitted frame is taken from the Parallel Input pin. 1 The bit in the transmitted frame is taken from the ASDR0 register

42.4.19 DSI Parallel Input Select Register 0 (DSPI_PISR0)

PISR0–3 select each data bit for the transmitted frame from 32 parallel input pins. Each Input Pin Select (IPS) field controls one bit in the transmitted frame. Each register contains control fields for 8 bits in the frame. The select field value is defined as a 4-bit signed integer number. The selected parallel input pin number is defined as a difference between the sum of the field number and the field value.

For example, if IPS16 is equal to the binary number 1111 (minus 1 decimal), then bit 16 in the frame is taken from parallel input pin number 15. When the IPS0 is equal to -1, then bit 0 in the frame is taken from parallel input 31. If DSI 64-bit is enabled (DSICR1[DSI64E]), bit 0 is taken from parallel input 63. When the IPS0 is equal to +1, then bit 0 in the frame is taken from Parallel Input 1 and so on.

Note that PISR0–3 only preselect the Parallel Input pins. The final selection to the transmitted frame is made with the SSR0-1 register bits or the DSICR0[TXSS] bit.

When DSI 64-bit mode is enabled (DSICR1[DSI64E]), PISR4-7 handle the 32 most-significant pins of the 64 parallel input pins.

Address: 0h base + D8h offset = D8h

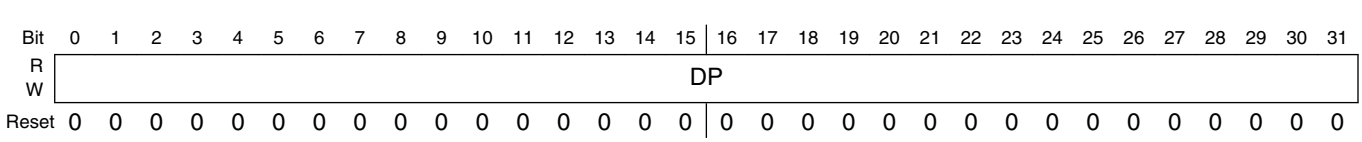
42.4.23 DSI Deserialized Data Interrupt Mask Register 0 (DSPI_DIMR0)

DIMR0 selects bits in the 32 least-significant bits of the received DSI frame to be checked to generate the DDI interrupt. When DSI 64-bit mode is enabled (DSICR1[DSI64E]), the concatenation of {DIMR1, DIMR0} provides the 64-bit Deserialized Data Interrupt Mask value.

Address: 0h base + E8h offset = E8h



DSPI_DIMR0 field descriptions

Field	Description
0–31 MASK	Mask Defines which bits in the 32 LSB of received deserialization data should be checked to produce the Deserialized Data Interrupt (DDI). 0 The bit in the received DSI frame does not produce a DDI interrupt. 1 The bit in the received DSI frame can produce a DDI interrupt if the data bit matches the configured polarity.

42.4.24 DSI Deserialized Data Polarity Interrupt Register 0 (DSPI_DPIR0)

DPIR0 defines which data bit value in the 32 least-significant bits of the received DSI frame generates the DDI interrupt. When DSI 64-bit mode is enabled (DSICR1[DSI64E]), the concatenation of {DPIR1, DPIR0} provides the 64-bit Deserialized Data Polarity Interrupt value.

Address: 0h base + ECh offset = ECh

DSPI_DPIR0 field descriptions

Field	Description
0–31 DP	Data Polarity Defines which value of the 32 LSB of received deserialization data sets the SR[DDIF] bit. 0 If the received bit is 0, the SR[DDIF] bit is set. 1 If the received bit is 1, the SR[DDIF] bit is set.

42.4.25 DSI Serialization Data Register 1 (DSPI_SDR1)

SDR1 contains the states of the 32 MSB parallel input signals. The states of these parallel input signals are latched into the SDR1 on the rising edge of every bus clock. The SDR1 is read-only. When the TXSS bit in the DSICR0 is cleared, the data in the SDR1 and SDR0 is used as the source of the DSI frames. The concatenation of {SDR1, SDR0} provides the 64-bit data to be serialized. This register is valid only when DSI 64-bit mode is enabled (DSICR1[DSI64E]).

Address: 0h base + F0h offset = F0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DSPI_SDR1 field descriptions

Field	Description
0–31 SER_DATA	Serialized Data Contains the 32 MSB signal states of the 64 parallel input signals. This field is valid only when DSICR1[DSI64E] is set. The concatenation of {SDR1, SDR0} provides the 64-bit data to be serialized.

42.4.26 DSI Alternate Serialization Data Register 1 (DSPI_ASDR1)

ASDR1 is used by host software to write the 32 MSB of the 64-bit data to be serialized. When the TXSS bit in the DSICR0 is set, the data in the ASDR1 and ASDR0 is the source of the DSI frames. Writes to the ASDR1 take effect on the next frame boundary. The concatenation of {ASDR1, ASDR0} provides the 64-bit alternate serialization data. This register is valid only when DSI 64-bit mode is enabled (DSICR1[DSI64E]).

Address: 0h base + F4h offset = F4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DSPI_ASDR1 field descriptions

Field	Description
0–31 ASER_DATA	Alternate Serialized Data Holds the 32 MSB of the 64-bit alternate data to be serialized. This field is valid only when DSICR1[DSI64E] is set. The concatenation of {ASDR1, ASDR0} provides the 64-bit alternate serialization data.

42.4.27 DSI Transmit Comparison Register 1 (DSPI_COMPR1)

COMPR1 holds a copy of the 32 MSB of the last transmitted 64-bit DSI data. COMPR1 is read-only. Upper 32 bits of the 64-bit DSI data is transferred to this register as it is loaded into the TX Shift Register. The concatenation of {COMPR1, COMPR0} provides the 64-bit transmit comparison data. This register is valid only when DSI 64-bit mode is enabled (DSICR1[DSI64E]).

Address: 0h base + F8h offset = F8h

DSPI_DDR1 field descriptions

Field	Description
0–31 DESER_DATA	Deserialized Data Holds 32 MSB of the deserialized data that is presented as signal states to the 64 Parallel Output signals.This field is valid only when DSICR1[DSI64E] is set. The concatenation of {DDR1, DDR0} provides the 64-bit deserialized data.

42.4.29 DSI Serialization Source Select Register 1 (DSPI_SSR1)

SSR1 is used to create a combined frame for transmission that contains bits from ASDR1 and SDR1. Each bit in the SSR1 register selects a corresponding bit to be serialized. When DSICR0[TXSS] is set, the SSR1 register value has no effect. The concatenation of {SSR1, SSR0} provides the 64-bit Serialization Source Select Value. This register is valid only when DSI 64-bit mode is enabled (DSICR1[DSI64E]).

Address: 0h base + 100h offset = 100h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	SS																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DSPI_SSR1 field descriptions

Field	Description
0–31 SS	Source Select Select the serialization source for the 32 MSB of the 64-bit DSI frame. Each SS bit selects data for a corresponded bit in the transmitted frame. This field is valid only when DSICR1[DSI64E] is set. The concatenation of {SSR1, SSR0} provides the 64-bit serialization source select value. 0 The bit in the transmitted frame is taken from the Parallel Input pin. 1 The bit in the transmitted frame is taken from the ASDR0/1 register

42.4.30 DSI Parallel Input Select Register 4 (DSPI_PISR4)

PISR4–7 are used to select each data bit for the transmitted frame from 32 parallel input pins. Each Input Pin Select (IPS) field controls one bit in the transmitted frame. Each register contains control fields for 8 bits in the frame. The select field value is defined as a 4-bit signed integer number. The selected parallel input pin number is defined as a difference between the sum of the field number and the field value.

For example, if IPS16 is equal to the binary number 1111 (minus 1 decimal), then bit 16 in the frame is taken from parallel input pin number 15. When the IPS0 is equal to -1, then bit 0 in the frame is taken from parallel input 31 (bit 0 is taken from parallel input 63 when DSICR1[DSI64E] is enabled). When the IPS0 is equal to +1, then bit 0 in the frame is taken from parallel input 1 and so on.

Note that PISR0–7 only preselect the parallel input pins. The final selection to the transmitted frame is made with the SSR0 and SSR1 register bits or the DSICR0[TXSS] bit.

When DSI 64-bit mode is enabled (DSICR1[DSI64E]), PISR4-7 are used to handle the extra 32 bits (32 MSB pins of the 64 parallel input pins). If DSI 64-bit mode is disabled, then PISR4-7 are not used.

Address: 0h base + 104h offset = 104h

DSPI_DIMR1 field descriptions

Field	Description
0–31 MASK	Mask Defines which of the 32 MSB in the received 64-bit deserialization data should be checked to produce the Deserialized Data Interrupt (DDI). 0 The bit in the received DSI frame does not produce a DDI interrupt. 1 The bit in the received DSI frame can produce a DDI interrupt if the data bit matches the configured polarity.

42.4.35 DSI Deserialized Data Polarity Interrupt Register 1 (DSPI_DPIR1)

DPIR1 defines which of the 32 MSB value in the received 64-bit DSI frame generates the DDI interrupt. The concatenation of {DPIR1, DPIR0} provides the 64-bit Deserialized Data Polarity Value. This register is valid only when DSI 64-bit mode is enabled (DSICR1[DSI64E]).

Address: 0h base + 118h offset = 118h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

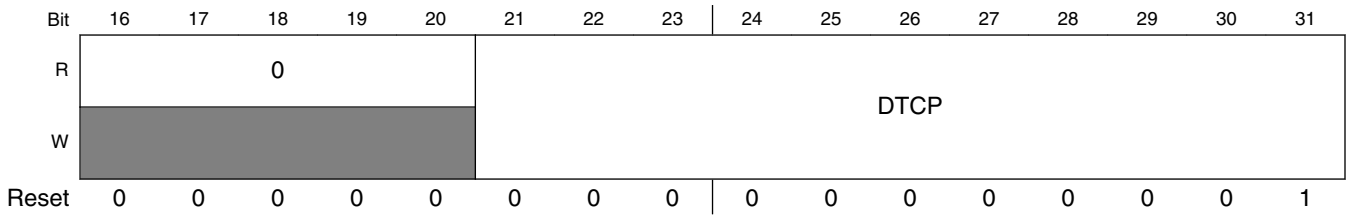
DSPI_DPIR1 field descriptions

Field	Description
0–31 DP	Data Polarity Defines which of the 32 MSB of the received 64-bit deserialization data sets the SR[DDIF] bit. 0 If the received bit is 0, the SR[DDIF] bit is set. 1 If the received bit is 1, the SR[DDIF] bit is set.



42.4.36 Clock and Transfer Attributes Register Extended (DSPI_CTARE*n*)

CTARE registers are used to define the extended transfer attributes for an SPI frame. These registers are valid only when Extended SPI mode is enabled (MCR[XSPI]).

When the module is configured as a SPI master, the CTAS field in CMD FIFO entry selects which of the CTARE registers is used.

Address: 0h base + 11Ch offset + (4d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

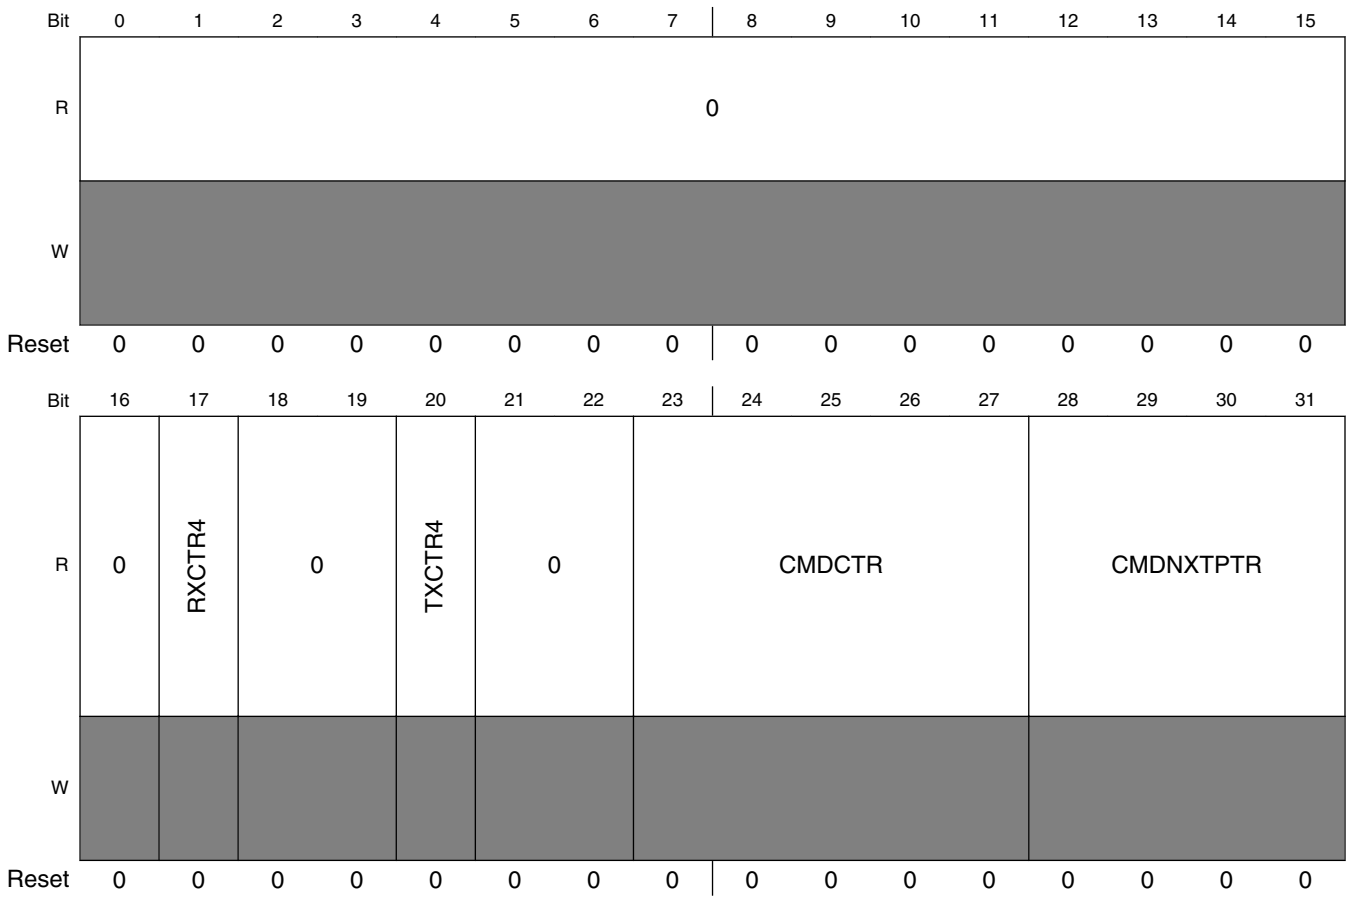
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



DSPI_CTARE*n* field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 FMSZE	Frame Size Extended This field is valid only when MCR[XSPI] is set. This field concatenated with CTAR[FMSZ] defines the Frame size of the SPI frames to be transmitted. Effective frame size would be the concatenation of {CTARE[FMSZE], CTAR[FMSZ]} plus 1. 0 Default Mode. Up to 16 bit SPI frames can be transferred. 1 Up to 32 bit SPI frames can be transferred. Each Frame transfer will be a result of 2 simulataneous TX FIFO Pop Operation.
16–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–31 DTCP	Data Transfer Count Preload This field is valid only when DSPIx_MCR[XSPI] is set. This field defines the number of data frames (whose size is defined by CTARE[FMSZE] and CTAR[FMSZ]) to be transmitted using the Command frame which selected this DSPIx_CTARE register. The value 0 is reserved and should not be written in this field. The default value of this field is 1.

42.4.37 Status Register Extended (DSPI_SREX)

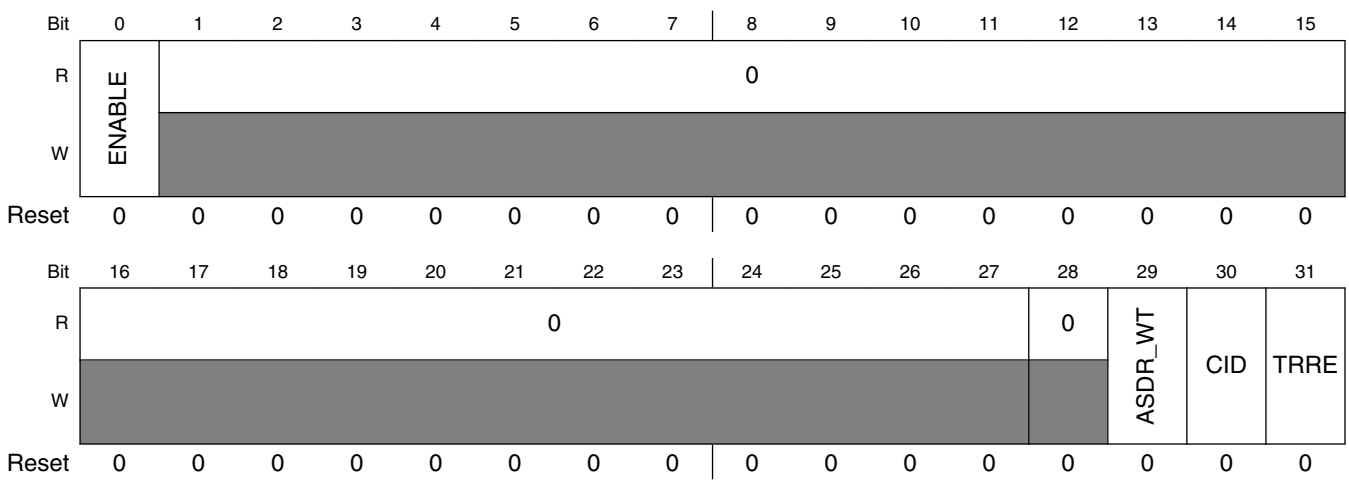
The register contains status fields. The fields reflect the status of the module and indicate the occurrence of events. This register is not writable.

Address: 0h base + 13Ch offset = 13Ch

DSPI_SREX field descriptions

Field	Description
0–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 RXCTR4	RX FIFO Counter[4] This bit is an extension of SR[RXCTR]. The concatenated field {RXCTR4, RXCTR} indicates the number of entries in the RX FIFO. This field is decremented every time the POPR is read. And this field is incremented every time data is transferred from the shift register to the RX FIFO.
18–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...



DSPI_SREX field descriptions (continued)

Field	Description
20 TXCTR4	TX FIFO Counter[4] This bit is an extension of SR[TXCTR]. The concatenated field {TXCTR4, TXCTR} indicates the number of valid entries in the TX FIFO. This field is incremented every time the PUSHR is written. And this field is decremented every time an SPI command is executed and the SPI data is transferred to the shift register.
21–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–27 CMDCTR	CMD FIFO Counter Indicates the number of entries in the CMD FIFO. The CMDCTR is incremented every time the command part of PUSHR is written. The CMDCTR is decremented every time a SPI command is executed (all data frames due to current command frame have been transmitted).
28–31 CMDNXTPTR	Command Next Pointer Indicates which CMD FIFO Entry is used during the next transfer. The CMDNXTPTR field is updated every time SPI data due to current command have been transmitted.

42.4.38 Trigger Register (DSPI_TRIG)

This register provides the user to configure trigger settings for various modes. The trigger settings in this register are activated only if the bit TRIG[ENABLE] is set.

Address: 0h base + 140h offset = 140h

DSPI_TRIG field descriptions

Field	Description
0 ENABLE	Trigger Register Enable This bit is used to enable the TRIG register.

Table continues on the next page...

DSPI_TRIG field descriptions (continued)

Field	Description
	0 TRIG register is disabled. Trigger settings configured in this register have no effect on the module. 1 TRIG register is enabled. Trigger settings configured in this register are valid.
1–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 ASDR_WT	ASDR Write Trigger Enable Enables the module to initiate a DSI frames transfer on a write operation performed on ASDR0 register. 0 ASDR0 write trigger disabled. 1 ASDR0 write trigger enabled.
30 CID	Change In Data Transfer Enable Enables a change in serialization data to initiate a DSI frames transfer in DSI and CSI configurations. When the CID bit is set, DSI frames are initiated when the current DSI data differs from the previous DSI data shifted out. **NOTE:** When TRIG[ENABLE] is set, the CID bit is given by TRIG[CID] which overrides DSICR0[CID].
31 TRRE	Trigger Reception Enable Enables the module to initiate a DSI frames transfer with an external trigger signal. **NOTE:** When TRIG[ENABLE] is set, the TRRE bit is given by TRIG[TRRE] which overrides DSICR0[TRRE]. 0 Trigger signal reception disabled. 1 Trigger signal reception enabled.

42.4.39 Time Slot Length Register (DSPI_TSL)

The TSL register is only valid when DSICR0[ITSB] is enabled and internal triggering mechanism is used. It provides the length of every time slot in terms of baud cycles.

Address: 0h base + 150h offset = 150h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

DSPI_TSL field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–7 TS3_LEN	Time Slot 3 Length This field provides the length of TS3 in terms of baud cycles. It must be ensured that the programmed value is greater than or equal to the length of the frame to be transmitted during TS3.Time Slot3 Length = TS3_LEN+1.This time slot shall be skipped if programmed to 0.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 TS2_LEN	Time Slot 2 Length This field provides the length of TS2 in terms of baud cycles. It must be ensured that the programmed value is greater than or equal to the length of the frame to be transmitted during TS2.Time Slot 2 Length = TS2_LEN+1.This time slot shall be skipped if programmed to 0.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–23 TS1_LEN	Time Slot 1 Length This field provides the length of TS1 in terms of baud cycles. It must be ensured that the programmed value is greater than or equal to the length of the frame to be transmitted during TS1.Time Slot 1 Length = TS1_LEN+1.This time slot shall be skipped if programmed to 0.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 TS0_LEN	Time Slot 0 Length This field provides the length of TS0 in terms of baud cycles. It must be ensured that the programmed value is greater than or equal to the length of the frame to be transmitted during TS0.Time Slot 0 Length = TS0_LEN+1.This time slot shall be skipped if programmed to 0.

42.4.40 Time Slot Configuration Register (DSPI_TS_CONF)

This register provides the basic configuration options available for the triggered implementation of MSC protocol. This register is only valid when DSICR0[ITSB] is enabled. Some configurations in this register check for the validity of command frame. The following conditions must be true for a command frame to be valid : a) The previous transmitted frame should not be a command frame. b) Data required to transmit the command frame should be available.

Address: 0h base + 154h offset = 154h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

42.5 Functional description

The module supports full-duplex, synchronous serial communications between chips and peripheral devices. The module can also be used to reduce the number of pins required for I/O by serializing and deserializing Parallel Input/Output signals.All communications are done with SPI-like protocol.

The module has the following configurations

- The SPI Configuration in which the module operates as a basic SPI or a queued SPI.
- DSI Configuration in which the module serializes and deserializes Parallel Input/ Output signals or bits from memory-mapped registers
- When Master mode is enabled, the module also supports CSI Configuration, which combines the functionality of the SPI and DSI configurations.

The DCONF field in the Module Configuration Register (MCR) determines the module Configuration. See Module Configuration Register (DSPI_MCR) for the DSPI configuration values.

The CTARn registers hold clock and transfer attributes. The SPI configuration allows to select which CTAR to use on a frame by frame basis by setting a field in the SPI command. The Extended SPI Mode (DSPIx_MCR[XSPI]) further allows the usage CTAREn (CTARn Extended) registers which allows the user to send multiple data frames using a single command frame.

The DSI configuration statically selects which CTAR to use. In CSI, Configuration priority logic determines if SPI data or DSI data is transferred and dictates what CTAR register is used for the data transfer. See Clock and Transfer Attributes Register (In

Master Mode) (DSPI_CTAR*n*) for information on the fields of CTAR registers. See Clock and Transfer Attributes Register Extended (DSPI_CTARE*n*) for information on the fields of CTARE registers.

Typical master to slave connections are shown in the following figure. When a data transfer operation is performed, data is serially shifted a predetermined number of bit positions. Because the modules are linked, data is exchanged between the master and the slave. The data that was in the master shift register is now in the shift register of the slave, and vice versa. At the end of a transfer, the Transfer Control Flag(TCF) bit in the Shift Register(SR) is set to indicate a completed frame transfer.

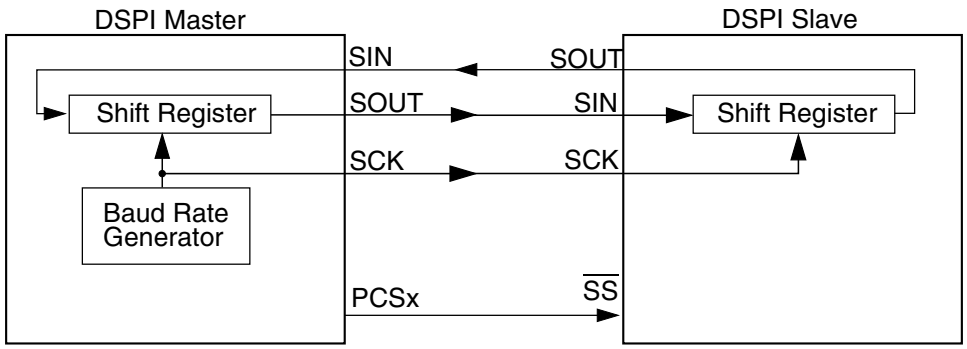

Figure 42-3. Serial protocol overview

Generally, more than one slave device can be connected to the module master. 6 Peripheral Chip Select (PCS) signals of the module masters can be used to select which of the slaves to communicate with. Refer to the chip specific section for details on the number of PCS signals used in this chip.

The three DSPI configurations share transfer protocol and timing properties which are described independently of the configuration in Transfer formats. The transfer rate and delay settings are described in Module baud rate and clock delay generation.

42.5.1 Start and Stop of module transfers

The module has two operating states: Stopped and Running. Both the states are independent of it's configuration. The default state of the module is Stopped. In the Stopped state, no serial transfers are initiated in Master mode and no transfers are responded to in Slave mode. The Stopped state is also a safe state for writing the various configuration registers of the module without causing undetermined results. In the Running state serial transfers take place.

The TXRXS bit in the SR indicates the state of module. The bit is set if the module is in Running state.

The module starts or transitions to Running when all of the following conditions are true:

- SR[EOQF] bit is clear
- Chip is not in the Debug mode or the MCR[FRZ] bit is clear
- MCR[HALT] bit is clear

The module stops or transitions from Running to Stopped after the current frame when any one of the following conditions exist:

- SR[EOQF] bit is set
- Chip in the Debug mode and the MCR[FRZ] bit is set
- MCR[HALT] bit is set

State transitions from Running to Stopped occur on the next frame boundary if a transfer is in progress, or immediately if no transfers are in progress.

42.5.2 Serial Peripheral Interface (SPI) configuration

The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes. The module is in SPI configuration when the DCONF field in the MCR is 0b00. The SPI frames can be 32 bits long. The host CPU or a DMA controller transfers the SPI data from the external to the module RAM queues to a TX FIFO buffer. The received data is stored in entries in the RX FIFO buffer. The host CPU or the DMA controller transfers the received data from the RX FIFO to memory external to the module. The operation of FIFO buffers is described in the following sections:

- Transmit First In First Out (TX FIFO) buffering mechanism
- Command First In First Out (CMD FIFO) Buffering Mechanism
- Receive First In First Out (RX FIFO) buffering mechanism

The interrupt and DMA request conditions are described in Interrupts/DMA requests.

The SPI configuration supports two block-specific modes—Master mode and Slave mode. In Master mode the module initiates and controls the transfer according to the fields of the executing SPI Command. In Slave mode, the module responds only to transfers initiated by a bus master external to it and the SPI command field space is reserved.

42.5.2.1 Master mode

In SPI Master mode, the module initiates the serial transfers by controlling the SCK and the PCS signals. The executing SPI Command determines which CTARs will be used to set the transfer attributes and which PCS signals to assert. The command field also contains various bits that help with queue management and transfer protocol. See PUSH TX FIFO Register In Master Mode (DSPI_PUSHR) for details on the SPI command fields. The data in the executing TX FIFO entry is loaded into the shift register and shifted out on the Serial Out (SOUT) pin. In SPI Master mode, each SPI frame to be transmitted has a command associated with it, allowing for transfer attribute control on a frame by frame basis. In Extended SPI Master Mode, multiple SPI frames can have a single command associated with them allowing for efficient SPI frame transfers requiring common transfer attributes. In addition, the Extended SPI Mode allows for larger frame sizes of up to 32 bits.

42.5.2.2 Slave mode

In SPI Slave mode the module responds to transfers initiated by an SPI bus master. It does not initiate transfers. Certain transfer attributes such as clock polarity, clock phase, and frame size must be set for successful communication with an SPI master. The SPI Slave mode transfer attributes are set in the CTAR0 and CTARE0. The data is shifted out with MSB first. Shifting out of LSB is not supported in this mode.

42.5.2.3 FIFO disable operation

The FIFO disable mechanisms allow SPI transfers without using the TX FIFO, CMD FIFO or RX FIFO. The module operates as a double-buffered simplified SPI when the FIFOs are disabled. The Transmit and Receive side of the FIFOs are disabled separately. Setting the MCR[DIS_TXF] bit disables the TX FIFO and CMD FIFO, and setting the MCR[DIS_RXF] bit disables the RX FIFO.

The FIFO disable mechanisms are transparent to the user and to host software. Transmit data and commands are written to the PUSHR and received data is read from the POPR.

When the TX FIFO and CMD FIFO are disabled:

- SR[TFFF], SR[TFUF], SR[CMDFFF], SREX[CMDCTR] and SR[TXCTR] behave as if there is a one-entry FIFO
- The contents of TXFRs, SR[TXNXTPTR] and SREX[CMDNXTPTR] are undefined

Similarly, when the RX FIFO is disabled, the RFDF, RFOF, and RXCTR fields in the SR behave as if there is a one-entry FIFO, but the contents of the RXFR registers and POPNXTPTR are undefined.

42.5.2.4 Transmit First In First Out (TX FIFO) buffering mechanism

The TX FIFO functions as a buffer of SPI data for transmission. The TX FIFO holds 4 words, each consisting of SPI data. The number of entries in the TX FIFO is device-specific. SPI data is added to the TX FIFO by writing to the Data Field of module PUSH FIFO Register (PUSHR). TX FIFO entries can only be removed from the TX FIFO by being shifted out or by flushing the TX FIFO.

The TX FIFO Counter field (TXCTR) in the module Status Register (SR) indicates the number of valid entries in the TX FIFO. The TXCTR is updated every time a 8- or 16-bit write takes place to PUSHR[TXDATA] or SPI data is transferred into the shift register from the TX FIFO.

The TXNXTPTR field indicates the TX FIFO Entry that will be transmitted during the next transfer. The TXFRn Registers are invalid in the Extended SPI Mode, since the TX FIFO and CMD FIFO can be used independently. The TXNXTPTR field is incremented every time SPI data is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR number and it rolls over after reaching the maximum.

42.5.2.4.1 Filling the TX FIFO

Host software or other intelligent blocks can add (push) entries to the TX FIFO and CMD FIFO by writing to the PUSHR. When the TX FIFO is not full, the TX FIFO Fill Flag (TFFF) in the SR is set. The TFFF bit is cleared when TX FIFO is full and the DMA controller indicates that a write to PUSHR is complete. Writing a '1' to the TFFF bit also clears it. The TFFF can generate a DMA request or an interrupt request. See Transmit FIFO Fill Interrupt or DMA Request for details.

The module ignores attempts to push data to a full TX FIFO, and the state of the TX FIFO does not change and no error condition is indicated.

42.5.2.4.2 Draining the TX FIFO

The TX FIFO entries are removed (drained) by shifting SPI data out through the shift register. Entries are transferred from the TX FIFO to the shift register and shifted out as long as there are valid entries in the TX FIFO. Every time an entry is transferred from the TX FIFO to the shift register, the TX FIFO Counter decrements by one. When Extended SPI Mode (DSPIx_MCR[XSPI]) is enabled, if the frame size of SPI Data to be transmitted is more than 16 bits, then it causes two Data entries to be popped from TX FIFO simultaneously which are transferred to the shift register. The first of the two popped entries forms the 16 least significant bits of the SPI frame to be transmitted. Such

an operation also causes TX FIFO Counter to decrement by two. At the end of a transfer, the TCF bit in the SR is set to indicate the completion of a transfer. The TX FIFO is flushed by writing a '1' to the CLR_TXF bit in MCR.

If an external bus master initiates a transfer with a module slave while the slave's TX FIFO is empty, the Transmit FIFO Underflow Flag (TFUF) in the slave's SR is set. See Transmit FIFO Underflow Interrupt Request for details.

42.5.2.5 Command First In First Out (CMD FIFO) Buffering Mechanism

The CMD FIFO functions as a buffer of SPI command used for SPI data transmission. When Extended SPI Mode (MCR[XSPI]) is disabled, the TX FIFO and CMD FIFO must be filled together, i.e. write enables should be given for both the Data and Command fields while performing a PUSHR operation.When Extended SPI Mode (MCR[XSPI]) is enabled, the TX FIFO and CMD FIFO can be filled independently.

The CMD FIFO holds 4 words, each representing SPI command fields. The number of entries in the CMD FIFO is device-specific. SPI Command is added to the CMD FIFO by writing to the command field of DSPI PUSH FIFO Register (PUSHR). CMD FIFO entries can only be removed from the CMD FIFO by being shifted out (to help transmit SPI data) or by flushing the CMD FIFO.

When Extended SPI Mode (MCR[XSPI]) is disabled, every CMD FIFO entry has a corresponding single TX FIFO entry attached to it because both these FIFO's are filled simultaneously.

When Extended SPI Mode (MCR[XSPI]) is enabled, every CMD FIFO entry can have multiple TX FIFO entries attached to it. Thus a single CMD FIFO entry can be used to transmit multiple TX FIFO entries. The CTARE[DTCP] field decides the number of SPI Data Frames having frame size as {FMSZE, FMSZ} to be transmitted using the current Command Entry. The CTAR/CTARE registers pointed by the CTAS field in the Command frame gives the FMSZ and FMSZE fields respectively. The time for which a command entry is in use is known as a Command Cycle. The Busy Flag SR[BSYF] is asserted for the duration of the Command Cycle except for the last SPI frame in the Command Cycle.

The CMD FIFO Counter field (CMDCTR) in the DSPI Status Register (SR) indicates the number of valid entries in the CMD FIFO. The CMDCTR field is updated every time a 8- or 16-bit write takes place on the lower half of DSPI_PUSHR or SPI data is transferred into the shift register from the TX FIFO.

The TXFRn Registers are invalid in the Extended SPI Mode, since the TX FIFO and CMD FIFO can be used independently. The CMDNXTPTR field indicates which CMD FIFO Entry will be used during the next command cycle. The CMDNXTPTR field is incremented every time the last SPI data in the command cycle is transferred from the TX FIFO to the shift register and it rolls over after reaching the maximum.

42.5.2.6 Receive First In First Out (RX FIFO) buffering mechanism

The RX FIFO functions as a buffer for data received on the SIN pin. The RX FIFO holds 4 received SPI data frames. The number of entries in the RX FIFO is device-specific. SPI data is added to the RX FIFO at the completion of a transfer when the received data in the shift register is transferred into the RX FIFO. SPI data are removed (popped) from the RX FIFO by reading the module POP RX FIFO Register (POPR). RX FIFO entries can only be removed from the RX FIFO by reading the POPR or by flushing the RX FIFO.

The RX FIFO Counter field (RXCTR) in the module's Status Register (SR) indicates the number of valid entries in the RX FIFO. The RXCTR is updated every time the POPR is read or SPI data is copied from the shift register to the RX FIFO.

The POPNXTPTR field in the SR points to the RX FIFO entry that is returned when the POPR is read. The POPNXTPTR contains the positive offset from RXFR0 in a number of 32-bit registers. For example, POPNXTPTR equal to two means that the RXFR2 contains the received SPI data that will be returned when the POPR is read. The POPNXTPTR field is incremented every time the POPR is read. The maximum value of the field is equal to the maximum implemented RXFR number and it rolls over after reaching the maximum.

42.5.2.6.1 Filling the RX FIFO

The RX FIFO is filled with the received SPI data from the shift register. While the RX FIFO is not full, SPI frames from the shift register are transferred to the RX FIFO. Every time an SPI frame is transferred to the RX FIFO, the RX FIFO Counter is incremented by one.

If the RX FIFO and shift register are full and a transfer is initiated, the RFOF bit in the SR is set indicating an overflow condition. Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

42.5.2.6.2 Draining the RX FIFO

Host CPU or a DMA can remove (pop) entries from the RX FIFO by reading the module POP RX FIFO Register (POPR). A read of the POPR decrements the RX FIFO Counter by one. Attempts to pop data from an empty RX FIFO are ignored and the RX FIFO Counter remains unchanged. The data, read from the empty RX FIFO, is undetermined.

When the RX FIFO is not empty, the RX FIFO Drain Flag (RFDF) in the SR is set. The RFDF bit is cleared when the RX_FIFO is empty and the DMA controller indicates that a read from POPR is complete or by writing a 1 to it.

42.5.3 Deserial Serial Interface (DSI) Configuration

The DSI Configuration supports pin count reduction by serializing Parallel Input signals or register bits and shifting them out in a SPI-like protocol. The timing and transfer protocol is described in Transfer formats. The received serial frames are converted to a parallel form (deserialized) and placed on the Parallel Output signals or in the DSPI_DDR register. The various features of the DSI Configuration are set in DSPI DSI Configuration Registers (DSPI_DSICR0/1).

The DSI frames can be from 4 to 32 bits. This can go up to 64 bits when DSICR1[DSI64E] is enabled.

With Multiple Transfer Operation (MTO) the DSPI supports serial chaining of DSPI blocks within the device to create DSI frames up to 64 bits, consisting of concatenated bits from multiple DSPIs. The DSPI also supports parallel chaining allowing several DSPIs and off-chip SPI devices to share the same Serial Communications Clock (SCK) and Peripheral Chip Select (PCS) signals. See Multiple Transfer Operation (MTO) for details on the serial and parallel chaining support.

Multiple Transfer Operation (MTO) and DSICR1[DSI64E] are not supported together and cannot be enabled simultaneously.

42.5.3.1 DSI Master Mode

In DSI master mode the DSPI initiates and controls the DSI transfers. The DSI master has different conditions that can initiate a transfer:

- Continuous
- Change in data
- Trigger signal

- ASDR write
- Trigger signal combined with a change in data
- Trigger signal combined with ASDR write
- Change in data combined with ASDR write
- Trigger signal combined with change in data combined with ASDR write

These transfer initiation conditions are described in DSI Transfer Initiation Control . Transfer attributes are set during initialization. The DSICTAS field in the DSPI_DSICR0 determines which of the DSPI_CTAR registers will control the transfer attributes.

42.5.3.2 Slave Mode

In DSI slave mode the DSPI responds to transfers initiated by a SPI or DSI bus master. In this mode the DSPI does not initiate DSI transfers. Certain transfer attributes such as clock polarity and phase must be set for successful communication with a DSI master. The DSI slave mode transfer attributes are set in the DSPI_CTAR1. The data is shifted out with MSB first.

If the CID bit in the DSPI_DSICR0 is set and the data in DSPI_COMPR0/1 differs from the selected source of the serialized data, the slave DSPI will assert the $\overline{\text{MTRIG}}$ signal. If the slave's HT signal is asserted and the TRRE is set, the slave DSPI asserts $\overline{\text{MTRIG}}$. Also, if TRIG[ASDR_WT] is set and an ASDR0 write is detected, the slave DSPI will assert the $\overline{\text{MTRIG}}$ signal. These features are included to support chaining of several DSPI. Details about the $\overline{\text{MTRIG}}$ signal is found in Multiple Transfer Operation (MTO).

42.5.3.3 DSI Serialization

In the DSI Configuration, up to 64 bits can be serialized using two different sources. The TXSS bit in the DSPI_DSICR0 selects between the DSPI DSI Serialization Data Register (DSPI_SDR0–1) and the DSPI DSI Alternate Serialization Data Register (DSPI_ASDR0–1) as the source of the serialized data. The DSPI_SDR0 holds the latest 32 Parallel Input signal values which is sampled at every rising edge of the bus clock. When DSICR1[DSI64E] is enabled, 64-bit DSI Frames are supported and hence DSPI_SDR1 holds up to 32 most significant parallel input signal values which is sampled at every rising edge of the bus clock.The DSPI_ASDR0–1 register is written by host software and used as an alternate source of serialized data. (DSPI_ASDR1 is only usable when DSICR1[DSI64E] is enabled).

The DSPI has to sample the inputs (from SDR0–1 or ASDR0–1) before it transmits a DSI frame. Due to the asynchronous clocking structure within DSPI, the sampled data (from SDR0–1 or ASDR0–1) must be synchronized into the Protocol Domain before being loaded into the Shift Register for transmission.
