Chapter 1
About this manual

1.1 Audience

This reference manual is intended for system software and hardware developers and applications programmers who want to develop products with this device. It assumes that the reader understands operating systems, microprocessor system design, and basic principles of software and hardware.

1.2 Organization

This manual begins with a global introduction of the chip, followed by chapters organized into *functional groups* that detail particular areas of functionality, such as system control, clocking, and timers. Each functional group can have two main types of chapters:

- *System-level* chapters contain information that applies to the components (modules) within the group.
- *Module-level* chapters contain technical descriptions of individual modules within the group.

Note that application-specific groups (such as timers) may only contain module-level chapters.

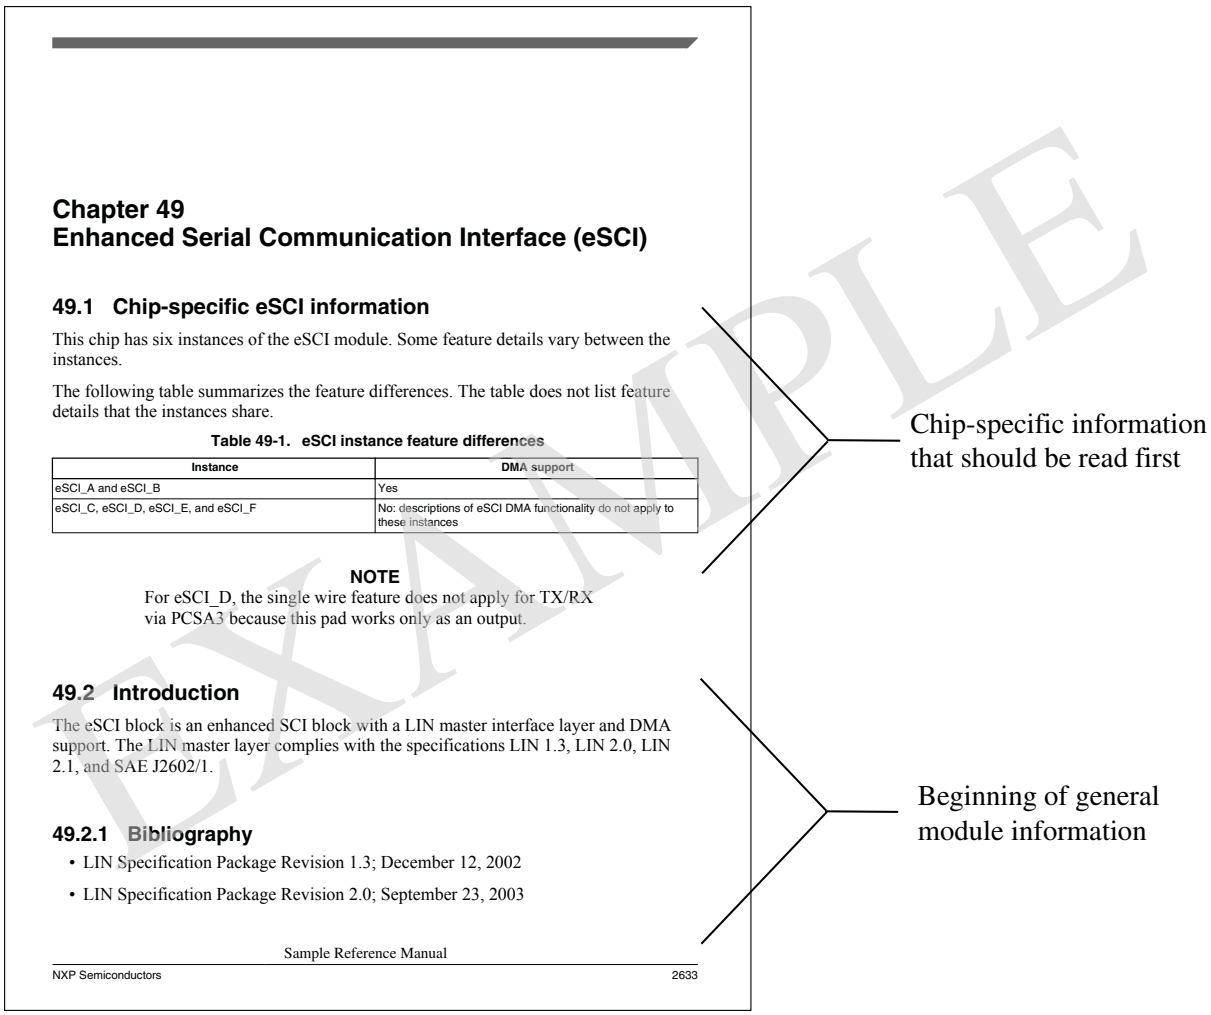
1.3 Module descriptions

Each module chapter has two main parts:

- **Chip-specific:** The first section, *Chip-specific [module name] information*, includes the number of module instances on the chip and possible implementation differences between the module instances, such as differences in FIFO depths or the number of channels supported. It may also include functional connections between the module instances and other modules. Read this section *first* because its content is crucial to understanding the information in other sections of the chapter.
- **General:** The subsequent sections provide general information about the module, including its signals, registers, and functional description.

NOTE

If there is a conflict between the chip-specific module information (first section) and the general module information (subsequent sections), the chip-specific information supersedes the general information.



Chapter 49
Enhanced Serial Communication Interface (eSCI)

49.1 Chip-specific eSCI information

This chip has six instances of the eSCI module. Some feature details vary between the instances.

The following table summarizes the feature differences. The table does not list feature details that the instances share.

Table 49-1. eSCI instance feature differences

Instance	DMA support
eSCI_A and eSCI_B	Yes
eSCI_C, eSCI_D, eSCI_E, and eSCI_F	No: descriptions of eSCI DMA functionality do not apply to these instances

NOTE
For eSCI_D, the single wire feature does not apply for TX/RX via PCSA3 because this pad works only as an output.

49.2 Introduction

The eSCI block is an enhanced SCI block with a LIN master interface layer and DMA support. The LIN master layer complies with the specifications LIN 1.3, LIN 2.0, LIN 2.1, and SAE J2602/1.

49.2.1 Bibliography

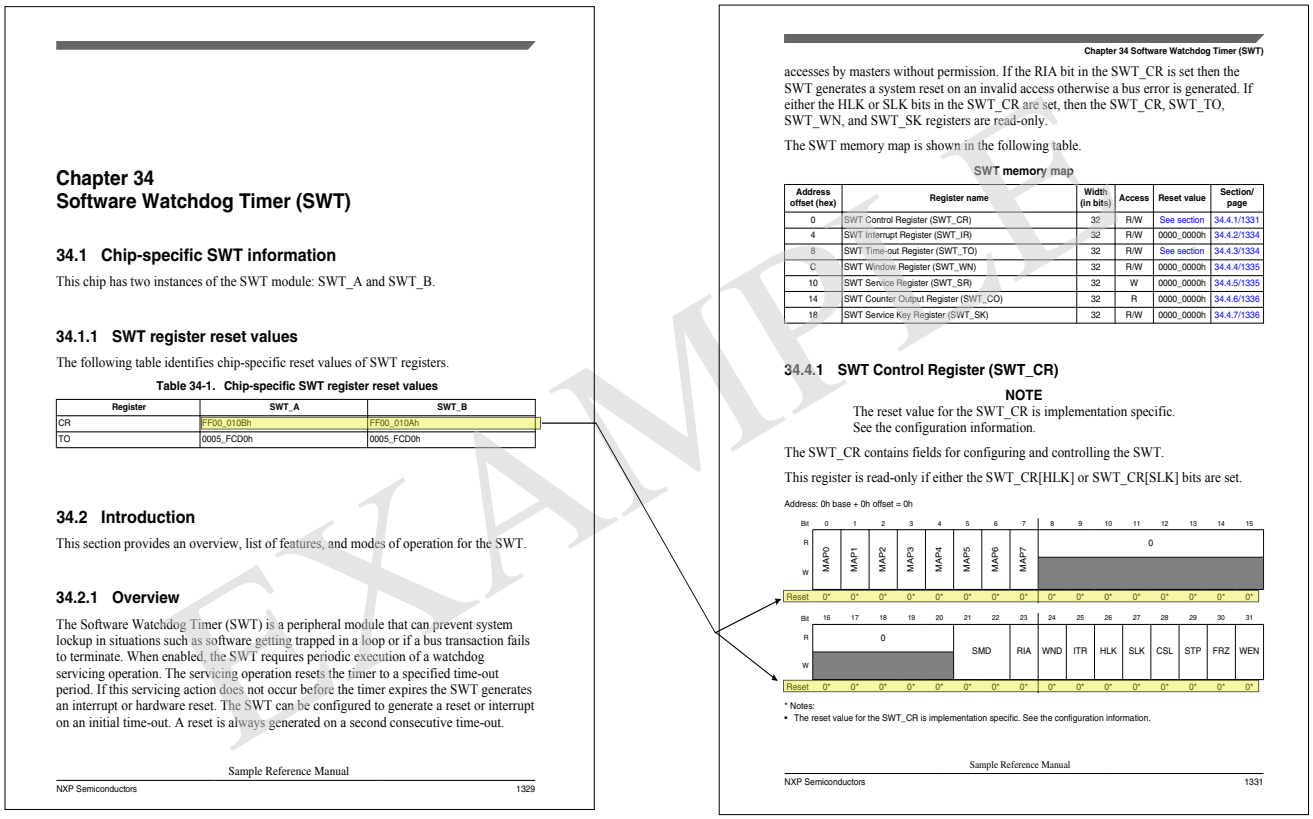
Figure 1. Example: chapter chip-specific information and general module information

1.3.1 Example: chip-specific information that supersedes content in the same chapter

The example below shows chip-specific information that supersedes general module information presented later in the chapter. In this case, the chip-specific register reset values supersede the reset values that appear in the register diagram.



Chapter 34
Software Watchdog Timer (SWT)

34.1 Chip-specific SWT information

This chip has two instances of the SWT module: SWT_A and SWT_B.

34.1.1 SWT register reset values

The following table identifies chip-specific reset values of SWT registers.

Table 34-1. Chip-specific SWT register reset values

Register	SWT_A	SWT_B
CR	FF00_010Bh	FF00_010Ah
TO	0005_FCD0h	0005_FCD0h

34.2 Introduction

This section provides an overview, list of features, and modes of operation for the SWT.

34.2.1 Overview

The Software Watchdog Timer (SWT) is a peripheral module that can prevent system lockup in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. When enabled, the SWT requires periodic execution of a watchdog servicing operation. The servicing operation resets the timer to a specified time-out period. If this servicing action does not occur before the timer expires the SWT generates an interrupt or hardware reset. The SWT can be configured to generate a reset or interrupt on an initial time-out. A reset is always generated on a second consecutive time-out.

Sample Reference Manual
NXP Semiconductors 1329

Chapter 34 Software Watchdog Timer (SWT)

accesses by masters without permission. If the RIA bit in the SWT_CR is set then the SWT generates a system reset on an invalid access otherwise a bus error is generated. If either the HLK or SLK bits in the SWT_CR are set, then the SWT_CR, SWT_TO, SWT_WN, and SWT_SK registers are read-only.

The SWT memory map is shown in the following table.

SWT memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	SWT Control Register (SWT_CR)	32	R/W	See section	34.4.1/1331
4	SWT Interrupt Register (SWT_IR)	32	R/W	0000_0000h	34.4.2/1334
8	SWT Time-out Register (SWT_TO)	32	R/W	See section	34.4.3/1334
C	SWT Window Register (SWT_WN)	32	R/W	0000_0000h	34.4.4/1335
10	SWT Service Register (SWT_SR)	32	W	0000_0000h	34.4.5/1335
14	SWT Counter Output Register (SWT_CO)	32	R	0000_0000h	34.4.6/1336
18	SWT Service Key Register (SWT_SK)	32	R/W	0000_0000h	34.4.7/1336

34.4.1 SWT Control Register (SWT_CR)

NOTE
The reset value for the SWT_CR is implementation specific.
See the configuration information.

The SWT_CR contains fields for configuring and controlling the SWT.

This register is read-only if either the SWT_CR[HLK] or SWT_CR[SLK] bits are set.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	MAP0	MAP1	MAP2	MAP3	MAP4	MAP5	MAP6	MAP7	0							
W																
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0					SMD	RIA	WND	ITR	HLK	SLK	CSL	STP	FRZ	WEN	
W																
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- The reset value for the SWT_CR is implementation specific. See the configuration information.

Sample Reference Manual
NXP Semiconductors 1331

Figure 2. Example: chip-specific information that supersedes content in the same chapter

1.4 Register descriptions

Module chapters present register information in:

- Memory maps including:
  - Addresses
  - The name and acronym/abbreviation of each register
  - The width of each register (in bits)
  - Each register's reset value
  - The page number on which each register is described
- Register figures
- Field-description tables
- Associated text

The register figures show the field structure using the conventions in the following figure.

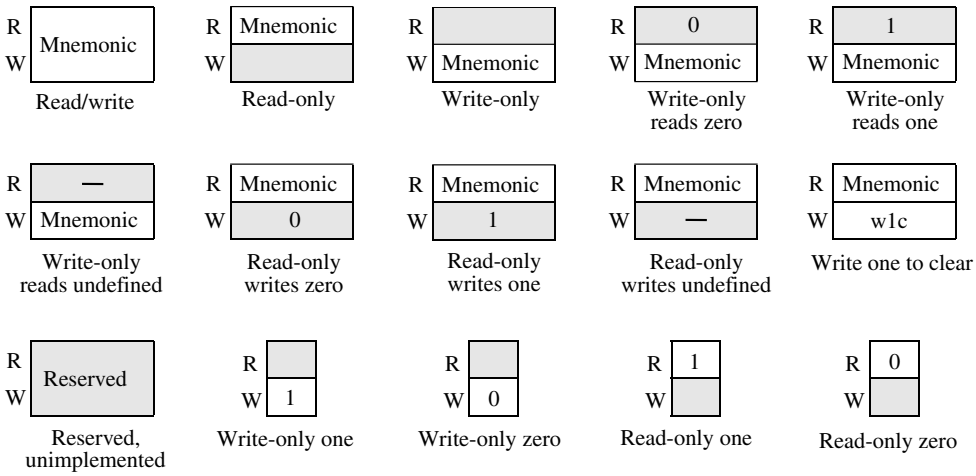


Figure 3. Register figure conventions

1.5 Conventions

1.5.1 Numbering systems

The following suffixes identify different numbering systems:

This suffix	Identifies a
b	Binary number. For example, the binary equivalent of the number 5 is written 101b. In some cases, binary numbers are shown with the prefix *0b*.
d	Decimal number. Decimal numbers are followed by this suffix only when the possibility of confusion exists. In general, decimal numbers are shown without a suffix.
h	Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is written 3Ch. In some cases, hexadecimal numbers are shown with the prefix *0x*.

1.5.2 Typographic notation

The following typographic notation is used throughout this document:

Example	Description
placeholder, x	Items in italics are placeholders for information that you provide. Italicized text is also used for the titles of publications and for emphasis. Plain lowercase letters are also used as placeholders for single letters and numbers.
`code`	Fixed-width type indicates text that must be typed exactly as shown. It is used for instruction mnemonics, directives, symbols, subcommands, parameters, and operators. Fixed-width type is also used for example code. Instruction mnemonics and directives in text and tables are shown in all caps; for example, BSR.
SR[SCM]	A mnemonic in brackets represents a named field in a register. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).
REVNO[6:4], XAD[7:0]	Numbers in brackets and separated by a colon represent either:

Table continues on the next page...

Table continued from the previous page...

Example	Description
	• A subset of a register's named field For example, REVNO[6:4] refers to bits 6–4 that are part of the COREREV field that occupies bits 6–0 of the REVNO register. • A continuous range of individual signals of a bus For example, XAD[7:0] refers to signals 7–0 of the XAD bus.

1.5.3 Special terms

The following terms have special meanings:

Term	Meaning
asserted	Refers to the state of a signal as follows: • An active-high signal is asserted when high (1). • An active-low signal is asserted when low (0).
deasserted	Refers to the state of a signal as follows: • An active-high signal is deasserted when low (0). • An active-low signal is deasserted when high (1). In some cases, deasserted signals are described as *negated*.
reserved	Refers to a memory space, register, field, or programming setting. Writes to a reserved location can result in unpredictable functionality or behavior. • Do not modify the default value of a reserved programming setting, such as the reset value of a reserved register field. • Consider undefined locations in memory to be reserved.
w1c	Write 1 to clear: Refers to a register bitfield that must be written as 1 to be "cleared."

Chapter 2
Introduction

2.1 Introduction

The MCX W71 microcontroller is a low-power, highly secure, Arm® Cortex-M33-based wireless device targeting these applications:

- Smart Home IoT
  - Smart Home environmental, occupancy and security sensors
  - Home Gateways and Bridges
  - Smart Lighting
  - Smart Plugs
  - Access Control
  - HVACs and Thermostats
  - Window Shades
- Industrial/IoT
  - Positioning/Localization
  - Building Control and Monitoring
  - Process/Factory Automation
  - Access Control

The device includes these key features:

Highly secure	• Arm Trustzone-M • Trusted resource domain controller (TRDC) providing access policies for embedded memory and peripherals • NXP's EdgeLock® Secure Enclave providing secure key management and storage plus hardware acceleration of cryptographic algorithms • Internal flash memory with on-the-fly encryption and decryption using a PRINCE XEX block cipher mode • Factory Root of Trust programming • Secure boot, debug and firmware updates
Power-efficient operating modes	• Less than 35 µA/MHz active current at 96 MHz • Less than 2 µA in Power Down mode with FRO32K active and 32 KB SRAM retention • Less than 1 µA in Deep Power Down mode with FRO32K active

2.2 Functional overview

The following figure shows a top-level organization of the modules within the device organized by functional category.

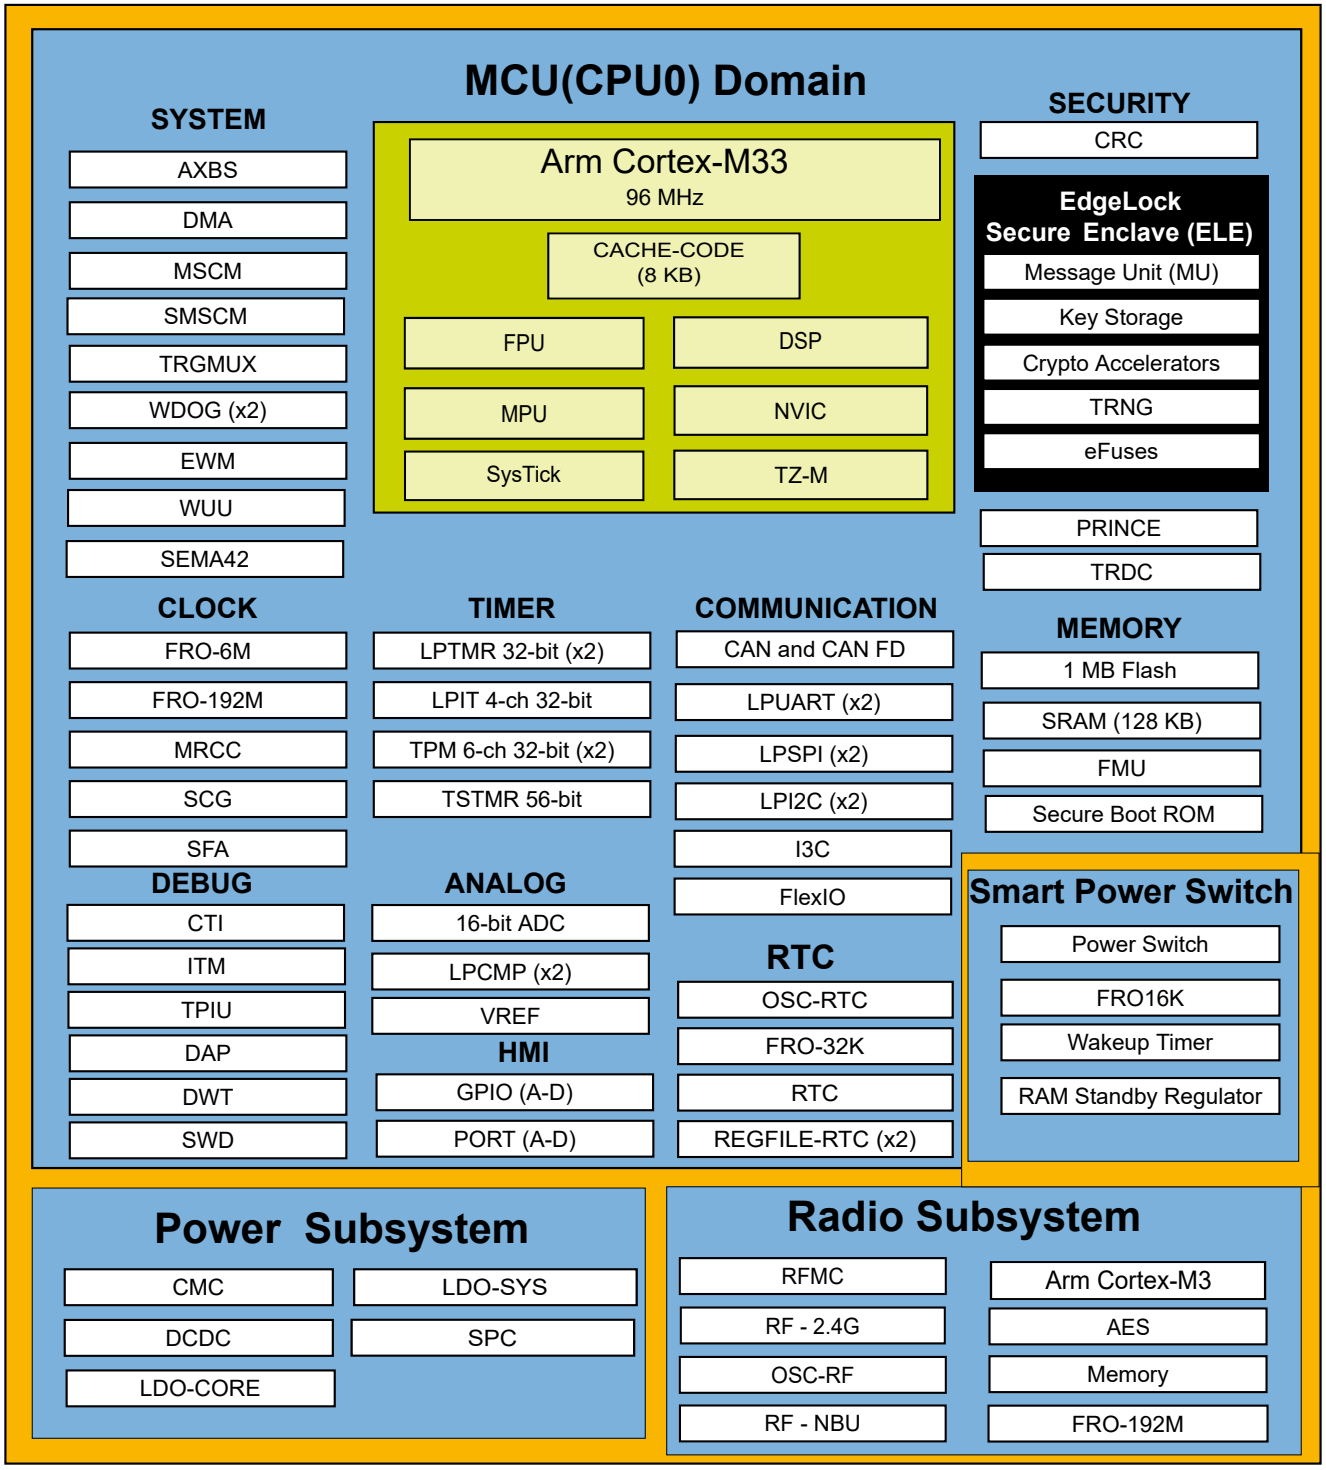

Figure 4. Features block diagram

Table 1. Module functional categories

Module category	Description
Core	The Arm® Cortex®-M33 is a member of the Cortex® M Series of processors targeting microcontroller cores focused on cost sensitive, deterministic, interrupt driven environments. The Cortex® M33 processor is based on the Arm®v8-M Architecture and ThumbR-2 ISA and is upward compatible with the Cortex® M7, M4, M3, M1 and M0/M0+.
System	• AHB Cross-Bar Switch (AXBS) • Core Mode Controller (CMC) • Direct Current / Direct Current Converter - Low Voltage (DCDC-LV) • Direct Memory Access (DMA) controller • External Watchdog Monitor (EWM) • Low Drop Out Regulator - Core (LDO_CORE) • Low Drop Out Regulator - System (LDO_SYS) • Miscellaneous System Control Module (MSCM) • Secure Miscellaneous System Control Module (SMSCM) • Semaphore Module (SEMA42) • System Power Controller (SPC) • Trigger Multiplexer (TRGMUX) • Wake-Up Unit (WUU) • Watchdog (WDOG)
Memory	• Flash Management Unit (FMU) • Read Only Memory - Boot (ROM_BOOT) • Register File - REGFILE • Static Random Access Memory (SRAM)
Clock	• Crystal Oscillator - Real Time Clock (OSC_RTC) • Free Running Oscillator - 32 kHz (FRO_32K) • Free Running Oscillator - 16 kHz (FRO_16K) • Free Running Oscillator - 6 MHz (FRO_6M) • Free Running Oscillator - 192 MHz (FRO_192M) • Radio Free Running Oscillator - 192 MHz (RFRO_192M) • Module Reset and Clock Control (MRCC) • System Clock Generator (SCG) • Signal Frequency Analyzer (SFA)
Security	• EdgeLock Secure Enclave

Table continues on the next page...

Table 1. Module functional categories (continued)

Module category	Description
	• Trusted Resource Domain Controller (TRDC) • Cyclic Redundancy Check (CRC) • Non-Volatile Memory PRINCE XEX (NPX) encryption/decryption • Up to 4 digital tamper pins
Timer	• Real Time Clock (RTC) • Low-Power Timer (LPTMR) • Low Power Periodic Interrupt Timers (LPIT) • Time Stamp Timer (TSTMR) • Timer/PWM Module (TPM)
Communication	• Controller Area Network with Flexible Data rate (CAN FD) • Flexible Input/Output (FlexIO) • Low Power Inter-Integrated Circuit (LPI2C) • Improved Inter-Integrated Circuit (I3C) • Low Power Serial Peripheral Interface (LPSPI) • Low Power Universal Asynchronous Receive/Transmit (LPUART)
HMI	• General Purpose Input/Output (GPIO) • Port Control (PORT)
Analog	• Analog-to-Digital Converter - General Purpose (ADC) • Low Power Comparator (LPCMP) • Voltage Reference (VREF)
Radio	• Radio Frequency - 2.4 GHz (RF-2.4G)

2.2.1 Core

The following core modules are available on this device.

Table 2. Core modules

Module	Description
CPU0	CPU0 is an Arm® Cortex®-M33, a member of the Cortex® M Series of processors targeting microcontroller cores focused on cost-sensitive, deterministic, interrupt-driven environments.
Code Cache Memory (CACHE-CODE)	The CACHE-CODE is an 8-KB cache for memory attached to the Code bus.
Digital Signal Processing Extensions (DSP)	The Cortex-M33 processor features extended single-cycle Multiply Accumulate (MAC) instructions, optimized Single Instruction Multiple Data (SIMD) arithmetic, and saturating arithmetic instructions.

Table continues on the next page...

Table 2. Core modules (continued)

Module	Description
Floating Point Unit (FPU)	The FPU provides single-precision floating point computation compliant to the IEEE Standard for Floating-Point Arithmetic (IEEE 754).
Memory Protection Unit (MPU)	The MPU provides support for eight unified protection regions, overlapping protection regions with ascending region priority, and access permissions. MPU mismatches and permission violations invoke the HardFault handler. See the Armv8-M Architecture Reference Manual for more information.
Nested Vectored Interrupt Controller (NVIC)	The Armv8-M exception model and Nested-Vectored Interrupt Controller (NVIC) implement a relocatable vector table supporting many external interrupts, a single non-maskable interrupt (NMI), and priority levels.
System Timer (SysTick)	See the Armv8-M Architecture Reference Manual for more information about this system timer.
TrustZone - M (TZM)	The TZM is an Arm security feature related to hardware-enforced access control mechanisms.

2.2.2 Debug

The following Debug (DBG) modules are available on this device:

Table 3. Debug modules

Module	Description
Cross Trigger Interface (CTI)	The CTI enables the device's debug logic to interact with (cross trigger) each other.
Data Watchpoint and Trace (DWT)	The DWT is a generic name for several modules that allow debug access of the Cortex-M33. The DWT is composed of the Debug Watchpoint and Trace (DWT) module and the Flash Patch and Breakpoint (FPB) unit.
Debug Access Port (DAP)	The DAP enables real-time access to the device registers from an external debugger without halting the processor cores.
Instruction Trace Macrocell (ITM)	The ITM provides a memory-mapped register interface that applications can use to write logging or event words for profiling software.
Serial Wire Debug (SWD)	The SWDv2 is a serial communication interface used for debugging devices with multiple cores while only requiring a single external interface.
Trace Port Interface Unit (TPIU)	The TPIU acts as a bridge between the on-chip trace data from the modules such as the Embedded Trace Macrocell (ETM) or the Instrumentation Trace Macrocell (ITM), which have separate system IDs, to the external world.

2.2.3 System

The following System (SYS) modules are available on this device:

Table 4. System modules

Module	Description
AHB Cross-Bar Switch (AXBS)	The AXBS connects bus masters and bus slaves, allowing all bus masters to access different bus slaves simultaneously and providing arbitration among the bus masters when they access the same slave.
Core Mode Controller (CMC)	The CMC provides control and protection on entry and exit to each power mode, control for the System Power Controller (SPC), and reset entry and exit for the complete device.
Direct Current / Direct Current Converter - Low Voltage (DCDC-LV)	An efficient voltage converter for generating the low voltage supply for internal Low Drop Out (LDO) regulators.
Enhanced Direct Memory Access (eDMA)	The eDMA controller provides programmable channels with transfer control descriptors for data movement via dual-address transfers for 8-, 16-, 32- and 128-bit data values.
External Watchdog Monitor (EWM)	Similar to the Watchdog timer, the EWM monitors internal and external system operations and forces a reset in case of failure.
Low Drop Out Regulator - Core (LDO-CORE)	A voltage regulator for generating the core voltage for the device.
Low Drop Out Regulator - System (LDO-SYS)	A voltage regulator for generating the system voltage for the device.
Miscellaneous System Control Module (MSCM)	The MSCM contains CPU configuration registers and on-chip memory controller registers.
Secure Miscellaneous System Control Module (SMSCM)	The SMSCM contains configuration registers related to security.
Semaphore Module (SEMA42)	The SEMA42 is a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve "lock and unlock" operations via a single write access. The hardware semaphore module provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.
System Power Controller (SPC)	The SPC provides control over the operation and configuration of the system power generation modules to optimize power consumption for the level of functionality needed.
Trigger Multiplexer (TRGMUX)	The TRGMUX allows the trigger output of one peripheral to be connected to the trigger input of a second peripheral.
Wake-Up Unit (WUU)	The WUU provides a mechanism for external or internal sources to initiate the exit of certain low-power modes.
Watchdog (WDOG)	The WDOG monitors internal system operation and forces a reset in case of failure. It can run from multiple clocks with a programmable refresh window to detect deviations in program flow or system frequency.

2.2.4 Clocks

The following Clock (CLK) modules are available on this device:

Table 5. Clock sources

Module	Description
Crystal Oscillator - Radio Frequency (OSC-RF)	The OSC-RF, in conjunction with an external crystal or resonator, generates a reference clock for the Radio that can also be used by the device.
Crystal Oscillator - Real Time Clock (OSC-RTC)	The OSC-RTC oscillator, in conjunction with an external 32 kHz crystal, generates a 32 kHz reference clock for the RTC that can also be used by the radio and other modules of the device.
Free Running Oscillator - 32 kHz (FRO-32K)	The FRO-32K is an internal clock source that generates a 32 kHz reference clock for the RTC that can also be used by the radio and other modules of the device.
Free Running Oscillator - 16 kHz (FRO-16K)	The FRO-16K is an internal clock source that generates a 16 kHz reference clock that is used by the Smart Power Switch domain.
Free Running Oscillator - 6 MHz (FRO-6M)	The FRO-6M is an internal clock source that generates a 6 MHz frequency for use by the radio and other modules of the device.
Free Running Oscillator - 192 MHz (FRO-192M)	The FRO-192M is an internal clock source that generates a 192 MHz frequency for use by the modules other than the radio of the device.
Radio Free Running Oscillator - 192 MHz (RFRO-192M)	The RFRO-192M is an internal clock source that generates a 192 MHz frequency for use by the radio module of the device.
Module Reset and Clock Control (MRCC)	The MRCC provides the user with access to the configuration control registers for the peripherals of the device.
System Clock Generator (SCG)	The SCG provides the user with access to the configuration control registers for the system level clock sources.
Signal Frequency Analyzer (SFA)	The SFA provides facilities for measurement of clock period/frequency as well as time between triggers.

2.2.5 Memory

The following Memory and Memory Interface (MEM) modules are available on this device:

Table 6. Memory modules

Module	Description
Flash Memory	Programmable flash memory — non-volatile flash memory that can store executable program code or data.
Flash Management Unit (FMU)	The FMU manages the interface between the device and the on-chip flash memory.
Read Only Memory - Boot (ROM-BOOT)	Provisions the internal flash with an embedded firmware image during manufacturing or at any time during the life of the device.
Register File - REGFILE	32-byte register file that can be retained in all power modes.

Table continues on the next page...

Table 6. Memory modules (continued)

Module	Description
Static Random Access Memory (SRAM)	Internal system SRAM memory. Each individual block of SRAM can be configured to be retained in low-power modes.

2.2.6 Security

The following Security modules are available on this device:

Table 7. Security modules

Module	Description
EdgeLock Secure Enclave	The EdgeLock Secure Enclave is a security sub system providing essential cryptographic services to the host system within a single microcontroller specifically in two areas: secret key storage and management, plus execution of symmetric and public key cryptographic services, for example, AES, DES/3DES, SHA-256, RSA and ECC, based on requests from the host
Cyclic Redundancy Check (CRC)	Hardware CRC generator provides error detection for all single, double, and many multi-bit errors.
Non-Volatile Memory PRINCE XEX (NPX)	Provides on-the-fly encryption/decryption of the embedded flash contents using a PRINCE XEX block cipher.
Trusted Resource Domain Controller (TRDC)	Provides programmable access control mechanisms for independent processing domains. Unique isolation and access mechanisms for memory and peripheral resources are configured on a domain basis.

2.2.7 Timers

The following Timer (TMR) modules are available on this device:

Table 8. Timer modules

Module	Description
Real Time Clock (RTC)	32-bit seconds counter with 32-bit Alarm Independent power supply
Low-Power Timer (LPTMR)	32-bit time or pulse counter with compare feature
Low Power Periodic Interrupt Timers (LPIT)	Four general purpose interrupt timers with 32-bit counter resolution and DMA support
Time Stamp Timer (TSTMR)	Montonic counter used for long term program debug 56-bit counter resolution
Timer/PWM Module (TPM)	Six channel timer with DMA support for electric motor and power management applications. Clocked by an asynchronous clock that can remain enabled in low power modes.

2.2.8 Communications

The following Communication (COM) modules are available on this device:

Table 9. Communication modules

Module	Description
Controller Area Network (CAN)	Supports the full implementation of the CAN Specification Version 2.0, Part B. FD Support.
Flexible Input/Output (FlexIO)	Functions in Sleep/Deep Sleep modes. DMA support
Low Power Inter-Integrated Circuit (LPI2C)	Allows communication between a number of devices. Also supports the System Management Bus (SMBus) Specification, version 2.
Improved Inter-Integrated Circuit (I3C)	I3C is an extension of the I2C bus protocol supporting higher speeds.
Low Power Serial Peripheral Interface (LPSPI)	Synchronous serial bus for communication to an external device.
Low Power Universal Asynchronous Receive/ Transmit (LPUART)	Asynchronous serial bus communication interface with programmable 8- or 9-bit data format.

2.2.9 Radio

The following are Radio Frequency (RF) modules.

Table 10. Radio modules

Module	Description
Radio Frequency - 2.4 GHz (RF-2.4G)	The 2.4 GHz band radio covers 2.36-2.4835 GHz and is built to support multiple protocols: • Bluetooth Low Energy V5.3 • Generic 2-level FSK/GFSK/MSK/GMSK • IEEE 802.15.4-2015

2.2.10 Human Machine Interface

The following Human Machine Interfaces (HMI) modules are available on this device:

Table 11. HMI modules

Module	Description
General Purpose Input/Output (GPIO)	All General Purpose Input / Output (GPIO) pins are capable of interrupt and DMA request generation.
Port Control	The Port Control (PORT) module provides support for pad control functions.

2.2.11 Analog

The following Analog (ANA) modules are available on this device:

Table 12. Analog modules

Module	Description
Dual Single End Analog-to-Digital Converter (ADC)	A Dual 16-bit Single End Successive-Approximation Register (SAR) Analog-to-Digital Converter (ADC)
Low Power Comparator (LPCMP)	Compares two analog input voltages across the full range of the supply voltage.
Voltage Reference (VREF)	The VREF module supplies an accurate voltage output that can be used by internal or external peripherals.

2.3 Block diagram

The following figure shows a detailed block diagram of the device.

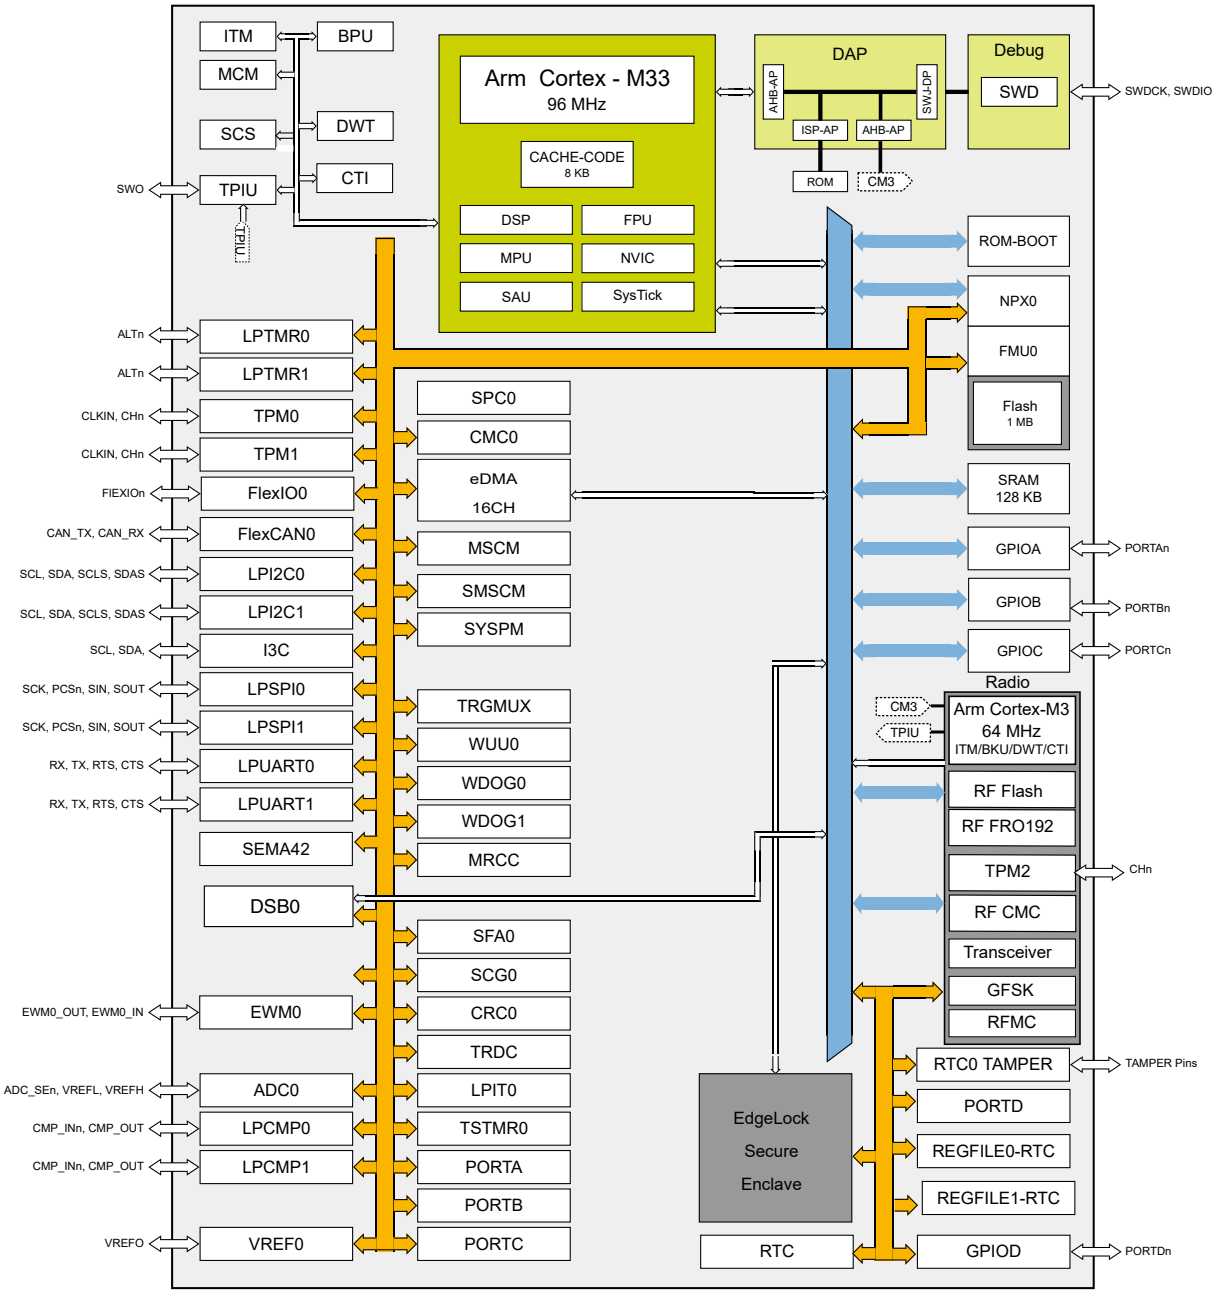

Figure 5. Bus architecture block diagram

2.4 Ordering information

The following table summarizes the part numbers of the devices covered by this document.

Table 13. Ordering information

Part number	Flash (KB)	SRAM (KB)	GPIOs	Pin Count	Package	CAN	802.15.4	Bluetooth 5.3	Qualification	Temperature	Packaging type
MCXW716CMFTAT	1024	128	29	48	HVQFN	Yes	Yes	Yes	Industrial	–40 °C to 125 °C	Tray

Chapter 3
Core Overview

3.1 Introduction

This section covers the core modules included in this device.

3.2 Cortex-M33 Code and System Buses

The Cortex-M33 processor implements a modified Harvard memory architecture using two 32-bit bus interfaces: the Code and System buses. The bus interfaces are activated by address range and can include both instruction fetches and operand data references on a given bus port. (A traditional Harvard architecture strictly separates instruction fetches and operand data references onto specific bus ports regardless of access address.)

The Code bus is typically used for instruction fetching and data accesses of PC-relative data, while the system bus is typically used for operand data references to the on- and off-chip memories and peripheral accesses. The bus structure fully supports concurrent instruction fetch and data accesses, but the Cortex-M33 implementations can generate both types of references on each bus.

NOTE

It is recommended that performance critical code be located such that it fetches from the Code bus interface as defined by addresses < 0x2000_0000.

3.2.1 Code Bus access

Code Bus accesses are routed to the Code TCM if they are mapped to that space. All other Code Bus accesses are routed to the Code Cache Controller. This controller then processes the cacheable accesses as needed, while bypassing the non-cacheable accesses or forwarding the cache write-through and cache miss accesses to the downstream memories through the master port of this cache controller.

3.2.2 System bus access

System Bus accesses are routed to the System TCM if they are mapped to that space. All other System Bus accesses are routed to the target address in destination memories through S1 port.

3.2.3 Access control

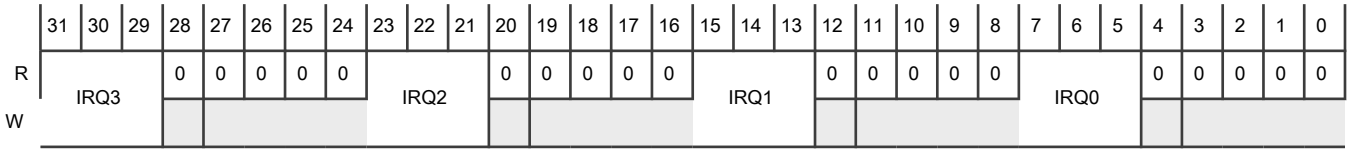
All core Code and System Bus accesses are checked by the core access control logic, that is, IDAU/SAU and MPU. All requests that miss or bypass the cache are checked by downstream TRDC logic. The caches include protection control signals (HPROT[3:0]) and processing domain bits as part of the tags. If a fetch address hits the cache but the protection control and/or domain bits are different, the cache controller forces a miss with the allocate location the same as the address hit location in the cache. This policy allows all the downstream checks to take place, and this new miss is loaded in the cache with the updated protection control and domain bits overwriting the line with the same address. This keeps the cache coherent while always checking accesses that need to see the downstream checks.

All requests are checked by normal platform slave bus checks in the corresponding Memory Block Controller (MBC).

3.3 Nested Vectored Interrupt Controller (NVIC)

3.3.1 Interrupt priority levels

This device supports 8 priority levels for interrupts. Therefore, in the NVIC each source in the IPR registers contains 3 bits. For example, IPR0 is shown below:



3.3.2 Non-Maskable Interrupt (NMI) configuration

The Non-Maskable Interrupt (NMI) request to the NVIC is controlled by the external NMI_b signal. The pin the NMI_b signal is multiplexed on, must be configured for the Non-Maskable Interrupt function to generate the non-maskable interrupt request.

3.3.3 Interrupt channel assignments

The interrupt source assignments are defined in the following table.

- Vector number — the value stored on the stack when an interrupt is serviced.
- IRQ number — non-core interrupt source count, which is the vector number minus 16.

The IRQ number is used within Arm's NVIC documentation.

Table 15. Interrupt Vector Assignments

Address	Vector	IRQ	NVIC non-IPR register number	NVIC IPR register number	Module	Source Description
0000_0000	0	-	-	-	Cortex-M33	Initial Stack Pointer

3.4 System memory map

The following table shows the device's high-level memory map. Additionally, the various sections are split into "Secure" and "Non-Secure" apertures for each IP. Although these apertures address the same IP, access through the "Secure" aperture can only be performed by code with the appropriate security settings.

Table 16. CPU0 memory map

Start address	Default [1]	Description	Alias	Size	Access	Cached
0000_0000	Non-Secure	Program Flash	FLASH	1024 KB	All Masters except data stream and RF	Code Cache
0010_0000		Reserved	—	—	—	—
0100_0000		Flash Logical Window	FLW	1024 KB	All Masters except data stream and RF	Code Cache

1. This is the default Targetted Security Attribute for the memory region at reset. It is set by the IDAU and the SAU configuration. The attribute listed is the intended use case for users of TrustZone-M (TZM) security function.

3.5 Peripheral bridge2 (PBRIDGE2)

The Peripheral Bridge2 (PBRIDGE2) is the portion of the bus fabric that connects the peripherals to the processor elements. Each peripheral has a base address where the processor elements can access them. The following sections provide the memory map of the peripherals connected to the PBRIDGE2.

3.5.1 Peripheral Bridge2 (PBRIDGE2) memory map

Table 17. Peripheral Bridge2

Base address (non-secure)	Base address (secure)	Slot	Module	
System modules				
4000_0000	5000_0000	0	AHB Crossbar Switch 0	AXBS0

4.1.1 Module instances

This device has one instance of the LPCAC module.

4.1.2 Additional cache control and status

In this device, the primary controls for the cache from outside the LPCAC include :

- Miscellaneous Control Module (MCM):
  - ISCR[CWBEE] - Should always set as 0 to disable the interrupt for cache write buffer error
  - ISCR[CWBER] - This field indicates whether the cache write buffer error is received.
  - ISCR[CPEE] - This field enables cache parity error reporting.
  - ISCR[CPES] - This field indicates whether the cache parity error is detected.
  - FATR register - This register indicates the faulting attributes, when a properly-enabled cache write buffer error interrupt event is detected.
  - FADR register - This register captures the faulting address when a properly-enabled cache write buffer error interrupt event is detected.
  - FDR register - This register indicates the captured faulting data, when a properly-enabled cache write buffer error interrupt event is detected.
  - CPCR2 register - This register configures code cache features.
- Secure Miscellaneous System Control Module (SMSCM):
  - OCMDR0[OCMCF2] bitfield has settings related to cache
- Miscellaneous System Control Module (MSCM):
  - There are status registers related to cache

4.2 Overview

LPCAC provides low-latency access to instructions or data. This decouples processor performance from system memory performance, increasing bus availability for other modules and improving system performance.

LPCAC has a 32-bit datapath AMBA-AHB input bus and a 32-bit datapath AMBA-AHB output bus.

4.2.1 Block diagram

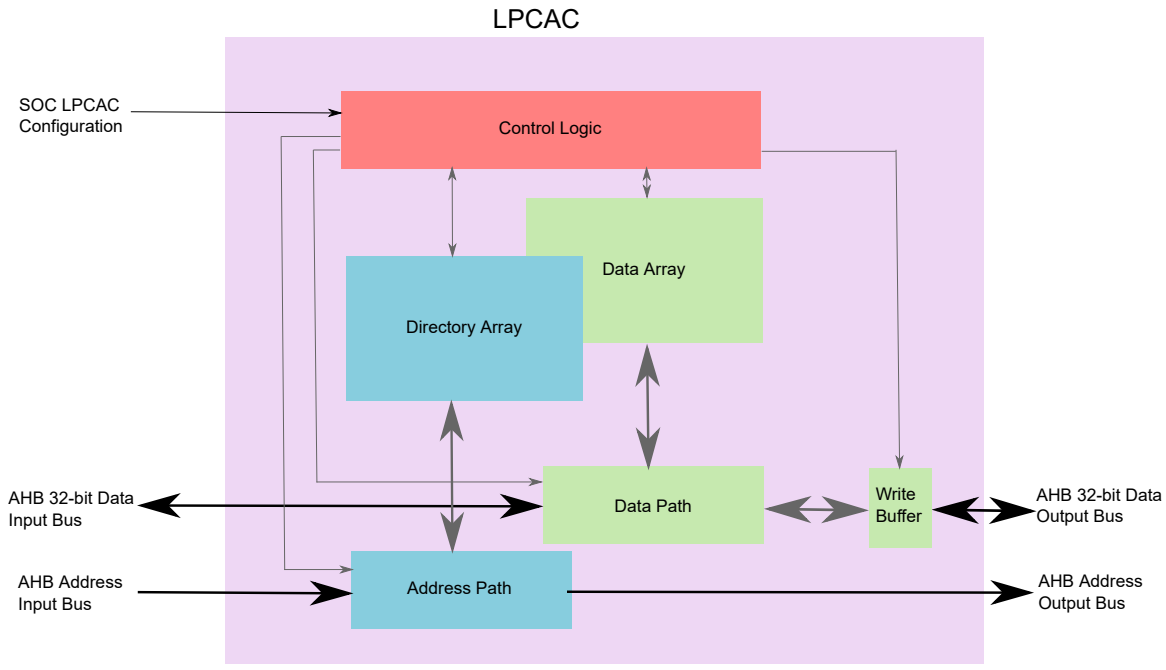

Figure 6. Block diagram

4.2.2 Features

LPCAC supports the following features:

- Nonblocking and write-through cache mode
- 8 KB total cache size
- Cache organization as an 8-way, 4-set-associative design based on 256-byte superpages
- Each way or superpage contains up to 16 sequential 16-byte pages
- Cache supports optional odd parity with one bit of odd parity per 4 bytes of cache data.
  - Cache can recover and scrub data parity errors by forcing miss on parity error and reloading data

4.3 Functional description

This section provides further information on the LPCAC module operation.

A reset signal clears and enables this module.

LPCAC examines every valid AHB input access. If the access hits the cache memory region and the cache is enabled, the access goes to the cache portion of the module. If the access is not cacheable, the access is passed directly to the AHB output bus.

The LPCAC cache has a 256-byte line subdivided into 16 16-byte sublines:

- Cache read accesses that are cache misses perform an aligned 16-byte subline-size burst cache read miss to the module's AHB output bus. Then the cache loads the needed data in the cache’s data storage. The cache miss uses a 4-beat (32 bits per beat), wrapped burst bus access to fetch the cache miss data.
- Cache read accesses that are cache hits return the desired read data from the cache.
- Cache write accesses that are cache misses perform the desired write operation only to the module's AHB output bus (for write-through mode accesses, AHB_LPCAC has a no allocation on write-miss policy).
- Cache write accesses that are cache hits perform the desired write operation to the cache and the module's AHB output bus.

LPCAC has a one entry write buffer. When enabled, cache write accesses with a bufferable attribute use the buffer. When enabled and available, the buffer allows write from the processor to receive an immediate (zero wait state) bus termination.

4.3.1 Cache functional description

The LPCAC cache is an 8-way, 4-set-associative, 256-byte per line write-through design. It supports a total cache capacity of 8 KB for a 32-bit wide cache miss datapath.

4.3.1.1 Cache controls

This module has controls to enable, disable, and clear the cache.

The cache control inputs are as follows:

- clr_lpcac: clear lpcac
- dis_lpcac: disable lpcac
- dis_lpcac_wtbf: disable write buffer
- lim_lpcac_wtbf: limit write buffer
- frc_no_alloc: force no allocation
- mode_ctl_hprot: ignore LPCAC Memory Regions
- parity_miss_en: enable parity, miss on parity error
- parity_fault_en: enable parity error reporting

See chip-specific section for details on how these signals are connected or controlled on a given device.

4.3.2 Clocks

The core clock domain defines the module's clock domain.

4.3.3 Reset

A reset signal clears and enables this module. See the chip-integration information for the resets that affect LPCAC.

4.3.4 Interrupts

This module has no interrupts.

4.4 Signal descriptions

This module has no external signals.

4.5 Memory regions and input control description

4.5.1 Memory regions

LPCAC decodes cacheable address regions. The cache memory region may be composed of one or more disjointed memory regions and the total size may be larger than the cache storage.

Any address not in the cacheable memory regions is in the pass-through memory region. All accesses to the pass-through memory regions are non-cacheable. For all accesses to the cacheable memory regions, the access is cacheable if the attributes of the access indicate that it can be cached, else the access is non-cacheable.

The following table defines the memory map.

Table 23. Memory map

Cache memory range	Cache memory range	Cache total memory address space
0000_0000h–07FF_FFFFh (128 MB)	1000_0000h–1FFF_FFFFh (256 MB)	384 MB

4.5.2 Input controls

The LPCAC does not have a module-resident programming model. An external block supplies the needed LPCAC control inputs.

Table 24. Control inputs for LPCAC

Function	Control input	Description
clear lpcac	clr_lpcac	One cycle active-high pulse clears the lpcac.
disable lpcac	dis_lpcac	• 0 = lpcac enabled (reset configuration) • 1 = lpcac disabled, all cacheable accesses pass from LPCAC input to output bus
disable write buffer	dis_lpcac_wtbf	• 0 = write buffer enabled • 1 = write buffer disabled
limit write buffer	lim_lpcac_wtbf	• 0 = If write buffer is enabled, buffer all writes to spaces that are bufferable • 1 = If write buffer is enabled, buffer all writes to spaces that are both bufferable and cacheable
force no allocation	frc_no_alloc/entry	When frc_no_alloc is asserted and the cache is enabled, all accesses to the cache search the cache. If they hit a valid entry that was loaded before frc_no_alloc was asserted, they operate normally. That is, read hits return cache data without going through the cache and write hits update cache data and write through the cache. If they miss, they bypass the cache (that is, even though a read access is to a cacheable space, it does not allocate on a cache miss). This control input is useful for debug. Say there is a software breakpoint, halting the processor. Then, using the debug port, cacheable memory as well as other address spaces are accessed. These debug accesses go through the processor, through the cache, and to the rest of the system. The idea is during the debug accesses the cache is placed on frc_no_alloc mode. In this way, debug access through the core and then through the cache do not disturb the state of the cache. Before restarting the processor, frc_no_alloc mode is negated. When the processor restarts, the cache state is the same or at least very similar as the cache state when the breakpoint was hit. • 0 = normal allocation on cache miss • 1 = no allocation on cache miss

Table continues on the next page...

Table 24. Control inputs for LPCAC (continued)

Function	Control input	Description
ignore CACHE_MAP	mode_ctl_hprot	• 0 = use LPCAC Memory Regions to determine if an access to a given address may be cached. Then, if the attributes of the access indicate it can be cached, the access is cached. • 1 = Use only the attributes of the access to indicate it can be cached.
parity miss enable	parity_miss_en	Enables miss on parity to scrub parity error and to reload the data line that had the parity error. • 0 = do not take a miss on a parity error • 1 = force a miss on a parity error
parity enable	parity_fault_en	Enables and disables parity error report. • 0 = disable • 1 = enable

Chapter 5
Peripheral Bridge2 (PBRIDGE2)

5.1 Chip-specific PBRIDGE2 information

Table 25. Reference links to related information

Topic	Related module	Reference
Full description	PBRIDGE	PBRIDGE
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

5.1.1 Module instances

This device has one PBRIDGE2.

5.2 Overview

Peripheral Bridge2 (PBRIDGE2) Controller converts an AMBA AHB interface to a peripheral interface. The peripheral interface has peripheral module enables allowing the controller to interface to multiple peripherals.

PBRIDGE2 has a configurable datapath width (32-bit or 64-bit) for the AMBA AHB input bus and 8 Bit, 16 Bit, and 32 Bit datapath peripheral output buses. Each peripheral bridge occupies a configurable amount of the address space, which is divided into either 128 4 Kbyte slots or 128 64 Kbyte slots. (It is possible that all the peripheral slots are not used. See the memory map chapter for details on slot assignments.)

5.2.1 Features

The PBRIDGE2 key features include:

- Supports peripheral slots with 8-, 16-, and 32-bit datapath width (See Memory Maps for details on slot datapath width assignments)
- Includes separate clock enable inputs for each of the slots to accommodate slower peripherals.
- Includes separate powered-down inputs for each of the slots to accommodate powering-down individual peripherals.

5.2.2 Number of Peripheral Bridges

This device contains 1 peripheral bridges.

5.3 Functional Description

This section provides further information on the PBRIDGE2 operation.

The peripheral bridge functions as a bus protocol translator between an AMBA AHB bus and the slave peripheral bus. The peripheral bridge manages all transactions destined for the attached slave devices and generates select signals for modules on the peripheral bus by decoding accesses within the attached address space.

The PBRIDGE2 examines every valid AHB input access. If the access hits a peripheral slot that is configured, not powered-down, and the access width is less than or equal to the slot data width, the access goes to that slot peripheral bus. If the access completes error free on the slot peripheral bus, the AHB access completes error free. If the AHB access is to a peripheral slot that is not configured, is powered-down, or has width greater than the slot data width or the access to the slot completes with an error on the slot peripheral bus, the AHB access terminates with a bus error.

5.3.1 Access Support

Aligned 32-bit, 16-bit, and byte accesses are supported for 32-bit peripherals, aligned 16-bit and byte accesses are supported for 16-bit peripherals, and byte accesses are supported for 8-bit peripherals. All accesses are performed with a single transfer. All accesses to the peripheral slots must be sized less than or equal to the designated peripheral slot size. If an access is attempted that is larger than the targeted port, an AHB bus error response is generated.

5.4 Memory Maps

The peripheral bridges are used to access the registers of most of the peripheral modules on this device. See the memory map section for the memory slot assignment for each module.

Chapter 6
Crossbar Switch (AXBS)

6.1 Chip-specific AXBS information

Table 26. Reference links to related information

Topic	Related module	Reference
Full description	AXBS	AXBS

S3	STCM0, STCM1, STCM4
S4	STCM5
S5	PBRIDGE2
S6	GPIOA, GPIOB, GPIOC
S7	Radio

6.2 Overview

This section provides information on the layout, configuration, and programming of the crossbar switch.

The crossbar switch connects bus masters and bus slaves using a crossbar switch structure. This structure allows all bus masters to access different bus slaves simultaneously, while providing arbitration among the bus masters when they access the same slave. A variety of bus arbitration methods and attributes may be programmed on a slave-by-slave basis.

6.2.1 Features

- Symmetric crossbar bus switch implementation
  - Allows concurrent access from different masters to different slaves
  - Slave arbitration attributes configured on a slave-by-slave basis
- Single-clock 32-bit transfer
- Support for burst transfers of 64 bits of data
- Support for low-power park mode
- 32-bit AHB crossbar bus switch compatible with ARM's AMBA Specification v2.0

6.3 Memory map and register definition

Each slave port of the crossbar switch contains configuration registers. Read- and write transfers require two bus clock cycles. The registers can be read from and written to only in supervisor mode. Additionally, these registers can be read from or written to only by 32-bit accesses.

A bus error response is returned if an unimplemented location is accessed within the crossbar switch.

The CRS*n* and PRS*n* registers can be programmed as read-only to prevent changes to their configuration. After being read-only protected, future writes to them terminate with a data storage error.

NOTE

This section shows the registers for all eight master and slave ports. If a master or slave is not used on this particular chip, then unexpected results occur when writing to its registers. See the chip configuration details for the exact master and slave assignments for your chip.

All references to the crossbar switch registers are based on the physical port connections.

6.3.1.2 Priority Slave Registers (PRS0 - PRS7)

Offset

Register	Offset
PRS0	0h
PRS1	100h
PRS2	200h
PRS3	300h
PRS4	400h
PRS5	500h
PRS6	600h
PRS7	700h

Function

The priority slave registers(PRS*n*) set the priority of each master port on a per slave port basis and reside in each slave port. The priority register can be accessed only with 32-bit access. After the CRS*n*[RO] bit is set, the PRS*n* register can only be read; attempts to write to it have no effect on PRS*n* and result in a bus-error response to the master initiating the write.

Two available masters must not be programmed with the same priority level. Attempts to program two or more masters with the same priority level result in a bus-error response and the PRS*n* is not updated.

NOTE

Valid values for the M*n* priority fields depend on which masters are available on the chip. This information can be found in the chip-specific information for the crossbar.

- If the chip contains fewer than three masters, only one bit is valid.
- If the chip contains fewer than five masters, only two bits are valid.
- If five or more masters are present, all three bits of the priority field are used.

6.3.1.3 Control Register (CRS0 - CRS7)

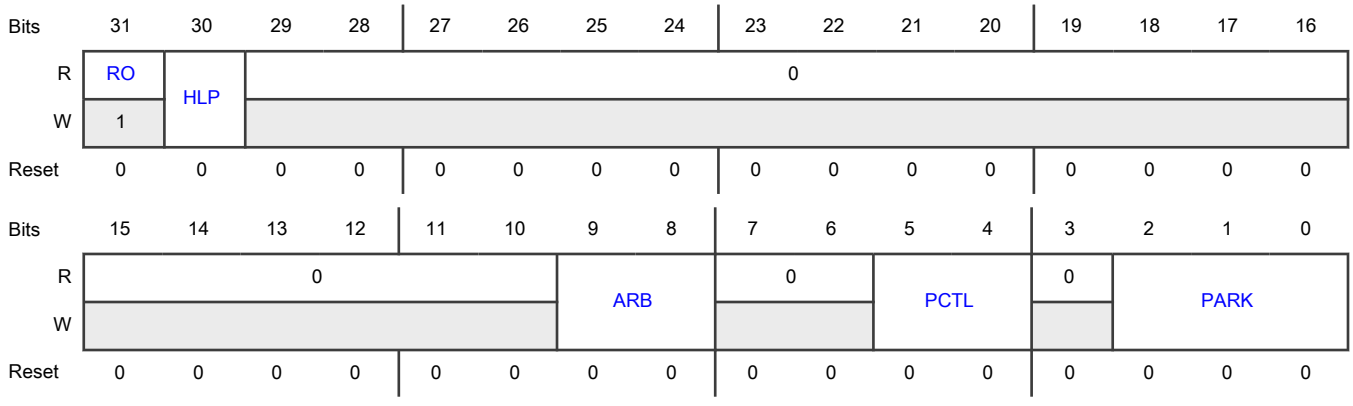
Offset

Register	Offset
CRS0	10h
CRS1	110h
CRS2	210h
CRS3	310h
CRS4	410h
CRS5	510h
CRS6	610h
CRS7	710h

Function

These registers control several features of each slave port and must be accessed using 32-bit accesses. After CRS*n*[RO] is set, the PRS*n* can only be read; attempts to write to it have no effect and resuresultsan error response.

Diagram



Fields

Field	Function
31 RO	Read Only This field forces the slave port's CSR*n* and PRS*n* registers to be read-only. Aftersettingt, only a hardware reset clears it. 0b - The slave port's registers are writeable. 1b - The slave port's registers are read-only and cannot be written. Attempted writes do not affect the registers and result in a bus error response.
30 HLP	Halt Low Priority This field sets the initial arbitration priority for low-power mode requests. Setting this bit will not affect the request for low-power mode from attaining the highest priority after it has control of the slave ports. 0b - The low-power mode request has the highest priority for arbitration on this slave port. 1b - The low-power mode request has the lowest initial priority for arbitration on this slave port.
29-10 —	Reserved
9-8 ARB	Arbitration Mode This field selects the arbitration policy for the slave port. 00b - Fixed priority 01b - Round-robin(RR) or rotating priority 10b - Reserved 11b - Reserved
7-6 —	Reserved
5-4 PCTL	Parking Control This field determines the slave port's parking control. The low-power park feature results in overall power saving if the slave port is not saturated. However, this forces an extra latency clock when a master tries to access the slave port when not in use because it is not parked on any master. 00b - When no master makes a request, the arbiter parks the slave port on the master port defined by the PARK field. 01b - When no master makes a request, the arbiter parks the slave port on the last master to be in control of the slave port. 10b - When no master makes a request, the slave port is not parked on a master and the arbiter drives all outputs to a constant safe state. 11b - Reserved
3 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
2-0 PARK	Park This field determines which master port the current slave port parks on when no masters are actively making requests and the PCTL bits are cleared. **NOTE** Select only those master ports that are present on the chip. Otherwise, undefined behavior may occur. 001b - Park on master port M1. 010b - Park on master port M2. 011b - Park on master port M3. 100b - Park on master port M4. 101b - Park on master port M5. 110b - Park on master port M6. 111b - Park on master port M0.

6.3.1.4 Master General Purpose Control Register (MGPCR0 - MGPCR5)

Offset

Register	Offset
MGPCR0	800h
MGPCR1	900h
MGPCR2	A00h
MGPCR3	B00h
MGPCR4	C00h
MGPCR5	D00h

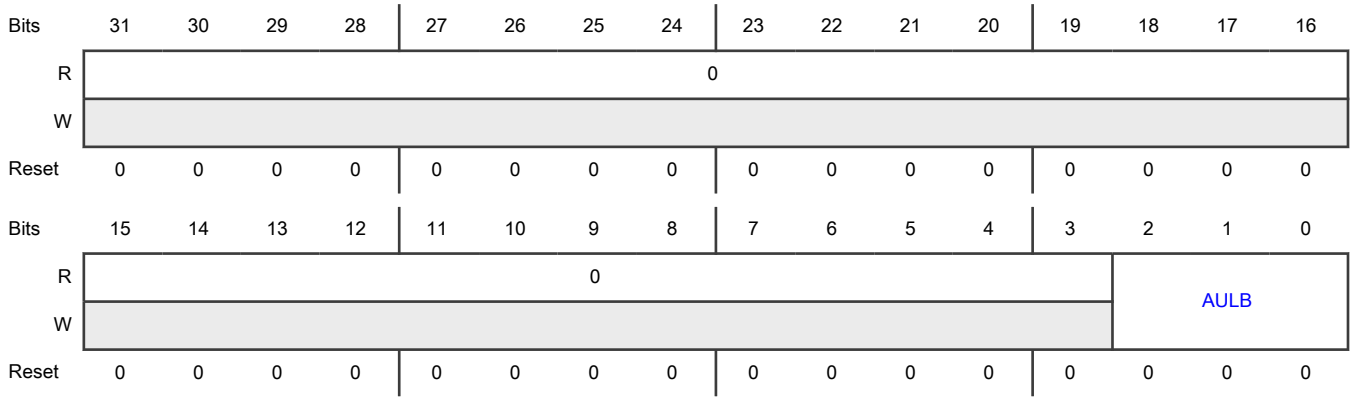
Function

The MGPCR controls only whether the master's undefined length burst accesses are allowed to complete uninterrupted or whether they can be broken by requests from higher priority masters. The MGPCR can be accessed only in supervisor mode with 32-bit accesses.

NOTE

If there are fewer than eight master ports, only the registers associated with those masters are present. Register addresses associated with master ports that are not present are reserved. See the module's chip-specific information for which master ports are present on this module.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 AULB	Arbitrates On Undefined Length Bursts This field determines whether, and when, the crossbar switch arbitrates away the slave port the master owns when the master is performing undefined length burst accesses. 000b - No arbitration is allowed during an undefined length burst. 001b - Arbitration is allowed at any time during an undefined length burst. 010b - Arbitration is allowed after four beats of an undefined length burst. 011b - Arbitration is allowed after eight beats of an undefined length burst. 100b - Arbitration is allowed after 16 beats of an undefined length burst. 101b - Reserved 110b - Reserved 111b - Reserved

6.4 Functional description

Information about general operation and arbitration are provided in this section.

6.4.1 General operation

When a master accesses the crossbar switch, the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. Single-clock or zero-wait-state accesses are possible through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the requesting master sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Because the crossbar switch appears to be just another slave to the master device, the master device does not know whether it owns the slave port it is targeting. The master waits while it does not have control of the slave port it is targeting.

After the master acquires control of the slave port, it controls the port until it relinquishes the port by running an IDLE cycle or by targeting a different slave port for its next access.

The master can also lose control of the slave port if another higher-priority master makes a request to the slave port. However, if the master is running a fixed- or undefined-length burst transfer, it retains control of the slave port until that transfer completes. Based on MGPCR[AULB], the master either retains control of the slave port when doing undefined-length, incrementing burst transfers or loses the bus to a higher-priority master.

The crossbar terminates all master IDLE transfers, as opposed to allowing the termination to come from one of the slave buses. Additionally, when no master is requesting access to a slave port, the crossbar drives IDLE transfers onto the slave bus, even though a default master may be granted access to the slave port.

When a slave bus is being idled by the crossbar, it can park the slave port on the master port indicated by CRS*n*[PARK]. This is done to save the initial clock of arbitration delay that otherwise would be seen if the same master had to arbitrate to gain control of the slave port. The slave port can also be put into low-power park mode to save power, by using CRS*n*[PCTL].

6.4.2 Register coherency

The operation of the crossbar is affected as soon as a register is written. The values of the registers do not track with slave-port-related master accesses, but instead track only with slave accesses.

The MGPCRx[AULB] bits are the exception to this rule. The update of these bits is only recognized when the master on that master port runs an idle cycle, even though the slave bus cycle to write them will have already terminated successfully. If the MGPCRx[AULB] bits are written between two burst accesses, the new AULB encodings do not take effect until an IDLE cycle is initiated by the master on that master port.

6.4.3 Arbitration

The crossbar switch supports the following arbitration algorithms:

- Fixed priority
- Round-robin

The arbitration scheme is independently programmable for each slave port.

6.4.3.1 Arbitration during undefined length bursts

Arbitration points during an undefined length burst are defined by the current master's MGPCR[AULB] field setting. When a defined length is imposed on the burst via the AULB bits, the undefined length burst is treated as a single or series of single back-to-back fixed-length burst accesses.

The following figure illustrates an example:

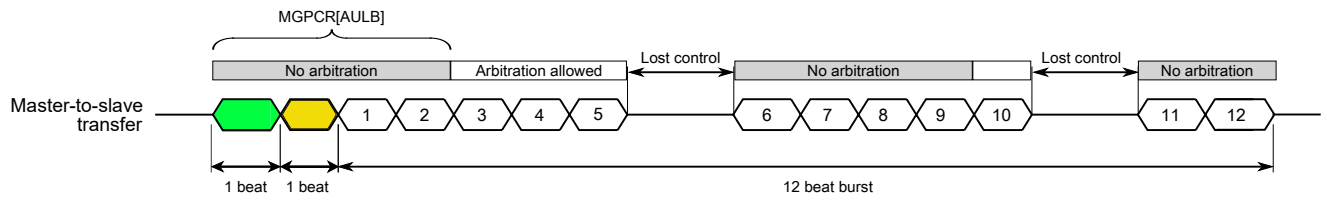


Figure 7. Undefined length burst example

In this example, a master runs an undefined length burst and the MGPCR[AULB] bits indicate arbitration occurs after the fourth beat of the burst. The master runs two sequential beats and then starts what will be a 12-beat undefined length burst access to a new address within the same slave port region as the previous access. The crossbar does not allow an arbitration point until the fourth overall access, or the second beat of the second burst. At that point, all remaining accesses are open for arbitration until the master loses control of the slave port.

Assume the master loses control of the slave port after the fifth beat of the second burst. After the master regains control of the slave port no arbitration point is available until after the master has run four more beats of its burst. After the fourth beat of the now continued burst, or the ninth beat of the second burst from the master's perspective, is taken, all beats of the burst are once again open for arbitration until the master loses control of the slave port.

Assume the master again loses control of the slave port on the fifth beat of the third now continued burst, or the 10th beat of the second burst from the master's perspective. After the master regains control of the slave port, it is allowed to complete its final two beats of its burst without facing arbitration.

NOTE

Fixed-length burst accesses are not affected by the AULB bits. All fixed-length burst accesses lockout arbitration until the last beat of the fixed-length burst.

6.4.3.2 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the priority registers (PRS*n*). If two masters request access to the same slave port, the master with the highest priority in the selected priority register gains control over the slave port.

NOTE

In this arbitration mode, a higher-priority master can monopolize a slave port, preventing access from any lower-priority master to the port.

When a master makes a request to a slave port, the slave port checks whether the new requesting master's priority level is higher than that of the master that currently has control over the slave port, unless the slave port is in a parked state. The slave port performs an arbitration check at every clock edge to ensure that the master, if any, has control of the slave port.

The following table describes possible scenarios based on the requesting master port.

Table 29. Methods of how the crossbar switch grants control of a slave port to a master

When	Then the crossbar switch grants control to the requesting master
Both of the following are true: • The current master is not running a transfer. • The new requesting master's priority level is higher than that of the current master.	At the next clock edge
Both of the following are true: • The current master is running a fixed-length burst transfer or a locked transfer. • The requesting master's priority level is higher than that of the current master.	At the end of the burst transfer or locked transfer
Both of the following are true: • The current master is running an undefined length burst transfer. • The requesting master's priority level is higher than that of the current master.	At the next arbitration point for the undefined length burst transfer **NOTE** Arbitration points for an undefined length burst are defined in the MGPCR for each master.
The requesting master's priority level is lower than the current master.	At the conclusion of one of the following cycles: • An IDLE cycle • A non-IDLE cycle to a location other than the current slave port

6.4.3.3 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the master port number. This relative priority is compared to the master port number (ID) of the last master to perform a transfer on the slave bus. The highest priority requests the master owns the slave bus at the next transfer boundary, accounting for locked and fixed-length burst transfers. Priority is based on how far ahead the ID of the requesting master is of the ID of the last master.

After a master is granted access to a slave port, a master may perform as many transfers as desired to that port until another master requests the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle, if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume that the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and masters 0, 4, and 5 make simultaneous requests, they are serviced in this order: 4,5, and then 0.

Parking may continue to be used in a round-robin mode, but does not affect the round-robin pointer unless the parked master performs a transfer. Handoff occurs to the next master in line after one cycle of arbitration. If the slave port is put into low-power park mode, the round-robin pointer is reset to point at master port 0, giving it the highest priority.

6.4.3.4 Clocking

This module has no clocking considerations.

6.4.3.5 Interrupts

This module has no interrupts.

6.4.3.6 Priority assignment

Each master port must be assigned a unique 3-bit priority level. If an attempt is made to program multiple master ports with the same priority level within the priority registers (PRS*n*), the crossbar switch responds with a bus error and the registers are not updated.

6.5 External signals

This module has no external signals.

6.6 Initialization/application information

No initialization is required for the crossbar switch.

Hardware reset ensures that all the register bits used by the crossbar switch are properly initialized to a valid state. However, the following settings and priorities may be programmed to achieve the maximum system performance:

- During the configuration of the crossbar switch, all other masters must be idle.
- To prevent reconfiguration of the crossbar switch, write 1 to CRS*n*[RO].

Flash Memory Controller (FMC)

7.1 Chip-specific FMC information

Table 30. Reference links to related information

Topic	Related module	Reference
Full description	FMC	FMC
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

See SMSCM_OCMDR0 for details on flash speculation and flash cache control.

NOTE

The FMC module includes an optional PRINCE encryption/decryption features that is not described here. For details on this feature, refer to the Security RM.

7.1.1 Module instances

This device has one instance of the FMC module.

7.2 Overview

The Flash Memory Controller (FMC) is a memory interface and acceleration unit providing:

- An interface between the device and the nonvolatile memory
- Buffers that can accelerate flash memory transfers

The FMC manages the interface between the device and the flash memory. The FMC receives status information describing the configuration of the memory and uses this information to ensure a proper interface. The next table shows the supported read/write operations.

Flash memory type	Read	Write
Program, IFR, IFR1 flash memory	8-bit, 16-bit, and 32-bit reads	16-byte and 128-byte writes

The FMC provides quick access to flash memory using 3 separate acceleration mechanisms:

- A flash-phrase-sized buffer holds the most recently accessed flash phrase
- An optional flash-phrase-sized speculation buffer can prefetch the next flash phrase
- An optional 4-way, set-associative cache can store previously accessed flash phrases

The FMC is controlled by a programmer's model external to the FMC module; see the chip-specific FMC information for details. The FMC's programming model provides a very configurable, high performance flexible memory controller, which can be optimized for the runtime characteristics of specific applications.

NOTE

Program the FMC's controls only while the flash controller is idle. Changing the configuration settings while a flash access is in progress can cause non-deterministic, unpredictable behavior.

7.2.1 Features

- Interface between the device and the flash memory:
  - The FMC's input bus supports 8-bit, 16-bit, and 32-bit read operations to flash memory.
  - The FMC's flash memory interface fetches a 128-bit flash phrase.
  - For input read requests, the FMC fetches a flash phrase with the desired read data from flash memory.
  - The FMC's flash memory interface can write aligned 16-byte flash write phrases or aligned 128-byte flash write pages to flash memory.
  - The FMC has a 16-byte aligned write buffer, used once for aligned 16-byte flash write phrases or used 8 times for aligned 128-byte flash write pages.
  - The FMC's input bus supports 32-bit write operations for flash memory writes to fill the FMC's write buffer.
  - For input write requests, the FMC must receive the 4-word write of an aligned phrase in order.
- Acceleration of data transfer from flash memory to the device:
  - A flash-phrase-sized buffer that holds the current decrypted flash phrase fetched due to a FMC read request. Subsequent FMC read requests *that hit in the current buffer* return data with no wait states.
  - A flash-phrase-sized prefetch speculation buffer with controls for prefetching on instructions and/or data reads. When prefetching is enabled, idle FMC-to-flash interface cycles are used to fetch the next sequential flash phrase and hold it in the prefetch buffer. Subsequent FMC read requests *that hit in the speculation buffer* return data with no wait states.
  - Input controls:
    - to disable data type speculation
    - to disable all speculation
    - to invalidate the current and speculation buffers
  - The flash cache has input controls:
    - to disable instruction caching
    - to disable operand caching
    - to disable all caching
    - to clear the cache
  - The size of the flash cache in bytes is calculated as follows:

    flash cache size = [number of ways] x [number of sets] x [flash phrase size (in bytes)]

    For example, a flash cache with 4 ways, 1 set, and a 128-bit flash phrase (= 16 bytes) has a total flash cache size = 64 bytes

    (4 ways) x (1 set) x (16 bytes per flash phrase) = 64 bytes, the size of the flash cache

    NOTE

    Clear the speculation buffer and flash cache before accessing recently modified flash addresses. The flash cache has a specific clear control bit. To clear the speculation buffer, first disable then re-enable the speculation.

7.3 Functional description

The FMC is a flash interface and acceleration unit, with flexible buffers for user configuration.

- The FMC's input bus can operate faster than the flash memory.
- The FMC-to-flash interface has flow control to add wait states as needed (for input bus reads that need flash accesses).

- The FMC also contains various configurable buffers that hold recent flash accesses. If an input bus read hits a valid buffer, then that access will complete with no wait states.

7.3.1 Modes of operation

The FMC only operates when a bus master accesses the flash memory.

For any device power mode where the flash memory cannot be accessed, the FMC is disabled.

7.3.2 Default configuration

After system reset, the FMC is configured to provide a significant level of buffering for transfers from the flash memory. For all banks:

- The current and speculation buffers are cleared by reset.
- Prefetch support for data and instructions is enabled.
- The cache is cleared by reset.
- The cache is configured for data or instruction replacement.

7.3.3 Configuration options

The default configuration provides a high degree of flash acceleration, however, advanced users may want to customize the FMC buffer configurations, to maximize throughput for their use cases. When reconfiguring the FMC for custom use cases, do not program the FMC's control registers while the flash memory is being accessed. Instead, change the control registers with a routine executing from RAM in supervisor mode.

The FMC's cache and buffering controls allow the tuning of resources to suit specific application requirements. The cache and buffer are each controlled individually. The controls enable buffering and prefetching per access type (instruction fetch or data reference).

As an application example: if both instruction fetches and data references are accessing flash memory, then control is available to send instruction fetches, data references, or both to the cache or the single-entry buffer. Likewise, speculation can be enabled or disabled for either type of access.

For best performance, the FMC cache and speculation buffering should be enabled for instruction and/or data fetching. The following is recommended for best performance:

- If the speculation buffer is enabled for both instruction and data speculation, also enable the flash cache for both instruction and data caching.
- If the speculation buffer is enabled for instruction speculation only, also enable the flash cache for at least instruction caching.

7.3.4 Wait states

Because the core, crossbar switch, and bus masters can be clocked at a higher frequency than the flash clock, flash memory accesses that do not hit in the speculation buffer or cache usually require wait states.

All wait states and synchronization delays are handled automatically by the Flash Memory Controller. No direct user configuration is required (or even allowed) to set up the flash wait states.

7.3.5 Speculative reads

The FMC has a single buffer that reads ahead to the next phrase in the flash memory if there is an idle cycle. Speculative prefetching is programmable for instruction and/or data accesses. Because many code accesses are sequential, using the speculative prefetch buffer improves performance in most cases.

When speculative reads are enabled, the FMC immediately requests the next sequential phrase address after a read completes. By requesting the next phrase immediately, speculative reads can help to reduce or even eliminate wait states when accessing sequential code and/or data.

7.3.6 Interrupts

This module has no interrupts.

7.4 External signals

The FMC has no external signals.

7.5 Initialization and application information

The FMC does not require user initialization. Flash acceleration features are enabled by default.

The FMC has no visibility into flash memory erase and program cycles because the Flash Memory module manages them directly. As a result, if an application is executing flash memory commands, the FMC's current buffer, speculation buffer, and cache might need to be disabled and/or flushed to prevent the possibility of returning stale data.

Chapter 8
System Performance Monitor (SYSPM)

8.1 Chip-specific SYSPM information

Table 31. Reference links to related information

Topic	Related module	Reference
Full description	SYSPM	SYSPM
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

8.1.1 Module instances

This device has one instance of the SYSPM module.

8.2 Overview

System Performance Monitor (SYSPM) is a memory mapped peripheral that enables the user to monitor system and/or CPU events. The SYSPM consists of sixteen 256 Byte sub-slots (SS). The first subslot is the configuration slot. The registers in the configuration SS0 describe the number of monitors, types of monitors and number of counters per monitor. Subsequent sub-slots are occupied by an optional Programmable System Activity Monitor (PSAM), and Performance Monitors (PERFMON) registers.

8.2.1 Features

The SYSPM includes the following features:

- Three 40-bit event counters
- Programmable event select
- Countable events that include cache, branch fetches, and stalls

Memory mapped performance monitor that counts instructions, cache, branch, IPS, and TCM stats

8.2.2 Block diagram

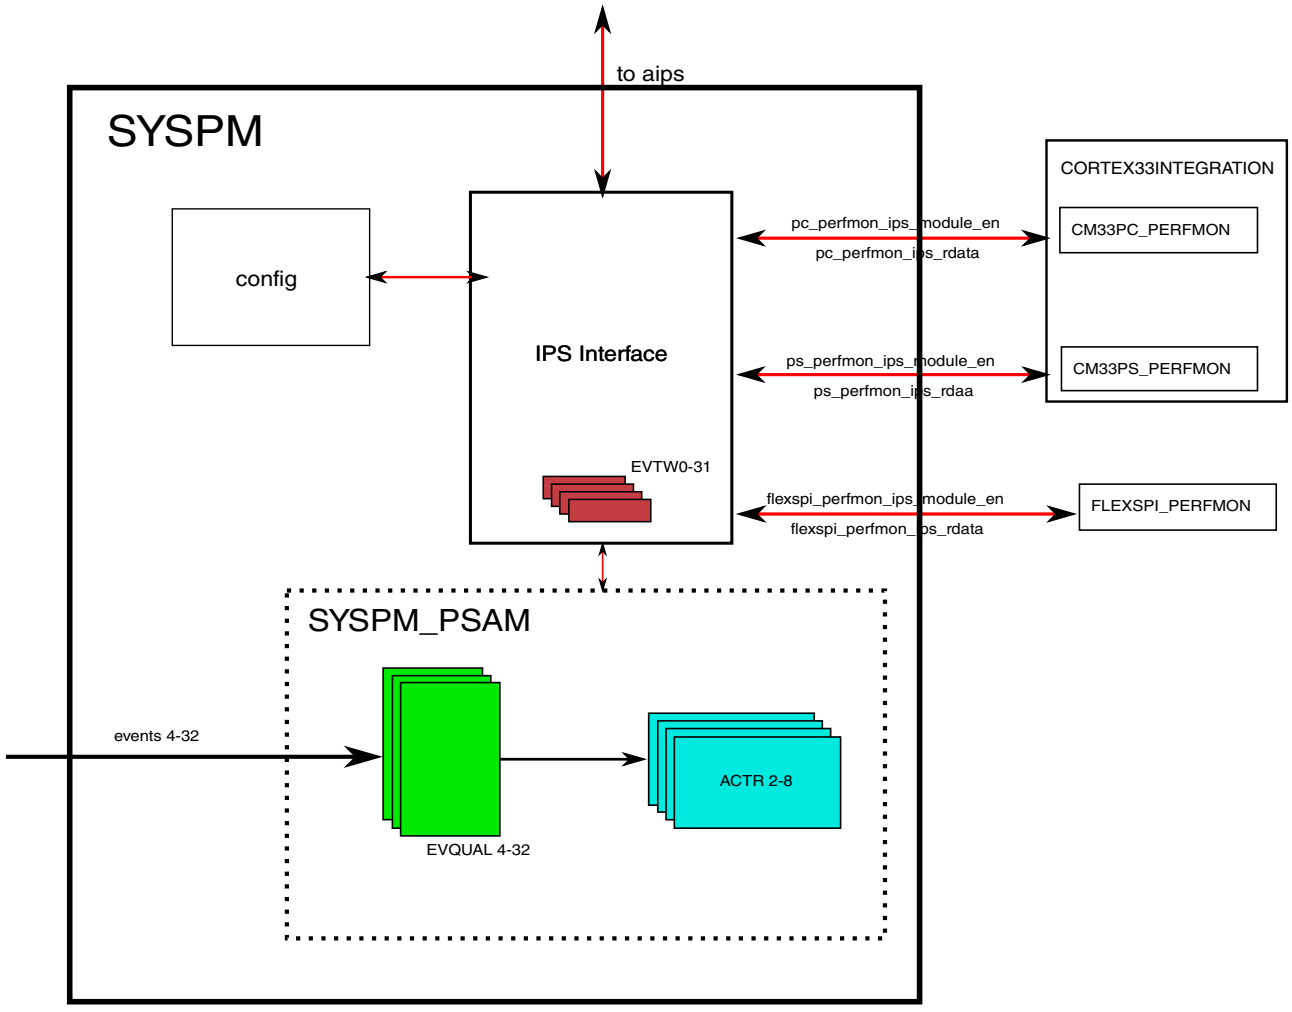

Figure 8. SYSPM Block Diagram

8.3 Functional description

8.3.1 Operating modes

There are no special operating modes for the SYSPM.

8.3.2 Operations

SYSPM routes transaction to CMX_PERFMON. See the chip-specific SYSPM information for details on the performance monitors. SYSPM also provides read-only identification registers that describe the types of monitors in each sub-slot.

8.3.3 Clocking

This module has no clocking considerations.

8.3.4 Interrupts

This module has no interrupts.

8.3.5 External signals

This module has no external signals.

8.3.6 Initialization

Initialization is not required for this module.

8.4 Memory Map and register definition

This section includes the SYSPM module memory map and detailed descriptions of all registers.

8.4.1.6 Performance Monitor Control Register (PMCR0 - PMCR1)

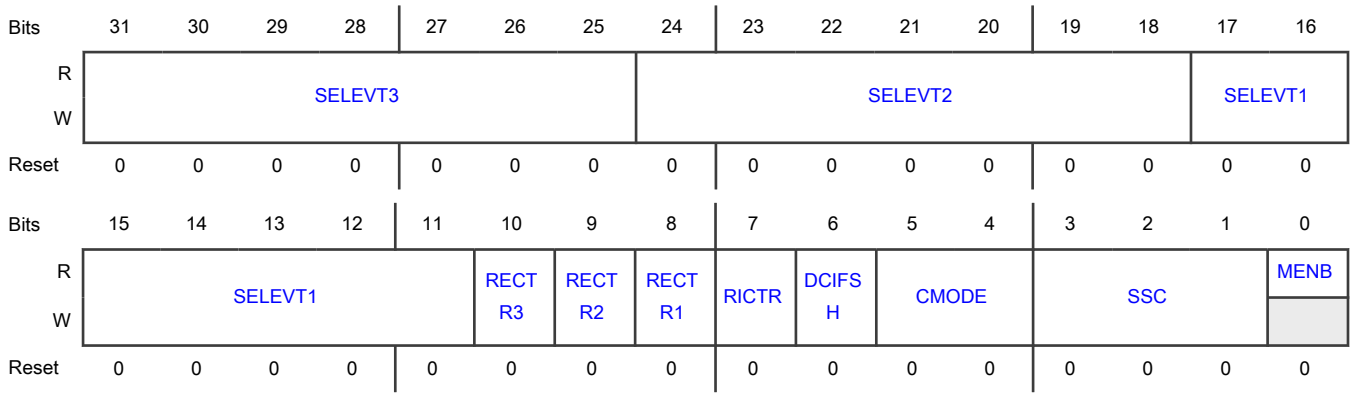
Offset

Register	Offset
PMCR0	200h
PMCR1	300h

Function

The performance monitor control register is used to select which events will be counted in PMCRn register, the count mode, start/stop control and the enables for the counters. See the chip-specific SYSPM information for detailed events.

Diagram



Fields

Field	Function
31-25 SELEVT3	Select Event 3 See Operations to select which event to be counted in PMECTR3.
24-18	Select Event 2

SELEVT2	See Operations to select which event to be counted in PMECTR2.
17-11 SELEVT1	Select Event 1 See Operations to select which event to be counted in PMECTR1.
10 RECTR3	Reset Event Counter 3 Write a one to clear event counter 3. This field must be zero to restart event counter 3. 0b - Counter runs normally 1b - Counter value resets at the end of the cycle
9 RECTR2	Reset Event Counter 2 Write a one to clear event counter 2. This field must be zero to restart event counter 2.
8 RECTR1	Reset Event Counter 1 Write a one to clear event counter 1. This field must be zero to restart event counter 1.
7 RICTR	Resets the Instruction Counter Write a one to clear the instruction counter. This field must be zero to restart the instruction counter. 0b - do not reset the instruction counter 1b - clear the instruction counter
6 DCIFSH	Disable Counters if Stopped or Halted 0b - Continue counting 1b - Stops counting when the CPU is halted
5-4 CMODE	Count Mode Determines if events are counted for privileged mode, user mode, or both privileged and user. This setting affects the operation of all three of the event counters. 00b - count in both user and privileged modes 01b - Reserved 10b - count only in user mode 11b - count only in privileged mode
3-1 SSC	Start/Stop Control This 3-bit field provides a three-phase mechanism to start/stop the counters. It includes a prioritized scheme with local start > local stop > global start > global stop > conditional TSTART > TSTOP. The global and conditional start/stop affect all configured PM/PSAM module concurrently so counters are "coherent". 000b - Idle 001b - local stop

9.2 Overview

The Trusted Resource Domain Controller (TRDC) provides an integrated, scalable architectural framework for access control, system memory protection and peripheral isolation. It allows software to assign chip resources including processor cores, non-core bus masters, memory regions and slave peripherals to processing *domains* to support enforcement of robust operational environments. First, each bus mastering resource is assigned to a domain identifier (domainID, DID). Typically, each processor is assigned to a unique domainID and all remaining non-processor bus masters assigned to a different domainID. Next, the access control policies for the individual domains are programmed into any number of registers implemented in the slave memory block and region checkers. Finally, all accesses throughout the device are monitored concurrently to determine the validity of each and every access. If a reference from a given domain has sufficient access rights, it is allowed to continue, else the access is aborted and error information captured.

The access control scheme defined by the TRDC supports a 4-level model, combining the traditional privileged (also known as supervisor) and user modes with an additional signal defining the secure, nonsecure attributes of each memory reference. The result is a 4-level hierarchical access control mechanism, where:

SecurePriv > SecureUser > NonsecurePriv > NonsecureUser

with different access control policies based on read, write and execute references. Combined with the secure/nonsecure and privileged/user attributes, a domainID is associated with every system bus transaction and forms the hardware basis for implementation of the TRDC's access control mechanisms.

9.2.1 Block diagram

As previously noted, the TRDC implementation is distributed across multiple submodules instantiated throughout the device. The TRDC submodules include:

- TRDC_MGR

— The Manager (MGR) submodule coordinates all programming model reads and writes

- TRDC_DAC
  - — The Domain Assignment Controller (DAC) handles resource assignments and generation of the domain identifiers.
- TRDC_MBC
  - — The Memory Block Checker (MBC) implements access controls for on-chip internal memories and slave peripherals based on a fixed-sized block format
- TRDC_MRC
  - — The Memory Region Checker (MRC) implements the access controls for external off-chip memories and peripherals based on the pre-programmed region descriptor registers.

NOTE

TRDC typically consists of various submodules like DAC, MGR, MBC and MRC. However, all the submodules as shown in block digram below may not be present for this configuration. For chip-specific implementation details of this module's instances, see the chip specific information.

See Figure 9 for a simplified TRDC block diagram focusing on topology and connections.

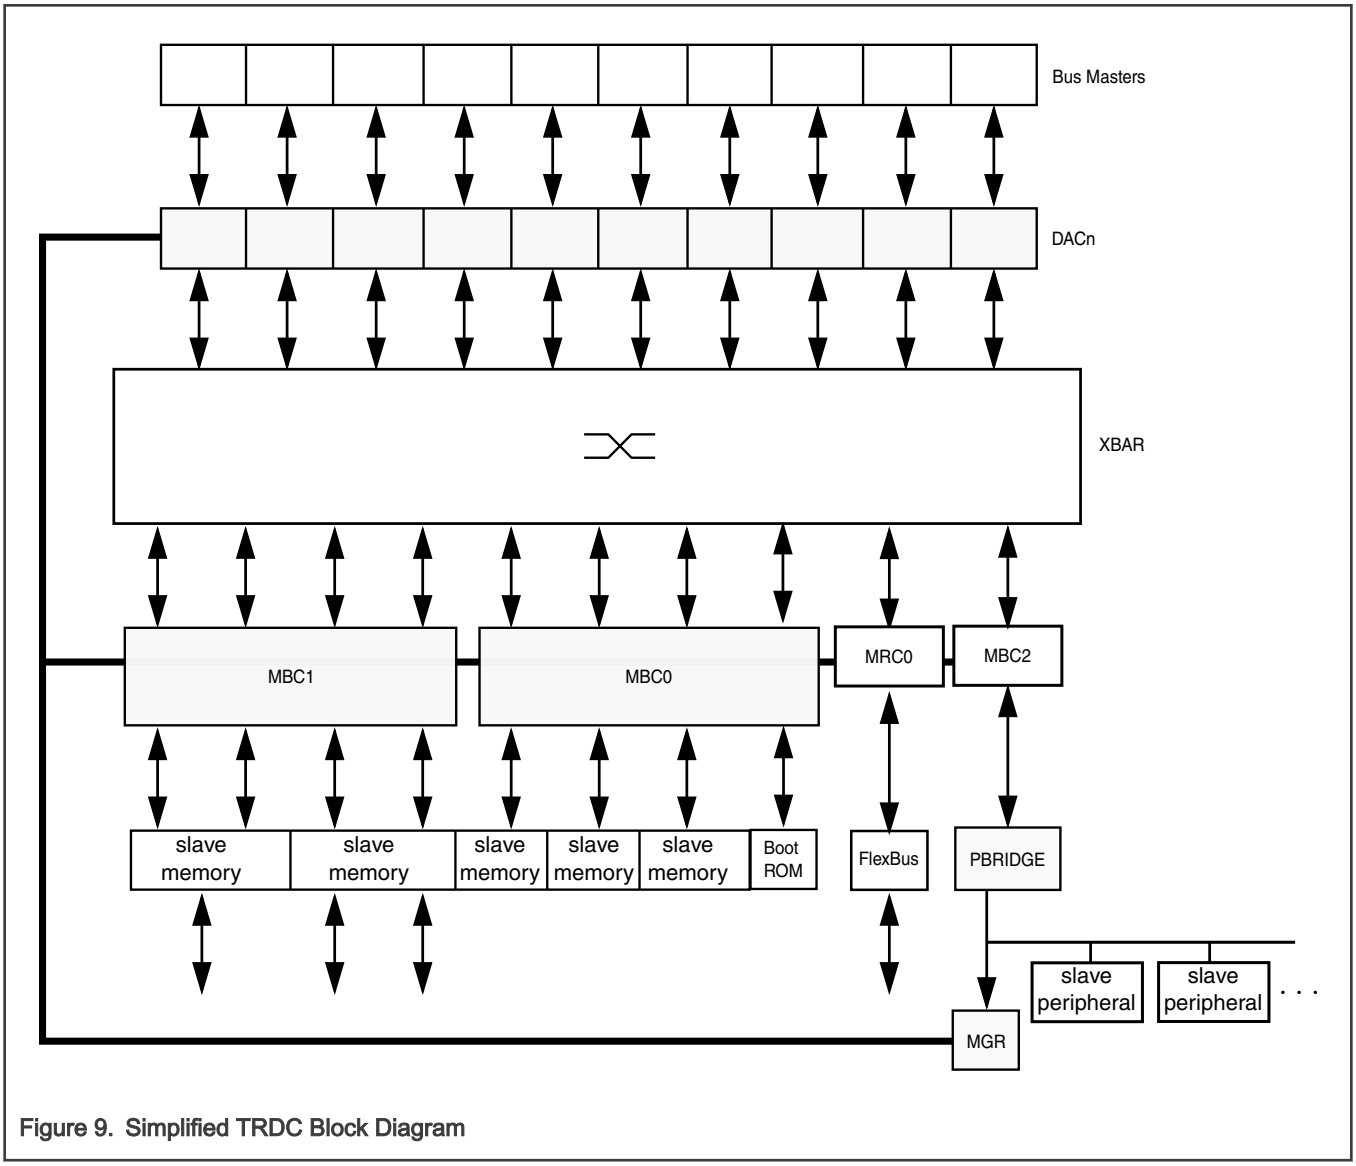

Figure 9. Simplified TRDC Block Diagram

9.2.2 Features

The key features of the TRDC include:

- Assignment of chip resources to processing "domains"
  - Processor cores, non-core bus masters, slave memories and slave peripherals
    - Processors typically assigned to unique domainIDs
    - Non-processor bus masters assigned to a shared domainID
    - Number of supported DIDs is typically (number of CPUs + 1)
  - Each processing domain is assigned a unique domain identifier (domainID, DID)
  - DomainID is an attribute associated with every system bus transaction
  - Used in conjunction with secure/nonsecure, privileged/user attributes
- Access rights to slave targets defined in memory block checkers for on-chip memories and peripherals and memory region checkers for external memories and peripherals
- Built upon a 4-level hierarchical access control model
  - SecurePriv > SecureUser > NonsecurePriv > NonsecureUser
  - Defined by multiple sets of user-programmable R/W/X (Read, Write, eXecute) flags per access state
- Programming model and hardware implementation is distributed across multiple submodules
  - Supports a broad, highly-configurable architecture definition
  - Supports efficient mechanisms for memory space context switch state changes using NSE (Nonsecure Enables) for memory blocks and regions

9.3 Functional description

This section provides more details on the operation and implementation of the TRDC submodules.

9.3.1 Modes of operation

The TRDC module does not support any special modes of operation. As a memory-mapped device located in the core platform's clock domain, it responds based strictly on the memory addresses of the connected system buses. Domain assignment and access control functions are evaluated on a reference-by-reference basis using the addresses and attributes connected to the system bus port(s).

9.3.2 Flash Logical Window

The FLW = Flash Logical Window logic provides a logical window (remapping) between a fixed physical address window and a programmable flash array window. Note that the whole flash image is also available at the normal flash array addresses.

The fixed physical address base and maximum window size is determined per project. The fixed physical address base is available in the read-only FLW Physical Base register. The functional size of the window is configured by programming the window size in the number of 32KByte blocks in the FLW Logical Block Count register. The flash array address base is set in the FLW Array Base register.

When the FLW is disabled, the physical address window is not mapped to any memory storage and all accesses to the window will fault. When the FLW is enabled, the physical address window, up to the size configured by the Logical Block Count, is mapped to the flash array window. When the FLW is enabled, access to the window beyond the size configured by the Logical Block Count will fault.

9.3.3 Manager (TRDC_MGR)

The MGR submodule is responsible for coordinating TRDC's programming model reads and writes.

The complete programming model is large. Additionally, the programming model is distributed across the various submodule instances (DAC, MBC, MRC). The MGR submodule provides the required hardware management for all programming model accesses, generating and distributing the appropriate address decodes and write data to the DAC, MBC and MRC submodule instances, collecting and combining all the register read data buses and responses.

MGR implements the Control Register, all the read-only hardware configuration registers (HWCFG[0-1], DACFGn, MBCFG, MRCFG) and the program-visible versions of the domain error capture registers. To support the domain error reporting functionality, the MGR submodule collects the individual captured error indicator output signals from all the submodule instances and remaps them so they are organized into an instance bitmap by domain as specified by the DERRLOCn register array.

9.3.4 Domain Assignment Controller (TRDC_DAC)

The DAC submodule is responsible for the generation of the domainID on every memory transaction for every bus master in the device. The resulting domainID and {nonsecure, privileged} signals are generated and then treated as address attributes and associated with each transaction as it moves through the system.

As a simple example, assume a system with two domainIDs.

- domainID 0 is for critical tasks.
- domainID 1 is for non-critical tasks.
- Two domainIDs require two MDA_Wm_n registers, MDA_W0 and MDA_W1.

During startup, software initializes the MDA_W[0-1] registers.

1. MDA_W0 = 0x8000_0F81
    - VLD = 1
    - PE = 2
    - DIDS = 0
    - DID = 1
2. MDA_W1 = 0x8000_0FC2
    - VLD = 1
    - PE = 3
    - DIDS = 0
    - DID = 2

A special mode is provided for driving the DID of non-processor masters. This is enabled with the DID bypass (DIDB) bit. The DAC has a DID input that can be driven by a master and used directly as the DID output. This allows variability in the DID as dictated by the master and is intended to be used by DMA masters that masquerade as, (that is, drive the DID of) the master that programmed it.

9.3.5 Access evaluation

Fundamental to the TRDC's operation is the actual access violation check performed by the memory block checker (MBC) and memory region (MRC).

Previous descriptions have detailed the domain assignment mechanisms and the tracking of the domain identifier as an address attribute through the system bus switching fabric(s). As transactions reach the slave memory and peripheral controllers, the address is used to select the appropriate memory region descriptor or block configuration register. Once the appropriate register has been selected, the next function is the actual access evaluation.

For this step, the 3-bit M{B,R}ACSEL field of the selected RGD or BLK_CFG register selects the appropriate GLBAC (global access control policy). The GLBAC register defines the access rights for the domain based on the 4-level model combined with the transaction's access attributes (read = 0/write = 1, secure = 0/nonsecure = 1, execute =1/non-execute=0, user = 0/privileged = 1).

The 4-level model is defined by the concatenation of two address attributes: secure/nonsecure and user/privileged attributes. These two attribute signals (nonsecure, privileged) and the resulting access levels are defined as:

```
if {nonsecure, privileged} == 0b00, then level = SecureUser
if {nonsecure, privileged} == 0b01, then level = SecurePriv(ileged)
if {nonsecure, privileged} == 0b10, then level = NonsecureUser
if {nonsecure, privileged} == 0b11, then level = NonsecurePriv(ileged)
```

The resulting hierarchical access control model specifies:

```
SecurePriv , SecureUser , NonsecurePriv , NonsecureUser
```

After the access evaluation is complete and the access error signal generated, the transaction is allowed to continue if it has sufficient access rights, else the access is aborted with the address and attribute information captured in the appropriate error registers.

9.3.6 Memory Block Checker (TRDC_MBC)

The TRDC's Memory Block Checker provides domain-based access control for all system bus references targeted to on-chip internal memories and slave peripherals. Using programmed block configuration registers which define the access rights per domain and block, the MBC concurrently monitors system bus transactions and evaluates the appropriateness of each transfer. Memory references that have sufficient access rights are allowed to complete, while references that have insufficient rights are terminated with an access error response.

The TRDC architectural framework supports up to 8 MBC instances where each MBC can support up to 4 sub-regions (MEM[s]). Note monitoring of an AXI memory counts as 2 sub-regions since there are independent read and write channels per AXI memory. Conversely, an AHB connection counts as a single subregion.

Each sub-memory is divided up in equal sized blocks. Sub-memory 0 (MEM0) can support up to 512 blocks while sub-memory 1-3 (MEM1-MEM3) can each support up to 64 blocks. The number of blocks and size of the block is defined in MBCm_MEMs_GLBCFG[NBLKS,SIZE_LOG2] register fields, where m is the MBC instance number, and s is the sub-memory number.

Each MBCm_DOMd_BLK_CFG_W contains eight access control structures. Each structure is comprised of a 1-bit NSE (NonSecure Enable) plus a 3-bit MBACSEL (Memory Block Access Control Select). The NSE controls secure/nonsecure access to the corresponding block, while the MBACSEL field selects a MBCm_MEMN_GLBACr register which controls the read/write/execute access to the corresponding block. There are 8 programmable MBCm_MEMn_GLBACr registers per block checker, each containing contain read-write-execute control flags for each of the four operating modes:

```
SPR, SPW, SPX - Secure    Privileged {Read, Write, Execute}
SUR, SUW, SUX - Secure    User       {Read, Write, Execute}
NPR, NPW, NPX - Nonsecure Privileged {Read, Write, Execute}
NUR, NUW, NUX - Nonsecure User       {Read, Write, Execute}
```

GLBAC1-7 also have a lock bit MBCm_MEMn_GLBACr[LK]. When LK=1, the GLBACr register is read-only until the next reset. Furthermore, if MBCm_DOMd_BLK_CFG_W[MBACSEL] selects a GLBAC that is locked, the 3-bit MBCACSEL field is also locked until the next reset. GLBAC0 cannot be locked.

The MBC also has MBCm_DOMd_MEMs_BLK_NSE_W registers. These registers are a bit map of the block NSE bits. Each word supports up to 32 blocks

```
MBCm_DOMd_MEM0_BLK_NSE_W[0-15] has a maximum of 16 words to support 512 blocks
MBCm_DOMd_MEM[1-3]_BLK_NSE_W[0-1] has a maximum of 2 words to support 64 blocks.
```

The block NSE bits can be programmed by writing these registers or by writing the MBCm_MEMN_BLK_{INDEX, SET, CLR, CLR_ALL} registers.

The MBCm_MEMn_NSE_BLK_{INDEX, SET, CLR, CLR_ALL} registers provide a mechanism to efficiently and quickly manipulate the NSE bitmap with bitmasks to set or clear individual blocks within the bitmap and a single operation to perform a clear all across multiple DIDs. The BLK_INDEX register provides the control definition for the BLK_SET and BLK_CLR operations.

9.3.6.1 Memory block hit determination

MBCm_MEMs_GLBCFG[NBLK, SIZE_LOG2] is used to determine which bits of the address correspond to block number.

```
block_n_hit = (addr[MSB:LSB] == n)
where LSB=SIZE_LOG2
MSB=f{NBLKS,LSB}
```

Note that the block hit determination is based only on the address comparison of the first byte being accessed; that is, the MBC does not check the size of the access to make sure it entirely fits within the region.

9.3.6.2 Memory block access evaluation

For a block n hit, the MBC logic evaluates the access rights defined by the MBCm_DOMd_BLK_CFG_Ww registers. The domainID attribute and block number hit selects the appropriate MBCm_DOMd_BLK_CFG_Ww register to use in the access evaluation. The {R,W,X}, nonsecure and privilege attributes of the access are compared with the MBC global access control policy defined in MBCm_DOMd_BLK_CFG_W[MBACSEL, NSE] fields.

While TRDC_CR[GVLDB] = 1, and for each sub-memory being monitored, the MBC performs a reduction-AND of all the individual error terms from each access evaluation.

Unlike the MRC access evaluation and termination, the MBC access evaluation terminates the access with a bus error and reports an access error for only one condition - when the access doesn't have sufficient access rights. By nature, the block checker can only hit in ONE block. And by implementation, there are no "miss" accesses. Accesses outside of the range covered by the MBC are not sent to the MBC. There also aren't any individual block valid bits. When TRDC_CR[GVLDB] = 1, checking on all blocks is always enabled.

9.3.7 Memory Region Checker (TRDC_MRC)

The TRDC's Memory Region Controller provides domain-based, hardware access control for all system bus references targeted at non-peripheral memory spaces. Using pre-programmed *region descriptors* which define memory spaces and their associated access rights per domain identifier, the MRC concurrently monitors system bus transactions and evaluates the appropriateness of each transfer. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with an access error response.

The TRDC architectural framework supports up to 16 MRC instances, where each MRC instance can support [1-16] region descriptors, concurrently monitoring up to 8 slave memory ports. Note, monitoring an AXI protocol port counts as two ports since there are independent read address and write address channels. Conversely, an AHB connection counts as a single port.

A partial, simplified one-dimensional block diagram of an instance of the MRC module is shown in Figure 10. In this figure, a single slave bus port is shown. When the remaining slave ports are considered, the MRC hardware's two-dimensional connection matrix, broadcasting each system bus slave port access across the implemented memory region descriptors, is the resulting structure with the basic access evaluation macro shown as the replicated submodule block. In Figure 10, the system bus fabric slave port is shown on the left, the memory region descriptor registers are in the middle, and the peripheral bus interface on the right side. The evaluation macro contains two magnitude comparators connected to the start and end address registers from each region descriptor as well as the combinational logic blocks to determine the region hit and, based on the domainID associated with the reference, access violations.

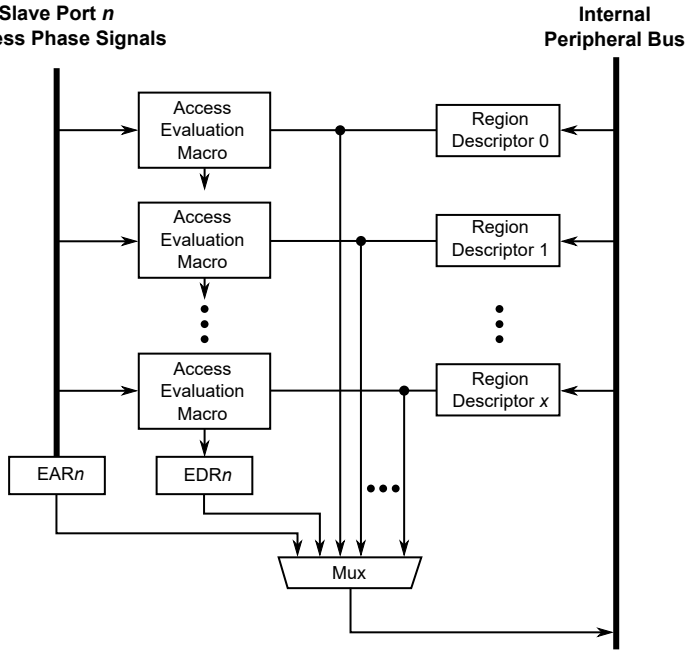

Figure 10. MRC access evaluation macro hardware structure

For each access, the MRC hardware performs a two-step evaluation process. First, the access is compared to all memory region descriptors to determine hit/miss status, and then, using the domainID associated with the reference plus the address attributes {write, nonsecure, privileged}, the access rights are examined using the method detailed in Access evaluation.

9.3.7.1 Memory region descriptor hit determination

To determine if the current reference hits in a given region, two magnitude comparators are used in conjunction with the region's start and end addresses. The boolean equation for this portion of the hit determination is defined as:

```
region_hit_n =
   ((addr >= start_addr) & (addr <= end_addr)) & valid
```

where `addr` is the current system reference address, `start_addr` and `end_addr` are the start and end addresses, and `valid` is the valid bit, all from memory region descriptor n.

Note there are *no hardware checks* to verify that `end_addr ≥ start_addr`, and it is software's responsibility to properly load appropriate values into these fields of the region descriptor.

Also, the region hit determination is based only on an address comparison of the first byte being accessed; that is, the MRC does *not* check the size of the access to make sure it entirely fits within the region.

9.3.7.2 Memory region access evaluation

For each region descriptor hit, the MRC logic evaluates the access rights defined by the MRCm_DOMd_RGDr_Ww registers. Specifically, the domainID attribute selects the appropriate MRCm_DOMd_RGDr_Ww register to use in the access evaluation. The {R,W,X}, nonsecure and privilege attributes of the access are compared with the MRC global access control policy defined in MRCm_DOMd_RGDr_W0[MRACSEL] and MRCm_DOMd_RGDr_W1[NSE] fields. See Access evaluation for additional details on this function.

While CR[GVLDR] = 1, and for each bus slave port being monitored, the MRC performs a **reduction-AND** of all the individual *(no_hit | error)* terms from each access evaluation macro. Recall as specified in Memory region descriptor hit determination, an *invalid* MRC_DOMd_RGDr_Ww (MRCm_DOMd_RGDr_W1[VLD] = 0) forces the region_hit_n evaluation to be negated.

This expression then terminates the bus cycle with an error and reports an access error for three conditions:

1. If the access does not hit in *any* region descriptor, an access error is reported.
2. If the access hits in a single region descriptor and that region signals a domain violation, then an access error is reported.
3. If the access hits in multiple (overlapping) regions and one region signals a violation, then an access error is reported.

The third condition reflects that priority is given to access denying over access allowing for overlapping regions.

Unimplemented domain IDs (DIDs) do not have any associated region descriptors and therefore have no access rights.

9.3.8 Interrupts

This module outputs an interrupt signal which can be connected to the system's interrupt controller. Please check chip specific interrupt assignment for details. Interrupt is asserted on detection of access violation by any checker, and it remains asserted until DERRLOCn registers are cleared

9.4 External signals

The TRDC module does not directly support any external interfaces.

The *internal* interfaces include a standard 32-bit slave bus for all programming model accesses, connections to the address phase signals associated with AHB and/or AXI system buses and connections to the slave peripheral buses as shown in TRDC block diagram.

9.5 Initialization

Out of reset, CR[GVLDR, GVLDB, GVLDM] bits are cleared, TRDC is disabled and in deny by default mode allowing secure privileged startup code to configure the entire programming model. In deny by default mode, only the DIDs that aren't denied by default are allowed to access memory and peripherals. The allowed DIDs are implementation defined. The initialization process typically is performed in 3 steps:

1. Read the various hardware configuration registers (HWCFG{0,1}, DACFGn, MBCm_MEMs_GLBCFG, MRC_GLBCFG) to obtain the implemented hardware capabilities for the device.
2. Using the information retrieved in Step 1 coupled with the desired domain architecture, program all the register data structures for domain assignment (MDA_Wm_n), memory block configuration (MBCm_DOMd_MEMs_BLK_CFG_Ww) and memory region descriptors (MRCm_DOMd_RGDr_Ww). There are individual valid bits included in these registers which typically would be asserted. Additionally, there are also lock mechanisms available if register settings need to be configured and marked as read-only.
3. Once the TRDC programming model is loaded, the CR is written with GVLD {R, B, M} asserted. Upon the assertion of the 3 GVLD bits, deny by default mode is exited and at that point, the TRDC is fully operational. The TRDC remains enabled until the next reset.

9.6 Application information

As described in Overview, the TRDC architecture is intended to provide a broad, highly-capable framework for access control, system memory protection and peripheral isolation. The resulting microarchitecture implementation is distributed throughout the core platform, highly configurable via hardware design parameters and software programmability.

9.6.1 Master domain assignments

The typical use case related to master domain assignments is to include one (or more) processor core(s) in a single domain, possibly coupled with other bus master devices like DMA, etc. The definition of a domain may be static, based simply on the combination of a processor and other optional bus masters. Alternatively, the processor's operation may be configured to dynamically select between a very small number of domains.

For example, "critical" tasks, whether safety-critical, performance-critical, etc. can be grouped together in one domain and all other tasks into a second domain. Non-processor bus masters typically have a single MDA_Wm_n configuration register associated with them. The domainID and {nonsecure, privileged} attributes are usually statically assigned, unless the module can "inherit" attributes from a processor programming it (certain modules like DMAs).

The MDA_Wm_n registers, along with the memory region descriptors and the peripheral domain access control registers all have lock features that allow the register resources to be converted into read-only resources to protect the written configuration.

9.6.2 Memory region descriptor management

There are important concepts to consider in managing the memory region descriptors.

Recall that the association between each MRCn instance and the slave memory regions it monitors is SoC-dependent. The device-specific configuration specifies the number of implemented memory region descriptors in a given instance and the specific port numbers associated with the slave memories being monitored.

9.6.3 Domain error capture management

Recall when a domain access violation is detected by either a memory region checker or a memory block checker, address and attribute information of the offending access is captured. The DERRLOCn read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_n and DERR_W1_n, the DERRLOCn registers provide the instance number details.

These registers are organized as a word array, *indexed by the faulting domain number*, with the contents of each register providing a bitmap signaling the instance number(s) associated with all submodules containing captured error information for that domain.

It is recommended that the exception handler begin by reading the HWCFG1 register to determine its domainID. Next, it uses the just-retrieved domainID to index into the DERRLOCn array. The resulting DERRLOCn value is then examined to determine the instance number of the reporting MBC and/or MRC submodule.

There may be multiple access violations, across multiple instances, pending for a given domain. It is suggested that exception handler use a "find first one" instruction (alternatively known as "count leading zeroes") to quickly and efficiently find the instance number containing access violation details. Once the instance number has been determined, the captured error address (DERR_W0_n) and attribute information (DERR_W1_n) can easily be retrieved from the domain error registers. The 2-bit DERR_W1_n[EST] field provides information signaling whether one or more errors have been detected by the submodule instance. A special write to DERR_W3_n is required to reset (and rearm) the EST error capture state machine.

This process is repeated until all errors associated with a given domainID have been processed.

A graphical representation of this 2-step retrieval of the domain error address and attributes is shown in Figure 11.

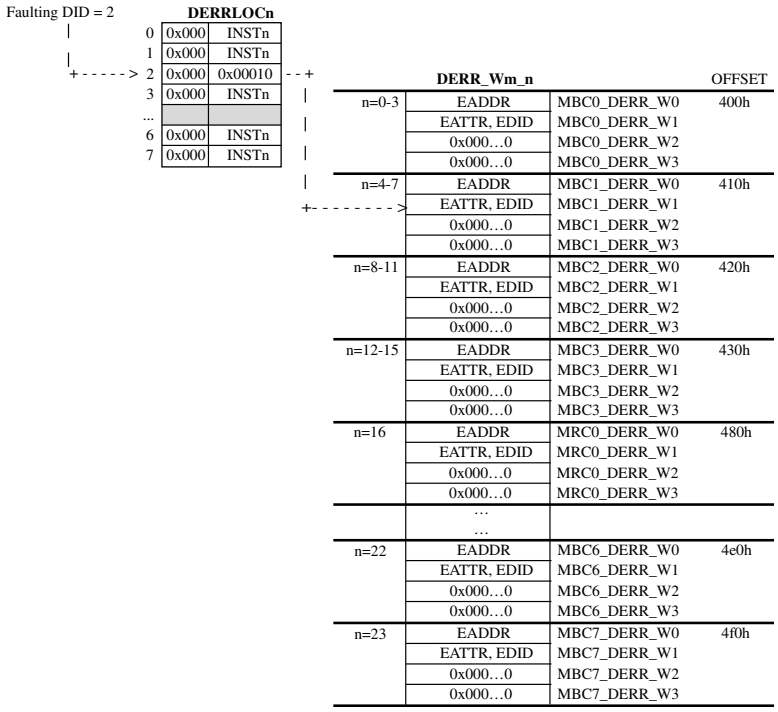

Figure 11. Two-step retrieval of domain error address and attributes

9.7 Register descriptions

If TZ-M is enabled, the TRDC programming model can only be accessed in SecurePrivileged mode. If TZ-M is disabled, it can only be accessed in Privileged mode regardless of Secure or NonSecure;q that is it can't be accessed in User mode. Unless noted otherwise, the programming model registers can be accessed via 8-, 16- or 32-bit reads and 32-bit write references. Attempted accesses in a different operating mode, using unsupported write data sizes, writes to read-only resources, or access to reserved spaces are terminated with an error unless noted otherwise. The TRDC programming model is partitioned into these groups of registers:

- Basic hardware control and configuration
- Domain errors: location and details
- Master domain assignments
- Memory block and region checkers

It should be noted that many of the programming model registers in TRDC are organized as 2-, 3- or 4- dimensional data structures. For the 2-dimensional structures, the generic arrays contain "m" words representing the "columns" and "n" instances of the structure representing the "rows". These may be described as `structure[n][m]`. They appear in the address space of the programming model memory map in the standard C language row-major layout, that is, the "m" words representing the "column" appear sequentially with the entire row replicated "n" times. The TRDC register structure uses the naming convention of *TRDC_<regname>_Wm_n*, where the column number "m" appears as a numeric suffix on the W (32-bit word) identifier, and the row identifier "n" appears as the final numerical suffix.

For the 4-dimensional structures, the generic arrays contain "m", "d", "s" or "r", and "w" indices corresponding to MBC/MRC instance, domain index, sub-memory or region index and word index. The naming convention for the MBC block configuration and MRC region descriptor word registers are: *MBCm_DOMd_MEMs_BLK_CFG_Ww* and *MRCm_DOMd_RGDr_Ww*

For the reset values in this section, a "*" indicates an initial value determined by the hardware configuration.

9.7.1.2 TRDC Register (TRDC_CR)

Offset

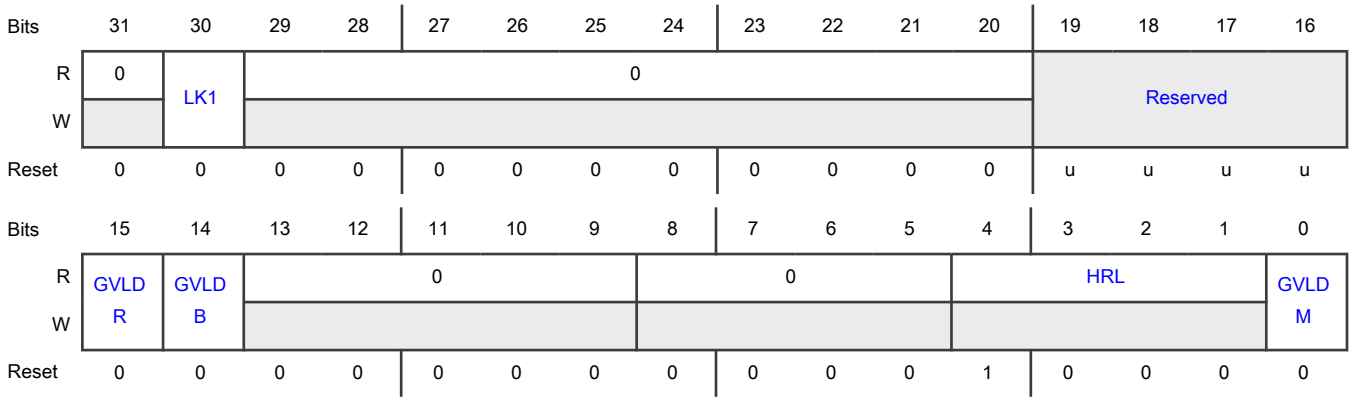
Register	Offset
TRDC_CR	0h

Function

This register provides status about the TRDC and global enable bits for the entire module's operation. A fully operational TRDC requires all global bits GVLD {R,B,M} to be asserted. Undefined behavior results if they are not all asserted. If there are no region checkers (MRCs) present in the configuration, GVLDR need not be asserted for a fully operational TRDC.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Diagram



Fields

Field	Function
31 —	Reserved
30 LK1	Lock Status This read-only field is the lock status of the TRDC_CR. This field is set when all GVLD bits are set; GVLDR=GVLDB=GVLDM=1b1. Once set, this bit remains asserted until the next reset. 0b - The CR can be written by any secure privileged write. 1b - The CR is locked (read-only) until the next reset.
29-20 —	Reserved
19-16 —	Reserved
15 GVLDR	Global Valid for Memory Region Checkers TRDC global MRC enable/disable. Once set, this bit remains set until the next reset. 0b - TRDC MRCs are disabled. 1b - TRDC MRCs are enabled.
14 GVLDB	Global Valid for Memory Block Checkers TRDC global MBC enable/disable. Once set, this bit remains set until the next reset. 0b - TRDC MBCs are disabled. 1b - TRDC MBCs are enabled.
13-9 —	Reserved
8-5 —	Reserved
4-1 HRL	Hardware Revision Level This read-only field specifies the TRDC's hardware and definition revision level. It can be read by software to determine the functional definition of the module.
0 GVLDM	Global Valid for Domain Assignment Controllers TRDC global DAC enable/disable. Once set, this bit remains set until the next reset. 0b - TRDC DACs are disabled. 1b - TRDC DACs are enabled.

9.7.1.3 Hardware Configuration Register 0 (TRDC_HWCFG0)

Offset

Register	Offset
TRDC_HWCFG0	F0h

Function

This read-only register contains information on the TRDC's hardware configuration. Specifically, it defines the number of implemented domains and bus masters along with the number of instances of memory block checkers (MBCs) and memory region checkers (MRCs). The register value at reset is device-specific. Attempted writes are error terminated.

Access: f TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Function
7-4 —	Reserved
3-0 NDID	Number of domains This read-only field defines the number of domains on the device [1-8].

9.7.1.4 TRDC Hardware Configuration Register 1 (TRDC_HWCFG1)

Offset

Register	Offset
TRDC_HWCFG1	F4h

Function

This register contains information on the TRDC's hardware configuration. It provides a mechanism for software to determine its domain number by simply reading the register. See Domain error capture management for more details on typical usage. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-3 —	Reserved
2-0 DID	Domain identifier number This field provides the domain number [0-7] of the requesting bus master.

9.7.1.5 Domain Assignment Configuration Register (DACFG0 - DACFG3)

Offset

Register	Offset
DACFG0	100h
DACFG1	101h
DACFG2	102h
DACFG3	103h

Function

This register defines the number of implemented domain assignment registers for bus master m, where m+1 can specify from 1 to 64 bus masters. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus master. Attempted writes are error terminated.

Register read will not return transfer error when DACFG for a master doesn't exist but it is in the same 32-bit group as DACFG for an existing master. For example, when there are only 2 DACFG0-1 registers for 2 master, and masters for DACFG2-3 don't exist, then access to DACFG2-3 won't return transfer error.

Typically, processor bus masters have one or more domain assignment registers, while non-processor masters have a single domain assignment register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram

Bits	7	6	5	4	3	2	1	0
R	NCM	0			NMDAR			
W								
Reset	See Register reset values.							

Register reset values

Register	Reset value
DACFG0	01h
DACFG1–DACFG3	81h

Fields

Field	Function
7 NCM	Non-CPU Master This read-only field signals that bus master m is a non-CPU master. It specifies that the format of the associated MDA_Wr_m register defines a non-processor domain assignment. This field is zero for a non-existent bus master.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Bus master is a processor. 1b - Bus master is a non-processor.
6-4 —	Reserved
3-0 NMDAR	Number of master domain assignment registers for bus master m This read-only field specifies the number of registers associated with the master domain assignment register for a given bus master. The value is limited to the range [0-8], where zero indicates a non-existent bus master and non-zero values indicate the number of implemented registers associated with this MDAm.

9.7.1.6 Memory Block Configuration Register (MBC0_CFG0)

Offset

Register	Offset
MBC0_CFG0	140h

Function

This register defines the hardware configuration of two of the sub-blocks within a memory block checker.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv read-only

Diagram

9.7.1.14 Memory Region Configuration Register (MRCFG0 - MRCFG7)

Offset

For r = 0 to 7:

Register	Offset
MRCFGr	160h + (r × 1h)

Function

This read-only register defines the number of implemented memory region descriptors for each MRCr, where r+1 can specify up to 16 instances. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. A zero value indicates a non-existent memory region checker instance. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram

Bits	7	6	5	4	3	2	1	0
R	0				NMRGD			
W								
Reset	See Register reset values.							

Register reset values

Register	Reset value
MRCFG0	08h
MRCFG1–MRCFG7	00h

Fields

Field	Function
7-5 —	Reserved
4-0 NMRGD	Number of memory region descriptors for memory region checker n Number of memory region descriptors for MRCr. This field specifies the number of memory region descriptors associated with a given memory region checker instance. The value is limited to the range [0-16], where zero indicates a non-existent MRC instance and non-zero values indicate the number of implemented memory region descriptors [0-16] associated with the TRDC_MRCm submodule.

9.7.1.15 TRDC IDAU Control Register (TRDC_IDAU_CR)

Offset

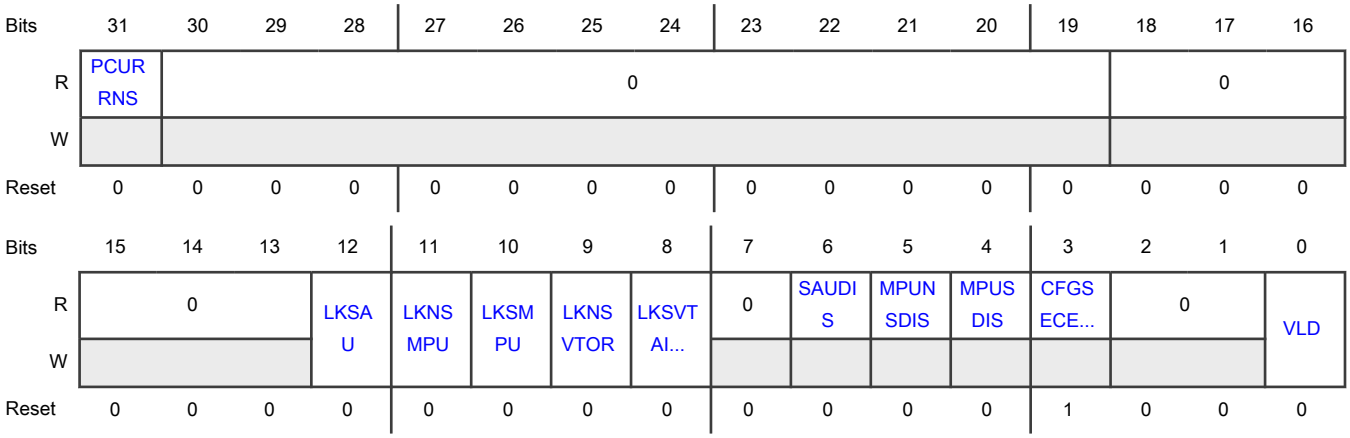
Register	Offset
TRDC_IDAU_CR	1C0h

Function

This register defines the configuration for the Implementation-Defined Attribution Unit which is tightly-coupled to the TZ-M extensions in the processor core. Many of the fields in this register explicitly control processor TZ-M functions.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Diagram



Fields

Field	Function
31 PCURRNS	Processor current security Current security state of the processor. 0b - Processor is in Secure state 1b - Processor is in Nonsecure state
30-19 —	Reserved
18-16 —	Reserved
15-13 —	Reserved
12 LKSAU	Lock SAU Asserting this bit prevents changes to the processor's Secure SAU memory regions already programmed. All processor writes to the registers are ignored. This bit is sticky, once set, it can only be cleared with a reset. 0b - Unlock these registers 1b - Disable writes to the SAU_CTRL, SAU_RNR, SAU_RBAR and SAU_RLAR registers from software or from a debug agent connected to the processor
11 LKNSMPU	Lock Nonsecure MPU Asserting this bit prevents changes to the processor's Nonsecure MPU memory regions already programmed. All processor writes to the registers are ignored. This bit is sticky, once set, it can only be cleared with a reset. 0b - Unlock these registers

Table continues on the next page...

Table continued from the previous page...

9.7.1.18 TRDC FLW Array Base (TRDC_FLW_ABASE)

Offset

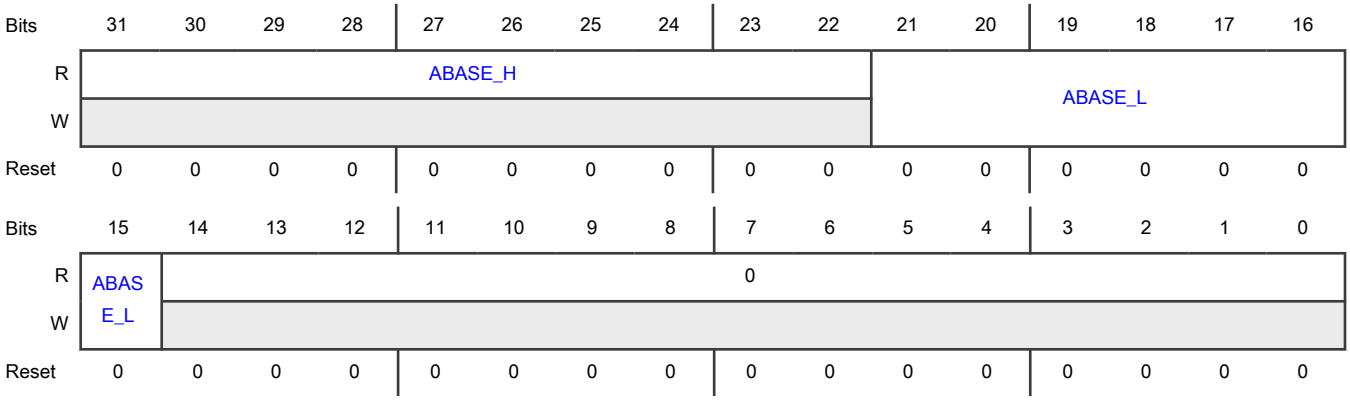
Register	Offset
TRDC_FLW_ABASE	1E8h

Function

This register gives the flash array base address of the Flash Logical Window.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write. This register is not writable if TRDC_FLW_CTL[LK]=1.

Diagram



Fields

Field	Function
31-22 ABASE_H	Array base address high Flash array address upper bits of the base of the FLW (mod 32KBytes).
21-15 ABASE_L	Array base address low Flash array address lower bits of the base of the FLW (mod 32KBytes).
14-0 —	Reserved

9.7.1.19 TRDC FLW Block Count (TRDC_FLW_BCNT)

Offset

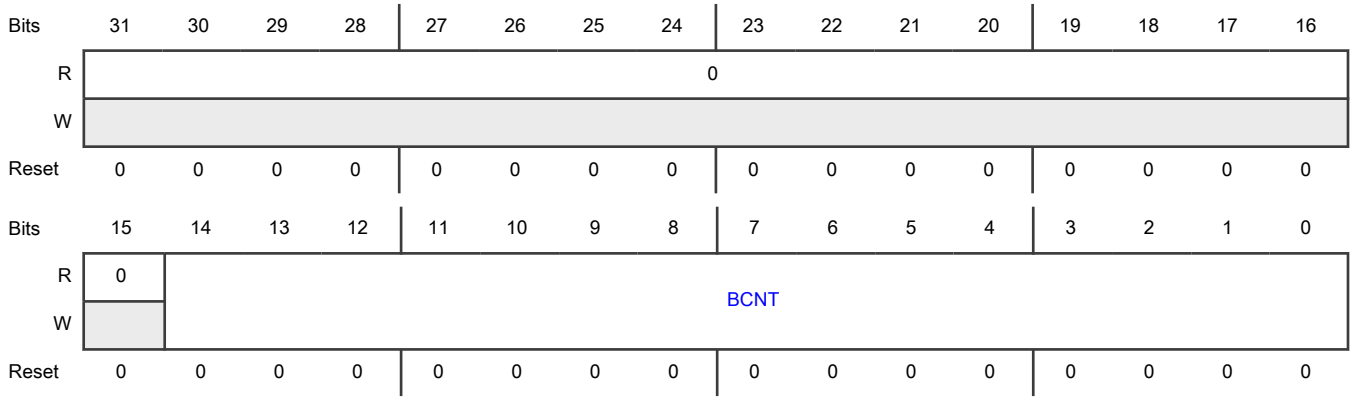
Register	Offset
TRDC_FLW_BCNT	1ECh

Function

This register gives the size of the Flash Logic Window in 32KByte blocks.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write. This register is not writable if TRDC_FLW_CTL[LK]=1.

Diagram



Fields

Field	Function
31-15 —	Reserved
14-0 BCNT	Block Count Size of FLW in number of 32KByte blocks.

9.7.1.20 TRDC Fault Domain ID (TRDC_FDID)

Offset

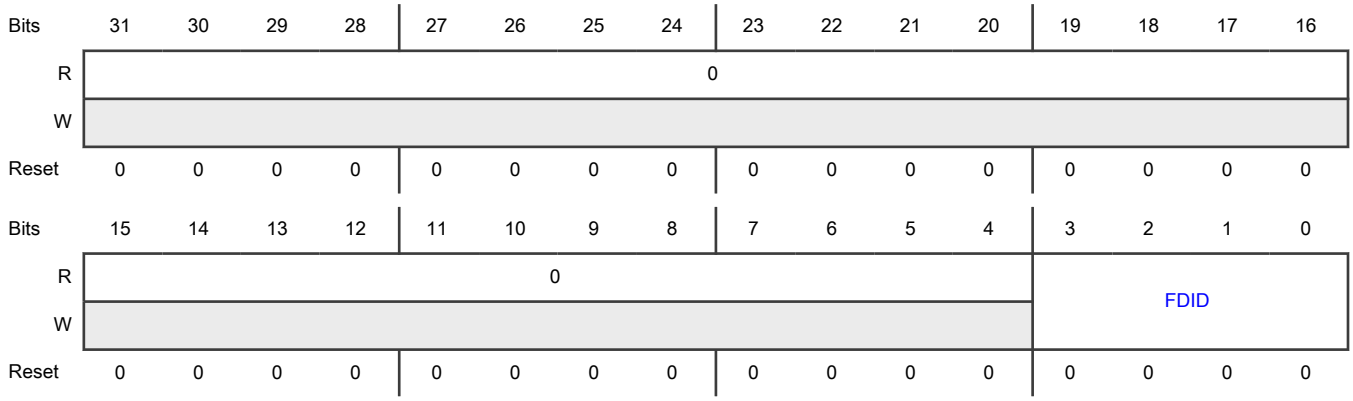
Register	Offset
TRDC_FDID	1FCh

Function

In the event of an access error, this register is used to specify the domainID of the faulting reference before indexing into the Domain Error registers.

If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 FDID	Domain ID of Faulted Access This field indicates the domainID of the fault used to index the array of domain error information. The user queries the DERRLOCx registers to find the DomainID of the faulting access and must write this register with the domain ID before reading the Domain Error registers.

9.7.1.21 TRDC Domain Error Location Register (TRDC_DERRLOC0 - TRDC_DERRLOC2)

Offset

Register	Offset
TRDC_DERRLOC0	200h
TRDC_DERRLOC1	204h
TRDC_DERRLOC2	208h

Function

This array of read-only registers provide the instance number of the submodule where (an) access violation(s) occurred. These registers are organized as a word array, indexed by the faulting domain number, d. The two fields of this register provide a bitmap of instances associated with all submodules containing captured error information for that domain. These instance numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, and DERR_W3_*i*register arrays. See Domain error capture management for more details.

When an access violation is detected by either a Memory Region Checker (MRC) or a Memory Block Checker (MBC), address and attribute information of the offending access is captured. Using the faulting domainID number as the index, d, this array of read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram

Fields

Field	Function
31-24 —	Reserved
23-16 MRCINST	MRC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MRC. The least-significant bit of this field (bit 16) corresponds to MRC instance 0. The most-significant bit of this field (bit 23) corresponds to MRC instance 7 (MRC instance = i-16 where i is the register bit number), and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MRCs. For each bit in this field: • 0 - The memory region checker has not detected an access violation or is not physically present. • 1 - The memory region checker has detected one or more access violations for this domain.
15-12 mbc3_err_slv	MBC3 ERROR SLAVE • 0001b - Error in Slave memory 0 • 0010b - Error in Slave memory 1 • 0100b - Error in Slave memory 2 • 1000b - Error in Slave memory 3
11-8 mbc2_err_slv	MBC2 ERROR SLAVE • 0001b - Error in Slave memory 0 • 0010b - Error in Slave memory 1 • 0100b - Error in Slave memory 2 • 1000b - Error in Slave memory 3
7-4	MBC1 ERROR SLAVE

Table continues on the next page...

Table continued from the previous page...

Field	Function
mbc1_err_slv	• 0001b - Error in Slave memory 0 • 0010b - Error in Slave memory 1 • 0100b - Error in Slave memory 2 • 1000b - Error in Slave memory 3
3-0 mbc0_err_slv	MBC0 ERROR SLAVE • 0001b - Error in Slave memory 0 • 0010b - Error in Slave memory 1 • 0100b - Error in Slave memory 2 • 1000b - Error in Slave memory 3

9.7.1.22 MBC Domain Error Word0 Register (MBC0_DERR_W0 - MBC2_DERR_W0)

Offset

Register	Offset
MBC0_DERR_W0	400h
MBC1_DERR_W0	410h
MBC2_DERR_W0	420h

Function

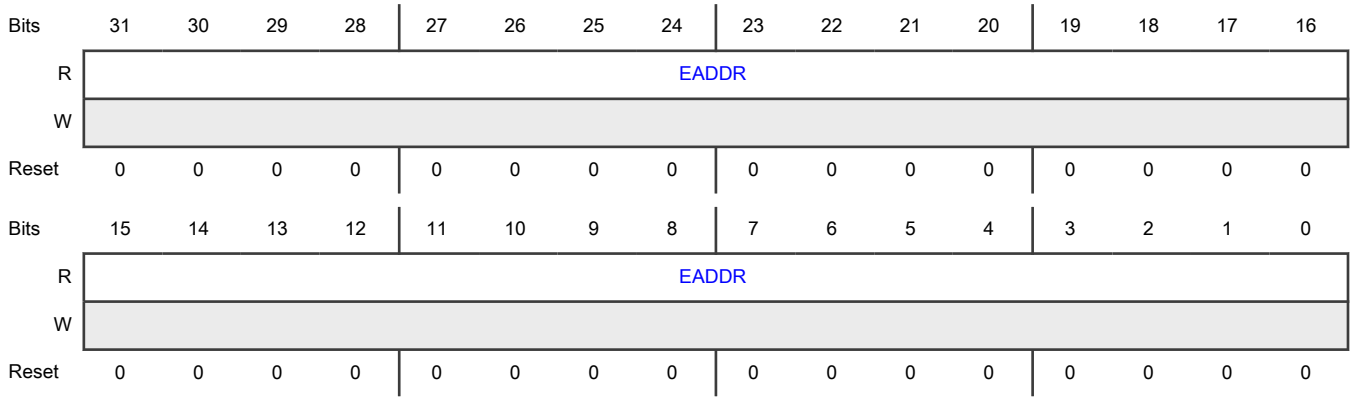
This read-only register array provides the address of an access violation detected by memory block checker (MBC). These registers are organized as a word array, which is indexed by the MBC instance number. That is, the index, i, of this array is the instance number of MBC with the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory mapped error capture detail registers are organized as 24 sequential 16 byte entries.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_i register. At that time, this register is cleared and re-enabled to capture the next access violation.

Attempted writes are error terminated as are attempted reads of an MBC instance that is not physically present.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram



Fields

Field	Function
31-0 EADDR	Error address This is the unaliased virtual address of the access that generated the access violation.

9.7.1.23 MBC Domain Error Word1 Register (MBC0_DERR_W1 - MBC2_DERR_W1)

Offset

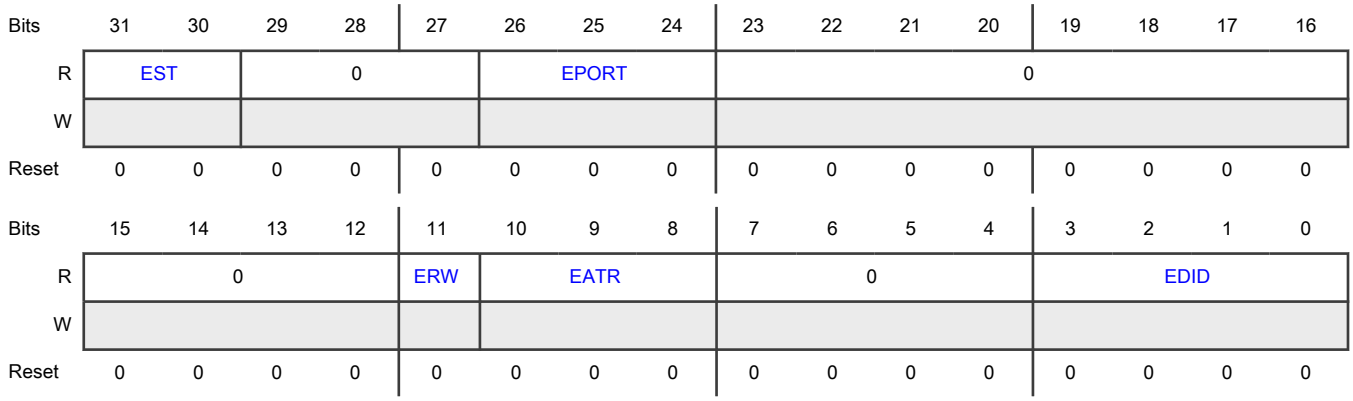
Register	Offset
MBC0_DERR_W1	404h
MBC1_DERR_W1	414h
MBC2_DERR_W1	424h

Function

This read-only register array provides the attributes of an access violation detected by Memory Block Checker (MBC). These registers are organized as a word array, which is indexed by the violating submodule instance number. Refer to register Domain Error Location(DERRLOCd), Domain Error Word0 Register(DERR_W0_i), and Domain error capture management for more information.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram



Fields

Field	Function
31-30 EST	Error state This field signals the state of access violations for this domain in this instance of the block checker or region checker. Once an access violation has been detected and the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. After retrieving the faulting address and attributes, the error capture mechanism must be rearmed by performing a write to DERR_W3_i. 00b - No access violation has been detected. 01b - No access violation has been detected. 10b - A single access violation has been detected. 11b - Multiple access violations for this domain have been detected by this submodule instance. Only the address and attribute information for the first error have been captured in DERR_W0_i and DERR_W1_i.
29-27 —	Reserved
26-24 EPORT	Error port This field identifies the encoded port number of the MBC that detected the access violation. The MBC port number connection is device-specific. See the chip configuration details for more information. This is the the MBC slave that has the violation. 000b - mbcxslv0 001b - mbcxslv1 010b - mbcxslv2 011b - mbcxslv3
23-12 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
11 ERW	Error read/write This field signals whether the captured access violation occurred on a read or write reference. 0b - Read access 1b - Write access
10-8 EATR	Error attributes This field captures attributes of the access violation. 000b - Secure user mode, instruction fetch access. 001b - Secure user mode, data access. 010b - Secure privileged mode, instruction fetch access. 011b - Secure privileged mode, data access. 100b - Nonsecure user mode, instruction fetch access. 101b - Nonsecure user mode, data access. 110b - Nonsecure privileged mode, instruction fetch access. 111b - Nonsecure privileged mode, data access.
7-4 —	Reserved
3-0 EDID	Error domain identifier This field captures the domain identifier of the access violation.

9.7.1.24 MBC Domain Error Word3 Register (MBC0_DERR_W3 - MBC2_DERR_W3)

Offset

Register	Offset
MBC0_DERR_W3	40Ch
MBC1_DERR_W3	41Ch
MBC2_DERR_W3	42Ch

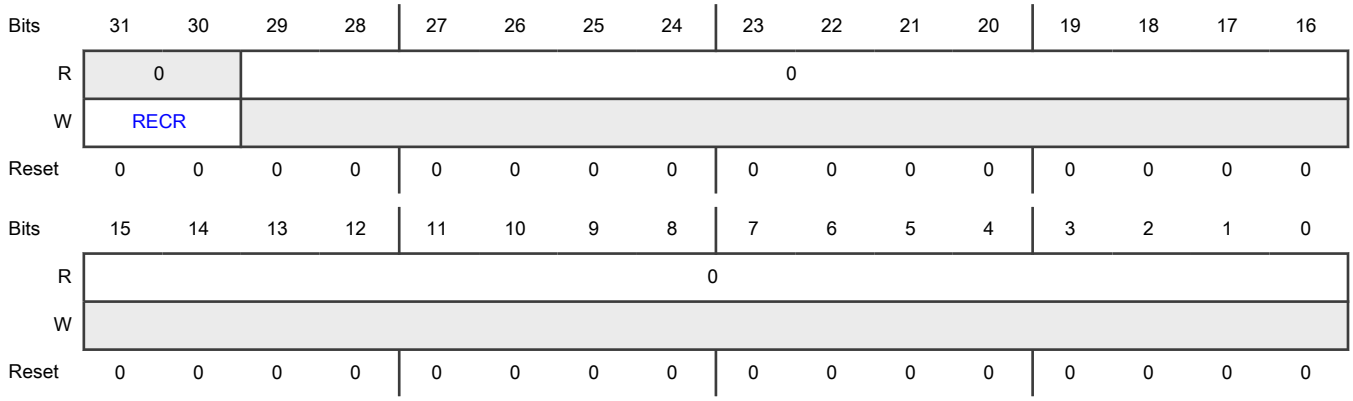
Function

This register is used to rearm the error capture logic and clear the DERR_W0_i and DERR_W1_i registers. After the domain access violation error details have been read, typically in an exception service routine, a 32-bit word write to this register is required to rearm the error capture logic.

A read of this location returns zeroes. Attempted reads of a Memory Region Checker (MRC) or Memory Block Checker (MBC) instance that is not physically present are error terminated.

See Domain error capture management for more details.

Diagram



Fields

Field	Function
31-30 RECR	Rearm Error Capture Registers This 2-bit, write-only field controls the rearming of the domain error capture registers. Once an access violation has been detected with the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. Writing 01b to this field rearms the error capture mechanism and clears the DERR_W0_i and DERR_W1_i registers. A write of any value other than 01b has no effect.
29-0 —	Reserved

9.7.1.25 MRC Domain Error Word0 Register (MRC0_DERR_W0)

Offset

Register	Offset
MRC0_DERR_W0	480h

Function

This read-only register array provides the address of an access violation detected by memory region checker (MRC). These registers are organized as a word array, which is indexed by the MRC instance number. That is, the index, i, of this array is the instance number of MRC with the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory mapped error capture detail registers are organized as 24 sequential 16 byte entries.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_i register. At that time, this register is cleared and re-enabled to capture the next access violation.

Attempted writes are error terminated as are attempted reads of an MRC instance that is not physically present.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

31-0 EADDR	Error address This is the unaliased virtual address of the access that generated the access violation.

9.7.1.26 MRC Domain Error Word1 Register (MRC0_DERR_W1)

Offset

Register	Offset
MRC0_DERR_W1	484h

Function

This read-only register array provides the attributes of an access violation detected by memory region checker (MRC). These registers are organized as a word array, which is indexed by the violating submodule instance number. Refer to register Domain Error Location(DERRLOCd), Domain Error Word0 Register(DERR_W0_i), and Domain error capture management for more information.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Fields

Field	Function
31-30 EST	Error state This field signals the state of access violations for this domain in this instance of the block checker or region checker. Once an access violation has been detected and the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. After retrieving the faulting address and attributes, the error capture mechanism must be rearmed by performing a write to DERR_W3_i. 00b - No access violation has been detected. 01b - No access violation has been detected. 10b - A single access violation has been detected. 11b - Multiple access violations for this domain have been detected by this submodule instance. Only the address and attribute information for the first error have been captured in DERR_W0_i and DERR_W1_i.
29-27 —	Reserved
26-24 EPORT	Error port This field identifies the encoded port number of the MRC that detected the access violation. The MRC port number connection is device-specific. See the chip configuration details for more information.
23-12 —	Reserved
11 ERW	Error read/write This field signals whether the captured access violation occurred on a read or write reference. 0b - Read access 1b - Write access
10-8 EATR	Error attributes This field captures certain attributes of the access violation. 000b - Secure user mode, instruction fetch access. 001b - Secure user mode, data access. 010b - Secure privileged mode, instruction fetch access. 011b - Secure privileged mode, data access. 100b - Nonsecure user mode, instruction fetch access. 101b - Nonsecure user mode, data access. 110b - Nonsecure privileged mode, instruction fetch access. 111b - Nonsecure privileged mode, data access.

9.7.1.28 DAC Master Domain Assignment Register (MDA_W0_0_DFMT0)

Offset

Register	Offset
MDA_W0_0_DFMT0	800h

Function

The MDA_Wr_m registers provide a 2-dimensional data structure for assigning bus masters to domains. The number of implemented registers is defined by DACFGm[NMDAR]. This per-master domain assignment is then repeated for each bus master (MDAm). Thus, m specifies the master number and r refers to the specific MDA register for a given bus master.

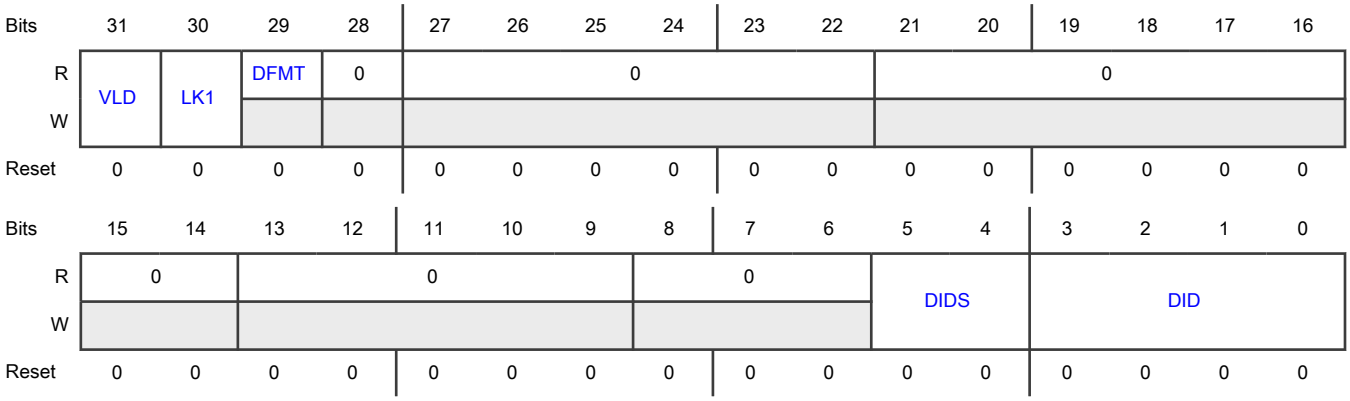
Each Wr within the MDAm structure is a word-sized definition; there are two formats supported, one for processor cores and another for non-processors. Processor masters typically support one or more Wr domain definitions, while non-processor masters support a single Wr.

The DAC submodule is responsible for the generation of domain identifiers for every transaction from every bus master. If there is a single Wr for a given master, then the specified domain identifier is used directly. If there are multiple Wr values for a given master, then the DAC evaluates the conditional terms to determine a “hit”. For all Wr hits, their corresponding domain identifiers are simply logically summed together (boolean OR). Use cases are typically expected to *hit in a single Wr* for a processor master. Special care is needed if *none* of the conditional terms hit in any Wr evaluation; for this case, the generated DID = 0 and software needs to be aware of any potential access rights granted for this DID.

Each MDA_Wr_m register has one of two programming models depending on the state of the domain format field, DFMT. The model described in this section is for DFMT = 0. This definition allows three different specifications of the DID for processors. The DFMT = 1 model is described in Master Domain Assignment (MDA_Wr_m_DFMT1) register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write

Diagram



Fields

Field	Function
31 VLD	Valid This field indicates the domain assignment is valid. It is further qualified by CR[GVLDM] = 1. If CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0b - The Wr domain assignment is invalid. 1b - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0b - Register can be written by any secure privileged write. 1b - Register is locked (read-only) until the next reset.
29 DFMT	Domain format Identifies this register's domain assignment format. **NOTE** This bitfield access is ROZ 0b - Processor-core domain assignment 1b - Non-processor domain assignment
28 —	Reserved

8-6 —	Reserved
5-4 DIDS	DID Select This field selects the source of the domain identifier. 00b - Use MDAm[3:0] as the domain identifier. 01b - Use the input DID as the domain identifier. 10b - Use MDAm[3:2] concatenated with the low-order 2 bits of the input DID (DID_in[1:0]) as the domain identifier. 11b - Reserved for future use.
3-0 DID	Domain identifier This 4-bit field is the domain ID attribute that is sent on the accesses from the bus master connected to the DAC when DIDS=00b. DID[3:2] is used when DIDS=10b

9.7.1.29 DAC Master Domain Assignment Register (MDA_W0_1_DFMT1 - MDA_W0_3_DFMT1)

Offset

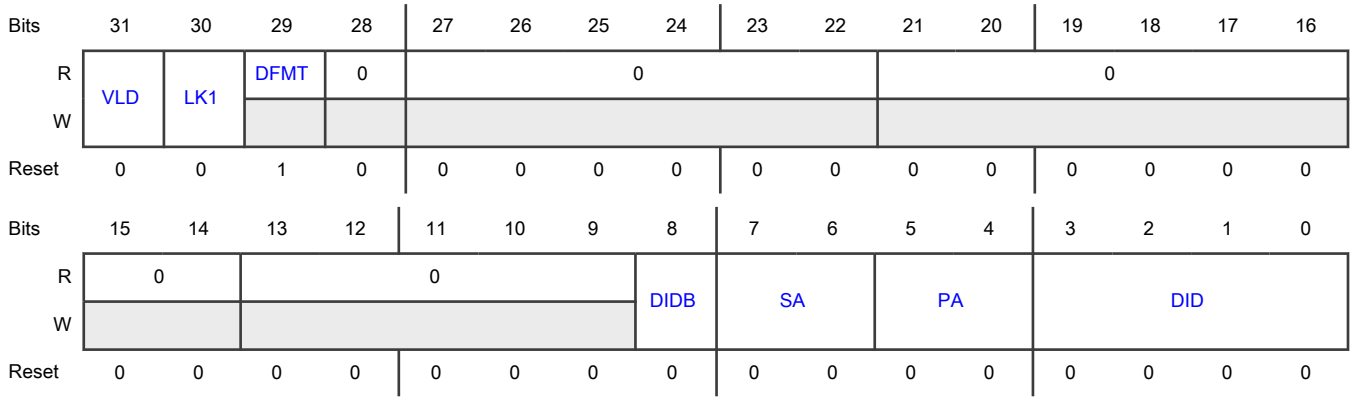
Register	Offset
MDA_W0_1_DFMT1	820h
MDA_W0_2_DFMT1	840h
MDA_W0_3_DFMT1	860h

Function

This register is identical to Master Domain Assignment (MDA_Wr_m_DFMT0) register except that the domain format field, DFMT, is 1 and the PID field is not used. This format supports two different specifications of the DID for non-core bus masters.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write

Diagram



Fields

Field	Function
31 VLD	Valid This field indicates the domain assignment is valid. It is further qualified by CR[GVLDM] = 1. If CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0b - The Wr domain assignment is invalid. 1b - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0b - Register can be written by any secure privileged write. 1b - Register is locked (read-only) until the next reset.

5-2 WNDX	Word index into the block NSE bitmap. It selects the BLK_NSE_Wn register, where WNDX determines the value of n.
1 —	Reserved
0 —	Reserved

9.7.1.32 MBC NonSecure Enable Block Set (MBC0_NSE_BLK_SET - MBC2_NSE_BLK_SET)

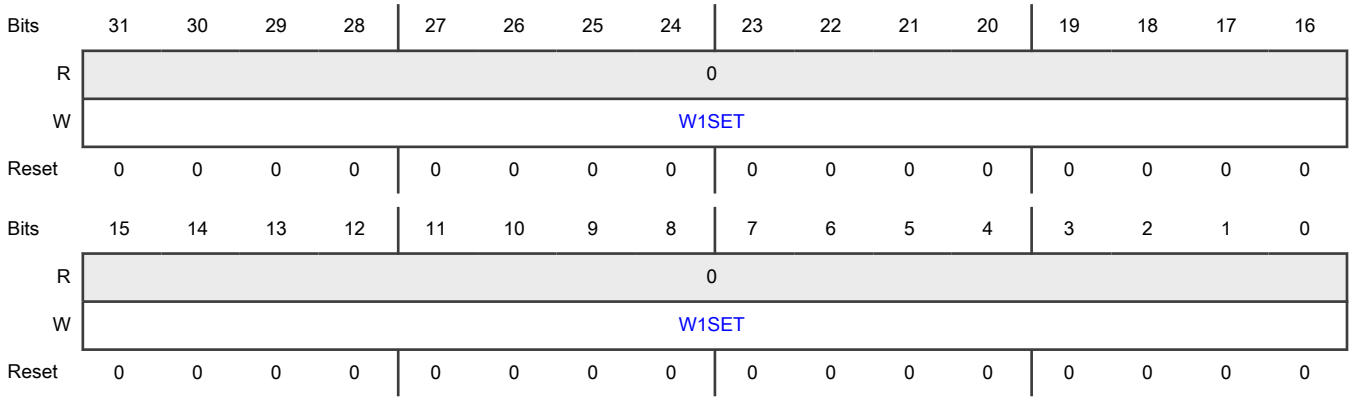
Offset

Register	Offset
MBC0_NSE_BLK_SET	1014h
MBC1_NSE_BLK_SET	2014h
MBC2_NSE_BLK_SET	3014h

Function

A write to this register sets the appropriate NSE Bits for the selected domains and memories defined at the word location NSE_BLK_INDEX[WDNX]. If NSE_BLK_INDEX[AI] = 1, then the NSE_BLK_INDEX[WDNX] field is incremented by 1 (modulo-16) after the write is completed. This register reads as zero.

Diagram



Fields

Field	Function
31-0 W1SET	Write-1 Set If set to 1, sets appropriate NSE bit for the selected domains and memories defined at the word location NSE_BLK_INDEX[WDNX]. Write with value 0 has no effect.

9.7.1.33 MBC NonSecure Enable Block Clear (MBC0_NSE_BLK_CLR - MBC2_NSE_BLK_CLR)

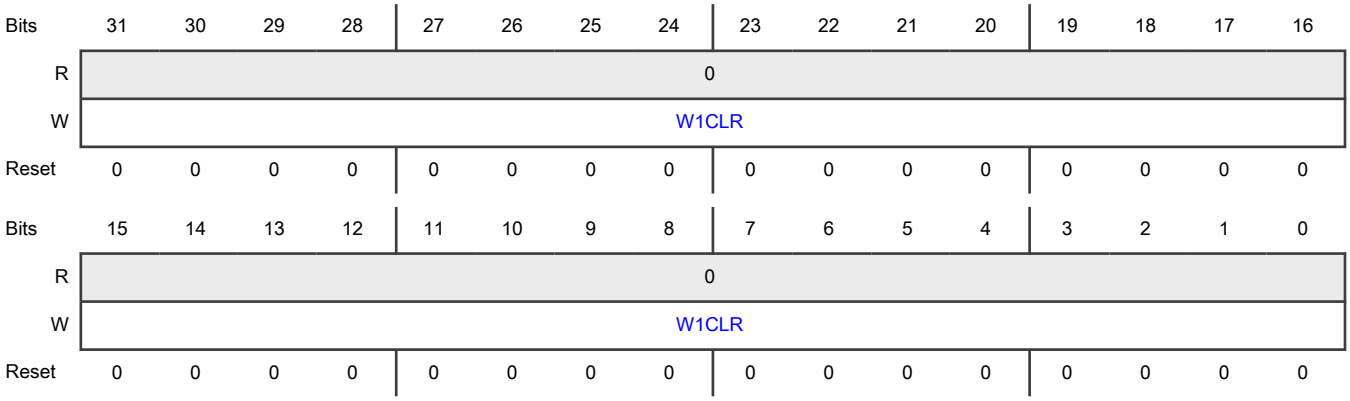
Offset

Register	Offset
MBC0_NSE_BLK_CLR	1018h
MBC1_NSE_BLK_CLR	2018h
MBC2_NSE_BLK_CLR	3018h

Function

A write to this location clears the appropriate NSE bits as defined by the W1CLR[n]=1 for the selected domains and memories Defined at the word location NSE_BLK_INDEX[WDNX]. If NSE_BLK_INDEX[AI] = 1, then the NSC_BLK_INDEX[WDNX] field is incremented by 1 (modulo-16) after the write is completed. This register reads as zero.

Diagram



Fields

Field	Function
31-0 W1CLR	Write-1 Clear If set to 1, Clear the appropriate NSE bit for the selected domains and memories defined at the word location NSE_BLK_INDEX[WDNX]. Write with value 0 has no effect.

9.7.1.34 MBC NonSecure Enable Block Clear All (MBC0_NSE_BLK_CLR_ALL - MBC2_NSE_BLK_CLR_ALL)

Offset

Register	Offset
MBC0_NSE_BLK_CLR_ALL	101Ch
MBC1_NSE_BLK_CLR_ALL	201Ch
MBC2_NSE_BLK_CLR_ALL	301Ch

Function

A write to this location clears all the block NSE bits for the selected domains and memories defined in the write data. This register reads as zero.

Diagram

Function

MBC[m]_DOM[d]_MEM[s]_BLK_CFG_W[w], where,

- m - mbc index
- d - domain index
- s - memory slave index
- w - word index

These registers are read/write for both the alternate view of the NSE bit and the 3-bit MBACSEL field. This is an array of 4 bit fields defining the block configuration for the given submemory. Each 4-bit field includes an alternative view of the associated NSE bit plus a 3-bit access control select that selects the global access control value that applies to the referenced memory block.

For a given memory block, B, if the value programmed in the MBACSELn field selects a locked MBC_MEMN_GLBACr register, the MBACSEL field is locked until the next reset. Depending on BLK_CFG_W, the NSEn/MBASELn fields correspond to different blocks. The following table describes the relationship between W (word index) and B (block number).

MEM0 supports up to 512 blocks ; W0 - W63

MEM1-3 supports up to 64 block ; W0 - W7

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

Function

MBC[m]_DOM[d]_MEM[s]_BLK_NSE_W[w], where,

- m - mbc index
- d - domain index
- s - memory slave index
- w - word index

This is the bitmap of the individual NSE bits for the memory block.

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

The following table describes the relationship between W (word index) and B (block number).

Table 36. Block Config Word to Block Number Relationship

Block NSE Word	BIT31	BIT30-BIT1	BIT0
W0	block 31	block 30 - block 1	block 0
W1	block 63	block 62 - block 33	block 32
For MEM0, block 64 - block 511			
W2	block 95	block 94 - block 65	block 64
. . .			
W3	block 511	block 510 - block 481	block 480

The NSE bitmap can be accessed directly by register reads and writes to these locations, or "indirectly" through writes to NSE_SET, NSE_CLR, NSE_CLR_ALL, and BLK_CFG[NSEn] registers.

9.7.1.39 MBC Global Access Control (MBC1_MEMN_GLBAC0)

Offset

Register	Offset
MBC1_MEMN_GLBAC0	2020h

Function

These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, Nonsecure User. The lock bit provides the ability to lock these contol access flags and to lock the MBC_BLK_CFG[MBACSEL] field when a locked MBC_MEMN_GLBAC register is selected.

Diagram

MBC1_MEMN_GLBAC5	2034h
MBC1_MEMN_GLBAC6	2038h
MBC1_MEMN_GLBAC7	203Ch

Function

These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, Nonsecure User. The lock bit provides the ability to lock these contol access flags and to lock the MBC_BLK_CFG[MBACSEL] field when a locked MBC_MEMN_GLBAC register is selected.

9.7.1.50 MRC Region Descriptor Word 0 (MRC0_DOM0_RGD0_W0 - MRC0_DOM2_RGD7_W0)

Offset

For d = 0 to 2; r = 0 to 7:

Register	Offset
MRC0_DOMd_RGDr_W0	4040h + (d × 100h) + (r × 8h)

Function

MRC[m]_DOM[d]_RGD[r]_W[w], where,

- m - mrc index
- d - domain index
- r - region descriptor index
- w - word index

The MRC[m]_DOM[d]_RGD[r]_W[w] registers provide a 3-dimensional data structure for defining access control policies per domain for each supported memory region.

Memory map/register definition:

There two word-size registers (W[w]) defined in each memory region. There are up to 8 memory region checkers (MRCs), m, each supporting up to 16 memory region descriptors (RGD), r. The number of MRCs is defined by HWCFG0[NMRC].

Diagram

10.1.1 Module instances

This device has one instance of the eDMA module.

10.1.2 Direct Memory Access Multiplexer (DMAMUX)

10.1.2.1 DMAMUX0 request sources

The peripheral request line for each channel of the Enhanced Direct Memory Access Controller 0 (eDMA0) is driven from a Direct Memory Access Multiplexer (DMAMUX). This is a flexible configuration that allows the user to select the appropriate peripheral to connect to each channel of the DMA Controller. The DMAMUX for this device allows up to 64 DMA request signals to be mapped to each channel. Because of the mux, there is not a correlation between any of the DMA request sources and a specific DMA channel.

The DMAMUX is an integrated component of the DMA Controller. This allows each DMA channel and DMA Multiplexer to configured as secure or non-secure on initial configuration of the device and not be changed without the correct permissions. For more information, please refer to the DMA Controller (DMA) chapter of the reference manual.

10.2 Overview

The enhanced direct memory access (eDMA) controller is capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 16 channels

10.2.1 Block diagram

Figure 12 illustrates the components of the eDMA system, including the eDMA module (engine).

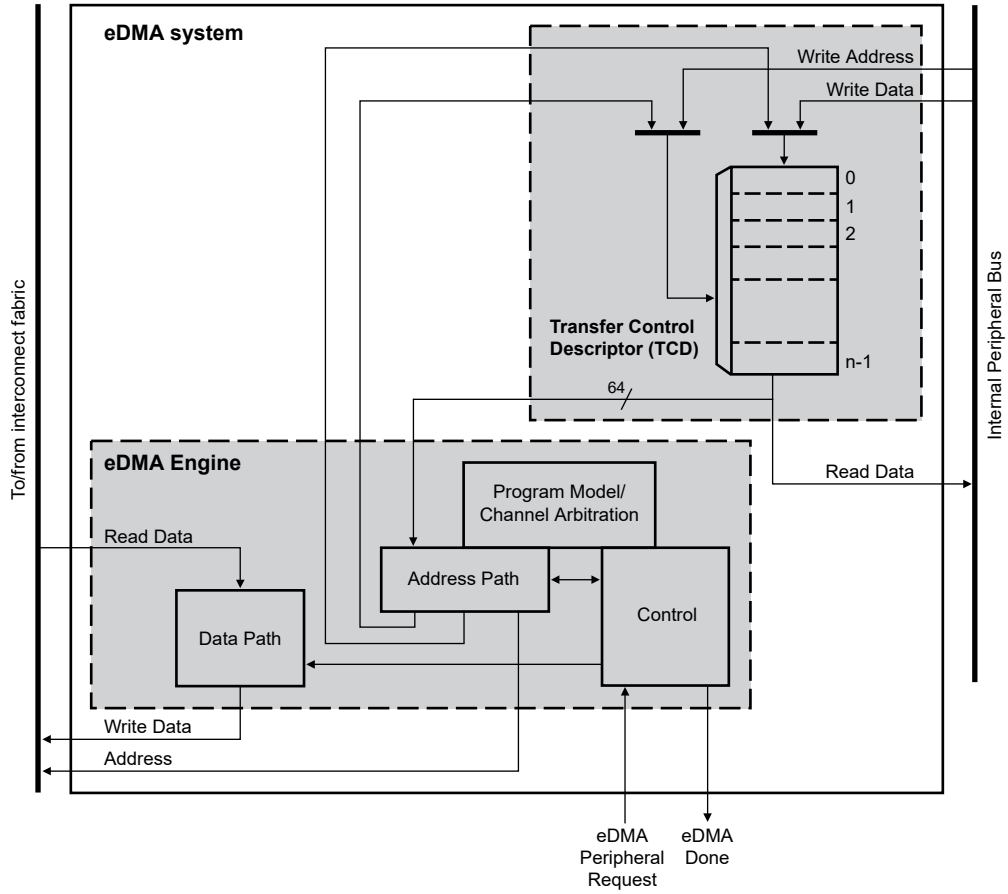

Figure 12. Block diagram

10.2.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 39. eDMA engine submodules

Submodule	Function
Address path	This block: • Implements a primary channel and secondary (preempt) channel • Manages all master bus-address calculations All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the primary channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by CH*n*_PRI[ECP]) where a large data transfer can be preempted to minimize the time another channel is blocked from execution.

Table continues on the next page...

Table 39. eDMA engine submodules (continued)

Submodule	Function
	When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD*n*_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCD*n*_CITER field, and a possible fetch of a new TCD*n* from memory as part of a scatter/gather operation. See Dynamic scatter/gather for more details.
Data path	This block implements the bus master read/write data path. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output. The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the first stage of the bus pipeline (address phase), and the data path module implements the second stage of the pipeline (data phase).
Program model/channel arbitration	This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
Control	This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has been moved from the source to the destination. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, the eDMA performs two reads, then one 32-bit write.

The transfer control descriptor local memory is further partitioned into:

Table 40. Transfer control descriptor memory

Submodule	Description
Memory controller	This logic implements the required dual-ported controller, and manages accesses from the eDMA engine as well as references from the internal peripheral bus. In simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
Memory array	TCD storage for each channel's transfer profile.

10.2.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and is not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for complex address calculations
- 16-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage for all transfers

  - Connections to the crossbar switch for bus mastering the data movement
- TCD organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests
  - One interrupt per channel, which can be asserted at completion of major iteration count
  - Programmable error terminations per channel that are logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing
- Support for complex data structures

In the discussion of this module, *n* is used to reference the channel number.

10.3 Functional description

The operation of eDMA is described in the following subsections.

10.3.1 Modes of operation

The eDMA operates in the following modes:

Table 41. Modes of operation

Mode	Description
Normal	In Normal mode, eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with eDMA. A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the TCD. The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.
Debug	eDMA operation is configurable in Debug mode via the control register: • If CSR[EDBG] is cleared to 0, eDMA continues to operate. • If CSR[EDBG] is set to 1, eDMA stops transferring data. If Debug mode is entered when a channel is active, eDMA continues operation until the channel retires.

10.3.2 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

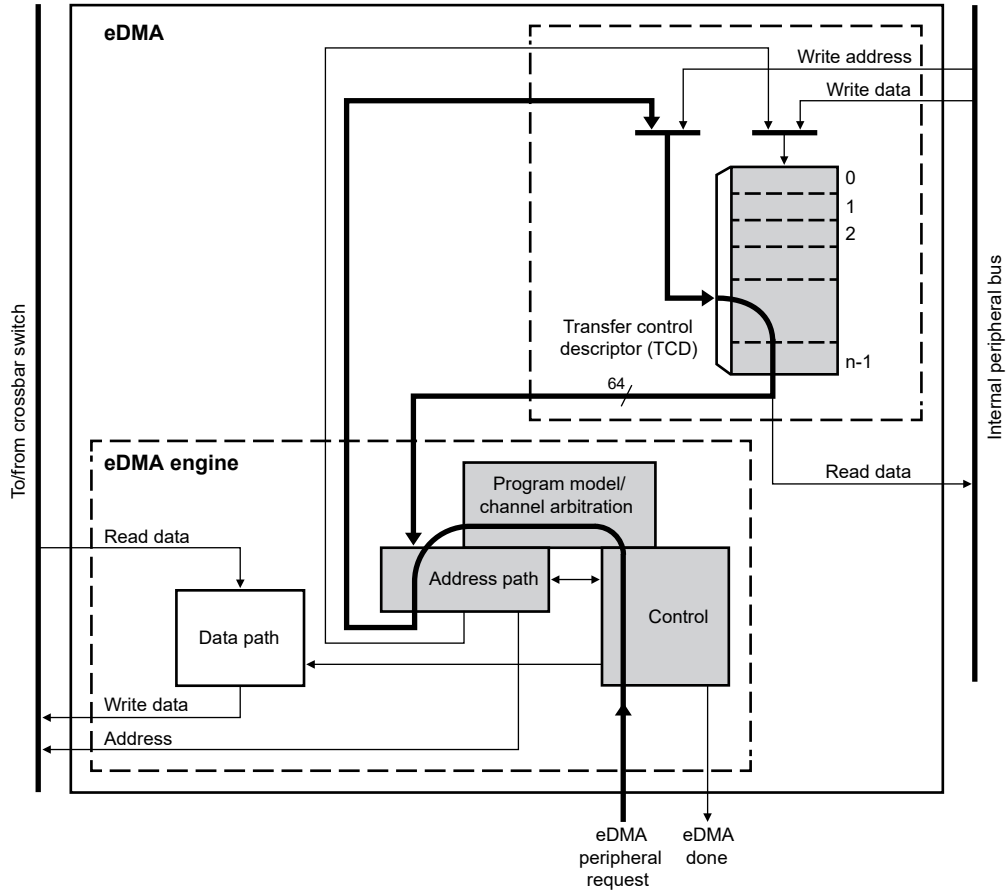

Figure 13. eDMA operation, part 1

This example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] field follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration.

In the next cycle, the channel arbitration begins using fixed-priority plus the optional round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the required descriptor is read from the local memory and then loaded into the eDMA engine address path's primary or secondary channel execution registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path registers.

The following diagram illustrates the second part of the basic data flow:

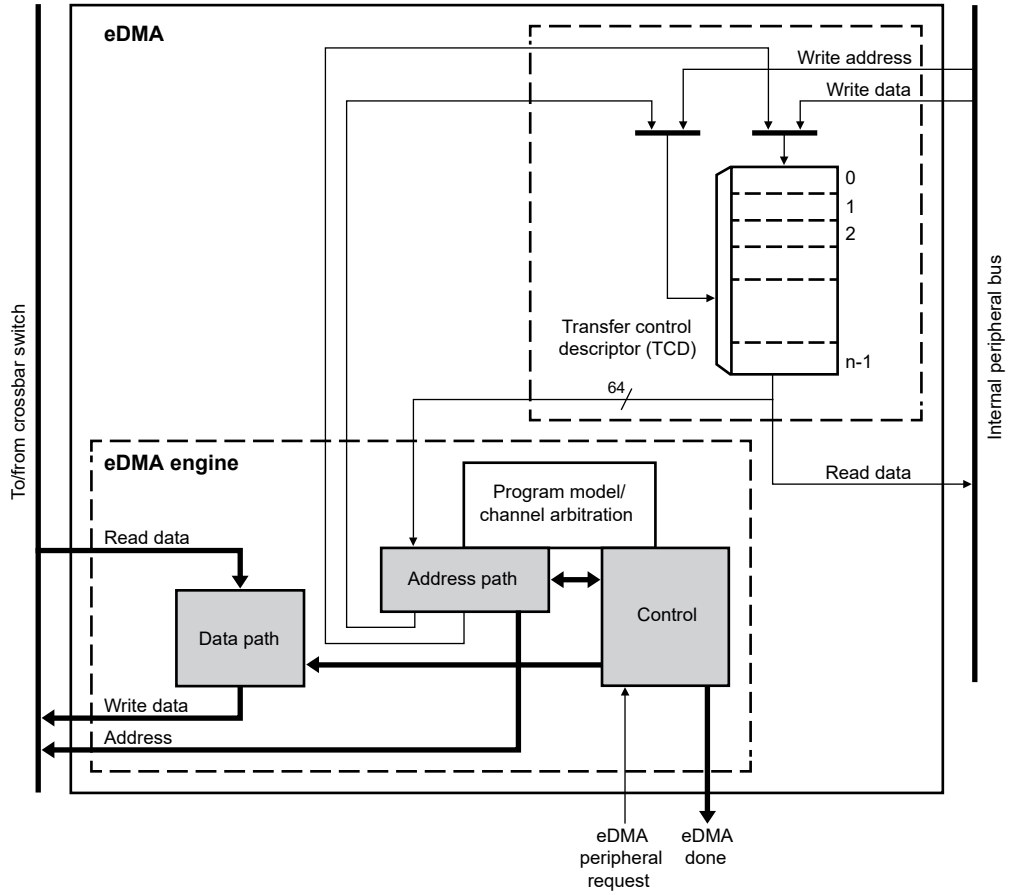

Figure 14. eDMA operation, part 2

The modules associated with the data transfer (address path, data path, and control) go through the required sequence of source reads and destination writes to perform the actual data movement. The source reads are initiated, and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the byte count, NBYTES, has been transferred.

After NBYTES of data has been moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD (for example, SADDR, DADDR, CITER). If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER field. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

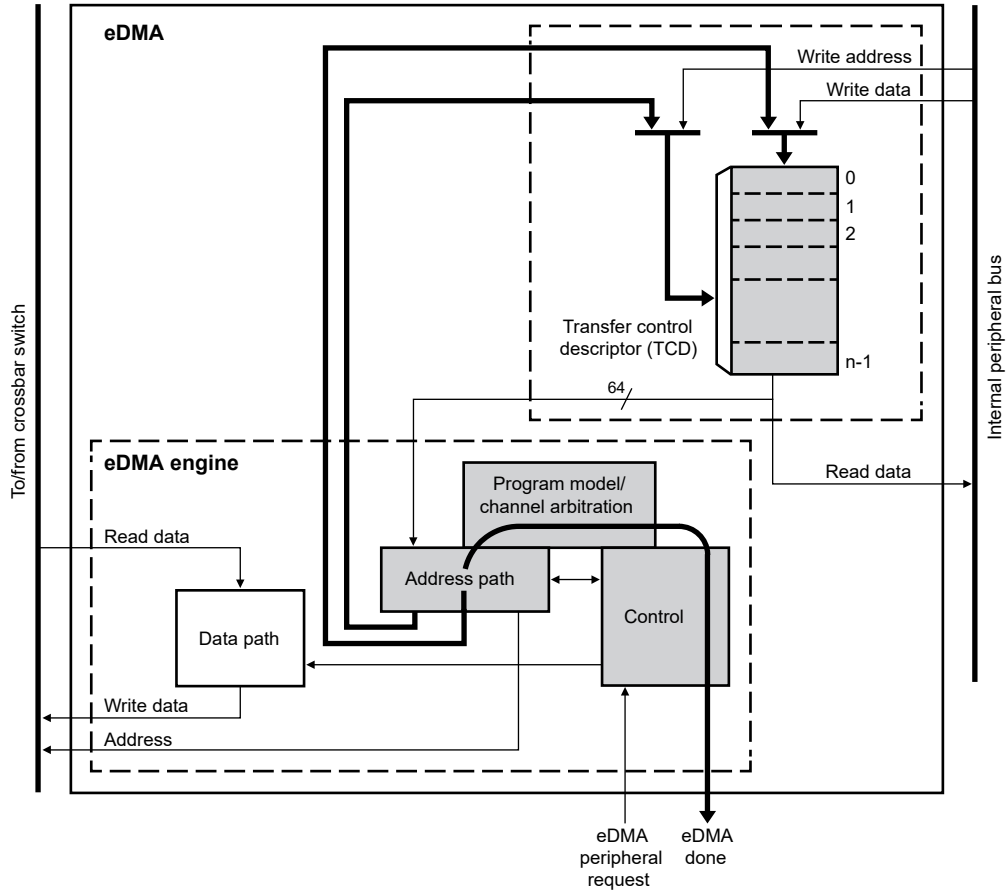

Figure 15. eDMA operation, part 3

10.3.3 Fault reporting and handling

Channel errors are reported in the Error Status register (CHn_ES) and can be caused by any of the following:

- A configuration error, which is an illegal setting in the transfer control descriptor
- An active channel canceled via a "cancel transfer with error" hardware or software request
- An error termination to a bus master read or write cycle

A configuration error is reported when an inconsistent state is represented by one of these factors:

- Starting source or destination address
- Source or destination offsets
- Minor loop byte count
- Transfer size

Each of these possible causes is detailed below:

- The addresses and offsets must be aligned on zero-modulo-transfer-sized boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size.

NOTE

To aid in debugging, set the Halt After Error field in the DMA's Control Status register, CSR[HAE]. Upon any error condition, the DMA is halted after the error is recorded. The DMA remains halted and does not process any channel service requests. After the error is fixed, the DMA may be enabled again by clearing the Halt field, CSR[HALT].

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (TCDn_DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[ELINK] field does not equal the TCDn_BITER[ELINK] field.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, are reported as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion if properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel field in the eDMA error register is set to 1. At the same time, the details of the error condition are loaded into the Error Status register (CHn_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag, and the possible assertion of an interrupt request are not affected when an error is detected.

After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

The error status fields are read-only. These error indicators are sticky and cannot be cleared. They show the last recorded error until the DMA is reset. CHn_ES[ERR] is used to determine if a new error condition exists. This field is the logical OR of each channel's error interrupt field (ERR).

After the software has resolved all errors and cleared all of the error interrupt fields, the MP_ES[VLD] is cleared to 0 but the cause of the last error is still indicated.

10.3.4 Channel preemption

The eDMA uses a priority vector value to determine the highest priority channel requesting service.

The priority vector is a combination of:

1. the channel's group priority, CHn_GRPRI
2. the channel's priority level, CHn_PRI[APL]
3. the channel number

Priority vector = ((CHn_GRPRI << 8) + (CHn_PRI[APL] << 5) + CHn_*)

A channel requesting service with the highest priority vector value will receive the next execution slot.

An execution slot is available:

1. immediately if the eDMA is idle
2. when an active channel retires
3. when valid preemption conditions exist

NOTE

Preemption is strictly priority based. Preemption is not bound by a specific group number as defined by CHn_GRPRI.

Channel preemption is enabled on a per-channel basis by setting the CHn_PRI[ECP] field. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher-priority channel. After the preempting channel has completed all of its minor loop data transfers, the preempted channel is restored and resumes execution.

After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended, and the higher-priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted.

A channel's ability to preempt another channel can be disabled by setting CHn_PRI[DPA] to 1. When a channel's preempt ability is disabled, that channel cannot suspend a lower-priority channel's data transfer, regardless of the lower-priority channel's ECP setting. This allows for a pool of low-priority, large-data-moving channels to be defined.

You can configure these low-priority channels to not preempt each other, thus preventing a low-priority channel from consuming the preempt slot normally available to a true high-priority channel. When you enable round-robin channel arbitration mode (CSR[ERCA] is set to 1), any channel with a priority level equal to 0 (CHn_PRI[APL] = 0) has preemption disabled and cannot preempt another channel.

10.3.5 Clocking

This module has no clocking considerations.

10.3.6 Interrupts

This module has no interrupts.

10.4 Memory map/register definition

The eDMA programming model is partitioned into three parts:

1. The first part defines a number of registers providing overall control functions and is known as the management page.
2. The second part corresponds to the channel (CH) control, status, and configuration.
3. The third part corresponds to the local TCD memory.

TCD memory

Each channel requires a 32-byte transfer control descriptor for defining the data movement operation. Each TCDn definition is presented as 11 registers of 16 or 32 bits. See "TCD memory map" for details.

TCD initialization

Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

TCD structure

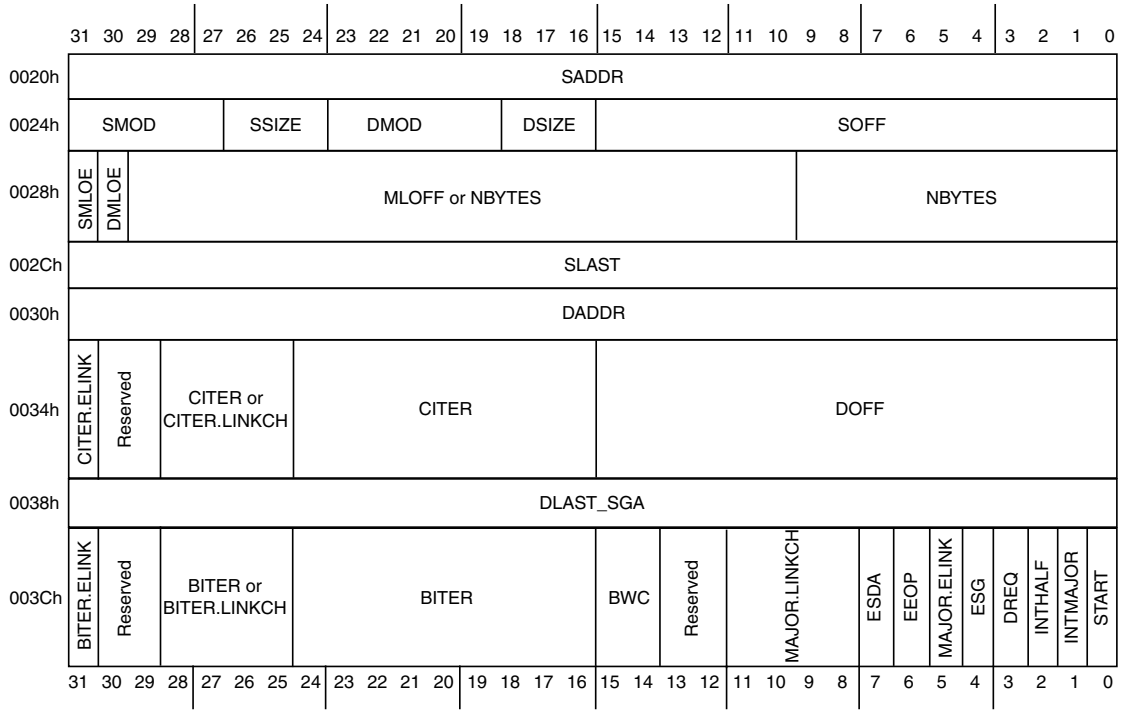

Figure 16. TCD structure

Accesses to reserved memory and fields

- Reading reserved fields in a register returns the value of zero.
- Writes to reserved fields in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

10.4.1 DMA MP register descriptions

10.4.1.1 MP memory map

DMA3.MP base address: 4000_2000h

NOTE

Ch	Management Page Hardware Request Status (MP_HRS)	32	R	0000_0000h	No
100h - 13Ch	Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI)	32	RW	0000_0000h	Yes

10.4.1.2 Management Page Control (MP_CSR)

Offset

Register	Offset
MP_CSR	0h

Function

The Management Page Control register defines the basic operating configuration of the DMA.

Arbitration uses a two-tier priority system; group and channel priority. The eDMA assigns each channel to a priority group. Group arbitration is fixed-priority and cannot be changed. Channel arbitration uses fixed priority and may be configured to use a selective round-robin scheme for specified channels within each priority group. For fixed-priority arbitration, eDMA selects for execution the highest priority channel requesting service in the highest priority arbitration group.

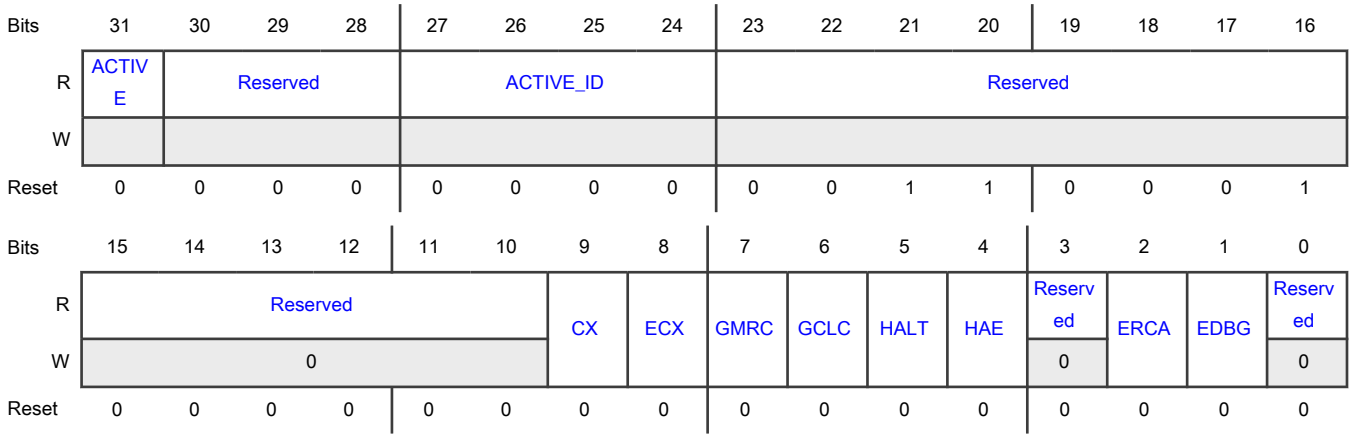
The channel priority registers assign the relative priorities within each arbitration group; see CHn_PRI. All channels with a non-zero CHn_PRI value use fixed-priority arbitration.

When you enable round-robin arbitration, all channels with channel priority set to zero do not have a priority and, of those channels requesting service, are cycled through (from high to low channel number) without regard to priority relative to each other within the same priority group. Any channel with a non-zero CHn_PRI value automatically has a higher priority over the round-robin channels. A channel's priority group is assigned in Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI).

NOTE

For correct operation, changes to the CSR[ERCA, GCLC, GMRC] fields must be performed when the DMA channels are inactive; that is, when the CSR[ACTIVE] field is 0.

Diagram



Fields

Field	Function
31 ACTIVE	DMA Active Status 0b - eDMA is idle 1b - eDMA is executing a channel
30-28 —	Reserved
27-24 ACTIVE_ID	Active Channel ID This field identifies the channel number that is executing when the ACTIVE bit is 1.
23-16 —	Reserved
15-10 —	Reserved
9 CX	Cancel Transfer When set to 1, this field cancels the remaining data transfer, stops the executing channel, and forces the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. CX clears itself to 0 after the cancel has been honored. This cancel retires the channel normally as if the minor loop had been completed. 0b - Normal operation 1b - Cancel the remaining data transfer
8 ECX	Cancel Transfer With Error Cancellation of the remaining data transfer is similar to that of the CX field. Execution of the channel is stopped and the minor loop is forced to finish. The cancellation takes effect after the last write of the current read/write sequence. The ECX field clears itself to 0 after the cancel is honored. In addition to

Table continues on the next page...

Table continued from the previous page...

Field	Function
	cancelling the transfer, ECX treats the cancel as an error condition, thus updating Management Page Error Status (MP_ES) and generating an optional error interrupt. 0b - Normal operation 1b - Cancel the remaining data transfer
7 GMRC	Global Master ID Replication Control **NOTE** If master ID replication is disabled, the nonsecure, user protection level for DMA transfers is used. 0b - Master ID replication disabled for all channels 1b - Master ID replication available and controlled by each channel's CHn_SBR[EMI] setting
6 GCLC	Global Channel Linking Control 0b - Channel linking disabled for all channels 1b - Channel linking available and controlled by each channel's link settings
5 HALT	Halt DMA Operations This field stalls the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this field is cleared to 0. 0b - Normal operation 1b - Stall the start of any new channels
4 HAE	Halt After Error When this field is set to 1, any error causes the HALT field to be set to 1. Then all service requests are ignored until the HALT field is cleared to 0. 0b - Normal operation 1b - Any error causes the HALT field to be set to 1
3 —	Reserved
2 ERCA	Enable Round Robin Channel Arbitration 0b - Round-robin channel arbitration disabled. Fixed priority arbitration used for channel selection 1b - Round-robin channel arbitration enabled. Round-robin arbitration used for channel selection
1 EDBG	Enable Debug When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. DMA resumes channel execution when the system exits debug mode or clears the EDBG field to 0. 0b - Debug mode disabled. When in debug mode, the DMA continues to operate

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Debug mode is enabled. When in debug mode, the DMA stalls the start of a new channel
0 —	Reserved

10.4.1.3 Management Page Error Status (MP_ES)

Offset

Register	Offset
MP_ES	4h

Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus master read or write cycle
- An uncorrectable error that occurred when the device was accessing the TCD SRAM
- A "cancel transfer with error" request was made via the corresponding cancel transfer field or input signal

Upon any error condition, the software must initialize the TCD of the channel that contains the error, as it is in an incomplete state after an error. See Fault reporting and handling for more details.

Table continued from the previous page...

Field	Function
VLD	0b - No ERR fields are set to 1 1b - At least one ERR field is set to 1, indicating a valid error exists that software has not cleared
30-28 —	Reserved
27-24 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error or last recorded error-canceled transfer.
23-9 —	Reserved
8 ECX	Transfer Canceled The ECX operation is a management page function. When employed, the targeted channel's CHn_ES register reports an unspecified error; that is, only the ERR field is set to 1. The management page has full view of the error condition. 0b - No canceled transfers 1b - Last recorded entry was a canceled transfer by the error cancel transfer input
7 SAE	Source Address Error When this field is 1, it indicates that TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SADDR field
6 SOE	Source Offset Error When this field is 1, it indicates that TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SOFF field
5 DAE	Destination Address Error When this field is 1, it indicates that TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DADDR field
4 DOE	Destination Offset Error When this field is 1, it indicates that TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DOFF field
3	NBYTES/CITER Configuration Error

Table continues on the next page...

Table continued from the previous page...

Field	Function
NCE	This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0b - No NBYTES/CITER configuration error 1b - The last recorded error was NBYTES equal to zero or a CITER not equal to BITER error. Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. 0b - No scatter/gather configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0b - No source bus error 1b - Last recorded error was a bus error on a source read
0 DBE	Destination Bus Error 0b - No destination bus error 1b - Last recorded error was a bus error on a destination write

10.4.1.4 Management Page Interrupt Request Status (MP_INT)

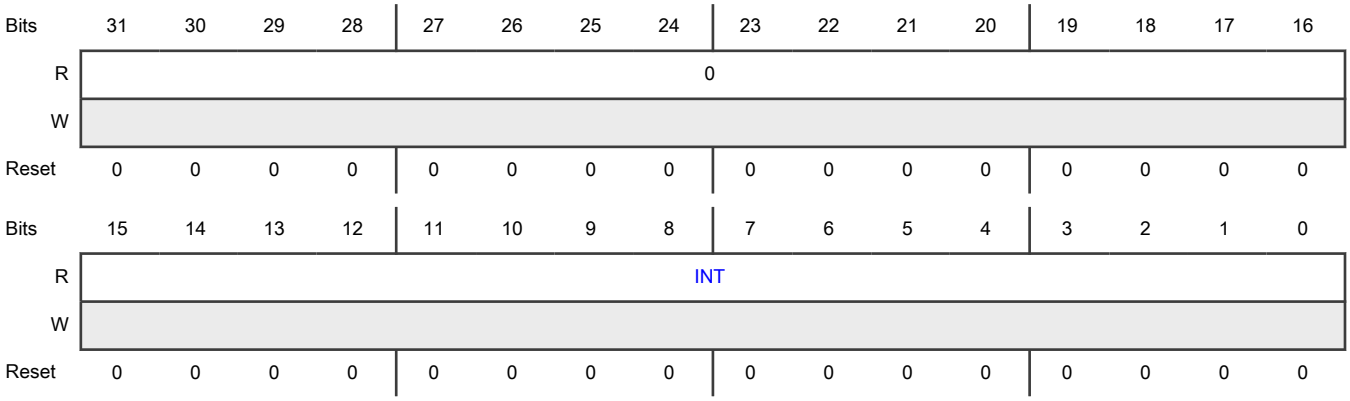
Offset

Register	Offset
MP_INT	8h

Function

This register shows the current state of the interrupt service requests for all eDMA channels.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 INT	Interrupt Request Status The INT register presents the interrupt request status for each eDMA channel. Depending on the appropriate field setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion or an error condition. The eDMA routes channel interrupt requests to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate field in the channel's interrupt request register, CHn_INT, thus negating the interrupt request. 0b - Interrupt request for corresponding channel not present 1b - Interrupt request for corresponding channel present

10.4.1.5 Management Page Hardware Request Status (MP_HRS)

Offset

Register	Offset
MP_HRS	Ch

Function

The hardware request status register (HRS) shows the current state of the hardware service request signaling as seen by eDMA's arbitration logic.

10.4.1.6 Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI)

Offset

For n = 0 to 15:

Register	Offset
CHn_GRPRI	100h + (n × 4h)

Function

The contents of this register define the arbitration group associated with each channel. Using a fixed-priority group arbitration scheme, eDMA evaluates the arbitration group priorities by numeric value from highest group number to lowest; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. The range of the group priority values is limited to the values of 0 through 31. Within each arbitration group, the channel priority assignment CH*n*_PRI determines the highest-priority channel.

Diagram

10.4.2.2 Channel Control and Status (CH0_CSR - CH15_CSR)

Offset

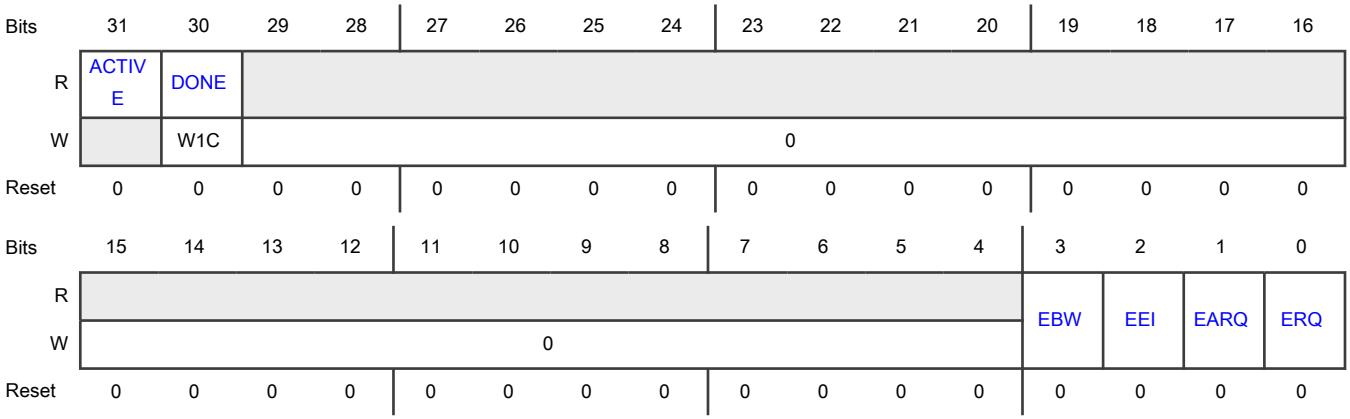
For n = 0 to 15:

Register	Offset
CHn_CSR	0h + (n × 1000h)

Function

This register contains several fields related to hardware and interrupt requests, configuration, and status for the given channel.

Diagram



Fields

Field	Function
31 ACTIVE	Channel Active The ACTIVE field indicates the channel was selected by arbitration and is executing the prescribed transfers. The eDMA sets it to 1 when channel service begins, and clears it to 0 as the minor loop completes or when any error condition is detected. Except for dynamic scatter/gather or dynamic channel linking, you must not modify the transfer control descriptor when a channel is active.
30 DONE	Channel Done The DONE field indicates the eDMA has completed the major loop. The eDMA engine sets this field as the CITER count reaches zero. If enabled, the eDMA generates an interrupt request corresponding to this completed channel. The software clears it, or the hardware clears it when the channel is activated. **NOTE** This field must be cleared to 0 before writing the MAJORELINK or ESG fields.
29-4 —	Reserved
3 EBW	Enable Buffered Writes When buffered writes are enabled, all writes except for the last write sequence of the minor loop are signaled by the eDMA as bufferable. 0b - Buffered writes on system bus disabled. Buffered writes on system bus disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Buffered writes on system bus enabled. Bufferable write signal asserted on all system bus writes except during last write sequence
2 EEI	Enable Error Interrupt The EEI field enables the error interrupt signal for the channel. The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller. 0b - Error signal for corresponding channel does not generate error interrupt 1b - Assertion of error signal for corresponding channel generates error interrupt request
1 EARQ	Enable Asynchronous DMA Request The enable asynchronous DMA request field (EARQ) does not affect DMA operations. When set to 1, this field allows the hardware service request enable field (ERQ) to propagate out of the DMA to the power controller. When cleared to 0, this field masks the hardware service request enable field to the power controller. 0b - Disable asynchronous DMA request for the channel 1b - Enable asynchronous DMA request for the channel
0 ERQ	Enable DMA Request Disable a channel's hardware service request at the source before clearing the channel's ERQ field. The DMA hardware request input signal and the enable request field (ERQ) must be asserted before a channel's hardware service request is accepted. The state of the eDMA enable request field does not affect a channel service request made explicitly through software or channel linking. The state of the ERQ field does not affect the channel's START field. 0b - DMA hardware request signal for corresponding channel disabled 1b - DMA hardware request signal for corresponding channel enabled

10.4.2.3 Channel Error Status (CH0_ES - CH15_ES)

Offset

For n = 0 to 15:

Register	Offset
CHn_ES	4h + (n × 1000h)

Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus master read or write cycle

The ERR field signals the presence of an error for the channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate field in this register. The outputs of this register are enabled by the contents of the CHn_CSR[EEI] field,

then logically summed across all channels to form an error interrupt request, which may be routed to the interrupt controller. In addition, this enabled error status is logically OR'd onto the channel done interrupt, CHn_INT[INT], thus forming a done or error interrupt on a per channel basis.

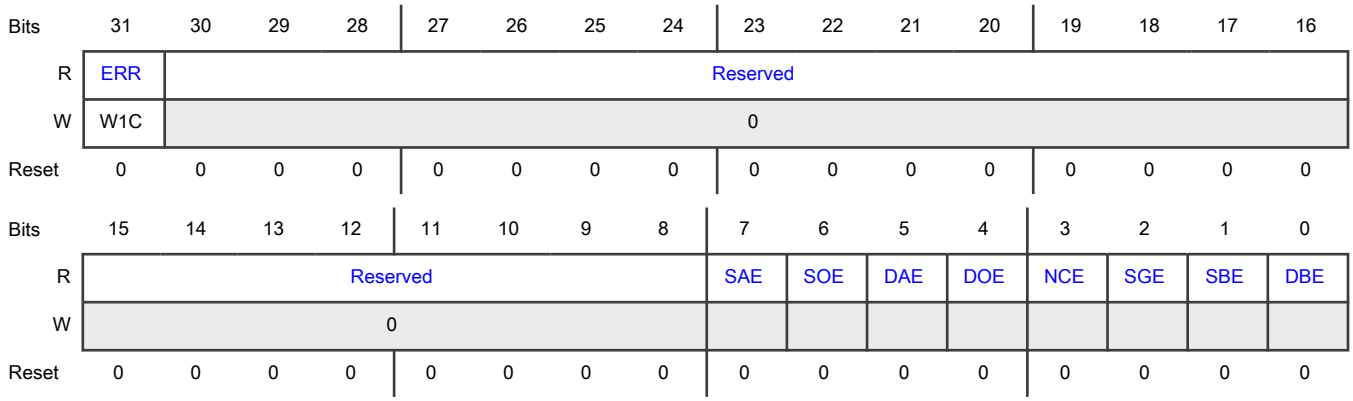
During the execution of the interrupt service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when eDMA detects an error. The contents of this ERR register field can also be polled because a non-zero value indicates the presence of a channel error, regardless of the state of the EEI mask.

The state of any given channel's error indicators is affected by writes to this register. Writing a 1 to the ERR field clears the channel's error status, and writing a 0 has no effect.

An unspecified error, where only the ERR field is set to 1, indicates that either a transfer was cancelled with an error. The Management Page Error Status register has full view of the error condition.

See Fault reporting and handling for more details.

Diagram



Fields

Field	Function
31 ERR	Error In Channel 0b - An error in this channel has not occurred 1b - An error in this channel has occurred
30-8 —	Reserved
7 SAE	Source Address Error TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SADDR field
6 SOE	Source Offset Error TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No source offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SOFF field
5 DAE	Destination Address Error TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DADDR field
4 DOE	Destination Offset Error TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DOFF field
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0b - No NBYTES/CITER configuration error 1b - Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG]is enabled. 0b - No scatter/gather configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0b - No source bus error 1b - Last recorded error was bus error on source read
0 DBE	Destination Bus Error 0b - No destination bus error 1b - Last recorded error was bus error on destination write

10.4.2.4 Channel Interrupt Status (CH0_INT - CH15_INT)

Offset

For n = 0 to 15:

Register	Offset
CHn_INT	8h + (n × 1000h)

Function

The INT field signals the presence of an interrupt request for the channel. Depending on the appropriate bit setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion or an error condition.

The outputs of this register are directly routed to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. On writes to INT, a 1 clears the channel's interrupt request. A zero has no effect on the channel's current interrupt status.

10.4.2.5 Channel System Bus (CH0_SBR - CH15_SBR)

Offset

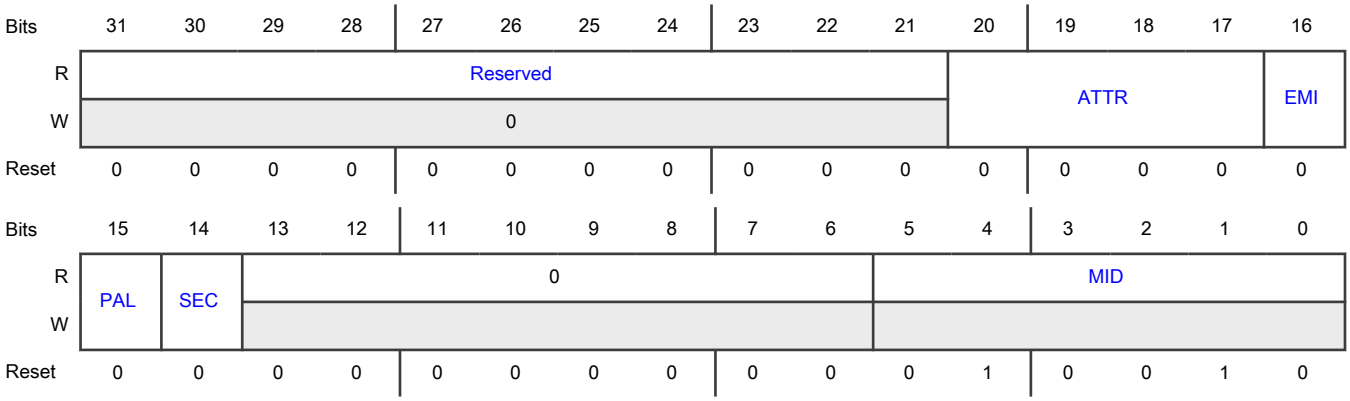
For n = 0 to 15:

Register	Offset
CHn_SBR	Ch + (n × 1000h)

Function

The Channel System Bus register places identification and attribute information on the system bus interface for the eDMA.

Diagram



Fields

Field	Function
31-21 —	Reserved
20-17 ATTR	Attribute Output DMA's system bus attribute output value.
16 EMI	Enable Master ID Replication The eDMA master ID replication field allows the eDMA to use the same protection level and system bus ID of the master programming the eDMA's TCD. When enabled, the eDMA uses the master ID and protection level stored in the CHn_SBR registers, instead of the eDMA's default values. When a master (for example a core) programs a TCD, its master ID is captured when the TCD*n*_CSR control attributes are written. A scatter/gather operation does not affect the CHn_SBR registers. You can write the EMI only if MP_CSR[GMRC] = 1, which means Global Master ID Replication Control is enabled; otherwise, the EMI is forced to zero. **NOTE** If master ID replication is disabled, the nonsecure, user protection level for DMA transfers is used. 0b - Master ID replication is disabled 1b - Master ID replication is enabled
15	Privileged Access Level

Table continues on the next page...

Table continued from the previous page...

Field	Function
PAL	This field controls DMA's protection level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other master writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0b - User protection level for DMA transfers 1b - Privileged protection level for DMA transfers
14 SEC	Security Level DMA's security level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other master writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0b - Nonsecure protection level for DMA transfers 1b - Secure protection level for DMA transfers
13-6 —	Reserved
5-0 MID	Master ID This field controls the DMA's master ID on the system bus when the channel is active. **NOTE** The ID captured in this register reflects the master ID of the core or other master writing the channel's security attributes, TCD*n*_SBR[SEC].

10.4.2.6 Channel Priority (CH0_PRI - CH15_PRI)

Offset

For n = 0 to 15:

Register	Offset
CHn_PRI	10h + (n × 1000h)

Function

The contents of these registers define unique priorities associated with each channel within the same channel group. Channel grouping is programmed via Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI).

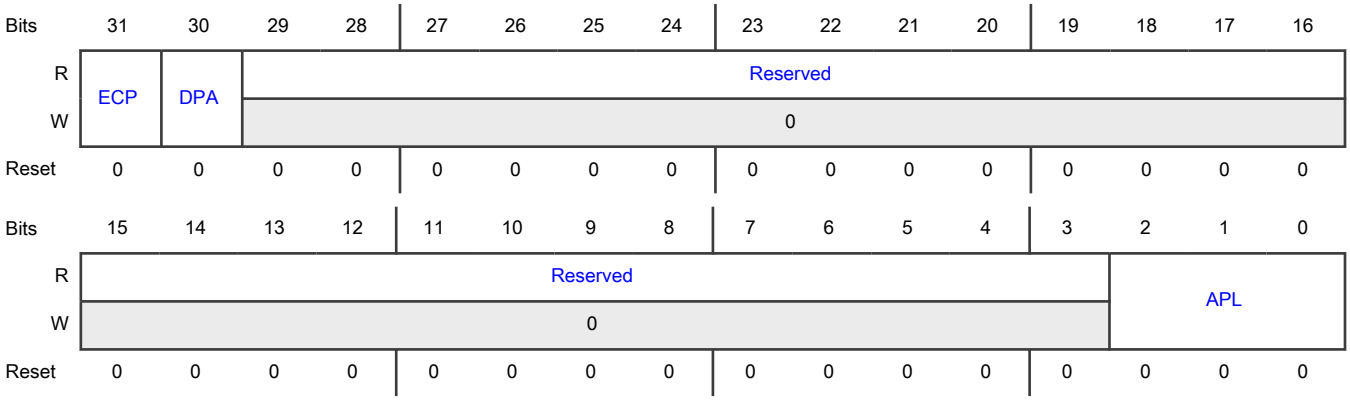
The channel priorities within a group are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values; otherwise, channel numbers with the same, non-zero value, will be selected based on channel number with the higher channel number having higher priority.

If more than one channel in a group has an arbitration priority level value of zero, then the arbitration mode field MP_CSR[ERCA] is used to determine the arbitration scheme for all channels with APL=0 within a group.

When you enable round-robin channel arbitration (MP_CSR[ERCA] = 1), all channels with APL=0 within a group will use a round-robin arbitration scheme, which rotates among these channels requesting service without regard to priority. Round-robin provides a fairness mechanism within an arbitration group.

When you enable fixed-priority channel arbitration (MP_CSR[ERCA] = 0), eDMA selects channels with APL=0 based on channel number, with the higher channel number having higher priority.

Diagram



Fields

Field	Function
31 ECP	Enable Channel Preemption 0b - Channel cannot be suspended by a higher-priority channel's service request 1b - Channel can be temporarily suspended by a higher-priority channel's service request
30 DPA	Disable Preempt Ability 0b - Channel can suspend a lower-priority channel 1b - Channel cannot suspend any other channel, regardless of channel priority
29-3 —	Reserved
2-0 APL	Arbitration Priority Level Channel priority level for arbitration within the assigned arbitration group.

10.4.2.7 Channel Multiplexor Configuration (CH0_MUX - CH15_MUX)

Offset

For n = 0 to 15:

Register	Offset
CHn_MUX	14h + (n × 1000h)

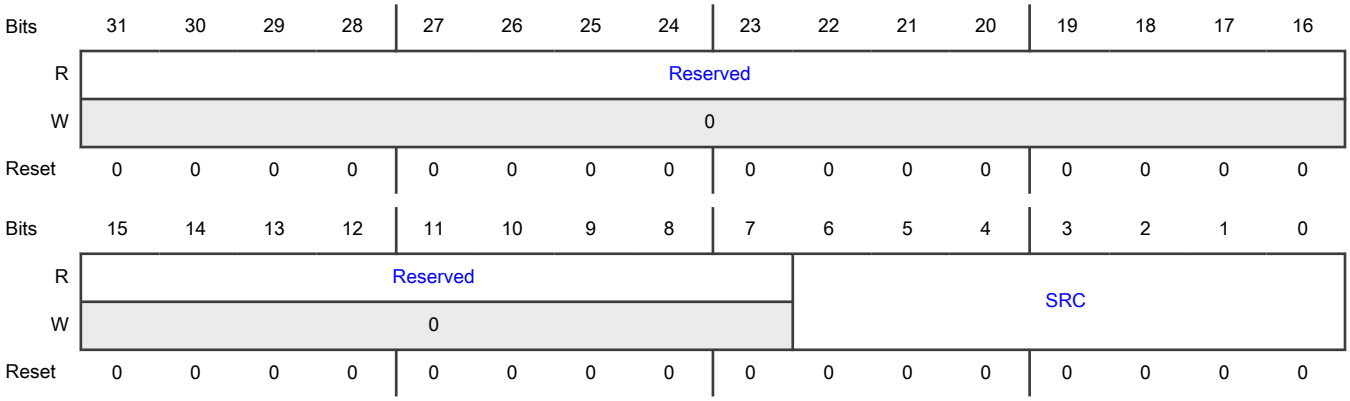
Function

Each of the DMA channels can be independently associated with various peripherals in the system. The Channel Multiplexor Configuration register selects the peripheral assigned to each channel. Service requests from the peripheral should be disabled when configuring a channel to a peripheral source.

Each channel must have a unique value when selecting a peripheral slot in the channel mux configuration. The only value that may overlap is source 0. If there is an attempt to write a mux configuration value that is already consumed by any channel, a mux configuration of 0 (SRC = 0) will be written.

All channels will default to source 0. When a particular peripheral is needed, the channel's mux configuration is set to that source number. When the peripheral is no longer needed, the mux configuration for that channel should be written to 0, thus releasing the resource.

Diagram



Fields

Field	Function
31-7 —	Reserved
6-0 SRC	Service Request Source Hardware service request source for the channel. **NOTE** With the exception of 0, attempts to write a value already in use will be forced to 0.

10.4.2.8 TCD Source Address (TCD0_SADDR - TCD15_SADDR)

Offset

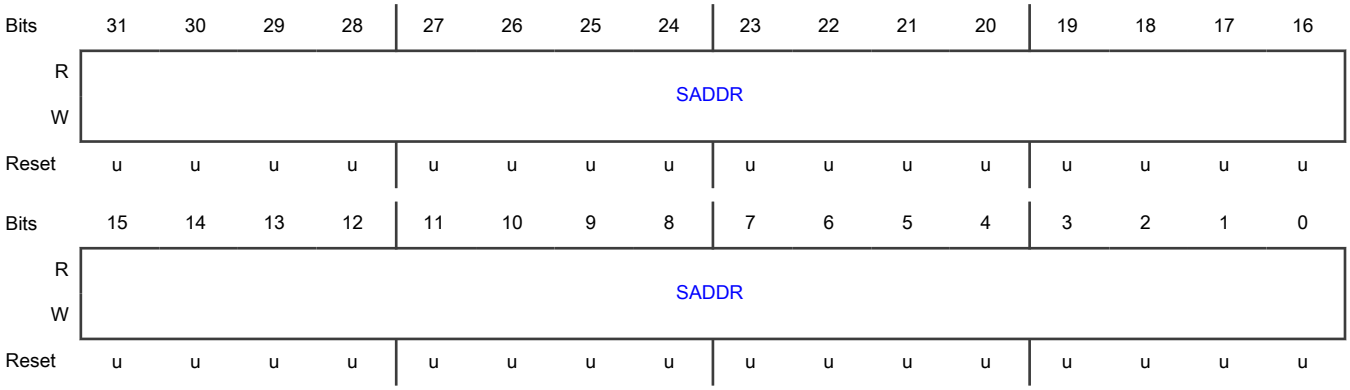
For n = 0 to 15:

Register	Offset
TCDn_SADDR	20h + (n × 1000h)

Function

This register contains the address for the read transactions.

Diagram



Fields

Field	Function
31-0 SADDR	Source Address Memory address pointing to the source data.

10.4.2.9 TCD Signed Source Address Offset (TCD0_SOFF - TCD15_SOFF)

Offset

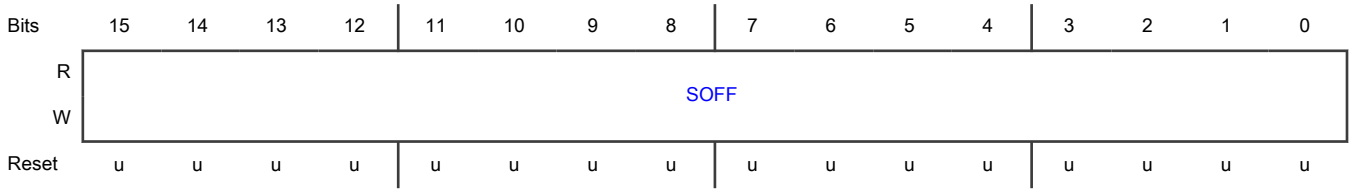
For n = 0 to 15:

Register	Offset
TCDn_SOFF	24h + (n × 1000h)

Function

This register contains the sign-extended value added to Source Address register after each read transaction.

Diagram



Fields

Field	Function
15-0 SOFF	Source Address Signed Offset Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.

10.4.2.10 TCD Transfer Attributes (TCD0_ATTR - TCD15_ATTR)

Offset

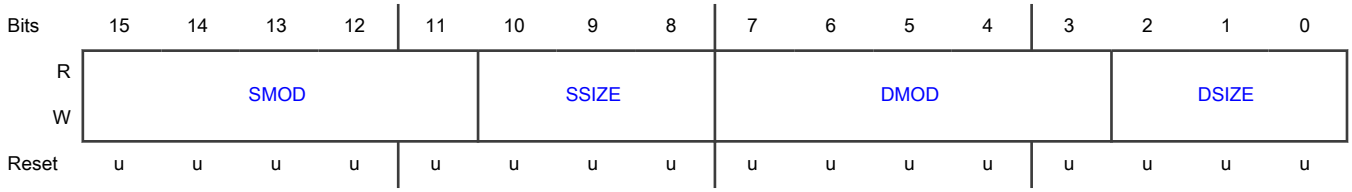
For n = 0 to 15:

Register	Offset
TCDn_ATTR	26h + (n × 1000h)

Function

This register contains size and option modulo addressing information for source and destination addresses.

Diagram



Fields

Field	Function
15-11 SMOD	Source Address Modulo This field defines a specific address range, which is the value after the SADDR + SOFF calculation is performed on the original register value. Setting this field makes it easy to implement a circular data queue. For data queues requiring power-of-2-sized bytes, the queue must start at a 0-modulo-size address and the SMOD field must be set to the appropriate value for the queue, freezing the required number of upper address bits.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The value programmed into this field specifies the number of lower address bits that are allowed to change. For a circular queue application, you typically set TCDn_SOFF[SOFF] to the transfer size to implement post-increment addressing, with the SMOD function constraining the addresses to a 0-modulo-size range. 0_0000b - Source address modulo feature disabled 0_0001b - Source address modulo feature enabled for any non-zero value [1-31]
10-8 SSIZE	Source Data Transfer Size 000b - 8-bit 001b - 16-bit 010b - 32-bit 011b - 64-bit 100b - 16-byte 101b - 32-byte 110b - Reserved 111b - Reserved
7-3 DMOD	Destination Address Modulo See the SMOD definition.
2-0 DSIZE	Destination Data Transfer Size See the SSIZE definition.

10.4.2.11 TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD15_NBYTES_MLOFFNO)

Offset

For n = 0 to 15:

Register	Offset
TCDn_NBYTES_MLOFFNO	28h + (n × 1000h)

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR), or destination address (TCDn_DADDR), upon minor loop completion. Minor loop completion is when the channel has finished the service request and has transferred NBYTES. When minor loop offsets are enabled, the minor loop offset value (TCDn_NBYTES_MLOFFYES[MLOFF]) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both, prior to the addresses being written back to the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (SMLOE or DMLOE is 1), TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is redefined. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is used to specify multiple fields:

- A source enable bit (SMLOE) to specify the minor loop offset must be applied to the source address (TCDn_SADDR) upon minor loop completion
- A destination enable bit (DMLOE) to specify the minor loop offset must be applied to the destination address (TCDn_DADDR) upon minor loop completion
- The sign extended minor loop offset value (MLOFF)

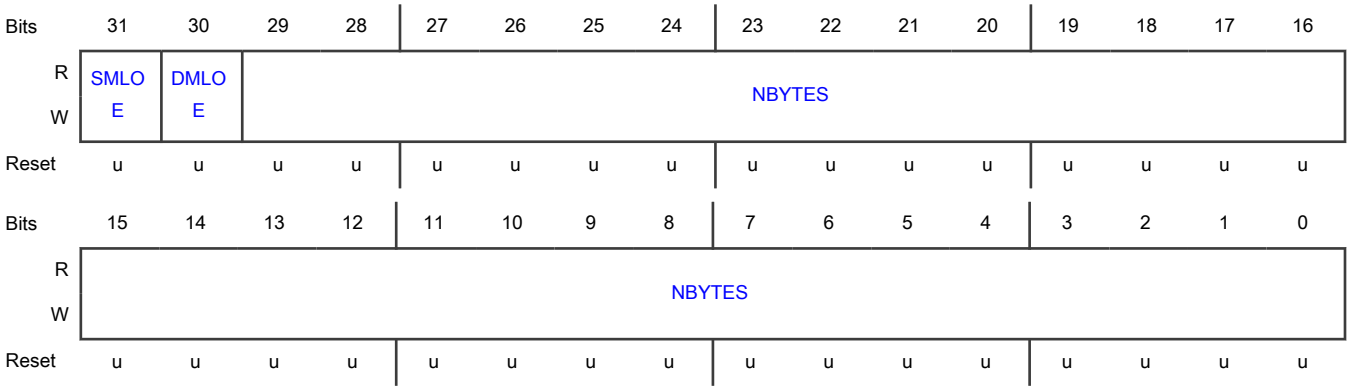
The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is defined as follows:

- If SMLOE = 0 and DMLOE = 0, then see the TCDn_NBYTES_MLOFFNO register description.
- If either SMLOE or DMLOE is 1, then see the TCDn_NBYTES_MLOFFYES register description.

Diagram



Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - Minor loop offset not applied to DADDR 1b - Minor loop offset applied to DADDR
29-0	Number of Bytes To Transfer Per Service Request

Table continues on the next page...

Table continued from the previous page...

Field	Function
NBYTES	Number of bytes to be transferred for each service request of the channel. When a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the byte transfer count has been reached. This process is normally an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the byte count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major loop iteration count (CITER) is decremented by one and written back to the TCD memory. If the major iteration count is complete, additional processing is performed.

10.4.2.12 TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD15_NBYTES_MLOFFYES)

Offset

For n = 0 to 15:

Register	Offset
TCDn_NBYTES_MLOFFYES	28h + (n × 1000h)

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offset is an address offset value added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. Minor loop completion occurs when the channel has finished the service request and has transferred NBYTES. Minor loop offsets are enabled by setting either the source enable bit (SMLOE) or the destination enable bit (DMLOE).

The source enable bit (SMLOE) specifies the minor loop offset value (MLOFF) that is to be applied to the source address (TCDn_SADDR) upon minor loop completion. The destination enable bit (DMLOE) specifies the minor loop offset (MLOFF) that is to be applied to the destination address (TCDn_DADDR) upon minor loop completion.

If the major loop is complete, the minor loop offsets are ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

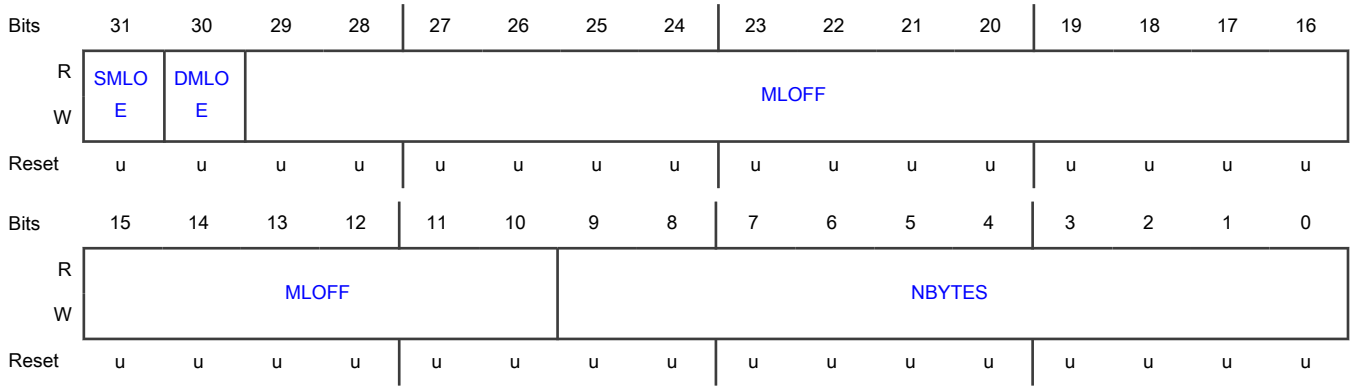
When you enable the minor loop offset overlay (either SMLOE or DMLOE is 1), eDMA redefines TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES specifies the sign-extended minor loop offset value (MLOFF). The same offset value (MLOFF) applies to both source and destination minor loop offsets. When the minor loop offset is enabled, you must align it to the transfer size of the source or destination it is associated with. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFNO) defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFYES is defined as follows:

- If either minor loop offset is enabled (SMLOE or DMLOE = 1), then see the TCDn_NBYTES_MLOFFYES register description.
- If SMLOE and DMLOE are both 0, then see the TCDn_NBYTES_MLOFFNO register description.

Diagram



Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - Minor loop offset not applied to DADDR 1b - Minor loop offset applied to DADDR
29-10 MLOFF	Minor Loop Offset If SMLOE or DMLOE is 1, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
9-0 NBYTES	Number of Bytes To Transfer Per Service Request The number of bytes to be transferred in each service request of the channel. As a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the minor byte transfer count has been reached. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major iteration count is decremented and restored to the TCD memory. If the major iteration count is complete, additional processing is performed.

10.4.2.13 TCD Last Source Address Adjustment / Store DADDR Address (TCD0_SLAST_SDA - TCD15_SLAST_SDA)

Offset

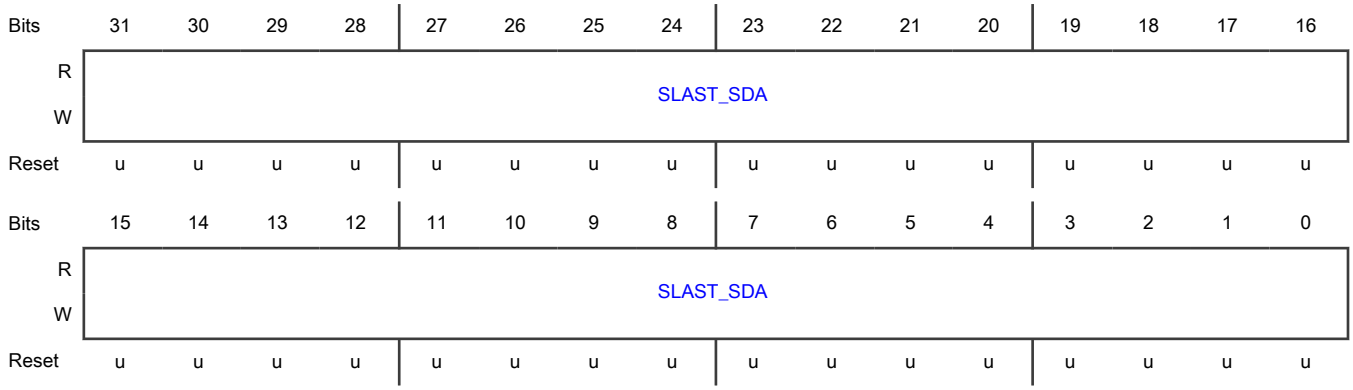
For n = 0 to 15:

Register	Offset
TCDn_SLAST_SDA	2Ch + (n × 1000h)

Function

This register contains the value added to the source address when the major loop is complete. When the store destination address option is enabled, this field provides a pointer to memory for storing the final destination address.

Diagram



Fields

Field	Function
31-0 SLAST_SDA	Last Source Address Adjustment / Store DADDR Address Source last address adjustment or the system memory address for destination address (DADDR) storage. If (TCDn_CSR[ESDA] = 0), then: • Adjustment value is added to the source address at the completion of the major iteration count. This value can be used to restore the source address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final source address adjustment. Otherwise: • This address points to the 32-bit-aligned memory location where the destination address (DADDR) is to be stored in system memory. By saving the final destination address in system memory via the ESDA feature, you are able to compute the size of a variable destination data buffer by simply subtracting the beginning DADDR from the final, saved DADDR. This feature is used together with the scatter/gather operation to prevent the loss of the final DADDR, which is overwritten during the scatter/gather operation. The "Store Destination Address" (SDA) value must be a 32-bit-aligned location because the eDMA forces the lower two address bits of the SLAST_SDA field to zero when ESDA is enabled. The module performs this write operation when the major loop is done; that is, when the major iteration count (CITER) decrements to zero.

10.4.2.14 TCD Destination Address (TCD0_DADDR - TCD15_DADDR)

Offset

For n = 0 to 15:

Register	Offset
TCDn_DADDR	30h + (n × 1000h)

Function

This register contains the address for the write transactions.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	DADDR															
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DADDR															
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

Fields

Field	Function
31-0 DADDR	Destination Address Memory address pointing to the destination data.

10.4.2.15 TCD Signed Destination Address Offset (TCD0_DOFF - TCD15_DOFF)

Offset

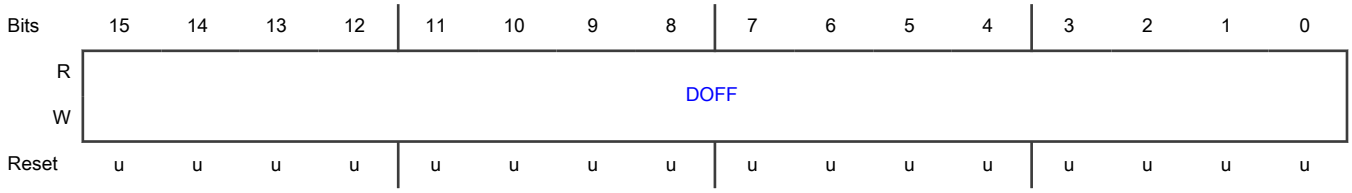
For n = 0 to 15:

Register	Offset
TCDn_DOFF	34h + (n × 1000h)

Function

This register contains the sign-extended value added to Destination Address register after each write transaction.

Diagram



Fields

Field	Function
15-0 DOFF	Destination Address Signed Offset Sign-extended offset that is applied to the current destination address to form the next-state value as each destination write is completed.

10.4.2.16 TCD Current Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD15_CITER_ELINKNO)

Offset

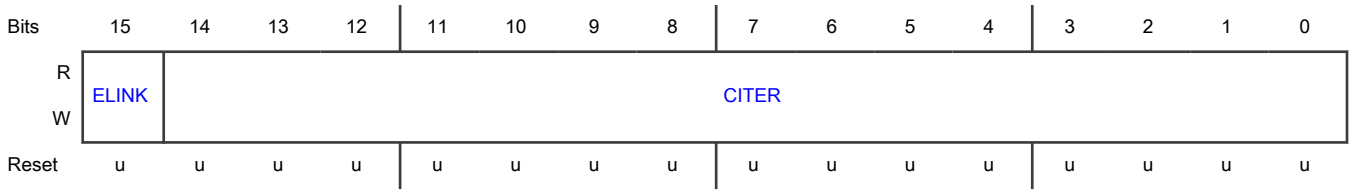
For n = 0 to 15:

Register	Offset
TCDn_CITER_ELINKNO	36h + (n × 1000h)

Function

If TCDn_CITER[ELINK] is 0, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel to 1. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

10.4.2.17 TCD Current Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD15_CITER_ELINKYES)

Offset

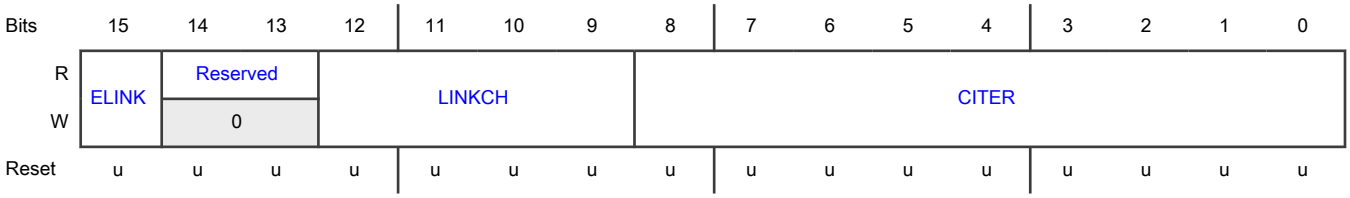
For n = 0 to 15:

Register	Offset
TCDn_CITER_ELINKYES	36h + (n × 1000h)

Function

If TCDn_CITER[ELINK] is 1, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. When enabled, an internal mechanism sets the TCDn_CSR[START] field of the specified channel (LINKCH) upon minor loop completion. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking. **NOTE** This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-13 —	Reserved
12-9 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted the eDMA engine initiates a channel service request to the channel defined by this field by writing that channel's TCDn_CSR[START] field to 1.
8-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to the TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

10.4.2.18 TCD Last Destination Address Adjustment / Scatter Gather Address (TCD0_DLAST_SGA - TCD15_DLAST_SGA)

Offset

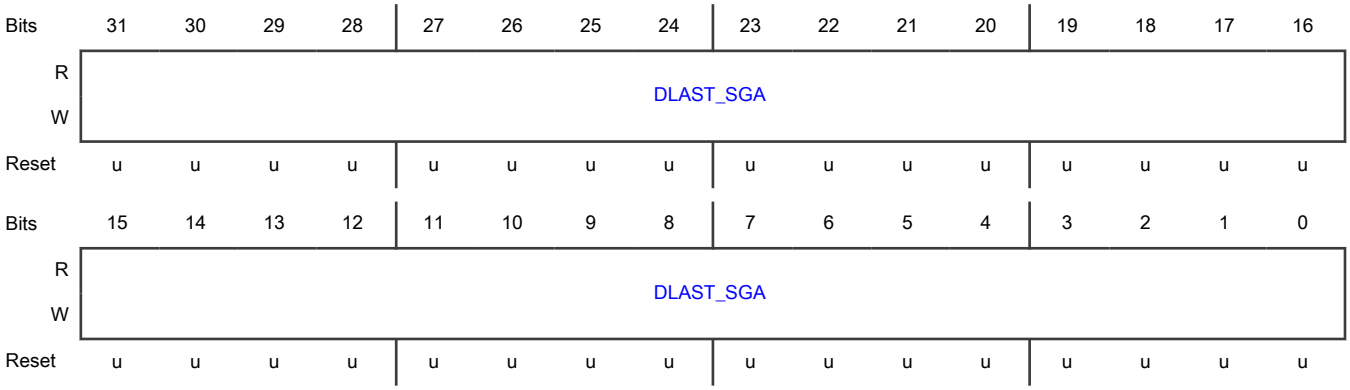
For n = 0 to 15:

Register	Offset
TCDn_DLAST_SGA	38h + (n × 1000h)

Function

This register contains the value added to the destination address when the major loop is complete. When the Scatter/Gather option is enabled, this field provides a pointer to memory for fetching a transfer control descriptor to reprogram the channel.

Diagram



Fields

Field	Function
31-0 DLAST_SGA	Last Destination Address Adjustment / Scatter Gather Address Adjustment of the last destination address or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0) then: • Adjustment value is added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo 32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo 32-byte, or else a configuration error is reported.

10.4.2.19 TCD Control and Status (TCD0_CSR - TCD15_CSR)

Offset

For n = 0 to 15:

Register	Offset
TCDn_CSR	3Ch + (n × 1000h)

Function

This register is used to enable optional features.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W			0													
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	0

Fields

Field	Function
15-14 BWC	Bandwidth Control Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces eDMA to stall after the completion of each read/write access, to control the bus request bandwidth seen by the system bus interconnect. **NOTE** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00b - No eDMA engine stalls 01b - Reserved 10b - eDMA engine stalls for 4 cycles after each R/W 11b - eDMA engine stalls for 8 cycles after each R/W
13-12 —	Reserved
11-8 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: • No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field to 1.
7 ESDA	Enable Store Destination Address As the channel completes the major loop by either the current iteration counter (CITER) decrementing to 0, or by receiving an enabled end-of-packet signal, this field enables writing the destination address (DADDR) to the address stored in the SLAST_SDA field. The value written to system memory is the last DADDR value prior to the DLAST_SGA offset being applied, or overwritten by an enabled scatter/gather operation. When the SDA bit is 1, SLAST_SDA contains the write pointer instead of the final source address offset. Because this is a pointer and not a final offset, a last source address offset of zero is applied to SADDR instead of the SLAST_SGA value. 0b - Ability to store destination address to system memory disabled 1b - Ability to store destination address to system memory enabled
6 EEOP	Enable End-Of-Packet Processing When enabled by the EEOP field, an end-of-packet hardware input signal directs eDMA to discontinue executing the active channel, and to treat the shutdown as the major-loop-completed event. If the EEOP field is 1, the end-of-packet signal from supported peripherals is accepted. If the EEOP field is 0, the end-of-packet input is ignored. With an end-of-packet retirement, the current TCD destination address (or ESDA-saved destination address), minus the software-saved initial address (DADDR), reflects the total amount of data transferred. 0b - End-of-packet operation disabled 1b - End-of-packet hardware input signal enabled
5 MAJORELINK	Enable Link When Major Loop Complete As the channel completes the major loop, this flag enables linking to another channel defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. **NOTE** To support the dynamic linking coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
4 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses TCDn_DLAST_SGA as a memory pointer to a 0-modulo 32-bit address containing a 32-byte data structure, which is loaded as the transfer control descriptor into local memory. **NOTE** To support the dynamic scatter/gather coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Current channel's TCD is normal format 1b - Current channel's TCD specifies scatter/gather format.
3 DREQ	Disable Request If this flag is 1, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches 0. 0b - No operation. Channel's ERQ field not affected 1b - Clear the ERQ field to 0 upon major loop completion, thus disabling hardware service requests. Channel's ERQ field cleared to 0 when major loop complete
2 INTHALF	Enable Interrupt If Major Counter Half-complete If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER = (BITER/2)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes, or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE** If BITER = 1, do not use INTHALF; use INTMAJOR instead. 0b - Halfway point interrupt disabled 1b - Halfway point interrupt enabled
1 INTMAJOR	Enable Interrupt If Major count complete If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count (CITER) reaches 0. 0b - End-of-major loop interrupt disabled 1b - End-of-major loop interrupt enabled
0 START	Channel Start If this flag is 1, the channel is requesting service. The eDMA hardware automatically clears this flag to 0 after the channel begins execution. 0b - Channel not explicitly started 1b - Channel explicitly started via a software-initiated service request

10.4.2.20 TCD Beginning Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_BITER_ELINKNO - TCD15_BITER_ELINKNO)

Offset

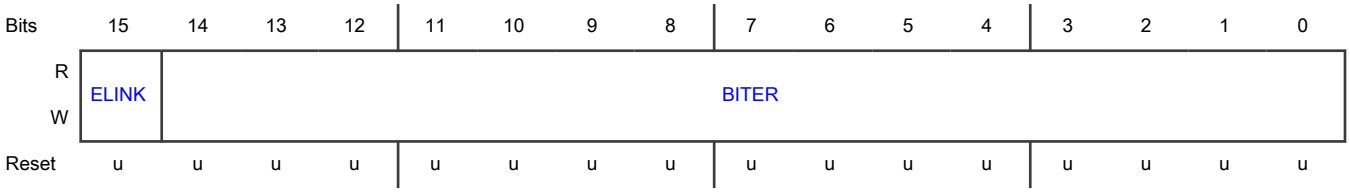
For n = 0 to 15:

Register	Offset
TCDn_BITER_ELINKNO	3Eh + (n × 1000h)

Function

If the TCDn_BITER[ELINK] field is 0, the TCDn_BITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enables Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

10.4.2.21 TCD Beginning Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_BITER_ELINKYES - TCD15_BITER_ELINKYES)

Offset

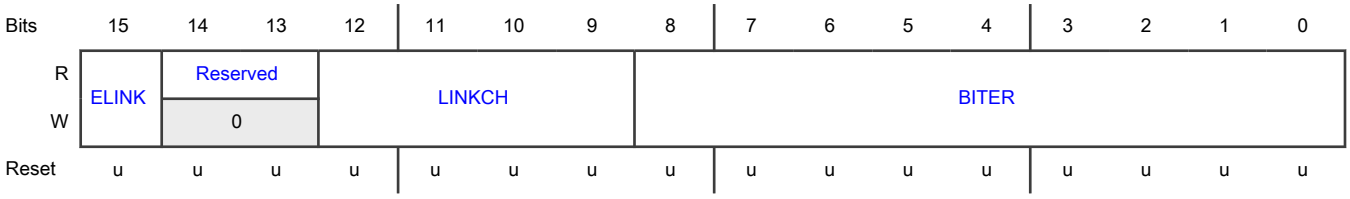
For n = 0 to 15:

Register	Offset
TCDn_BITER_ELINKYES	3Eh + (n × 1000h)

Function

If the TCDn_BITER[ELINK] field is set, the TCDn_BITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-13 —	Reserved
12-9 LINKCH	Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field.
8-0	Starting Major Iteration Count

Table continues on the next page...

Table continued from the previous page...

Field	Function
BITER	As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

10.5 External signals

This module has no external signals.

10.6 Initialization

The following sections discuss initialization of the eDMA and programming considerations.

10.6.1 eDMA initialization

To initialize the eDMA:

1. Write to the MP_CSR if a configuration other than the default is wanted.
2. Write the channel priority levels to the CHn_PRI registers and group priority levels to the CHn_GRPRI registers if a configuration other than the default is wanted.
3. Enable error interrupts in the CHn_CSR[EEI] registers if they are wanted.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the CHn_CSR[ERQ] registers.
6. Request channel service via either:
   - Software: setting TCDn_CSR[START]
   - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in Table 42, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, defined by TCDn_SADDR, to the destination, defined by TCD_DADDR, continue until the number of bytes specified by TCDn_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCDn_SADDR, TCDn_DADDR, and TCDn_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, then eDMA executes further post-processing, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 42. TCD control and status (TCDn_CSR) fields

TCDn_CSR field name	Description
START	Control field to start the channel explicitly when using a software-initiated DMA service (automatically cleared by hardware)
EEOP	Control field to enable end-of-packet processing

Table continues on the next page...

Table 42. TCD control and status (TCDn_CSR) fields (continued)

TCDn_CSR field name	Description
ESDA	Control field to enable storing of the destination address to system memory after the major loop completes
DREQ	Control field to disable hardware-initiated DMA service requests after major loop completion
BWC	Control field for throttling the bandwidth control of a channel
ESG	Control field to enable the scatter-gather feature
INTHALF	Control field to enable interrupt when major loop is half-complete
INTMAJOR	Control field to enable interrupt when major loop completes

Table 43. Channel control and status (CHn_CSR) fields

CHn_CSR field name	Description
ACTIVE	Status field indicating the channel is currently in execution
DONE	Status field indicating major loop completion (cleared by software when a channel begins execution)
EEI	Control field to enable error interrupts
EARQ	Control field to enable external, asynchronous wakeup event in conjunction with the ERQ field
ERQ	Control field to enable hardware service requests

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

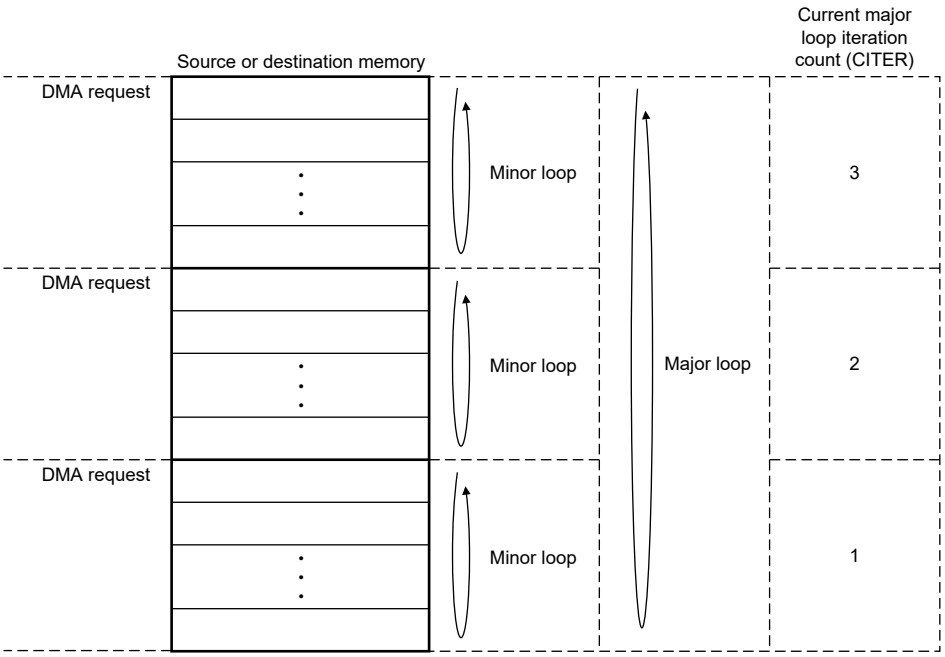


Figure 17. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings are related.

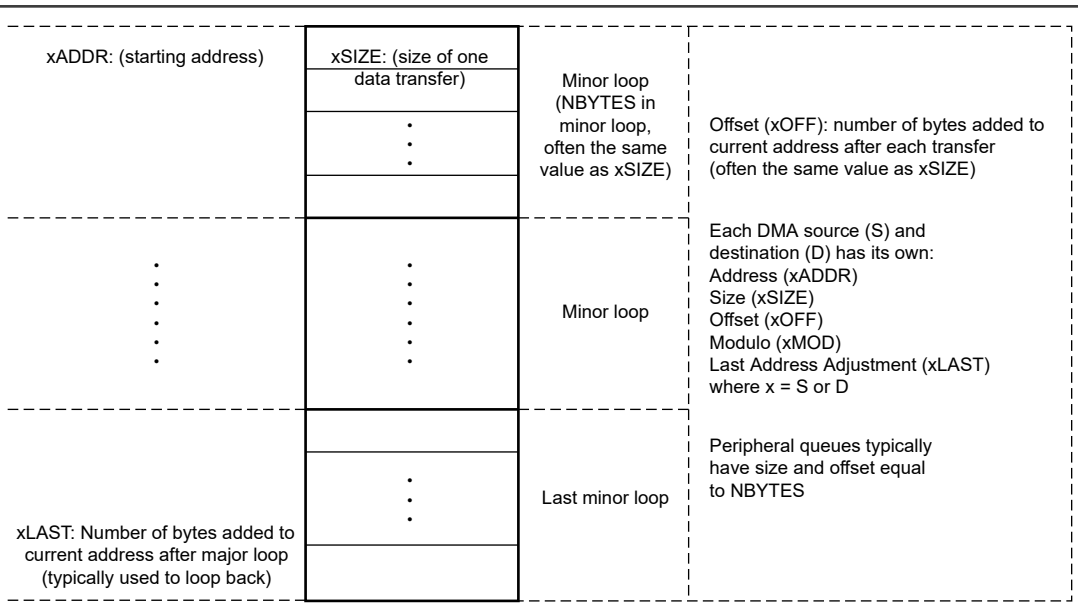

Figure 18. Memory array terms

10.6.2 eDMA arbitration

The eDMA uses a layered arbitration scheme composed of multiple priority levels. The eDMA uses a fixed-priority arbitration scheme with optional round-robin arbitration under specific conditions. The priorities are evaluated in the following order:

Table 44. eDMA arbitration priorities

Priority	Scheme	Description
1 (Highest)	Arbitration group priority	Each channel is assigned an arbitration group via the CHn_GRPRI registers. Priority is given to the highest value (31 being the highest possible value) down to the lowest value (zero, the default).
2	Channel priority	Each channel is assigned a channel priority level via the CHn_PRI registers. The channel priority is a relative priority level within an arbitration group. Priority is given to the highest value (seven being the highest possible value) down to the lowest value (zero, the default). Channel priorities within each arbitration group need not be unique. If multiple channels have the same channel priority level, the channel number will be used to determine priority as defined in row three.
3	Channel number	When two or more channels have the same arbitration group priority and channel priority, the channel number (CHn_NUM) is used to determine the highest priority. Priority is giver to the highest channel number. Lowest priority is channel 0. The channel numbers are static and cannot be changed in the programmer's model.
4 (Lowest)	Round-robin	When round-robin is enabled, any channel configured for round-robin operation has lowest priority within an arbitration group. Round-robin is enabled by setting the MP_CSR[ERCA] field to 1. After being enabled, channels with a channel priority of zero (CHn_PRI=0) will use round-robin arbitration. Round-robin arbitration will rotate the channel selection among the channels requesting service with CHn_PRI=0 within the arbitration group. Any non-zero channel within the arbitration group will continue to use fixed-priority arbitration, and if requesting service will be selected over any round-robin channels.

For fixed arbitration, the overall priority can be considered a number composed of three concatenated priority levels: CHn_GRPRI:CHn_PRI:CH_NUM. The largest number has the highest priority and the lowest number has the lowest priority.

For round-robin arbitration, the priority number is CHn_GRPRI:0:X. The module rotates through the CHn_PRI=0 channels requesting service without regard to priority among these channels. Any channel within the arbitration group for which CHn_PRI is greater than 0 will be serviced before the round-robin channels.

10.6.3 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data.

The channel number causing the error is recorded in the Error Status register (CHn_ES). If the error source is not removed before the next activation of the problematic channel, the error is detected and recorded again. Setting the halt after error field, CSR[HAE], will halt the DMA and prevent recurrence of the error.

10.6.4 Arbitration mode considerations

This section discusses arbitration considerations for eDMA.

10.6.4.1 Fixed group arbitration, fixed channel arbitration

In this mode, eDMA selects for execution the channel service request from the highest-priority channel in the highest-priority group. If eDMA is programmed so that the channels within a high-priority group have a high number of requests or large data transfers, that group may consume all the bandwidth of the eDMA controller. That is, no lower-priority groups are serviced if there is always at least one DMA request pending on a channel in the highest-priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly.

10.6.4.2 Fixed group arbitration, round-robin channel arbitration

The highest-priority group with a request is serviced. Lower-priority groups are serviced if no pending requests exist in the higher-priority groups.

Within each group, channels are serviced starting with the highest non-zero channel priority. For all channels with a channel priority programmed to 0, selection begins with the highest channel number requesting service and then rotates through to the lowest channel number requesting service. The round-robin channel arbitration can provide a fairness mechanism to lower-priority channels.

This scenario could cause the same bandwidth consumption problem as indicated in Fixed group arbitration, fixed channel arbitration, but all the channels in the highest-priority group will be serviced. Service latency is short on the highest-priority group, but could potentially be very much longer as the group priority decreases.

10.6.5 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

10.6.5.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the CH*n*_CSR[DONE] field is set to 1 and an interrupt is generated if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte-wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source, and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
```

```
TCDn_DLAST_SGA= -16
TCDn_CSR[INTMAJ] = 1
TCDn_CSR[START] = 1 (should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] field requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes:
   - CH*n*_CSR[DONE] = 0
   - TCD*n*_CSR[START] = 0
   - CH*n*_CSR[ACTIVE] = 1
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
   c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
   e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
   g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h. Write 32 bits to location 0x200C → last iteration of the minor loop → major loop complete.
6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

10.6.5.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop, transferring 16 bytes per iteration. After the channel's hardware requests are enabled via the CHn_CSR[ERQ] register field, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware (eDMA peripheral) requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:

a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
h. Write 32 bits to location 0x200C → last iteration of the minor loop.

6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0.
8. The channel retires, which concludes one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware (eDMA peripheral) requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads: Channel TCD data from local memory to internal register file.
13. The source-to-destination transfers are executed as follows:
    a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
    b. Write 32 bits to location 0x2010 → first iteration of the minor loop.
    c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
    d. Write 32 bits to location 0x2014 → second iteration of the minor loop.
    e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
    f. Write 32 bits to location 0x2018 → third iteration of the minor loop.
    g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
    h. Write 32 bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2 (TCD*n*_BITER).
15. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
16. The channel retires, which concludes with the major loop complete. The eDMA goes idle or services the next channel.

10.6.5.3 Using the modulo feature

The modulo feature of the eDMA allows implementation of a circular data queue in which the size of the queue is a power of 2. xMOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature. Modulo addressing applies to cases where the minor loop offset is enabled; that is, the upper address bits remain the same after the minor loop offset is added to the source or destination address.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value but the 28 upper address bits (0x1234567*x*) retain their original value. In this example, the source address is set to 0x12345670, the offset is set to four bytes, and the MOD field is set to four, which allows for a 2^4 byte (16 byte) queue size.

Table 45. Modulo example

Transfer number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

10.6.6 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

10.6.6.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software-initiated service requests.

1. The first method is to read the TCDn_CITER field and test for a change.
2. The second method, extracted from the sequence shown below, is to test the TCDn_CSR[START] field and the CHn_CSR[ACTIVE] field. The minor-loop-complete condition is indicated by both fields reading 0 after TCDn_CSR[START] is set to 1. Polling the CHn_CSR[ACTIVE] field only may be inconclusive because the active status may be missed if the channel execution is short in duration.

The CHn_CSR and TCDn_CSR status fields execute the following sequence for a software-activated channel:

Stage	TCDn_CSR field	CHn_CSR fields		State
	START	ACTIVE	DONE	
1	1	0	0	Initiate channel service request via software.
2	0	1	0	Channel is executing.
3a	0	0	0	Channel has completed the minor loop and is idle.
3b	0	0	1	Channel has completed the major loop and is idle.

The best method to test for minor-loop completion when using hardware-initiated (that is, peripheral-initiated) service requests is to read the TCDn_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status fields execute the following sequence for a hardware-activated channel:

Stage	TCDn_CSR field	CHn_CSR fields		State
	START	ACTIVE	DONE	
1	0	0	0	Initiate channel service request via hardware (peripheral request asserted).
2	0	1	0	Channel is executing.
3a	0	0	0	Channel has completed the minor loop and is idle.
3b	0	0	1	Channel has completed the major loop and is idle.

For both activation types, the major-loop-complete status is explicitly indicated via the CHn_CSR[DONE] field.

The TCDn_CSR[START] field is cleared to 0 automatically when the channel begins execution, regardless of how the channel activates.

10.6.6.2 Reading the transfer descriptors of active channels

The eDMA reads back the true TCDn_SADDR, TCDn_DADDR, and TCDn_NBYTES values if they are read when a channel executes. The true values of SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file, and not the values in the TCD local memory for that channel. The addresses, SADDR and DADDR, and NBYTES (which decrements to zero as the transfer progresses), can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

10.6.6.3 Checking channel preemption status

A preemptive situation is one in which a preempt-enabled channel is executing and a higher-priority request becomes active. When round-robin channel arbitration mode is enabled, all channels with their channel priority set to 0 lose their preempt ability. Channel priorities of 0 are treated as equal, that is, they are constantly rotating, when round-robin arbitration mode is enabled.

The CHn_CSR[ACTIVE] field for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended when the preempting channel executes one major loop iteration. If two CHn_CSR[ACTIVE] fields are set simultaneously in the global TCD map, a higher-priority channel is actively preempting a lower-priority channel.

10.6.7 Channel linking

Channel linking (or chaining) is a mechanism in which one channel sets the TCDn_CSR[START] field of another channel (or itself), thus initiating a service request for that channel. When properly enabled, the eDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCDn_CITER[ELINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, using an initial field setting of:

```
TCDn_CITER[ELINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJORELINK] = 1
TCDn_CSR[MAJORLINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] field

2. Minor loop done → set TCD12_CSR[START] field
3. Minor loop done → set TCD12_CSR[START] field
4. Minor loop done, major loop done→ set TCD7_CSR[START] field

When minor loop linking is enabled (TCDn_CITER[ELINK] = 1), the TCDn_CITER[CITER] field uses a nine-bit vector to form the current iteration count. When minor loop linking is disabled (TCDn_CITER[ELINK] = 0), the TCDn_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCDn_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

NOTE

The TCDn_CITER[ELINK] field and the TCDn_BITER[ELINK] field must be equal — if they are not, a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop halfway done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, that is, use another channel's TCD, at the end of a loop.

Table 46. Channel linking parameters

Wanted link behavior	TCD control field name	Description
Link at end of minor loop	TCDn_CITER[ELINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	TCDn_CITER[LINKCH]	Link channel number when linking at end of minor loop (current iteration)
Link at end of major loop	TCDn_CSR[MAJORELINK]	Enable channel-to-channel linking on major loop completion
	TCDn_CSR[MAJORLINKCH]	Link channel number when linking at end of major loop

10.6.8 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

10.6.8.1 Dynamically changing the channel priority

To change group or channel priority levels:

1. Halt the DMA by writing 1 to the CSR[HALT] field.
2. Change the group or channel priorities as wanted.
3. Enable normal DMA operations by writing 0 to the CSR[HALT] field.

10.6.8.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCDn_CSR[MAJORELINK] field during channel execution (see the diagram in TCD structure). This field is read from the TCD local memory at the end of channel execution, thus allowing you to enable the feature during channel execution.

Because you are allowed to change the configuration during execution, you need a coherency model. Consider the scenario where you attempt to execute a dynamic channel link by enabling the TCDn_CSR[MAJORELINK] field at the same time the eDMA engine is retiring the channel. TCDn_CSR[MAJORELINK] would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

We recommend that you use the following coherency model when executing a dynamic channel link request.

1. Write 1 to the TCDn_CSR[MAJORELINK] field.

2. Read back the TCDn_CSR[MAJORELINK] field.
3. Test the TCDn_CSR[MAJORELINK] request status:
   - If TCDn_CSR[MAJORELINK] = 1, the dynamic link attempt was successful.
   - If TCDn_CSR[MAJORELINK] = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCDn_CSR[MAJORELINK] field to 0 on any writes to a channel's TCDn_CSR[7:0] after that channel's CHn_CSR[DONE] field is set to 1, indicating the major loop is complete.

NOTE

You must clear the CHn_CSR[DONE] field to 0 before writing to the TCDn_CSR[MAJORELINK] field. The CHn_CSR[DONE] field is cleared to 0 automatically by the eDMA engine after a channel begins execution.

10.6.8.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in the eDMA programmer's model, thus replacing the current descriptor.

Because you are allowed to change the configuration during execution, you need a coherency model. Consider the scenario where you attempt to execute a dynamic scatter/gather operation by enabling the TCDn_CSR[ESG] field at the same time the eDMA engine is retiring the channel. The TCDn_CSR[ESG] field would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods are recommended for executing a dynamic scatter/gather request. Whenever the TCDn_CSR is written, the TCD local memory controller forces the TCDn_CSR[ESG] field to 0 on any writes to a channel's TCDn_CSR[7:0] after that channel's CHn_CSR[DONE] field has been set to 1, indicating the major loop is complete. If attempting to set the ESG, ensure the DONE field is cleared to 0.

NOTE

You must clear the CHn_CSR[DONE] field to 0 before writing the TCDn_CSR[MAJORELINK] or TCDn_CSR[ESG] fields. The CHn_CSR[DONE] field is cleared to 0 automatically by the eDMA engine after a channel begins execution and is set to 1 upon major loop completion.

10.6.8.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCDn_CSR[MAJORELINK] field is 0, the TCDn_CSR[MAJORLINKCH] field is not used by the eDMA. In this case, the TCDn_CSR[MAJORLINKCH] bits may be used for other purposes. This method uses the TCDn_CSR[MAJORLINKCH] field as a TCDn_CSR identification (ID).

When the descriptors are built, write a unique TCDn_CSR ID in the TCDn_CSR[MAJORLINKCH] field for each TCDn_CSR associated with a channel using dynamic scatter/gather.

1. Write a 1 to the TCDn_CSR[DREQ] field. Should a dynamic scatter/gather attempt fail, setting the TCDn_CSR[DREQ] field to 1 will prevent future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST final offset value.
2. Write the TCDn_DLAST_SGA field with the scatter/gather address.
3. Write a 1 to the TCDn_CSR[ESG] field.
4. Read back the 16-bit TCDn_CSR control/status field.
5. Test the TCDn_CSR[ESG] request status and TCDn_CSR[MAJORLINKCH] value:
   - If ESG = 1, the dynamic scatter/gather attempt was successful.

- If ESG = 0 and the MAJORLINKCH (ID) did not change, the dynamic scatter/gather attempt was not successful (the channel was already retiring).
- If ESG = 0 and the MAJORLINKCH (ID) changed, the dynamic scatter/gather attempt was successful (the new TCDn_CSR's ESG value cleared the ESG field to 0).

10.6.8.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCDn_DLAST_SGA field as a TCD identification (ID).

1. Write a 1 to the TCDn_CSR[DREQ] field. Should a dynamic scatter/gather attempt fail, setting the DREQ field to 1 will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (DADDR) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST final offset value.
2. Write the TCDn_DLAST_SGA field with the scatter/gather address.
3. Write a 1 to the TCDn_CSR[ESG] field.
4. Read back the TCDn_CSR[ESG] field.
5. Test the TCDn_CSR[ESG] request status:
   - If ESG = 1, the dynamic scatter/gather attempt was successful.
   - If ESG = 0, read the 32-bit TCDn_DLAST_SGA field.
   - If ESG = 0 and the TCDn_DLAST_SGA did not change, the dynamic scatter/gather attempt was not successful (the channel was already retiring).
   - If ESG = 0 and the TCDn_DLAST_SGA changed, the dynamic scatter/gather attempt was successful (the new TCDn_CSR's ESG value cleared the ESG field to 0).

10.6.9 Suspend/resume a DMA channel with active hardware service requests

The DMA allows you to move data from memory or peripheral registers to another location in memory or to peripheral registers without CPU interaction. After the DMA and peripherals are configured and active, it is rare but supported to suspend a peripheral's service request dynamically. In this scenario, there are certain restrictions to disabling a DMA hardware service request. For coherency, you must follow a specific procedure. This section provides guidance on how to coherently suspend and resume a Direct Memory Access (DMA) channel when the DMA is triggered by a slave module such as the Serial Peripheral Interface (DSPI), Sigma Delta Analog to Digital Convertor (SDADC), or other module.

10.6.9.1 Suspend an active DMA channel

To suspend an active DMA channel:

1. Stop the DMA service request at the peripheral first. Confirm it has been disabled by reading back the appropriate register in the peripheral.
2. Check the DMA's Hardware Request Status (MP_HRS) to ensure there is no service request to the DMA channel being suspended. Then disable the hardware service request by clearing the ERQ field to 0 on the appropriate DMA channel.

For example, assume the DSPI is set as a master for transmitting data via a DMA service request when the TXFIFO has an empty slot. The DMA will transfer the next command and data to the TXFIFO upon the request. If you need to suspend the DMA/DSPI transfer loop, perform the following steps:

1. Disable the DMA service request at the source by writing 0 to DSPI_RSER[TFFF_RE]. Confirm that DSPI_RSER[TFFF_RE] is 0.
2. Ensure there is no DMA service request from the DSPI by verifying that MP_HRS[HRS] is 0 for the appropriate channel. If no service request is present, disable the DMA channel by clearing the channel's ERQ field to 0. If a service request is present, wait until the request has been processed and the HRS field reads 0.

10.6.9.2 Resume a DMA channel

To resume a DMA channel:

1. Enable the DMA service request on the appropriate channel by setting its ERQ field to 1.
2. Enable the DMA service request at the peripheral.

Chapter 11
Miscellaneous System Control Module (MSCM)

11.1 Chip-specific MSCM information

Table 47. Reference links to related information

Topic	Related module	Reference
Full description	MSCM	MSCM
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

11.1.1 Module instances

This device has one instance of the MSCM module.

11.1.2 OCMDR1[OCMSZ]

OCMDR1[OCMSZ] = 1000b, indicates the device boot ROM is 96 KB.

11.1.3 SID[FAMID]

For MCX W71, SID[FAMID] = 0000b.

11.2 Overview

The Miscellaneous System Control Module (MSCM) contains CPU configuration registers and on-chip memory controller registers.

11.2.1 Block Diagram

The MSCM block diagram is shown below in Figure 19:

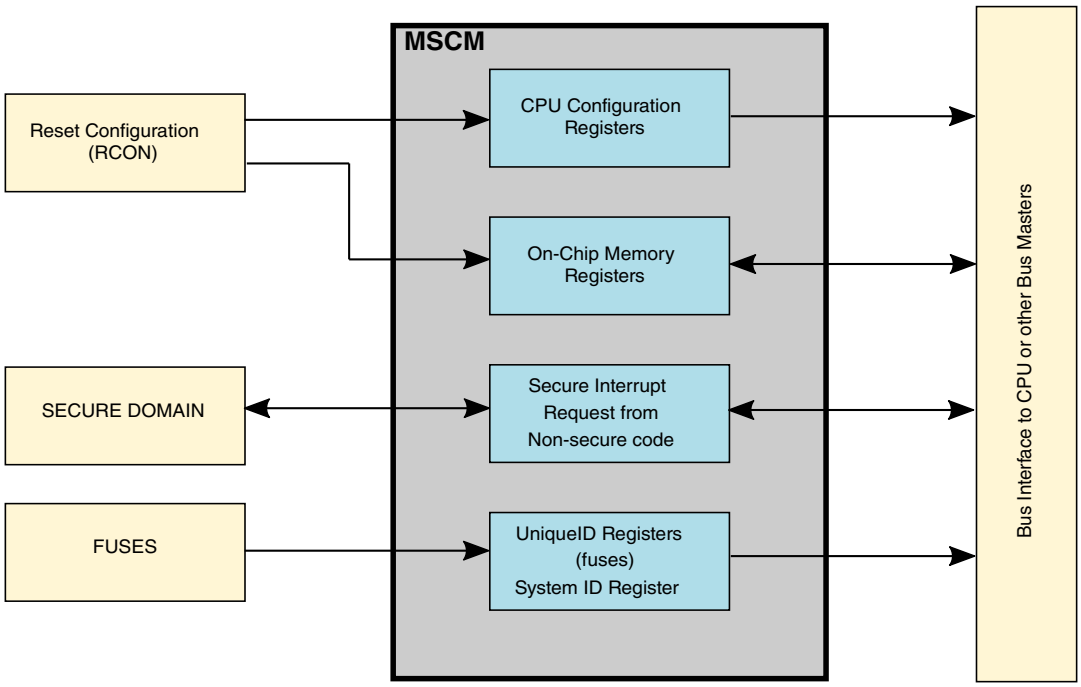

Figure 19. MSCM Block Diagram

11.2.2 Features

The MSCM has the following registers:

- Generic processor "x" configuration registers - These registers are only accessible by the main processor core
- Configuration registers containing information for processor 0 (main processor core) - These registers are accessible to any bus master
- On-Chip Memory Descriptor Registers - Provides static information about the attached memories. These registers are only accessible to the processor core or debugger
- Secure interrupt register - Provides a mechanism for non-secure code to generate a low latency pulsed exception into the secure privileged domain and can only be written in nonsecure mode
- Unique ID registers - Loaded directly from UUID fuse words
- System ID register - Loaded from IFR

11.3 Functional Description

11.3.1 Chip Configuration and Boot

The device's logical definition is controlled via chip-specific configuration bits, supported memory sizes and packing options. Collectively, these configuration bits define a reset configuration value (RCON).

Once the core has fetched the reset vector(s), core and system configuration information is read from a globally-accessible slave peripheral that properly converts the information into more appropriate values. More specifically, the core accesses configuration information from a common set of peripheral addresses and the chip configuration logic properly evaluates based on the requesting processor and returns the appropriate value for the given processor, including core identification.

As an example, there is a single 32-bit read-only location for the core identification. A 32-bit read from this location returns a 4-character ASCII string: 0x4D333301 .

The programming model associated with the core configuration information is included as part of the Miscellaneous System Control Module (MSCM). It specifically includes multiple views of the processor configuration; one view that is available generically to the core, and other views that are available to any bus masters in the system.

11.4 MSCM Memory Map/Register Definition

11.4.1 CPU Configuration Memory Map and Registers

The CPU configuration portion of the MSCM module provides a set of memory-mapped read-only addresses defining the processor set-up. This portion of the MSCM programming model can only be accessed with 32-bit read references; any other size is terminated with an error. If the processor is logically not included in the chip configuration, then reads of its configuration registers return zeroes.

The CPU Configuration registers are organized based on the logical processor number (not any type of physical port number) and partitioned into the following equal sections:

Table 48. CPU Configuration Register Sections

Offset addresses	Function
0x000 - 0x01F	Defines the generic processor "x" configuration. This region is only accessible to the processor core; reads by non-core bus masters are treated as read-as-zero (RAZ) accesses.
0x020 - 0x03F	Defines the configuration information for processor 0 (CP0). This region is accessible to any bus master.

11.4.2.2 Processor X Type Register (CPxTYPE)

Offset

Register	Offset
CPxTYPE	0h

Function

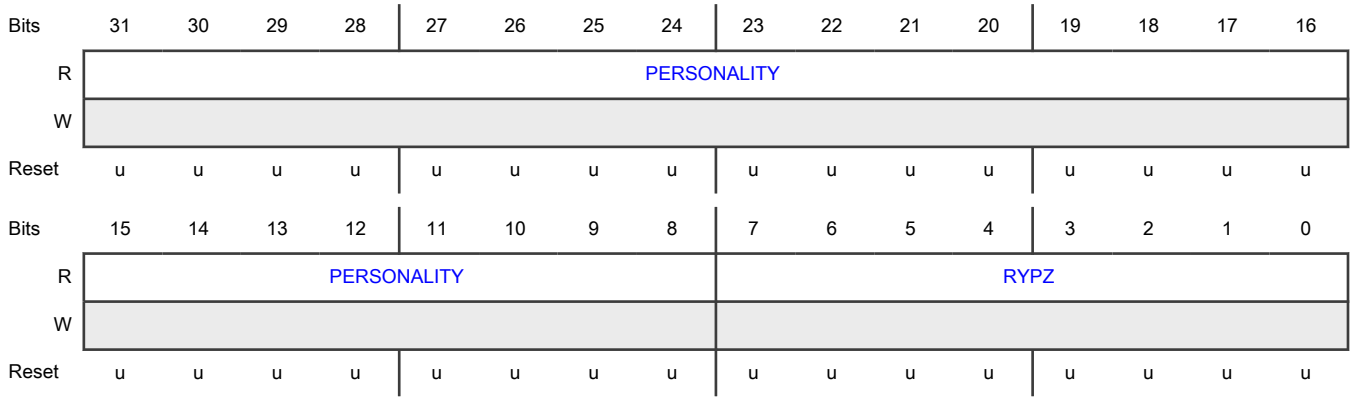
The register provides a CPU-specific response indicating the personality of the core making the access. The 32-bit response includes 3 ASCII characters that define the CPU type, along with a byte that defines the logical revision number. The logical revision number follows Arm's rYpZ nomenclature.

NOTE

CPxTYPE value(s) for this device:

- If CPU0 is making the access, then the value read is 0x4D333301
- If the read access is not from a CPU, then the value read is 0x00000000

Diagram



Fields

Field	Function
31-8 PERSONALITY	Processor x Personality This read-only field defines the processor personality for CPUx
7-0 RYPZ	Processor x Revision This read-only field defines the processor revision for CPUx: 0x00 corresponds to the r0p0 core release. 0x01 corresponds to the r0p1 core release. ...

11.4.2.3 Processor X Number Register (CPxNUM)

Offset

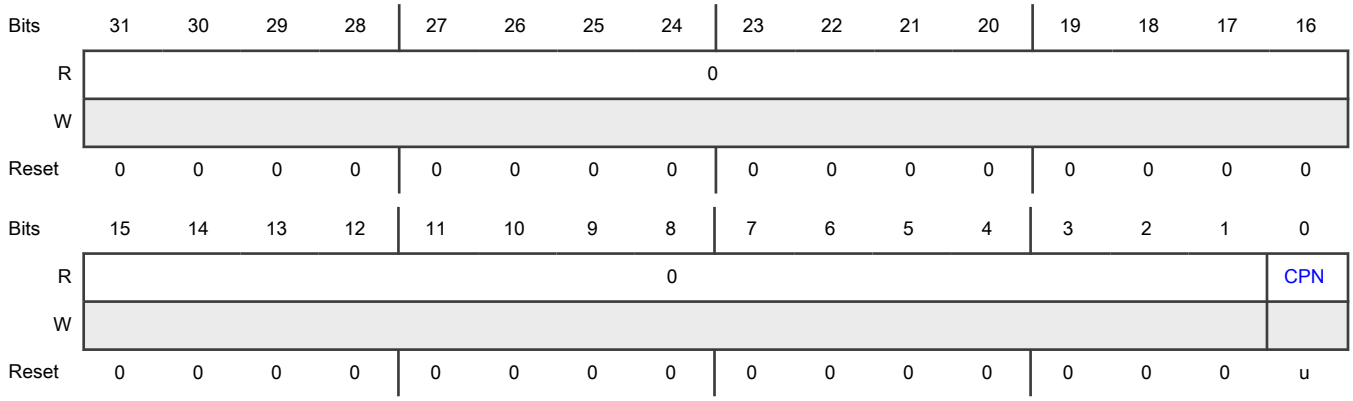
Register	Offset
CPxNUM	4h

Function

The register provides a CPU-specific response indicating the logical processor number of the core making the access. The logical processor number is always 0.

If the read access is not from a CPU, then the value read is 0x00000000.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 CPN	Processor x Number This zero-filled word defines the logical processor number for CPUx If single core configuration, then CPN = 0

11.4.2.4 Processor X Master Register (CPxMASTER)

Offset

Register	Offset
CPxMASTER	8h

Function

The register provides a CPU-specific response indicating the physical bus master number of the core that is making the access. The 32-bit response defines the physical master number for processor x.

- CPxMASTER = 0x00000000

NOTE

A read from a CPU returns the appropriate processor information. Reads from a non-CPU bus master returns all zeroes. Write accesses are terminated with an error.

11.4.2.6 Processor X Configuration Register 0 (CPxCFG0)

Offset

Register	Offset
CPxCFG0	10h

Function

The CPxCFG0 register provides a CPU-specific response detailing configuration information, in this case, information on the Level 1 caches (if present).

NOTE

Reset values for the Processor X Configuration Register 0:

- For CPU0, the CPxCFG0 value read is 0x04080000
- If the read access is not from a CPU, then the value read is 0x00000000

11.4.2.18 On-Chip Memory Descriptor Register (OCMDR0)

Offset

Register	Offset
OCMDR0	400h

Function

This section of the programming model is an array of 32-bit generic on-chip memory descriptor registers that provide static information about the attached memories, as well as configurable controls (where appropriate).

- The access permissions for this module are set in the TRDC.
- 32-bit reads from a processor core or the debugger return the appropriate processor information.
- Reads from any other bus master return all zeroes.
- Writes from a processor core or the debugger to writeable registers update the appropriate fields.
- Writes from other bus masters are ignored.
- Any access with a size other than 32 bits are terminated with an error.

The following table describes the OCMDRn reset values and the associated memory type:

OCMDRn	Reset Value	On-Chip Memory Type
OCMDR0	0xEB089000	Program Flash
OCMDR1	0xD8047000	ROM
OCMDR2	0xE5041000	System RAM

11.4.2.19 On-Chip Memory Descriptor Register (OCMDR1)

Offset

Register	Offset
OCMDR1	404h

Function

This section of the programming model is an array of 32-bit generic on-chip memory descriptor registers that provide static information about the attached memories, as well as configurable controls (where appropriate).

- The access permissions for this module are set in the TRDC.
- 32-bit reads from a processor core or the debugger return the appropriate processor information.
- Reads from any other bus master return all zeroes.
- Writes from a processor core or the debugger to writeable registers update the appropriate fields.
- Writes from other bus masters are ignored.
- Any access with a size other than 32 bits are terminated with an error.

The following table describes the OCMDRn reset values and the associated memory type:

OCMDRn	Reset Value	On-Chip Memory Type
OCMDR0	0xEB089000	Program Flash

11.4.2.24 Secure Interrupt Request (SECURE_IRQ)

Offset

Register	Offset
SECURE_IRQ	800h

Function

The SECURE_IRQ register provides a mechanism for non-secure code to generate a low latency pulsed exception into the secure privileged domain. This register is accessible in a non-secure peripheral address slot that non-secure code can write a specific value that forces an interrrupt that executes as a secure exception and enters the secure domain.

This register can only be written in nonsecure mode.

12.1.1 Module instances

This device has one instance of the SMSCM module.

12.1.2 On-chip memory control

The SMSCM can control the following on-chip memory (OCRAM) with registers, See TCM arrays for more details about the TCM SRAM assignment.

Table 50. On-chip memory (OCRAM) control

OCRAM	SRAM instance	ECC
OCRAM0	Program Flash	—
OCRAM2	CTCM0-CTCM1	Yes
OCRAM3	STCM0-STCM2	Yes
OCRAM5	STCM5	Yes
Others	Reserved	—

12.2 Overview

The Secure Miscellaneous System Control Module (SMSCM) contains secure CPU configuration registers and secure on-chip memory controller registers.

The SMSCM has two 32-bit registers to allow software to read the values of the LIFECYCLE and LIFECYCLE_B fuses. The SMSCM inputs these fuses, which can change during POR or warm reset. The fuse are stable as reset is negated. After reset is deasserted, if the LIFECYCLE and LIFECYCLE_B values are not complements, a security violation is asserted. The security violation is sent to the security subsystem.

12.3 SMSCM Memory Map/Register Definition

12.3.1 Replicated Control Registers

For certain critical control and configuration functions, a special three D flip-flop (DFF3) register implementation is used.

This design uses a pole, anti-pole implementation where the 101b state represents the negated register state and 010b is the asserted state. In the following register descriptions, the replicated function is shown as a single read data bit plus a 3-bit write data field. The register read data bit is aligned as the "middle bit" within the 3-bit field and the 3-bit write data field is defined as "W2S, W5C". This nomenclature defines a 3-bit write data field of value 2 (010b) is needed to set the asserted state of the three

DFFs, while a 3-bit write data field of value 5 (101b) is required to clear the combined DFF3 state. All other write data values do not affect the register state. For reads, the 3-bit field returns {0,register_state,0}b, that is, the register state in the middle bit and zeroes for both adjacent bits.

To change the control state, the user must write BOTH pole and anti-pole registers. The order of the register writes, pole then anti-pole versus anti-pole then pole does not matter. The programming model is updated after the first register is written, however the control state in the hardware doesn't change until the second register is written.

The control state is asserted when the pole register is written with 010b and the anti-pole register is written with 101b. The control state is deasserted when the pole register is written with 101b and the antipole register is written with 010b. If both pole and anti-pole registers are written with the same legal value (010b or 101b), a security violation is asserted. The security violation remains asserted until system reset asserts.

12.3.2 SMSCM register descriptions

12.3.2.1 SMSCM memory map

Writes to the SMSCM programming model must be 32-bits. Non 32-bit writes are terminated with a bus error.

Reads of 8-bit, 16-bit and 32-bit size are allowed.

Writes to read-only registers and reads of write-only registers are terminated with a bus error.

The access permissions for this module are set in the TRDC.

12.3.2.2 Debug Enable (DBGEN)

Offset

Register	Offset
DBGEN	0h

Function

This register implements debug access control in six 3-bit pole, anti-pole states (DFF3) while the DBGEN_B register implements independent complement versions of the same debug access control states. This register only resets on POR. For warm resets, the value remains in the register and updated when the fuses are valid.

The DBGEN/SPIDEN/NIDEN/SPNIDEN register fields can be updated when DBGEN_LOCK[LOCK] = 000b. The ALTDBGEN register field can be updated when DBGEN_LOCK[ALT_DBGEN_LOCK] = 000b. The ALTEN register field can be updated when DBGEN_LOCK[ALT_EN_LOCK] = 000b. The register is fields are unlocked at reset.

Writes to locked register fields are simply ignored and are not error terminated. Therefore, software must read the DBGEN register after each write to ensure the write completed.

As power-on reset is negated and the fuse initialization is complete, the DBGEN and DBGEN_B are loaded with values determined by the encoded converged lifecycle fuses.

The pole/anti-pole updating sequence works independently for ALTEN, ALTDBGEN, SPNIDEN, NIDEN, SPIDEN, DBGEN bitfields.

For reads, each of the DFF3 3-bit fields return {0,register_state,0}b.

21-4 ROMWA	ROM Watermark Address The first accessible address (0-mod-16) after the lockout region. When ROM_LOCKOUT[REGLOCK] = 010b, reads to addresses below this watermark value result in an error response.
3-0 —	Reserved

12.3.2.9 Security Counter Register (SCTR)

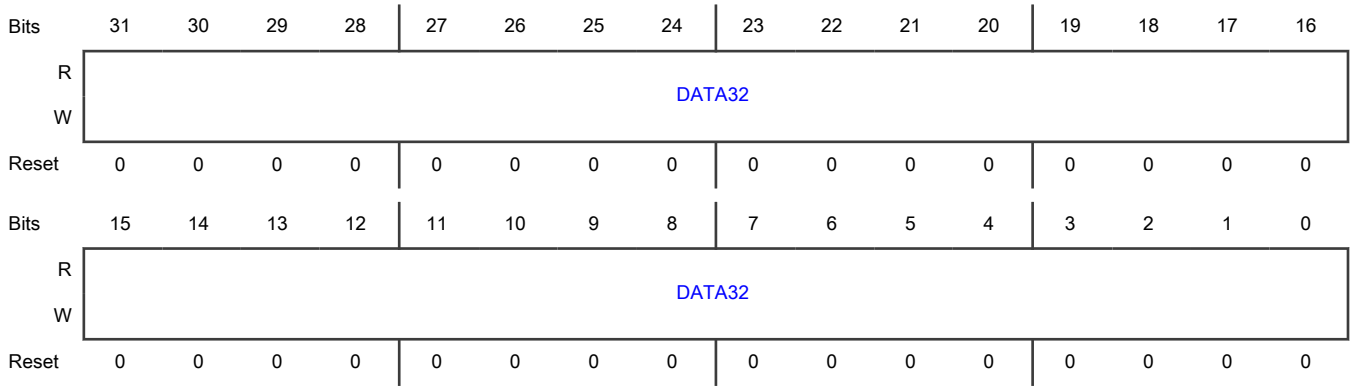
Offset

Register	Offset
SCTR	100h

Function

This register provides a security counter function, which is intended to validate the control flow integrity of CPU code execution. This register is the actual counter register; there are four additional virtual registers that support a set of arithmetic operations including {+1, -1, +x, -x} where x is any 32-bit operand.

Diagram



Fields

Field	Function
31-0 DATA32	Data, 32 bits This is the 32-bit value contained as the security counter.

12.3.2.10 Security Counter Plus 1 Register (SCTRP1)

Offset

Register	Offset
SCTRP1	104h

Function

This virtual write-only register provides a security counter arithmetic function - register writes to this address increment the security counter by 1 (+1). The security counter provides a mechanism to validate the control flow integrity of CPU code execution. This is one of four virtual registers that support a set of arithmetic operations including {+1, -1, +x, -x} where x is any 32-bit operand.

12.3.2.14 On-Chip Memory Descriptor Register (OCMDR0)

Offset

Register	Offset
OCMDR0	400h

Function

This section of the programming model is an array of 32-bit generic on-chip memory descriptor registers that provides configurable controls (where appropriate).

- Any access with a size other than 32 bits are terminated with an error.

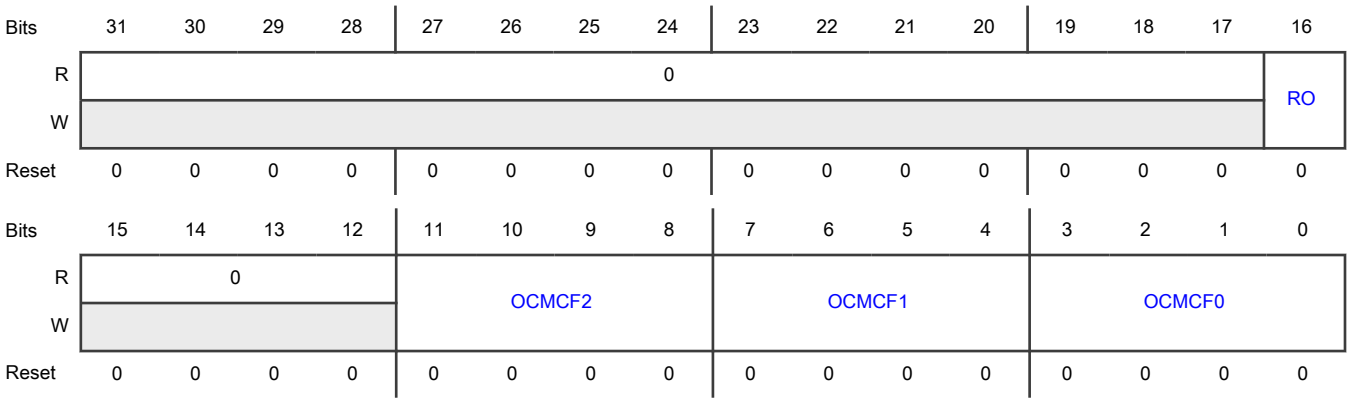
An on-chip memory has a corresponding SMSCM OCMDRn register when one of the following is true:

- The memory type is data flash
- The memory type is program flash
- The memory type is system RAM and ECC = true

The following table describes each on-chip memory type:

On-chip memory n	On-Chip Memory Type
On-chip memory 0	Program Flash
On-chip memory 2	System RAM
On-chip memory 3	System RAM
On-chip memory 5	System RAM

Diagram



Fields

Field	Function
31-17 —	Reserved
16 RO	Read-Only This register bit provides a mechanism to “lock” the configuration state defined by OCMDRn[11:0]. Once asserted, attempted writes to the OCMDRn[11:0] register are ignored until the next reset clears the flag. 0b - Writes to the OCMDRn[11:0] are allowed 1b - Writes to the OCMDRn[11:0] are ignored
15-12 —	Reserved
11-8	OCMEM Control Field 2

Table continues on the next page...

Table continued from the previous page...

Field	Function
OCMCF2	The flash controller needs to be idle when writing to an OCMDRn register associated with Flash memory. Changing controller configuration while active can cause undesired results. The flash cache on this device is a small, read-only cache to help accelerate flash accesses. The 4 bits in CF2 configure and maintain this cache. CF2 = Control Field 2 - for flash cache • CF2[3] - disable flash cache • CF2[2] - disable instruction caching • CF2[1] - disable flash data caching • CF2[0] - clear flash cache CF2[3:1] • 000b - the flash cache is enabled and will cache both flash instruction and flash data fetches • 001b - the flash cache is enabled and will cache flash instruction fetches but not flash data fetches • 010b - the flash cache is enabled and will cache flash data fetches but not flash instruction fetches • 011b - the flash cache is enabled but will not be used (basically disabled) • 1xxb - the flash cache is diabled CF2[0] • 0b - do not clear the flash cache • 1b - clear the flash cache (negate all valid bits in the cache)
7-4 OCMCF1	OCMEM Control Field 1 The flash controller needs to be idle when writing to an OCMDRn register associated with Flash memory. This means no read/erase/execute/etc operations from the Flash memory should be made while writing to the OCMDRn register associated with that memory. Changing controller configuration while active can cause undesired results. CF1 = Control Field 1 - for flash controller CF1[3] LKIFR1 - Lock IFR1 • 0b = IFR1 space can be accessed. • 1b = IFR1 space cannot be accessed. This bit is sticky. Once set, it is cleared with reset. CF1[2] Reserved CF1[1] DFS - Disable Flash Speculate • 0b = Enable Flash Speculate • 1b = Disable Flash Speculate CF1[0] DDP - Disable Data Prefetch • 0b = Enable Data Prefetch • 1b = Disable Data Prefetch

Table continues on the next page...

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>CF1[1:0] bits controls whether prefetches (or speculative accesses) are initiated in response to instruction fetches or data references.

On new flash accesses, the flash controller reads 128-bit aligned data and stores it in a normal read buffer while bypassing the desired 32-bit to the input AHB bus. Subsequent accesses to the same 128-bits of flash data can be serviced from this buffer without re-reading the flash arrays and has buffers to hold a flash access. The flash controller also has a 128-bit speculation buffer. During idle cycles or cycles where the flash controller accesses are being serviced from the flash cache or the normal buffer, the flash controller will read the next sequential 128-bits of flash data and store it in the speculation buffer. Then, subsequent sequential accesses can hit this speculation buffer without accessing the flash. The following CF1[1:0] bits configure and maintain this speculation buffer.

<table>
<tr><th>CF1[1]
Flash Speculate Disable</th><th>CF1[0]
Data Prefetch Disable</th><th>Result</th></tr>
<tr><td>Disabled (1b)</td><td>Disabled (1b)</td><td rowspan="2">All speculation disabled and speculation buffer is cleared</td></tr>
<tr><td>Disabled (1b)</td><td>Enabled (0b)</td></tr>
<tr><td>Enabled (0b)</td><td>Disabled (1b)</td><td>Speculation for Instruction enabled and Speculation for Data disabled</td></tr>
<tr><td>Enabled (0b)</td><td>Enabled (0b)</td><td>Speculation for both Instruction and Data enabled</td></tr>
</table>

The reset state for CF1[1:0] is 00b - the speculation buffer is enabled and speculation will occur for both flash instruction accesses and flash data accesses.

Note, whenever the speculation buffer is disabled (CF1[1:0] = 1xb, the speculation buffer is cleared (its valid bit is negated). This provides a way to clear the speculation buffer. The speculation buffer is also cleared when the flash controller is reset.</td></tr>
<tr><td>3-0

OCMCF0</td><td>OCMEM Control Field 0

OCMCF0 is used to Program or Data Flash and System RAM ECC.

The flash controller needs to be idle when writing to an OCMDRn register associated with Flash memory. This means no read/erase/execute/etc operations from the Flash memory should be made while writing to the OCMDRn register associated with that memory. Changing controller configuration while active can cause undesired results.

CF0 = Control Field 0 - for ECC control functions.

CF0[3] DNCBED - Disable non-correctable bus errors on flash data fetches

• 0b = Bus error for non-correctable error on data fetch from flash

• 1b = Disable bus error response for non-correctable error on data fetch from flash

CF0[2] DNCBEI - Disable non-correctable bus errors on flash instruction fetches

• 0b = Bus error for non-correctable error on instruction fetch from flash</td></tr>
</table>

12.3.2.16 On-Chip Memory ECC Control Register (OCMECR)

Offset

Register	Offset
OCMECR	480h

Function

The On-Chip Memory ECC Control Register is an 32-bit control register for specifying which types of memory errors are reported. In systems with ECC, the occurrence of a non-correctable error causes the current access to be terminated with an error condition. In many cases, this error termination is reported directly by the initiating bus master. However, there are certain situations where the occurrence of this type of non-correctable error is *not* reported by the master. Examples include speculative instruction fetches which are discarded due to a change-of-flow operation, and buffered operand writes. The ECC reporting logic in MSCM provides an optional error interrupt mechanism to signal all non-correctable memory errors. In addition to the interrupt generation, the MSCM captures specific information (memory address, attributes and data, bus master number, etc.) which may be useful for subsequent failure analysis.

Single bit memory corrections are performed on-the-fly, returning the corrected read data to the requesting bus master. For these single bit corrections, another configuration bit allows reporting of these events.

12.3.2.20 On-Chip Memory ECC Fault Data High Register (OCMFDRH)

Offset

Register	Offset
OCMFDRH	498h

Function

The OCMFDR is a 64-bit read-only register for capturing the read data of the last, properly-enabled ECC event in the on-chip memory. OCMFDRH is the upper 32 bits. Depending on the state of the On-Chip Memory ECC Control Register (OCMECR), an ECC event in the on-chip memory causes the address, attributes and read data associated with the access to be loaded into the OCMFAR, OCMFTR and OCMFDR registers, and the appropriate flag in the On-Chip Memory ECC Interrupt Register to be asserted. The read data is captured after it has been processed by the ECC logic, that is, in the case of a correctable single-bit ECC event, the read data is the corrected value. The contents of OCMFTR[EFSYN] can be used to locate the original faulted data bit. Attempted writes are ignored.

12.3.2.22 Core Platform Control Register (CPCR)

Offset

Register	Offset
CPCR	C00h

Function

This register provides the ability to control the round robin arbitration mode in the various bus crossbars in the system.

Diagram

Fields

Field	Function
31-1 —	Reserved
0 AXBS0_RREN	AXBS0 Round Robin Enable When set, this forces the AXBS0 to round robin arbitration mode out of reset. To change the arbitration mode after reset is negated, the AXBS0 programming model must be used. Enabled at reset. 0b - AXBS0 in fixed priority arbitration mode at reset. 1b - AXBS0 in round robin arbitration mode at reset.

Chapter 13
Miscellaneous Control Module (MCM)

13.1 Chip-specific MCM information

Table 51. Reference links to related information

Topic	Related module	Reference
Full description	MCM	MCM
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing
Cache	LPCAC	Low Power Cache Controller (LPCAC)

13.1.1 Module instances

This device has one instance of the MCM module.

13.1.2 LMFATR[PEFSYN]

LMFATR[PEFSYN] field indicates the master that accesses the cache when the LMEM fault is detected.

- 0x0 - Core
- 0x1 - Debug tool
- Others - Reserved

13.1.3 ISCR[CWBEE]

In this device, the ISCR[CWBEE] must be configured as 0.

13.2 Overview

The Miscellaneous Control Module (MCM) provides a myriad of miscellaneous control functions.

13.2.1 Features

The MCM includes the following features:

- Program-visible information on the platform configuration and revision
- Error status and interrupts for the cache write buffer
- Error status and interrupts for the core's floating-point unit (FPU)

13.3 Functional description

This section describes the functions of the MCM module.

13.3.1 Interrupts

The MCM's interrupt is generated if any of the following is true:

- FPU input denormal interrupt is enabled (FIDCE) and an input is denormalized (FIDC)
- FPU inexact interrupt is enabled (FIXCE) and a number is inexact (FIXC)

- FPU underflow interrupt is enabled (FUFCE) and an underflow occurs (FUFC)
- FPU overflow interrupt is enabled (FOFCE) and an overflow occurs (FOFC)
- FPU divide-by-zero interrupt is enabled (FDZCE) and a divide-by-zero occurs (FDZC)
- FPU invalid operation interrupt is enabled (FIOCE) and an invalid occurs (FIOC)
- PC data parity error
- PC tag parity error
- Cache write buffer error

13.3.2 Determining source of the interrupt

To determine the exact source of the interrupt, check the interrupt status flags with the corresponding interrupt enable bits.

1. From MCM_ISCR[31:16] and MCM_ISCR[15:0]
2. Search the result for asserted flags, which indicate the exact interrupt sources

NOTE

Parity interrupts are determined by LMEPECR (interrupt enable) and LMPEIR (interrupt source).

13.4 Memory map/register descriptions

The memory map and register descriptions below describe the registers using byte addresses. The programming model for the Miscellaneous Control Module is accessed via the core's Private Peripheral Bus (PPB).

13.4.1 MCM register descriptions

13.4.1.1 MCM memory map

MCM base address: E008_0000h

Offset	Register	Width (In bits)	Access	Reset value
Ch	Core Platform Control (CPCR)	32	RW	See section
10h	Interrupt Status and Control (ISCR)	32	RW	0000_0000h
20h	Write Buffer Fault Address (FADR)	32	R	See section
24h	Store Buffer Fault Attributes (FATR)	32	R	See section
28h	Store Buffer Fault Data (FDR)	32	R	See section

13.4.1.2 Core Platform Control (CPCR)

Offset

Register	Offset
CPCR	Ch

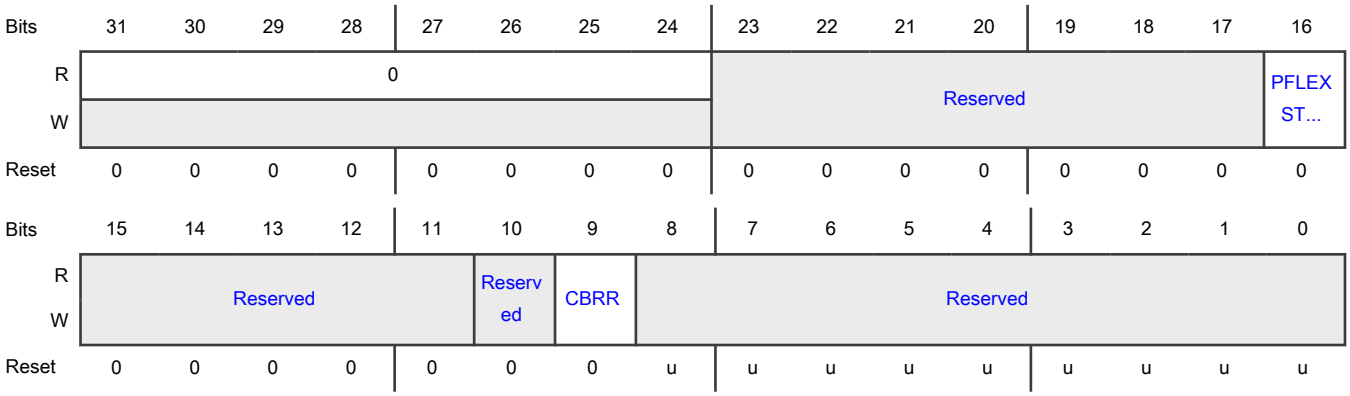
Function

The Core Platform Control Register (CPCR) configures the arbitration.

NOTE

Bits 8-0 are undefined after reset.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-17 —	Reserved
16 PFLEXSTALL	Flash Stall Enable This field configures whether to enable flash stall when the flash is busy.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Flash stall is disabled when flash is busy. 1b - Flash stall is enabled when flash is busy.
15-11 —	Reserved
10 —	Reserved
9 CBRR	Crossbar Round-robin Arbitration Enable This field configures the crossbar slave ports to fixed-priority or round-robin arbitration. 0b - Fixed-priority arbitration 1b - Round-robin arbitration
8-0 —	Reserved

13.4.1.3 Interrupt Status and Control (ISCR)

Offset

Register	Offset
ISCR	10h

Function

The Interrupt Status and Control Register (ISCR) configures and reports status of core-related interrupt exception conditions. The individual event indicators are first checked with their exception enables and then logically summed to form an interrupt request sent to the core's NVIC.

Bits 15-8 are read-only indicator flags based on the processor's FPSCR register. Attempted writes to these bits are ignored. Once set, the flags remain asserted until software clears the corresponding FPSCR bit.

Bits 31-24 controls interrupt enablement. If an interrupt enablement control bit is set as 1, the MCM will generate an interrupt when the corresponding status bit is 1.

Diagram

26 FOFCE	FPU Overflow Interrupt Enable 0b - Disable interrupt 1b - Enable interrupt
25 FDZCE	FPU Divide-by-zero Interrupt Enable 0b - Disable interrupt 1b - Enable interrupt
24 FIOCE	FPU Invalid Operation Interrupt Enable 0b - Disable interrupt 1b - Enable interrupt
23-22	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
21 CPEE	Cache Parity Error Enable This field enables the generation of an interrupt in response to the cache parity error. 0b - Disable error interrupt. 1b - Enable error interrupt.
20 CWBEE	Cache Write Buffer Error Enable This field enables the generation of an interrupt in response to a bus error termination reported on a system bus transfer initiated from the cache's write buffer. 0b - Disable error interrupt 1b - Enable error interrupt
19-16 —	Reserved
15 FIDC	FPU Input Denormal Interrupt Status This read-only field is a copy of the core's FPSCR[IDC] bit and indicates input denormalized number has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IDC] bit. 0b - No interrupt 1b - Interrupt occurred
14-13 —	Reserved
12 FIXC	FPU Inexact Interrupt Status This read-only field is a copy of the core's FPSCR[IXC] bit and indicates an inexact number has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IXC] bit. 0b - No interrupt 1b - Interrupt occurred
11 FUFC	FPU Underflow Interrupt status This read-only field is a copy of the core's FPSCR[UFC] bit and indicates an underflow has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[UFC] bit. 0b - No interrupt 1b - Interrupt occurred
10 FOFC	FPU Overflow Interrupt Status This read-only field is a copy of the core's FPSCR[OFC] bit and indicates an overflow has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[OFC] bit.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No interrupt 1b - Interrupt occurred
9 FDZC	FPU Divide-by-zero Interrupt Status This read-only field is a copy of the core's FPSCR[DZC] bit and indicates a divide-by-zero has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[DZC] bit. 0b - No interrupt 1b - Interrupt occurred
8 FIOC	FPU Invalid Operation Interrupt Status This read-only bit is a copy of the core's FPSCR[IOC] bit and indicates an illegal operation has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IOC] bit. 0b - No interrupt 1b - Interrupt occurred
7-6 —	Reserved
5 CPES	Cache Parity Error Status This field indicates whether a cache parity error is detected. This field can be set only when the corresponding enable bit (CPEE) is set. 0b - A cache parity error is not detected. 1b - A cache parity error is detected.
4 CWBER	Cache Write Buffer Error Status This field indicates whether a data transfer from the core's cache write buffer was terminated because of a bus error. This field can be set only when the corresponding enable bit (CWBEE) is set. The corresponding core fault address, attributes and write data are typically retrieved from the FADR, FATR, and FDR registers during the interrupt service routine before clearing the CWBER flag. 0b - No error 1b - Error occurred
3-1 —	Reserved
0 —	Reserved

13.4.1.4 Write Buffer Fault Address (FADR)

Offset

Register	Offset
FADR	20h

Function

The Write Buffer Fault Address Register (FADR) captures the faulting address when a properly-enabled cache write buffer error interrupt event is detected. The MCM logic captures a single cache write buffer bus error event; if a subsequent error is detected before the captured error information has been read from the corresponding registers and the MCM_ISCR[CWBER] indicator cleared, the MCM_FATR[BEOVR] flag is set. However, no additional information is captured.

The bits in this register are set by hardware when MCM_ISCR[CWBER] is asserted. Attempted writes have no effect.

Diagram

Fields

Field	Function
31-0 ADDRESS	Fault address

13.4.1.5 Store Buffer Fault Attributes (FATR)

Offset

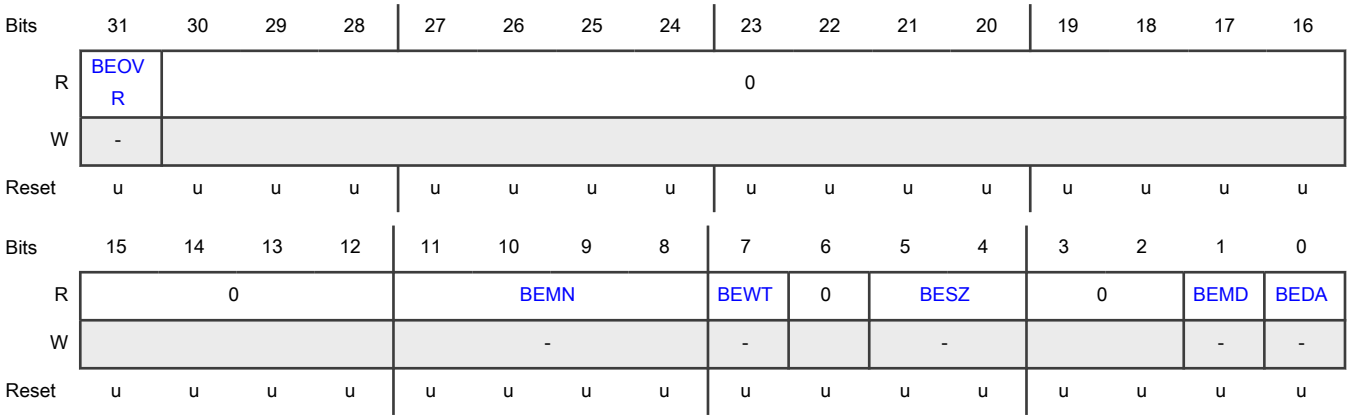
Register	Offset
FATR	24h

Function

The Store Buffer Fault Attributes Register (FATR) indicates the faulting attributes, when a properly-enabled cache write buffer error interrupt event is detected

The bits in this register are set by hardware and signaled by the assertion of MCM_ISCR[CWBER]. Attempted writes have no effect.

Diagram



Fields

Field	Function
31 BEOVR	Bus Error Overrun This field indicates if another cache write buffer bus error is detected before system software has retrieved all the error information from the original event. The time window is from the detection of the original cache write buffer error termination to the ISCR[CWBER] is written with a 1 to clear it and rearm the capture logic. This bit is set by the hardware and cleared whenever software writes a 1 to the ISCR[CWBER] bit. 0b - No bus error overrun 1b - Bus error overrun occurred. The FADR and FDR registers and the other FATR bits will not be updated to reflect this new bus error.
30-12 —	Reserved
11-8 BEMN	Bus Error Master Number This field indicates the crossbar switch bus master number of the captured cache write buffer bus error. For this device, this value is always 0x1.
7 BEWT	Bus Error Write This field indicates the type of system bus access when the cach write buffer error was detected. Since this logic is monitoring data transfers from the cache write buffer, this bit is always a logical one, indicating a write operation. 0b - Read access 1b - Write access
6 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
5-4 BESZ	Bus Error Size This field indicates the size of the cache write buffer access when the error was detected. 00b - 8-bit access 01b - 16-bit access 10b - 32-bit access 11b - Reserved
3-2 —	Reserved
1 BEMD	Bus Error Privilege level This field indicates the privilege level of the cache write buffer access when the error was detected. 0b - User mode 1b - Supervisor/privileged mode
0 BEDA	Bus Error Data Access Type This field indicates the type of cache write buffer access when the error was detected. This attribute is always logical one because only data access is performed on cache write buffer. 0b - Instruction 1b - Data

13.4.1.6 Store Buffer Fault Data (FDR)

Offset

Register	Offset
FDR	28h

Function

The Store Buffer Fault Data Register (FDR) indicates the captured faulting data, when a properly-enabled cache write buffer error interrupt event is detected.

The field in this register is set by hardware when the MCM_ISCR[CWBER] is asserted. For byte and halfword writes, only the accessed byte lanes contain valid data; the contents of the other bytes are undefined. Attempted writes have no effect.

13.4.1.8 Local Memory Descriptor 2 (LMDR2)

Offset

Register	Offset
LMDR2	408h

Function

The Local Memory Descriptor Register (LMDR] is an array of 32-bit generic on-chip memory descriptor registers that indicate static information on the attached memories as well as configurable controls (where appropriate).

NOTE

See chip specific section for the LMDRn registers mapping to the LMEMs

Chapter 14
Memories

14.1 Memory architecture

The memory architecture supports a wide range of applications and maximizes performance while maintaining low power consumption.

14.2 Memory hierarchy

The memory hierarchy is an arrangement of different types of memories with different capacities and operating speeds, to approximate the ideal memory behavior in a cost-efficient way. The following figure shows the memory hierarchical architecture implemented on this device.

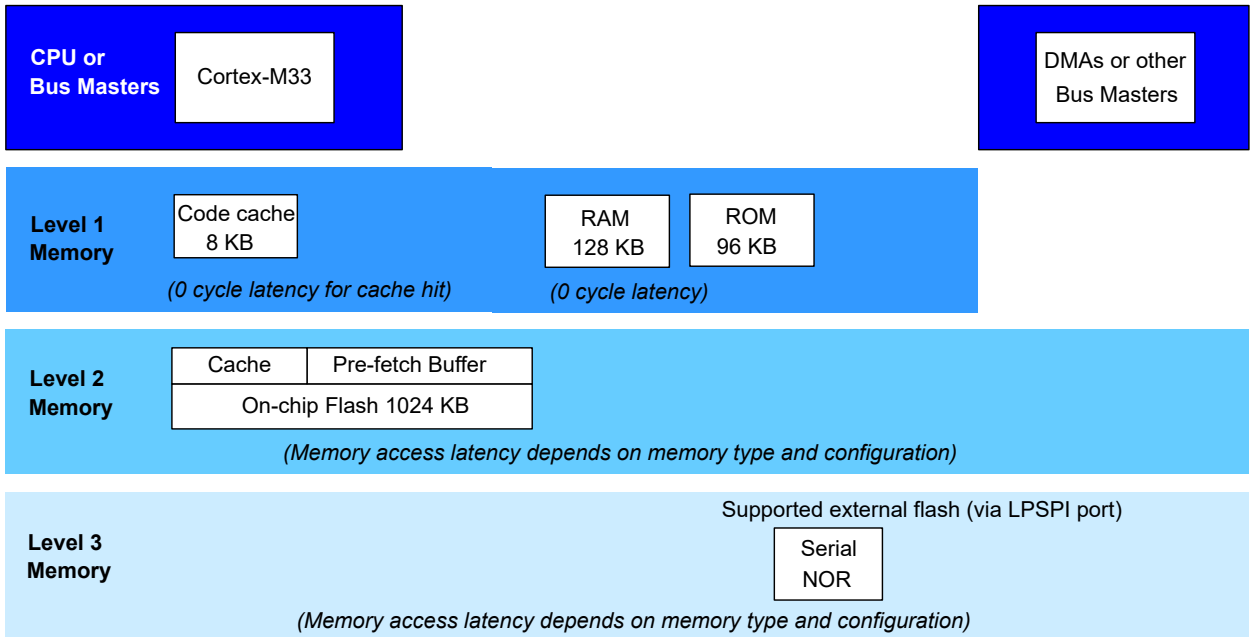

Figure 20. Memory hierarchy

14.3 TCM SRAMs

The core's local Tightly Coupled Memory (TCM) consists of two logical arrays, Code TCM (CTCM) and System TCM (STCM).

14.3.1 TCM SRAM configurations

- The CTCM is 16 KB
  - CTCM array 0: 8 KB
  - CTCM array 1: 8 KB
- The STCM is 112 KB
  - STCM array 0: 16 KB
  - STCM array 1: 16 KB

- STCM array 2: 32 KB
- STCM array 3: 32 KB
- STCM array 4: 8 KB
- STCM array 5: 8 KB

The address ranges of the TCMs are provided in the System memory map section

14.3.2 TCM SRAM retention

The TCM SRAMs can be retained in Sleep, Deep Sleep, and Power Down modes. Each instantiated block of TCM SRAM can be individually power gated. This allows the user to achieve the proper balance of power savings versus data retention.

Entering Deep Power Down mode will automatically power gate all of the SRAM instantiations, and all data is lost.

The last 8 KB RAM (0x2001_A000) is from independent power switch domain which can keep data retention in all power modes.

The first 16 KB of STCM (STCM0) is reserved for ROM use, and it will be initialized when waking up from Power Down mode

14.4 L1 Cache

A cache is a block of high-speed memory locations containing address information, which is commonly known as a tag, and the associated data. The purpose is to decrease the average time of a memory access to lower-level memory. The primary cache, or Level 1 (L1) cache, resides close to the CPU and is used for temporary storage of instructions and data organized in blocks of cache-line size.

This device implements one instance of L1 - the Code cache. The Code cache is accessible through the Code bus of Cortex-M33 core.

14.4.1 L1 cache principles

L1 caches operate on two principles of locality:

- Spatial locality - An access to one location is likely to be followed by accesses to adjacent locations, such as when executing sequential instructions or accessing a data structure. The spatial locality property is used to group several locations together using the same tag. This logical block is commonly known as a cache line.
- Temporal locality - An access to an area of memory is likely to be repeated within a short time period, such as when executing a code loop.

14.4.2 L1 cache features

Each L1 cache instance has following features:

- 8 KB cache array
- 32-bit wide SRAM for data storage
- Register based tags
- 8-way set associative
- 4-word (or 16-byte) lines
- Performs 4-beat, 32-bit wrapped burst to fetch 16 bytes of the cache line when a read misses
- Entire cache can be flushed at once

14.4.3 Cache policies

The following cache interaction policies with lower-level memories are applied to the Code cache:

- Write Through (WT) - accesses to address spaces with this cache mode are cacheable.

- A read miss in the cache causes a line read of a 16-byte aligned memory address containing the desired address in the lower-level memory. This miss data is loaded into the cache and is marked as valid and not modified.
- A read hit to a valid cache location returns data from the cache with no bus access to lower-level memory.
- A write miss bypasses the cache and writes to the lower-level memory; that means no allocate on write miss policy for write-through mode spaces.
- A write hit updates the cache hit line with the write data and writes to the desired address in the lower-level memory.

- Non-Cacheable (NC) - accesses to address spaces with this cache mode are not cacheable. These accesses bypass the cache and access the lower-level memory directly.

14.4.4 Cache control

In normal operation, caches are self-managing, with the updates occurring automatically on demand. Whenever the processor wants to access a cacheable location, the cache is checked. If the access is a cache hit, the access occurs immediately. Otherwise, a location is allocated and the cache line is loaded from lower-level memory.

The Code Cache doesn't have a programming model; all control comes from the Miscellaneous Control Module (MCM). The MCM has cache enable, cache clear, and cache force-no-allocate mode control per cache instance.

14.4.5 Low Power

The caches can be put in state retention or powered down in any of low power modes. The caches need to be flushed before being powered down. This affects the time it takes for the system to transition into the new power mode.

14.5 Read Only Memory (ROM)

The internal ROM memory is used to store the boot code and time-critical software library routines. After a reset, the Cortex-M33 processor starts its code execution from this memory.

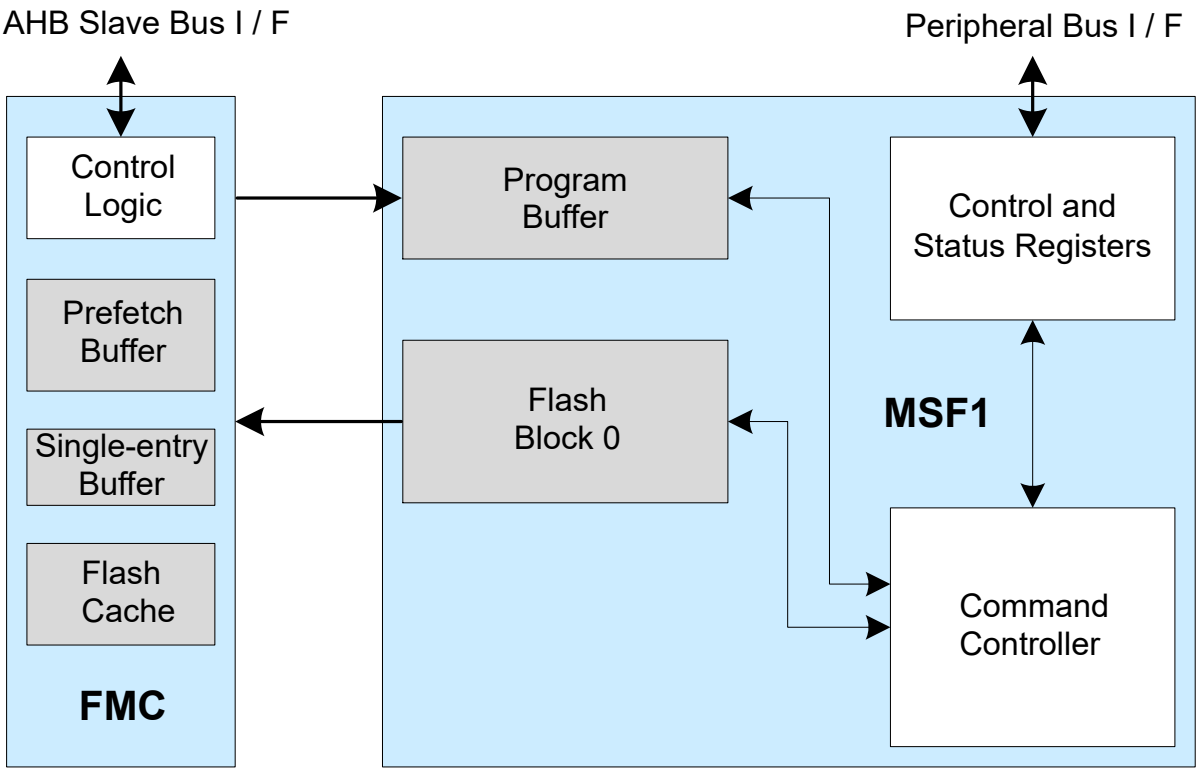
14.5.1 ROM size

The Boot ROM of this device is 96 KB.

14.6 Internal flash

This device embeds 1024 KB of flash.

The following figure shows the high-level block diagram of the on-chip flash.



14.6.1 Flash memory controller

The Flash Memory Controller (FMC) manages accesses performed by the bus masters of the system to the flash memory. The FMC accelerates flash memory transfers to allow program code execution at higher clock frequency than flash memory.

The FMC provides three separate mechanisms for accelerating read operations to the flash memory:

- A single-entry 128-bit buffer, which can store previously accessed flash memory
- A 128-bit prefetch buffer, which can prefetch the next 128-bit flash memory location
- A 64-Byte cache organized as a one set, four way associative cache with 128-bit (or 16-Byte) size entries.

Note the FMC has no visibility into flash memory erase and program cycles because the Flash Memory module manages them directly.

14.6.1.1 Single entry buffer

The width of the bus between the FMC and the flash blocks is 128-bit. A single read of the flash will return an entire bus width worth of data. Because the flash bus is wider than the master's bus, the Single-Entry Buffer is used to store data from the last flash read for quick access times on subsequent reads if the buffer is hit.

The FMC provides invalidation control for the Single-Entry Buffer.

14.6.1.2 Prefetch buffer

When speculative reads are enabled, the FMC immediately requests the next sequential address after a read completes. The next 128-bit memory location is read and placed in the Prefetch Buffer. The speculative prefetch mechanism improves performance by reducing or even eliminating wait states when accessing sequential code and/or data.

Speculative prefetching is programmable for each bank of memory. The FMC provides invalidation control for the Prefetch Buffer.

14.6.1.3 Flash cache

Cache memory stores already executed code. This code is immediately available for repeated execution without any wait states, if needed.

The FMC provides controls for flash replacement algorithm, lock per way, and invalidation per way. The ways are numbered 0-3 and the sets are numbered 0-3. The cache supports Least Recently Used (LRU) replacement algorithm per set across all 4 ways.

The cache entries, both data and tag/valid, can be read at any time.

Software is required to maintain memory coherence when any segment of the flash cache is programmed. For example, all buffer data associated with the reprogrammed flash should be invalidated. Accordingly, cache program visible writes must occur after a programming or erase event is completed and before the new memory image is accessed.

Chapter 15
ROM Bootloader

15.1 Introduction

ROM bootloader is the boot code resident in the internal read-only memory (ROM). The ROM bootloader begins its execution when the Cortex-M33 processor is released from reset. This chapter highlights the features supported by the bootloader and describes its execution flow logic.

15.2 Boot ROM

In this device, the ROM bootloader supports automated booting from internal flash and downloading image from serial interface (in-system programming via LPUART, LPI2C, LPSPI, CAN).

The ROM bootloader is in the memory region starting from the address 0x1480 0000. The following diagram shows the memory map in-use during ROM execution. The first 16 KB of Tightly Coupled Memory - System (STCM) (0x30000000 – 0x30004000) needs to be reserved for ROM bootloader execution and some ROM API execution. Please note that STCM has ECC enabled. To avoid STCM ECC error, users must always program word-aligned data to word-aligned address before the first time reading after power-on reset.

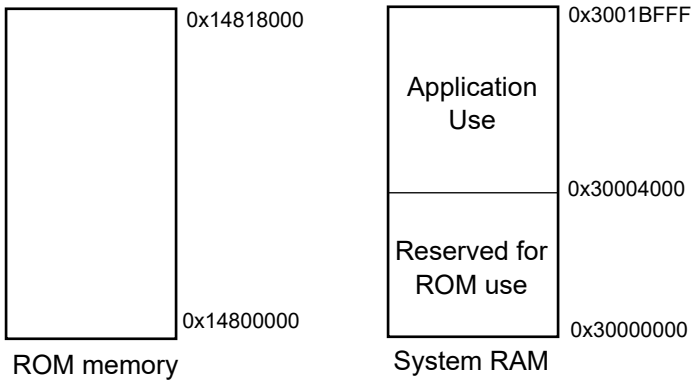


Figure 21. ROM bootloader memory usage

There are several alternate paths through the ROM bootloader:

- Normal boot path with security and TrustZone Mode (TZ-M) option.
- In-system programming (ISP) path.
- Debugger mailbox path which supports debug authentication.
- Low power wakeup path.

The decision about which path to take depends on fuses, boot configuration in user IFR, boot pin, debug request and low power wakeup configuration. Figure below shows the top-level boot flow.

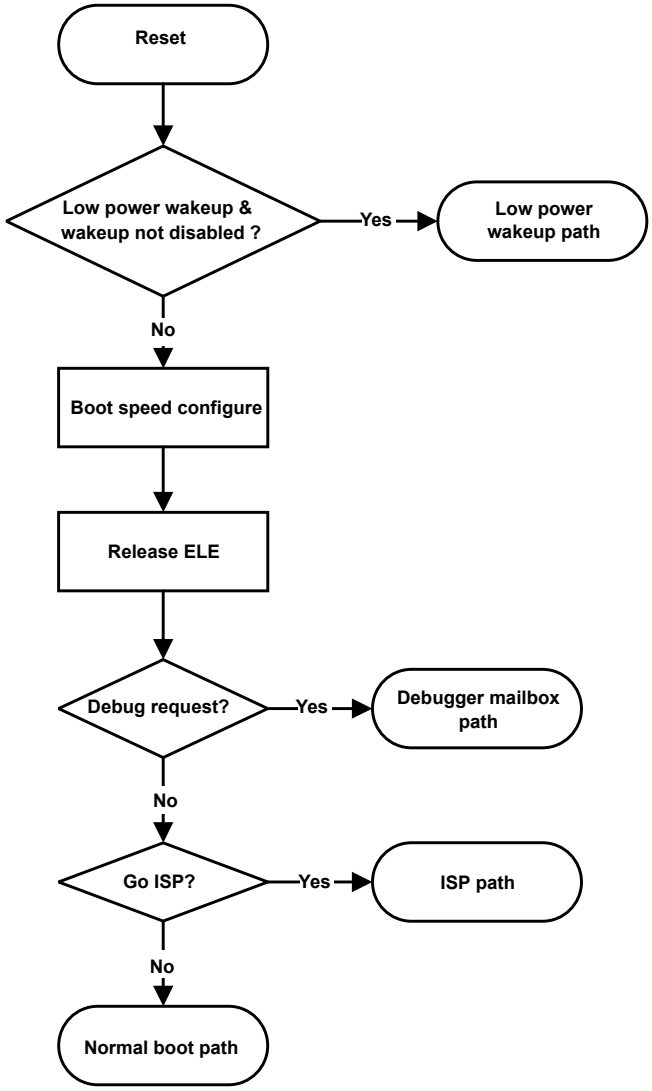

Figure 22. Top-level boot flow

15.2.1 Lifecycle and fuses

The table and diagram below describe the lifecycle states and transitions. ROM behaviour is different at different lifecycle state. The lifecycle fuse needs to be programmed correctly, otherwise ROM bootloader will not boot. The NA in the table means the feature is not available.

Table 52. Lifecycle states

LIFECYCLE	Lifecycle state [0:7]	CM33 image authentication required to boot?	Radio core (CM3) locked if radio authentication fails	Debug authentication required to debug CM33?	Debug authentication required to debug radio core (CM3)?	Able to access radio flash from CM33 after exiting ROM?
0000_0000	Blank	NA	NA	NA	NA	NA

Table continues on the next page...

Table 52. Lifecycle states (continued)

LIFECYCLE	Lifecycle state [0:7]	CM33 image authentication required to boot?	Radio core (CM3) locked if radio authentication fails	Debug authentication required to debug CM33?	Debug authentication required to debug radio core (CM3)?	Able to access radio flash from CM33 after exiting ROM?
0000_0111	OEM Open	No (Boot even if authentication fails)	Yes	No	Yes	No
0000_1111	OEM Secure World Closed	Yes	Yes	Yes[1]	Yes	No
0001_1111	OEM Closed	Yes	Yes	Yes	Yes	No
1001_1111	OEM Locked	Yes	Yes	NA	NA	No
0011_1111	OEM Return	NA	NA	No	Yes	No

1. For secure world only.

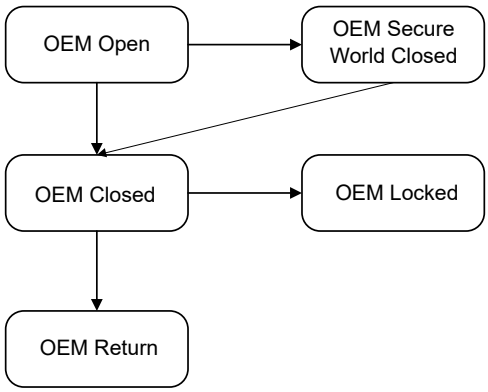

Figure 23. Lifecycle transitions

In addition to the lifecycle fuses, there are a handful of other fuse fields that will be used by the ROM bootloader during its operation. These fuse fields are shown in the table below.

Table 53. Additional fuse fields of interest

Name	Fuse index	Description
LIFECYCLE	0x0A	Lifecycle state. Corresponding product state can be determined from Table 52.
DBG_EN_LOCK	0x0B	Debug Enable Lock 0b - The debug access control registers are not write-locked when jumping to customer code. 1b - The debug access control registers are write-locked before jumping to customer code.
DBG_AUTH_DIS	0x0C	Debug Authentication Disabled

Table continues on the next page...

Table 53. Additional fuse fields of interest (continued)

Name	Fuse index	Description
		0b - Debug Authentication enabled. 1b - Debug Authentication disabled.
TZM_EN	0x0D	Trust Zone Mode Enable 0b - TZ-M is disabled by default. 1b - TZ-M is enabled.
SERIAL_DIS	0x11	Serial Download Disabled 0b - ISP path is enabled. 1b - ISP path is disabled.
WAKEUP_DIS	0x12	Wakeup Disabled 0b - Boot-ROM LP wakeup is enabled. 1b - Boot-ROM LP wakeup is disabled.
CUST_PROD_OEMFW_AUTH_PUK_REVOKE[3:0]	0x13	Key revocation indicators of CUST_PROD_OEMFW_AUTH_PUK.
DBG_AUTH_VU[15:0]	0x15	These Debug Authentication Vendor Usage fuses are used by customers to restrict debug certificates.
IMG_KEY_REVOKE[15:0]	0x16	These fuses are used to revoke image signing keys separately from root keys.
CUST_PROD_OEMFW_AUTH_PUK	0x1f	256-bit RoTKTH (customer trusted root key) used for CM33 main flash image authentication.
CUST_PROD_OEMFW_ENC_SK	0x20	256-bit encryption key used to protect confidentiality of OEM firmware, required for firmware updates using sb3 (SB3KDK).
DCFG_CC_SOCU_L1[16:0]	0x22	Debug authentication configuration for OEM1 customer.
DCFG_CC_SOCU_L2[16:0]	0x23	Debug authentication configuration for OEM2 customer.
SOC_VER_CNT	0x24	512-bits of version counter for various software components in SoC. Each software component version counter has dedicated fuse index 0x25 to 0x29.
CM33_S_VER_CNT	0x25	64-bit monotonic counter indicating the version of the secure OEM CM33 firmware. The number of set bits equals the version number.
CM33_NS_VER_CNT	0x26	256-bit monotonic counter indicating the version of the non-secure OEM CM33 firmware. The number of set bits equals the version number.
RADIO_VER_CNT	0x27	128-bit monotonic counter indicating the version of the radio firmware. The number of set bits equals the version number.
SNT_VER_CNT	0x28	32-bit monotonic counter indicating the version of the ELE loadable firmware. The number of set bits equals the version number.
CM33_BOOTLOADER_VER_CNT	0x29	Reserved for future usage of additional NXP software deliverable.

Table continues on the next page...

Table 53. Additional fuse fields of interest (continued)

Name	Fuse index	Description
GD_EN	0x30	• 0b - Core VDD glitch detection does not generate a hardware reset. • 1b - Boot ROM configures/enables Core VDD Glitch detection based reset.
CM33_S_VER_CNT_VIRTUAL	0x2A	64-bit virtual counter indicating the version of the secure OEM CM33 firmware. The integer value of this field indicates the number of set bits in CM33_S_VER_CNT and that number equals the version number.
CM33_NS_VER_CNT_VIRTUAL	0x2B	256-bit virtual counter indicating the version of the non-secure OEM CM33 firmware. The integer value of this field indicates the number of set bits in CM33_NS_VER_CNT and that number equals the version number.
RADIO_VER_CNT_VIRTUAL	0x2C	128-bit virtual counter indicating the version of the radio firmware. The integer value of this field indicates the number of set bits in RADIO_VER_CNT and that number equals the version number.
SNT_VER_CNT_VIRTUAL	0x2D	32-bit virtual counter indicating the version of the ELE loadable firmware. The integer value of this field indicates the number of set bits in SNT_VER_CNT and that number equals the version number.
CM33_BOOTLOADER_VER_CNT_VIRTUAL	0x2E	Reserved for future usage of additional NXP software deliverable.
HVD_EN	0x2F	• 0b - Core VDD high-voltage event does not generate hardware reset. • 1b - Boot ROM configures/enables Core VDD High voltage detection based reset.

ROM bootloader provides following ways to do the fuse reading and programming:

- nboot API (See #unique_433 for more details about fuse programming using nboot API),
- ISP fuse-program and fuse-read command,
- sbloader “programFuses” command in sb3.1 file

15.2.2 User IFR (IFR0) configuration

User IFR, known as IFR0 is reserved for software usage. First sector of User IFR is not able to be erased and is write-once. Other three sectors are erasable and programmable.

The allocation of User IFR pages is as follows:

Table 54. User IFR allocation

Sector	Start address	End address	Name	Description
0	0x02000000	0x2001FFF	ROMCFG	ROM Bootloader configurations
1	0x02002000	0x2003FFF	User	Reserved for customer usage

Table continues on the next page...

Table 54. User IFR allocation (continued)

Sector	Start address	End address	Name	Description
2	0x02004000	0x2005FFF	CMAC table	Used to save hashes of multiple boot components.
3	0x02006000	0x2007FFF	OTACFG	Used for Over-the-Air update

15.2.2.1 ROM bootloader configuration

Sector 0 of User IFR is ROM and ISP configuration, which provide configuration for ROM bootloader.

Table 55. ROM configuration fields

Offset	Size (bytes)	Configuration Field	Description
0x0000	1	Restore FLW Flag	Bit 0 – FLW state, whether enable dual image boot • 1 = Uninitialized • 0 = Normal, use specified mapping Bit 7:1 – Reserved
	7	Reserved	Reserved
	8	FLW region definition	Fields to be used for FLW configuration
0x0010	1	Configure NPX for Normal Boot	Bit 0 – Configure NPX to use PRINCE • 1 = Not configure NPX • 0 = Configure NPX Bit 1: • 0=Global lock enable • 1=Global lock disable Bit 2: • 0=System lock enable • 1=System lock disable Bit 3: • 0=Global decryption enable • 1=Global decryption disable Bit 4: • 0=Global encryption enable • 1=Global encryption disable Bit 7:5 – Reserved
	1	Sticky NPX Configuration for Waking up from Deep Power Down	Bit 0 – Configure NPX required: • 1 = Not required; ROM follows Low-power wakeup path • 0 = NPX config. required; ROM follows normal boot path Bit 7:1 – Reserved

Table continues on the next page...

Table 55. ROM configuration fields (continued)

Offset	Size (bytes)	Configuration Field	Description
	6	Reserved	Reserved
	56	NPX Region Definitions	Setting for NVM PRINCE XEX, the inline flash encryption IP module
0x0050	1	Boot Configuration	Bit 0 - Enable ISP or not • 0 = BOOT_CFG pin disabled • 1 = BOOT_CFG pin enabled Bit 2:1 – Boot speed • 00 = Normal boot (32 MHz) • 10 = Fast Boot (96 MHz) • 01, 11 = Normal boot (default) bit 7:3 – Reserved
	15	Reserved	Reserved
0x0070	16	Reserved	Reserved
0x0080	64	Boot Image Base Address	Start address of Boot image, should align with 32 KB. ROM Bootloader does search from 0x80 and the first not 0xFFFFFFFF 32-bit will be the boot address. So, it's better to program from 0xB0 to 0x80, users will have 4 chances to update boot address.
0x00C0	64	Reserved	Reserved
0x0100	1	Peripherals Enable	Bit 0 – LPUART1 peripheral for ISP • 0 = LPUART1 disabled • 1 = LUPART1 enabled Bit 1 – LPI2C1 peripheral for ISP • 0 = LPI2C1 disabled • 1 = LPI2C1 enabled Bit 2 – LPSPI1 peripheral for ISP • 0 = LPSPI1 disabled • 1 = LPSPI1 enabled Bit 3 – CAN peripheral for ISP • 0 = CAN disabled • 1 = CAN enabled Bit 7:4 – Reserved
	3	Reserved	Reserved
	2	Peripheral Detection Timeout	If 0xFFFF, defaults to no timeout.

Table continues on the next page...

Table 55. ROM configuration fields (continued)

Offset	Size (bytes)	Configuration Field	Description
			If not 0xFFFF, use this value as timeout in milliseconds for active peripheral detection.
	2	Reserved	Reserved
	1	I2C Slave Address	If 0xFF, defaults to 0x10 for LPI2C slave address. If not 0xFF, use this value as the 7-bit LPI2C slave address.
	1	Reserved	Reserved
	2	Reserved	Reserved
	2	CANTxID	TxID
	2	CANRxID	RxID
0x110	4	ELE Loadable FW Entry Address	ELE loadable firmware resides address
	12	Reserved	Reserved
0x120	4	Secure Hash based image verification feature (for faster subsequent boot)	0xFFFFFFFF – Disabled (ECDSA based verification will be used). If 0x48534148 (“HASH”) – Enabled.
	12	Reserved	Reserved

Restore FLW Flag and FLW Region Definitions fields are Flash Logic Window configurations used for dual image boot. When dual image boot is enabled, there are two boot images on the internal flash. ROM bootloader first tries to boot the boot image with latest version, if fails, ROM bootloader tries to boot the other boot image. To enable the dual image boot, Restore FLW Flag needs to be enabled, Boot Image Base Address field and FLW Region Definition fields need to be configured correctly. Boot Image Base Address indicates the start address of one boot image. FLW Region Definitions indicate the start address and the size of the alternative boot image. Here is the FLW Region Definition structure:

```
struct flw_region {
   uint32_t abase;
   uint32_t bcnt; };
```

The FLW region descriptors simply consist of FLW ABASE, the starting address of the alternative boot image, and, FLW BCNT, the size of the alternative boot image in 32 KB blocks.

If dual image boot is not enabled, ROM bootloader boots from Boot Image Base Address. If Boot Image Base Address is not configured, ROM bootloader will boot from the beginning of flash.

Configure NPX for Normal Boot, NPX Region Definitions fields are used for NPX feature.

Bit 0 of Boot Configuration field is used to enable ISP path for ROM bootloader. BOOT_CFG pin will be enabled if this bit is set. The pull-down on the BOOT_CFG pin is to ensure the device does not enter ISP by default. When BOOT_CFG pin is enabled and the BOOT_CFG pin is not pulled down, ROM bootloader will enter ISP path.

Boot Speed bits will be loaded by ROM bootloader to decide how to configure the power and clock. Bit 1:2 of Boot Configuration indicates the boot speed:

Table 56. Boot speed

Boot speed value in IFR0	Clock source	CPU_CLK/BUS_CLK/SLOW_CLK	DCDC & CORE_LDO voltage
11/00/01: Normal Boot (default)	FRO_192M	32/32/16 MHz	1.0 V
10: Fast Boot	FRO_192M	96/96/24 MHz	1.1 V

15.2.2.2 Token

Token needs to be programmed to the SECURE_PHANTOM_CONFIG fuse to change the ownership of radio firmware. By default, radio firmware is owned by NXP.

If developer at “OEM Open” lifecycle state requires an unrestricted access to radio flash for their own firmware development and debugging purposes, token is mandatory. Token contents must be programmed to SECURE_PHANTOM_CONFIG fuse, 0xddccbbaa (OEM1) or 0xaabbccdd (OEM2). If programmed token is valid, OEM_Enablement_Token fuse contents are used for NBU firmware authentication. Following a reset, specific decisions about locking radio core, blocking radio access, and debug authentication for CM3 core are made by boot ROM as described in Lifecycle states.

15.2.2.3 IFR0 Sector 2 (hash structure/cmac table maintenance)

This IFR0 dedicated page is used to store hash for boot images in a structured format as shown below. Note that, Buffer size of hash table to be reprogrammed must be at max. 48*4 bytes (to save flash programming time) but phrase-by-phrase programming can also be done as boot ROM progresses through various stages.

```
enum _cmac_table_index
{
kCmacIndexPrim = 0x0U,
kCmacIndexOEM = 0x1U,
kCmacIndexNBU = 0x2U,
kCmacIndexReserved = 0x3U,
kCmacIndexLast = 0x4U,
};

typedef struct{
uint32_t update_needed;
uint32_t reserved0[3];
uint8_t imgHash[NBOOT_CMAC_SIZE_IN_BYTES];
}cmac_info_t;

typedef struct {
cmac_info_t components[kCmacIndexLast]; /*!< Upto 4 components: 2 images (dual), 1 radio, 1 extended
bootloader (TBD) */
}cmac_table_t;
```

Table 57.

Offset	Size (bytes)	Field description	Description
0x0000	4	Hash update needed	0xFFFFFFFF - Yes 0x00000000 – No
	12	Reserved	Reserved

Table continues on the next page...

Table 57. (continued)

Offset	Size (bytes)	Field description	Description
0x0010	16	16 byte CMAC for application image	Hash of main flash primary boot image data at 0x0, or Hash of Image data at ABASE (if FLW is enabled)
0x0020	4	Hash update needed	0xFFFFFFFF - Yes 0x00000000 – No
	12	Reserved	Reserved
0x0030	16	16 byte CMAC for fallback image	Hash of fallback image data (if “Image 1 Base Address” field in IFR0 page0 is not 0xFFFFFFFF)
0x0040	4	Hash update needed	0xFFFFFFFF - Yes 0x00000000 – No
	12	Reserved	Reserved
0x0050	16	16 byte CMAC for radio image	Hash of radio (NBU) flash image data
0x0060	4	Reserved	Reserved
	12	Reserved	Reserved
0x0070	16	Reserved	Reserved

15.2.2.4 Over-the-air (OTA) update configuration

Table 58. OTA update configuration

Offset	Size (bytes)	Configuration Field	Description
0x00	4	Update available	0x746f4278u = Indicates update is available
	12	Reserved	Reserved
0x10	4	Update(sb3) dumped location	0x74784578 = sb3 is dumped in external flash
			Other values = sb3 is dumped in internal flash
0x14	4	Baud rate (in bps)	Value used to configure LPSPI NOR flash if update(sb3) is dumped in external flash.
0x18	4	Update(sb3) dump address	Start address (internal/external flash) where update(sb3) is dumped.
0x1c	4	Update(sb3) file bytes	Size of update(sb3) file in number of bytes.
0x20	4	FW update status	0x5ac3c35a = Indicates update was success 0x4412d283/0x2d61e1ac = Indicates failure to process sb3 file OR failure to erase/write update status to OTACFG page

Table continues on the next page...

Table 58. OTA update configuration (continued)

Offset	Size (bytes)	Configuration Field	Description
	12	Reserved	Reserved
0x30	16	Feature unlock key	To use FW update feature offered by ROM (instead of extended bootloader) 16-byte key must be programmed. updKey[16] = {0x61, 0x63, 0x74, 0x69, 0x76, 0x61, 0x74, 0x65, 0x53, 0x65, 0x63, 0x72, 0x65, 0x74, 0x78, 0x4d};

15.2.3 Normal boot path

ROM bootloader follows this path when device goes through a WARM reset or PoR if not getting request to go to another path. Boot ROM prepares the system for execution of application code residing in internal flash.

Please note that WDOG0 is disabled during normal boot path and enabled before jumping to the boot image. Meanwhile, the WDOG0 timeout value (TOVAL) has been set to longest (0xFFFF).

Figure 24 shows the flow of normal boot.

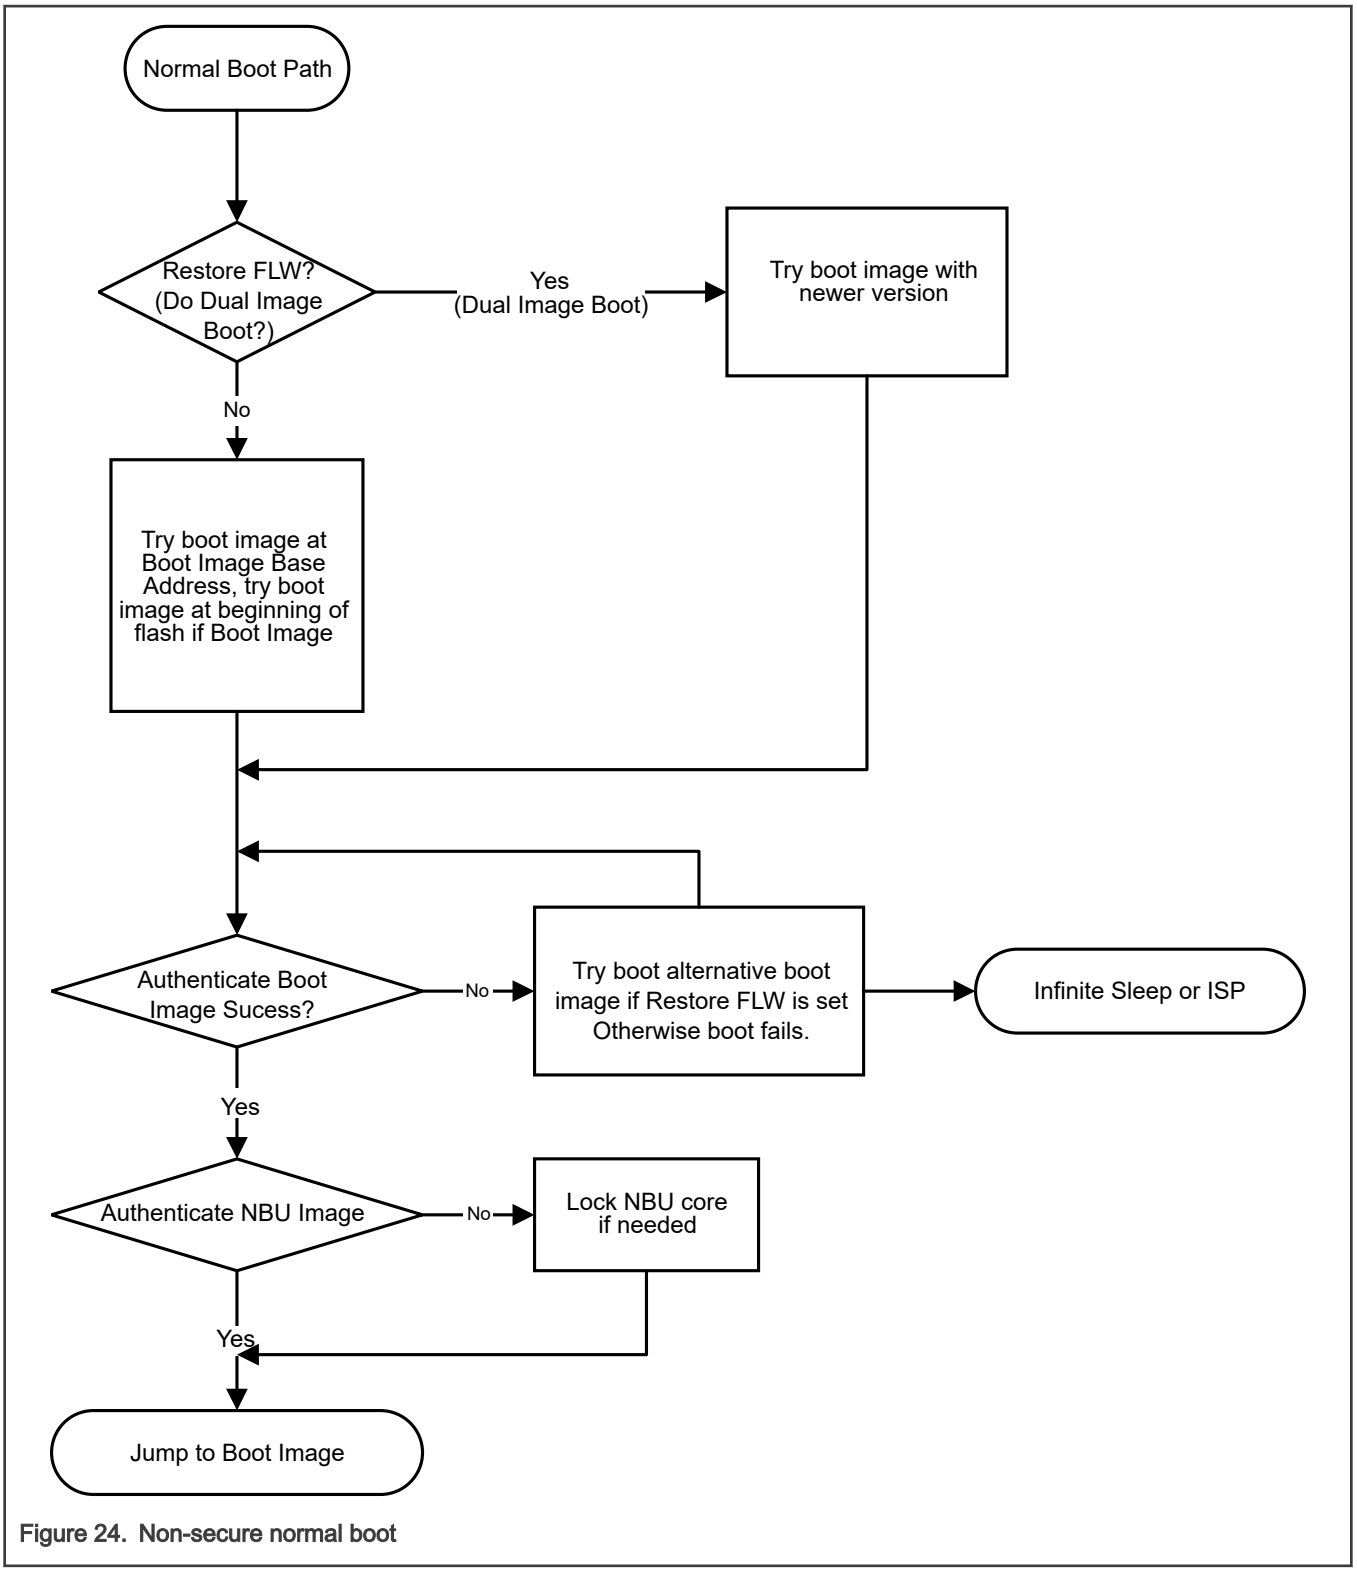

Figure 24. Non-secure normal boot

15.2.3.1 Dual image boot

Boot ROM supports dual image boot, useful in scenario where primary image fails to boot for any reason so secondary image (as a backup) can boot. This is achieved in conjunction with Flash Logical Window feature. It will allow developing for position independent code. That means same linker file can be used for creating multiple application images to be treated as primary (experimental or latest firmware image) and secondary (as a backup redundant image).

Use case example of dual boot:

1. “Restore FLW Flag” bit 0 is set to indicate ROM to use FLW feature.
2. Primary image is placed at address 0x10000 and “Boot Image Base Address” field of ROMCFG in user IFR0 is programmed accordingly.
3. Secondary image (fallback/backup) is placed at address 0x20000 and “ABASE” field in FLW region definitions of ROMCFG in user IFR0 is programmed accordingly.
4. Make sure BCNT field of FLW region definitions is set correctly to indicate image size as multiple of 32 KB block size.
5. Boot ROM will compare versions of primary and secondary image.
6. Boot ROM will try to boot latest versioned image. At the same time older versioned image base address is stored in ROM runtime context.
7. If both images have same version, then image located at address specified by “Boot Image Base Address” field of ROMCFG in user IFR0 is considered for boot.
8. For any reason (mainly authentication failure or rollback protection) latest versioned image fails to boot then boot ROM falls back to the older versioned image.

15.2.4 Faster subsequent boot

Boot ROM supports secure boot primarily using an ECDSA verification. And it can also support secure boot using hash (cmac) based image verification for faster subsequent boot.

- The user needs to:
  - Program IFR0 sector 0 at offset 0x120 to request hash based image verification.
  - Include an sbloader command to erase IFR0 sector 2 for every FW update.
- The ROM handles this request with the following steps:
  - First time after resetting to boot or trying to boot using jump/execute sbloader command after successful FW update, requires ROM to compute hash of image data.
  - Boot ROM computes hash (cmac) for multiple boot components, namely main flash image (application) and radio FW, and stores it in an IFR0 sector 2 in structured format. So it can be used to achieve faster boot time from next boot attempt.
  - But for very first time post FW update, after calculating hash of image data, boot ROM will still use ECDSA based image verification mechanism to perform secure boot.
  - For all subsequent FW updates, it is user’s responsibility to erase IFR0 sector 2. So that boot ROM understands it needs to calculate hash for multiple bootable components and store it in a structured format.
  - If no FW update is required/performed then triggering multiple resets could utilize faster secure boot sequence.
- If hash based image authentication fails
  - Images are still expected to have signature. So boot ROM would fall back to ECDSA based verification as a primary secure boot mechanism.

15.2.5 Debugger mailbox path

Debugger Mailbox (DM) is a register-based mailbox operating over Serial Wire Debug Port (SWD). It can be accessed via a Debug Access port (DM-AP) which is always enabled. The external world can send and receive data to/from the ROM bootloader via Debugger Mailbox. One important feature of Debugger Mailbox is that it supports NXP Debug Authentication Protocol, which allows users to enable debug access for CM33 when security is required. Meanwhile, users can utilize Debugger Mailbox to initiate a debugging session when there is no valid boot image.

The communication to the Debugger Mailbox is initiated by the debugger. It does so by setting a re-synchronization request and then resets the chip. ROM bootloader can observe the request and go to Debugger Mailbox Path.

15.2.5.1 Quick guide of using debugger mailbox

To make ROM bootloader enter the Debugger Mailbox, the debugger needs to select DM-AP and set the RESYNCH_REQ bit and the CHIP_RESET_REQ bit to 1 in the CSW register. Following a successful initial re-synchronization and reset, communication by the debugger to the device is achieved using 32-bit DM-AP command writes to the REQUEST register in the Debug Mailbox (DM-AP Commands are shown in table below) The debugger can read results of communications via the RETURN register. Response codes are shown in DM-AP return codes.

The example below shows how to enter debug mailbox and do the communication:

```
// Pseudo Code Syntax
// ------------------------------------------------------------------------
// WriteDP <register> <value>
// value = ReadDP <register>
// AP transactions presume the DM AP is selected
// WriteAP <register> <value>
// value = ReadAP <register> <value>
// ------------------------------------------------------------------------
// Read AP ID register to identify DM AP at index 2
WriteDP 2 0x020000F0
// The returned AP ID should be 0x002A0000
value = ReadAP 3
print "AP ID: ", value
// Select DM AP index 2
WriteDP 2 0x02000000
// Write DM RESYNC_REQ + CHIP_RESET_REQ
WriteAP 0 0x21
// Write DM-AP Command START DM-AP (1) to REQUEST register (1)
WriteAP 1 1
// Read the return code of START DM-AP command from RETURN register (2), 0x0 means success
ReadAP 2
// Write Get Lifecycle (2) to REQUEST register (1)
WriteAP 1 2
// Read the value of current lifecycle from RETURN register (2)
ReadAP 2
```

When doing debug authentication, Debug Auth Start command needs to be sent first and DAC needs to be read back. Then sending Debug Auth Response command with DAR. Pseudo code below shows how to use debug authentication commands. See Debug authentication for more details.

```
// Assume already in Debugger Mailbox
// Write Debug Auth Start (0x10) to REQUEST register (1)
WriteAP 1 0x10
// Read the data count of DAC
ReadAP 2
// Assume reading back 0x82000000, then the length of DAC is 0x200 word (4-byte)
// Send the ACK_TOKEN with the length of remaining data (word) to receive
WriteAP 1 0x0200A5A5
// Read DAC data
ReadAP 2
WriteAP 1 0x01FFA5A5
ReadAP 2
…
WriteAP 1 0x0001A5A5
ReadAP 2
// Get the whole DAC, generate DAR using DAC, assume length of DAR is 0x400 word (4-byte)
// Write Debug Auth Response (0x11) with DAR length to REQUEST register (1)
WriteAP 1 0x04000011
// Read the ACK_TOKEN from RETURN register (2), should be 0x0400A5A5
```

```
ReadAP 2
// Send DAR data, use 0x00000000 as an example of data
WriteAP 1 0x00000000
// Read the ACK_TOKEN, should be 0x03FFA5A5
ReadAP 2
// Send next DAR data
WriteAP 1 0x00000000
ReadAP 2
…
WriteAP 1 0x00000000
// Complete sending DAR when ACK_TOKEN is 0x0000A5A5
ReadAP 2
```

15.2.5.1.1 DM-AP commands

Commands for the DM-AP are listed below. These would be written to the REQUEST register. Please note that BulkErase/ISP Mode/Set FA Mode can only be issued after debug authentication is successful. These commands are not available in OEM Open.

Table 59. DM-AP commands

Command	ID	Parameter/Response	Description
Start DM-AP	0x01	*Parameters*: None *Response*: 32-bit status	Cause the device to enter DM-AP command mode. This must be done prior to Get Lifecycle command. This command is provided for backwards compatibility and does not need to be used for most commands.
Get Lifecycle	0x02	*Parameters*: None *Response*: 32-bit value	Return the value of current lifecycle.
Bulk Erase	0x03	*Parameters*: None *Response*: 32-bit status	Erase the entire CM33 Program Flash (IFR0 not included).
Exit DM-AP	0x04	*Parameters*: None *Response*: 32-bit status	Cause the device to exit DM-AP command mode. The device returns to normal boot path.
Enter ISP Mode	0x05	*Parameters*: dataWordCount: 0x1 data[0]: ISP mode enum. 0xffffffff – Auto detection 0x1 - LPUART 0x2 - LPI2C 0x4 - LPSPI 0x8 - CAN Others - Reserved *Response*: 32-bit status	Enter specified ISP path.

Table continues on the next page...

Table 59. DM-AP commands (continued)

Command	ID	Parameter/Response	Description
Set FA Mode	0x06	*Parameters*: data[]: FA Request *Response*: 32-bit status	Set the part permanently in Fault Analysis (FA or RMA) mode bit in PFR field, and return the part to NXP for FA/RMA testing. ROM erases customer sensitive assets (key codes) stored in PFR.
Start Debug Session	0x07	*Parameters*: None *Response*: 32-bit status	This command is used to indicate ROM the intention of connecting debugger. ROM bootloader enables debug access (if no debug authentication required) and enters while(1) loop.
Debug Auth Start	0x10	*Parameters*: dataWordCount: 0x0 *Response*: data[] : DAC	Start Debug Authentication Protocol. ROM responds to debugger with *DAC (Debug Authentication Challenge)* message.
Debug Auth Response	0x11	*Parameters*: data[] : DAR *Response*: 32-bit status	Debug Authentication Response.

15.2.5.1.2 DM-AP return codes

Return codes for DM-AP commands are listed below. These commands can be read from the RETURN register. See table below.

Table 60. DM-AP return codes

Return code	Descriptions
0x0000 0000	Command succeeded.
0x0010 0001	Debug mode not entered. This is returned if other commands are sent prior to the “Enter DM-AP” command.
0x0010 0002	Command not recognized. A command was received other than the ones defined above.
0x0010 0003	Command failed.

15.2.5.2 Debugger Mailbox protocol

ROM Bootloader implements debug mailbox protocol to interact with host debug systems over the SWD interface. The protocol has following features:

- Request/response based.
- Support for relatively large command and response data.
- All commands and responses are 32-bit word aligned.
- Supports data above 32 bits by using an ACK_TOKEN that moderates the transfer in 32-bit value chunks.
- Requests and responses use the same basic structure.

15.2.5.2.1 Mailbox registers

The registers in the debug mailbox are shown in Table below. These registers are readable by the CPU and are intended primarily to allow on-chip ROM routines to implement requests from an external debugger.

Table 61. Register overview: DBGMailbox (base address = 0x58000000)

Name	Access	Offset	Description	Reset value
CSW	R/W	0x000	Command and status word	0x0
REQ	R/W	0x004	Request from the debugger to the device	0x0
RETURN	R/W	0x008	Return value from the device to the debugger	0x0
ID	RO	0x0FC	Identification register	0x002A0000

15.2.5.2.1.1 Command and Status Word Register (CSW)

The CSW register contains command and status bits to facilitate communication between the debugger and the device.

Table 62. Command and Status Word register (CSW, offset = 0x000)

Bit	Symbol	Description	Reset Value
0	RESYNCH_REQ	The debugger sets this bit to request a re-synchronization.	0x0
1	REQ_PENDING	A request is pending for the debugger: a value is waiting to be read from the REQUEST register.	0x0
2	DBG_OR_ERR	When 1, a debug overrun has occurred: a REQUEST value has been overwritten by the debugger before it was read by the device.	0x0
3	AHB_OR_ERR	When 1, an AHB overrun has occurred: a RETURN value has been overwritten by the device before it was read by the debugger.	0x0
4	SOFT_RESET	Setting this write-only bit in the CSW register of the DM-AP by an external debugger resets the DM-AP state machine and its registers. While setting RESYNCH_REQ only resets the DP and CPU handshake state machine.	0x0
5	CHIP_RESET_REQ	This write-only bit causes the device (but not the DM-AP) to be reset by generating SYSRESET_REQ.	0x0
31:6	Reserved		-

15.2.5.2.1.2 Request value register

The REQUEST register is used by a debugger to send action requests to the device.

Table 63. Request value register (REQUEST, offset = 0x004)

Bit	Symbol	Description	Reset Value
31:0	REQUEST	Request value. Reads as 0 when no new request is present. Cleared by the device. Can be read back by the debugger in order to confirm communication.	0x0

15.2.5.2.1.3 Return value register

The RETURN register provides any response from the device to the debugger.

Table 64. Return value register (RETURN, offset = 0x008)

Bit	Symbol	Description	Reset Value
31:0	RET	Return value. This is any response from the device to the debugger. If no new data is present, a debugger read will be stalled until new data is available.	0x0

15.2.5.2.1.4 Identification register

The ID register provides an identification of the DM-AP interface.

Table 65. Identification register (ID, offset = 0x0FC)

Bit	Symbol	Description	Reset Value
31:0	ID	Identification value.	0x002A0000

15.2.5.2.2 Mailbox commands

15.2.5.2.2.1 Request

The first word transmitted in a request is a header word containing the command ID and number of following data words. Following the header are the number of 32-bit words specified in the header.

Table 66. Request register byte description

Word	Byte 0	Byte 1	Byte 2	Byte 3
0	commandID[7:0]	commandID[15:8]	dataWordCount[7:0]	dataWordCount[15:8]
1	*data...*			

The C structure definition for a request is as follows:

```
struct dm_request {
  uint16_t commandID;
  uint16_t dataWordCount;
  uint32_t data[]; };
```

15.2.5.2.2.2 Response

The first word transmitted in a response is a header word containing the command status and number of following data words.

- To support legacy command and response value, Bit_31 in header will be used to indicate that the response follows new protocol structure.

Table 67. Response register byte description

Word	Byte 0	Byte 1	Byte 2	Byte 3
0	commandStatus[7:0]	commandStatus[15:8]	dataWordCount[7:0]	dataWordCount[14:8] new_protocol[15]
1	*data...*			

The C structure definition for a response is as follows:

```
struct dm_response {
    uint16_t commandStatus;
    uint16_t dataWordCount;
    uint32_t data[];
};
```

15.2.5.2.2.3 ACK_TOKEN

- When command has parameters the debugger should wait for ACK_TOKEN (sent through DBG_MB_RETURN register) before sending next 32-bit value.
- Similarly when response packet has data to send back to debugger, ROM will wait for debugger to send ACK_TOKEN (sent through DBG_MB_REQUEST register) before sending next 32-bit value.
- Upper 16 bits are set by receiving end with number of remaining words expected.
- Lower 16 bits are always set to 0xA5A5.

Table 68. ACK_TOKEN register byte description

Word	Byte 0	Byte 1	Byte 2	Byte 3
0	0xA5	0xA5	remainCount[7:0]	remainCount[15:8]

The C structure definition for a ACK_TOKEN is as follows:

```
struct dm_ack_token {
    uint16_t token; /* always set to 0xA5A5 */
    uint16_t remainCount; /* count of remaining word */};
```

15.2.5.2.2.4 Error handling

If an overrun occurs from either side of the communication, the appropriate error flag is set in the CSW. The state machine hardware will prevent further communication in any direction once an overrun has occurred in that direction, so if such an error occurs, the debugger will need to start with a new re-synchronization request in order to clear the error flag.

15.2.5.3 Debug authentication

The fundamental principles of debugging, which require access to the system state and system information, conflict with the principles of security, which require the restriction of access to assets. Thus, many products disable debug access completely before deploying the product. This causes challenges for product design teams to do proper Return Material Analysis (RMA). To address these challenges, the ROM bootloader offers a debug authentication protocol as a mechanism to authenticate the debugger (an external entity) has the credentials approved by the product manufacturer before granting debug access to the device.

The debug authentication scheme is a challenge-response scheme and assures that debugger in possession of required debug credentials only can successfully authenticate over debug interface and access restricted parts of the device. This protocol is divided into steps as shown in description and figure below.

1. The debugger initiates the Debug Mailbox message exchange by setting the RESYNCH_REQ bit and CHIP_RESET_REQ bit in the CSW register of DM-AP.
2. The debugger waits (minimum 30ms) for the devices to restart and enter debug mailbox request handling loop.

3. The debugger sends Debug Authentication Start command (command code 0x10) to the device.
4. The device responds back with Debug Authentication Challenge (DAC) packet based on the debug access rights pre-configured in CMPA fields, which are collectively referred as Device Credential Constraints Configuration (DCFG_CC). The response packet also contains a 32 bytes random challenge vector.
5. The debugger responds to the challenge with a Debug Authentication Response (DAR) message by using an appropriate debug certificate, matching the device identifier in the DAC. The DAR packet contains the debug access permission certificate, also referred as Debug Credential (DC), and a cryptographic signature binding the DC and the challenge vector provided in the DAC.
6. The device on receiving the DAR, validates the contents by verifying the cryptographic signature of the message using the debugger's public key present in the embedded the Debug Credential (DC). On successful validation of DAR, the device enables access to the debug domains permitted in the DC.

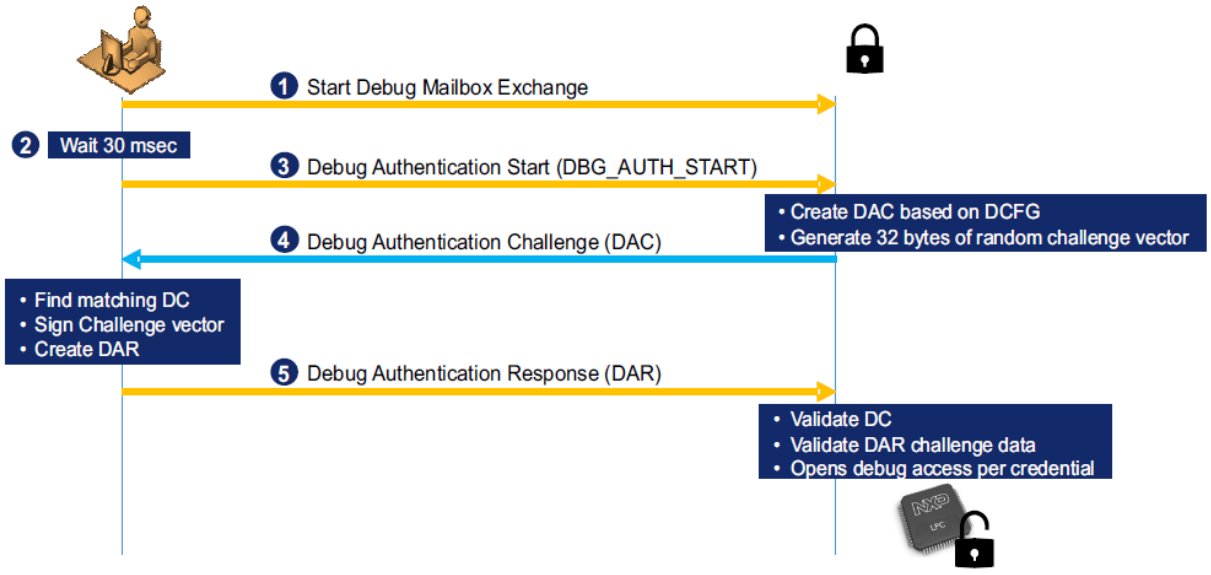

Figure 25. Debug authentication flow

15.2.5.3.1 Debug access control configuration

The ROM bootloader handles the device side of Debug authentication process. However, the debug access control rights and security policies can be configured by programming the following configuration fields which are collectively referred to as Device Configuration for Credential Constraints (DCFG_CC).

- DCFG_VER: This field controls the cryptographic primitives used during authentication.
- DCFG_ROTID: This field defines the Root of trust identifier (ROTID). The ROTID field is used to bind the devices to specific Certificate Authority (CA) keys issuing the debug credentials. These CA keys are also referred as Root of Trust (RoTK) keys.
- DCFG_UUID: Controls whether to enforce UUID check during Debug Credential (DC) validation. If this field is set only DC with matching device UUID can unlock the debug access.
- DCFG_CC_SOCU: This configuration field specifies access rights to various debug domains.
- DCFG_VENDOR_USAGE: This field can be used to define vendor specific debug policy use case such as DC revocations or department identifier. It is recommended to use field for revocation of already issued debug certificates.

15.2.5.3.1.1 Protocol Version (DCFG_VER)

This device supports Debug authentication protocol version 2.1, which are defined based on the secp384r1 curve.

NOTE

Both debug authentication certificates and image signing certificates use same Root of Trust keys (RoTK).

15.2.5.3.1.2 Root of Trust Identifier (DCFG_ROTID)

The Root of Trust Identifier used in debug authentication protocol is composed of two elements.

- A 256-bit cryptographic hash (SHA256 or leading 32 bytes of SHA384, according root certificates EC types, secp256r1->SHA256 or secp384r1->SHA384) over the Root of Trust Keys hash table.
- A 32-bit field containing revocation bits for the four Root of Trust keys in the table.

15.2.5.3.1.3 Enforce UUID checking (DCFG_UUID)

Controls whether to enforce UUID check during Debug Credential (DC) validation. If this field is set, then only DC containing a UUID attribute that is an exact match to the device can unlock the debug access.

This field can be set by programming UUID_CHECK (bit 16) in CC_SOCU.

This device-specific constraint, if enabled, is in addition to all the other constraints defined and enforced by the authentication protocol

15.2.5.3.1.4 Credential Constraints (DCFG_CC_SOCU)

The DCFG_CC_SOCU is a configuration that specifies debug access restrictions per debug domain. These access restrictions are also referred as constraint attributes in this section. The debug subsystem is sub-divided into multiple debug domains to allow finer access control. Table 70 shows debug domains and their corresponding control bit position in DCFG_CC_SOCU. Which is logically composed of two components:

- SOCU_PIN (bit 7-0 in CC_SOCU): A bitmask that specifies which debug domains are predetermined by device configuration.
- SOCU_DFLT (bit 15-8 in CC_SOCU): Provides the final access level for those bits that the SOCU_PIN field indicated are predetermined by device configuration.

The following table shows the restriction levels:

Table 69. Access restriction levels

Restriction Level	SOCU_PIN [n]	SOCU_DFLT [n]	Description
0	1	1	Access to the sub-domain is always enabled. This setting is provided for module use case scenario where DCFG_CC_SOCU_NS would be used to define further access restrictions before final deployment of the product.
1	0	0	Access to the sub-domain is disabled at start up. But the access can be enabled through debug authentication process by providing appropriate Debug Credential (DC) certificate.
2	0	1	Illegal setting. Part may lock-up if this setting is selected.
3	1	0	Access to the sub-domain is permanently disabled and cannot be reversed. This setting offers the highest level of restriction.

Debug domains supported by this device are shown in table below.

Table 70. CC_LIST_Table

Bit[1]	Symbol	Description
0	PIN_NIDEN	Controls non-Invasive debugging of TrustZone for Arm8-M defined non-secure domain of CM33.
1	PIN_DBGEN	Controls invasive debugging of TrustZone for Arm8-M defined non-secure domain of CM33.
2	PIN_SPNIDEN	Controls non-Invasive debugging of TrustZone for Arm8-M defined secure domain of CM33.
3	PIN_SPIDEN	Controls invasive debugging of TrustZone for Arm8-M defined secure domain of CM33.
4	PIN_NBU_DBGEN	Controls debugging of NBU (radio, CM3)
5	PIN_FA_CMD_EN	Controls whether DM-AP command, Set FA Mode (command code: 0x06), can be issued through after authentication.
6	PIN_ISP_CMD_EN	Controls whether ISP boot flow DM-AP command (command code: 0x05) can be issued after authentication.
7	PIN_ME_CMD_EN	Controls whether DM-AP command, Bulk Erase (command code: 0x02), can be issued through after authentication.
8	DFLT_NIDEN	Controls non-Invasive debugging of TrustZone for Arm8-M defined non-secure domain of CM33.
9	DFLT_DBGEN	Controls invasive debugging of TrustZone for Arm8-M defined non-secure domain of CM33.
10	DFLT_SPNIDEN	Controls non-Invasive debugging of TrustZone for Arm8-M defined secure domain of CM33.
11	DFLT_SPIDEN	Controls invasive debugging of TrustZone for Arm8-M defined secure domain of CM33.
12	DFLT_NBU_DBGEN	Controls debugging of NBU (radio, CM3)
13	DFLT_FA_CMD_EN	Controls whether DM-AP command, Set FA Mode (command code: 0x06), can be issued through after authentication.
14	DFLT_ISP_CMD_EN	Controls whether ISP boot flow DM-AP command (command code: 0x05) can be issued after authentication.
15	DFLT_ME_CMD_EN	Controls whether DM-AP command, Bulk Erase (command code: 0x02), can be issued through after authentication.
16	UUID_CHECK	Used for UUID matching required flag.
17:31	Reserved	Reserved

1. Bits [7:0] is SOCU pinned value, and bits [15:8] is SOCU default value.

15.2.5.3.1.5 DCFG_VENDOR_USAGE

This field can be used to define vendor specific debug policy use case such as Debug Credential (DC) certificate revocations or department identifier or model identifier. During Debug Authentication Response (DAR) processing the device checks that the value specified in Vendor Usage field of DC matches exactly the value programmed in DBG_AUTH_VU fields of device configurations. During debug authentication this value has to mach cc_vu value in debug credentials. For example user can define DBG_AUTH_VU for every product and then issue debug credential just for specific product.

15.2.5.3.2 Debug Authentication Challenge (DAC)

The debug authentication protocol begins with a DEBUG_AUTH_START request, issued by the debugger to the device, which replies by Authentication Challenge (DAC) message, issued by the device to the debugger. The DAC carries information about current device state to the debugger, inputs from DAC are necessary to find existing or request generation of new Debug Credential (DC). Protocol version 2.x uses ECC for digital signatures: minor version 1 (“2.1”) points to secp384r1.

Structure of DAC message is shown in following Figure.

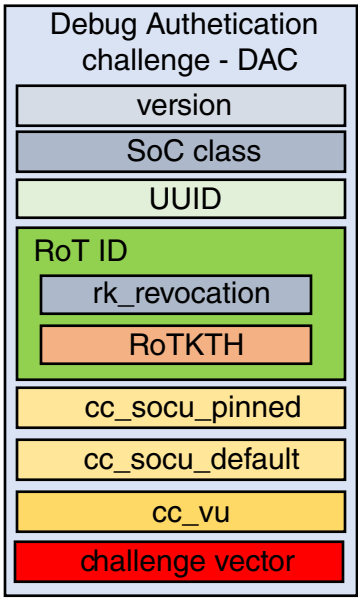

Figure 26. Debug Authentication Challenge (DAC)

- **version** – uint32_t, little endian

  Fixed to value 0x02000100u "2.1" (major =2, minor = 1) -> secp384r1 used as RoTKTH

- **SoC class** – uint32_t, little endian

  Fixed to 0x5u for this device, identify the device family

- **UUID** – uint32_t[4], little endian

  Unique ID of device.

- **RoT ID** – object

  Identifier of root of trust settings in device.

  - **rk_revocation** – uint32_t, little endian

    1 bit per RoTK (up to 4 RoTK can be defined for device, bit is 1 – RoTK is revoked (not usable for debug auth), bit is 0 – RoTK can be used.

    rk_revocation[bits 31:4] -> reserved for future use.

    rk_revocation[bit 3] -> bit value 0 = RoTK[3] OK / bit value 1 = RoTK[3] revoked

rk_revocation[bit 2] -> bit value 0 = RoTK[2] OK / bit value 1 = RoTK[2] revoked

rk_revocation[bit 1] -> bit value 0 = RoTK[1] OK / bit value 1 = RoTK[1] revoked

rk_revocation[bit 0] -> bit value 0 = RoTK[0] OK / bit value 1 = RoTK[0] revoked

- **RoTKTH** – uint8_t[32]

  RoTKTH (Root of Trust Key Table Hash) value is stored in device fuses. If RoTKTH size is 48 bytes (RoTKTH is SHA384 digest of the RoT Key Table), then this field value carries only leading 32 bytes of RoTKTH full value.

- **cc_socu_pinned** – uint32_t, little endian

  Actual value of CC_SOCU_PINNED in device, which is based on actual device lifecycle, DCFG_CC_SOCU_L1 and DCFG_CC_SOCU_L2 fuses combination. For bit representation of CC_SOCU_PINNED please refer to Table 69.

- **cc_socu_default** – uint32_t, little endian

  Actual value of CC_SOCU_DEFAULT, which is based on actual device lifecycle, DCFG_CC_SOCU_L1 and DCFG_CC_SOCU_L2 fuses combination. For bit representation please refer to Table 69.

- **cc_vu** – uint32_t, little endian

  Vendor usage value, custom value provided by vendor, stored in DBG_AUTH_VU fuse in device, value needs to be the same as value specified present later in debug certificate (DC), used for pairing of corresponding DC.

- **challenge vector** – uint8_t[32]

  Random number generated for each request to be signed in debug authentication response (DAR) to avoid reusing of DAR.

15.2.5.3.3 Debug Credential (DC)

Prior to generating debug credential, it is necessary to generate EC keypair (secp384r1) for debugger known as Debug Credential Key (DCK). The public key part of DCK (DCK_{public}) is used to represent the identity of the debugger through the creation of a DC, which binds that public key to some usage attributes (UUID, CC_SOCU), and is then authorized/signed by the vendor's Roots of Trust key ($RoTK_{private}$) using ECDSA algorithm. If RoTK is based on secp384r1then DCK also needs to be based on secp384r1. Combining of EC types is not allowed in DC.

The private part of DCK ($DCK_{private}$) will be used later for signing of Debug Authentication Response (DAR).

The DC structure is illustrated in the following figure.

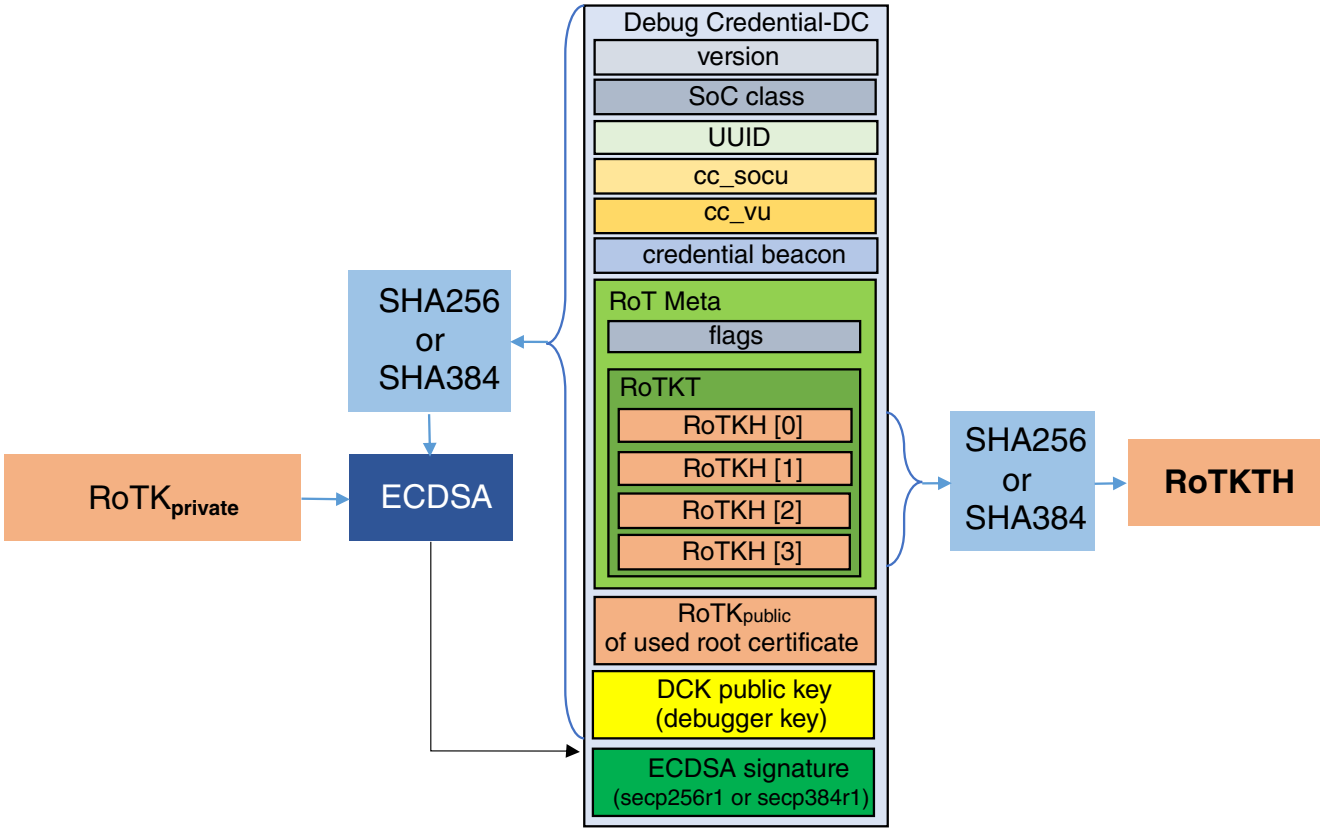

Figure 27. Debug Credential (DC)

The data structure is represented as a packed binary concatenation of its component fields as shown in the list below:

- **version** – uint32_t, little endian

  Fixed to value 0x02000100u “2.1” (major =2, minor = 1) -> secp384r1 used as RoTK

- **SoC class** – uint32_t, little endian

  Fixed to 0x5u, identify the device family.

- **UUID** – uint32_t[4], little endian

  Unique ID of device. Can be set to 0 when debug credential is used for SoC class matching (one debug credential can be used to open debug ports on all devices with same CTRK and same SoC class, UUID matching in device have to be disabled – default). If UUID matching in device is enabled, then UUID value needs to correspond with UUID value of the device received in DAC.

- **cc_socu** – uint32_t, little endian

  Proposed value of SOCU, will be validated and combined on device with current lifecycle, DCFG_CC_SOCU_L1 and DCFG_CC_SOCU_L2 fuses values to have final state of debug ports, which will be applied on device. Refer to Table 69 for Bit details.

- **cc_vu** – uint32_t, little endian

  Vendor usage value need to be matched with value of DBG_AUTH_VU in device fuses (received on DAC).

- **credential beacon** – uint32_t, little endian

  Value loaded to the beacon register after successful debug authentication. Value is used by application to control debug ports. Mask 0xFFFFu is applied to the value of credential beacon and is connected with authentication beacon value from DAR as following formula: beacon = (credentialBeacon & 0xFFFFu) | ((authenticationBeacon & 0xFFFFu) << 16). If final

beacon value is non zero, debug ports are not enabled by ROM bootloader itself and debug ports configuration is delegated to booted application, which can control debug ports according final beacon value available in register (e.g. third party secondary bootloader will open debug just before jump to loaded application, debug of secondary bootloader can be enabled only by special beacon value of credential beacon).

- **RoT meta** – object

  Device root of trust meta data object.

  — **flags** – uint32_t, little endian

  Configuration details of RoT meta object, needs to be matched with RoT ID received in DAC.

  ◦ **flags[bit 31]**: CA flag, always 1 in DC.

  ◦ **flags[bits 30:12]**: Reserved for future use.

  ◦ **flags[bits 11:8]**: Used root cert number [0-3] (specify RoTK used to DC signature), used only when more than 1 RoTK specified for device.

  ◦ **flags[bits 7:4]**: Number of records in RoTKT [1-4], when equal to 1, then RoTKT not present in DC.

  ◦ **flags[bits 3:0]**: Reserved for future use.

  — **RoTKT** – object

  Root of Trust keys Table, optional object (in case when is specified only one RoTK for device, RoTKT is not present, 1 to 4 RoTK can be specified for device), so if RoTKT is present in DC, then RoTKT table contains at least two RoTKH and maximally 4 RoTKH records.

  ◦ **RoTKH[0-3]** – uint8_t[32] or uint8_t[48]

  Root of Trust Key Hash is SHA256 or SHA384 of RoTKpublic. Hash algorithm is selected based on RoTK EC type (secp256r1 -> SHA256 or secp384r1 -> SHA384). Same RoTKs and RoTKTH values are shared between debug authentication, SB3.1 firmware update container and signed boot image.

- **$RoTK_{public}$** – uint8_t[64] or uint8_t[96]

  X and Y coordinates of public key of selected RoTK, which will be used for signing and verification of DC, field size depends on EC type (secp256r1 or secp384r1)

- **DCK_{public}** – uint8_t[64] or uint8_t[96]

  X and Y coordinates of public key of DCK, field size depends on EC type of DCK key (secp256r1 or secp384r1). DCK and RoTKs must be defined on same EC type, combination of EC types is not allowed.

- **ECDSA signature** – uint8_t[64] or uint8_t[96]

  SHA256 or SHA384 of all Debug Credential data (as described on previous figure) used for ECDSA signature. Hash algorithm selected according to EC type of RoTK (secp256r1 -> SHA256 or secp384r1 -> SHA384). Signature coordinates (r,s) stored in big-endian.

15.2.5.3.4 Debug Authentication Response (DAR)

Debugger will find existing or request generation of new corresponding DC according to the inputs from DAC message. The $DCK_{private}$ key is used as input for calculation of ECDSA signature of the corresponding DC including device UUID and Challenge vector from received DAC (Challenge vector is not part of DAR, but it is used as last input to hash of DAR). For signature used SHA256 or SHA384 hash algorithm based on DCK EC type (secp256r1 or secp384r1), if secp256r1-> SHA256, if secp384r1->SHA384. The DAR structure and generation process is described in following figure.

Because regular debuggers usually don't offer feature for ECDSA signing, some PC tool communicating with debugger is needed. NXP offers tool nxpcertgen.exe for generation of DC and nxpdebugmbox.exe for full debug authentication process. Usage of mentioned tools is described in separate user manual related to them.

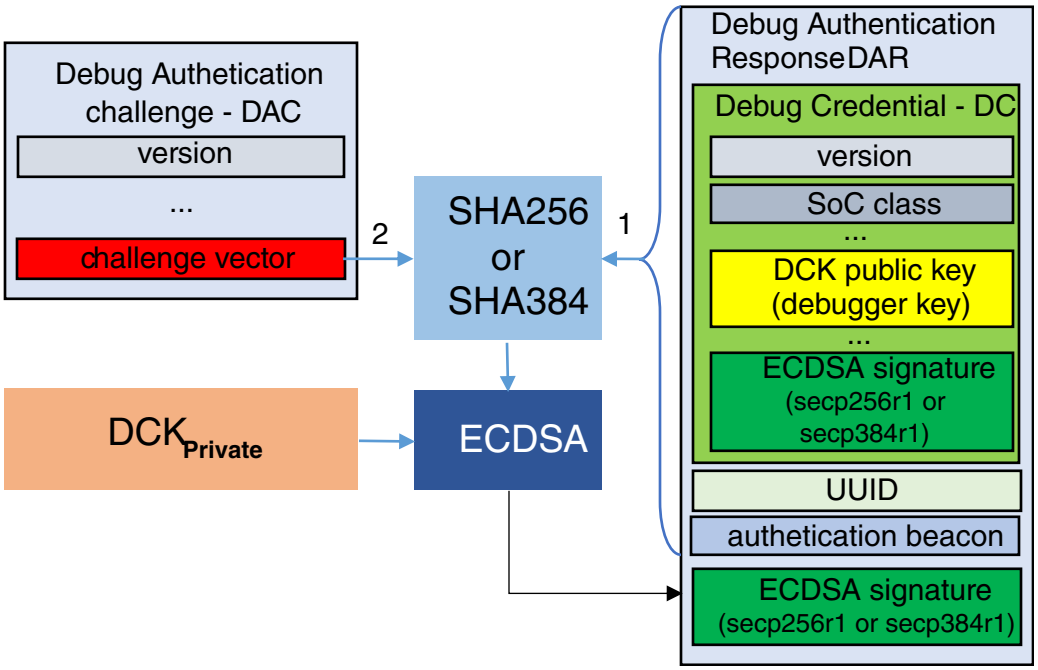

Figure 28. Debug Authentication Response (DAR)

- **Debug credential** – object

  Matched debug credential based on data received from DAC message.

- **authentication beacon** – uint32_t, little endian

  Value loaded to the beacon register after successful debug authentication. Value is used by running application to control debug ports. Mask 0xFFFFu is applied to the value and is connected with credential beacon value from DC as following formula: beacon. Beacon = (credentialBeacon & 0xFFFFu) | ((authenticationBeacon & 0xFFFFu) << 16). If final beacon value is non zero, debug ports are not enabled by ROM bootloader itself and debug ports configuration is delegated to booted application, which can control debug ports according final beacon value available in register (e.g. third party secondary bootloader will open debug just before jump to loaded application, debug of secondary bootloader can be protected by special beacon value).

- **UUID** – uint32_t[4], little endian

  Unique ID of device, must be same as UUID value provided by device in DAC message

15.2.5.3.5 Device processing the DAR

The device BootROM will process DAR received from debugger. As a part of the validation step, device will:

1. Verify DC: Validate DC version, SoCC, UUID, RoT, VU, and DC signature.
2. Verify that the DAR has a valid signature that binds it to the CV from the DAC.

If all the steps are successfully completed, it can be deduced that:

- The debugger possesses the private key corresponding to the vendor/RoT-signed credential.
- The credential satisfies the constraints specified in the device configuration.
- The response of the debugger to the challenge from the device is produced and signed in response to the challenge (because of its cryptographic dependency on the challenge vector). The response is not replayed from a previous authentication where a different challenge vector is used.

After completion of processing DAR, if authentication is successful, Debug Access will be granted. If authentication fails, no special response is issued but further debug access request will be ignored, and device will enter in a failure loop (infinite loop waiting for debug attach)

15.2.5.3.6 Debug authentication use cases

15.2.5.3.6.1 Return Material Analysis (RMA) use case

The diagram below shows RMA flow using debug authentication scheme, where a debug credential certificate is issued for each field technician.

1. Vendor generates RoT key pairs and programs the device with SHA256 hash of RoT public key hashes before shipping
2. Field technician generates his own key pair and provides public key to vendor for authorization.
3. Vendor attests the field technician's public key. In the debug credential certificate, vendor assigns the access rights.
4. End customer having issues with a locked product takes it to field technician.
5. Field technician uses his credentials to authenticate with device and un-locks the product for debugging.

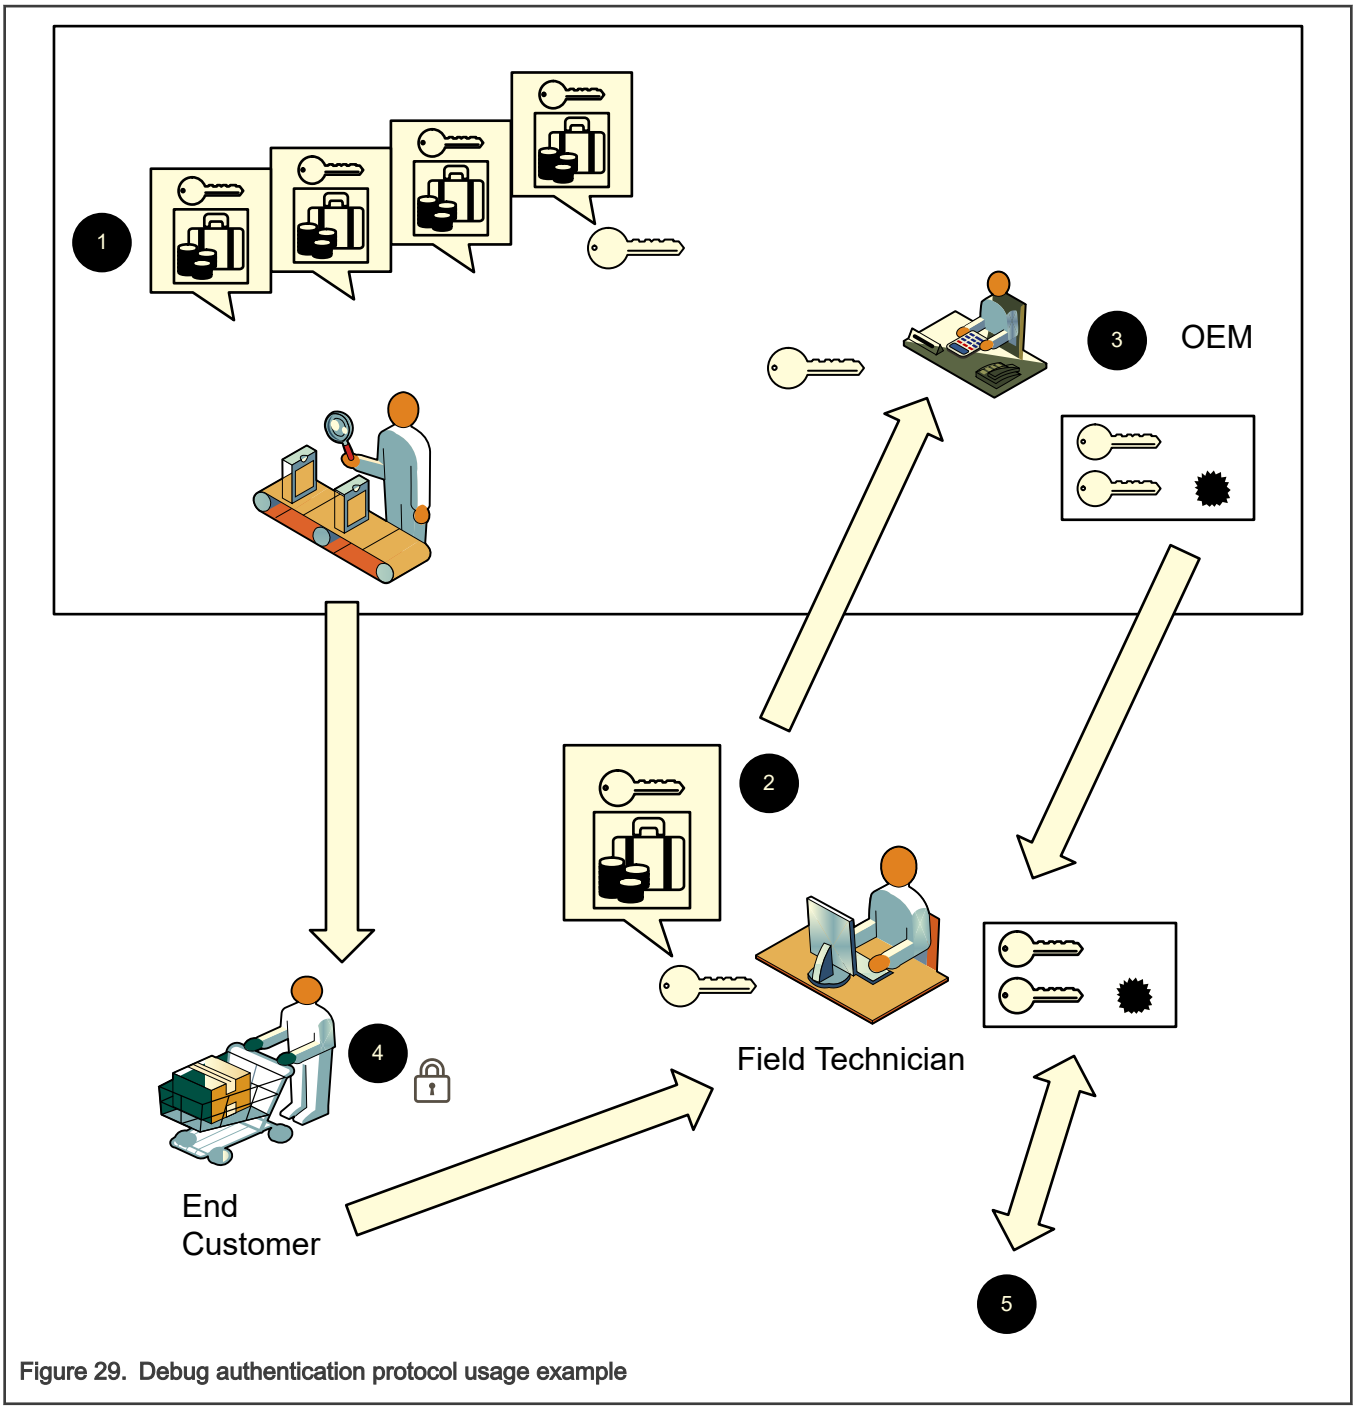

Figure 29. Debug authentication protocol usage example

15.2.5.3.6.2 Module use case with OEM tier1 and tier2 Lifecycle states

The CC_SOCU_PIN_NS & CC_SOCU_DFLT_NS is provided to allow module-maker and OEM using the module to implement tiered protection approach.

- The module maker who is referred as Tier-1 developer can develop secure code and define access rights to his module using CC_SOCU_PIN & CC_SOCU_DFLT.
- Configuration can be such that debug access to secure module is blocked but non-secure debug is always allowed.
- Once the module is ready, Tier-1 developer can release the module to OEM (a.k.a. tier-2 developer), but block debug access to secure mode and enable debug access to non-secure mode.

- Tier-2 developer can develop non-secure module and extend access rights configuration to that module using CC_SOCU_DFLT_NS and CC_SOCU_PIN_NS.

15.2.5.3.7 Fault Analysis (FA) mode

The ROM bootloader offers an FA Mode (Set FA Mode) command handler to enable to delete sensitive information (for example, Keys) before handling over the device to OEM for fault analysis. ROM allows Set FA Mode command only when corresponding flag, FA_CMD_EN, is set. Users must pass an FA request message to Set_FA_Mode command to enter FA mode.

Set FA Mode command will perform the following:

- Erase all OEM Keys in fuse
- Erase the internal flash
- Flush all temporary key registers
- Move the lifecycle to OEM Return

15.2.6 Low-power wakeup path

ROM bootloader goes to low-power wakeup path if the register SPC0->WAKEUP is set to a non-zero value, WAKEUP_DIS is 0 indicating wakeup path is not disabled and Sticky NPX Configuration for Waking up from Deep Power Down is not set. Please note that ROM bootloader does not configure/service/disable Watchdog for low power wakeup path. And ELE is not released for this path. Figure below shows the flow of low power wakeup path.

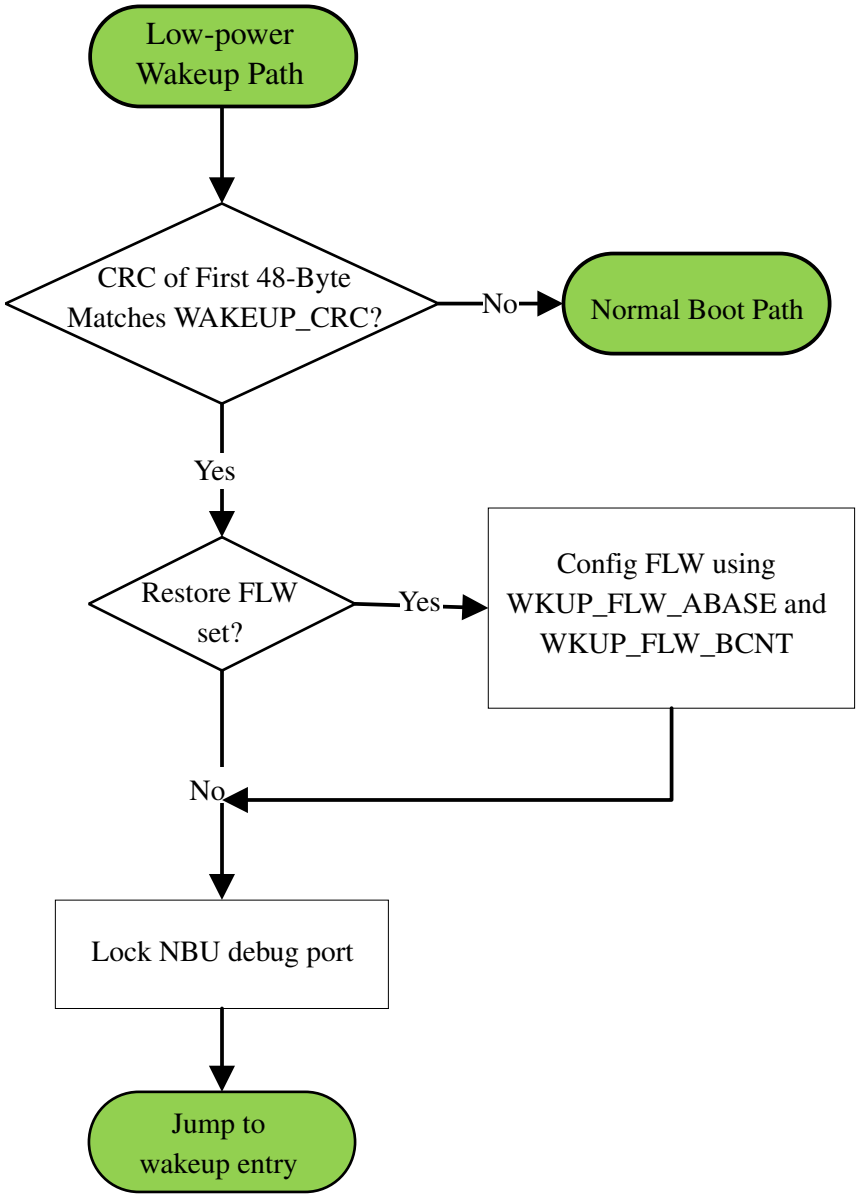

Figure 30. Low power wakeup flow

If WAKEUP_CRC in REGFILE1 (REG0 of REGFILE1) is set correctly, matching the CRC for first 48 bytes of wakeup image, ROM bootloader jumps to the wakeup process entry stored in SPC0->WAKEUP. Otherwise, ROM bootloader exits low power wakeup path and go to normal boot path. Please note that CM3 debug port is locked for low power wakeup path.

In addition, if Flash Logic Window needs to be configured for low power wakeup path, Restore FLW Flag, WAKEUP_FLW_ABASE (REG1 of REGFILE1) and WAKEUP_FLW_BCNT (REG2 of REGFILE1) need to be set correctly. ROM bootloader will configure the FLW using the value from WAKEUP_FLW_ABASE and WAKEUP_FLW_BCNT registers. Please note that Wini_applicatiohalting_executing_immediately_following_rom_AKEUP_FLW_BCNT has three fields, including Valid bit (bit 31), Lock bit (bit 30) and Block Count (bit 0 to bit 14).

15.2.7 Radio firmware update feature

Boot ROM can perform a firmware update remotely. It can be used for updating main flash (CM33) as well as radio flash (CM3) firmware.

Use case example of remote radio firmware update:

1. Main flash (CM33) contains a customer's application image along with NXP delivered OTA client.
2. NXP OTA client helps in fetching image over-the-air via wireless protocol.
3. Image blocks fetched over-the-air are dumped in either internal or external flash unused regions.
4. Once the entire image is received, OTA client must indicate and provide meta data information for update to be performed in User IFR0 OTACFG page. (See OTA update configuration).
5. Application is responsible of triggering a software reset upon which boot ROM uses data provided in OTACFG page to start firmware update.
6. Upon successful update, IFR0 OTACFG page is erased and “FW update status” is updated by boot ROM and reset is triggered to follow "Normal boot path".

If the external flash is used, LPSPI1 is configured to master mode and pin assignment is showed in table below.

Table 71. LPSPI1 pin assignment when external flash used and LPSPI1 configured to master mode

Pin name	Pin assignment	Alt
LPSPI1_SCK	PTB2	2
LPSPI1_SIN	PTB1	2
LPSPI1_SOUT	PTB3	2
LPSPI1_DATA2	PTB5	2
LPSPI1_DATA3	PTB4	2
LPSPI1_SS0	PTB0	2

15.2.8 Initiate a debug session

When ROM bootloader is executing (i.e., instructions are fetched from the ROM memory address range), the debug access port (AP) of CM33 is disabled irrespective of device life-cycle state or token settings. This mechanism is referred as 'Boot-ROM protection' in this document. Thus, the method to initiate a debug session will vary depending on the device state and intended debug scenario. The scenarios described in the rest of these section are as follows:

- Flash does not contain a valid, bootable image. If the flash does not contain a valid image, the ROM bootloader will proceed to ISP mode and wait to be connected via one of its serial interfaces; in ISP mode the debug interface is disabled.
- ISP mode initiated because the ISP pin was asserted on the device at reset.
- Connection to a device running a valid application, with the intent to update flash with a new application.
- Connection to a device running a valid application in flash, with the intent to debug without updating flash (also called a "debug attach").

15.2.8.1 Debug session with invalid flash image or ISP mode

When the device boots, there may be no valid image in the boot media, at which point the ROM bootloader enters the In-System Programming (ISP) path, and debug access is disabled for security reasons. Another scenario is where the device may be placed into ISP mode because the ISP has been asserted as the device leaves reset.

To start a debug session under these scenarios, users need to enter Debugger Mailbox and send the DM-AP command Start Debug Session. Upon receiving the command, the ROM bootloader ensures any unwanted peripheral interrupts are disabled and secrets managed before enabling debug access. After configuring debug access, the ROM enters a while (1) loop. For lifecycle which does not require debug authentication, once the Start Debug Session has been successfully executed, the AP for CM33 and CM3 will be accessible and can used to set breakpoints, etc. as with other Cortex-M devices. For lifecycle which requires debug authentication, DM-AP commands Debug Auth Start and Debug Auth Response need to be done successfully before sending Start Debug Session command to ensure AP for CM33 or CM3 can be accessible.

Example below shows how a debug session is initiated at lifecycle which debug authentication is not required:

```
// Pseudo Code Syntax
// ------------------------------------------------------------------------
// WriteDP <register> <value>
// value = ReadDP <register>
// AP transactions presume the DM AP is selected
// WriteAP <register> <value>
// value = ReadAP <register> <value>
// ------------------------------------------------------------------------
// Read AP ID register to identify DM AP at index 2
WriteDP 2 0x020000F0
// The returned AP ID should be 0x002A0000
value = ReadAP 3
print "AP ID: ", value
// Select DM AP index 2
WriteDP 2 0x02000000
// Write DM RESYNC_REQ + CHIP_RESET_REQ
WriteAP 0 0x21
// Write DM START_DBG_SESSION to REQUEST register (1)
WriteAP 1 7
// Poll RETURN register (2) for zero return
value = -1
while value != 0 {
        value = (ReadAP 2 & 0xFFFF)
}
print "DEBUG_SESSION_REQ: ", value
```

15.2.8.2 Debug session with valid application in flash

In this scenario, ROM bootloader configures debug access before jumping to the application in flash. If the device is at some lifecycle debug authentication is not required and debug has not been disabled by an application already in flash, the APs of CM33 and radio (CM3) are accessible, a debug session can be initialized without any other operation. If debug authentication is required, entering Debugger Mailbox, doing the debug authentication successfully and exiting Debugger Mailbox need to be done before ROM bootloader booting the application. By doing so, users can initialize a debug session after ROM bootloader jumping to the application in flash.

15.2.9 Clock

15.2.9.1 Clock gating

The heart of the clocking architecture is the System Clock Generator (SCG) module. The SCG controls multiple clock sources (FIRC/SIRC/SOSC/ROSC/CORECLK/BUSCLK/SLOWCLK) that can then be distributed to the Module Reset and Clock Control (MRCC) module. Clock gating of modules helps users to only consume power for modules that are needed for their end application. The clock to each module can be gated on or off via a programmable register.

Each peripheral has independent clock gating for both the peripheral interface clock and the peripheral functional clock. This clock gating is controlled via MRCC module. MRCC provides a clock select field, a clock disable, a divider of the selected clock source, and a peripheral reset bit that provides independent resetting of the peripheral. MRCC routes interface clocks and functional clocks for all peripherals.

The CPU_CLK, BUS_CLK, and SLOW_CLK are always enabled in the various RUN and Wait modes. If these clocks are not used in low-power stop modes, they will be disabled via the Core Mode Controller (CMC) and System Power Controller (SPC) modules.

15.2.9.2 Module/Peripheral clocking

Most peripheral clocks by default are disabled, ROM will un-gate the peripheral clocks as needed by the boot flow and also enables functional clock.

Here are some of the clocks used by ROM and their setup values:

- TRDC CPU_CLK
- CRC0 BUS_CLK
- LPSPI1 BUS_CLK
- LPUART1 BUS_CLK
- LPI2C1 BUS_CLK
- CAN BUS_CLK
- ELE CPU_CLK
- GPIO{B/C} CPU_CLK
- PORT{A/B} CPU_CLK

Chapter 16
ROM ISP

16.1 Overview

ROM bootloader provides in-system programming utility that operates over a serial connection on the MCUs. It enables quick and easy programming of MCUs through the entire product lifecycle, including application development, final product manufacturing, and beyond. Host-side command line tool is available to communicate with the bootloader. Users can utilize host tools to upload/download application code and do manufacturing via the bootloader.

When ROM bootloader enters ISP mode and it will auto-detect activity on the LPI2C/LPSPI/LPUART or CAN interface. The auto-detect looks for activity on the LPUART, LPI2C, LPSPI and CAN interface and selects the appropriate interface once a properly formed frame is received. If an invalid frame is received, the data is discarded and scanning resumes.

One method to make ROM bootloader go to ISP path is by pressing the BOOT_CONFIG pin (PTA4) since BOOT_CONFIG pin is enabled by default in User IFR (IFR0). See ROM bootloader configuration for details of config BOOT_CONFIG pin. In addition, ROM bootloader will go to ISP path when no boot image is found, PC and SP are not valid and some other boot failure conditions.

16.2 Available peripherals

Table below shows the peripheral instances and pin assignments used by ISP.

Table 72. Peripheral instances and pin assignments used by ISP

Peripheral instances	Pin name	Pin assignment	Alt
LPUART1	LPUART1_TX	PTC3	3
	LPUART1_RX	PTC2	3
LPSPI1	LPSPI1_PCS0	PTB0	2
	LPSPI1_SIN	PTB1	2
	LPSPI1_SCK	PTB2	2
	LPSPI1_SOUT	PTB3	2
CAN0	CAN0_TX	PTC4	3
	CAN0_RX	PTC5	3
LPI2C1	LPI2C1_SCL	PTB5	4
	LPI2C1_SDA	PTB4	4
Boot pin	BOOT_CONFIG	PTA4	Default

16.3 Available ISP commands

ISP commands availability is controlled by lifecycle. Table below shows the ISP commands available for each lifecycle. Details of several commands can be found in sections below.

Table 73. Available ISP commands for different lifecycle

Command	Description	At OEM Open	After OEM Open
Reset	Reset the device	Available	Available

Table continues on the next page...

Table 73. Available ISP commands for different lifecycle (continued)

Command	Description	At OEM Open	After OEM Open
get-property <tag>	Query about various properties and settings	Available	Available
set-property <tag> <value>	Change properties or options in ROM Bootloader	Available	Available
receive-sb-file <file>	Receive a file in Secure Binary (SB) format	Available	Available
flash-erase-region	Erase one or more sectors of the flash memory	CM33 only	NA
flash-erase-all [<memoryID>]	Erase the entire flash memory specified by memoryID	CM33 only	NA
read-memory <addr> <byte_count> [<file>]	Read memory at specified address	CM33 only	NA
write-memory <addr> [<file> | {{<hex-data>}}]	Write memory at specified address from file or string of hex values Note: When write to SRAM, make sure the length of file or hex-data is 4-byte aligned	CM33 only	NA
fill-memory <addr> <byte_count> <pattern> [word | short | byte]	Fill memory with pattern; pattern size can be word(default), short or byte	CM33 only	NA
fuse-program <index> [<file> | {{<hex-data>}}]	Program fuse at the specified index from file or string of hex values	Available	NA
fuse-read <index> <byte_count> [<file>]	Read fuse from the specified index	Available	NA
Execute <address> <arg> <stackpointer>	Jumps to code at the provided address and does not return to the ROM bootloader	Available	NA

16.3.1 Available properties

Table below shows the available properties (tag) for this device.

Table 74. Supported properties in GetProperty and SetProperty

Name	Writable	Tag value	Size in Bytes	Description
CurrentVersion	no	1	4	The current bootloader version.
AvailablePeripherals	no	2	4	The set of peripherals supported on this chip.
FlashStartAddress	no	3	4	Start address of program flash.
FlashSizeInBytes	no	4	4	Program flash size in bytes.
FlashSectorSize	no	5	4	The size of one sector of program flash in bytes.
FlashBlockCount	no	6	4	The number of blocks of the on-chip flash.
AvailableCommands	no	7	4	The set of commands supported by the bootloader.
CRCCheckStatus	no	8	4	The status of the application CRC check.

Table continues on the next page...

Table 74. Supported properties in GetProperty and SetProperty (continued)

Name	Writable	Tag value	Size in Bytes	Description
VerifyErase	yes	10	4	Controls whether the bootloader verifies erase to flash. The VerifyErase feature is enabled by default: 1 = Enable 0 = Disable
MaxPacketSize	no	11	4	Maximum supported packet size for the currently active peripheral interface.
ReservedRegions	no	12	4	List of memory regions reserved by the bootloader. Returned as value pairs (<startaddress-ofregion>, <end-addressof-region>).
RAMStartAddress	no	14	4	Start address of RAM
RAMSizeInBytes	no	15	4	RAM size in bytes.
SystemDeviceId	no	16	4	System Device ID
SecurityState	no	17	4	Security status
UniqueDeviceId	no	18	16	Unique device identification
BootStatus	no	20	4	Value of Boot Status Register
LoadableFWVersion	no	21	4	ELE loadable firmware version
FuseProgramVoltage	yes	22	4	Control the System LDO VDD Regulator Voltage Level. To program fuse, System LDO VDD regulator level needs to be regulated to Over Drive Voltage (2.5 V). The default System LDD VDO Regulator Voltage Level is regulated to Normal Voltage (1.8 V). 0 = System LDO VDO Regulator Voltage Level is related to Normal Voltage (1.8 V) 1 = System LDO VDD regulator level is regulated to Over Drive Voltage (2.5 V)
TargetVersion	no	24	4	Target version

16.3.2 Fuse reading and programming

A set of fuses can be read / programmed using fuse-program and fuse-read commands. The index of fuses can be found in Lifecycle and fuses.

Please note that -- set-property 22 1 needs to be used before -- fuse-program command to ensure fuse can be programmed successfully. And -- set-property 22 0 needs to be done after all the fuse programming completes.

16.3.3 Commands with limitation

At OEM Open lifecycle, flash-erase-region/ flash-erase-all/ read-memory/ write-memory/ fill-memory commands can be used to Program Flash (CM33) with no restriction. But for radio flash, the accessibility is controlled by Token. If Token is owned by OEM1,

these commands can be used to read/write/erase radio flash. Otherwise, these commands return error when trying to access radio flash.

Command flash-erase-all can have memoryID as a parameter, if no ID is specified or 0 is specified, the entire Program Flash will be erased. If 2 is specified as memoryID, the entire radio Program Flash will be erased. If 3 is specified as memoryID, the entire radio User IFR (IFR0) will be erased. See Table 96 for details about memory ID.

16.3.4 receive-sb-file

receive-sb-file command is used to do image update on CM33 flash or radio (CM3) flash when security is enforced. It receives a secure binary (SB) file, decrypt, authenticate and program the image to the target memory. CUST_PROD_OEMFW_ENC_SK fuse needs to be programmed correctly to ensure this command can be used successfully. Please note that -- set-property 22 1 needs to be used before receive-sb-file command if the sb file contains "programFuses" command. And -- set-property 22 0 needs to be done after receive-sb-file is done.

16.4 In-System Programming protocol

This section explains the general protocol for the packet transfers between the host and the ROM Bootloader. The description includes the transfer of packets for different transactions, such as commands with no data phase and commands with incoming or outgoing data phase. The next section describes various packet types used in a transaction.

Each command sent from the host is replied to with a response command.

Commands may include an optional data phase.

- If the data phase is incoming (from the host to the bootloader), it is part of the original command.
- If the data phase is outgoing (from the bootloader to host), it is part of the response command.

16.4.1 Command with no data phase

The protocol for a command with no data phase contains:

- Command packet (from the host)
- Generic response command packet (to host)

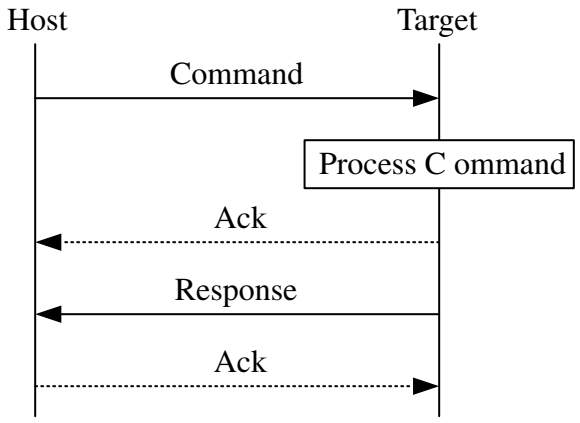

Figure 31. Command with no data phase

NOTE

In these diagrams, the ACK sent in response to a command or a data packet can arrive at any time before, during, or after the command or data packet has processed.

16.4.2 Command with incoming data phase

The protocol for a command with incoming data phase contains:

- Command packet (from host) (kCommandFlag_HasDataPhase set).
- Generic response command packet (to host).
- Incoming data packets (from the host).
- Generic response command packet.

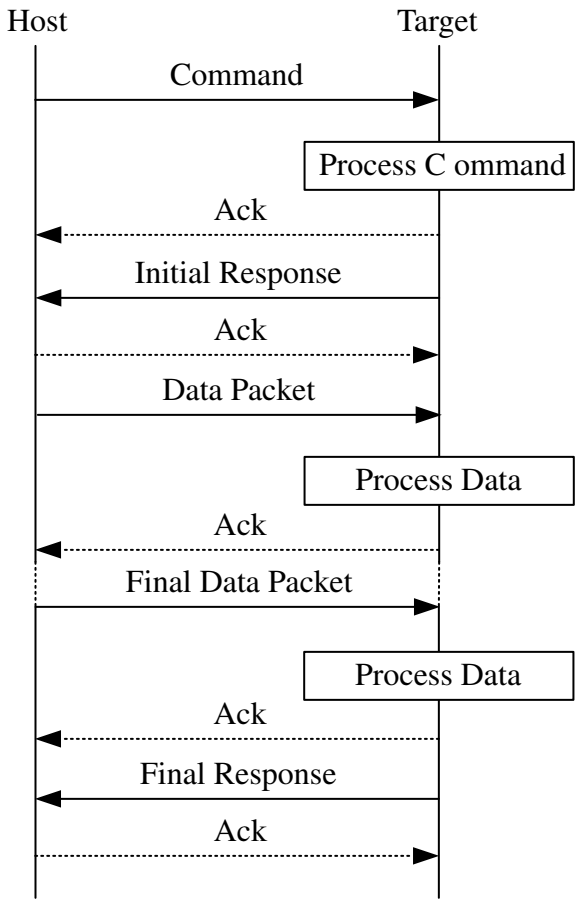

Figure 32. Command with incoming data phase

NOTE

- The host may not send any further packets while it is waiting for the response to a command.
- The data phase is aborted if the Generic Response packet prior to the start of the Data phase does not have a status of kStatus_Success.
- Data phases may be aborted by the receiving side by sending the final GenericResponse early with a status of kStatus_AbortDataPhase. The host may abort the data phase early by sending a zero-length data packet.
- The final Generic Response packet sent after the data phase includes the status of the entire operation.

16.4.3 Command with outgoing data phase

The protocol for a command with an outgoing data phase contains:

- Command packet (from the host).

- ReadMemory Response command packet (to host) (kCommandFlag_HasDataPhase set).
- Outgoing data packets (to host).
- Generic response command packet (to host).

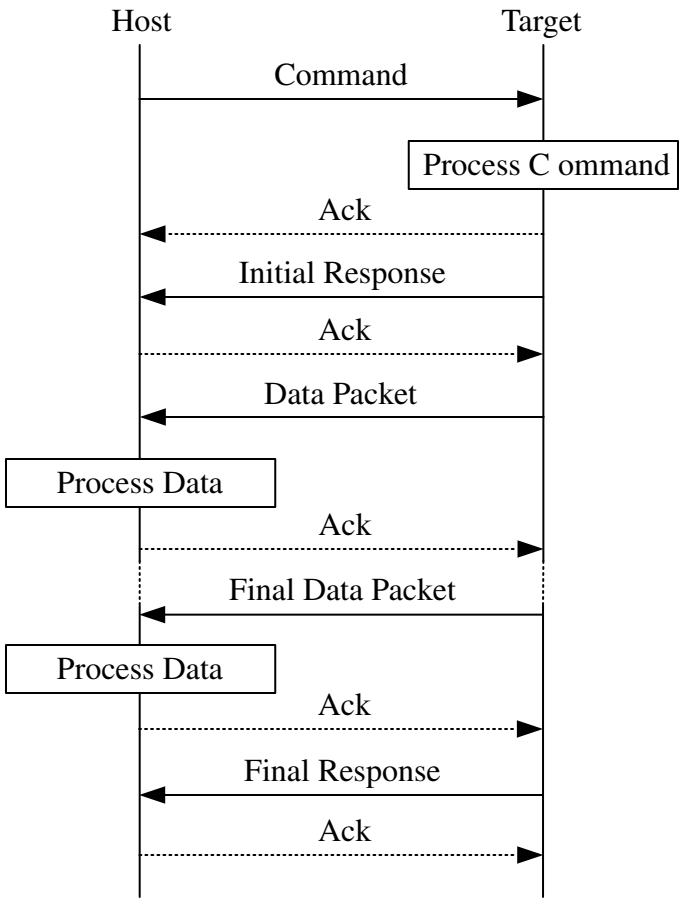

Figure 33. Command with outgoing data phase

NOTE

- The data phase is considered part of the response command for the outgoing data phase sequence. The host may not send any further packets while the host is waiting for the response to a command.
- The data phase is aborted if the ReadMemory Response command packet, prior to the start of the data phase, does not contain the kCommandFlag_HasDataPhase flag. Data phases may be aborted by the host sending the final Generic Response early with a status of kStatus_AbortDataPhase. The sending side may abort the data phase early by sending a zero-length data packet.
- The final Generic Response packet sent after the data phase includes the status of the entire operation.

16.5 ISP packet type

The bootloader device works in slave mode. All data communications are initiated by a host, which is either a PC or an embedded host. The bootloader device is the target, which receives a command or data packet. All data communications between host and target are packetized.

There are six types of packets used:

- Ping packet.

- Ping Response packet.
- Framing packet.
- Command packet.
- Data packet.
- Response packet.

All fields in the packets are in little-endian byte order.

16.5.1 Ping packet

The Ping packet is the first packet sent from a host to the target to establish a connection on the selected peripheral in order to run autobaud detection. The Ping packet can be sent from host to target at any time that the target is expecting a command packet. If the selected peripheral is LPUART, a ping packet must be sent before any other communications. For other serial peripherals, it is optional.

In response to a Ping packet, the target sends a Ping Response packet, discussed in later sections.

Table 75. Ping packet format

Byte #	Value	Name
0	0x5A	start byte
1	0xA6	ping

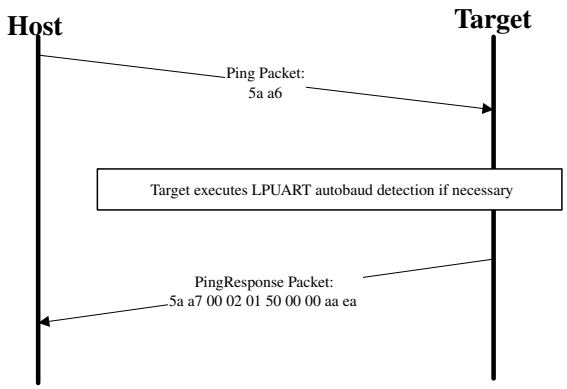

Figure 34. Ping packet protocol sequence

16.5.2 Ping response packet

The target sends a Ping Response packet back to the host after receiving a Ping packet. If communication is over an LPUART peripheral, the target uses the incoming Ping packet to determine the baud rate before replying with the Ping Response packet. Once the Ping Response packet is received by the host, the connection is established, and the host starts sending commands to the target.

Table 76. ping response packet format

Byte #	Value	Parameter
0	0x5A	Start byte
1	0xA7	Ping response code

Table continues on the next page...

Table 76. ping response packet format (continued)

Byte #	Value	Parameter
2	0x00	Protocol bugfix
3	0x03	Protocol minor
4	0x01	Protocol major
5	0x50	Protocol name = 'P' (0x50)
6	0x00	Options low
7	0x00	Options high
8	0xaa	CRC16 low
9	0xea	CRC16 high

The Ping Response packet can be sent from host to target any time the target expects a command packet. For the LPUART peripheral, it must be sent by the host when a connection is first established, in order to run outbound. For other serial peripherals, it is optional but recommended to determine the serial protocol version. The version number is in the same format as the bootloader version number returned by the GetProperty command.

16.5.3 Framing packet

The framing packet is used for flow control and error detection for the communications links that do not have such features built-in. The framing packet structure sits between the link layer and the command layer. It wraps command and data packets as well.

Every framing packet containing data sent in one direction results in a synchronizing response framing packet in the opposite direction.

The framing packet described in this section is used for serial peripherals including the LPUART, LPI2C, and LPSPI.

Table 77. Framing packet format

Byte #	Value	Parameter	Remark
0	0x5A	Start byte	
1		packetType	
2		length_low	Length is a 16-bit field that specifies the entire command or data packet size in bytes.
3		length_high	
4		crc16_low	This is a 16-bit field. The CRC16 value covers entire framing packet, including the start byte and command or data packets, but does not include the CRC bytes. See the CRC16 algorithm after this table.
5		crc16_high	
6 . . . n		Command or Data packet payload	

A special framing packet that contains only a start byte and a packet type is used for synchronization between the host and target.

Table 78. Special framing packet format

Byte #	Value	Parameter
0	0x5A	Start byte
1	0xA*n*	packetType

The Packet Type field specifies the type of the packet from one of the defined types (below):

Table 79. packetType field

packetType	Name	Description
0xA1	kFramingPacketType_Ack	The previous packet was received successfully; the sending of more packets is allowed.
0xA2	kFramingPacketType_Nak	The previous packet was corrupted and must be re-sent.
0xA3	kFramingPacketType_AckAbort	Data phase is being aborted.
0xA4	kFramingPacketType_Command	The framing packet contains a command packet payload.
0xA5	kFramingPacketType_Data	The framing packet contains a data packet payload.
0xA6	kFramingPacketType_Ping	Sent to verify the other side is alive. Also used for LPUART autobaud.
0xA7	kFramingPacketType_PingResponse	A response to Ping; contains the framing protocol version number and options.

16.5.4 CRC16 algorithm

This section provides the CRC16 algorithm.

The CRC is computed over each byte in the framing packet header, excluding the crc16 field itself, plus all of the payload bytes. The CRC algorithm is the XMODEM variant of CRC-16.

Table 80. Characteristics of the XMODEM variant

Variant	Values
Width	16
Polynomial	0x1021
Init value	0x0000
Reflect in	False
Reflect out	False
xor out	0x0000
Check result	0x31c3

The check result is computed by running the ASCII character sequence "123456789" through the algorithm.

```
uint16_t crc16_update(const uint8_t * src, uint32_t lengthInBytes)
{
   uint32_t crc = 0;
   uint32_t j;
   for (j=0; j < lengthInBytes; ++j)
   {
        uint32_t i;
    uint32_t byte = src[j];
     crc ^= byte << 8;
     for (i = 0; i < 8; ++i)
      {
         uint32_t temp = crc << 1;
         if (crc & 0x8000)
          {
              temp ^= 0x1021;
          }
          crc = temp;
      }
   }
   return crc;
}
```

16.5.5 Command packet

The command packet carries a 32-bit command header and a list of 32-bit parameters.

Table 81. Command packet format (32 bytes)

Command Header (4 bytes)				28 bytes for Parameters (Max 7 parameters)						
Tag	Flags	Rsvd	Param Count	Param1 (32-bit)	Param2 (32-bit)	Param3 (32-bit)	Param4 (32-bit)	Param5 (32-bit)	Param6 (32-bit)	Param7 (32-bit)
Byte 0	Byte 1	Byte 2	Byte 3	-	-	-	-	-	-	-

Table 82. Command header format

Byte #	Command Header Field	Remark
0	Command or Response tag	The command header is 4 bytes long, with these fields.
1	Flags	
2	Reserved. Should be 0x00.	
3	ParameterCount	

The header is followed by 32-bit parameters up to the value of the ParameterCount field specified in the header. Because a command packet is 32 bytes long, only 7 parameters can fit into the command packet.

Command packets are also used by the target to send responses back to the host. As mentioned earlier, command packets and data packets are embedded into framing packets for all the transfers.

Table 83. Command tags

Command Tag	Name	Remark
0x01	FlashEraseAll	The command tag specifies one of the commands supported by the bootloader. The valid command tags for the bootloader are listed here.
0x02	FlashEraseRegion	
0x03	ReadMemory	
0x04	WriteMemory	
0x05	FillMemory	
0x06	Reserved	
0x07	GetProperty	
0x08	ReceiveSbFile	
0x09	Execute	
0x0A	Reserved	
0x0B	Reset	
0x0C	SetProperty	
0x0D	Reserved	
0x0E	Reserved	
0x0F	Reserved	
0x10	Reserved	
0x11	Reserved	
0x12	Reserved	
0x13	Reserved	
0x14	FuseProgram	
0x15	Reserved	
0x16	Reserved	
0x17	FuseRead	

Table 84. Response tags

Response Tag	Name	Remark
0xA0	GenericResponse	The response tag specifies one of the responses the bootloader (target) returns to the host. The valid response tags are listed here.
0xA3	ReadMemoryResponse	
0xA7	GetPropertyResponse (used for sending responses to GetProperty command only)	
0xA3	ReadMemoryResponse (used for sending responses to ReadMemory command only)	
0xAF	FlashReadOnceResponse (used for sending responses to FlashReadOnce command only)	
0xB5	KeyProvisionResponse	

Flags: Each command packet contains a Flag byte. Only bit 0 of the flag byte is used. If bit 0 of the flag byte is set to 1, then data packets follow the command sequence. The number of bytes that are transferred in the data phase is determined by a command specific parameter in the parameters array.

ParameterCount: The number of parameters included in the command packet.

Parameters: The parameters are word-length (32 bits). With the default maximum packet size of 32 bytes, a command packet can contain up to 7 parameters.

16.5.6 Response packet

The responses are carried using the same command packet format wrapped with framing packet data. Types of responses include:

- GenericResponse
- GetPropertyResponse
- ReadMemoryResponse
- FlashReadOnceResponse
- KeyProvisionResponse

GenericResponse: After the bootloader has processed a command, the bootloader sends a generic response with status and command tag information to the host. The generic response is the last packet in the command protocol sequence. The generic response packet contains the framing packet data and the command packet data (with generic response tag = 0xA0) and a list of parameters (defined in the next section). The parameter count field in the header is always set to 2, for status code and command tag parameters.

Table 85. GenericResponse parameters

Byte #	Parameter	Description
0 - 3	Status code	The Status codes are errors encountered during the execution of a command by the target. If a command succeeds, then a kStatus_Success code is returned.
4 - 7	Command tag	The Command tag parameter identifies the response to the command sent by the host.

GetPropertyResponse: The GetPropertyResponse packet is sent by the target in response to the host query that uses the GetProperty command. The GetPropertyResponse packet contains the framing packet data and the command packet data, with the command/response tag set to a GetPropertyResponse tag value (0xA7).

The parameter count field in the header is set to greater than 1, to always include the status code and one or many property values.

Table 86. GetPropertyResponse parameters

Byte #	Parameter
0 - 3	Status code
4 - 7	Property value
. . .	. . .
	Can be up to maximum 6 property values, limited to the size of the 32-bit command packet and property type.

ReadMemoryResponse: The ReadMemoryResponse packet is sent by the target in response to the host sending a ReadMemory command. The ReadMemoryResponse packet contains the framing packet data and the command

packet data, with the command/response tag set to a ReadMemoryResponse tag value (0xA3), the flags field set to kCommandFlag_HasDataPhase (1).

The parameter count set to 2 for the status code and the data byte count parameters shown below.

Table 87. ReadMemoryResponse parameters

Byte #	Parameter	Description
0 - 3	Status code	The status of the associated Read Memory command.
4 - 7	Data byte count	The number of bytes sent in the data phase.

FlashReadOnceResponse: The FlashReadOnceResponse packet is sent by the target in response to the host sending a FlashReadOnce command. The FlashReadOnceResponse packet contains the framing packet data and the command packet data, with the command/response tag set to a FlashReadOnceResponse tag value (0xAF), and the flags field set to 0. The parameter count is set to 2 plus the number of words requested to be read in the FlashReadOnceCommand.

Table 88. FlashReadOnceResponse parameters

Byte #	Parameter
0 – 3	Status Code
4 – 7	Byte count to read
…	…
	Can be up to 20 bytes of requested read data.

The KeyProvisionResponse packet is sent by the target in response to the host sending a KeyProvision command. The KeyProvisionResponse packet contains the framing packet data and command packet data, with the command/response tag set to a KeyProvisionResponse tag value (0xB5), and the flags field set to kCommandFlag_HasDataPhase (1).

Table 89. KeyProvisionResponse parameters

Byte #	Parameter
0 – 3	Status Code
4 – 7	Data byte count

16.6 Bootloader command set

All bootloader commands follow the command packet format wrapped by the framing packet as explained in previous sections.

See Available ISP commands for different lifecycle for a list of commands supported by the bootloader.

16.6.1 GetProperty command

The GetProperty command is used to query the bootloader about various properties and settings. Each supported property has a unique 32-bit tag associated with it. The tag occupies the first parameter of the command packet. The target returns a GetPropertyResponse packet with the property values for the property identified with the tag in the GetProperty command.

Properties are the defined units of data that can be accessed with the GetProperty or SetProperty commands. Properties may be read-only or read-write. All read-write properties are 32-bit integers, so they can easily be carried in a command parameter.

The 32-bit property tag is the only parameter required for GetProperty command.

Table 90. Parameters for GetProperty Command

Byte #	Command
0 - 3	Property tag See Available properties for more details.
4 - 7	External Memory Identifier (only applies to get property for external memory)

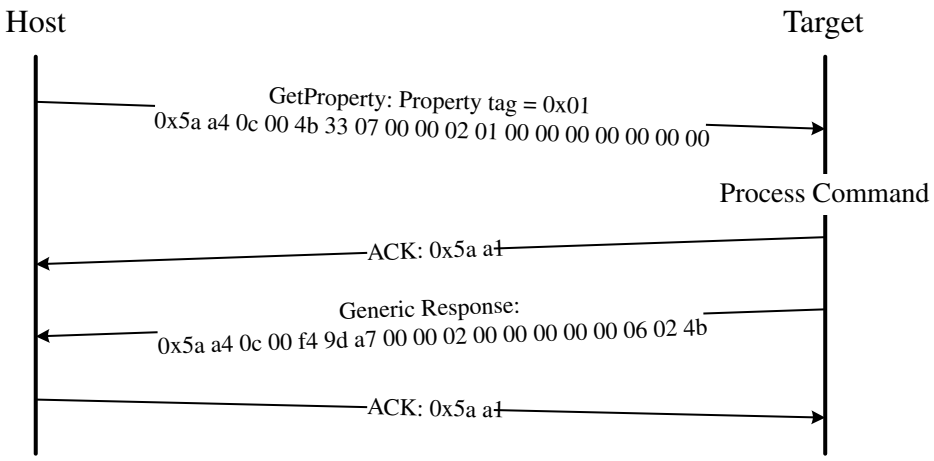

Figure 35. Protocol Sequence for GetProperty Command

Table 91. GetProperty Command Packet Format (Example)

GetProperty	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x0C 0x00
	crc16	0x4B 0x33
Command packet	commandTag	0x07 – GetProperty
	flags	0x00
	reserved	0x00
	parameterCount	0x02

Table continues on the next page...

Table 91. GetProperty Command Packet Format (Example) (continued)

	propertyTag	0x00000001 - CurrentVersion
	Memory ID	0x00000000 - Internal Flash

The GetProperty command has no data phase.

Response: In response to a GetProperty command, the target sends a

GetPropertyResponse packet with the response tag set to 0xA7. The parameter count indicates the number of parameters sent for the property values, with the first parameter showing status code 0, followed by the property value(s). The next table shows an example of a GetPropertyResponse packet.

Table 92. GetProperty Response Packet Format (Example)

GetPropertyResponse	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x0c 0x00 (12 bytes)
	crc16	0x07 0x7a
Command packet	responseTag	0xA7
	flags	0x00
	reserved	0x00
	parameterCount	0x02
	status	0x00000000
	propertyValue	0x0000014b - CurrentVersion

16.6.2 SetProperty command

The SetProperty command is used to change or alter the values of the properties or options of the bootloader. The command accepts the same property tags used with the GetProperty command. However, only some properties are writable--see Available properties. If an attempt to write a read-only property is made, an error is returned indicating the property is read-only and cannot be changed.

The property tag and the new value to set are the two parameters required for the SetProperty command.

Table 93. Parameters for SetProperty Command

Byte #	Command
0 - 3	Property tag See Available properties for more details.
4 - 7	Property value

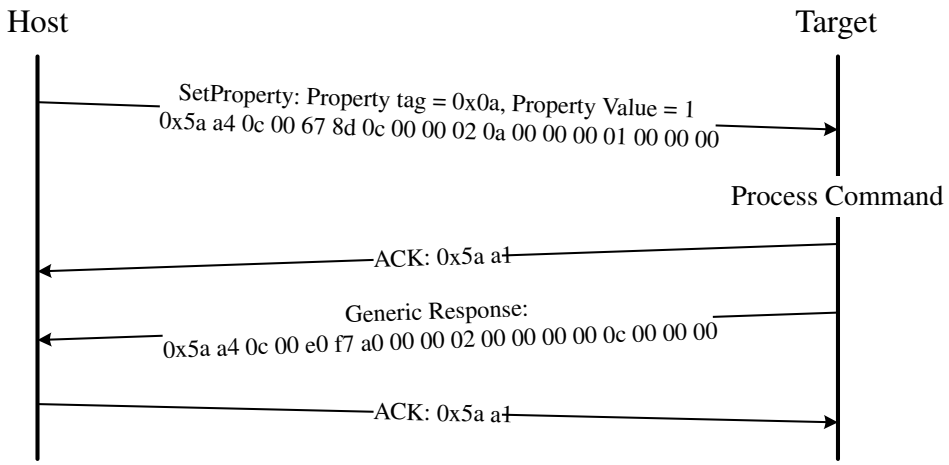

Figure 36. Parameters for SetProperty Command

Table 94. SetProperty Command Packet Format (Example)

SetProperty	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x0C 0x00
	crc16	0x67 0x8D
Command packet	commandTag	0x0C – SetProperty with property tag 10
	flags	0x00
	reserved	0x00
	parameterCount	0x02
	propertyTag	0x0000000A - VerifyWrites
	propertyValue	0x00000001

The SetProperty command has no data phase.

Response: The target returns a GenericResponse packet with one of following status codes:

Table 95. SetProperty Response Status Codes

Status Code
kStatus_Success
kStatus_ReadOnly
kStatus_UnknownProperty
kStatus_InvalidArgument

16.6.3 FlashEraseAll command

The FlashEraseAll command performs an erase of the entire flash memory. If any flash regions are protected, then the FlashEraseAll command fails and returns an error status code. The Command tag for FlashEraseAll command is 0x01 set in the commandTag field of the command packet.

The FlashEraseAll command requires memory ID. If memory ID is not specified, the internal flash (memory ID =0) will be selected as default.

Table 96. Parameter for FlashEraseAll Command

Byte #	Parameter	
	Memory ID	Descriptions
0-3	0x000	Internal Flash
	0x002	Radio PFlash
	0x003	Radio User IFR

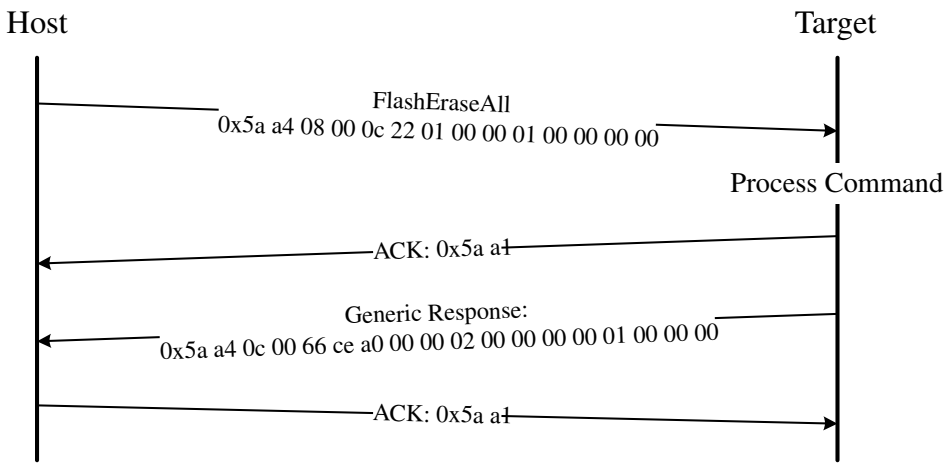

Figure 37. Protocol Sequence for FlashEraseAll Command

Table 97. FlashEraseAll Command Packet Format (Example)

FlashEraseAll	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x08 0x00
	crc16	0x0C 0x22
Command packet	commandTag	0x01 - FlashEraseAll
	flags	0x00
	reserved	0x00
	parameterCount	0x01
	Memory ID	refer to the above table

The FlashEraseAll command has no data phase.

Response: The target returns a GenericResponse packet with status code either set to kStatus_Success for successful execution of the command or set to an appropriate error status code.

16.6.4 FlashEraseRegion command

The FlashEraseRegion command performs an erase of one or more sectors of the flash memory.

The start address, and number of bytes are the 2 parameters required for the FlashEraseRegion command. The start and byte count parameters must be 32-byte aligned ([3:0] = 0000), or the FlashEraseRegion command fails and returns kStatus_FlashAlignmentError (101). If the region specified does not fit in the flash memory space, the FlashEraseRegion command fails and returns kStatus_FlashAddressError (102). If any part of the region specified is protected, the FlashEraseRegion command fails and returns kStatus_MemoryRangeInvalid (10200).

Table 98. Parameters for FlashEraseRegion Command

Byte #	Parameter
0 - 3	Start address
4 - 7	Byte count
8 - 11	Memory ID

The FlashEraseRegion command has no data phase.

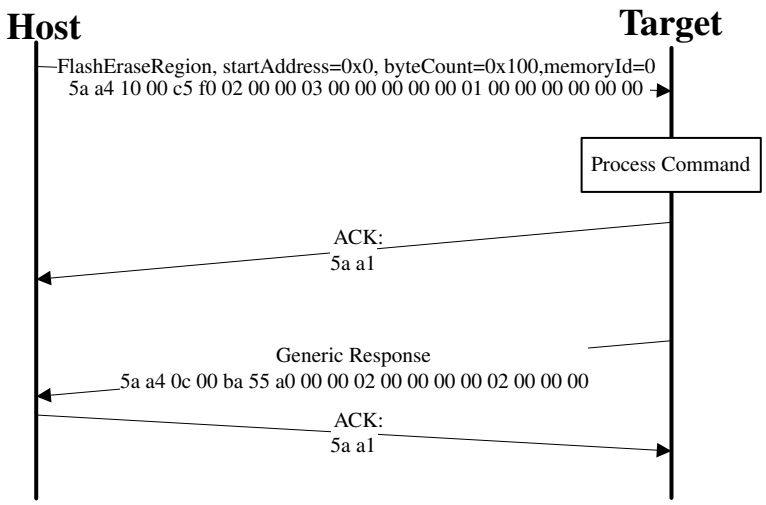

Figure 38. Protocol Sequence for FlashEraseRegion Command

Response: The target returns a GenericResponse packet with one of following error status codes.

Table 99. FlashEraseRegion Response Status Codes

Status Code
kStatus_Success (0)
kStatus_MemoryRangeInvalid (10200)
kStatus_FlashAlignmentError (101)
kStatus_FlashAddressError (102)
kStatus_FlashAccessError (103)
kStatus_FlashCommandFailure (105)

16.6.5 ReadMemory command

The ReadMemory command returns the contents of memory at the given address, for a specified number of bytes. This command can read any region of memory accessible by the CPU and not protected by security.

The start address, and number of bytes are the two parameters required for ReadMemory command. The memory ID is optional. Internal memory will be selected as default if memory ID is not specified.

Table 100. Parameters for read memory command

Byte	Parameter	Description
0-3	Start address	Start address of memory to read from
4-7	Byte count	Number of bytes to read and return to caller
8-11	Memory ID	Internal or external memory Identifier

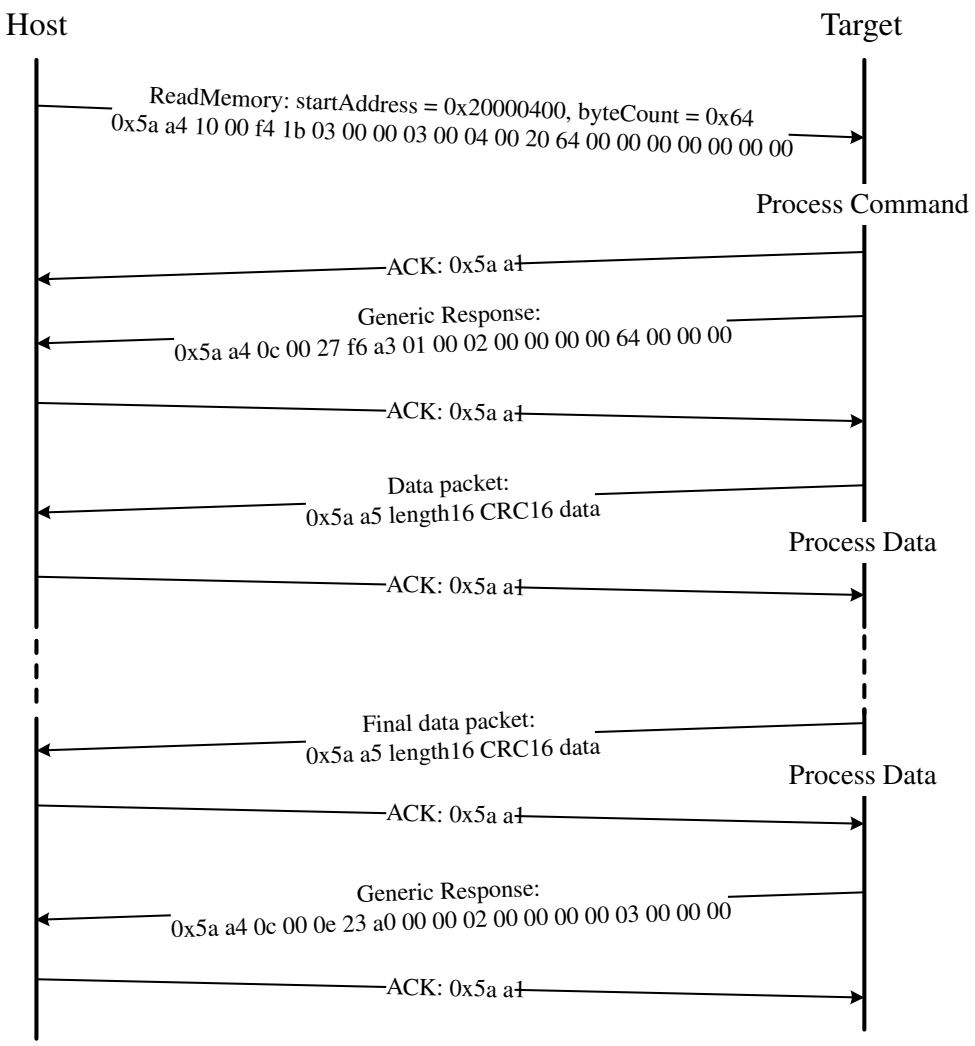

Figure 39. Command sequence for ReadMemory

Table 101. ReadMemory Command Packet Format (Example)

ReadMemory	Parameter	Value
Framing packet	Start byte	0x5A0xA4,
	packetType	kFramingPacketType_Command
	length	0x10 0x00
	crc16	0xF4 0x1B
Command packet	commandTag	0x03 - readMemory

Table continues on the next page...

Table 101. ReadMemory Command Packet Format (Example) (continued)

	flags	0x00
	reserved	0x00
	parameterCount	0x03
	startAddress	0x20000400
	byteCount	0x00000064
	memoryID	0x0

Data Phase: The ReadMemory command has a data phase. Because the target works in slave mode, the host needs to pull data packets until the number of bytes of data specified in the byteCount parameter of ReadMemory command are received by host.

Response: The target returns a GenericResponse packet with a status code either set to kStatus_Success upon successful execution of the command or set to an appropriate error status code.

16.6.6 WriteMemory command

The WriteMemory command writes data provided in the data phase to a specified range of bytes in memory (flash or RAM). However, if flash protection is enabled, then writes to protected sectors fail.

Special care must be taken when writing to flash.

- First, any flash sector written to must have been previously erased with a FlashEraseAll or FlashEraseRegion.
- First, any flash sector written to must have been previously erased with a FlashEraseAll or FlashEraseRegion command.
- Writing to flash requires the start address to be 16-byte aligned ([3:0] = 0000).
- The byte count is rounded up to a multiple of 4, and trailing bytes are filled with the flash erase pattern (0xff).
- If the VerifyWrites property is set to true, then writes to flash also performs a flash verify program operation.

When writing to RAM, the start address does not need to be aligned, and the data is not padded.

The start address and number of bytes are the 2 parameters required for WriteMemory command. The memory ID is optional. Internal memory will be selected as default if memory ID is not specified.

Table 102. Parameters for WriteMemory Command

Byte #	Command
0 - 3	Start address
4 - 7	Byte count
8 - 11	Memory ID

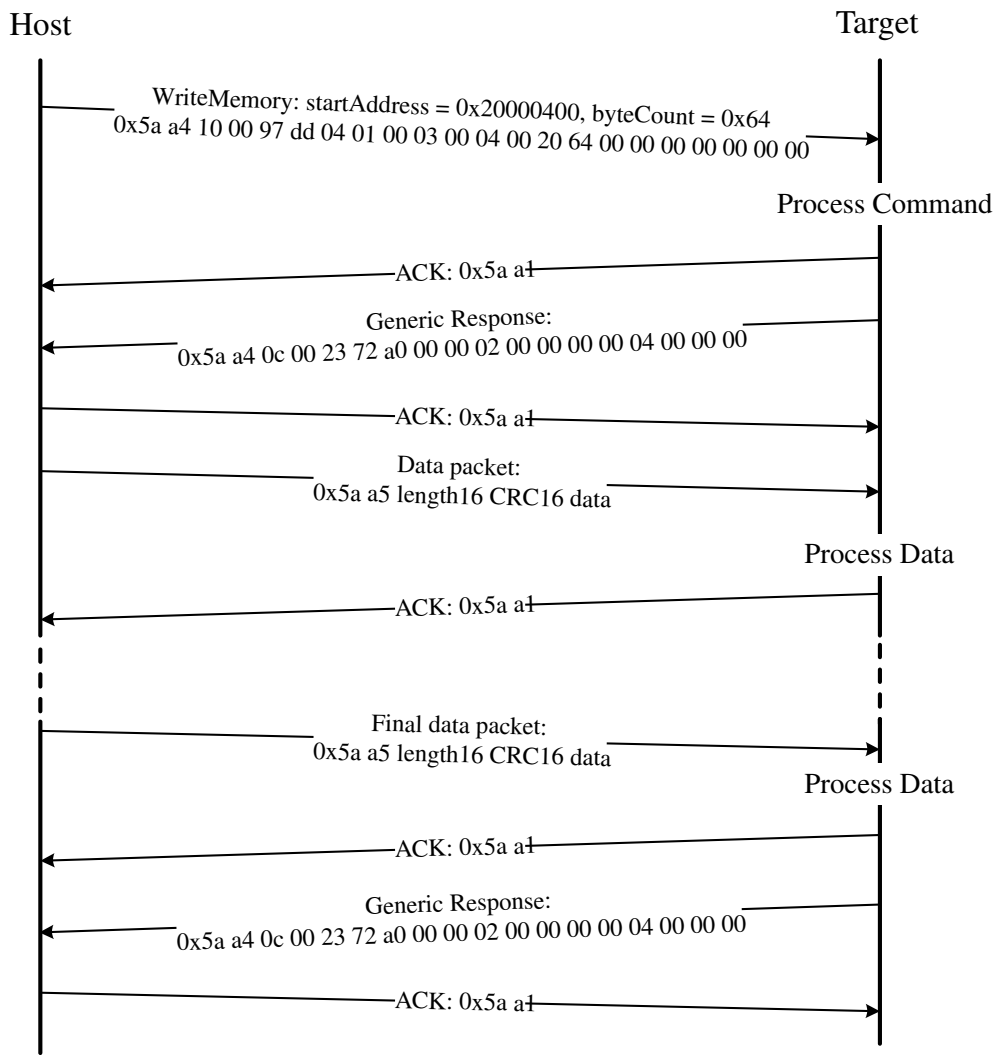

Figure 40. Protocol Sequence for WriteMemory Command

Table 103. WriteMemory Command Packet Format (Example)

WriteMemory	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x10 0x00

Table continues on the next page...

Table 103. WriteMemory Command Packet Format (Example) (continued)

	crc16	0x97 0xDD
Command packet	commandTag	0x04 - writeMemory
	flags	0x01
	reserved	0x00
	parameterCount	0x03
	startAddress	0x20000400
	byteCount	0x00000064
	memoryID	0x0

Data Phase: The WriteMemory command has a data phase; the host sends data packets until the number of bytes of data specified in the byteCount parameter of the WriteMemory command are received by the target.

Response: The target returns a GenericResponse packet with a status code set to kStatus_Success upon successful execution of the command, or to an appropriate error status code.

16.6.7 FillMemory command

The FillMemory command fills a range of bytes in memory with a data pattern. It follows the same rules as the WriteMemory command. The difference between FillMemory and WriteMemory is that a data pattern is included in FillMemory command parameter, and there is no data phase for the FillMemory command, while WriteMemory does have a data phase.

Table 104. Parameters for FillMemory Command

Byte #	Command
0 - 3	Start address of memory to fill
4 - 7	Number of bytes to write with the pattern • The start address should be 32-bit aligned. • The number of bytes must be evenly divisible by 4.
8 - 11	32-bit pattern

- To fill with a byte pattern (8-bit), the byte must be replicated 4 times in the 32-bit pattern.
- To fill with a short pattern (16-bit), the short value must be replicated 2 times in the 32-bit pattern.

For example, to fill a byte value with 0xFE, the word pattern is 0xFEFEFEFE; to fill a short value 0x5AFE, the word pattern is 0x5AFE5AFE.

Special care must be taken when writing to flash.

- First, any flash sector written to must have been previously erased with a FlashEraseAll, or FlashEraseRegion command.
- First, any flash sector written to must have been previously erased with a FlashEraseAll or FlashEraseRegion command.
- Writing to flash requires the start address to be 16-byte aligned ([3:0] = 0000).
- If the VerifyWrites property is set to true, then writes to flash also performs a flash verify program operation.

When writing to RAM, the start address does not need to be aligned, and the data is not padded.

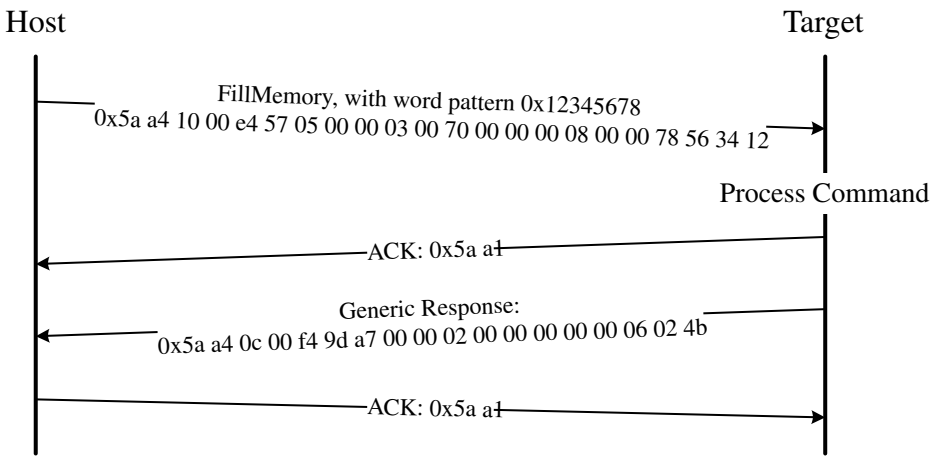

Figure 41. Protocol Sequence for FillMemory Command

Table 105. FillMemory Command Packet Format (Example)

FillMemory	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x10 0x00
	crc16	0xE4 0x57
Command packet	commandTag	0x05 – FillMemory
	flags	0x00
	Reserved	0x00
	parameterCount	0x03
	startAddress	0x00007000
	byteCount	0x00000800
	patternWord	0x12345678

The FillMemory command has no data phase.

Response: upon successful execution of the command, the target (Kinetis bootloader) returns a GenericResponse packet with a status code set to kStatus_Success, or to an appropriate error status code.

16.6.8 Execute command

The execute command results in the bootloader setting the program counter to the code at the provided jump address, R0 to the provided argument, and a Stack pointer to the provided stack pointer address. Prior to the jump, the system is returned to the reset state.

The Jump address, function argument pointer, and stack pointer are the parameters required for the Execute command. If the stack pointer is set to zero, the called code is responsible for setting the processor stack pointer before using the stack.

Table 106. . Parameters for Execute Command

Byte #	Command
0 - 3	Jump address
4 - 7	Argument word
8 - 11	Stack pointer address

The Execute command has no data phase.

Response: Before executing the Execute command, the target validates the parameters and return a GenericResponse packet with a status code either set to kStatus_Success or an appropriate error status code.

16.6.9 Call command

The Call command executes a function that is written in memory at the address sent in the command. The address needs to be a valid memory location residing in accessible flash (internal or external) or in RAM. The command supports the passing of one 32-bit argument. Although the command supports a stack address, at this time the call still takes place using the current stack pointer. After execution of the function, a 32-bit return value is returned in the generic response message.

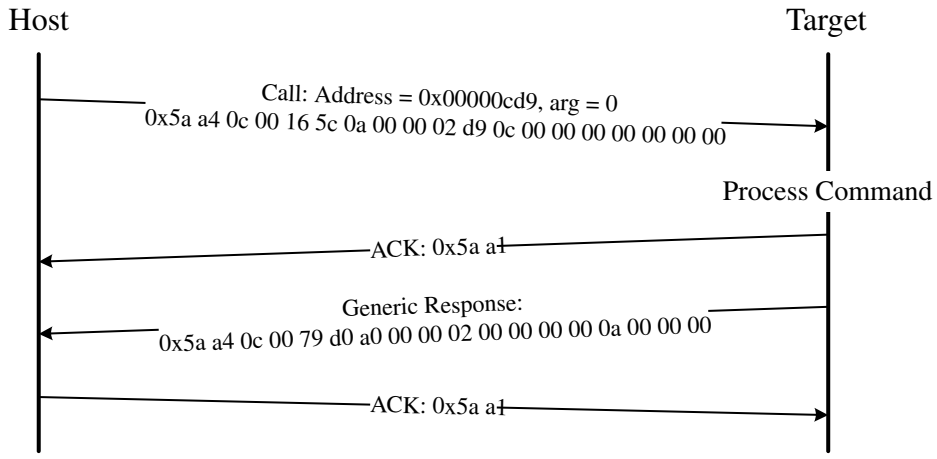

Figure 42. Protocol sequence for Call command

Table 107. Parameters for Call Command

Byte #	Command
0 - 3	Call address
4 - 7	Argument word
8 - 11	Stack pointer

Response: The target returns a GenericResponse packet with a status code either set to the return value of the function called or set to kStatus_InvalidArgument (105).

16.6.10 Reset command

The Reset command results in the bootloader resetting the chip.

The Reset command requires no parameters.

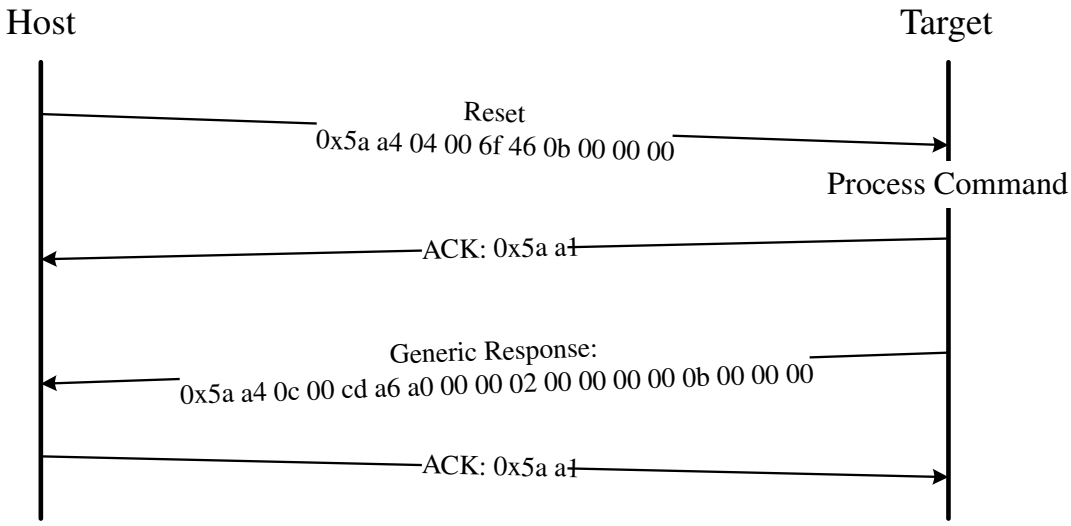

Figure 43. Protocol Sequence for Reset Command

Table 108. Reset Command Packet Format (Example)

Reset	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x04 0x00
	crc16	0x6F 0x46

Table continues on the next page...

Table 108. Reset Command Packet Format (Example) (continued)

Command packet	commandTag	0x0B - reset
	flags	0x00
	reserved	0x00
	parameterCount	0x00

The Reset command has no data phase.

Response: The target returns a GenericResponse packet with status code set to kStatus_Success, before resetting the chip.

The reset command can also be used to switch boot from flash after successful flash image provisioning via ROM bootloader. After issuing the reset command, allow 5 seconds for the user application to start running from Flash.

16.6.11 ReceiveSBFile command

The Receive SB File command (ReceiveSbFile) starts the transfer of an SB file to the target. The command only specifies the size in bytes of the SB file that is sent in the data phase. The SB file is processed as it is received by the bootloader. See the Secure boot related sections for more details about the SB file.

Table 109. . Parameters for Receive SB File Command

Byte #	Command
0 – 3	Byte count

Data Phase: The Receive SB file command has a data phase; the host sends data packets until the number of bytes of data specified in the byteCount parameter of the Receive SB File command are received by the target.

Response: The target returns a GenericResponse packet with a status code set to the kStatus_Success upon successful execution of the command or set to an appropriate error code.

16.7 LPUART ISP

The bootloader integrates an autobaud detection algorithm for the LPUART peripheral, thereby providing flexible baud rate choices.

Autobaud feature: If LPUART*n* is used to connect to the bootloader, then the LPUART*n*_RX pin must be kept high and not left floating during the detection phase in order to comply with the autobaud detection algorithm. After the bootloader detects the ping packet (0x5A 0xA6) on LPUART*n*_RX, the bootloader firmware executes the autobaud sequence.

If the baudrate is successfully detected, then the bootloader sends a ping packet response [(0x5A 0xA7), protocol version (4 bytes), protocol version options (2 bytes) and crc16 (2 bytes)] at the detected baudrate. The Kinetis bootloader then enters a loop, waiting for bootloader commands via the LPUART peripheral.

NOTE

The data bytes of the ping packet must be sent continuously (with no more than 80 ms between bytes) in a fixed LPUART transmission mode (8-bit data, no parity bit and 1 stop bit). If the bytes of the ping packet are sent one-by-one with more than 80 ms delay between them, then the autobaud detection algorithm may calculate an incorrect baud rate. In this instance, the autobaud detection state machine should be reset.

Supported baud rates: The baud rate is closely related to the MCU core and system clock frequencies. Typical baud rates supported are 9600, 19200, 38400, 57600, 115200 and 230400.

NOTE

The peripheral baud rate mentioned here is just at ISP packet level, the actual download speed in ISP is lower than the baud rate because of overhead in the ISP protocol and packet handling.

Packet transfer: After autobaud detection succeeds, bootloader communications can take place over the LPUART peripheral. The following flow charts show:

- How the host detects an ACK from the target
- How the host detects a ping response from the target
- How the host detects a command response from the target

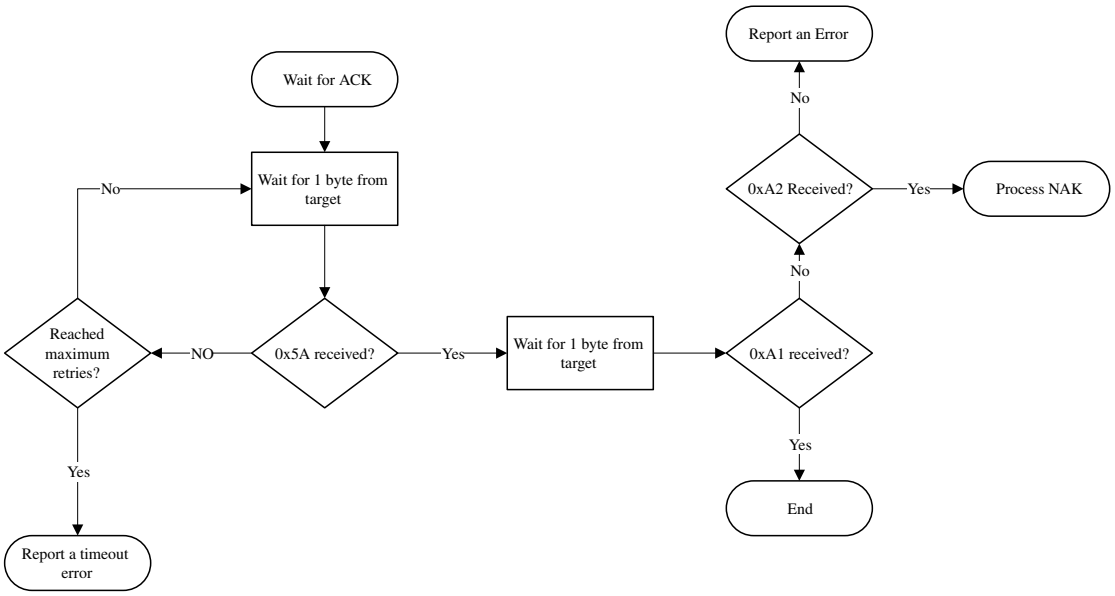

Figure 44. Host reads an ACK from target via LPUART

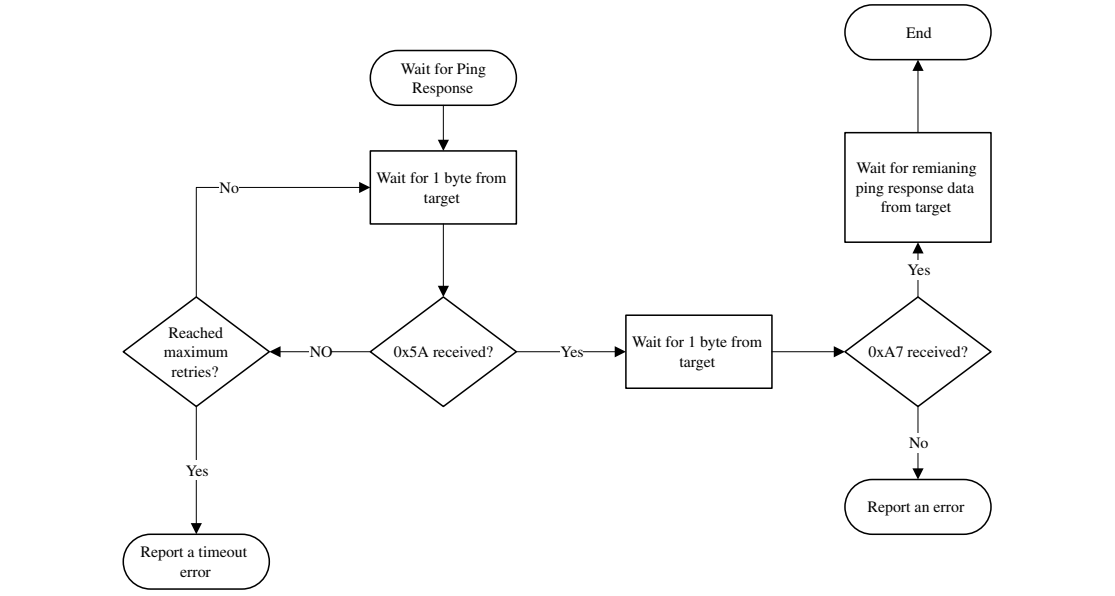

Figure 45. Host reads a ping response from target via LPUART

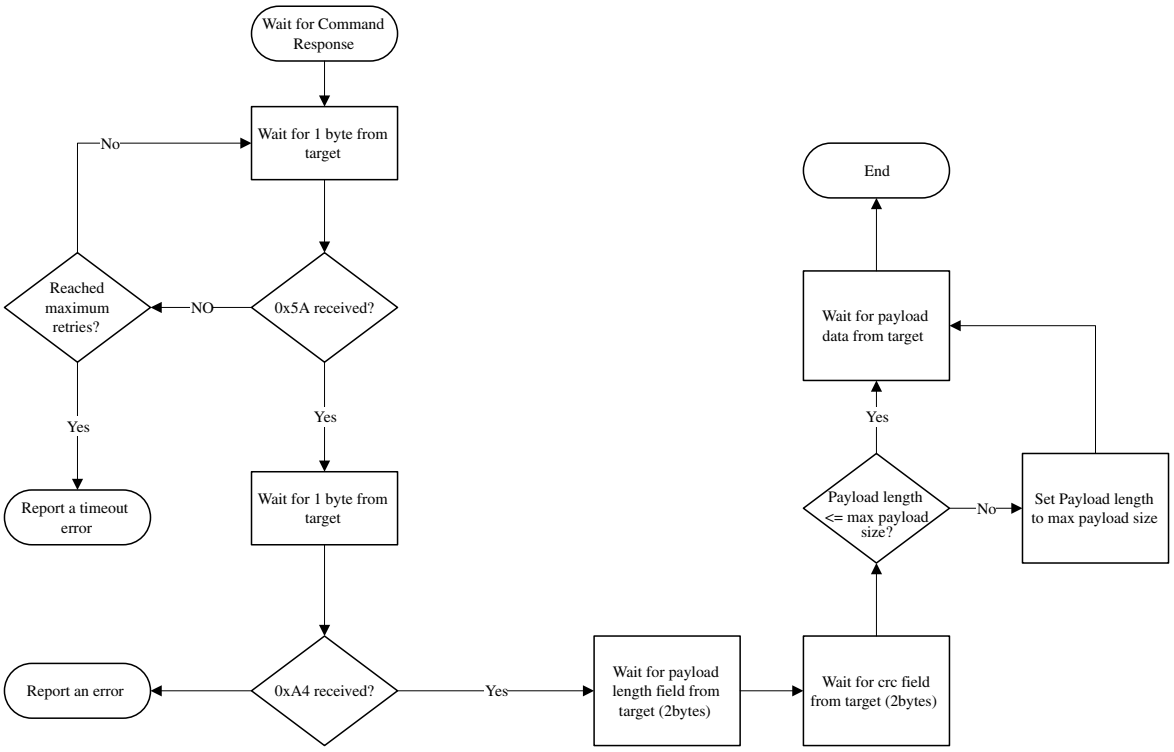

Figure 46. Host reads a command response from target via LPUART

For information on commands and formats, see ISP packet type

16.8 LPI2C ISP

The bootloader supports In-System Programming or serial boot via the LPI2C peripheral, where the LPI2C peripheral serves as the LPI2C slave. The bootloader uses 0x10 as the 7-bit LPI2C slave address and supports up to 400 kbit/s speed during transfer. The maximum supported LPI2C baud rate depends on the core clock frequency when the bootloader is running. The typical baud rate is 400 kbit/s with factory settings.

NOTE

The peripheral baud rate mentioned here is just at ISP packet level, the actual download speed in ISP is lower than the baud rate because of overhead in the ISP protocol and packet handling.

The LPI2C peripheral serves as an LPI2C slave device, hence each transfer should be started by the host, and each outgoing packet should be fetched by the host as well.

- An incoming packet is sent by the host with a selected LPI2C slave address and the direction bit is set to write.
- An outgoing packet is read by the host with a selected LPI2C slave address and the direction bit is set as read.
- 0x00 is sent as the response to host if the target is busy with processing or preparing data.

The following charts show the communication flow of the host reading the ACK packet and the corresponding responses from the target.

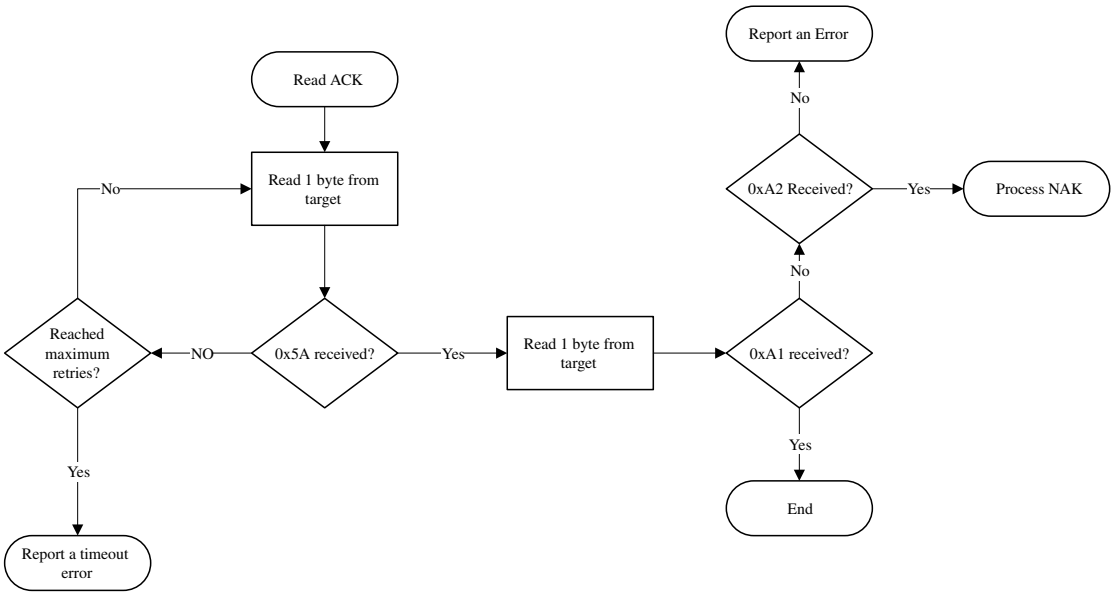

Figure 47. Host reads ACK packet from target via LPI2C

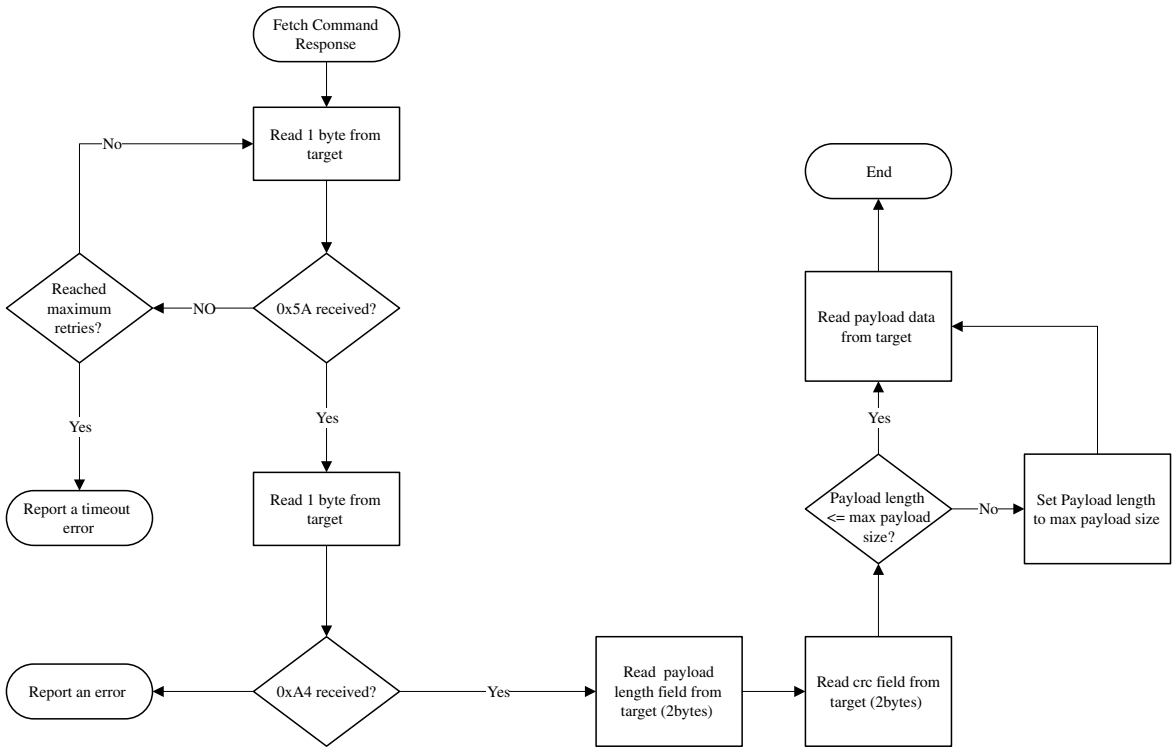

Figure 48. Host reads response from target via LPI2C

For information on commands and formats, see ISP packet type

16.9 LPSPI ISP

The bootloader supports In-System Programming or serial boot via the LPSPI peripheral.

The maximum supported baud rate of the LPSPI depends on the core clock frequency when the bootloader is running. The typical baud rate is 1 MHz with the factory settings. The actual baud rate is up to 4 MHz when the core is running at high-speed boot mode.

The LPSPI peripheral in the bootloader serves as an LPSPI slave device. Each transfer, therefore, must be started by the host, and each outgoing packet should be fetched by the host as well.

NOTE

The peripheral baud rate mentioned here is just at ISP packet level, the actual download speed in ISP is lower than the baud rate because of overhead in the ISP protocol and packet handling.

Compared to LPUART and LPI2C peripherals, the transfer on LPSPI is slightly different:

- The host receives 1 byte after it sends out any byte.
- Received bytes should be ignored when the host is sending out bytes to the target
- The host starts reading bytes by sending 0x00s to target
- The byte 0x00 is sent as a response to host if the target is under the following conditions:
  - Processing incoming packet
  - Preparing outgoing data
  - Received invalid data

The following flowcharts show how the host reads a ping response, an ACK and a command response from target via LPSPI without the nIRQ pin enabled.

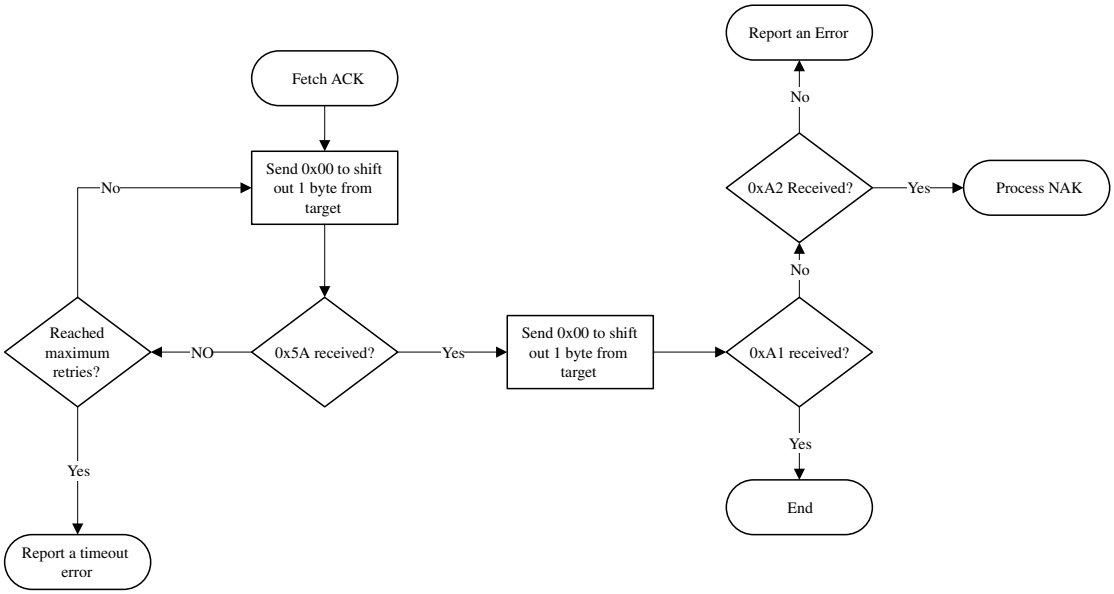

Figure 49. Host reads ACK from target via LPSPI

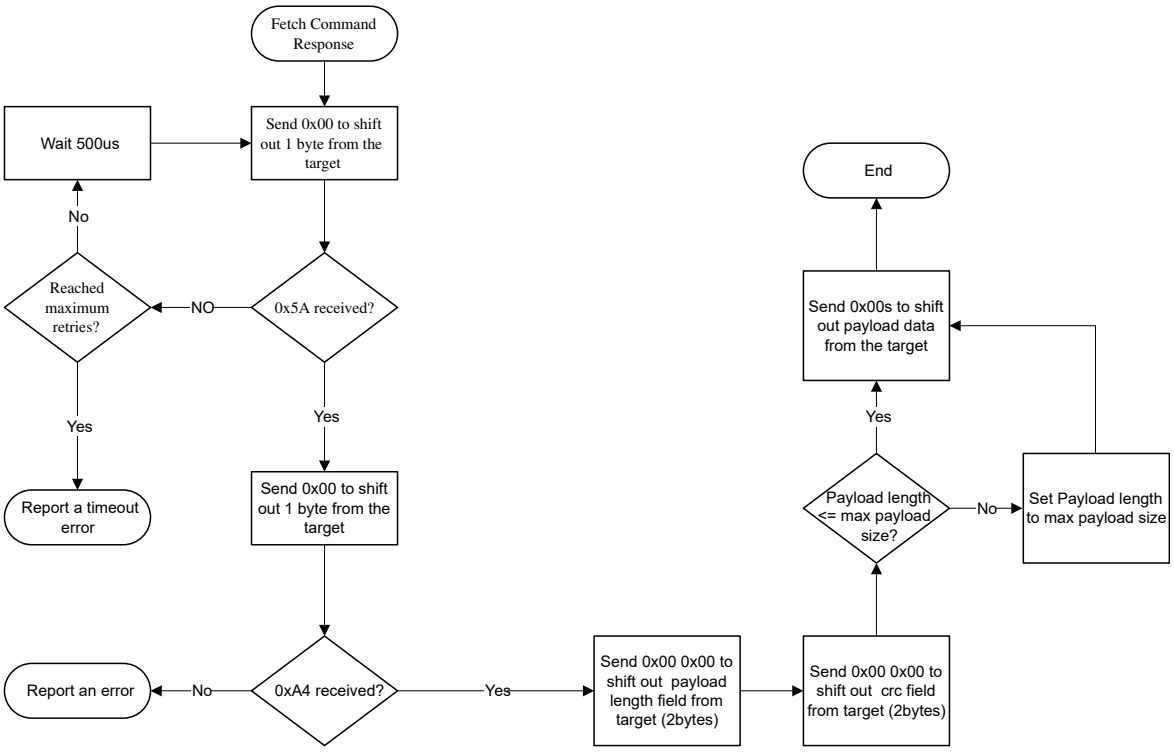

Figure 50. Host reads response from target via LPSPI

For information on commands and formats, see ISP packet type

16.10 CAN ISP

The bootloader supports loading data into flash via the FlexCAN peripheral. It supports four predefined speeds on FlexCAN transferring:

- 125 kHz
- 250 kHz
- 500 kHz
- 1 MHz

NOTE

The peripheral baud rate mentioned here is just at ISP packet level, the actual download speed in ISP is lower than the baud rate because of overhead in the ISP protocol and packet handling.

In host applications, the user can specify the speed for FlexCAN by providing the speed index as 0 through 4, which represents those 5 speeds (default is 1 MHz).

In bootloader, this supports the auto speed detection feature within supported speeds. In the beginning, the bootloader enters the listen mode with the initial speed (default speed 1 MHz). Once the host starts sending a ping to a specific node, it generates traffic on the FlexCAN bus. Because the bootloader is in a listen mode. It can check if the local node speed is correct by detecting errors. If there is an error, some traffic will be visible, but it may not be on the right speed to see the real data. If this happens, the speed setting changes and checks for errors again. No error means the speed is correct. The settings change back to the normal receiving mode to see if there is a package for this node. It then stays in this speed until another host is using another speed and try to communicate with any node. It repeats the process to detect a right speed before sending host timeout and aborting the request.

The host side should have a reasonable time tolerance during the auto speed detect period. If it sends as timeout, it means there is no response from the specific node, or there is a real error and it needs to report the error to the application.

The flow chart below shows the communication flow for how the host reads the ping packet, ACK, and response from the target.

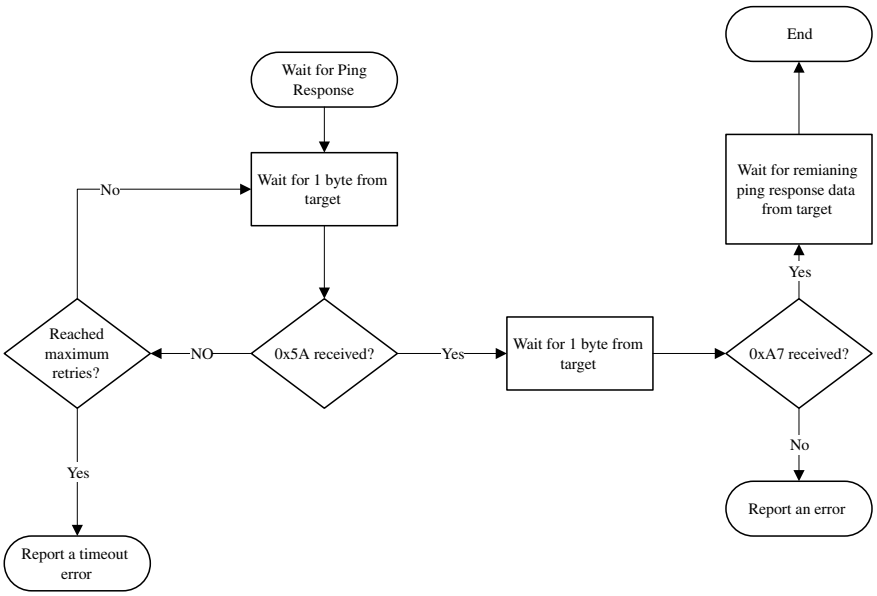

Figure 51. Host reads ping response from target via FlexCAN

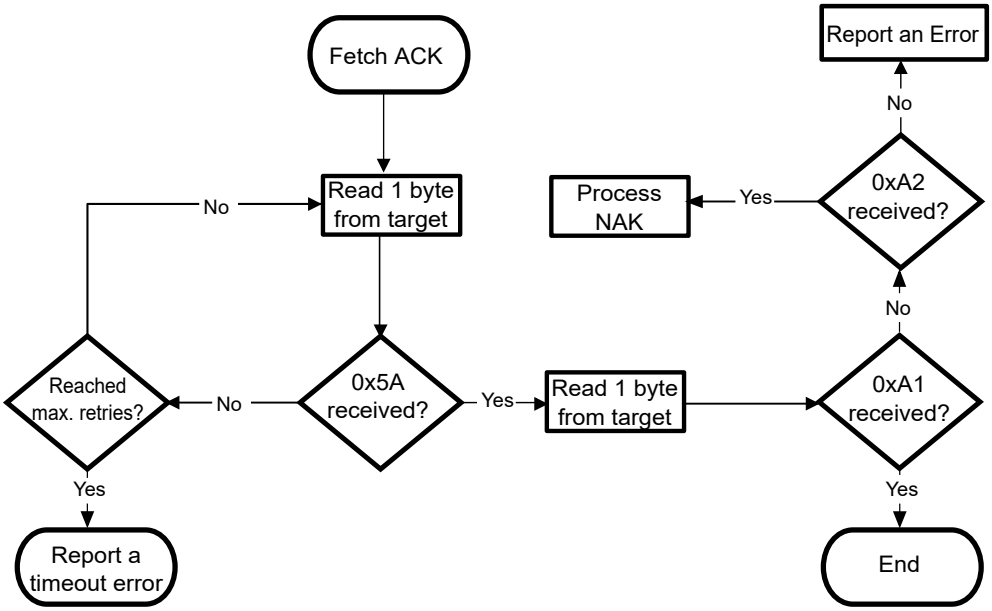

Figure 52. Host reads ACK packet from target via FlexCAN

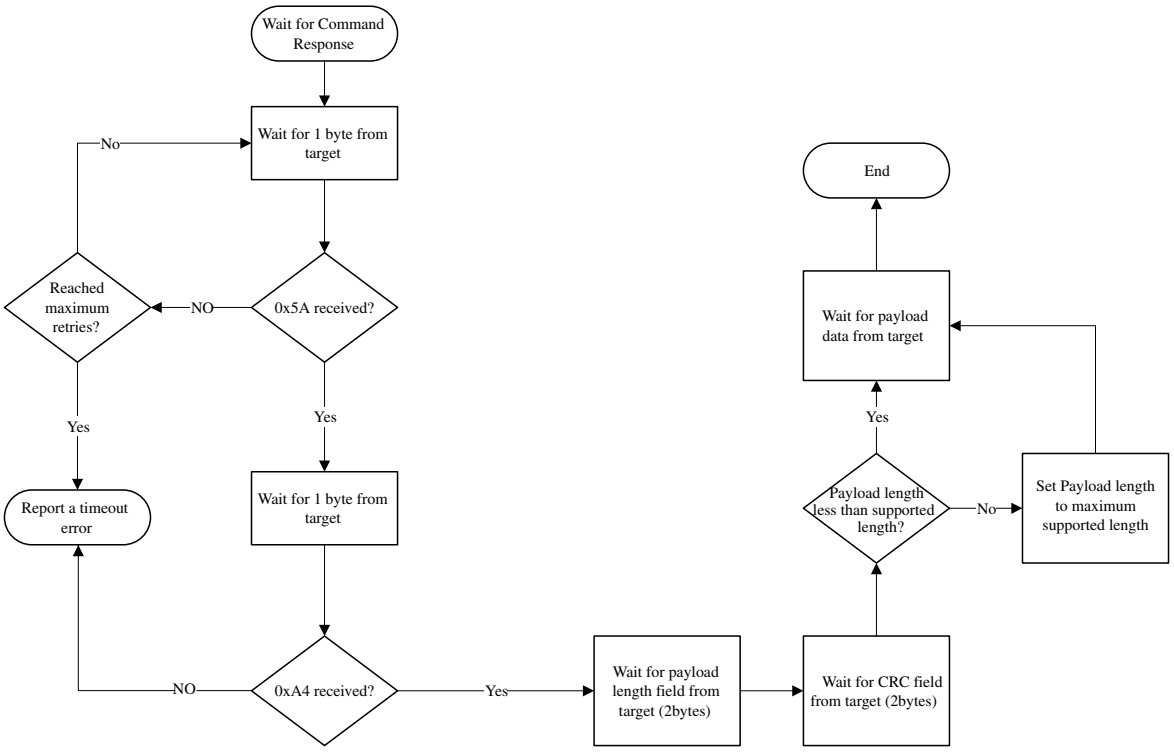

Figure 53. Host reads command response from target via FlexCAN

Chapter 17
ROM API

17.1 Overview

ROM bootloader provides several APIs for users. Disabling the interrupts before making any ROM API call is suggested, since API code does not deal with interrupts. Flash APIs are mainly used to manage flash including read, write and erase. Similarly, SPI NOR APIs are mainly used to manage SPI NOR including read, write and erase. nboot APIs are mainly used to do security related operations including image authentication and fuse programming. kb APIs are mainly used to process SB file. Please note that 5 KB of SRAM (0x30002000 - 0x30003400) needs to be reserved when calling flash api, SPI NOR API and kb APIs in user application.

The ROM API table locates at address 0x14816fe0. See Figure below for the ROM API layout.

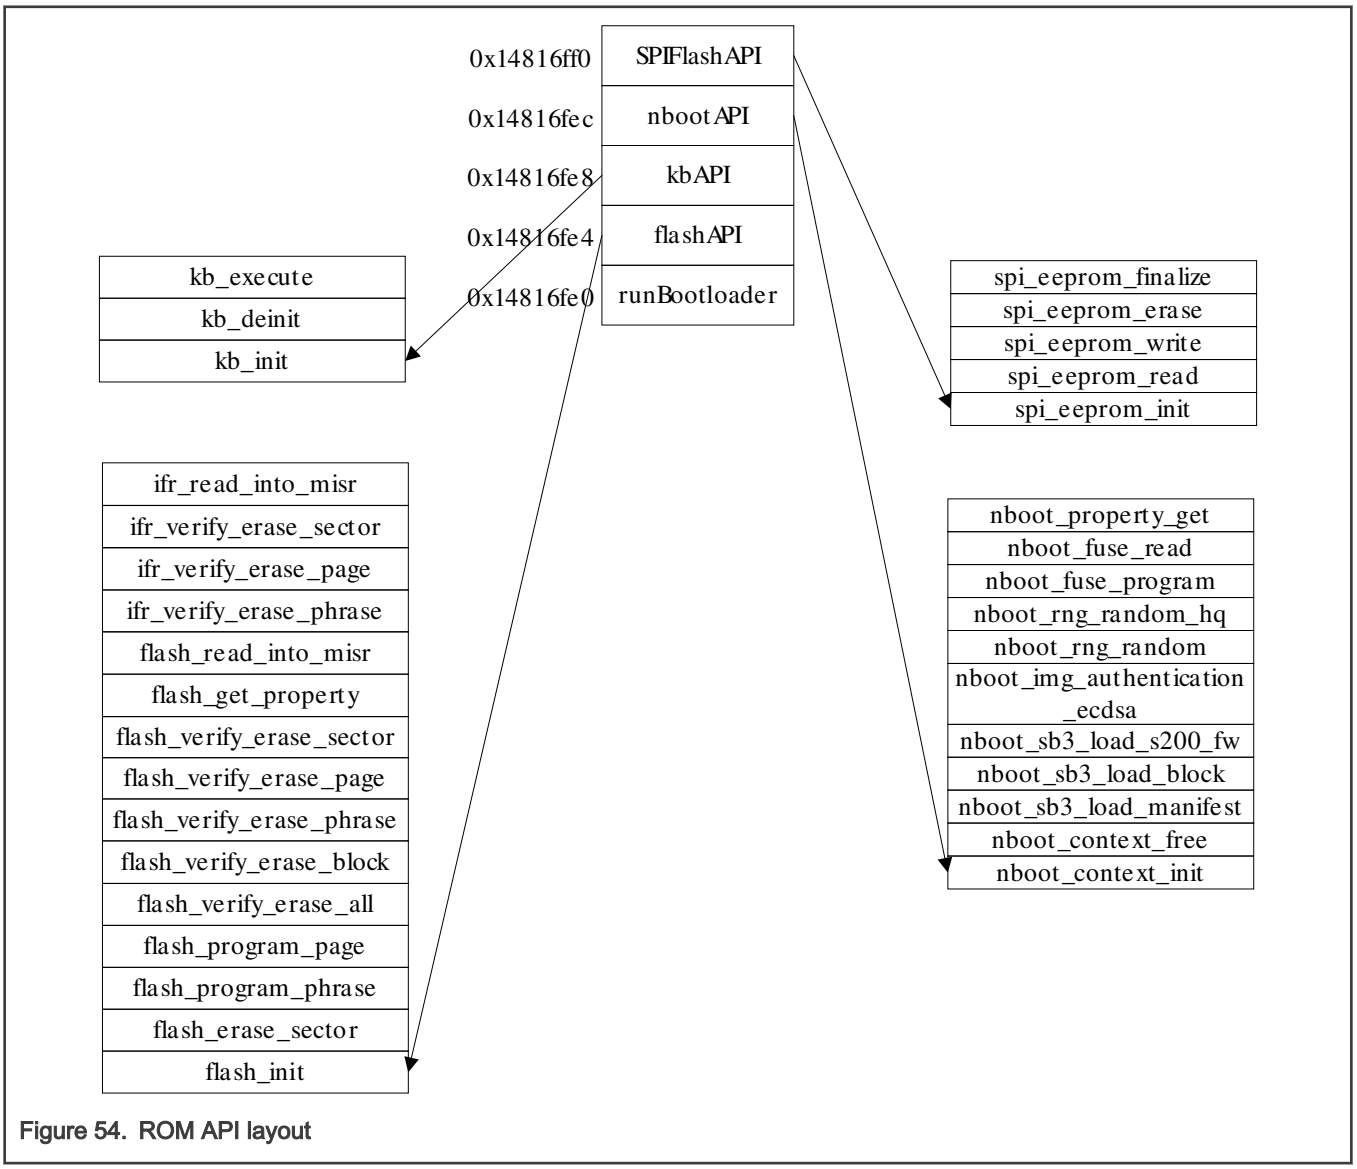

Figure 54. ROM API layout

17.2 Flash API

Flash APIs implement all the flash operation supported by CM33 FMU and RF-FMU1. Please note that operations to RF_FMU1 are only allowed when lifecycle is at OEM Open and Token indicates OEM1 ownership. Details of each API is described in this section.

17.2.1 flash_init

This API is used for initializing the flash controller and the flash_config context. It must be called before calling other flash APIs.

Prototype

```
status_t flash_init (flash_config_t *config);
```

Parameters

Table 110. flash_init parameters

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.

flash_config_t is defined as following:

```
typedef struct _flash_mem_descriptor {
    uint32_t blockBase;
    uint32_t totalSize;
    uint32_t blockCount;
} flash_mem_desc_t;

typedef struct _flash_ifr_desc {
    uint32_t pflashIfr0Start;
    uint32_t pflashIfr0MemSize;
} flash_ifr_desc_t;

typedef struct _msf1_config {
    flash_mem_desc_t flashDesc;
    flash_ifr_desc_t ifrDesc;
} msf1_config_t;

typedef struct _flash_config {
    msf1_config_t msf1Config[2];
} flash_config_t;
```

Example:

```
typedef struct
{
    __I void (*runBootloader)(void *arg);           //!< Function to start the bootloader executing.
    __I FLASH_API_Type *flashApiBase;         //!< Internal Flash driver API.
    __I KB_API_Type *kbApiBase;               //!< Bootloader API.
__I NBOOT_API_Type *nbootApiBase;         //!< Image authentication API.
    __I SPI_FLASH_API_Type *spiflashApiBase;             //!< SPI Flash API.

} ROM_API_TYPE;
/** ROM API base address */
#define ROM_API_BASE                        (0x14816fe0u)
/** ROM API base pointer */
#define ROM_API                             ((ROM_API_TYPE*) ROM_API_BASE)
```

```
/** FLASH API base pointer */
#define FLASH_API                          (ROM_API->flashApiBase)
static flash_config_t flashConfig;
FLASH_API->flash_init(&flashConfig);
```

17.2.2 flash_erase_sector

This API is used for erasing specified flash sector (8 KB) in flash or User IFR(IFR0). This API will erase sectors which include the start address and (start + lengthInBytes - 1) address.

Prototype

```
status_t flash_erase_sector (flash_config_t *config, FMU_Type *base, uint32_t start, uint32_t
lengthInBytes, uint32_t key);
```

Parameters

Table 111. flash_erase_sector parameters

Parameter	Description
Config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of the required flash memory to be erased. The starting address must be phrase-aligned (4-word or 16-byte).
lengthInBytes	The length, given in bytes (not words or long words) to be erased.
Key	Key is used to validate erase operation. Must be set to "kFLASH_ApiEraseKey"

Example:

```
#define FOUR_CHAR_CODE(a, b, c, d) (((d) << 24) | ((c) << 16) | ((b) << 8) | ((a)))
#define CM33_FMU                                    ((FMU_Type *)0x40020000u)
enum _flash_driver_api_keys
{
           kFLASH_ApiEraseKey = FOUR_CHAR_CODE('l', 'f', 'e', 'k')
};
result = FLASH_API->flash_erase_sector(&flashConfig, CM33_FMU, 0x0, 4, kFLASH_ApiEraseKey);
```

17.2.3 flash_program_phrase

This API is used for programming phrase-aligned data to a previously erased flash or User IFR phrase.

Prototype

```
status_t flash_program_phrase (flash_config_t *config, FMU_Type *base, uint32_t start,
                          uint32_t *src, uint32_t lengthInBytes);
```

Parameters

Table 112. flash_program_phrase parameters

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1

Table continues on the next page...

Table 112. flash_program_phrase parameters (continued)

Parameter	Description
Start	The starting address of the required flash memory to be programmed. The starting address must be phrase-aligned (4-word or 16-byte).
Src	Pointer to the source buffer of data that is to be programmed into flash.
lengthInBytes	The length, given in bytes (not words or long words) to be programmed. The lengthInBytes must be phrase-aligned (4-word or 16-byte).

17.2.4 flash_program_page

This API is used for programming page aligned data to a previously erased flash or User IFR page.

Prototype

```
status_t flash_program_page (flash_config_t *config, FMU_Type *base, uint32_t start,
                        uint32_t *src, uint32_t lengthInBytes);
```

Parameters

Table 113. flash_program_page parameters

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of the required flash memory to be programmed. The starting address must be page-aligned (32-word or 128-byte).
Src	Pointer to the source buffer of data that is to be programmed into flash.
lengthInBytes	The length, given in bytes (not words or long words) to be programmed. The lengthInBytes must be page-aligned (32-word or 128-byte).

17.2.5 flash_verify_erase_all

This API is used for checking if all flash and IFR space are in the erased state..

Prototype

```
status_t flash_verify_erase_all (FMU_Type *base);
```

Parameters:

Table 114. flash_verify_erase_all parameters

Parameter	Description
FMU base	Base pointer to FMU or RF-FMU1

17.2.6 flash_verify_erase_block

This API is used for checking if a flash block is in the erased state.

Prototype

```
status_t flash_verify_erase_block (flash_config_t *config, FMU_Type *base, uint32_t blockaddr);
```

Parameters

Table 115. flash_verify_erase_block parameters

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
blockaddr	Starting address of a flash block, needs to be block-aligned

17.2.7 flash_verify_erase_phrase

This API is used for checking if specified flash phrases are in the erased state.

Prototype

```
status_t flash_verify_erase_phrase (flash_config_t *config, FMU_Type *base, uint32_t start, uint32_t
lengthInBytes);
```

Parameters

Table 116. flash_verify_erase_phrase parameters

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of required flash memory to be checked. The starting address must be phrase-aligned (4-word or 16-byte).
lengthInBytes	The length, given in bytes (not words or long words) to be checked. The lengthInBytes must be phrase-aligned (4-word or 16-byte).

17.2.8 flash_verify_erase_page

This API is used for checking if specified flash pages are in the erased state.

Prototype

```
status_t flash_verify_erase_page (flash_config_t *config, FMU_Type *base, uint32_t start, uint32_t
lengthInBytes);
```

Parameters

Table 117. flash_verify_erase_page parameters

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of required flash memory to be checked. The starting address must be page-aligned (32-word or 128-byte).
lengthInBytes	The length, given in bytes (not words or long words) to be checked. The lengthInBytes must be page-aligned (32-word or 128-byte).

17.2.9 flash_verify_erase_sector

This API is used for checking if specified IFR0 sectors are in the erased state.

Prototype

```
status_t flash_verify_erase_sector (flash_config_t *config, FMU_Type *base, uint32_t start, uint32_t
lengthInBytes);
```

Parameters

Table 118. flash_verify_erase_sector parameters

Parameter	Description
Config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of required flash memory to be checked. The starting address must be sector-aligned (8192-byte).
lengthInBytes	The length, given in bytes (not words or long words) to be checked. The lengthInBytes must be sector-aligned (8192-byte).

17.2.10 flash_read_into_misr

This API is used for generating a signature based on the contents of the selected flash memory using an embedded MISR.

Prototype

```
status_t flash_read_into_misr (flash_config_t *config, FMU_Type *base, uint32_t start, uint32_t end,
uint32_t *seed, uint32_t *signature);
```

Parameters

Table 119. flash_read_into_misr parameters

Parameter	Description
Config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of the selected flash region . The start address must be page-aligned (32-word or 128-byte).
End	The ending address of the selected flash region. Ending address must be flash phrase aligned (4-word or 16-byte) and the last phrase in a page.
Seed	MISR seed
Signature	Pointer to buffer expecting signature after successful generation

17.2.11 ifr_verify_erase_phrase

This API is used for checking if specified IFR0 phrases are in the erased state.

Prototype

```
status_t ifr_verify_erase_phrase (flash_config_t *config, FMU_Type *base, uint32_t start, uint32_t
lengthInBytes);
```

Parameters

Table 120. ifr_verify_erase_phrase parameters

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of the required IFR0 memory to be checked. The starting address must be phrase-aligned (4-word or 16-byte).
lengthInBytes	The length, given in bytes (not words or long words) to be checked. The lengthInBytes must be phrase-aligned (4-word or 16-byte).

17.2.12 ifr_verify_erase_page

This API is used for checking if specified IFR0 pages are in the erased state.

Prototype

```
status_t ifr_verify_erase_page (flash_config_t *config, FMU_Type *base, uint32_t start, uint32_t
lengthInBytes);
```

Parameters

Table 121. ifr_verify_erase_page parameters

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of the required flash memory to be checked. The start address must be page-aligned (32-word or 128-byte).
lengthInBytes	The length, given in bytes (not words or long words) to be checked. The lengthInBytes must be page-aligned (32-word or 128-byte).

17.2.13 ifr_verify_erase_sector

This API is used for checking if specified IFR0 sectors are in the erased state.

Prototype

```
status_t ifr_verify_erase_sector (flash_config_t *config, FMU_Type *base, uint32_t start, uint32_t
lengthInBytes);
```

Parameters

Table 122. ifr_verify_erase_sector parameters

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of the required flash memory to be checked. The start address must be sector-aligned(8192-byte).

Table continues on the next page...

Table 122. ifr_verify_erase_sector parameters (continued)

Parameter	Description
lengthInBytes	The length, given in bytes (not words or long words) to be checked. The lengthInBytes must be sector-aligned(8192-byte).

17.2.14 ifr_read_into_misr

This API is used for generating a signature based on the contents of the selected IFR0 space using an embedded MISR.

Prototype

```
status_t ifr_read_into_misr (flash_config_t *config, FMU_Type *base, uint32_t start, uint32_t end,
uint32_t *seed, uint32_t *signature);
```

Parameters

Table 123. ifr_read_into_misr parameters

Parameter	Description
Config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of the selected flash region . The start address must be page-aligned (32-word or 128-byte).
End	The ending address of the selected flash region. Ending address must be flash phrase aligned (4-word or 16-byte) and the last phrase in a page.
Seed	MISR seed
Signature	Pointer to buffer expecting signature after successful generation

17.2.15 flash_get_property

This API returns the required flash property, which includes base address, block size, and other options.

Prototype

```
status_t flash_get_property (flash_config_t *config, flash_property_tag_t whichProperty, uint32_t
*value);
```

Parameters

Table 124. flash_get_property parameters

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
whichProperty	The required property from the list of properties.
Value	Property value return to value pointer

Table 125. Property definition

Property Definition	Value
FMU_SectorSize	0x00
FMU_TotalSize	0x01
FMU_BlockSize	0x02
FMU_BlockCount	0x03
FMU_BlockBaseAddr	0x04
RF-FMU1_TotalSize	0x11
RF-FMU1_BlockSize	0x12
RF-FMU1_BlockCount	0x13
RF-FMU1_BlockBaseAddr	0x14

17.2.16 Flash API status code

Table 126. Flash API status code

Status	Code	Description
kStatus_FLASH_Success	0	The flash operation is successful
kStatus_FLASH_InvalidArgument	4	Invalid argument detected during executing a FLASH API.
kStatus_FLASH_SizeError	100	Invalid size detected during executing a FLASH API.
kStatus_FLASH_AlignmentError	101	Alignment error detected during executing a FLASH API.
kStatus_FLASH_AddressError	102	Address error detected during executing a FLASH API.
kStatus_FLASH_AccessError	103	Access error detected during executing a FLASH API.
kStatus_FLASH_ProtectionViolation	104	Command Protection Violation Flag which indicates an attempt was made to modify a protected area of flash memory during a command operation.
kStatus_FLASH_CommandFailure	105	Command failure detected during executing a FLASH API.
kStatus_FLASH_UnknownProperty	106	Unknown property for flash_get_property API.
kStatus_FLASH_EraseKeyError	107	Incorrect EraseKey for flash_erase API.
kStatus_FLASH_CommandAborOption	121	Operation is aborted

17.3 nboot API

The ROM API table is located at address 0x14816fe0 and contains absolute ROM API function addresses which can be called using function pointers. Only secure boot related functions are described in this chapter.

The main purpose of these APIs is to provide access to functions used and implemented in ROM to authenticate the application image and processing sb3 files.

17.3.1 nboot_context_init

This API is used for initializing the nboot context data structure. It must be called before calling other nboot APIs which performs authentication and sb3 processing.

Prototype:

```
nboot_status_t nboot_context_init(nboot_context_t *context);
```

Parameters

Table 127. nboot_context_init parameters

Parameter	Description
context	Pointer to nboot_context_t data structure in memory to store runtime state.

17.3.2 nboot_context_free

This API is used to release context used by all nboot functions.

Prototype:

```
nboot_status_t nboot_context_free(nboot_context_t *context);
```

Parameters

Parameter	Description
context	Pointer to nboot_context_t data structure in memory used to store runtime state.

17.3.3 nboot_sb3_load_manifest

This API is used to verify nboot sb3.1 manifest. It loads keys into the key store so that they can be used for subsequent operations such as nboot_sb3_load_block. NBOOT context must be initialized by the API nboot_context_init before calling this API.

Prototype:

```
nboot_status_t nboot_sb3_load_manifest(nboot_context_t *context, uint32_t *manifest);
```

Parameters

Table 128. nboot_sb3_load_manifest parameters

Parameter	Description
context	Pointer to nboot_context_t data structure in memory to store runtime state.
manifest	Pointer to the input manifest buffer.

17.3.4 nboot_sb3_load_block

This API is used to verify and decrypt NBOOT SB3.1 block. Decryption is performed in-place. NBOOT context must be initialized by the API nboot_context_init before calling this API.

Prototype:

```
nboot_status_t nboot_sb3_load_block(nboot_context_t *context, uint32_t *block);
```

Parameters

Table 129. nboot_sb3_load_block parameters

Parameter	Description
context	Pointer to nboot_context_t data structure in memory to store runtime state.
block	Pointer to the input block

17.3.5 nboot_sb3_load_s200_fw

This API is used to verify and decrypt sb3.1 file with the ELE firmware. Decryption is performed to the ELE RAM and firmware automatically started after successful load operation. NBOOT context must be initialized by the API nboot_context_init before calling this API.

Prototype:

```
nboot_status_t nboot_sb3_load_s200_fw(nboot_context_t *context, uint32_t *sb3Data);
```

Parameters

Table 130. nboot_sb3_load_s200_fw parameters

Parameter	Description
context	Pointer to nboot_context_t data structure in memory to store runtime state.
block	Pointer to the sb3.1 block with the ELE firmware.

17.3.6 nboot_img_authenticate_ecdsa

This API is used to authenticate signed image with asymmetric cryptography.

Prototype:

```
nboot_status_t nboot_img_authenticate_ecdsa(nboot_context_t *context, uint8_t imageStartAddress[],
nboot_bool_t *isSignatureVerified);
```

Parameters

Table 131. nboot_img_authenticate_ecdsa

Parameter	Description
context	Pointer to nboot_context_t data structure in memory to store runtime state.
imageStartAddress	Pointer to start of the image in memory (32-bit word aligned)
isSignatureVerified	Pointer to memory holding function call result. typedef enum { kNBOOT_TRUE = 0x3C5AC33Cu, kNBOOT_TRUE256 = 0x3C5AC35Au, kNBOOT_TRUE384 = 0x3C5AC3A5u, kNBOOT_FALSE = 0x5AA55AA5u, kNBOOT_OperationAllowed = 0x3c5a33ccU,

Table continues on the next page...

Table 131. nboot_img_authenticate_ecdsa (continued)

Parameter	Description
	kNBOOT_OperationDisallowed = 0x5aa5cc33U, } nboot_bool_t;

17.3.7 nboot_rng_random

This API is used to get random number(s).

Prototype:

```
nboot_status_t nboot_rng_random(nboot_context_t *context, void *buf, size_t bufLen);
```

Parameters

Table 132. nboot_rng_random

Parameter	Description
context	Pointer to nboot_context_t data structure in memory to store runtime state.
Buf	Pointer to buffer in memory to store random number
bufLen	Buffer length in number of bytes.

17.3.8 nboot_rng_random_hq

This API is used to get high quality random number(s).

Prototype:

```
nboot_status_t nboot_rng_random_hq(nboot_context_t *context, void *buf, size_t bufLen);
```

Parameters

Table 133. nboot_rng_random_hq

Parameter	Description
context	Pointer to nboot_context_t data structure in memory to store runtime state.
Buf	Pointer to buffer in memory to store random number
bufLen	Buffer length in number of bytes.

17.3.9 nboot_fuse_program

This API is used to program a fuse word at a given address with new data. Before using this API, voltage must be regulated for over-drive and normalize voltage after operation is completed.

Prototype:

```
nboot_status_t nboot_fuse_program(nboot_context_t *context, uint32_t addr, uint32_t *data, uint32_t
systemClockFrequencyMHz);
```

Parameters

Table 134. nboot_fuse_program

Parameter	Description
context	Pointer to nboot_context_t data structure in memory to store runtime state.
Addr	Fuse index
Data	Pointer to data expected to be programmed in fuse
systemClockFrequencyMHz	Boot frequency

17.3.10 nboot_fuse_read

This API is used to read a fuse word.

Prototype:

```
nboot_status_t nboot_fuse_read(nboot_context_t *context,
                                    uint32_t addr,
                                    uint32_t *data,
                                    uint32_t systemClockFrequencyMHz);
```

Parameters

Table 135. nboot_fuse_read

Parameter	Description
context	Pointer to nboot_context_t data structure in memory to store runtime state.
Addr	Fuse index
Data	Pointer to data buffer expecting fuse contents after successful read
systemClockFrequencyMHz	Boot frequency

17.3.11 nboot_property_get

This API is used to read property. One of the important properties that can be read is the property that last authentication of signed image container has succeeded.

Prototype:

```
nboot_status_t nboot_property_get(nboot_context_t *context,
                                  uint32_t propertyId,
                                  uint8_t *destData,
                                  size_t *dataLen);
```

Parameters

Table 136. nboot_property_get parameters

Parameter	Description
context	Pointer to nboot_context_t data structure in memory to store runtime state.
propertyId	Property ID must be supported by nboot

Table continues on the next page...

Table 136. nboot_property_get parameters (continued)

Parameter	Description
destData	Pointer to data buffer for storing returned contents
dataLen	Data buffer length

Property IDs supported are as follows:

Table 137. Supported property IDs

Property	ID	Description
DICE_CDI	0x10	Returns 32 bytes of CDI value.
IMAGE_HASH	0x20	Return 64 bytes (SHA-512) value containing hash of the last authenticated image.
PSA_BOOT_SEED	0x30	Returns 32 bytes boot seed.
LAST_AUTH_STATE	0x40	Returns 4 bytes status of last authentication.
ELE_ROM_VERSION	0x50	Returns 8 bytes of ELE ROM version.
ELE_FW_VERSION	0x51	If ELE FW not loaded successfully, returns 0xFFFFFFFF as 1st word. Else returns 2 words, 1st word: version, 2nd word – commit id.
DTRK_ATTEST_PUBK	0x60	Returns 64 bytes value – public part of the DTRK_ATTEST private key
RADIO_IMG_OWNER	0x80	Returns 4 byte to indicate radio ownership as follows: 0x0 = NXP 0xAABBCCDD = OEM1 (Can be a radio firmware developer outside NXP based on token). 0xDDCCBBAA = OEM2
UUID	0x90	Returns UUID to serve as device unique identifier.

17.3.12 nboot API status code

The following table lists the nboot API status code.

Table 138. nboot API status code

Status	Code
kStatus_NBOOT_Success	0x5a5a5a5a
kStatus_NBOOT_Fail	0x5a5aa5a5
kStatus_NBOOT_InvalidArgument	0x5a5aa501
kStatus_NBOOT_RequestTimeout	0x5a5aa502
kStatus_NBOOT_ResourceBusy	0x5a5aa503
kStatus_NBOOT_OperationNotAvaialable	0x5a5aa5e5
kStatus_NBOOT_MemcpyFail	0x5a5a845a

17.4 kb API

This set of APIs provides interface to bootloader API functions. The main purpose of this APIs is to provide ROM functions that can be used to process SB file.

17.4.1 kb_init

This API is used to initialize bootloader and nboot context necessary to process sb3 file format.

Prototype:

```
status_t kb_init(void);
```

This API is expected to return kStatus_Success (0) on success and kStatus_Fail (1) on failure.

17.4.2 kb_deinit

This API is used to release nboot context and finalize sb3 file processing.

Prototype:

```
status_t kb_deinit(void)
```

17.4.3 kb_execute

This API is used to decrypt sb3 file and store signed image contents specified by loader command supported while generating sb3 image through Json configuration. If sb3 file to be processed includes sblaoder command “programFuses” then voltage must be regulated for over-drive and normalize voltage once operation is completed.

Prototype:

```
status_t kb_execute(const uint8_t *data, uint32_t dataLength, , uint32_t isUpdateExt);
```

Parameters

Table 139. kb_execute parameters

Parameter	Description
data	Pointer to start of sb file data in memory
dataLength	sb file data length in bytes
isUpdateExt	Indicator for update(sb) file start address is in internal or external flash. 0x74784578u = External flash Other values = Internal flash

17.5 SPI Flash API

17.5.1 spi_eeprom_init

This API is used to initialize SPI Flash with requested baud rate and reads JEDEC ID as sanity check.

Prototype:

```
status_t spi_eeprom_read(uint8_t *dest, uint32_t NoOfBytes, uint32_t address, bool
requestFastRead);
```

Parameters

Table 140. spi_eeprom_init parameters

Parameter	Description
baudRate	Value used to configure SPI NOR flash for subsequent operations.

17.5.2 spi_eeprom_read

This API is used to read SPI Flash memory contents.

Prototype:

```
status_t spi_eeprom_read(uint8_t *dest, uint32_t NoOfBytes, uint32_t address, bool
requestFastRead);
```

Parameters

Table 141. spi_eeprom_read parameters

Parameter	Description
dest	Pointer to destination buffer to store memory contents read from SPI flash.
NoOfBytes	Number of bytes to read.
address	Absolute start address of SPI Flash from which read operation should be prformed.
requestFastRead	true = Uses FAST READ (0Bh) false = Uses simple read READ (03h) • User must check AC chacracteristics of Flash memory model and should know SPI functional clock before requesting requestFastRead. Otherwise requestFastRead option can cause a bootleneck in data transaction speed as command buffer involves dummy byte.

17.5.3 spi_eeprom_write

This API is used to program data to SPI flash.

Prototype:

```
status_t spi_eeprom_write(uint8_t *data, uint32_t NoOfBytes, uint32_t address);
```

Parameters

Table 142. spi_eeprom_write parameter

Parameter	Description
data	Pointer to the buffer of data that is to be programmed into SPI flash.
NoOfBytes	Number of bytes to be programmed.
Address	Start address of the SPI Flash memory to be programmed.

17.5.4 spi_eeprom_erase

This API is used to erase SPI flash contents with specific erase size.

Prototype:

```
status_t spi_eeprom_erase(uint32_t address, eraseOptions_t option);
```

Parameters

Table 143. spi_eeprom_erase parameters

Parameter	Description
address	Start address of the SPI Flash memory to be erased.

option	Following are the options supported for erase operation:
	`typedef enum`
	`{`
	`  kSize_ErasePage = 0x1,`
	`  kSize_Erase4K = 0x2,`
	`  kSize_Erase32K = 0x3,`
	`  kSize_Erase64K = 0x4,`
	`  kSize_EraseAll = 0x5,`
	`} eraseOptions_t;`
	NOTE
	kSize_ErasePage option is not supported for all memory models. Example: Adesto flash can support page erase commands but not Micron.

17.5.5 spi_eeprom_finalize

This API is used de-initialize IOMUX and clock settings used for SPI Flash operations and resets all LPSPI logic and control registers.

Prototype:

```
void spi_eeprom_finalize(void);
```

17.5.6 SPI Flash API status code

The following table lists the SPI Flash API status code.

Table 144. SPI Flash API status code

Status	Code
kStatus_Success	0
kStatus_Fail	1

Chapter 18
Flash Memory Unit (FMU)

18.1 Chip-specific FMU information

Table 145. Reference links to related information

Topic	Related module	Reference
Full description	FMU	FMU
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

NOTE

For the SoC 32 KB IFR0, the first 8 KB is program once and never allows to be erased.

18.1.1 Module instances

This device has one instance of the FMU module, FMU0.

18.1.2 IFR map

For this device, refer to User IFR allocation for Table 176.

18.2 Overview

The flash module includes the following accessible memory regions:

- Program flash memory for vector space and code store
- Separate flash memory for parameter store

Flash memory is ideal for single-supply applications, permitting in-the-field erase and reprogramming operations without the need for any external high voltage power sources.

The flash module includes a command controller that executes commands to modify flash memory contents. An erased bit reads '1' and a programmed bit reads '0'. The programming operation is unidirectional; it can only move bits from the '1' state (erased) to the '0' state (programmed). Only the erase operation restores bits from '0' to '1'; bits cannot be programmed from a '0' to a '1'.

CAUTION

A flash memory location must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a flash phrase or page is not allowed. Re-programming of existing 0s to 0 is not allowed as this overstresses the device.

The standard shipping condition for flash memory is erased. Data loss over time may occur due to degradation of the erased ('1') states and/or programmed ('0') states. Therefore, it is recommended that flash memory be re-erased immediately prior to factory programming to ensure that the full data retention capability is achieved.

18.2.1 Glossary

Block Checker — MCU IP that provides a mechanism to set access rights to the flash memory for read and write operations.

Command write sequence — A series of MCU writes to the Flash FCCOB register group and FSTAT[CCIF] that initiates and controls the execution of flash algorithms that are built into the flash module.

Endurance — The number of times that an aligned flash or IFR phrase can be erased and reprogrammed.

FCCOB (Flash Common Command Object Block) — A group of flash registers that are used to pass command, address, data, and any associated parameters to the command controller.

Flash block — A macro within the flash module which provides the nonvolatile memory storage with an aligned block address being the first address in the block.

Flash module — All flash blocks plus a flash management unit providing command control and an interface to MCU buses.

Flash page — 128 bytes of flash main memory with an aligned page having byte-address[6:0] = 00h; represents the largest portion of the flash memory that can be programmed in one operation.

Flash phrase — 16 bytes of flash main memory with an aligned phrase having byte-address[3:0] = 0000b; represents the smallest portion of the flash memory that can be programmed in one operation.

Flash sector — 8 Kbytes of flash main memory with an aligned sector having byte-address[12:0] = 0000h; represents the smallest portion of the flash memory that can be erased in one operation.

FLW — The Flash Logical Window module allows a specific logical address range to access a programmable physical address range in the flash memory with programmable FLW default settings stored in IFR space.

FMC — Flash Memory Controller module manages flash memory reads and writes.

IFR — Information flash region separate from the main flash memory array. Each flash block has 32 Kbytes of user IFR space. Sometimes referred to as IFR0.

IFR1 — Information flash region separate from the main memory array reserved for array trim, MCU trim, and test. Each flash array has 8 Kbytes of IFR1 space.

IFR page — 128 bytes of IFR or IFR1 space with an aligned IFR page having byte-address[6:0] = 00h; represents the largest portion of IFR space that can be programmed.

IFR phrase — 16 bytes of IFR or IFR1 space with an aligned IFR phrase having byte-address[3:0] = 0000b; represents the smallest portion of IFR space that can be programmed in one operation.

IFR sector — 8 Kbytes of IFR or IFR1 space with an aligned IFR sector having byte-address[12:0] = 0000h; represents the smallest portion IFR space that can be erased.

MISR — Multiple-input signature register used to generate a signature based on flash memory contents read.

MSF — Microcontroller Secure Flash.

NVM — Nonvolatile memory. The flash block is an NVM using NOR-type flash memory technology.

Program flash — Program flash memory provides nonvolatile storage for vectors and code store.

Retention — The length of time that data (erased or programmed) can be kept in the NVM without experiencing errors upon readout.

Security/Privilege protection levels — The Flash module supports 4 levels of security/privilege protection for flash commands:

1. Secure (Trusted) / Privileged
2. Secure (Trusted) / User
3. Non-secure (Non-Trusted) / Privileged
4. Non-secure (Non-Trusted) / User

18.2.2 Block diagram

The block diagram of the flash module is shown in the following figure.

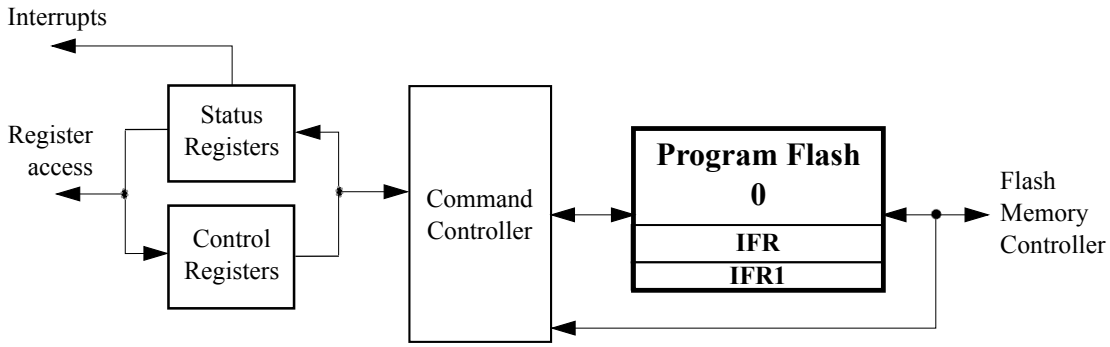

Figure 55. Flash block diagram

18.2.3 Features

The flash memory module provides the following features:

- Sector size of 8 Kbytes
- Single-bit error correction and double-bit error detection for each flash or IFR phrase
- Signature generation for flash contents
- Command-based flash program, erase, and verify operations
- Internal high-voltage supply generator for flash program and erase operations
- Optional interrupt generation upon flash command completion
- Optional interrupt generation upon double-bit error detection during flash reads from the FMC

NOTE

See the chip configuration details for the exact amount of flash memory available.

18.2.4 Modes of Operation

18.2.4.1 Sleep mode

If the CPU enters sleep mode while a flash command is executing, the flash module can wake the CPU via the command complete interrupt (see Interrupts).

18.2.4.2 Non-Active Power mode

If a flash command is active (CCIF = 0) when the MCU requests a non-active power mode, the command execution completes before the MCU is allowed to enter the non-active power mode.

18.2.4.3 Low Speed Active Power mode

While the MCU is in low speed active power mode (FCTRL[LSACTIVE]=1), the flash module will accept flash commands. While a flash command is in progress (FSTAT[CCIF]=0), the LSACTIVE bit is not writable.

18.3 External signal description

The flash module contains no signals that connect off-chip.

18.4 Functional description

The following sections describe functional details of the flash module.

18.4.1 Interrupts

The flash module can generate interrupt requests to the MCU upon the occurrence of various flash module events. These interrupt events and their associated status and control bits are shown in the following table.

Table 146. Flash Module Interrupt Sources

Flash Event	Readable Status Bit	Interrupt Enable Bit
Flash Command Complete	FSTAT[CCIF]	FCNFG[CCIE]
Flash ECC Fault Detected	FSTAT[DFDIF]	FCNFG[DFDIE]

NOTE

Vector addresses and their relative interrupt priority are determined at the MCU level.

18.4.2 Flash command operations

Flash command operations are typically used to modify flash memory contents. The next sections describe:

- Command write sequence used to set flash command parameters and launch execution
- Available flash commands
- Commands impacted by Block Checker and FMC access protection

18.4.2.1 Command write sequence

Flash commands are accomplished using a command write sequence illustrated in Figure 56. The command controller monitors the transaction protection level on writes during the command write sequence, performs various checks on the command (FCCOB) content, and continues with command execution if all requirements are fulfilled.

Before launching a command, the ACCERR, PVIOL, and CMDABT flags in the FSTAT register must be zero and the CCIF flag must be one to verify that any previous command has completed. The FAIL flag in the FSTAT register is cleared by the command controller when a command is launched unless the FAIL flag was set during initialization due to FMU parameters not being loaded from IFR1. If CCIF is clear, the previous command execution is still active, a new command write sequence cannot be started, and all writes to the FCCOB registers are ignored.

Attempts to launch a flash command while the radio is active are ignored.

While a flash command is executing, attempts to write to FCTRL[LSACTIVE] are ignored.

18.4.2.1.1 Load the FCCOB Registers

The user must load the FCCOB registers with all parameters required by the specific flash command. The contents of any FCCOB register not used by the specific flash command are ignored except for FCCOB1 (command options) where undefined bits should be cleared. The individual registers that make up the FCCOB data set can be written in any order. All writes to the FCCOB registers in a command write sequence must occur at the same transaction protection level. Any write to the FCCOB registers that violates this rule will be ignored.

Addresses loaded into FCCOB registers assume the flash and IFR spaces start at 0000_0000h.

18.4.2.1.2 Launch the Command by Clearing CCIF

Once all relevant command parameters have been loaded, the user launches the command by clearing the FSTAT[CCIF] bit by writing a '1' to it. The write to clear CCIF must occur at the same transaction protection level as the writes used to load

the FCCOB registers. Any write to clear CCIF that violates this rule will be ignored. The CCIF flag remains clear until the flash command completes.

The FSTAT register contains a blocking mechanism which prevents a new flash command from launching (unable to clear CCIF) if the previous command resulted in the setting of an access error (ACCERR), protection violation (PVIOL), or active command abort flag (CMDABT). In error scenarios, two writes to FSTAT are required to initiate the next command: the first write to clear these flags, the second write to clear CCIF. The write to clear these flags can occur at any transaction protection level.

18.4.2.1.3 Command Execution and Error Reporting

Flash command processing contains the following steps:

1. The command controller performs a series of parameter checks, if applicable, which are unique to each command. If the parameter check fails, the FSTAT[ACCERR] flag is set. ACCERR reports invalid instruction codes or options, out of bounds or misaligned addresses, or missing FMU parameters. In the case FMU parameters were not loaded from IFR1 during initialization, the ACCERR flag sets and the FSTAT[FAIL] flag remains set. Command processing never proceeds to execution when the parameter check fails. Instead, command processing is terminated after setting the FSTAT[CCIF] flag. Note that for program and erase operations, PEWEN will not set if FMU parameters were not loaded and PERDY will not set if program or erase related writes to flash or IFR space violate command requirements.
2. If necessary, the command controller performs a protection check to see if the command is allowed to execute on the requested memory space. If the protection check fails, the FSTAT[PVIOL] flag is set. Command processing never proceeds to execution when the protection check fails. Instead, command processing is terminated after setting the FSTAT[CCIF] flag.
3. If the parameter and protection checks pass, the command proceeds to execution. Run-time errors, such as failure to verify, may occur during the execution phase and are reported in the FAIL flag. A flash command may have access errors, protection violations, and run-time errors, but the run-time errors are not seen until all access errors and protection violations have been corrected.
4. If FCTRL[ABTREQ] sets during command execution, the operation will abort with the FSTAT[CMDABT] flag set.
5. Command execution results, if applicable, are reported back to the user via the FCCOB registers.
6. The command controller sets FSTAT[CCIF] signifying that the command has completed.

CAUTION

If the FAIL flag is set along with ACCERR, FMU parameters were not loaded from IFR1 during initialization. In this case, it is recommended that the flash module be reinitialized. If the issue persists, flash commands will continue to set the ACCERR and FAIL flags.

The flow for a generic command write sequence is illustrated in the following figure.

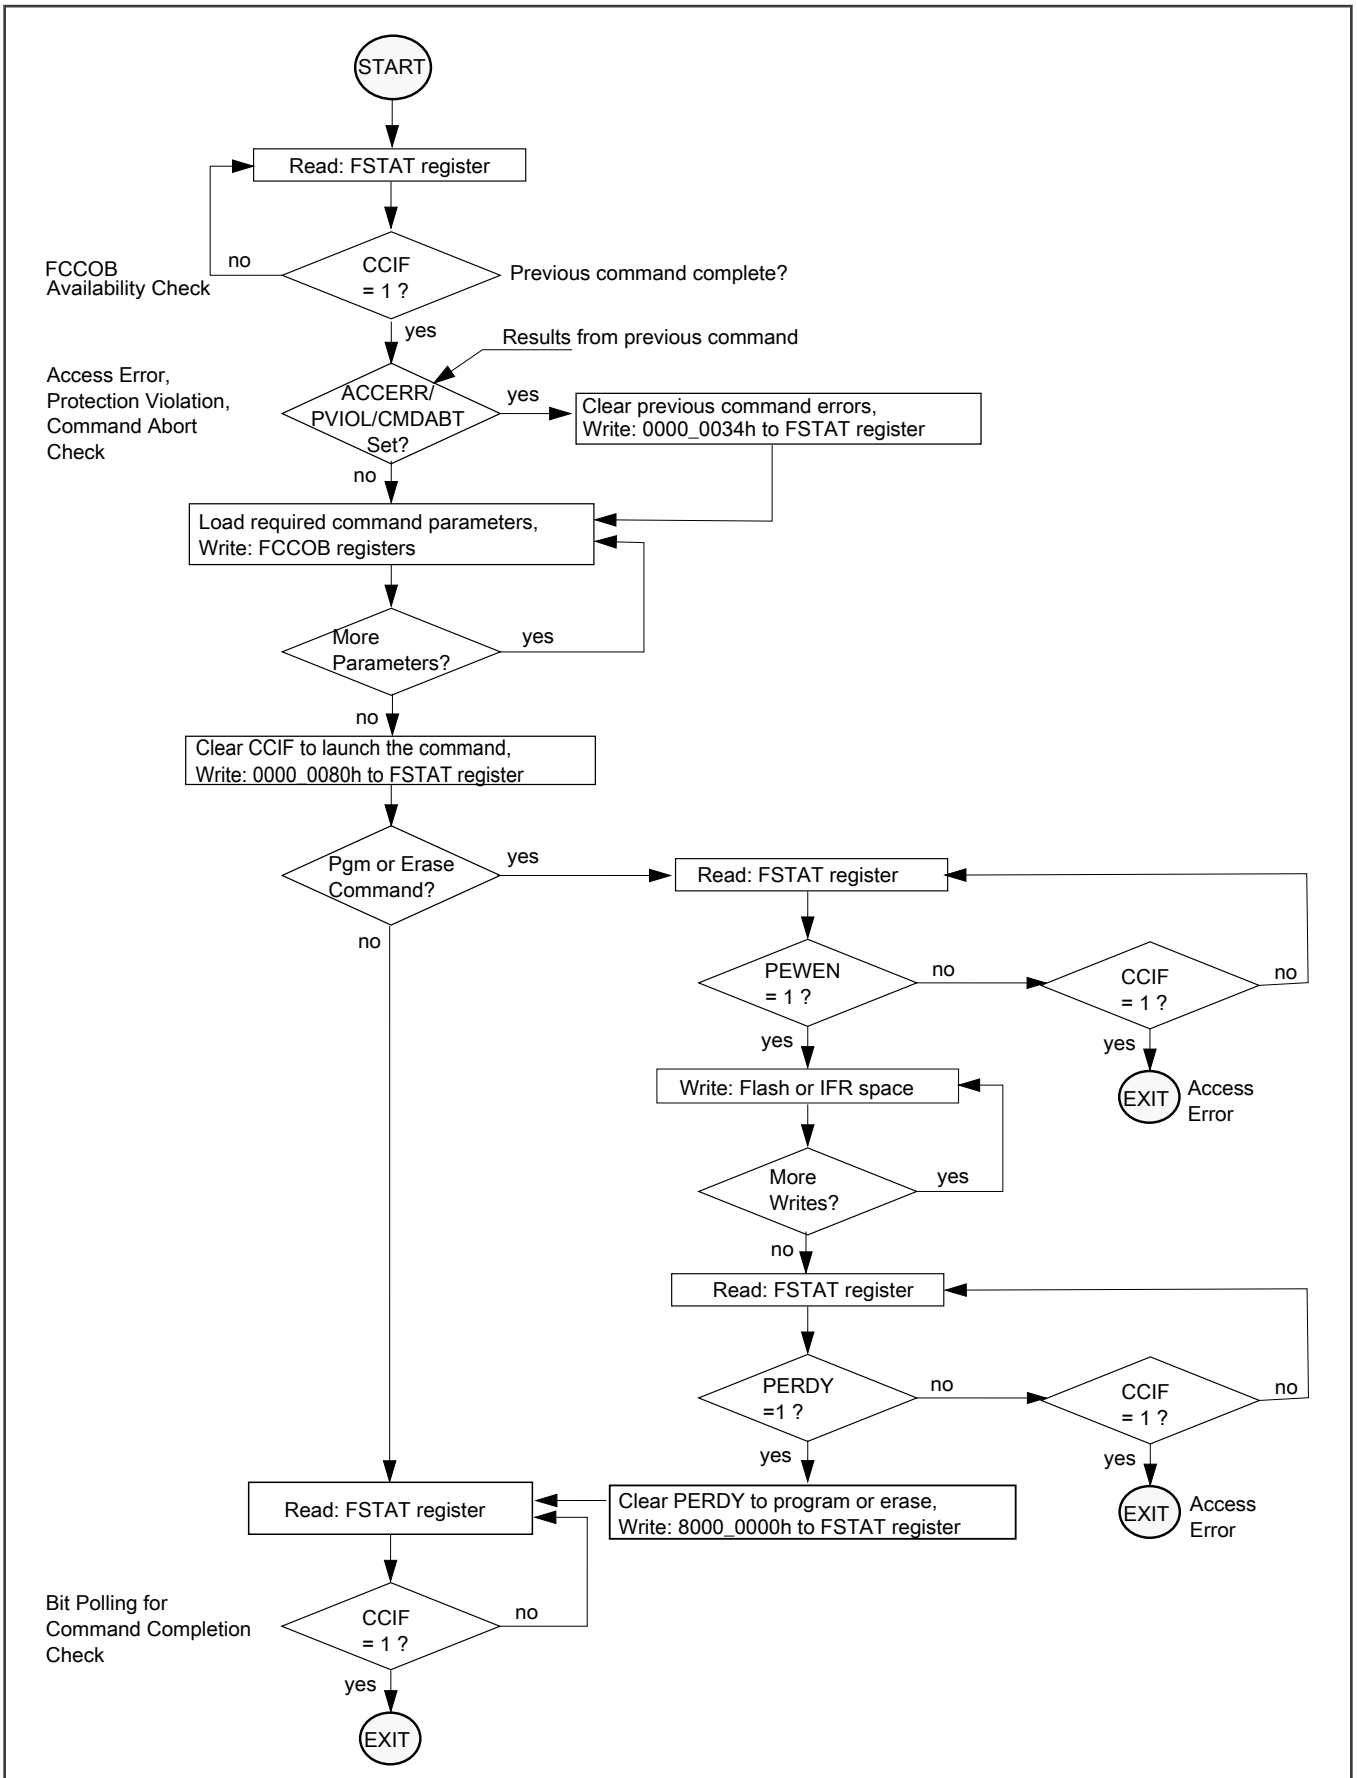

Figure 56. Generic Flash Command Write Sequence Flowchart

18.4.2.1.4 Aborting a Command Write Sequence or Command Operation

FSTAT[CMDP] sets at the start of a command write sequence, typically by writing to one of the FCCOB registers. With CMDP set, setting the FCTRL[ABTREQ] bit allows a user to abort a command write sequence and take control over a new command write sequence. The ABTREQ bit can only be set by a user with the same domain ID as indicated by FSTAT[CMDDID] and at the same or higher security/privilege protection level when compared to FSTAT[CMDPRT], the current owner of the command write sequence. While ABTREQ is set, CCIF cannot be cleared to launch a command.

If FSTAT[CCIF] is high when ABTREQ is set, the command write sequence will abort and ownership transferred to the user setting the ABTREQ bit. The FSTAT[CWSABT] flag will set and the CMDPRT field will be updated based on the write transaction that set the ABTREQ bit. The ABTREQ bit will then be cleared automatically.

If CCIF is low when ABTREQ is set, the command controller will abort execution of the current command operation, set FSTAT[CMDABT], and set CCIF. The CMDPRT field will be updated based on the write transaction that set the ABTREQ bit. The ABTREQ bit will then be cleared automatically. While CMDABT is set, CCIF cannot be cleared to launch a command. Aborting a program or erase operation may leave the flash or IFR space being modified in an indeterminate state.

NOTE

Aborting certain flash commands may take longer to abort than to execute. See the device data sheet for flash command timing specifications.

18.4.2.2 Flash commands

The following table summarizes the function of all flash commands. If any column is marked with an 'X', the flash command is relevant to that particular memory resource.

FCMD	Command	Program flash 0	IFR	Function
00h	Read 1s All (RD1ALL)	x	x	Verify that all flash and IFR space is erased
01h	Read 1s Block (RD1BLK)	x		Verify that a flash block is erased
02h	Read 1s Sector (RD1SCR)	x		Verify that a flash sector is erased
03h	Read 1s Page (RD1PG)	x		Verify that a flash page is erased
04h	Read 1s Phrase (RD1PHR)	x		Verify that a flash phrase is erased
05h	Read into MISR (RDMISR)	x		Generate MISR signature for range of flash pages
12h	Read 1s IFR Sector (RD1ISCR)		x	Verify that an IFR sector is erased
13h	Read 1s IFR Page (RD1IPG)		x	Verify that an IFR page is erased
14h	Read 1s IFR Phrase (RD1IPHR)		x	Verify that an IFR phrase is erased
15h	Read IFR into MISR (RDIMISR)		x	Generate MISR signature for range of IFR pages

Table continues on the next page...

Table continued from the previous page...

FCMD	Command	Program flash 0	IFR	Function
23h	Program Page (PGMPG)	x	x	Program data to a flash or IFR page
24h	Program Phrase (PGMPHR)	x	x	Program data to a flash or IFR phrase
40h	Erase All (ERSALL)	x	x	Erase all flash and IFR space if enabled
42h	Erase Sector (ERSSCR)	x	x	Erase a flash sector

18.4.2.3 Flash commands impacted by Block Checker and FMC access protection

The following flash commands are impacted by Block Checker and FMC access protection:

- Program Phrase (PGMPHR)
- Program Page (PGMPG)
- Erase Sector (ERSSCR)

During execution of these flash commands, a sequence of AHB writes to flash or IFR space are required with validity checked by the Block Checker or FMC. When writes are enabled by the FMU, violations detected by the FMC are reported as an access error in the FMU. The other violations are handled by the Block Checker or FMC.

Table 147. Flash Write Access Checks

Flash Write Violation Condition	Block Checker	FMC	FMU
Flash or IFR address out-of-range	X		
Flash or IFR write permission check fails	X		
Write to IFR1 space		X	
Write width not 32-bit		X	
Writes not enabled by FSTAT[PEWEN]		X	
First write in sequence not properly aligned per FSTAT[PEWEN]			X
Non-sequential write after first aligned write in sequence			X
Bus permissions for the AHB write do not match the bus permissions of the APB write that launched the flash command			X

18.4.3 Flash command descriptions

This section describes all flash commands that can be launched by a valid command write sequence. The flash module sets the FSTAT[ACCERR] bit and aborts the command execution if any of the following illegal conditions occur:

- There is an unrecognized command code in the FCCOB FCMD field.
- There is an error in an FCCOB field for the specific command. Refer to the error handling table provided for each command.

The ACCERR, PVIOL, and CMDABT flags in the FSTAT register should be cleared prior to starting a command write sequence. As described in Launch the Command by Clearing CCIF, a new command cannot be launched while these flags are set.

Do not attempt to read a flash block while a flash command is running (CCIF = 0) on that same block. The flash module may return a transfer error to the FMC resulting in a bus fault. The exception to this rule is during program operations where the flash block is still readable after the command is launched up until the time the FSTAT[PERDY] flag is cleared.

CAUTION

Flash data must be in the erased state before being programmed. Cumulative programming of bits (adding more zeros) is not allowed.

18.4.3.1 Read 1s All Command

The Read 1s All command checks if all flash and IFR space are in the erased state.

Table 148. Read 1s All Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	00h (RD1ALL)

Upon clearing CCIF to launch the Read 1s All command, the command controller:

- verifies that all flash and IFR space are in the erased state

If all flash and IFR space are not in the erased state, the FSTAT[FAIL] flag is set. The CCIF flag sets after the Read 1s All operation completes.

Table 149. Read 1s All Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

18.4.3.2 Read 1s Block Command

The Read 1s Block command checks if a flash block is in the erased state.

Table 150. Read 1s Block Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	01h (RD1BLK)
2	Block address

Upon clearing CCIF to launch the Read 1s Block command, the command controller:

- verifies that the selected flash block is in the erased state

If the selected flash block is not in the erased state, the FSTAT[FAIL] flag is set. The CCIF flag sets after the Read 1s Block operation completes.

Table 151. Read 1s Block Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]

Table continues on the next page...

Table 151. Read 1s Block Command Error Handling (continued)

Error Condition	Error Bit
Address is not valid	FSTAT[ACCERR]
Address is not block aligned	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

18.4.3.3 Read 1s Sector Command

The Read 1s Sector command checks if a flash sector is in the erased state.

Table 152. Read 1s Sector Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	02h (RD1SCR)
2	Sector address

Upon clearing CCIF to launch the Read 1s Sector command, the command controller:

- verifies that the selected flash sector is in the erased state

If the selected flash sector is not in the erased state, the FSTAT[FAIL] flag is set. The CCIF flag sets after the Read 1s Sector operation completes.

Table 153. Read 1s Sector Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Address is not valid	FSTAT[ACCERR]
Address is not sector aligned	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

18.4.3.4 Read 1s Page Command

The Read 1s Page command checks if a flash page is in the erased state.

Table 154. Read 1s Page Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	03h (RD1PG)
2	Page address

Upon clearing CCIF to launch the Read 1s Page command, the command controller:

- verifies that the selected flash page is in the erased state

If the selected flash page is not in the erased state, the FSTAT[FAIL] flag is set. The CCIF flag sets after the Read 1s Page operation completes.

Table 155. Read 1s Page Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Address is not valid	FSTAT[ACCERR]
Address is not page aligned	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

18.4.3.5 Read 1s Phrase Command

The Read 1s Phrase command checks if a flash phrase is in the erased state.

Table 156. Read 1s Phrase Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	04h (RD1PHR)
2	Phrase address

Upon clearing CCIF to launch the Read 1s Phrase command, the command controller:

- verifies that the selected flash phrase is in the erased state

If the selected flash phrase is not in the erased state, the FSTAT[FAIL] flag is set. The CCIF flag sets after the Read 1s Phrase operation completes.

Table 157. Read 1s Phrase Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Address is not valid	FSTAT[ACCERR]
Address is not phrase aligned	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

18.4.3.6 Read into MISR command

The Read into MISR operation generates a signature based on the contents of the selected flash memory using an embedded MISR.

Table 158. Read into MISR Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	05h (RDMISR) [7:0]
2	Starting flash page address
3	Ending flash phrase address
4	Word 0 of MISR seed
5	Word 1 of MISR seed
6	Word 2 of MISR seed
7	Word 3 of MISR seed
Returned values	
4	Word 0 of MISR signature
5	Word 1 of MISR signature
6	Word 2 of MISR signature
7	Word 3 of MISR signature

Upon clearing CCIF to launch the Read into MISR command, the command controller:

1. initializes the MISR with the seed provided
2. processes flash data starting with the starting flash page address provided
3. continues until the ending flash phrase address has been processed (must be the last phrase in a page)
4. returns the resulting signature into the FCCOB register bank unless an uncorrectable ECC fault is detected

The CCIF flag sets after the Read into MISR operation completes. If the operation is aborted by setting FCTRL[ABTREQ], a signature will not be returned if the abort occurs prior to the operation writing the signature.

MISR polynomial is $X^{128} + X^{126} + X^{101} + X^{99} + 1$.

Table 159. Read into MISR Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Address is not valid	FSTAT[ACCERR]
Starting address is not flash page aligned	FSTAT[ACCERR]
Ending address is not flash phrase aligned	FSTAT[ACCERR]
Ending address is not the last phrase in a page	FSTAT[ACCERR]
Starting address is larger than the ending address	FSTAT[ACCERR]
Requested range crosses a flash block boundary	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Uncorrectable ECC error is detected	FSTAT[FAIL]

18.4.3.7 Read 1s IFR Sector Command

The Read 1s IFR Sector command checks if an IFR sector is in the erased state.

Table 160. Read 1s IFR Sector Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	12h (RD1ISCR)
2	IFR sector address

Upon clearing CCIF to launch the Read 1s IFR Sector command, the command controller:

- verifies that the selected IFR sector is in the erased state

If the selected IFR sector is not in the erased state, the FSTAT[FAIL] flag is set. The CCIF flag sets after the Read 1s IFR Sector operation completes.

Table 161. Read 1s IFR Sector Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Address is not valid	FSTAT[ACCERR]
Address is not IFR sector aligned	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

18.4.3.8 Read 1s IFR Page Command

The Read 1s IFR Page command checks if an IFR page is in the erased state.

Table 162. Read 1s IFR Page Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	13h (RD1IPG)
2	IFR page address

Upon clearing CCIF to launch the Read 1s IFR Page command, the command controller:

- verifies that the selected IFR page is in the erased state

If the selected IFR page is not in the erased state, the FSTAT[FAIL] flag is set. The CCIF flag sets after the Read 1s IFR Page operation completes.

Table 163. Read 1s IFR Page Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Address is not valid	FSTAT[ACCERR]
Address is not IFR page aligned	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]

Address is not valid	FSTAT[ACCERR]
Address is not IFR phrase aligned	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

18.4.3.10 Read IFR into MISR command

The Read IFR into MISR operation generates a signature based on the contents of the selected IFR space using an embedded MISR.

Table 166. Read IFR into MISR Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	15h (RDIMISR) [7:0]
2	Starting IFR page address
3	Ending IFR phrase address
4	Word 0 of MISR seed
5	Word 1 of MISR seed
6	Word 2 of MISR seed

Table continues on the next page...

Table 166. Read IFR into MISR Command FCCOB Requirements (continued)

FCCOB Number	FCCOB Contents
7	Word 3 of MISR seed
Returned values	
4	Word 0 of MISR signature
5	Word 1 of MISR signature
6	Word 2 of MISR signature
7	Word 3 of MISR signature

Upon clearing CCIF to launch the Read IFR into MISR command, the command controller:

1. initializes the MISR with the seed provided
2. processes IFR data starting with the starting IFR page address provided
3. continues until the ending IFR phrase has been processed (must be the last phrase in a page)
4. returns the resulting signature into the FCCOB register bank unless an uncorrectable ECC fault is detected

The CCIF flag sets after the Read IFR into MISR operation completes. If the operation is aborted by setting FCTRL[ABTREQ], a signature will not be returned if the abort occurs prior to the operation writing the signature.

MISR polynomial is $X^{128} + X^{126} + X^{101} + X^{99} + 1$.

Table 167. Read IFR into MISR Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Address is not valid	FSTAT[ACCERR]
Starting address is not IFR page aligned	FSTAT[ACCERR]
Ending address is not IFR phrase aligned	FSTAT[ACCERR]
Ending address is not the last phrase in a page	FSTAT[ACCERR]
Starting address is larger than the ending address	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Uncorrectable ECC error is detected	FSTAT[FAIL]

18.4.3.11 Program Page command

The Program Page operation programs 32 words of data to a previously erased flash or IFR page.

CAUTION

The page must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a page is not allowed.

Table 168. Program Page Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	23h (PGMPG) [7:0]

Upon clearing CCIF to launch the Program Page command, the command controller:

1. sets FSTAT[PEWEN] to enable writes to the flash and IFR space in the system memory map
2. waits for the user to write 32 consecutive words to the flash or IFR space with the first write being page aligned
3. clears FSTAT[PEWEN] field
4. sets FSTAT[PERDY]
5. waits for the user to clear FSTAT[PERDY]
6. programs the data into the targeted page written to in step 2
7. verifies bits to be programmed are programmed to the program verify level

The CCIF flag sets after the Program Page operation completes. The Program Page operation can be aborted by setting FCTRL[ABTREQ]. If the operation is aborted, the operation terminates with the FSTAT[CMDABT] flag set. Once CCIF is set, the Program Page command may be repeated (same addresses, same data) to complete the program operation without erasing the sector containing the targeted page. Invalid writes to flash or IFR space based on Block Checker or FMC access protection are trapped outside of the flash module.

CAUTION

The Program Page operation will not react to the early indicator for radio activity. Therefore, FSTAT[PERDY] must not be cleared if there is a concern about inadequate power available to support both radio activity and the Program Page operation.

Table 169. Program Page Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Protection level of the writes to flash or IFR space do not match the protection level of the command write sequence	FSTAT[ACCERR]
Initial address is not page aligned and subsequent addresses phrase aligned	FSTAT[ACCERR]
Number of writes to flash or IFR space is more than expected	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

18.4.3.11.1 Page programming

The standard process of programming one or more flash or IFR pages is as follows:

1. If required, launch the Erase Sector command to erase the flash or IFR sector to be programmed (repeat for additional sectors).
2. Launch the Program Page command to enable writes to the flash space.
3. After the command controller sets FSTAT[PEWEN], write 32 consecutive words to the flash space with the first word page aligned. The data written to the flash space is not readable until the program operation has successfully completed.
4. After the flash page has been written, the command controller will stall and set FSTAT[PERDY].
5. Clear PERDY allowing the command controller to resume and program the 32 words into the flash or IFR space written to in step 3.
6. Wait for CCIF to set indicating the program operation has completed.
7. To program additional flash or IFR pages in previously erased flash memory, repeat steps 2 through 6.

18.4.3.12 Program Phrase command

The Program Phrase operation programs 4 words of data to a previously erased flash or IFR phrase.

CAUTION

The phrase must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a phrase is not allowed.

Table 170. Program Phrase Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	24h (PGMPHR) [7:0]

Upon clearing CCIF to launch the Program Phrase command, the command controller:

1. sets FSTAT[PEWEN] to enable writes to the flash and IFR space in the system memory map
2. waits for the user to write 4 consecutive words to the flash or IFR space with the first write being phrase aligned
3. clears FSTAT[PEWEN] field
4. sets FSTAT[PERDY]
5. waits for the user to clear FSTAT[PERDY]
6. programs the data into the targeted phrase written to in step 2.
7. verifies bits to be programmed are programmed to the program verify level

The CCIF flag sets after the Program Phrase operation completes. The Program Phrase operation can be aborted by setting FCTRL[ABTREQ]. If the operation is aborted, the operation terminates with the FSTAT[CMDABT] flag set. Once CCIF is set and the CMDABT flag is cleared, the Program Phrase command may be repeated (same addresses, same data) to complete the program operation without erasing the sector containing the targeted phrase. Invalid writes to flash or IFR space based on Block Checker or FMC access protection are trapped outside of the flash module.

CAUTION

The Program Phrase operation will not react to the early indicator for radio activity. Therefore, FSTAT[PERDY] must not be cleared if there is a concern about inadequate power available to support both radio activity and the Program Phrase operation.

Table 171. Program Phrase Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Protection level of the writes to flash or IFR space do not match the protection level of the command write sequence	FSTAT[ACCERR]
Address is not phrase aligned	FSTAT[ACCERR]
Number of writes to flash or IFR space is more than expected	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

18.4.3.12.1 Phrase programming

The standard process of programming one or more flash or IFR phrases is as follows:

1. If required, launch the Erase Sector command to erase the flash or IFR sector to be programmed (repeat for additional sectors).
2. Launch the Program Phrase command to enable writes to the flash and IFR space.
3. After the command controller sets FSTAT[PEWEN], write 4 consecutive words to the flash or IFR space with the first word phrase aligned. The data written to the flash or IFR space is not readable until the program operation has successfully completed.
4. After the flash or IFR phrase has been written, the command controller will stall the operation and set FSTAT[PERDY].
5. Clear PERDY allowing the command controller to resume and program the 4 words into the flash or IFR space written to in step 3.
6. Wait for CCIF to set indicating the program operation has completed.
7. To program additional flash or IFR phrases in previously erased flash memory, repeat steps 2 through 6.

18.4.3.13 Erase All command

The Erase All operation erases all flash and IFR space if enabled by the MCU.

Table 172. Erase All Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	40h (ERSALL) [7:0]

Upon clearing CCIF to launch the Erase All command, the command controller:

1. erases flash block 0 sector-by-sector
2. verifies flash block 0 is erased; if not, skips IFR space in block 0
3. erases IFR space in block 0 sector-by-sector
4. verifies IFR space in block 0 is erased
5. clears FSTAT[CMDP] flag

The CCIF flag sets after the Erase All operation completes. If either the flash or IFR space is not in the erased state, FSTAT[FAIL] sets.

CAUTION

The Erase All operation will not react to the early indicator for radio activity. Therefore, the Erase All command must not be launched if there is a concern about inadequate power available to support both radio activity and the Erase All operation.

Table 173. Erase All Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Command is disabled by the MCU	FSTAT[PVIOL]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

18.4.3.14 Erase Sector command

The Erase Sector operation erases a flash of IFR sector to prepare the sector for programming.

Table 174. Erase Sector Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	42h (ERSSCR) [7:0]

Upon clearing CCIF to launch the Erase Sector command, the command controller:

1. sets FSTAT[PEWEN] to enable writes to the flash and IFR space in the system memory map
2. waits for the user to write 4 consecutive words to the flash or IFR space with the first write being phrase (or sector) aligned
3. clears FSTAT[PEWEN] field
4. sets FSTAT[PERDY]
5. waits for the user to clear FSTAT[PERDY]
6. erases the selected flash or IFR sector
7. verifies the selected flash or IFR sector is erased

If the selected flash or IFR sector is not in the erased state, FSTAT[FAIL] is set. The CCIF flag sets after the Erase Sector operation completes. The Erase Sector operation can be aborted by setting FCTRL[ABTREQ]. If the operation is aborted, the operation terminates with the FSTAT[CMDABT] flag set. Once CCIF is set, the Erase Sector command may be repeated to complete the erase operation. Invalid writes to flash or IFR space based on Block Checker or FMC access protection are trapped outside of the flash module.

CAUTION

The Erase Sector operation will not react to the early indicator for radio activity. Therefore, the Erase Sector command must not be launched if there is a concern about inadequate power available to support both radio activity and the Erase Sector operation.

Table 175. Erase Sector Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Protection level of the writes to flash or IFR space do not match the protection level of the command write sequence	FSTAT[ACCERR]
Address is not flash or IFR phrase aligned	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
IFR Sector is protected (see FCNFG register)	FSTAT[PVIOL]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

18.4.4 Mass Erase

If enabled by the MCU, MCU resources can be used to launch a mass erase operation without accessing the flash registers.

To know how to enable/disable mass erase for your device, refer the chip-specific section.

The status of the mass erase request is reflected in the FCNFG[ERSREQ] bit. When launched, the mass erase operation occurs regardless of the state of the CMDP, ACCERR, PVIOL, or CMDABT flags in the FSTAT register but requires FSTAT[CCIF] to be set and the MCU to enable mass erase. When mass erase is launched with CCIF set, the CMDP, CCIF, CWSABT, PVIOL, and CMDABT flags in the FSTAT register clear. The ACCERR and FAIL flags also clear unless the FMU parameters were not loaded from IFR1 during initialization in which case the mass erase operation terminates without performing any erase of flash memory.

Upon successful launch of the mass erase operation, the command controller (same steps as the Erase All command):

1. erases flash block 0 sector-by-sector
2. verifies flash block 0 is erased; if not, skips IFR space in block 0
3. erases IFR space in block 0 sector-by-sector
4. verifies IFR space in block 0 is erased

The CCIF flag sets and the ERSREQ bit clears once the operation completes and the FSTAT[FAIL] flag sets if any verify step fails during the mass erase operation. This method of erasing the flash memory cannot be aborted by setting FCTRL[ABTREQ].

CAUTION

The mass erase operation occurs regardless of the state of the early indicator for radio activity and will not react to this early indicator during the operation. Therefore, mass erase must not be launched if there is a concern about inadequate power available to support both radio activity and the mass erase operation.

18.5 Initialization

On each reset, the command controller initializes the following based on IFR1 content:

1. FCTRL[RWSC]
2. FMU Parameters (FMUPARM)

The FSTAT[CCIF] flag is cleared throughout the initialization flow. The flash module also holds off all access to flash registers and flash memory during initialization. Completion of the initialization flow is marked by setting FSTAT[CCIF]. If an uncorrectable ECC error is detected during initialization, the FSTAT[FAIL] flag sets. The FAIL flag also sets if FMU parameters are not loaded from IFR1 during initialization. In this case, attempts to launch a flash command terminate with the ACCERR and FAIL flags set. The recommendation is to refrain from launching flash commands if the FAIL flag sets after initialization.

If a reset occurs while any flash command is in progress, that command is immediately aborted. The state of the flash memory or IFR space being programmed or erased is not guaranteed. Command operations do not automatically resume after exiting reset.

18.6 Memory map and registers

This section describes the flash memory map for IFR/IFR1 space and registers. See the MCU system memory map for the location of all flash memory space and registers. Data read from unimplemented memory space in the flash module is undefined.

18.6.1 IFR description

Each flash block contains IFR space separate from the main flash memory. IFR space is memory mapped (see the MCU system memory map). IFR space is divided into IFR pages programmable using the Program Page command. IFR pages are further divided into IFR phrases programmable using the Program Phrase command. Once programmed, IFR phrases can be reprogrammed after a successful erase using the Erase Sector command operation unless the IFR sector is protected by the FCNFG register.

Table 176. IFR map

Offset Byte Address	IFR Field Name	IFR Field Size (Bytes)	IFR Field Description
Block 0 IFR Sector 0			
0000h-1FFFh	USER	8,192	Available for customer usage.
Block 0 IFR Sector 1			
2000h-3FFFh	ROMCFG	8,192	ROM and ISP configuration. Refer to ROM Bootloader chapter for more information.

Table continues on the next page...

Table 176. IFR map (continued)

Offset Byte Address	IFR Field Name	IFR Field Size (Bytes)	IFR Field Description
Block 0 IFR Sector 2			
4000h-5FFFh	FLW0	8,192	FLW configuration set 0. Refer to ROM Bootloader chapter for more information.
Block 0 IFR Sector 3			
6000h-7FFFh	FLW1	8,192	FLW configuration set 1. Refer to ROM Bootloader chapter for more information.

Each flash block also contains IFR1 space separate from the main flash memory. IFR1 space in program flash block 0 is memory mapped for read-only access (see the MCU system memory map). IFR1 space cannot be erased or programmed by the user.

Table 177. IFR1 map

Offset Byte Address	IFR1 Field Name	IFR1 Field Size (Bytes)	IFR1 Field Description
Block 0 IFR1 Sector			
0000h-15FFh		5,632	Reserved
1600h-16FFh	FMUPARM	256	FMU Parameters
1700h-1FFFh		2,304	Reserved

18.6.2 Register descriptions

The flash module contains a set of memory-mapped control and status registers.

NOTE

While a command is running (FSTAT[CCIF]=0), register writes are allowed to FSTAT[PERDY,DFDIF,CWSABT], FCNFG, and FCTRL[ABTREQ,FDFD,RWSC].

18.6.2.1 Flash register descriptions

18.6.2.1.1 Flash memory map

18.6.2.1.2 Flash Status Register (FSTAT)

Offset

Register	Offset
FSTAT	0h

Function

The FSTAT register reports the operational status of the flash module.

NOTE

When set, ACCERR, PVIOL, and CMDABT flags prevent the launch of any more commands until the flag is cleared (by writing a one to it).

CAUTION

When clearing the DFDIF flag, be careful not to use read-modify-write on the entire FSTAT register and inadvertently clear CCIF to launch a command.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	CMDDID				CMDP	0	CMDPRT		CCIF	CWSABT	ACCERR	PVIOL	0	CMDABT	0	FAIL
W									W1C	W1C	W1C	W1C		W1C		
Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	u

Fields

Field	Function
31 PERDY	Program-Erase Ready Control/Status Flag The PERDY flag is set by the command controller when a program or sector erase command operation has successfully completed the write phase. The command controller will stall the command operation until the user clears the PERDY flag by writing a 1 to PERDY. Failure to clear PERDY will leave the command controller stalled but the flash or IFR space targeted by the command operation will remain readable by the FMC. If FCTRL[ABTREQ] is set while the PERDY flag is set, the command controller will clear PERDY, abort the command operation, and set both CCIF and CMDABT. 0b - Program or sector erase command operation not stalled 1b - Program or sector erase command operation ready to execute
30-26 —	Reserved
25-24 PEWEN	Program-Erase Write Enable Control During program or sector erase command operations, writes are enabled to flash or IFR space in the system memory map. For phrase programming or sector erase, writes are enabled for 4 consecutive words (16 bytes) with address phrase aligned. For page programming, writes are enabled for 8 consecutive phrases (128 bytes) with address page aligned. For programming, data written to erased flash or IFR space for program commands is not available until the program operation has successfully completed. PEWEN will not assert if FMU parameters were not loaded from IFR1 during initialization. 00b - Writes are not enabled 01b - Writes are enabled for one flash or IFR phrase (phrase programming, sector erase) 10b - Writes are enabled for one flash or IFR page (page programming) 11b - Reserved
23-18 —	Reserved
17 SALV_USED	Salvage Used for Erase operation This flag indicates salvage was used during the last Erase Sector, Erase All, or Mass Erase operation and is valid at the end of the operation. Salvage involves using ECC to pass erase verify allowing single-bit faults per phrase verified. This flag remains valid until any flash command or Mass Erase operation launches at which time the flag clears. Use of salvage does not guarantee that the erase operation succeeds but only that salvage was used on at least one phrase. 0b - Salvage not used during last operation 1b - Salvage used during the last erase operation
16 DFDIF	Double Bit Fault Detect Interrupt Flag The DFDIF flag indicates an uncorrectable ECC fault was detected during a valid flash read access from the FMC. The DFDIF flag is cleared by writing a 1 to DFDIF. Writing a 0 to DFDIF has no effect. 0b - Double bit fault not detected during a valid flash read access

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Double bit fault detected (or FCTRL[FDFD] is set) during a valid flash read access
15-12 CMDDID	Command domain ID While the CMDP flag is set, the CMDDID bits reflect the domain ID of the write transaction controlling a command write sequence or aborting a command operation. Writes to load an FCCOB register, clear CCIF, clear PERDY, or write FCTRL[LSACTIVE] must have the same domain ID as the write transaction that started the command write sequence. The CMDDID bits persist after the CMDP flag clears until the CMDP flag sets again at the start of a new command write sequence. Writes to clear the CWSABT, ACCERR, PVIOL, or CMDABT flags are not influenced by the state of the CMDDID bits.
11 CMDP	Command protection status flag The CMDP flag sets when a command write sequence starts with a write to load an existing FCCOB register or clear CCIF while ACCERR, PVIOL, and CMDABT are clear. Clearing the CWSABT, ACCERR, PVIOL, or CMDABT flags as part of a command write sequence will not set the CMDP flag. While the CMDP flag is set, the protection level of any subsequent write transaction to load an FCCOB register, clear CCIF, clear PERDY, or write FCTRL[LSACTIVE] must match the CMDPRT bits and the domain ID must match the CMDDID bits. The CMDP flag remains set until cleared when CCIF is set after a command operation or Power Down recovery completes unless the CMDABT flag is set. The CMDP flag is cleared even if the operation ends with ACCERR or PVIOL set. When the CMDP flag is cleared, the CMDPRT and CMDDID bits remain unchanged. The CMDP flag is also cleared by a mass erase request with CCIF set. 0b - Command protection level and domain ID are stale 1b - Command protection level (CMDPRT) and domain ID (CMDDID) are set
10 —	Reserved
9-8 CMDPRT	Command protection level While the CMDP flag is set, the CMDPRT bits reflect the secure/privilege protection level of the write transaction controlling a command write sequence or aborting a command operation. Writes to load an existing FCCOB register, clear CCIF, clear PERDY, or write FCTRL[LSACTIVE] must occur with the same protection level as indicated by the CMDPRT bits. Writes to clear the CWSABT, ACCERR, PVIOL, or CMDABT flags are not influenced by the state of the CMDPRT bits. If FCTRL[ABTREQ] is set while CCIF is high or low, the CMDPRT bits will change to reflect the security/privilege protection level of the write transaction that set the ABTREQ bit. 00b - Secure, normal access 01b - Secure, privileged access 10b - Nonsecure, normal access 11b - Nonsecure, privileged access
7 CCIF	Command Complete Interrupt Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The CCIF flag indicates that a flash command has completed. The CCIF flag is cleared by writing a 1 to CCIF to launch a flash command. The CCIF flag stays low until the command completes. The CCIF flag is cleared by a mass erase request with CCIF set. The CCIF flag is also cleared upon entry into Deep Sleep, Power Down, and Deep Power Down modes and stays low until the end of recovery from these non-active power modes. The CCIF flag is reset to 0 but is set to 1 at the end of flash initialization. 0b - Flash command, initialization, or power mode recovery in progress 1b - Flash command, initialization, or power mode recovery has completed
6 CWSABT	Command Write Sequence Abort Flag The CWSABT flag indicates whether a request to abort a command write sequence prior to command launch has been granted. If FCTRL[ABTREQ] is set while CCIF is high, the CWSABT flag will get set. Once CWSABT is set, ABTREQ will get cleared. While the CWSABT flag is set, ABTREQ cannot be set. The CWSABT flag is cleared by writing a 1 to CWSABT while CCIF is set or clear and ABTREQ is clear. Writing a 0 to the CWSABT flag has no effect. The CWSABT flag is cleared by a mass erase request with CCIF set. 0b - Command write sequence not aborted 1b - Command write sequence aborted
5 ACCERR	Command Access Error Flag The ACCERR flag indicates an illegal attempt was made to launch a flash command due to a violation of the command write sequence or by providing invalid command parameters. The ACCERR flag also sets during command execution if FMU parameters were not loaded from IFR1 during initialization. While the ACCERR flag is set, the CCIF flag cannot be cleared to launch a command. The ACCERR flag is cleared by writing a 1 to ACCERR while CCIF is set. Writing a 0 to the ACCERR flag has no effect. The ACCERR flag is cleared by a mass erase request with CCIF set but is not cleared during Power Down recovery. 0b - No access error detected 1b - Access error detected
4 PVIOL	Command Protection Violation Flag The PVIOL flag indicates an attempt was made to modify a protected area of flash memory during a command operation. While the PVIOL flag is set, the CCIF flag cannot be cleared to launch a command. The PVIOL flag is cleared by writing a 1 to PVIOL while CCIF is set. Writing a 0 to the PVIOL flag has no effect. The PVIOL flag is cleared by a mass erase request with CCIF set but is not cleared during Power Down recovery. 0b - No protection violation detected 1b - Protection violation detected
3	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
2 CMDABT	Command Abort Flag The CMDABT flag indicates FCTRL[ABTREQ] was set during a command operation while CCIF was clear. This event will result in the termination of the operation unless it occurs during the exit routine of the operation. Once CMDABT is set, ABTREQ will get cleared. While the CMDABT flag is set, ABTREQ cannot be set and the CCIF flag cannot be cleared to launch a command. The CMDABT flag is cleared by writing a 1 to CMDABT while CCIF is set and ABTREQ is clear. Writing a 0 to the CMDABT flag has no effect. The CMDABT flag is cleared by a mass erase request with CCIF set. 0b - No command abort detected 1b - Command abort detected
1 —	Reserved
0 FAIL	Command Fail Flag The FAIL flag is set if an error is detected during execution of a flash command, mass erase operation, or flash initialization. If the FAIL flag sets along with ACCERR after launching a flash command or mass erase operation, FMU parameters were not loaded from IFR1 during initialization and a clean POR where FMU parameters are successfully loaded is required to clear the FAIL flag. As a status flag, this bit cannot (and need not) be cleared by the user like some of the other flags in this register. The value of the FAIL flag for "command-N" is valid only at the end of the "command-N" execution when CCIF=1 and before the next command has been launched. At some point during the execution of "command-N+1," the FAIL flag is cleared unless FMU parameters were not loaded from IFR1 during initialization. The FAIL flag is cleared by a mass erase request with CCIF set unless FMU parameters were not loaded from IFR1 during initialization. The FAIL flag is not cleared during Power Down recovery. 0b - Error not detected 1b - Error detected

18.6.2.1.3 Flash Configuration Register (FCNFG)

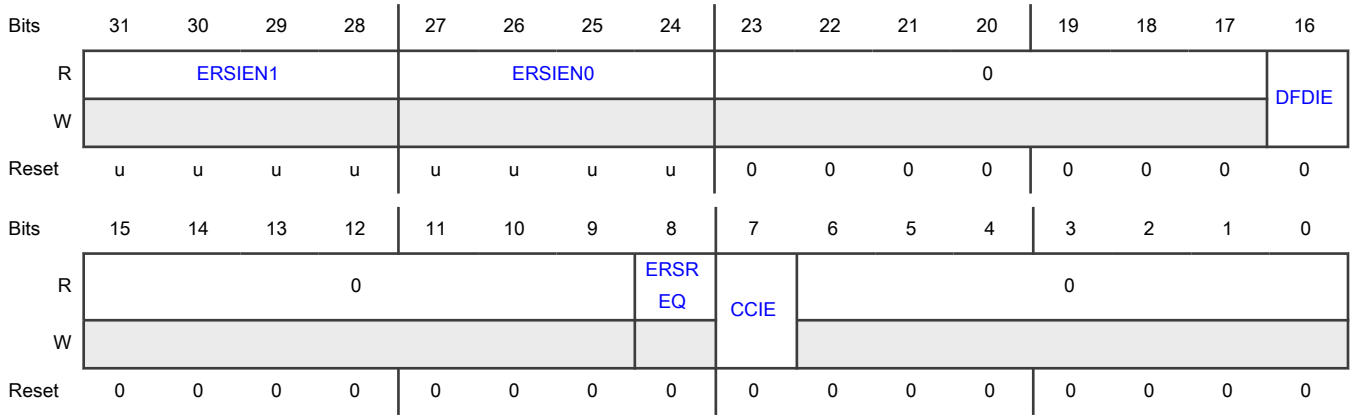
Offset

Register	Offset
FCNFG	4h

Function

This register provides information on the current functional state of the flash module.

Diagram



Fields

Field	Function
31-28 ERSIEN1	Erase IFR Sector Enable - Block 1 (for dual block configs) This field controls the ability to erase the IFR sectors in block 1 using the ERSSCR command. These bits are loaded from sideband signals during initialization. Note: These bits have no effect on single block configurations. Note: The ERSALL command and MCU mass erase request do not adhere to these restrictions. X equals 0, 1, 2, or 3. Any and all bits in the field are independently configured. 0000b - Block 1 IFR Sector X is protected from erase by ERSSCR command 0001b - Block 1 IFR Sector X is not protected from erase by ERSSCR command
27-24 ERSIEN0	Erase IFR Sector Enable - Block 0 This field controls the ability to erase the IFR sectors in block 0 using the ERSSCR command. These bits are loaded from sideband signals during initialization. Note: The ERSALL command and MCU mass erase request do not adhere to these restrictions. X equals 0, 1, 2, or 3. Any and all bits in the field are independently configured. 0000b - Block 0 IFR Sector X is protected from erase by ERSSCR command 0001b - Block 0 IFR Sector X is not protected from erase by ERSSCR command
23-17 —	Reserved
16 DFDIE	Double Bit Fault Detect Interrupt Enable The DFDIE bit controls interrupt generation when an uncorrectable ECC fault is detected during a valid flash read access from the platform flash controller. 0b - Double bit fault detect interrupt disabled 1b - Double bit fault detect interrupt enabled. An interrupt request is generated whenever the FSTAT[DFDIF] flag is set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-9 —	Reserved
8 ERSREQ	Mass Erase Request This bit indicates whether a sideband request has been received by the command controller to execute the Mass Erase operation. ERSREQ is not directly writable but sets when a Mass Erase request is received by the flash module while CCIF is set. ERSREQ is cleared by the command controller when the operation completes. 0b - No request or request complete 1b - Request to run the Mass Erase operation
7 CCIE	Command Complete Interrupt Enable The CCIE bit controls interrupt generation when a flash command completes. 0b - Command complete interrupt disabled 1b - Command complete interrupt enabled. An interrupt request is generated whenever the FSTAT[CCIF] flag is set.
6-0 —	Reserved

18.6.2.1.4 Flash Control Register (FCTRL)

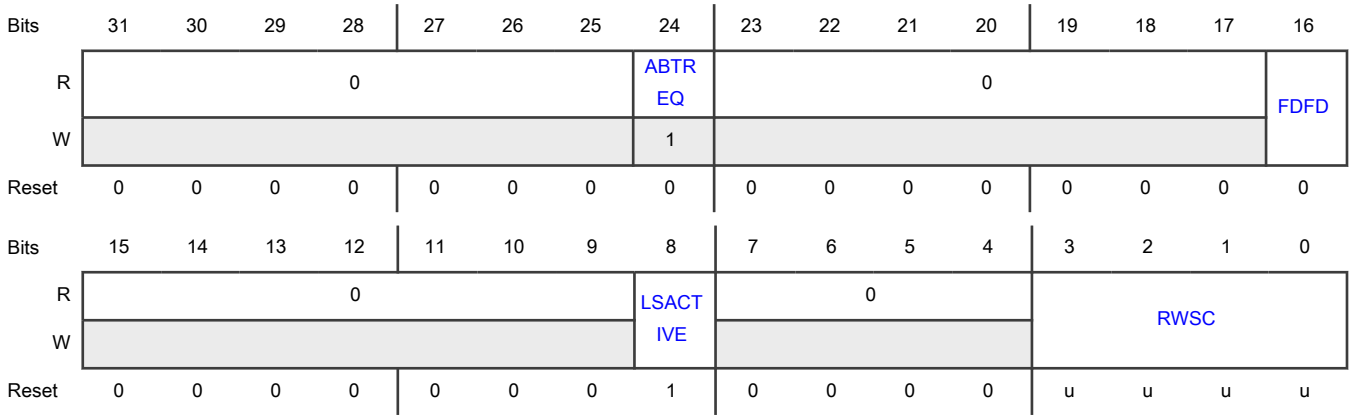
Offset

Register	Offset
FCTRL	8h

Function

The flash control register controls activity associated with flash memory reads and command operations.

Diagram



Fields

Field	Function
31-25 —	Reserved
24 ABTREQ	Abort Request With FSTAT[CMDP] set, setting the ABTREQ bit allows a user to abort a command write sequence or command operation. The ABTREQ bit can only be set by a user with the same domain ID as indicated by FSTAT[CMDDID] and the same or higher security/privilege protection level than is indicated by FSTAT[CMDPRT]. While ABTREQ is set, CCIF cannot be cleared to launch a command. If FSTAT[CCIF] is high when ABTREQ is set, the command write sequence will abort and ownership transferred to the user setting the ABTREQ bit. The FSTAT[CWSABT] flag will set and the CMDPRT field will be updated based on the write transaction that sets the ABTREQ bit. The ABTREQ bit will then be cleared automatically. If FSTAT[CCIF] is low when ABTREQ is set, the command operation will abort and ownership transferred to the user setting the ABTREQ bit. The FSTAT[CMDABT] flag will set and the CMDPRT field will be updated based on the write transaction that sets the ABTREQ bit. The ABTREQ bit will then be cleared automatically. While CWSABT or CMDABT are high, writes to ABTREQ will be ignored. 0b - No request to abort a command write sequence 1b - Request to abort a command write sequence
23-17 —	Reserved
16 FDFD	Force Double Bit Fault Detect The FDFD bit enables the user to emulate the setting of the FSTAT[DFDIF] flag to check the associated interrupt routine. The FDFD bit is cleared by writing a 0 to FDFD. 0b - FSTAT[DFDIF] sets only if a double bit fault is detected during a valid flash read access from the platform flash controller

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - FSTAT[DFDIF] sets during any valid flash read access from the platform flash controller. An interrupt request is generated if the DFDIE bit is set.
15-9 —	Reserved
8 LSACTIVE	Low speed active mode This bit controls entry into the low speed active mode. Flash memory reads are supported in low speed active mode. All flash commands are supported in low speed active mode but the LSACTIVE bit is not writable while a flash command is executing (CCIF=0) or during a non-active power mode. If the FSTAT[CMDP] is set, the protection level of any write transaction to the LSACTIVE bit must match the CMDPRT bits and the domain ID must match the CMDDID bits. Note: If a device does not support low speed active mode, the LSACTIVE bit will reset to 0b and will not be writable. 0b - Full speed active mode requested 1b - Low speed active mode requested
7-4 —	Reserved
3-0 RWSC	Read Wait-State Control These bits control the number of wait-states added to account for the ratio of system clock period to flash access time during full speed and low speed active power modes. Ratios greater than one require non-zero settings for the RWSC field for proper flash accesses. The required settings are documented in the device data sheet. 0h - no additional wait-states are added (single cycle access) 1h - 1 additional wait-state is added 2h - 2 additional wait-states are added ... Fh - 15 additional wait-states are added These bits are loaded from IFR1 during initialization.

18.6.2.1.5 Flash Common Command Object Registers (FCCOB0 - FCCOB7)

Offset

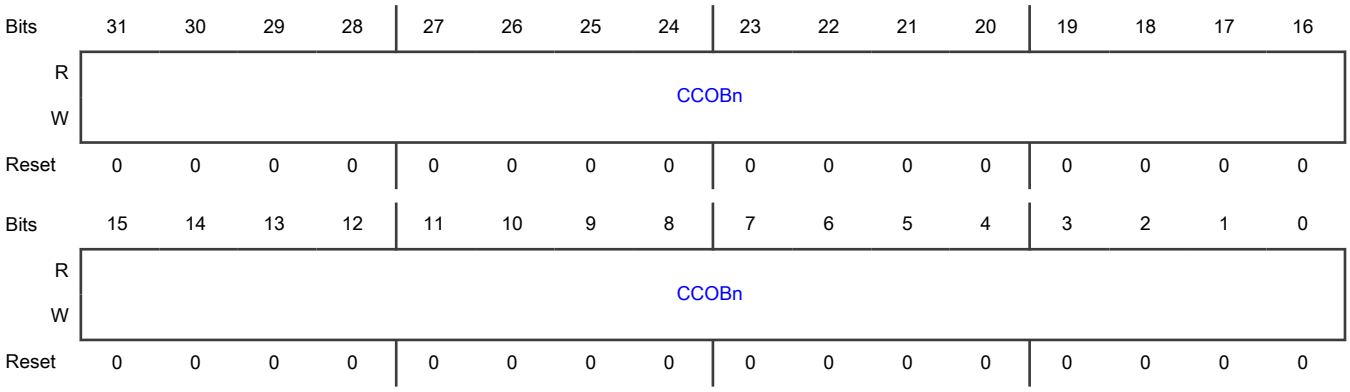
For a = 0 to 7:

Register	Offset
FCCOBa	10h + (a × 4h)

Function

The FCCOB register group provides fields for command codes and parameters. The individual words within the set append a 0-7 hex identifier to the FCCOB register name: FCCOB0, FCCOB1, ..., FCCOB7.

Diagram



Fields

Field	Function
31-0 CCOBn	CCOBn The FCCOB register group provides a command code and relevant parameters to the command controller. The individual registers that compose the FCCOB data set can be written in any order, but you must provide all needed values, which vary from command to command. First, set up all required FCCOB fields and then initiate the command execution by writing a 1 to the FSTAT[CCIF] bit. This clears the CCIF bit, which locks all FCCOB parameter fields and they cannot be changed by the user until the command completes (CCIF returns to 1). No command buffering or queueing is provided; the next command can be loaded only after the current command completes. Some commands return information to the FCCOB registers. Any values returned to FCCOB are available for reading after the FSTAT[CCIF] flag returns to 1. The following table shows a generic flash command format. The first FCCOB register, FCCOB0, always contains the command code. This 8-bit value defines the command to be executed. The command code is followed by the parameters required for this specific flash command, typically an address and/or data values.

NOTE

The command parameter table is written in terms of FCCOB Number (which is equivalent to the word number). This number is a reference to the FCCOB register name and is not the register address.

FCCOB Number[1]	Typical Command Parameter Contents [31:0]
0	FCMD [7:0] (flash command code, bits [31:8] are not writable)
1	FCMDOPT [7:0] (flash command options, bits [31:8] are not writable)
2	Flash address 1 (start)
3	Flash address 2 (end)
4	Data Word 0

Field	Function

FCCOB Number[1]	Typical Command Parameter Contents [31:0]
5	Data Word 1
6	Data Word 2
7	Data Word 3

1. Refers to FCCOB register name, not register address

Table 178. Reference links to related information

Topic	Related module	Reference
Full description	REGFILE	REGFILE
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

19.1.1 Module instances

This device has two instances of the REGFILE module, REGFILE0, and REGFILE1. REGFILE0 has no WAR or RAR registers while REGFILE1 has WAR and RAR registers.

19.1.2 Module reset

REGFILE0 retains its contents during low-voltage detect (LVD) events and is only reset during a power-on reset. REGFILE1 can be reset by every reset except wakeup from Power Down and Deep Power Down.

19.1.3 Low-power wakeup booth path

This device embeds a ROM bootloader code resident in the ROM area. Low-power wakeup boot flow requires the usage of REGFILE1 REG0 to store WAKEUP CRC data to verify the ROM wakeup word, therefore, REGFILE1 REG0 should not be used to store application data when low-power wakeup boot is enabled, but it should contain the valid WAKEUP CRC parameter to ensure proper boot sequence. See the Low_power wakeup path for more information about REGFILE1 REG0 usage during low-power boot flow.

19.2 Overview

The REGFILE module is used to store data, which is written to the Register File Registers, to be persistent.

19.3 Memory Map and Registers

19.3.1 REGFILE register descriptions

19.3.1.1 REGFILE memory map

REGFILE0 base address: 4002_1000h

REGFILE1 base address: 4002_2000h

Field	Function
31-8 —	Reserved
7-0 RARn	REGn Register Read Access 0b - Not allow to read the REGn register until next reset. Reading corresponding REGn register returns all 0. 1b - Allow to read the REGn register.

19.4 Functional description

REGFILE can be used to store data that must be persistent across the low power modes. Write the information into the Register File Registers and read the information back.

If a REGFILE instance supports Write Access Register (WAR) and Read Access Register (RAR), they can lock write and read operations on the Register File Registers until the next reset is performed.

NOTE

Not all the instances support WAR and RAR registers, refer to WAR and RAR registers for instances that support them.

19.4.1 Power mode

The REGFILE module is powered in all power modes unless it is in the VDD_SWITCH domain. In VDD_SWITCH domain, the REGFILE module is only powered down to Deep Power Down mode.

19.4.2 Reset

See chip-specific section for the reset of REGFILE module.

Chapter 20
Signal Muxing and Pinout

20.1 Introduction

To optimize functionality in small packages, pins have several functions available via signal multiplexing. This chapter illustrates which of this device's signals are multiplexed on which external pin.

20.2 Pinout Table

Topic	Related module	Reference
Full description	PORT	PORT
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

21.1.1 Module instances

This device has four instances of the port module, PORTA, PORTB, PORTC, and PORTD.

21.1.2 Port B EFT detect clear (EDCR)

Port B and Port C pins share the same EFT detector clear control from PORTC_EDCR register. Any write to the PORTB_EDCR does not take effect.

21.1.3 Port voltage range (CONFIG[RANGE])

PORTA_CONFIG[RANGE] controls the voltage ranges of Port A, B, and C. Reading or writing PORTB_CONFIG[RANGE] and PORTC_CONFIG[RANGE] does not take effect.

21.2 Overview

PORT provides support for pad control functions. You can configure most functions independently for each pin, in the 32-bit port, and affect the pin regardless of its pin multiplexing state.

There exists a single instance of the PORT module for each port, and not all pins within each port are implemented on a specific chip.

21.2.1 Block diagram

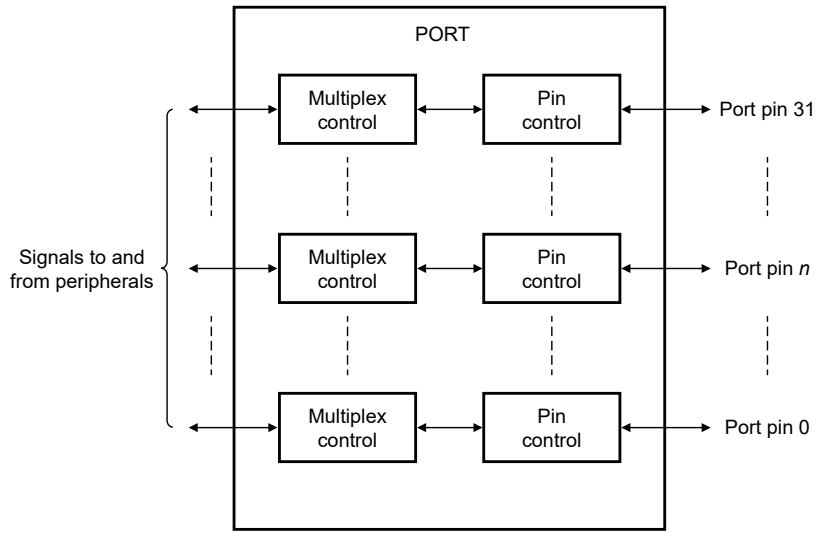

Figure 59. Block diagram

21.2.2 Features

- Individual pull control fields with pullup, pulldown, and pull-disable support
- Individual drive strength fields supporting high and low drive strengths
- Individual slew rate fields supporting fast and slow slew rates
- Individual PCR*n*[PFE] fields that enable and disable individual input passive filters on selected pins
- Individual PCR*n*[ODE] fields that enable and disable individual open drain outputs
- Individual electrical fast transient (EFT) detect with an EFT detect flag and associated interrupt
- Individual mux control fields supporting analog or pin disabled, GPIO, and up to 10 chip-specific digital functions

21.3 Functional description

21.3.1 Pin control

Each port pin has a corresponding Pin Control Register (PCR) associated with it that helps you configure the following functions for each pin within the 32-bit port:

- Pullup or pulldown enable
- Drive strength configuration
- Slew rate configuration
- Open drain enable
- Passive input filter enable on selected pins
- EFT detection
- Software configuration lock
- Pin multiplexing mode

These functions apply across all digital pin multiplexing modes, and individual peripherals do not override the configuration in PCR*n* unless otherwise noted. For example, if an I^2C function is enabled on a pin, it does not override the pullup or open drain configuration for that pin.

PCR*n*[LK] allows the configuration for each pin to be locked until the next system reset. When locked, writes to the lower half of that PCR*n* are ignored, although a bus error is not generated on an attempted write to a locked register.

The configuration of each PCR*n* is retained when the PORT module is disabled.

When you configure a pin in a digital pin multiplexing mode, the input buffer for that pin is enabled, allowing the pin state to be read via the corresponding GPIO.PDIR or allowing a pin interrupt or DMA request to be generated. If a pin is always floating when its input buffer is enabled, it can cause an increase in power consumption. This situation must be avoided. A pin can be floating because of an input pin that is not connected or an output pin that is tristated (output buffer is disabled).

Enabling the internal pull resistor (or implementing an external pull resistor) ensures that a pin does not float when its input buffer is enabled. The internal pull resistor is automatically disabled whenever the output buffer is enabled, allowing PCR*n*[PE] to remain 1. Configuring Pin Multiplexing mode to disabled or analog (PCR*n*[MUX] = 0) disables the pin's input buffer and results in lowest power consumption.

21.3.2 Global pin control

Global Pin Control Low (GPCLR) and Global Pin Control High (GPCHR) allow a single register write to update the lower 16 bits of PCR*n* for up to 16 pins, all with the same value. You cannot write to locked registers by using Global Pin Control Low (GPCLR) and Global Pin Control High (GPCHR).

Global Pin Control Low (GPCLR) and Global Pin Control High (GPCHR) enable you to quickly configure multiple pins within the same port and with the same peripheral function. These are write-only registers that always read as 0.

21.3.3 EFT detection

The EFT detect circuit is active whenever PORT is powered and EDCR[EDLC] and EDCR[EDHC] are 0.

The EFT high detect circuit for each pin is reset whenever EDCR[EDHC] = 1. Likewise, the EFT low detect circuit for each pin is reset whenever EDCR[EDLC] = 1 and that pin's EFT high detect is not asserted.

21.3.4 Interrupt

When EFT on a pin is detected, an interrupt request is generated to indicate the detection of EFT on that pin. This interrupt is enabled when EDIER[EDIE*n*] = 1. Writing 0 to these fields clears the interrupt request but does not affect EFT detection on the corresponding pin (EDFR[EDF*n*]).

21.4 Initialization

To initialize PORT, perform the following procedure:

1. Initialize the pin functions:
   - Initialize single pin functions by writing appropriate values to PCR*n*.
   - Initialize multiple pins (up to 16) with the same configuration by writing appropriate values to Global Pin Control Low (GPCLR) or Global Pin Control High (GPCHR).
2. Lock the configuration for a given pin, by writing 1 to PCR*n*[LK], so that it cannot be changed until the next reset.

21.5 Application information

21.5.1 Determine polarity of an asserted EFT detection

You can determine the polarity of an asserted EFT detect by performing this procedure:

1. Read EFT Detect Flag (EDFR).

2. Write 1 and then write 0 to EDCR[EDLC].
3. Read EFT Detect Flag (EDFR) again. Any field that has now become 0 indicates triggering of the EFT low detector only (no EFT high detector triggering).
4. Write 1 and then write 0 to EDCR[EDHC].
5. Read EFT Detect Flag (EDFR) again. Any field that has now become 0 indicates triggering of the EFT high detector. Any field that did not become 0 indicates triggering of both the EFT high and EFT low detectors.
6. Write 1 and then write 0 to both EDCR[EDLC] and EDCR[EDHC] to ensure that all detectors are reset.

21.6 Memory map and register definition

Any read or write access to the PORT memory space, outside the valid memory map, results in a bus error. All register accesses complete with zero wait states.

21.6.1 PORT register descriptions

21.6.1.1 PORT memory map

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 MAJOR	Major Version Number Indicates the major version number for the specification.
23-16	Minor Version Number

Table continues on the next page...

Table continued from the previous page...

Field	Function
MINOR	Indicates the minor version number for the specification.
15-0 FEATURE	Feature Specification Number Indicates the feature set number. 0000_0000_0000_0000b - Basic implementation

21.6.1.3 Global Pin Control Low (GPCLR)

Offset

Register	Offset
GPCLR	10h

Function

Controls writes to the PCR15–PCR0 registers.

NOTE

This register supports only 32-bit writes and ignores any 16-bit or 8-bit writes.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W	GPWD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 GPWEn	Global Pin Write Enable Configures the corresponding lower 16-bit field of PCR*n* to be updated with the value in the GPWD field. If a selected PCR is locked, the write to that register is ignored. 0b - Not updated

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Updated
15-0 GPWD	Global Pin Write Data Is written to PCR*n*[15:0] if GPWE*n* = 1.

21.6.1.4 Global Pin Control High (GPCHR)

Offset

Register	Offset
GPCHR	14h

Function

Controls writes to the PCR31–PCR16 registers.

NOTE

This register supports only 32-bit writes and ignores any 16-bit or 8-bit writes.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

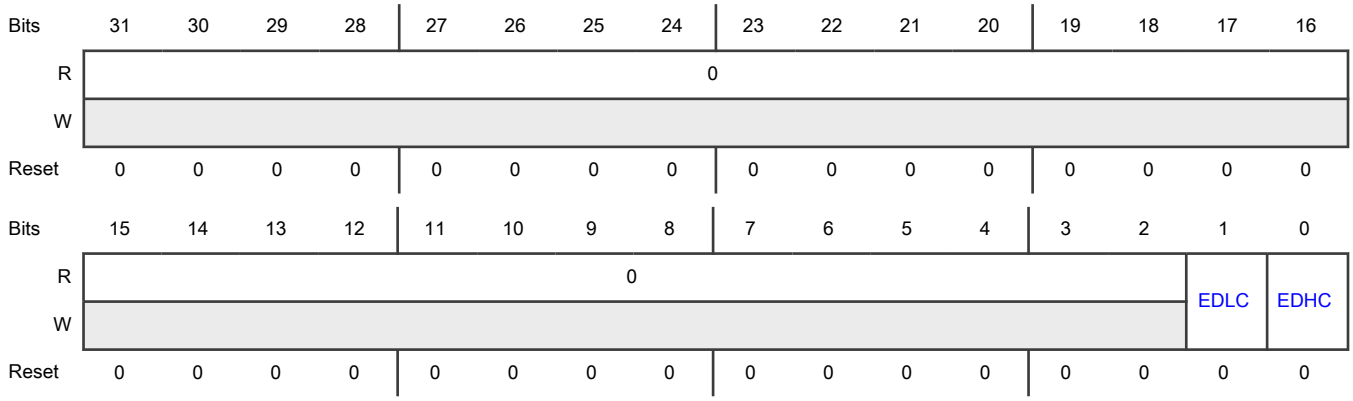
21.6.1.8 EFT Detect Clear (EDCR)

Offset

Register	Offset
EDCR	48h

Function
Clears EFT detectors. The EFT detect logic is cleared per port.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 EDLC	EFT Detect Low Clear Clears low EFT detectors. If this field = 1, all low EFT detectors for which the corresponding high EFT detectors are not asserted are cleared. 0b - Does not clear 1b - Clears
0 EDHC	EFT Detect High Clear Clears high EFT detectors. 0b - Does not clear 1b - Clears

21.6.1.9 Pin Control 0 (PCR0)

Offset

Register	Offset
PCR0	80h

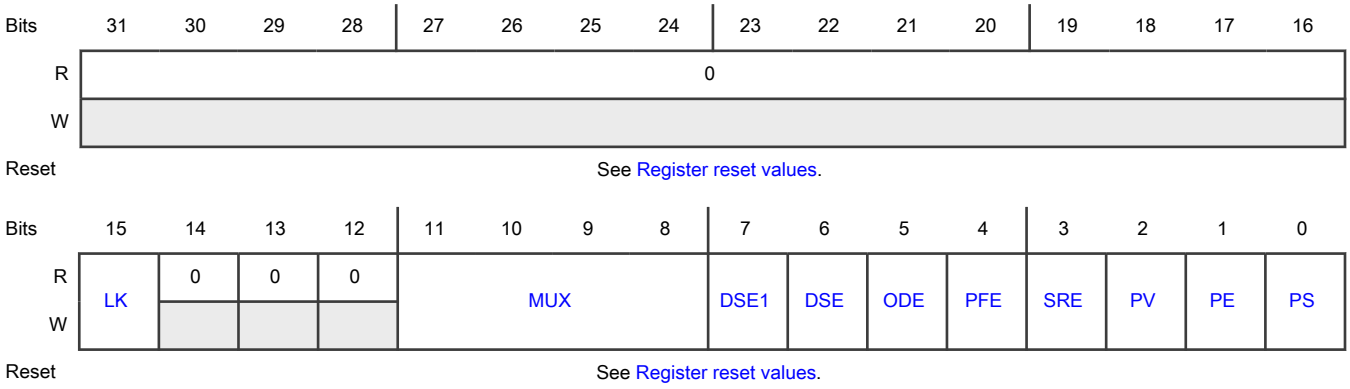
Function

Configures pin control features on each pin.

NOTE

Do not modify pin configuration registers associated with pins that are unavailable in your selected package. All unbonded pins unavailable in your package default to the Disabled state for lowest power consumption.

Diagram



Register reset values

Register	Reset value

Topic	Related module	Reference
Full description	GPIO	GPIO
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

22.1.1 Module instances

This device has four instances of the GPIO module, GPIOA, GPIOB, GPIOC, and GPIOD.

22.1.2 GPIO interrupts

For each GPIO module, two interrupt channels have been assigned. Refer to Interrupt channel assignments for more details.

22.2 Overview

The GPIO module communicates to the processor core via a zero wait-state interface for maximum pin performance.

22.2.1 Block diagram

The following figure shows the block diagram for the GPIO module.

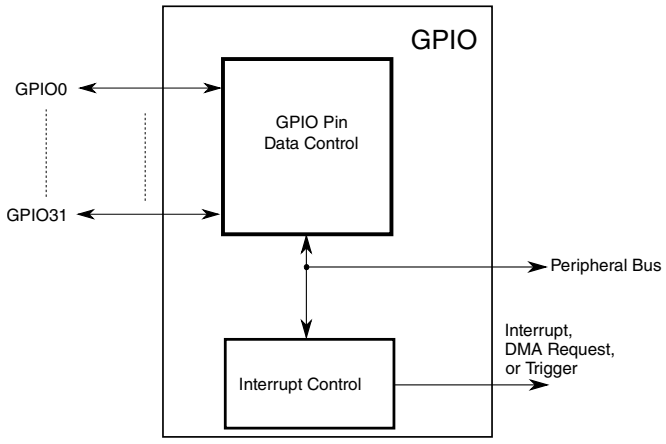

Figure 60. GPIO block diagram

22.2.2 Features

The GPIO module includes the following features:

- Port Data Input (PDIR) register displays the logic value on each pin when the pin is configured for any digital function provided the corresponding Port Control and Interrupt module for that pin are enabled.

- Port Data Output (PDOR) register with corresponding set/clear/toggle registers controls output data of each pin when the pin is configured for the GPIO function.
- Port Data Direction (PDDR) register controls the direction of each pin when the pin is configured for the GPIO function.
- Port Input Disable (PIDR) register controls the disable of the input for each general-purpose pin.
- Pin interrupts
  - Interrupt flag and enable registers for each pin are functional in all digital pin muxing modes.
  - Support for interrupt, peripheral trigger, or DMA request configured per pin.
  - Support for edge sensitive (rising or falling, or both) or level sensitive (low, high) configured per pin.
  - Asynchronous wake-up in Low-Power modes.
  - GPIO module generates a total of 2 interrupts, 2 output triggers and 2 DMA requests.
  - Each pin can be used to generate a single interrupt, output trigger or DMA request.
- Protection registers
  - Each pin is configured for Secure or Non-Secure and Privilege/Non-Priviliege access.
  - Each interrupt, trigger and DMA request domain is configured for Secure or Non-Secure and Privilege/Non-Priviliege access.

22.3 Functional description

22.3.1 Low-Power modes

The GPIO module can be configured to exit the Low-Power mode via an asynchronous wake-up signal if an enabled interrupt is detected.

22.3.2 Debug mode

The GPIO module remains functional in debug mode.

22.3.3 General-purpose input

The logic state of each pin is available via the Port Data Input registers (PDIR) if,

- the corresponding bit in the Port Input Disable Register (PIDR) is clear, and
- the pin is configured for a digital function.

22.3.4 General-purpose output

The logic state of each pin is controlled via the Port Data Output Registers(PDOR) and Port Data Direction Registers(PDDR), provided the pin is configured for the GPIO function. The following table depicts the conditions for a pin to be configured as input/output.

If	Then
A pin is configured for the GPIO function and the corresponding PDDR bit is clear.	The pin is configured as an input.
A pin is configured for the GPIO function and the corresponding PDDR bit is set.	The pin is configured as an output and the logic state of the pin is equal to the corresponding PDOR.

For efficient bit manipulation on the general-purpose outputs, pin data set, pin data clear, and pin data toggle registers allows one or more outputs within one port to be set, cleared, or toggled from a single register write, eliminating the need for a read-modify-write operation to prevent changing pins accidentally.

22.3.5 External interrupts

The external interrupt capability of the GPIO module is available in all digital pin muxing modes.

GPIO module generates a total of 2 interrupts, 2 output triggers and 2 DMA requests. Each pin can be individually configured for interrupt, output trigger or DMA request.

- Each output implements a separate interrupt status flag register for that domain
- Each output generates a single interrupt
- Each output generates a single DMA request
- Each output generates a single peripheral trigger output

Each pin can be individually configured for any of the following external interrupt modes:

Table 181. Available pin configuration for external interrupt

Signal conditions	Software polling using flags	Peripheral triggers	Interrupts	DMA requests
Rising-edge	Yes	—	Yes	Yes
Falling-edge	Yes	—	Yes	Yes
Rising- and falling-edge	Yes	—	Yes	Yes
High-level	—	Yes	Yes	—
Low-level	—	Yes	Yes	—

The interrupt status flag is set when the configured edge or level is detected on the pin. Unless the GPIO module is in a Low-Power mode, the input is first synchronized to the system clock to detect the configured level or edge transition.

The GPIO module generates a pin interrupt that asserts when the interrupt status flag is set for any enabled interrupt for that output. The interrupt negates after the interrupt status flags for all enabled interrupts are cleared by writing a logic 1 to the ISF flag in either the ISFR or ICRn registers.

The GPIO module generates a DMA request that asserts when the interrupt status flag is set for any enabled DMA request in that output. The DMA request negates after the DMA transfer is completed, because that clears the interrupt status flags for all enabled DMA requests.

In Low-Power mode, the interrupt status flag for any enabled interrupt is asynchronously set if the required level or edge is detected. This also generates an asynchronous wake-up signal to exit the Low-Power mode.

The GPIO module generates a peripheral trigger output that asserts if any pin configured for active high trigger is logic one, or any pin triggered for active low trigger is logic zero. The peripheral trigger output asynchronously updates from the value on the configured pins.

22.3.6 Global interrupt control

The two global interrupt control registers (GICLR and GICHR) allow a single register write to update the upper 16-bit of the Interrupt Control Register for up to 16 pins, all with the same value.

The global interrupt control registers allow software to quickly configure multiple pins within the same port with the same interrupt configuration.

The global interrupt control registers are write-only registers and always read as 0.

22.3.7 Access protection

The GPIO module implements access protection registers (PCNS and PCNP) for each pin as follows:

Access	Description
Secure	Pins configured for Secure access can only be written or read by software in Secure state.
Non-Secure	Pins configured for Non-Secure access can only be written or read by software in Non-Secure state.
Privilege	Pins configured for Privilege access can only be written by software in Privilege state.
Non-Privilege	Pins configured for Non-Privilege access can be written by software in both Privilege and Non-Privilege states.

The GPIO module implements access protection registers (ICNS and ICNP) for each interrupt, trigger output and DMA request as follows:

Access	Description
Secure	Outputs configured for Secure access can only be configured by software in Secure state.
Non-Secure	Outputs configured for Non-Secure access can only be configured by software in Non-Secure state.
Privilege	Outputs configured for Privilege access can only be configured by software in Privilege state.
Non-Privilege	Outputs configured for Non-Privilege access can be configured by software in both Privilege and Non-Privilege states.

The access protection registers (PCNS, PCNP, ICNS and ICNP) can only be written by software in secure-privilege state and can be optionally locked until the next reset.

Configuring a pin interrupt/trigger output/DMA request requires the following access permissions:

- Access permission to configure that pin.
- Access permission to configure to the desired interrupt/trigger output/DMA request, or writing IRQC=0.
- Access permission to configure with the existing interrupt/trigger output/DMA request, or currently IRQC=0.
- The interrupt configuration is not locked.

22.4 External signals

Table 182. GPIO external signals

Signal	Description		Direction
GPIO31 - GPIO0	General-purpose input/output		I/O
	State meaning	Asserted: The pin is logic 1. Deasserted: The pin is logic 0.	
	Timing	Assertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock.	

Table continues on the next page...

Table 182. GPIO external signals

Signal	Description		Direction
		Deassertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock.	

NOTE

Not all pins within each GPIO are implemented on each device. See the chapter on signal multiplexing for the number of GPIO pins within each port available in the device.

22.5 Initialization

To initialize the GPIO module:

1. Initialize GPIO pins for output function
   a. Configure the output logic value for each pin by using PDOR register.
   b. Configure the direction for each pin by using PDDR register.
2. Initialize interrupt function
   - Write to ICRn for the corresponding pins and desired configuration.
   - If the pin is previously used for a different function, first write 0x0100_0000 to ICRn register to disable the previous function and clear the flag.

22.6 Application information

The GPIO module has the following applications:

- Read the state of a single pin
  - Perform a byte read of PnDR register.
- Update the state of a single pin
  - Perform a byte write to PnDR register.
- Read the state of multiple pins
  - Read PDIR register.
- Update the state of multiple pins
  - Write to PDOR register bits.
  - Write to PSOR register to set PDOR register bits.
  - Write to PCOR register to clear PDOR register bits.
  - Write to PTOR register to toggle PDOR register bits.

22.7 Memory map and register definition

The GPIO registers support 8-bit, 16-bit, or 32-bit accesses. Any read or write access to the GPIO memory space that is outside the valid memory map results in a bus error.

NOTE

For simplicity, each GPIO port's register appears with the same width of 32 bits, corresponding to 32 pins. The actual number of pins per port (and therefore the number of usable control bits per port register) is chip-specific. See the Signal Multiplexing for exact control bits for each port.

Fields

Field	Function
31-2 —	Reserved
1-0 NPEn	Non-Privilege Enable This field configures Privilege/Non-Privilege access protection for each interrupt/trigger output/DMA request. 0b - The pin is configured for Privilege access. Only software in Privilege state can configure a pin to use the corresponding interrupt/trigger output/DMA request or reconfigure a pin that is already configured to use the corresponding interrupt/trigger output/DMA request. 1b - The pin is configured for Non-Privilege access. Software in either Privilege or Non-Privilege state can configure a pin to use the corresponding interrupt/trigger output/DMA request or reconfigure a pin that is already configured to use the corresponding interrupt/trigger output/DMA request.

22.7.1.9 Port Data Output Register (PDOR)

Offset

Register	Offset
PDOR	40h

Function

Configures the logic levels that are driven on each general-purpose output pin.

NOTE

Do not modify the pin configuration registers associated with pins that are not available in your selected package. These unbonded pins are default set to Disbale state for lowest power consumption.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 PIDn	Port Input Disable This field is used to disable a pin for general-purpose input 0b - Pin is configured for general-purpose input provided, the pin is configured for any digital function. 1b - Pin is disabled for general-purpose input.

22.7.1.16 Pin Data Register a (P0DR - P31DR)

Offset

For a = 0 to 31:

Register	Offset
PaDR	60h + (a × 1h)

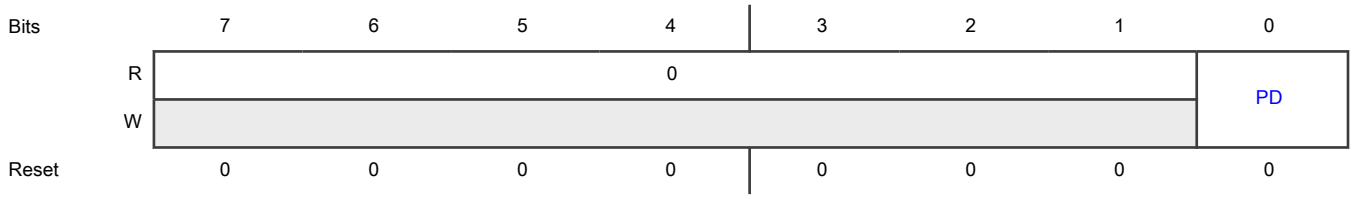
Function

Configures the data feature of a pin. Pin that is unimplemented or not configured for a digital function reads as zero.

NOTE

Do not modify PaDR registers associated with the pins that are not available in your selected package. These unbonded pins are default set to Disable state for lowest power consumption.

Diagram



Fields

Field	Function
7-1 —	Reserved
0 PD	Pin Data (input and output) Writing to this bit field of PaDR register will update corresponding bit a in the PDOR register, reading this bit field of PaDR register will return value in the corresponding bit a of the PIDR register. 0b - Pin logic level is logic zero or not configured for use by digital function. 1b - Pin logic level is logic one.

22.7.1.17 Interrupt Control Register a (ICR0 - ICR31)

Offset

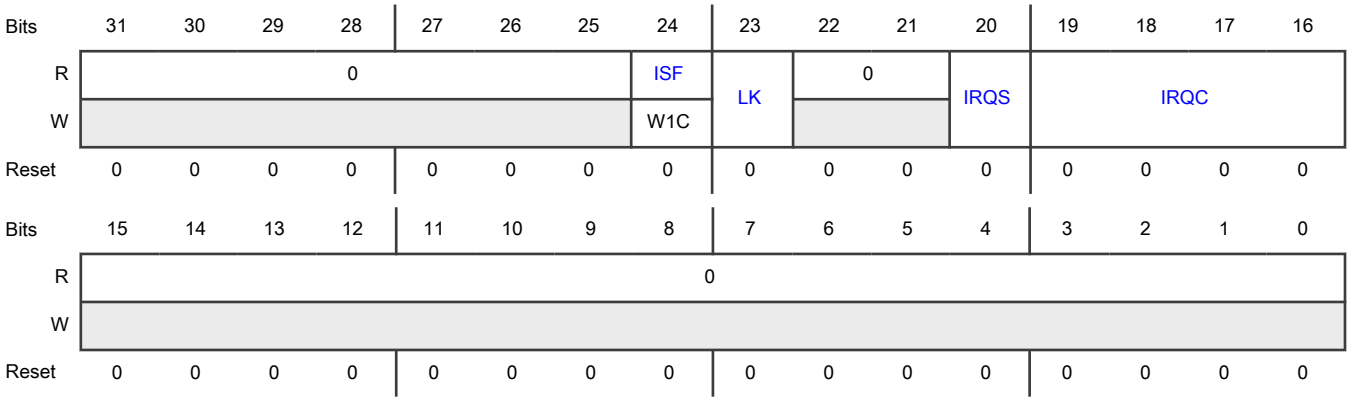
For a = 0 to 31:

Register	Offset
ICRa	80h + (a × 4h)

Function

Configures interrupt features on each pin.

Diagram



Fields

Field	Function
31-25 —	Reserved
24 ISF	Interrupt Status Flag This field indicates whether the configured interrupt is detected. The pin interrupt configuration is valid in all digital pin muxing modes. The bit fields in the ISFR register have the same function. The interrupt status flag can be cleared with either register bit. 0b - Configured interrupt is not detected. 1b - Configured interrupt is detected. If the pin is configured to generate a DMA request, then the corresponding flag will be cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic 1 is written to the flag. If the pin is configured for a level sensitive interrupt and the pin remains asserted, then the flag is set again immediately after it is cleared.
23 LK	Lock Register This field is used to lock ICR[23:0], and the locked field cannot be updated until the next system reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Interrupt configuration by ICR[23:0] is not locked and can be updated. 1b - Interrupt configuration by ICR[23:0] is locked and cannot be updated until next system reset.
22-21 —	Reserved
20 IRQS	Interrupt Select This field configures the interrupt/trigger output/DMA request. 0b - Interrupt/trigger output/DMA request 0. 1b - Interrupt/trigger output/DMA request 1.
19-16 IRQC	Interrupt Configuration The pin interrupt configuration is valid in all digital pin muxing modes. When changing the interrupt configuration, it is recommended to first disable the interrupt status flag and then write the new configuration. The corresponding pin is configured to generate interrupt, trigger or DMA request as follows: 0000b - Interrupt Status Flag (ISF) is disabled. 0001b - ISF flag and DMA request on rising edge. 0010b - ISF flag and DMA request on falling edge. 0011b - ISF flag and DMA request on either edge. 0100b - Reserved. 0101b - ISF flag sets on rising edge. 0110b - ISF flag sets on falling edge. 0111b - ISF flag sets on either edge. 1000b - ISF flag and Interrupt when logic 0. 1001b - ISF flag and Interrupt on rising-edge. 1010b - ISF flag and Interrupt on falling-edge. 1011b - ISF flag and Interrupt on either edge. 1100b - ISF flag and Interrupt when logic 1. 1101b - Enable active high trigger output, ISF flag on rising edge. Pin state is ORed with other enabled triggers to generate the output trigger, for use by other peripherals. 1110b - Enable active low trigger output, ISF flag on falling edge. Pin state is inverted and ORed with other enabled triggers to generate the output trigger, for use by other peripherals. 1111b - Reserved.
15-0 —	Reserved

22.7.1.18 Global Interrupt Control Low Register (GICLR)

Offset

Register	Offset
GICLR	100h

Function
Only 32-bit writes are supported to this register, any 16-bit or 8-bit writes are ignored.

Diagram

Fields

Field	Function
31-16 GIWD	Global Interrupt Write Data Write value that is written to upper 16 bits of the Interrupt Control Registers that are selected by GIWE.
15-0 GIWEn	Global Interrupt Write Enable This field selects whether the upper 16-bit field of the Interrupt Control Register ICR(n) will be updated with the value in GIWD. 0b - Upper 16-bit of corresponding Interrupt Control Register is not updated with the value in GIWD. 1b - Upper 16-bit of corresponding Interrupt Control Register is updated with the value in GIWD.

22.7.1.20 Interrupt Status Flag Register (ISFR0 - ISFR1)

Offset

Register	Offset
ISFR0	120h
ISFR1	124h

Function

The Interrupt Status Flag Register (ISFR) indicates whether the related configured interrupt is detected on each pin. The pin interrupt configuration is valid in all digital pin muxing modes. The Interrupt Status Flag for each pin is also visible in the corresponding Interrupt Control Register, and each flag can be cleared in either location.

There is a separate Interrupt Status Flag Register for each interrupt, trigger, or DMA request domain. Each status flag is only visible in the register that corresponds to that flag's domain as configured in IRCa[IRQS].

Fields

Field	Function
31-0 ISFn	Interrupt Status Flag Each bit in the field indicates the detection of the configured interrupt on each pin of the same number. 0b - Configured interrupt is not detected on the pin of the same number. 1b - Configured interrupt is detected on the pin of the same number. If the pin is configured to generate a DMA request, then the corresponding flag will be cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic 1 is written to the flag. If the pin is configured for a level sensitive interrupt and the pin remains asserted, then the flag is set again immediately after it is cleared.

Chapter 23
Debug

23.1 Introduction

This chapter describes the debug architecture of this device.

Features:

- The Arm CoreSight™ Architecture is adapted for software trace and debug.
- Serial wire debug (SWD) and Debug Access Port (DAP) to support debugger tools.
- Instrumentation Trace Macrocell (ITM) is supported for the Cortex-M33 core and Radio Cortex-M3 core.
- Data Watchpoint and Trace (DWT) and breakpoint unit (BPU) are supported for the Cortex-M33 and Radio Cortex-M3 core subsystem.
- Cross trigger interface (CTI) are supported for the Cortex-M33 core and radio Cortex-M3 sbsystem.
- 1-bit SWO trace port for efficiently accessing Cortex-M33 trace information from the system.

The following figure shows the system level debug architecture.

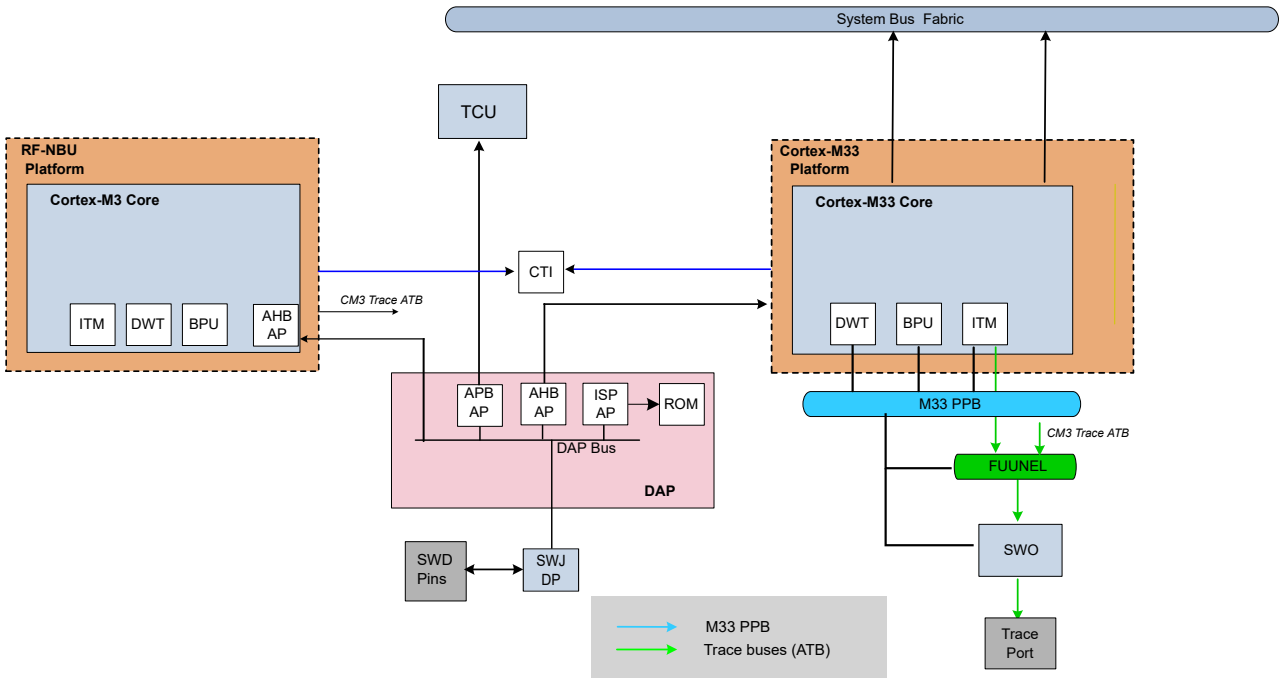

Figure 61. Debug architecture

23.2 Test and debug port connectivity

The following figure shows the connectivity of test and debug port on this device.

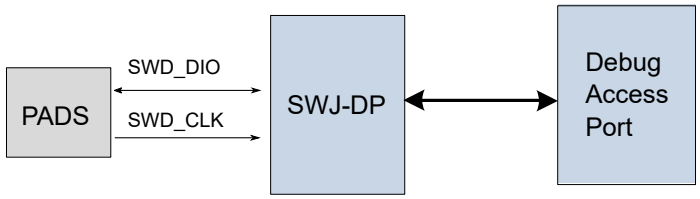

Figure 62. Debug port connectivity

The SWD signals are summarized in the following table.

Table 183. SWD signals summary

Pin Name	SWD		Internal pull up/down
	Type	Description	
SWD_DIO	I/O	Data	Pull-up
SWD_CLK	I	Clock	Pull-down

23.2.1 Serial wire debug (SWD)

The serial wire debug is a 2-pin electrical interface with a clock (SWD_CLK) and a single bi-directional data pin (SWD_DIO) to provide debug and test functionality.

23.2.2 Debug access port

Debug Access Port (DAP) is a standard Arm CoreSight component. The DAP provides multiple master driving ports, all of which are accessible and controlled through a single external interface port to provide system-wide debug. The DAP Instruction Register codes are listed in the following table.

Table 184. DAP IR Codes

Code	DAP IR
4'b1000	ABORT
4'b1010	DPACC
4'b1011	APACC
4'b1110	IDCODE

The DAP offers AHB and APB master interfaces to access system buses. It also exports the internal DAP bus to allow to extend the access ports as per the system requirement. For more information on DAP TAP, refer to Arm Debug Interface v5 Architecture specification on arm.com.

The exported DAP bus is used to host AHB AP, APB AP, MDM AP and ISP AP. The APB-AP implements registers which are used for Test mode control on the device. The MDM-AP hosts system level debug status and control registers (refer to Debug Status and Control Registers) which can be used for low power and other miscellaneous control and status. The ISP AP supports software debug feature at platform level. The selection of different access ports in the DAP is done based on the APSEL value set in the SELECT register of SWJ-DP.

The following figure shows the configuration of the DAP on this device.

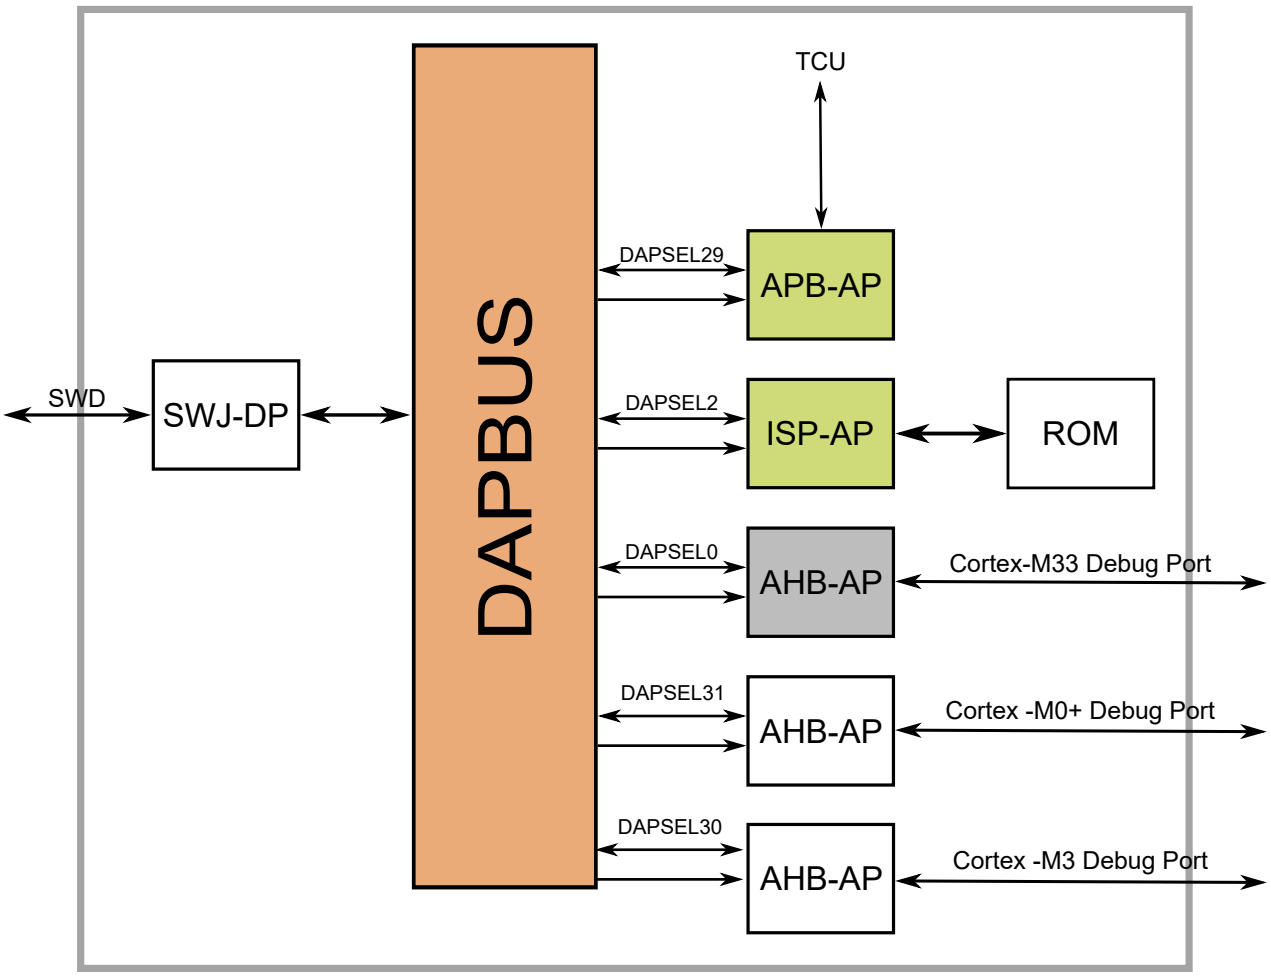

Figure 63. Debug Access Port configuration

23.3 Debug ROM tables

The debug ROM tables hold information about different debug components and help identify them. The following ROM table is available:

1. CM33 ROM: This table resides in the CM33 core and contains entries for CM33 debug components

23.4 Cortex M33 debug

This section covers the debug mechanisms associated with the CM33 processor.

23.4.1 CM33 software debug and trace

The following figure shows the data flow of software debug and trace information for the Cortex-M33 core on this device.

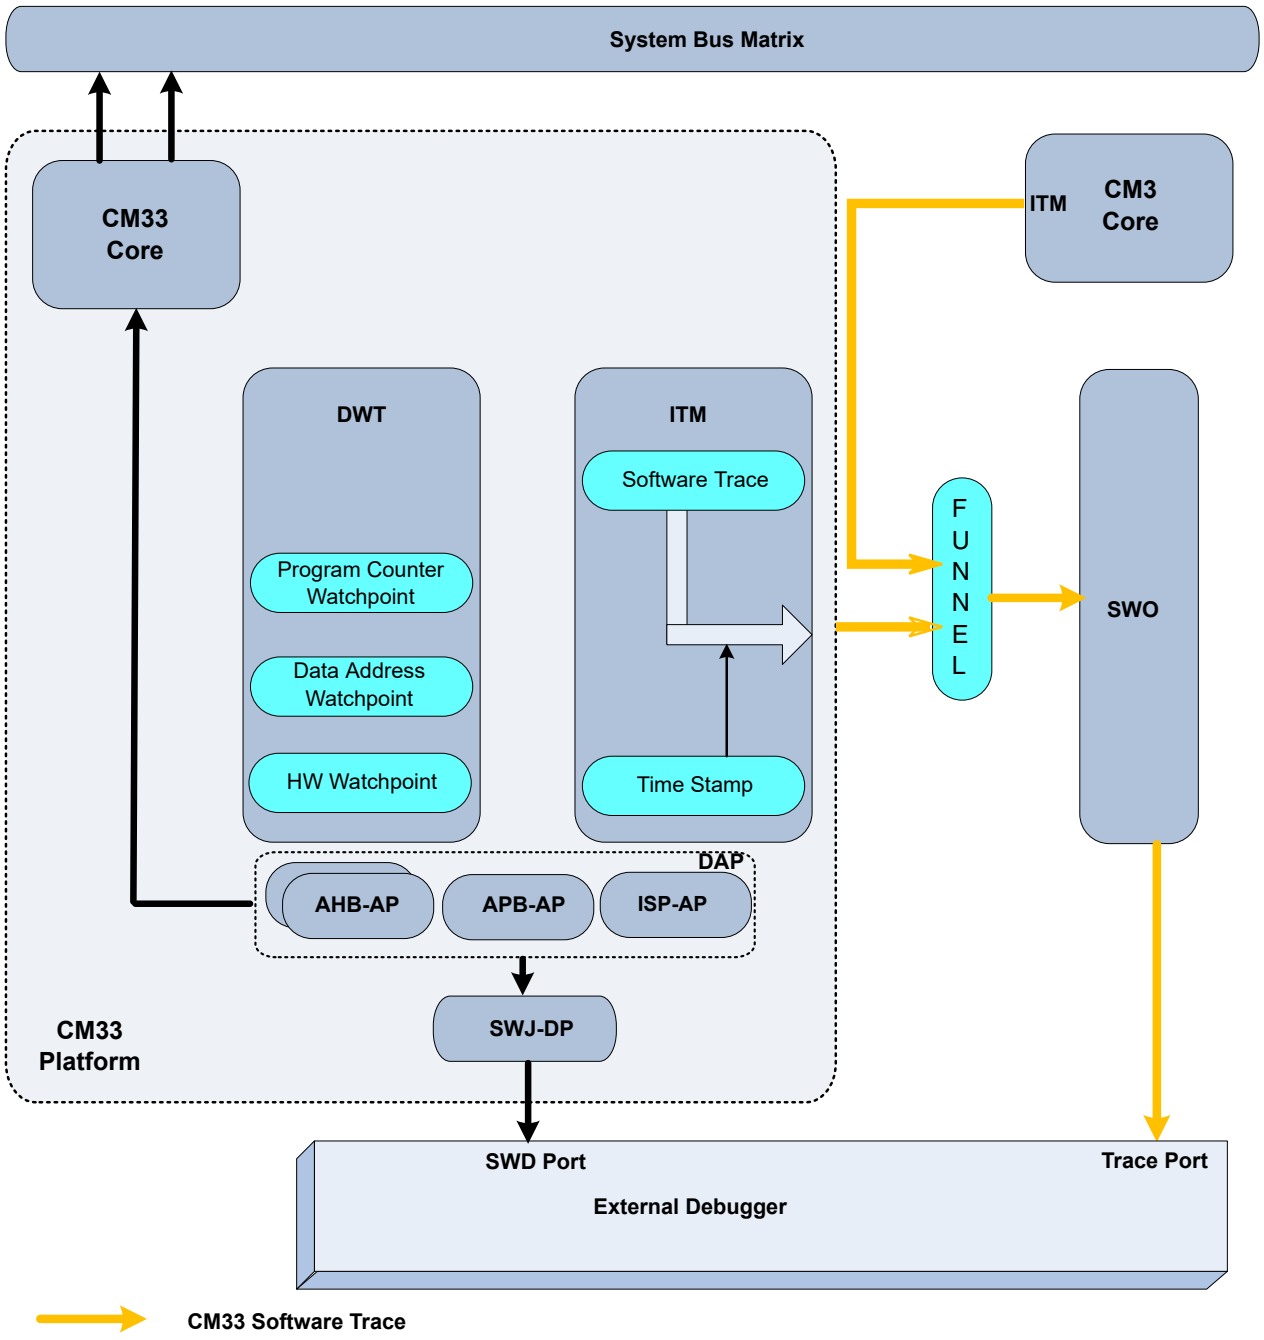

Figure 64. Software debug and trace flow

23.4.2 Data Watchpoint and Trace

The CM33 Data Watchpoint and Trace (DWT) module generates trace information in the core. It has 4 independent watchpoints which can be programmed to compare data, address, or to function as a hardware watchpoint. The DWT can be configured to generate PC samples at defined intervals and to generate interrupt event information. The CM33 DWT also provides periodic requests for protocol synchronization to the ITM and the SWO.

23.4.3 Breakpoint Unit

The CM33 Breakpoint Unit (BPU) module comprises up to 8 instruction address comparators. It provides breakpoint functionality on all instructions fetched across the entire address range in which code can be located.

23.4.4 Instrumentation Trace Macrocell (ITM)

The ITM generates trace information as packets. There are multiple sources that can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output. The sources in decreasing order of priority are:

- Software Trace: Application software can write console messages directly to ITM stimulus ports, and output them to the host as trace packets.
- Hardware trace: The DWT generates these packets, and the ITM outputs them.
- Timestamping: ITM can generate timestamp packets that are inserted in to the trace stream, to help the host debugger to find out the timing of events. Timestamps are generated relative to packets. The ITM contains a 21-bit counter to generate the timestamp.

Trace data from ITM will be forwarded to SWO and streamed out via the trace port.

23.5 Cryptographic Acceleration Unit V3 (CAU3) debug

This section covers the debug mechanisms associated with the CAU3 security module.

23.6 Cross Trigger Interface (CTI)

Table 185. CTI input triggers (CM33)

Table 186. CTI output triggers (CM33) (continued)

Trigger bit	Description	Connection	Acknowledge, handshake
3	Interrupt request 1	CTI to system	Acknowledged by writing to the CTINTACK register in ISR
2	Interrupt request 0		
1	Processor restart	CTI to processor	Processor restarted
0	Processor debug request		Acknowledged by the debugger writing to the CTINTACK register

Table 187. CTI input triggers (CM3)

Trigger Bit	Source Signal	Source Module	Description
7	--	--	--
6	ETMTRIGGER[2]	Processor DWT	Processor DWT trigger
5	ETMTRIGGER[1]	Processor DWT	Processor DWT trigger
4	ETMTRIGGER[0]	Processor DWT	Processor DWT trigger
3	--	--	--
2	--	--	--
1	--	--	--
0	HALTED	Processor core	Processor core's output indicating that it has entered the debug mode.

Here the "Source Signal" is the output port of the "Source Module". They are connected to the input triggers of the CTI.

Table 188. CTI output triggers (CM3)

Trigger Bit	Destination Signal	Destination Module	Description
7	DBGRESTART	Processor core	Request Processor core to quit the debug mode
6	--	--	--
5	--	--	--
4	--	--	--
3	cti_irq	NVIC	CTI interrupt
2	cti_irq	NVIC	CTI interrupt
1	--	--	--
0	EDBGRQ	Processor core	External request Processor core to enter the debug mode

Here the "Destination Signal" is the input port of the "Destination Module". The output triggers of the CTI are connected to the input port of the destination modules.

23.7 Low power debug

Low power debug is controlled by DBGCTL[SOD] field in the CMC. When set, the debugger is disabled (debug power up acknowledge negates) when the CM33 sleeps and the device fully enters the low power mode. When clear, the clocks to the CM33 remain enabled when the CM33 sleeps and debug is attached (debug power up request is asserted) to maintain the debug connection, and the low power mode is not completely entered. Software can modify DBGCTL[SOD] before each low power entry. There are two modes supported:

- Clock gated mode
- Power gated mode

23.7.1 Clock gated modes

- If the DAP CXXXPWRUPREQ is high and the system attempts to enter STOP mode, the DAP clock and the Core clock continue to run to support core register access and trace, in this case the debug module will have access to core registers but not to modules which are clock gated.
- If the device is in STOP mode (core clock gated), the debugger can assert EDBGRQ (CM33 EDBGRQ) in dap_ctrl_halt_req register, this will wake up the core and will move it into a halted state.

23.7.2 Power gated modes

During power gated modes, the debugger will loose connection and it cannot gather any data in the duration when device stays in low power mode. If the device is expected to go into low power mode and it is desired to gain control of device when it exits low power modes.

Chapter 24
Reset

24.1 Introduction

The following reset sources exist in this device:

Table 189. Reset sources

Reset type	Source
Power	• System Power-On Reset (POR) • System Low-Voltage Detect (LVD) • System High-Voltage Detect (HVD)
External	• External Pin Reset (RESET_b) • Wake-Up Unit (WUU)
Internal	• Watchdog (WDOG) timer • Software (SW) • System Clock Generator (SCG) • Reset Acknowledge timeout (RSTACK) • Low Power Acknowledge (LPACK) • Lockup (LOCKUP) • Debug Access Port (DAP) • EdgeLock Secure Enclave (ELE) • Tamper

Each system reset source has a corresponding bit that is maintained in the System Reset Status register through reset. This information can be used to take appropriate action when coming out of a reset.

24.2 Power reset sources

To ensure predictable operation of the device, the supply voltages must remain in their specified ranges during execution. Because this is not possible during power-up and power-down, the device implements multiple voltage monitors to detect when the supply is outside an acceptable range. When this occurs, the voltage monitor asserts a reset to halt execution and prevent unexpected behavior. The voltage monitors detect power-on events as well as low and high voltage events.

24.2.1 Power-on reset (POR)

The POR voltage monitor is used to ensure that the voltage applied to the system is high enough for other analog modules such as the bias circuits and low voltage monitors to operate correctly. When voltage is initially applied to the device or when the supply voltage drops below the POR falling threshold, the POR monitor triggers the POR reset condition to the device.

The POR reset condition asserts POR reset to all power domains. A POR reset sets the appropriate bits in the CMC registers so that software can determine that a POR reset has occurred.

24.2.2 Low-voltage detect (LVD)

The LVD monitors are used to ensure that the voltage supplies to the device are high enough for the logic and memories to operate correctly. When voltage is initially applied to the device, the POR voltage monitor holds the LVD monitors in reset until the voltages are high enough. The LVD monitors continue to hold the device in reset until all monitoring voltages have risen above the respective default LVD Low thresholds (VLVDL). The LVD monitors are enabled by default.

When enabled, the LVD monitor generates a reset when the voltage drops below the V_{LVD} threshold. The voltage threshold at which the LVD reset asserts is programmable. This ensures that the device halts operation and remains in reset while the monitored voltage is not within the desired range.

The LVD monitors are available in the Active, Sleep, Deep Sleep and Power Down modes. Except VDD_VSYS LVD, the other LVD monitors are disabled in Deep Power Down modes. See Module operation in low power modes for the available modes.

The reset sources triggered by individual LVD monitors are combined into a single LVD reset. The LVD reset condition asserts a POR reset in all power domains with only the POR/LVD/HVD detection logic remaining operational. An LVD reset sets the appropriate bits in the CMC registers so that software can determine that an LVD reset has occurred.

24.2.3 High-voltage detect (HVD)

The HVD monitors are used to ensure that the voltage supplies to the device are within operation range for the logic and memories using those power supplies. The HVD monitors are disabled by default, but when an HVD circuit is enabled, the HVD monitor generates a reset when the voltage rises above the V_{HVD} threshold. This ensures that the device halts operation and remains in reset while the monitored voltage is not within the desired range.

The HVD monitors are available in the Active, Sleep, Deep Sleep and Power Down modes. Except VDD_VSYS HVD, the other HVD monitors are disabled in Deep Power Down modes. See Module operation in low power modes for the available modes.

The reset source triggered by individual HVD monitors are combined into a single HVD reset. The HVD reset condition asserts a reset to all power domains with only the POR/LVD/HVD detection logic remaining operational. An HVD reset sets the appropriate bits in the CMC registers so that software can determine that an HVD reset has occurred.

24.3 External reset sources

External resets are provided so that the device can be reset or awakened from very low power states. This allows the device to start at the correct time from a known state.

24.3.1 External pin reset (RESET_b)

The RESET_b pin is a bi-directional open-drain pin with internal pull-up resistor. The RESET_b pin is functional in two modes:

- During active and low power modes, the RESET_b pin can be asserted externally to force the device into Pin reset condition.
- During reset, the RESET_b drives low until the device has completed hardware initialization, at which point the RESET_b pin is released. If the RESET_b pin is asserted externally, then the device will remain in reset until the RESET_b input is pulled high.

The RESET_b pin implements a digital filter that software can configure to filter out glitches on the RESET_b pin that are less than 1-32 CMC clock cycles. The filter is bypassed in low power modes if the CMC clock is disabled. The CMC reset filter clock source is the SLOW_CLK.

The RESET_b is multiplexed on PTD0 pin on this device. RESET_b is the default function of this GPIO pin. Asserting RESET_b wakes the device from any mode.

The PIN reset condition triggers the CMC to assert a WARM reset to all power domains. A PIN reset sets the appropriate fields in the CMC registers so that software can determine that a PIN reset has occurred.

24.3.2 Wake-up unit (WAKEUP)

The Wake-Up Unit (WUU) provides for a number of external pins and on-chip peripherals to wake the device from Power Down or Deep Power Down modes. See the WUU chapter for a list of external and internal reset sources connected to the WUU.

On a wakeup from Power Down or Deep Power Down modes, the power management logic triggers a WAKEUP reset in the power domains that had been powered off.

The WAKEUP reset condition triggers the CMC to assert a POR reset to the power domains that were powered down. The system voltage domain is not affected by a WAKEUP reset. A WAKEUP reset sets the appropriate fields in the CMC registers so that software can determine that a WAKEUP reset has occurred.

24.4 Internal reset sources

Internal resets are provided so that the device can be reset when certain erroneous conditions are detected. This allows the device to recover from the erroneous conditions and restart from a known state.

24.4.1 Watchdog (WDOG) timer

The WDOG reset is generated by one of the WDOG modules.

The WDOG monitors the operation of the system by receiving periodic communication from software, known as servicing or refreshing the WDOG. If this periodic servicing does not occur, then the Watchdog triggers a WDOG reset condition.

The WDOG reset condition triggers the CMC to assert a WARM reset to all power domains. A WDOG reset sets the appropriate fields in the CMC registers so that software can determine that a WDOG reset has occurred.

24.4.2 Software (SW)

During execution, if the software detects erroneous operation, the software can initiate a reset to restart the device from a known state.

The SW reset condition triggers the CMC to assert a WARM reset to all power domains. A SW reset sets the appropriate fields in the CMC registers so that software can determine that a SW reset has occurred.

24.4.3 System Clock Generation (SCG)

The SCG module contains a clock monitor, which, if enabled, detects a loss of the external clock. A loss of external clock triggers the SCG reset condition.

The SCG reset condition will assert a WARM reset in all power domains. The CMC_SRS[SCG] and CMC_SRS[WARM] status bits are set on a SCG reset condition.

The SCG clock monitor must be enabled for a loss of clock to be detected. For details on enabling the clock monitor, see the SCG chapter. To prevent unexpected reset events, clock monitors must be disabled before entering any low-power modes that the external clocks are not present.

24.4.4 Reset Acknowledge timeout (RSTACK)

The reset state machine includes a timeout counter that is triggered by the reset state machine not progressing within 8192 cycles of the FRO-6MHz/DIV6 clock, this will trigger the RSTACK reset condition.

The RSTACK reset condition triggers the CMC to assert a WARM reset to all power domains. An RSTACK reset sets the appropriate fields in the CMC registers so that software can determine that an RSTACK reset has occurred.

24.4.5 Low Power Acknowledge timeout (LPACK)

The low power entry state machine includes a timeout counter that is triggered if a module does not acknowledge entry into a low power mode after 8192 cycles of the FRO-6MHz/DIV6 clock, this will trigger the LPACK reset condition.

The LPACK reset condition triggers the CMC to assert a WARM reset to all power domains. An LPACK reset sets the appropriate fields in the CMC registers so that software can determine that an LPACK reset has occurred.

24.4.6 Lock up (LOCKUP)

The Cortex-M33 core will enter the lockup state as a result of certain illegal operations, this will trigger the LOCKUP reset condition.

The LOCKUP reset condition triggers the CMC to assert a WARM reset to all power domains. A LOCKUP reset sets the appropriate fields in the CMC registers so that software can determine that a LOCKUP reset has occurred.

24.4.7 Debug Port (DAP)

Any debug access port that can initiate a reset request from a connected debugger triggers the DAP reset condition.

The DAP reset condition triggers the CMC to assert a WARM reset to all power domains. A DAP reset sets the appropriate fields in the CMC registers so that software can determine that a DAP reset has occurred.

24.4.8 EdgeLock secure enclave (ELE)

Internal EdgeLock enclave resets are provided so that the security module can be reset when security violation or certain erroneous conditions are detected. This allows security module to recover from the erroneous conditions. The reset sources in the security module available in this device are as follows.

- Security violation
- Security Watchdog timer
- Security software
- Security CPU lockup
- Security debug
- eFuse loading error

Whenever the security module detects a security violation or an erroneous condition, this will trigger the EdgeLock enclave reset condition.

The EdgeLock enclave reset condition will trigger the Core Mode Controller (CMC) to assert a WARM reset to all power domains. An EdgeLock enclave reset will set the appropriate bits in the CMC registers so that software can determine that an EdgeLock enclave reset has occurred.

24.4.9 Tamper detect (TAMPER)

Whenever a tamper detection module detects a tamper event, this will trigger the TAMPER reset condition.

The TAMPER reset condition triggers the CMC to assert a WARM reset to all power domains. A TAMPER reset sets the appropriate fields in the CMC registers so that software can determine that a TAMPER reset has occurred.

24.4.10 Radio reset request

Radio reset request could happen when NBU CM3 meet timeout or NBU system hang. It should be configured in advance to decide reset Radio subsystem or whole chip.

How to handle reset is under discussion. Will share more when available

24.5 Reset type

This section describes the different resets that can be generated on this device and their respective reset sequences. Reset conditions on this device are categorized into two types, POR and WARM resets.

24.5.1 POR reset

Each power domain generates a POR that is used to reset the entire device, including debug logic and mode control logic. The POR for each power domain can assert as a result of the following events.

- Initial power-up of MCU
- Low or High Voltage Detect
- Power domain wakeup from Power Down or Deep Power Down (varies per domain)

A POR does not guarantee the contents of on-chip SRAM, except for a Power Down wakeup and then only for the SRAM that is configured to retain state.

24.5.1.1 POR reset sequence

The following steps are performed as part of the POR (or LVD/HVD) sequence:

1. RESET_b pin is driven low and internal reset signals assert.
2. POR and LVD signals negate and clocks are enabled in their default configuration.
3. Internal reset remains asserted for 15 clock cycles.
4. Internal reset to Flash and Fuse controller negate and their initialization sequences commence.
5. Initialization sequences for Flash and Fuse complete.
6. Internal trim registers are loaded and RESET_b pin is tri-stated.
7. Reset state machine waits for RESET_b pin input to pull high or drive high externally.
8. Internal reset signals negate.
9. Core exits reset and fetches the initial program counter and stack pointer from Boot ROM.

When the device wakes up from Deep Power Down or Power Down mode, the reset sequence is slightly different from the POR reset sequence. They are described in the subsequent sections.

24.5.1.2 Deep Power Down (DPD) reset sequence

The following steps are performed as part of the Deep Power Down wakeup sequence:

1. Internal reset signals assert.
2. Wakeup signal negates and clocks are enabled in their default configuration.
3. Internal reset remains asserted for 15 clock cycles.
4. Internal reset to Flash and Fuse controller negate and their initialization sequences commence.
5. Initialization sequences for Flash and Fuse complete.
6. Internal trim registers are loaded.
7. Internal reset signals negate.
8. Core exits reset and fetches the initial program counter and stack pointer from Boot ROM.

The RESET_b pin is not driven low by a Deep Power Down reset sequence unless the RESET_b pin was used as the wake up source.

A wakeup from Deep Power Down via the RESET_b pin will follow the warm reset sequence.

24.5.1.3 Power Down (PD) reset sequence

The following steps are performed as part of the Power Down wakeup sequence:

1. Internal reset signals assert.
2. Clocks are enabled in their default configuration.
3. Internal reset remains asserted for 15 clock cycles.
4. Internal trim registers are loaded.
5. Internal reset signals negate.
6. Core exits reset and fetches the initial program counter and stack pointer from Boot ROM.

The RESET_b pin is not driven low by a Power Down reset sequence unless the RESET_b pin was used as the wake up source.

A wakeup from Power Down via the RESET_b pin will follow the warm reset sequence.

24.5.2 Warm reset

A WARM reset re-initializes the device to a known state once it has already been running for a period of time.

A WARM reset resets most of the logic in each power domain. Warm resets are divided into fatal reset sources and non-fatal reset sources. See the CMC chapter for which reset sources are fatal resets.

Non-fatal reset sources can be configured to generate an interrupt instead of the WARM reset. If software can clear the non-fatal reset source (including status flag) within 8192 cycles of the FRO-6MHz/DIV6 clock then the WARM reset is averted. Non-fatal resets retain the contents of on-chip SRAM.

Fatal reset sources cannot be configured to generate an interrupt, and do not guarantee the contents of on-chip SRAM.

The following steps are performed as part of the warm reset sequence:

1. RESET_b pin drives low and internal reset signals assert.
2. Clocks are enabled in their default configuration.
3. Internal reset remains asserted for 15 clock cycles.
4. Internal reset to Flash and Fuse controller negate and their initialization sequences commence.
5. Initialization sequences for Flash and Fuse complete.
6. Internal trim registers are loaded and RESET_b pin is tri-stated.
7. Reset state machine waits for RESET_b pin input to pull high or drive high externally.
8. Internal reset signals negate.

Core exits reset and fetches the initial program counter and stack pointer from Boot ROM.

Chapter 25
Clocking

25.1 Introduction

The heart of the clocking architecture is the System Clock Generator (SCG) module. The SCG controls multiple clock sources that are distributed to the main CPU platform, the memory modules and the peripheral modules. The peripheral modules have an *interface* clock that is used by the CPU/DMA to interface with each module's registers. When applicable, modules may also have *functional* clocks to provide the main timing function of the module's application. For example, functional clocks can be used to source the baud rate for a serial communications peripheral or to clock the counter of a timer peripheral.

Each module's interface clock comes directly from the SCG. The SCG provides functional clock options via the Module Reset and Clock Control (MRCC) module. Software configures the MRCC module to select a module's functional clock. The MRCC module also provides functional clock dividers as needed.

The following diagram shows the clock sources and clock trees.

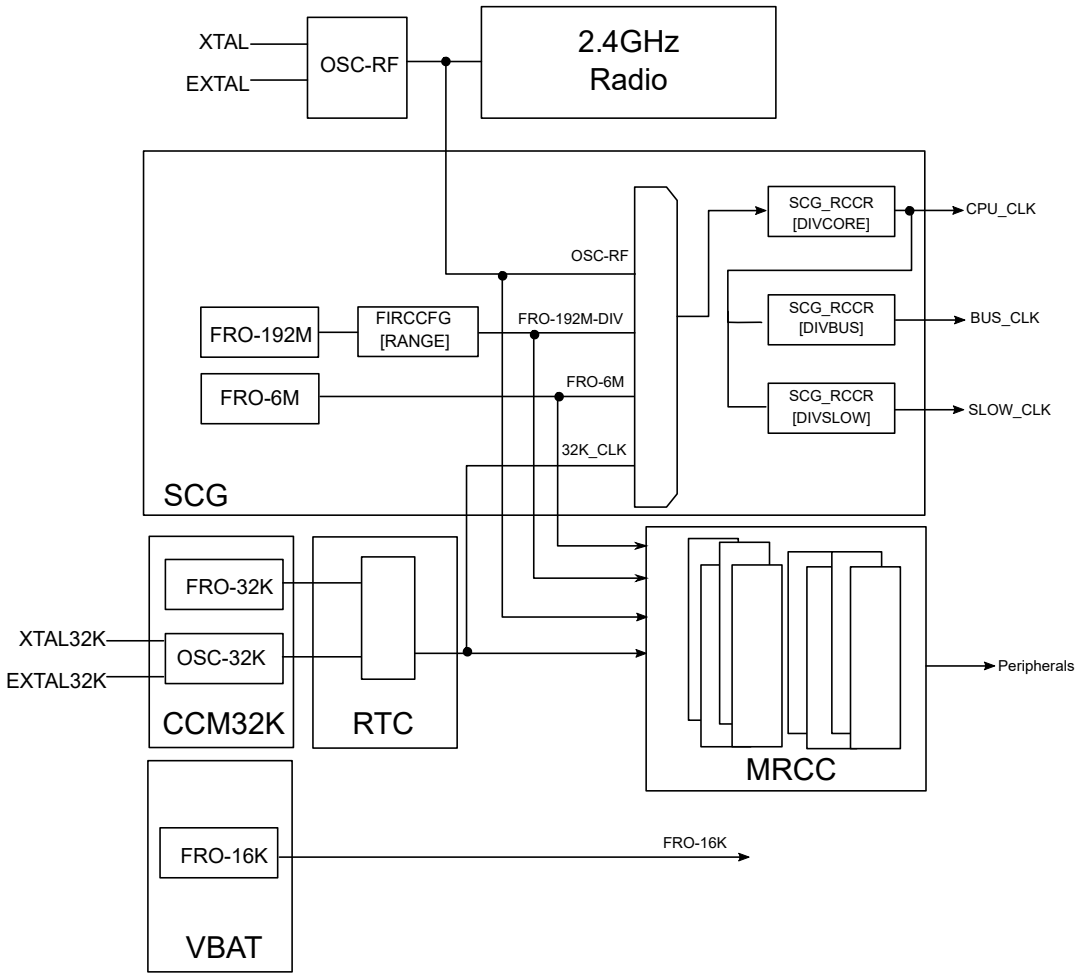

Figure 65. Device clock sources and trees

The CPU_CLK can be sourced directly from the following:

- FRO-192M-DIV (96 MHz) – general default
- FRO-6M (~6 MHz) – optional default

- 32K_CLK
- OSC-RF

Each of the above clock sources can be divided via the SCG_RCCR[DIVCORE] divider to avoid clocking above the max CPU frequency or to reduce the CPU frequency for lower power consumption.

Other major clock trees are fed from the CPU_CLK for the on-chip peripheral and memory interfaces that are required to be either equal to the CPU_CLK frequency or an integer divide or multiple of the CPU_CLK.

The BUS_CLK and the SLOW_CLK are both sourced from the CPU_CLK. Each of this clock tree has its own independent clock divider to provide frequencies that are an integer divide of the CPU_CLK.

Modules that are required to function at a faster frequency than the CPU_CLK obtain a functional clock via the MRCC.

25.2 Clock definitions

The following table describes the clocks in the device.

Table 190. Clock definitions

Clock name	Description
CPU_CLK[1]	The main CPU clock. The CPU_CLK can be provided by one of the clock sources within the SCG, and also from the clock sources not specifically configured by the SCG. The selected clock source is fed through the DIVCORE divider stage prior to clocking the CPU. The CPU_CLK can be gated off, while other clock trees are allowed to function. The maximum frequency of the CPU_CLK is 96 MHz.
BUS_CLK[1]	The BUS_CLK provides synchronization between the CPU and the peripherals. The BUS_CLK is an integer divide or equal to the CPU_CLK. It is fed via the SCG_RCCR[DIVBUS] divider stage. The BUS_CLK can be gated off, while other clock trees are allowed to function. The maximum frequency of the BUS_CLK is 96 MHz.
SLOW_CLK	The SLOW_CLK provides synchronization between the CPU and peripherals that operate at lower frequencies. The SLOW_CLK is an integer divide of the CPU_CLK. The SLOW_CLK is fed from the CPU_CLK via the SCG_RCCR[DIVSLOW] divider stage. The SLOW_CLK can be gated off, while other clock trees are allowed to function. The maximum frequency of the BUS_CLK is 24 MHz.
OSC-32K	Oscillator with external crystal resonator of 32 kHz
OSC-RF	External crystal oscillator (26 MHz or 32 MHz) used by the Radio Frequency modules
FRO-32K	32 kHz Free Running Oscillator clock reference
32K_CLK	32 kHz clock source from either OSC-32K or FRO-32K
FRO-6M	6 MHz Free Running Oscillator clock source
FRO-192M-DIV	192 MHz Free Running Oscillator clock source with dividers that can be used for high speed operation

1. The maximum frequency of this clock is different depending on VDD_CORE, see data sheet for details.

25.3 MRCC clock outputs

The SCG provides output clock trees for peripheral modules that require functional clocks. Functional clocks are used as the fundamental timing for applications of a module, providing asynchronous clocking from the CPU main clock. This allows modules to operate at different rates compared to the CPU platform. Examples of how functional clocks are used include:

- Clocking the reference counter of a timer module
- Sourcing the baud rate for the external communication of a serial communications peripheral

Each module that needs functional clocking has its own MRCC register that provides a clock select field, a clock disable, a divider of the selected clock source, and a peripheral reset bit that provides independent resetting of the peripheral.

25.4 Clock gating

Clock gating of modules helps consume power only for modules needed for their end application. The clock to each module can be gated on or off via a programmable register.

Each peripheral has independent clock gating for both the peripheral interface clock and the peripheral functional clock. This clock gating is controlled via the peripheral's MRCC register. Clearing MRCC[CC] disables both the interface clock and functional clock of a peripheral.

The CPU_CLK, BUS_CLK, and SLOW_CLK are always enabled in the Active modes. If these clocks are not used in low-power modes, they are disabled via the CMC and SPC modules.

25.5 Module/Peripheral clocking

The following tables detail the various clocks associated with a specific module/peripheral.

Table 191. Module/Peripheral clocking options

Peripheral/Module	Interface clock	Module/Peripheral condition out of POR/ reset condition [1]	External/Alternative input clocks	External output clocks
CPU and system modules				
EWM0	SLOW_CLK	Disabled	—	—

1. The flash read cycles could be multiple of CPU clock cycle which is configured by FMU_FCTRL[RWSC]

Chapter 26
System Clock Generator (SCG)

26.1 Chip-specific SCG information

Table 193. Reference links to related information

Topic	Related module	Reference
Full description	SCG	SCG
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

26.1.1 Module instances

This device has one instance of the SCG module, SCG0.

26.1.2 Clock naming

Each device that has an SCG module generally has a few differences from SCG modules in different devices. This section describes those differences.

Signal name differences

Table 194. Device signal names = SCG signal names

Device signal		SCG chapter signal	
Free-Running Oscillator – 192 MHz	FRO_192M	FIRC	Fast internal reference clock
Free-Running Oscillator – 6 MHz	FRO_6M	SIRC	Slow internal reference clock
FRO-32K or OSC-32K is selected to become the 32K_CLK (See note below)	32K_CLK	ROSC	Real-time clock oscillator clock
OSC-RF	OSC_RF	RFOSC, SOSC	External RF clock, system oscillator clock
Not available		LPFLL	Low power FLL clock

NOTE

Separate Power Domain: The FRO-32K and the OSC-32K clocks are generated in a separate module CCM32K (32 kHz Clock Control Module) within a different power domain. The different power domain can be powered independently, allowing the RTC module (also in this separate power domain) to be clocked by one of these clock sources (FRO-32K or OSC-32K). The input to the SCG from this separate power domain is called 32K_CLK. The OSC-RF is generated in the RF module within a different power domain. The input to the SCG from this power domain is called OSC-RF.

26.1.3 SCG clock section CLKOUTCNFG[CLKOUTSEL]

The SCG can select the system clock from the following source by CLKOUTCNFG[CLKOUTSEL]:

- 0001b - System OSC (SOSC_CLK)

- 0010b - Slow IRC (SIRC_CLK)
- 0011b - Fast IRC (FIRC_CLK)
- 0100b - RTC OSC (ROSC_CLK)

NOTE

The SCG slow clock cannot be selected as SCG system clock.

26.2 Introduction

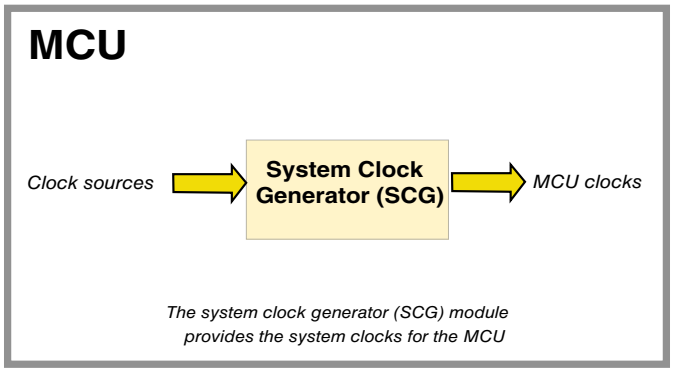

Figure 66. System Clock Generator (SCG) in MCU

The system clock generator (SCG) module provides the system clocks for the MCU. The SCG takes clock inputs from a variety of sources and generates the types of clocks that the MCU requires.

- Available clock source inputs for the SCG include:
  - System oscillator clock (SOSC)
  - Slow internal reference clock (SIRC)
  - Fast internal reference clock (FIRC)
  - Real-Time Oscillator (ROSC)

Clock dividers are available for:

- core clock (DIVCORE)
- peripheral interface clock (DIVSLOW)
- bus clock (DIVBUS)

26.2.1 Features

Key features of the SCG module are:

- 2 Internal reference clock (IRC) generators:
  - High frequency free-running oscillator (FRO_192M) with trim capability
  - Low frequency running oscillator (FRO_6M) with trim capability
  - Either of the free-running oscillators (FRO_192M, FRO_6M) can be selected as the clock source for the system clocks

— The external clock source (RFOSC) can also be used as a source clock for the systems clocks.

- System Crystal Oscillator:
  — Can be selected as the clock source for the system clocks
- Real Time Oscillator Clock (ROSC):
  — Can be selected as the clock source for the device. See the chip specific sections to ascertain which signal the RTC input maps to.
- Clock monitor with reset and interrupt request capability for SOSC, ROSC clocks

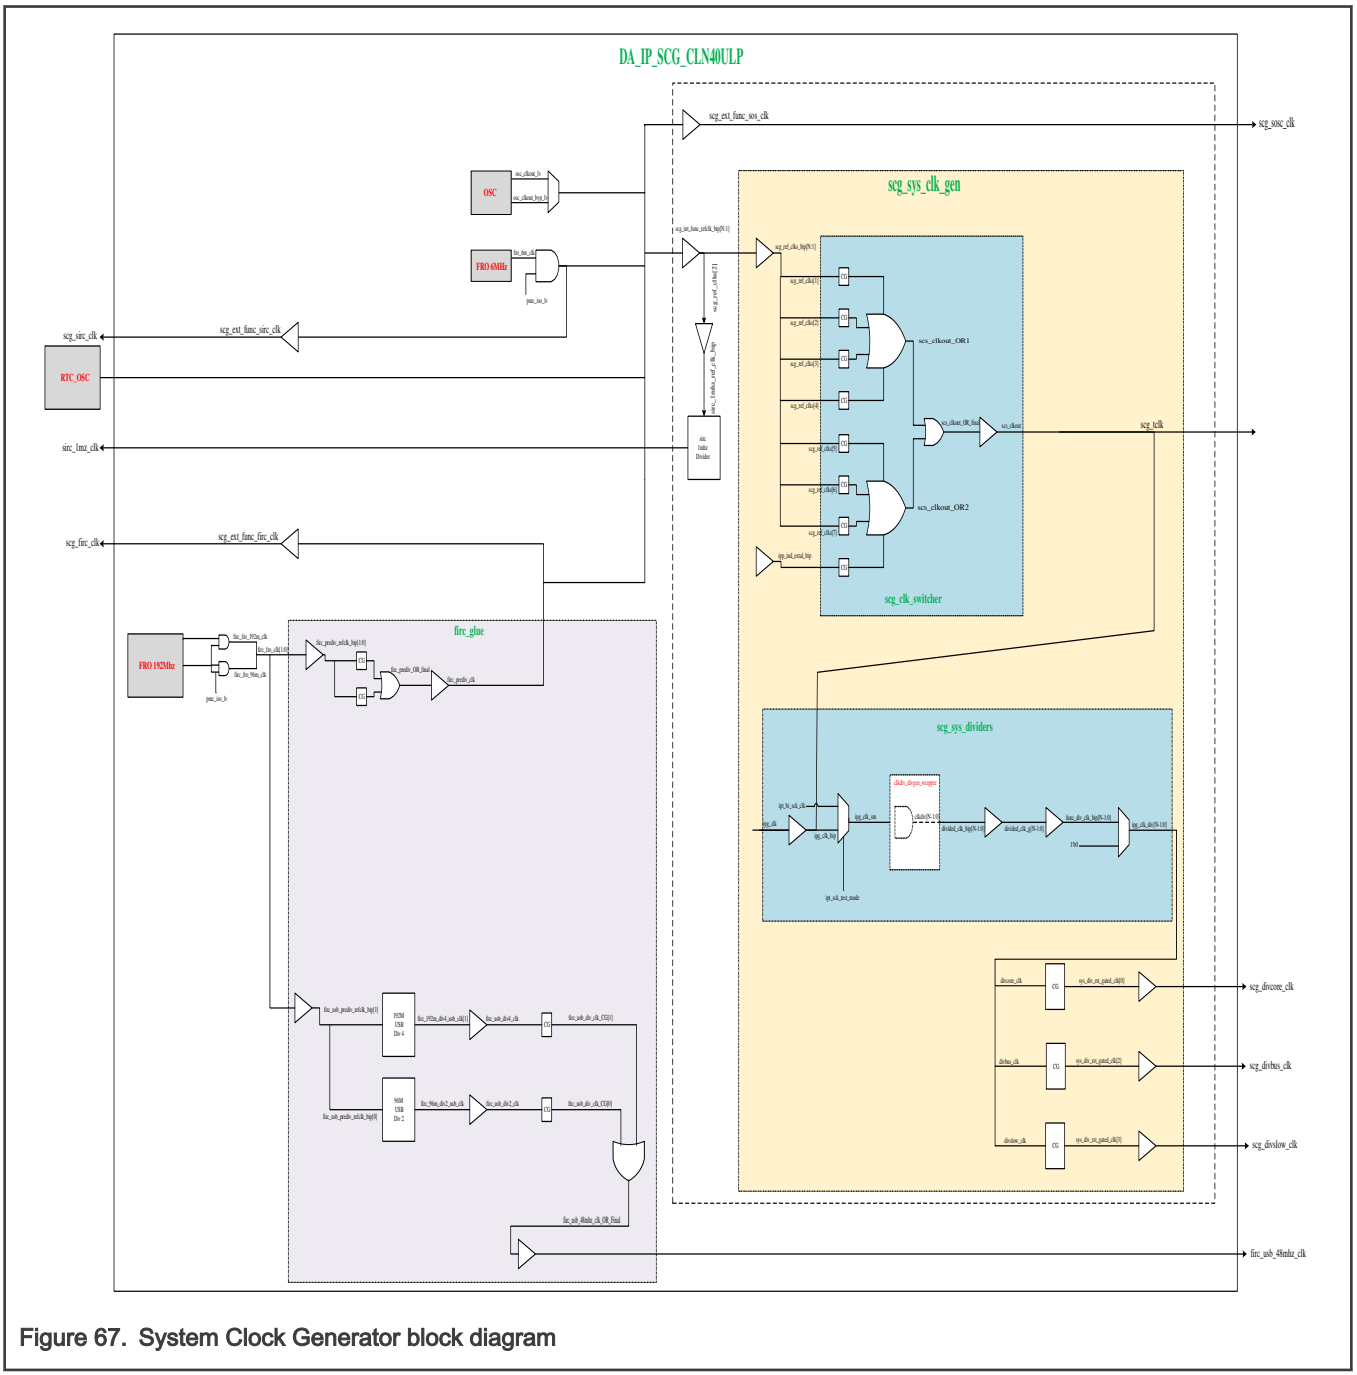

Figure 67. System Clock Generator block diagram

NOTE

To identify the oscillators used in your specific device, see the chip-specific SCG information or clocking chapters.

26.3 Functional description

26.3.1 SCG Clock Mode Transitions

The following figure shows the valid clock mode transitions supported by SCG.

Slow IRC (SIRC) boot mode is not supported on this device.

Figure 68. SCG Valid Mode Transitions

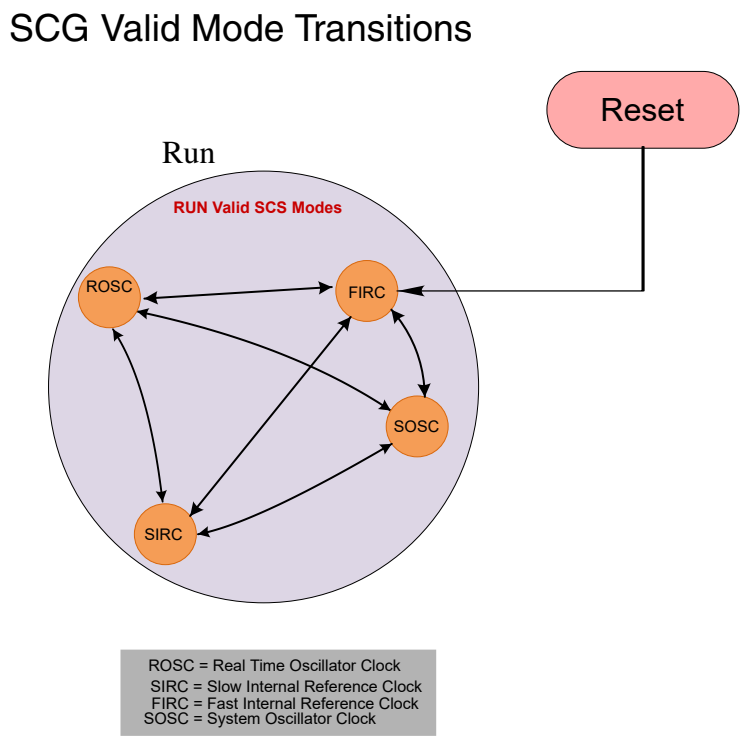

Figure 69. SCG Valid Mode Transitions

The SCG will restrict programming into invalid clock modes and writes to System Clock Source (SCS) bits will be ignored. When a transition between run modes or a transition into wait mode occurs, the SCG completes the switch to the clock mode as defined in the Run Clock Control Register (RCCR). When completed, the system switches to the selected run/wait mode.

The modes of operation listed in the following table are the valid modes for this implementation of the SCG.

Table 195. SCG modes of operation

Mode	Description
System Oscillator Clock (SOSC)	System Oscillator Clock (SOSC) mode is entered when all the following conditions occur: • RUN MODE:

Table continues on the next page...

Table 195. SCG modes of operation (continued)

Mode	Description
	— 0001 is written to RCCR[SCS] • SOSCEN = 1 • SOSCVLD = 1 In SOSC mode, SCSCLKOUT and system clocks are derived from the external System Oscillator Clock (SOSC).
Slow Internal Reference Clock (SIRC)	Slow Internal Reference Clock (SIRC) mode is entered when all the following conditions occur: • RUN MODE: — 0010 is written to RCCR[SCS] • SIRCVLD = 1 In SIRC mode, SCSCLKOUT and system clocks are derived from the slow internal reference clock.
Fast Internal Reference Clock (FIRC)	Fast Internal Reference Clock (FIRC) mode is the default clock mode of operation and is entered when all the following conditions occur: • RUN MODE: — 0011 is written to RCCR[SCS] • FIRCEN = 1 • FIRCVLD = 1 In FIRC mode, SCSCLKOUT and system clocks are derived from the fast internal reference clock. Two frequency range settings are available for FIRC clock as described in the FIRC[RANGE] register definition. Changes to FIRC range settings will be ignored when FIRC clock is enabled.
Real Time Clock Oscillator (RTCOSC)	Real Time Clock Oscillator (RTCOSC) mode is entered when all the following conditions occur: • RUN MODE: — 0100 is written to RCCR[SCS] • ROSCVLD = 1 In RTCOSC mode, SCSCLKOUT and systems clocks are derived from the external RTC Oscillator Clock (RTCOSC).
Stop	Entered whenever the MCU enters a Stop state. The power modes are chip-specific. For power mode assignments, see the chapter that describes how modules are configured and SCG behaviour during Stop recovery. Entering Stop mode, all SCG clock signals are static, including SCG system clocks (DIVCORE, DIVBUS, DIVSLOW). There are exceptions; the following clocks can continue to run and stay enabled in the following cases: SIRC is available in SLEEP mode when all the following conditions become true: • SIRCCSR[SIRCSTEN] = 1 FIRC is available in SLEEP mode when all the following conditions become true: • FIRCCSR[FIRCEN] = 1

Table continues on the next page...

Table 195. SCG modes of operation (continued)

Mode	Description
	• FIRCCSR[FIRCSTEN] = 1 SOSC is available in SLEEP mode when all the below conditions are true. • SOSCCSR[SOSCEN] = 1 • SOSCCSR[SOSCSTEN] = 1

26.4 Memory Map/Register Definition

This section includes the memory map and register definition.

The SCG registers can only be written when in supervisor mode. Write accesses when in user mode will result in a bus transfer error. Read accesses may be performed in both supervisor and user mode.

26.4.1 SCG register descriptions

- For any writeable SCG registers, only 32-bit writes are allowed. 8-bit or 16-bit writes will result in transfer errors.

26.4.1.1 SCG memory map

26.4.1.4 Clock Status Register (CSR)

Offset

Register	Offset
CSR	10h

Function

The Clock Status Register (CSR) returns the currently configured system clock source and the system clock dividers for the core (DIVCORE) and peripheral interface clock (DIVSLOW). The SCG_CSR reports the configuration set by one of the clock control registers SCG_RCCR.

Note: Writing to the Clock Status Register (CSR) will result in a transfer error.

26.4.1.5 Run Clock Control Register (RCCR)

Offset

Register	Offset
RCCR	14h

Function

This register controls the system clock source and the system clock dividers for the core, platform, external and bus clock domains when in Run mode only. This register can only be written using a 32-bit write. Selecting a different clock source when

in RUN requires that clock source to be enabled first and be valid before system clocks switch to that clock source. If system clock divide ratios also change when selecting a different clock mode when in RUN, new system clock divide ratios will not take affect until a new clock source is valid.

NOTE

Switching to new system clock source and system clock dividers must be done after previous RCCR changes have been completed and the Clock Status Register has updated to match the present RCCR setting.

Table continued from the previous page...

Field	Function
26-16 TRIMDIV	Fast IRC Trim Predivide Divider of SOSC for FIRC trimming. **NOTE** When selecting SOSC as FIRC trimming source the TRIMDIV register must be set to correct div ratio to generate 1 MHz output reference trimming clock. **NOTE** TRIMDIV is a N-Divider supporting a div ratio of 1 (TRIMDIV=0x000) to a div ratio of 2048 (TRIMDIV=0x7ff).
15-11 —	Reserved
10-8 —	Reserved
7-2 —	Reserved
1-0 TRIMSRC	Trim Source Configures the external clock source to tune the Fast IRC. TRIMSRC must be configured before programming FIRCSTAT register for trim update 00b - Reserved 01b - Reserved 10b - System OSC. This option requires that SOSC be divided using the TRIMDIV field to get a frequency of 1 MHz. 11b - RTC OSC (32.768 kHz)

26.4.1.12 Fast IRC Status Register (FIRCSTAT)

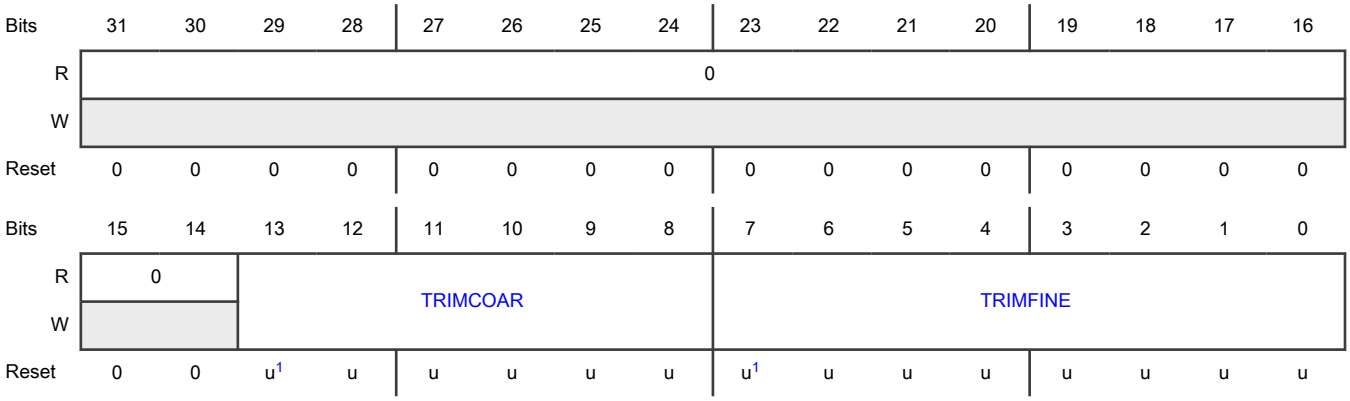
Offset

Register	Offset
FIRCSTAT	318h

Function

This register is loaded from IFR during reset. This register is uploaded with the trim values generated by FIRC auto-trimming which is enabled when FIRC is enabled and FIRCTREN=1 and FIRCTRUP=1. When FIRC auto-trimming is enabled and FIRCTRUP is off (Note: TRIMSRC needs to be programmed to TRIMSRC=10 or TRIMSRC=11), writes to this register are allowed and values written to this register are used to trim FIRC clock.

Diagram



1. Reset values are loaded out of IFR.

Fields

Field	Function
31-16 —	Reserved
15-14 —	Reserved
13-8 TRIMCOAR	Trim Coarse TRIMCOAR bits are used to coarsely trim the Fast IRC Clock to within approximately ±TBD% of the target frequency. When FIRC is enabled and auto trimming is enabled (FIRCTREN=1 and FIRCTRUP=1), then TRIMCOAR register gets uploaded with the trimmed coarse value. When FIRCTRUP=0, TRIMCOAR register is writable, to allow user programming of coarse trim values.
7-0 TRIMFINE	Trim Fine See the device's datasheet for the trim values.

26.4.1.13 RTC OSC Control Status Register (ROSCCSR)

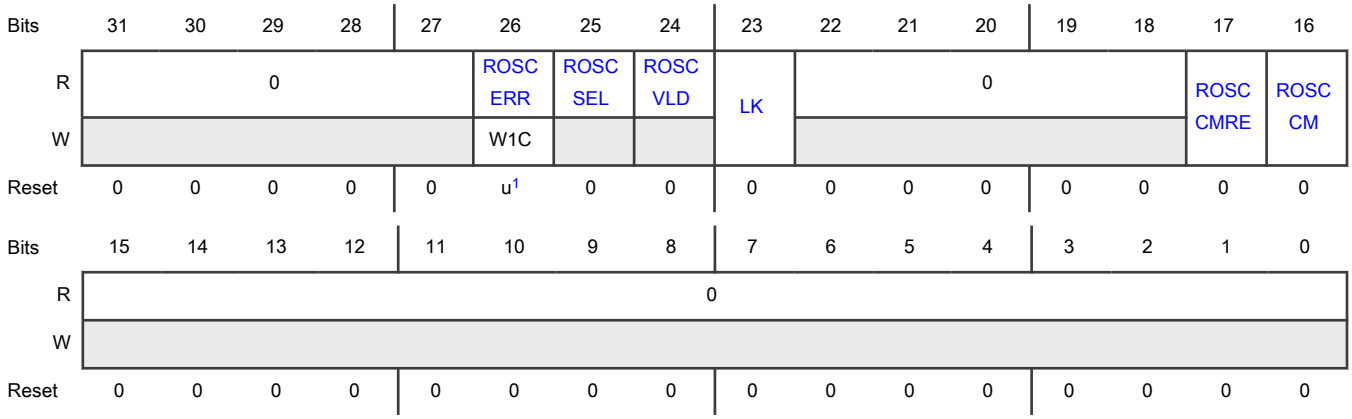
Offset

Register	Offset
ROSCCSR	400h

Function

Contains RTC OSC Clock Error, RTC OSC Selected, RTC OSC Valid, Lock Register, RTC OSC Clock Monitor Reset Enable, RTC OSC Clock Monitor.

Diagram



1. Reset values are loaded out of IFR.

Fields

Field	Function
31-27 —	Reserved
26 ROSCERR	RTC OSC Clock Error This flag is reset on Chip POR only, software can also clear this flag by writing a logic one 0b - RTC OSC Clock Monitor is disabled or has not detected an error 1b - RTC OSC Clock Monitor is enabled and detected an RTC loss of clock error
25 ROSCSEL	RTC OSC Selected 0b - RTC OSC is not the system clock source 1b - RTC OSC is the system clock source
24 ROSCVLD	RTC OSC Valid 0b - RTC OSC is not enabled or clock is not valid 1b - RTC OSC is enabled and output clock is valid
23 LK	Lock Register This bit field can be cleared/set at any time. 0b - Control Status Register can be written. 1b - Control Status Register cannot be written.
22-18 —	Reserved
17 ROSCCMRE	RTC OSC Clock Monitor Reset Enable 0b - Clock Monitor generates interrupt when error detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Clock Monitor generates reset when error detected
16 ROSCCM	RTC OSC Clock Monitor Enables the clock monitor when ROSCVLD is set. **NOTE** ROSC clock monitor remains enabled in SLEEP mode only if ROSCCM is enabled. When the clock monitor is disabled in a low power mode, it remains disabled until the clock valid flag is set following exit from the low power mode. **NOTE** The reference clock used to monitor the ROSC is the SIRC. SIRC clock must be programmed to be enabled in order to monitor the ROSC. SIRC is automatically disabled in DSLEEP, PDOWN, and DPDOWN power modes and clock monitor of ROSC will be disabled. 0b - RTC OSC Clock Monitor is disabled 1b - RTC OSC Clock Monitor is enabled
15-0 —	Reserved

1. Refer to Ordering information for parts have this module.

27.2 Introduction

The Module Reset and Clock Control (MRCC) module provides reset control and clock configuration for on-chip modules. Each module has its own configuration register.

27.3 Features

Per individual module, the MRCC module enables software to:

- Gate all clocks to the module
- Select the source of the functional clock
- Divide the functional clock
- Hold the module in reset

Below is a block diagram of the MRCC module:

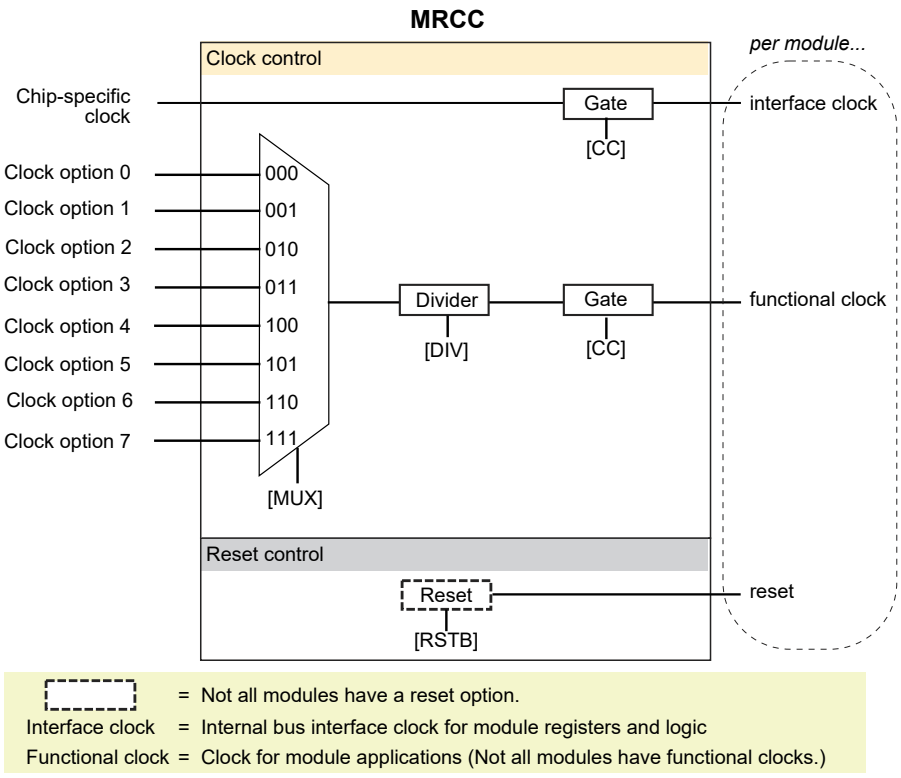

Figure 70. MRCC Block Diagram

27.4 Functional description

The MRCC module provides on-chip modules their own dedicated MRCC registers for clock gating, reset control and configuration options. Generally, each module's MRCC register contains a clock configuration (CC) field for the module's clocks.

NOTE

Before a module can be used, its clocks must be enabled (CC does not equal 00) and it must be released from reset (RSTB = 1). If a module is *not* released from reset (RSTB = 0), an attempt to access a register within that module is terminated with a bus error.

If a module has a functional clock, its MRCC register may provide options for the clock source, selected by programming the mux select (MUX) field. The selected functional clock source can then be divided by programming the divider (DIV) field. The divider factor is given by DIV+1.

NOTE

Before configuring a functional clock, the module's clocks must be disabled (CC = 00).

27.5 Memory map and register definition

Each module has its own dedicated MRCC register. See each module's MRCC register for details.

NOTE

To configure the clocking options available to a given module or to modify an existing configuration, first disable the module's clocks by writing 00 to its CC field.

28.2 Overview

The Signal Frequency Analyser (SFA) provides functionality to perform measurements of clock frequency, clock period, and time between triggers.

28.2.1 Block Diagram

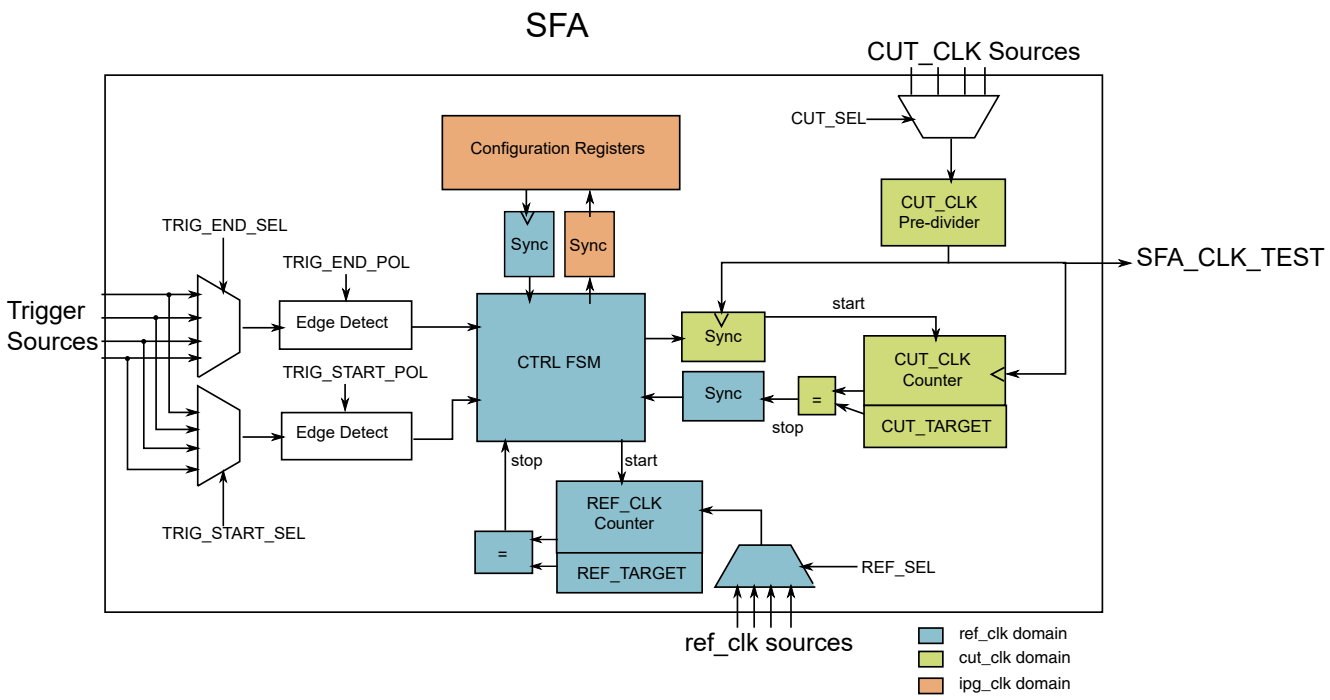

Figure 71. Signal Frequency Analyser Block Diagram

28.2.2 Features

The Signal Frequency Analyser includes the following features.

- Two 32-bit counters, one connected to the bus clock (REF clock), which serves as a reference, and the other connected to the clock under test (CUT).
- An 8-bit predivider is provided to divide down the CUT clock.
- A target count register for both the REF clock and CUT clock are provided to stop the counters.

- Selectable measurement modes to optimize test time by analysing either the frequency (for fast clocks), or the period (for slow clocks) of the CUT clock.
- Selectable sources for reference clock and CUT clock
- Support interrupt for CUT clk freq exceed setting freq limit

28.3 Functional Description

The Signal Frequency Analyser can be used to measure frequencies, periods, and time between events. The following use cases demonstrate how these capabilities can be used.

28.3.1 Frequency Measurements

The Signal Frequency Analyser can be used to measure the frequency of CUT CLK. The use cases below demonstrate how these capabilities can be used.

In general, either of the following methods may then be used to measure clock frequencies. To measure in frequency mode, register bit CTRL[MODE] must be set to 0x0 or 0x1.

Method 1 (when CUT frequency < REF frequency)(CTRL[MODE] == 0x0):

1. Set CUT and REF count targets
2. Perform a dummy write to REF counter (clears the *COUNT, *STARTED and *STOPPED bits)
3. Poll the CUT_STOPPED bit to make sure it cleared
4. Perform a dummy write to the CUT counter. This triggers:
    a. REF counter starts counting immediately
    b. CUT counter starts counting after a ~2 CUT cycle sync delay
5. When CUT counter reaches 1, MEAS_STARTED bit asserts after a ~2 REF cycle sync delay
6. Upon assertion of MEAS_STARTED, the REF_COUNT_ST_SAVED (a saved version of the current REF counter, which keeps running) will be written.
7. When CUT counter reaches target, CUT_STOPPED bit asserts after a ~2 REF cycle sync delay
8. Upon assertion of CUT_STOPPED, the REF_COUNT_END_SAVED (which is a saved version of the actual REF counter, which keeps running) will be written.
9. The measurement is considered complete once the REF_STOPPED and CUT_STOPPED bits have been asserted in the CUT_CNT register. The user can either poll the REF_STOPPED and CUT_STOPPED bits or enable SFA_IRQ_EN. If SFA_IRQ_EN is asserted than an interrupt will be issued when the measurement is complete.
10. Calculate CUT frequency by using the difference in the REF_COUNT_END_SAVED and REF_COUNT_ST_SAVED in comparison to the CUT target
11. If the value (REF_COUNT_END_SAVED-REF_COUNT_ST_SAVED) greater than the value setting in REG_HIGH_LIMIT_CNT , it means the measured cut clk frequency is less than minimum limit,if according enable bit is set, the FREQ_LT_MIN_IRQ will be generated
12. If the value (REF_COUNT_END_SAVED-REF_COUNT_ST_SAVED) less than the value setting in REG_LOW_LIMIT_CNT , it means the measured cut clk frequency is greater than maximum limit, if according enable bit is set, the FREQ_GT_MAX_IRQ will be generated

The following two figures represent two possible cases for frequency measurement with CTRL[MODE] = 0x0. The first image illustrates a complete frequency measurement. Note, it is assumed that the user has started the measurement some time before this waveform snapshot was taken. Therefore, the register writes to CUT counter and REF counter are omitted. In this example the CUT target of 0x0000_FFFF is reached before the REF target count is reached. The two significant measurement events occur when MEAS_STARTED is asserted and REF_CNT_STOPPED is asserted.

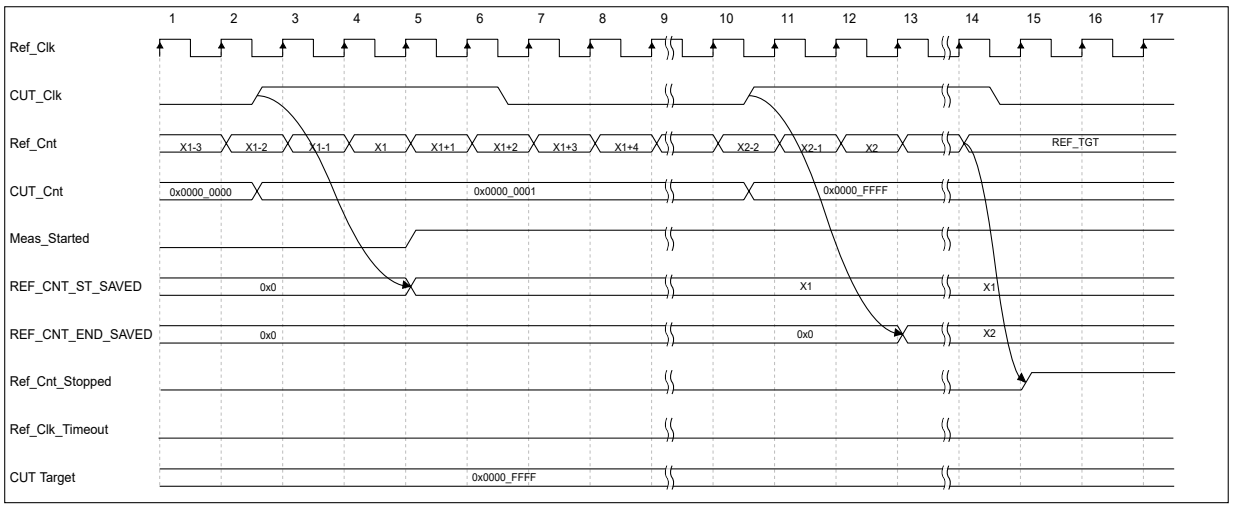

Figure 72. CUT Frequency Measurement with CUT Freq less than REF Freq

The next image illustrates the case when the frequency measurement is unable to be completed before REF_CNT_STOPPED is asserted. This is known as a reference clock timeout. In this example the CUT Target is set to 0x0000_FFFF; however, this value is never reached before REF_CNT = REF_CNT_STOPPED.

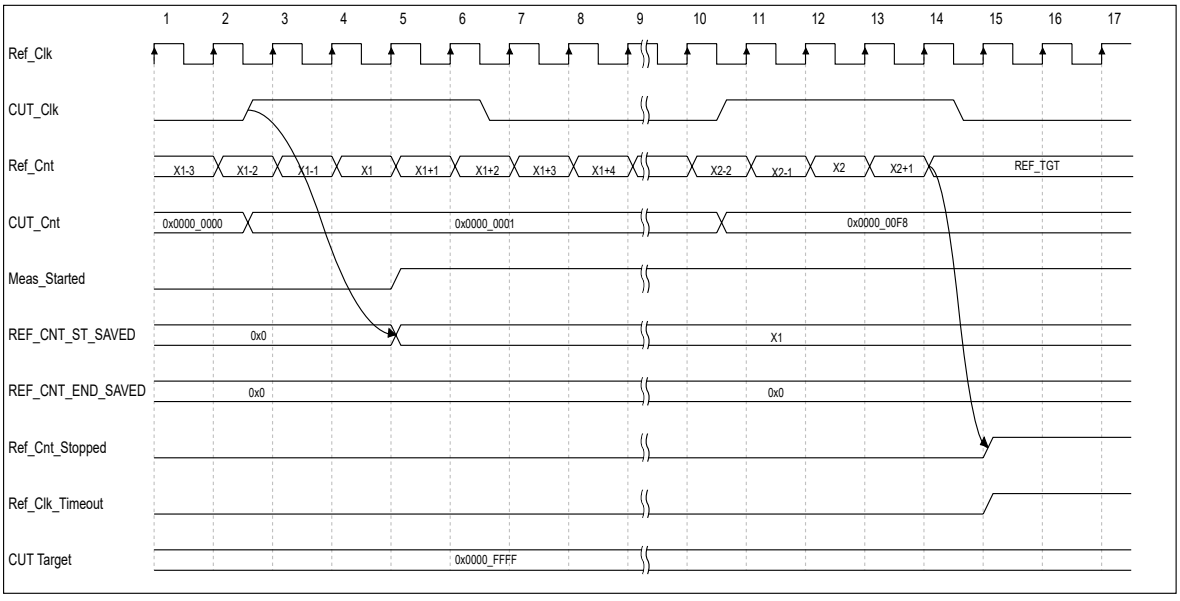

Figure 73. CUT Frequency Measurement Timeout with CUT Freq less than REF Freq

Method 2 (when CUT frequency > REF frequency)(CTRL[MODE] == 0x1):

1. Set CUT and REF count targets (Note: recommend CUT target be set to 0xFFFF_FFFF. There is no CUT_CNT_TIMEOUT flag.)
2. Perform a dummy write to REF counter (clears the *COUNT, *STARTED and *STOPPED bits)
3. Poll the CUT_STOPPED bit to make sure it is clear
4. Perform a dummy write to the CUT counter. This triggers:
    a. REF counter starts counting immediately
    b. CUT counter starts counting after a ~2 CUT cycle sync delay
5. When REF_COUNT reaches target, the CUT counter stops after a ~2 CUT cycle sync delay, and the CUT_STOPPED bit then sets after a ~2 REF cycle sync delay
6. Calculate CUT frequency by using the CUT_COUNT and REF target
7. To determine when the measurement has been completed, the user can either poll the CUT_STOPPED bit or enable SFA_IRQ_EN. An interrupt will be issued, if SFA_IRQ_EN is asserted and when both CUT_STOPPED and REF_STOPPED are asserted.
8. If the value CUT_CNT is greater than the value setting in CUT_HIGH_LIMIT_CNT , it means the measured cut clk frequency or trigger period is greater than maximum limit. If FREQ_GT_MAX interrupt flag is set, FREQ_GT_MAX IRQ will be generated.
9. If the value CUT_CNT less than the value setting in CUT_LOW_LIMIT_CNT , it means the measured cut clk frequency or trigger period is less than minimum limit, if according enable bit is set, the FREQ_LT_MIN_IRQ will be generated

The following image represents an example frequency measurement with CTRL[MODE] = 0x1. In this case, the CUT frequency should be greater than the REF frequency. This measurement is used to count the number of CUT_CLK cycles that occur in REF_TARGET REF clk cycles. Note that registers REF_CNT_*_SAVED should not be read during this mode. It can be implied that REF_CNT_END_SAVED - REF_CNT_ST_SAVED = REF_TARGET.

When performing a CTRL[MODE] = 0x1 measurement, the CUT_TARGET should be set to the max value to prevent a CUT_TARGET timeout. The measurement will end when REF_CNT reaches the value stored in REF_TARGET. If CUT_TARGET is reached before REF_TARGET is reached, this will indicate an error condition. There is no flag to indicate a CUT_TARGET timeout. This is why CUT_TARGET should be set to the maximum value. The CUT_CNT timeout occurs when CUT_CNT is equal to CUT_TARGET. To detect that the CUT_CNT timeout did not occur, the CUT_CNT register should be less than CUT_TARGET at the end of a CTRL[MODE] = 0x1 measurement. When CUT_CNT is less than CUT_TARGET, the measurement stops when REF_TARGET is met.

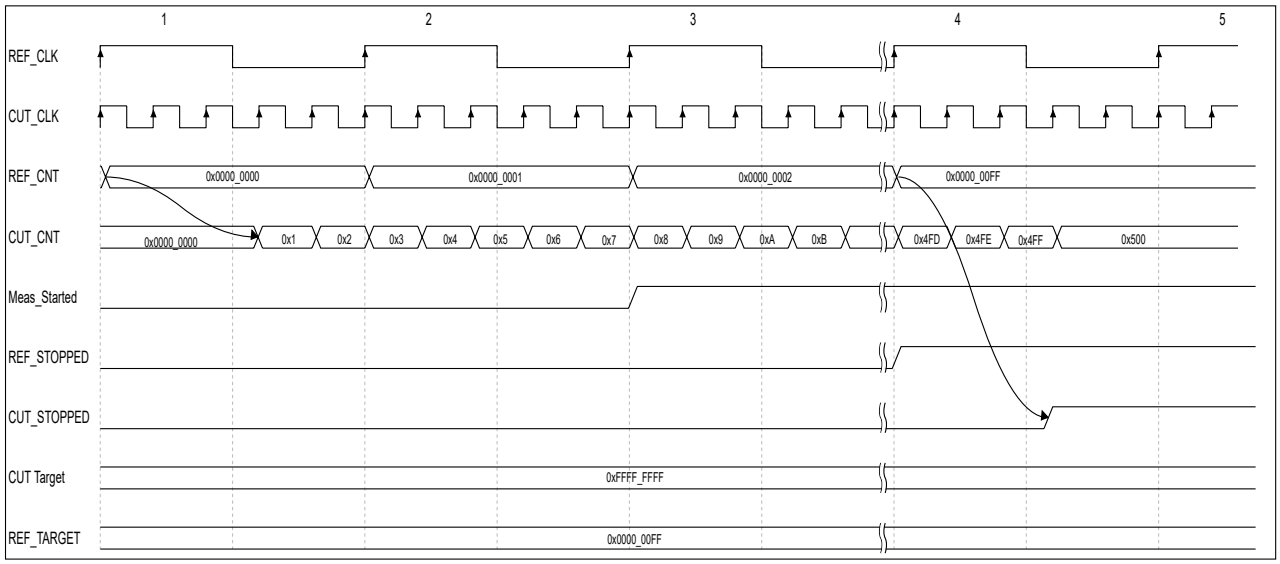

Figure 74. REF Frequency Measurement: CUT Freq greater than REF Freq

28.3.2 Clock Period Measurements

The signal frequency analyser has the capability to measure the period of CUT clock. To operate in clock period mode, the register CTRL[MODE] must be set to 0x2. This mode is used to count the number of REF CLK periods which occur during one period of CUT CLK.

Clock Period Measurement (CTRL[MODE] == 0x2). This mode is used to measure the period of CUT clock. It is assumed that CUT frequency < < REF frequency:

1. Select the source of CUT clock with CTRL[CUT_SEL], and configure any CUT pre-divide with CTRL[CUT_PREDIV].
2. Select a value for REF_TARGET. This value acts as a time-out function. The test will always end when REF_CNT == REF_TARGET.
3. Perform a dummy write to the REF counter. This triggers:
    a. REF counter starts counting immediately
    b. All previous counters will be cleared.
4. The MEAS_STARTED bit will indicate when the measurement sequence has begun.
5. The MEAS_STARTED bit is asserted on the first rising edge of the CUT after the dummy write to the REF counter. Upon assertion of MEAS_STARTED, the REF_COUNT_ST_SAVED (which is a saved version of the actual REF counter, which keeps running) will be written with the current REF_CNT value.
6. The REF_STOPPED bit will indicate when the measurement sequence has been completed.
7. Upon completion of one full period measurement (performed from one rising edge to the next rising edge), the REF_COUNT_END_SAVED (which is a saved version of the actual REF counter, which keeps running) will be written with the current value of REF_CNT.
8. Note that REF_STOPPED may be set before the measurement has been completed. This may indicate the REF_CNT reached REF_TARGET before receiving a full period of CUT CLK. In this case, the CNT_STAT[REF_CNT_TIMEOUT] will be set to 0b1 to indicate that a time-out occurred.

9. Calculate the period width by using the difference between the values of REF_CNT_END_SAVED and REF_COUNT_ST_SAVED.
10. To determine when the measurement has been completed, the user can either poll the REF_STOPPED bit or enable SFA_IRQ_EN. If SFA_IRQ_EN is asserted than an interrupt will be issued when REF_STOPPED is asserted.
11. If the value (REF_COUNT_END_SAVED-REF_COUNT_ST_SAVED) greater than the value setting in REG_HIGH_LIMIT_CNT , it means the measured cut clk frequency is less than minimum limit,if according enable bit is set, the FREQ_LT_MIN_IRQ will be generated
12. If the value (REF_COUNT_END_SAVED-REF_COUNT_ST_SAVED) less than the value setting in REG_LOW_LIMIT_CNT , it means the measured cut clk frequency is greater than maximum limit, if according enable bit is set, the FREQ_GT_MAX_IRQ will be generated

Figure 75 illustrates a CUT Clk period measurement cycle. It is assumed this timing diagram occurs sometime after beginning the measurement (dummy write to REF counter) with CTRL[MODE] == 0x2. In addition, it is assumed that SFA_IRQ_EN is asserted. In Figure 75 , the REF_TARGET register was set sufficiently high to receive a full period of CUT before REF_CNT timeout.

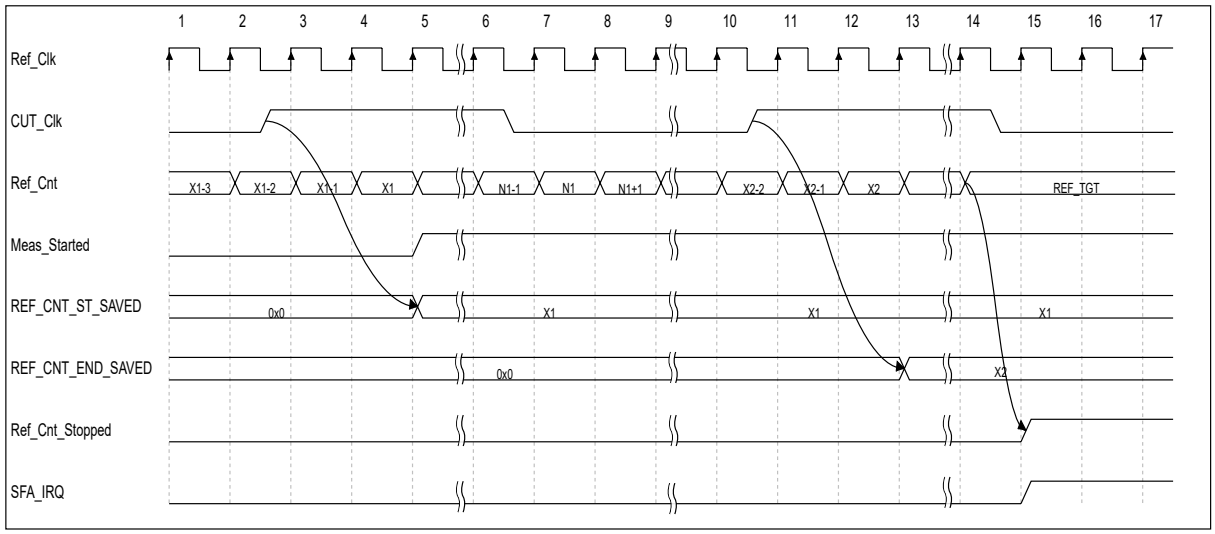

Figure 75. CUT Clk Period Measurement

Figure 76 illustrates what happens when REF_CNT reaches REF_TARGET before the SFA receives a full period of CUT Clk. The result will be an incomplete measurement, and REF_CNT_TIMEOUT will be asserted along with REF_STOPPED.

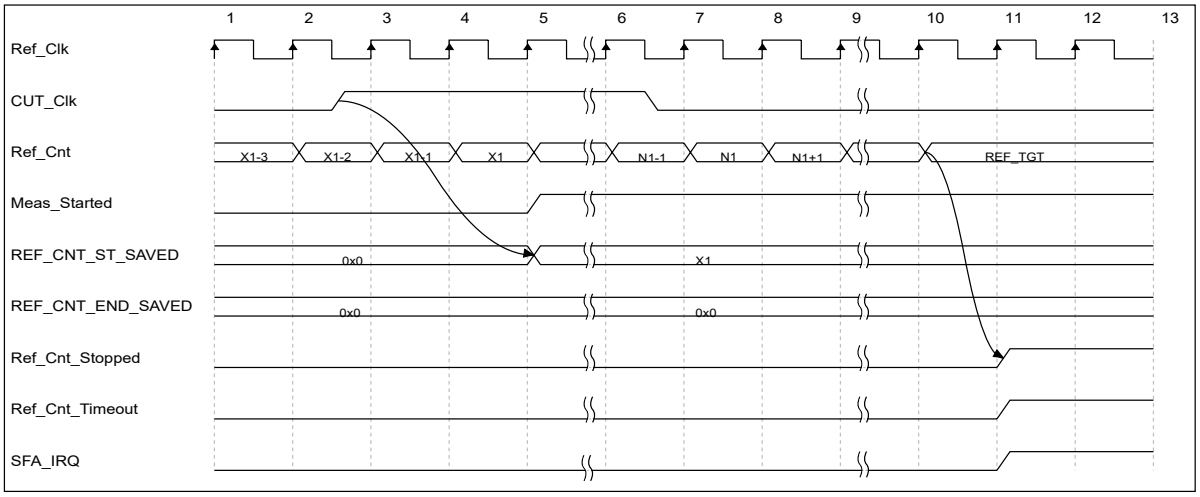

Figure 76. CUT Clk Period Timeout

28.3.3 Interrupts

This module has single interrupt: ipi_init. This interrupt is asserted when:

- CNT_STAT[4] is set and CTRL [5] is enabled
- CNT_STAT[5] is set and CTRL2[16] is enabled
- CNT_STAT[6] is set and CTRL2[17] is enabled

Fields

Field	Function
31-7 —	Reserved
6 FREQ_LT_MIN_IRQ	FREQ_LT_MIN interrupt flag FREQ_LT_MIN interrupt flag, it means the cut clk frequency is lower than minimum setting,or trigger measurement period is greater than maximum setting
5 FREQ_GT_MAX_IRQ	FREQ_GT_MAX interrupt flag FREQ_GT_MAX interrupt flag, it means the cut clk frequency is greater than maximum setting,or trigger measurement period is less than minimum setting
4 SFA_IRQ	SFA Interrupt Request This flag indicates that REF_CNT has reached REF_TARGET. More generally, this flag indicates that a measurement has been completed and an interrupt has been issued. Writing a 0x1 to this bit position will clear the interrupt request.
3 REF_CNT_TIMEOUT	Reference Counter Time Out This flag indicates the REF counter reached REF_TARGET before the desired measurement was completed. Every test will commence when REF_CNT == REF_TARGET. For measurement accuracy, this bit should be equal to 0b0 when REF_STOPPED == 0b1. This bit will be cleared on any write to REF_CNT when not performing a measurement.
2 MEAS_STARTED	Measurement Started Flag In frequency measurement mode, this flag indicates when the CUT counter has started counting. Set when CUT counter increments to 1. In period measurement mode, this flag indicates that the first edge of the CUT has been received for period measurement. In edge to edge signal measurement mode, this flag will indicate when TRIGGER[TRIG_START_SEL] has been received for measurement. This event will also push the REF_CNT to the REF_CNT_ST_SAVED register. This flag is only active during CTRL[MODE] == 0x0, 0x2 or 0x3. Cleared on any write to REF_CNT when not performing a measurement.
1 CUT_STOPPED	CUT_STOPPED This flag indicates the CUT counter has stopped counting. Set when either REF or CUT counter has reached its target. Cleared on any write to REF_CNT when not performing a measurement.
0 REF_STOPPED	REF_STOPPED This flag indicates the REF counter has stopped counting. Set when REF counter has reached its target. Cleared on any write to REF_CNT when not performing a measurement. This bit can be polled to indicate when a measurement is complete.

28.4.1.5 Signal Frequency Analyser Clock Under Test Counter (CUT_CNT)

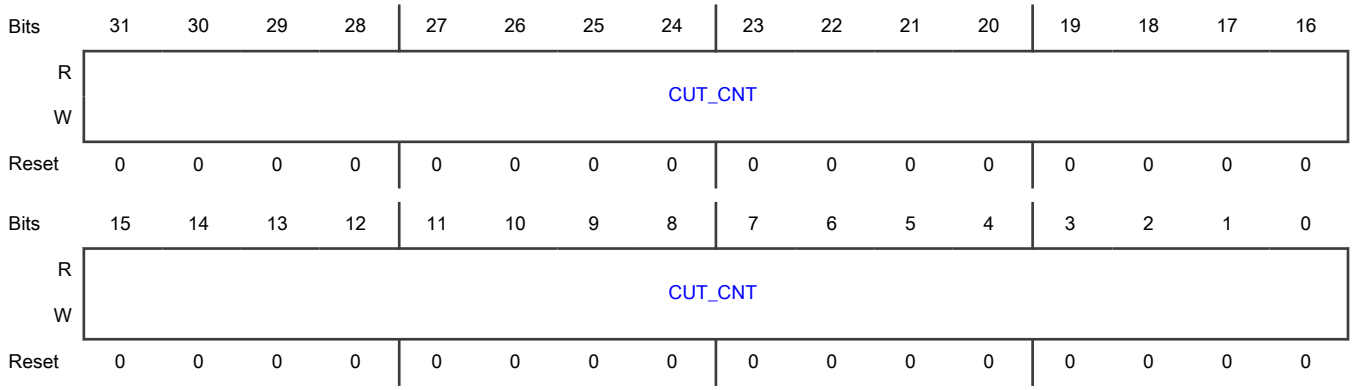
Offset

Register	Offset
CUT_CNT	Ch

Function

This register contains the current count of the clock under test. Writes to this register will start the clock under test and reference counters. Counting will stop when either the count matches the contents of the clock under test target count register or when reference counter matches the reference target count register.Note, attempts to read this register before the CUT_STOPPED flag has set will return 0x0000_0000

Diagram



Fields

Field	Function
31-0 CUT_CNT	CUT_CNT Current clock under test count. Writes to this register will start the clock under test and reference counters.

28.4.1.6 Signal Frequency Analyser Reference Clock Counter (REF_CNT)

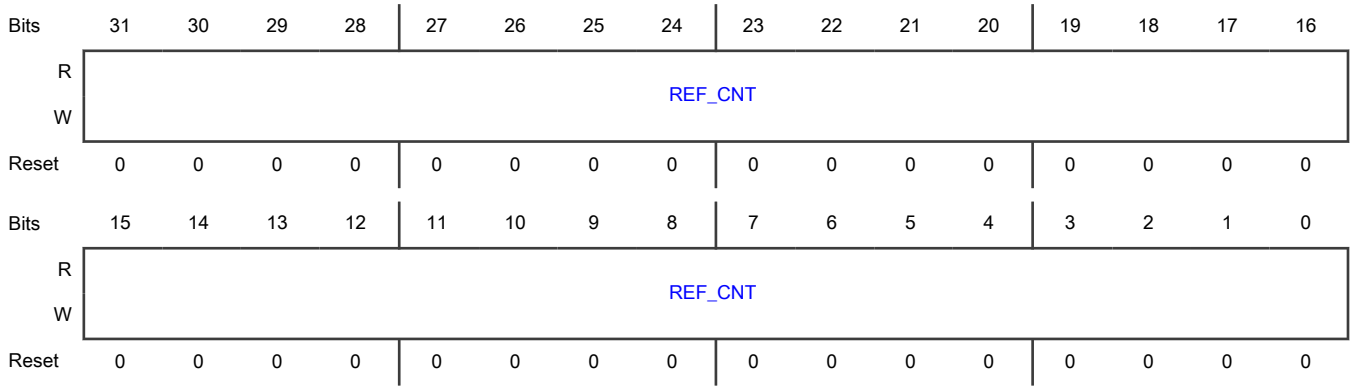
Offset

Register	Offset
REF_CNT	10h

Function

This 32-bit register contains the current count of the reference clock. Writes to this register will clear the clock under test and reference counters. Counting will stop if the count matches the contents of the reference clock target count register.

Diagram



Fields

Field	Function
31-0 REF_CNT	REF_CNT Current reference clock count. Writing to this register with any value will clear the clock under test and reference clock count and status flags registers.

28.4.1.7 Signal Frequency Analyser Clock Under Test Target Count (CUT_TARGET)

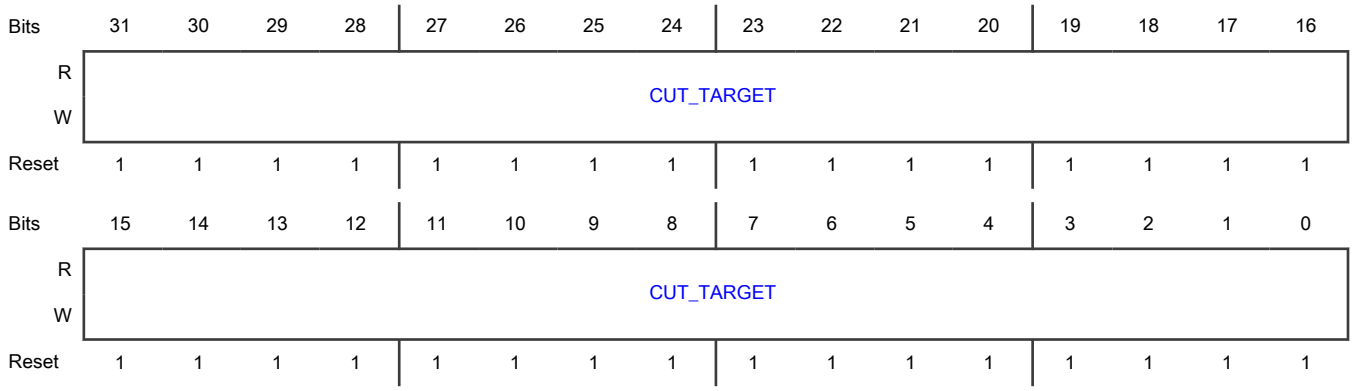
Offset

Register	Offset
CUT_TARGET	14h

Function

This register contains the target count for the clock under test. Both the reference and clock under test count will stop if the clock under test count matches the contents of this register.

Diagram



Fields

Field	Function
31-0 CUT_TARGET	CUT_TARGET Target count for the clock under test. Note, a measurement of type MODE = 0x0 or 0x1 is not valid if CUT_TARGET = 0x00000000. This value must be set to an integer > 0x0 to perform a valid measurement.

28.4.1.8 Signal Frequency Analyser Reference Clock Target Count (REF_TARGET)

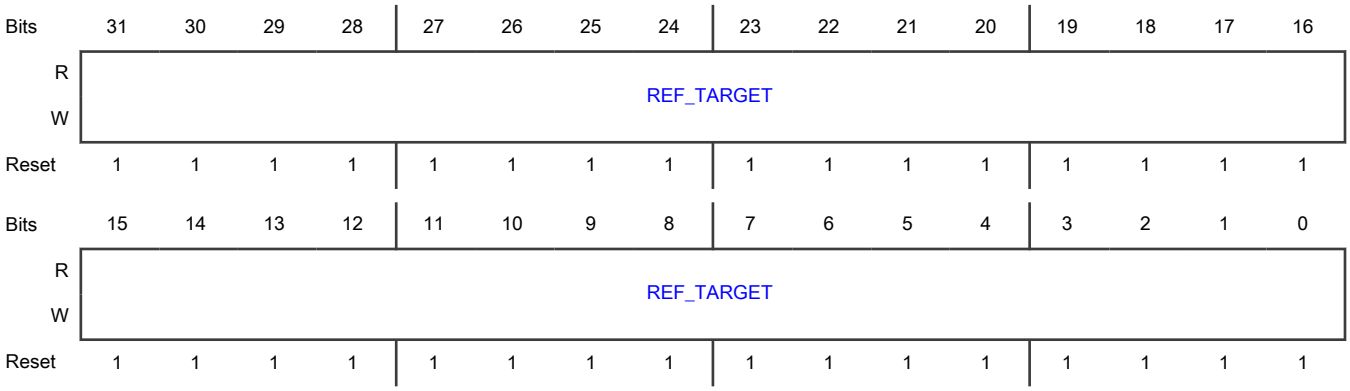
Offset

Register	Offset
REF_TARGET	18h

Function

This register contains the target count for the reference clock. Both the reference and clock under test count will stop if the reference clock count matches the contents of this register.

Diagram



Fields

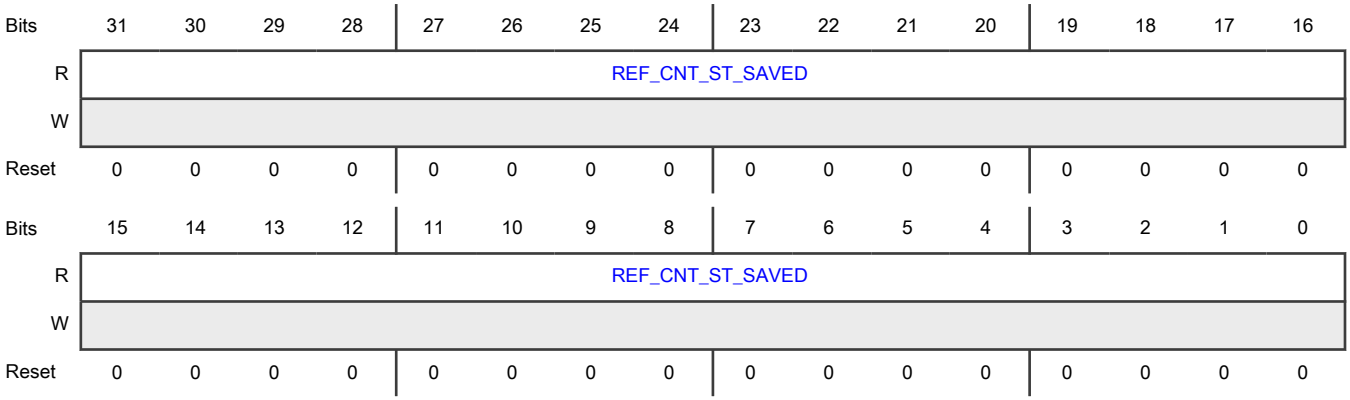
Field	Function
31-0 REF_TARGET	REF_TARGET Target count for the reference clock. Note, a measurement is not valid if REF_TARGET = 0x00000000. This value must be set to an integer > 0x0 to perform a valid measurement.

28.4.1.9 Signal Frequency Analyser Reference Clock Count Start Saved Register (REF_CNT_ST_SAVED)

Offset

Register	Offset
REF_CNT_ST_SAVED	1Ch

Diagram



Fields

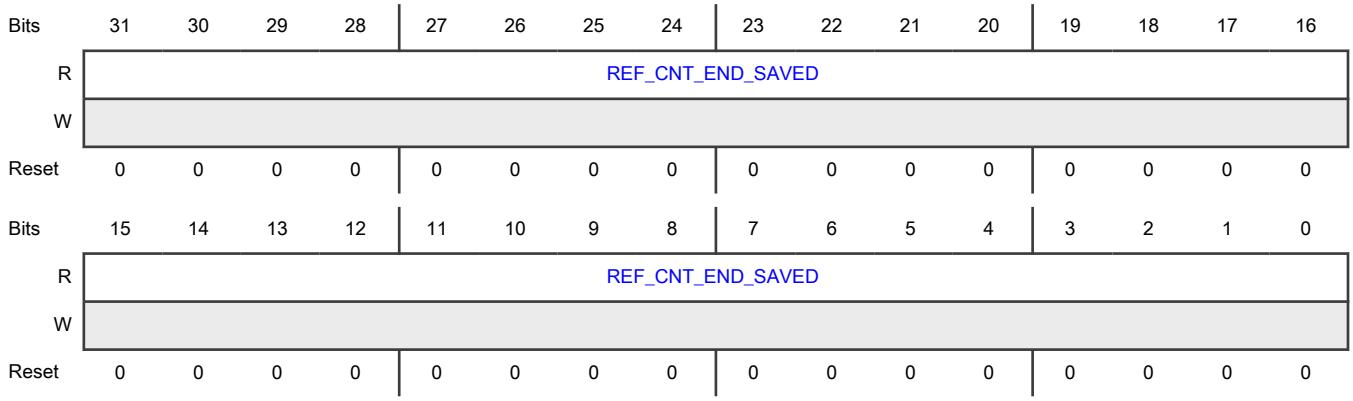
Field	Function
31-0 REF_CNT_ST_SAVED	REF_CNT_ST_SAVED Saved reference clock counter. This register is loaded with the current value of REF_CNT on assertion of the MEAS_STARTED flag. Note, during frequency measurements with CTRL[MODE] = 0x1, this register will be unused. It is assumed that the REF CNT start will be 0x0. This register is cleared on any write to REF_CNT when not performing a measurement.

28.4.1.10 Signal Frequency Analyser Reference Clock Count End Saved Register (REF_CNT_END_SAVED)

Offset

Register	Offset
REF_CNT_END_SAVED	20h

Diagram



Fields

Field	Function
31-0 REF_CNT_END_SAVED	REF_CNT_END_SAVED Saved reference clock counter. This register is loaded with the current value of REF_CNT on assertion of either the CUT_STOPPED or REF_STOPPED flags. Note, during frequency measurements with CTRL[MODE] = 0x1, this register will be unused. It is assumed that the REF_CNT_END will be equal to REF_TARGET. Cleared on any write to REF_CNT when not performing a measurement.

28.4.1.11 Extended control register for SFA (CTRL2)

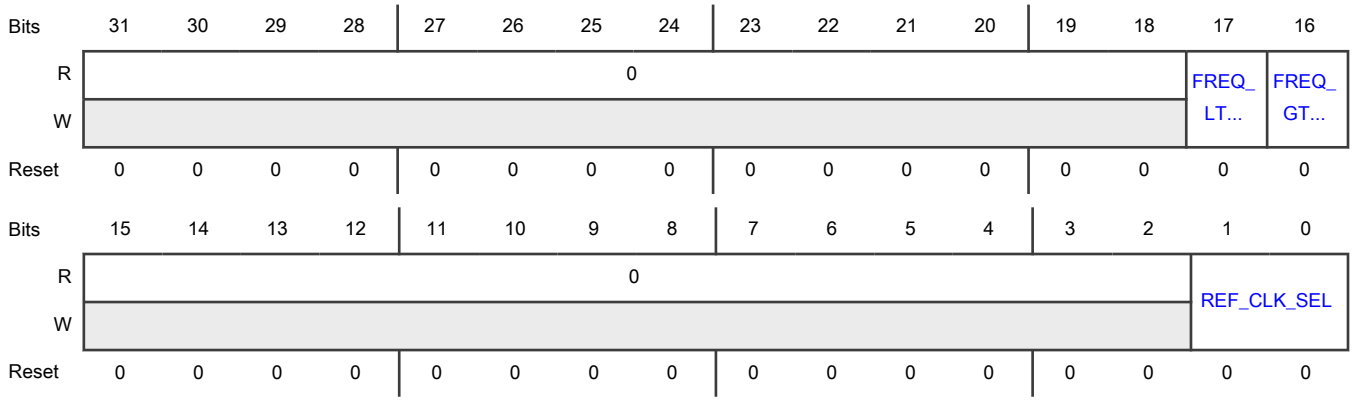
Offset

Register	Offset
CTRL2	24h

Function

This register an extended control register for SFA

Diagram



Fields

Field	Function
31-18 —	Reserved
17 FREQ_LT_MIN_IRQ_EN	FREQ_LT_MIN interrupt enable This bit used to enable FREQ_LT_MIN interrupt.
16 FREQ_GT_MAX_IRQ_EN	FREQ_GT_MAX interrupt enable This bit used to enable FREQ_GT_MAX interrupt.
15-2 —	Reserved
1-0 REF_CLK_SEL	Reference clock select These bits control which SoC clock is connected to the reference clock. **NOTE** This field is not supported in every instance. The following table includes only supported registers.

Instance	Field supported in	Field not supported in
RF_SFA	CTRL2[0]	CTRL2[1]
SFA0	CTRL2	—

28.4.1.12 Record the low limit reference clock count (REF_LOW_LIMIT_CNT)

Offset

Register	Offset
REF_LOW_LIMIT_CNT	28h

Function
Record the low limit reference clock count.

Diagram

Chapter 29
32 kHz Clock Control Module (CCM32K)

29.1 Chip-specific CCM32K information

Table 204. Reference links to related information

Topic	Related module	Reference
Full description	CCM32K	CCM32K
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

29.1.1 Module instances

This device has one instance of the CCM32K module.

29.1.2 Reset

The CCM32K module supports only the POR.

29.2 Overview

The 32 kHz Clock Control Module (CCM32K) provides the 32 kHz clock to the device. This module includes the free running oscillator (FRO) and Crystal Oscillator (OSC) which serve as the clock generators of 32 kHz clock. The module has an internal clock validation mechanism to ensure the clock from OSC is stable; and switch from the FRO to OSC when clock from OSC is stable or switch back to FRO clock if software disables the OSC.

29.2.1 Block diagram

The following figure shows a block diagram for the CCM32K module.

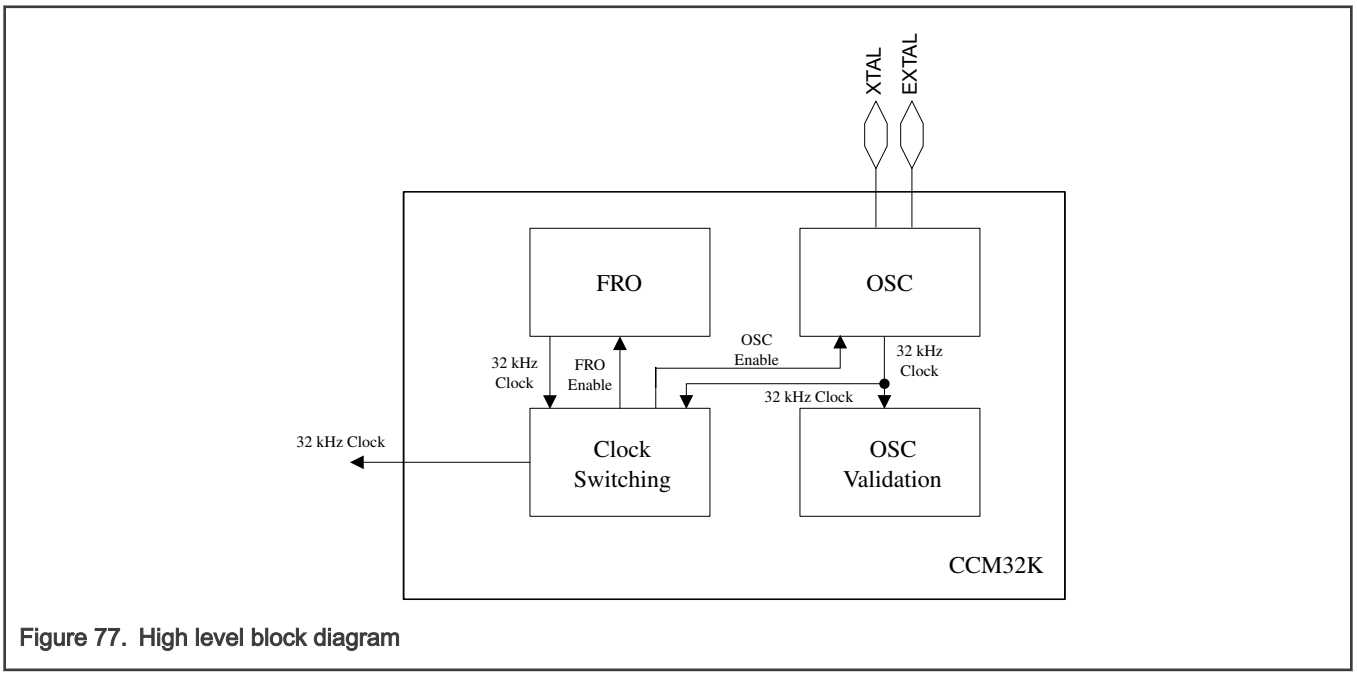

Figure 77. High level block diagram

29.2.2 Features

The CCM32K module has the following features:

- 32-kHz Free Running Oscillator (FRO) that is enabled after POR to provide clock to the device. The FRO can be disabled by software if needed.
- FRO trim values are loaded from IFR which can be overriden by software if needed.
- 32-kHz Crystal Oscillator (OSC) that is kept disabled after POR. The OSC can be enabled by software when needed.
- Clock validation logic that checks for the quality of clock from OSC and indicates if the clock from the OSC is stable.
- Clock switching logic that switches to OSC clock when it is stable and switches back to FRO clock when software disables the OSC.
- Locking mechanism for all registers for OSC and FRO. Once locked, the registers cannot be unlocked until the next POR. This prevents unwanted modifications to the registers.
- The loss of clock (LOC) monitoring for the external 32-khz crystal oscillator with internal 32-khz FRO as reference clock.

29.3 Functional description

The following sections describe functional details of the CCM32K module.

29.3.1 OSC clock validation

The clock from the external crystal oscillator is not stable immediately after enabling it and takes certain time before it becomes stable and can be used. The clock validation mechanism ensures that sufficient amount of clock cycles have passed before enabling the clock to other modules on the device that require 32 kHz clock. When STATUS[OSC32K_ACTIVE] and STATUS[OSC32K_RDY] are asserted, 32 kHz oscillator clock can be used by other modules.

29.3.2 Clock switching

Clock switching between OSC32K and FRO32K

- Switch FRO32K to OSC32K by configuring CGC32K[CLK_SEL_32K] to 1b if OSC32K clock is available.
- Switch OSC32K to FRO32K by configuring CGC32K[CLK_SEL_32K] to 0b if FRO32K clock is available.
- No clock source active if CGC32K[CLK_SEL_32K] is high and OSC32K is disabled.
- No clock source active if CGC32K[CLK_SEL_32K] is low and FRO32K is disabled.

29.3.3 Clock monitor

CCM32K has two clock monitors. One uses FRO_ 32K as its clock source. The other uses OSC_32K as its clock source. Each monitor checks a divided version of the other clock at the same frequency but divided by 16. The monitor expects a clock edge every 8 cycles, and you can trim the monitor to assert after 10, 12, 14, or 16 cycles with no edge.

Changing the trim makes the clock monitor more sensitive and reduces the latency, but also makes it more susceptible to variation in the duty cycle. The accuracy and latency of the monitor can vary by a cycle due to synchronization differences, so for each trim point:

- At 2 cycles after the expected edge the monitor asserts between 12.5% and 37.5% frequency variation with a maximum latency of 11 cycles
- At 4 cycles after the expected edge the monitor asserts between 37.5% and 62.5% frequency variation with a maximum latency of 13 cycles
- At 6 cycles after the expected edge the monitor asserts between 62.5% and 87.5% frequency variation with a maximum latency of 15 cycles
- At 8 cycles after the expected edge the monitor asserts between 87.5% and 112.5% frequency variation with a maximum latency of 17 cycles

The frequency of the clock monitor can also be trimmed to either 1 kHz or 64 Hz. Configuring to a slower clock increases the detector's latency but reduces power consumption.

NOTE

You must enable both the FR032k and OSC32k and OSC_RDY sets before enabling the clock monitor.

29.4 External signals

This table describes the CCM32K signals that are SoC level pins.

Signal	I/O	Description
EXTAL32K	I/O	32-kHz Crystal pin
XTAL32K	I/O	32-kHz Crystal pin

29.5 Initialization

This section describes the initialization of the CCM32K module.

The CCM32K module powers up, loads the default trims from flash and starts up the FRO after Power-On-Reset (POR) is complete. The trim values get loaded after POR into their respective registers. Software must follow the steps below to further configure the module.

- FRO32K as clock source
  1. Enable the FRO32K by setting FRO32K_CTRL[FRO_EN] as 1b. The FRO32K_CTRL[FRO_EN] is reset to 1b by default.
  2. Wait until the STATUS[FRO32K_ACTIVE] is 1b to identify FRO32K available.
  3. Clear CGC32K[CLK_SEL_32K] to be 0b to select FRO32K as clock source. The CGC32K[CLK_SEL_32K] is reset to 0b by default.
- OSC32K as clock source
  1. Set OSC32K_CTRL[OSC_EN] and OSC32K_CTRL[SOX_EN] as 1b,
  2. Select internal capacitance bank value through OSC32K_CTRL[XTAL_CAP_SEL] and OSC32K_CTRL[EXTAL_CAP_SEL] if internal capacitance back is enabled (OSC32K_CTRL[CAP_SEL_EN]).
  3. Wait until theSTATUS[OSC32K_RDY] is 1b to identify OSC32K available.
  4. Set CGC32K[CLK_SEL_32K] as 1b to select OSC32K as clock source.
- OSC32K bypass clock as clock source
  1. Set OSC32K_CTRL[OSC_EN] and OSC32K_CTRL[OSC_BYP_EN] high.
  2. Wait until theSTATUS[OSC32K_RDY] is 1b to identify OSC32K available.
  3. Set CGC32K[CLK_SEL_32K] high , then OSC32K bypass clock is selected as clock source. This clock is treated as same clock on EXTAL32 pad.

NOTE

OSC32K_ACTIVE or FRO32_ACTIVE will be asserted only when related oscillator is selected as clock source and CGC32K[CLK_OE_32K] is not all 0.

29.6 Memory Map and register definition

This section includes the CCM32K module memory map and detailed descriptions of all registers.

29.6.1 CCM32K register descriptions

29.6.1.1 CCM32K memory map

CCM32K base address: 4001_F000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Free Running 32 kHz Oscillator Control Register (FRO32K_CTRL)	32	RW	0088_0001h
4h	Free Running 32 kHz Oscillator Trim Register (FRO32K_TRIM)	32	RW	0000_0400h
8h	32 kHz OSC Control Register (OSC32K_CTRL)	32	RW	See section
Ch	Status Register (STATUS)	32	R	0000_0010h
14h	Clock Monitor Control Register (CLKMON_CTRL)	32	RW	0000_0000h
18h	Clock Monitor Test Register (CLKMON_TST)	32	RW	0000_0000h
1Ch	32 kHz Clock Gate Control Register (CGC32K)	32	RW	0000_001Fh

29.6.1.2 Free Running 32 kHz Oscillator Control Register (FRO32K_CTRL)

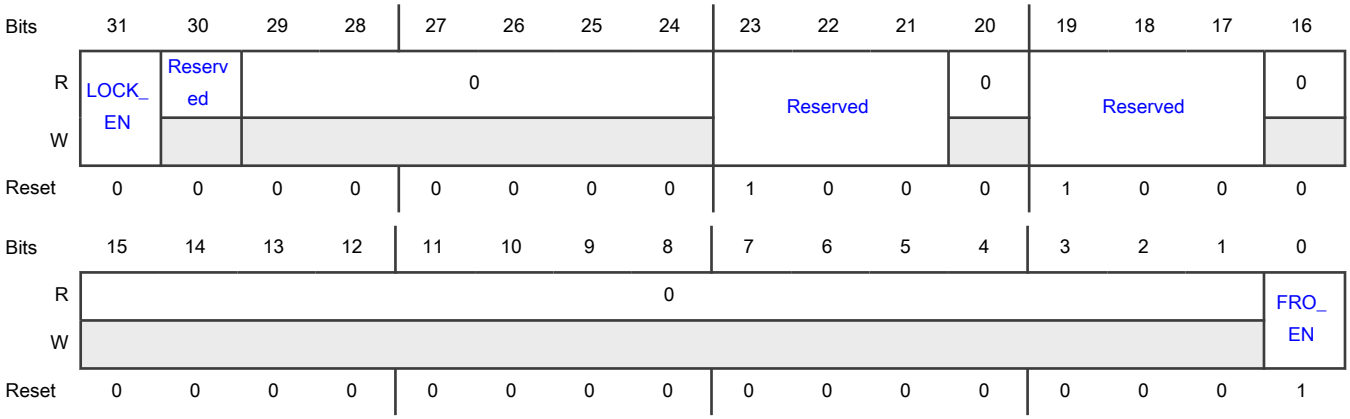
Offset

Register	Offset
FRO32K_CTRL	0h

Function

The Free Running 32 kHz Oscillator Control Register (FRO32K_CTRL) provides control fields for the 32 kHz Free Running Oscillator.

Diagram



Fields

Field	Function
31 LOCK_EN	Write Access Lock When set to '1', this field locks all further write accesses to this register until a POR occurs. Writing '0' after setting this field to '1' has no effect. 0b - Register write access is unlocked 1b - Register write access is locked
30 —	Reserved bits. Reads only zeros.
29-24 —	Reserved bits. Reads only zeros.
23-21 —	Reserved bits. Reads only zeros. Writes have no effect but it is preferred that these bits are not written to.
20 —	Reserved bits. Reads only zeros.
19-17 —	Reserved bits. Reads only zeros. Writes have no effect but it is preferred that these bits are not written to.
16-1 —	Reserved bits. Reads only zeros.
0 FRO_EN	FRO Enable This field enables the FRO analog oscillator. There is a 120 µs typical start-up time before clocks are output from the FRO. 0b - FRO is disabled 1b - FRO is enabled

29.6.1.3 Free Running 32 kHz Oscillator Trim Register (FRO32K_TRIM)

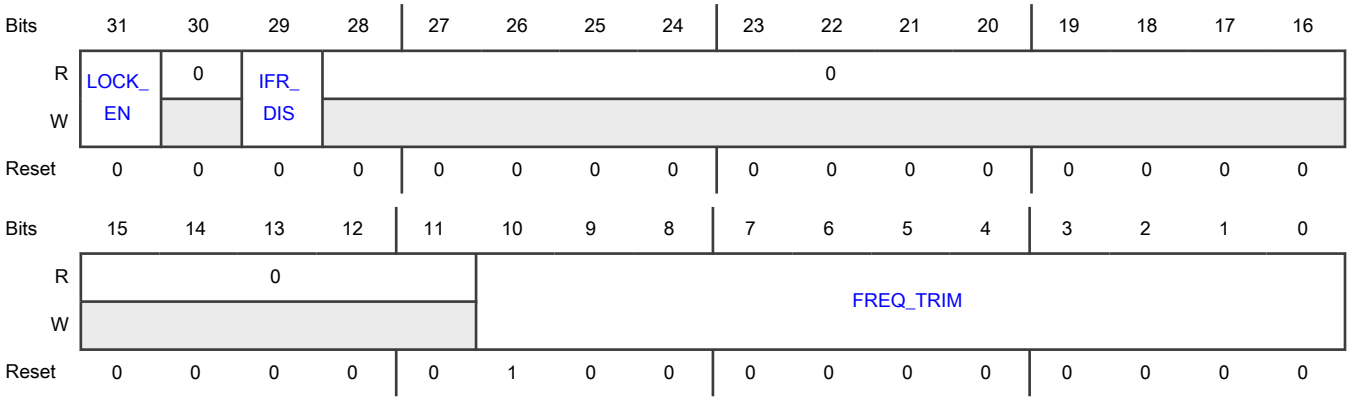
Offset

Register	Offset
FRO32K_TRIM	4h

Function

The Free Running 32 kHz Oscillator Trim Register (FRO32K_TRIM) provides frequency trim configuration for the 32 kHz Free Running Oscillator.

Diagram



Fields

Field	Function
31 LOCK_EN	Write Access Lock When set to '1', this field locks all further write accesses to this register until a POR occurs. Writing '0' after setting this field to '1' has no effect. 0b - Register write access is unlocked 1b - Register write access is locked
30 —	Reserved
29 IFR_DIS	IFR Loading Disable Control This field controls whether the FREQ_TRIM field gets overwritten when IFR value gets loaded in the SoC. Setting this field to '1' blocks the FREQ_TRIM field from being loaded again. If LOCK_EN bit is set to '1', this field is ignored and no IFR values get loaded. 0b - IFR loading is enabled 1b - IFR loading is disabled
28-11 —	Reserved
10-0 FREQ_TRIM	Frequency Trim These field controls the frequncy of the FRO. The frequency is decreased monotonically when this field is changed progressively from 00000000000b to 11111111111b. This field is set from the IFR (Flash) but can be overridden by software. This field can be changed only when the FRO32K_CTRL[FRO_EN] field is '0'. **NOTE** To ensure monotonic change in frequency in a closed loop mode, the bit 0 of this field should always be kept '0'. The IFR_DIS and LOCK_EN fields control how this field gets loaded. If IFR_DIS is '1', this field will not be loaded with IFR value. If LOCK_EN bit is '1', this field will be locked for both IFR load and software writes. 100_0000_0000b - Default trim value

29.6.1.4 32 kHz OSC Control Register (OSC32K_CTRL)

Offset

Register	Offset
OSC32K_CTRL	8h

Function

The 32 kHz OSC Control Register (OSC32K_CTRL) controls the 32 kHz Crystal Oscillator.

Diagram

11-8 EXTAL_CAP_SEL	Crystal load capacitance selection bits Selects the internal capacitance for the EXTAL pin from the capacitor bank. The final load capacitance can be calculated as $C_L = ((C_{extal} . C_{xtal})/(C_{extal} + C_{xtal})) + C_{shunt}$ where: • C_{extal} is the selected capacitance on EXTAL pin • C_{xtal} is the selected capacitance on XTAL pin • C_{shunt} is the internal shunt capacitance whose value can be determined from the device's datasheet The selected capacitance value is shown below. 0000b - Invalid configuration 0001b - 2 pF 0010b - 4 pF 0011b - 6 pF 0100b - 8 pF 0101b - 10 pF 0110b - 12 pF 0111b - 14 pF 1000b - 16 pF 1001b - 18 pF 1010b - 20 pF 1011b - 22 pF 1100b - 24 pF 1101b - 26 pF 1110b - 28 pF 1111b - 30 pF
7 CAP_SEL_EN	Crystal Load Capacitance Selection Enable Enables the internal capacitor banks on the EXTAL and XTAL pins that vary the load capacitance on these pins.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Internal capacitance bank is not enabled 1b - Internal capacitance bank is enabled
6-5 —	Reserved bits. Do not write to these bits.
4-3 —	Reserved bits. Reads only zeros. Writes have no effect but it is preferred that these bits are not written to.
2 —	Reserved bits. Reads only zeros.
1 OSC_BYP_EN	Crystal Oscillator Bypass Enable When this field is set to 1b, the crystal oscillator will be bypassed, and the output of the crystal oscillator is the same as that of the external oscillator from the EXTAL pin. Both OSC_EN and this bit must be set together to 1b to enable the bypass mode of the oscillator. To exit bypass mode, both OSC_EN and OSC_BYP_EN bits must be set to '0'. User must not move the OSC from bypass mode directly to normal mode. 0b - Crystal oscillator is not bypassed 1b - Crystal oscillator is bypassed
0 OSC_EN	Crystal Oscillator Enable This field enables the crystal oscillator when set to '1'. The oscillator will start giving the clock output but the clock is not available to the device until the STATUS[OSC_RDY] and STATUS[OSC_ACTIVE] fields are asserted. 0b - Oscillator is disabled 1b - Oscillator is enabled

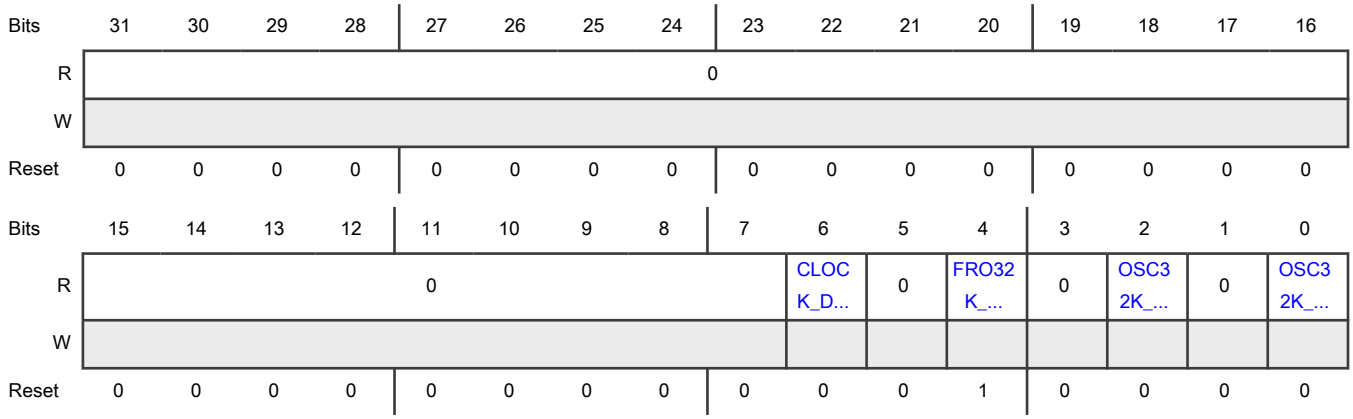
29.6.1.5 Status Register (STATUS)

Offset

Register	Offset
STATUS	Ch

Function
This register provides status bits for the CCM32K module.

Diagram



Fields

Field	Function
31-7 —	Reserved bits. Reads only zeros.
6 CLOCK_DET	Clock Detect The Clock monitor has detected an error. 0b - Clock error is not detected 1b - Clock error is detected
5 —	Reserved bits. Reads only zeros.
4 FRO32K_ACTIVE	32 kHz FRO active bit Indicates whether the 32 kHz free running oscillator is active and in use as the clock source or not. 0b - FRO32K is not the active clock source 1b - FRO32K is the active clock source
3 —	Reserved bits. Reads only zeros.
2 OSC32K_ACTIVE	32 kHz Oscillator active bit Indicates whether the 32 kHz crystal oscillator is active and in use as the clock source or not. 0b - OSC32K is not the active clock source 1b - OSC32K is the active clock source
1 —	Reserved bits. Reads only zeros.
0	32 kHz Oscillator ready bit.

Table continues on the next page...

Table continued from the previous page...

Field	Function
OSC32K_RDY	A '1' on this bit indicates that clock output from the crystal oscillator is stable. The software can decide to switch to the OSC32K clock when this bit is set. However, this bit does not clear when due to any reason the OSC32K stops providing a clock. Other on-chip tamper detection methods might indicate if clock has stopped due to removal of crystal or other reasons. This bit de-asserts during a POR event OR if the OSC32K_CTRL[OSC_EN] bit set to 0. 0b - Clock output from crystal oscillator is not stable. 1b - Clock output from crystal oscillator is stable.

29.6.1.6 Clock Monitor Control Register (CLKMON_CTRL)

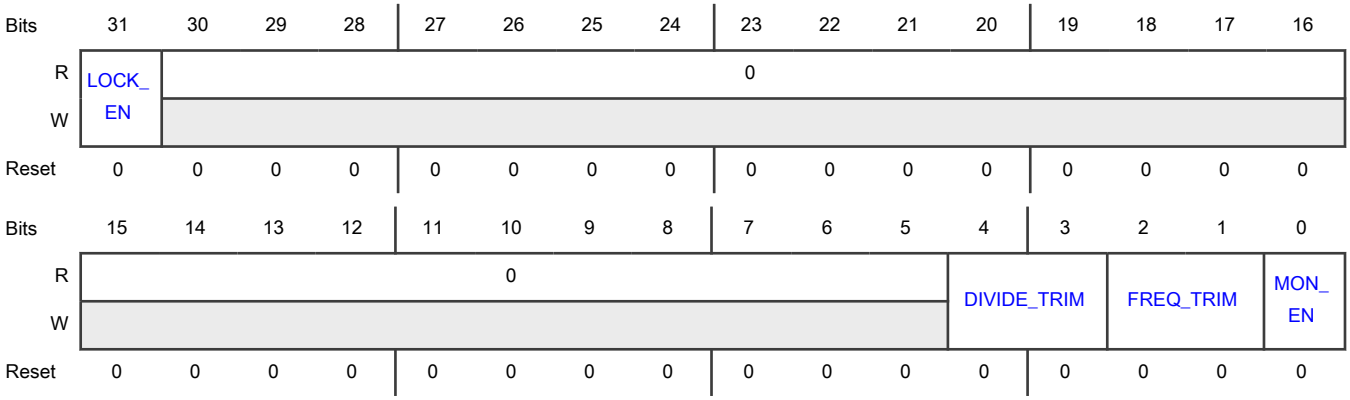
Offset

Register	Offset
CLKMON_CTRL	14h

Function

Provides control bits for clock monitor.

Diagram



Fields

2-1 FREQ_TRIM	Frequency trim bits Clock monitor frequency trim 00b - Clock monitor asserts 2 cycle after expected edge (assert after 10 cycles with no edge) 01b - Clock monitor asserts 4 cycles after expected edge (assert after 12 cycles with no edge) 10b - Clock monitor asserts 6 cycles after expected edge (assert after 14 cycles with no edge) 11b - Clock monitor asserts 8 cycles after expected edge (assert after 16 cycles with no edge)
0 MON_EN	CLKMON Enable Enables the CLKMON when set to '1'. 0b - CLKMON is disabled 1b - CLKMON is enabled

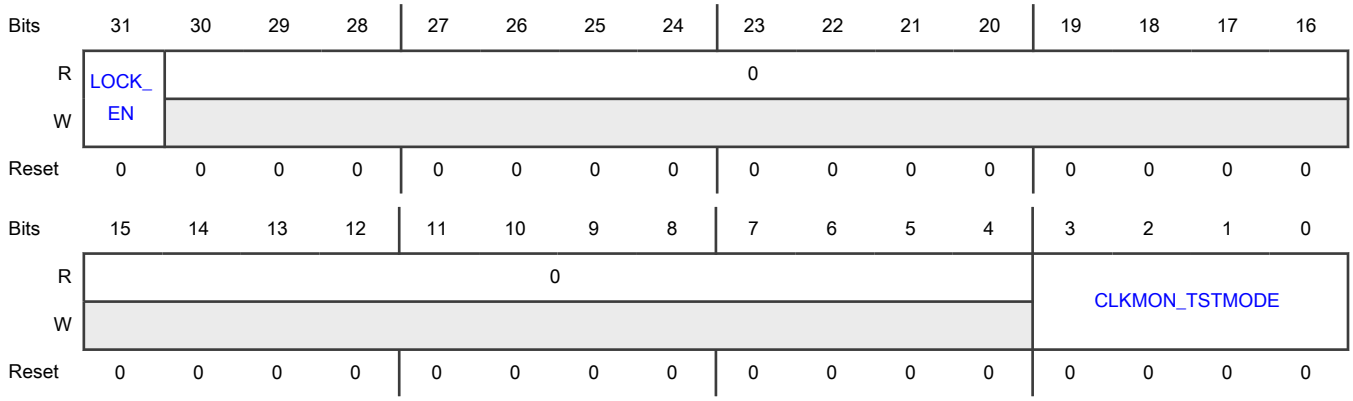
29.6.1.7 Clock Monitor Test Register (CLKMON_TST)

Offset

Register	Offset
CLKMON_TST	18h

Function
Provides control bits for clock monitor test.

Diagram



Fields

Field	Function
31 LOCK_EN	Write Access Lock bit When set to '1', this bit will lock all further write accesses to this register until a POR occurs. Writing '0' after setting this bit to '1' has no effect. 0b - Register write access is unlocked 1b - Register write access is locked
30-4 —	Reserved bits. Reads only zeros.
3-0 CLKMON_TSTMODE	Test Mode Configure the CLKMON test mode. Fields '0' and '1' indicate the reference clock and enable signal respectively after entering test mode. Moreover, fields '2' and '3' are for monitored clock part. When set to '0000' following '0101' after resetting CLKMON_CTRL [MON_EN], these fields can completely turn off clock monitor.

29.6.1.8 32 kHz Clock Gate Control Register (CGC32K)

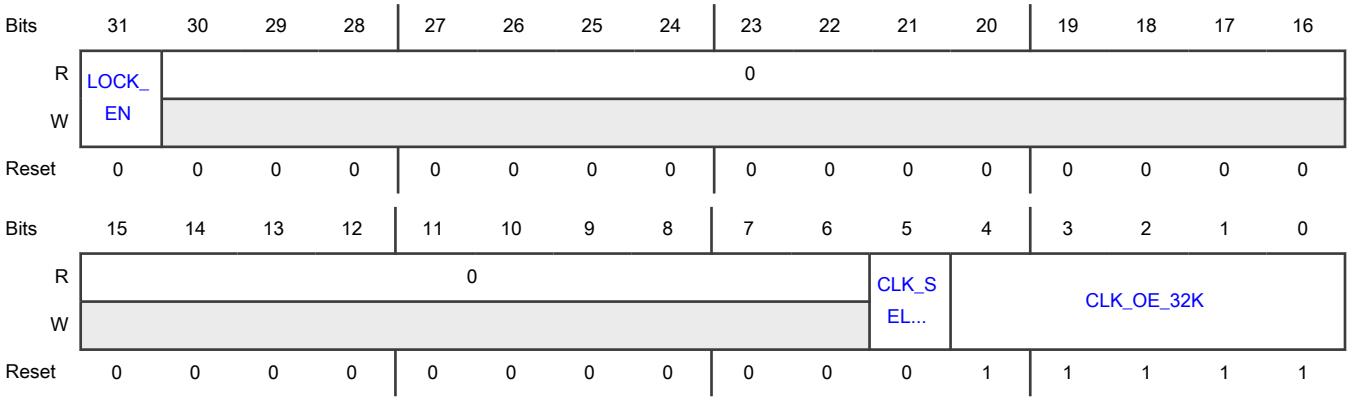
Offset

Register	Offset
CGC32K	1Ch

Function

Provides 32 kHz clock output gate control bits for peripherals.

Diagram



Fields

Field	Function
31 LOCK_EN	Write Access Lock bit When set to '1', this bit will lock all further write accesses to this register until a POR occurs. Writing '0' after setting this bit to '1' has no effect. 0b - Register write access is unlocked 1b - Register write access is locked
30-6 —	Reserved bits. Reads only zeros.
5 CLK_SEL_32K	32 kHz clock source selection bit 0b - FRO32K clock output is selected as clock source 1b - OSC32K clock output is selected as clock source
4-0 CLK_OE_32K	32 kHz clock output enable bits Each bit is used by different peripherals. • CLK_OE_32K [0]: RTC • CLK_OE_32K [1]: RFMC • CLK_OE_32K [2]: NBU • CLK_OE_32K [3]: WUU/RMC/PORTD • CLK_OE_32K [4]: Other modules 0_0000b - Clock output is disabled 0_0001b - Clock output is enabled

Chapter 30
Power Management

30.1 Introduction

This chapter describes the power modes supported with this device. It also describes the power domains and the voltage supply options connected to these power domains.

NOTE

Refer to Radio low power mode for power management of radio sub-system.

30.2 Power domains

A power domain is a collection of circuits that can be powered off even when a voltage source is still supplied. This section shows the power domains within the device and the modules belong to these domains.

NOTE

If a module belongs to several power domains, the module will be powered off when any of the power domain is powered off.

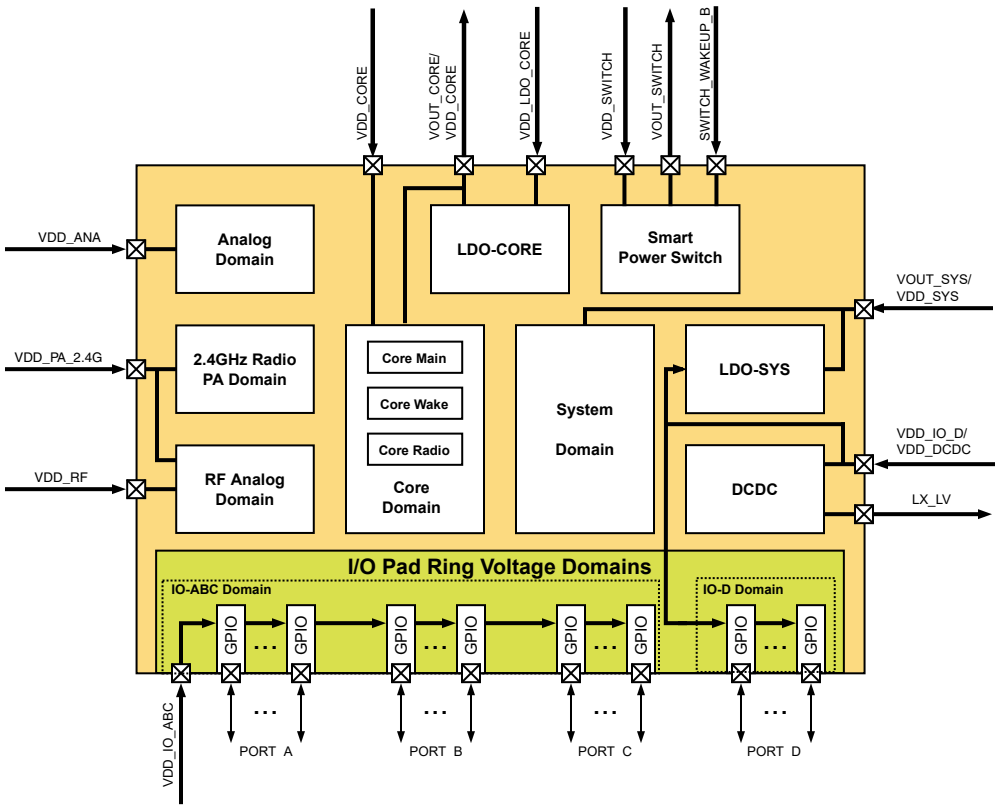


Figure 78. Power domains and voltage supplies

Table 205 lists all the power domains in the figure, and Table 206 lists all the regulators in the figure. Refer to Smart power switch for details of the smart power switch.

LDO-CORE	VDD_LDO_CORE	LDO-CORE provides the lower cost option.
LDO-SYS	VDD_IO_D	—

30.3 Power modes

The device supports Active, Sleep, Deep Sleep, Power Down, and Deep Power Down modes. Any reset brings the chip back to the Active mode.

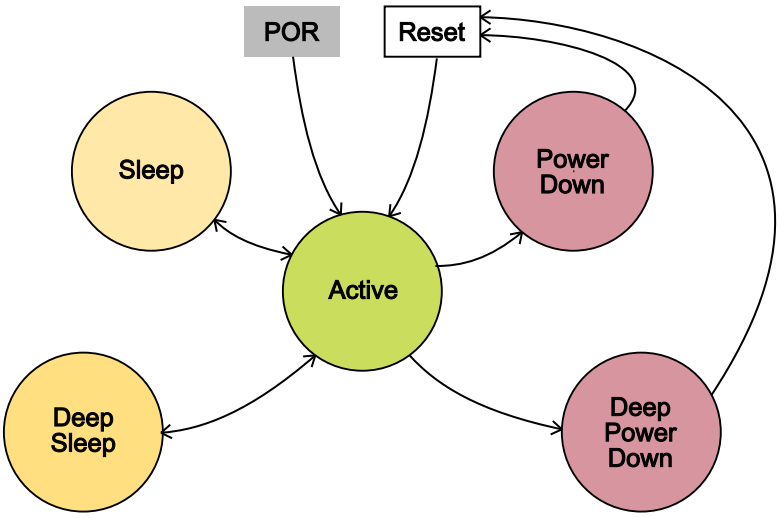

Figure 79. Power modes

30.3.1 Active mode

In Active mode, CPU execution is possible.

To achieve the performance requirements of a given system application while minimizing power consumption, Active mode permits the following power-saving options when possible:

- Configure the VDD_CORE subdomains voltage level to balance power and performance.
- Individually configure SRAM as active/shutdown by software.
- Gate the clocks to unused modules.
- Configure the unused VDD_CORE subdomains to state retention mode.
- Power-gate the unused VDD_CORE subdomains.

30.3.2 Sleep mode

In Sleep mode, CPU execution is halted. The core clock is gated off. The system clock as well as the bus clocks, if enabled, continue to operate.

Sleep mode supports the following behaviors based on different clock configurations:

- CPU clock is OFF. The system clock and bus clock remain ON. Most modules can remain operational.
- CPU clock, system clock and bus clock are all OFF. Some modules can remain operational with low power asynchronous clock sources and serve as wake-up sources.

Wake from Sleep mode is triggered by an interrupt or a wakeup event.

Sleep mode also supports a partial wake-up where a bus master other than the CPU (eg. DMA) is recovered by a wakeup event. The device automatically re-enters sleep mode after this module finishes its task.

To achieve the performance requirements of a given system application while minimizing power consumption, Sleep mode permits the following power-saving options when possible:

- Configure the VDD_CORE subdomains voltage level to balance power and performance.
- Individually configure SRAM as active / deep sleep / shutdown by software.
- Gate the clocks to unused modules.

- Configure the unused VDD_CORE subdomains to state retention mode.
- Power-gate the unused VDD_CORE subdomains.

30.3.3 Deep Sleep mode

Deep Sleep mode places most of the chip into a static state. It is the lowest power mode that can retain all registers.

The device wakes from Deep Sleep mode through the interrupt routine or wake-up event.

The core clock, system clock and the bus clock are gated off.

In Deep Sleep mode, the whole VDD_CORE_MAIN subdomain is put into state retention mode.

In Deep Sleep mode, the peripherals inside the VDD_CORE_WAKE subdomain can remain operational using an asynchronous clock and can wake the device.

Refer to Low Power Mode Controllers for peripherals in the VDD_CORE_2.4G.

External signals via GPIO or VDD_SYS domain peripherals can wake the device.

The VDD_CORE subdomains voltage level can be independently selected from either the VDD_CORE voltage or the reduced voltage scaling (IVS) voltage to balance different module clock frequencies and the power leakage.

SRAM can also be individually configured as deep sleep or shutdown by software.

30.3.4 Power Down mode

Power Down mode places the chip in power off state.

The device wakes from Power Down mode through the reset routine.

In Power Down mode, the whole VDD_CORE_MAIN subdomain is power gated.

In Power Down mode, the peripherals inside the VDD_CORE_WAKE subdomain can optionally remain operational using an asynchronous clock and can wake the device.

Refer to Low Power Mode Controllers for peripherals in the VDD_CORE_2.4G.

External signals via GPIO, VDD_SYS domain peripherals, or the RTC power domain peripherals can wake the device.

SRAM can also be individually configured as retention or off by software.

30.3.5 Deep Power Down mode

Deep Power Down mode permits the lowest power level.

The device wakes from Deep Power Down mode through the Reset routine.

In Deep Power Down mode, the whole VDD_CORE domain (including all subdomains) is power gated.

In Deep Power Down mode, the on-chip regulator for VDD_CORE is powered off. The VDD_SYS on-chip regulator is powered on , and the VDD_SYS power domain is enabled. The external power supply to any of the on-chip regulators that are disabled should be turned off to avoid extra leakage.

External reset or the VDD_SYS domain peripherals can wake the device.

SRAMs without RAM LDO supplied cannot be retained in Deep Power Down mode.

30.4 Module operation in low power modes

The following table shows module functionality in low power modes.

Table 207. Cortex M33 core module operation in low power modes

Module	Sleep	Deep Sleep	Power Down	Deep Power Down

VDD_CORE_2P4G_SRAM [2]	ACT/RET/OFF	ACT/RET/OFF	ACT/RET/OFF	ACT/RET/OFF	OFF
VDD_SYS	ACT	ACT	ACT	ACT	ACT

1. System SRAM is partitioned and each part is individually configurable by CMC.
2. Radio SRAM is partitioned into Tx/Rx RAM and each part is individually configurable by Radio.

Since VDD_CORE_MAIN, VDD_CORE_WAKE and VDD_CORE_2P4G are independent power domain, there are various low-power mode combinations among them. The SPC will do the arbitration on their low-power requests and select the highest low-power mode as system power mode.

From system point of view, it has several scenarios:

1. MCU in low-power mode, Radio switch between run and low-power mode (typical case for Bluetooth LE event without CPU involved)
2. Radio wakeup MCU to deal with connectivity upper layer software like Bluetooth LE Host or applications
3. MCU switch between run and low-power mode for general application, Radio in low-power mode (Radio is not enabled)

30.5 Power supply configurations

This section shows some of the most common power supply configurations.

30.5.1 Recommended configuration for tradeoff between cost and power efficiency

The following figure shows a power efficient configuration of the device power supplies.

In this configuration:

- External 3.3 V for DCDC, VDD_IO_D, VDD_IO_ABC, LDO-SYS

- LDO-CORE, VDD_RF come from DCDC output
- Generate VPA_2P4GHZ internally from VDD_RF

NOTE

VPA_2P4GHZ voltage depends on Tx power level. It can be powered internally or externally. When internal supply is used, VDD_RF voltage must be equal to or exceed VPA + 275 mV. For this specific configuration, it can support up to +10 dBm.

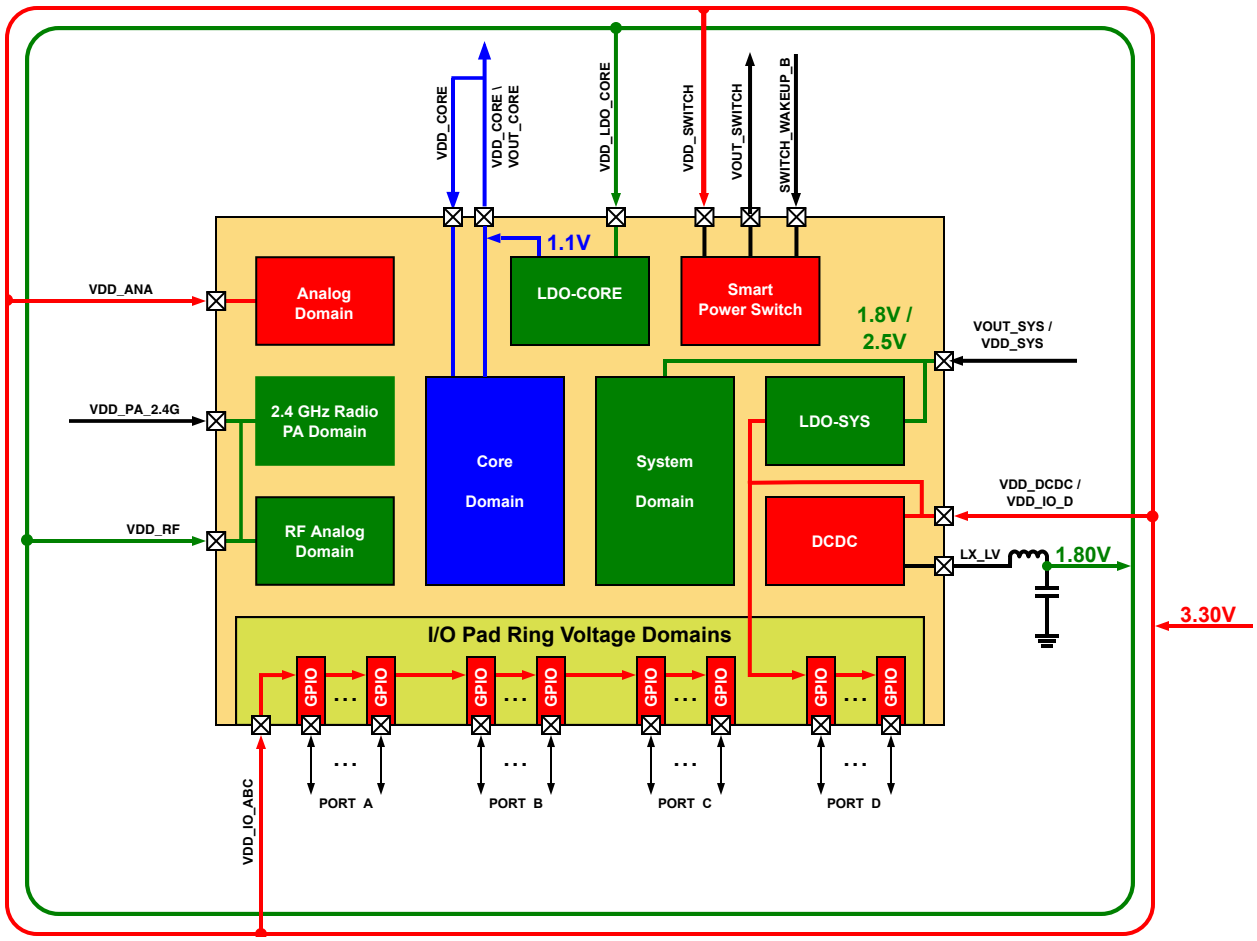

Figure 80. Power efficient schematic

30.5.2 Low cost supply configuration

The following figure shows a low cost configuration of the device power supplies.

In this configuration:

- Bypass DCDC
- External 3.3 V (range: 1.71 – 3.6 V) for LDO-CORE, LDO-SYS, VDD_IO_D, VDD_IO_ABC and VDD_RF
- Generate VPA_2PGHZ internally from VDD_RF

NOTE

VPA_2P4GHZ voltage depends on Tx power level. It can be powered internally or externally. When internal supply is used, VDD_RF voltage must be equal to or exceed VPA + 275 mV.

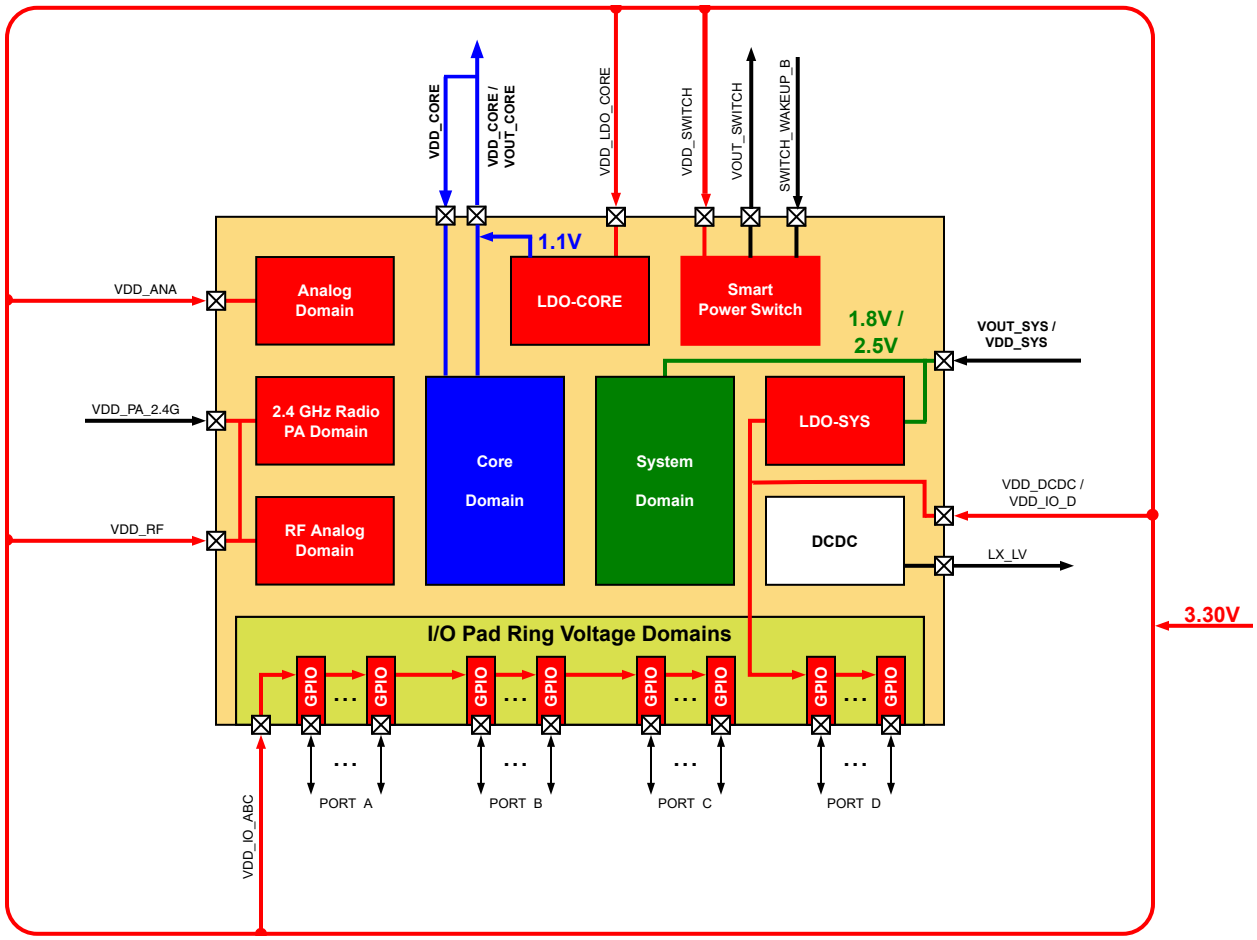

Figure 81. Low cost schematic

30.5.3 PMIC supply configuration

The following figure shows a PMIC configuration of the device power supplies.

In this configuration:

- Bypass LDO_CORE/DCDC
- External 1.2 V for VDD_CORE
- External 3.3 V for VDD_IO_D, VDD_IO_ABC
- External 1.2V for VDD_RF
- External 2.4 V for VPA_2P4GHZ

NOTE

VPA_2P4GHZ voltage depends on Tx power level. It can be powered internally or externally. When internal supply is used, VDD_RF voltage must be equal to or exceed VPA + 275 mV.

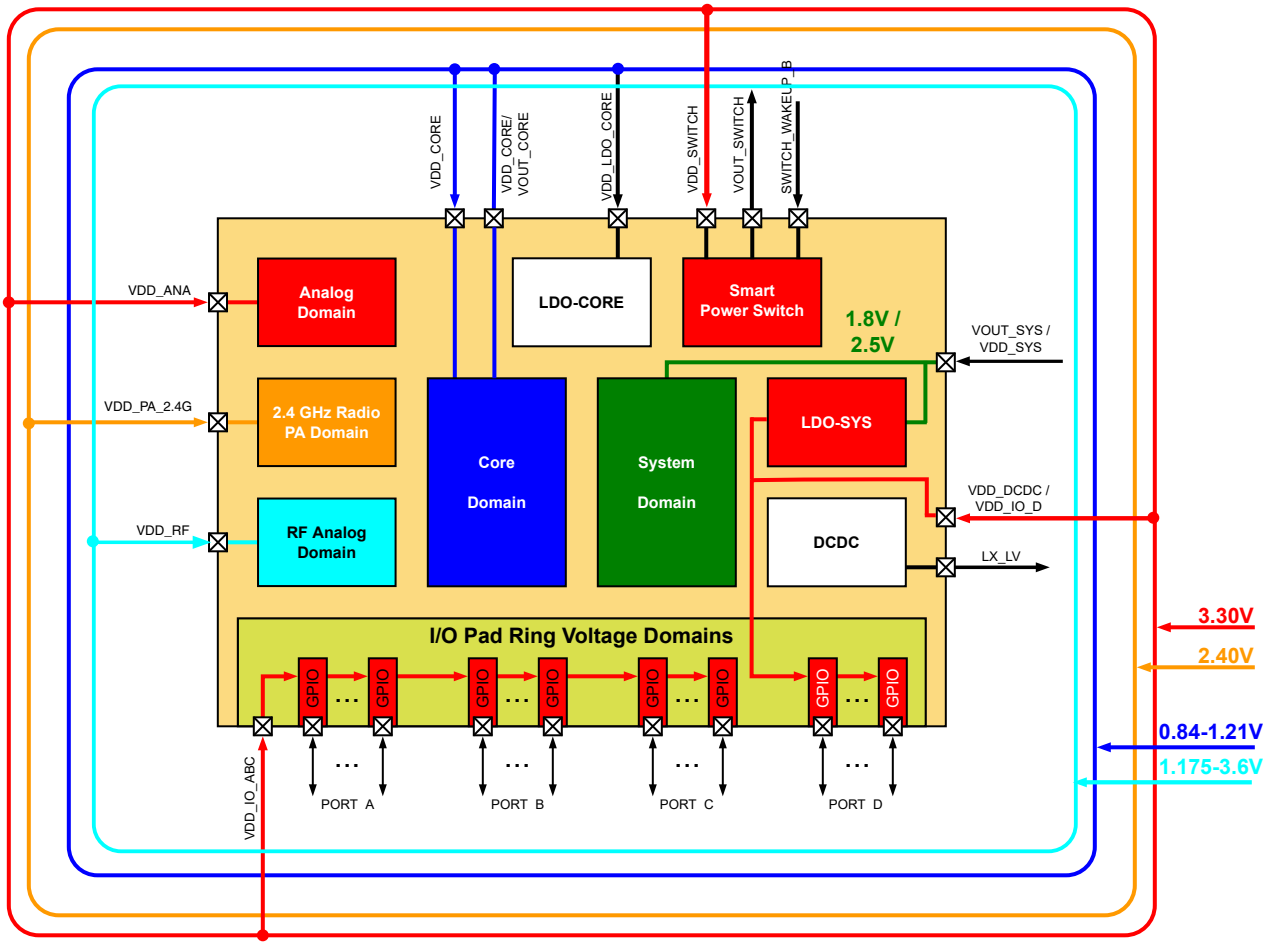

Figure 82. PMIC schematic

Additionally, LDO_SYS can also be bypassed. It requires connecting VOUT_SYS/VDD_SYS and VDD_LDO_SYS to 1.8 V and disabling the LDO_SYS at SPC_CNTRL[SYSLDO_EN]. Consider that fuse programming is not allowed while LDO_SYS is bypassed.

30.6 Power optimization

30.6.1 VDD_CORE voltage scaling

This device supports VDD_CORE voltage scaling for different performance and power consumption.

This device supports the following VDD_CORE voltage scaling methods:

- By adjusting VDD_CORE power supply input level directly with internal IVS disabled. This method is available for all power modes. The user must configure VDD_CORE voltage level through SPC registers when VDD_CORE is supplied by on-chip regulators (LDO-CORE). The device power consumption can benefit from the regulator high efficiency when DCDC is used as VDD_CORE source. However, the VDD_CORE voltage needs time to reach new levels for charging or discharging the VDD_CORE pin capacitor.
- By internal IVS (internal voltage scaling) module. This method will apply only to Deep Sleep and Power Down modes. The user should configure the target IVS output voltage level before entering low power modes. The VDD_CORE input voltage will remain unchanged. The IVS manipulates the internal supply voltage directly. The voltage will reach the new target value much faster.

Each VDD_CORE subdomain can independently enable or disable their own IVS in low power modes. For example, the VDD_CORE_MAIN subdomain can enable its IVS for a lower supply voltage. At the same time, the VDD_CORE_WAKE subdomain can continue operating with the higher supply level from VDD_CORE.

30.6.2 SRAM Configuration

The SRAM is partitioned, allowing the mode of each SRAM partition to be independently configured:

SRAM power mode	Description
Active	SRAM can be accessed normally.
Deep Sleep	SRAM cannot be accessed, but the data is retained.
Shutdown	SRAM cannot be accessed, and the data is not retained.

Depending on the requirements of the system application, software can optionally configure an individual SRAM partition to be in a lower, power-saving mode relative to the overall device power mode:

When the overall device power mode is...	An SRAM partition may be configured into this mode...
Active	Active or Shutdown
Sleep	Active or Deep Sleep or Shutdown
Deep Sleep or Power Down	Deep Sleep or Shutdown

NOTE

All SRAM partitions are forced into Shutdown mode after the device enters Deep Power Down mode.

30.6.3 Flash low power options

To balance power usage versus performance requirements, the flash module can be configured independent of the overall device power mode:

Flash power mode	Description
Full power	Supports full speed read, program and erase.
Low speed active	Supports reduced frequency read, program, and erase.

The flash module supports low-power feature by configuring CMC_FLASHCR registers. It can configure Flash in low-power mode when MCU is in Active mode or CM33 CORE is sleeping. In parallel, it provide option to automatic wakeup Flash from low-power mode when any flash access.

NOTE

To avoid unexpected access latencies, take care when configuring the flash module to a low power mode when the overall device is in Active mode. The flash module needs time to recover full-speed functionality after entering a low power mode.

30.6.4 Peripheral clock gating

To conserve power, the clocks to modules can be turned off or divided by configuring the MRCC module registers.

30.6.5 Voltage monitor optimization

Depending on the requirements of the system application, software can disable individual voltage monitors (LVD and/or HVD) within the different power domains to save power.

30.6.6 Wake-up time consideration

This device supports different low power modes for power consumption level and wake-up time balance.

The wake-up time from Sleep/Deep Sleep mode is the accumulation of following time:

- VDD_CORE power source recovery time
- The longer of the following:
  - Clock recovery time
  - Flash recovery time
- Interrupt Latency

The wake-up time from Power Down mode is the accumulation of following time:

- VDD_CORE power source recovery time
- The longer of the following:
  - Clock recovery time
  - Flash recovery time
- System Reset Latency

The wake-up time from Deep Power Down mode is:

- The boot-up time required after device released by POR. This includes everything included in a cold power-up, including the Boot ROM latency.

The clock recovery time can be affected by following factors:

- The system clock source status in low power modes. There will be no recovery time needed if the clock remains ON in low power mode.
- The system clock source before entering low power mode.

The flash recovery time depends on the flash status in low power mode.

The VDD_CORE power source recovery time can be affected by following factors:

- The regulator type used. On-chip linear regulator starts up faster than on-chip DCDC.
- The regulator status in low power modes. There will be no recovery time needed if the regulator remains in full-power regulation in low power mode.
- Whether VDD_CORE voltage scaling is enabled before and after entering low power modes
- The VDD_CORE domain voltage scaling method used. Voltage scaling by internal IVS recovers faster.
- The external capacitor on VDD_CORE pin will affect recovery time if scaling is achieved by adjusting VDD_CORE voltage directly.

30.7 Smart power switch

The smart power switch supports two major use-cases:

- It can be used to switch off all or part of MCU power supply to get lower power consumption than deep power down mode. See Figure 83 as an example.

- It can be used to power external device. For example, sensor device will be power off most of time and can keep power when measurement. Figure 80 is the example with the VOUT_SWITCH powering an external sensor, and Figure 84 is another example to power an external sensor and an I/O rail.

It has several ways to turn on power switch

- The POR of power switch input supply
- external SWITCH_WAKEUP_B pin. Once driven low, it can turn on power switch;
- internal wakeup logic from SPC if VSYS is powered ON;
- internal timer using internal FRO16K

NOTE

To support standby RAM LDO and RAM power switch, smart power switch input supply (VDD_SWITCH) is required to be powered permanently.

In Figure 83:

- External 3.3 V supply to Smart Power Switch
- Power switch output connected to DCDC, LDO-SYS, VDD_ANA, VDD_IO_D and VDD_IO_ABC
- DCDC output connected to LDO-CORE, VDD_RF

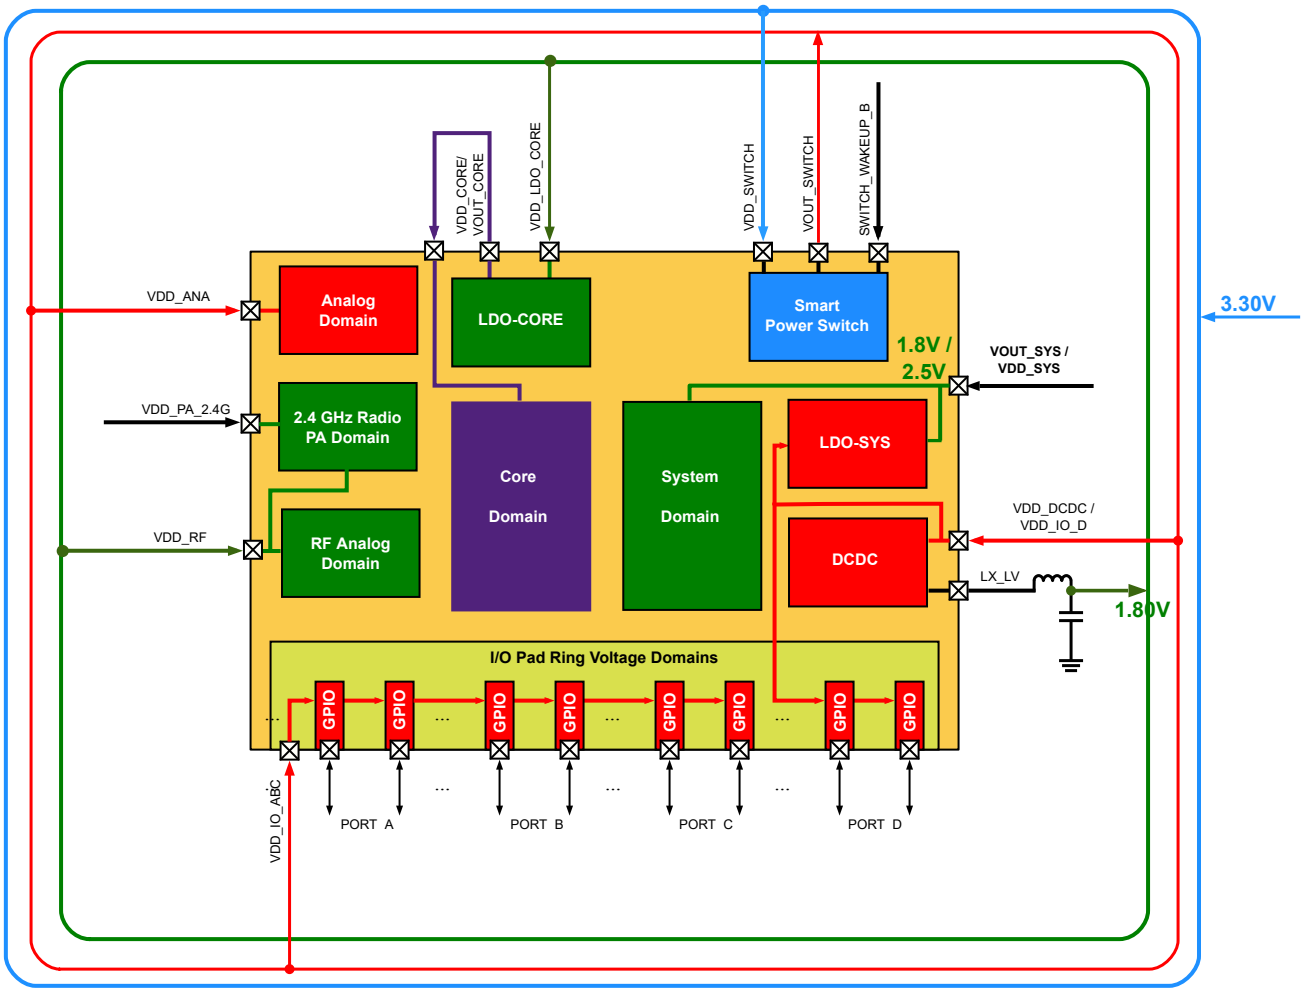

Figure 83. Power all supply

In Figure 84:

- External 3.3 V supply to Smart Power Switch and VDD_DCDC/VDD_IO_D
- Power switch output connected to VDD_ANA and VDD_IO_ABC
- DCDC output connected to LDO-CORE, VDD_RF

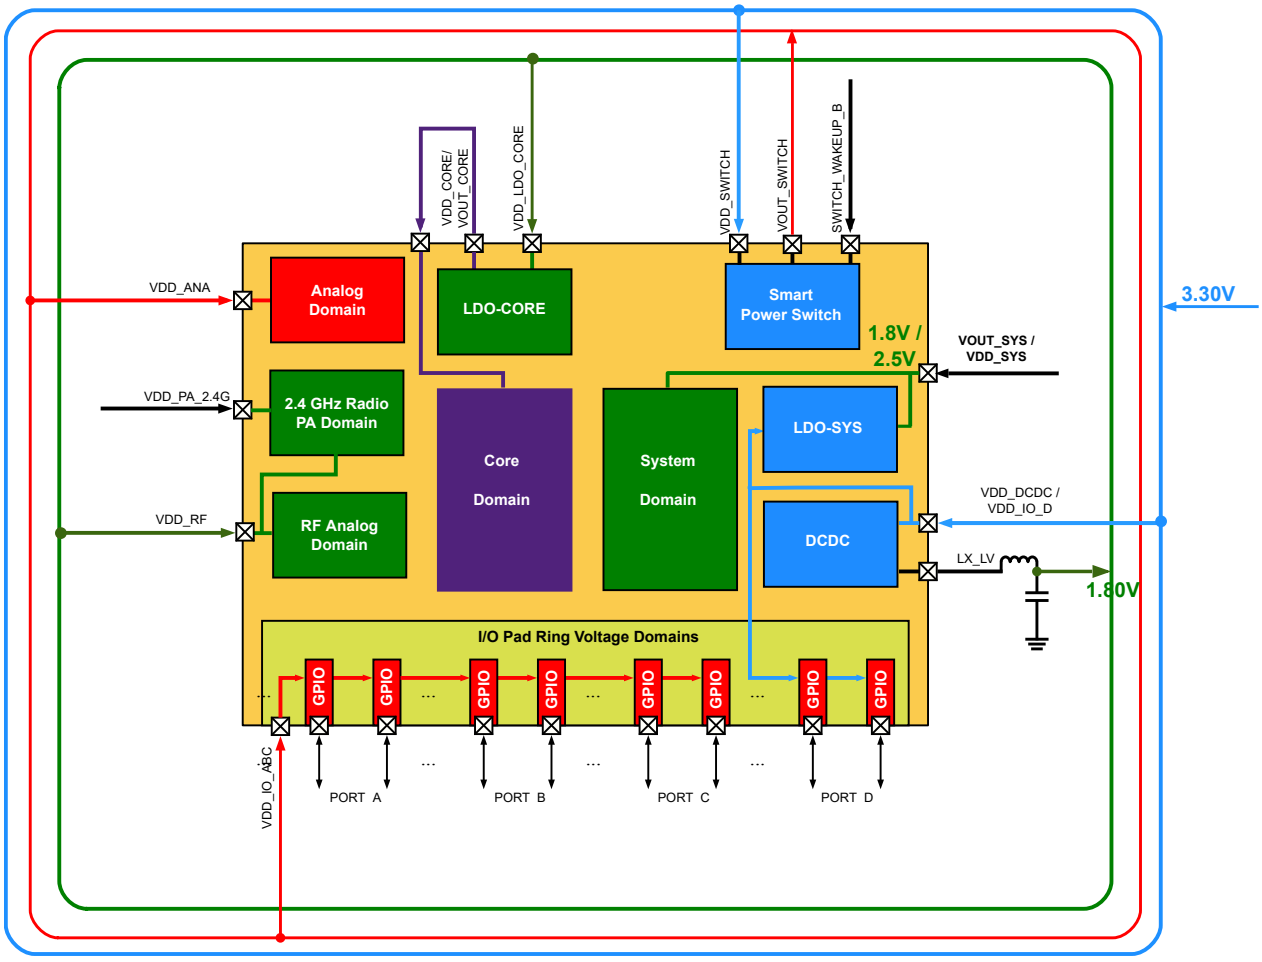

Figure 84. Power all supply except VDD_IO_D/VDD_DCDC

Signal multiplexing	Port control	Signal multiplexing

31.1.1 Module instances

This device has one instance of the CMC module, CMC0.

31.1.2 TCM arrays

Table 211. TCM SRAM assignment

TCM	SRAM instance	AXBS slave port assignment	Size	Base Address	Controlled by	ECC
Code TCM	CTCM0[1]	S1	8 KB	0x0400_0000	CMC_SRAMSDR0[SDE0] CMC_SRAMDSR0[DSE0]	Yes
	CTCM1[1]	S1	8 KB	0x0400_2000	CMC_SRAMSDR0[SDE1] CMC_SRAMDSR0[DSE1]	Yes
System TCM	STCM0[1]	S2	16 KB	0x2000_0000	CMC_SRAMSDR0[SDE2] CMC_SRAMDSR0[DSE2]	Yes
	STCM1[1]	S2	16 KB	0x2000_4000	CMC_SRAMSDR0[SDE3] CMC_SRAMDSR0[DSE3]	Yes
	STCM2[1]	S2	32 KB	0x2000_8000	CMC_SRAMSDR0[SDE4] CMC_SRAMDSR0[DSE4]	Yes
	STCM3[1]	S3	32 KB	0x2001_0000	CMC_SRAMSDR0[SDE5] CMC_SRAMDSR0[DSE5]	No
	STCM4[1]	S3	8 KB	0x2001_8000	CMC_SRAMSDR0[SDE6] CMC_SRAMDSR0[DSE6]	No
	STCM5[2]	S4	8 KB	0x2001_A000	VBAT_LDORAMC[ISO]	Yes

1. If the corresponding SRAMSDR0[SDE] bit is set, any access to the TCM will trig bus fault.
2. If VBAT_LDORAMC[ISO] bit is set and ECC is enabled, any access to the STCM5 will trig ECC fault.

31.2 Overview

CMC provides the sequencing of the CPU and associated logic through the different operating modes.

This chapter describes the available CPU operating modes, including reset, active mode, and low-power modes.

31.2.1 Block diagram

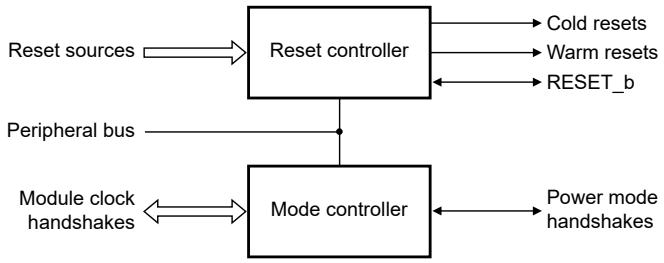

Figure 85. Block diagram

31.2.2 Features

- Configures the low-power mode options
- Provides reset controller including reset status register and warm reset configuration
- Provides boot mode register and status bits

31.3 Functional description

This section provides the functional description of the block.

31.3.1 Modes of operation

The Arm Cortex-M CPU enters a low-power mode with the execution of a WFI or WFE instruction or via the SLEEPONEXIT mechanism. CMC configures the low-power mode that is entered.

The following table describes the low-power modes available to each core.

Table 212. Operating modes

Mode	Entry	Exit	Description
Reset	POR Warm reset WUU via Power-Down	Active	Core and peripherals are reset. SRAM optionally retained on power-down wake-up.
Active	Reset NVIC WUU	WFI WFE SLEEPONEXIT	Core executing instructions, peripherals optionally active.

Table continues on the next page...

Table 212. Operating modes (continued)

Mode	Entry	Exit	Description
Sleep	WFI WFE SLEEPONEXIT	NVIC Reset	Core waiting for interrupt or event, peripherals optionally active. Core and peripherals retain state, SRAM optionally retained.
Deep Sleep	WFI WFE SLEEPONEXIT	WUU via Active Reset	Core and peripherals waiting for wake-up. Core and peripherals retain state, SRAM optionally retained.
Power-Down	WFI WFE SLEEPONEXIT	WUU via Reset Reset	Core and peripherals not retained, SRAM optionally retained.
Deep-Power Down	WFI WFE SLEEPONEXIT	WUU via Reset Reset	Core, peripherals, and SRAM not retained.

31.3.2 Active mode

This section describes power options in Active mode.

31.3.2.1 Flash memory

This section describes the Flash Memory Low-Power mode.

You can place the internal flash memory in Low-Power mode under the following conditions:

- Under software control (FLASHCR[FLASHDIS])
- When CPU is sleeping (FLASHCR[FLASHDOZE])
- When the chip enters a low-power mode

When FLASHCR[FLASHDIS] or FLASHCR[FLASHDOZE] becomes 1, you can configure the internal flash memory to automatically exit Low-Power mode during the access on any attempted access to flash memory space. FLASHCR[FLASHWAKE] controls this.

When the internal flash memory enters a low-power mode, the wake-up time of the flash memory automatically delays the first access upon exit from Low-Power mode. If there is no access between the internal flash memory exiting Low-Power and subsequent re-entry of Low-Power mode, the wake-up time of the flash memory delays the re-entry.

31.3.2.2 System SRAM

The system SRAM is divided into 8 different power partitions. You can individually power gate these partitions either all the time or only in low-power modes. System SRAM contents in a power gated partition are not retained. You must not access system SRAM partitions when they are power gated.

- Write 1 to SRAMSDR[i] to always power gate system SRAM power partition "i".
- Write 1 to SRAMDSR[i] to power gate system SRAM power partition "i" during a low-power mode only.

31.3.3 Low-power modes

This section describes the low-power modes.

31.3.3.1 Low-power entry

The following steps occur during the Low-Power mode entry sequence.

Table 213. Entry sequence

Step	CKMODE (min)	LPMODE (min)	Description
1	0h	0h	Core enters Low-Power mode by WFI/WFE instruction or via SLEEPONEXIT.
2	1h	0h	• Wake-up interrupt controller is enabled. • Core is clock gated.
3	3h	0h	• Request AHB initiators to enter Low-Power mode. • Wait for acknowledge. • AHB initiators are clock gated.
4	3h	0h	• Request AHB peripherals to enter Low-Power mode. • Wait for acknowledge. • AHB peripherals are clock gated.
5	7h	0h	• Request peripherals to enter Low-Power mode. • Wait for acknowledge. • Peripherals are clock gated.
6	Fh	0h	Request power management (regulators, bandgap) to enter Low-Power mode.
7	Fh	1h	• SRAMs enter Low-Power mode. • System clocks are gated.
8	Fh	3h	Power domain is placed in Low-Power retention state (Deep Sleep).
9	Fh	7h	Power domain is switched off (Power-Down).
10	Fh	Fh	Regulators are powered off (Deep Power-Down).

31.3.3.2 DMA wakeup

You can configure the DMA to generate a wake-up when a DMA request for configured channel asserts. This is supported when you request the DMA to enter Low-Power mode and retain the DMA state (not Power Down or Deep Power Down).

The DMA wakeup triggers an exit from Low-Power mode for everything except the core, which remains clock gated. Re-enter Low-Power mode after the DMA request negates, and the normal low-power mode entry sequence is followed.

Because a DMA wake-up results in everything except the core from exiting Low-Power mode, you must ensure that other modules not involved in the wakeup remain in a known state. To accomplish this, disable the modules before the initial entry in Low-Power mode or configure the Doze field in selected modules.

If the flash memory is not required during the DMA wakeup, NXP recommends that FLASHCR[FLASHDOZE] = 1.

NOTE

If the DMA request does not negate due to the DMA transfer, the chip remains in a higher power state until an interrupt or other wake-up sources can wakeup the core.

An interrupt that occurs during a DMA wakeup causes an immediate exit from Low-Power mode without affecting the DMA transfer.

31.3.3.3 Power domains

CMC configures Low-Power mode of 2 different power domains when the core enters a low-power mode with CKMODE = Fh. You can configure the different power domains to enter different low-power modes , but you must not configure the WAKE domain to a lower-power mode than any of the other domains.

NOTE

The WAKE domain LPMODE register setting must always be less than or equal to the LPMODE register setting for all other power domains.

CMC controls the following power domains:

- MAIN
- WAKE

The table below lists allowed combinations for MAIN and WAKE.

Table 214. Power Mode Combinations for MAIN and WAKE

CMC PMCTRLMAIN	CMC PMCTRLWAKE
0x0	0x0
0x1	0x1
0x3	0x3
0x3	0x1
0xF	0xF

Configure all power domains to the same Low-Power mode using Global Power Mode Control (GPMCTRL). Alternatively, configure each PMCTRL register to assign an individual low-power mode to each domain.

31.3.3.4 Debug in low-power modes

When the debugger asserts CDBGPWRUPREQ, it requests the debug logic to power up and enable the functionality depending on DBGCTL[SOD].

- When DBGCTL[SOD] = 0, the core clock remains enabled even when the core is sleeping (CKMODE = 0h). CDBGPWRUPACK remains asserted.
- When DBGCTL[SOD] = 1, ignore the debug request when the core sleeps. CDBPWRUPQACK negates when the core is sleeping.

NOTE

Do not attach a debugger when the JTAG/SWD logic is powered down.

31.3.4 Clocks

- The slow bus clock clocks CMC registers and logic.
- FRO 1 MHz clock clocks the timeout counters.

31.3.5 Reset

This section describes the sources of reset and the different resets that you can generate.

31.3.5.1 Reset sources

This section describes the different reset sources.

Power-on reset (POR)

When you initially apply power to the MCU or the supply voltage is below the POR falling threshold, the POR circuit triggers the POR condition.

The POR condition asserts a cold reset in all power domains. SRS[POR] and SRS[LVD] become 1 on a POR condition.

Low voltage detect (LVD)

The LVD circuit enables by default and keeps the MCU in reset until the supply voltage rises above the LVD rising threshold. When the LVD circuit is enabled, it triggers an LVD reset condition if the supply voltage is below the LVD falling threshold.

SRS[LVD] becomes 1 on an LVD reset condition. The LVD reset condition asserts a cold reset in all power domains. Only the LVD or HVD detection logic is unaffected by LVD or HVD resets.

High voltage detect (HVD)

The HVD circuit disables by default, but when enabled, it triggers an HVD reset condition if the supply voltage exceeds the HVD threshold.

SRS[HVD] becomes 1 on an HVD reset condition. The HVD reset condition asserts a cold reset in all power domains. Only the LVD or HVD detection logic is unaffected by LVD or HVD resets.

Wakeup (WAKEUP)

On a wakeup from Power Down or Deep-Power Down mode, the power management logic triggers a Wake-up reset in the power domains that had powered off.

The wake-up reset condition asserts a cold reset in all power domains that were powered down. The system power domain, including the RESET_b pin, is unaffected by a wake-up from Power Down or Deep-Power Down mode (unless another reset source triggers the wake-up). SRS[WAKEUP] becomes 1 on a wake-up reset condition.

External pin reset (RESET_b)

The RESET_b pin is a bidirectional open-drain pin with an internal pull-up resistor. The RESET_b pin function depends on the mode:

- During reset, the RESET_b drives low until the MCU completes initialization, at which point the RESET_b pin is released. If the RESET_b pin asserts externally, then the MCU remains in reset until the RESET_b input is pulled high.
- During active and low-power modes, the RESET_b pin can assert externally to force the MCU into the PIN reset condition.

The RESET_b pin implements a digital filter that you can configure to filter out glitches on the RESET_b pin that are less than 1–32 CMC clock cycles. The filter bypasses in low-power modes when you disable the CMC clock.

The PIN reset condition asserts a warm reset in all power domains. SRS[PIN] and SRS[WARM] become 1 on a PIN reset condition.

Debug access port reset (DAP)

Any debug access port that can initiate a reset request from a connected debugger triggers the DAP reset condition.

The DAP reset condition asserts a warm reset in all power domains. SRS[DAP] and SRS[WARM] become 1 on a DAP reset condition.

Reset timeout (RSTACK)

The reset state machine includes a timeout counter that is triggered by the reset state machine not progressing within 8192 cycles of the FRO 1 MHz clock. This triggers the RSTACK reset condition.

The RSTACK reset condition asserts a warm reset in all power domains. SRS[RSTACK], SRS[FATAL], and SRS[WARM] become 1 on an RSTACK reset condition.

Low-power timeout (LPACK)

The low-power entry state machine includes a timeout counter that triggers if a module does not acknowledge entry into Low-Power mode after 8192 cycles of the FRO 1 MHz clock. This triggers the LPACK reset condition.

The LPACK reset condition asserts a warm reset in all power domains. SRS[LPACK] and SRS[WARM] become 1 on an LPACK reset condition.

System clock generation (SCG)

The system clock generation includes loss of clock and loss of lock monitors that you can configure to generate a reset, this triggers the SCG reset condition.

The SCG reset condition asserts a warm reset in all power domains. SRS[SCG], SRS[FATAL], and SRS[WARM] become 1 on an SCG reset condition.

Watchdog 0 (WDOG0)

The watchdog timer monitors the software by expecting periodic refreshing of the watchdog counter. When this does not occur, it triggers the WDOG0 reset condition.

The WDOG0 reset condition asserts a warm reset in all power domains. SRS[WDOGO] and SRS[WARM] become 1 on a WDOG0 reset condition.

Software (SW)

The software can request a system reset by configuring the system reset request in the Cortex-M33 core, this triggers the software reset condition.

The software reset condition asserts a warm reset in all power domains. SRS[SW] and SRS[WARM] become 1 on a software reset condition.

Lockup (LOCKUP)

The Cortex-M33 core enters Lockup state as a result of certain illegal operations, this triggers the LOCKUP reset condition.

The LOCKUP reset condition asserts an MCU reset in all power domains. SRS[LOCKUP] and SRS[WARM] become 1 on a LOCKUP reset condition.

Watchdog 1 (WDOG1)

The watchdog timer monitors the software by expecting periodic refreshing of the watchdog counter. When this does not occur, it triggers the WDOG1 reset condition.

The WDOG1 reset condition asserts a warm reset in all power domains. SRS[WDOG1] and SRS[WARM] become 1 on a WDOG1 reset condition.

Security violation (SECVIO)

When a security module detects a security violation, it triggers the SECVIO reset condition.

The SECVIO reset condition asserts a warm reset in all power domains. SRS[SECVIO], SRS[FATAL], and SRS[WARM] become 1 on a SECVIO reset condition.

31.3.5.2 Reset types

This section describes the different resets that you can generate.

Cold reset

Each power domain generates a cold reset to reset the debug logic and mode control logic. The cold reset for each power domain can assert as a result of the following events.

- Initial POR of the chip
- Voltage detect monitor (LVD, for example)
- Power domain wake-up from Power Down or Deep-Power Down (varies per domain)

A cold reset does not guarantee the contents of on-chip SRAM, except for a Power Down wake-up and then only for the SRAM that is configured to retain state.

Warm reset

- Cold Reset or any of the remaining warm reset sources generates a warm reset.
- A warm reset resets most of the logic in each power domain.
- Warm resets are divided into fatal reset sources and non-fatal reset sources.

You can configure the non-fatal reset sources to generate an interrupt instead of the warm reset. The warm reset averts if you can clear the non-fatal reset source (including status flag) within 8192 cycles of the FRO 1 MHz clock. Non-fatal resets retain the contents of on-chip SRAM.

You cannot configure the fatal reset sources to generate an interrupt and do not guarantee the contents of on-chip SRAM.

31.3.5.3 Reset sequence

Power-on reset

Perform the following steps as part of the POR (or voltage detect monitor) sequence:

1. RESET_b pin drives low and internal reset signals asserted.
2. POR or LVD signals negate and clocks are enabled in their default configuration.
3. Internal reset remains asserted for 8 CMC clock cycles.
4. Internal reset to flash memory and fuse controllers negates and their initialization sequences commence.
5. Initialization sequences for flash memory and fuse complete.
6. Internal trim registers are loaded and RESET_b pin is tri-stated.
7. Reset state machine waits for RESET_b pin input to pull high or drive high externally.
8. Internal reset signals negate.
9. Core exits reset and fetches the initial program counter and stack pointer from ROM.

Deep-power down wake-up

Perform the following steps as part of the deep-power down wake-up sequence:

1. Internal reset signals asserted.
2. Wake-up signal negates and clocks are enabled in their default configuration.
3. Internal reset remains asserted for 8 CMC clock cycles.
4. Internal reset to flash memory and fuse controllers negates and commence their initialization sequences.
5. Initialization sequences for flash memory and fuse complete.
6. Internal trim registers are loaded.
7. Internal reset signals negate.
8. Core exits reset and fetches the initial program counter and stack pointer from ROM.

A wake-up from deep-power down via the RESET_b pin follows the warm reset sequence.

Power down wake-up

Perform the following steps as part of the power down wake-up sequence:

1. Internal reset signals asserted.
2. Clocks are enabled in their default configuration.
3. Internal reset remains asserted for 8 CMC clock cycles.
4. Internal trim registers are loaded.
5. Internal reset signals negate.
6. Core exits reset and fetches the initial program counter and stack pointer from ROM.

A wake-up from power down via the RESET_b pin follows the warm reset sequence.

Warm reset

Perform the following steps as part of the warm reset sequence:

1. RESET_b pin drives low and internal reset signals asserted.
2. Clocks are enabled in their default configuration.
3. Internal reset remains asserted for 8 CMC clock cycles.
4. Internal reset to flash memory and fuse controllers negates and commence their initialization sequences.
5. Initialization sequences for flash memory and fuse complete.
6. Internal trim registers are loaded and RESET_b pin is tri-stated.
7. Reset state machine waits for RESET_b pin input to pull high or drive high externally.
8. Internal reset signals negate.
9. Core exits reset and fetches the initial program counter and stack pointer from ROM.

31.3.6 Interrupts

CMC generates a single interrupt, which System Reset Interrupt Enable (SRIE) configures.

31.4 External signals

Table 215. External signals

Signal	Description	Direction
RESET_B	Bidirectional open-drain reset pin with pullup that asserts low during warm reset except when waking up from a low-power mode.	Input or output
BOOT_CONFIGn	The input pin is sampled at the end of the RESET_B assertion and stored in Mode (MR0).	Input

31.5 Initialization

By default, the digital glitch filter is disabled on RESET_b pin. To enable the filter, configure:

- RPC[LPFEN], RPC[FILTEN], or both.
- RPC[FILTCFG].

31.6 Application information

To configure for Deep-Power Down Low-Power mode entry:

1. Write Fh to Clock Control (CKCTRL)
2. Write 8h to Power Mode Protection (PMPROT)
3. Write Fh to Global Power Mode Control (GPMCTRL)
4. Execute WFI instruction

To configure for Power-Down Low-Power mode entry:

1. Write Fh to Clock Control (CKCTRL)
2. Write 4h to Power Mode Protection (PMPROT)
3. Write 7h to Global Power Mode Control (GPMCTRL)
4. Execute WFI instruction

To configure for Deep Sleep Low-Power mode entry:

1. Write Fh to Clock Control (CKCTRL)
2. Write 2h to Power Mode Protection (PMPROT)
3. Write 3h to Global Power Mode Control (GPMCTRL)
4. Execute WFI instruction

To configure for MAIN in power-down and WAKE in Deep Sleep Low-Power mode entry:

1. Write Fh to Clock Control (CKCTRL)
2. Write 3h to Power Mode Protection (PMPROT)
3. Write 3h to PMCTRLMAIN
4. Write 1h to PMCTRLWAKE
5. Execute WFI instruction

31.7 Memory map and register descriptions

This section describes the registers in the CMC module.

31.7.1 CMC register descriptions

NOTE

Different CMC registers reset on different reset types.

NOTE

You must read back the last register written to before executing the WFI instruction. This ensures that before the MCU enters the low power mode, all register writes associated with setting up the low power mode are complete, failure to do this may result in the low power mode not being entered correctly.

31.7.1.1 CMC memory map

CMC0 base address: 4000_1000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Version ID (VERID)	32	R	0301_0000h
10h	Clock Control (CKCTRL)	32	RW	0000_0000h

110h	Core Control (CORECTL)	32	RW	0000_0000h
120h	Debug Control (DBGCTL)	32	RW	0000_0000h

31.7.1.2 Version ID (VERID)

Offset

Register	Offset
VERID	0h

Function

Contains version numbers for module design and feature set.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	FEATURE															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 MAJOR	Major Version Number Returns the major version number for the module specification.
23-16 MINOR	Minor Version Number Returns the minor version number for the module specification.
15-0 FEATURE	Feature Specification Number Returns the feature set number.

31.7.1.3 Clock Control (CKCTRL)

Offset

Register	Offset
CKCTRL	10h

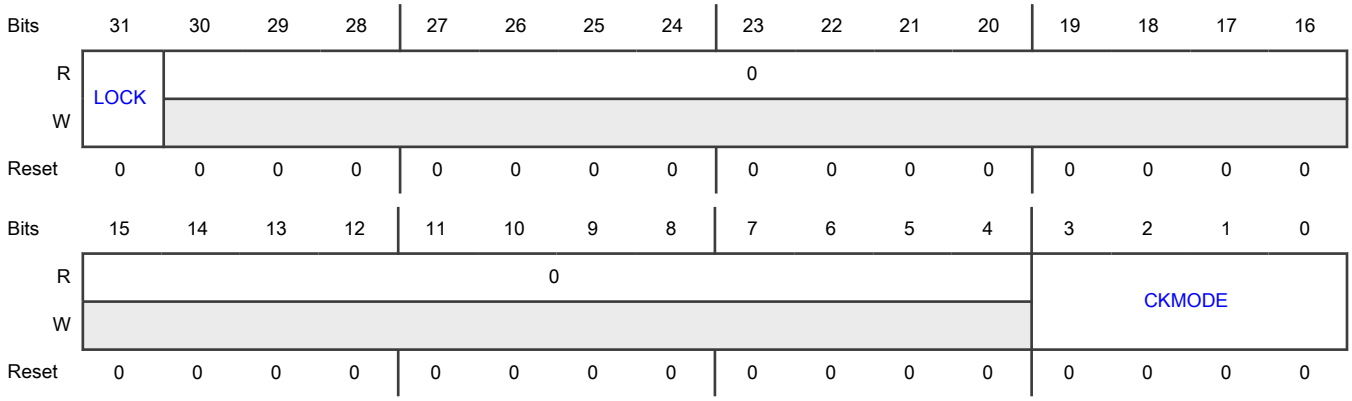
Function

Configures the amount of clock gating when the core asserts sleeping due to WFI, WFE, or SLEEPONEXIT.

NOTE

This register resets on WAKE warm reset.

Diagram



Fields

Field	Function
31 LOCK	Lock Locks the register and blocks writes until the next reset. 0b - Allowed 1b - Blocked
30-4 —	Reserved
3-0 CKMODE	Clocking Mode Configures the amount of clock gating when the core enters a low-power mode because of WFI, WFE or SLEEPONEXIT. Configuring CKMODE > 0 requires the SLEEPDEEP field in the Arm core to become 1. Configuring PMCTRLx[LPMODE] > 0 requires writing Fh to CKMODE. 0000b - Core clock is on 0001b - Core clock is off 0011b - Core and platform clocks are gated 0111b - Core, platform, and peripheral clocks are gated, but no change in Low-Power mode 1111b - Core, platform, and peripheral clocks are gated, and core enters Low-Power mode.

31.7.1.4 Clock Status (CKSTAT)

Offset

Register	Offset
CKSTAT	14h

Function

Returns the clock gating status and wake-up source from the previous Low-Power mode entry, provided the core was clock gated. This requires configuring CKCTRL[CKMODE] > 0 and the wake-up event must occur after the core is clock gated. The register contents are only valid when CKSTAT[VALID] = 1.

NOTE

This register resets on WAKE warm reset.

Diagram

Fields

Field	Function
31 VALID	Clock Status Valid Indicates that the core clock was gated since you last wrote 0 to this field. 0b - Core clock not gated 1b - Core clock was gated due to Low-Power mode entry
30-15 —	Reserved
14-8 WAKEUP	Wake-up Source Returns any wake-up sources from the previous Low-Power mode entry. [0] - Wake-up source is reset interrupt or wakeup from Deep Power-Down [1] - Wake-up source is debug request [2] - Wake-up source is interrupt [3] - Wake-up source is DMA wakeup [4] - Wake-up source is WUU request [5] - Wake-up source is bus master wakeup [6] - Wake-up source is bus master wakeup A wakeup from Power-Down or Deep Power-Down writes 1 to WAKEUP[0]. Depending on Low-Power mode, other wake-up bits may not become 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-4 —	Reserved
3-0 CKMODE	Low Power Status Returns the result of the previous Low-Power mode entry. 0000b - Core clock not gated 0001b - Core clock was gated 0011b - Core and platform clocks were gated 0111b - Core, platform, and peripheral clocks were gated 1111b - Core, platform, and peripheral clocks were gated, and power domain entered Low-Power mode All other values are reserved.

31.7.1.5 Power Mode Protection (PMPROT)

Offset

Register	Offset
PMPROT	18h

Function

Provides protection for entry in low-power modes, you must allow a low-power mode before configuring any Power Mode Control register (PMCTRLx) to that mode.

NOTE

This register resets on WAKE warm reset.

Diagram

31.7.1.7 Power Mode Control (PMCTRLMAIN - PMCTRLWAKE)

Offset

Register	Offset
PMCTRLMAIN	20h
PMCTRLWAKE	24h

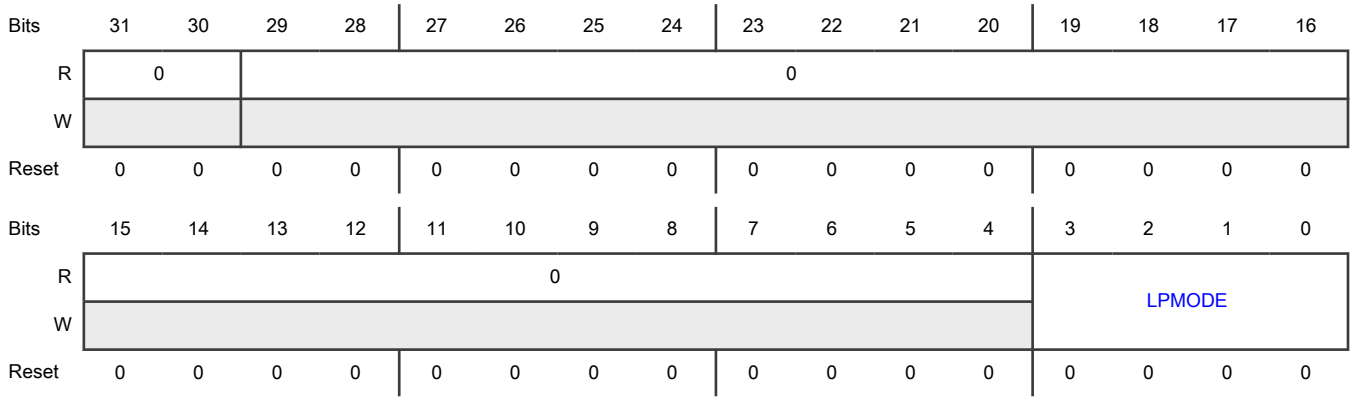
Function

Configures entry into low-power modes for each power domain, provided that the selected power mode is allowed via an appropriate setting of Power Mode Protection (PMPROT), and CKMODE = Fh.

NOTE

This register resets by WAKE cold reset.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-4 —	Reserved
3-0 LPMODE	Low-Power Mode Selects the desired Low-Power mode when a core executes WFI or WFE instruction. Writes to this field are blocked if you have not enabled the protection level using Power Mode Protection (PMPROT). You must not configure this field for the WAKE domain to a lower power mode than any other power domain. **NOTE** See Power domains section for details on allowed combinations. 0000b - Active 0001b - Sleep 0011b - Deep Sleep 0111b - Power Down 1111b - Deep-Power Down

31.7.1.8 System Reset Status (SRS)

Offset

Register	Offset
SRS	80h

Function

Updates on every MAIN warm reset to indicate the type/source of the most recent reset.

Fields

Field	Function
31-10 —	Reserved
9 LPFEN	Low-Power Filter Enable Enables the low-power reset pin filter in both Active and Low-Power modes when this field = 1. The RESET_b pin must assert for more than three FRO 1 MHz clock cycles to always propagate through the filter. A glitch less than two FRO 1 MHz clock cycles never propagates through the filter. 0b - Disables 1b - Enables
8 FILTEN	Filter Enable Enables the slow clock reset pin filter in Active modes. The RESET_b pin must assert for more than FILTCFG + 1 slow system clock cycles to always propagate through the filter. A glitch less than FILTCFG slow system clock cycles never propagates through the filter. If RPC[LPFEN] also becomes 1, then the filters operate in series. 0b - Disables 1b - Enables
7-5 —	Reserved
4-0 FILTCFG	Reset Filter Configuration Configures the reset pin filter's width from 1 to 32 slow system clock cycles.

31.7.1.10 Sticky System Reset Status (SSRS)

Offset

Register	Offset
SSRS	88h

Function

Stores all sources of system reset that has generated a system reset since the last WAKE cold reset and that you have not cleared. SSRS does not update following a core software reset.

NOTE

This register resets on WAKE cold reset.

31.7.1.11 System Reset Interrupt Enable (SRIE)

Offset

Register	Offset
SRIE	8Ch

Function

Delays the assertion of a system reset for 8194 cycles of the FRO 1 MHz clock when an interrupt is generated. This allows you to perform a graceful shutdown or to abort the warm reset provided you can clear the pending reset source by resetting the source and then clearing the pending flag. This feature cannot delay a cold or fatal warm reset source. System Reset Status (SRS) updates after the warm reset occurs.

The reset interrupt is not supported in Power Down or Deep-Power Down mode.

NOTE

This register is reset on WAKE Cold Reset.

31.7.1.16 SRAM Shut Down Register (SRAMDIS0)

Offset

Register	Offset
SRAMDIS0	C0h

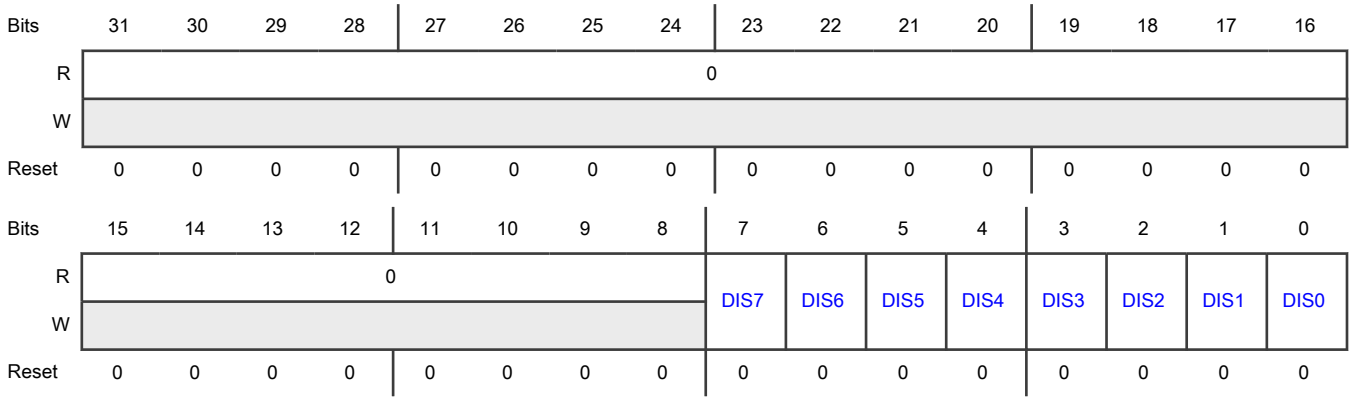
Function

Powers off the specific on-chip System SRAM arrays whenever the corresponding register field becomes 1. You must not access the SRAM array and also do not retain the SRAM array contents.

NOTE

This register resets on MAIN warm reset.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 DISn	Shut Down Enable **NOTE** See the chip-specific CMC section for register bit details.

31.7.1.17 SRAM Deep Sleep Register (SRAMRET0)

Offset

Register	Offset
SRAMRET0	D0h

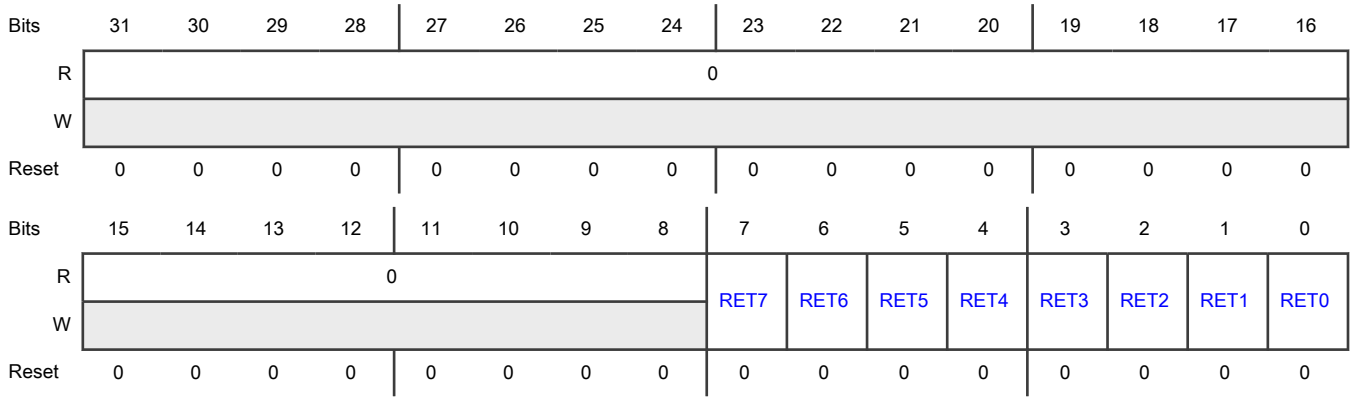
Function

Configures if the on-chip System SRAM arrays are retained or powered off in low-power modes.

NOTE

This register resets on WAKE warm reset.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 RETn	Deep Sleep Enable Controls whether the SRAM array is retained or powered off in Low-Power modes. **NOTE** You cannot retain SRAM arrays in Low-Power modes if their power domain is switched off. See the chip-specific CMC section for register bit details.

31.7.1.18 Flash Control (FLASHCR)

Offset

Register	Offset
FLASHCR	E0h

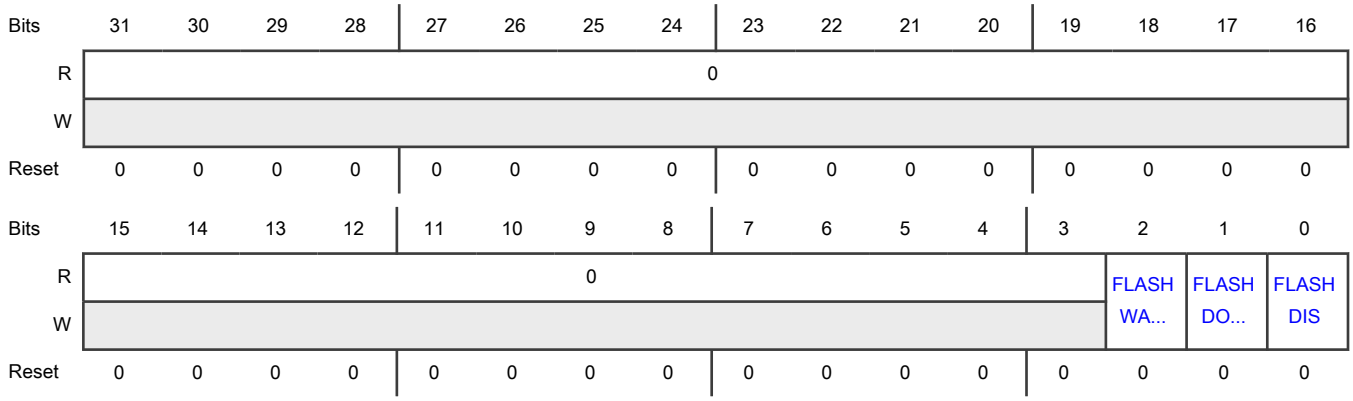
Function

Controls Low-Power mode of the on-chip flash memory.

NOTE

This register resets on WAKE warm reset.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 FLASHWAKE	Flash Wake Specifies that when this field becomes 1, an attempt to access the flash memory when it is in Low-Power state because of FLASHCR[FLASHDIS] or FLASHCR[FLASHDOZE], causes the flash memory to exit Low-Power state for the duration of the flash memory access. 0b - No effect 1b - Flash memory is not disabled during flash memory accesses
1 FLASHDOZE	Flash Doze Disables flash memory accesses and places flash memory in Low-Power state whenever the core clock is gated (CKMODE > 0) because of execution of WFI, WFE, or SLEEPONEXIT. Other bus masters that attempt to access the flash memory stalls until the core is no longer sleeping. 0b - No effect 1b - Flash memory is disabled when core is sleeping (CKMODE > 0)
0 FLASHDIS	Flash Disable Places flash memory in Low-Power state when this field becomes 1. Relocate the interrupts out of flash memory before disabling it. 0b - No effect 1b - Flash memory is disabled

31.7.1.19 BootROM Status Register (BSR)

Offset

Register	Offset
BSR	100h

Function

The BootROM Status Register and BootROM Lock Register can only be written when the Lock field equals 010. All other values are reversed and will lock the BootROM registers.

NOTE

This register resets on WAKE cold reset.

Diagram

Chapter 32
System Power Control (SPC)

32.1 Chip-specific SPC information

Table 216. Reference links to related information

Topic	Related module	Reference
Full description	SPC	SPC
System memory map		System memory map
Power Management		Power Management
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing
Reset		Reset

NOTE

The "switch" in this chapter refers to the "smart power switch" in the Power Management.

32.1.1 Module instances

- This device has one instance of the SPC module, SPC0.
- If the LPCMP is being used in DPDOWN then the low power IREF must remain enabled.

32.1.2 Voltage regulators

This section describes the various on-chip regulators.

Table 217. On-chip regulators

Regulator name	Description
DCDC_LV	The DCDC_LV can be used to power VDD_SYS domain. It can power the IO ring, other on-chip modules, and external components as well. However, user should take care that the total load current doesn't exceed the maximum capacity.
LDO_CORE	The LDO_CORE can be used to power VDD_CORE domain.
LDO_SYS	The LDO_SYS can be used to power VDD_SYS domain. It can power the IO ring, other on-chip modules, and external components as well. However, user should take care that the total load current doesn't exceed the maximum capacity.

32.1.3 Voltage monitors

32.1.3.1 VDD_SYS voltage monitors

The following sections describe the voltage monitors inspecting the VDD_SYS supply.

32.1.3.1.1 Power-On-Reset (POR)

During power-on, the POR keeps the device under reset until the VDD_SYS supply voltage reaches the specified threshold. When VDD_SYS is above the VPOR limit, the device POR reset is released. However, the device stays in reset until the LVD on VDD_SYS is released.

32.1.3.1.2 Low Voltage Detect

This device integrates a Low Voltage Detector (LVD) circuit on VDD_SYS input voltage. The LVD monitors the VDD_SYS power supply voltage by comparing it to a programmable threshold. When VDD_SYS drops below the threshold, the user has the option of generating an LVD reset or an LVW interrupt. The VDD_SYS LVD circuit is ON by default. The user can disable the VDD_SYS LVD through software.

32.1.3.1.3 High Voltage Detect

This device integrates a High Voltage Detector (HVD) circuit on VDD_SYS input voltage. The HVD monitors the VDD_SYS power supply voltage by comparing it to a programmable threshold. When VDD_SYS rises above the threshold, the user has the option of generating an HVD reset or an HVW interrupt. The VDD_SYS HVD circuit is OFF by default. The user can enable the VDD_SYS HVD through software.

32.1.3.2 VDD_CORE voltage monitors

The following sections describe the voltage monitors for the VDD_CORE supply.

32.1.3.2.1 Low Voltage Detect

This device integrates a Low Voltage Detector (LVD) circuit on VDD_CORE input voltage. The LVD monitors the VDD_CORE power supply voltage by comparing it to a programmable threshold. When VDD_CORE drops below the threshold, the user has the option of generating an LVD reset or an LVW interrupt. The VDD_CORE LVD circuit is ON by default. The user can disable the VDD_CORE LVD through software.

32.1.3.2.2 High Voltage Detect

This device integrates a High Voltage Detector (HVD) circuit on VDD_CORE input voltage. The HVD monitors the VDD_CORE power supply voltage by comparing it to a programmable threshold. When VDD_CORE rises above the threshold, the user has the option of generating an HVD reset or an HVW interrupt. The VDD_CORE HVD circuit is OFF by default. The user can enable the VDD_CORE HVD through software.

32.1.3.3 VDD_IO_ABC voltage supply monitors

The following sections describe the voltage monitors for the power supply that powers PORTA, PORTB and PORTC.

32.1.3.3.1 Low Voltage Detect

This device integrates a Low Voltage Detector (LVD) circuit on the input voltage that powers PORTA. The LVD monitors that power supply voltage by comparing it to a programmable threshold. When input voltage powering PORTA drops below the threshold, the user has the option of generating an LVD reset or an LVW interrupt. The LVD circuit for this power supply is ON by default. The user can disable the LVD through software.

32.1.3.3.2 High Voltage Detect

This device integrates a High Voltage Detector (HVD) circuit on the input voltage that powers PORTA. The HVD monitors that power supply voltage by comparing it to a programmable threshold. When the input voltage powering PORTA rises above the threshold, the user has the option of generating an HVD reset or an HVW interrupt. The HVD circuit for this power supply is OFF by default. The user can enable the HVD through software.

32.1.4 SC[ISO_CLR] bits

Each bit in the SC[ISO_CLR] field controls the ISO for one of the chip LV power domains:

- Bit 16 - Core Main domain
- Bit 17 - Core Wake domain
- Bit 18 - Core Radio domain

Refer to Power domains for more details.

32.1.5 EVD_CFG[EVDISO], EVD_CFG[EVDLPISO], and EVD_CFG[EVDSTAT] fields

Each bit of the EVDISO, EVDLPISO, and EVSTAT fields corresponds to one of the IO or analog supplies.

- [0] - VDD_IO_ABC
- [1] - VDD_IO_D
- [2] - VDD_ANA

32.1.6 SRAMCTL[VSM] field

For this device, the VSM has only two options.

- [01b] - SRAM configured for 1.0 V operation and the values in SRAM_TMTR1 is loaded for the read/write timing margin
- [10b] - SRAM configured for 1.1 V operation and the values in SRAM_TMTR2 is loaded for the read/write timing margin

Follow the steps below to change the SRAM settings, refer to #unique_937 for more details.

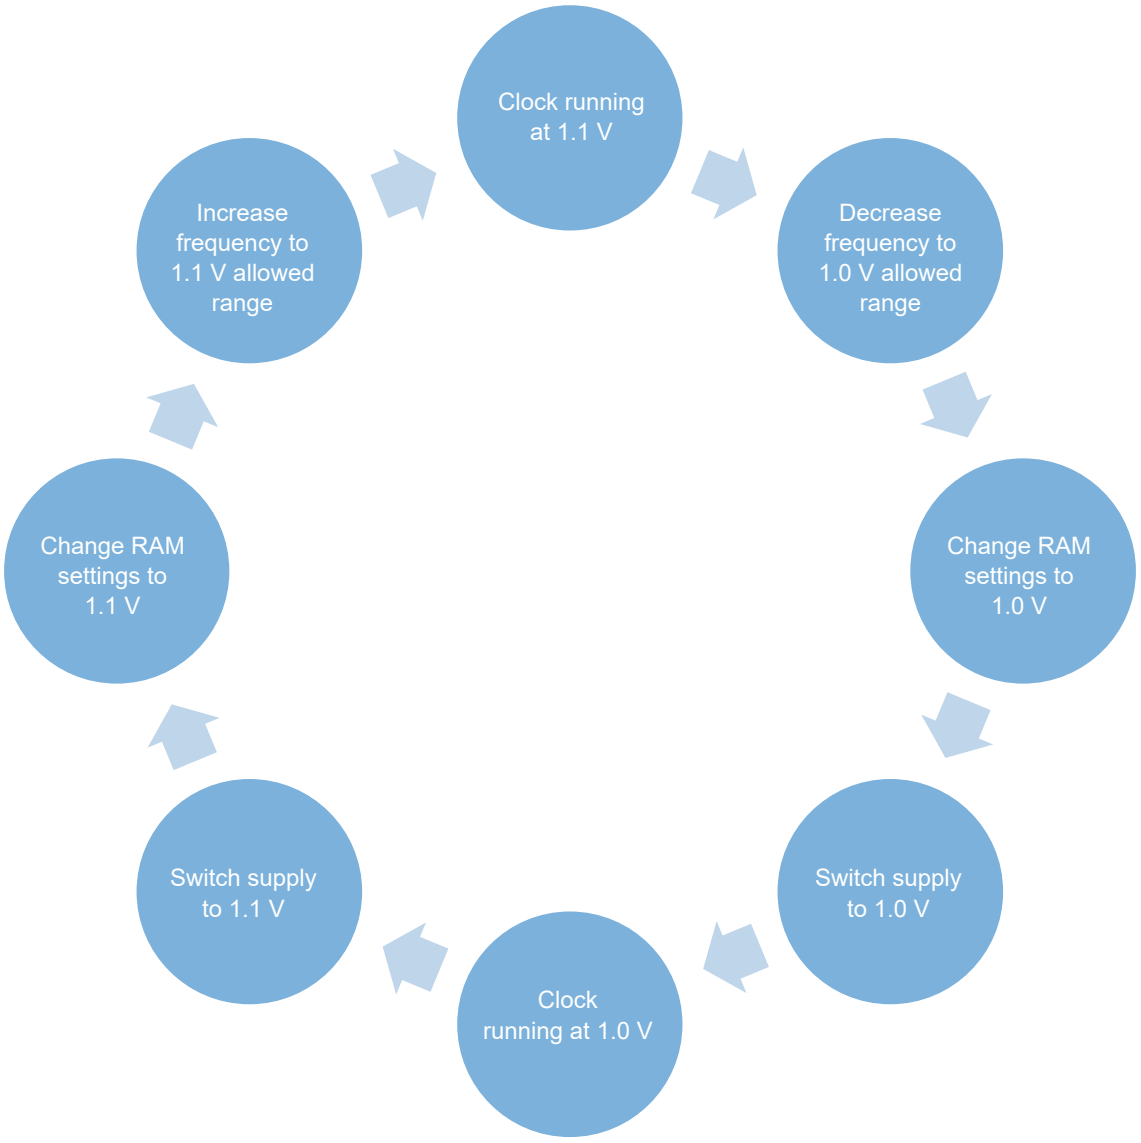

Figure 86. SRAM settings change steps

32.1.7 LP_CFG[IO_HVDE] field

If the LP_CFG[IO_HVDE] is set to 1, it monitors VDD_IO_ABC on PORTA, PORTB and PORTC.

32.1.8 DCDC pulsed mode clocking

DCDC can optionally enter in DCDC pulsed mode. In DCDC pulsed mode, the DCDC refresh period is based on a clock counter which is feed by the 32K_CLK clock in this device.

32.2 Overview

SPC contains and controls the following components:

- Two low-drop-out (LDO) voltage regulators (1.1 V LDO_CORE and 1.8 V LDO_SYS)
- One DCDC used for regulating system, core, and radio power

- Circuits that monitor and assure correct voltage levels:
  - Power-on reset (POR)
  - Low-voltage detect (LVD)
  - Analog glitch detector
  - High-voltage detect (HVD)

SPC turns these components on and off, and switches them to different power mode levels based on power-mode change requests from each of the chip power domains.

32.2.1 Block diagram

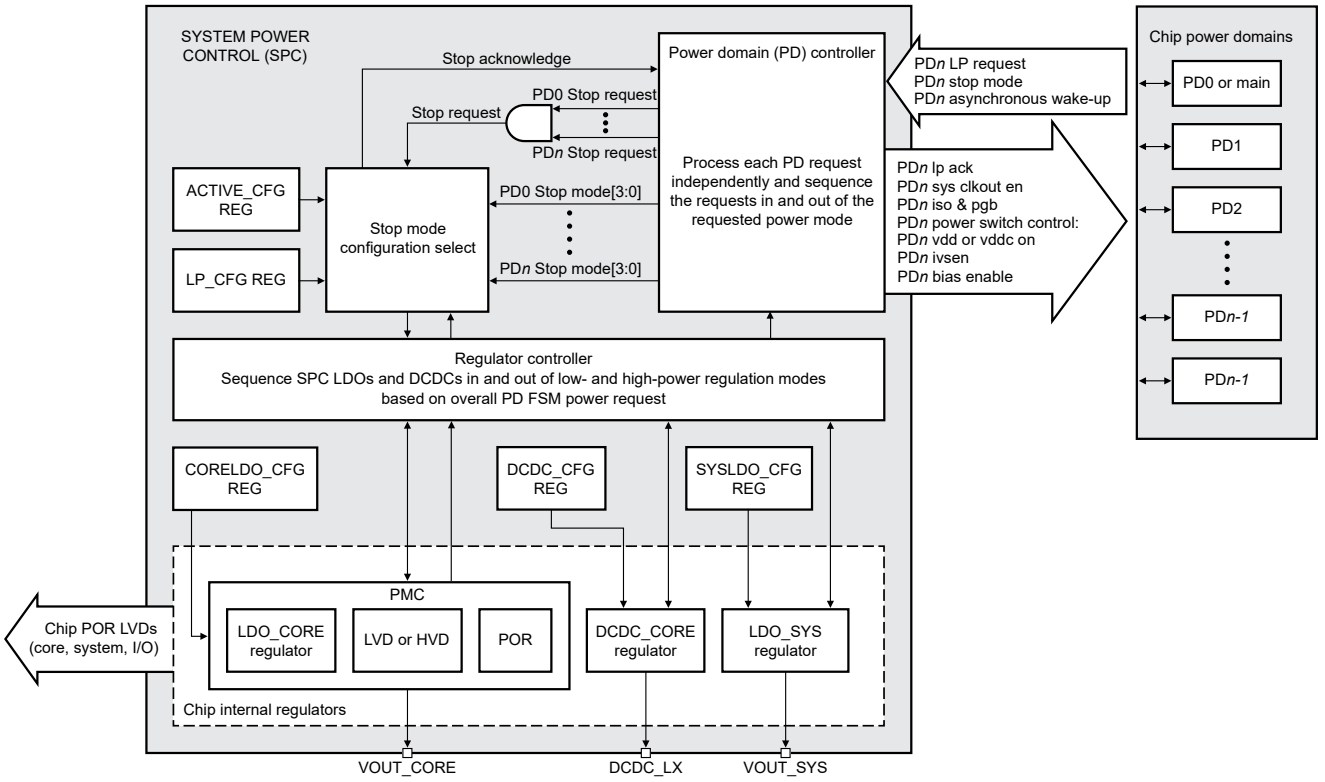

Figure 87. Block diagram

32.2.2 Features

- Selectable core internal voltage regulator (1.2 V LDO_CORE or 1.8 V DCDC)
- Selectable system internal voltage regulator (1.8 V LDO_SYS)
- Radio voltage regulator (1.8 V LDO_SYS or 1.8 V DCDC)
- Active POR providing brown-out detect
- Low-voltage detect
- High-voltage detect
- Core power gate control
- Analog glitch detector

32.3 Functional description

32.3.1 Power mode transitions

Figure 88 shows the power mode state transitions available for each power-down domain. A POR or LVD reset initially returns the power-down domains to ACTIVE state.

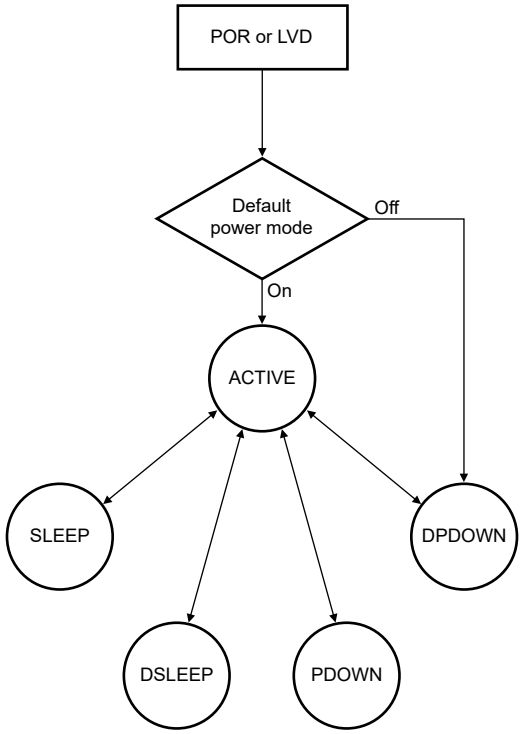

Figure 88. Power mode state diagram

SPC allows each power domain to enter or exit low-power modes independently of the other. You must ensure that any common system resources (for example, clock sources) are always available whenever required for a power-domain current power mode. For example, if a clock source in power domain 0 drives power domain 1, you must ensure that power domain 0 does not enter a low-power mode, because that would disable the clock source.

Figure 89 defines the low-power entry and exit flow for each of the SPC power-down domains.

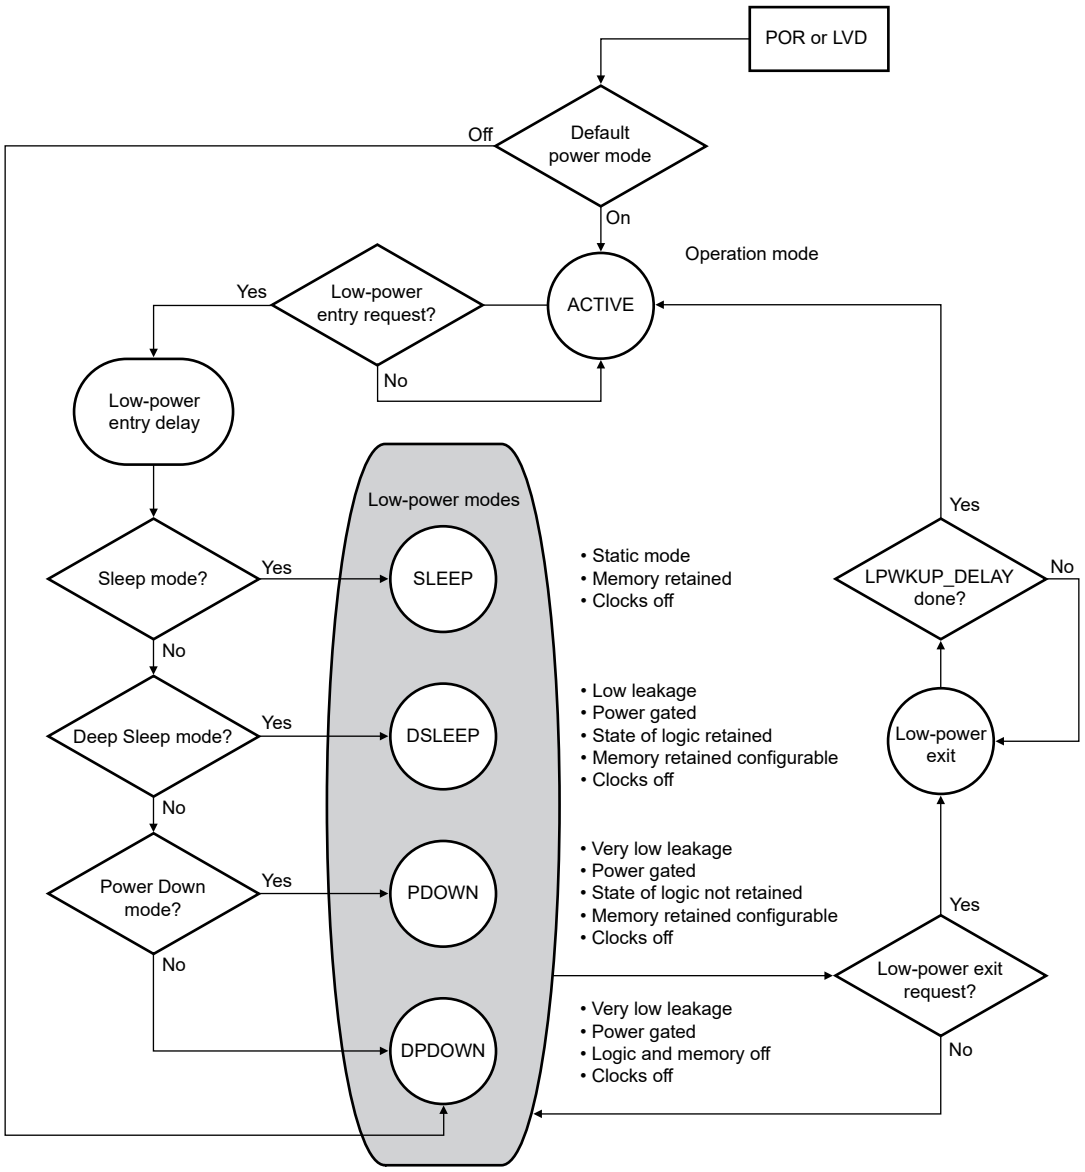

Figure 89. SPC regulator power mode state diagram

NOTE

This section mentions the power modes supported by the module. For the power modes supported on your device, see the chip-specific Power management chapter.

32.3.2 Active mode voltage updates

This section describes voltage and frequency changes in Active mode.

You can alter the operating voltage and frequency during Active mode to optimize power consumption depending on the application's performance requirements.

When increasing voltage and frequency in Active mode, you must perform the following steps:

1. Increase voltage to a new level (ACTIVE_CFG[CORELDO_VDD_LVL] and/or ACTIVE_CFG[DCDC_VDD_LVL]).
2. Wait for voltage change to complete (SC[BUSY] = 0).

3. Configure flash memory to support higher voltage level and frequency (FMU_FCTRL[RWSC].
4. Configure SRAM to support higher voltage levels (SRAMCTL[VSM]).
5. Request SRAM voltage update (write 1 to SRAMCTL[REQ]).
6. Wait for SRAM voltage change to complete (SRAMCTL[ACK] = 1).
7. Clear request for SRAM voltage change (write 0 to SRAMCTL[REQ]).
8. Increase frequency to a new level (for example, SCG_RCCR).
9. You can continue execution.

When decreasing voltage and frequency in Active mode perform the following steps:

1. Decrease frequency to a new level (for example, SCG_RCCR).
2. Configure flash memory to support lower voltage level and frequency (FMU_FCTRL[RWSC].
3. Configure SRAM to support lower voltage levels (SRAMCTL[VSM]).
4. Request SRAM voltage update (write 1 to SRAMCTL[REQ]).
5. Wait for SRAM voltage change to complete (SRAMCTL[ACK] = 1).
6. Clear request for SRAM voltage change (write 0 to SRAMCTL[REQ]).
7. Decrease voltage to a new level (ACTIVE_CFG[CORELDO_VDD_LVL] and/or ACTIVE_CFG[DCDC_VDD_LVL]).
8. Wait for voltage change to complete (SC[BUSY] = 0).
9. You can continue execution.

32.3.3 Low-Power Request (LPREQ) pin

The LPREQ pin asserts after low-power entry and negates after low-power wakeup.

The pin is intended to communicate with an external PMIC (for example, to enter low-power mode) or to control external switches (for example, if certain power supply rails are switched off in the low-power mode). The pin can eliminate the latency when communicating with PMIC—for example, through I^2C—for quick power-state transitions. The PMIC can be configured to use the LPREQ pin to switch between two preconfigured power states.

SPC controls the state of the LPREQ pin based on how you configure Low-Power Request Configuration (LPREQ_CFG). You control the LPREQ pin in Active mode. SPC controls the pin when the chip transitions from Active to a low-power mode, and after wake-up from these power modes.

NOTE

If the power supply rails are switched off externally, software must configure the internal isolation of these power domains using External Voltage Domain Configuration (EVD_CFG).

To use the LPREQ pin:

1. Specify the pin polarity (LPREQ_CFG[LPREQPOL]).
2. Enable the pin output (LPREQ_CFG[LPREQOE]).
3. Configure the pin mux for the desired pin using the PORT PCR registers.
4. If the external PMIC or switch needs additional time after wake-up, use Low Power Wake-Up Delay (LPWKUP_DELAY) to extend the wake-up time.

32.3.4 DCDC

DCDC is a hysteretic converter. It is active during a burst period, when it switches the output to charge to a specific voltage. Then DCDC stops switching for a quiet period until the output voltage drops to a lower level, and it does another active burst.

32.3.4.1 DCDC drive strength

DCDC supports multiple drive strength options that you can choose:

- Normal
- Low
- Pulse refresh

The normal and low drive strengths differ in these DCDC characteristics:

- Maximum load current
- Quiescent current
- Transient response

With low drive strength, you can benefit from the lower quiescent current if:

- The load current is below the I_{LOAD} specification in the data sheet.
- Your application can tolerate the slower transient response.

Be careful when choosing low drive strength. If you exceed I_{LOAD} or require faster transient response, you must use normal drive strength. Furthermore, most other DCDC features are only available with normal drive strength.

Pulse-refresh drive strength offers even lower quiescent current in low-power modes, by deactivating DCDC when not active. This strength has an active pulsing period where DCDC charges the output voltage. Then DCDC deactivates for a configurable amount of time. No analog comparator is powered to monitor the DCDC output voltage. Instead, this drive strength is time-based using an SPC timer where DCDC_BURST_CFG[PULSE_REFRESH_CNT] specifies the timer period. Every period, SPC enables DCDC to charge the voltage again. When DCDC is off, no voltage regulation occurs. You must specify DCDC_BURST_CFG[PULSE_REFRESH_CNT] to manage the voltage drop on the DCDC capacitor and avoid a brownout condition.

32.3.4.2 DCDC burst

You can control and monitor the DCDC burst. Synchronizing with the quiet period between bursts can be valuable for noise-sensitive applications—for example, during a high-resolution ADC measurement or a radio transmission.

Before requesting a burst to start, clear the DCDC_BURST_CFG[BURST_ACK] flag. Then, your firmware can request a burst by writing 1 to DCDC_BURST_CFG[BURST_REQ]. SPC sets the DCDC_BURST_CFG[BURST_ACK] flag when the burst has completed and DCDC enters a quiet period.

SPC also provides signals to synchronize the burst activity with other peripherals in the chip. If DCDC_BURST_CFG[EXT_BURST_EN] = 1 before a burst starts, the output DCDC_BURST_TRIG_PULSE signal asserts when a burst completes, and can trigger other actions such as an ADC conversion. Another SPC output signal is DCDC_BURST_ACTIVE, which EXT_BURST_EN does not gate. DCDC_BURST_ACTIVE can also trigger other peripherals such as a timer. You can use this signal to estimate the power that DCDC delivers.

When bursting, you can control the DCDC switching center frequency with the frequency-stabilization feature. DCDC_CFG[FREQ_CNTRL_ON] enables this feature, and when the feature is enabled, DCDC_CFG[FREQ_CNTRL] controls it. The main parameters that control the period between active bursts and quiet period are:

- Load current
- External capacitor
- DCDC hysteresis

NOTE

Writing 1 to DCDC_CFG[FREQ_CNTRL_ON] stabilizes the frequency by limiting DCDC current. See the DCDC I_{LOAD} maximum limit in the data sheet for this mode.

32.3.4.3 DCDC voltage changes

To support power optimization of applications, DCDC can provide multiple output voltages.

Two separate registers, which specify Active mode output and Low-Power mode output, independently control the DCDC output voltage. Whenever an SoC mode change occurs, by using two independent registers, there is no need to reconfigure the output voltage. ACTIVE_CFG[DCDC_VDD_LVL] controls the DCDC output voltage when the SoC mode is Active or in Sleep mode. The DCDC drive strength is normal (ACTIVE_CFG[DCDC_VDD_DS] = 10b). LP_CFG[DCDC_VDD_LVL] controls the DCDC output voltage when the SoC mode is in a Low-Power mode (i.e., not Active or Sleep mode) or the DCDC drive strength is low (ACTIVE_CFG[DCDC_VDD_DS] = 01b) and the SoC is in an Active or Sleep mode.

When Active Power Mode Configuration (ACTIVE_CFG) controls the output, DCDC output options present:

- 1.25 V
- 1.35 V
- 1.8 V
- 2.5 V

See Active mode voltage updates to change the DCDC output level in Active mode.

When Low-Power Mode Configuration (LP_CFG) controls the output, DCDC output options present:

- 1.25 V
- 1.35 V
- 1.8 V

You have to configure LPWKUP_DELAY to the correct value. In Deep Sleep mode, you must also align the output voltage with the clock frequencies of any clocks kept alive in the Low-Power mode. If you keep some clock sources active, ensure to leave the bandgap enabled.

To change the DCDC output level in Low-Power mode, follow this procedure:

1. Configure LP_CFG[DCDC_VDD_LVL] to desired level.
2. Configure LP_CFG[DCDC_VDD_DS] = 0x1.
3. Configure ACTIVE_CFG[DCDC_VDD_LVL] to same level as in configure LP_CFG[DCDC_VDD_LVL].

32.3.5 Clocking

Table 218. Clocks

SPC component:	Clock source
Registers and logic	Slow bus clock
Delay counters	10 MHz internal clock

SPC uses the internal clock that PMC analog block generates to sequence the system regulator and chip power domains in and out of different power modes. This clock has a frequency of 10 MHz. SPC automatically enables the clock when it detects a power mode change, including entry into low-power modes and exit from low-power modes of any of the system power domains, or configuration changes to either Active Power Mode Configuration (ACTIVE_CFG) or Low-Power Mode Configuration (LP_CFG). This clock cannot run unless the PMC bandgap is up and enabled. Once SPC completes all transactions and is not busy, that is, SC[BUSY] = 0, this clock will turn off synchronously.

32.3.6 Reset

32.3.6.1 Reset sources

32.3.6.1.1 Power-on reset (POR)

When you initially apply power to the chip, or the supply voltage is below the POR falling threshold, the POR circuit triggers the POR condition. The POR condition asserts a cold reset in all power domains.

32.3.6.1.2 Low-voltage detect (LVD)

SPC supports the following LVD circuits:

- Core VDD
- System VDD
- I/O VDD

Each of these circuits is enabled by default and keeps the chip in reset until each of these supply voltages rises above the LVD rising threshold. Enabling any of the LVD circuits triggers an LVD reset condition if the corresponding supply voltage is below the LVD falling threshold.

The LVD reset condition asserts a cold reset in all power domains. The LVD- and HVD-detection logic is the only logic that HVD and LVD resets do not affect. The corresponding status fields in Voltage Detect Status (VD_STAT) become 1 after the corresponding LVD reset condition occurs.

32.3.6.1.3 High-voltage detect (HVD)

SPC supports the following HVD circuits:

- Core VDD
- System VDD
- I/O VDD

Each of these circuits is enabled by default and triggers an HVD reset condition if the corresponding supply voltage is above the HVD threshold.

Any of these reset condition asserts a cold reset in all power domains. The LVD- and HVD-detection logic is the only logic that HVD and LVD resets do not affect. The corresponding status fields in Voltage Detect Status (VD_STAT) become 1 after the corresponding HVD reset condition occurs.

32.3.6.1.4 Glitch detect

This chip guards against short pulses on the core VDD and VSS. This security feature can detect glitches due to a hacking attack and alerts the core to reset the chip or generate an interruptn operation.

After power-on reset, the core VDD glitch-detect system is enabled. When the system is in Active mode, use ACTIVE_CFG[GLITCH_DETECT_DISABLE] to enable or disable the glitch-detect system. When the system is in Low-Power mode, use LP_CFG[GLITCH_DETECT_DISABLE] to enable or disable the glitch-detect system.

The glitch-detect system uses a 4-bit ripple counter to monitor the quantity of detected glitches. The VDD_CORE_GLITCH_DETECT_SC[GLITCH_DETECT_FLAG] status flags capture the state of each of these counters.

NOTE

The chip has analog voltage glitch detector (aGDET) that enhances protection against voltage manipulation. After the chip is out of reset, the NXP FMU logic configures aGDET to reset the chip when voltage manipulation is detected. The aGDET is validated on silicon across multiple process, voltage, and temperature corners by activating a large number of possible data paths. To avoid false detections due to unforeseen environment or application behavior, NXP recommends disabling aGDET in the early start-up code. You can also configure hardware interrupt for aGDET and handle action in the interrupt handler by disabling default reset actions. aGDET can be used by the application when security-critical operations, for example, cryptographic operation using private or symmetric keys (digital signature, encryption, decryption, and so on) or sensitive decision-making process. However, you must ensure that the system remains free from false detections in those circumstances. See the SDK example in this document for details on sensor usage.

32.3.6.2 Reset sequence

The following steps occur as part of the POR, LVD, or HVD sequence:

1. The RESET_b pin deasserts.
2. The internal reset signals assert.
3. The POR or LVD signals negate.
4. System clocks are enabled.

32.3.7 Interrupts

SPC generates a single interrupt. The trigger for this interrupt comes from:

- Any of the LVD, HVD, or glitch-detect circuits when they are not configured for reset and their corresponding HVDIE or LVDIE register.
- The Interrupt Enable (IE) register (for the glitch-detect case).

32.4 External signals

Signal	Description	Direction
LPREQ	Low-power request pin used to signal external power-management circuits for a change in supply voltage	Output
VOUT_CORE	Output of the LDO_CORE regulator	Output
VOUT_SYS	Output of the LDO_SYS regulator	Output
DCDC_LX	Output of the DCDC_CORE regulator	Output

32.5 Initialization

To initialize SPC with LDO_CORE off, write 0 to CNTRL[CORELDO_EN].

To initialize SPC with LDO_SYS off, write 0 to CNTRL[SYSLDO_EN].

To initialize SPC with DCDC_CORE off, write 0 to CNTRL[DCDC_EN].

Except for the above, SPC does not require any special initialization.

32.6 Application information

To change DCDC level in Low-Power mode:

1. Configure LP_CFG[DCDC_VDD_LVL] to desired level.

2. Configure LP_CFG[DCDC_VDD_DS] = 0x1
3. Configure ACTIVE_CFG[DCDC_VDD_LVL] to same level programmed in Configure LP_CFG[DCDC_VDD_LVL]

To disable Bandgap in Active mode:

1. Disable all LVD's and HVD's in ACTIVE_CFG[29:24]= 0x00
2. Disable Glitch Detect, ACTIVE_CFG[GLITCH_DETECT_DISABLE] = 1
3. Configure LDO's and DCDC to Low Drive Strength in ACTIVE_CFG register
4. Configure ACTIVE_CFG[BGMODE] = 0x0

To disable Bandgap in Low-Power mode:

1. Disable all LVD's and HVD's in LP_CFG[29:24]= 0x00
2. Disable Glitch Detect, LP_CFG[GLITCH_DETECT_DISABLE] = 1
3. Configure LDO's and DCDC to Low Drive Strength in LP_CFG register
4. Configure LP_CFG[BGMODE] = 0x0

32.7 SPC register descriptions

Different chip reset types affect the reset of different SPC registers. Each register description provides details. See the Reset chapter for more information about the types of reset on this chip.

You may use only 32-bit writes for any writable SPC registers. 8-bit or 16-bit writes cause a transfer error.

32.7.1 SPC memory map

32.7.3 Status Control (SC)

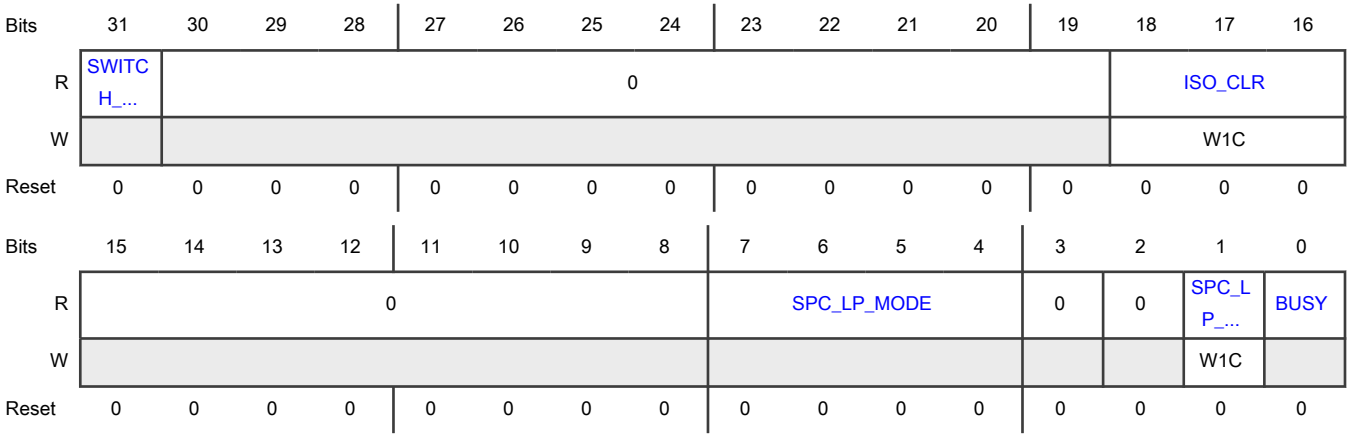
Offset

Register	Offset
SC	10h

Function

Indicates the current SPC status.

Diagram



Fields

Field	Function
31	Power Switch State

Table continues on the next page...

Table continued from the previous page...

Field	Function
SWITCH_STATE	Indicates the power switch state. 0b - Off 1b - On
30-19 —	Reserved
18-16 ISO_CLR	Isolation Clear Flags Indicates whether certain peripherals and I/O pads are in a latched state as a result of having been in PDOWN mode. Each bit of this field is a flag associated with a module on this chip. See the chip-specific SPC information for the module-bit association. For each flag: • A value of 0 means that peripherals and I/O pads are in the normal run state. • A value of 1 means that peripherals and I/O pads can retain their state in their power domain. If a flag in this field is 1, writing 1 to that flag clears the flag and releases the I/O pads and peripherals to their normal run-mode state. After recovering from a power-down mode, you must restore the chip configuration before clearing a flag in this field. In particular, you must restore the pin configuration for enabled WUU wake-up to avoid any WUU flag from being falsely set when the associated ISO_CLR flag is cleared. This field resets after a system reset.
15-8 —	Reserved
7-4 SPC_LP_MODE	Power Domain Low-Power Mode Request Indicates the last low-power mode that the power domain requested. 0000b - Sleep mode with system clock running 0001b - SLEEP with system clock off 0010b - DSLEEP with system clock off 0100b - PDOWN with system clock off 1000b - DPDOWN with system clock off
3 —	Reserved
2 —	Reserved
1 SPC_LP_REQ	SPC Power Mode Configuration Status Flag Indicates when all power-down domains requested low-power mode and SPC entered a low-power state.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - SPC is in Active mode; the ACTIVE_CFG register has control 1b - All power domains requested low-power mode; SPC entered a low-power state; power-mode configuration based on the LP_CFG register When writing 0b - No effect 1b - Clear the flag
0 BUSY	SPC Busy Status Flag Indicates whether SPC is busy. SPC sets this flag: • When SPC executes any type of power mode transition in Active mode or any of the chip low-power modes. • Due to LP_CFG[CORELDO_VDD_LVL] and LP_CFG[DCDC_VDD_LVL] changes while in Active mode. **NOTE** Wait until this flag is clear before changing power-mode configuration registers. 0b - Not busy 1b - Busy

32.7.4 SPC Regulator Control (CNTRL)

Offset

Register	Offset
CNTRL	14h

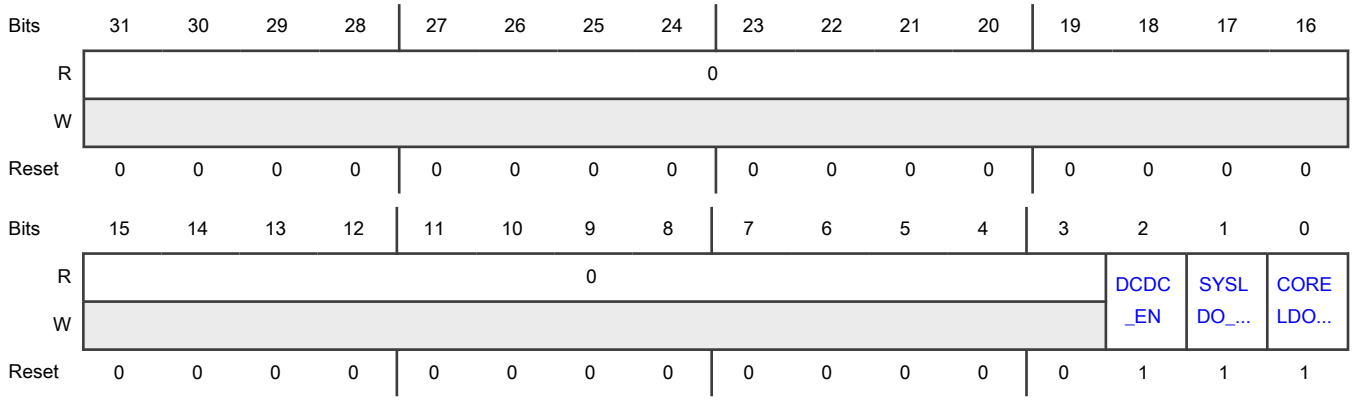
Function

Enables the SPC regulators.

You can write to the fields in this register only one time.

The register resets only after a POR, LVD, or HVD event.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 DCDC_EN	DCDC_CORE Regulator Enable 0b - Disable 1b - Enable
1 SYSLDO_EN	LDO_SYS Regulator Enable 0b - Disable 1b - Enable
0 CORELDO_EN	LDO_CORE Regulator Enable 0b - Disable 1b - Enable

32.7.5 Low-Power Request Configuration (LPREQ_CFG)

Offset

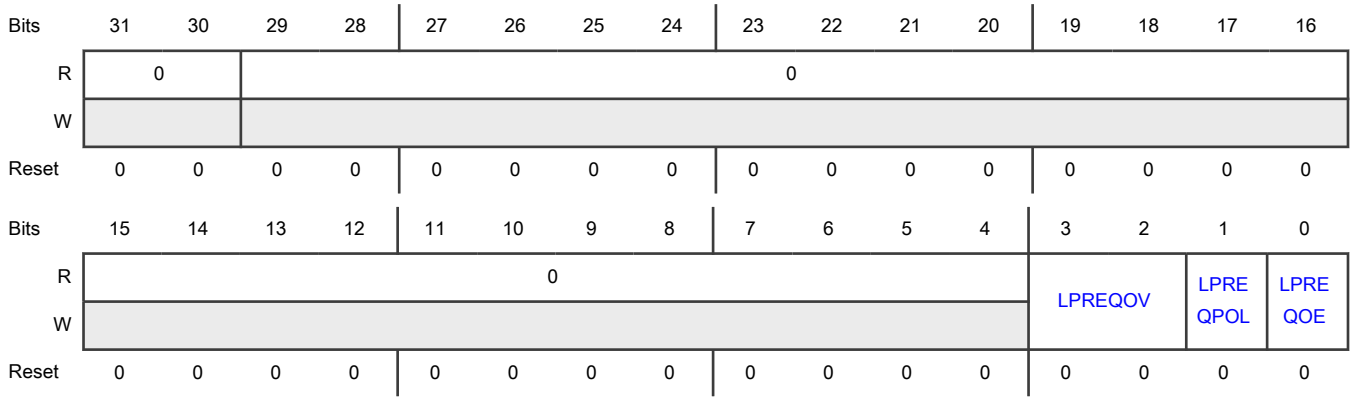
Register	Offset
LPREQ_CFG	1Ch

Function

Configures the low-power output request pin.

The register resets only after a POR, LVD, or HVD event.

Diagram



Fields

Field	Function

29-4 —	Reserved
3-2 LPREQOV	Low-Power Request Output Override Forces the low-power request pin high. 00b - Not forced 01b - Reserved 10b - Forced low (ignore LPREQPOL settings) 11b - Forced high (ignore LPREQPOL settings)
1 LPREQPOL	Low-Power Request Output Pin Polarity Control Controls the true polarity of the low-power request output pin. 0b - High 1b - Low
0 LPREQOE	Low-Power Request Output Enable Enables the low-power request output pin. 0b - Disable 1b - Enable

32.7.6 SPC Configuration (CFG)

Offset

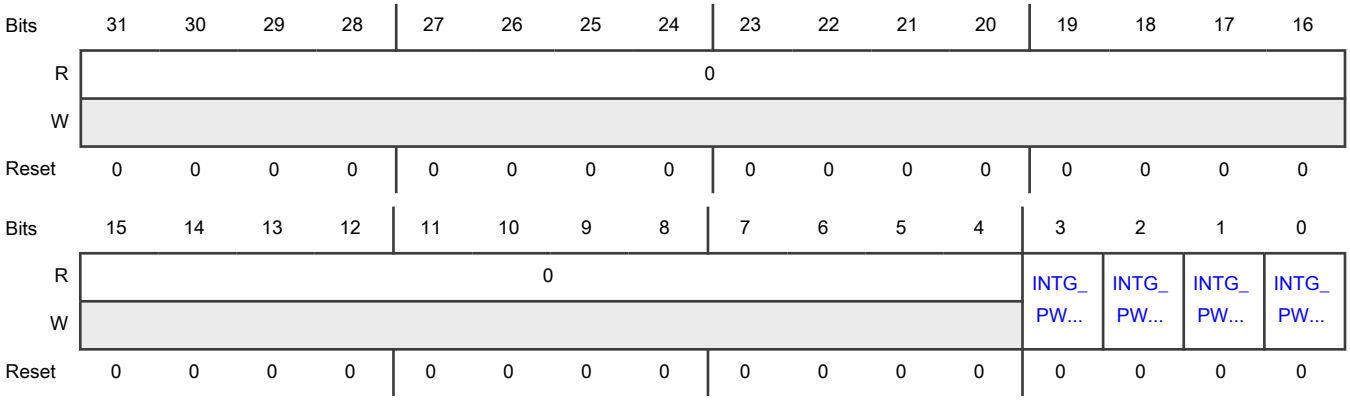
Register	Offset
CFG	20h

Function

Controls the features of the integrated power switch that you can use to gate board-level supplies.

The register resets only after a POR, LVD, or HVD event.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 INTG_PWSWTCH_WKUP_ACTIVE_EN	Integrated Power Switch Wake-up Enable Enables the switch in active mode. When this field is 1, SPC drives a pin in active mode to close the switch. 0b - Disable 1b - Enable
2 INTG_PWSWTCH_SLEEP_ACTIVE_EN	Integrated Power Switch Active Enable Disables the switch in active mode. When this field is 1, SPC drives a pin in active mode to open the switch. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 INTG_PWSWTCH_WKUP_EN	Integrated Power Switch Wake-up Enable Enables the switch after waking up from any low-power mode. When this field is 1, SPC drives a pin during low-power wake-up sequence to close the switch. 0b - Disable 1b - Enable
0 INTG_PWSWTCH_SLEEP_EN	Integrated Power Switch Sleep Enable Disables the switch entering in any low-power mode. When this field is 1, SPC drives a pin during low-power entry sequence to open the switch. 0b - Disable 1b - Enable

32.7.7 SPC Power Domain Mode Status (PD_STATUS0 - PD_STATUS2)

Offset

Register	Offset
PD_STATUS0	30h
PD_STATUS1	34h
PD_STATUS2	38h

Function

Indicates power mode status for each of the SPC power domains. See the chip-specific SPC information to determine which power domains are associated with this register.

Diagram

3-1 —	Reserved
0 PWR_REQ_STATUS	Power Request Status Flag Indicates whether the power domain requested low-power mode. 0b - Did not request 1b - Requested

32.7.8 SRAM Control (SRAMCTL)

Offset

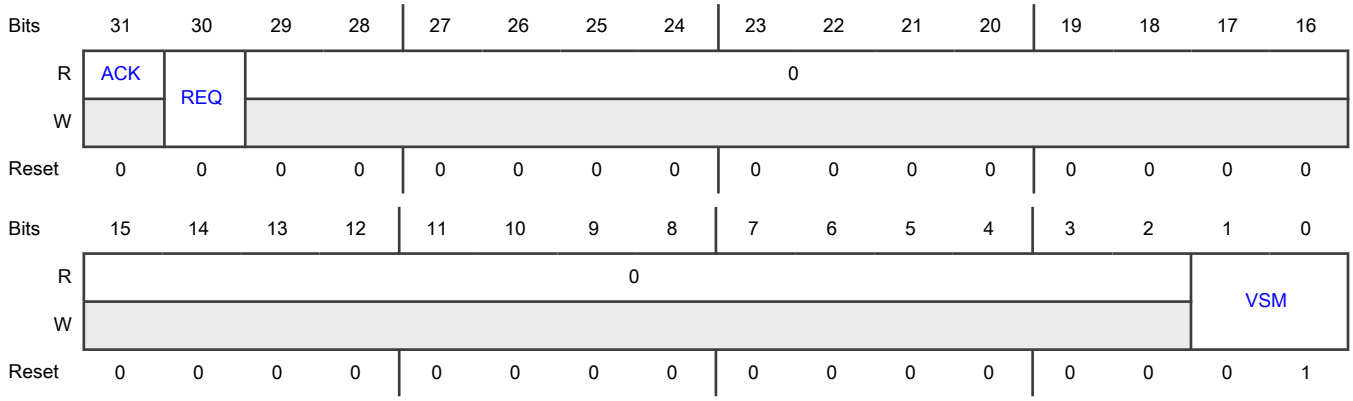
Register	Offset
SRAMCTL	40h

Function

Configures the SRAM timing for different voltage levels.

When transitioning between two voltage levels, you must keep the SRAM timing at the lowest voltage level until the voltage change is complete.

Diagram



Fields

Field	Function
31 ACK	SRAM Voltage Update Request Acknowledge Indicates whether SPC acknowledged the request for an SRAM trim-value change. 0b - Not acknowledged 1b - Acknowledged
30 REQ	SRAM Voltage Update Request Allows you to request an SRAM trim value change. After requesting the change, you must wait for the ACK field to become 1, then write 0 to REQ. 0b - Do not request 1b - Request
29-2 —	Reserved
1-0 VSM	Voltage Select Margin Specifies the operating voltage for the SRAM's read/write timing margin. 00b - Reserved 01b - 1.0 V 10b - 1.1 V 11b - SRAM configured for 1.1 V operation

32.7.9 General Purpose Wake-up (WAKEUP)

Offset

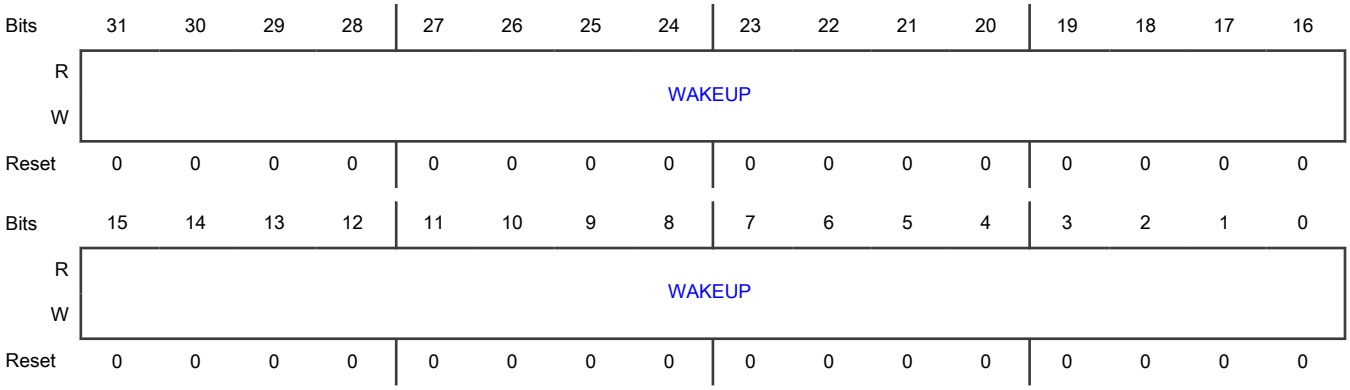
Register	Offset
WAKEUP	E0h

Function

Specifies the wake-up value that the boot ROM uses.

This register resets after POR, LVD ,or any system reset except wake-up from Power Down or Deep Power Down modes.

Diagram



Fields

Field	Function
31-0 WAKEUP	Wake-up Specifies the value that the boot ROM uses to quickly restore Cortex-M33 core context or to switch execution to a defined address in the flash memory or SRAM after wake-up.

32.7.10 Active Power Mode Configuration (ACTIVE_CFG)

Offset

Register	Offset
ACTIVE_CFG	100h

Function

Controls the SPC regulators settings in the Active power mode.

Changes to the drive strength or voltage level for any of the LDOs or DCDC sets the SC[BUSY] flag until SPC changes its state to the new value.

NOTE

The LVDE and HVDE fields reset only with a POR. All other fields reset only with a system reset.

Field	Function
IO_LVDE	Enables the IO low-voltage detection. When IO_LVDE = 1, you must write a value to BGMODE that enables the bandgap. Only a POR resets this field. This field monitors VDD IO on PORT. See the chip-specific SPC information for port details. 0b - Disable 1b - Enable
25 SYS_LVDE	System Low-Voltage Detection Enable Enables the system low-voltage detection. When SYS_LVDE = 1, you must write a value to BGMODE that enables the bandgap. Only a POR resets this field. 0b - Disable 1b - Enable
24 CORE_LVDE	Core Low-Voltage Detection Enable Enables the core low-voltage detection. When CORE_LVDE = 1, you must write a value to BGMODE that enables the bandgap. Only a POR resets this field. 0b - Disable 1b - Enable
23 —	Reserved
22 —	Reserved
21-20 BGMODE	Bandgap Mode Specifies the bandgap mode configuration. SPC forces BGMODE to 01b to enable the Bandgap, if: • A write to disable the Bandgap is detected. • Any of the regulators are in normal drive strength. • Any of the LVD or HVDs are enabled. • VDD CORE glitch detection is enabled. 00b - Bandgap disabled 01b - Bandgap enabled, buffer disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - Bandgap enabled, buffer enabled 11b - Reserved
19 —	Reserved
18 LPBUFF_EN	CMP Bandgap Buffer Enable Enables the buffer-stored reference voltage to CMP. 0b - Disable 1b - Enable
17-13 —	Reserved
12 GLITCH_DETECT_DISABLE	Glitch Detect Disable Reset on POR only State of GLITCH_DETECT_DISABLE will be ignored if Bandgap is disabled and Glitch Detect hardware will be forced to OFF state. 0b - Low Voltage Glitch Detect enabled 1b - Low Voltage Glitch Detect disabled
11-10 DCDC_VDD_LVL	DCDC VDD Regulator Voltage Level Specifies the DCDC VDD regulator level. When switching the DCDC drive strength from low to normal, ensure that the DCDC high VDD LVL setting is set to the same level that was set prior to switching the DCDC to low drive strength. Otherwise, if the LVDs are enabled, an unexpected LVD can occur. 00b - Low undervoltage (1.25 V) 01b - Midvoltage (1.35 V) 10b - Normal voltage (2.5 V) 11b - Safe-mode voltage (1.8 V)
9-8 DCDC_VDD_DS	DCDC VDD Drive Strength Specifies the DCDC VDD regulator drive strength. If you specify normal drive strength, you must write a value to ACTIVE_CFG[BGMODE] that enables the bandgap. 01b - Low 10b - Normal All other values are reserved.
7	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
6 SYSLDO_VDD_LVL	LDO_SYS VDD Regulator Voltage Level Specifies the LDO_SYS VDD regulator level. You must write 0 to SYS_HVDE before writing 1 to SYSLDO_VDD_LVL. The VDD_SYS voltage can only operate at the overdrive voltage for a limited amount of time for the life of the chip. See the chip data sheet for the maximum voltage and time specifications. This is intended only for programming eFuses. 0b - Normal voltage (1.8 V) 1b - Overdrive voltage (2.5 V)
5 —	Reserved
4 SYSLDO_VDD_DS	LDO_SYS VDD Drive Strength Specifies the LDO_SYS VDD regulator drive strength If you specify normal drive strength, you must write a value to ACTIVE_CFG[BGMODE] that enables the bandgap. If you have enabled LVDs or HVDs, and attempt to specify low drive strength, SPC ignores the attempt. SPC forces a normal drive strength when SYSLDO_VDD_LVL = 1. 0b - Low 1b - Normal
3-2 CORELDO_VDD_LVL	LDO_CORE VDD Regulator Voltage Level Selects the LDO_CORE VDD regulator level. If the CORELDO_VDD_DS fields are set to the same value in both the ACTIVE_CFG and LP_CFG registers, the CORELDO_VDD_LVL's in the ACTIVE_CFG and LP_CFG register must be set to the same voltage level settings. You can change the core VDD levels for the LDO_CORE low power regulator only when CORELDO_VDD_DS=1. When switching CORELDO_VDD_DS from low to normal drive strength, ensure the LDO_CORE high VDD LVL setting is set to the same level that was set prior to switching to the LDO_CORE drive strength (CORELDO_VDD_DS). Otherwise, if the LVDs are enabled, an unexpected LVD can occur. You must specify the same level for both CORELDO_VDD_LVL and DCDC_VDD_LVL, even if LDO_CORE is off. 00b - Reserved 01b - Regulate to mid voltage (1.05 V) 10b - Regulate to normal voltage (1.1 V) 11b - Regulate to safe-mode voltage (1.15 V)

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 —	Reserved
0 CORELDO_VDD_DS	LDO_CORE VDD Drive Strength Selects the LDO_CORE VDD regulator drive strength **NOTE** When setting CORELDO_VDD_DS to Normal, BGMODE must be programmed to a value that enables the Bandgap. Writes to set drive strength to Low will be ignored if LVD/HVDs are kept enabled. 0b - Low 1b - Normal

32.7.11 Low-Power Mode Configuration (LP_CFG)

Offset

Register	Offset
LP_CFG	104h

Function

Controls the SPC regulator settings in low-power stop modes.

This register resets only after a POR or LVD event.

Diagram

Fields

Field	Function
31-30 —	Reserved
29 IO_HVDE	IO High Voltage Detect Enable This field monitors VDD IO on PORT. For port details, see the chip-specific SPC information. This field resets only after a POR, LVD, or HVD event. When IO_HVDE = 1, you must use LP_CFG[BGMODE] to enable the bandgap. If you enable the bandgap to support voltage detection, the low-power mode Idd increases. 0b - Disable 1b - Enable
28 SYS_HVDE	System High Voltage Detect Enable This field resets only after a POR, LVD, or HVD event. When SYS_HVDE = 1, you must use LP_CFG[BGMODE] to enable the bandgap. If you enable the bandgap to support voltage detection, the low-power mode Idd increases. 0b - Disable 1b - Enable
27 CORE_HVDE	Core High Voltage Detect Enable This field resets only after a POR, LVD, or HVD event. When CORE_HVDE = 1, you must use LP_CFG[BGMODE] to enable the bandgap. If you enable the bandgap to support voltage detection, the low-power mode Idd increases. 0b - Disable 1b - Enable
26 IO_LVDE	IO Low Voltage Detect Enable This field monitors VDD IO on PORT. For port details, see the chip-specific SPC information. This field resets only after a POR, LVD, or HVD event. When IO_LVDE = 1, you must use LP_CFG[BGMODE] to enable the bandgap. If you enable the bandgap to support voltage detection, the low-power mode Idd increases. 0b - Disable 1b - Enable
25 SYS_LVDE	System Low Voltage Detect Enable This field resets only after a POR, LVD, or HVD event. When SYS_LVDE = 1, you must use LP_CFG[BGMODE] to enable the bandgap. If you enable the bandgap to support voltage detection, the low-power mode Idd increases. 0b - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enable
24 CORE_LVDE	Core Low Voltage Detect Enable This field resets only after a POR, LVD, or HVD event. When CORE_LVDE = 1, you must use LP_CFG[BGMODE] to enable the bandgap. If you enable the bandgap to support voltage detection, the low-power mode Idd increases. 0b - Disable 1b - Enable
23 LP_IREFEN	Low-Power IREF Enable You can disable the low-power IREF only in DPDOWN mode. In all other low-power modes, writing 1 to this field has no effect and the low-power IREF is always enabled. See the chip-specific SPC information for the modules that require the low-power IREF to be enabled in DPDOWN mode when you use the module in DPDOWN mode. 0b - Disable for power saving in Deep Power Down mode 1b - Enable
22 —	Reserved
21-20 BGMODE	Bandgap Mode Specifies the bandgap mode configuration. BGMODE will be set to 01b to keep the Bandgap enabled if a write to disable Bandgap is detected while keeping any of the regulators in normal drive strength or if any of the LVD/HVDs are kept enabled or if VDD CORE glitch detect are kept enabled. 00b - Bandgap disabled 01b - Bandgap enabled, buffer disabled 10b - Bandgap enabled, buffer enabled 11b - Reserved
19 —	Reserved
18 LPBUFF_EN	CMP Bandgap Buffer Enable Enables the buffer-stored reference voltage to CMP. The CMP bandgap buffer is automatically disabled and turned off in DPDOWN mode. 0b - Disable 1b - Enable
17	CORE VDD Internal Voltage Scaling (IVS) Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
COREVDD_IVS_EN	Enables the IVS regulator. When enabled, the IVS regulator scales the external input CORE VDD to a lower voltage level to reduce internal leakage during Deep Sleep and Power Down modes. COREVDD_IVS_EN is automatically 0 in SLEEP or DPDOWN modes. CORE VDD can only get IVS in DSLEEP and PDOWN modes. 0b - Disable 1b - Enable
16 —	Reserved
15-13 —	Reserved
12 GLITCH_DETECT_DISABLE	Glitch Detect Disable This field resets only after a POR, LVD, or HVD event. If you have disabled the bandgap, SPC ignores the value of GLITCH_DETECT_DISABLE and deactivates the glitch-detect hardware. 0b - Enable 1b - Disable
11-10 DCDC_VDD_LVL	DCDC VDD Regulator Voltage Level Specifies the DCDC VDD regulator level. 00b - Low under voltage (1.25 V) 01b - Mid voltage (1.35 V) 10b - Reserved 11b - Safe-mode voltage (1.8 V)
9-8 DCDC_VDD_DS	DCDC VDD Drive Strength Specifies the drive strength of the DCDC VDD regulator. If you specify normal drive strength, you must write a value to LP_CFG[BGMODE] that enables the bandgap. The DCDC regulator is always turned off and disabled in DPDOWN mode. Pulse Refresh mode is invalid in SLEEP mode. If you have enabled LVDs or HVDs, and attempt to specify low or pulse drive strength, SPC ignores the attempt and forces the normal drive strength. SPC ignores writes to reserved values. 00b - Pulse refresh

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01b - Low 10b - Normal 11b - Reserved
7 —	Reserved
6-5 —	Reserved
4 SYSLDO_VDD_DS	LDO_SYS VDD Drive Strength Specifies the drive strength of the LDO_SYS VDD regulator. If you specify normal drive strength, you must write a value to LP_CFG[BGMODE] that enables the bandgap. If you have enabled LVDs or HVDs, and attempt to specify low drive strength, SPC ignores the attempt. 0b - Low 1b - Normal
3-2 CORELDO_VDD_LVL	LDO_CORE VDD Regulator Voltage Level Specifies the LDO_CORE VDD regulator level for low-power sleep modes. If the CORELDO_VDD_DS fields are set to the same value in both the ACTIVE_CFG and LP_CFG registers, the CORELDO_VDD_LVL's in the ACTIVE_CFG and LP_CFG register must be set to the same voltage level settings. You can change the core VDD levels for the LDO_CORE low power regulator only when ACTIVE_CFG[CORELDO_VDD_DS] = 1. So, before entering any of the low-power states (DSLEEP, PDOWN, DPDOWN) with LDO_CORE low power regulator selected (LP_CFG[CORELDO_VDD_DS] = 0), you must use CORELDO_VDD_LVL to select the correct regulation level during ACTIVE run mode. Updating CORELDO_VDD_LVL sets the SC[BUSY] flag. That flag remains set for at least the total time delay that Active Voltage Trim Delay (ACTIVE_VDELAY) specifies. Before changing CORELDO_VDD_LVL, you must wait until the SC[BUSY] flag clears before entering the selected low-power sleep mode. This ensures the correct core VDD voltage levels are set after the chip is in the chosen mode. When LP_CFG[DCDC_VDD_LVL] is not 00b, you must program LP_CFG[CORELDO_VDD_LVL] to have same value as LP_CFG[DCDC_VDD_LVL], even if LDO_CORE is off. When LP_CFG[DCDC_VDD_LVL] is 00b, you must disable VDD_CORE LVD in Low-Power mode, and LP_CFG[CORELDO_VDD_LVL] can be different with LP_CFG[DCDC_VDD_LVL]. 00b - Retention voltage 01b - Mid voltage (1.05 V) 10b - Normal voltage (1.1 V) 11b - Safe-mode voltage (1.15 V)

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 —	Reserved
0 CORELDO_VDD_DS	LDO_CORE VDD Drive Strength Specifies the drive strength of the LDO_CORE VDD regulator. The LDO_CORE regulator is forced to disabled in DPDOWN Sleep mode. If you specify normal drive strength, you must write a value to LP[BGMODE] that enables the bandgap. If you have enabled LVDs or HVDs, and attempt to specify low drive strength, SPC ignores the attempt. 0b - Low 1b - Normal

32.7.12 Low Power Wake-Up Delay (LPWKUP_DELAY)

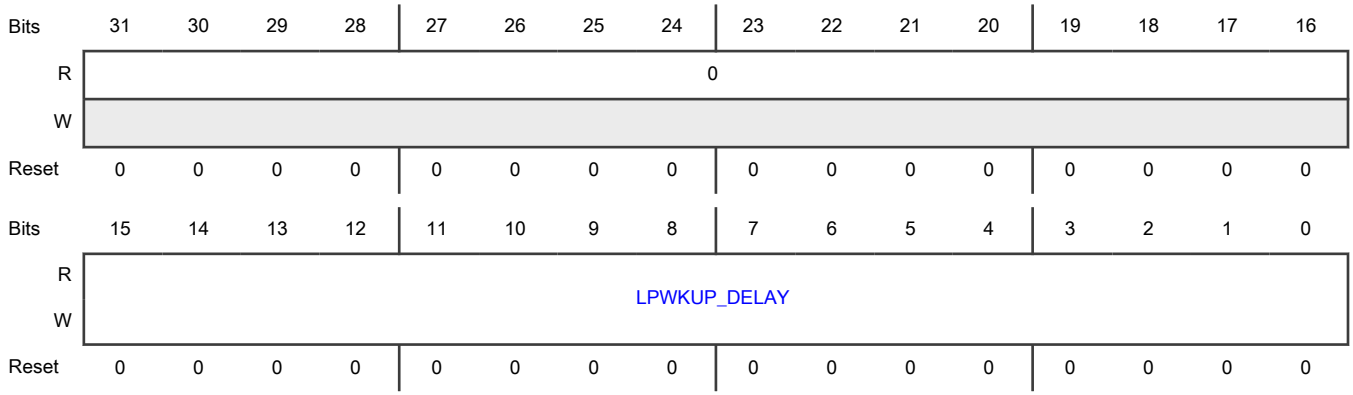
Offset

Register	Offset
LPWKUP_DELAY	120h

Function

Works with the LPREQ pin to extend the wake-up time if the external PMIC or switch needs additional time after wake-up.

Diagram



Fields

Field	Function
31-16	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
15-0 LPWKUP_DELAY	Low-Power Wake-Up Delay Specifies the number of SPC timer clock cycles that SPC waits after exiting low-power modes. This field resets only after a POR, LVD, or HVD event. When voltage levels are not the same between ACTIVE mode and Low Power mode, you must write a nonzero value to this field.

32.7.13 Active Voltage Trim Delay (ACTIVE_VDELAY)

Offset

Register	Offset
ACTIVE_VDELAY	124h

Function

Specifies the delay due to voltage level changes to the regulators in Active mode.

This register resets only after a POR event.

SPC loads the ACTIVE_VDELAY values are loaded from IFR or FUSE after any reset. NXP trims this reset value for the recommended wait time.

32.7.15 Core Voltage Detect Configuration (VD_CORE_CFG)

Offset

Register	Offset
VD_CORE_CFG	134h

Function

Provides these functions:

- Configures the low-voltage trip point.
- Enables the core LVD reset and interrupts.

This register resets only after a POR event.

NOTE

If you write 1 to both LVDRE and LVDIE, SPC generates an interrupt after exiting from LVDRE reset. If you don't want this to occur, configure the LVD or HVD so only one is enabled.

32.7.18 External Voltage Domain Configuration (EVD_CFG)

Offset

Register	Offset
EVD_CFG	140h

Function

Isolates signals from external voltage domains under certain conditions.

Chip pins supply the external voltage domains. These domains are controlled at the board level. This register allows you to control internal isolations for signals from these domains if either of the following conditions is true:

- They are not powered on the board.
- They are powered off externally in low-power modes (using the SPC_LPREQ pin).

Any logic in the isolated voltage domain also resets, because the voltage domain is assumed to be powered off. This reset does not impact any VDD_CORE internal power domains or registers—only I/O pads, analog components, or both.

This register resets only after a POR event.

Each bit of the EVDISO, EVDLPISO, and EVDSTAT fields corresponds to one of the I/O or analog supplies according to Table 219.

Table 219. Mapping of bits to supplies

Bit position in field	Description
0	VDD_IO_ABC
1	VDD_IO_D
2	VDD_ANA

NOTE

Bit 0 VDD_IO_ABC should not be set in EVD_CFG[EVDISO] and it should only be set in EVD_CFG[EVDLPISO] when moving to Deep Power Down mode.

Diagram

Fields

Field	Function
31-19 —	Reserved
18-16 EVDSTAT	External Voltage Domain Status Indicates the status of the external voltage domains. See Table 219 for the mapping of each bit of this field. Each bit's value has the following meaning: 0b - Isolated or not powered 1b - Not isolated
15-11 —	Reserved
10-8 EVDLPISO	External Voltage Domain Low-Power Isolation Isolates the external voltage domain in low-power modes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Use this field if you use the SPC_LPREQ pin to power off any voltage domain in low-power modes. See Table 219 for the mapping of each bit of this field. Each bit's value has the following meaning: 0b - Not isolated 1b - Isolated
7-3 —	Reserved
2-0 EVDISO	External Voltage Domain Isolation Isolates the external voltage domain. Use this field if any voltage domain is always powered off on the board, or whenever a voltage domain is powered off under software control. See Table 219 for the mapping of each bit of this field. Each bit's value has the following meaning: 0b - Not isolated 1b - Isolated

32.7.19 Glitch Detect Status Control (GLITCH_DETECT_SC)

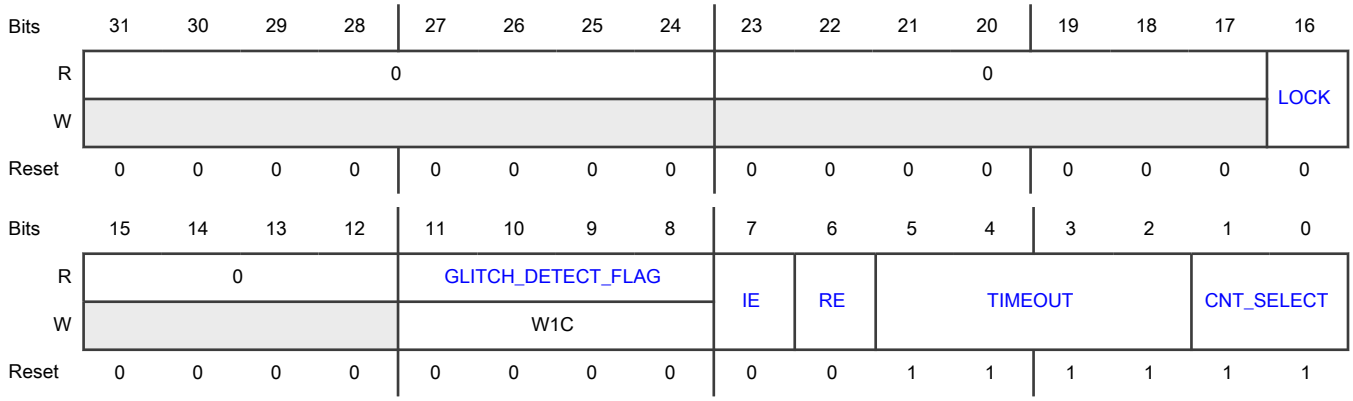
Offset

Register	Offset
GLITCH_DETECT_SC	144h

Function

Controls the GLITCH_DETECT operation.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-17 —	Reserved
16 LOCK	Glitch Detect Reset Enable Lock Bit Used to prevent writes to the GLITCH_RE register bit. 0b - Writes to RE are allowed. 1b - Writes to RE are ignored.
15-12 —	Reserved
11-8 GLITCH_DETECT_FLAG	GLITCH_DETECT_FLAG State of 4-bit Glitch Ripple Counter output. Based on CNT_SELECT program value, the correct 4-bit output state is monitored to generate interrupt or reset based on the settings of IE and RE.
7 IE	Glitch Detect Interrupt Enable Enables GLITCH_DETECT_FLAG[CNT_SELECT] to generate a hardware interrupt. **NOTE** Setting IE with GLITCH_DETECT_FLAG[CNT_SELECT] set will cause an automatic glitch detect interrupt to get generated. 0b - GLITCH_DETECT_FLAG[CNT_SELECT] does not generate hardware interrupt (user polling) 1b - GLITCH_DETECT_FLAG[CNT_SELECT] does generate hardware interrupt
6 RE	Glitch Detect Reset Enable Enables GLITCH_DETECT_FLAG[CNT_SELECT] to generate a POR/LVD reset. **NOTE** Writes to this bit require the VDD_CORE_GLITCH_DETECT_SC[LOCK] bit to be cleared. 0b - GLITCH_DETECT_FLAG[CNT_SELECT] does not generate POR/LVD reset 1b - GLITCH_DETECT_FLAG[CNT_SELECT] does generate POR/LVD reset
5-2 TIMEOUT	Timeout Specifies the timeout value used to reset glitch detect and compare logic after an initial glitch is detected. The timeout is based on the internal 10 MHz reference clock. After initial glitch is detected, the total timeout used to reset the glitch-detect logic is (TIMEOUT + initialization of internal timer clock).

Table continues on the next page...

Table continued from the previous page...

23-20 —	Reserved
19 —	Reserved
18 VOUT2P5_SEL	2.5 V Output Select Specifies the value of DCDC Vout. This field is only meaningful in Active Mode when DCDC drive strength is set to Normal. When VOUT2P5_SEL = 1, the DCDC_VTRIM[LVL10] trim values adjust the DCDC 2.5 V output. 0b - From DCDC_VDD_LVL register 1b - 2.5 V

Table continues on the next page...

Table continued from the previous page...

Field	Function
17-16 —	Reserved
15-14 —	Reserved
13-8 FREQ_CNTRL	DCDC Burst Frequency Control Specifies the frequency of the current burst.
7-4 —	Reserved
3-1 —	Reserved
0 FREQ_CNTRL_ON	DCDC Burst Frequency Control Enable Enables DCDC frequency stabilization. 0b - Disable 1b - Enable

32.7.23 DCDC Burst Configuration (DCDC_BURST_CFG)

Offset

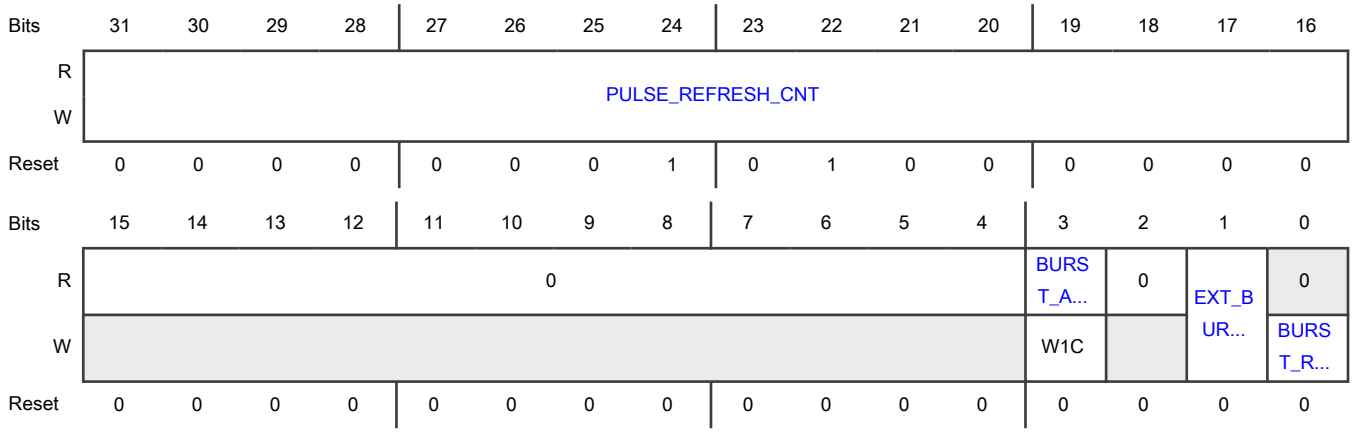
Register	Offset
DCDC_BURST_CFG	504h

Function

Controls the DCDC burst operation.

This register resets only after a POR, LVD, or HVD event.

Diagram



Fields

Field	Function
31-16 PULSE_REFRESH_CNT	Refresh Count Value Controls the DCDC refresh frequency when DCDC is in Pulse Refresh mode. When DCDC is enabled and running in Pulse Refresh mode, PULSE_REFRESH_CNT controls how often the DCDC is pulsed on and off based on a low-power reference clock. You must specify a count value that is long enough to allow a DCDC burst to occur. The pulse duration (time between on and off) is: (reference clock period) × (PULSE_REFRESH_CNT + 2) **NOTE** See the chip-specific information for more on DCDC pulsed mode clocking.
15-4 —	Reserved
3 BURST_ACK	Burst Acknowledge Flag Indicates that the DCDC burst completed, and therefore DCDC entered Quiet mode. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Did not complete 1b - Completed When writing 0b - No effect 1b - Clear the flag
2 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 EXT_BURST_EN	External Burst Request Enable Enables external burst requests. When this field is 1, SPC asserts the output burst trigger DCDC_BURST_TRIG_PULSE after the DCDC burst request has been acknowledged. **NOTE** Enable external bursts before writing 1 to BURST_REQ and after BURST_ACK is 0. 0b - Disable 1b - Enable
0 BURST_REQ	Software Burst Request Generates a software burst request to DCDC. **NOTE** Do not generate a new burst request until the previous burst request has completed and you acknowledged this by clearing the BURST_ACK flag. 0b - Do not generate 1b - Generate

Chapter 33
Smart Power Switch (VBAT)

33.1 Chip-specific VBAT information

Table 220. Reference links to related information

Topic	Related module	Reference
Full description	VBAT	VBAT

Power management		Power management map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

33.1.1 Signal naming

The table below lists the VBAT signal in this device.

Table 221. Device signal name - VBAT signal name

Device signal name	VBAT signal name
SWITCH_WAKEUP_B	WAKEUP_b

33.1.2 VBAT supply

VBAT is supplied from the chip power supply VDD_SWITCH.

33.1.3 VBAT backup SRAM LDO for memory retention

VBAT module in the device can optionally retain the contents of the 8KB SRAM STCM8 array that supports ECC.

33.2 Overview

VBAT works with the power management system to implement power-saving mechanisms. It provides bandgap timers and a voltage regulator to supply retention SRAM in low-power modes.

VBAT implements the 16 kHz internal clock source via FRO 16kHz.

33.2.1 Block diagram

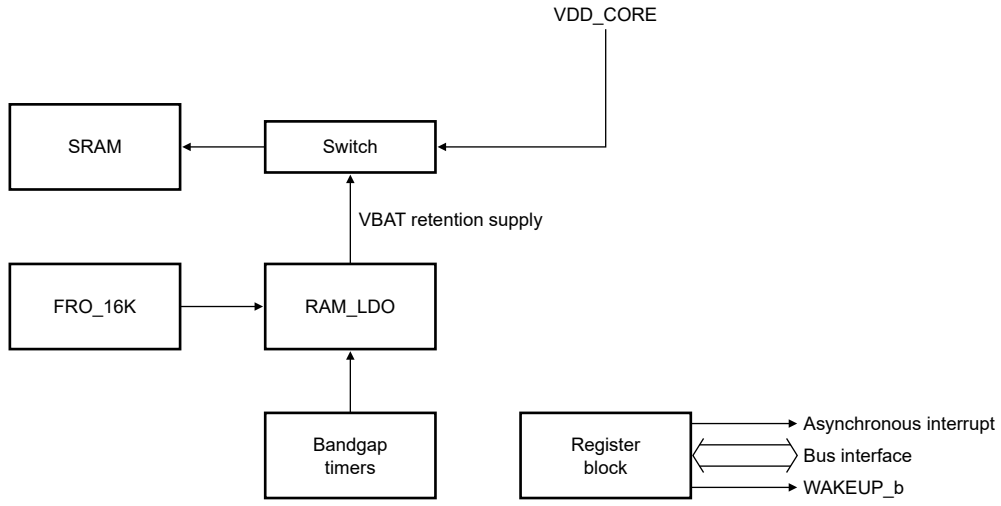

Figure 90. Block diagram

33.2.2 Features

- Supports internal 16 kHz free-running oscillator (FRO16K)
- Supports backup retention SRAM regulator

33.3 Functional description

The following sections describe the functional details of VBAT.

33.3.1 Operations

This section describes the operations of VBAT.

33.3.1.1 FRO 16.384 kHz clock

FRO16K is enabled by default on POR. You can disable it or lock it to prevent any change to the enable field. FRO 16k should be enabled prior to enabling the backup SRAM LDO regulator or VBAT bandgap timers.

33.3.1.2 SRAM LDO

SRAM LDO is a retention regulator that retains VBAT retention SRAM in low-power modes, including when VBAT is the only available supply. When IRQENA[LDO_RDY] becomes 1, the chip can enter into a low-power mode where the VBAT supply retains SRAM. Enable the bandgap and LDO before entering a low-power mode where the VBAT supply powers the retention SRAM. Enable Refresh mode for the lowest power consumption.

It takes approximately 8ms for the LDO_RDY flag to set after software enables the bandgap and LDO. When using the SRAM LDO it is recommended to leave it enabled in active modes to avoid this delay before entering a low power mode.

Although SRAM is automatically retained in all low-power modes, you can manually switch SRAM to the VBAT retention supply anytime. Do not access the SRAM when it receives power from the VBAT retention supply. You must manually reverse these steps before accessing the SRAM again.

To manually switch VBAT to power the SRAM:

1. Isolate the SRAM array (write 1 to LDORAMC[ISO]).
2. Switch the supply from VDD_CORE to the VBAT retention LDO (write 1 to LDORAMC[SWI]).

When SRAM LDO is disabled, LDORAMC[RETn] controls whether the retention of VBAT SRAM happens using VDD_CORE in low-power modes.

In general, using the SRAM LDO to retain the VBAT retention SRAM is a lower power option than using VDD_CORE directly.

NOTE

Enable FRO16K before enabling SRAM LDO or the bandgap.

33.3.1.3 Bandgap timer

Two software-configurable bandgap timers are available when the SRAM LDO bandgap is enabled. These timers share logic with the bandgap timer refresh logic to minimize power, so they use the FRO16K clock source and are only available when the bandgap is enabled. When you change the configured timeout, NXP recommends that you:

1. Disable the timer.
2. Clear the flag.
3. Write the new timeout value.
4. Enable the timeout again.

33.3.2 Low-power modes

VBAT remains functional in all low-power modes.

33.3.3 Debug mode

Debug modes do not affect VBAT.

33.3.4 Clocks

VBAT implements the following clock domains:

- Bus interface clock - access the registers
- FRO16 kHz internal clock

33.3.5 Reset

Only the POR resets VBAT.

33.3.6 Interrupts

VBAT generates one interrupt combining the following sources:

- VBAT POR
- Wake-up pin assertion
- Bandgap timer 0
- Bandgap timer 1

33.4 External signals

Table 222. External signals

Signal	Description	Direction
WAKEUP_b	Active low wake-up pin, falling edge sets the WAKEUP_FLAG. When WAKEUP_b pin is configured for open drain operation, an external wakeup source can drive this pin low, and the falling edge will assert the WAKEUP_FLAG	Input/Output

33.5 Initialization

To enable and lock the FRO16K:

1. Write 1h to FROCTLA[FRO_EN].
2. Write 1h to FROLCKA[LOCK].
3. Alter FROCLKE[CLKE] to clock gate different FRO16K outputs to different peripherals to reduce power consumption.

To enable and lock the LDO and bandgap:

1. Enable the FRO16K.
2. Write 7h to LDO_RAM Control A (LDOCTLA).
3. Wait for STATUSA[LDO_RDY] to become 1.
4. Write 1h to LDOLCKA[LOCK].

33.6 Application information

Configure the VBAT LDO to retain the state of any required SRAM to guard against an unexpected loss of power to the system:

1. Enable the LDO and bandgap.
2. Configure LDORAMC[RETn] to retain the appropriate arrays.

For a software-controlled power down, follow these steps to ensure robust retention of memory before switching off external power:

1. Write 1b to LDORAMC[ISO].
2. Write 1b to LDORAMC[SWI].

You must reverse the above steps to access the SRAM arrays, which the VBAT LDO retains. That is, follow these steps after external power is again switched on:

1. Write 0b to LDORAMC[SWI].
2. Write 0b to LDORAMC[ISO].

33.7 Memory map and register definition

This section includes VBAT memory map and detailed descriptions of all registers.

NOTE

The VBAT registers are reset on VBAT Cold Reset only (VBAT POR).

33.7.1 VBAT register descriptions

33.7.1.1 VBAT memory map

VBAT0 base address: 4002_B000h

31 TIMEN	Bandgap Timeout Period Enable 0b - Disable 1b - Enable
30-24 —	Reserved
23-0 TIMCFG	Timeout Configuration Configures the bandgap timeout 1 period. Configures timeout in number of seconds, ranging from 1 to 16,777,216 s. You can change this field when the timer is disabled.

Chapter 34
External Watchdog Monitor (EWM)

34.1 Chip-specific EWM information

Table 223. Reference links to related information

Topic	Related module	Reference
Full description	EWM	EWM
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

34.1.1 Module instances

This device has one instance of the EWM module, EWM0.

34.2 Overview

For safety purposes, a redundant watchdog system, EWM, is designed to monitor external circuits and the MCU software flow. This provides a backup mechanism to the internal watchdog that resets the MCU's CPU and peripherals.

The internal watchdog is used to monitor the flow and execution of the embedded software within the MCU. It consists of a counter that, if allowed to overflow, forces an internal, asynchronous reset to all on-chip peripherals. The counter also optionally asserts the RESET_B pin to reset external devices and circuits. The watchdog counter must not overflow if the software code works well and services the watchdog to restart the actual counter.

The EWM does not reset the MCU's CPU and peripherals, making it different from internal watchdog. The EWM module provides an independent ewm_out_b signal that, when asserted, resets or places an external circuit into a safe mode. The ewm_out_b signal asserts upon EWM counter timeout. An optional external input, ewm_in, allows additional control when asserting the ewm_out_b signal.

34.2.1 Block diagram

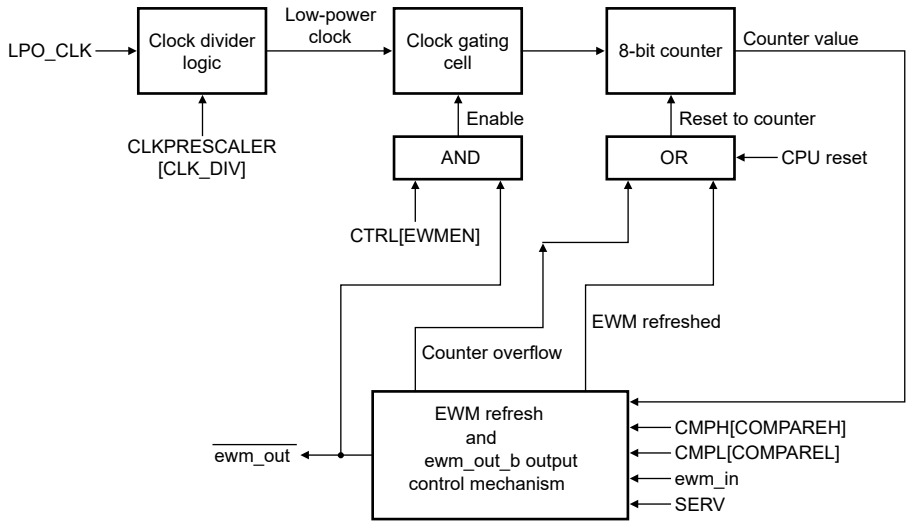

Figure 91. Block diagram

34.2.2 Features

- Independent LPO_CLK source
- Programmable timeout period, specified in terms of the number of EWM LPO_CLK cycles
- Windowed refresh option that provides:
  - A robust check to confirm that the program flow is faster than expected.
  - A programmable window.
  - Refresh outside the window, leading to assertion of the ewm_out_b signal.
- Robust refresh mechanism:
  - Write values of B4h and 2Ch to Service (SERV) within 15 peripheral bus clock cycles.
- One output port, ewm_out_b, which when asserted is used to reset or place the external circuit into Safe mode
- One input port, ewm_in, which allows an external circuit to control the assertion of the ewm_out_b signal

34.3 Functional description

The following sections discuss these aspects of EWM:

- Functional details
- Operating modes

NOTE

If the BUS_CLK is lost, EWM does not generate the ewm_out_b signal and no refresh operation is possible.

34.3.1 Modes of operation

34.3.1.1 Stop mode

When EWM is in Stop mode, the CPU cannot refresh EWM. After entering Stop mode, the EWM counter freezes.

Following are the possible ways to exit Stop mode:

- Through a reset: EWM remains disabled in this case.
- Through an interrupt: EWM is re-enabled and the counter continues to be clocked from the same value as prior to Stop mode entry.

NOTE

Consider the following if EWM enters Stop mode during the CPU refresh mechanism:

- While exiting Stop mode through an interrupt, the refresh mechanism starts from the previous state. That is, if you write the refresh command correctly and EWM enters Stop mode immediately, you must write the next command in *15* peripheral bus clocks after exiting Stop mode.
- You must mask all interrupts before executing the EWM refresh instructions.

34.3.1.2 Debug mode

EWM remains unimpacted when entering Debug mode:

- If EWM is enabled before entering Debug mode, it remains enabled.
- If EWM is disabled before entering Debug mode, it remains disabled.

34.3.2 Using the EWM counter

EWM uses an 8-bit ripple counter that is fed by a clock source independent of the peripheral bus clock source. As the preferred timeout is between 1 ms and 100 ms, the actual clock source must be in the kHz range.

The counter is reset to 0 in these conditions:

- After CPU reset
- After the EWM refresh action completes
- At counter overflow

The CPU cannot access the counter value.

34.3.3 Using compare registers

You can write to Compare Low (CMPL) and Compare High (CMPH) only once after a CPU reset and you cannot modify them until another CPU reset occurs. These registers are used to create a refresh window for the EWM module.

You cannot program Compare Low (CMPL) and Compare High (CMPH) with the same value. In case of any attempt, the ewm_out_b signal asserts as soon as the counter reaches the value of Compare Low (CMPL) + 1.

NOTE

You must update Compare Low (CMPL) and Compare High (CMPH) before enabling EWM, after which the counter resets to 0. Therefore, you must provide a reasonable time after POR for the external monitoring circuit to stabilize. You must also ensure that the ewm_in pin is deasserted.

34.3.4 Using the refresh mechanism

Other than the initial configuration of EWM, the CPU can access EWM only through Service (SERV). The CPU must access this register by correctly writing unique data within the windowed time frame, as determined by Compare Low (CMPL) and Compare High (CMPH) for the correct EWM refresh operation. The following table describes conditions that exist and the refresh mechanisms that apply to those conditions.

Table 224. Refresh mechanisms

Condition	Mechanism
The EWM refresh action completes when the value of Compare Low (CMPL) ≤ the counter value < the value of Compare High (CMPH).	The software behaves as expected and the EWM counter resets to 0. The ewm_out_b output signal remains in Deasserted state if, during the EWM refresh action, the ewm_in input is in Deasserted state.
The EWM refresh action completes when the counter value < the value of Compare Low (CMPL).	The software refreshes EWM before the windowed time frame, the counter resets to 0, and the ewm_out_b output signal asserts no matter what the value of the ewm_in input signal is.
The counter value reaches the value of Compare High (CMPH) prior to completion of the EWM refresh action.	The software does not refresh EWM. The EWM counter resets to 0 and the ewm_out_b output signal asserts no matter what the value of the ewm_in input signal is.

See Service (SERV) for more on the refresh mechanism.

34.3.5 Interrupt

When the ewm_out_b signal asserts, an interrupt request can be generated to indicate the assertion of the EWM reset out signal. The interrupt is enabled when CTRL[INTEN] = 1. Writing 0 to this field clears the interrupt request but does not affect the ewm_out_b signal, which can be deasserted only by forcing a system reset.

34.3.6 Clocking

The following table shows EWM clocks.

Table 225. EWM Clocks

Clock	Description
IPG_CLK	This is the system clock and should be turned on for EWM to be able to work properly. During low power modes in which the core is powered down, this clock is disabled,
IPG_CLK_S	This is the IPS clock and is synchronous with IPG_CLK. It is disabled except during IPS write accesses. it is enabled with EWM's IPS_MODULE_EN
IPO_CLOCK	This is a low power clock used for running EWM counter. This clock is gated when EWM is disabled or when ewm_out_b is asserted.

34.3.7 Using the counter clock prescaler

You can program CLKPRESCALER[CLK_DIV] to divide the EWM counter clock source. This divided clock is used to run the EWM counter.

NOTE

The divided clock used to run the EWM counter must not exceed half the frequency of the bus clock.

34.4 External signals

EWM includes external signals, as shown in the following table.

NOTE

All active-low signals are represented with the suffix "_b" throughout the chapter.

Table 226. Signal descriptions

Signal	Description	I/O
ewm_in	EWM's input for the safety status of external safety circuits. You can program the polarity of ewm_in by using CTRL[ASSIN]. The default polarity is active-low.	I
ewm_out_b	EWM's reset out signal	O

34.4.1 Using the ewm_out_b signal

The ewm_out_b signal is a digital output signal used to gate an external circuit (application-specific) that controls critical safety functions.

The ewm_out_b signal remains deasserted when the CPU regularly refreshes EWM within the programmable refresh window, indicating that the application code is executing as expected.

The ewm_out_b signal asserts in any of the following conditions:

- An EWM refresh action occurs when the counter value is less than the value of Compare Low (CMPL).
- The EWM counter value reaches the value of Compare High (CMPH) and no EWM refresh occurs.
- The functionality of the ewm_in pin is enabled and the ewm_in pin asserts when refreshing EWM.
- After any reset.

The ewm_out_b signal asserts after any reset by the virtue of the external pulldown mechanism on the ewm_out_b pin. To deassert the ewm_out_b signal, write 1 to CTRL[EWMEN] to enable EWM.

If the ewm_out_b signal shares its pad with a digital I/O pin, this actual pad defers to being an input signal on reset. The ewm_out_b signal controls the pad state only after CTRL[EWMEN] enables EWM.

NOTE

The ewm_out_b pad must be in Pulldown state when the EWM functionality is being used and EWM is under reset.

34.4.2 Using the ewm_out_b pin state in low-power modes

During Wait, Stop, and Power-Down modes, the ewm_out_b pin enters a high-impedance state. You have the option to control the logic state of the pin by using an external pull device or by configuring the internal pull device. When the CPU enters Run mode from Wait or Stop mode recovery, the pin resumes its previous state before entering Wait or Stop mode. When the CPU enters Run mode after exiting Power-Down mode, the pin returns to its reset state.

34.4.3 Using the ewm_in signal

The ewm_in signal is a digital input signal for the safety status of external safety circuits. This signal allows an external circuit to control the assertion of the ewm_out_b signal. For example, in the application, an external circuit monitors a critical safety function, and if there is a fault with the safety function, the external circuit can actively initiate the ewm_out_b signal, which controls the gating circuit.

The ewm_in signal is ignored if EWM is disabled, or if CTRL[INEN] = 0 after any reset.

After you enable EWM (by writing 1 to CTRL[EWMEN]) and the ewm_in functionality (by writing 1 to CTRL[INEN]), the ewm_in signal must be in Deasserted state before the CPU starts refreshing EWM. This ensures that the ewm_out_b signal stays in Deasserted state; otherwise, the ewm_out_b output signal asserts.

34.5 Memory map and register definitions

This section contains the module memory map and registers.

NOTE

EWM supports only 8-bit register accesses; 16-bit and 32-bit accesses are not supported.

34.5.1 EWM register descriptions

34.5.1.1 EWM memory map

EWM0 base address: 4001_3000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Control (CTRL)	8	RW	00h
1h	Service (SERV)	8	W	00h
2h	Compare Low (CMPL)	8	RW	00h
3h	Compare High (CMPH)	8	RW	FFh
5h	Clock Prescaler (CLKPRESCALER)	8	RW	00h

34.5.1.2 Control (CTRL)

Offset

Register	Offset
CTRL	0h

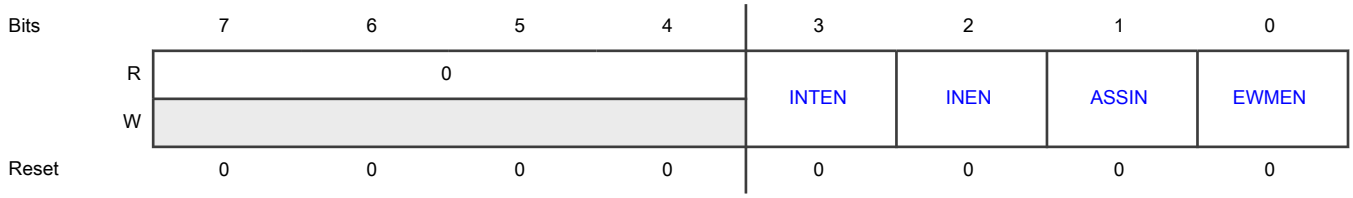
Function

Controls the functionality of EWM.

NOTE

You can write to CTRL[INEN], CTRL[ASSIN], and CTRL[EWMEN] only once after a CPU reset. Modifying these fields more than once generates a bus transfer error.

Diagram



Fields

Field	Function
7-4 —	Reserved
3 INTEN	Interrupt Enable Enables interrupt request generation. If this field = 1 and the ewm_out_b signal is asserted, an interrupt request is generated. To deassert interrupt requests, write 0 to this field. 0b - Deasserts interrupt requests 1b - Generates interrupt requests
2 INEN	Input Enable Enables the ewm_in port. When this field = 1, it enables the ewm_in port. 0b - Disables 1b - Enables
1 ASSIN	Assertion State Select Specifies the asserted state of the ewm_in signal. By default, the asserted state of the ewm_in signal is logic 0 (active-low), which is when this field = 0. When this field = 1, the ewm_in asserted state is logic 1 (active-high). You can use this field to change the expected polarity of the ewm_in signal. 0b - Logic 0 1b - Logic 1
0 EWMEN	EWM Enable Enables the EWM module. This field resets the EWM counter to 0 and deasserts the ewm_out_b signal. If this field = 1, it enables the EWM module, and if the field = 0, it disables the EWM module. You cannot re-enable this field until the next reset because of its write-once nature. 0b - Disables 1b - Enables

34.5.1.3 Service (SERV)

Offset

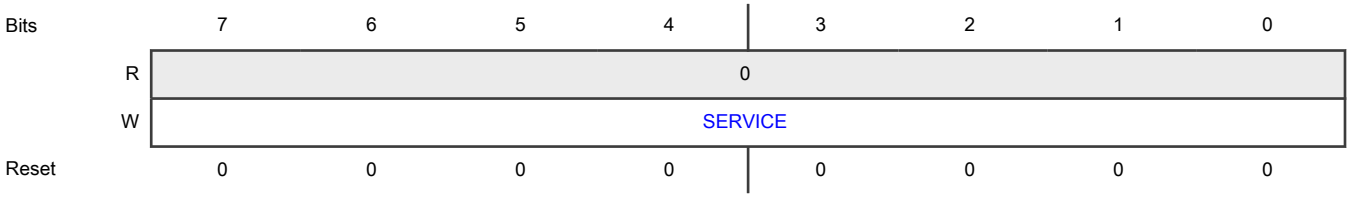
Register	Offset
SERV	1h

Function

Provides an interface from the CPU to the EWM module.

Attempted reads of this register return 0.

Diagram



Fields

Field	Function
7-0 SERVICE	Service Provides an interface from the CPU to the EWM module. The EWM refresh mechanism requires the CPU to write these values to this field: a first data byte of B4h, followed by a second data byte of 2Ch. The EWM refresh action is invalid if either of the following conditions is true: • The first or second data byte is not written correctly. • The second data byte is not written within a fixed number of peripheral bus cycles of the first data byte, known as EWM_refresh_time. The number of peripheral bus clock cycles required for EWM_refresh_time is 15.

34.5.1.4 Compare Low (CMPL)

Offset

Register	Offset
CMPL	2h

Function

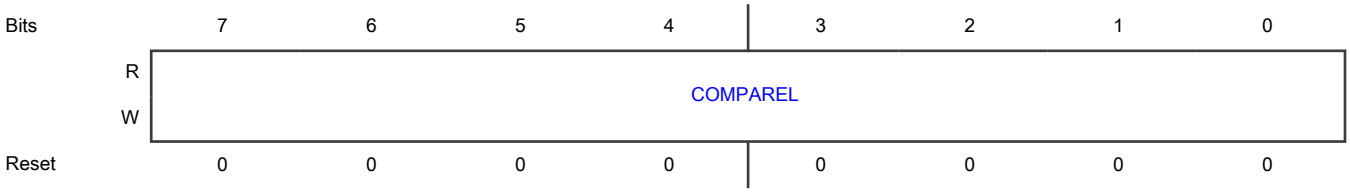
Determines the lower value of the windowed time frame for the correct EWM refresh operation.

This register is reset to 0 after a CPU reset. This provides no minimum time for the CPU to refresh the EWM counter.

NOTE

You can write to this register only once after a CPU reset. Writing to the register more than once generates a bus transfer error.

Diagram



Fields

Field	Function
7-0 COMPAREL	Compare Low Configures the minimum counter value when refreshes are allowed. If a refresh is attempted while the counter value is lower than COMPAREL, then the ewm_out_b signal is asserted. To prevent runaway code from changing the value of this field, you must write to this field after a CPU reset even if the (default) minimum refresh time is required.

34.5.1.5 Compare High (CMPH)

Offset

Register	Offset
CMPH	3h

Function

Determines the higher value of the windowed time frame for the correct EWM refresh operation.

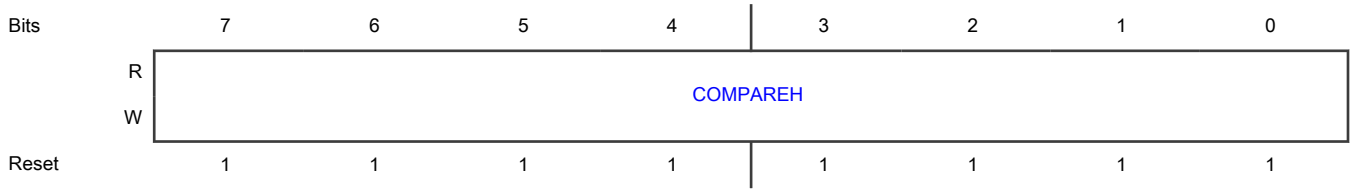
This register is reset to FFh after a CPU reset. This provides a maximum time of up to 256 clocks for the CPU to refresh the EWM counter.

NOTE

You can write to this register only once after a CPU reset. Writing to the register more than once generates a bus transfer error.

The valid values for this register are up to FEh because the EWM counter never expires when the value of COMPAREH = FFh. The expiration happens only if the EWM counter is greater than the value of COMPAREH.

Diagram



Fields

Field	Function
7-0 COMPAREH	Compare High Configures the maximum counter value till when refreshes are allowed. If a refresh is not attempted while the counter value is greater than COMPAREH, then the ewm_out_b signal is asserted. To prevent runaway code from changing the value of this field, you must write to this field after a CPU reset.

34.5.1.6 Clock Prescaler (CLKPRESCALER)

Offset

Register	Offset
CLKPRESCALER	5h

Function

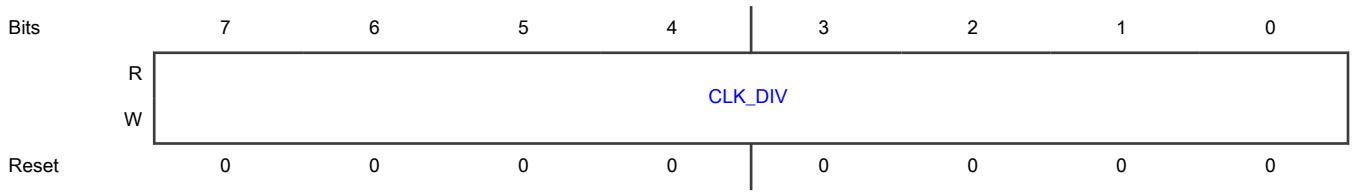
Prescales the EWM counter clock source by a clock divider.

This register is reset to 00h after a CPU reset.

NOTE

You can write to this register only once after a CPU reset. Writing to the register more than once generates a bus transfer error. You must write the required prescaler value before enabling EWM.

Diagram



Fields

Field	Function
7-0	Clock Divider Prescales the selected low-power clock source for running the EWM counter:

Table continues on the next page...

Field	Function
CLK_DIV	Prescaled clock frequency = low-power clock source frequency ÷ (1 + the value of CLK_DIV) See chip-specific information for low-power clock source frequency used in your device.

35.2 Overview

TRGMUX allows software to configure the trigger inputs for various peripherals.

35.2.1 Block diagram

The block diagram below shows the trigger selection logic of the TRGMUX module.

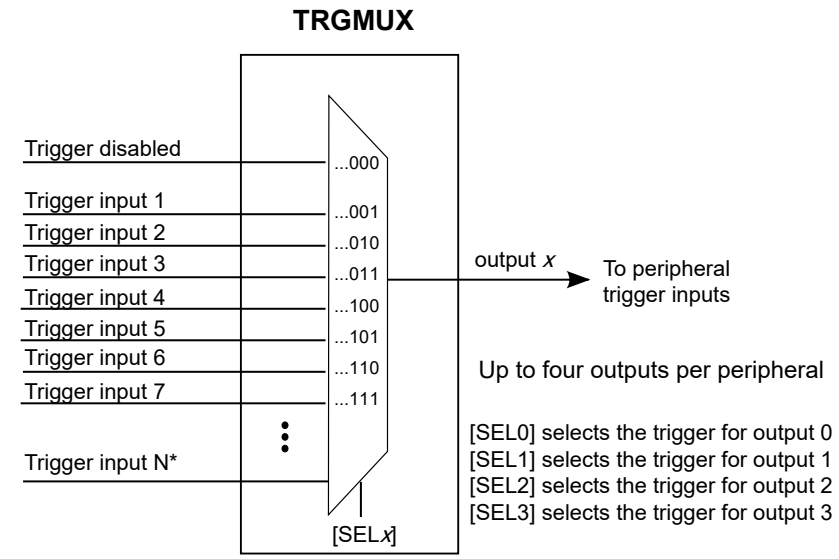

Figure 92. TRGMUX block diagram

35.2.2 Features

The TRGMUX module allows software to select the trigger source for peripherals.

Each peripheral has its own dedicated TRGMUX register. See each peripheral's TRGMUX register for details.

35.3 Functional description

The following sections describe functional details of the TRGMUX module.

35.3.1 Clocking

This module has no clocking considerations.

35.3.2 Interrupts

This module has no interrupts.

35.4 External signals

This module has no external signals.

35.5 Initialization

This module does not require initialization.

35.6 Memory map and register definition

The TRGMUX registers contain fields for selecting trigger sources for peripheral modules.

TRGMUX registers can be written only in supervisor mode.

35.6.1 TRGMUX register descriptions

35.6.1.1 TRGMUX memory map

36.1.1 Module instances

This device contains one instance of the WUU module, WUU0.

36.1.2 WUU0 sources

The device uses the following inputs as wakeup sources to the WUU0 module. The WUU0_Px inputs are connections to external physical pins. The WUU0_MxIF inputs are connections to the internal peripheral interrupt flags from different modules that can operate in low-power modes. The WUU0_MxDR inputs are connections to the internal peripheral Asynchronous DMA or module Triggers from different modules that can operate in low-power modes.

NOTE

In addition to the WUU0 wakeup sources, the device also wakes from low power modes when NMI_b or RESET_b pins are enabled and the respective pin is asserted.

36.1.3 LPO clock

The LPO mentioned in this chapter is the 32 kHz clock from CCM32K, see 32 kHz Clock Control Module (CCM32K) for details.

36.2 Overview

WUU allows software to select external pins and on-chip modules as interrupt wake-up sources from Deep Sleep/Power Down power modes. External pins can also be configured as interrupt wake-up sources from all power modes. WUU lets modules generate a temporary wake-up from Deep Sleep to allow servicing of DMA or trigger events. WUU also allows pins to generate a temporary wake-up from Deep Sleep for servicing DMA or trigger events. Digital filtering is also available for the external wakeup pins.

Input sources to WUU are described in the chip-specific WUU information section.

36.2.1 Features

The WUU module features include:

- Support for external input pins and on-chip modules with individual enable bits to wake the chip from low leakage modes.
- Input sources may be external pins or from on-chip modules capable of running in Deep Sleep or Power Down. See the chip-specific WUU information for the wakeup input sources for this device.
- Support to configure on-chip modules as DMA or trigger sources for temporary wakeup from Deep Sleep.
- Support to configure external pins as DMA request or trigger sources for temporary wakeup from Deep Sleep.
- External input pins programmable for falling-edge, rising-edge, or any-edge detection.
- Optional digital filters provided to qualify an external pin detect. Note that when the LPO clock is disabled, filters are disabled and bypassed.
- All external input pins can be filtered, but only 8'd2 filters are available at a given time.
- Support to enable external input pin and filter detection in *all* power modes (not limited to Deep Sleep/Power Down).

36.2.2 Block diagram

The following figure is the block diagram for the WUU module.

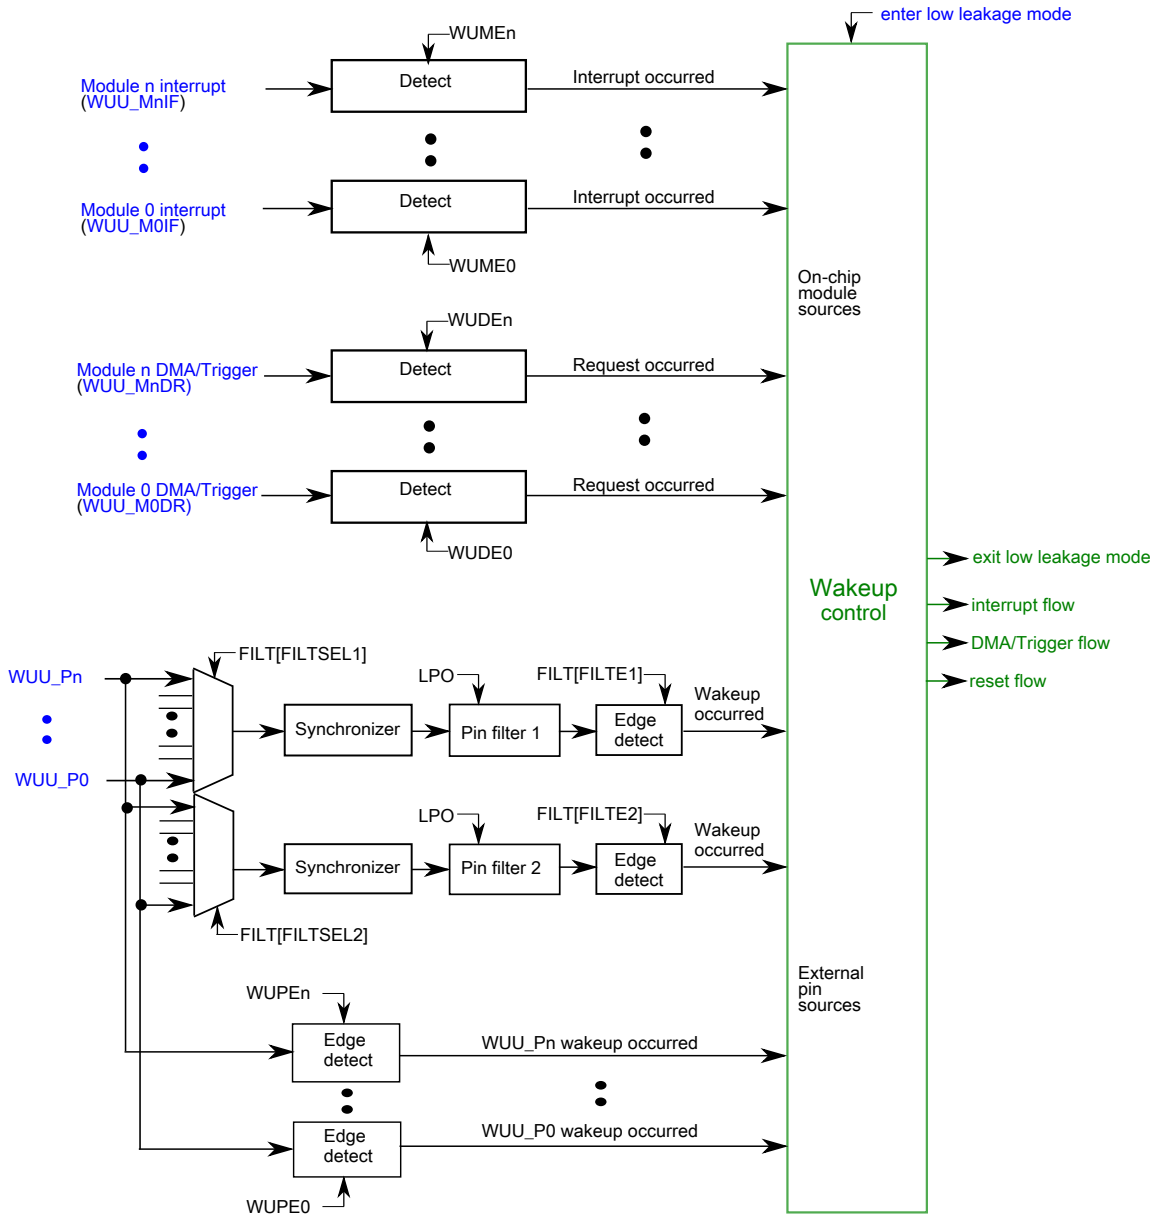

Figure 93. WUU block diagram

36.3 Functional description

The low-leakage wakeup unit (WUU) module allows on-chip modules and external input pins as a source of wakeup from low-leakage modes.

The WUU module contains pin enables for each external pin and on-chip module. For each external pin, the user can disable or select the edge type for the wakeup with the following options:

- Falling-edge
- Rising-edge
- Either-edge

Exit due to a pin event will trigger an WUU interrupt after wakeup is complete. When an external pin is enabled as a wakeup source, the pin must be configured as an input pin. A pin can also be configured to generate an interrupt from Deep Sleep/Power Down or a DMA/trigger request for temporary wakeup from Deep Sleep. Detection logic for a pin can optionally remain enabled during all power modes using the PMC register.

The WUU implements optional 3-cycle glitch filters, based on the LPO clock. A detected external pin is required to remain asserted until the enabled glitch filter times out. Additional latency of up to 2 cycles is due to synchronization, which results in a total of up to 5 cycles of delay before the detect circuit alerts the system to the wakeup event when the filter function is enabled. Two wakeup detect filters are available for selected external pins. Glitch filtering is not provided for the on-chip modules. A filter can be configured to generate an interrupt from Deep Sleep/Power Down or a DMA/trigger request for temporary wakeup from Deep Sleep. Detection logic for a filter can optionally remain enabled during all power modes using the FMC register.

For on-chip module interrupts, the WUMEx bit of the Module Interrupt Enable (ME) register enables the associated module interrupt as a wakeup source. Exit due to a module interrupt will not trigger an WUU interrupt.

For on-chip module DMA/trigger requests, the DE[WUDEx] bit enables the associated module DMA/trigger request as a wakeup source. Exit due to a module DMA/trigger request will not trigger a WUU interrupt.

36.3.1 Modes of operation

The WUU module becomes functional on entry into a low-leakage power mode. After recovery from Deep Sleep, the WUU is immediately disabled. After recovery from Power Down, the WUU continues to detect wake-up events until the user has reinitialized the system and deasserted isolation. Detection of external pin/filter events can also optionally remain enabled in all power modes using the PMC/FMC registers.

36.3.1.1 Deep Sleep mode

Wakeup events due to either an external pin input (WUU_Px) or an on-chip module interrupt (WUU_MxIF), result in a CPU interrupt flow to begin user code execution. The source of the wakeup determines the subsequent path of code execution:

- Pin events trigger the WUU interrupt service routine.
- Module interrupts trigger that same module's interrupt service routine.

NOTE

The WUU interrupt must not be masked by the interrupt controller to avoid a scenario where the system does not fully recover from Deep Sleep after an external pin event.

Wakeup events due to an on-chip module request (WUU_MxDR) DMA/trigger request result in a temporary exit from Deep Sleep to allow the request to be serviced while the CPU clock remains gated. After the request is serviced, the system re-enters Deep Sleep.

Wakeup events due to an external pin (WUU_Px) DMA/trigger request, result in a temporary exit from Deep Sleep to allow the request to be serviced while the CPU clock remains gated. After the request is serviced, the system re-enters Deep Sleep.

36.3.1.2 Power Down modes

For any WUU wakeup from Power Down, recovery is always via a reset flow. The source of the wakeup determines the subsequent path of code execution:

- Pin events trigger the WUU interrupt service routine.
- Module interrupts trigger that same module's interrupt service routine.

36.3.1.3 Non-low leakage modes

The WUU is inactive in all non-low leakage modes, with the exception of external pin/filter detection which can explicitly be kept enabled during all power modes using the PMC/FMC registers. The WUU registers are accessible in non-low leakage modes and are available for configuring and reading status when bus transactions are possible.

36.3.2 Clocking

To provide the wakeup function for the chip, make sure clocking is available for WUU during chip low-power operation. See the chip-specific WUU information for the chip clock connection details.

WUU filters are clocked by the LPO clock.

36.3.3 Interrupts

On-chip module interrupts can be enabled as wakeup sources in Module Interrupt Enable (ME)

36.4 External signals

WUU signals are shown in the table found here.

Table 231. WUU signal descriptions

Signal	Description	I/O
WUU_Pn	External pin wakeup inputs. Can be enabled to detect a rising-edge, a falling-edge, or any change.	I
WUU_MnIF	On-chip module interrupt flags	I
WUU_MnDR	On-chip module DMA/trigger requests	I

36.5 Initialization

For an enabled module wakeup input, the module's flag must be cleared by software before entering Deep Sleep or Power Down mode to avoid an immediate exit from the mode.

Flags associated with external input pins, filtered and unfiltered, must also be cleared by software prior to entry to Deep Sleep or Power Down mode.

When an external wake-up pin filter is first enabled in the FILT register, filter operation begins immediately. After enabling an external pin filter or changing its source pin, wait at least five LPO clock cycles to allow the filter to initialize before entering Deep Sleep or Power Down mode or before enabling filter detection for all power modes in the FMC register.

NOTE

After recovering from a Power Down mode, software must restore the chip configuration before relaxing any power domain isolation controls. In particular, to avoid any WUU flag from being falsely set, restore the pin configuration for the enabled WUU wake-up pins before removing any voltage isolation between power domains.

36.6 Memory map/register definition

Information about WUU registers can be found here.

36.6.1 WUU register descriptions

When an external pin has been configured to be an active wakeup source in all power modes (PMC[WUPMCn] = 1), then the corresponding wakeup pin enable (PEx[WUPEn]) and wakeup pin configuration (PDCx[WUPDCn]) settings for that pin must not be changed. To modify the WUPEn or WUPDCn settings, follow these steps:

1. Clear the WUPMCn value for that pin.
2. Update the corresponding WUPEn or WUPDCn settings as needed.
3. Set the WUPMCn value for that pin back to 1.

NOTE

WUU registers can be written only in supervisor mode. Write accesses in user mode are blocked and result in a bus error.

All WUU registers are reset by Chip Reset not Power Down and by reset types that trigger Chip Reset not Power Down. WUU registers are unaffected by reset types that do not trigger Chip Reset not Power Down.

36.6.1.8 Pin Flag (PF)

Offset

Register	Offset
PF	20h

Function

Contains the wakeup flags indicating which wakeup source caused the MCU to exit Deep Sleep (if the corresponding pin-mode configuration bit PMC[WUPMCn] = 1) or Power Down mode. For Deep Sleep, this is the source causing the CPU interrupt flow. For Power Down, this is the source causing the MCU reset flow.

To clear a flag, write a 1 to the corresponding WUF*n* bit. If set, the wakeup flag (WUF*n*) remains set even if the associated pin wakeup is disabled in its WUPE*n* field.

NOTE

This register is reset on Chip Reset not Power Down and by reset types that trigger Chip Reset not Power Down. It is unaffected by reset types that do not trigger Chip Reset not Power Down.

36.6.1.10 Pin DMA/Trigger Configuration 1 (PDC1)

Offset

Register	Offset
PDC1	38h

Function

Configures the available external wakeup input pins in the range from WUU_P0 to WUU_P15 to generate an interrupt, DMA or a trigger request when detected.

- When configured as an interrupt, the interrupt is asserted when the edge programmed in the PE1 register is detected and remains asserted until the corresponding flag is cleared in the PF register.
- When configured as a DMA request, the request is asserted when the edge programmed in the PE1 register is detected and remains asserted until either the corresponding flag is cleared in the PF register or until the requested DMA transfer is complete.
- When configured as a trigger request, the trigger is asserted when the level programmed in the PE1 register is detected and remains asserted while the input pin is asserted. The corresponding flag in the PF register will not be set.

NOTE

Do not modify the value of a WUPDCn field when its corresponding PMC[WUPMCn] = 1.

NOTE

This register is reset on Chip Reset not Power Down and by reset types that trigger Chip Reset not Power Down. It is unaffected by reset types that do not trigger Chip Reset not Power Down.

36.6.1.11 Pin DMA/Trigger Configuration 2 (PDC2)

Offset

Register	Offset
PDC2	3Ch

Function

Configures the available external wakeup input pins in the range from WUU_P16 to WUU_P31 to generate an interrupt, DMA or a trigger request when detected.

- When configured as an interrupt, the interrupt is asserted when the edge programmed in the PE2 register is detected and remains asserted until the corresponding flag is cleared in the PF register.
- When configured as a DMA request, the request is asserted when the edge programmed in the PE2 register is detected and remains asserted until either the corresponding flag is cleared in the PF register or until the requested DMA transfer is complete.
- When configured as a trigger request, the trigger is asserted when the level programmed in the PE2 register is detected and remains asserted while the input pin is asserted. The corresponding flag in the PF register will not be set.

NOTE

Do not modify the value of a WUPDCn field when its corresponding PMC[WUPMCn] = 1.

NOTE

This register is reset on Chip Reset not Power Down and by reset types that trigger Chip Reset not Power Down. It is unaffected by reset types that do not trigger Chip Reset not Power Down.

36.6.1.12 Pin Filter DMA/Trigger Configuration (FDC)

Offset

Register	Offset
FDC	48h

Function

Configures the external pin filters to generate an interrupt, DMA or a trigger request when detected.

- When configured as an interrupt, the interrupt is asserted when the edge programmed in the FILTEn field is detected and remains asserted until the corresponding FILTFn flag is cleared.
- When configured as a DMA request, the request is asserted when the edge programmed in the FILTEn field is detected and remains asserted until either the corresponding FILTFn flag is cleared or until the requested DMA transfer is complete.
- When configured as a trigger request, the trigger is asserted when the level programmed in the FILTEn register is detected and remains asserted while the input pin is asserted. The corresponding FILTFn flag will not be set.

NOTE

This register is reset on Chip Reset not Power Down and by reset types that trigger Chip Reset not Power Down. It is unaffected by reset types that do not trigger Chip Reset not Power Down.

36.6.1.14 Pin Filter Mode Configuration (FMC)

Offset

Register	Offset
FMC	58h

Function

Configures the detection logic for external pin filters to remain enabled during all power modes, not just during Deep Sleep/ Power Down.

NOTE

This register is reset on Chip Reset not Power Down and by reset types that trigger Chip Reset not Power Down. It is unaffected by reset types that do not trigger Chip Reset not Power Down.

Watchdog Timer (WDOG)

37.1 Chip-specific WDOG information

Table 232. Reference links to related information

Topic	Related module	Reference
Full description	WDOG	WDOG
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

37.1.1 Module instances

This device has two instances of the WDOG module, WDOG0 and WDOG1.

NOTE

On reset, the WDOG0 is enabled and the WDOG1 is disable by default.

37.1.2 CS[CLK] fields

The CS[CLK] configures the clock source that feeds the watchdog counter as below.

- 00b - SLOW_CLK
- 01b - 32K_CLK
- 10b - FRO-6M
- 11b - OSC-RF

37.2 Overview

The Watchdog Timer (WDOG) module is an independent timer that is available for system use. It provides a safety feature to ensure that software is executing as planned and that the CPU is not stuck in an infinite loop or executing unintended code. If the WDOG module is not serviced (refreshed) within a certain period, it resets the MCU.

37.2.1 Block diagram

The following figure shows a block diagram of the WDOG module.

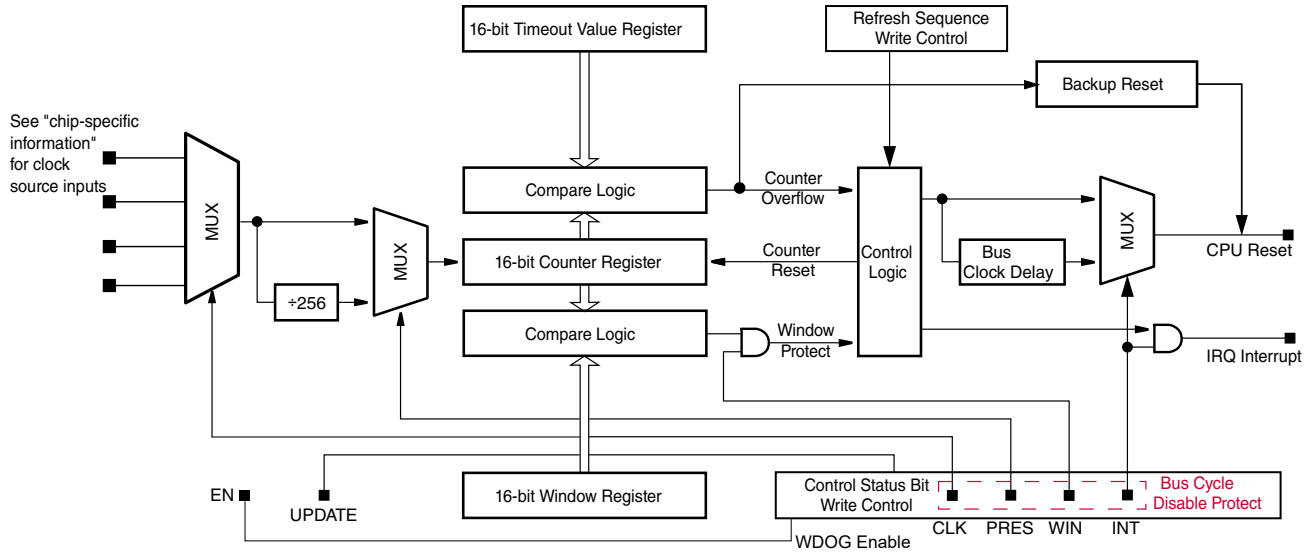

Figure 94. WDOG block diagram

37.2.2 Features

Features of the WDOG module include:

- Configurable clock source inputs independent from the bus clock
- Programmable timeout period
  - Programmable 16-bit timeout value
  - Optional fixed 256 clock prescaler when longer timeout periods are needed
- Robust write sequence for counter refresh
  - Refresh sequence of writing the watchdog counter register (CNT)
- Window mode option for the refresh mechanism
  - Programmable 16-bit window value
  - Provides robust check that program flow is faster than expected
  - Early refresh attempts trigger a reset
- Optional timeout interrupt to allow post-processing diagnostics
  - Interrupt request to CPU with interrupt vector for an interrupt service routine (ISR)
  - Forced reset occurs 128 bus clocks after the interrupt vector fetch
- Configuration bits are write-once-after-reset to ensure watchdog configuration cannot be mistakenly altered
- Robust write sequence for unlocking write-once configuration bits
  - Unlock sequence of writing the watchdog counter register (CNT), for allowing updates to write-once configuration bits
  - Software must make updates within 128 bus clocks after unlocking and before WDOG closing unlock window

37.3 Functional description

The WDOG module provides a fail safe mechanism to ensure the system can be reset to a known state of operation in case of system failure, such as the CPU clock stopping or there being a run away condition in the software code. The watchdog counter

runs continuously off a selectable clock source and expects to be serviced (refreshed) periodically. If it is not, it generates a reset triggering event.

37.3.1 Watchdog refresh mechanism

The watchdog resets the MCU if the watchdog counter is not refreshed. A robust refresh mechanism makes it very unlikely that the watchdog can be refreshed by runaway code.

To refresh the watchdog counter, software must execute a refresh write sequence before the timeout period expires. In addition, if window mode is used, software must not start the refresh sequence until after the time value set in the WIN register. See the following figure.

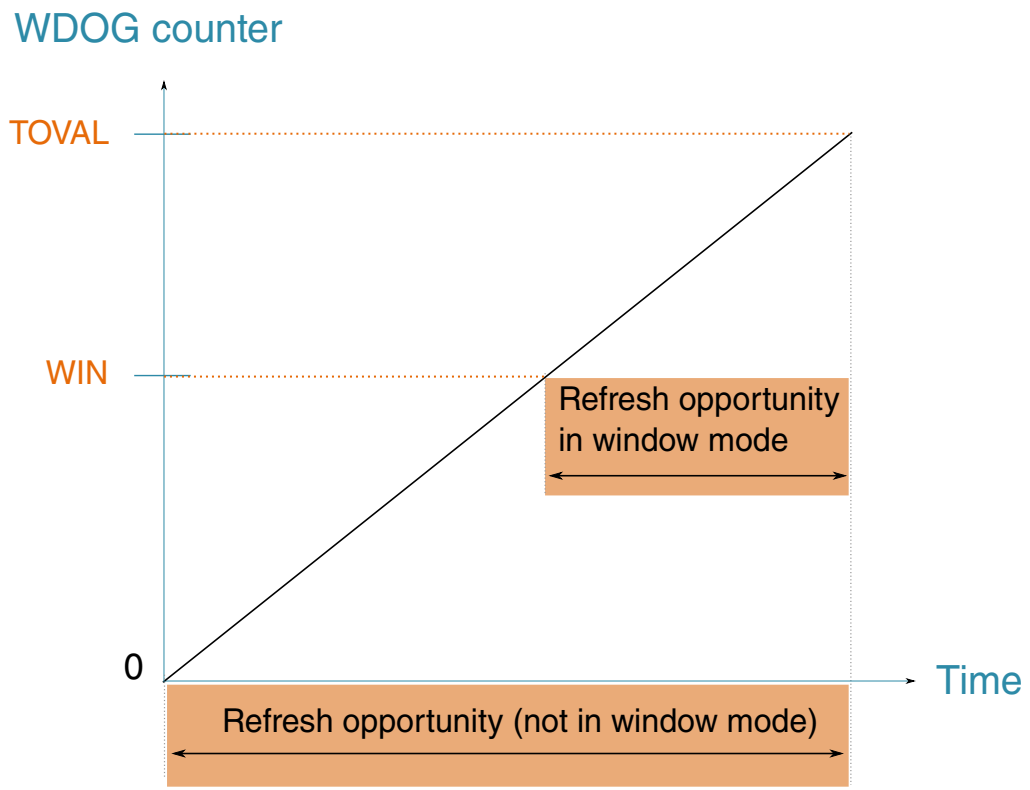

Figure 95. Refresh opportunity for the Watchdog counter

37.3.1.1 Window mode

Software finishing its main control loop faster than expected could be an indication of a problem. Depending on the requirements of the application, the WDOG can be programmed to force a reset when refresh attempts are early.

When Window mode is enabled, the watchdog must be refreshed after the counter has reached a minimum expected time value; otherwise, the watchdog resets the MCU. The minimum expected time value is specified in the WIN register. Setting CS[WIN] enables Window mode.

37.3.1.2 Refreshing the Watchdog

The refresh write sequence can be

- either two 16-bit writes (0xA602, 0xB480) or four 8-bit writes (0xA6, 0x02, 0xB4, 0x80) if WDOG_CS[CMD32EN] is 0;
- one 32-bit write (0xB480_A602) if WDOG_CS[CMD32EN] is 1.

to the CNT register. Both methods must occur before the WDG timeout; otherwise, the watchdog resets the MCU.

NOTE

Before starting the refresh sequence, disable the global interrupts. Otherwise, an interrupt could effectively invalidate the refresh sequence, if the interrupt occurs before the refresh writes finish. After the sequence finishes, restore the global interrupt control state.

For the example code snippets, see Application Information.

37.3.2 Configuring the Watchdog

37.3.2.1 Configuring the Watchdog Once

All watchdog control bits, timeout value, and window value are write-once after reset. This means that after a write has occurred they cannot be changed unless a reset occurs. This is guaranteed by the user configuring the window and timeout value first, followed by the other control bits, and ensuring that CS[UPDATE] is also set to 0.

This provides a robust mechanism to configure the watchdog and ensure that a runaway condition cannot mistakenly disable or modify the watchdog configuration after configured.

The new configuration takes effect only after all registers except CNT are written after reset. Otherwise, the WDOG uses the reset values by default. If window mode is not used (CS[WIN] is 0), writing to WIN is not required to make the new configuration take effect.

37.3.2.2 Reconfiguring the Watchdog

In some cases (like when supporting a bootloader function), you may want to reconfigure or disable the watchdog, *without forcing a reset first*.

- By setting CS[UPDATE] to 1 on the initial configuration of the watchdog after a reset, you can reconfigure the watchdog at any time by executing an unlock sequence.
- Conversely, if CS[UPDATE] remains 0, the only way to reconfigure the watchdog is by initiating a reset.

The unlock sequence is similar to the refresh sequence but uses different values.

37.3.2.2.1 Unlocking the Watchdog

The unlock sequence is

- either two 16-bit writes (0xC520, 0xD928) or four 8-bit writes (0xC5, 0x20, 0xD9, 0x28) if WDOG_CS[CMD32EN] is 0;
- one 32-bit write (0xD928_C520) if WDOG_CS[CMD32EN] is 1.

to the CNT register at any time after the watchdog has been configured. Improper unlock sequence causes the WDOG to reset. On completing the unlock sequence, the user must reconfigure the watchdog within 128 bus clocks; otherwise, the watchdog closes the unlock window.

NOTE

Due to the 128 bus clocks requirement for reconfiguring the watchdog, some delays must be inserted before executing STOP or WAIT instructions after reconfiguring the watchdog. This ensures that the watchdog's new configuration takes effect before the MCU enters low power mode. Otherwise, the MCU may not be waken up from low power mode.

37.3.4 Fast testing of the watchdog

Before executing application code in safety critical applications, users are required to test that the watchdog works as expected and resets the MCU. Testing every bit of a 16-bit counter by letting it run to the overflow value takes a relatively long time (64 k clocks).

To help minimize the startup delay for application code after reset, the watchdog has a feature to test the watchdog more quickly by splitting the counter into its constituent byte-wide stages. The low and high bytes are run independently and tested for timeout against the corresponding byte of the timeout value register. (For complete coverage when testing the high byte of the counter,

the test feature feeds the input clock via the 8th bit of the low byte, thus ensuring that the overflow connection from the low byte to the high byte is tested.)

Using this test feature reduces the test time to 512 clocks (not including overhead, such as user configuration and reset vector fetches). To further speed testing, use a faster clock (such as the bus clock) for the counter reference.

On a power-on reset, the POR bit in the system reset register is set, indicating the user should perform the WDOG fast test.

37.3.4.1 Testing each byte of the counter

The test procedure follows these steps:

1. Program the preferred watchdog timeout value in the TOVAL register during the watchdog configuration time period.
2. Select a byte of the counter to test using the CS[TST] = 10b for the low byte; CS[TST] = 11b for the high byte.
3. Wait for the watchdog to timeout. Optionally, in the idle loop, increment RAM locations as a parallel software counter for later comparison. Because the RAM is not affected by a watchdog reset, the timeout period of the watchdog counter can be compared with the software counter to verify the timeout period has occurred as expected.
4. The watchdog counter times out and forces a reset.
5. Confirm the WDOG flag in the system reset register is set, indicating that the watchdog caused the reset. (The POR flag remains clear.)
6. Confirm that CS[TST] shows a test (10b or 11b) was performed.

If confirmed, the count and compare functions work for the selected byte. Repeat the procedure, selecting the other byte in step 2.

NOTE

CS[TST] is cleared by a POR only and not affected by other resets.

37.3.4.2 Entering user mode

After successfully testing the low and high bytes of the watchdog counter, the user can configure CS[TST] to 01b to indicate the watchdog is ready for use in application user mode. Thus if a reset occurs again, software can recognize the reset trigger as a real watchdog reset caused by runaway or faulty application code.

As an ongoing test when using the default clock source, software can periodically read the CNT register to ensure the counter is being incremented.

37.3.5 Clocking

The watchdog counter has the clock source options selected by programming CS[CLK]. See the "chip-specific information" section for available clock inputs and the default option for this device.

The options allow software to select a clock source independent of the bus clock for applications that need to meet more robust safety requirements. Using a clock source other than the bus clock ensures that the watchdog counter continues to run if the bus clock is somehow halted; see Backup reset.

NOTE

The *default* clock source of WDOG should be enabled after its functional reset is deasserted, for the WDOG module to function properly.

An optional fixed prescaler for all clock sources allows for longer timeout periods. When CS[PRES] is set, the clock source is prescaled by 256 before clocking the watchdog counter.

The following table summarizes the different watchdog timeout periods which could be available, as an example.

Table 233. Watchdog timeout availability

Reference clock	Prescaler	Watchdog time-out availability
REF_CLK	Pass through	1×RCP to 65535×RCP [1]
	Enable	256×RCP to 16776960×RCP

1. RCP means Reference Clock Period.

NOTE

When the programmer switches clock sources during reconfiguration, the watchdog hardware holds the counter at zero for 2.5 periods of the previous clock source and 2.5 periods of the new clock source after the configuration time period (128 bus clocks) ends. This delay ensures a smooth transition before restarting the counter with the new configuration.

37.3.6 Backup reset

The backup reset function is a safeguard feature that independently generates a reset in case the main WDOG logic loses its clock (the bus clock) and can no longer monitor the counter. If the watchdog counter overflows twice in succession (without an intervening reset), the backup reset function takes effect and generates a reset.

NOTE

A clock source other than the bus clock must be used as the reference clock for the counter; otherwise, the backup reset function is not available.

Backup reset becomes valid when interrupt is enabled and the watchdog clock is from non bus clock. If interrupt is enabled, once the bus clock is cut off before exiting interrupt routine, the normal watchdog reset will be blocked. Under this case, the second overflow will cause backup reset directly.

37.3.7 Reset and interrupts

An interrupt request can be generated to delay resets.

- **When interrupts are enabled (CS[INT] = 1):** After a reset-triggering event (like a counter timeout or invalid refresh attempt), the watchdog first generates an interrupt request. Next, the watchdog delays 128 bus clocks (from the interrupt vector fetch, not the reset-triggering event) before forcing a reset, to allow the interrupt service routine (ISR) to perform tasks (like analyzing the stack to debug code).
- **When interrupts are disabled (CS[INT] = 0):** the watchdog does not delay before forcing a reset.

37.4 External signals

This module has no external signals.

37.5 Initialization

See Configuring the Watchdog Once.

37.6 Application Information

To disable or reconfigure the watchdog, it should be completed before the first watchdog timeout. Disabling or reconfiguring the watchdog should occur at the very beginning of the software code, e.g. the beginning of the startup or main function.

NOTE

When the watchdog is configured by user, it needs at least 2.5 periods of watchdog clock to take effect. This means the interval between the two configurations by user must be larger than 2.5 clocks.

NOTE

When the chip starts up from BOOT ROM and then jumps to flash, the watchdog should be disabled at the beginning of bootloader and enabled after it exits. To reconfigure the watchdog using the flash program, it also needs the interval of at least 2.5 watchdog clocks after the bootloader exits.

To disable or reconfigure the watchdog without forcing a reset, WDOG_CS[UPDATE] bit must be set during the initial configuration of the WDOG module. The unlock sequence can then be used at any time within the timeout limit to reconfigure the watchdog.

Disable Watchdog

To disable the watchdog, first do the unlock sequence, then unset the WDOG_CS[EN] bit. The code snippet below shows an example for 32-bit write.

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
WDOG_CS &= ~WDOG_CS_EN_MASK; //disable watchdog
EnableInterrupts; //enable global interrupt
```

Disable Watchdog after Reset

All of the watchdog registers are unlocked by reset. Therefore, an unlock sequence is unnecessary but it needs to write all of watchdog registers to make the new configuration take effect. The code snippet below shows an example of disabling watchdog after reset.

```
DisableInterrupts; // disable global interrupt
WDOG_CS &= ~WDOG_CS_EN_MASK; // disable watchdog
WDOG_TOVAL= 0xFFFF;
while(WDOG_CS[ULK]);  // waiting for lock
while(~WDOG_CS[RCS]); // waiting for new configuration to take effect
EnableInterrupts; // enable global interrupt
```

Configure Watchdog

The watchdog can be configured once by setting the WDOG_CS[UPDATE]=0. After that, the watchdog cannot be reconfigured until a reset. To reconfigure without forcing a reset, set WDOG_CS[UPDATE]=1 when configuring the watchdog. The following example code shows how to configure the watchdog without window mode, clock source as LPO, interrupt enabled and timeout value to 256 clocks. The code snippet below shows an example for 32-bit write.

Configure once

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
while(WDOG_CS[ULK]==0);  //wait until registers are unlocked
WDOG_TOVAL = 256; //set timeout value
WDOG_CS = WDOG_CS_EN(1) | WDOG_CS_CLK(1) | WDOG_CS_INT(1) |
          WDOG_CS_WIN(0) | WDOG_CS_UPDATE(0);
while(WDOG_CS[RCS]==0); //wait until new configuration takes effect
EnableInterrupts; //enable global interrupt
```

Configure for reconfigurable

```
DisableInterrupts; //disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
while(WDOG_CS[ULK]==0);  //wait until registers are unlocked
WDOG_TOVAL = 256; //set timeout value
WDOG_CS = WDOG_CS_EN(1) | WDOG_CS_CLK(1) | WDOG_CS_INT(1) |
          WDOG_CS_WIN(0) | WDOG_CS_UPDATE(1);
```

```
while(WDOG_CS[RCS]==0); //wait until new configuration takes effect
EnableInterrupts; //enable global interrupt
```

Refreshing the Watchdog

To refresh the watchdog and reset the watchdog counter to zero, a refresh sequence is required. The code snippet below shows an example for 32-bit write.

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xB480A602; // refresh watchdog
EnableInterrupts; // enable global interrupt
```

37.7 Memory map and register definition

37.7.1 WDOG register descriptions

37.7.1.1 WDOG memory map

WDOG0 base address: 4001_A000h

WDOG1 base address: 4001_B000h

Ch	Window Register (WIN)	32	RW	0000_0000h

37.7.1.2 Control and Status Register (CS)

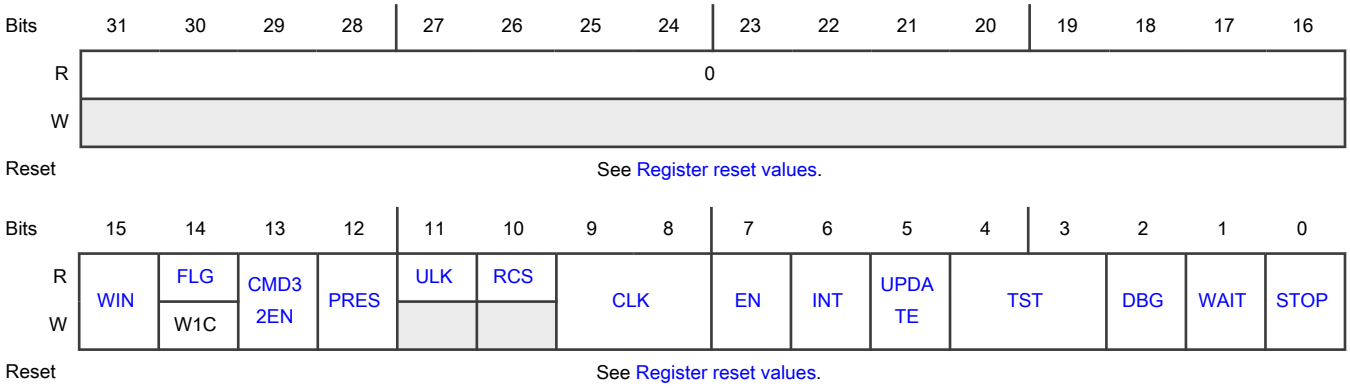
Offset

Register	Offset
CS	0h

Function

Implements control and indicates status of the module.

Diagram



Register reset values

Register	Reset value
CS	WDOG0: 0000_3A80h WDOG1: 0000_3A00h

Fields

Field	Function
31-16 —	Reserved
15 WIN	Watchdog Window This write-once bit enables window mode. See Window mode for details. 0b - Disables 1b - Enables
14 FLG	Watchdog Interrupt Flag This bit is an interrupt indicator when CS[INT] is set. Write 1 to clear it. 0b - No interrupt occurred. 1b - An interrupt occurred.
13 CMD32EN	Enables or disables WDOG support for 32-bit (otherwise 16-bit or 8-bit) refresh/unlock command write words This is write-once field, and the user needs to unlock WDOG after writing this field for reconfiguration. 0b - Disables support for 32-bit refresh/unlock command write words. Only 16-bit or 8-bit is supported. 1b - Enables support for 32-bit refresh/unlock command write words. 16-bit or 8-bit is NOT supported.

Table continues on the next page...

Table continued from the previous page...

Field	Function
12 PRES	Watchdog prescaler This write-once bit enables a fixed 256 pre-scaling of watchdog counter reference clock. (The block diagram shows this clock divider option.) 0b - 256 prescaler disabled. 1b - 256 prescaler enabled.
11 ULK	Unlock status Indicates whether WDOG is unlocked or not. 0b - Locked 1b - Unlocked
10 RCS	Reconfiguration Success Indicates whether the reconfiguration is successful or not. Default reset value is 0. This bit is set when new configuration takes effect, and is cleared by successful unlock command. 0b - Reconfiguring WDOG. 1b - Reconfiguration is successful.
9-8 CLK	Watchdog Clock This write-once field indicates the clock source that feeds the watchdog counter. See the "chip-specific information" section for clock source inputs.
7 EN	Watchdog Enable This write-once bit enables the watchdog counter to start counting. 0b - Watchdog disabled. 1b - Watchdog enabled.
6 INT	Watchdog Interrupt This write-once bit configures the watchdog to immediately generate an interrupt request upon a reset-triggering event (timeout or illegal write to the watchdog), before forcing a reset. After the interrupt vector fetch (which comes after the reset-triggering event), the reset occurs after a delay of 128 bus clocks. 0b - Watchdog interrupts are disabled. Watchdog resets are not delayed. 1b - Watchdog interrupts are enabled. Watchdog resets are delayed by 128 bus clocks from the interrupt vector fetch.
5 UPDATE	Allow updates This write-once bit allows software to reconfigure the watchdog without a reset. 0b - Updates not allowed. After the initial configuration, the watchdog cannot be later modified without forcing a reset. 1b - Updates allowed. Software can modify the watchdog configuration registers within 128 bus clocks after performing the unlock write sequence.

Table continues on the next page...

Table continued from the previous page...

Field	Function
4-3 TST	Watchdog Test Enables the fast test mode. The test mode allows software to exercise all bits of the counter to demonstrate that the watchdog is functioning properly. See Fast testing of the watchdog. **NOTE** This write-once field is cleared (0:0) on POR only. Any other reset does not affect the value of this field. 00b - Watchdog test mode disabled. 01b - Watchdog user mode enabled (test mode disabled). After testing the watchdog, software should use this setting to indicate the watchdog is functioning normally in user mode. 10b - Watchdog test mode enabled, only the low byte is used. CNT[CNTLOW] is compared with TOVAL[TOVALLOW]. 11b - Watchdog test mode enabled, only the high byte is used. CNT[CNTHIGH] is compared with TOVAL[TOVALHIGH].
2 DBG	Debug Enable This write-once bit enables the watchdog to operate when the chip is in debug mode. 0b - Disables 1b - Enables
1 WAIT	Wait Enable This write-once bit enables the watchdog to operate when the chip is in wait mode. 0b - Disables 1b - Enables
0 STOP	Stop Enable This write-once bit enables the watchdog to operate when the chip is in stop mode. 0b - Disables 1b - Enables

37.7.1.3 Counter Register (CNT)

Offset

Register	Offset
CNT	4h

Function

Provides access to the value of the free-running watchdog counter. Software can read the counter register at any time.

Software cannot write directly to the watchdog counter; however, two write sequences to the register have special functions:

1. The *refresh sequence* resets the watchdog counter to 0x0000. See the "Refreshing the Watchdog" section in Application Information.
2. The *unlock sequence* allows the watchdog to be reconfigured without forcing a reset (when CS[UPDATE] = 1). See the "Configure for reconfigurable" section in Application Information.

NOTE

All other writes to this register are illegal and force a reset.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

37.7.1.4 Timeout Value Register (TOVAL)

Offset

Register	Offset
TOVAL	8h

Function

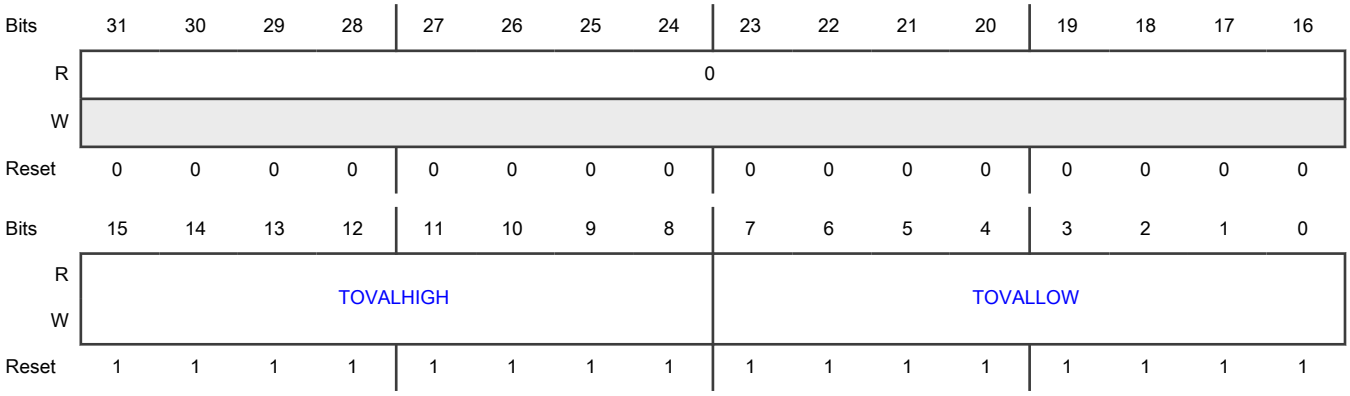
Contains the 16-bit value used to set the timeout period of the watchdog.

The watchdog counter (CNT) is continuously compared with the timeout value (TOVAL). If the counter reaches the timeout value, the watchdog forces a reset triggering event.

NOTE

Do not write 0 to the TOVAL register (if CS[TST]=11b, then TOVALHIGH cannot be written as 0; if CS[TST]=10b, then TOVALLOW cannot be 0); otherwise, the watchdog always generates a reset.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 TOVALHIGH	High byte of the timeout value
7-0 TOVALLOW	Low byte of the timeout value

37.7.1.5 Window Register (WIN)

Offset

Register	Offset
WIN	Ch

Function

When the window mode is enabled (CS[WIN] is set), this WIN register determines the earliest time that a refresh sequence is considered valid. See Watchdog refresh mechanism.

NOTE

The WIN register value must be less than the TOVAL register value.

Chapter 38
EdgeLock Secure Enclave (ELE)

38.1 Introduction

While the emerging application space known as the Internet of Things (IoT) provides an incredible market and business opportunity, it also brings a variety of technical challenges for the microcontrollers located as edge nodes in massively-connected networks. Clearly, one of the most important technical issues remains the definition of an appropriate level of device security for the MCU devices - an application area where simple hardware acceleration of cryptographic functions is no longer an acceptable solution.

Indeed, the IoT market represents a perfect storm where the combined legacy security models for static microcontroller configurations and networked devices are no longer appropriate; instead a new paradigm for MCU security is emerging and NXP is using its industry-leading position as the preeminent supplier of secure solutions to lead the way. An EdgeLock secure enclave, or simply EdgeLock enclave (ELE) has been defined and implemented that significantly raises the level of security provided by a traditional connected MCU device.

The EdgeLock secure enclave is an independent black box processing element providing essential cryptographic services to the host system within a single microcontroller specifically in two areas: secret key storage and management, plus execution of symmetric and public key cryptographic services, including secure hashing, based on requests from the host. By design, it is intended to provide a secure environment within an otherwise non-secure device in which applications can execute secure cryptographic services.

38.1.1 Block Diagram

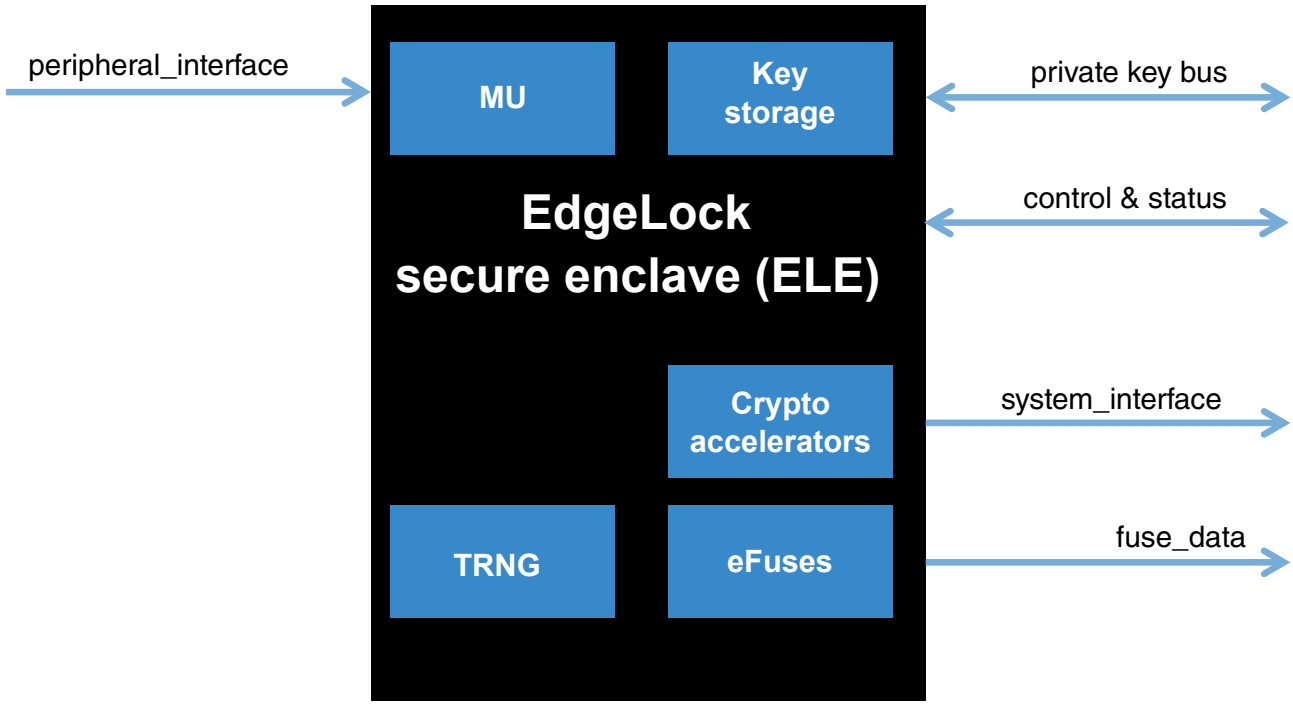

Figure 96. Block Diagram

From EdgeLock's perspective, there are two major interfaces:

```
   peripheral_interface              // host-to-peripheral interface (APB) to access the
messaging unit
```

```
    system_interface             // ELE-to-system interface (AHB) to access host memories
```

Additionally, there are three “minor” interfaces:

```
  control & status        // miscellaneous i/o connections for control & status
  private_key_bus         // secure output bus to distribute keys to host IP modules
  fuse_data               // output bus to distribute fuse values to host
```

38.1.2 Features

The key EdgeLock enclave architecture features include an independent processing element with optimized crypto IP for acceleration focused on two security functions:

1. Secret key generation, storage and management
   - Hardware key derivation from non-volatile memory within the SoC
   - Implements bus and memory obfuscation for cryptographic protection
2. Secure crypto services during secure boot and normal runtime
   - Simple peripheral interface with the host processor to minimize attack surface
     - Host application makes function calls to EdgeLock enclave via a messaging unit
     - Mailbox messages used to pass crypto services commands, pointers and data
     - EdgeLock enclave implements a run to completion execution model for crypto tasks
   - EdgeLock enclave has access to host's internal and external memories via a system interface
   - Operations and services controlled by CryptoLib software

38.1.2.1 Symmetric algorithms

“Symmetric-key cryptography refers to encryption methods in which both the sender and receiver share the same key (or, less commonly, in which their keys are different, but related in an easily computable way). This was the only kind of encryption publicly known until June 1976.

Symmetric key ciphers are implemented as either block ciphers or stream ciphers. A block cipher enciphers input in blocks of plaintext as opposed to individual characters, the input form used by a stream cipher.”[1]

[1] Taken from *https://en.wikipedia.org/wiki/Cryptography*

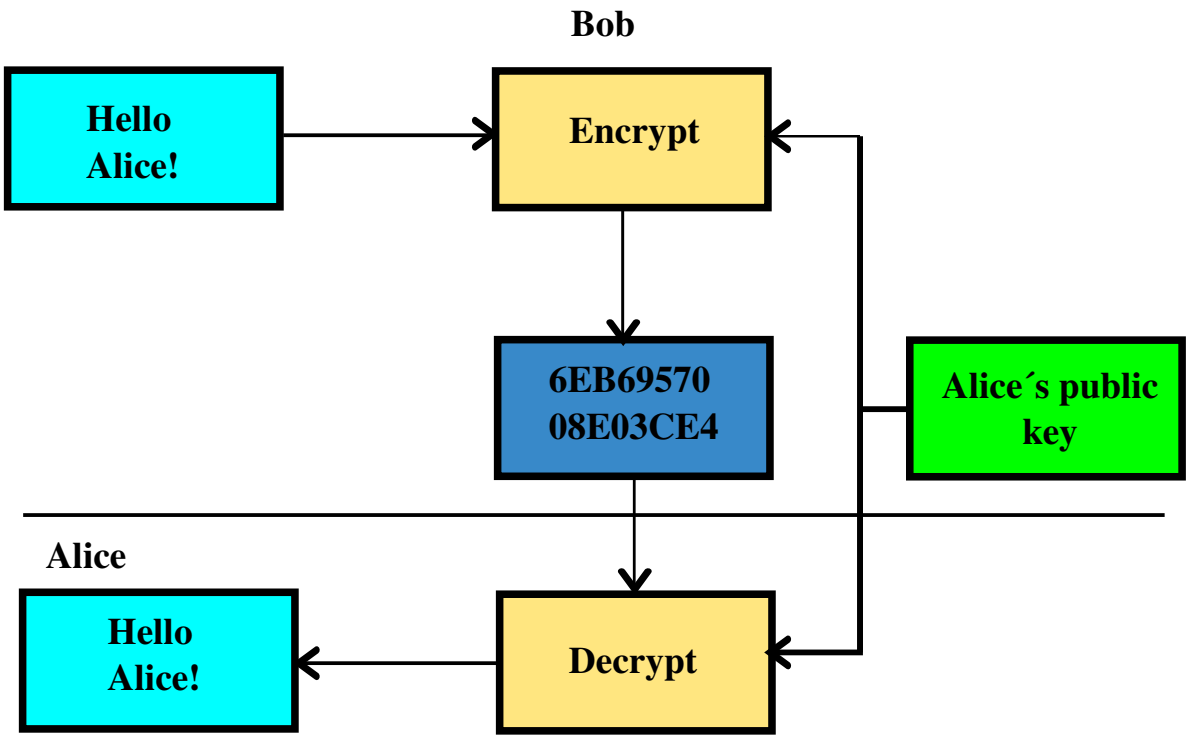

Figure 97. Symmetric-key cryptography, where a single key is used for encryption and decryption [1]

Advanced Encryption Standard (AES) - The AES algorithm is a symmetric block cipher. The algorithm processes 128-bit data blocks using the cipher key. The cipher key can be 128-, 192-, or 256-bits in length. These different versions of the AES algorithm are known as AES-128, AES-192, and AES-256. The amount of processing performed by the AES algorithm is determined by the length of the cipher key and affects the number of rounds used in the calculations.

The AES algorithm was standardized by the U.S. National Institute of Standards and Technology (NIST) in 2001. For more information on the details of the AES algorithm, please refer to Federal Information Processing Standard Publication 197 (FIPS 197) that can be downloaded from the NIST website at https://www.nist.gov.

EdgeLock enclave natively supports the following AES algorithms along with a variety of block cipher modes:

- Advanced Encryption Standard 128 (AES-128)
- Advanced Encryption Standard 192 (AES-192)
- Advanced Encryption Standard 256 (AES-256)

38.1.2.2 Asymmetric algorithms

“Symmetric-key cryptosystems use the same key for encryption and decryption of a message, although a message or group of messages can have a different key than others. A significant disadvantage of symmetric ciphers is the key management necessary to use them securely. Each distinct pair of communicating parties must, ideally, share a different key, and perhaps for each ciphertext exchanged as well. The number of keys required increases as the square of the number of network members, which very quickly requires complex key management schemes to keep them all consistent and secret.

A public key system is so constructed that calculation of one key (the 'private key') is computationally infeasible from the other (the 'public key'), even though they are necessarily related. Instead, both keys are generated secretly, as an interrelated pair. The historian David Kahn described public-key cryptography as "the most revolutionary new concept in the field since polyalphabetic substitution emerged in the Renaissance".

In public-key cryptosystems, the public key may be freely distributed, while its paired private key must remain secret. In a public-key encryption system, the public key is used for encryption, while the private or secret key is used for decryption. While Diffie and Hellman could not find such a system, they showed that public-key cryptography was indeed possible by presenting the Diffie–Hellman key exchange protocol, a solution that is now widely used in secure communications to allow two parties to secretly agree on a shared encryption key."[1]

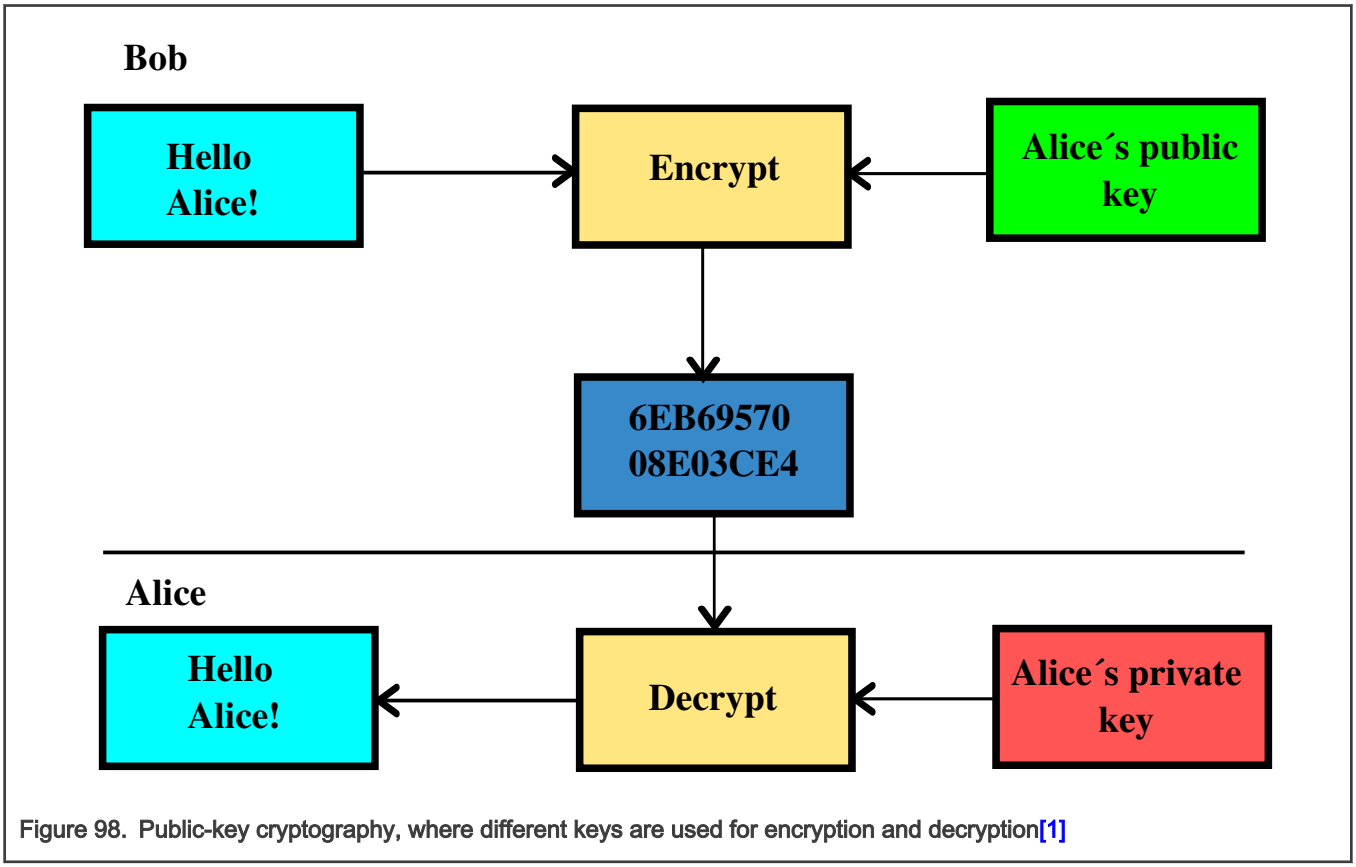

Figure 98. Public-key cryptography, where different keys are used for encryption and decryption[1]

Elliptic-Curve Cryptography (ECC) - The ECC algorithms are based on algebraic operations on elliptic curves over finite fields. The algorithms can be used for digital signatures, key agreement, plus encryption and can operate over prime fields or binary fields with varying cipher key lengths.

The ECC curves were originally standardized by the U.S. National Institute of Standards and Technology (NIST) in 2000. For more information on the details of the ECC curves, please refer to Federal Information Processing Standard Publication 186-4 (FIPS 186-4) that can be downloaded from the NIST website at https://www.nist.gov.

EdgeLock enclave natively support the following ECC curves:

- Elliptic Prime Curves (P-192, P-224, P-256, P-384, P-521)
- Elliptic Prime Curve 25519

38.1.2.3 Hash functions

"Cryptographic hash functions are a third type of cryptographic algorithm. They take a message of any length as input, and output a short, fixed length hash, which can be used in (for example) a digital signature. For good hash functions, an attacker cannot find two messages that produce the same hash.

Unlike block and stream ciphers that are invertible, cryptographic hash functions produce a hashed output that cannot be used to retrieve the original input data. Cryptographic hash functions are used to verify the authenticity of data retrieved from an untrusted source or to add a layer of security.

Message authentication codes (MACs) are much like cryptographic hash functions, except that a secret key can be used to authenticate the hash value upon receipt; this additional complication blocks an attack scheme against bare digest algorithms, and so has been thought worth the effort."[1]

Secure Hash Algorithm 2 (SHA-2) - The SHA-2 algorithms are cryptographic hash functions. The algorithms process the input information and generate a hash value. This hash value is known as a message digest. The hash value can be 224-, 256-, 384-, or 512-bits in length. These hashes are known as SHA-224, SHA-256, SHA-384, and SHA-512. The message digest can be used to verify the integrity of a set of information.

The SHA-2 algorithms were standardized by the U.S. National Institute of Standards and Technology (NIST) in 2001.

For more information on the details of the SHA-2 algorithms, please refer to Federal Information Processing Standard Publication 180-4 (FIPS 180-4) that can be downloaded from the NIST website at https://www.nist.gov.

EdgeLock enclave hardware supports:

- Secure Hash Algorithm 256 (SHA-256)

38.1.2.4 Nonce

A nonce is a random or pseudo-random number that is used only once in a cryptographic calculation. Nonces are important for initialization vectors and cryptographic hash functions.

EdgeLock Enclave natively supports:

- A True Random Number Generator (TRNG) which is a source of entropy that can be used to generate random numbers for use in cryptographic algorithms.

38.2 Messaging Unit (ELE_MU)

38.2.1 Overview

The Messaging Unit module enables two processing elements within the SoC to communicate and coordinate by passing messages (e.g., data, status and control) through its interfaces. The EdgeLock Enclave Messaging Unit (ELE_MU) is specifically targeted for use in Edgelock enclave. The ELE_MU also provides the ability for one processing element to signal the other processing element using interrupts based on data transmission status.

This module's design is based on synchronous clock domain crossings, that is, each side of the ELE_MU operates in a phase-aligned clock domain. The two clock domains may be operating at integer multipliers or dividers, but they are phase aligned so there is no need for logic to handle asynchronous clock domain crossings. The ELE_MU accomplishes synchronization using two sets of matching registers (Processor A-facing, Processor B-facing).

In the Edgelock enclave application, the ELE_MU "A-side" port corresponds to the SoC host processor while the ELE_MU "B-side" port is the security subsystem.

Throughout this chapter, "ELE_MUA" is used to denote hardware resources associated with the "A-side" port, and "ELE_MUB" denotes those associated with the "B-side" port. This manual only documents the MU "A-side" programming model as it is visible and accessible to the host processor, while the MU "B-side" programming model is restricted to the internal operation of the EdgeLock enclave and not visible nor accessible to the host processor.

Finally, the ELE_MUA port implements a secure semaphore (SEMA4) function to provide hardware enforcement of the Edgelock enclave serialization mechanism in multi-core/multi-host device configurations.

38.2.1.1 Block Diagram

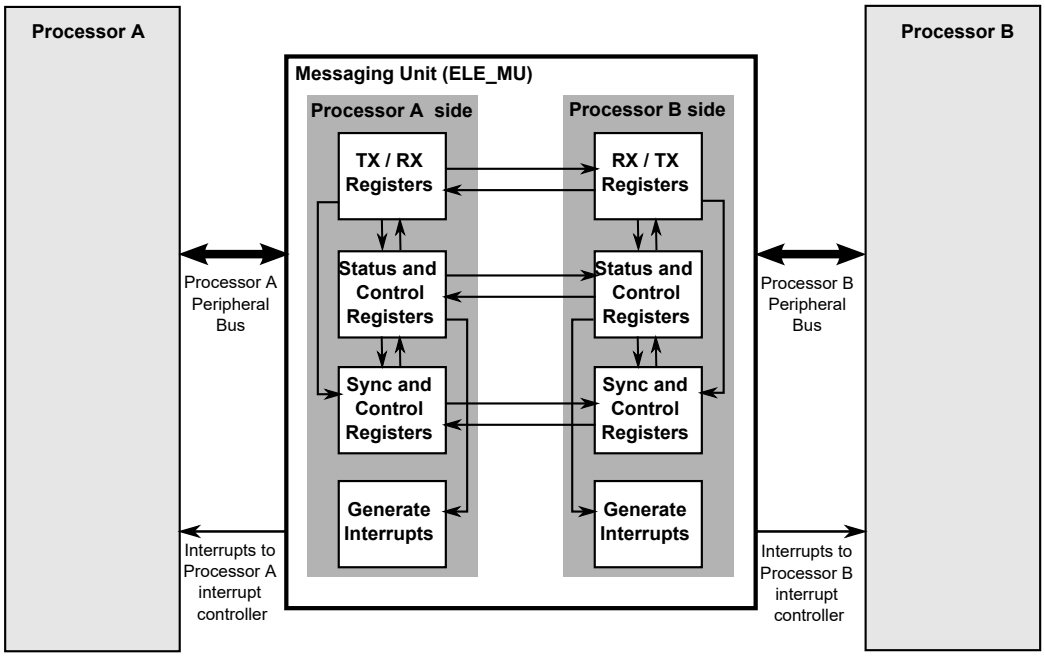

Figure 99. ELE_MU Block Diagram

38.2.1.2 Features

The ELE_MU includes the following features:

1. Memory-Mapped Registers
   - The ELE_MU is connected with separate peripheral buses on Processor A-side and Processor B-side.
2. Synchronous Message Transfers between Processing Elements
   - For sending data or messages between the processing elements, ELE_MUA provides 16 transmit registers and 2 receive registers, while ELE_MUB provides 2 transmit registers and 16 receive registers.
   - The transfer of data messages between processing elements uses transmit empty and receive full flags provided on both sides of the ELE_MU.
   - The update of these transmit and receive flags is accomplished using a fully synchronous mechanism. Upon a register read or write, the corresponding transmit or receive flags are updated at the completion of the register access cycle.
3. Secure Semaphore
   - The ELE_MUA port implements a semaphore function to support hardware enforcement of Edgelock enclave (ELE) serialization mechanisms in certain device configurations. This logic also provides read-only information on the ELE status.

38.2.2 Functional Description

The Messaging Unit (ELE_MU) enables two processing elements (Processor A and Processor B) to communicate with each other, by passing message/data information to each other, and by enabling one side to wake up the other side using data transmission interrupts.

The messaging, control, and status registers of the Processor A and Processor B sides for the ELE_MU are mapped to the processing element A and processing element B address spaces using a standard peripheral bridge memory slot. The peripheral data bus is 32 bits wide inside the ELE_MU module.

Most of the messaging mechanisms are symmetric. They are duplicated and are available on both the A-side and the B-side. The messaging mechanisms are:

- Sixteen 32-bit ELE_MUA transmit registers, which are each reflected in sixteen read-only ELE_MUB receive registers. These registers can be used to transfer 32-bit word messages or pass information for messages written to the shared memory (number of words, address pointers, and message type code).
- Two 32-bit ELE_MUB transmit registers, which are each reflected in two read-only ELE_MUA receive registers. These registers can be used to transfer 32-bit word messages or pass information for messages written to the shared memory (number of words, address pointers, and message type code).
- A write to a transmit register clears the corresponding “transmitter empty” bit in the Status Register on the transmitter side, and sets the appropriate “receiver full” bit in the Status Register on the receiver side. The setting of the bit at the receiver side can optionally trigger an interrupt at the receiver side (maskable receive interrupt).
- A read of one of the receive registers clears the corresponding “receiver full” bit in the Status Register at the receiver side, and sets the appropriate “transmitter empty” bit in the Status Register on the transmitter side. The setting of the “transmitter empty” bit can optionally trigger an interrupt at the transmitter side (maskable transmit interrupt).

A write to a transmit register signals the receiver side that data is ready for retrieval.

- Writing to the transmit register again without verifying that the data was retrieved is prohibited, because the transmitter side has no way of knowing the exact time that the receiver retrieves the data.
- Before attempting to write the transmit register again, the transmitter side waits for a “Transmitter Empty” interrupt, or polls the “Transmitter Empty” bit in the Transmit Status Register.

A read of a receive register signals the transmitter side that new data can be written to that register. In the same way, the receiver processor should not read a receive register before receiving a “Receiver Full” interrupt or polling the “Receiver Full” bit in the Receive Status Register.

- Reading the receive register again without verifying that the data was written is prohibited, because the receiver side has no way of knowing the exact time that the transmitter writes the data.
- Before attempting to read the receive register again, the receiver side waits for a “Receiver Full” interrupt, or polls the “Receiver Full” bit in the Receive Status Register.

38.2.2.1 Hardware Semaphore

The ELE_MU includes the following features:

To provide a mechanism to serialize ownership of the Edgelock enclave subsystem, ELE_MUA implements a hardware semaphore (SEMA4) register. Typically, and especially in multi-core host configurations, when a task wants to send crypto service requests to Edgelock enclave, it first establishes ownership of the subsystem by acquiring the semaphore. After the crypto task requests are completed, the host task relinquishes ownership of the semaphore, making the hardware available to other tasks.

Once the semaphore is acquired (locked), only writes to the ELE_MUA TR[0-14] registers from the semaphore owner are allowed; all other attempted writes are error terminated.

In addition to the physical 32-bit SEMA4 register, the ELE_MUA logic supports five read-only 32-bit virtual register programming model. The registers include a Edgelock enclave status register, the secure semaphore owner identity, operations to acquire and release the semaphore, plus a mechanism to force the release of the semaphore.

The physical register information includes the locked/unlocked semaphore state plus the domain identifier and the secure/nonsecure, privileged/user access mode attributes of the locking task.

Accesses to the five virtual registers can be classified into two groups:

1. Two simple register reads that return status (SEMA4_SR) and the secure 32-bit semaphore owner value (OWNR).

2. Three (atomic) compound W/R operations (ACQ, REL, FREL) that potentially update the semaphore state and then return the new secure owner value.

The three compound virtual register operations first perform a “write” and then return the standard 32-bit semaphore owner value. The owner value returns one of three possible values: 0x0000_0000 if the semaphore is unlocked, 0x0000_0055 if the semaphore is owned by the requesting host task (based on domain identifier and the 2-bit {secure/nonsecure, privileged/user} access mode attributes) and 0xFFFF_FFAA is the semaphore is locked but not by the requesting host task.

For the compound W/R operations, the (virtual) register IPS address encodes the write operation to be performed in the address. The actual bus transaction from the initiating host task is always a simple 32-bit data read.

38.2.3 Register Definition

The ELE_MU provides transmit and receive data registers for the communication between Processor A and Processor B. Some control and status registers to the Processor A and Processor B sides are for control operations (such as interrupts), and for status checking of the other ELE_MU-side. The following diagram shows the ELE_MU registers schematic.

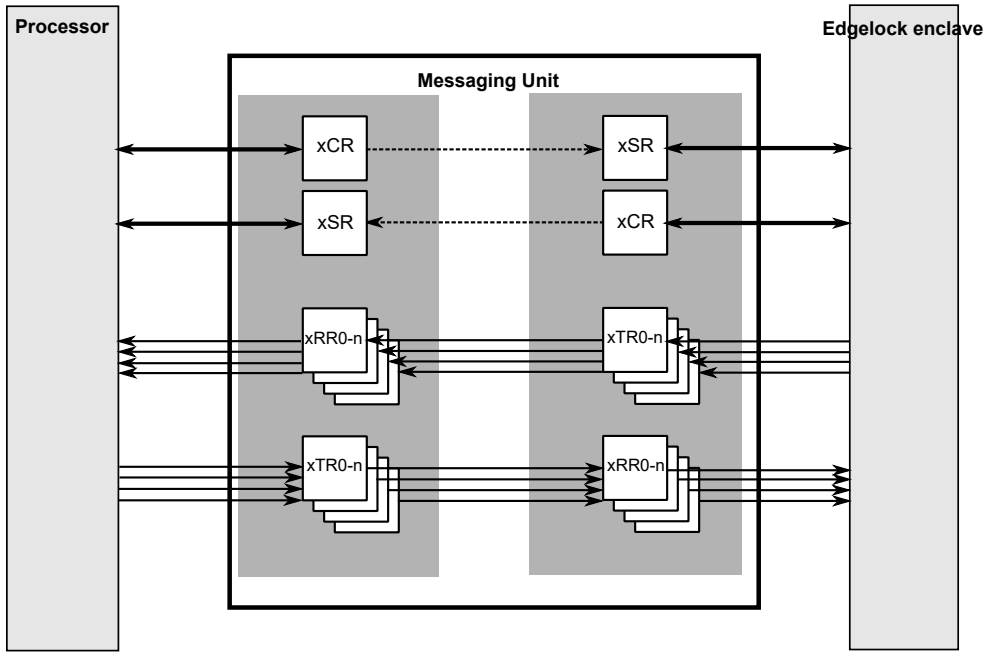

Figure 100. ELE_MU Registers

The detailed ELE_MU register definition can be found below.

NOTE

Read of a write-only, read zero (WORZ) register returns 0. Writes to a read-only (RO) register are ignored. Byte/halfword accesses are supported.

A read/write access to any illegal location of the ELE_MU generates a bus transfer error acknowledge to the Processor A or Processor B. Writes to "RSVD" registers are ignored and reads to "RSVD" registers return 0.

38.2.3.1 ELE_MUA register descriptions

This section contains the detailed register descriptions for the ELE_MUA registers.

38.2.3.1.1 ELE_MUA memory map

ELEMU.ELE_MUA base address: 4002_4000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Version ID Register (VER)	32	R	0100_0000h

38.3 Software Architecture and API Examples

The software abstractions of EdgeLock enclave services are defined and used in the form of a standard set of application-callable API functions. In the context of the software application programming interfaces (APIs), the EdgeLock enclave Security SubSystem is simply referenced as the SSS. Accordingly, the software interface detailed here is called the SSS API.

As the SSS is not customer programmable, to use the SSS-provided services, the user programmable host core must initialize, and access said services by interacting with the SSS through a specified interface. This interface is exposed as a low-level

Application Programming Interface that operates with the SSS Messaging Unit (ELE_MU). Serialization of the SSS API is also defined as the Security Subsystem Communication Protocol (SSCP).

Selected requirements for the SSS API include:

- Stateful function context is kept on the host side and is transferred to/from subsystem for stateful operation
- Session context to establish a virtual connection between an application/user context and specific security subsystem and functions
- Key store (secure storage of persistent and transient keys and other attributes)
- Key management (key revocations, key usage constraints)
- Crypto operations (symmetric cipher, authenticated encryption with additional data, message digest, message authentication code, asymmetric crypto, key derivation)
- Integrated with mbedTLS in MCUXpresso SDK

The SSS API is intended to easily integrate with generic software crypto libraries. As an out of box example, the MCUXpresso SDK delivers a version of Arm mbedTLS library integrated with the SSS API, thus enabling the EdgeLock enclave in applications with TLS/DTLS protocol.

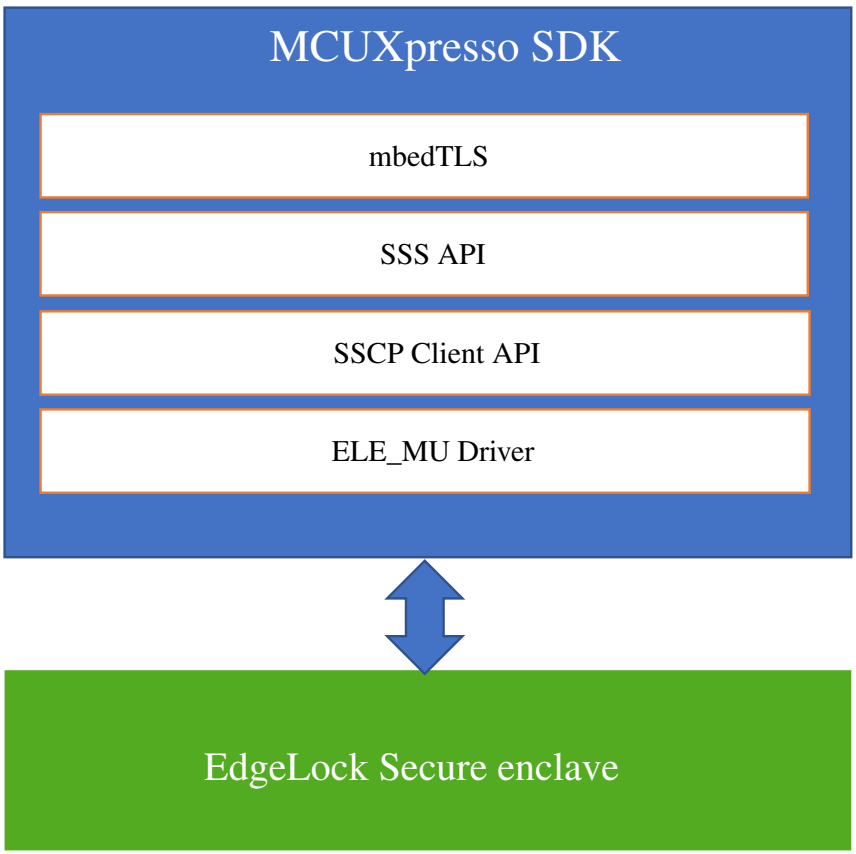

Figure 101. Host SW Security Stack

38.3.1 AES128-ECB encryption examples

In this example, consider the operation of performing a 128-bit AES encryption on a single 16-byte block of data using ECB (Electronic Code Book) mode, the simplest symmetric key mode of operation.

At https://tls.mbed.org/api/aes_8h.html, the Arm mbed site, the following API is defined:

```
int mbedtls_aes_crypt_ecb
(
 mbedtls_aes_context  *ctx,
 int                  mode,
 const unsigned char  input[16],
 unsigned char        output[16]
)
```

This function performs an AES single-block encryption or decryption operation.

It performs the operation defined in the mode parameter (encrypt or decrypt) on the input data buffer defined in the input [*] pointer.

mbedtls_aes_init(), and either mbedtls_aes_setkey_enc() or mbedtls_aes_setkey_dec() must be called before the first call to this API with the same context.

Table 234. mbedtls_aes_crypt_ecb parameters

Parameters	Description
ctx	AES context to use for encryption and decryption It must be initialized and bound to a key
mode	AES operation: MBEDTLS_AES_ENCRYPT (1), MBEDTLS_AES_DECRYPT (0)
input	Buffer holding the input data It must be readable and at least 16 bytes long
output	Buffer where the output data will be written Must be writeable and at least 16 bytes long
ReturnValues	
0	Operation completed successfully

```
sss_status_t sss_cipher_one_go
           (
             sss_symmetric_t *context,
             uint8_t         *iv,
             size_t          ivLen,
             const uint8_t   *srcData,
             uint8_t         *destData,
             size_t          dataLen
           )
```

This function performs an assortment of symmetric key calculations including an AES single-block encryption or decryption operation. Since this function supports a superset of the required AES_ECB computation, some of the input parameters are unused in this instance.

Table 235. status_t sss_cipher_one_go parameters

Parameters	Description
context	Pointer to the symmetric crypto context

Table continues on the next page...

Table 235. status_t sss_cipher_one_go parameters (continued)

Parameters	Description
	Must be initialized and bound to a key
iv	Pointer to the symmetric operation Initialization Vector Unused for AES_ECB
ivLen	Length of the Initialization Vector [bytes] Unused for AES_ECB
srcData	Pointer to buffer containing the input data Must be readable and at least 16 bytes long
destData	Pointer to buffer containing the output data Must be writeable and at least 16 bytes long
dataLen	Size of the input and output data buffer [bytes]
ReturnValues	
kStatus_SSS_Success	Operation completed successfully (0)
kStatus_SSS_Fail	Operation failed (!0)

The ELE_MU driver running on the host processor executes a series of register writes to the ELE_MUA_TRn registers to transmit the service request's parameters to the EdgeLock enclave. When the EdgeLock enclave execution is complete, the ELE_MUB_TRn registers are written with status information which is retrieved by the host processor by reading the ELE_MUA_RRn registers.

The mbedTLS arguments and the SSS API are designed to very efficiently connect with the EdgeLock enclave's ELE_MU hardware interface to maximize performance of the crypto service request's initiation and termination response.

38.3.2 AES128-CBC encryption/decryption example

This is an example of a more complex block cipher mode, consider the mbedTLS and SSS APIs for an AES-CBC (Cipher Block Chaining) service request:

```
int mbedtls_aes_crypt_cbc
                    (
                     mbedtls_aes_context  *ctx,
                     int                  mode,
                     size_t               length,
                     unsigned char        iv[16],
                     const unsigned char  input[16],
                     unsigned char        output[16]
                    )
```

This function performs an AES-CBC encryption or decryption operation on full blocks.

It performs the operation defined in the mode parameter (encrypt or decrypt) on the input data buffer defined in the input parameter.

It can be called as many times as needed, until all the input data is processed. mbedtls_aes_init(), and either mbedtls_aes_setkey_enc() or mbedtls_aes_setkey_dec() must be called before the first call to this API with the same context.

NOTE

This function operates on full blocks, that is, the input size must be a multiple of the AES block size of 16 bytes.

Upon exit, the content of the IV is updated so that you can call the same function again on the next block(s) of data and get the same result as if it was encrypted in one call. This allows a "streaming" usage, that is, the cipher block chaining supports the hardware's ability to continue to add new data blocks into the crypto calculation as the new data becomes available.. If you need to retain the contents of the IV, you should either save it manually or use the cipher module instead.

Table 236. mbedtls_aes_crypt_cbc parameters

Parameters	Description
ctx	AES context to use for encryption and decryption It must be initialized and bound to a key
mode	AES operation: MBEDTLS_AES_ENCRYPT (1) or MBEDTLS_AES_DECRYPT (0)
length	The length of the input data in bytes. This must be a multiple of the block size (16 bytes).
iv	Initialization vector (updated after use). It must be a readable and writeable buffer of 16 bytes.
input	Buffer holding the input data It must be readable and of size of length bytes.
output	Buffer where the output data will be written It must be writeable and of size length bytes.
Return Values	
0	Operation completed successfully
!0	MBEDTLS_ERR_AES_INVALID_INPUT_LENGTH on failure

The SSS API is the same one previously used in the AES_ECB function call.

```
sss_status_t sss_cipher_one_go
                    (
                      sss_symmetric_t *context,
                      uint8_t         *iv,
                      size_t          ivLen,
                      const uint8_t   *srcData,
                      uint8_t         *destData,
                      size_t          dataLen
                     )
```

For this function, all the input parameters are used (unlike the simpler AES_ECB call).

To summarize, the combination of the ELE_MU hardware module plus the security software stack defining the interface from the mbedTLS APIs through the SSS API and eventually the EdgeLock enclave software provides an efficient, secure mechanism to process host crypto service requests.

Chapter 39
Cyclic Redundancy Check (CRC)

39.1.1 Module instances

This device has one instance of the CRC module, CRC0.

39.2 Overview

CRC generates 16-bit and 32-bit CRC codes for error detection. You calculate these codes for 32 bits of data at a time.

This module provides a programmable polynomial and other parameters that you require to implement the 16-bit and 32-bit CRC standards.

39.2.1 Block diagram

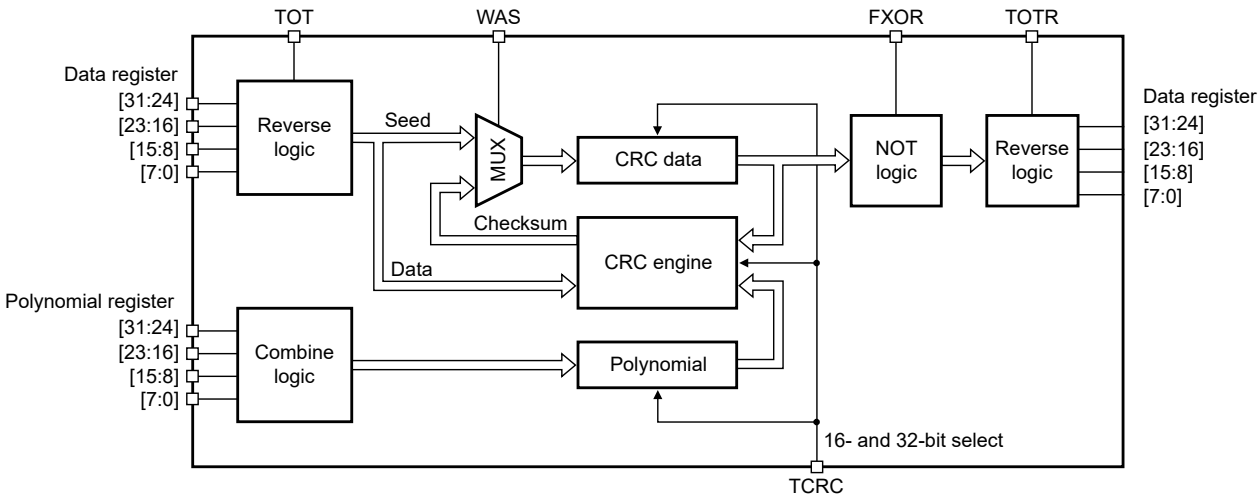

Figure 102. Block diagram

39.2.2 Features

- Hardware CRC generator circuit using 16-bit and 32-bit programmable shift registers.
- Programmable initial seed value and polynomial.

- Option to transpose input or output data (the CRC result) bitwise or bytewise: this option is required for certain CRC standards. You cannot perform a bytewise transpose operation when accessing CRC Data (DATA) via 8-bit accesses. You can only perform the bytewise transpose function.
- Option to invert the final CRC result.
- 32-bit CPU register programming interface.

39.3 Memory map and register descriptions

NOTE

Write accesses to the register addresses that are not mapped to the peripheral but included in the address space of the peripheral may result in unpredictable functionality. You must reconfigure CRC in case a transfer error occurs.

39.3.1 CRC register descriptions

39.3.1.1 CRC memory map

CRC0 base address: 4002_3000h

Offset	Register	Width (In bits)	Access	Reset value
0h	CRC Data (DATA)	32	RW	FFFF_FFFFh
4h	CRC Polynomial (GPOLY)	32	RW	0000_1021h
8h	CRC Control (CTRL)	32	RW	0000_0000h

39.3.1.2 CRC Data (DATA)

Offset

Register	Offset
DATA	0h

Function

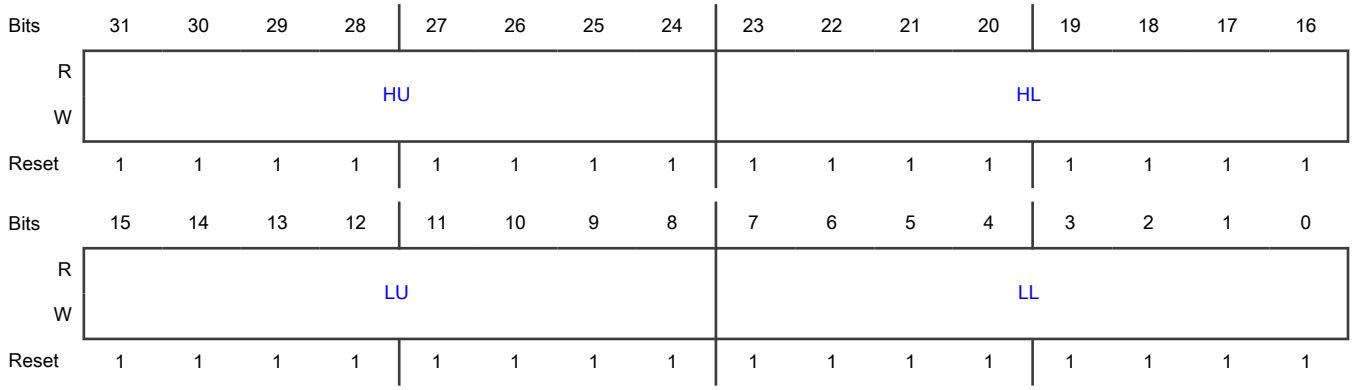
Contains the value of the seed, data, and checksum. When CTRL[WAS] = 1 , any write to this register is regarded as the seed value. When CTRL[WAS] becomes 0, any write to this register is regarded as data for general CRC computation.

In 16-bit CRC mode, the DATA[HU] and DATA[HL] are not used for programming the seed value, and reads of these fields return an indeterminate value. In 32-bit CRC mode, all fields are used for programming the seed value.

When programming data values, you can write 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous; with the MSB of data value written first.

After writing all data values, you can read the CRC result from this register. In 16-bit CRC mode, the CRC result is available in DATA[LU] and DATA[LL]. In 32-bit CRC mode, all fields contain the result. Reads of this register, at any time, return the intermediate CRC value, if the CRC module is configured.

Diagram



Fields

Field	Function
31-24 HU	CRC High Upper Byte Generates CRC checksum in both 16-bit and 32-bit CRC modes if CTRL[WAS] = 0. • In 16-bit CRC mode (CTRL[TCRC] = 0), this field is not used for programming a seed value. • In 32-bit CRC mode (CTRL[TCRC] = 1), values written to this field are part of the seed value when CTRL[WAS] = 1.
23-16 HL	CRC High Lower Byte Generates CRC checksum in both 16-bit and 32-bit CRC modes if CTRL[WAS] = 0. • In 16-bit CRC mode (CTRL[TCRC] = 0), this field is not used for programming a seed value. • In 32-bit CRC mode (CTRL[TCRC] = 1), values written to this field are part of the seed value when CTRL[WAS] = 1.
15-8 LU	CRC Low Upper Byte Generates CRC checksum when CTRL[WAS] = 0. When CTRL[WAS] = 1, values written to this field are part of the seed value.
7-0 LL	CRC Low Lower Byte Generates CRC checksum when CTRL[WAS] = 0 . When CTRL[WAS] = 1 , values written to this field are part of the seed value.

39.3.1.3 CRC Polynomial (GPOLY)

Offset

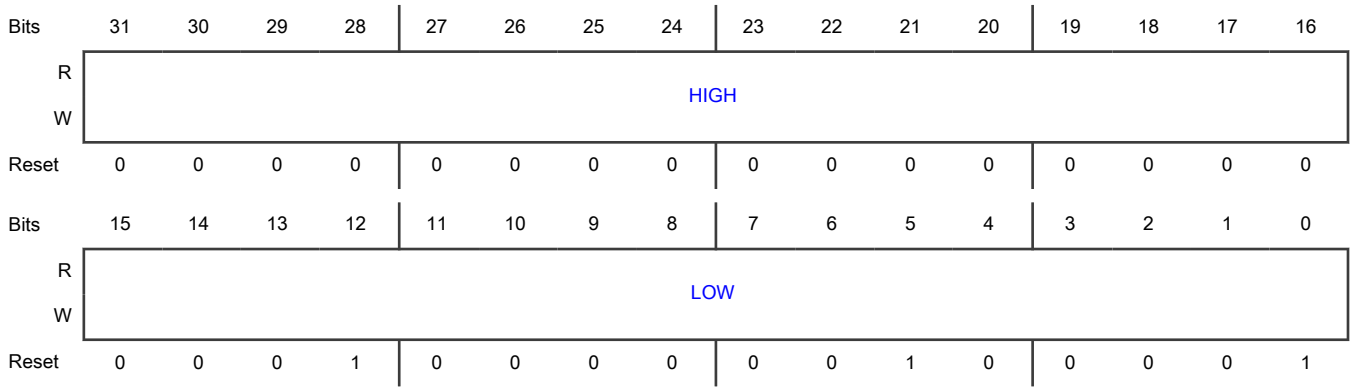
Register	Offset
GPOLY	4h

Function

Contains the value of the polynomial for CRC calculation.

- GPOLY[HIGH] contains the upper 16 bits of the CRC polynomial that are used only in 32-bit CRC mode. Writes to this field are ignored in 16-bit CRC mode.
- GPOLY[LOW] contains the lower 16 bits of the CRC polynomial that are used in both 16-bit and 32-bit CRC modes.

Diagram



Fields

Field	Function
31-16 HIGH	High Polynominal Half-Word Writable and readable in 32-bit CRC mode (CTRL[TCRC] = 1). You cannot write to this field in 16-bit CRC mode (CTRL[TCRC] = 0).
15-0 LOW	Low Polynominal Half-Word Writable and readable in both 16-bit and 32-bit CRC modes.

39.3.1.4 CRC Control (CTRL)

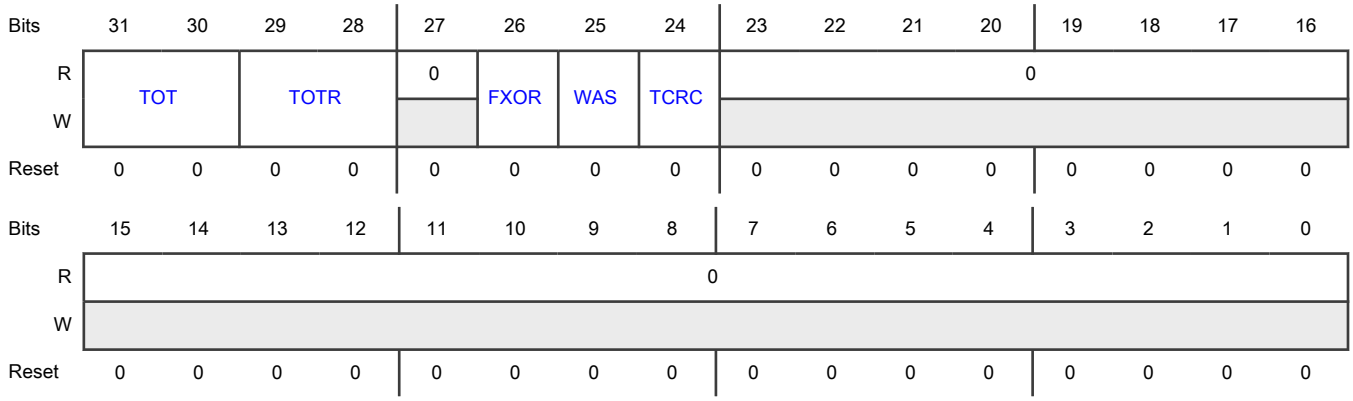
Offset

Register	Offset
CTRL	8h

Function

Controls the configuration and working of CRC module. You must write 1 to the appropriate fields of this register before starting a new CRC calculation, which you can initialize by writing 1 to CTRL[WAS] and then writing the seed into CRC Data (DATA).

Diagram



Fields

Field	Function
31-30 TOT	Transpose Type for Writes Defines the transpose configuration of the data written to CRC Data (DATA). See Transpose feature for the available transpose options. 00b - No transposition 01b - Bits in bytes are transposed; bytes are not transposed 10b - Both bits in bytes and bytes are transposed 11b - Only bytes are transposed; no bits in a byte are transposed
29-28 TOTR	Transpose Type for Read Identifies the transpose configuration of the value read from CRC Data (DATA). See Transpose feature for the available transpose options. 00b - No transposition 01b - Bits in bytes are transposed; bytes are not transposed 10b - Both bits in bytes and bytes are transposed 11b - Only bytes are transposed; no bits in a byte are transposed
27 —	Reserved
26 FXOR	Complement Read of CRC Data Register Enables on-the-fly complementing of read data. Some CRC protocols require the final checksum to be XORed with FFFFFFFFh or FFFFh. 0b - No XOR on reading 1b - Inverts or complements the read value of the CRC Data
25	Write as Seed Specifies whether writes to CRC Data (DATA) are data values or seed values.

Table continues on the next page...

Table continued from the previous page...

Field	Function
WAS	When this field = 1, the value that you write to CRC Data (DATA) is considered as seed value. When this field = 0, the value that you write to CRC Data (DATA) is considered as data for CRC computation. 0b - Data values 1b - Seed values
24 TCRC	TCRC Defines the width of the CRC protocol. 0b - 16-bit 1b - 32-bit
23-0 —	Reserved

39.4 Functional description

39.4.1 Modes of operation

The following sections discuss the various modes that affect the functionality of CRC.

39.4.1.1 Run mode

This is the basic mode of operation.

39.4.1.2 Low-Power mode

An in-progress CRC calculation stops when the chip enters Low-Power mode that disables the module clock. The calculation resumes after the clock is enabled or via system reset for exiting Low-Power mode. Clock gating for the module is dependent on the chip.

39.4.2 CRC calculations

In 16-bit and 32-bit CRC modes, data values can be programmed as 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous. Noncontiguous bytes can lead to an incorrect CRC computation.

39.4.2.1 Computing a 16-bit CRC

Perform these steps to compute a 16-bit CRC:

1. Write 0 to CTRL[TCRC] to enable 16-bit CRC mode.
2. Program the transpose and complement options in CRC Control (CTRL) as required for the CRC calculation. See Transpose feature and Result complement for details.
3. Write a 16-bit polynomial to GPOLY[LOW].

   GPOLY[HIGH] is is not usable in 16-bit CRC mode.
4. Write 1 to CTRL[WAS] to program the seed value.
5. Write a 16-bit seed to DATA[LU] and DATA[LL].

   DATA[HU] and DATA[HL] are not used.

6. Write 0 to CTRL[WAS] to write data values.
7. Write data values into DATA[HU], DATA[HL], DATA[LU], and DATA[LL].

   CRC is computed on every data value write and the intermediate CRC result is stored back into DATA[LU] and DATA[LL].
8. Read the final CRC result from DATA[LU] and DATA[LL].

The transpose and complement operations are performed on-the-fly when reading or writing values. See Transpose feature and Result complement for details.

39.4.2.2 Computing a 32-bit CRC

Perform these steps to compute a 32-bit CRC:

1. Write 1 to CTRL[TCRC] to enable 32-bit CRC mode.
2. Program the transpose and complement options in CRC Control (CTRL) as required for CRC calculation. See Transpose feature and Result complement for details.
3. Write a 32-bit polynomial to GPOLY[HIGH] and GPOLY[LOW].
4. Write 1 to CTRL[WAS] to program the seed value.
5. Write a 32-bit seed to DATA [HU], DATA [HL], DATA [LU], and DATA [LL].
6. Write 0 to CTRL[WAS] to start writing data values.
7. Write data values DATA[HU], DATA[HL], DATA[LU], and DATA[LL].

   CRC is computed on every data value write and the intermediate CRC result is stored back into DATA[HU], DATA[HL], DATA[LU], and DATA[LL].
8. Read the final CRC result from DATA[HU], DATA [HL], DATA [LU], and DATA [LL].

   CRC is calculated bytewise and two clocks are required to complete one CRC calculation.

The transpose and complement operations are performed on-the-fly when reading or writing values. See Transpose feature and Result complement for details.

39.4.3 Transpose feature

The transpose feature is not enabled by default. However, the CRC standards require the input data and/or the final checksum to be transposed. You have an option to configure each transpose operation separately, as desired by the CRC standard. The data is transposed on-the-fly while being read or written.

Some protocols use the little-endian format for the data stream to calculate a CRC. In this case, the transpose feature usefully flips the bits. This transpose option is one of the types supported by the CRC module.

39.4.3.1 Types of transpose

CRC provides several types of transpose functions to flip the bits and/or bytes, for both writing input data and reading the CRC result, separately using the CTRL[TOT] and CTRL[TOTR] according to the CRC calculation being used.

The following types of transpose functions are available for writing to and reading from CRC Data (DATA).

1. CTRL[TOT] or CTRL[TOTR] is 0.

   No transposition occurs.
2. CTRL[TOT] or CTRL[TOTR] is 1.

   Bits in a byte are transposed when bytes are not transposed.

   reg[31:0] becomes {reg[24:31], reg[16:23], reg[8:15], reg[0:7]}. See the following figure.

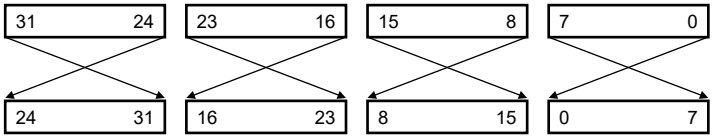


Figure 103. Transpose type 1b

3. CTRL[TOT] or CTRL[TOTR] is 10b.

   Both bits in bytes and bytes are transposed.

   reg[31:0] becomes {reg[0:7], reg[8:15], reg[16:23], reg[24:31]}. See the following figure.

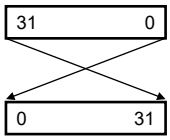

Figure 104. Transpose type 10b

4. CTRL[TOT] or CTRL[TOTR] is 11b.

   Bytes are transposed but bits are not transposed.

   reg[31:0] becomes {reg[7:0], reg[15:8], reg[23:16], reg[31:24]}. See the following figure.

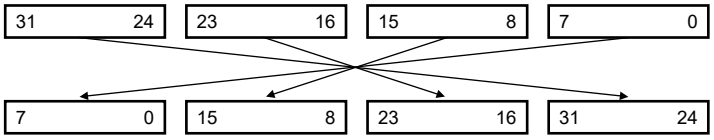

Figure 105. Transpose type 11b

NOTE

For 8-bit and 16-bit write accesses to CRC Data (DATA), the data is transposed with 0s on the unused byte or bytes (taking 32 bits as a whole), but CRC is calculated on the valid byte(s) only. When reading the CRC Data (DATA) for a 16-bit CRC result and using transpose options 10 and 11, the resulting value after transposition resides in DATA[HU] and DATA[HL]. You must account for this situation when reading the 16-bit CRC result, so reading 32 bits is preferred.

39.4.4 Result complement

When CTRL[FXOR] = 1, the checksum is complemented. The CRC result complement function outputs the complement of the checksum value stored in CRC Data (DATA) every time CRC Data (DATA) is read. When CTRL[FXOR] = 0, reading CRC Data (DATA) accesses the raw checksum value.

39.5 Use cases

The following tables use the little-endian format.

39.5.1 CTRL programming

The following table shows CRC Control (CTRL) programming for 16-bit CRC.

Table 238. CTRL programming for 16-bit CRC

Algorithm	Polynomial	Seed	Ref in	Ref out	XOR out	CTRL[TOT]	CTRL[TOTR]	CTRL[FXOR]
CRC-16_CCITT_FALSE	1021h	FFFFh	0	0	0000h	0h	0h	0h

CRC-32_XFER	[31:0] = Valid data

39.6 External signals

There is no CRC signal that connects off chip.

39.7 CRC initialization and reinitialization

To enable CRC calculation, you must program:

- CTRL[WAS].
- CRC Polynomial (GPOLY).
- Parameters for transposition and CRC result inversion in the applicable registers.

Writing 1 to CTRL[WAS] enables you to program the seed value into CRC Data (DATA).

After a CRC calculation completes, you can reinitialize the module for a new CRC computation by again writing 1 to CTRL [WAS] and programming a new, or previously used, seed value. You must set all other parameters before programming the seed value and subsequent data values.

40.1.3 ADC voltage reference options

The ADC voltage references are:

- CFG[REFSEL]=00, VDD_ANA supply pin
- CFG[REFSEL]=01, VREFO voltage reference driven from the VREF block
- CFG[REFSEL]=10, VREFH reference pin

40.1.4 ADC trigger inputs

ADC Trigger sources get routed through the Trigger Multiplexer (TRGMUX). See the TRGMUX chapter for available trigger sources.

40.1.5 ADC-VREF dependency

The ADC module requires biasing a voltage from VREF module. For proper ADC operation, the Low-Power Bandgap Buffer Enable and Low-Power Bandgap Enable bitfields (bit 2, LPBG_BUF_EN and bit 1, LPBGEN) in the VREF Control and Status Register (VREF[CSR]) must be enabled prior to use the ADC peripheral. Attempting to use the ADC without the VREF biasing voltage leads to unexpected behavior of the ADC.

40.2 Overview

The 16-bit analog-to-digital converter (ADC) is a dual successive approximation ADC designed for operation within an integrated microcontroller system-on-a-chip.

NOTE

For chip-specific modes of operation, see the power management information for the device.

40.2.1 Block diagram

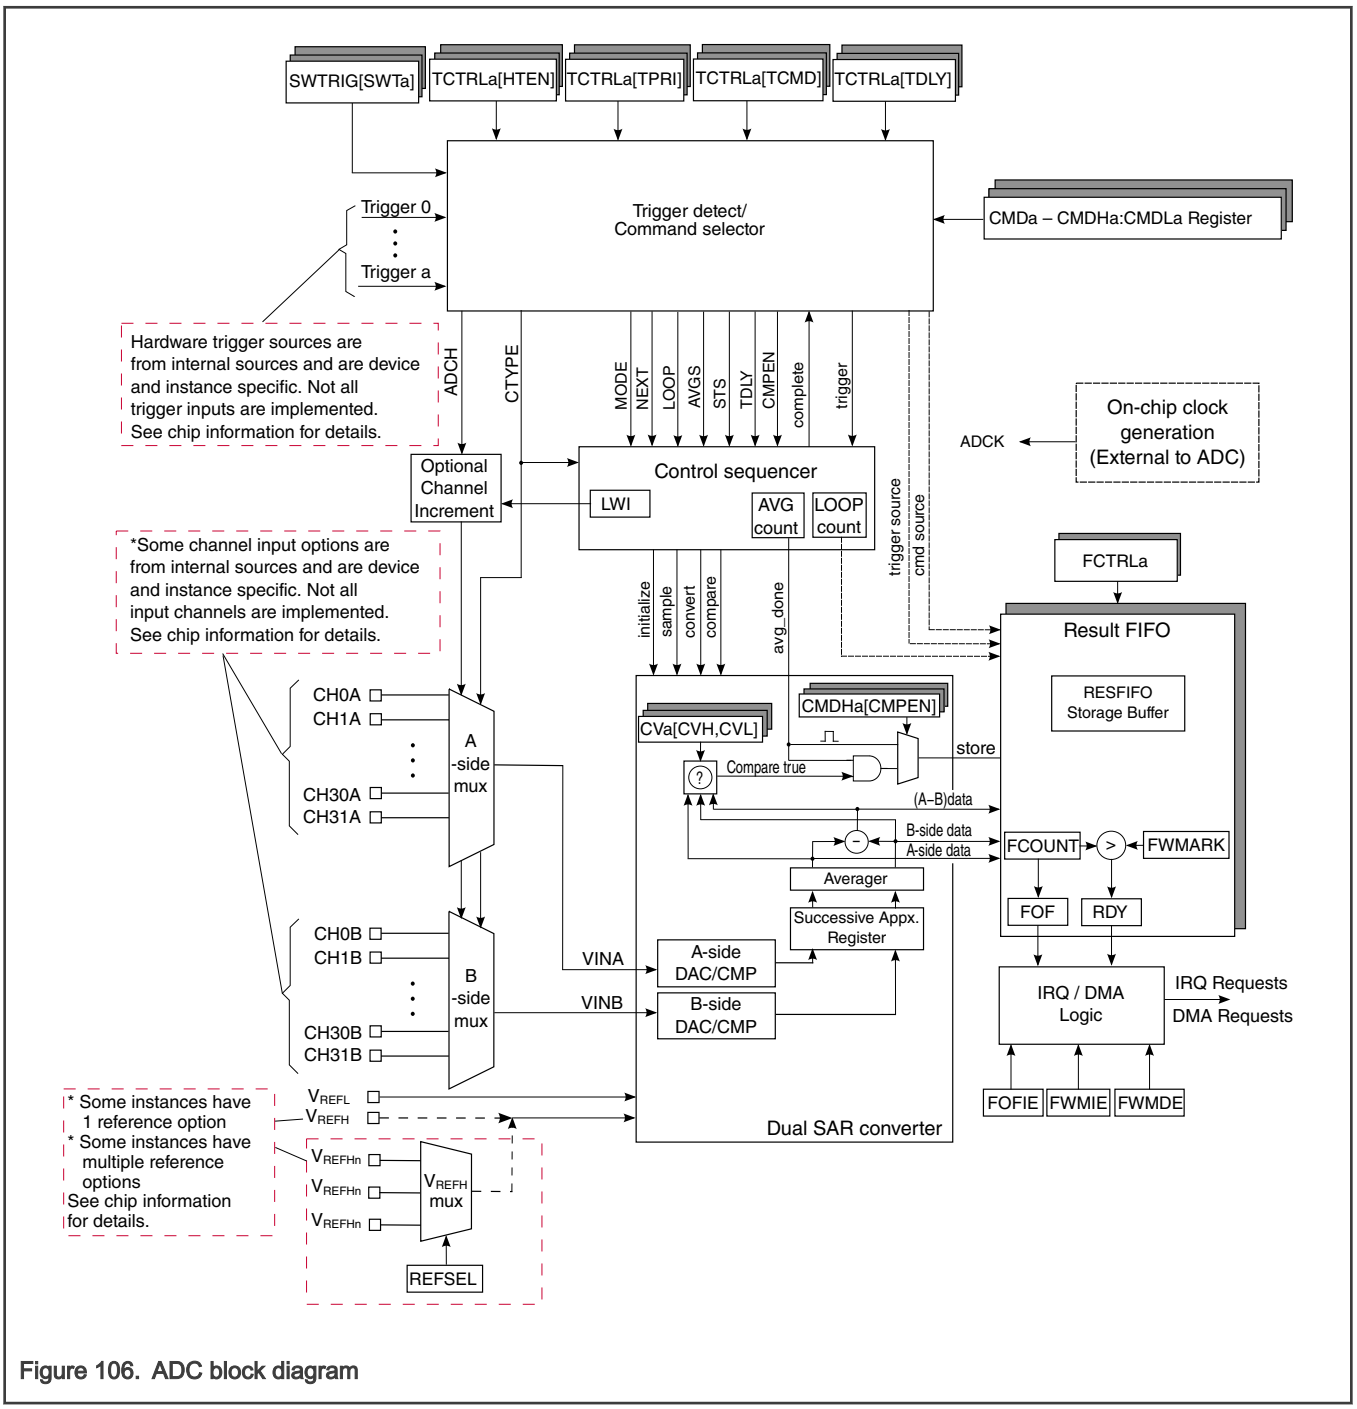

Figure 106. ADC block diagram

40.2.2 Features

ADC has these features:

- Linear successive approximation algorithm
  - Differential operation with 16-bit or 13-bit resolution
  - Single-ended operation with 16-bit or 12-bit resolution
  - Support for two simultaneous single-ended conversions
- Configurable analog input sample time
- Configurable speed options to accommodate operation in low-power modes of SoC
- Trigger detection with up to 4 trigger sources with priority level configuration. Software or hardware trigger option for each.
- 15 command buffers, to allow independent options selection and channel sequence scanning
- Automatic comparisons for less-than, greater-than, within range, or out-of-range with "store on true" and "repeat until true" options
- 2 independent result FIFOs, each containing 16 entries. Each FIFO has configurable watermark and overflow detection.
- Interrupt, DMA, or polled operation
- Linearity and gain adjustment calibration logic

40.3 Functional description

ADC performs analog-to-digital conversions on any of the software-selectable analog input channels via a successive approximation algorithm.

The ADC module can average the result of multiple conversions on a channel before storing the calculated result. The hardware average function is enabled by setting CMDHn[AVGS] to a non-zero value. The function operates in any conversion mode or configuration.

ADC can compare the result of a conversion with the contents of two value registers for less-than, greater-than, inside-range, or outside-range detection. The compare function operates in any conversion mode or configuration.

When the conversion and averaging loops finish, the resulting data is placed in one of 2 available FIFO data buffers . The data includes tag information associated with the result. When the number of stored data words exceeds the setting, a configurable watermark level supports interrupts or DMA requests. Interrupts can also be enabled to indicate when FIFO overflow errors occur.

The module initializes to its lowest power state during reset.

The ADC analog circuits can be pre-enabled to begin conversions sooner at the expense of higher idle currents. Conversions are initiated by selectable trigger events from software or hardware sources.

The trigger-detection logic includes a configurable enable and priority scheme for available trigger sources.

ADC includes multiple command buffers to provide flexibility for channel scanning and independent channel selections for different trigger sources. These command buffers can be configured for:

- Differential or single-ended conversion
- Sample time
- Averaging on a per-channel basis

ADC includes offset and linearity calibration logic. A request for calibration should be made upon reset or power up. Each successive approximation register (SAR) conversion uses calibration data calculated during the calibration routine.

The sequencing of an ADC command is summarized in the flow diagram below.

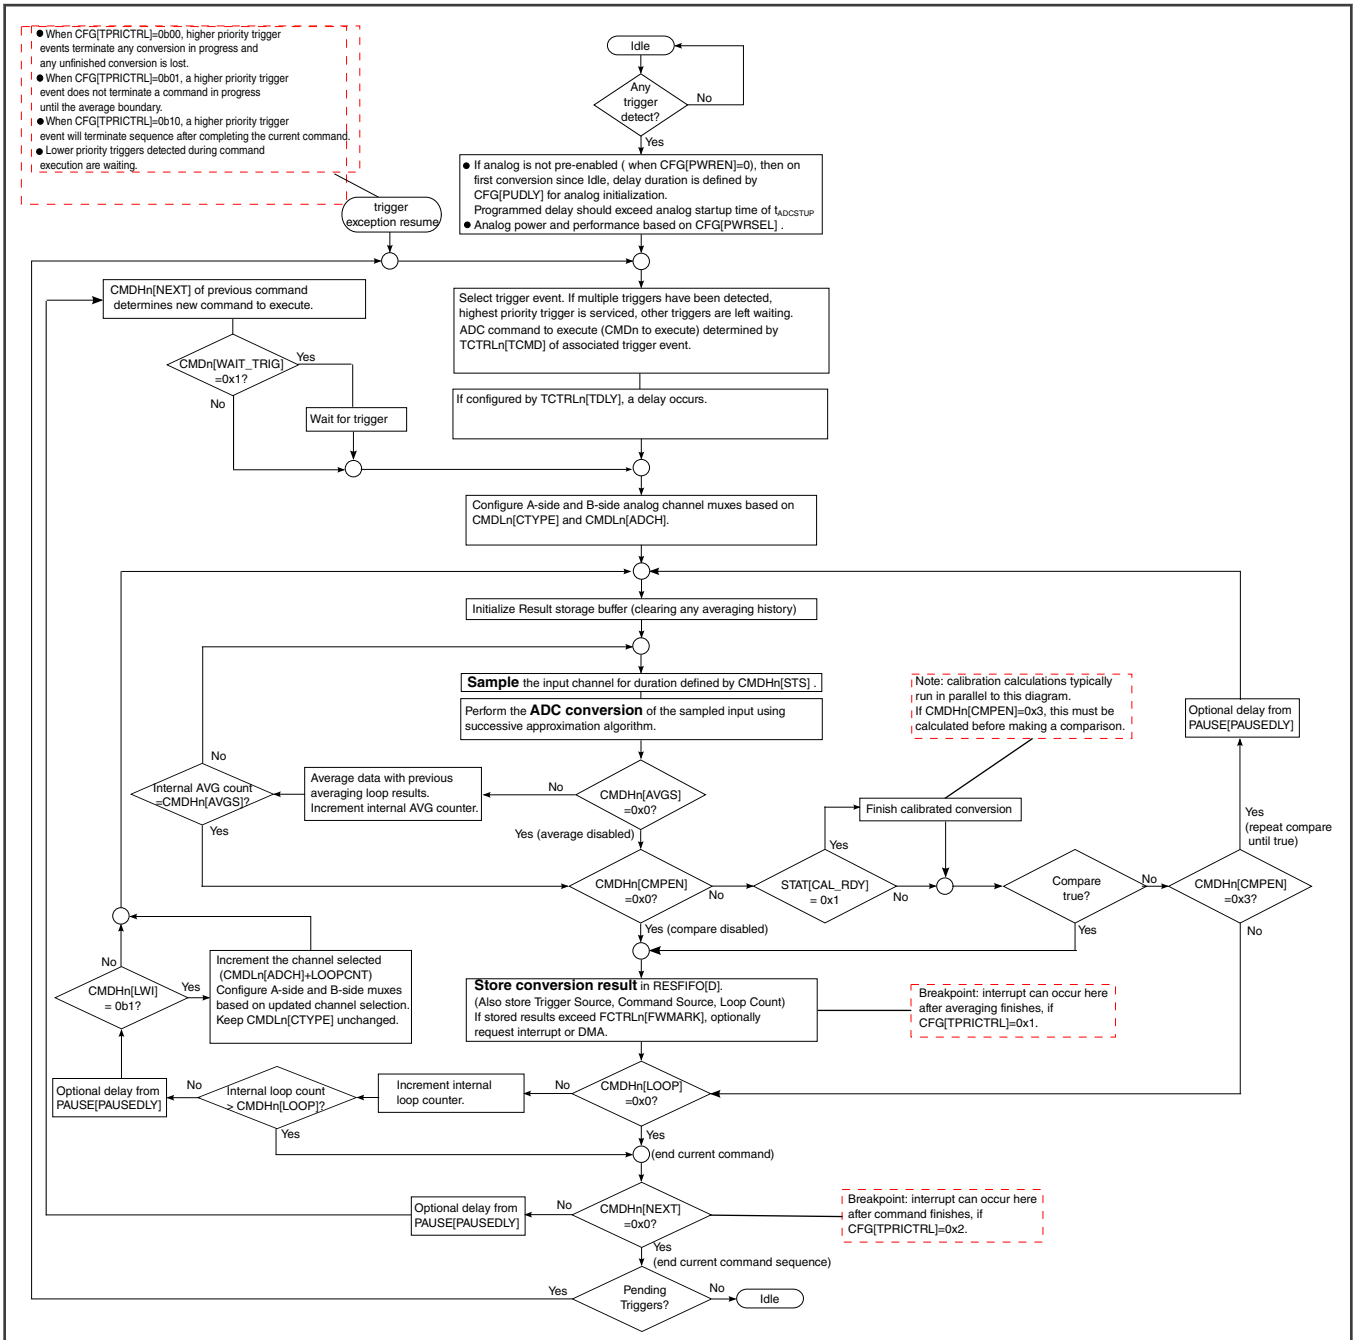

Figure 107. ADC command execution flow diagram

40.3.1 Power control mode

By default, the ADC analog circuits are disabled while ADC is in its idle state. When a trigger is detected and ADC command processing is initiated, the analog circuits are enabled. These circuits require a period of initialization before the first conversion cycle.

The value of CFG[PUDLY] should be set to incur a delay longer than $t_{ADCSTUP}$. The accuracy of initial conversions after activation is degraded if the value of CFG[PUDLY] is too low.

You can achieve faster conversion startup times by setting CFG[PWREN] to pre-enable the analog circuits of ADC. This faster conversion consumes extra power, even while ADC is in an idle state. When CFG[PWREN] is 1, the Power Enable timer is

activated. The timer enforces the minimum time required (configured by CFG[PUDLY]) before detected triggers can initiate ADC conversions.

ADC also has options for controlling power and performance summarized in the table below. See the device data sheet for specification of the available power modes.

Table 243. Power option settings

CFG[PWRSEL]	Description
0xb (Default)	Slow speed and low power
1xb	Fast speed and high power

40.3.2 ADC modes of operation

The ADC module supports the chip low power modes described in the following table. See section Clock operation for more information.

Table 244. Chip modes supported by the ADC module

Chip mode	ADC Operation
Run	Normal operation
Deepsleep/Sleep	When the Doze Enable bit (CTRL[DOZEN]) is 0, the ADC can continue to operate and the module is using an external or internal clock source which remains operating during Deepsleep/Sleep modes. ADC is allowed to continue operation while the system is transitioned to the low power state. Any conversion in progress is not disrupted. External hardware trigger detect and active conversions are operational. When the DOZEN bit is 1, the module waits for the current averaging iteration/FIFO storage to complete before acknowledging Deepsleep or Sleep mode entry. There is no associated ack/handshake and the system transitions to low power state without ADC interaction. ADC operation should terminate after completion of any conversion in progress.
Deep Powerdown	The Doze Enable (CTRL[DOZEN]) bit is ignored and the module waits for the current transfer to complete any pending operation before acknowledging Deep Powerdown mode entry.

40.3.3 Voltage reference

The voltage reference high (V_{REFH}) used by ADC is supplied from either an on-chip voltage reference source or from an off-chip source via external pins. V_{REFL} is always from an external pin and must be at the same voltage as V_{SSA}.

This block supports a programmable selection of the Voltage Reference High used for ADC conversions (via CFG[REFSEL]).

See the chip configuration information on the voltage reference options specific to this packaged device.

40.3.4 Trigger detect and command execution

See Figure 107 for a flow diagram of command execution sequencing.

ADC command execution is initiated from up to 4 trigger sources. Each trigger can be software-generated by writing 1b to the corresponding SWTRIG[SWTn] field. Alternatively, asynchronous input sources at the periphery of the module can generate hardware triggers. The number and sources of hardware triggers implemented is device-specific. See the chip-specific ADC information for descriptions of available hardware trigger sources for this device.

Each hardware trigger source is enabled by setting the associated enable field (TCTRLn[HTEN]). Each trigger source is assigned a priority via the associated priority control field (TCTRLn[TPRI]). Each of the trigger sources is associated with a command buffer via the associated command select field (TCTRLn[TCMD]).

When a hardware trigger input is enabled, hardware trigger events are detected on the rising edge of the associated hardware trigger source.

Each trigger source has an associated priority field TCTRLn[TPRI] which allows arbitration between trigger sources. Arbitration selects two things: which trigger sequence to execute next, and how to handle a trigger exception. Trigger exceptions are defined as allowing a higher-priority trigger sequence to interrupt operation of a lower-priority sequence. When a trigger exception occurs, programmable arbitration allows the configurable stop and resume points for low-priority sequences. The fields affecting arbitration are CFG[HPT_EXDI], CFG[TCMDRES], CFG[TRES], and CFG[TPRICTRL].

1. When CFG[HPT_EXDI] = 1b, trigger exceptions are disabled and any higher priority triggers are left pending until the current sequence completes. New triggers are accepted based on priority.
2. When CFG[HPT_EXDI] = 0b (default), exceptions are enabled and the higher-priority sequence begins executing at a user-specified breakpoint.

Breakpoint locations are determined by CFG[TPRICTRL], which affects latency for accepting trigger exceptions.

1. When CFG[TPRICTRL] = 0h, a higher-priority trigger causes an immediate command abort and the new command specified by the trigger is immediately started.
2. When CFG[TPRICTRL] = 1h, the current conversion is allowed to complete (including averaging) before the higher-priority exception starts. In this mode, if the command is running through a series of averages, this series completes. However, there is no requirement to finish the entire command before being interrupted. For example, if the command consists of four loop iterations, there is no requirement to complete all four iterations before the interrupt occurs.
3. When CFG[TPRICTRL] = 2h, a higher-priority trigger begins once the current command is completed. If a command consists of five loop iterations each containing eight averages, then all 40 conversions must be completed before accepting the trigger exception.

CFG[TCMDRES] and CFG[TRES] determine what ADC does after accepting a trigger exception. The module can be programmed to resume commands after returning from a trigger exception.

1. When CFG[TRES] = 0h, commands are not automatically resumed after being stopped by an exception. However, an interrupt is set to indicate that this case has occurred. The flag TSTAT[TEXC_NUM] can be used to resolve which trigger was stopped by the exception.
2. When CFG[TRES] = 1h, ADC automatically resumes commands after they were stopped by an exception.

Using CFG[TRES] with CFG[TCMDRES], the module can be programmed to resume commands at one of two possible locations.

1. When CFG[TCMDRES] = 0h, the trigger which was stopped by an exception is resumed from the beginning of its associated command sequence. Triggers that are waiting to be resumed take the same priority programmed to TCTRLn[TPRI].
2. When CFG[TCMDRES] = 1h, the trigger is resumed from the command that it was executing before being interrupted by an exception.

If a trigger occurs with priority lower than the priority of the currently executing command, trigger detection is left pending until the current command sequence finishes. Lower-priority trigger events cannot be serviced until a higher-priority triggered command (or command sequence) completes.

When a conversion is completed (including hardware averaging when CMDHn[AVGS] is non-zero), the result is placed in a RESFIFO buffer. When an ADC command selects looping (when CMDHn[LOOP] is non-zero) a command stores multiple conversion results to the FIFO during execution of that command.

At the end of command execution, CMDHn[NEXT] selects the next command to be executed. Multiple commands can be executed sequentially by configuring the CMDHn[NEXT] field of each command. Setting the next command to 0h causes conversions to terminate at the completion of the current command. Unending circular command execution is allowed by setting the CMDHn[NEXT] field of the last command in a sequence to the first command in the sequence.

By default, command sequences execute automatically in the order in which CMDHn[NEXT] fields are programmed. However, by using CMDHn[WAIT_TRIG], command execution can be stalled and launched based on trigger inputs. For example, if TRIGGER2 is programmed to start the command sequence CMD1, CMD2, CMD3, then this sequence is run once unconditionally to

completion upon receiving TRIGGER2. If CMDH2[WAIT_TRIG] = 1h, however, the sequence pauses after CMD1 until TRIGGER2 is received again. In this way, sequences can be stalled until a trigger assertion is received.

Disabling ADC by writing 0b to CTRL[ADCEN] terminates any active ADC command processing. Writing 0b to CTRL[ADCEN] causes the current command (or command sequence) to terminate, clears any pending triggers, and sends the ADC module to an idle state.

40.3.5 Pause option

When an application does not require the maximum conversion rate, the effective conversion rate can be reduced:

- By implementing periodic trigger events to initiate ADC conversions, or
- By selecting a reduced-frequency clock as the ADCK source.

Both options are chip-specific and are dependent on ADC triggering and clocking options external to the ADC module. The latency associated with ADC analog power-up delays limits the maximum conversion rate when using periodic triggering.

Conversion rates can also be reduced by inserting a pause of a programmable duration:

- Between loop iterations
- Between commands in a sequence
- Between conversions, when a command is executing in the Compare Until True configuration

When PAUSE[PAUSEEN] = 1, PAUSE[PAUSEDLY] controls the duration of pausing during command execution sequencing. The pause delay is a count of (PAUSE[PAUSEDLY] * 4) ADCK cycles.

NOTE

Do not change the PAUSE register while CTRL[ADCEN] = 1. Writes to the PAUSE register while CTRL[ADCEN] is 1 can lead to metastable operation.

See Figure 107 for the places during command execution sequencing where the pause can be inserted.

40.3.6 Temperature Sensor

The ADC module has a dedicated input channel for an on-chip temperature sensor. See the chip specific channel definition to determine which channel is connected to the on-chip temperature sensor.

To calculate the temperature, application software must first execute a conversion of the temperature sensor channel with configuration requirements. The sequence to convert the temperature sensor channel is:

1. Configure a command buffer register to convert the temperature sensor channel (CMDLn[ADCH]).
2. Program the command buffer with the following parameters:
   - Differential: CMDLn[CTYPE] = 2h
   - Max averaging: CMDHn[AVGS] = 7h
   - Max sample time: CMDHn[STS] = 7h
   - LOOP set to 1: CMDHn[LOOP] = 1h
   - Loop with increment disabled: CMDHn[LWI] = 0h
   - Compare function disabled: CMDHn[CMPEN] = 0h
3. Configure a trigger control register TCTRLn with the following parameters:
   - TCTRLn[TCMD] = command buffer used in steps 2 and 3.
   - TCTRLn[FIFO_SEL_A] directs conversion results to FIFO0 or FIFO1
4. Trigger a conversion of the temperature sensor channel. Software triggers the conversion by writing 1 to the associated bit in Software Trigger Register (SWTRIG) (that is, the trigger configured in the previous step).

After completing the conversion of the temperature sensor channel, two results are stored in the FIFO selected by TCTRLn[FIFO_SEL_A]. Each result corresponds to a component of the overall temperature value. Application software reads these values from the FIFO and uses the equation below to calculate the ambient temperature.

$$\text{Temp} = A\left[\frac{\alpha(\text{Vbe8} - \text{Vbe1})}{\text{Vbe8} + (\alpha(\text{Vbe8} - \text{Vbe1}))}\right] - B$$

Figure 108. Temperature sensor function

Where:

- Vbe1 is the first value stored to the FIFO as a result of the temperature sensor channel conversion.
- Vbe8 is the second value stored to the FIFO as a result of the temperature sensor channel conversion.
- A is the slope factor.
- B is the offset factor.
- α is the bandgap coefficient.

A, B, and α are specified constant values from the ADC electrical information in the device datasheet.

40.3.7 Result FIFO operation

ADC includes 2 16-entry FIFOs in which the result of ADC conversions are stored. In addition, a valid indicator bit, the trigger source, the source command, and the loop count are also stored with the data. FCTRLn[FCOUNT] indicates how many valid data words are stored in each RESFIFO.

A programmable watermark threshold supports configurable notification of data availability. When FCTRLn[FCOUNT] is greater than FCTRLn[FWMARK], the associated RDY flag is asserted. When IE[FWMIEn] = 1, a watermark interrupt request is issued. When DE[FWMDEn] = 1, a DMA request is issued. Reading RESFIFO provides the oldest unread data word entry in the FIFO and decrements FCTRLn[FCOUNT]. When FCTRLn[FCOUNT] falls equal to or below FCTRLn[FWMARK], the RDY flag is cleared.

Each FIFO can be emptied by successive reads of RESFIFOn. When RESFIFOn[VALID] is 1, the associated FIFO entry is valid. Reading RESFIFOn when the FIFO is empty (when RESFIFOn[VALID] = 0 and FCTRLn[FCOUNT] = 0h) provides an undefined data word. All FIFOs are reset by writing 1b to CTRL[RSTFIFOn].

If ADC attempts to store a data word to the FIFO when the FIFO is full, the FIFO overflow flag (FCTRLn[FOF]) is set. When IE[FOFIEn] = 1, an overflow interrupt request is issued. The FOF flag is cleared by writing 1 to STAT[FOFn]. When overflow events occur, no new data is stored and the data associated with the storage event that triggered the overflow is lost.

Conversion results can be steered to any FIFO in the design. TCTRLn[FIFO_SEL_A] and TCTRLn[FIFO_SEL_B] determine into which FIFO the final result is written. Depending on which trigger is executing, the results can be steered to different locations. Depending on the type of conversion selected, the FIFO destination register fields are interpreted differently. During either differential or single-ended mode (CMDLn[CTYPE] != 3h) only one result is produced. The destination during these modes is determined from TCTRLn[FIFO_SEL_A]. In dual-single-ended mode, both TCTRLn[FIFO_SEL_A] and TCTRLn[FIFO_SEL_B] determine the Channel A and Channel B destinations respectively.

40.3.8 Sampling Modes

The ADC module supports three different sampling modes: dual single-ended, single-ended, and differential. The sampling mode is determined by the currently executing command using CMDLn[CTYPE].

When executing a command in dual single-ended mode, two independent conversion results are calculated and stored in selectable FIFO destinations. Command processing, however, is not individually controlled for each independent channel being sampled. When operating in dual single-ended mode both channels are sampled and processed simultaneously. The input channels selected for dual single-ended mode are controlled by CMDLn[ADCH] and are always fixed pairs of inputs (CH0A/CH0B, CH1A/CH1B, and so on).

If comparisons are enabled in dual single-ended mode, only the A-side channels (CH0A, CH1A, and so on) are used for the comparison. The A-side comparison determines whether both the A-side and B-side results are written to the FIFOs.

- If the A-side comparison passes, both the A-side and B-side results are stored.
- If the A-side comparison fails, A-side and B-side results are not written to the FIFOs.

Single-ended mode is configurable to allow either A-side or B-side channels to be sampled. In single-ended mode, the results from each conversion can be written to a selectable FIFO using TCTRLn[FIFO_SEL_A].

In differential mode, the final SAR calculation is equivalent to V(CHA) - V(CHB). If the result is negative, then the value is stored in sign-extended two's complement format. TCTRLn[FIFO_SEL_A] also determines where differential conversion results are stored.

In dual single-ended mode, however, two independent results are produced. Individual control is provided by using TCTRLn[FIFO_SEL_A] and TCTRLn[FIFO_SEL_B] to select a FIFO destination for both results during this mode. Both single-ended results may be written to the same destination by programming TCTRLn[FIFO_SEL_A] = TCTRLn[FIFO_SEL_B]. In this case, the CH_A result is always stored before the CH_B result.

40.3.9 Compare Function

After the input is sampled and converted and any averaging iterations are performed, CMDHn[CMPEN] determines:

- Whether to use the automatic compare function, storing the conversion result when true.
- Whether to repeat the channel acquisition until the automatic compare function returns a true result.

The command-sequencing options related to the compare function are summarized in the table below.

NOTE

Latency is added to the end of a compare-until-true conversion to resolve the next command or loop in a sequence. This latency is necessary to calibrate the SAR data before resolving the result of a comparison. Delay for this feature is only added when resolving the result of a conversion. Intermediate samples during averaging do not include extra latency; only loop and command boundaries experience this delay. The latency is always less than or equal to five ADC clock cycles.

Table 245. Compare modes

CMDHn[CMPEN]	Compare function	Description
00b	Compare disabled	Do not perform compare operation. Always store the conversion result to the FIFO.
01b	Reserved	
10b	Store on true	Perform compare operation. Store conversion result to FIFO after averaging only when the result of the comparison is true. Regardless of the comparison result, the LOOP setting is considered. The LOOP counter is incremented before deciding whether the current command has completed or additional LOOP iterations are required.
11b	Repeat compare until true	Perform compare operation. Store conversion result to FIFO after averaging only when the result of the comparison is true. Once a comparison is true, the LOOP setting is considered. The LOOP counter is incremented before deciding whether the current command has completed or additional LOOP iterations are required. When a comparison is false, the conversion is repeated without considering the LOOP setting, and the LOOP counter is not incremented.

The compare operation checks the result based on the values of CVn[CVH] and CVn[CVL], as shown in the following table.

Table 246. Compare operations

CVn[CVL] vs. CVn[CVH]	Operation	Description
set CVn[CVL] < CVn[CVH]	Outside range (General form)	True if the result is less than CVn[CVL] **or** greater than CVn[CVH].
set CVn[CVH] to maximum value set CVn[CVL] to compare point	Less than	True if the result is less than CVn[CVL].
set CVn[CVL] to minimum value set CVn[CVH] to compare point	Greater than	True if the result is greater than CVn[CVH].
set CVn[CVL] > CVn[CVH]	Inside range	True if the result is less than CVn[CVL] **and** greater than CVn[CVH].

NOTE

When ADC continues operating in a low-power mode, the compare function can monitor the voltage and wake the device only when the compare condition is met.

40.3.10 Clock operation

The ADC operates from the ADCK clock input provided from an on-chip clock select block and is used by the SAR conversion control sequencing logic and the FIFO storage buffer. The ADCK frequency must be within the specified frequency range for ADCK and varies based on configuration of CFG[PWRSEL]. Refer to the device datasheet for supported frequency ranges.

The ADC continues operating in Deepsleep and Sleep modes provided the Doze Enable bit (CTRL[DOZEN]) is clear and the on-chip clock select block continues to supply an ADCK clock source. Note, in Deepsleep mode with CTRL[DOZEN] == 0b0, the bus clock can be shut off, and asynchronous interrupts and DMA requests can be configured. In addition, the ADC continues processing commands and writing data to the internal FIFO. The ADC has four sources for async interrupts during Deepsleep mode: watermark, FIFO overflow, TCOMP, and TEXC. To enable them, properly configure the bits IE[FWMIEx], IE[FOFIEx], IE[TCOMP_IE], and IE[TEXC_IE] before entering Deepsleep mode.

When the DOZEN bit is set in Deepsleep and Sleep modes, the ADC waits for the current averaging iteration/FIFO storage to complete before acknowledging Deepsleep or Sleep mode entry. Any pending triggers are dropped when a Deepsleep/Sleep mode request is made with DOZEN set. The ADC is forced into its lowest power setting after acknowledging the DOZEN Deepsleep/Sleep mode request. The same behavior is observed when entering a Deep Powerdown Mode.

40.3.11 Resets

Table 247. ADC Resets

Reset source	Description
Chip reset	The logic and registers for the ADC are reset to their default state on a chip reset.
Software reset	The ADC implements a software reset bit in its Control Register. The CTRL[RST] bit resets all logic and registers to their default state, except for the CTRL register itself.
FIFO reset	The ADC implements write-only control that reset the FIFO0 (CTRL[RSTFIFO0]) and FIFO1 (CTRL[RSTFIFO1]). After a FIFO is reset, that FIFO is empty.

40.3.12 Interrupts and DMA requests

The ADC includes several sources for interrupts and/or DMA requests. The table below summarizes these sources.

A programmable watermark threshold supports configurable notification of data availability and can generate either an interrupt exception or a DMA request. When FCTRLn[COUNT] is greater than FCTRLn[FWMARK], the associated RDYn flag is asserted. Masking for this exception is controlled by the IE[FWMIEn] and DE[FWMDEn] control bits. When RDYn is asserted and mask control bit IE[FWMIEn] is set, a watermark interrupt request is issued. When RDYn is asserted and mask control bit DE[FWMDEn] is set, a DMA request is issued.

The other exception sources can only generate interrupts and do not have a DMA request option. Each of these sources has a mask control bit in the IE register and no corresponding bit in the DE register.

Table 248. ADC Interrupts and DMA Requests

Status Register (STAT)		Description	Can generate		
Flag	Name		Interrupt?	DMA Request?	Low Power Wakeup?
RDYn	Result FIFO n Ready Flag	Conversion result data is written to Result FIFO and has a watermark configurable trigger level to generate an exception request as controlled by FCTRLn[FWMARK].	Y	Y	Y
FOFn	Result FIFO n Overflow Flag	Attempts to store data to the FIFO when the FIFO is full is an error condition.	Y	N	Y
TCOMP_INT	Trigger Completion Flag	A trigger sequence has been completed (all associated commands have been run).	Y	N	Y
TEXC_INT	High Priority Trigger Flag	A high priority trigger exception has occurred.	Y	N	Y

40.4 External signals

The ADC module supports analog channel inputs with differential and single-ended conversion options for all channels. ADC requires supply and ground connections.

Table 249. ADC signal descriptions

Signal	Description	I/O
V_{DDA}	Analog Power Supply	I
V_{SSA}	Analog Ground	I
CHnA - CH0A[1]	A-side Analog Channel Inputs	I
CHnB - CH0B[1]	B-side Analog Channel Inputs	I

1. where n is the maximum channel number supported in the chip. See the chip-specific information for the number of channels supported on your device.

40.4.1 Analog channel inputs (CHnA and CHnB)

CMDLn[ADCH] and CMDLn[CTYPE] control selection of paired or individual input channels. Each ADC command independently makes a channel and conversion type selection. Each CMDLn[ADCH] channel selection has an associated A side and an associated B side input. Each CMDLn[ADCH] pair can be converted in differential mode, but only limited pairs should be converted as differential channels (for example, adjacent pins designed with matched impedance). For the pin pairings available for differential conversions for your device, see the Chip Configuration details.

NOTE

Some input channels from on-chip sources, such as temperature sensors and reference voltage sources, may only be connected to individual instances of ADC. Some input channel options in the field-setting descriptions may not be available for your device. See chip-specific information for the channels supported on this device.

40.5 Initialization

40.5.1 Calibration functions

The ADC module has multiple calibration functions that must be executed as part of ADC setup to achieve the specified accuracy. Calibration must be run after any reset and before a conversion is initiated. Before offset calibration or calibration, the user must configure the clock source and frequency of ADC for the clock source availability and needs of the application. ADC must be enabled (CTRL[ADCEN] = 1h) before a calibration function runs. If calibration is requested while ADC is actively converting, that sequence completes before starting calibration.

Averaging multiple conversions can achieve improved accuracy during the calibration routines. CTRL[CAL_AVGS] is used during a calibration routine to control how many samples are averaged together. If the application uses ADC in a wide variety of configurations, the configuration for which the highest accuracy is required should be selected. Alternatively, multiple calibrations can be done for the different configurations.

40.5.1.1 Offset calibration

The Offset Trim Register (OFSTRIM) is used to trim for ADC comparator offset voltage. The ADC supports an offset calibration function in which the OFSTRIM register is automatically updated. To perform offset calibration:

1. Configure for the desired averaging via CTRL[CAL_AVGS].
2. Initiate Offset Calibration by setting CTRL[CALOFS].
3. Poll the STAT[CAL_RDY] flag. When STAT[CAL_RDY] is asserted, the offset calibration function has completed, and the OFSTRIM register has updated.

40.5.1.2 ADC Calibration

ADC includes hardware calibration logic in which the A-side and B-side converters are calibrated for gain error and linearity error correction of the raw conversion result. GCR0[GCALR] and the CAL_GAR registers control calibration for the A-side converter. GCR1[GCALR] and the CAL_GBR registers control calibration for the B-side converter. ADC supports a calibration function in which the CAL_GAR and CAL_GBR registers are automatically updated. The calibration function also updates GCC0[GAIN_CAL] (associated with A-side calibration) and GCC1[GAIN_CAL] (associated with B-side calibration). For A-side calibration, a software calculation is required to derive GCR0[GCALR] from GCC0[GAIN_CAL]. For B-side calibration, a corresponding calculation is required to derive GCR1[GCALR] from GCC1[GAIN_CAL].

To complete calibration setup:

1. Execute Offset calibration steps. The Offset Trim Register (OFSTRIM) is used during calibration to trim for comparator offset voltage.
2. Configure the averaging via CTRL[CAL_AVGS].
3. Initiate the calibration routine by writing 1 to CTRL[CAL_REQ]. CTRL[CAL_REQ] remains 1 until the CAL routine has been accepted by the ADC. After acceptance, CTRL[CAL_REQ] automatically becomes 0.
4. The A-side calibration data is updated first. Poll the GCR0[RDY] flag. When it is asserted, the hardware controlled A-side calibration operation is complete, and CAL_GAR and GCC0[GAIN_CAL] registers are updated. The updated value in GCC0[GAIN_CAL] is required for further software processing described in the following steps.
5. Read GCC0[GAIN_CAL] and store for use in the gain_adjustment calculation.
6. Calculate the A-side gain_adjustment: (131072)/(131072-GCC0[GAIN_CAL]). GCC0[GAIN_CAL] is a 16-bit unsigned value. This calculation results in a floating point value between 1 and 2.

7. The integer value of the gain_adjustment calculation is always 1 and can be discarded. The fractional component must be stored to GCR0[GCALR]. Write the fractional component value to GCR0[GCALR].
8. Execute the same calculation for the B-side converter. Poll the GCC1[RDY] flag. When it is asserted, the hardware controlled B-side calibration operation is complete, and CAL_GBR and GCC1[GAIN_CAL] registers are updated. The updated value in GCC1[GAIN_CAL] is needed for further software processing.
9. Read the GCC1[GAIN_CAL] register and store for use in the gain_adjustment calculation.
10. Calculate the B-side gain_adjustment = (131072)/(131072-GCC1[GAIN_CAL]). Formatting for the value is the same as the A-side.
11. Like the A-side, round the fractional component of the B-side gain_adjustment to 16-bits and store it in GCR1[GCALR].
12. Once GCR0[GCALR] and GCR1[GCALR] contain the results from the gain_adjustment calculations, set the GCR0[RDY] and GCR1[RDY] flags to indicate they are valid. It is acceptable for the GCRn[GCALR] and corresponding GCRn[RDY] field to be updated on the same write cycle.

After completing the steps above, the calibration sequence is complete and the STAT[CAL_RDY] flag is set. The STAT[CAL_RDY] flag remains set until the user resets the system or requests a new calibration sequence.

When STAT[CAL_RDY] is set, ADC is configured to run in calibrated mode. Each conversion uses a combination of linearity and gain calibration results to correct SAR data. Calibration conversion latency is required to process each sample. However, due to the pipelined nature of data and control sequences, each conversion can still be initiated without experiencing this calibration delay.

40.5.1.3 Calibration General A-Side and B-Side Widths

The general calibration value registers CAL_GARn and CAL_GBRn have non-uniform widths. The following table defines the bit widths of each register.

Table 250. Calibration General Widths

Element CAL_GxR[N]	Width (Bits)
N = 00h, 20h	11
N = 01h	12
N = 02h–03h	13
N = 0x04–07h	14
N = 0x08–0Fh	15
N = 0x10–1Fh	16

These registers are typically updated automatically during the self-calibration sequence. To reduce the latency associated with ADC setup, the CAL_GxR values from a calibration sequence can be stored in non-volatile memory after an initial calibration. These values can then be written to the CAL_GxR registers via software prior to the first ADC conversion. If these registers are set to values not generated by the calibration function, the linearity error specifications may not be met.

NOTE

These values can only be written in a single access, byte accesses are not supported.

40.6 ADC register descriptions

This section describes the ADC registers.

40.6.1 ADC memory map

ADC0 base address: 4004_7000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Version ID Register (VERID)	32	R	0200_2C0Bh
4h	Parameter Register (PARAM)	32	R	0F0F_1004h
10h	Control Register (CTRL)	32	RW	0000_0000h
14h	Status Register (STAT)	32	RW	0000_0000h
18h	Interrupt Enable Register (IE)	32	RW	0000_0000h

Fields

Field	Function
31-24 MAJOR	Major Version Number Returns the major version number for the module specification.
23-16 MINOR	Minor Version Number Returns the minor version number for the module specification.
15 —	Reserved
14-12 NUM_FIFO	Number of FIFOs Indicates the number of result FIFOs implemented in the design. 000b - N/A 001b - One 010b - Two 011b - Three 100b - Four

Table continues on the next page...

Table continued from the previous page...

Field	Function
11 NUM_SEC	Number of Single-Ended Outputs Supported Indicates the number of single-ended channels which can be processed simultaneously. 0b - One 1b - Two
10 CALOFSI	Calibration Function Implemented Indicates whether ADC contains hardware calibration functions. When supported, CTRL[CAL_REQ] can be used to request the calibration routine. 0b - Not implemented 1b - Implemented
9 IADCKI	Internal ADC Clock Implemented Indicates whether this implementation of the ADC block includes an internal clock source. 0b - Not implemented 1b - Implemented
8 VR1RNGI	Voltage Reference 1 Range Control Bit Implemented Indicates whether a control bit is implemented to select the input voltage range on Voltage Reference Option 1. 0b - Range control not required. 1b - Range control required.
7 —	Reserved
6-4 CSW	Channel Scale Width Indicates whether channel scaling is supported. When supported, each command buffer has a control field (CMDLn[CSCALE]) for setting input scaling. 000b - Not supported. 001b - Supported with one-bit CSCALE control field. 110b - Supported with six-bit CSCALE control field.
3 MVI	Multiple Vref Implemented Indicates whether multiple voltage reference high (VREFH) inputs are supported. When multiple voltage references are supported, CFG[REFSEL] selects voltage reference high options. 0b - Single VREFH input supported. 1b - Multiple VREFH inputs supported.
2	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
1 DIFFEN	Differential Supported Indicates whether differential operation is supported. When supported, each command buffer has control fields (CMDLn[CTYPE]) for configuring for differential operation and expanding the number of supported channels from 32 to 64. 0b - Not supported 1b - Supported. CMDLn[CTYPE] controls fields implemented.
0 RES	Resolution Indicates the maximum accuracy supported. 0b - Up to 13-bit differential or 12-bit single-ended resolution supported. 1b - Up to 16-bit differential or 16-bit single-ended resolution supported. CMDLn[MODE] available for selecting the resolution of conversions for the associated command.

40.6.3 Parameter Register (PARAM)

Offset

Register	Offset
PARAM	4h

Function

The Parameter register indicates the size of several variable integration options for this instance on the device.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 CMD_NUM	Command Buffer Number Indicates number of command buffers implemented.
23-16 CV_NUM	Compare Value Number Indicates number of compare value registers implemented.
15-8 FIFOSIZE	Result FIFO Depth Indicates the maximum number of conversion data words that can be stored in the result FIFO before an overflow occurs. 0000_0001b - 2 0000_0100b - 4 0000_1000b - 8 0001_0000b - 16 0010_0000b - 32 0100_0000b - 64
7-0 TRIG_NUM	Trigger Number Number of Triggers implemented.

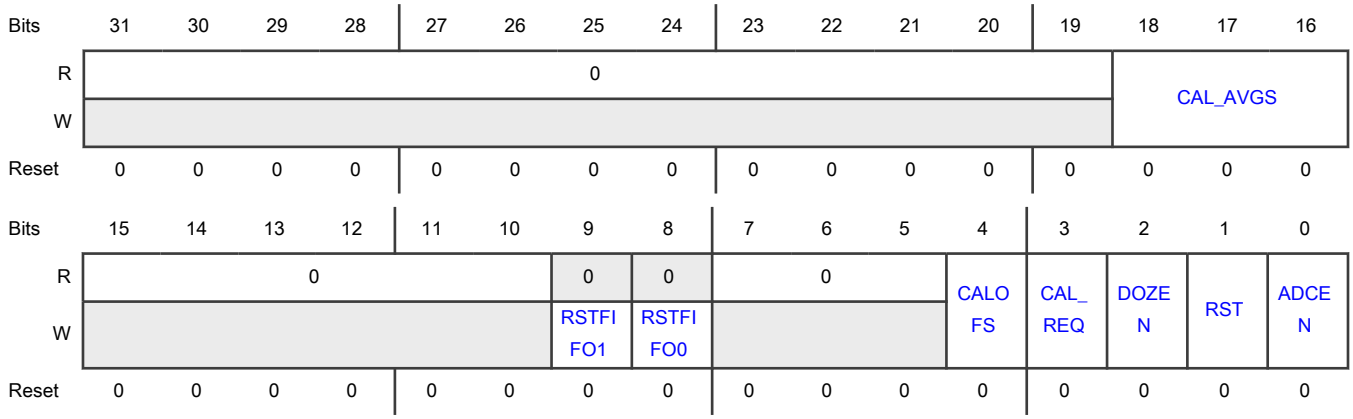
40.6.4 Control Register (CTRL)

Offset

Register	Offset
CTRL	10h

Function
Includes primary control bits.

Diagram



Fields

Field	Function
31-19 —	Reserved
18-16 CAL_AVGS	Auto-Calibration Averages Selects how many ADC conversions are averaged to calculate each calibration value. Selecting a higher number of averages will lead to more accurate conversions after completing calibration. The CAL_AVGS bit field applies to both CALOFS and CAL_REQ calibration types. This value should be fixed when requesting and running calibration with CTRL[CAL_REQ] or CTRL[CALOFS]. 000b - Single conversion. 001b - 2 conversions averaged. 010b - 4 conversions averaged. 011b - 8 conversions averaged. 100b - 16 conversions averaged. 101b - 32 conversions averaged. 110b - 64 conversions averaged. 111b - 128 conversions averaged.
15-10 —	Reserved
9 RSTFIFO1	Reset FIFO 1 0b - No effect. 1b - FIFO 1 is reset.
8 RSTFIFO0	Reset FIFO 0 0b - No effect. 1b - FIFO 0 is reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-5 —	Reserved
4 CALOFS	Offset Calibration Request Indicates whether a request for a hardware calibration calculation has been made. Writing 1 to this field initiates a hardware offset calibration calculation. Any conversions in progress are completed before launching the offset calibration function. After being accepted, ADC calculates the OFSTRIM[OFSTRIM] value and updates the OFSTRIM register automatically. This field becomes 0 upon completion of the offset calibration calculation. STAT[CAL_RDY] indicates when the offset calibration routine has completed. 0b - Calibration function disabled 1b - Request for offset calibration function
3 CAL_REQ	Auto-Calibration Request Indicates whether a request for the hardware calibration routine has been made. Automatically becomes 0 when the system accepts the hardware calibration request. STAT[CAL_RDY] indicates when this calibration routine has been completed. 0b - No request made. 1b - Request has been made.
2 DOZEN	Doze Enable Controls system transition to Deep-sleep/ and Sleep power modes while ADC is converting. When 0, immediate entries to Deep-sleep or Sleep modes are allowed and ADC conversion functions remain enabled. Any conversion in progress is not disrupted. The selected clock source provided from the on-chip clock source must be able to continue operating. When 1, the ADC waits for the current averaging iteration or FIFO storage to complete before acknowledging the low-power entry request. After entering the low-power state, ADC is kept inactive until the system exits the low-power state. When the system enters Deep Power-down mode, the DOZEN bit is ignored and ADC waits for the current transfer to complete any pending operation. 0b - ADC is enabled in low-power mode. 1b - ADC is disabled in low-power mode.
1 RST	Software Reset Resets all internal logic and registers, except the CTRL register. Remains 1 until cleared by software. 0b - ADC logic is not reset. 1b - ADC logic is reset.
0 ADCEN	ADC Enable 0b - Disabled 1b - Enabled

40.6.5 Status Register (STAT)

Offset

Register	Offset
STAT	14h

Function

Provides the status of the ADC module.

Diagram

27-24 CMDACT	Command Active Indicates the command actively being processed. Commands are only shown here when they are actively being processed by the SAR routine. Use with STAT[ADC_ACTIVE] to determine which conversion is running. 0000b - No command currently in progress. 0001b - Command 1 currently being executed. 0010b - Command 2 currently being executed. 0011b-1111b - Associated command number currently being executed.
23-18 —	Reserved
17-16 TRGACT	Trigger Active

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates the trigger actively being processed. This field can be used to determine which trigger is running through a trigger delay or being converted by the SAR routine. The command associated with this field is running through a conversion when STAT[CMDACT] is not zero. 00b - Command (sequence) associated with Trigger 0 currently being executed. 01b - Command (sequence) associated with Trigger 1 currently being executed. 10b - Command (sequence) associated with Trigger 2 currently being executed. 11b - Command (sequence) associated with Trigger 3 currently being executed.
15-12 —	Reserved
11 ADC_ACTIVE	ADC Active Indicates whether the module is processing a conversion, or has pending triggers to service. 0b - ADC is idle. There are no pending triggers to service and no active commands are being processed. 1b - ADC is processing a conversion, running through the power-up delay, or servicing a trigger.
10 CAL_RDY	Calibration Ready Indicates whether the ADC request for calibration (CTRL[CAL_REQ] or CTRL[CALOFS]) has been completed and the results are ready. This flag is automatically cleared when a new hardware calibration or OFSTRIM request is made. 0b - Calibration is incomplete or has not been run. 1b - ADC is calibrated.
9 TCOMP_INT	Interrupt Flag For Trigger Completion Indicates when a trigger sequence has been completed (all associated commands have been run). IE[TCOMP_IE] must be 1 for the specific trigger source to flag an interrupt upon completion. 0b - Either IE[TCOMP_IE] = 0, or no trigger sequences have run to completion. 1b - Trigger sequence has been completed and all data is stored in the associated FIFO.
8 TEXC_INT	Interrupt Flag For High-Priority Trigger Exception Indicates when a high-priority trigger exception has occurred and CFG[TRES] = 0. This flag only asserts if trigger exception interrupts are enabled (IE[TEXC_IE] = 1h). This flag can be used with TSTAT[TEXC_NUM] to resolve which trigger source was interrupted. 0b - No trigger exceptions have occurred. 1b - A trigger exception has occurred and is pending acknowledgment.
7-4 —	Reserved
3	Result FIFO1 Overflow Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
FOF1	Indicates that more data has been written to the Result FIFO 1 than it can hold. The newer data is not stored and the FIFO holds the original contents. This flag asserts regardless of the value of IE[FOFIE1]. However, an interrupt request is issued only if IE[FOFIE1] is 1. 0b - No result FIFO1 overflow has occurred since the last time that the flag was cleared. 1b - At least one result FIFO1 overflow has occurred since the last time that the flag was cleared.
2 RDY1	Result FIFO1 Ready Flag Indicates when the number of valid data words in the result FIFO 1 is greater than the level set in FCTRL0[FWMARK]. This flag asserts regardless of the value of IE[FWMIE1]. However, an interrupt request or DMA request occurs only when the associated control bit (IE[FWMIE1] and DE[FWMDE1]) is set. This flag is cleared when FCTRL0[FCOUNT] (which decrements on each read of the RESFIFO register) is less than or equal to the level set in FCTRL0[FWMARK]. 0b - Not above watermark 1b - Above watermark
1 FOF0	Result FIFO 0 Overflow Flag Indicates that more data has been written to the Result FIFO 0 than it can hold. The newer data is not stored and the FIFO holds the original contents. This flag asserts regardless of the value of IE[FOFIE0]. However, an interrupt request is issued only if IE[FOFIE0] is 1. 0b - No result FIFO 0 overflow has occurred since the last time that the flag was cleared. 1b - At least one result FIFO 0 overflow has occurred since the last time that the flag was cleared.
0 RDY0	Result FIFO 0 Ready Flag Indicates when the number of valid data words in the result FIFO 0 is greater than the watermark set in FCTRL0[FWMARK]. This flag asserts regardless of the value of IE[FWMIE0]. However, an interrupt request or DMA request occurs only when the associated control field (IE[FWMIE0] and DE[FWMDE0]) is 1. This flag is cleared when the FCTRL0[FCOUNT] (which decrements on each read of the RESFIFO register) is less than or equal to the level set in FCTRL0[FWMARK]. 0b - Not above watermark 1b - Above watermark

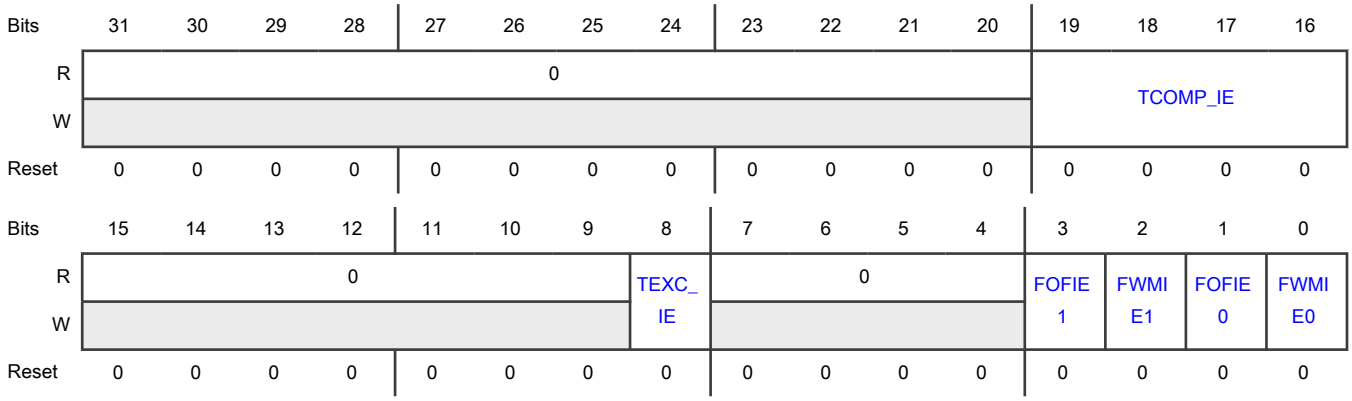
40.6.6 Interrupt Enable Register (IE)

Offset

Register	Offset
IE	18h

Function
Includes system interrupt masking control bits.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-16 TCOMP_IE	Trigger Completion Interrupt Enable Enables generation of interrupt requests to indicate when complete trigger command sequences are executed. Each bit in TCOMP_IE corresponds to a trigger source. (TCOMP_IE[0] corresponds to trigger 0, and so on.) All results are stored in the FIFO when a sequence is considered complete. 0000b - All disabled 0001b - Trigger completion interrupts are enabled for trigger source 0 only. 0010b - Trigger completion interrupts are enabled for trigger source 1 only. 0011b-1110b - Associated trigger completion interrupts are enabled. 1111b - All enabled
15-9 —	Reserved
8 TEXC_IE	Trigger Exception Interrupt Enable Enables ADC to assert an interrupt request when a high-priority trigger exception occurs. TSTAT[TEXC_NUM] contains the value of the corresponding trigger affected by the exception. 0b - Disabled 1b - Enabled
7-4 —	Reserved
3 FOFIE1	Result FIFO1 Overflow Interrupt Enable Enables generation of overflow interrupt requests when FOF1 flag is asserted.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
2 FWMIE1	FIFO1 Watermark Interrupt Enable Enables generation of watermark interrupt requests when STAT[RDY1] flag is asserted. 0b - Disabled 1b - Enabled
1 FOFIE0	Result FIFO 0 Overflow Interrupt Enable Enables generation of overflow interrupt requests when FOF flag is asserted. 0b - Disabled 1b - Enabled
0 FWMIE0	FIFO 0 Watermark Interrupt Enable Enables generation of watermark interrupt requests when STAT[RDY0] flag is asserted. 0b - Disabled 1b - Enabled

40.6.7 DMA Enable Register (DE)

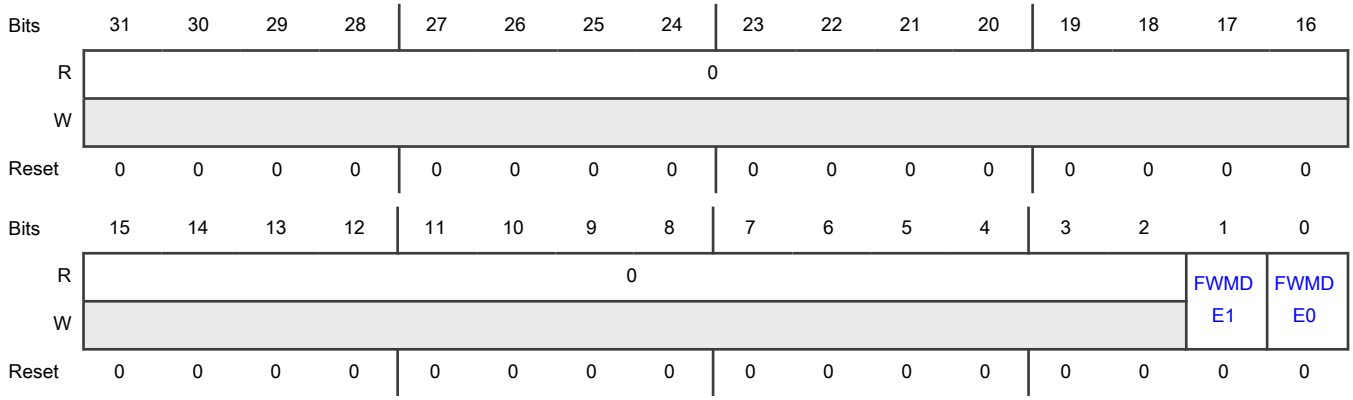
Offset

Register	Offset
DE	1Ch

Function

Includes DMA request-masking control bits.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 FWMDE1	FIFO1 Watermark DMA Enable Enables generation of DMA requests when STAT[RDY1] flag is asserted. 0b - Disabled 1b - Enabled
0 FWMDE0	FIFO 0 Watermark DMA Enable Enables generation of DMA requests when STAT[RDY0] flag is asserted. 0b - Disabled 1b - Enabled

40.6.8 Configuration Register (CFG)

Offset

Register	Offset
CFG	20h

Function

Controls ADC functions common to all commands. When CTRL[ADCEN] = 1, this register cannot be changed and writes to this register are ignored.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 —	Reserved
30 —	Reserved
29 —	Reserved
28 PWREN	ADC Analog Pre-Enable Enables the ADC analog circuits. When setting this field, user code should delay for a period exceeding the analog startup time of $t_{ADCSTUP}$ before enabling ADC for operation. The module is still operational even when this field is 0, but command execution start is delayed for a period defined by CFG[PUDLY]. See the device data sheet for ADC idle and active power consumption parameters. 0b - ADC analog circuits are only enabled while conversions are active. Analog startup delays affect performance. 1b - ADC analog circuits are pre-enabled and ready to execute conversions without startup delays, at the cost of higher DC current consumption. A single power-up delay (CFG[PUDLY]) is executed immediately once PWREN is set. No detected triggers begin ADC operation until the power-up delay time has passed. After this initial delay expires, the analog circuits remain pre-enabled, and no additional delays are executed.
27-24 —	Reserved
23-16 PUDLY	Power-up Delay Defines the power-up delay executed after an initial trigger wakes ADC from its idle state. Must be programmed to a non-zero value to enable the ADC. Depending on the value of CFG[PWREN], the delay is executed in one of two modes: • When CFG[PWREN] = 0, the ADC analog circuits are only powered on while the module is active. The power-up delay allows time for the analog circuits to stabilize after being powered on. The startup delay count of (PUDLY * 4) ADCK cycles must result in a longer delay than the analog startup time of $t_{ADCSTUP}$. Accuracy of the initial conversions after activation is degraded if CFG[PUDLY] is set to too small a value. After active conversions, if no subsequent conversions are pending, the ADC analog circuits are automatically reverted to their low-power idle state. When ADC is awakened with a later trigger, the power-up delay runs again. • When CFG[PWREN] = 1 prior to ADC activation, the analog circuits are pre-enabled and the activation delay defined by CFG[PUDLY] is executed immediately. After the delay has been executed, the analog circuits remain enabled regardless of ADC activity. This configuration begins conversions immediately after trigger event detection, at the cost of increased DC power consumption in the analog circuits.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE ADC does not begin an initial conversion until the power-up delay has executed, regardless of the value of CFG[PWREN].
15 —	Reserved
14-11 —	Reserved
10 HPT_EXDI	High-Priority Trigger Exception Disable Disables high-priority trigger exceptions. See Trigger detect and command execution for a detailed description on trigger exception handling. When 1, exceptions are disabled and CFG[TCMDRES], CFG[TRES], and CFG[TPRICTRL] are ignored. 0b - Enabled 1b - Disabled
9 TCMDRES	Trigger Command Resume Determines where a trigger sequence resumes when interrupted by a high-priority trigger exception. To use this field, CFG[TRES] must be 1. 0b - Trigger sequence automatically restarted. 1b - Trigger sequence resumed from the command that was executed prior to the exception.
8 TRES	Trigger Resume Enable Determines whether trigger sequences interrupted by a high-priority exception are automatically resumed or restarted. If 1, the sequence can be resumed along command boundaries or restarted from the beginning of a sequence, as determined by CFG[TCMDRES]. If 0, interrupted triggers can be resumed via software by monitoring STAT[TEXC_INT] (or via ISR handling for trigger exception interrupt when IE[TEXC_IE] = 1). Software determines which trigger was interrupted by reading TSTAT[TEXC_NUM] and restarts the trigger by writing 1 to the corresponding field in the SWTRIG register. 0b - Not automatically resumed or restarted 1b - Automatically resumed or restarted
7-6 REFSEL	Voltage Reference Selection Selects the voltage reference high used for conversions. **NOTE** See the chip-specific ADC information for voltage reference options specific to this packaged device.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - Option 1 01b - Option 2 10b - Option 3 11b - Reserved
5-4 PWRSEL	Power Configuration Select Configures the module for power and performance. In the high-power setting, the highest conversion rates are possible. See the device data sheet for power and performance capabilities for each setting. 0xb - Low power 1xb - High power
3-2 —	Reserved
1-0 TPRICTRL	ADC Trigger Priority Control Controls how higher-priority trigger exceptions are handled when they are received during command processing. See Trigger detect and command execution for a detailed explanation of trigger event handling. 00b - Current conversion is aborted and the new command specified by the trigger is started. 01b - Current command is stopped after completing the current conversion. If averaging is enabled, the averaging loop is completed. CMDHn[LOOP] is ignored and the higher-priority trigger is serviced. 10b - Current command is completed (averaging, looping, compare) before servicing the higher-priority trigger. 11b - Reserved

40.6.9 Pause Register (PAUSE)

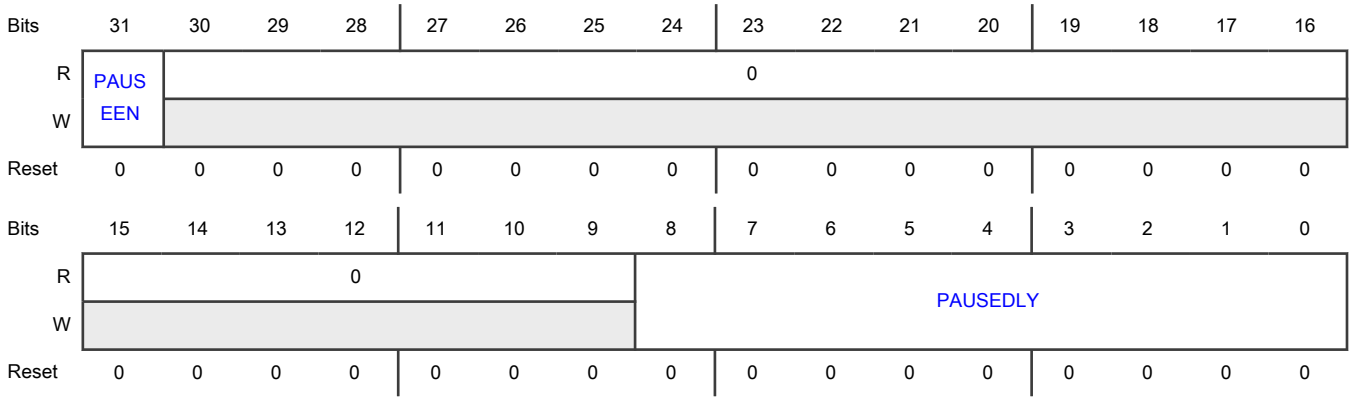
Offset

Register	Offset
PAUSE	24h

Function

Controls the optional inserted delay between conversions. When CTRL[ADCEN] = 1, this register should not be modified.

Diagram



Fields

Field	Function
31 PAUSEEN	Pause Enable Enables the ADC pausing function. When enabled, a programmable delay is inserted during command execution sequencing: • Between LOOP iterations. • Between commands in a sequence. • Between conversions, when a command is executing in compare-until-true configuration. **NOTE** CMDHn[WAIT_TRIG] and PAUSE are mutually exclusive. CMDHn[WAIT_TRIG] takes priority over PAUSE between commands when both are enabled. 0b - Disabled 1b - Enabled
30-9 —	Reserved
8-0 PAUSEDLY	Pause Delay Controls the duration of pauses during command execution sequencing when PAUSE[PAUSEEN] = 1. The pause delay is a count of (PAUSEDLY * 4) ADCK cycles.

40.6.10 Software Trigger Register (SWTRIG)

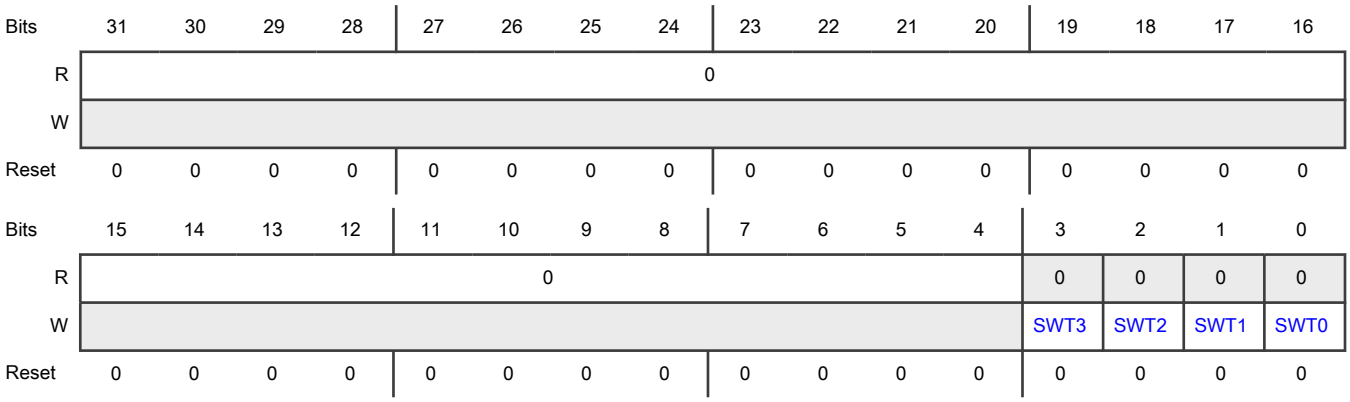
Offset

Register	Offset
SWTRIG	34h

Function

Initiates software-triggered conversions when written to. Writes to this register are ignored while CTRL[ADCEN] = 0. There is an approximately three ADC-clock-cycle synchronization delay between asserting CTRL[ADCEN] and when SWTRIG can be accepted.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 SWT3	Software Trigger 3 Write 1 to SWT3 generates a trigger 3 event. Writing 1 to SWT3 is ignored while the trigger 3 event is being serviced or is pending. 0b - No trigger 3 event generated. 1b - Trigger 3 event generated.
2 SWT2	Software Trigger 2 Write 1 to SWT2 generates a trigger 2 event. Writing 1 to SWT2 is ignored while the trigger 2 event is being serviced or is pending. 0b - No trigger 2 event generated. 1b - Trigger 2 event generated.
1 SWT1	Software Trigger 1 Write 1 to SWT1 generates a trigger 1 event. Writing 1 to SWT1 is ignored while the trigger 1 event is being serviced or is pending. 0b - No trigger 1 event generated. 1b - Trigger 1 event generated.
0 SWT0	Software Trigger 0 Generates a trigger 0 event. Writing 1 to this field is ignored while the trigger 0 event is being serviced or is pending.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No trigger 0 event generated. 1b - Trigger 0 event generated.

40.6.11 Trigger Status Register (TSTAT)

Offset

Register	Offset
TSTAT	38h

Function

Contains status flags to indicate when trigger sequences have been completed or interrupted by a high-priority trigger exception. Each field in this register is set by hardware and cleared by software.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0												TCOMP_FLAG

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0												TEXC_NUM			
W													W1C			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-20 —	Reserved
19-16 TCOMP_FLAG	Trigger Completion Flag Indicates which triggers have been completed. Each bit in this field corresponds to a trigger. When a trigger sequence has completed, the corresponding bit in TCOMP_FLAG is set. For example, if trigger 3 has been completed, then bit 19 is set in the TSTAT register. This register is active only if the corresponding bit in IE[TCOMP_IE] = 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE A synchronization delay may be added to the end of the final conversion in a sequence, prior to this flag being set. This delay can range from two to four ADC CLK cycles. 0000b - No triggers have been completed. Trigger completion interrupts are disabled. 0001b - Trigger 0 has been completed and trigger 0 has enabled completion interrupts. 0010b - Trigger 1 has been completed and trigger 1 has enabled completion interrupts. 0011b-1110b - Associated trigger sequence has completed and has enabled completion interrupts. 1111b - Every trigger sequence has been completed and every trigger has enabled completion interrupts.
15-4 —	Reserved
3-0 TEXC_NUM	Trigger Exception Number Indicates which triggers have been interrupted by exceptions. Each bit in this field corresponds to a trigger. When the corresponding trigger sequence is interrupted by a high-priority trigger exception, the corresponding bit is set. For example, if trigger 3 has been interrupted, then bit 3 is set in this register. This register is active regardless of the value in IE[TEXC_IE]. 0000b - No triggers have been interrupted by a high-priority exception. Or CFG[TRES] = 1. 0001b - Trigger 0 has been interrupted by a high-priority exception. 0010b - Trigger 1 has been interrupted by a high-priority exception. 0011b-1110b - Associated trigger sequence has interrupted by a high-priority exception. 1111b - Every trigger sequence has been interrupted by a high-priority exception.

40.6.12 Offset Trim Register (OFSTRIM)

Offset

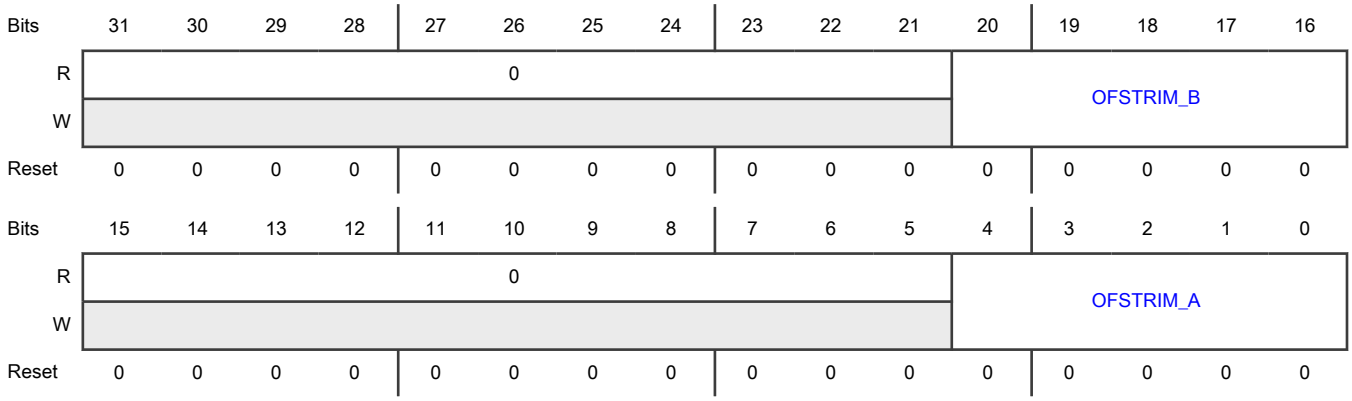
Register	Offset
OFSTRIM	40h

Function

Used to trim for offset. ADC supports a calibration step in which the ADC determines the value needed in the OFSTRIM register.

To determine the value to put in the OFSTRIM register, write 1 to CTRL[CALOFS]. This setting automatically begins a sequence to calculate this value. Once the sequence has completed, the OFSTRIM register is updated with a signed value between -16 and 15. This value is used to minimize offset during normal operation.

Diagram



Fields

Field	Function
31-21 —	Reserved
20-16 OFSTRIM_B	Trim for Offset OFSTRIM is a 5-bit signed value between -16 and 15. This value applies to the ADC B-side conversion results.
15-5 —	Reserved
4-0 OFSTRIM_A	Trim for Offset OFSTRIM_A is a 5-bit signed value between -16 and 15. This value applies to the ADC A-side conversion results.

40.6.13 Trigger Control Register (TCTRL0 - TCTRL3)

Offset

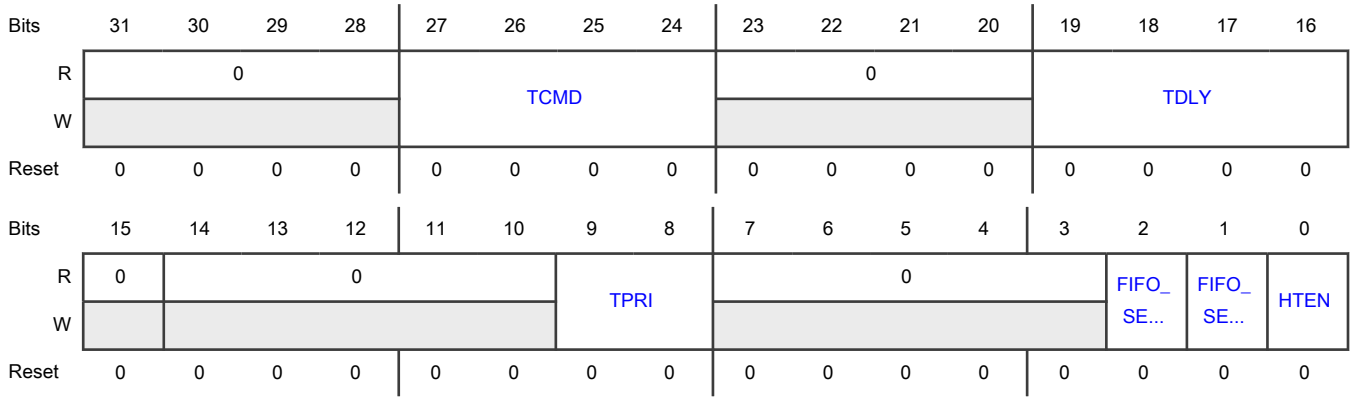
Register	Offset
TCTRL0	A0h
TCTRL1	A4h
TCTRL2	A8h
TCTRL3	ACh

Function

Implements control fields associated with each trigger source. When ADC is executing commands, only one TCTRLn register controls ADC conversions.

Do not update the controlling TCTRLn register while ADC is active. Writing to a TCTRLn register while that trigger control register controls the ADC operation may cause unpredictable behavior.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 TCMD	Trigger Command Select Selects the command from the command buffer to execute upon detection of the associated trigger event. When a higher-priority trigger is received while ADC is converting, the command in this register associated with the new trigger is executed. This execution is done under the control of CFG[TPRICTRL]. See Trigger detect and command execution for details about the relationship between CFG[TPRICTRL] and TCMD. 0000b - Not a valid selection from the command buffer. Trigger event is ignored. 0001b - CMD1 0010b-1110b - Corresponding CMD is executed 1111b - CMD15
23-20 —	Reserved
19-16 TDLY	Trigger Delay Select Selects the trigger delay duration for the start of servicing a trigger event. Each trigger source has an associated programmable delay prior to beginning an initial conversion. When this field is 0, no delay is incurred. When this field is set to a non-zero value, the duration of the delay is 2^{TDLY} ADCK cycles.
15 —	Reserved
14-10 —	Reserved
9-8	Trigger Priority Setting

Table continues on the next page...

Table continued from the previous page...

Field	Function
TPRI	Sets the priority of the associated trigger source. If two or more triggers have the same priority level, the lower-order trigger event has the higher priority. If Trigger 0 and Trigger 1 are pending triggers and TCTRL0[TPRI] is configured the same as TCTRL1[TPRI], the Trigger 0 command is serviced first. 00b - Highest priority, Level 1 01b-10b - Set to corresponding priority level. 11b - Lowest priority, Level 4
7-3 —	Reserved
2 FIFO_SEL_B	SAR Result Destination for Channel B Indicates the FIFO to which SAR results are written for Channel B. This field is only used in dual single-ended mode (CMDLn[CTYPE] = 11b). In this mode, the SAR result from Channel B is written to the FIFO number specified by this field. See Sampling Modes for more information. 0b - FIFO 0 1b - FIFO 1
1 FIFO_SEL_A	SAR Result Destination for Channel A Indicates the FIFO to which SAR results are written for Channel A. This field provides the destination for all single-ended and differential conversions and for all A-side conversions in dual single-ended mode. Conversion results are stored in the FIFO number specified, under the following conditions: • Single-ended mode: CMDLn[CTYPE] = 00b or CMDLn[CTYPE] = 01b. • Differential mode: CMDLn[CTYPE] = 10b. • Dual single-ended mode: CMDLn[CTYPE] = 11b. 0b - FIFO 0 1b - FIFO 1
0 HTEN	Trigger Enable Enables hardware trigger source to initiate conversion on the rising edge of the input trigger source. **NOTE** Enabling the hardware trigger does not disable software triggers. 0b - Disabled 1b - Enabled

40.6.14 FIFO Control Register (FCTRL0 - FCTRL1)

Offset

Register	Offset
FCTRL0	E0h
FCTRL1	E4h

Function

Contains control and status fields for each FIFO in the design. A programmable watermark can be set for each FIFO, which can be used to trigger an interrupt. In addition, the number of entries stored in each FIFO can be monitored by reading FCTRLn[FCOUNT].

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0												FWMARK			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0												FCOUNT			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-20 —	Reserved
19-16 FWMARK	Watermark Level Selection Selects the storage threshold for the ADC Result FIFO. When the number of data words stored in the FIFO is greater than this value, the STAT[RDY0] flag is asserted. When IE[FWMIEn] = 1, an interrupt request is generated. When DE[FWMDEn] = 1, a DMA request is generated.
15-5 —	Reserved
4-0 FCOUNT	Result FIFO Counter Indicates the number of data words stored in the result FIFO. This value may be used with PARAM[FIFOSIZE] to calculate how much room is left in the result FIFO. This field is incremented with each storage of new data into the result FIFO and decrements with each read of the result FIFO. The FIFO is reset by writing to CTRL[RSTFIFOn], which initializes FCTRLn[FCOUNT] to 0h.

40.6.15 Gain Calibration Control (GCC0 - GCC1)

Offset

Register	Offset
GCC0	F0h
GCC1	F4h

Function

Holds intermediate values used as part of the calibration steps. GCC0 is associated with the A-side converter and GCC1 is associated with the B-side converter. GCCn[GAIN_CAL] is calculated with hardware and automatically updated during the calibration steps. Once the hardware calibration sequence has updated, GCCn[RDY] is asserted automatically.

Requesting a calibration routine automatically clears the GCCn[RDY] flag until the new GCCn[GAIN_CAL] value is calculated. To complete calibration, further software processing is needed, where GCCn[GAIN_CAL] is used to calculate the gain adjustment. The result is stored to GCRn[GCALR]. See Calibration functions.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0							RDY	0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	GAIN_CAL															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-25 —	Reserved
24 RDY	Gain Calibration Value Valid Indicates whether the data stored in GCCn[GAIN_CAL] is valid and should be used to derive GCRn[GCALR]. If the data in GCCn[GAIN_CAL] is invalid, you can run the hardware calibration routine to correct this issue. 0b - Invalid 1b - Valid
23-16	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
15-0 GAIN_CAL	Gain Calibration Value Indicates the calculated value of the gain calibration. As part of the hardware calibration steps, this field is automatically updated with a 16-bit unsigned number. It is used in the gain adjustment calculations to derive the value written to GCRn[GCALR]. See Calibration functions.

40.6.16 Gain Calculation Result (GCR0 - GCR1)

Offset

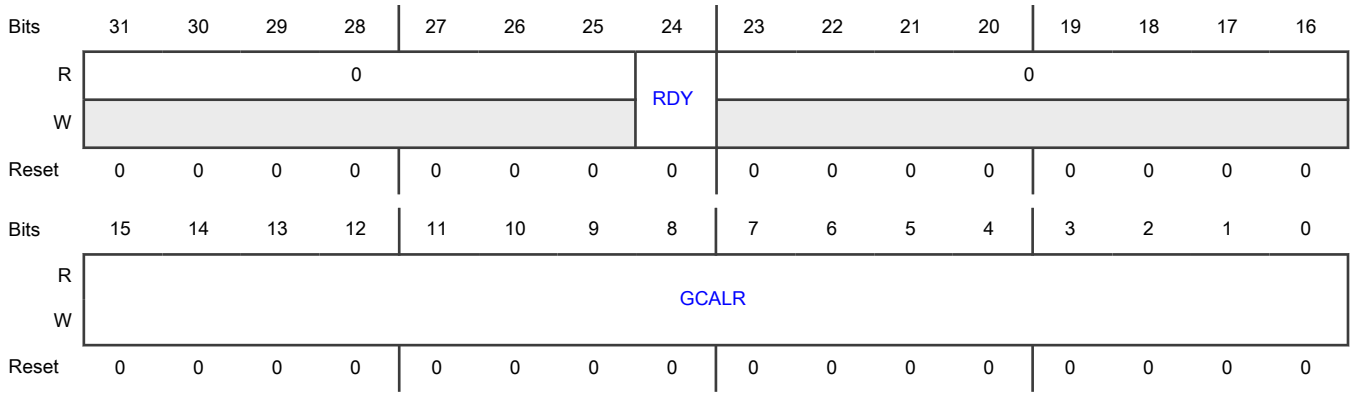
Register	Offset
GCR0	F8h
GCR1	FCh

Function

Used during ADC conversions for automated gain error adjustment. GCR0 is associated with the A-side converter and GCR1 is associated with the B-side converter. Determining the values to store to GCR0[GCALR] and GCR1[GCALR] is the result of software calculations described in setup steps in Calibration functions. Upon writing the GCRn[GCALR] value, the user should also write 1 to GCRn[RDY] to indicate that the gain adjustment result is valid.

A calibration sequence begins by writing 1 to CTRL[CAL_REQ], and the calibration sequence is not complete until GCRn[GCALR] is calculated and GCRn[RDY] is 1. The gain adjustment calculation produces a floating-point value between 1 and 2. GCRn[GCALR] holds the 16-bit fractional component of the gain adjustment calculation. To convert the GCRn[GCALR] value to the gain adjustment value in decimal format, use this formula: 1 + 0.5 * GCRn[15] + 0.25 * GCRn[14] + 0.125 * GCRn[13] + (and so on)

Diagram



Fields

Field	Function
31-25 —	Reserved
24 RDY	Gain Calculation Ready Indicates whether the data stored in GCRn[GCALR] is valid and is used for gain adjustment. GCRn[GCALR] must be written from memory or calculated each time the calibration routine is run. The user must write 1 to this GCRn[RDY] after writing valid data to GCRn[GCALR]. This field becomes 0 automatically when requesting a new calibration sequence. 0b - Invalid 1b - Valid
23-16 —	Reserved
15-0 GCALR	Gain Calculation Result Holds the 16-bit fractional component generated from the gain adjustment calculation during the auto-calibration routine.

40.6.17 Command Low Buffer Register (CMDL1 - CMDL15)

Offset

For a = 1 to 15:

Register	Offset
CMDLa	F8h + (a × 8h)

Function

Controls channel selection and conversion options. There are 15 command buffers (CMDn), each constructed from two 32-bit registers (CMDHn:CMDLn) that can be configured for different channel selection and varying conversion options. Any command buffer is selected and used as the controlling command by association with a trigger event via configuration of TCTRLn[TCMD]. When ADC is executing commands, only one of the CMD buffers controls ADC conversions. Do not update the controlling CMD buffer while ADC is active. A write to a CMD buffer while that CMD buffer controls the ADC operation may cause unpredictable behavior.

NOTE

The 15 command buffers are numbered [CMDH1:CMDL1] through [CMDH15:CMDL15]. In NXP-supplied header files, these buffers are likely to be defined as two 15-element arrays that are indexed from 0. For example, the type declaration would be:

```
unsigned int CMDH[15];
unsigned int CMDL[15];
```

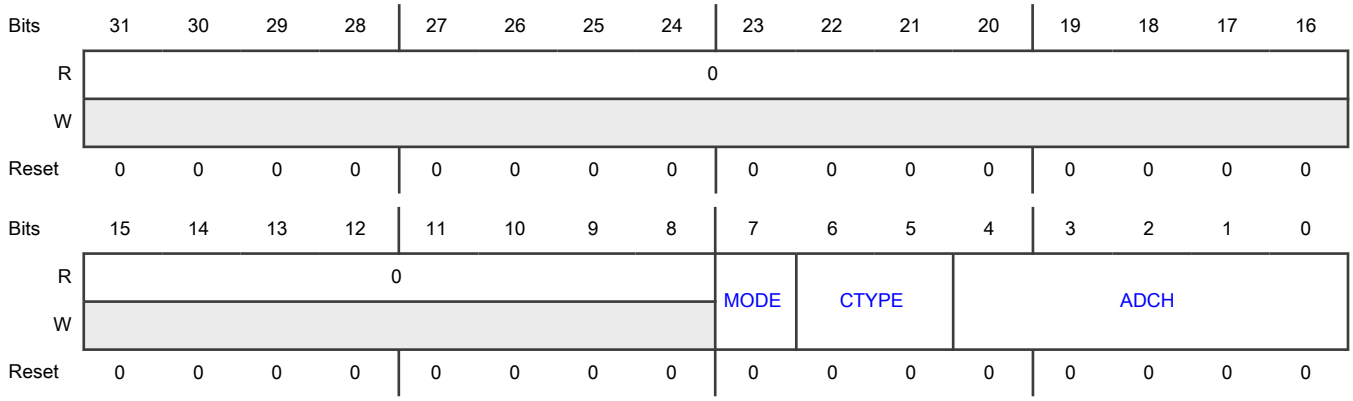
and software would access ADC0 CMDH1 as `ADC0->CMDH[0]` and ADC0 CMDL15 as `ADC0->CMDL[14]`.

The CMDLn[ADCH] and CMDLn[CTYPE] fields control selection of paired or individual input channels. Each ADC command independently makes a channel and conversion type selection. Each ADCH channel selection has an associated A-side and B-side input. Each ADCH pair can be converted in differential mode, but only limited pairs should be converted as differential channels (for example, adjacent pins designed with matched impedance). For the pin pairings available for differential conversions for your device, see the Chip Configuration details.

NOTE

Some input channels are from on-chip sources such as temperature sensors and reference voltage sources and may only be connected to individual instances of ADC. Some input channel options in the field descriptions may not be available for your device. See the chip-specific information for the channels supported on this device.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 —	Reserved
7 MODE	Select Resolution of Conversions Selects the ADC resolution. 0b - Standard resolution. Single-ended 12-bit conversion; differential 13-bit conversion with 2's complement output. 1b - High resolution. Single-ended 16-bit conversion; differential 16-bit conversion with 2's complement output.
6-5 CTYPE	Conversion Type Chooses how a pair of A and B channels are converted. 00b - Single-Ended mode. Only A-side channel is converted. 01b - Single-Ended mode. Only B-side channel is converted.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - Differential mode. A-B. 11b - Dual-Single-Ended mode. Both A-side and B-side channels are converted independently.
4-0 ADCH	Input Channel Select Selects the input from one of the channel inputs or one of the input pairs, with CMDLn[CTYPE]. Each ADCH channel selection has an associated A-side and B-side input. **NOTE** Not all pairs should be converted as differential channels. See the chip-specific information for the pin pairings available for differential conversions for your device. **NOTE** Some input channels are from internal resources such as temperature sensors and band gap voltage sources and may only be connected to individual instances of ADC. Some input channel options in field descriptions might not be available for your device. See the chip-specific information for the ADC channel assignments for your device. 0_0000b - CH0A or CH0B or CH0A/CH0B pair. 0_0001b - CH1A or CH1B or CH1A/CH1B pair. 0_0010b - CH2A or CH2B or CH2A/CH2B pair. 0_0011b - CH3A or CH3B or CH3A/CH3B pair. 0_0100b-1_1101b - Select corresponding channel CHnA or CHnB or CHnA/CHnB pair. 1_1110b - CH30A or CH30B or CH30A/CH30B pair. 1_1111b - CH31A or CH31B or CH31A/CH31B pair.

40.6.18 Command High Buffer Register (CMDH1 - CMDH15)

Offset

For a = 1 to 15:

Register	Offset
CMDHa	FCh + (a × 8h)

Function

Controls channel selection and conversion options. There are 15 command buffers (CMDn), each constructed from two 32-bit registers (CMDHn:CMDLn) that can be configured for different channel selection and conversion options. Any command buffer is selected and used as the controlling command by association with a trigger event via configuration of TCTRLn[TCMD]. When ADC is executing commands, only one of the CMD buffers controls ADC conversions. Do not update the controlling CMD buffer while ADC is active. A write to a CMD buffer while that CMD buffer controls the ADC operation may cause unpredictable behavior.

NOTE

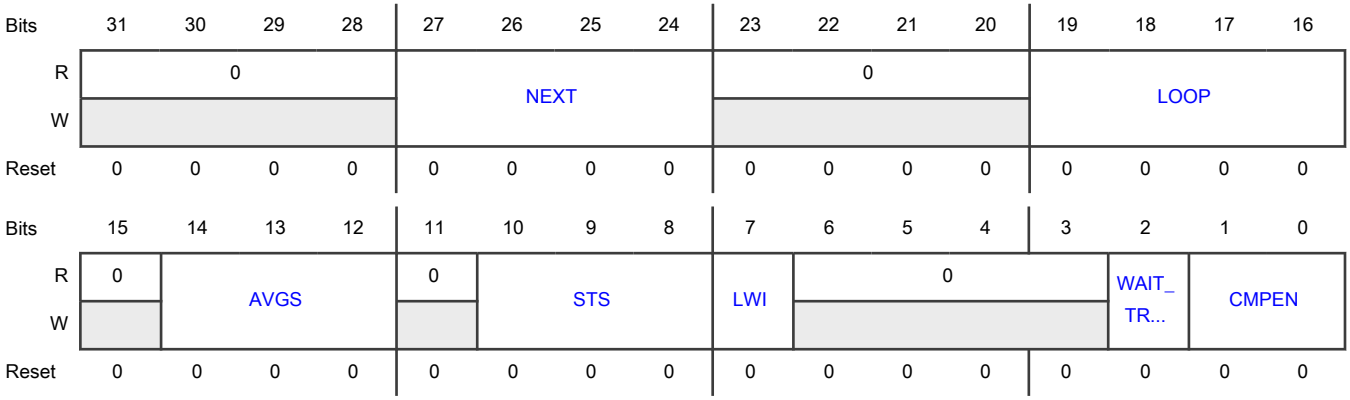
The 15 command buffers are numbered [CMDH1:CMDL1] through [CMDH15:CMDL15]. In NXP-supplied header files, these buffers are likely to be defined as two 15-element arrays that are indexed from 0. For example, the type declaration would be:

```
unsigned int CMDH[15];

unsigned int CMDL[15];
```

and software would access ADC0 CMDH1 as `ADC0->CMDH[0]` and ADC0 CMDL15 as `ADC0->CMDL[14]`.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 NEXT	Next Command Select Selects the next command to be executed after this command completes. Multiple commands can be configured in a scan configuration by linking the next command in a daisy-chain sequence. The command buffer number is not indicative of any particular order. The order of execution is strictly controlled by this field. For example, a sequence of commands could be CMD2 to CMD1 to CMD3. Unending circular command execution can be configured by setting the NEXT field in the last command in a sequence to the first command in the sequence. It is also allowed for a command to set the next command to itself, resulting in a continuous conversion configuration. Setting the next command to 0h causes conversions to terminate at the completion of the command. Lower-priority trigger events cannot be serviced until a higher-priority triggered command (or sequence of commands) completes. 0000b - No next command defined. Terminate conversions at completion of current command. If lower priority trigger pending, begin command associated with lower priority trigger. 0001b - CMD1 0010b-1110b - Select corresponding CMD command buffer register as next command 1111b - CMD15
23-20	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
19-16 LOOP	Loop Count Select Selects the number of times that this command executes (and stores conversion result to RESFIFO) before finishing and transitioning to the next command or idle state. CMDHn[LWI] controls whether a single channel is converted on each iteration or an automatic channel increment results in channel scanning functionality. 0000b - Looping not enabled. Command executes one time. 0001b - Loop one time. Command executes two times. 0010b - Loop two times. Command executes three times. 0011b-1110b - Loop corresponding number of times. Command executes LOOP + 1 times. 1111b - Loop 15 times. Command executes 16 times.
15 —	Reserved
14-12 AVGS	Hardware Average Select Selects how many ADC conversions are averaged to create the ADC result (2^{AVGS}). An internal storage buffer captures temporary results while the averaging iterations are executed. Hardware averaging is a nested loop control and does not extend across LOOP boundaries. See Functional description for usage of AVGS, LOOP, and NEXT fields in command execution sequencing. 000b - Single conversion 001b - 2 010b - 4 011b - 8 100b - 16 101b - 32 110b - 64 111b - 128
11 —	Reserved
10-8 STS	Sample Time Select Selects the total sampling time. When this field contains a non-zero value, the sample time is ($3.5 + 2^{STS}$) ADCK cycles. The shortest sample time maximizes conversion speed for lower-impedance inputs. Extending sample time allows higher-impedance inputs to be sampled accurately. Longer sample times can lower overall power consumption when command looping and sequencing are configured and high conversion rates are not required. 000b - Minimum sample time of 3.5 ADCK cycles.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	001b - 5.5 ADCK cycles. (3.5 + 2^1 ADCK cycles) 010b - 7.5 ADCK cycles. (3.5 + 2^2 ADCK cycles) 011b - 11.5 ADCK cycles. (3.5 + ^{3} ADCK cycles) 100b - 19.5 ADCK cycles. (3.5 + 2^4 ADCK cycles) 101b - 35.5 ADCK cycles. (3.5 + 2^5 ADCK cycles) 110b - 67.5 ADCK cycles. (3.5 + 2^6 ADCK cycles) 111b - 131.5 ADCK cycles. (3.5 + 2^7 ADCK cycles)
7 LWI	Loop with Increment Enables automatic channel incrementing. When 0, the LOOP field selects the number of times the selected channel is converted consecutively. When 1, automatic channel incrementing is enabled and the LOOP field defines how many consecutive channels are converted as part of the command execution. Example 1: LOOP = 8h, LWI = 0b, CMDLn[CTYPE] = 0h, CMDLn[ADCH] = Dh. Convert on channel 13A 9 times. Example 2: LOOP = 8h, LWI = 1b, CMDLn[CTYPE] = 0h, CMDLn[ADCH] = Dh. Run channels 13A-21A each one time. Maximum channel scanning using a single command buffer is defined by the maximum value of the LOOP field (16). 0b - Disabled 1b - Enabled
6-3 —	Reserved
2 WAIT_TRIG	Wait for Trigger Assertion Before Execution Selects whether commands execute automatically or a trigger must be received before execution. When 0, wait states are added before the command until the active trigger is asserted again. When WAIT_TRIG = 0, each command is automatically executed when called. 0b - Command executes automatically. 1b - Active trigger must be asserted again before executing this command.
1-0 CMPEN	Compare Function Enable Enables the automatic compare function. Selects whether to store only when the comparison operation is true, following ADC channel input sampling, conversion, and averaging. When the compare function is enabled, the conversion result is compared to the compare value registers (CVn[CVH] and CVn[CVL]). See Compare Function for details about the options for command sequencing related to the compare function. 00b - Disabled 01b - Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - Enabled. Store on true. 11b - Enabled. Repeat channel acquisition (sample, convert, and compare) until true.

40.6.19 Compare Value Register (CV1 - CV15)

Offset

For a = 1 to 15:

Register	Offset
CVa	1FCh + (a × 4h)

Function

Contains values used to compare the conversion result when the compare function is enabled. This register is formatted like the D field in Data Result FIFO Register (RESFIFO0 - RESFIFO1), which has in different definitions for bit position and value format in different modes. There is a direct association of each compare value register to a specific command buffer register. For example, CV1 is only used during execution of CMD1 command.

When ADC is executing commands, do not update the CVn register associated with the active command (CMDn). Writes to associated CVn register during this time may result in unpredictable behavior.

NOTE

The 15 compare value registers are numbered [CV1] through [CV15]. In NXP-supplied header files, these registers are likely to be defined as a 15-element array indexed from 0. For example, the type declaration would be:

```
unsigned int CV[15];
```

and software would access ADC0 CV1 as `ADC0->CV[0]` and ADC0 CV15 as `ADC0->CV[14]`.

R W	CVL															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 CVH	Compare Value High Determines the high compare value. The compare function can be configured to check whether the result: • Is less than comparison values • Is greater than comparison values • Falls within a range of two comparison values • Falls outside a range of two comparison values. After the input is sampled and converted and any averaging iterations are performed, CVL and CVH can be used in a compare operation on the result. See Compare Function for a description of CVH usage.
15-0 CVL	Compare Value Low Determines the low compare value. The compare function can be configured to check whether the result: • Is less than comparison values • Is greater than comparison values • Falls within a range of two comparison values • Falls outside a range of two comparison values. After the input is sampled and converted and any averaging iterations are performed, CVL and CVH can be used in a compare operation on the result. See Compare Function for a description of CVL usage.

40.6.20 Data Result FIFO Register (RESFIFO0 - RESFIFO1)

Offset

Register	Offset
RESFIFO0	300h
RESFIFO1	304h

Function

Stores the data result of ADC conversions in a 16-entry FIFO. Several tag fields of source command and trigger information are stored with the data. FCTRLn[FCOUNT] indicates how many valid data words are stored in the RESFIFO. Reading RESFIFO provides the oldest unread data word entry in the FIFO and decrements FCTRLn[FCOUNT]. The FIFO can be emptied by successive reads of RESFIFO. The FIFO is reset by writing 0b1 to CTRL[RSTFIFOn].

The following table describes the format of data in the result FIFO in different modes of operation. The sign bit is the MSB in signed 2's complement modes. For example, when configured for 12-bit single-ended mode, D[15] and D[2:0] become 0. When configured for 13-bit differential mode, D[15] is the sign bit, and D[2:0] becomes 0.

Table 251. Data result register format description

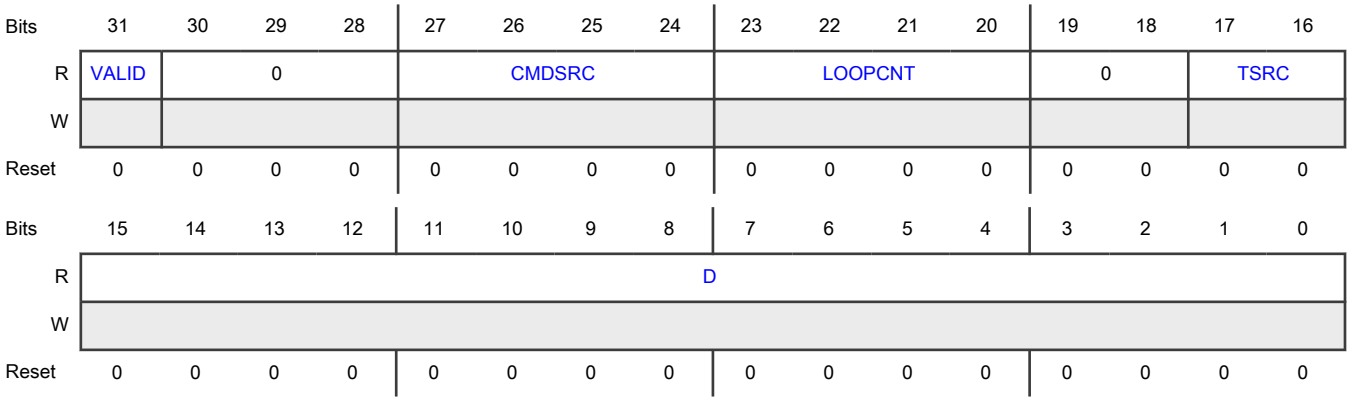
Conversion mode	D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0	Format
16-bit differential	S	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	Signed 2's complement
16-bit single-ended	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	Unsigned, 16-bit magnitude
13-bit differential	S	D	D	D	D	D	D	D	D	D	D	D	D	0	0	0	Signed 2's complement, left justified, zero extended
12-bit single-ended	0	D	D	D	D	D	D	D	D	D	D	D	D	0	0	0	Unsigned, zero in D[15] and D[2:0]

NOTE

S: Sign bit;

D: Data, 2's complement data when indicated

Diagram



Fields

Field	Function
31 VALID	FIFO Entry is Valid Indicates whether the FIFO entry is valid, which determines what happens to reads from RESFIFO. 0b - FIFO is empty. Discard any read from RESFIFO. 1b - FIFO contains data. FIFO record read from RESFIFO is valid.
30-28 —	Reserved
27-24	Command Buffer Source

Table continues on the next page...

Table continued from the previous page...

Field	Function
CMDSRC	Indicates the executed command buffer that generated this result. 0000b - Not a valid value CMDSRC value for a data word in RESFIFO. 0h is only found in the initial FIFO state, prior to the storage of an ADC conversion result into a RESFIFO buffer. 0001b - CMD1 0010b-1110b - Corresponding command buffer used as control settings for this conversion. 1111b - CMD15
23-20 LOOPCNT	Loop Count Value Indicates the loop count value during the command that generated this result. When CMDHn[LOOP] is non-zero, results are stored multiple times during command execution at the loop boundary. 0000b - Result is from initial conversion in command. 0001b - Result is from second conversion in command. 0010b-1110b - Result is from (LOOPCNT + 1) conversion in command. 1111b - Result is from 16th conversion in command.
19-18 —	Reserved
17-16 TSRC	Trigger Source Indicates the trigger source that initiated a conversion and generated this result. When multiple commands are chained together using CMDHn[NEXT], this field indicates the trigger source that started the command sequence. 00b - Trigger source 0 01b - Trigger source 1 10b-10b - Corresponding trigger source initiated this conversion. 11b - Trigger source 3
15-0 D	Data Result Contains the result of an ADC conversion. The formatting for the data in D is summarized in Table 251.

40.6.21 Calibration General A-Side Registers (CAL_GAR0)

Offset

Register	Offset
CAL_GAR0	400h

Function

Corrects for linearity errors of the A-side converter. All 33 A-side general calibration value registers (CAL_GAR0-CAL_GAR32) contain calibration information that is automatically updated during the self-calibration sequence. See Calibration functions for more information on completing ADC calibration steps.

The calibration values in the CAL_GAR registers affect the conversion result by conditionally being subtracted from the conversion before the result is transferred into the FIFOs. Calibration must be run each time ADC is powered down or a hard reset is issued. To reduce the latency required to run calibration, the CAL_GAR values can be stored in non-volatile memory after an initial calibration. These values can be recovered prior to the first ADC conversion. If these registers are set to values not generated by the calibration function, the linearity error specifications may not be met.

The CAL_GAR registers are only read-and-write accessible when ADC is disabled with CTRL[ADCEN] = 0. Access time when writing to these registers is larger than three ADC clock cycles. Wait states are inserted on the bus to meet synchronization timing to the associated CAL_GAR register. The width of each register in this array is non-uniform. The exact width of each register is summarized in Calibration General A-Side and B-Side Widths.

Chapter 41
Low Power Comparator (LPCMP)

41.1 Chip-specific LPCMP information

Table 252. Reference links to related information

Topic	Related module	Reference
Full description	LPCMP	LPCMP
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

41.1.1 Module instances

This device has two instances of the LPCMP module, LPCMP0 and LPCMP1.

41.1.2 Input connections

Table 253. Input connections

Index	CMP0	CMP1	Description
0	CMP0_IN0	CMP1_IN0	Pinned out in VDD_IO
1	—	CMP1_IN1	VDD_IO domain
2	CMP0_IN2	—	VDD_IO domain
3	CMP0_IN3	—	VDD_IO domain
4	PMC BG	PMC BG	VDD_SYS domain
5	VREFO	VREFO	VDD_ANA domain
7	CMP0 8-bit DAC	CMP1 8-bit DAC	Internal DAC

41.1.3 VREFH_EXT

The DCR[VRSEL] is used to configure the VREFH_EXT:

- VRSEL=0, VREFH0 is selected, which is VDD_IO_ABC
- VRSEL=1, VREFH1 is selected, which is VREF_OUT (must be in VREFH / VDD_ANA domain)

41.2 Overview

The LPCMP module provides a circuit to compare two analog input voltages. It includes the following:

- A comparator (CMP)
- A DAC
- An analog mux (ANMUX)

See Block diagram for more information.

CMP can operate across the full range of the supply voltage, known as rail-to-rail operation.

DAC is a 256-tap resistor ladder network that provides a selectable voltage reference for applications requiring a voltage reference. DAC divides the supply reference V_{in} into 256 voltage levels. An 8-bit digital signal input selects the output voltage level, which varies from V_{in} to $V_{in}/256$.

You can select V_{in} from the following voltage sources:

- vrefh0
- vrefh1

See the chip-specific LPCMP information for more information on source of vrefh0 and vrefh1.

NOTE

The LPCMP's internal DAC output is available as an on-chip internal signal only and is not available for an external chip pin.

ANMUX allows you to select an analog input signal from among eight channel options. One channel option is the DAC output. Other chip resources are connected to the other channels. See the chip-specific LPCMP information section for more information. ANMUX can operate across the full range of the supply voltage.

41.2.1 Block diagram

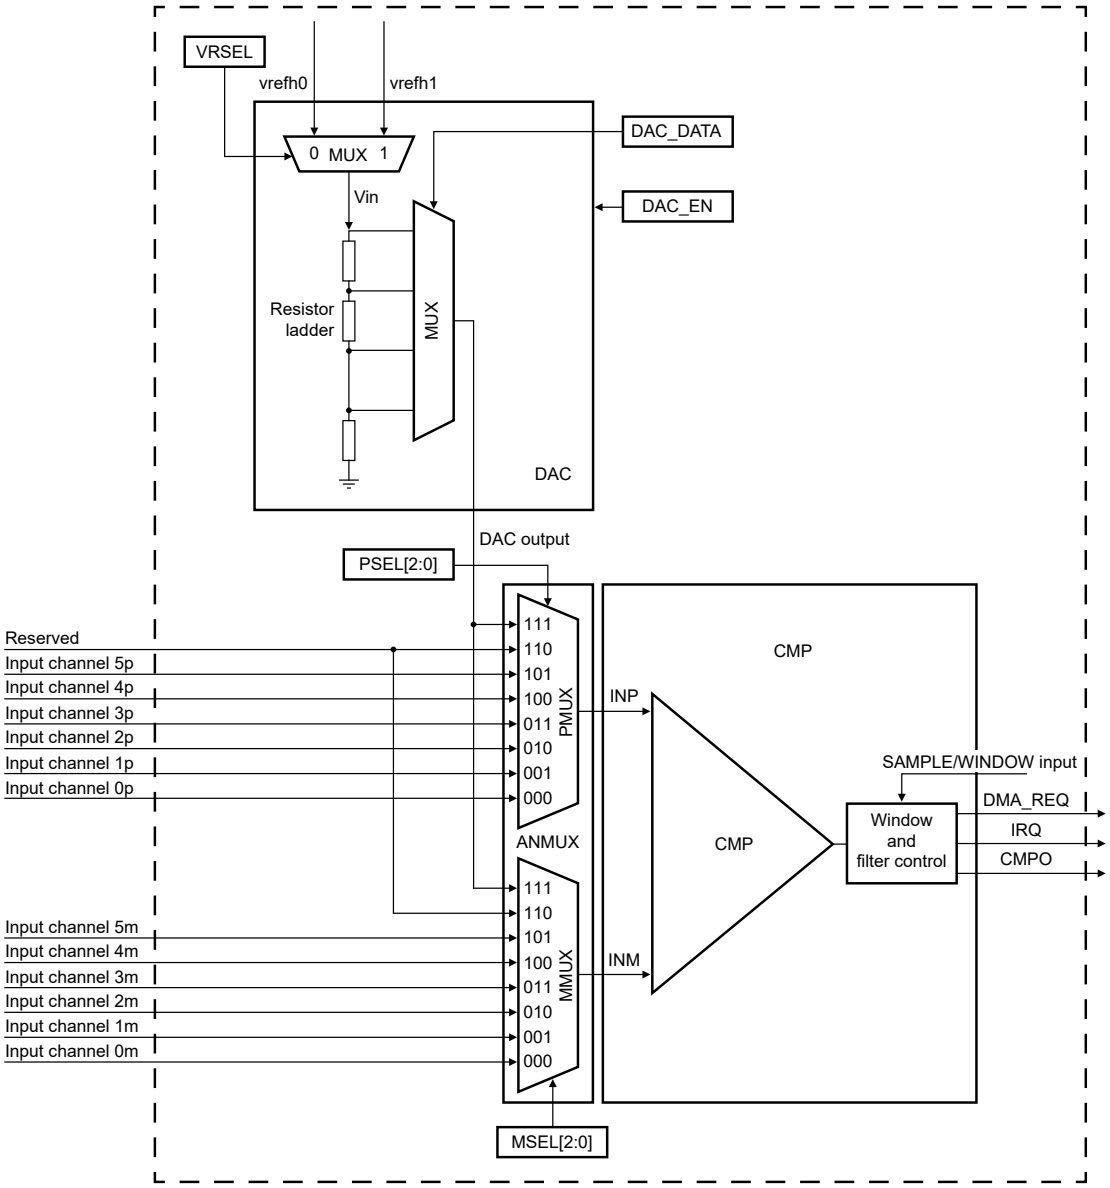

Figure 109. Block diagram

41.2.2 Features

The features of the LPCMP module include：

- Includes two 8-to-1 channel MUXes to select input signal from eight channels
- Supports multiple operation modes to produce a wide range of outputs such as:
  - Sampled
  - Windowed, which is ideal for certain PWM zero-crossing-detection applications
  - Digitally filtered
- Provides the following advance features for window and sample:

- Window and sample signals can be inverted.
- CMPO rising, falling or both edges closes the window.
- CMPO level can be defined when window is closed.

- Provides selectable performance levels:
  - Nano-Power mode
  - Low-Power (speed) mode
  - High-Power (speed) mode
- Supports programmable hysteresis control
- Provides a selectable inversion on comparator output
- Uses an external hysteresis at the same time the output filter is used for internal functions
- Provides interrupt and DMA support
- Includes an 8-bit resolution DAC
- Provides a selectable supply reference source for DAC
- Provides a configurable Low-Power (speed) mode or High-Power (speed) mode for DAC

41.3 Functional description

41.3.1 Functional block diagram

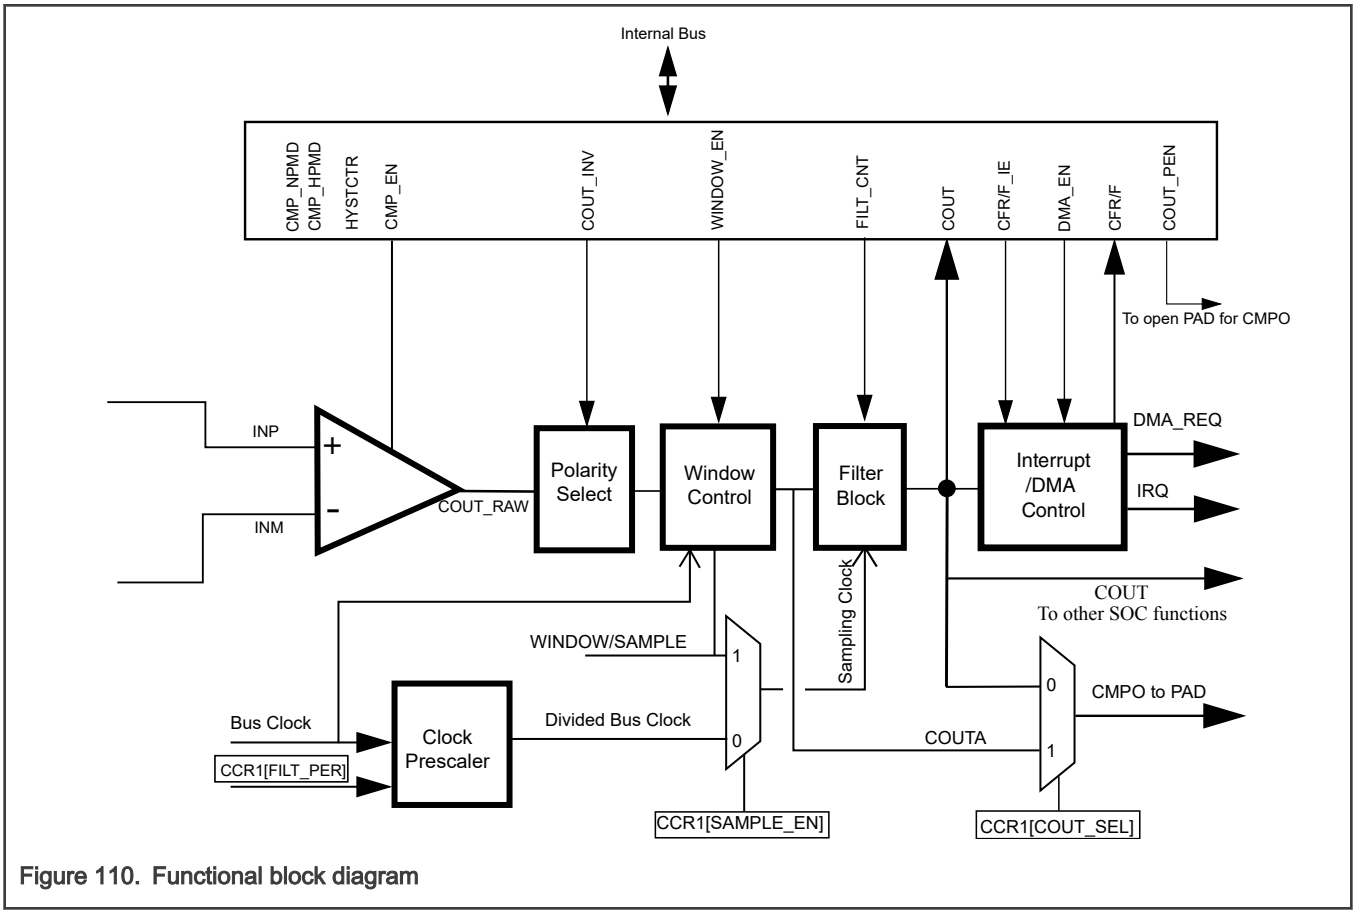

Figure 110. Functional block diagram

As shown in the block diagram, the functions are:

- Compared two analog input voltages applied to INP and INM, COUT_RAW is high when the INP input voltage is greater than the INM input voltage, and COUT_RAW is low when the INP input voltage is less than the INM input voltage.
- The COUT_RAW signal can be inverted by enabling CCR1[COUT_INV].
- The optionally inverted comparator output COUT_RAW is sampled on every bus clock when you enable the CCR1[WINDOW_EN] to generate COUTA. In this case, the comparator output is ignored during time periods when the input voltages are not valid. This is useful when you implement zero-crossing-detection for certain PWM applications.
- The window control block is bypassed when CCR1[WINDOW_EN] is disabled.
- The filter block acts as a simple sampler when CCR1[FILT_CNT] is set to 01h.
- The filter block acts as a filter based on multiple samples when CCR1[FILT_CNT] is set to be greater than 01h.
  - If CCR1[SAMPLE_EN] is set to 1, use the external SAMPLE input as the sampling clock.
  - If CCR1[SAMPLE_EN] is set to 0, use the divided bus clock as the sampling clock.
- Bypasses the filter block when it is not in use.

```
Bypass_Filter_Block = (FILT_CNT == 0x00) |  (~SAMPLE_EN & (FILT_PER == 0x00))
```

- Both COUTA and COUT can be configured as module output CMPO by configuring CCR1[COUT_SEL], and are used for different purposes within the system.
- The optionally filtered COUT can be read directly in CSR[COUT].
- The SAMPLE/WINDOW signal can be inverted by setting CCR1[WINDOW_INV].
- The SAMPLE/WINDOW signal can be closed by CMPO's falling edge and/or rising edge by setting CCR1[WINDOW_CLS] in Window mode.
- In Window mode, when window is closed, define the COUTA value as CCR1[COUTA_OW] by setting CCR1[COUTA_OWEN]. If CCR1[COUTA_OWEN] is not set, COUTA holds the last sampled value.

NOTE

See the chip configuration section for the source of SAMPLE/WINDOW input.

41.3.2 Low-pass filter mode

The low-pass filter mode operates on an unfiltered, optionally inverted comparator output COUTA, and generates the filtered and synchronized output COUT. You can configure both COUTA and COUT as module outputs and use for different purposes within the system.

Synchronization and edge detection determine the bit values of status register. They also apply to COUT for all sampling and windowed modes. You can perform filtering using an internal timebase defined by CCR1[FILT_PER], or use an external sample input to determine sample time.

The need for digital filtering and the amount of filtering depends on your requirements. Filtering can become more useful in the absence of an external hysteresis circuit. Without external hysteresis, generate a high-frequency oscillations at COUTA when the selected INM and INP input voltages differ by less than the offset voltage of the differential comparator.

41.3.2.1 Enabling low-pass filter mode

You can enable low-pass filter mode by setting the following:

- CCR1[FILT_CNT] > 01h
- CCR1[FILT_PER] to a nonzero value or writing 1 to CCR1[SAMPLE_EN].

If you use the divided bus clock to drive the low-pass filter, it samples COUTA every CCR1[FILT_PER] bus clock cycle.

If CCR1[SAMPLE_EN] is set to 1, the low-pass filter samples COUTA on each positive transition of the sample input. The output state of the filter changes when all the consecutive CCR1[FILT_CNT] samples agree that the output value has changed.

41.3.2.2 Latency issues

Program the value of CCR1[FILT_PER] or sample period such that the sampling period is longer than the period of the expected noise, ensuring that a given noise spike corrupts only one sample. You must choose the value of CCR1[FILT_CNT] to reduce the probability of noisy samples causing an incorrect transition to recognize. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of CCR1[FILT_CNT].

You must trade off the values of CCR1[FILT_PER] or sample period and CCR1[FILT_CNT] against the need for minimal latency in recognizing actual comparator output transitions. The probability of detecting an actual output change within the nominal latency is the probability of a correct sample raised to the power of CCR1[FILT_CNT].

Table 255 summarizes maximum latency values for the various modes of operation in the absence of noise. Filtering latency restarts each time the noise masks an actual output transition.

41.3.3 Low power mode operation

Below table introduces the mode of operation of lower power.

Table 254. Low power mode operation

Mode of operation	Description
Sleep	LPCMP can operate only in Continuous mode.

41.4 Functional modes

You can combine the comparator window and filter features as shown in the following table.

Table 255. Functional modes

Mode #	CMP_EN	WINDOW_EN	SAMPLE_EN	FILT_CNT	FILT_PER	Operation	Maximum latency[1]
1	0	X	X	X	X	See the Disabled mode (#1).	N/A
2A	1	0	X	0x00	X	See the Continuous mode (#2A and #2B).	T_{PD}
2B	1	0	0	X	0x00		
3A	1	0	1	0x01	X	See the Sampled, non-filtered mode (#3A and #3B).	$T_{PD} + T_{SAMPLE} + 3T_{per}$
3B	1	0	0	0x01	> 0x00		$T_{PD} + (FILT\_PER * T_{per}) + 3T_{per}$
4A	1	0	1	> 0x01	X	See the Sampled, filtered mode (#4A and #4B).	$T_{PD} + (FILT\_CNT * T_{SAMPLE}) + 3T_{per}$
4B	1	0	0	> 0x01	> 0x00		$T_{PD} + (FILT\_CNT * FILT\_PER \times T_{per}) + 3T_{per}$
5A	1	1	0	0x00	X	See the Windowed mode (#5A and #5B).	$T_{PD} + 2T_{per}$
5B	1	1	0	X	0x00		

Table continues on the next page...

Table 255. Functional modes (continued)

Mode #	CMP_EN	WINDOW_EN	SAMPLE_EN	FILT_CNT	FILT_PER	Operation	Maximum latency[1]
6	1	1	0	0x01	> 0x00	See the Windowed/ Resampled mode (#6).	T_{PD} + (FILT_PER * T_{per}) + 3T_{per}
7	1	1	0	> 0x01	> 0x00	See the Windowed/ Filtered mode (#7).	T_{PD} + (FILT_CNT * FILT_PER x T_{per}) + 3T_{per}
All other combinations of CMP_EN, WINDOW_EN, SAMPLE_EN, FILT_CNT, and FILT_PER are illegal.							

1. T_{PD} represents the intrinsic delay of the analog component plus the polarity select logic. T_{SAMPLE} is the clock period of the external sample clock. T_{per} is the period of the bus clock.

41.4.1 Disabled mode (#1)

In this mode:

- The analog comparator is non-functional and consumes no power.
- CSR[COUT] and CMPO are the same as CCR1[COUT_INV].

41.4.2 Continuous mode (#2A and #2B)

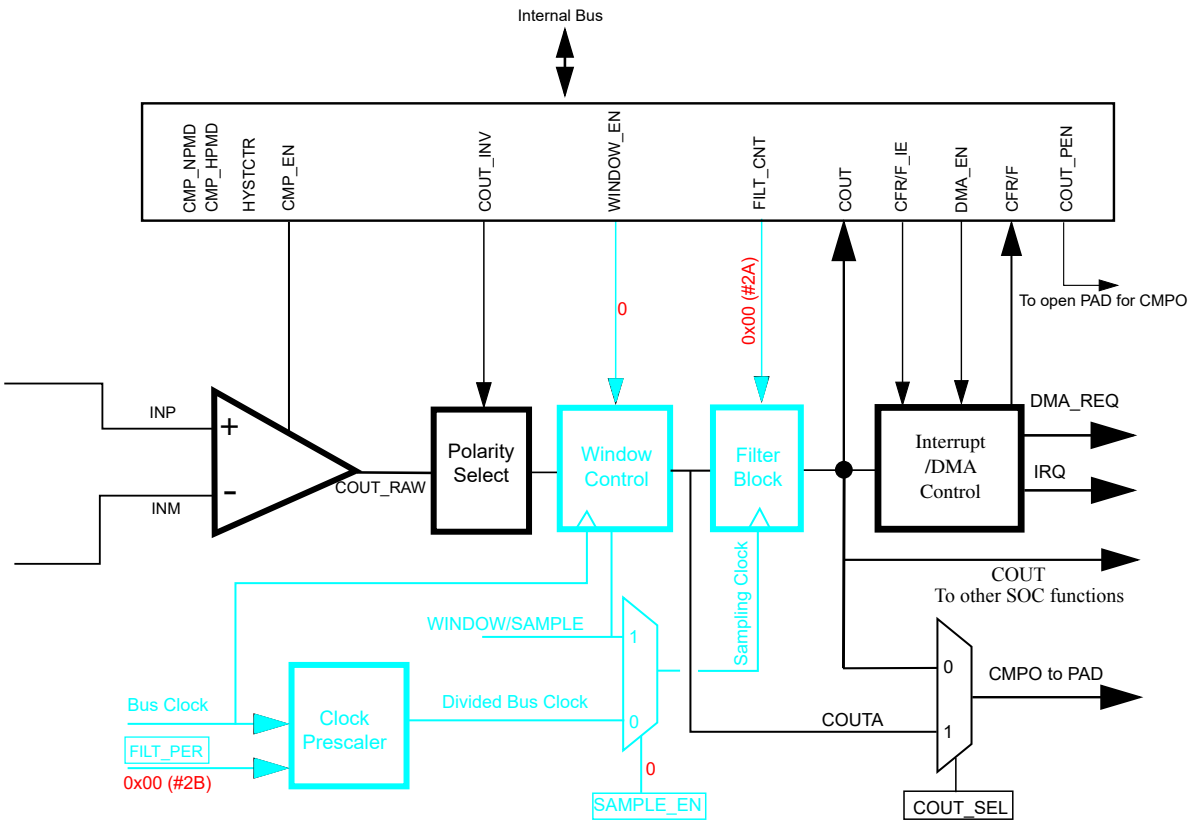

Figure 111. Comparator operation in continuous mode

COUT_RAW is optionally inverted in this mode but is not subject to external sampling or filtering. Both window control and filter blocks bypass completely, and CSR[COUT] updates continuously. The path from comparator input pins to output pins operates in a combinational (unclocked) mode. COUT and COUTA are identical in this mode.

For cases where a comparator drives a fault input, you must configure it to operate in Continuous mode so that an external fault can immediately pass to the target fault circuitry through the comparator.

41.4.3 Sampled, non-filtered mode (#3A and #3B)

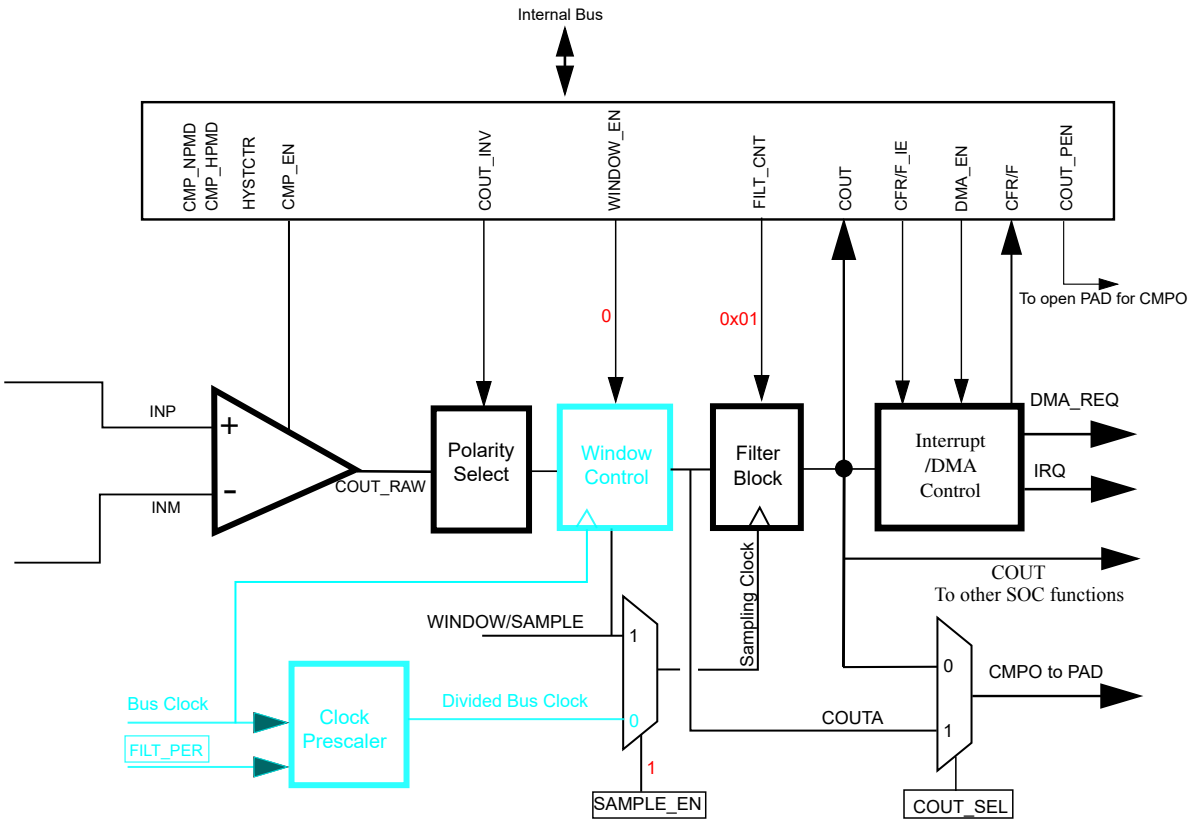

Figure 112. Sampled, non-filtered (#3A): sampling point externally driven

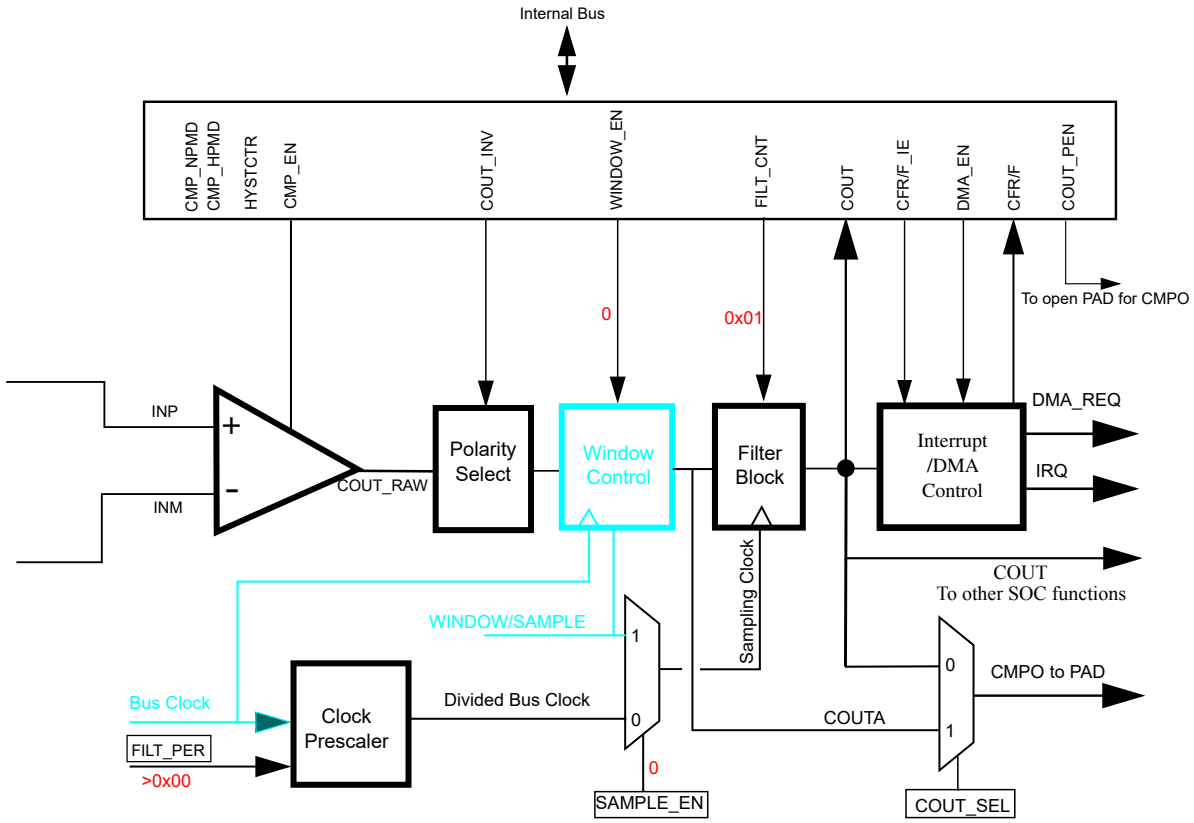

Figure 113. Sampled, Non-Filtered (#3B): sampling interval internally derived

In this mode, the path from analog inputs to COUTA is combinational (unclocked). Windowing control bypasses completely. You can sample COUTA whenever you detect a rising edge on the sampling clock.

The difference in two operation modes (#3A and #3B) of sampled, non-filtered mode is that how you drive the clock to the filter block. In #3A, the clock to filter block drives externally, and in #3B, the clock to filter block drives internally.

The filter block has no other function than sample or hold of the comparator output in this mode.

The following figure shows the comparator operation in this mode, assuming that the polarity select sets to a non-inverting state.

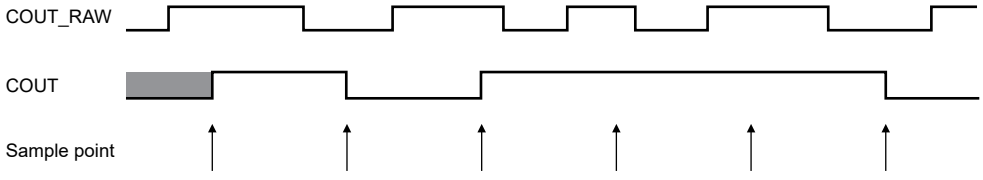

Figure 114. Sampled, Non-Filtered mode timing diagram

41.4.4 Sampled, filtered mode (#4A and #4B)

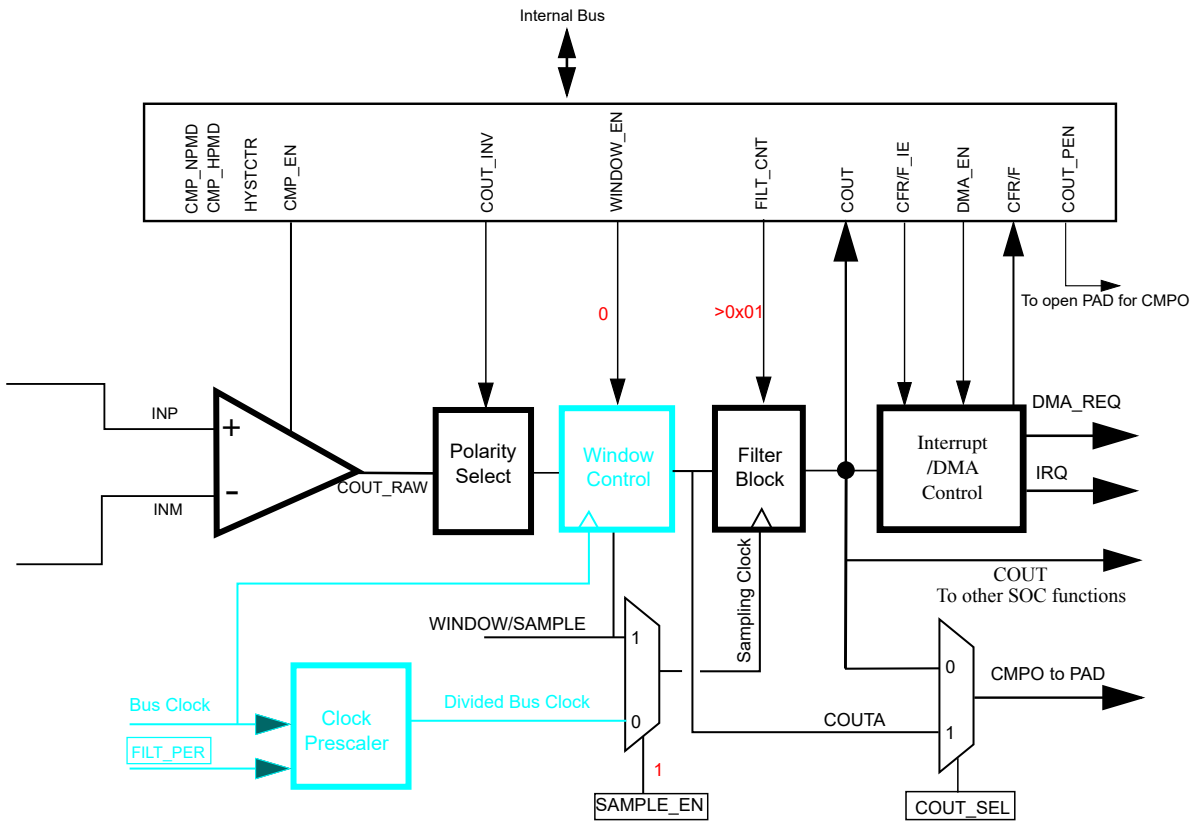

Figure 115. Sampled, filtered (#4A): sampling point externally driven

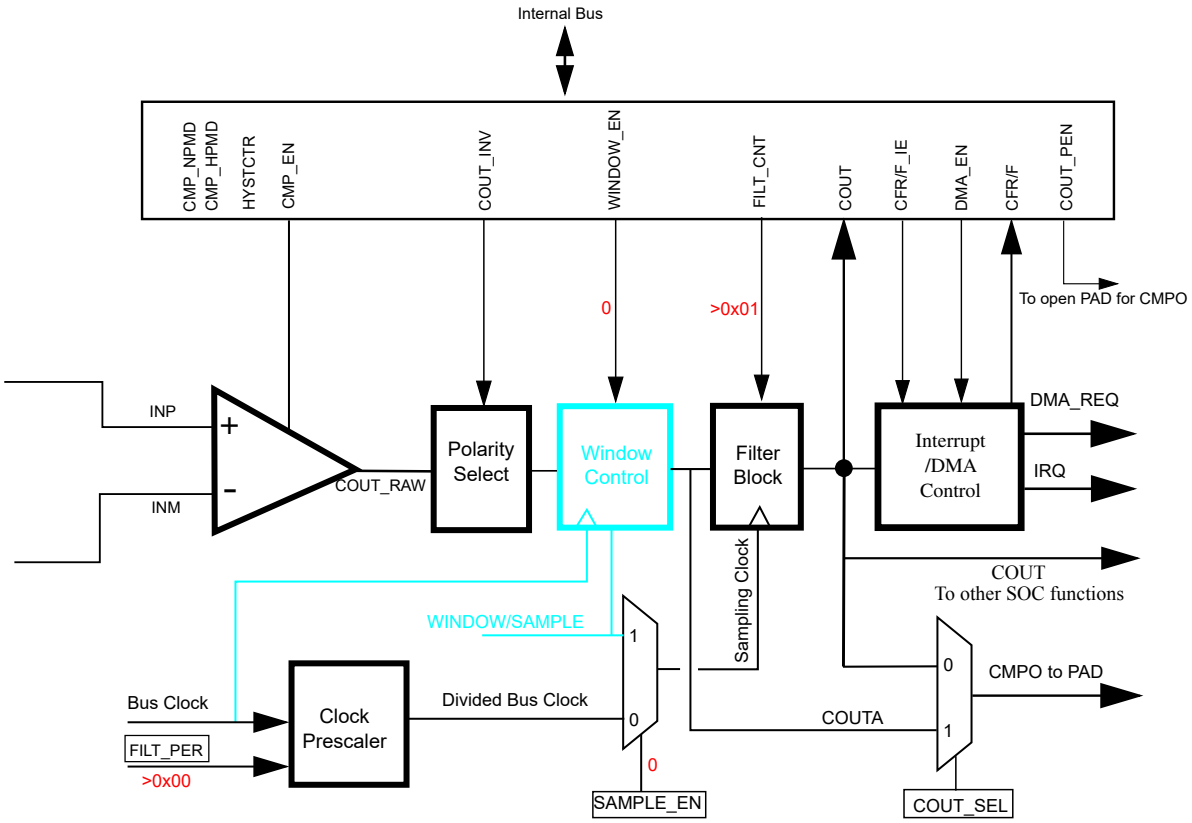

Figure 116. Sampled, filtered (#4B): sampling point internally derived

In this mode, the path from the analog inputs to COUTA is combinational(unclocked). Windowing control bypasses completely. You can sample COUTA whenever you detect a rising edge on the sampling clock.

The only difference in operation between sampled, non-filtered (#3A) mode and sampled, filtered (#4A) mode is that CCR1[FILT_CNT] is larger than 1, which activates filter operation.

The only difference in operation between sampled, non-filtered (#3B) mode and sampled, filtered (#4B) mode is that CCR1[FILT_CNT] is larger than 1, which activates filter operation.

41.4.5 Windowed mode (#5A and #5B)

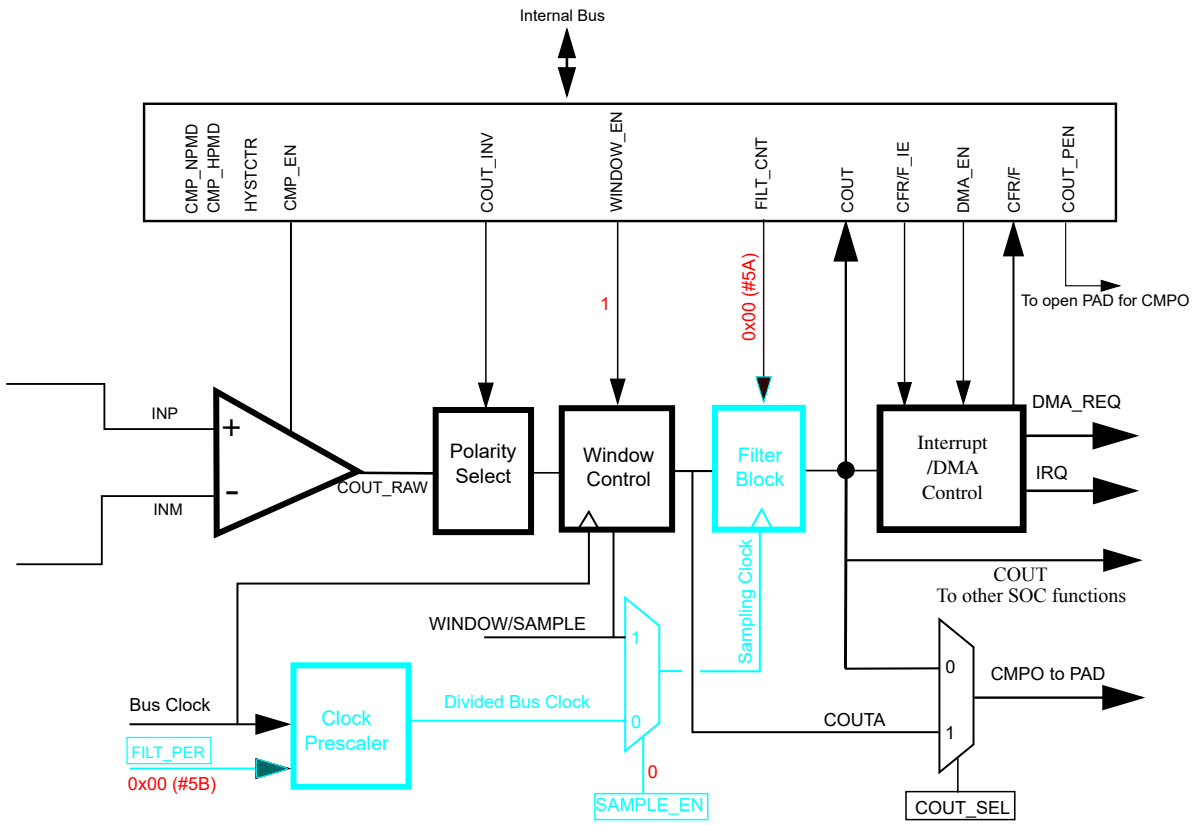

Figure 117. Windowed mode

The bus clock clocks COUTA whenever you enable the window in this mode. The last latched value holds after you disable the window and the filter block is bypassed.

The following figure shows the comparator operation in this mode, ignoring the latency of the analog comparator, polarity select, and window control block. The polarity select sets to a non-inverting state.

COUTA may lag the analog inputs by up to two functional clock cycles plus the combinational path delay through the comparator and polarity select logic in the actual operation.

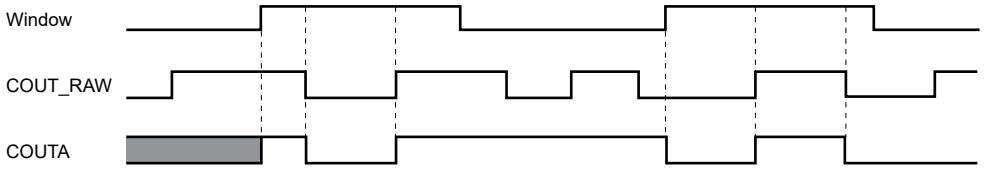

Figure 118. Windowed mode timing diagram

The following figure shows that if CCR1[COUTA_OWEN] becomes 1, you can define COUTA level as CCR1[COUTA_OW], after you closes the window.

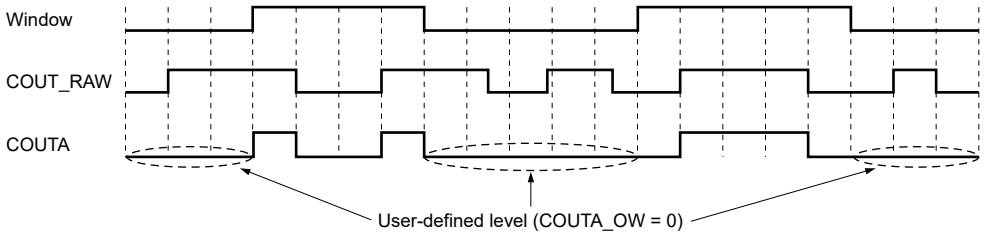

Figure 119. Windowed mode timing diagram with user defined value 0 outside window

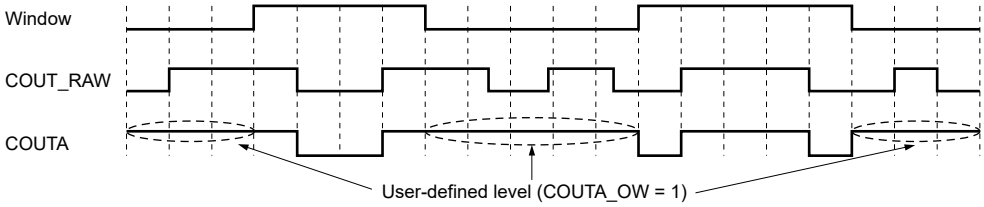

Figure 120. Windowed mode timing diagram with user defined value 1 outside window

NOTE

When the window is open, COUT_A will switch from COUTA_OW to COUT_RAW. When the window is closed, COUT_A will switch from COUT_RAW to COUTA_OW. This may generate unnecessary transition flags, for instance, CFR or CFF. User needs to choose COUTA_OW carefully according to the actual application, and select the appropriate flag CFR or CFF to generate interrupt.

If CCR1[WINDOW_CLS] becomes 1, you can define the CMPO event (rising edge, falling edge or both edges that CCR1[EVT_SEL] selects) to close the window. The external window signal has to go to zero and back to one to enable the internal window again. The following figure shows an example that CMPO rising edge closes the internal window.

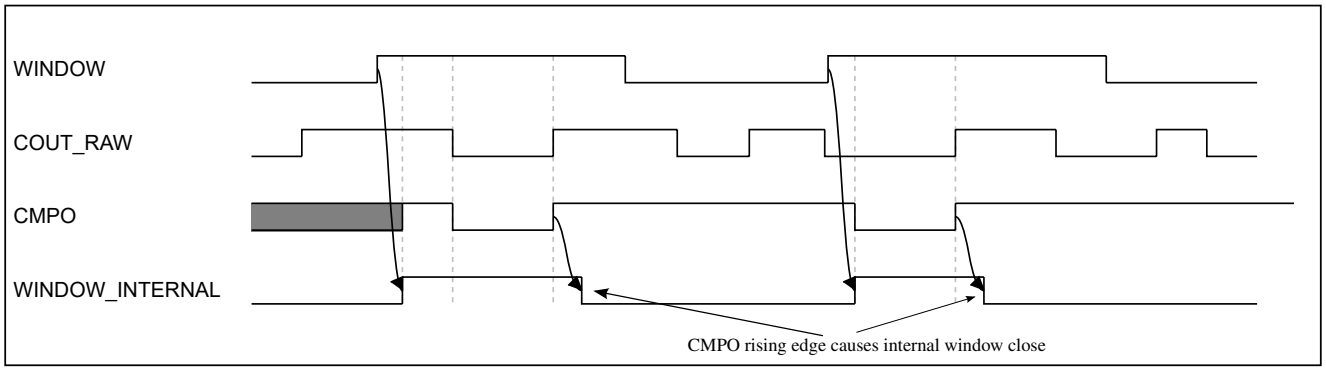

Figure 121. Windowed mode timing diagram with CMPO rising edge close window

The following figure shows that if CCR1[WINDOW_INV] becomes 1, you can invert the window signal before you use it.

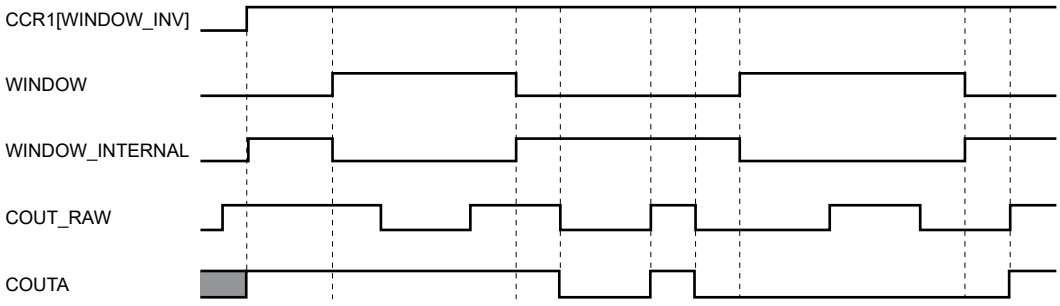

Figure 122. Windowed mode timing diagram with window signal inverted

41.4.6 Windowed/Resampled mode (#6)

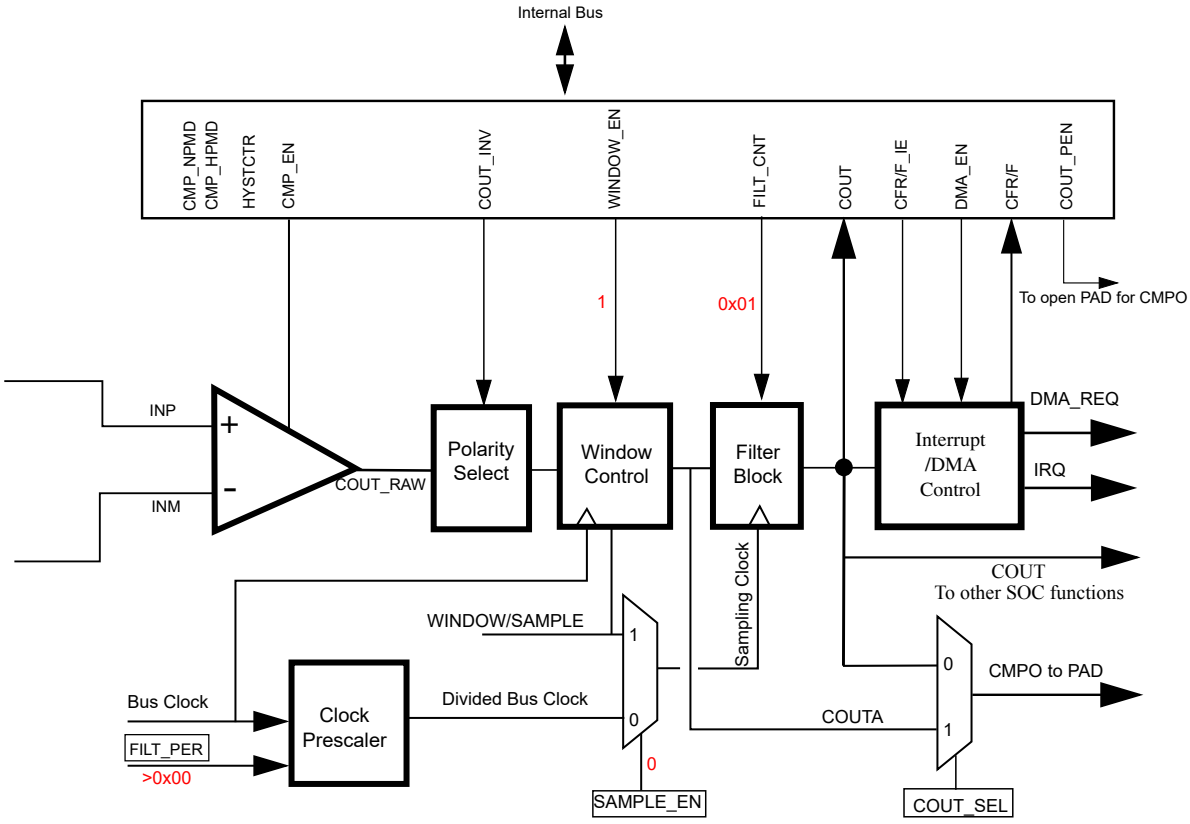

Figure 123. Windowed/Resampled mode

This mode of operation results in an unfiltered string of comparator samples where CCR1[FILT_PER] and the bus clock rate determines the interval between the samples. The following section shows that the configuration for this mode is virtually identical to that for the Windowed/Filtered mode. The only difference is that the value of CCR1[FILT_CNT] must be 1 in this mode.

The following figure uses the same input stimulus shown in Figure 118, and adds resampling of COUTA to generate COUT. The arrows in the figure indicate the time points at which the samples are taken. You can ignore prop delays and latency for clarity.

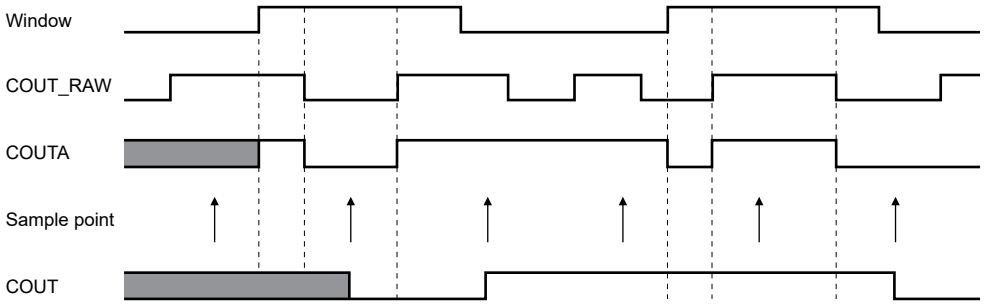

Figure 124. Windowed/Resampled mode operation

This example demonstrates the operation of the comparator in Windowed/Resampled mode, and does not reflect any specific application. Based on the sampling rate and window placement, COUT may not see zero-crossing events that the analog comparator detects. You must carefully consider the sampling period and/or window placement for a given application.

41.4.7 Windowed/Filtered mode (#7)

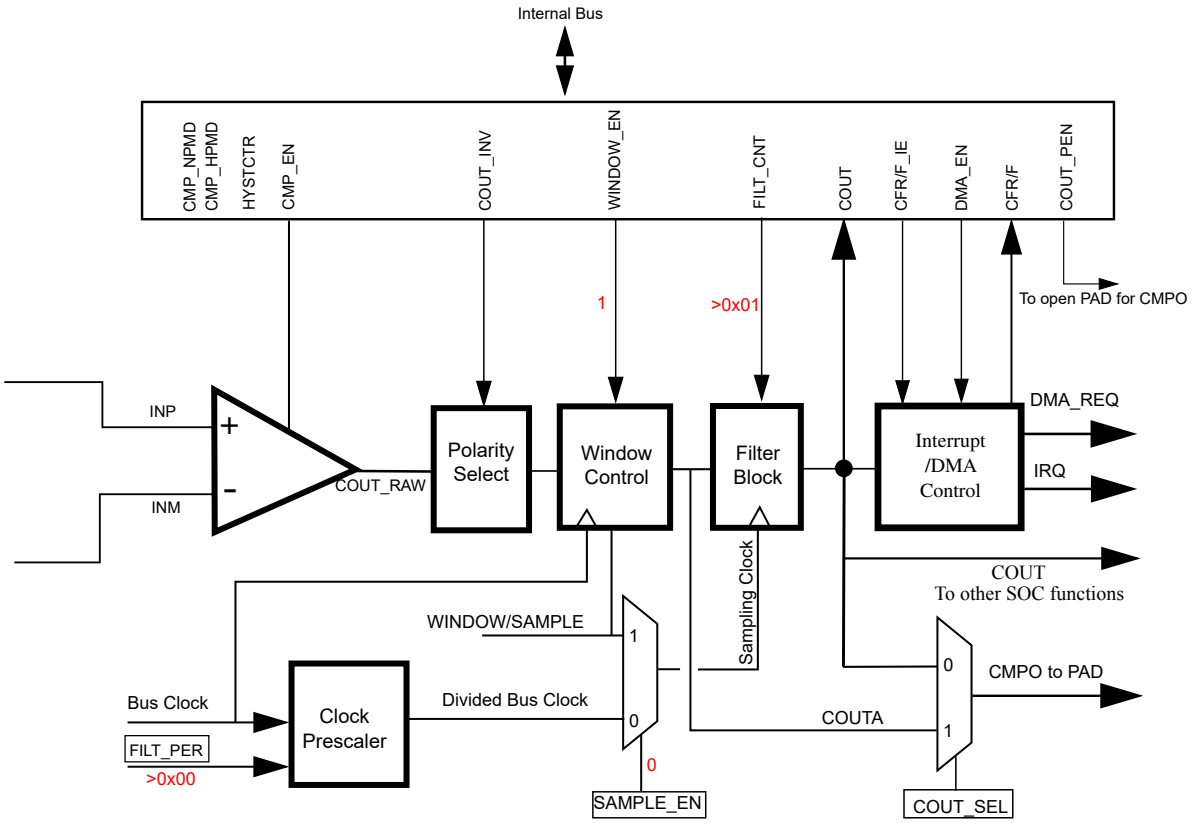

Figure 125. Windowed/Filtered mode

The only difference in operation between Windowed/Resampled mode (#6) and Windowed/Filtered mode (#7) is that CCR1[FILT_CNT] is >1, which activates filter operation.

This mode is the most complex mode of operation for the comparator block, as it utilizes both windowing and filtering features. It also has the highest latency of any of the modes. This is approximately: up to 2 peripheral clock synchronization in the window function + ((CCR1[FILT_CNT] x CCR1[FILT_PER]) + 1) x peripheral clock for the filter function.

41.5 DMA

After the DMA support enables by writing 1 to CCR1[DMA_EN] and the interrupt enables by writing 1 to IER[CFR_IE], IER[CFF_IE], or both, the corresponding change on COUT forces a DMA transfer request rather than a CPU interrupt. After the DMA completes the transfer, it sends a transfer completing indicator signal that deasserts the DMA transfer request and clears the flags (both CSR[CFR] and CSR[CFF]) to allow a subsequent change on comparator output to occur and forces another DMA request.

The comparator can remain functional in Sleep modes if CCR0[CMP_STOP_EN] becomes 1. A DMA transfer request wakes up the system from Sleep mode. After completing the data transfer, the system go back again to Sleep mode. See the DMA chapters in this document for more information on the asynchronous DMA function.

41.6 Clocking

LPCMP requires the following clocks to operate:

- Uses bus clock for register access and window/filter function.

41.7 Resets

The global chip reset signal resets LPCMP.

41.8 Interrupts

After the corresponding IER becomes 1, CSR[CFR], CSR[CFF], and can generate an interrupt, assuming that CCR1[DMA_EN] is not 1. You can clear either the flag or IER to deassert the interrupt.

41.9 External signal descriptions

Below table introduces external signals.

Table 256. External signal descriptions

Signal	Description	I/O
CMPO	Filtered or unfiltered comparator output	O
Input_Analog_Channels	Analog input channels (see the chip-specific information for more on the connections).	I
VREFH_EXT	External reference voltage for the CMP-DAC (see the chip-specific information for more on the connections).	I
RR_ACTIVE	Round-robin trigger mode enabled.	O

41.10 Initialization

You can enable LPCMP by writing 1 to CCR0[CMP_EN], and then configuring the control registers (CCR1, CCR2, DCR, and so on).

To disable LPCMP, write 0 to CCR0[CMP_EN]. Switching operation modes or changing control register fields on-the-fly (when CCR0[CMP_EN] is set to 1) may cause noise on the COUT or COUTA signals. To avoid unwanted signal noise, you must ensure to disable the module before switching modes or changing control fields.

The time required to stabilize COUT is the power-on delay of the comparators plus the largest propagation delay from a selected analog source through the analog comparator, windowing function, and filter, see the datasheet for more information on power-on delays of the comparators. Table 255 specifies the delay, which the windowing and filter function causes.

During operation, you must always consider the propagation delay of the selected data paths. It can take many bus clock cycles for COUT and CSR[CFR]/CSR[CFF] to reflect an input change or a configuration change to one of the components involved in the data path.

41.11 Application information

41.11.1 Round-robin trigger mode programing recommendation

Configure the Round-robin trigger mode as follows:

1. Configure the comparison cycles by RRCR0[RR_NSAM]. Note: It is a mandatory request that the round robin cycling period must set longer than the time that all the active channels complete the specified comparison cycles set by RRCR0[RR_NSAM].
2. Configure CMP initialization delay by RRCR0[RR_INITMOD]. Note: In programming RRCR0[RR_INITMOD], the RR_INITMOD x round robin clock period must be longer than the initialization delay, see the chip datasheet for more information.
3. Configure RRCR1[FIXP] to select the fixed port of CMP and RRCR1[FIXCH] to select the fixed channel.
4. Configure channels for comparison by RRCR1[RR_CHnEN].
5. Write RRCSR[RR_CHnOUT] to define the pre-set state of channel n.
6. Clear channel flags RRSR[RR_CHnF].
7. Enable round robin interrupt by IER[RRF_IE] (disable IER[CFR_IE] and IER[CFF_IE]).
8. Enable round-robin trigger mode by setting RRCR0[RR_EN] to 1.

41.11.2 Hysteresis

The following diagram illustrates implementation of an external hysteresis resistor bridge between the asynchronous comparator output and the INP input of the Comparator. Since positive feedback is required, CCR1[COUT_INV] must be set to 0 when the hysteresis resistor bridge is added to the INP input of the comparator. CCR1[COUT_INV] must be set to 1 when the hysteresis resistor bridge is added to the INM input of the comparator.

The option of adding an external resistor bridge for the purpose of adding hysteresis to the comparator and the amount of hysteresis depends on the user's individual requirements. Hysteresis can be important in some system designs. In the absence of hysteresis, the continuous comparison of nearly identical analog inputs may add noise and waste power by generating high-frequency oscillations at CMPO.

If external hysteresis is added to the comparator, the bridge must be designed to consider other issues than simply how much hysteresis is needed. The resistor values must be sufficiently high so that they do not cause the drive strength of the digital output driver in the CMPO IO cell to be exceeded. Also, if any digital function other than CMPO must operate on the CMPO pad in the presence of such a bridge, the resistor values must be sufficiently high so that the IO cell can function appropriately in its digital role.

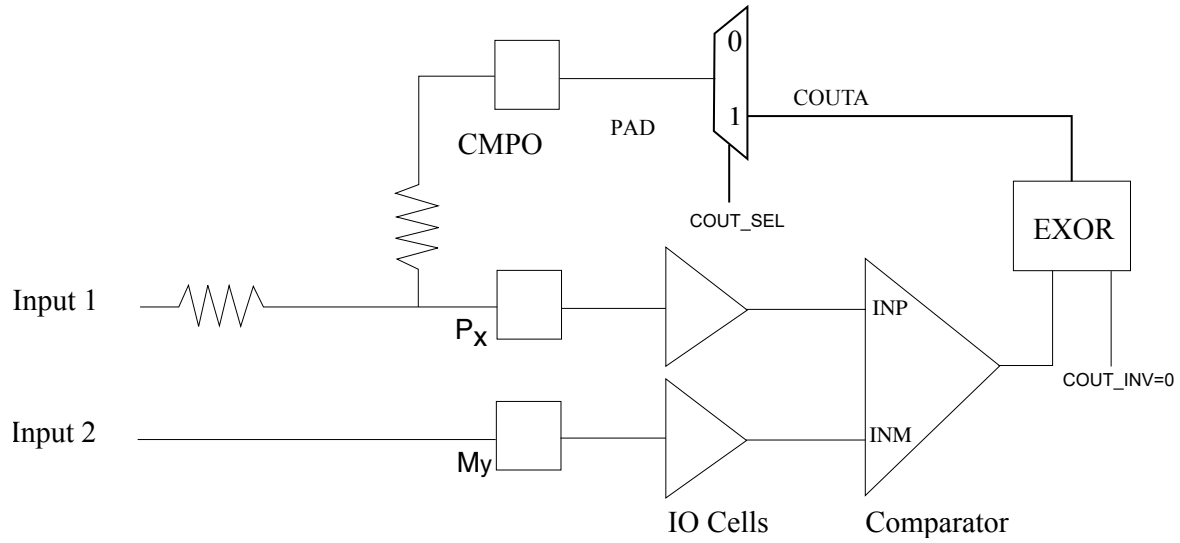

Figure 126. External hysteresis circuit

41.12 LPCMP register descriptions

The memory map comprises of 32-bit aligned registers, which you can access via 8-, 16- or 32-bit reads and 32-bit write. Attempted accesses using unsupported write data sizes, writes to read-only resources, or to reserved spaces terminate with an error. Read access to reserved address generates a transfer error and the read data bus shows all 0s.

41.12.1 LPCMP memory map

LPCMP0 base address: 4004_8000h

LPCMP1 base address: 4004_9000h

Offset	Register	Width (In bits)	Access	Reset value

8 COUT	Analog Comparator Output Returns the current value of the analog comparator output when read. This field resets to 0 and reads as CCR1[COUT_INV] after the analog comparator module disables when CCR0[CMP_EN] = 0. Writing to this field is ignored.
7-2 —	Reserved
1 CFF	Analog Comparator Flag Falling Detects when a falling edge on COUT occurs. Write 1 to clear this field when CCR1[DMA_EN] is disabled. If CCR1[DMA_EN] is enabled, the flag automatically clears after DMA is done. This field clears when CCR0[CMP_EN] is not 1. 0b - Not detected 1b - Detected
0 CFR	Analog Comparator Flag Rising Detects when a rising edge on COUT occurs. Write 1 to clear this field when CCR1[DMA_EN] is disabled. If CCR1[DMA_EN] is enabled, the flag automatically clears after DMA is done. This field clears when CCR0[CMP_EN] is not 1. 0b - Not detected 1b - Detected

Chapter 42
Voltage Reference (VREF)

42.1 Chip-specific VREF information

Table 257. Reference links to related information

Topic	Related module	Reference
Full description	VREF	VREF
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

NOTE

The VREF_OUT signal introduced in this chapter is the VREFO signal in the Signal Muxing and Pinout.

42.1.1 Module instances

This device has one instance of the VREF module, VREF0.

42.2 Overview

VREF provides a buffered reference voltage that you can set to levels ranging from 1.0 V to 2.1 V for use as an external reference. When VREF is enabled, the reference voltage, VREF_OUT, is connected to a dedicated output pin. In addition, the buffered reference is available internally for use with on-chip peripherals.

You can trim the VREF voltage output in fine or coarse voltage steps:

- For fine-tuning, use UTRIM[VREFTRIM] to trim the output with (0.05% x VREF_OUT) resolution, where VREF_OUT is the value of the voltage reference output (measured in volts) after using UTRIM[TRIM2V1] to trim the output. For example, after using UTRIM[TRIM2V1] to trim the output VREF_OUT = 1 V, the fine step resolution is : (0.05% x 1) = 0.5 mV.
- For coarse-tuning, use UTRIM[TRIM2V1] to trim the output with 100 mV resolution. For details about possible configurations of the voltage reference, see Table 258

42.2.1 Features

- Programmable User Trim (UTRIM) with 0.05% x VREF_OUT steps in fine-tuning and 100 mV in coarse-tuning. When reset, User Trim (UTRIM) is automatically loaded with a factory-trimmed value.
- Programmable Buffer mode selection:
  - Off
  - Standby mode (Bandgap enabled and output buffer disabled)
  - High-Power Buffer mode (output buffer enabled in High-Power mode)
  - Low-Power Buffer mode (output buffer enabled in Low-Power mode)
- Low-power bandgap and high-accurate bandgap selection
- Support for a dedicated output pin, VREF_OUT

42.2.2 Block diagram

Figure 127 shows the VREF block diagram.

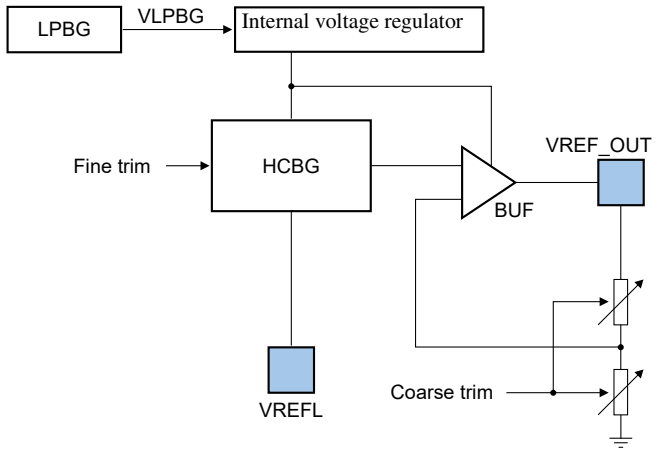

Figure 127. VREF block diagram

42.3 Functional description

VREF is a bandgap buffer system that uses unity gain amplifiers. Both internal and external peripherals use the VREF_OUT signal in Low- and High-Power Buffer modes.

NOTE

When using VREF, a 220 nF capacitor must always be connected between VREF_OUT and Analog Domain Power Supply Ground.

If CSR[HCBGEN] = 1, the voltage reference is enabled, you must set different modes by using CSR[BUF21EN] and CSR[HI_PWR_LV].

The following table shows possible configurations of the voltage reference.

Table 258. VREF_OUT values and related settings

1011	2.1
11XX	1.0

42.3.1 Voltage reference disabled

When CSR[LPBGEN] = 0, CSR[HCBGEN] = 0, and CSR[BUF21EN] = 0, the voltage reference is disabled and the VREF bandgap and output buffers are disabled. VREF is in Off mode.

42.3.2 Voltage reference enabled

Enabling voltage reference results into the following main high-level configuration options:

- Write 1 to CSR[LPBGEN] and CSR[LPBG_BUF_EN]. This configuration enables the low power bandgap (LPBG) bias current and voltage output.
- Write 1 to CSR[LPBGEN], CSR[REGEN], CSR[BUF21EN], and CSR[HCBGEN], this configuration enables the VREF supply voltage on VREF_OUT.

42.3.2.1 CSR[BUF21EN] = 0, CSR[HI_PWR_LV] = X

In Standby mode, the internal VREF bandgap is enabled to generate an accurate 1.0 V output that you can trim by using UTRIM[VREFTRIM]. The bandgap requires time for startup and stabilization. Monitor CSR[VREFST] to determine whether the stabilization and startup are complete when the chop oscillator is not enabled. When chop oscillator is used, the internal bandgap reference voltage settles within the chop oscillator startup time, Tchop_osc_stup.

The output buffer is disabled in this mode, and there is no buffered voltage output. VREF is in Standby mode. If you select this mode first and Low-Power or High-Power Buffer mode is subsequently enabled, there is a delay before the buffer output settles to its final value. This is the buffer startup delay (Tstup), as specified in the appropriate chip data sheet.

42.3.2.2 CSR[BUF21EN] = 1, CSR[HI_PWR_LV] = 1

In High-Power buffer mode, the internal VREF bandgap is on, and the High-Power Buffer is enabled to generate a buffered voltage to VREF_OUT. The available voltage levels range from 1.0 to 2.1 V and can be adjusted in 0.1 V steps using UTRIM[TRIM2V1]. VREF bandgap can also be used as a reference to internal analog peripherals such as an ADC channel or analog comparator input.

If this mode is entered from Standby mode (CSR[BUF21EN] = 0), there is a delay before the buffer output settles to its final value. This is the buffer startup delay (Tstup), as specified in the appropriate device data sheet.

If this mode is entered when VREF is enabled, you must wait longer than Tstup or until CSR[VREFST] = 1 when the chop oscillator is not enabled. If the chop oscillator is being used, wait for the time specified by Tchop_osc_stup (chop oscillator startup time) to ensure that the VREF output has stabilized.

NOTE

In this mode, a 220-nF capacitor is required to connect between the VREF_OUT pin and Analog Domain Power Supply Ground.

42.3.2.3 CSR[BUF21EN] = 1, CSR[HI_PWR_LV] = 0

In Low-Power buffer mode, the internal VREF bandgap is on, and the low-power buffer is enabled to generate a buffered voltage to VREF_OUT. The available voltage levels range from 1.0 to 2.1 V and you can adjust them in 0.1 V steps using UTRIM[TRIM2V1]. VREF bandgap can be used as a reference to internal analog peripherals such as an ADC channel or analog comparator input.

If this mode is entered from Standby mode (CSR[BUF21EN] = 0), there is a delay before the buffer output settles to its final value. This is the buffer startup delay (Tstup), as specified in the appropriate chip data sheet.

If this mode is entered when the VREF module is enabled, you must wait longer than Tstup or until CSR[VREFST] = 1 when the chop oscillator is not enabled. If the chop oscillator is being used, wait for the time specified by Tchop_osc_stup (chop oscillator startup time) to ensure that the VREF output has stabilized.

NOTE

In this mode, a 220-nF capacitor connects the VREF_OUT pin and Analog Domain Power Supply Ground.

42.3.3 Internal voltage regulator

VREF contains an internal voltage regulator that you can enable to provide additional supply noise rejection. The module also contains an internal chop oscillator to generate the chop clock. When possible, enable the internal regulator and chop oscillator to attain optimum VREF performance.

When using the chop function, you must also enable the internal voltage regulator. Perform the following procedure when enabling the internal regulator:

1. Enable the internal regulator by writing 1 to CSR[REGEN].
2. Enable the chop oscillator by writing 1 to CSR[CHOPEN].
3. Write 1 to CSR[LPBGEN] and CSR[HCBGEN].

42.3.4 Low-Power modes

VREF can run when the chip is in a low-power mode. To use the VREF regulator and/or the chop oscillator in a low-power mode, the system reference voltage (also known as the bandgap voltage reference) must also be enabled in these modes. See the chip-specific VREF information on how to enable the system reference voltage.

Having the VREF regulator enabled increases the current consumption. Depending on the requirements of the system application, consider disabling the VREF regulator to minimize the current consumption in low-power modes. However, not using the VREF regulator reduces the accuracy of the output voltage by as much as several mV.

42.3.5 Clocking

See the chip-specific VREF information for the required clocking.

42.3.6 Reset

System reset, VREF convert to initial state with buffer cleared and waiting to load new register.

42.3.7 Interrupts

This module has no interrupts.

42.4 External signals

Table 259. External signals

Signal	Description	I/O
VREF_OUT	Internally generated voltage reference output. When the VREF output buffer is disabled, the VREF_OUT signal state is high-impedance.	O

42.5 Initialization

VREF_OUT requires time for startup and stabilization. After writing 1 to CSR[HCBGEN], monitor CSR[VREFST] to determine whether the stabilization and startup are complete when the chop oscillator is not enabled. If the chop oscillator is enabled, Tchop_osc_stup defines the settling time of the internal bandgap reference. You must wait for this time (Tchop_osc_stup) after the internal bandgap is enabled to ensure that the VREF internal reference voltage is stabilized.

After VREF_OUT is enabled and stabilized, changing the value of CSR[HI_PWR_LV] temporarily destabilizes the output voltage at the VREF_OUT pin, even though CSR[VREFST] remains 1. The time it takes for VREF_OUT to settle again is the same as the buffer startup delay (Tstup), as specified in the appropriate device data sheet. Also, applying a step change of the load current to the VREF_OUT pin incurs some time delay to resettle.

To enable the internal 1.75 V VREF regulator, see Internal voltage regulator for the required sequence. When the internal regulator is disabled, the VREF_OUT voltage is more sensitive to supply voltage variation. Use the internal regulator to achieve optimum VREF_OUT performance.

NOTE

You must write 1 to CSR[CHOPEN], CSR[REGEN], and CSR[ICOMPEN] to achieve the performance stated in the device data sheet.

Real Time Clock (RTC)

43.1 Chip-specific RTC information

Table 260. Reference links to related information

Topic	Related module	Reference
Full description	RTC	RTC
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

43.1.1 Module instances

- This device has one instance of the RTC module, RTC0.
- In this device, the independent RTC supply is internally tied to VDD_IO_D.
- Not all the tamper pins are available for each package, see #unique_1319 for details.

43.1.2 RTC_CLKOUT and RTC_WAKEUP_b

This device has no direct pinout for RTC_CLKOUT or RTC_WAKEUP_b, but the TAMPER pins can be configured to get these signals:

- CR[CPE] can be used to enable RTC_CLKOUT function on TAMPER1 or TAMPER2 if available
- CR[WPE] can be used to enable RTC_WAKEUP_b function on TAMPER0 if available.

43.2 Introduction

43.2.1 Features

The RTC module features include:

- 32-bit seconds counter with roll-over protection and 32-bit alarm
- 16-bit prescaler with compensation that can correct errors between 0.12 ppm and 3906 ppm
- Register write protection
  - Lock register requires POR or software reset to enable write access
- Configurable 1, 2, 4, 8, 16, 32, 64 or 128 Hz square wave output with optional interrupt
- 64-bit monotonic counter with roll-over protection
- Up to 4 tamper input pins with optional interrupt and seconds timestamp when interrupt asserts

43.2.2 Modes of operation

The RTC remains functional in all low power modes and can generate an interrupt to exit any low power mode.

43.2.3 RTC signal descriptions

Table 261. RTC signal descriptions

Signal	Description	I/O
RTC_CLKOUT	Prescaler square-wave output or RTC 32.768 kHz clock	O
RTC_WAKEUP_b	Active low wakeup for external device	O
RTC_TAMPER[3:0]	Tamper pin input	I

43.2.3.1 RTC clock output

The RTC_CLKOUT signal can output either a square wave prescaler output (configurable to 1, 2, 4, 8, 16, 32, 64 or 128 Hz) or the RTC 32.768 kHz clock.

43.2.3.2 RTC wakeup pin

The RTC wakeup pin is an open drain, active low, output that allows the RTC to wakeup the chip via an external component. The wakeup pin asserts when the wakeup pin enable is set and either the RTC interrupt is asserted or the wakeup pin is turned on via a register bit. The wakeup pin does not assert from the RTC seconds interrupt.

NOTE

The wakeup pin is optional and may not be implemented on all devices.

43.2.3.3 RTC Tamper pins

The RTC tamper pins are input pins that can be used to generate an interrupt or invalidate the time counter. The first tamper pin to assert an interrupt will also capture a timestamp of the seconds register.

43.3 Register definition

All registers must be accessed using 32-bit writes and all register accesses incur three wait states.

Writing to a register protected by the lock register does not generate a bus error, but the writes will not be completed.

Offset

Register	Offset
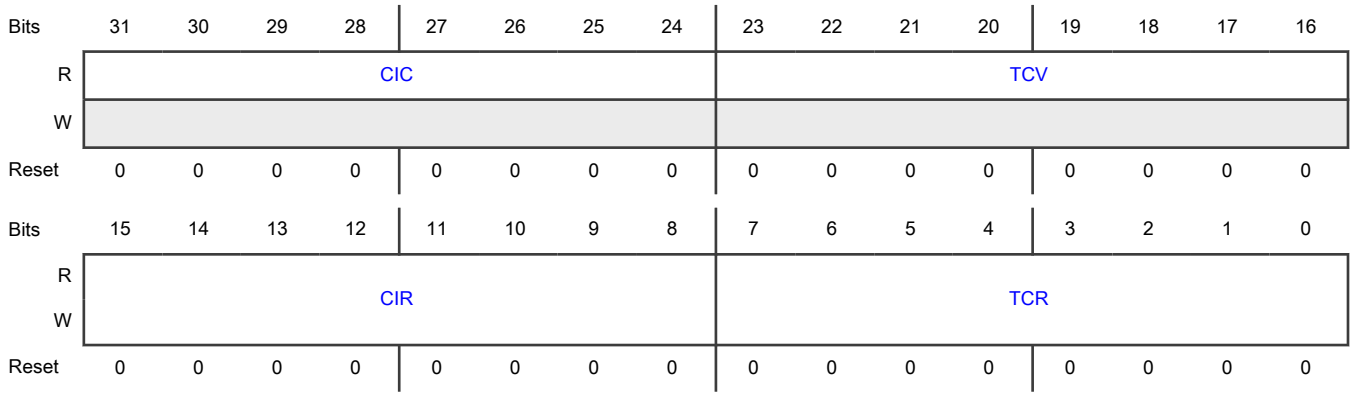
TCR	Ch

Diagram



Fields

Field	Function
31-24	Compensation Interval Counter

Table continues on the next page...

Table continued from the previous page...

Field	Function
CIC	Current value of the compensation interval counter. If the compensation interval counter equals zero then it is loaded with the contents of the CIR. If the CIC does not equal zero then it is decremented once a second. Reading this register at the same time as the seconds counter is incrementing can result in an incorrect value being read.
23-16 TCV	Time Compensation Value Current value used by the compensation logic for the present second interval. Updated once a second if the CIC equals 0 with the contents of the TCR field. If the CIC does not equal zero then it is loaded with zero (compensation is not enabled for that second increment). Reading this register at the same time as the seconds counter is incrementing can result in an incorrect value being read.
15-8 CIR	Compensation Interval Register Configures the compensation interval in seconds from 1 to 256 to control how frequently the TCR should adjust the number of 32.768 kHz cycles in each second. The value written should be one less than the number of seconds. For example, write zero to configure for a compensation interval of one second. This register is double buffered and writes do not take affect until the end of the current compensation interval.
7-0 TCR	Time Compensation Register Configures the number of 32.768 kHz clock cycles in each second, equal to 32,768 - TCR (where TCR is a twos complement sign extended value). This register is double buffered and writes do not take affect until the end of the current compensation interval. Some example values are show below. 0000_0000b - Time Prescaler Register overflows every 32768 clock cycles. 0000_0001b - Time Prescaler Register overflows every 32767 clock cycles. 0111_1110b - Time Prescaler Register overflows every 32642 clock cycles. 0111_1111b - Time Prescaler Register overflows every 32641 clock cycles. 1000_0000b - Time Prescaler Register overflows every 32896 clock cycles. 1000_0001b - Time Prescaler Register overflows every 32895 clock cycles. 1111_1111b - Time Prescaler Register overflows every 32769 clock cycles.

43.4 Functional description

43.4.1 Power, clocking, and reset

The RTC is an always powered block that remains active in all low power modes.

The time counter within the RTC is clocked by default from a 32.768 kHz clock.

The power-on-reset signal initializes all RTC registers to their default state. A software reset bit can also initialize all RTC registers.

43.4.1.1 Software reset

Writing 1 to CR[SWR] forces the equivalent of a POR to the rest of the RTC module. CR[SWR] is not affected by the software reset and must be cleared by software.

43.4.2 Time counter

The time counter consists of a 32-bit seconds counter that increments once every second and a 16-bit prescaler register that increments once every 32.768 kHz clock cycle.

Reading the time counter (either seconds or prescaler) while it is incrementing may return invalid data due to synchronization of the read data bus. If it is necessary for software to read the prescaler or seconds counter when they could be incrementing, it is recommended that two read accesses are performed and that software verifies that the same data was returned for both reads.

The time seconds register and time prescaler register can be written only when SR[TCE] is clear. Always write to the prescaler register before writing to the seconds register, because the seconds register increments on the falling edge of bit 14 of the prescaler register.

The time prescaler register increments provided SR[TCE] is set, SR[TIF] is clear, SR[TOF] is clear, and the 32.768 kHz (or 1 kHz) clock source is present. After enabling the oscillator, wait the oscillator startup time before setting SR[TCE] to allow time for the oscillator clock output to stabilize.

If the time seconds register overflows then the SR[TOF] will set and the time prescaler register will stop incrementing. Clear SR[TOF] by initializing the time seconds register. The time seconds register and time prescaler register read as zero whenever SR[TOF] is set.

SR[TIF] is set on VBAT POR, software reset, and when an enabled tamper source is detected. It is cleared by clearing the enabled tamper detect flag and then initializing the time seconds register. The time seconds register and time prescaler register read as zero whenever SR[TIF] is set.

43.4.3 Compensation

The compensation logic provides an accurate and wide compensation range and can correct errors as high as 3906 ppm and as low as 0.12 ppm. The compensation factor must be calculated externally to the RTC and supplied by software to the compensation register. The RTC itself does not calculate the amount of compensation that is required, although the 1 Hz clock is output to an external pin in support of external calibration logic.

Crystal compensation can be supported by using firmware and crystal characteristics to determine the compensation amount. Temperature compensation can be supported by firmware that periodically measures the external temperature via ADC and updates the compensation register based on a look-up table that specifies the change in crystal frequency over temperature.

The compensation logic alters the number of 32.768 kHz clock cycles it takes for the prescaler register to overflow and increment the time seconds counter. The time compensation value is used to adjust the number of clock cycles between -127 and +128. Cycles are added or subtracted from the prescaler register when the prescaler register equals 0x3FFF and then increments. The compensation interval is used to adjust the frequency at which the time compensation value is used, that is, from once a second to once every 256 seconds.

Updates to the time compensation register will not take effect until the next time the time seconds register increments and provided the previous compensation interval has expired. When the compensation interval is set to other than once a second then the compensation is applied in the first second interval and the remaining second intervals receive no compensation.

Compensation is disabled by configuring the time compensation register to zero.

43.4.4 Time alarm

The Time Alarm register (TAR), SR[TAF], and IER[TAIE] allow the RTC to generate an interrupt at a predefined time. The 32-bit TAR is compared with the 32-bit Time Seconds register (TSR) each time it increments. SR[TAF] will set when TAR equals TSR and TSR increments.

SR[TAF] is cleared by writing TAR. This will usually be the next alarm value, although writing a value that is less than TSR, such as 0, will prevent SR[TAF] from setting again. SR[TAF] cannot otherwise be disabled, although the interrupt it generates is enabled or disabled by IER[TAIE].

43.4.5 Update mode

The Update Mode field in the Control register (CR[UM]) configures software write access to the Time Counter Enable (SR[TCE]) field. When CR[UM] is clear, SR[TCE] can be written only when LR[SRL] is set. When CR[UM] is set, SR[TCE] can also be written when SR[TCE] is clear or when SR[TIF] or SR[TOF] are set. This allows the time seconds and prescaler registers to be initialized whenever time is invalidated, while preventing the time seconds and prescaler registers from being changed on the fly. When LR[SRL] is set, CR[UM] has no effect on SR[TCE].

CR[UM] also configures software write access to the Monotonic Counter Enable (MER[MCE]) bit. When CR[UM] is clear, MER[MCE] can be written only when LR[MEL] is set. When CR[UM] is set, MER[MCE] can also be written when MER[MCE] is clear or when SR[TIF] or SR[MOF] are set. This allows the monotonic counter register to be initialized whenever the monotonic counter is invalid, while preventing the monotonic counter from being changed on the fly. When LR[MEL] is set, CR[UM] has no effect on MCR[MCE].

43.4.6 Monotonic counter

The 64-bit Monotonic Counter is a counter that cannot be exhausted or return to any previous value, once it has been initialized. If the monotonic overflow flag is set, the monotonic counter returns zero and does not increment.

Depending on the value of the monotonic counter enable bit, writing to the monotonic counter either initializes the register with the value written, or increments the register by one (and the value written is ignored).

When the monotonic counter is enabled, the monotonic counter high increments on either a write to the monotonic counter high register or if the monotonic counter low register overflows (due to a write to the monotonic counter low register). The monotonic overflow flag sets when the monotonic counter high register overflows and is cleared by writing the monotonic counter high register when the monotonic counter is disabled.

The monotonic counter is held in reset whenever the time invalid flag is set. Always clear the time invalid flag before initializing the monotonic counter.

43.4.7 Tamper detect

Each external tamper pin and internal tamper source can be configured to generate a tamper interrupt. The contents of the seconds register are latched in the tamper time seconds register when the tamper interrupt asserts. Read the tamper time seconds register before clearing the flag in the tamper detect register.

Writing the tamper time seconds register at any time will set the time invalid flag. Since this is a software initiated tamper, there is no status flag to indicate this tamper source. To disable the software initiated tamper, lock the tamper time seconds register to prevent write accesses to that register.

43.4.8 Register lock

The Lock register (LR) can be used to block write accesses to certain registers until the next POR or software reset. Locking the Control register (CR) will disable the software reset. Locking LR will block future updates to LR.

Write accesses to a locked register are ignored and do not generate a bus error.

43.4.9 Interrupt

The RTC interrupt is asserted whenever a status flag and the corresponding interrupt enable bit are both set. It is always asserted on POR, and software reset. The RTC interrupt is enabled at the chip level by enabling the chip-specific RTC clock gate control bit. The RTC interrupt can be used to wakeup the chip from any low-power mode. If the RTC wakeup pin is enabled and the chip is powered down, the RTC interrupt will cause the wakeup pin to assert.

The RTC interrupt is also asserted when a configured tamper flag asserts and the corresponding tamper interrupt enable bit is set. Both internal tamper events and external tamper pins can cause the tamper interrupt to assert. The contents of the seconds register are recorded in the tamper time seconds register when the tamper interrupt asserts.

The RTC seconds interrupt is an edge-sensitive interrupt with a dedicated interrupt vector that is generated once a second and requires no software overhead (there is no corresponding status flag to clear). It is enabled in the RTC by the time seconds

interrupt enable bit and enabled at the chip level by setting the chip-specific RTC clock gate control bit. The frequency of the seconds interrupt defaults to 1 Hz, but can instead be configured to trigger every 2, 4, 8, 16, 32, 64 or 128 Hz. The RTC seconds interrupt does not cause the RTC wakeup pin to assert.

Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

44.1.1 Module instances

This device has two instances of the LPTMR module, LPTMR0, and LPTMR1.

44.1.2 LPTMR clocks

The prescaler and glitch filter of the LPTMR module (the module functional clock) can be clocked from one of four sources determined by LPTMRx_PSR[PCS]. The following table shows the clock assignments for this field.

NOTE

The chosen clock must remain enabled if the LPTMR is to continue operating in all required low-power modes.

The LPTMR allows the maximum clock frequency of 24 MHz.

Table 263. LPTMRn prescaler/glitch filter clocking options

LPTMRn_PSR[PCS]	Prescaler/glitch filter clock number	Chip clock
00	0	FRO-6MHz - Free Running Oscillator - 6MHz clock source.
01	1	Reserved
10	2	32K_CLK - Selectable clock output from the Battery Backed domain produced by either the OSC-32K or the FRO-32K.
11	3	Reserved

44.1.3 LPTMR pulse counter input options

LPTMRn_CSR[TPS] configures the input source used in pulse counter mode. The following table shows the input assignments for this field.

Table 264. LPTMRn pulse counter input options

LPTMRn_CSR[TPS]	Pulse counter input number	Chip input
00	0	CMP0_OUT
01	1	CMP1_OUT

LPTMRn_CSR[TPS]	Pulse counter input number	Chip input
10	2	LPTMRn_Alt2
11	3	LPTMRn_Alt3

44.2 Overview

The low-power timer (LPTMR) can be configured to operate as a time counter with optional prescaler, or as a pulse counter with optional glitch filter, across all power modes, including the low-power modes. It is reset only on Power on Reset (POR), allowing it to be used as a time-of-day counter.

44.2.1 Block diagram

The following figure shows a detailed block diagram for an LPTMR module.

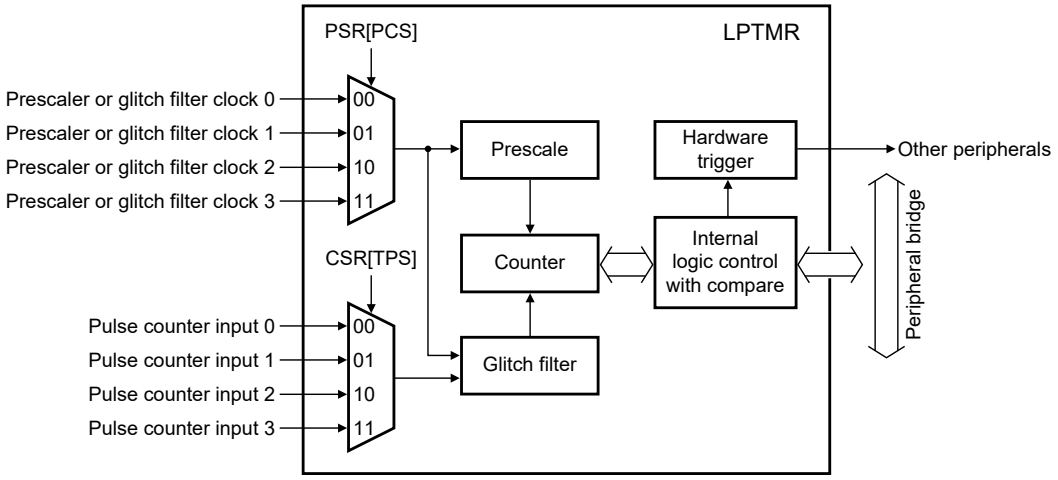

Figure 128. Functional block diagram

44.2.2 Features

- 32-bit time counter or pulse counter with compare
  - Optional interrupt can generate asynchronous wake-up from any low-power mode.
  - Hardware trigger output.
  - Counter supports free-running mode or reset on compare.
- Configurable clock source for prescaler/glitch filter
- Configurable input source for pulse counter
  - Rising-edge or falling-edge

44.3 Functional description

44.3.1 Low-power modes

In low-power modes, LPTMR continues to operate normally. You can configure LPTMR to exit the low-power mode by generating either an interrupt or a DMA request.

44.3.2 Clocks

The LPTMR prescaler/glitch filter can be clocked by one of the clocks configured by PSR[PCS]. You must enable the clock source before you enable LPTMR.

NOTE

You may need to configure the clock source selected by PSR[PCS] for it to remain enabled in low-power modes. Otherwise LPTMR will not operate in low-power modes.

In Pulse Counter mode, with the glitch filter bypassed, the selected input source directly clocks the CNR and no other clock source is required. To minimize power in this case, configure the glitch filter clock source for a clock that is disabled.

NOTE

The clock source or pulse input source selected for the LPTMR must not exceed the maximum frequency of f_{LPTMR} defined in the chip data sheet.

44.3.3 Reset

LPTMR is reset only on Power on Reset (POR). When configuring the LPTMR registers, you must initially write CSR with LPTMR disabled, before configuring PSR and CMR. Then, you must set CSR[TIE] as the last step in the initialization. Doing so ensures that LPTMR is configured correctly and the LPTMR counter is reset to zero following a Power on Reset (POR).

44.3.4 Prescaler and glitch filter

The LPTMR prescaler and glitch filter share the same logic, which operates as a prescaler in Time Counter mode and as a glitch filter in Pulse Counter mode.

NOTE

The prescaler/glitch filter configuration must not be altered when LPTMR is enabled.

44.3.4.1 Prescaler enabled

In Time Counter mode, when the prescaler is enabled, the output of the prescaler directly clocks the CNR. When LPTMR is enabled, the CNR increments every 2^1 to 2^{16} prescaler clock cycles. After LPTMR is enabled, the first increment of the CNR takes an additional one or two prescaler clock cycles due to synchronization logic.

44.3.4.2 Prescaler bypassed

In Time Counter mode, when the prescaler is bypassed, the selected prescaler clock increments the CNR on every clock cycle. When LPTMR is enabled, the first increment takes an additional one or two prescaler clock cycles due to synchronization logic.

44.3.4.3 Glitch filter

In Pulse Counter mode, when the glitch filter is enabled, the output of the glitch filter directly clocks the CNR. When LPTMR is first enabled, the output of the glitch filter is asserted, that is, logic 1 for active-high and logic 0 for active-low. The following table shows the change in glitch filter output with the selected input source.

Table 265. Glitch filter output with the selected input source

If	Then
The selected input source remains deasserted for at least 2^1 to 2^{15} consecutive prescaler clock rising edges	The glitch filter output also deasserts.
The selected input source remains asserted for at least 2^1 to 2^{15} consecutive prescaler clock rising edges	The glitch filter output also asserts.

NOTE

The input is only sampled on the rising clock edge.

The CNR increments each time the glitch filter output asserts. In Pulse Counter mode, the maximum rate at which the CNR can increment is once every 2^2 to 2^{16} glitch filter clock edges. When first enabled, the glitch filter waits an additional one or two glitch filter clock edges due to synchronization logic.

44.3.4.4 Glitch filter bypassed

In Pulse Counter mode, when the glitch filter is bypassed, the selected input source increments the CNR every time it asserts. Before LPTMR is first enabled, the selected input source is forced to be asserted. This prevents the CNR from incrementing if the selected input source is already asserted when LPTMR is first enabled.

44.3.5 Counter

The counter (CNR) increments by one on every:

- Prescaler clock in Time Counter mode with prescaler bypassed
- Prescaler output in Time Counter mode with prescaler enabled
- Input source assertion in Pulse Counter mode with glitch filter bypassed
- Glitch filter output in Pulse Counter mode with glitch filter enabled

The CNR is reset when LPTMR is disabled or if the counter register overflows. If CSR[TFC] = 0, then the CNR is also reset whenever CSR[TCF] = 1.

When the core is halted in Debug mode:

- If configured for Pulse Counter mode, the CNR continues incrementing.
- If configured for Time Counter mode, the CNR stops incrementing.

The CNR cannot be initialized, but can be read at any time. On each read of the CNR, software must first write to the CNR with any value. This synchronizes and registers the current value of the CNR into a temporary register. The contents of the temporary register are returned on each read of the CNR.

When reading the CNR, the bus clock must be at least two times faster than the rate at which the LPTMR counter is incrementing, otherwise incorrect data may be returned.

44.3.6 Compare

On the next CNR increment when the CNR is equal to the value of the CMR, the following events occur:

- CSR[TCF] is read as 1b.
- LPTMR generates interrupt if CSR[TIE] = 1 also.
- LPTMR generates hardware trigger.
- LPTMR writes 0 to CNR if CSR[TFC] = 0.

When LPTMR is enabled, the CMR can be altered only when CSR[TCF] = 1. When updating the CMR, the CMR must be written and CSR[TCF] must be cleared before the LPTMR counter has incremented past the new LPTMR compare value.

NOTE

When LPTMR is enabled in Time Counter mode, the first increment will take an additional one or two clock cycles due to synchronization logic. This will result in the first compare (and therefore interrupt and hardware trigger) occurring slightly later. A faster prescaler clock or larger prescaler value will minimize this impact.

44.3.7 Interrupt

LPTMR generates an interrupt whenever CSR[TIE] and CSR[TCF] = 1. CSR[TCF] is cleared by disabling LPTMR or by writing a logic 1 to it.

You can alter CSR[TIE] and write 1 to CSR[TCF] when LPTMR is enabled.

LPTMR generates an interrupt asynchronously to the system clock. The interrupt can be used to generate a wake-up from any low-power mode, provided LPTMR is enabled as a wake-up source.

44.3.8 Hardware trigger

The LPTMR hardware trigger asserts at the same time CSR[TCF] is set and can be used to trigger hardware events in other peripherals without software intervention. The hardware trigger is always enabled.

Table 266.

When	Then
CMR = 0 and CSR[TFC] = 0.	The LPTMR hardware trigger asserts on the first compare and does not deassert.
CMR is set to a nonzero value, or if CSR[TFC] = 1.	The LPTMR hardware trigger asserts on each compare and deasserts on the following increment of CNR.

LPTMR_ALT*n*	Pulse Counter Input LPTMR can select one of the input pins to be used in Pulse Counter mode.		I
	State meaning	Assertion—If configured for pulse counter mode with active-high input, then assertion causes the CNR to increment. Deassertion—If configured for pulse counter mode with active-low input, then deassertion causes the CNR to increment.	
	Timing	Assertion or deassertion may occur at any time; input may assert asynchronously to the bus clock.	

44.5 Initialization

Execute these steps to initialize LPTMR:

1. Configure CSR for the selected mode and pin configuration but with CSR[TEN]=0. A value of CSR[TEN]=0 resets the counter and clears the flag.
2. Configure PSR with the selected clock source and prescale/glitch filter configuration.
3. Configure CMR with the selected compare point.
4. Write 1 to CSR[TEN] to enable LPTMR.

44.6 Application information

Application 1: Generate an interrupt every 100 ms using 32.768 kHz clock source

1. Disable LPTMR by writing 0 to CSR[TEN].
2. Select 32.768 kHz clock source by configuring PSR[PCS].
3. Bypass the prescaler/glitch filter by writing 1 to PSR[PBYP].
4. Assert interrupt every 3277 cycles by configuring CMR[COMPARE]=0CCCh.
5. Enable LPTMR by writing 1 to CSR[TEN].
6. Enable the LPTMR interrupt by writing 1 to CSR[TIE].

Application 2: Generate an interrupt once a minute using 32.768 kHz clock source

1. Disable LPTMR by writing 0 to CSR[TEN].
2. Select 32.768 kHz clock source by configuring PSR[PCS].
3. Select the prescaler to divide the prescaler clock by 32768 to increment the counter once a second by configuring PSR[PRESCALE] = 00h.
4. Assert an interrupt every 60 seconds by configuring CMR[COMPARE]=003Bh.
5. Enable LPTMR by writing 1 to CSR[TEN].
6. Enable the LPTMR interrupt by writing 1 to CSR[TIE].

44.7 Memory map and register definition

NOTE

The LPTMR registers are reset only on Power on Reset (POR). See Reset for more details.

44.7.1 LPTMR register descriptions

44.7.1.1 LPTMR memory map

LPTMR0 base address: 4002_D000h

LPTMR1 base address: 4002_E000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Control Status (CSR)	32	RW	0000_0000h
4h	Prescale and Glitch Filter (PSR)	32	RW	0000_0000h
8h	Compare (CMR)	32	RW	0000_0000h
Ch	Counter (CNR)	32	RW	0000_0000h

44.7.1.2 Control Status (CSR)

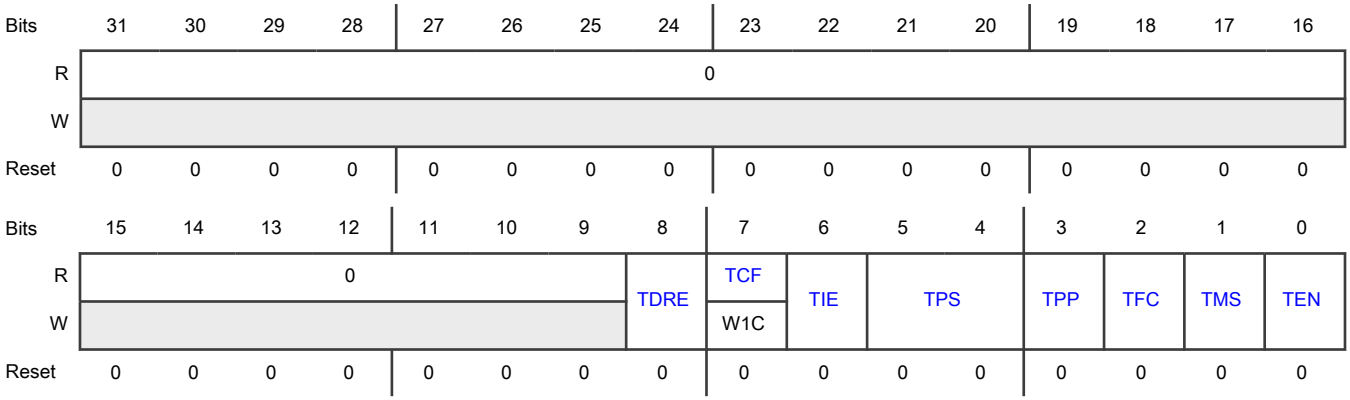
Offset

Register	Offset
CSR	0h

Function

Controls various features of LPTMR.TDRE

Diagram



Fields

Field	Function
31-9 —	Reserved
8 TDRE	Timer DMA Request Enable Enables timer DMA request. When TDRE is set, the LPTMR DMA Request is generated whenever TCF is also set. Then the TCF is cleared after the DMA Controller completes. 0b - Disable 1b - Enable
7 TCF	Timer Compare Flag Sets on the next CNR increment when LPTMR is enabled and CNR equals CMR. TCF is cleared when LPTMR is disabled or a logic 1 is written to it. **NOTE** Clear this field before enabling the Timer interrupt or DMA request. 0b - CNR ≠ (CMR + 1) 1b - CNR = (CMR + 1)

Table continues on the next page...

Table continued from the previous page...

Field	Function
6 TIE	Timer Interrupt Enable If TIE = 1, then LPTMR generates an interrupt if TCF = 1 also. 0b - Disable 1b - Enable
5-4 TPS	Timer Pin Select Configures the input source to be used in Pulse Counter mode. You must alter TPS only when LPTMR is disabled. The input connections vary by device. For details see the chip configuration information about connections to these inputs. 00b - Input 0 01b - Input 1 10b - Input 2 11b - Input 3
3 TPP	Timer Pin Polarity Configures the polarity of the input source in Pulse Counter mode. You must change TPP only when LPTMR is disabled. If TPP = 0, then the pulse counter input source is active-high, and the CNR increments on the rising edge. If TPP = 1, then the pulse counter input source is active-low, and the CNR increments on the falling edge. 0b - Active-high 1b - Active-low
2 TFC	Timer Free-Running Counter You must alter TFC only when LPTMR is disabled. If TFC = 0, then LPTMR resets CNR whenever TCF = 1. If TFC = 1, then LPTMR resets CNR on overflow. 0b - Reset if TCF set 1b - Reset on overflow
1 TMS	Timer Mode Select Configures the mode of LPTMR. You must alter TMS only when LPTMR is disabled. 0b - Time Counter mode 1b - Pulse Counter mode
0 TEN	Timer Enable Enables LPTMR timer. When TEN is clear, it resets the LPTMR internal logic, including the CNR and TCF. When TEN is set, LPTMR is enabled. When writing 1 to this field, CSR[5:1] must not be altered. 0b - Disable 1b - Enable

44.7.1.3 Prescale and Glitch Filter (PSR)

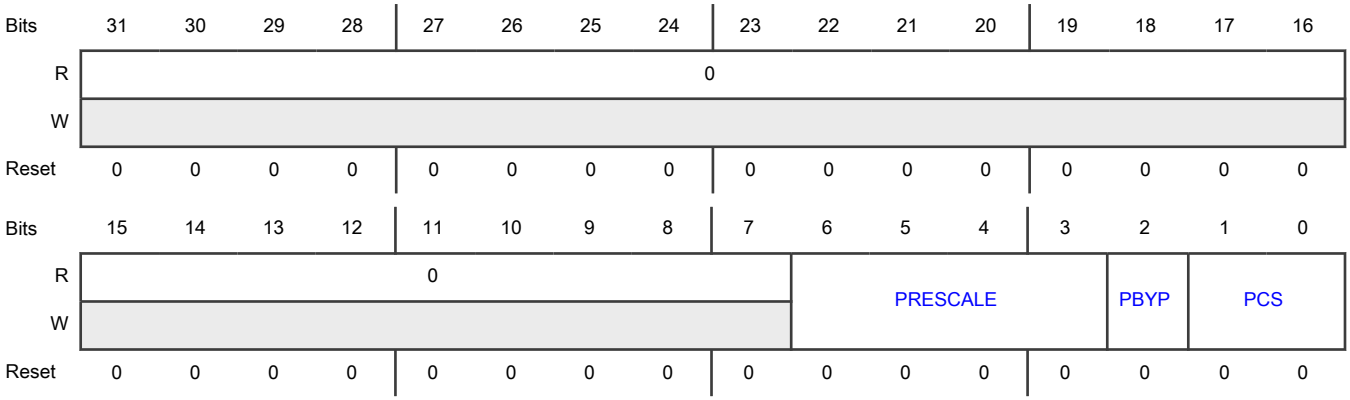
Offset

Register	Offset
PSR	4h

Function

Configures features related to the prescaler/glitch filter.

Diagram



Fields

Field	Function
31-7 —	Reserved
6-3 PRESCALE	Prescale/Glitch Filter Value Configures the size of the prescaler in Time Counter mode or the width of the glitch filter in Pulse Counter mode. The width of the glitch filter can vary by 1 cycle due to synchronization of the pulse counter input. PRESCALE must be altered only when LPTMR is disabled. 0000b - Prescaler divides the prescaler clock by 2; glitch filter does not support this configuration. 0001b - Prescaler divides the prescaler clock by 4; glitch filter recognizes change on input pin after 2 rising clock edges. 0010b - Prescaler divides the prescaler clock by 8; glitch filter recognizes change on input pin after 4 rising clock edges. 0011b - Prescaler divides the prescaler clock by 16; glitch filter recognizes change on input pin after 8 rising clock edges. 0100b - Prescaler divides the prescaler clock by 32; glitch filter recognizes change on input pin after 16 rising clock edges.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0101b - Prescaler divides the prescaler clock by 64; glitch filter recognizes change on input pin after 32 rising clock edges. 0110b - Prescaler divides the prescaler clock by 128; glitch filter recognizes change on input pin after 64 rising clock edges. 0111b - Prescaler divides the prescaler clock by 256; glitch filter recognizes change on input pin after 128 rising clock edges. 1000b - Prescaler divides the prescaler clock by 512; glitch filter recognizes change on input pin after 256 rising clock edges. 1001b - Prescaler divides the prescaler clock by 1024; glitch filter recognizes change on input pin after 512 rising clock edges. 1010b - Prescaler divides the prescaler clock by 2048; glitch filter recognizes change on input pin after 1024 rising clock edges. 1011b - Prescaler divides the prescaler clock by 4096; glitch filter recognizes change on input pin after 2048 rising clock edges. 1100b - Prescaler divides the prescaler clock by 8192; glitch filter recognizes change on input pin after 4096 rising clock edges. 1101b - Prescaler divides the prescaler clock by 16,384; glitch filter recognizes change on input pin after 8192 rising clock edges. 1110b - Prescaler divides the prescaler clock by 32,768; glitch filter recognizes change on input pin after 16,384 rising clock edges. 1111b - Prescaler divides the prescaler clock by 65,536; glitch filter recognizes change on input pin after 32,768 rising clock edges.
2 PBYP	Prescaler/Glitch Filter Bypass Controls clocking of CNR. When PBYP = 1, the selected prescaler clock in Time Counter mode, or else the selected input source in Pulse Counter mode, directly clocks the CNR. When PBYP = 0, the output of the prescaler/glitch filter clocks the CNR. You must change PBYP only when LPTMR is disabled. 0b - Prescaler/glitch filter enable 1b - Prescaler/glitch filter bypass
1-0 PCS	Prescaler/Glitch Filter Clock Select Selects the clock to be used by the LPTMR prescaler/glitch filter. You must alter PCS only when LPTMR is disabled. See the chip configuration details for information on the connections to these inputs. • In Time Counter mode, PCS selects the input clock to the prescaler. • In Pulse Counter mode, PCS selects the input clock to the glitch filter. 00b - Clock 0 01b - Clock 1 10b - Clock 2 11b - Clock 3

44.7.1.4 Compare (CMR)

Offset

Register	Offset
CMR	8h

Function
Configures the compare values to the CNR (see Compare for details).

Chapter 45
Low Power Periodic Interrupt Timer (LPIT)

45.1 Chip-specific LPIT information

Table 268. Reference links to related information

Topic	Related module	Reference
Full description	LPIT	LPIT
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

45.1.1 Module instances

This device has one instance of the LPIT module, LPIT0. The LPIT0 contains 4 channels.

45.1.2 External trigger source

If the TCTRLx[TRG_SRC] is set to 1, it selects to use external trigger source from TRGMUX, refer to TRGMUX0 outputs for more details.

45.2 Overview

LPIT is a low power periodic interrupt timer with multiple timer channels. After a timer reaches a programmed count, the respective timer channel generates pre-trigger and trigger output signals, and these pre-trigger and trigger outputs can be used to trigger other modules on the device.

45.2.1 Block Diagram

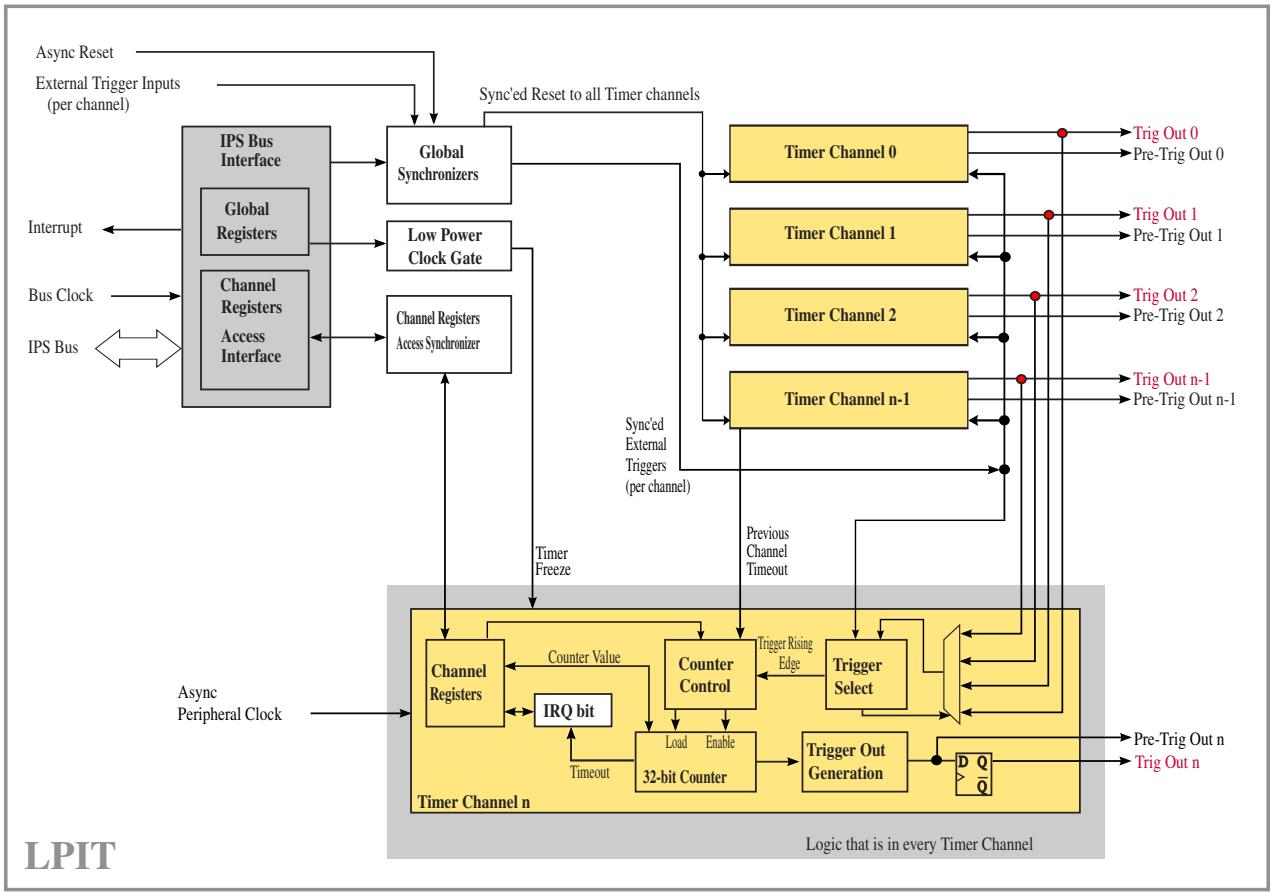

Figure 129. Detailed Block Diagram

45.2.2 Features

- Timers can be configured to be controlled using:
  - external triggers (triggers from outside the LPIT module)
  - or internal triggers (triggers from other timer channels inside the LPIT module).
- The timer channels can be chained together, to form a larger width timer.
- Depending on the timer modes, the timer channels may reload and count again, or stop after reaching the programmed count.

45.3 Functional description

45.3.1 LPIT programming model

The programming model comprises a global register set (common to all timer channels), and registers for each timer channel (that control their respective timer channels). Access to these registers gets synchronized to the asynchronous peripheral clock, then affects the timer channel registers.

- Each timer channel contains a 32-bit counter that loads the starting value and down counts on every peripheral clock's positive edge.
- After reaching a zero value (a channel timer timeout), a trigger output is generated.
- The counter enable is controlled using a timer enable register control bit, external or internal triggers or via previous channel timeout (when using timer chaining).
- After a channel timer timeout, an interrupt bit is also set, to tell the CPU about the timer timeout.

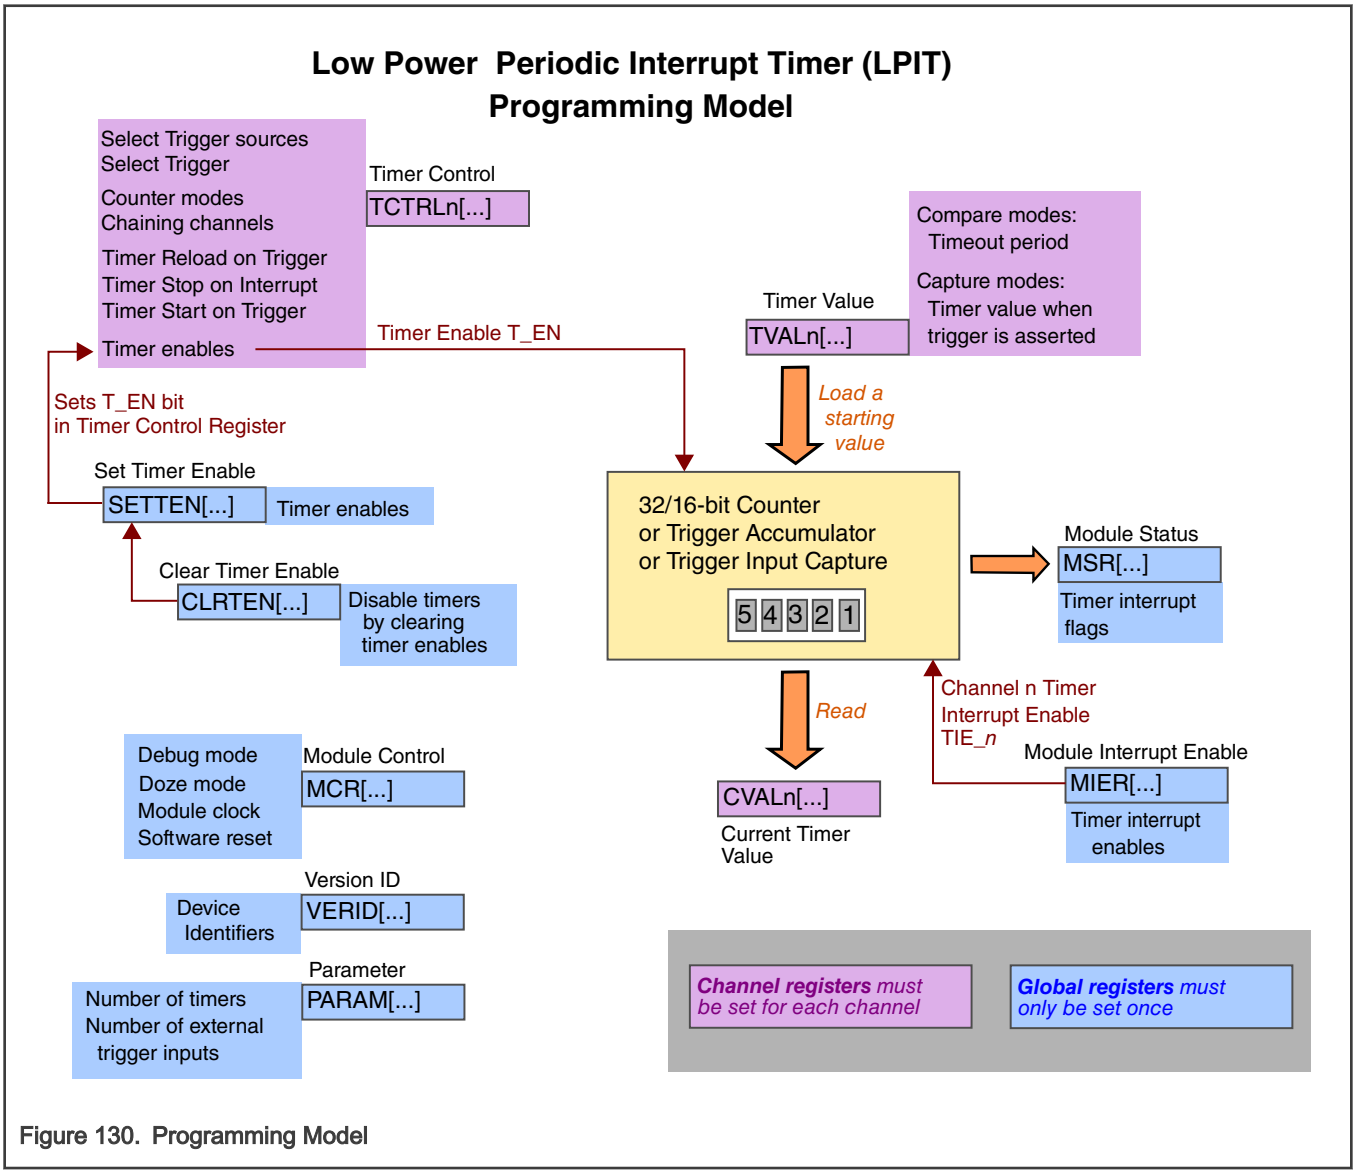

Figure 130. Programming Model

Global registers need only be set once:

- Version ID Register (VERID)
- Parameter Register (PARAM)
- Module Control Register (MCR)
- Module Status Register (MSR)
- Module Interrupt Enable Register (MIER)
- Set Timer Enable Register (SETTEN)

- Clear Timer Enable Register (CLRTEN)

Channel registers must be set for each channel:

- Timer Value Register (TVAL0 - TVAL3)
- Current Timer Value (CVAL0 - CVAL3)
- Timer Control Register (TCTRL0 - TCTRL3)

45.3.2 LPIT interface with other modules on the SoC

The next figure shows the interface of an LPIT module to the other modules on the SoC.

- The CPU interface provides the clock, reset, register read/write bus interface and handles interrupts from an LPIT.
- The trigger output signals from an LPIT may trigger other modules on the SoC, like the DMA, ADC, and other modules.
- Similarly, other timer modules may provide trigger inputs to an LPIT module, to control when an LPIT timer channel starts.

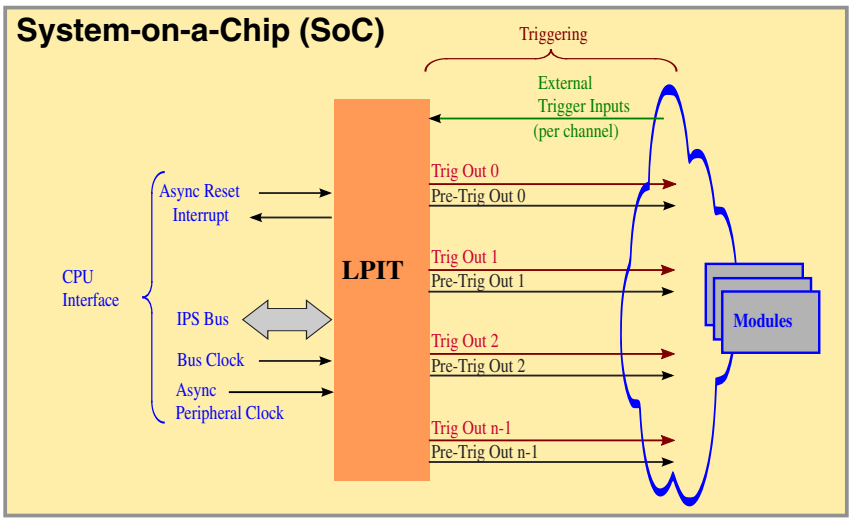

Figure 131. LPIT Interface in SoC

45.3.3 Chip power modes

The LPIT module supports the following chip power modes.

Table 269. Chip modes supported by the LPIT module

Chip mode	LPIT Operation
Run	Normal operation
Sleep	Can continue operating, if the Doze Enable bit (MCR[DOZE_EN]) is set and the LPIT is using an external or internal clock source that remains operating during Sleep mode.
Low Power Stop (also called Deep Sleep)	The Doze Enable (MCR[DOZE_EN]) bit is ignored and the LPIT will be disabled for the duration of Low Power mode.

Table continues on the next page...

Table 269. Chip modes supported by the LPIT module (continued)

Chip mode	LPIT Operation
Debug	Can continue operating provided the Debug Enable bit (MCR[DBG_EN]) is set.

45.3.4 Timer modes

The timer mode is configured by setting an appropriate value in the MODE bits in TCTRLn register.

Table 270. Timer modes that are supported

Timer mode	Operation
32-bit Periodic Counter	• The counter will load, decrement down to 0 • which will set the timer interrupt flag and assert the output pre-trigger.
Dual 16-bit Periodic Counter	• The counter will load, then the lower 16-bits will decrement down to 0 • which will assert the output pre-trigger. • The upper 16-bits will then decrement down to 0 • which will set the timer interrupt flag and then negate the output pre-trigger.
32-bit Trigger Accumulator	• The counter will load on the 1st trigger rising edge and then decrement down to 0 on each trigger rising edge • which will set the timer interrupt flag and assert the output pre-trigger.
32-bit Trigger Input Capture	• The counter will load with 0xFFFF_FFFF and then decrement down to 0. • If a trigger rising edge is detected, — then it will store the inverse of the current counter value in the timer value register — which will set the timer interrupt flag and assert the output pre-trigger.

The timer operation is controlled by Trigger Control bits (TSOT, TSOI, TROT) which control the timer load, reload, start, and restart of the timers.

NOTE

- The trigger output is asserted one Peripheral Timer Clock cycle later than pre-trigger output. The trigger output and the pre-trigger output de-assert at the same time.
- The pre-trigger output is asserted for 2 clock cycles and the trigger output is asserted for 1 clock cycle (except in 16-bit Periodic Counter mode, where both pre-trigger and trigger are asserted for many cycles depending on TMR_VAL[31:16]).
- Timer changes *that are based on external triggers* take effect after 4 peripheral clocks after the actual external trigger assertion (due to clock synchronization, rise edge detection and timer update).

45.3.5 Timer channel modes

Each timer channel in LPIT can be configured to work in either compare modes or capture modes.

- **In compare mode:** the timers decrement when enabled and generate an output pre-trigger and trigger output. The trigger output is 1 clock cycle delayed of the pre-trigger pulse. Each timer channel start, reload and restart can be controlled via control bits. The timer can be configured to always decrement from a programmed start value, or decrement on selected

trigger inputs or previous channel timeout (when channels are chained). By chaining timer channels, applications can achieve larger timeout durations.

- **In capture mode:** the timer can be used to perform measurements as the timer value is captured (in the timer value register) when a selected trigger input is asserted. The timer can support once-off or multiple measurements (like frequency measurements).

The timer channels operate on an asynchronous clock, which is independent from the register read/write access clock. Clock synchronization between the clock domains ensures normal operations.

45.3.6 Trigger control for timers

Various programmable bits control how the trigger inputs and the timer operate. TRG_SEL and TRG_SRC select the timer triggers:

- Trigger Select (TRG_SEL) selects the input trigger for the channel from all of the other channel's trigger outputs.
- Trigger Source (TRG_SRC) selects between the internal trigger and the external trigger inputs to the channel.

The selected trigger affects how the timer operates, using the configuration of the TROT, TSOI and TSOT bits.

Table 271. How bits control timer operations

If	=	Then
TSOI *Timer Stop On Interrupt*	1	then the counter stops on a Timer Interrupt flag (MSR[TIFn]) assertion. To reload and decrement, it requires: • a trigger (if TSOT = 1) • a T_EN rising edge (if TSOT = 0)
	0	then the counter does not stop after timeout
TROT *Timer Reload On Trigger*	1	then the counter is loaded on each trigger
	0	then the counter is loaded on every T_EN rising edge or timeout rising edge (timeout not used in Capture modes)
TSOT *Timer Start On Trigger*	1	then the counter will start to decrement on a trigger. Subsequent triggers are ignored until the counter times out.
	0	then the counter decrements immediately on the next clock edge. When channel is Chained or in Capture mode, TSOT has no effect.

In different timer modes, these programmable bits affect the timer operation differently:

Table 272. Time modes and programmable bits

Mode	Which programmable bits affect timer operations
32-bit Periodic Counter	All bits (TSOT, TSOI, TROT) affect the timer operation as described previously.
Dual 16-bit Periodic Counter	
32-bit Trigger Accumulator	• Only the TSOI bit controls the timer function. • TROT and TSOT bits have no effect on timer operations.
32-bit Input Trigger Capture	• Only TSOI and TROT bits control the timer function. • TSOT bit has no effect on timer operations.

45.3.7 Channel chaining

Individual timer channels can be chained together to achieve a larger value of timeout. Chaining the timer channel causes them to work in a *'nested loop'* manner thereby leading to an effective timeout value of $TVAL_{CHn} \times (TVAL_{CHn-1} + 1)$.

The channels are chained by setting the CHAIN bit in corresponding channel's $TCTRL_{CHn}$ register. When a channel is chained, that channel's timer decrements on previous channel's timeout pulse, regardless of the timer mode (MODE bits). The TSOT bit does not have any effect if the channel timer (Channel 'n') is chained to previous channel's timer (Channel 'n-1').

45.3.8 Detailed timing

NOTE

The timing diagrams in these sections are not *cycle-accurate* (that is, some cycles may not be shown), but the timing diagrams do show the timer channel behavior across several clock cycles.

Table 273. Timing diagrams list

Mode		Timing Diagram	TSOT	TROT	TSOI	CHAIN

Mode=01: 16-bit dual periodic counter (compare mode)

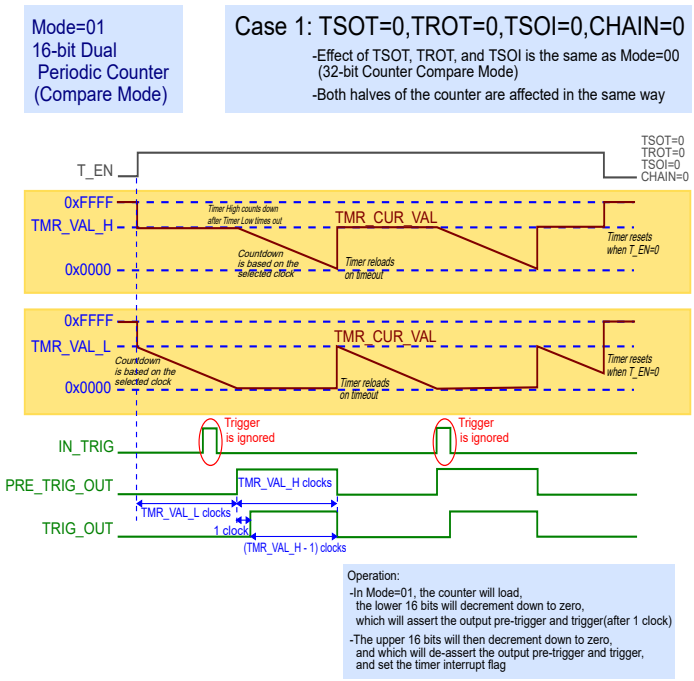

Figure 140. Case 1: TSOT = 0, TROT = 0, TSOI = 0, CHAIN = 0

Effect of Timer Control Bits in Mode=01:

- Effect of timer control bits are the same as for Mode=00. Refer to the individual figures of Mode=00.
- The Timer Interrupt (timeout) asserts when {TMR_H,TMR_L} = 0x0000_0000.
- Behavior for Mode = 01 is explained in the next table.

Table 274. Mode=01 timer control bits

TSOT	TROT	TSOI	Function	Effect on Timer
0	0	0	• For repeated interrupts with reload • Trigger outputs will have equal periods	Similar to Figure 140.
0	0	1	One-shot mode	• Both timers stop after first count down and then time out • Timers will not count again until T_EN is made 1 again • Similar to Figure 133.
0	1	0	• For repeated interrupts with reload • Trigger outputs will have unequal periods	• Both timers will reload TMR_VAL on trigger rise edge

Table continues on the next page...

Table 274. Mode=01 timer control bits (continued)

TSOT	TROT	TSOI	Function	Effect on Timer
				• Output triggers will clear on reload, if asserted • Similar to Figure 134.
0	1	1	Reloadable one-shot mode	• If a trigger occurs before timeout, then both timers reload and count down (as shown); the timers stop after timeout • A trigger assertion after timeout simply reloads TMR_VAL into the timers • The timers will not count again until T_EN is set to 1 again • Similar to Figure 135.
1	0	0	• For generating periodic interrupts after a predefined event (input trigger) • Output triggers will have equal periods	After T_EN rises, the timers do not start until the first trigger's rising edge • Subsequent triggers will have no effect • Similar to Figure 136.
1	0	1	• Triggered one-shot timer mode • Output trigger period will depend on input trigger	After T_EN rises, the timers do not start until the first trigger's rising edge. • The timer stops counting after a timeout assertion (a timeout is asserted) • The timer does not start counting again until a new trigger's rising edge is detected • Similar to Figure 137.
1	1	0	• For repeated interrupts with reload timer mode • Output triggers will have unequal periods	After T_EN rises, the timers do not start until the first trigger's rising edge • Subsequent triggers will cause the timer to reload TMR_VAL into both counters • The output triggers will clear after a reload, if asserted • Similar to Figure 138.
1	1	1	• For a non-periodic input trigger • If input trigger is periodic and greater than timer timeout, then this will be the same as TROT=0 (which is triggered one-shot timer mode; output trigger period will depend on input trigger)	After T_EN rises, the timers do not start until the first trigger's rising edge • The timers stops counting after a timeout assertion (a timeout is asserted) • A trigger's rising edge will cause the timers to reload and then count down • Similar to Figure 139.

Mode=10: 32-bit trigger accumulator mode

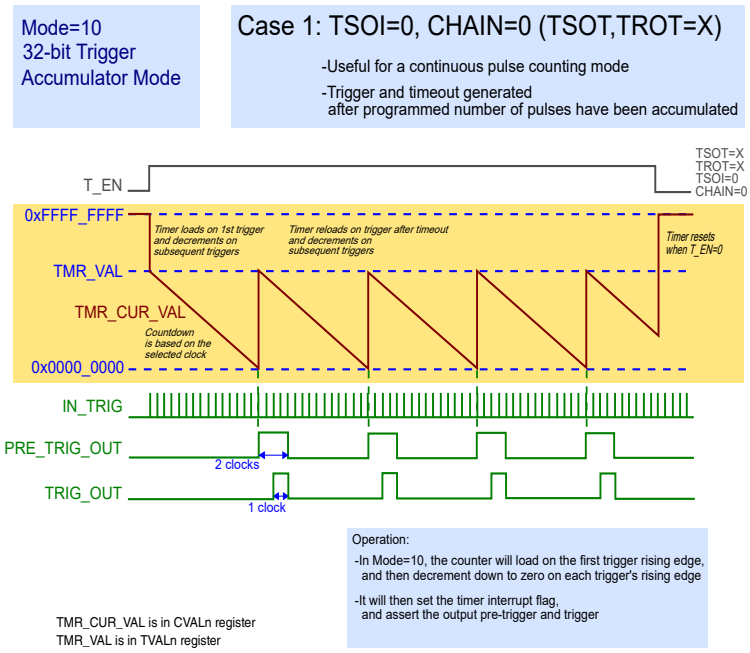

Figure 141. Case 1: TSOT = X, TROT = X, TSOI = 0, CHAIN = 0

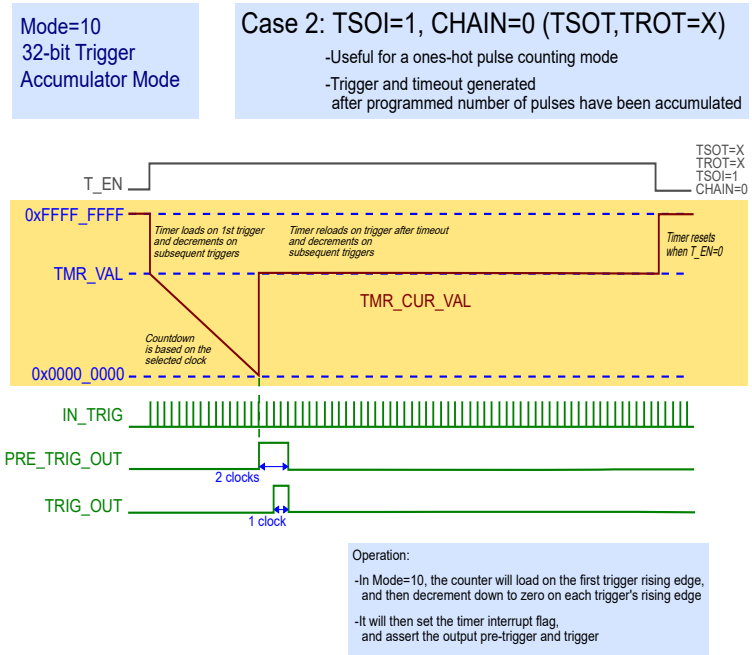

Figure 142. Case 2: TSOT = X, TROT = X, TSOI = 1, CHAIN = 0

Mode=11: 32-bit trigger capture mode

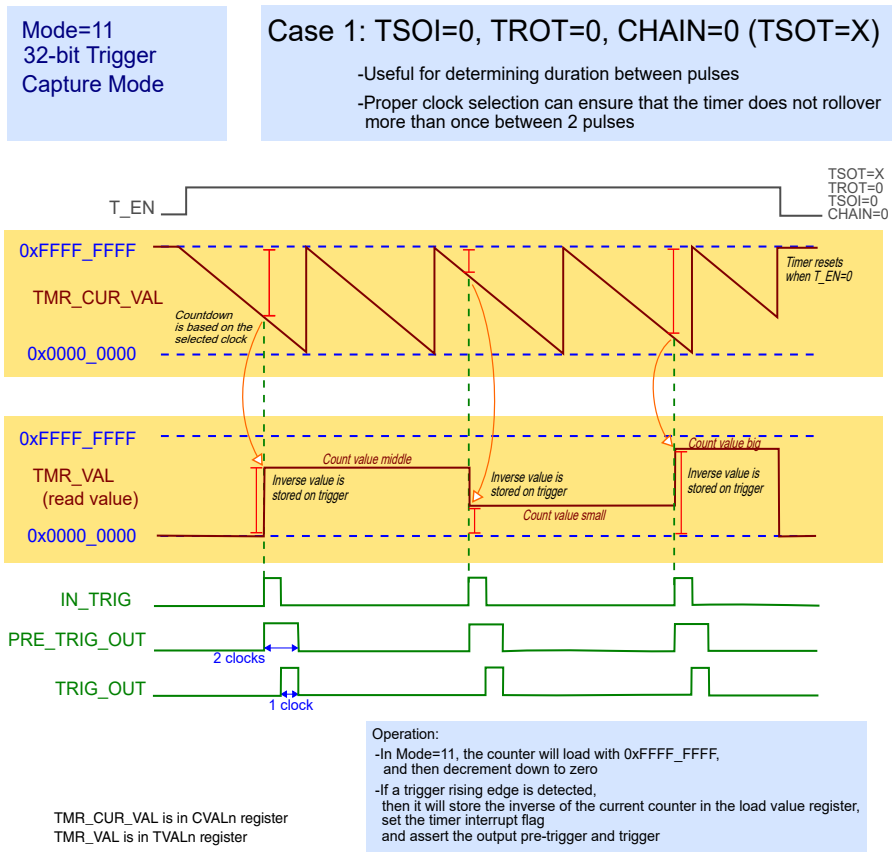

Figure 143. Case 1: TSOT = X, TROT = 0, TSOI = 0, CHAIN = 0

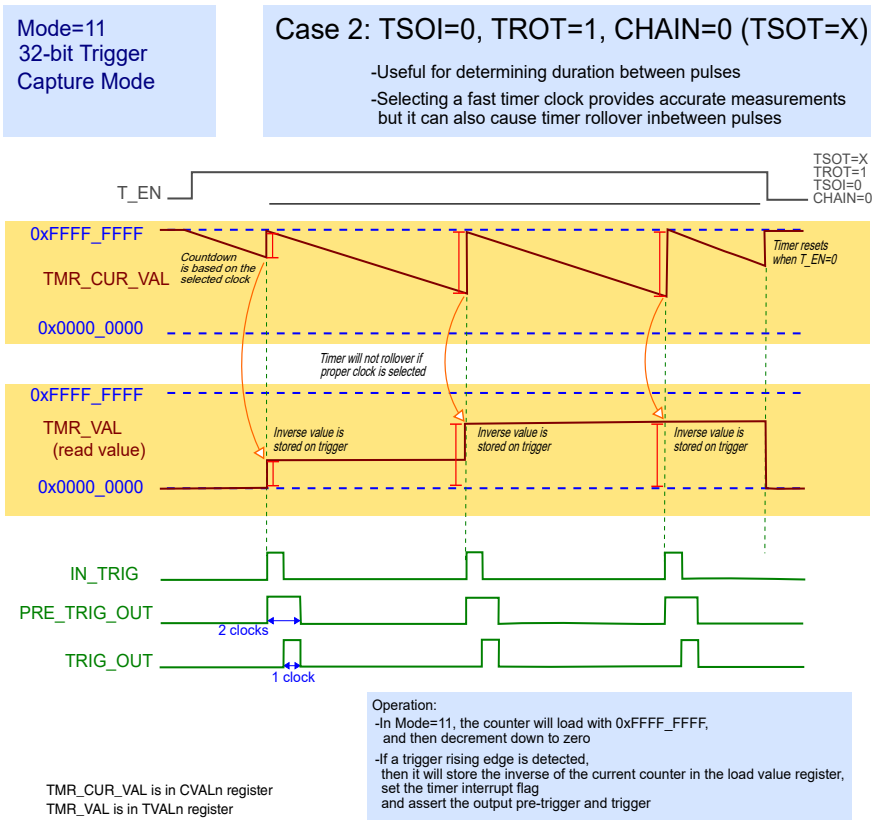

Figure 144. Case 2: TSOT = X, TROT = 1, TSOI = 0, CHAIN = 0

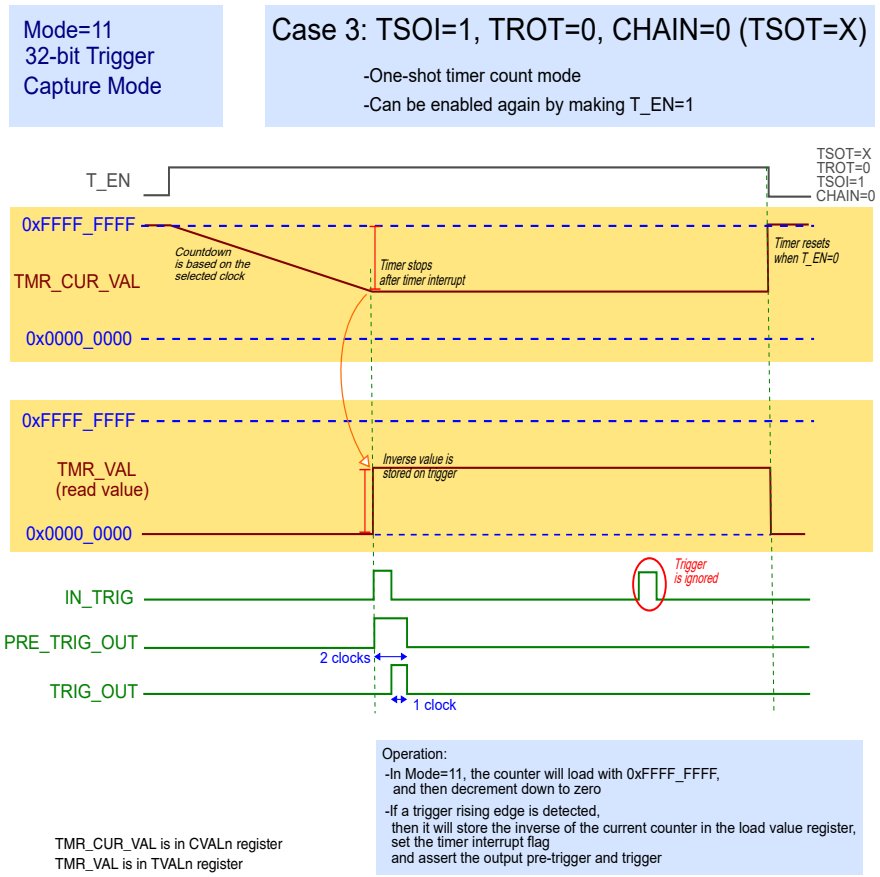

Figure 145. Case 3: TSOT = X, TROT = 0, TSOI = 1, CHAIN = 0

Case 4: TSOT = X, TROT = 1, TSOI = 1, CHAIN = 0

Same as previous case (Case 3), except that the timer reloads to 0xFFFF_FFFF and then stops. The timer does not start until T_EN is made 1 again. Case 4 is not a very useful case, because Case 3 covers this.

Timer chaining

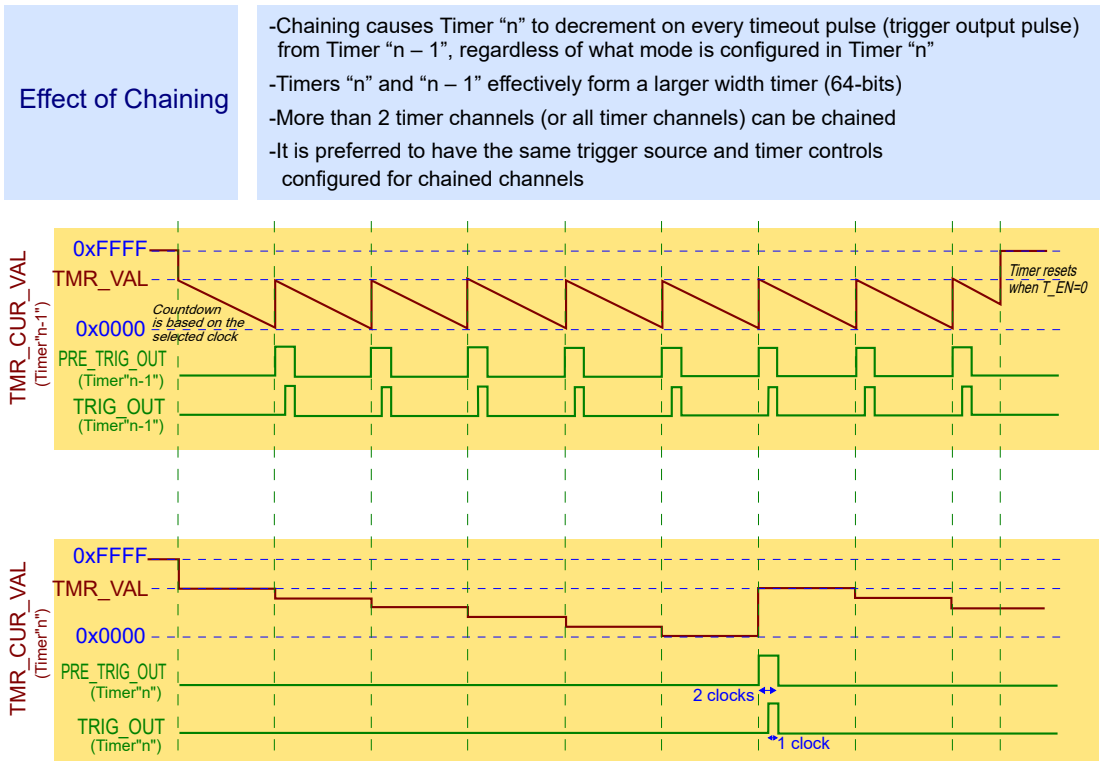

Figure 146. Chaining Effects

45.4 Initialization

Table 275. Initializing the LPIT module

Step		How? Why?
1	Enable the peripheral clock	by setting the Module Clock Enable bit (M_CEN) in the Module Control Register (MCR) register. **NOTE** • Accessing certain registers (MSR, SETTEN, CLRTEN, TVAL, CVAL, and TCTRL) while M_CEN = 0 will lead to assertion of a transfer error for that bus access. — Writing to CVAL and Reserved registers will generate a transfer error. • There might be additional clock gating bits in the device that gate the peripheral clock to this module. When enabling the clock to this module, ensure that software is configuring those additional clock gating bits (in addition to M_CEN bit).
2	Wait for 4 peripheral clock cycles	to allow time for clock synchronization and reset de-assertion.

Table continues on the next page...

Table 275. Initializing the LPIT module (continued)

Step		How? Why?
3	Configure timer control bits	for each timer channel that is to be enabled: • timer mode of operation bits TCTRLn[MODE] • trigger source selection bits TCTRLn[TRG_SEL, TRG_SRC] • trigger control bits TCTRLn[TROT, TSOT, TSOI] **NOTE** Timer controls should only be updated when the timer is disabled. There are 2 ways to disable a timer: write 1 to the specific timer's Clear Timer Enable register bit (CLRTEN[CLR_T_EN_n]) or set the timer enable bit (TCTRLn[T_EN]) = 0 for that channel.
4	Configure the channels that are to be chained	by setting the CHAIN bit in the corresponding channel's TCTRLn register.
5	Set the timer timeout value	for channels configured in Compare Mode, by programming the appropriate value in TVAL register for those channels.
6	Configure TIEn bits in MIER register	for those channels that are required to generate interrupts on timer timeouts.
7	Configure the low power modes of the module	by setting the DBG_EN and DOZE_EN bits in the MCR register. This is common to all timer channels.
8	Enable the channel timers	by setting the corresponding T_EN bit in the corresponding channel's TCRTLn register.

NOTE

When the Timer Channel is enabled in Compare Mode, the first decrement takes an additional one or two clock cycles due to synchronization logic. This results in the first compare (and therefore interrupt and hardware trigger) occurring slightly later. A faster counter clock minimizes this impact.

Also:

- For channels configured in Capture Mode, the timer value can be read from TVALn register when a channel timeout occurs.
- At any time, the current value of the timer for any channel can be read by reading the corresponding channel's CVALn register. The M_CEN bit must be '1' when doing so.
- The timer interrupt flag bits (TIFn) in MSR register get asserted on timer timeout. To clear these timer interrupt flag bits, write '1' to them.

45.5 Memory Map and Registers

45.5.1 LPIT register descriptions

The memory map comprises 32-bit aligned registers, which can be accessed via 8-bit, 16-bit, or 32-bit accesses.

- Write access to reserved locations will generate a transfer error.
- Read access to reserved locations will also generate a transfer error, and the read data bus will show all 0s.

NOTE

- The Memory Map and complete module is in Big Endian format.
- The LPIT module will not check if programmed values in the registers are correct; software must ensure that correct programmed values are being written.

45.5.1.1 LPIT memory map

LPIT0 base address: 4002_F000h

0 TIE0	Channel 0 Timer Interrupt Enable Enables interrupt generation when: • the Channel 0 Timer Interrupt Enable bit (TIE0) is set to 1 • and if the corresponding Timer Interrupt Flag (MSR[TIF0]) is asserted (=1, timeout has occurred) 0b - Disabled 1b - Enabled

45.5.1.7 Set Timer Enable (SETTEN)

Offset

Register	Offset
SETTEN	14h

Function

The Set Timer Enable register allows the simultaneous enabling of timer channels.

- Timer channels can be enabled by

— either by writing '1' to Timer Enable bit (T_EN) in the respective TCTRLn register,

— or by setting the corresponding Set Timer Enable bit (SET_T_EN_*n*) in the Set Timer Enable register (SETTEN).

- To disable timer channels simultaneously, use the Clear Timer Enable register (CLRTEN).
- Writing a '0' to the Set Timer Enable register has no effect.

NOTE

Unless the Module Clock Enable bit (MCR[M_CEN]) is set (=1, peripheral clock to timers is enabled)), reading or writing the Set Timer Enable register will generate a transfer error.

Diagram

Offset

Register	Offset
TVAL0	20h
TVAL1	30h
TVAL2	40h
TVAL3	50h

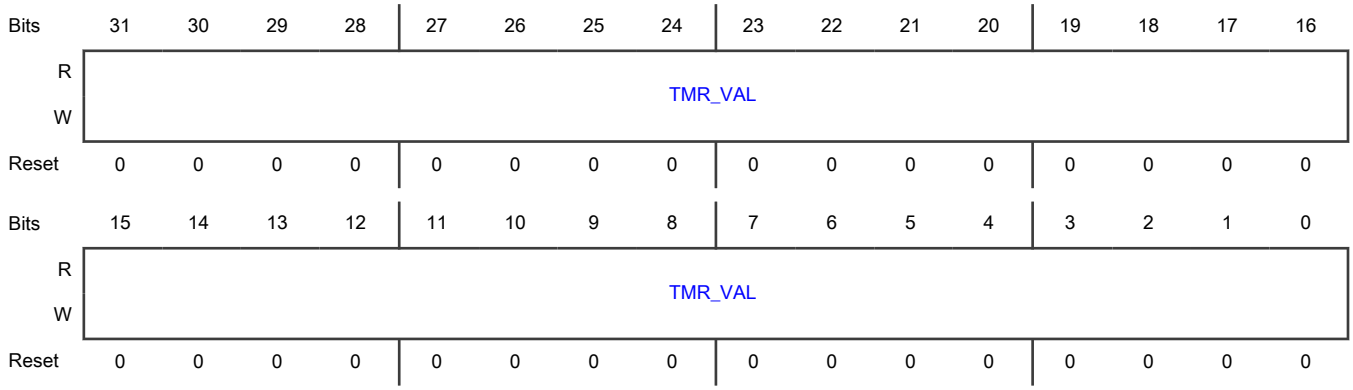
Function

- In compare modes: the Timer Value Registers (TVAL*n*) select the timeout period for the timer channels.
- In capture modes: the Timer Value Registers (TVAL*n*) are loaded with the value of the counter when the trigger asserts.

NOTE

Unless the Module Clock Enable bit (MCR[M_CEN]) is set (=1, peripheral clock to timers is enabled), then reading or writing the TVALn register will generate a transfer error.

Diagram



Fields

Field	Function
31-0 TMR_VAL	Timer Value • In compare mode: Timer Value (TMR_VAL) is the timer channel start value. — The timer counts down for (TVALn + 1) cycles until the timer reaches 0, then the timer generates an interrupt and loads the Timer Value register (TVAL*n*) value again. — Writing a new value to the Timer Value register (TVAL*n*) will not restart the timer channel; instead the new value will be loaded *after the timer expires*. — To abort the current timer cycle and start a timer period with a new value, the timer channel must be disabled and enabled *again*. • In capture mode: whenever the trigger asserts, the Timer Value register stores the inverse of the counter value. 0000_0000_0000_0000_0000_0000_0000_0000b,0000_0000_0000_0000_0000_0000_0000_0001b - Invalid load value in compare mode 0000_0000_0000_0000_0000_0000_0000_0010b-1111_1111_1111_1111_1111_1111_1111_1111b - In compare mode: the value to be loaded; in capture mode, the value of the timer

45.5.1.10 Current Timer Value (CVAL0 - CVAL3)

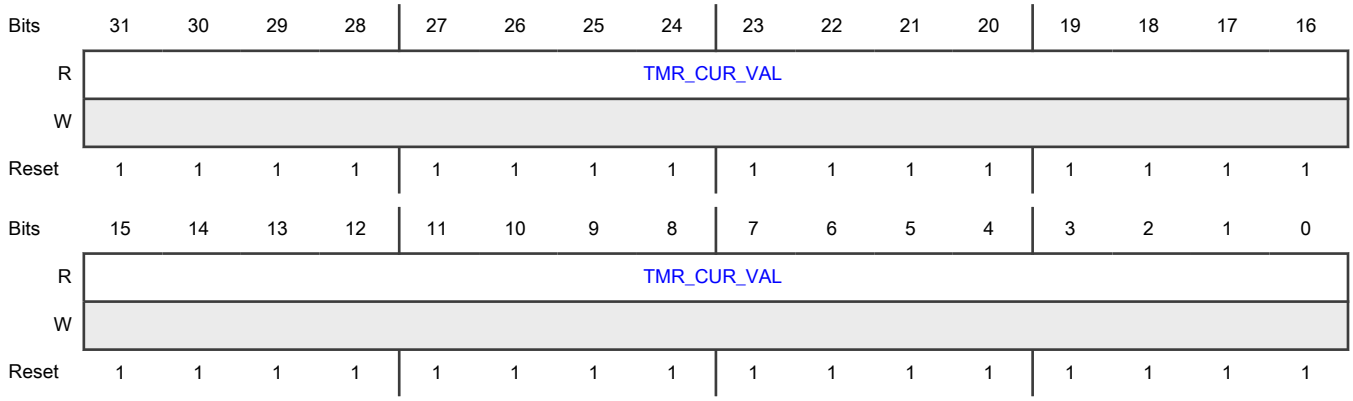
Offset

Register	Offset
CVAL0	24h
CVAL1	34h
CVAL2	44h
CVAL3	54h

Function

The Current Timer Value registers indicate the current timer counter value.

Diagram



Fields

Field	Function
31-0 TMR_CUR_VAL	Current Timer Value Represents the current timer value, if the timer is enabled.

45.5.1.11 Timer Control (TCTRL0 - TCTRL3)

Offset

Register	Offset
TCTRL0	28h
TCTRL1	38h
TCTRL2	48h
TCTRL3	58h

Function

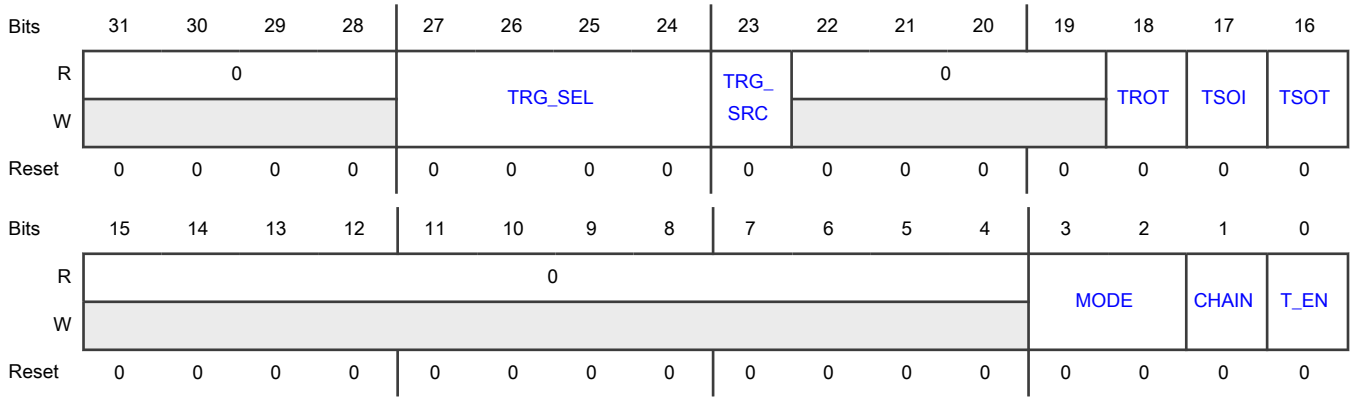
The Timer Control registers contain the control bits for each timer channel.

NOTE

- Unless the peripheral clock to the timers is enabled (Module Clock Enable bit (MCR[M_CEN]) is set (=1)), then reading or writing the Timer Control register will generate a transfer error.
- Timer controls should only be updated when the timer is disabled. In the Timer Control Register TCTRLn, these timer controls include:
  - Trigger Select TRG_SEL
  - Trigger Source TRG_SRC
  - Timer Reload On Trigger TROT
  - Timer Stop On Interrupt TSOI
  - Timer Start On Trigger TSOT
  - Timer Operation Mode MODE
  - Chain Channel CHAIN

  There are 2 ways to disable a timer: write 1 to the specific timer's Clear Timer Enable register bit (CLRTEN[CLR_T_EN_n]) or set the timer enable bit (TCTRLn[T_EN]) = 0 for that channel.

Diagram



Fields

Field	Function
31-28 —	This read-only field is reserved and always has the value 0
27-24 TRG_SEL	Trigger Select Selects the trigger to use for starting and/or reloading the LPIT timer. • The TRG_SEL field selects one trigger from the set of internal or external triggers that are selected by the Trigger Source bit (TRG_SRC) • Recall that the TRG_SRC bit selects between internal and external trigger signals for each channel **NOTE** The Trigger Select field should only be changed when the LPIT timer channel is disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0000b-0011b - Timer channel 0 - 3 trigger source is selected 0100b-1111b - Reserved
23 TRG_SRC	Trigger Source Selects between internal or external trigger sources. The trigger to be used is selected using the TRG_SRC and TRG_SEL bits. See LPIT chip-specific information for available external trigger options. If a channel does not have an associated external trigger, then set the Trigger Source bit (TRG_SRC) = 1. 0b - Selects external triggers 1b - Selects internal triggers
22-19 —	This read-only field is reserved and always has the value 0
18 TROT	Timer Reload On Trigger When set, the LPIT timer will reload when a rising edge is detected on the selected trigger input. The trigger input is ignored if the LPIT is disabled during debug mode (DBGEN = 0) or DOZE mode (DOZE_EN = 0) 0b - Timer will not reload on the selected trigger 1b - Timer will reload on the selected trigger
17 TSOI	Timer Stop On Interrupt Controls whether the channel timer will stop after it (the channel timer) times out or not. 0b - The channel timer does not stop after timeout 1b - The channel timer will stop after a timeout, and the channel timer will restart based on Timer Start On Trigger bit (TSOT). When TSOT = 0, the channel timer will restart after a rising edge on the Timer Enable bit (T_EN) is detected (which means that the timer channel is disabled and then enabled). When TSOT = 1, the channel timer will restart after a rising edge on the selected trigger is detected.
16 TSOT	Timer Start On Trigger Controls when the timer starts decrementing. 0b - Timer starts to decrement immediately based on the restart condition (controlled by the Timer Stop On Interrupt bit (TSOI)) 1b - Timer starts to decrement when a rising edge on a selected trigger is detected
15-4 —	This read-only field is reserved and always has the value 0
3-2 MODE	Timer Operation Mode Configures the channel timer's mode of operation. The MODE bits control how the timer decrements.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - 32-bit Periodic Counter 01b - Dual 16-bit Periodic Counter 10b - 32-bit Trigger Accumulator 11b - 32-bit Trigger Input Capture
1 CHAIN	Chain Channel When enabled, the timer channel will decrement when timer channel N-1 trigger asserts. Timer channel 0 cannot be chained. 0b - Channel Chaining is disabled. The channel timer runs independently. 1b - Channel Chaining is enabled. The timer decrements on the previous channel's timeout.
0 T_EN	Timer Enable Enables or disables the Timer Channel 0b - Timer Channel is disabled 1b - Timer Channel is enabled

Chapter 46
Time Stamp Timer (TSTMR)

46.1 Chip-specific TSTMR information

Table 276. Reference links to related information

Topic	Related module	Reference
Full description	TSTMR	TSTMR
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

46.1.1 Module instances

This device has one instance of the TSTMR module, TSTMR0.

46.2 Overview

The Time Stamp Timer (TSTMR) is a 56-bit clock cycle counter, reset by system reset.

46.2.1 Features

- Free-running Time Stamp Timer

46.3 Functional description

The TSTMR module is a free running incrementing counter that starts running after system reset de-assertion and can be read at any time by the software for determining the software ticks. However, the software must follow the read sequence as mentioned in the TSTMR register descriptions for correctly reading the TSTMR value. The TSTMR is a 56-bit counter and hence requires two 32-bit reads to read the full value. The TSTMR runs off the 1 MHz clock and resets on every system reset. The counter only stops when the clock to the TSTMR is disabled.

See the chip-specific TSTMR information for implementation details of this module's instances.

46.4 TSTMR Memory map and register definition

The TSTMR Memory Map/Register Definition can be found here.

NOTE

TSTMR registers can be read with 32-bit accesses only.

46.4.1 TSTMR register descriptions

This section contains the detailed register descriptions for the TSTMR registers.

46.4.1.1 TSTMR memory map

TSTMR0.TSTMR0 base address: 4003_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Time Stamp Timer Register Low (LOW)	32	R	0000_0000h
4h	Time Stamp Timer Register High (HIGH)	32	R	0000_0000h

46.4.1.2 Time Stamp Timer Register Low (LOW)

Offset

Register	Offset
LOW	0h

Function

The Time Stamp Timer is a 56-bit clock cycle counter, reset by system reset. It is readable by way of the TSTMR HIGH and LOW registers. Only 32-bit read accesses are allowed. Any other access will generate a transfer error.

Note the following:

- A complete read operation should include both TSTMR LOW and HIGH reads. If a HIGH read does not follow a LOW read, then any other Time Stamp value read will be locked at a fixed value.
- The TSTMR LOW read should occur first, followed by the TSTMR HIGH read.

23-0 VALUE	Time Stamp Timer High Upper 24 bits of the 56-bit time stamp value. The software must read the LOW first, followed by a read to HIGH to retrieve the complete value. The all-zero reset value may not be readable because the value will increment before it can be read by the software.

Chapter 47
Timer/PWM Module (TPM)

47.1 Chip-specific TPM information

Table 277. Reference links to related information

Topic	Related module	Reference
Full description	TPM	TPM
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

47.1.1 Module instances

This device has three instances of the TPM module, TPM0, TPM1, and TPM2.

47.2 Overview

The TPM (Timer/PWM Module) is a 6-channel timer that supports input capture, output compare, and the generation of PWM signals to control electric motor and power management applications. The counter, compare and capture registers are clocked by an asynchronous clock that can remain enabled in low power modes.

47.2.1 Block diagram

The TPM uses one input/output (I/O) pin per channel, CHn (TPM channel (n)) where n is the channel number.

The following figure shows the TPM structure. The central component of the TPM is the 32-bit counter with programmable final value and its counting can be up or up-down.

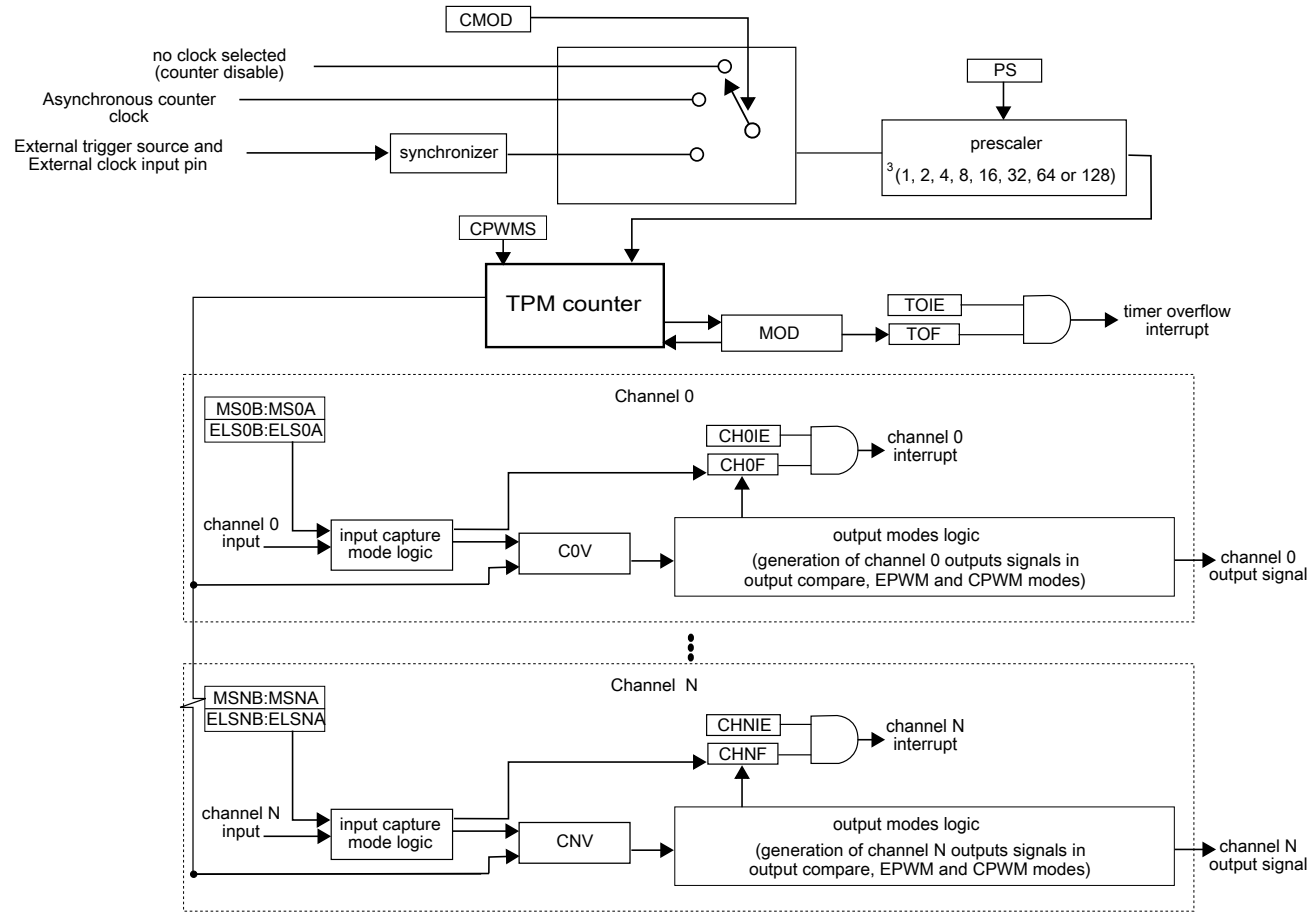

Figure 147. TPM block diagram

47.2.2 Features

The TPM features include:

- TPM clock mode is selectable
  - Can increment on every edge of the asynchronous counter clock
  - Can increment on rising edge of an external clock input synchronized to the asynchronous counter clock
- Prescaler divide-by 1, 2, 4, 8, 16, 32, 64, or 128
- TPM includes a 32-bit TPM counter
  - It can be a free-running counter or modulo counter
  - The counting can be up or up-down
- Includes 6 channels that can be configured as follows:
  - Input capture mode: the capture can occur on rising edges, falling edges or both edges
  - Output compare mode: the output signal can be set, cleared, pulsed, or toggled on match
  - Edge-aligned or center-aligned PWM mode for all channels
- Support the generation of an interrupt and/or DMA request per channel
- Support the generation of an interrupt and/or DMA request when the counter overflows

- Support selectable trigger input to optionally reset or cause the counter to start incrementing.
  - The counter can also optionally stop incrementing on counter overflow
- Support the generation of hardware triggers when the counter overflows and per channel

47.3 Functional description

The following sections describe the TPM features.

47.3.1 Clock domains

TPM supports two clock domains.

The bus clock domain is used by the register interface and for synchronizing interrupts and DMA requests.

The TPM counter clock domain is used to clock the counter and prescaler along with the output compare and input capture logic. The TPM counter clock is considered asynchronous to the bus clock, can be a higher or lower frequency than the bus clock and can optionally remain operational in low power modes. When the global timebase feature is enabled, any TPM instance that is sharing the global timebase must be clocked by the same TPM counter clock.

47.3.1.1 Counter Clock Mode

The CMOD[1:0] bits in the SC register either disable the TPM counter or select one of three possible clock sources for the TPM counter. After any reset, CMOD[1:0] = 0:0 so the TPM counter is disabled. The CMOD[1:0] can configure one of the following counter clock sources.

- Asynchronous counter clock
- External clock input pin
- External trigger source

The CMOD[1:0] bits may be read or written at any time. Disabling the TPM counter by writing zero to the CMOD[1:0] bits does not affect the TPM counter value or other registers, but must be acknowledged by the TPM counter clock domain before they read as zero.

The external clock input and external trigger source pass through a synchronizer clocked by the TPM counter clock to ensure that counter transitions are properly aligned to counter clock transitions. Therefore, to meet Nyquist criteria considering also jitter, the frequency of the external clock source must be less than half of the counter clock frequency.

47.3.2 Prescaler

The selected counter clock source passes through a prescaler that is a 7-bit counter. The value of the prescaler is selected by the PS[2:0] bits. The following figure shows an example of the prescaler counter and TPM counter.

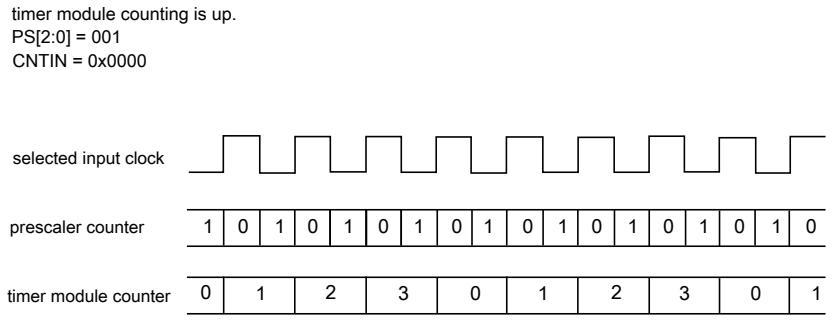

Figure 148. Example of the Prescaler Counter

47.3.3 Counter

TPM has a 32-bit counter that is used by the channels for either input or output modes. The counter updates from the selected clock divided by the prescaler. The TPM counter has these modes of operation:

- Up counting
- Up-down counting

47.3.3.1 Up counting

Up counting is selected when SC[CPWMS] = 0.

The value of zero is loaded into the TPM counter, and the counter increments until the value of MOD is reached, at which point the counter is reloaded with zero.

The TPM period when using up counting is (MOD + 0x0001) × period of the TPM counter clock.

The TOF bit is set when the TPM counter changes from MOD to zero.

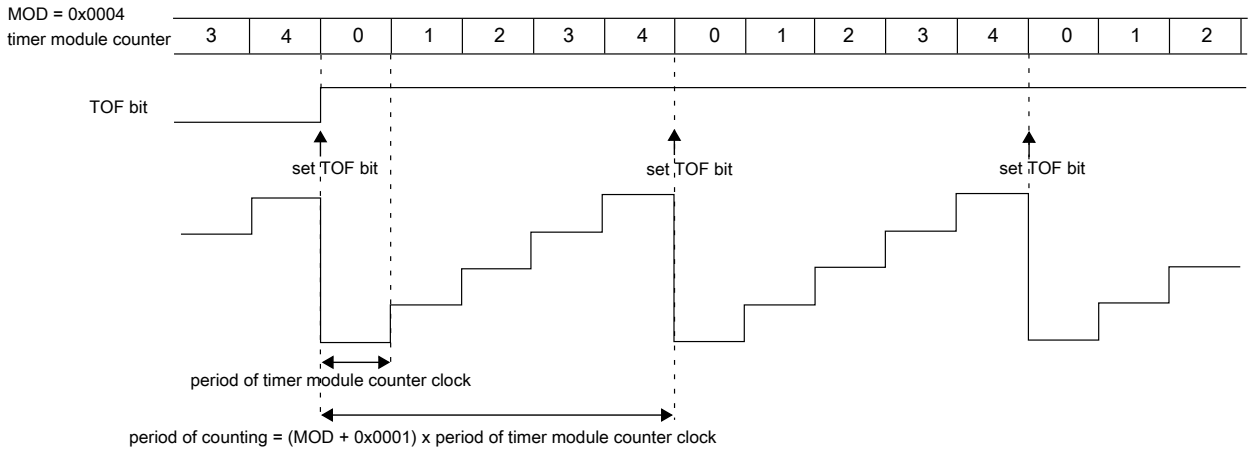

Figure 149. Example of TPM Up Counting

NOTE

- Configuring MOD = 0 is a redundant condition. In this case, the TPM counter is always equal to MOD and the TOF bit is set in each rising edge of the TPM counter clock.
- Configuring MOD = 1 and PS = 0 will attempt to set the TOF bit every second TPM counter clock. Due to synchronization delays between the TPM counter clock and the bus clock, the TOF must be cleared by software two counter clock cycles before TOF can be set again.

47.3.3.2 Up-down counting

Up-down counting is selected when SC[CPWMS] = 1. When configured for up-down counting, configuring MOD to less than 2 is not supported.

The value of 0 is loaded into the TPM counter, and the counter increments until the value of MOD is reached, at which point the counter is decremented until it returns to zero and the up-down counting restarts.

The TPM period when using up-down counting is 2 × MOD × period of the TPM counter clock.

The TOF bit is set when the TPM counter changes from MOD to (MOD – 1).

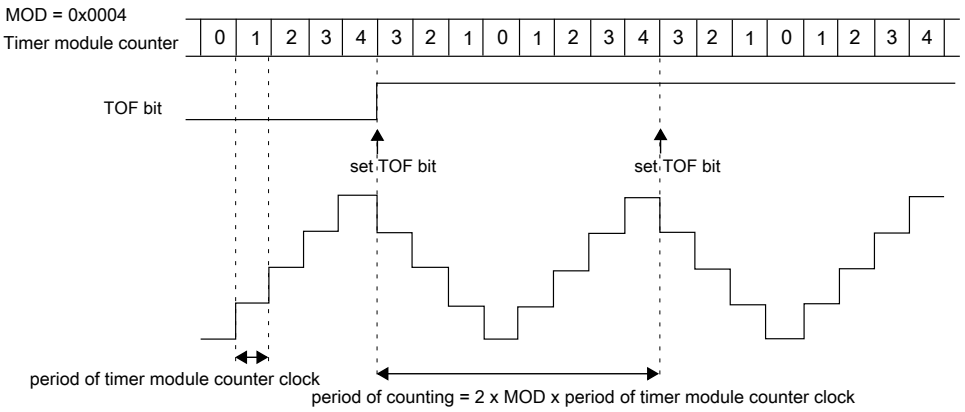

Figure 150. Example of up-down counting

47.3.3.3 Counter Reset

Any write to CNT resets the TPM counter and the channel outputs to their initial values (except for channels in output compare mode).

47.3.3.4 Global time base (GTB)

The global time base (GTB) is a TPM function that allows multiple TPM modules to share the same timebase. When the global time base is enabled (CONF[GTBEEN] = 1), the local TPM channels use the counter value, counter enable and overflow indication from the TPM generating the global time base. If the local TPM counter is not generating the global time base, then it can be used as an independent counter or pulse accumulator.

The local TPM counter can also be configured to synchronize to the global time base, by configuring (GTBSYNC = 1). When synchronized to the global time base, the local counter will use the counter enable and counter overflow indication from the TPM generating the global time base. This enables multiple TPM to be configured with the same phase, but with different periods (although the global time base must be configured with the longest period).

47.3.3.5 Counter trigger

The TPM counter can be configured to start, stop or reset in response to a hardware trigger input. The trigger input is synchronized to the asynchronous counter clock, so there is a 3 counter clock delay between the trigger assertion and the counter responding.

- When (CSOT = 1), the counter will not start incrementing until a rising edge is detected on the trigger input.
- When (CSOO= 1), the counter will stop incrementing whenever the TOF flag is set. The counter does not increment again unless it is disabled, or if CSOT = 1 and a rising edge is detected on the trigger input.
- When (CROT= 1), the counter will reset to zero as if an overflow occurred whenever a rising edge is detected on the trigger input. Any PWM channels will update to their reload state.
- When (CPOT = 1), the counter will pause incrementing whenever the trigger input is asserted. The counter will continue incrementing when the trigger input negates. PWM output channels are forced to their default state.

The polarity of the external input trigger can be configured by the TRGPOL register bit.

When an internal trigger source is selected, the trigger input is selected from one or more channel input capture events. The input capture filters are used with the internal trigger sources and the POLn bits can be used to invert the polarity of the input channels. Note that following restrictions apply with input capture channel sources.

- When (CSOT = 1), the counter will only start incrementing on a rising edge on the channel input, provided ELSnA = 1.
- When (CROT= 1), the counter will reset to zero on either edge of the channel input, as configured by ELSnB:ELSnA.

- When (CPOT = 1), the counter will pause incrementing whenever the channel input is asserted. PWM output channels are forced to their default state.

47.3.4 Input Capture Mode

The input capture mode is selected when (CPWMS = 0), (MSnB:MSnA = 0:0), and (ELSnB:ELSnA ≠ 0:0).

When a selected edge occurs on the channel input, the current value of the TPM counter is captured into the CnV register, at the same time the CHnF bit is set and the channel interrupt is generated if enabled by CHnIE = 1 (see the following figure).

When a channel is configured for input capture, the CHn pin is an edge-sensitive input. ELSnB:ELSnA control bits determine which edge, falling or rising, triggers input-capture event. Note that the maximum frequency for the channel input signal to be detected correctly is counter clock divided by 4, which is required to meet Nyquist criteria for signal sampling.

Writes to the CnV register are ignored in input capture mode.

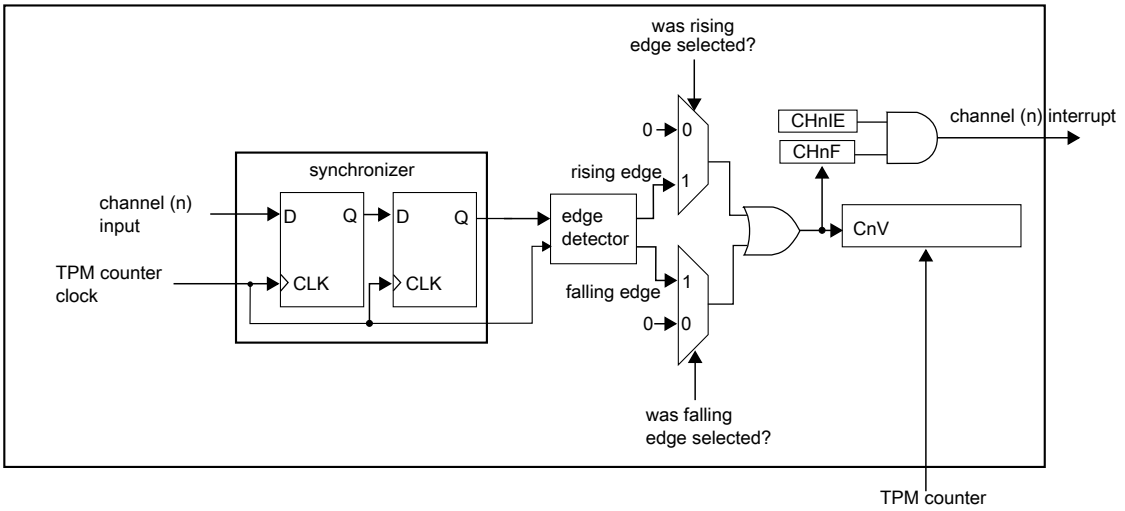

Figure 151. Input capture mode

The CHnF bit is set on the third rising edge of the TPM counter clock after a valid edge occurs on the channel input.

47.3.5 Output Compare Mode

The output compare mode is selected when (CPWMS = 0), and (MSnB:MSnA = X:1).

In output compare mode, the TPM can generate timed pulses with programmable position, polarity, duration, and frequency. When the TPM counter matches the value in the CnV register of an output compare channel, the channel (n) output can be set, cleared or toggled if MSnB is clear. If MSnB is set then the channel (n) output is pulsed high or low for as long as the TPM counter matches the value in the CnV register.

When a channel is initially configured to output compare mode, the channel output updates with its negated value (logic 0 for set/toggle/pulse high and logic one for clear/pulse low).

The CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (TPM counter = CnV).

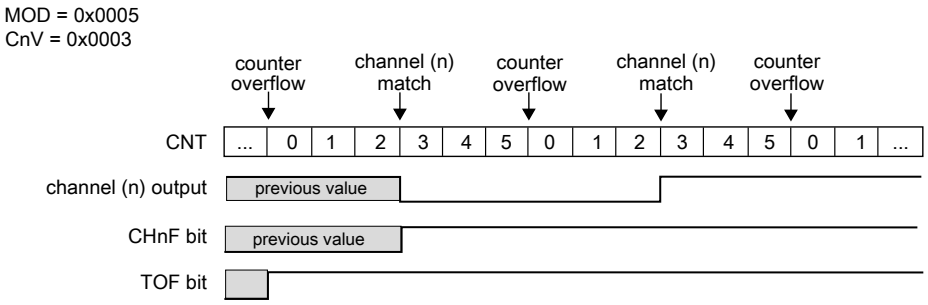

Figure 152. Example of the output compare mode when the match toggles the channel output

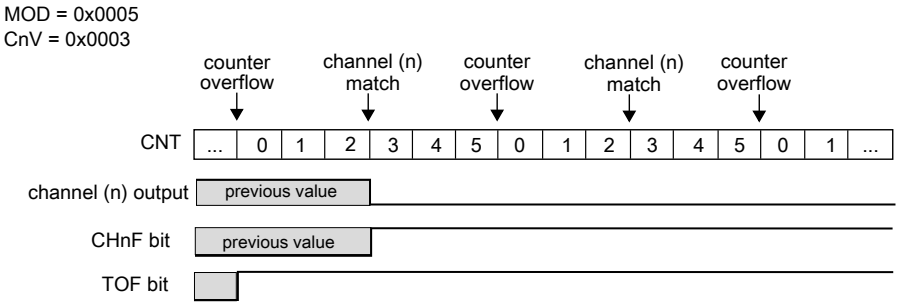

Figure 153. Example of the output compare mode when the match clears the channel output

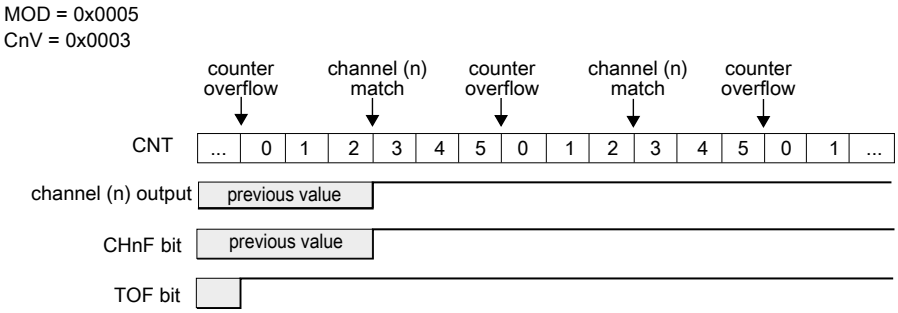

Figure 154. Example of the output compare mode when the match sets the channel output

Software can also use the output compare mode with (MSnB:MSnA = 0:1) and (ELSnB:ELSnA = 0:0). In this case (known as software compare mode), when the TPM counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1); however, the channel (n) output is not modified or controlled by TPM.

47.3.6 Edge-Aligned PWM (EPWM) Mode

The edge-aligned mode is selected when (CPWMS = 0), and (MSnB:MSnA = 1:0). The EPWM period is determined by (MOD + 0x0001) and the pulse width (duty cycle) is determined by CnV.

The CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (TPM counter = CnV), that is, at the end of the pulse width.

This type of PWM signal is called edge-aligned because the leading edges of all PWM signals are aligned with the beginning of the period, which is the same for all channels within an TPM.

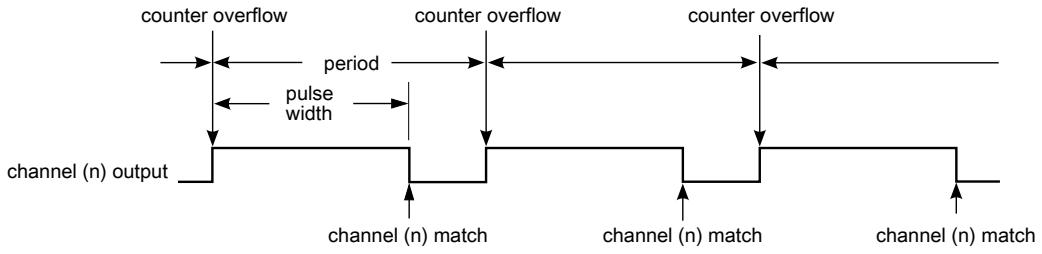

Figure 155. EPWM period and pulse width with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the counter overflow or reload (when the zero is loaded into the TPM counter), and it is forced low at the channel (n) match (TPM counter = CnV). When first enabled or whenever the TPM counter is paused, the channel (n) output is forced high.

If (ELSnB:ELSnA = 0:0), then the channel (n) output is forced high at the counter overflow or reload (when the zero is loaded into the TPM counter), and it is forced low at the channel (n) match (TPM counter = CnV). When first enabled or whenever the TPM counter is paused, the channel (n) output is forced low.

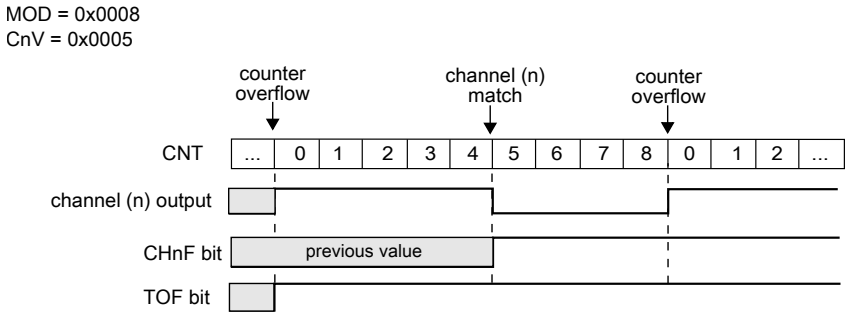

Figure 156. EPWM signal with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = 0:1), then the channel (n) output is forced low at the counter overflow or reload (when zero is loaded into the TPM counter), and it is forced high at the channel (n) match (TPM counter = CnV). When first enabled or whenever the TPM counter is paused, the channel (n) output is forced low.

If (ELSnB:ELSnA = 1:1), then the channel (n) output is forced low at the counter overflow or reload (when zero is loaded into the TPM counter), and it is forced high at the channel (n) match (TPM counter = CnV). When first enabled or whenever the TPM counter is paused, the channel (n) output is forced high.

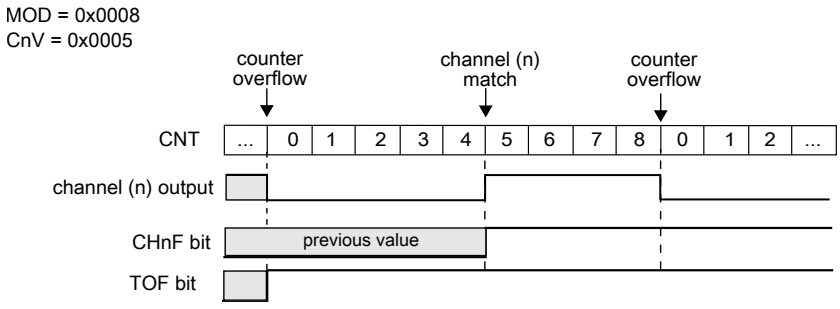

Figure 157. EPWM signal with ELSnB:ELSnA = 0:1

If (CnV = 0x0000), then the channel (n) output is a 0% duty cycle EPWM signal. If (CnV > MOD), then the channel (n) output is a 100% duty cycle EPWM signal and CHnF bit is not set since there is never a channel (n) match. Therefore, MOD must be less than 0xFFFF in order to get a 100% duty cycle EPWM signal.

47.3.7 Center-Aligned PWM (CPWM) Mode

The center-aligned mode is selected when (CPWMS = 1) and (MSnB:MSnA = 1:0).

The CPWM pulse width (duty cycle) is determined by 2 × CnV and the period is determined by 2 × MOD (see the following figure). MOD must be kept in the range of 0x0001 to 0x7FFF because values outside this range can produce ambiguous results.

In the CPWM mode, the TPM counter counts up until it reaches MOD and then counts down until it reaches zero.

The CHnF bit is set and channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (TPM counter = CnV) when the TPM counting is down (at the begin of the pulse width) and when the TPM counting is up (at the end of the pulse width).

This type of PWM signal is called center-aligned because the pulse width centers for all channels are when the TPM counter is zero.

The other channel modes are not designed to be used with the up-down counter (CPWMS = 1). Therefore, all TPM channels should be used in CPWM mode when (CPWMS = 1).

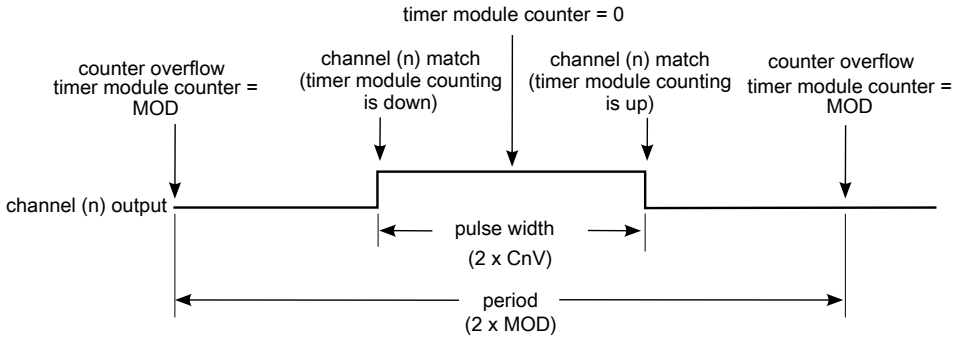

Figure 158. CPWM period and pulse width with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the channel (n) match (TPM counter = CnV) when counting down, and it is forced low at the channel (n) match when counting up. When first enabled, when the TPM counter is reloaded, or whenever the TPM counter is paused, the channel (n) output is forced high.

If (ELSnB:ELSnA = 0:0), then the channel (n) output is forced high at the channel (n) match (TPM counter = CnV) when counting down, and it is forced low at the channel (n) match when counting up. When first enabled, when the TPM counter is reloaded, or whenever the TPM counter is paused, the channel (n) output is forced low.

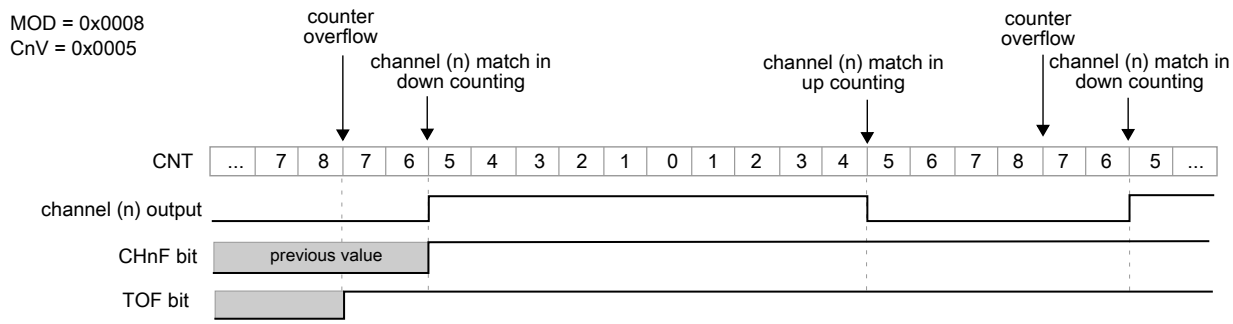

Figure 159. CPWM signal with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = 0:1), then the channel (n) output is forced low at the channel (n) match (TPM counter = CnV) when counting down, and it is forced high at the channel (n) match when counting up. When first enabled, when the TPM counter is reloaded, or whenever the TPM counter is paused, the channel (n) output is forced low.

If (ELSnB:ELSnA = 1:1), then the channel (n) output is forced low at the channel (n) match (TPM counter = CnV) when counting down, and it is forced high at the channel (n) match when counting up. When first enabled, when the TPM counter is reloaded, or whenever the TPM counter is paused, the channel (n) output is forced high.

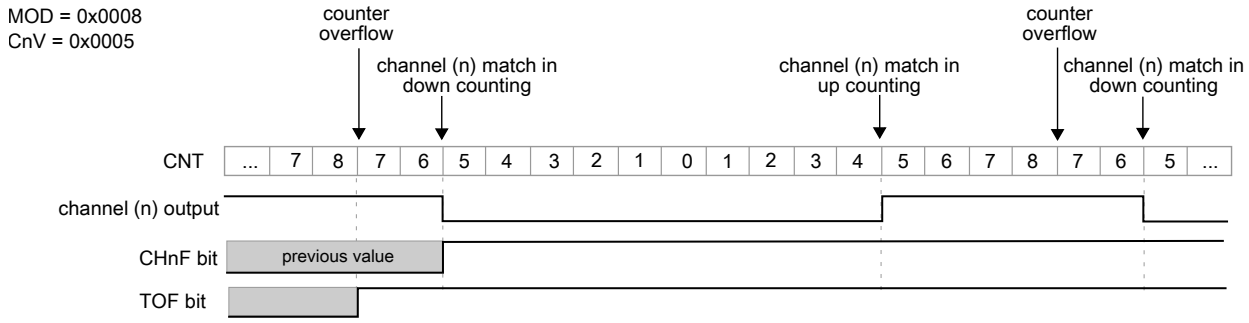

Figure 160. CPWM signal with ELSnB:ELSnA = 0:1

If (CnV = 0x0000) then the channel (n) output is a 0% duty cycle CPWM signal.

If (CnV > MOD), then the channel (n) output is a 100% duty cycle CPWM signal, although the CHnF bit is set when the counter changes from incrementing to decrementing. Therefore, MOD must be less than 0xFFFF in order to get a 100% duty cycle CPWM signal.

47.3.8 Combine PWM mode

The Combine PWM mode is selected when:

- MSnB:MSnA = 10
- COMBINEn = 1
- QUADEN = 0, and
- CPWMS = 0

In Combine PWM mode, an even channel (n) and adjacent odd channel (n+1) are combined to generate a PWM signal in the channel (n) output.

The PWM period is determined by (MOD + 0x0001) and the PWM pulse width (duty cycle) is determined by (|C(n+1)V − C(n)V|). If [C(n)V = C(n+1)V = 0x0000], then the channel (n) output has a 0% duty cycle. If [C(n)V = C(n+1)V > MOD], then the channel (n) output has a 100% duty cycle, and CHnF is not set since there is never a channel (n) match. Therefore, MOD must be less than 0xFFFF in order to get a 100% duty cycle signal.

The CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (TPM counter = C(n)V). The CH(n+1)F bit is set and the channel (n+1) interrupt is generated, if CH(n+1)IE = 1, at the channel (n+1) match (TPM counter = C(n+1)V).

If channel (n) (ELSnB:ELSnA = 0:1), then the channel (n) output is forced low at the beginning of the period (TPM counter is zero) and at the channel (n+1) match (TPM counter = C(n+1)V). It is forced high at the channel (n) match (TPM counter = C(n)V).

If channel (n) (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the beginning of the period (TPM counter is zero) and at the channel (n+1) match (TPM counter = C(n+1)V). It is forced low at the channel (n) match (TPM counter = C(n)V).

When (COMSWAPn = 1), then the channel (n) output is forced low or high at the beginning of the period (TPM counter is zero) and at the channel (n) match (TPM counter = C(n)V). It is forced high or low at the channel (n+1) match (TPM counter = C(n+1)V).

The channel (n+1) output is generated the same as the channel (n) output, but the output polarity is controlled by the channel (n+1) ELSnB:ELSnA configuration.

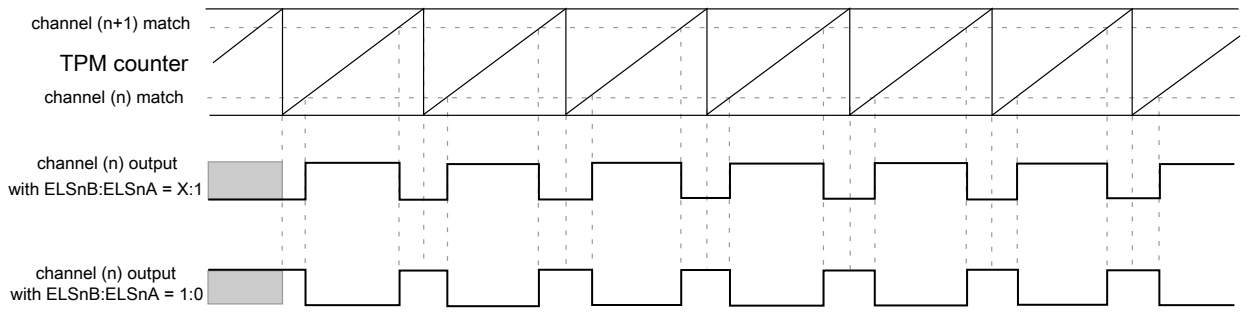

Figure 161. Combine mode

The following figures illustrate the PWM signals generation using Combine mode.

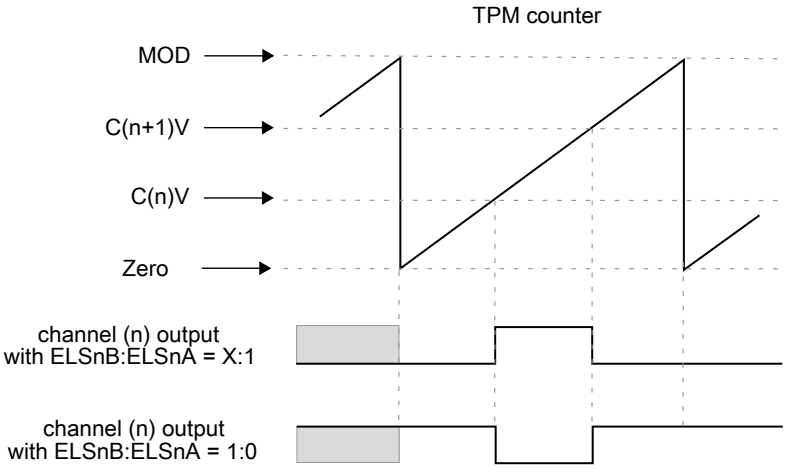

Figure 162. Channel (n) output if (C(n)V < MOD) and (C(n+1)V < MOD) and (C(n)V < C(n+1)V)

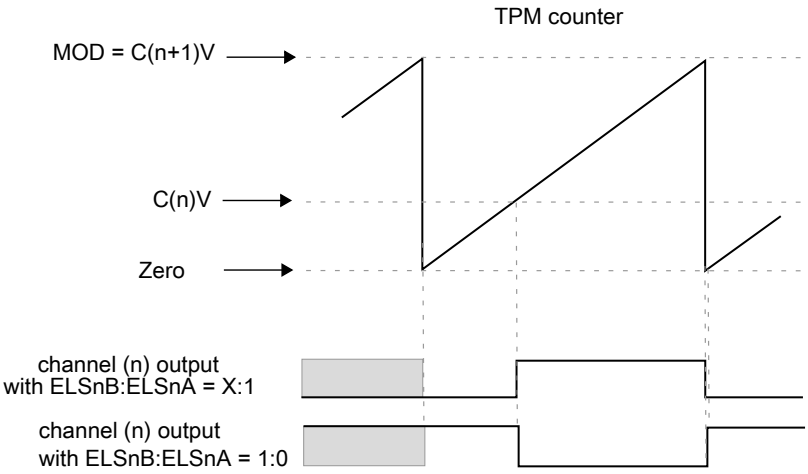

Figure 163. Channel (n) output if (C(n)V < MOD) and (C(n+1)V = MOD)

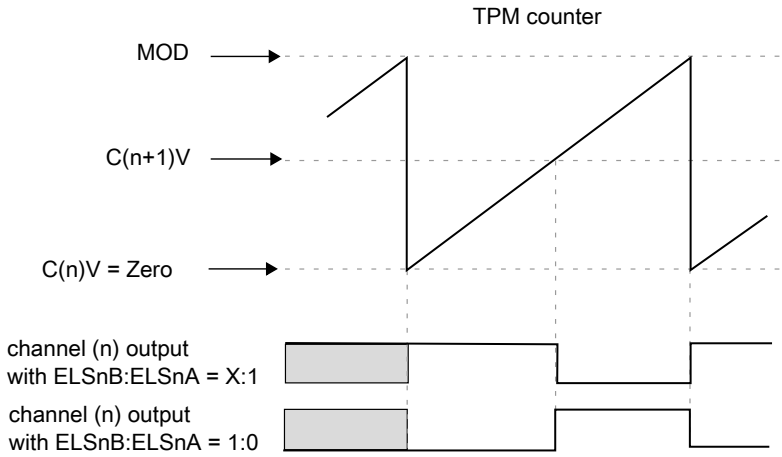

Figure 164. Channel (n) output if (C(n)V = zero) and (C(n+1)V < MOD)

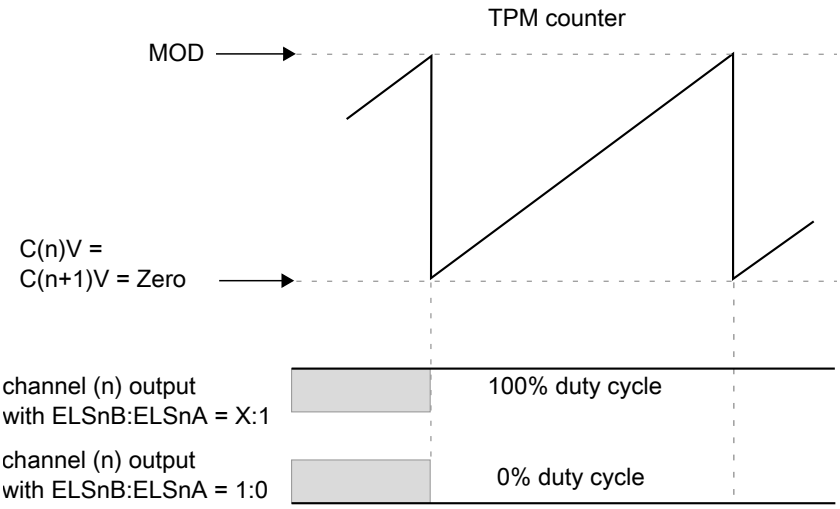

Figure 165. Channel (n) output if (C(n)V = C(n+1)V = zero)

47.3.9 Combine Input Capture mode

The Combine Input Capture mode is selected if COMBINEn= 1 and MSnB:MSnA = 00 and ELSnB:ELSnA ≠ 00. This mode allows to measure a pulse width of the signal on the input of channel (n) of a channel pair. The channel (n) filter can be active in this mode.

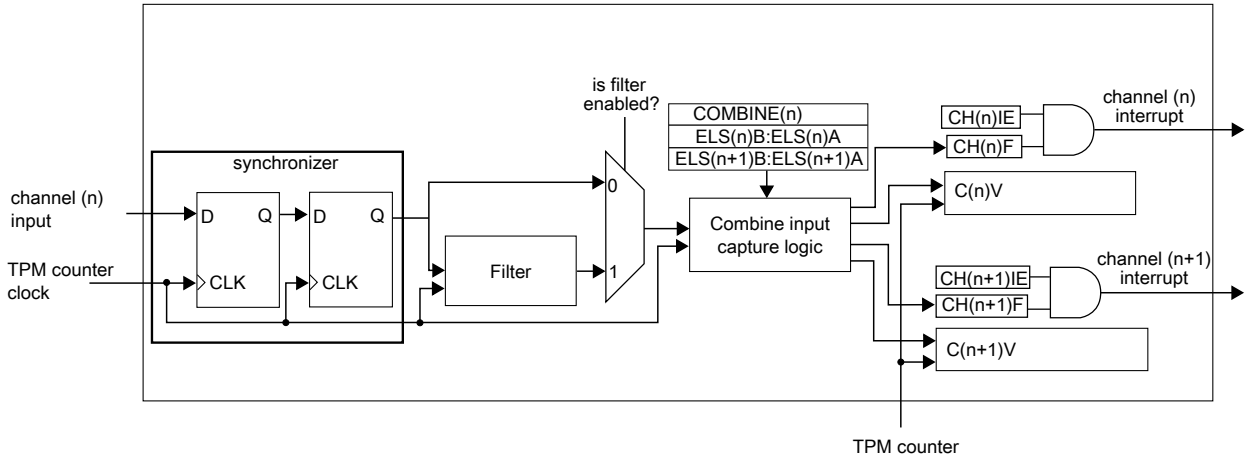

Figure 166. Combine Input Capture mode block diagram

The ELS(n)B:ELS(n)A bits select the edge that is captured by channel (n), and ELS(n+1)B:ELS(n+1)A bits select the edge that is captured by channel (n+1).

In the Combine Input Capture mode, only channel (n) input is used and channel (n+1) input is ignored, when COMSWAPn=1 then only channel (n+1) input is used and channel (n) input is ignored.

If the selected edge by channel (n) bits is detected at channel (n) input, then CH(n)F bit is set and the channel (n) interrupt is generated (if CH(n)IE = 1). If the selected edge by channel (n+1) bits is detected at channel (n) input, then CH(n+1)F bit is set and the channel (n+1) interrupt is generated (if CH(n+1)IE = 1).

The C(n)V register stores the value of TPM counter when the selected edge by channel (n) is detected at channel (n) input. The C(n+1)V register stores the value of TPM counter when the selected edge by channel (n+1) is detected at channel (n) input.

NOTE

- The CH(n)F, CH(n)IE, MS(n)A, ELS(n)B, and ELS(n)A bits are channel (n) bits.
- The CH(n+1)F, CH(n+1)IE, MS(n+1)A, ELS(n+1)B, and ELS(n+1)A bits are channel (n+1) bits.
- The Combine Input Capture mode must be used with ELS(n)B:ELS(n)A = 0:1 or 1:0, ELS(n+1)B:ELS(n+1)A = 0:1 or 1:0.

47.3.10 Input Capture Filter

The input capture filter function is only in input capture mode, or in software compare mode when quadrature decoder mode is enabled.

First, the input signal is synchronized by the TPM counter clock. Following synchronization, the input signal enters the filter block. See the following figure.

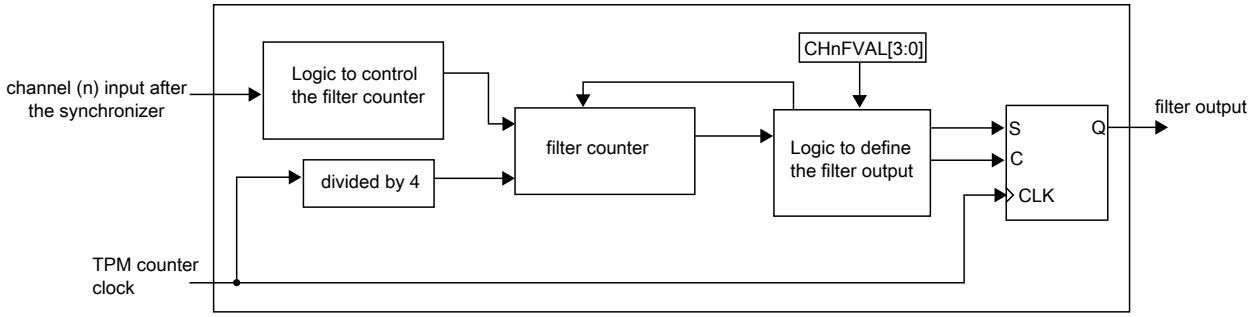

Figure 167. Channel input filter

When there is a state change in the input signal, the counter is reset and starts counting up. As long as the new state is stable on the input, the counter continues to increment. When the counter is equal to (CHnFVAL[3:0] × 4), the state change of the input signal is validated.

If the opposite edge appears on the input signal before it can be validated, the counter is reset. At the next input transition, the counter starts counting again. Any pulse that is shorter than the minimum value selected by (CHnFVAL[3:0] × 4 counter clocks) is regarded as a glitch and is not passed through the filter. A timing diagram of the input filter is shown in the following figure.

The filter function is disabled when CHnFVAL[3:0] bits are zero. In this case, the input signal is delayed by 2 rising edges of the counter clock. If (CHnFVAL[3:0] ≠ 0000), then the input signal is delayed by the minimum pulse width (CHnFVAL[3:0] × 4 system clocks) plus a further 3 rising edges of the system clock: two rising edges to the synchronizer, plus one more to the edge detector. In other words, CHnF is set (3 + 4 × CHnFVAL[3:0]) counter clock periods after a valid edge occurs on the channel input.

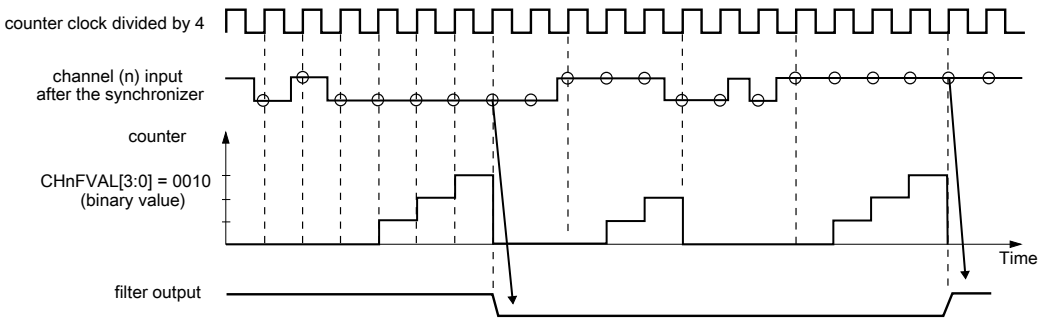

Figure 168. Channel input filter example

47.3.11 Deadtime insertion

The deadtime insertion is enabled in PWM combine modes for each pair of channels when CH(n)FVAL and CH(n+1)FVAL are non-zero. The deadtime delay that is used for each TPM channel is defined as (CH(n+1)FVAL[3:0] x 64) + (CH(n)FVAL[3:0] x 4).

The deadtime delay insertion ensures that no two complementary signals (even channel (n) and odd channel (n+1)) drive the active state at the same time.

If ELSnB:ELSnA = 0:1, ELS(n+1)B:ELS(n+1)A = 1:0, COMSWAPn = 0, and the deadtime is enabled, then when the channel (n) match (TPM counter = C(n)V) occurs, the channel (n) output remains at the low value until the end of the deadtime delay when the channel (n) output is set. Similarly, when the channel (n+1) match (TPM counter = C(n+1)V) occurs, the channel (n+1) output remains at the low value until the end of the deadtime delay when the channel (n+1) output is set. See the following figures.

If ELSnB:ELSnA = 1:0, ELS(n+1)B:ELS(n+1)A = 0:1, COMSWAPn = 1,and the deadtime is enabled, then when the channel (n+1) match (TPM counter = C(n+1)V) occurs, the channel (n+1) output remains at the low value until the end of the deadtime delay when the channel (n+1) output is set. Similarly, when the channel (n) match (TPM counter = CnV) occurs, the channel (n) output remains at the low value until the end of the deadtime delay when the channel (n) output is set.

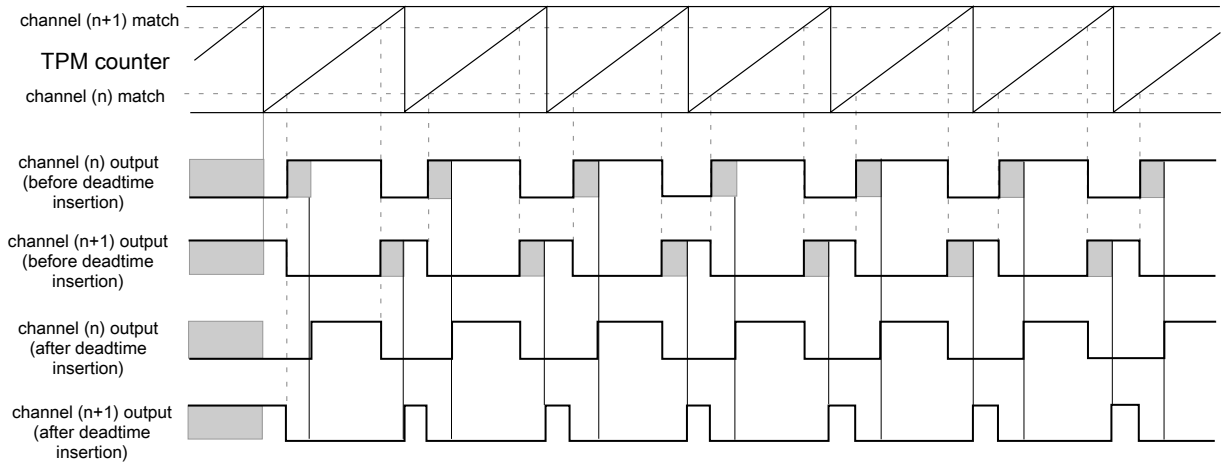

Figure 169. Deadtime insertion with ELSnB:ELSnA = 0:1, ELS(n+1)B:ELS(n+1)A = 1:0, COMSWAPn = 0

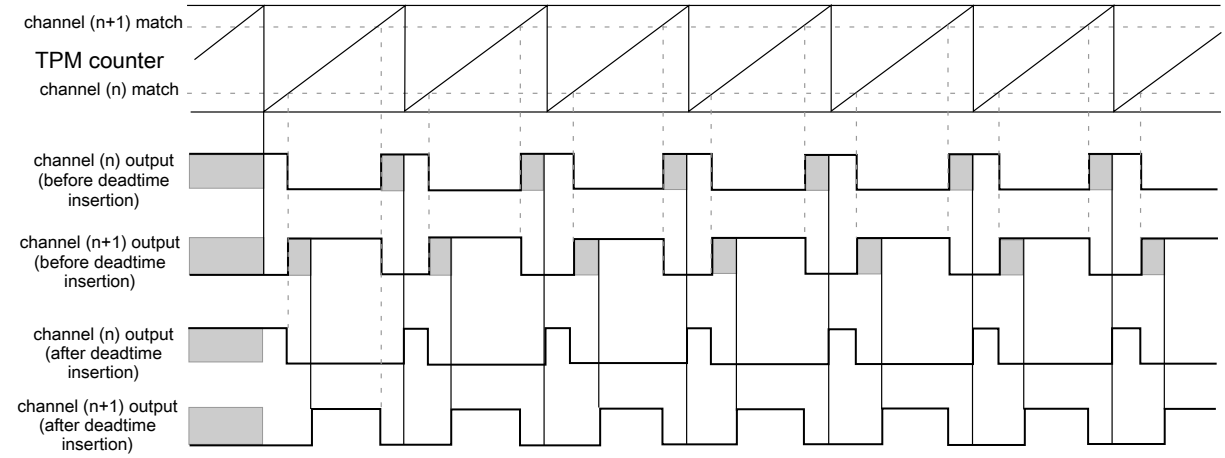

Figure 170. Deadtime insertion with ELSnB:ELSnA = 1:0, ELS(n+1)B:ELS(n+1)A = 0:1, COMSWAPn = 1

47.3.12 Quadrature Decoder mode

The Quadrature Decoder mode is selected if (QUADEN = 1). The Quadrature Decoder mode uses the channel 0 (phase A) and channel 1 (phase B) input signals to control the TPM counter increment and decrement. The following figure shows the quadrature decoder block diagram.

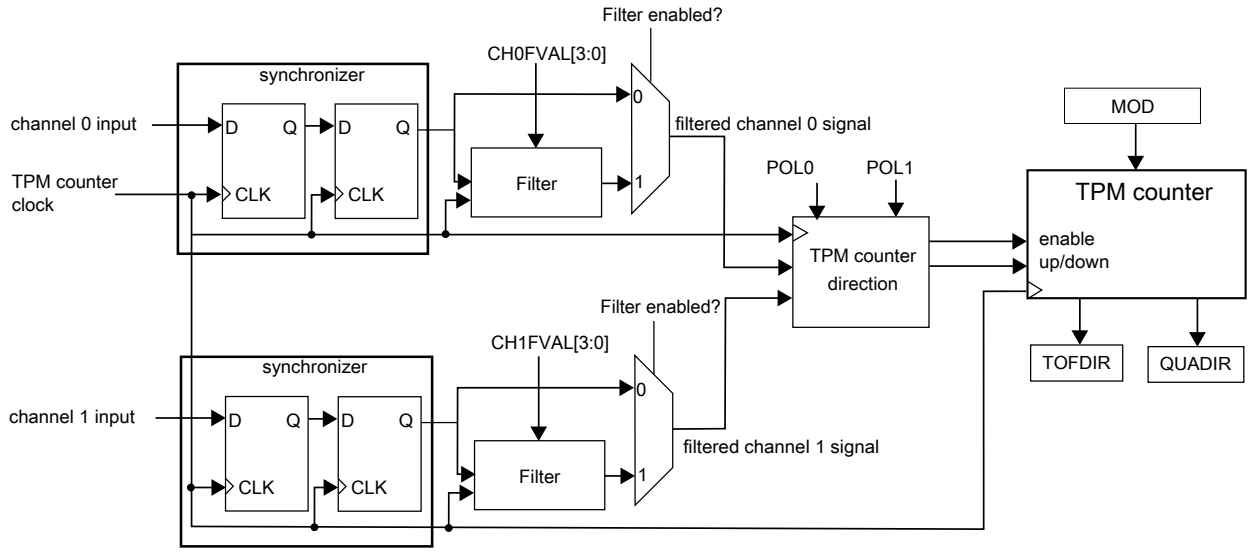

Figure 171. Quadrature Decoder block diagram

The input capture filter and channel polarity registers are used to configure the input filter and polarity for the channel 0 and channel 1 inputs in quadrature decode mode.

NOTE

Notice that the TPM counter is clocked by the channel 0 and channel 1 input signals when quadrature decoder mode is selected. Therefore In quadrature decoder mode, channel 0 and channel 1 can only be used in software compare mode and other TPM channels can only be used in input capture or output compare modes.

The QUADMODE selects the encoding mode used in the Quadrature Decoder mode. If QUADMODE = 1, then the count and direction encoding mode is enabled; see the following figure. In this mode, the channel 1 input value indicates the counting direction, and the channel 0 input defines the counting rate. The TPM counter is updated when there is a rising edge at channel 0 input signal.

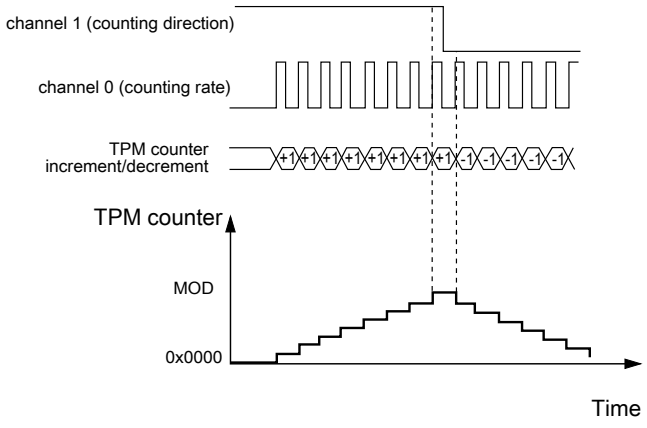

Figure 172. Quadrature Decoder – Count and Direction Encoding mode

If QUADMODE = 0, then the Phase Encoding mode is enabled; see the following figure. In this mode, the relationship between channel 0 and channel 1 signals indicates the counting direction, and channel 0 and channel 1 signals define the counting rate. The TPM counter is updated when there is an edge either at the channel 0 or channel 1 signals.

If CH0POL= 0 and CH1POL = 0, then the TPM counter increment happens when:

- there is a rising edge at channel 0 signal and channel 1 signal is at logic zero;

- there is a rising edge at channel 1 signal and channel 0 signal is at logic one;
- there is a falling edge at channel 1 signal and channel 0 signal is at logic zero;
- there is a falling edge at channel 0 signal and channel 1 signal is at logic one;

and the TPM counter decrement happens when:

- there is a falling edge at channel 0 signal and channel 1 signal is at logic zero;
- there is a falling edge at channel 1 signal and channel 0 signal is at logic one;
- there is a rising edge at channel 1 signal and channel 0 signal is at logic zero;
- there is a rising edge at channel 0 signal and channel 1 signal is at logic one.

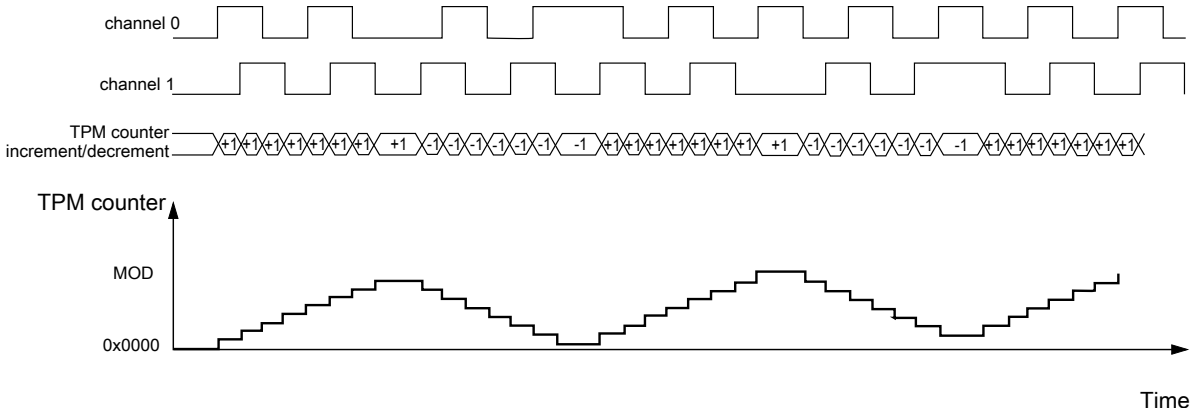

Figure 173. Quadrature Decoder – Phase Encoding mode

The following figure shows the TPM counter overflow in up counting. In this case, when the TPM counter changes from MOD to zero, TOF and TOFDIR bits are set. TOF bit indicates the TPM counter overflow occurred. TOFDIR indicates the counting was up when the TPM counter overflow occurred.

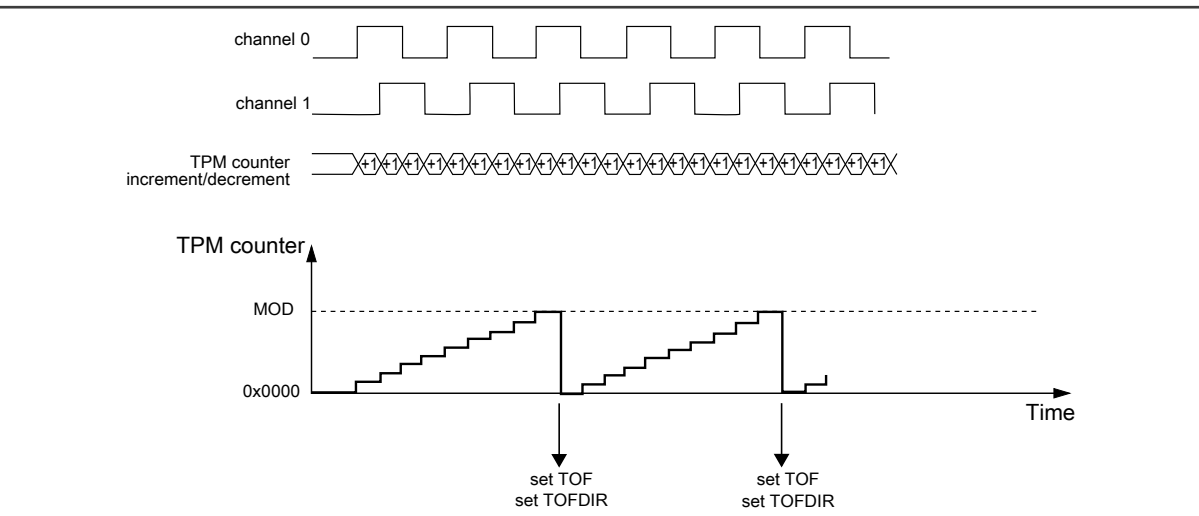

Figure 174. TPM Counter overflow in up counting for Quadrature Decoder mode

The following figure shows the TPM counter overflow in down counting. In this case, when the TPM counter changes from zero to MOD, TOF bit is set and TOFDIR bit is cleared. TOF bit indicates the TPM counter overflow occurred. TOFDIR indicates the counting was down when the TPM counter overflow occurred.

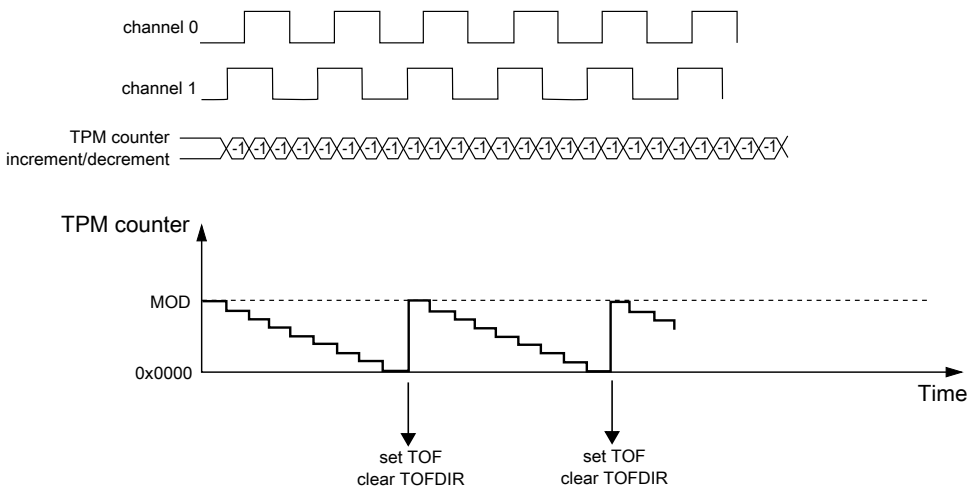

Figure 175. TPM counter overflow in down counting for Quadrature Decoder mode

47.3.13 Registers Updated from Write Buffers

47.3.13.1 MOD Register Update

If (CMOD[1:0] = 0:0) then MOD register is updated when MOD register is written.

If (CMOD[1:0] ≠ 0:0), then MOD register is updated according to the CPWMS bit, that is:

- If the selected mode is not CPWM then MOD register is updated after MOD register was written and the TPM counter changes from MOD to zero.
- If the selected mode is CPWM then MOD register is updated after MOD register was written and the TPM counter changes from MOD to (MOD – 1).

47.3.13.2 CnV Register Update

If (CMOD[1:0] = 0:0) then CnV register is updated when CnV register is written.

If (CMOD[1:0] ≠ 0:0), then CnV register is updated according to the selected mode, that is:

- If the selected mode is output compare then CnV register is updated on the next TPM counter increment (end of the prescaler counting) after CnV register was written.
- If the selected mode is EPWM then CnV register is updated after CnV register was written and the TPM counter changes from MOD to zero.
- If the selected mode is CPWM then CnV register is updated after CnV register was written and the TPM counter changes from MOD to (MOD – 1).

47.3.14 DMA

The channel and overflow flags generate a DMA transfer request according to DMA and CHnIE/TOIE bits. See the following table for more information.

Table 278. DMA Transfer Request

DMA	CHnIE/ TOIE	Channel/Overflow DMA Transfer Request	Channel/Overflow Interrupt
0	0	The channel/overflow DMA transfer request is not generated.	The channel/overflow interrupt is not generated.
0	1	The channel/overflow DMA transfer request is not generated.	The channel/overflow interrupt is generated if (CHnF/TOF = 1).
1	0	The channel/overflow DMA transfer request is generated if (CHnF/TOF = 1).	The channel/overflow interrupt is not generated.
1	1	The channel/overflow DMA transfer request is generated if (CHnF/TOF = 1).	The channel/overflow interrupt is generated if (CHnF/TOF = 1).

If DMA = 1, the CHnF/TOF bit can be cleared either by DMA transfer done or writing a one to CHnF/TOF bit (see the following table).

Table 279. Clear CHnF/TOF Bit

DMA	How CHnF/TOF Bit Can Be Cleared
0	CHnF/TOF bit is cleared by writing a 1 to CHnF/TOF bit.
1	CHnF/TOF bit is cleared either when the DMA transfer is done or by writing a 1 to CHnF/TOF bit.

47.3.15 Peripheral Triggers

The connection of the TPM peripheral triggers with other peripherals are device specific.

Output Triggers

The TPM generates output triggers for the counter and each channel that can be used to trigger events in other peripherals. The counter trigger asserts whenever the TOF is set and remains asserted until the next increment.

Each TPM channel generates both a pre-trigger output and a trigger output. The pre-trigger output asserts whenever the CHnF is set, the trigger output asserts on the first counter increment after the pre-trigger asserts, and then both the trigger and pre-trigger negate on the first counter increment after the trigger asserts.

When (COMBINEn = 1) in output compare modes, the pre-trigger output for both channel (n) and channel (n+1) will assert when CH(n)F is set and will negate when CH(n+1)F is set. The trigger continues to assert on the first counter increment after the pre-trigger asserts and negates at the same time as the pre-trigger negation.

Input Trigger

The TPM input trigger can be configured to perform the following operations with configurable polarity:

- Increment the counter on trigger rising edge
- Start incrementing the counter on trigger rising edge
- Reset/reload the counter on trigger rising edge
- Pause the counter while trigger high

The TPM input trigger is synchronized and must assert for at least two counter clock cycles so that the input trigger can be detected.

47.3.16 Reset Overview

The TPM is reset whenever any chip reset occurs.

When the TPM exits from reset:

- the TPM counter and the prescaler counter are zero and are stopped (CMOD[1:0] = 0:0);
- the timer overflow interrupt is zero;
- the channels interrupts are zero;
- the channels are in input capture mode;
- the channels outputs are zero;
- the channels pins are not controlled by TPM (ELS(n)B:ELS(n)A = 0:0).

47.3.17 TPM Interrupts

This section describes TPM interrupts.

47.3.17.1 Timer Overflow Interrupt

The timer overflow interrupt is generated when (TOIE = 1) and (TOF = 1).

47.3.17.2 Channel (n) Interrupt

The channel (n) interrupt is generated when (CHnIE = 1) and (CHnF = 1).

47.3.18 Low power modes

During a chip low-power mode, TPM can be configured to operate normally or to pause all counting.

Chip mode	TPM operation
Low power mode	• When CONF[DOZEEN] = 0 and TPM uses an external or internal clock source that remains functional, counting continues. TPM can generate an asynchronous interrupt to exit the chip from the low power mode. • When CONF[DOZEEN] = 1, counting pauses for the duration of the low power mode. Trigger inputs and input capture events are ignored, and PWM outputs are forced to their initial state.

47.3.19 Debug mode

During chip debug mode, TPM can be configured to operate normally or to temporarily pause all counting.

Chip mode	TPM operation
Debug (core is in Debug/Halted mode)	• When CONF[DBGMODE] = 0b00, counting pauses until the core returns to normal user operating mode. Trigger inputs and input capture events are ignored, and PWM outputs are forced to their initial state. • When CONF[DBGMODE] = 0b11, counting continues.

47.4 External signals

Table 280 shows the user-accessible signals for the TPM.

Table 280. TPM signal descriptions

Signal	Description	Direction
EXTCLK	External Clock If selected in SC[CMOD], EXTCLK increments the TPM counter on every rising edge synchronized to the TPM counter clock. EXTCLK must be less than half of the TPM counter clock frequency. The TPM counter prescaler selection and settings are also used when EXTCLK is selected.	I
CH*n*	Channel *n* I/O Pin (where *n* = 5 to 0) Each CH*n* can be configured to operate either as input or output. CH*n* is an output when configured in an output compare or PWM mode and the TPM counter is enabled; otherwise, the CH*n* is an input	I/O

47.5 Application information

An example of using the TPM with the asynchronous DMA is described in AN4631:Using the Asynchronous DMA features of the Kinetis L Series.

47.6 Memory Map and Register Definition

This section provides a detailed description of all TPM registers.

Attempting to access a reserved register location in the TPM memory map will generate a bus error.

47.6.1 TPM register descriptions

47.6.1.1 TPM memory map

TPM0 base address: 4003_1000h

TPM1 base address: 4003_2000h

TPM2 base address: 4898_4000h

Offset	Register	Width (In bits)	Access	Reset value

47.6.1.2 Version ID (VERID)

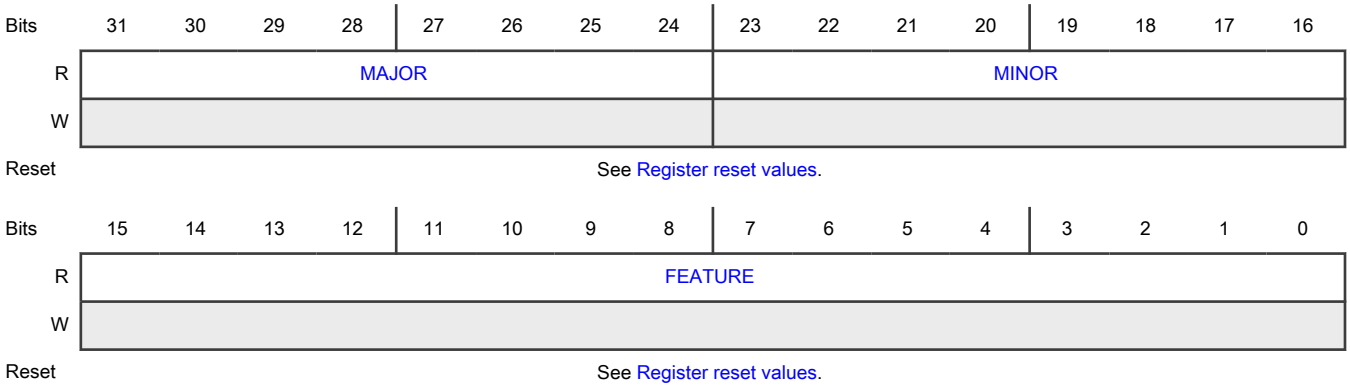
Offset

Register	Offset
VERID	0h

Function

Contains the module version ID and feature information.

Diagram



Register reset values

Register	Reset value
VERID	TPM0,TPM1: 0600_0007h TPM2: 0600_0003h

Fields

Field	Function
31-24 MAJOR	Major Version Number This read only field returns the major version number for the module specification.
23-16 MINOR	Minor Version Number This read only field returns the minor version number for the module specification.
15-0 FEATURE	Feature Identification Number 0000_0000_0000_0001b - Standard feature set. 0000_0000_0000_0011b - Standard feature set with Filter and Combine registers implemented. 0000_0000_0000_0101b - Standard feature set with Quadrature registers implemented. 0000_0000_0000_0111b - Standard feature set with Filter, Combine and Quadrature registers implemented.

47.6.1.3 Parameter (PARAM)

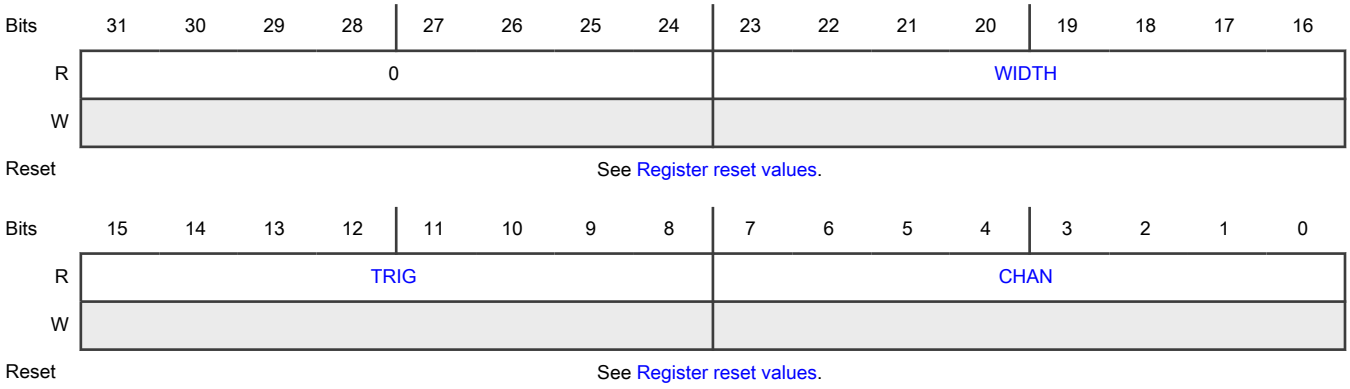
Offset

Register	Offset
PARAM	4h

Function

Contains values of module parameters.

Diagram



Register reset values

Register	Reset value
PARAM	TPM0,TPM1: 0020_0406h TPM2: 0020_0402h

Fields

Field	Function
31-24 —	Reserved
23-16 WIDTH	Counter Width Width of the counter and timer channels.
15-8 TRIG	Trigger Count Number of trigger inputs implemented.
7-0 CHAN	Channel Count Number of timer channels implemented.

47.6.1.4 TPM Global (GLOBAL)

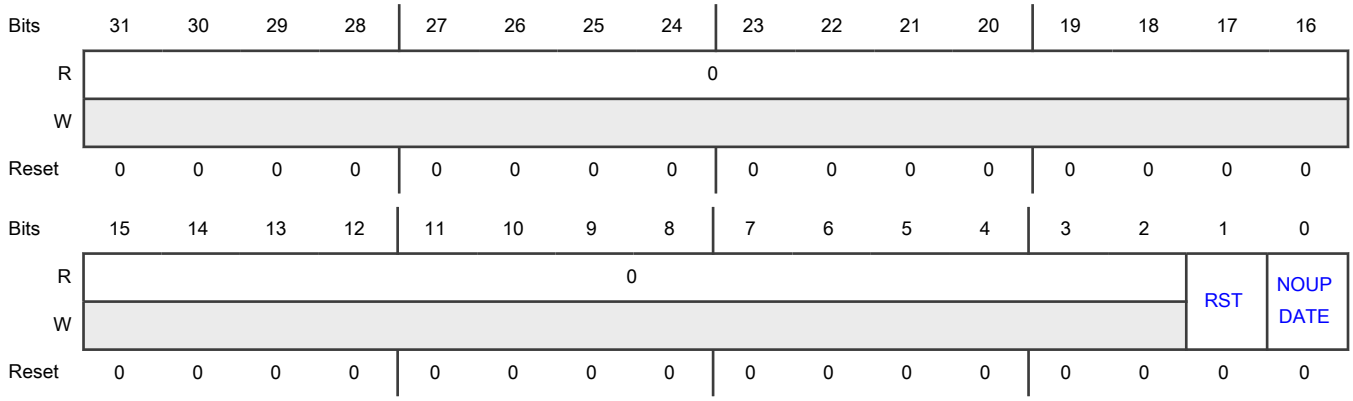
Offset

Register	Offset
GLOBAL	8h

Function

Includes the software reset control bit.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RST	Software Reset Reset all internal logic and registers, except the Global Register. Remains set until cleared by software. 0b - Module is not reset. 1b - Module is reset.
0 NOUPDATE	No Update Blocks updates to all internal double buffered registers while it remains set. Software can still update the software visible registers, but changes cannot take effect until this bit is cleared at which point they update as normal. 0b - Internal double buffered registers update as normal. 1b - Internal double buffered registers do not update.

47.6.1.5 Status and Control (SC)

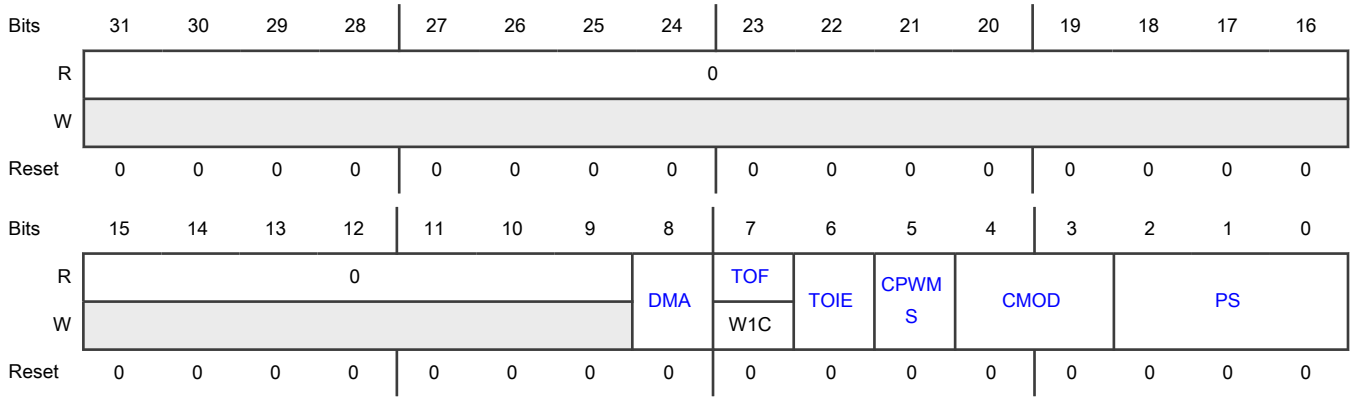
Offset

Register	Offset
SC	10h

Function

Contains the overflow status flag and control bits used to configure the interrupt enable, module configuration and prescaler factor. These controls relate to all channels within this module.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 DMA	DMA Enable Enables DMA transfers for the overflow flag. 0b - Disables DMA transfers. 1b - Enables DMA transfers.
7 TOF	Timer Overflow Flag Set by hardware when the TPM counter equals the value in the MOD register and increments. Writing a 1 to TOF clears it. Writing a 0 to TOF has no effect. If another TPM overflow occurs between the flag setting and the flag clearing, the write operation has no effect; therefore, TOF remains set indicating another overflow has occurred. In this case a TOF interrupt request is not lost due to a delay in clearing the previous TOF. 0b - TPM counter has not overflowed. 1b - TPM counter has overflowed.
6 TOIE	Timer Overflow Interrupt Enable Enables TPM overflow interrupts. 0b - Disable TOF interrupts. Use software polling or DMA request. 1b - Enable TOF interrupts. An interrupt is generated when TOF equals one.
5 CPWMS	Center-Aligned PWM Select Selects CPWM mode. This mode configures the TPM to operate in up-down counting mode. This field is write protected. It can be written only when the counter is disabled. 0b - TPM counter operates in up counting mode. 1b - TPM counter operates in up-down counting mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
4-3 CMOD	Clock Mode Selection Selects the TPM counter clock modes. When disabling the counter, this field remains set until acknolwedged in the TPM clock domain. 00b - TPM counter is disabled 01b - TPM counter increments on every TPM counter clock 10b - TPM counter increments on rising edge of EXTCLK synchronized to the TPM counter clock 11b - TPM counter increments on rising edge of the selected external input trigger.
2-0 PS	Prescale Factor Selection Selects one of 8 division factors for the clock mode selected by CMOD. This field is write protected. It can be written only when the counter is disabled. 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64 111b - Divide by 128

47.6.1.6 Counter (CNT)

Offset

Register	Offset
CNT	14h

Function

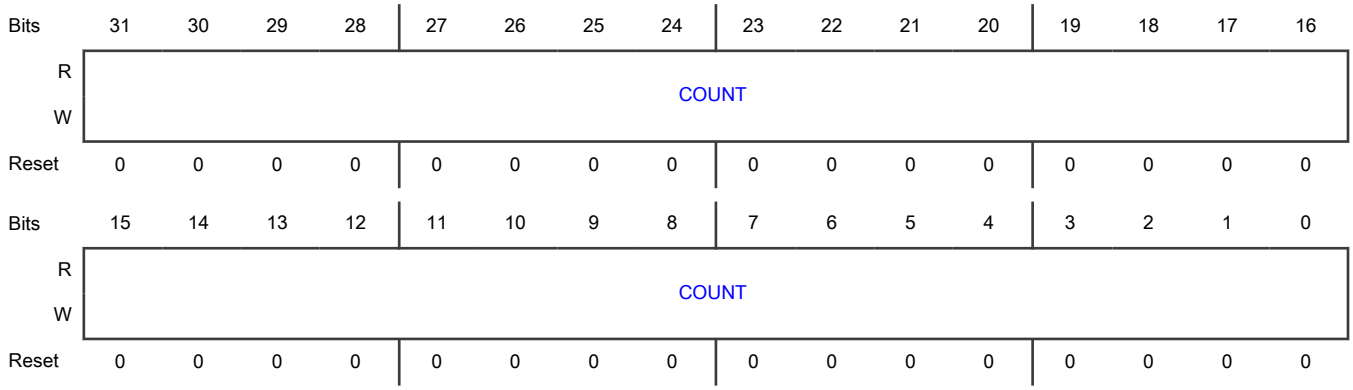
Contains the TPM counter value.

Reset clears the CNT register. Writing any value to COUNT triggers a reload of the counter, forcing PWM outputs to their reload state.

When debug is active, the TPM counter does not increment unless configured otherwise.

Reading the CNT register adds two wait states to the register access due to synchronization delays.

Diagram



Fields

Field	Function
31-0 COUNT	Counter value

47.6.1.7 Modulo (MOD)

Offset

Register	Offset
MOD	18h

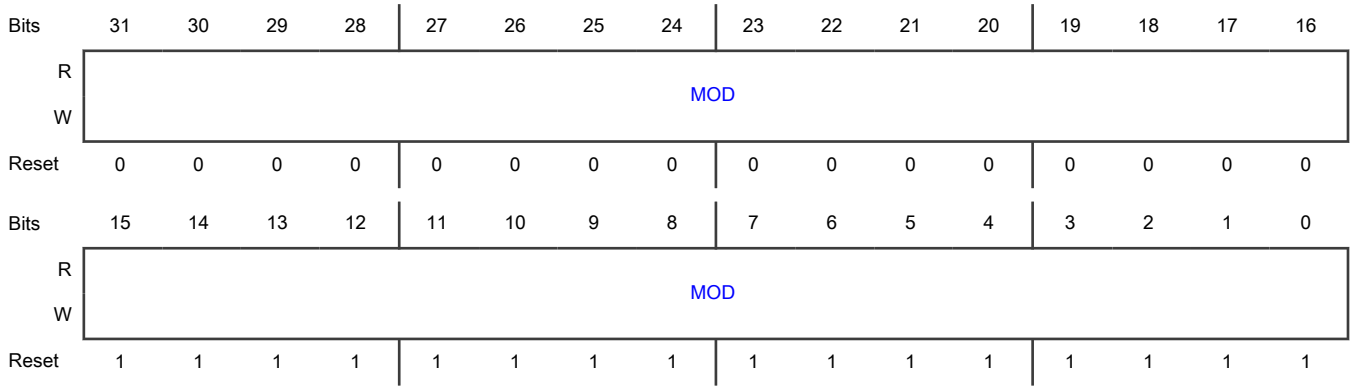
Function

Contains the modulo value for the TPM counter. When the TPM counter reaches the modulo value and increments, the overflow flag (TOF) is set and the next value of TPM counter depends on the selected counting method (see Counter).

Writing to the MOD register latches the value into a buffer. The MOD register is updated with the value of its write buffer according to MOD Register Update. Additional writes to the MOD write buffer are ignored until the register has been updated.

Initialize the TPM counter (write to CNT) before writing to the MOD register to avoid confusion about when the first counter overflow will occur.

Diagram



Fields

Field	Function
31-0 MOD	Modulo value This field must be written with single 16-bit or 32-bit access.

47.6.1.8 Capture and Compare Status (STATUS)

Offset

Register	Offset
STATUS	1Ch

Function

Contains a copy of the status flag, CnSC[CHnF] for each TPM channel, as well as SC[TOF], for software convenience. Each CHnF bit in STATUS is a mirror of CHnF bit in CnSC. All CHnF bits can be checked using only one read of STATUS. All CHnF bits can be cleared by writing all ones to STATUS.

Hardware sets the individual channel flags when an event occurs on the channel. Writing a 1 to CHF clears it. Writing a 0 to CHF has no effect.

If another event occurs between the flag setting and the write operation, the write operation has no effect; therefore, CHF remains set indicating another event has occurred. In this case a CHF interrupt request is not lost due to the clearing sequence for a previous CHF.

Fields

Field	Function
31-8 —	Reserved
7 CHF	Channel Flag Set by hardware when an event occurs on the channel. CHF is cleared by writing a 1 to the CHF bit. Writing a 0 to CHF has no effect. If another event occurs between the CHF sets and the write operation, the write operation has no effect; therefore, CHF remains set indicating another event has occurred. In this case a CHF interrupt request is not lost due to the delay in clearing the previous CHF. 0b - No channel event has occurred. 1b - A channel event has occurred.
6 CHIE	Channel Interrupt Enable Enables channel interrupts. 0b - Disable channel interrupts. 1b - Enable channel interrupts.
5 MSB	Channel Mode Select Used for further selections in the channel logic. Its functionality is dependent on the channel mode.
4 MSA	Channel Mode Select Used for further selections in the channel logic. Its functionality is dependent on the channel mode.
3 ELSB	Edge or Level Select The functionality of ELSB and ELSA depends on the channel mode.
2 ELSA	Edge or Level Select The functionality of ELSB and ELSA depends on the channel mode.
1 —	Reserved
0 DMA	DMA Enable Enables DMA transfers for the channel. 0b - Disable DMA transfers. 1b - Enable DMA transfers.

47.6.1.10 Channel (n) Value (C0V - C5V)

Offset

Register	Offset
C0V	24h
C1V	2Ch
C2V	34h
C3V	3Ch
C4V	44h
C5V	4Ch

Function

Contain the captured TPM counter value for the input modes or the match value for the output modes.

In input capture mode, any write to a CnV register is ignored.

In compare modes, writing to a CnV register latches the value into a buffer. A CnV register is updated with the value of its write buffer according to CnV Register Update . Additional writes to the CnV write buffer are ignored until the register has been updated.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
TPM0	C0V–C5V	—
TPM1	C0V–C5V	—
TPM2	C0V–C1V	C2V–C5V

0 COMBINE0	Combine Channels 0 and 1 Enables the combine feature for channels 0 and 1. In input capture mode, the combined channels use the even channel input. In software compare modes, the even channel match asserts the output trigger and the odd channel match negates the output trigger. In PWM modes, the even channel match is used for the 1st compare and odd channel match for the 2nd compare. 0b - Channels 0 and 1 are independent. 1b - Channels 0 and 1 are combined.

47.6.1.12 Channel Trigger (TRIG)

Offset

Register	Offset
TRIG	6Ch

Function

In input capture mode, configures the trigger input that is used by the channel to capture the counter value. In output compare or PWM mode, configures the trigger input used to modulate the channel output. When modulating the output, the output is forced to the channel initial value whenever the trigger is not asserted. Note that the even numbered channels share the first input trigger source and the odd numbered channels share the second input trigger source.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
TPM0	TRIG	—
TPM1	TRIG	—
TPM2	—	TRIG

Diagram

47.6.1.14 Filter Control (FILTER)

Offset

Register	Offset
FILTER	78h

Function

Selects the filter value of the channel inputs, and an additional output delay value for the channel outputs. In PWM combine modes, the filter can be used to implement deadtime insertion.

NOTE

To write values to the FILTER[CHnFVAL] bits, ensure that the corresponding channel-interrupt-status flag and control (CnSC[5:2]) bits are set to zero.

48.1.1 Module instances

This device has two instances of the LPI2C module, LPI2C0, and LPI2C1.

48.1.2 Host request configuration

Both of the LPI2C0 and LPI2C1 support host request feature.

The input trigger that can be used as host request input is from TRGMUX, refer to Trigger multiplexer (TRGMUX) for more details.

48.2 Overview

LPI2C is a low-power Inter-Integrated Circuit (I2C) module that supports an efficient interface to an I2C bus as a controller and/or as a target.

- Implements logic support for Standard, Fast, Fast+ and Ultra Fast modes of operation.
- Uses little CPU overhead, with DMA offloading of FIFO register accesses.
- Continues operating in Sleep modes if an appropriate clock is available.

The LPI2C module also complies with the System Management Bus (SMBus) Specification, version 3. The SMBus is a single-ended simple two-wire bus, which is typically used for low-bandwidth communications.

NOTE

The I^2C (Inter-Integrated Circuit) serial bus is multi-controller, multi-target, packet-switched, and single-ended, and is often used to attach microcontroller ICs to lower-speed peripheral ICs.

NOTE

Terminology in this chapter has been updated to align with I^2C-bus specification, Rev. 7.0.

Table 283. Updated terms

Updated term	Deprecated term

48.2.1 Block diagram

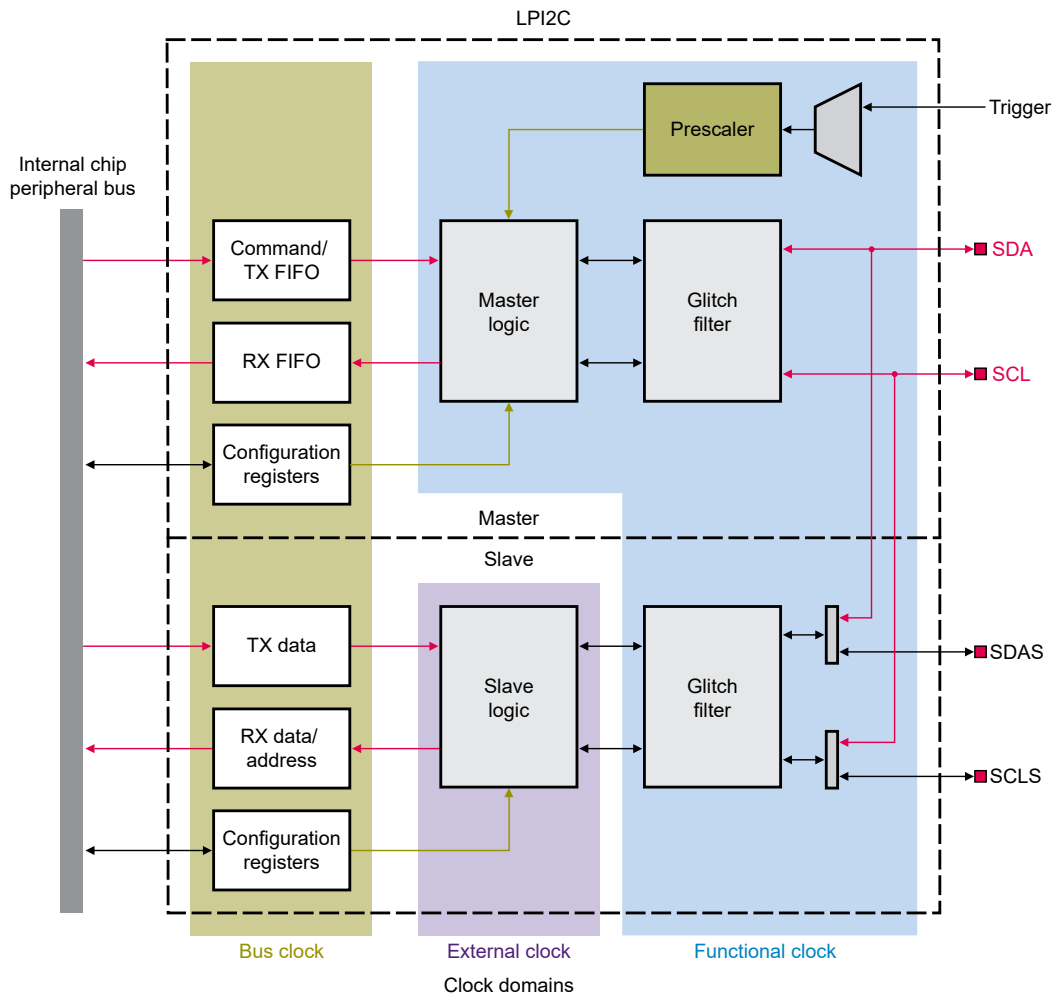

Figure 176. LPI2C block diagram

48.2.2 Features

The LPI2C supports:

- Standard, Fast, Fast+ and Ultra Fast modes
- High-speed mode (HS) in target mode
- High-speed mode (HS) in controller mode
- Multi-controller, including synchronization and arbitration. Multi-controller means that any number of controller nodes can be present. Additionally, controller and target roles may be changed between messages (after a STOP is sent).
- Clock stretching. Sometimes multiple I2C nodes may drive the lines at the same time. If any I2C node is driving a line low, then that line is low. I2C nodes that are starting to transmit a logical one (by letting the line float high) can detect that the line is low. In this way, the nodes can identify that another I2C node is active at the same time.
  - When node detection is used on the SCL line, it is called clock stretching. Clock stretching is used as an I2C flow control mechanism.
  - When node detection is used on the SDA line, it is called arbitration. Arbitration ensures that there is only one I2C node transmitter at a time.

- General call, seven-bit addressing, and ten-bit addressing
- Software reset, START byte, and Device ID (also require software support)

The LPI2C controller supports:

- Command/transmit FIFO of 4 words (8-bit transmit data + 3-bit command).
- Receive FIFO of 4 words (8-bit receive data).
- Command FIFO waits for idle I2C bus before initiating transfer.
- Command FIFO can initiate (repeated) START and STOP conditions and one or more controller-receiver transfers.
- Generating a STOP condition from command FIFO, or generating it automatically when the transmit FIFO is empty.
- Generating interrupt on data match and/or discard unwanted data, via flexible receive data match.
- Flags and optional interrupt signals at repeated START condition, STOP condition, loss of arbitration, unexpected NACK, and command word errors.
- Configurable bus idle timeout and pin-stuck-low timeout.

The LPI2C target supports:

- Separate I2C target registers to minimize software overhead because of controller/target switching.
- 7-bit or 10-bit addressing, address range, SMBus alert, and general call address.
- Transmit data register that supports interrupt or DMA requests.
- Receive data register that supports interrupt or DMA requests.
- Software-controllable ACK or NACK, with optional clock stretching on ACK/NACK bit.
- Configurable clock stretching, to avoid transmit-FIFO-underrun and receive-FIFO-overrun errors.
- Flags and optional interrupt at end of packet, STOP condition, or bit error detection.

48.3 Functional description

48.3.1 Controller mode

The LPI2C controller logic operates independently from the target logic to perform all controller-mode transfers on the I2C bus.

48.3.1.1 Transmit and Command FIFO commands

The transmit FIFO stores command data to initiate various I2C operations. The following operations can be initiated through commands in the transmit FIFO:

- START or repeated START condition with address byte, expecting ACK or NACK.
- Transmit data. This operation is the default for zero-extended-byte writes to the transmit FIFO.
- Receive 1-256 bytes of data. This operation can also be configured to discard received data and not to store it in the receive FIFO.
- STOP condition. This operation can also be configured to send a STOP condition when the transmit FIFO is empty.

Multiple transmit and receive commands can be inserted between the START condition and STOP condition. To comply with the I2C specification, transmit and receive commands must not be interleaved. The receive data command and the receive data and discard commands can be interleaved. This interleaving ensures that only the desired received data is stored in the receive FIFO (or compared with the data match logic).

The LPI2C controller automatically transmits a NACK on the last byte of a receive data command. It transmits the NACK unless the next command in the FIFO is also a receive data command. If the transmit FIFO is empty when a receive data command completes, a NACK is also automatically transmitted.

The LPI2C controller supports 10-bit addressing through:

1. A (repeated) START condition,
2. Followed by a transmit data byte containing the second address byte,
3. Followed by any number of data bytes with the controller transmit data.

A START or repeated START condition expecting a NACK (for example, high-speed mode controller code) must be followed by a STOP or (repeated) START condition.

48.3.1.2 Controller operations

Whenever LPI2C is enabled, it monitors the I2C bus to detect when the I2C is idle (MSR[BBF]). If either SCL or SDA are low, the I2C bus is no longer considered idle. The bus becomes idle if a STOP condition is detected or if a bus idle timeout is detected (as configured by MCFGR2[BUSIDLE]). After the bus is idle, if the transmit FIFO is not empty and the host request is asserted or disabled, the LPI2C controller initiates a transfer on the bus. This transfer involves the following steps:

1. Wait the bus idle time equal to (MCCR0[CLKLO] + 1) multiplied by the prescaler (MCFGR1[PRESCALE]).
2. Transmit a START condition and address byte using the timing configuration in Controller Clock Configuration 0 (MCCR0). If a high-speed mode transfer is configured, the timing configuration from Controller Clock Configuration 1 (MCCR1) is used instead.
3. Perform controller transmit or controller receive transfers, as configured by the transmit FIFO.
4. Transmit NACK on the last byte of a controller receive transfer. This action is done unless the next command in the transmit FIFO is also a receive data command and the transmit FIFO is not empty.
5. Transmit a Repeated START or STOP condition as configured by the transmit FIFO and/or MCFGR1[AUTOSTOP]. A repeated START can change which timing configuration register is used.

Whenever MCFGR0[RELAX] is 1, the LPI2C controller does not wait for the I2C bus to be idle before starting a transfer. It also relaxes some restrictions on the order of FIFO commands. For example, it allows a STOP command when idle to generate a START condition, followed by one SCL clock pulse and then a STOP condition.

When the LPI2C controller is disabled, LPI2C continues emptying the transmit FIFO until a STOP condition is transmitted. (The controller could be disabled due to MCR[MEN] being 0, or automatically due to mode entry.) However, LPI2C no longer stalls the I2C bus by waiting for the transmit or receive FIFO. After the transmit FIFO is empty, the LPI2C generates a STOP condition automatically.

The LPI2C controller can stall the I2C bus under certain conditions. This stalling results in SCL pulled low continuously on the first bit of a byte, until these conditions change:

- LPI2C controller is enabled and busy, the transmit FIFO is empty, and MCFGR1[AUTOSTOP] is 0. The LPI2C controller continues to stall the bus until the transmit FIFO is loaded with more data.
- LPI2C controller is enabled and receiving data, receive data is not being discarded (due to command or receive data match), and the receive FIFO is full. The LPI2C controller continues to stall the I2C bus until the receive FIFO is emptied.

The LPI2C controller aborts the existing transfer when MCFGR0[ABORT] becomes 1. This action causes the LPI2C controller to complete the existing word and then transmit a STOP condition. If the receive FIFO is full when the receive operation is aborted, the last received data is discarded. A new transfer does not start while MCFGR0[ABORT] is 1.

48.3.1.3 Receive FIFO and data matching

The receive FIFO stores receive data during controller-receiver transfers. The LPI2C controller can be configured to discard received data instead of storing it in the receive FIFO. This option is configured by the command word in the transmit FIFO.

Received data supports a receive data match function that can match received data against one of two bytes, or against a masked data byte. The data match function can be configured to compare only the first one or two data words received since the last (repeated) START condition. Received data that is already discarded due to the command word cannot cause a data match. It delays the match on the first data word received until after the discarded data is received.

The receiver match function can be configured to discard all received data until a data match is detected, using the MCFGR0[RDMO] control bit. When clearing the MCFGR0[RDMO] control bit following a data match, write 0 to MCFGR0[RDMO] before writing 0 to MSR[DMF], to allow all subsequent data to be received.

48.3.1.4 Timing parameters

The following timing parameters can be configured by the LPI2C controller. Parameters are configured separately for high-speed mode (Controller Clock Configuration 1 (MCCR1)) and other modes (Controller Clock Configuration 0 (MCCR0)). This separation allows the high-speed mode controller code to be sent using regular timing parameters. Then it allows a switch to high-speed mode timing (following a repeated START) until the next STOP condition.

The LPI2C controller timing parameters in LPI2C functional clock cycles are configured as follows. They must be configured to meet the I2C timing specification for the required mode.

Table 284. Timing Parameters

I2C Specification Timing Parameter	I2C Specification Timing Symbol	LPI2C Timing Parameter (LPI2C functional clock cycles)
SCL clock period	tSCL	(CLKHI + CLKLO + 2 + SCL_LATENCY) x (2 ^ PRESCALE)
hold time (repeated) START condition	tHD:STA	(SETHOLD +1) x (2 ^ PRESCALE)
LOW period of the SCL clock	tLOW	(CLKLO + 1) x (2 ^ PRESCALE)
HIGH period of the SCL clock	tHIGH	(CLKHI + 1 + SCL_LATENCY) x (2 ^ PRESCALE)
setup time for a repeated START condition or STOP condition	tSU:STA, tSU:STO	(SETHOLD + 1 + SCL_LATENCY) x (2 ^ PRESCALE)
data hold time	tHD:DAT	(DATAVD + 1) x (2 ^ PRESCALE)
data setup time	tSU:DAT	(SDA_LATENCY + 1) x (2 ^ PRESCALE)
bus free time between a STOP and START condition	tBUF	(CLKLO + 1 + SDA_LATENCY) x (2 ^ PRESCALE)
data valid time, data valid acknowledge time	tVD:DAT, tVD:ACK	(DATAVD + 1) x (2 ^ PRESCALE)

The latency parameters are defined in the following table. These parameters assume that the risetime is less than one LPI2C functional clock cycle. The risetime depends on a number of factors, including the I/O propagation delay, the I2C bus loading, and the external pull-up resistor sizing. A larger risetime increases the number of cycles that the signal takes to propagate through the synchronizer (and glitch filter), which increases the latency.

Table 285. Synchronization Latency

Timing Parameter	Timing Definition
SCL_LATENCY	ROUNDDOWN ((2 + FILTSCL + SCL_RISETIME) / (2 ^ PRESCALE))
SDA_LATENCY	ROUNDDOWN ((2 + FILTSDA + SDA_RISETIME) / (2 ^ PRESCALE))

The following timing restrictions must be enforced to avoid unexpected START or STOP conditions on the I2C bus. These restrictions also avoid unexpected START or STOP conditions detected by the LPI2C controller. The timing restrictions can be summarized as **SDA cannot change when SCL is high outside a transmitted (repeated) START or STOP condition**.

Table 286. LPI2C Timing Parameter Restrictions

Timing Parameter	Minimum	Maximum	Comment
CLKLO	03h	-	Also: CLKLO x (2 ^ PRESCALE) > SCL_LATENCY
CLKHI	01h	-	Configure CLKHI to meet the duty cycle requirements in the I2C specification
SETHOLD	02h	-	Also: SETHOLD x (2 ^ PRESCALE) > SDA_LATENCY
DATAVD	01h	CLKLO - SDA_LATENCY - 1	Configure DATAVD to meet the data hold requirement in the I2C specification
FILTSCL	00h	[CLKLO x (2 ^ PRESCALE)] - 3	FILTSCL and FILTSDA are the only parameters not multiplied by (2 ^ PRESCALE)
FILTSDA	FILTSCL	[CLKLO x (2 ^ PRESCALE)] - 3	Configuring FILTSDA greater than FILTSCL can delay the SDA input to compensate for board level skew
BUSIDLE	(CLKLO+SETHOLD+2) x 2	-	Must also be greater than (CLKHI+1)

The timing parameters must be configured to meet the requirements of the I2C specification. This configuration depends on the mode being supported and the LPI2C functional clock frequency. When switching between two modes using the different clock configuration registers (for example, fast and high-speed mode), the PRESCALE factor must remain constant between the modes. Example timing configurations are provided below.

Table 287. LPI2C Example Timing Configurations

I2C Mode	Clock Frequency	Baud Rate	PRESCALE	FILTSCL / FILTSDA	SETHOLD	CLKLO	CLKHI	DATAVD
Fast	8 MHz	400 kbit/s	0h	0h/0h	04h	0Bh	05h	02h
Fast+	8 MHz	1 Mbit/s	0h	0h/0h	02h	03h	01h	01h
Fast	48 MHz	400 kbit/s	0h	1h/1h	1Dh	3Eh	35h	0Fh
Fast	48 MHz	400 kbit/s	2h	1h/1h	07h	11h	0Bh	03h

HS-mode	48 MHz	3.2 Mbit/s	0h	0h/0h	07h	08h	03h	01h
Fast	60 MHz	400 kbit/s	1h	2h/2h	11h	28h	1Fh	08h
Fast+	60 MHz	1 Mbit/s	1h	2h/2h	07h	0Fh	0Bh	01h
HS-mode	60 MHz	3.33 Mbit/s	1h	0h/0h	04h	04h	02h	01h

48.3.1.5 Error conditions

The LPI2C controller monitors for errors while it is active. The following conditions generate an error flag and block a new START condition from being sent, until the flag is cleared by software:

- A START or STOP condition is detected and is not generated by the LPI2C controller (MSR[ALF] becomes 1).
- Transmitting data on SDA and different values are received (MSR[ALF] becomes 1). LPI2C controller stops driving SDA immediately, but continues to drive SCL for the remainder of the byte.

- NACK is detected when transmitting data, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- NACK is detected and is expecting ACK for the address byte, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- ACK is detected and is expecting NACK for the address byte, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- Transmit FIFO is requesting to transmit or receive data without a START condition (MSR[FEF] becomes 1). This restriction is ignored when MCFGR0[RELAX] is 1.
- SCL (or SDA if MCFGR1[TIMECFG] is 1) is low for (MCFGR2[TIMELOW] * 256) prescaler cycles without a pin transition (MSR[PLTF] becomes 1).

Software must respond to the MSR[PLTF] flag to terminate the existing command either cleanly (by writing 0 to MCR[MEN]), or abruptly (by writing 1 to MCR[RST]).

The MCFGR0[RELAX] control bit can be used to attempt to write 0 to a target with SDA stuck low. If MCFGR0[RELAX] is 1, the LPI2C controller does not wait for the I2C bus to be idle before starting a transfer. Initiating a START command with general call address 00h, then the STOP condition, should generate sufficient SCL clock edges to cause the target to release SDA.

The MCFGR2[BUSIDLE] field can be used to force the I2C bus to be considered idle when SCL and SDA remain high for (BUSIDLE+1) prescaler cycles. The bus is considered idle when the LPI2C controller is first enabled. When BUSIDLE is configured greater than zero, then SCL and/or SDA must be high for (BUSIDLE+1) prescaler cycles before the I2C bus is considered idle.

48.3.1.6 Pin configuration

- **Open-drain support:** The LPI2C controller defaults to open-drain configuration of the SDA and SCL pins. Support for true open drain depends on the specific device, and requires the pins where LPI2C pins are muxed to support true open drain.
- **High-speed mode support:** Support for high-speed mode depends on the specific device. This mode requires the SCL pin to support the current source pull-up required in the I2C specification.
- **Ultra-fast mode support:** The LPI2C controller supports the output-only push-pull function required for I2C ultra-fast mode using the SDA and SCL pins. Support for ultra-fast mode also requires the MCFGR1[IGNACK] bit to be 1.
- **Push-pull two-wire support:** A push-pull two-wire configuration is available to the LPI2C controller. If LPI2C is the only controller and all I2C pins on the bus are at the same voltage, this configuration may support a partial high-speed mode. This configuration sets the SCL pin as push-pull for every clock except the ninth clock pulse, to allow high-speed-mode-compatible targets to perform clock stretching. In this mode, the SDA pin is tristated for controller-receive data bits and controller-transmit ACK/NACK bits, and is configured as push-pull at other times. To avoid the risk of contention when SDA is push-pull, the pin can be configured for open-drain operation, as part of the device-specific configuration.
- **Push-pull four-wire support:** The push-pull four-wire configuration separates the SCL input data and output data into separate pins. It also separates the SDA input data and output data into separate pins. The SCL/SDA pins are used for input data; the SCLS/SDAS pins are used for output data, with configurable polarity. This configuration simplifies external connections when connecting the LPI2C to the I2C bus through external level shifters or discrete components. When using this four-wire configuration, the LPI2C controller logic and LPI2C target logic are not able to connect to separate I2C buses.

48.3.2 Target mode

To perform all target mode transfers on the I2C bus, the LPI2C target logic operates independently from the LPI2C controller logic.

48.3.2.1 Address Matching

The LPI2C target can be configured:

- To match one of two addresses, using either seven-bit or ten-bit addressing modes for each address.
- To match a range of addresses in either seven-bit or ten-bit addressing modes.
- To match the General Call Address and generate appropriate flags.
- To match the SMBus Alert Address and generate appropriate flags.

- To detect the high-speed mode controller code, and to disable the digital filters and output valid delay time until the next STOP condition is detected.

After a valid address is matched, the LPI2C target automatically performs target-transmit or target-receive transfers until:

- A NACK is detected (unless SCFGR1[IGNACK] becomes 1).
- A bit error is detected (the LPI2C target is driving SDA, but a different value is sampled).
- A (repeated) START or STOP condition is detected.

When SCFGR1[RXALL] is 1, the LPI2C target receives all addresses and data on the I2C bus. Unless the address was matched, however, it never drives the SDA pin. The LPI2C target should be configured to match only on seven-bit address mode when this feature is enabled. Ten-bit address mode can be supported in software. This option is intended for debugging the contents of an I2C transfer between another controller and target. The SCFGR1[SDCFG] and SCFGR1[RSCFG] likewise configure the STOP or repeated START flags to assert on all STOP or repeated START conditions, even when there was no address match.

48.3.2.2 Transmit and Receive Data

- The Transmit and Receive Data registers are double-buffered and only update during a target-transmit and target-receive transfer, respectively.
- The target address that was received can be configured to be read from the Receive Data register (for example, when using DMA to transfer data). It can also be configured to be read from the Address Status register.
- The Transmit Data register can be configured to request data only after a target-transmit transfer is detected. It can also be configured to request new data whenever the Transmit Data register is empty.
- The Transmit Data register should only be written when the Transmit Data flag (SSR[TDF]) is 1.
- The Receive Data register should only be read when the Received Data flag (SSR[RDF]) is 1 (or the Address Valid Flag (SSR[AVF]) is 1 and SCFGR1[RXCFG] = 1).
- The Address Status register should only be read when the Address Valid Flag (SSR[AVF]) is 1.

48.3.2.3 Read request

The LPI2C target generates a read request when the I2C bus is idle and software writes 1 to the SCFGR0[RDREQ] bit. This occurrence causes the LPI2C target to pull SDA pin low until either the first SCL falling edge or the SCFGR0[RDREQ] becomes 0. Following the next STOP condition or a software timeout, software can proceed as follows:

- If the LPI2C target was accessed at the correct address, the read request is acknowledged, and software should write 0 to SCFGR0[RDREQ].
- If the SCFGR0[RDACK] is 1, then the read request was acknowledged by a START followed by one SCL pulse followed by a STOP condition. Software should write 0 to SCFGR0[RDREQ].
- If neither of the first two cases occurred, then the read request was not acknowledged. Software should write 0 and then 1 to SCFGR0[RDREQ] after an appropriate delay, provided the I2C bus is idle.
- If a software timeout occurs, the read request was not acknowledged, and software should write 0 to SCFGR0[RDREQ]. Another request can be generated after an appropriate delay.

Writing SCFGR0[RDREQ] when the I2C bus is busy results in a logic 0 being written. Software should first write 1 to SCFGR0[RDREQ] and then confirm that the register was written correctly. If the register did not update correctly, then the I2C bus is no longer idle and the read request should be attempted later.

48.3.2.4 Clock stretching

The LPI2C target supports many configurable options for clock stretching. The following conditions can be configured to perform clock stretching:

- The Address Valid flag becomes 1 during the ninth clock pulse of the address byte.
- The Transmit Data flag becomes 1 during the ninth clock pulse of a target-transmit transfer.

- The Receive Data flag becomes 1 during the ninth clock pulse of a target-receive transfer.
- The Transmit ACK flag becomes 1 during the eighth clock pulse of an address byte or a target-receive transfer. In high-speed mode, this option is disabled.
- Clock stretching can be extended for CLKHOLD cycles, to allow additional setup time to sample the SDA pin externally. In high-speed mode, this option is disabled.

When clock stretching is enabled, clock stretching extends for one peripheral bus clock cycle after SDA updates, unless extended by the CLKHOLD configuration.

48.3.2.5 Timing parameters

The LPI2C target can configure the following timing parameters:

- SDA data valid time from SCL negation to SDA update
- SCL hold time when clock stretching is enabled to increase setup time when sampling SDA externally
- SCL glitch filter time
- SDA glitch filter time

These parameters are disabled when SCR[FILTEN] is 0, when SCR[FILTDZ] is 1 in Doze mode, and when LPI2C target detects high-speed mode. When disabled, the LPI2C target is clocked directly from the I2C bus. In this case, the target may not satisfy all timing requirements of the I2C specification (such as SDA minimum hold time in Standard/Fast mode).

The LPI2C target places the following restrictions on the timing parameters:

- FILTSDA must be configured to greater than or equal to FILTSCL (unless compensating for board level skew between SDA and SCL).
- DATAVD must be configured less than the minimum SCL low period.

48.3.2.6 Error conditions

The LPI2C target can flag the following error conditions:

- The bit error flag becomes 1 when the LPI2C target is driving SDA but it samples a different value than what is expected.
- The FIFO error flag becomes 1 due to a transmit data underrun or a receive data overrun. To eliminate the possibility of underrun and overrun, enable clock stretching. When SCFGR1[RXNACK] is 1, the LPI2C target generates a NACK on a receive data overrun.
- The FIFO error flag also becomes 1 due to an address overrun, but only when SCFGR1[RXCFG] is 1. To eliminate the possibility of overrun, enable clock stretching. When SCFGR1[RXNACK] is 1, the LPI2C target generates a NACK on an address overrun regardless of SCFGR1[RXCFG].

The LPI2C target does not implement a timeout due to SCL and/or SDA being stuck low. If this detection is required, use the LPI2C controller logic so the software can reset the LPI2C target when this condition is detected.

48.3.3 Low-power modes

Table 288. LPI2C low-power modes

Mode	LPI2C operation
Run	Normal operations
Sleep	If MCR[DOZEN] = 0 and LPI2C uses an external or internal clock source that operates during Sleep mode, can continue operating in Sleep mode. LPI2C can generate an interrupt or DMA request to cause a wake-up from Sleep mode.

Table continues on the next page...

Table 288. LPI2C low-power modes (continued)

Mode	LPI2C operation
Deep Sleep	Before entering Deep Sleep mode, the LPI2C waits for the current transfer to finish any pending operation, while temporarily ignoring MCR[DOZEN].

48.3.4 Debug mode

Table 289. LPI2C debug mode

Mode	LPI2C operation
Debug	If MCR[DBGEN] = 1, can continue operating in debug mode.

48.3.5 Interrupts and DMA requests

Depending on the configuration, interrupts and DMA requests can be combined:

- LPI2C controller and target interrupts
- LPI2C controller and target transmit DMA requests
- LPI2C controller and target receive DMA requests

48.3.5.1 Controller mode

The table below lists the Controller mode sources that can generate LPI2C controller interrupts and LPI2C controller transmit/receive DMA requests.

Table 290. Controller interrupts and DMA requests

Controller Status (MSR)		Description	Can generate		
Flag	Name		Interrupt?	DMA request?	Low-power wake-up?
TDF	Transmit Data Flag	Data can be written to Transmit FIFO, as configured by the Transmit FIFO Watermark MFCR[TXWATER].	Y	TX	Y
RDF	Receive Data Flag	Data can be read from the Receive FIFO, as configured by the Receive FIFO Watermark MFCR[RXWATER].	Y	RX	Y
EPF	End Packet Flag	Controller has transmitted a Repeated START or STOP condition.	Y	N	Y
SDF	STOP Detect Flag	Controller has transmitted a STOP condition and optionally the LPI2C controller is idle.	Y	N	Y
NDF	NACK Detect Flag	• During an address byte, the controller expects an ACK but detects a NACK. • During an address byte, the controller expects a NACK but detects an ACK. • During a controller-transmitter data byte, the controller detects a NACK.	Y	N	Y

Table continues on the next page...

Table 290. Controller interrupts and DMA requests (continued)

Controller Status (MSR)		Description	Can generate		
Flag	Name		Interrupt?	DMA request?	Low-power wake-up?
ALF	Arbitration Lost Flag	• The controller lost arbitration due to a START/STOP condition detected at the wrong time, • Or the controller was transmitting data but received data different from the data that was transmitted.	Y	N	Y
FEF	FIFO Error Flag	The controller expects a START condition in the Command FIFO, but the next entry in the Command FIFO is not a START condition.	Y	N	Y
PLTF	Pin Low Timeout Flag	Pin low timeout is enabled and SCL (or SDA, if configured) is low for longer than the configured timeout.	Y	N	Y
DMF	Data Match Flag	The received data matches the configured data match, but the received data is not discarded due to a command FIFO entry.	Y	N	Y
STF	START Detect Flag	A START condition is detected on the I2C bus, and optionally, LPI2C controller is idle.	Y	N	Y
MBF	Controller Busy Flag	LPI2C controller is busy transmitting/ receiving data.	N	N	N
BBF	Bus Busy Flag	LPI2C controller is enabled and activity is detected on the I2C bus, but no STOP condition is detected and no bus idle timeout (if enabled) occurred.	N	N	N

48.3.5.2 Target mode

The table below lists the target mode sources that can generate LPI2C target interrupts and LPI2C target transmit/receive DMA requests.

Table 291. Target interrupts and DMA requests

Target Status (SSR)		Description	Can generate		
Flag	Name		Interrupt?	DMA request?	Low-power wake-up?
TDF	Transmit Data Flag	Data can be written to the Target Transmit Data (STDR).	Y	TX	Y
RDF	Receive Data Flag	Data can be read from the Target Receive Data (SRDR).	Y	RX	Y
AVF	Address Valid Flag	Address can be read from the Target Address Status (SASR).	Y	RX	Y

Table continues on the next page...

Table 291. Target interrupts and DMA requests (continued)

Target Status (SSR)		Description	Can generate		
Flag	Name		Interrupt?	DMA request?	Low-power wake-up?
TAF	Transmit ACK Flag	ACK/NACK can be written to the Target Transmit ACK (STAR).	Y	N	Y
RSF	Repeated Start Flag	Target has detected an address match followed by a repeated START condition.	Y	RX	Y
SDF	STOP Detect Flag	Target has detected an address match followed by a STOP condition.	Y	RX	Y
BEF	Bit Error Flag	Target was transmitting data, but received data different from what was transmitted.	Y	N	Y
FEF	FIFO Error Flag	• Transmit data underrun • Receive data overrun • Address status overrun (when Receive Data Configuration SCFGR1[RXCFG] = 1). FEF flag can only become 1 when clock stretching is disabled.	Y	N	Y
AM0F	Address Match 0 Flag	Target detected an address match with SAMR[ADDR0] field.	Y	N	N
AM1F	Address Match 1 Flag	Target detected an address match with SAMR[ADDR1] field or using an address range.	Y	N	N
GCF	General Call Flag	Target detected an address match with the General Call address.	Y	N	N
SARF	SMBus Alert Response Flag	Target detected an address match with the SMBus Alert address.	Y	N	N
SBF	Target Busy Flag	LPI2C target is busy receiving an address byte or is transmitting/receiving data.	N	N	N
BBF	Bus Busy Flag	LPI2C target is enabled and a START condition is detected on I2C bus, but no STOP condition has been detected.	N	N	N

48.3.5.3 End-of-packet DMA transfer

End-of-packet functionality serves serial interfaces where the transfer size may not be known by software in advance and the data is pushed by an external device. Examples include UART receive, I2C target mode, and SPI target mode. End-of-packet processing is intended to ensure that data does not become stranded in either the receive FIFO or the DMA receive buffer. Support for end-of-packet processing must be implemented in both the serial interfaces and the DMA controller.

The condition that signals the end of packet differs for each serial interface but is processed by the serial peripheral and DMA in the same way. For example:

- UART end of packet is signaled by an idle line condition.

- I2C end of packet is signaled by STOP and/or repeated START condition.
- SPI end of packet is signaled by PCS negation.

When the serial peripheral is configured to signal an end-of-packet condition to the DMA and the serial interface detects an end-of-packet condition, it asserts the DMA request for the receive FIFO regardless of the watermark configuration. For larger watermark configurations, this behavior ensures that the last few words of the transfer are first flushed from the receive FIFO.

The DMA then reads the contents of the receive FIFO, depending on the first word in the FIFO.

- If the receive FIFO is empty, the serial interface signals an end-of-packet condition to the DMA controller.
- If the receive FIFO is not empty, but the first word in the FIFO starts a new packet, data is not pulled from the receive FIFO. Also, the serial interface signals an end-of-packet condition to the DMA controller.
- If the receive FIFO is not empty, and the first word in the FIFO does not start a new packet, the DMA transfers data as normal.

Because the DMA may transfer multiple words per request, the end-of-packet condition persists until the DMA minor loop finishes and no additional data is pulled from the FIFO. The status flag that triggered the end-of-packet condition is cleared when the minor loop completes after the end of packet is signaled to the DMA controller.

When the DMA detects the end-of-packet condition, it writes all received words up to the end of packet into system memory. It also saves the destination address for the word after the last valid data. The DMA then terminates the channel as if the major loop completed, including final offsets and optional interrupts, channel linking and scatter-gather. The final destination address can be saved to system memory or is available in the destination address register.

Because the DMA terminates the major loop, the receive FIFO is not serviced until the DMA is reconfigured. This reconfiguration can be done through either software or hardware (for example, channel linking or scatter-gather). This delay should be minimized to avoid receiver FIFO overrun. Automatic DMA end-of-packet processing is not recommended when there are only a few words transferred between end-of-packet conditions. In this case, the DMA spends more time processing the end of packet than transferring the data. For example, to avoid an excessive number of idle conditions, the UART idle line length should be increased as needed.

48.3.6 Clocks

Table 292. LPI2C clocks

LPI2C functional clock	The LPI2C functional clock is asynchronous to the bus clock. It can remain enabled in low-power modes to support I2C bus transfers by the LPI2C controller. The functional clock is also used by the LPI2C target to support digital filter and data hold time configurations. The LPI2C controller divides the functional clock by a prescaler (MCFGR1[PRESCALE]) and the resulting frequency must be at least eight times faster than the I2C bus bandwidth.
External clock	The LPI2C target logic is clocked directly from the external pins SCL and SDA (or SCLS and SDAS, if controller and target are implemented on separate pins). This clocking allows the LPI2C target to remain operational, even when the LPI2C functional clock is disabled. **NOTE** If the LPI2C functional clock is disabled, the LPI2C target digital filter must be disabled. This condition can affect compliance with some of the timing parameters of the I2C specification, such as data hold time.
Bus clock	The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPI2C controller and target registers.

For device-specific clocking information, see the Clocking chapter.

48.3.7 Resets

Table 293. LPI2C resets

Chip reset	The logic and registers for the LPI2C controller and target are reset to their default state on a chip reset.
Software reset	• The LPI2C controller implements a software reset bit in its Control Register. MCR[RST] resets all controller logic and registers to their default state, except for the MCR register itself. • The LPI2C target implements a software reset bit in its Control Register. SCR[RST] resets all target logic and registers to their default state, except for the SCR register itself.
FIFO reset	• The LPI2C controller implements write-only control bits that reset the transmit FIFO (MCR[RTF]) and receive FIFO (MCR[RRF]). After a FIFO is reset, that FIFO is empty. • The LPI2C target implements write-only control bits that reset the transmit data register (SCR[RTF] and receive data register (SCR[RRF]). After a data register is reset, that data register is empty.

48.3.8 Peripheral Triggers

The connection of the LPI2C peripheral triggers to other peripherals depend upon the specific device being used.

Table 294. LPI2C triggers

Trigger	Description
Controller Output Trigger	The LPI2C controller generates an output trigger that can be connected to other peripherals on the device. The controller output trigger asserts on either a repeated START or a STOP condition. The trigger remains asserted for one cycle of the LPI2C functional clock divided by MCFGR1[PRESCALE].
Target Output Trigger	The LPI2C target generates an output trigger that can be connected to other peripherals on the device. The target output trigger asserts on either a repeated START or a STOP condition that occurs after a target address match. The target output trigger remains asserted until the next target SCL pin negation.
Input Trigger	Controls the start of a LPI2C bus transfer. The input trigger is synchronized. To be detected, the input trigger must assert for at least two cycles of the LPI2C functional clock divided by MCFGR1[PRESCALE].

48.4 External signals

Table 295. Signals

Signal	Name	Two-Wire Scheme	Four-Wire Scheme	I/O
SCL	LPI2C clock line	SCL	In Four-wire mode, this pin is the SCL input pin.	I/O
SDA	LPI2C data line	SDA	In Four-wire mode, this pin is the SDA input pin.	I/O
SCLS	Secondary I2C clock line	Not used	In Four-wire mode, this pin is the SCLS output pin. If LPI2C controller/target are configured to use separate pins, then this pin is the LPI2C target SCL pin.	I/O

Table continues on the next page...

Table 295. Signals (continued)

Signal	Name	Two-Wire Scheme	Four-Wire Scheme	I/O
SDAS	Secondary I2C data line	Not used	In Four-wire mode, this pin is the SDAS output pin. If LPI2C controller/target are configured to use separate pins, then this pin is the LPI2C target SDA pin.	I/O

The I2C Two-wire serial bus diagram shows the two signal connection.

48.5 Memory Map and Registers

NOTE

Writing a Read-Only (RO) register or reading a Write-Only (WO) register can cause bus errors. This module will not check if programmed values in the registers are correct; the application software must ensure that valid programmed values are being written.

Fields

Field	Function
31-26 —	Reserved
25 BBF	Bus Busy Flag Indicates that the I2C bus is busy. 0b - Idle 1b - Busy
24 MBF	Controller Busy Flag Indicates that the I2C controller is busy. 0b - Idle 1b - Busy
23-16 —	Reserved
15 STF	START Flag Indicates that a START condition has been detected on the bus when the bus is idle. When MCFGR1[STARTCFG] is 0, STF only asserts if LPI2C controller is also idle. When MCFGR1[STARTCFG] is 1, STF asserts for any START condition when the I2C bus is idle. 0b - START condition not detected. 1b - START condition detected.
14 DMF	Data Match Flag Indicates that the received data has matched the MDMR[MATCH0] and/or MDMR[MATCH1] fields (as configured by MCFGR1[MATCFG]. Received data discarded due to CMD field does not cause DMF to become 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Have not received matching data 1b - Have received matching data
13 PLTF	Pin Low Timeout Flag Becomes 1 when the SCL and/or SDA input is low for more than PINLOW cycles (Pin Low Timeout, MCFGR3[PINLOW]), even when the LPI2C controller is idle. • Software is responsible for resolving the pin low condition. • PLTF cannot become 0 as long as the pin low timeout continues. • Before the LPI2C can initiate a START condition, the PLTF must be written 0. See MCFGR1[TIMECFG] for the SCL and/or SDA timeout settings. 0b - Pin low timeout has not occurred or is disabled 1b - Pin low timeout has occurred
12 FEF	FIFO Error Flag Detects an attempt to send or receive data without first generating a (repeated) START condition. This error can occur if the transmit FIFO underflows when MCFGR1[AUTOSTOP] = 1. When FEF is 1, the LPI2C controller sends a STOP condition (if busy), and does not initiate a new START condition until FEF is 0. 0b - No error 1b - Controller sending or receiving data without a START condition
11 ALF	Arbitration Lost Flag Becomes 1 if either of these conditions exist: • The LPI2C controller transmits a logic 1 and detects a logic 0 on the I2C bus • The LPI2C controller detects a START or STOP condition while the LPI2C controller is transmitting data When ALF becomes 1, the LPI2C controller releases the I2C bus (goes idle), and the LPI2C controller does not initiate a new START condition until the ALF becomes 0. 0b - Controller has not lost arbitration 1b - Controller has lost arbitration
10 NDF	NACK Detect Flag Becomes 1 if the LPI2C controller detects a NACK it was not expecting when transmitting an address or data. When 1, the controller does not initiate a new START condition until NDF has been written 0. If a NACK is expected for a given address (as configured by the command word), then the NDF is 1 if a NACK is not generated. When NDF is 1, the LPI2C controller automatically transmits a STOP condition if MCFGR1[AUTOSTOP] = 1, or the transmit FIFO is not empty. 0b - Unexpected NACK was not detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Unexpected NACK was detected
9 SDF	STOP Detect Flag Becomes 1 when the LPI2C controller generates a STOP condition. When MCFGR1[STOPCFG] = 0 the flag asserts for any STOP condition. When MCFGR1[STOPCFG] = 1 the flag only asserts if the LPI2C controller is also idle (transmit FIFO is empty). 0b - Controller has not generated a STOP condition 1b - Controller has generated a STOP condition
8 EPF	End Packet Flag Becomes 1 when the LPI2C controller generates either a repeated START condition or a STOP condition. Does not write 1 when the controller first generates a START condition. 0b - Controller has not generated a STOP or Repeated START condition 1b - Controller has generated a STOP or Repeated START condition
7-2 —	Reserved
1 RDF	Receive Data Flag Becomes 1 when the number of words in the receive FIFO is greater than MFCR[RXWATER]. 0b - Receive data is not ready 1b - Receive data is ready
0 TDF	Transmit Data Flag Becomes 1 when the number of words in the transmit FIFO is equal or less than MFCR[TXWATER]. 0b - Transmit data is not requested 1b - Transmit data is requested

48.5.1.6 Controller Interrupt Enable (MIER)

Offset

Register	Offset
MIER	18h

Function
Contains:

- Transmit and receive data interrupt enables
- START, STOP, and NACK detect interrupt enables
- DMA interrupt enables

Diagram

48.5.1.8 Controller Configuration 0 (MCFGR0)

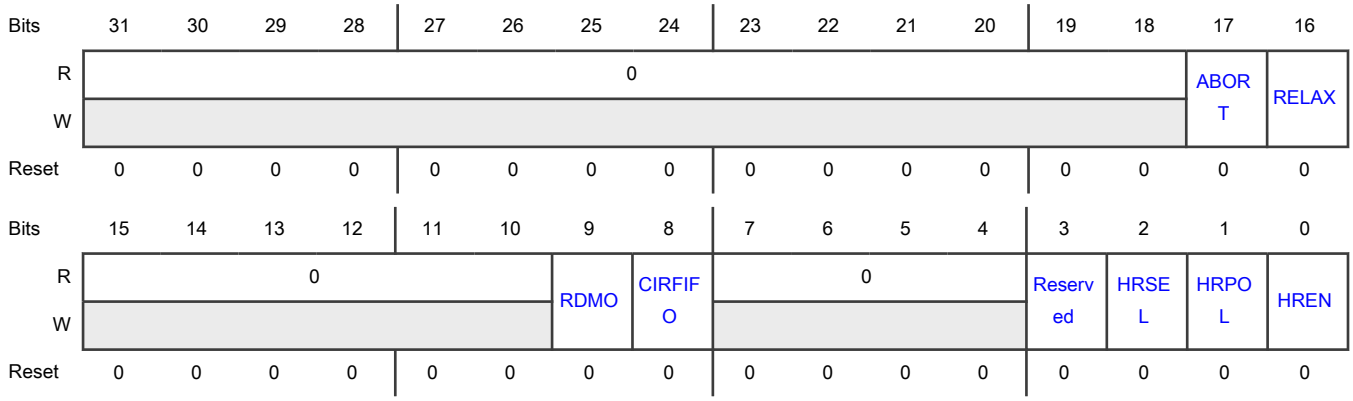
Offset

Register	Offset
MCFGR0	20h

Function

Contains host settings and other receive and transfer settings.

Diagram



Fields

Field	Function
31-18 —	Reserved
17 ABORT	Abort Transfer When 1, the LPI2C controller completes the existing byte and then sends a STOP condition. A new transfer does not start while this bit is 1. 0b - Normal transfer 1b - Abort existing transfer and do not start new transfer
16 RELAX	Relaxed Mode When enabled, the LPI2C controller relaxes several of the transfer restrictions. Transfers start if the bus is busy and FIFO commands are not checked for errors. This mode can be used to attempt to recover a stuck I2C target by toggling SCL pin. 0b - Normal transfer 1b - Relaxed transfer
15-10 —	Reserved
9 RDMO	Receive data match only When enabled, all received data that does not cause the Data Match Flag (MSR[DMF]) to become 1 is discarded. After MSR[DMF] is 1, the RDMO configuration is ignored. When disabling RDMO, write 0 to this bit before writing 0 to MSR[DMF], to ensure that no receive data is lost. 0b - Received data is stored in the receive FIFO 1b - Received data is discarded unless the Data Match Flag (MSR[DMF]) is 1.
8 CIRFIFO	Circular FIFO enable When enabled, the transmit FIFO read pointer is saved to a temporary register. The transmit FIFO empties as normal, but after the LPI2C controller is idle and the transmit FIFO is empty, then the

Table continues on the next page...

Table continued from the previous page...

Field	Function
	read pointer value will be restored from the temporary register. This setting causes the contents of the transmit FIFO to be cycled through repeatedly. If MCFGR1[AUTOSTOP] is 1, then a STOP condition is sent whenever the transmit FIFO is empty and the read pointer is restored. 0b - Circular FIFO is disabled 1b - Circular FIFO is enabled
7-4 —	Reserved
3 —	Reserved
2 HRSEL	Host request select Selects the source of the host request input. When host request is enabled, this bit should not change. 0b - Reserved 1b - Host request input is input trigger
1 HRPOL	Host request polarity Configures the polarity of the host request input. When host request is enabled, this bit should not change. 0b - Active low 1b - Active high
0 HREN	Host request enable When enabled, the LPI2C controller only initiates a START condition if the host request input is asserted and the bus is idle. A repeated START is not affected by the host request. 0b - Host request input is disabled 1b - Host request input is enabled

48.5.1.9 Controller Configuration 1 (MCFGR1)

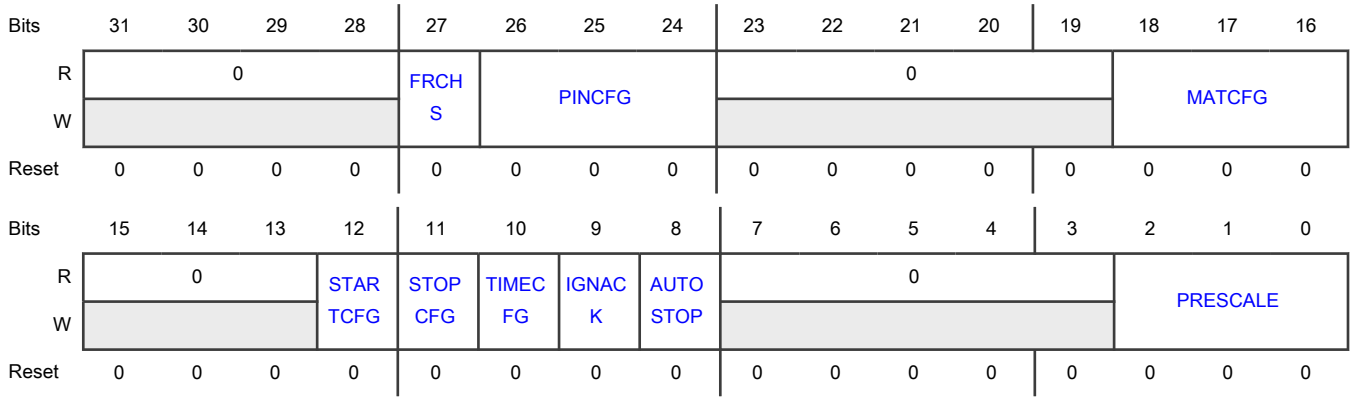
Offset

Register	Offset
MCFGR1	24h

Function

Should only be written when the I2C controller is disabled.

Diagram



Fields

Field	Function
31-28 —	Reserved
27 FRCHS	Force HS mode When 1, forces the LPI2C pin state into HS mode. Writing 1 does not impact the digital filter configuration or digital timing parameters. 0b - No effect 1b - LPI2C pin state forced into HS mode.
26-24 PINCFG	Pin Configuration Configures the pin mode for LPI2C. 000b - Two-pin open drain mode. SCL/SDA pins: Bidirectional open drain for controller and target. SCLS/SDAS pins: Not used. 001b - Two-pin output only mode (ultra-fast mode). SCL/SDA pins: Output-only (ultra-fast mode) open drain for controller and target. SCLS/SDAS pins: Not used. 010b - Two-pin push-pull mode. SCL/SDA pins: Bidirectional push-pull for controller and target. SCLS/SDAS pins: Not used. 011b - Four-pin push-pull mode. SCL/SDA pins: Input only for controller and target. SCLS/SDAS pins: Output-only push-pull for controller and target. 100b - Two-pin open drain mode with separate LPI2C target. SCL/SDA pins: Bidirectional open drain for controller. SCLS/SDAS pins: Bidirectional open drain for target. 101b - Two-pin output only mode (ultra-fast mode) with separate LPI2C target. SCL/SDA pins: Output-only (ultra-fast mode) open drain for controller. SCLS/SDAS pins: Output-only open drain for target. 110b - Two-pin push-pull mode with separate LPI2C target. SCL/SDA pins: Bidirectional push-pull for controller. SCLS/SDAS pins: Bidirectional push-pull for target. 111b - Four-pin push-pull mode (inverted outputs). SCL/SDA pins: Input only for controller and target. SCLS/SDAS pins: Inverted output-only push-pull for controller and target.

Table continues on the next page...

Table continued from the previous page...

Field	Function
23-19 —	Reserved
18-16 MATCFG	Match Configuration Configures the condition that causes MSR[DMF] to become 1. See Controller Data Match (MDMR). 000b - Match is disabled 001b - Reserved 010b - Match is enabled (first data word equals MDMR[MATCH0] OR MDMR[MATCH1]) 011b - Match is enabled (any data word equals MDMR[MATCH0] OR MDMR[MATCH1]) 100b - Match is enabled (first data word equals MDMR[MATCH0] AND second data word equals MDMR[MATCH1) 101b - Match is enabled (any data word equals MDMR[MATCH0] AND next data word equals MDMR[MATCH1) 110b - Match is enabled (first data word AND MDMR[MATCH1] equals MDMR[MATCH0] AND MDMR[MATCH1]) 111b - Match is enabled (any data word AND MDMR[MATCH1] equals MDMR[MATCH0] AND MDMR[MATCH1])
15-13 —	Reserved
12 STARTCFG	START Configuration Configures the assertion of the START Flag (MSR[STF]). 0b - MSR[STF] asserts on START condition provided both I2C bus and LPI2C controller are idle (that is, any non-repeated START condition initiated by any other controller on the bus but not the LPI2C controller). 1b - MSR[STF] asserts on START condition provided I2C bus is idle (that is, any non-repeated START condition initiated by any controller on the bus including the LPI2C controller).
11 STOPCFG	STOP Configuration Configures the assertion of the STOP Detect Flag (MSR[SDF]). 0b - MSR[SDF] asserts on any STOP condition generated by LPI2C controller. 1b - MSR[SDF] asserts on last STOP condition before LPI2C controller is idle (that is, the transmit FIFO is empty at the time of the STOP condition).
10 TIMECFG	Timeout Configuration Configures the timeout settings for the Pin Low Timeout Flag field (MSR[PLTF]). 0b - MSR[PLTF] becomes 1 if SCL is low for longer than the configured timeout. 1b - MSR[PLTF] becomes 1 if either SCL or SDA is low for longer than the configured timeout.

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 IGNACK	Ignore NACK When 1, the received NACK field is ignored and assumed to be ACK. Required to be 1 in Ultra-Fast Mode. 0b - No effect 1b - LPI2C controller treats a received NACK as if it (NACK) was an ACK and the NACK Detect Flag is never written 1.
8 AUTOSTOP	Automatic STOP Generation When enabled, a STOP condition is generated whenever the LPI2C controller is busy and the transmit FIFO is empty. The STOP condition can also be generated using a transmit FIFO command. 0b - No effect 1b - STOP condition is automatically generated when the transmit FIFO is empty and the LPI2C controller is busy
7-3 —	Reserved
2-0 PRESCALE	Prescaler Configures the clock prescaler used for all LPI2C controller logic, except for the digital glitch filters. 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64 111b - Divide by 128

48.5.1.10 Controller Configuration 2 (MCFGR2)

Offset

Register	Offset
MCFGR2	28h

Function
Should only be written when the I2C controller is disabled.

48.5.1.13 Controller Clock Configuration 0 (MCCR0)

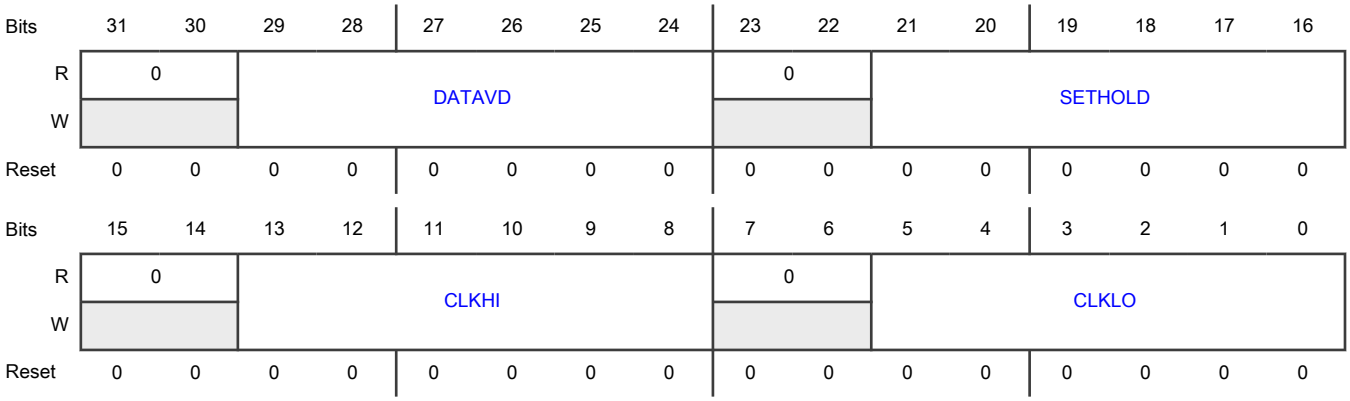
Offset

Register	Offset
MCCR0	48h

Function

Cannot be changed when the I2C controller is enabled and is used for standard, fast, fast-mode plus and ultra-fast transfers.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 DATAVD	Data Valid Delay Minimum number of cycles (minus one) that is used as the data hold time for SDA. Must be configured less than the minimum SCL low period.
23-22 —	Reserved
21-16	Setup Hold Delay

Table continues on the next page...

Table continued from the previous page...

Field	Function
SETHOLD	Minimum number of cycles (minus one) that is used by the controller for these conditions: • Hold time for a START • Setup and hold time for a repeated START • Setup time for a STOP The setup time is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) / 2^PRESCALE cycles.
15-14 —	Reserved
13-8 CLKHI	Clock High Period Minimum number of cycles (minus one) that the SCL clock is driven high by the controller. The SCL high time is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) / 2^PRESCALE cycles.
7-6 —	Reserved
5-0 CLKLO	Clock Low Period Minimum number of cycles (minus one) that the SCL clock is driven low by the controller. The Clock Low Period value is also used for the minimum bus free time between a STOP and a START condition. This period is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) / 2^PRESCALE cycles.

48.5.1.14 Controller Clock Configuration 1 (MCCR1)

Offset

Register	Offset
MCCR1	50h

Function

Cannot be changed when the I2C controller is enabled and is used for high-speed-mode transfers. The separate clock configuration for high-speed mode allows arbitration to take place in Fast mode (with timing configured by Controller Clock Configuration 0 (MCCR0)), before switching to high-speed mode (with timing configured by MCCR1).

Diagram

Field	Function
31-26 —	Reserved
25 BBF	Bus busy flag Indicates if an I2C bus is idle or busy. 0b - Idle 1b - Busy
24 SBF	Target busy flag Indicates if an I2C target is idle or busy. 0b - Idle 1b - Busy
23-16 —	Reserved
15	SMBus alert response flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
SARF	• Becomes 0 by reading the Target Address Status (SASR) register. • Cannot generate an asynchronous wakeup. 0b - SMBus alert response is disabled or not detected 1b - SMBus alert response is enabled and detected
14 GCF	General call flag Indicates whether a target has detected the General Call Address. • Becomes 0 by reading the Target Address Status (SASR) register. • Cannot generate an asynchronous wakeup. 0b - Target has not detected the General Call Address or the General Call Address is disabled 1b - Target has detected the General Call Address
13 AM1F	Address match 1 flag Indicates that the received address has matched the ADDR1 field or ADDR0 to ADDR1 range as configured by SCFGR1[ADDRCFG]. • Becomes 0 by reading the Target Address Status (SASR) register. • Cannot generate an asynchronous wakeup. 0b - ADDR1 or ADDR0/ADDR1 range matching address not received 1b - ADDR1 or ADDR0/ADDR1 range matching address received
12 AM0F	Address match 0 flag Indicates that the received address has matched the ADDR0 field as configured by SCFGR1[ADDRCFG]. • Becomes 0 by reading the Target Address Status (SASR) register. • Cannot generate an asynchronous wakeup. 0b - ADDR0 matching address not received 1b - ADDR0 matching address received
11 FEF	FIFO error flag Can only become 1 when clock stretching is disabled. 0b - FIFO underflow or overflow was not detected 1b - FIFO underflow or overflow was detected
10 BEF	Bit error flag Becomes 1 if the LPI2C target transmits a logic 1 and detects a logic 0 on the I2C bus. The target ignores the rest of the transfer until the next (repeated) START condition. 0b - Target has not detected a bit error 1b - Target has detected a bit error

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 SDF	STOP detect flag Becomes 1 when the LPI2C target detects a STOP condition and if the LPI2C target matched the last address byte. When SCFGR1[SDCFG] becomes 1, this bit becomes 1 on any STOP condition. 0b - Target has not detected a STOP condition 1b - Target has detected a STOP condition
8 RSF	Repeated start flag Becomes 1 when the LPI2C target detects a repeated START condition and if the LPI2C target matched the last address byte. When SCFGR1[RSCFG] becomes 1, this bit becomes 1 on any repeated START condition. The RSF does not become 1 when the target first detects a START condition. 0b - Target has not detected a Repeated START condition 1b - Target has detected a Repeated START condition
7-4 —	Reserved
3 TAF	Transmit ACK flag Becomes 0 by writing to the Target Transmit ACK (STAR) register. 0b - Transmit ACK/NACK is not required 1b - Transmit ACK/NACK is required
2 AVF	Address valid flag Becomes 0 by reading the Target Address Status (SASR) register. When SCFGR1[RXCFG] = 1, SSR[AVF] also becomes 0 by reading the Target Receive Data (SRDR) register. 0b - Address Status Register is not valid 1b - Address Status Register is valid
1 RDF	Receive data flag Becomes 0 by reading the Target Receive Data (SRDR) register. When SCFGR1[RXCFG] = 1, this bit does not become 0 when reading the Target Receive Data (SRDR) register and if SSR[AVF] is 1. 0b - Receive data is not ready 1b - Receive data is ready
0 TDF	Transmit data flag Becomes 0 by writing the to the Target Transmit Data (STDR) register. When SCFGR1[TXCFG] = 0 and if a NACK or a Repeated START or STOP condition is detected, then this bit also becomes 0. 0b - Transmit data not requested 1b - Transmit data is requested

48.5.1.22 Target interrupt enable (SIER)

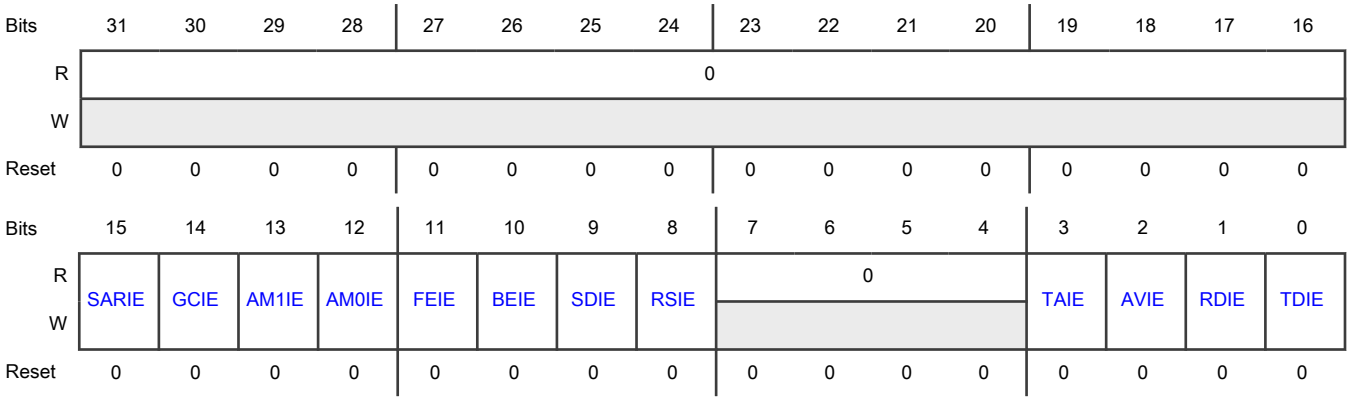
Offset

Register	Offset
SIER	118h

Function

Contains transmit and receive data interrupt enables, start and stop detect interrupt enables, and other target interrupt enables.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 SARIE	SMBus alert response interrupt enable Enables interrupt for SMBus alert response. 0b - Disabled 1b - Enabled
14 GCIE	General call interrupt enable Enables interrupt for general call. 0b - Disabled 1b - Enabled
13 AM1IE	Address match 1 interrupt enable Enables interrupt for address match 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
12 AM0IE	Address match 0 interrupt enable Enables interrupt for address match 0. 0b - Disabled 1b - Enabled
11 FEIE	FIFO error interrupt enable Enables interrupt for FIFO error. 0b - Disabled 1b - Enabled
10 BEIE	Bit error interrupt enable Enables interrupt for bit error. 0b - Disabled 1b - Enabled
9 SDIE	STOP detect interrupt enable Enables interrupt for STOP detection. 0b - Disabled 1b - Enabled
8 RSIE	Repeated start interrupt enable Enables interrupt for repeated start. 0b - Disabled 1b - Enabled
7-4 —	Reserved
3 TAIE	Transmit ACK interrupt enable Enables interrupt for transmit ACK. 0b - Disabled 1b - Enabled
2 AVIE	Address valid interrupt enable Enables interrupt for valid address.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
1 RDIE	Receive data interrupt enable Enables interrupt for receive data. 0b - Disabled 1b - Enabled
0 TDIE	Transmit data interrupt enable Enables interrupt for transmit data. 0b - Disabled 1b - Enabled

48.5.1.23 Target DMA Enable (SDER)

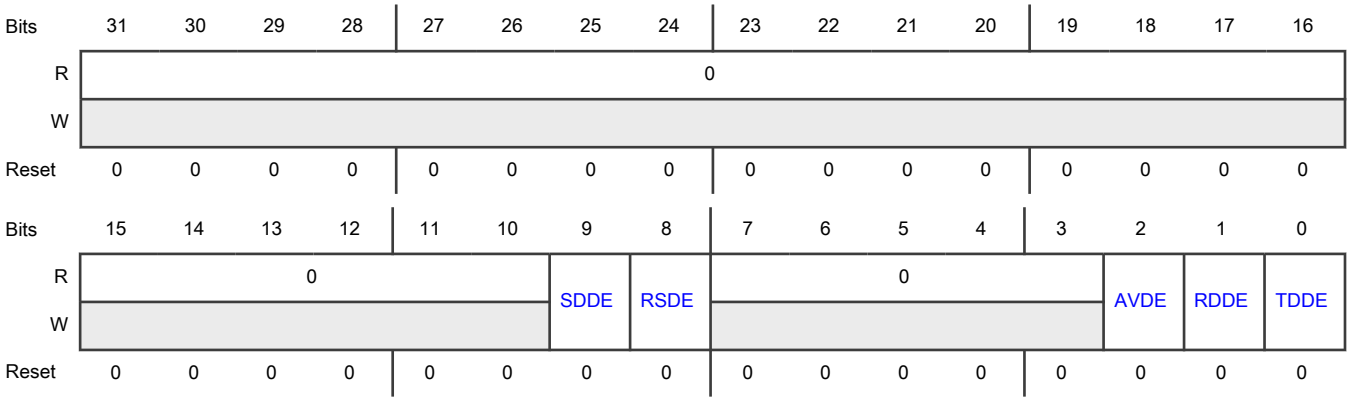
Offset

Register	Offset
SDER	11Ch

Function

Contains the transmit, request, and receive enables for DMA.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 SDDE	Stop detect DMA enable Enables DMA end-of-packet processing on stop detection. Reading the Receive Data register when the Receive Data register is empty: • Generates a DMA end-of-packet response. • Returns 0x0000_40FF. • Writes 0 to the STOP Detect Flag (MSR[SDF]) 0b - DMA request is disabled 1b - DMA request is enabled
8 RSDE	Repeated start DMA enable Enables DMA end-of-packet processing on repeated start. Reading the Receive Data register when the Receive Data register is empty: • Generates a DMA end of packet response. • Returns 0x0000_40FF. • Writes 0 to the Receive Data Flag (MSR[RSF]). 0b - DMA request is disabled 1b - DMA request is enabled
7-3 —	Reserved
2 AVDE	Address valid DMA enable The Address Valid DMA request is shared with the Receive Data DMA request. If both Address Valid DMA request and Receive Data DMA request are enabled, then set SCFGR1[RXCFG] = 1, to allow the DMA to read the address from the Target Receive Data (SRDR) register. 0b - DMA request is disabled 1b - DMA request is enabled
1 RDDE	Receive data DMA enable Enables receive data for DMA. 0b - DMA request is disabled 1b - DMA request is enabled
0 TDDE	Transmit data DMA enable Enables transmit data for DMA.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - DMA request is disabled 1b - DMA request is enabled

48.5.1.24 Target Configuration 0 (SCFGR0)

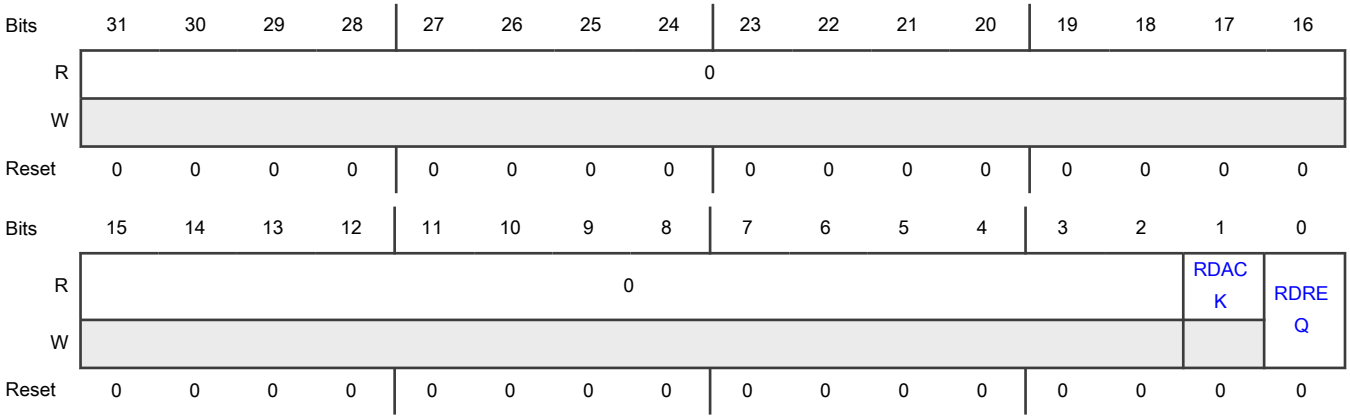
Offset

Register	Offset
SCFGR0	120h

Function

Configures the read request feature

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RDACK	Read Acknowledge Indicates whether the read request was acknowledged by a START then STOP sequence with one SCL pulse in-between while RDREQ was asserted. This status flag becomes 0 by writing 0 to RDREQ. 0b - Read Request not acknowledged 1b - Read Request acknowledged
0	Read Request

Table continues on the next page...

Table continued from the previous page...

Field	Function
RDREQ	Writing 1 to this bit when the I2C bus is idle causes the LPI2C target to drive SDA low, triggering a START condition. The LPI2C target releases SDA on the next falling edge of SCL or if software writes 0 to the Read Request configuration bit. Initiating a second read request (for example following I2C bus activity that did not acknowledge the request) requires software to write 0 and then 1 to this bit. Writing this register when the I2C bus is busy always writes 0 to this bit. 0b - Disabled 1b - Enabled

48.5.1.25 Target Configuration 1 (SCFGR1)

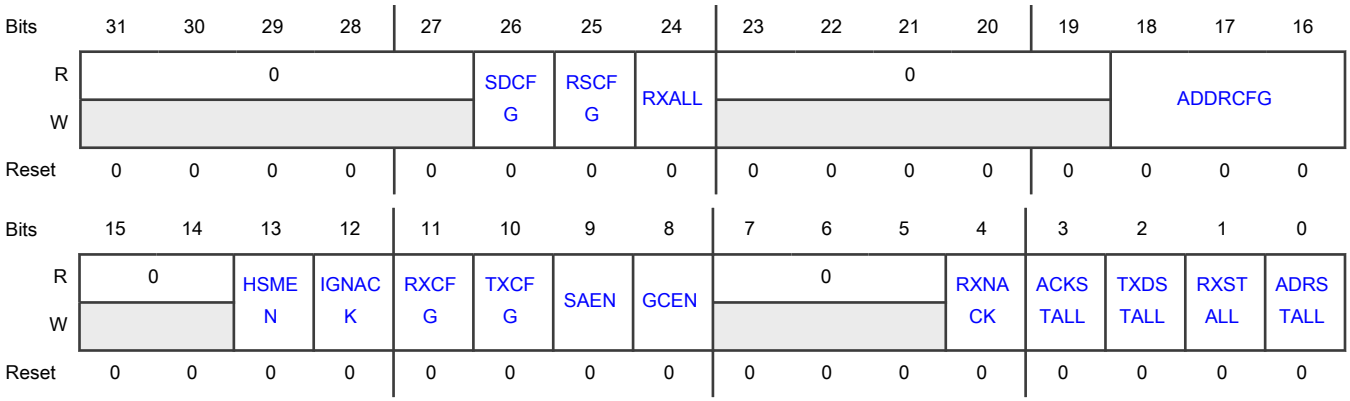
Offset

Register	Offset
SCFGR1	124h

Function

Should only be written when the I2C target is disabled.

Diagram



Fields

Field	Function
31-27 —	Reserved
26	Stop Detect Configuration

Table continues on the next page...

Table continued from the previous page...

Field	Function
SDCFG	Configures the conditions under which the stop detect flag becomes 1. 0b - Any STOP condition following an address match 1b - Any STOP condition
25 RSCFG	Repeated start configuration Configures the conditions under which the repeated start flag becomes 1. 0b - Any repeated START condition following an address match 1b - Any repeated START condition
24 RXALL	Receive all When enabled, the LPI2C target stores all addresses on the I2C bus in the Address Status Register and all data on the I2C bus in the Receive Data Register. However, the LPI2C target does not drive SDA (for ACK or target-transmit transfer) unless there was an address match. The LPI2C target can drive SCL if clock stretching is enabled. When RXALL is 1, only 7-bit addressing modes are supported by the LPI2C target (ADDRCFG must be configured for 7-bit address match) although 10-bit addresses can be supported in software. The first byte of a 10-bit address is saved to the address match register and the second byte is saved as the first data byte in the receive data register. Receive all is intended to aid debugging of the I2C bus by saving all data on the bus without altering the state of the bus. When RXALL is 1, it is recommended to also write 1 to RSCFG and SDCFG so that software can track the full state of the I2C bus. 0b - Receive all disabled 1b - Receive all enabled
23-19 —	Reserved
18-16 ADDRCFG	Address configuration Configures the condition that causes an address to match. 000b - Address match 0 (7-bit) 001b - Address match 0 (10-bit) 010b - Address match 0 (7-bit) or Address match 1 (7-bit) 011b - Address match 0 (10-bit) or Address match 1 (10-bit) 100b - Address match 0 (7-bit) or Address match 1 (10-bit) 101b - Address match 0 (10-bit) or Address match 1 (7-bit) 110b - From Address match 0 (7-bit) to Address match 1 (7-bit) 111b - From Address match 0 (10-bit) to Address match 1 (10-bit)
15-14	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
13 HSMEN	High-speed mode enable Enables detection of the high-speed mode controller code of target address 0000_1XX, but does not cause an address match on this code. When this field is 1 and any high-speed mode controller code is detected, SCR[FILTEN] and SCFGR1[ACKSTALL] bits are ignored until the next STOP condition is detected. 0b - Disable 1b - Enable
12 IGNACK	Ignore NACK When Ignore NACK is 1, the LPI2C target continues transfers after a NACK is detected. Ignore NACK bit is required to be 1 in Ultra-Fast mode. 0b - Target ends transfer when NACK is detected 1b - Target does not end transfer when NACK detected
11 RXCFG	Receive Data Configuration 0b - Reading the Receive Data register returns received data and writes 0 to the Receive Data flag. See MSR[RDF]. 1b - Reading the Receive Data register when the Address Valid flag (SSR[AVF]) is 1, returns the Address Status register and writes 0 to SSR[AVF]. Reading the Receive Data register when SSR[AVF] is 0, returns received data and writes 0 to the Receive Data flag (MSR[RDF]). See SSR[AVF] and MSR[RDF].
10 TXCFG	Transmit flag configuration Always becomes 1 before a NACK is detected at the end of a target-transmit transfer. This change can cause an extra word to be written to the transmit data FIFO. • When 0, the Transmit Data register is automatically emptied when a target-transmit transfer is detected. This setting causes the transmit data flag to become 1 whenever a target-transmit transfer is detected, and causes the transmit data flag to become 0 at the end of the target-transmit transfer. • When 1, MSR[TDF] becomes 1 whenever the Transmit Data register is empty, and MSR[TDF] becomes 0 when the Transmit Data register is full. This setting allows the Transmit Data register to be filled before a target-transmit transfer is detected, but can cause the Transmit Data register to be written before a NACK is detected on the last byte of a target-transmit transfer. 0b - MSR[TDF] becomes 1 only during a target-transmit transfer when the Transmit Data register is empty 1b - MSR[TDF] becomes 1 whenever the Transmit Data register is empty
9 SAEN	SMBus alert enable Enables a match on an SMBus alert. 0b - Disables match on SMBus Alert 1b - Enables match on SMBus Alert

Table continues on the next page...

Table continued from the previous page...

Field	Function
8 GCEN	General call enable Enables a general call address. 0b - General Call address is disabled 1b - General Call address is enabled
7-5 —	Reserved
4 RXNACK	Receive NACK When 1, the LPI2C target responds with a NACK under the following conditions: • SSR[AVF] should become 1 due to matching an address, but the flag is already 1 (address overrun). • SSR[RDF] should become 1 due to receiving data, but the flag is already 1 (receive data overrun). 0b - ACK/NACK always written 1 by TXNACK 1b - NACK always generated on address overrun or receive data overrun, otherwise ACK/NACK is written 1 by TXNACK.
3 ACKSTALL	ACK SCL stall Enables SCL clock stretching during target-transmit address byte(s) and target-receiver address and data byte(s), to allow software to write the Target Transmit ACK (STAR) register before the ACK or NACK is transmitted. Clock stretching occurs when transmitting the ninth bit, and is therefore not compatible with high-speed mode. When enabled, there is no need to write 1 to either RX SCL Stall (SCFGR1[RXSTALL]) or Address SCL Stall (SCFGR1[ADRSTALL]). When ACKSTALL is enabled and there is an address match on the first byte of a 10-bit address, SSR[AVF] becomes 1, allowing software to read the Received Address before writing to the Target Transmit ACK (STAR) register. 0b - Disabled 1b - Enabled
2 TXDSTALL	Transmit data SCL stall Enables SCL clock stretching when the SSR[TDF] = 1 during a target-transmit transfer. Clock stretching occurs following the ninth bit, and is therefore compatible with high-speed mode. 0b - Disabled 1b - Enabled
1 RXSTALL	RX SCL stall Enables SCL clock stretching when SSR[RDF] = 1 during a target-receive transfer. Clock stretching occurs following the ninth bit, and is therefore compatible with high-speed mode. 0b - Disabled 1b - Enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 ADRSTALL	Address SCL stall Enables SCL clock stretching when SSR[AVF] = 1. Clock stretching only occurs following the ninth bit, and is therefore compatible with high-speed mode. 0b - Disabled 1b - Enabled

48.5.1.26 Target Configuration 2 (SCFGR2)

Offset

Register	Offset
SCFGR2	128h

Function
Should only be written when the I2C target is disabled.

Diagram

Fields

Field	Function
31-28 —	Reserved
27-24 FILTSDA	Glitch filter SDA Configures the I2C target digital glitch filters for SDA input. • A configuration of 0 disables the glitch filter.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Glitches equal to or less than FILTSDA cycles long are filtered out and ignored. • The latency through the glitch filter is equal to FILTSDA + 3 cycles, and must be configured to be less than the minimum SCL low or high period. • The glitch filter cycle count is not affected by MCFGR1[PRESCALE], and the glitch filter cycle count is disabled in high-speed mode.
23-20 —	Reserved
19-16 FILTSCL	Glitch filter SCL Configures the I2C target digital glitch filters for SCL input. • A configuration of 0 disables the glitch filter. • Glitches equal to or less than FILTSCL cycles long are filtered out and ignored. • The latency through the glitch filter is equal to FILTSCL + 3 cycles, and must be configured to be less than the minimum SCL low or high period. • The glitch filter cycle count is not affected by MCFGR1[PRESCALE], and the glitch filter cycle count is disabled in high-speed mode.
15-14 —	Reserved
13-8 DATAVD	Data valid delay Configures the SDA data valid delay time for the I2C target, which is equal to FILTSCL+DATAVD+3 cycles. • The data valid delay must be configured to be less than the minimum SCL low period. • The I2C target data valid delay time is not affected by MCFGR1[PRESCALE], and the I2C target data valid delay time is disabled in high-speed mode.
7-4 —	Reserved
3-0 CLKHOLD	Clock hold time Configures the minimum clock hold time for the I2C target, when clock stretching is enabled. • The minimum hold time is equal to CLKHOLD + 3 cycles. • The I2C target clock hold time is not affected by MCFGR1[PRESCALE], and the I2C target clock hold time is disabled in high-speed mode.

48.5.1.27 Target Address Match (SAMR)

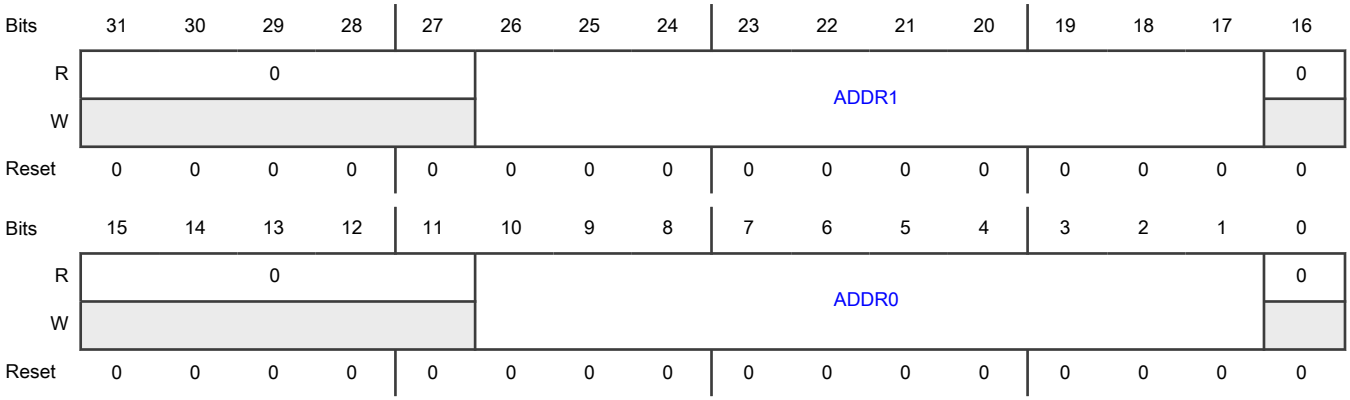
Offset

Register	Offset
SAMR	140h

Function

Should only be written when the I2C target is disabled.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-17 ADDR1	Address 1 value Compared against the received address to detect the Target Address. • In 10-bit mode, the first address byte is compared to { 11110, ADDR1[26:25] } and the second address byte is compared to ADDR1[24:17]. • In 7-bit mode, the address is compared to ADDR1[23:17].
16-11 —	Reserved
10-1 ADDR0	Address 0 value Compared against the received address to detect the Target Address. • In 10-bit mode, the first address byte is compared to { 11110, ADDR0[10:9] } and the second address byte is compared to ADDR0[8:1]. • In 7-bit mode, the address is compared to ADDR0[7:1].

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 —	Reserved

48.5.1.28 Target Address Status (SASR)

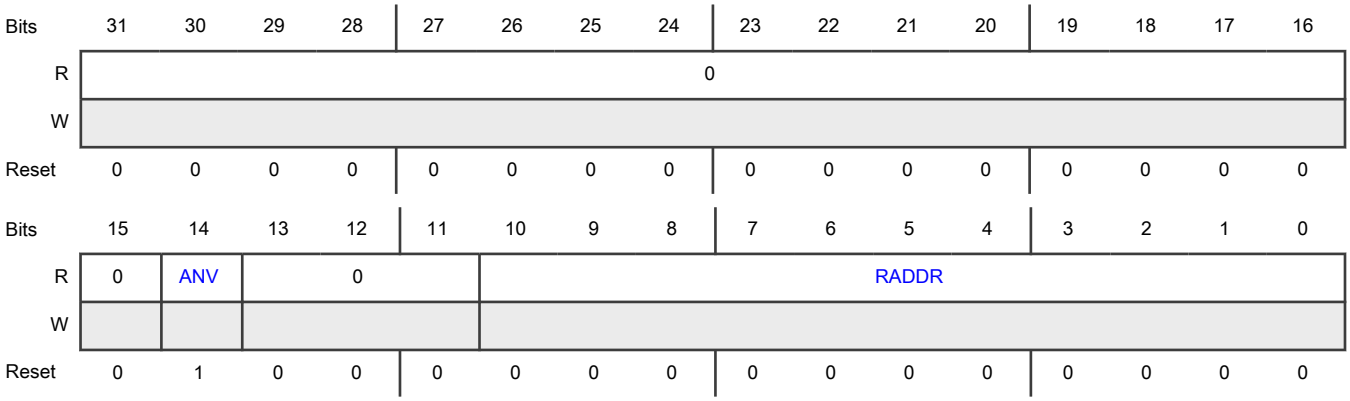
Offset

Register	Offset
SASR	150h

Function

Contains the read-only RADDR and ANV fields.

Diagram



Fields

Field	Function
31-15 —	Reserved
14 ANV	Address not valid 0b - Received Address (RADDR) is valid 1b - Received Address (RADDR) is not valid
13-11 —	Reserved
10-0	Received Address

Table continues on the next page...

Table continued from the previous page...

Field	Function
RADDR	Updates whenever SSR[AM0F] or SSR[AM1F] becomes 1. SSR[AM0F] or SSR[AM1F] become 0 by reading the Target Address Status register. • In 7-bit mode, the address byte is stored in RADDR[7:0]. • In 10-bit mode, the first address byte is { 11110, RADDR[10:9], RADDR[0] } and the second address byte is RADDR[8:1]. The R/W bit is therefore always stored in RADDR[0]. • When SCFGR1[ACKSTALL] is 1, if the first address byte matches in 10-bit mode, then the first address byte is stored in RADDR[7:0] so software can read the Received Address before writing the Transmit ACK. The Received Address then updates with the full 10-bit address if the second address byte matches.

48.5.1.29 Target Transmit ACK (STAR)

Offset

Register	Offset
STAR	154h

Function

Can only be written when the ACK SCL Stall bit (SCFGR1[ACKSTALL]) is 1.

- SCFGR1[ACKSTALL] enables clock stretching during the ACK/NACK bit slot, and during this time, the STAR register can be written by software.
- The logic ensures that the clock stretching continues for at least one bus clock cycle after the STAR register is updated.
- This clock stretching time can be extended using the Clock Hold Time field (SCFGR2[CLKHOLD]).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0															TXNACK
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-1 —	Reserved
0 TXNACK	Transmit NACK After receiving each word, software can transmit either an ACK (logic 0) or a NACK (logic 1). This bit field selects which to use: ACK or NACK. • When SCFGR1[ACKSTALL] is 1, a Transmit NACK must be written once for each matching address byte and each received word. ACKSTALL must be 1, because that setting stalls the data transfer until software reads the received word (and decides whether to respond with an ACK or NACK). • To configure the default ACK/NACK, Transmit NACK can also be written when LPI2C target is disabled or idle. 0b - Write a Transmit ACK for each received word 1b - Write a Transmit NACK for each received word

48.5.1.30 Target Transmit Data (STDR)

Offset

Register	Offset
STDR	160h

Function

Clock stretching (enabled or disabled) affects when the transmit data is transferred. The SCFGR1[TXDSTALL] bit enables clock stretching during the first data bit of a target-transmit transfer.

- **If clock stretching is enabled (SCFGR1[TXDSTALL] = 1)**, then the transmit data transfer is stalled until the STDR is updated. Clock stretching is extended by at least 1 bus clock cycle after STDR is updated, and clock stretching can be delayed even more using the Clock Hold Time field (SCFGR2[CLKHOLD].
- **If clock stretching is disabled (SCFGR1[TXDSTALL] = 0)**, then the transmit data should be written before the start of the target-transmit transfer. If the transmit data is not written before the start of the target-transmit transfer, the FIFO Error Flag (SSR[FEF]) becomes 1.

10-8 RADDR	Received address When both SCFGR1[RXCFG] and SSR[AVF] are 1, the Address Status Register (SASR[RADDR]) bits [10:8] are returned. Otherwise this field returns zero.
7-0 DATA	Receive data When both SCFGR1[RXCFG] and SSR[AVF] are 1, the Address Status Register (SASR[RADDR]) bits [7:0] are returned.

Chapter 49
Improved Inter-Integrated Circuit (I3C)

49.1 Chip-specific I3C information

Table 296. Reference links to related information

Topic	Related module	Reference
Full description	I3C	I3C
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

49.1.1 Module instances

This device has one instance of the I3C module, I3C0.

49.1.2 PORT module configuration for I3C mode pull-up resistor control

In order to work in the I3C mode, the PV (pull value), PE (pull enable) and PS (pull select) values in the corresponding PORT_PCR registers should be correctly configured in advance.

The following table lists the required PORT_PCR register bit fields configuration of corresponding I3C pins to support I3C pull-up resistor control.

Table 297. PORT module configuration to support different I3C pull-up resistor control

I3C pins	Weak pull-up resistor enable	Strong pull-up resistor enable
I3C0_SDA	Corresponding PCRx[PE] = 1, PCRx[PV] = 0, PCRx[PS] = 1	Corresponding PCRx[PE] = 1, PCRx[PV] = 1, PCRx[PS] = 1
I3C0_SCL	Corresponding PCRx[PE] = 1, PCRx[PS] = 1	–

49.1.3 DMA wake-up support in I3C mode

In order to support I3C mode DMA wake-up, the CMC_CKCTRL[CKMODE] should be configured as 0x0 (No clock gating), 0x1 (Core clock is gated), or 0x3 (Core and platform clocks are gated).

49.2 Overview

The MIPI Alliance Improved Inter-Integrated Circuit (MIPI I3C) brings major improvements in use and power over I2C, and provides an alternative to SPI for mid-speed applications. The I3C bus is designed to support future sensor interface architectures, widely expected in Internet-of-Things applications.

The I3C bus is intended to be used by microcontrollers (MCU) and application processors (AP) to connect to sensors, actuators, and other MCUs (as slaves). Connecting an MCU to other MCUs and connecting an AP to an MCU are considered to be the major use cases.

The I3C bus protocol supports:

- In-band interrupts: interrupts can go from Slave to Master without extra wires, such that the Master knows which Slave sent the interrupt.
- Common Command Codes (CCC)

- Dynamic addressing
- Multi-master / multi-drop
- Hot-Join
- I2C compatibility

49.2.1 Features

I3C module:

- 2-wire multi-drop bus capable of 12 MHz clock speeds, with up to 11 devices.
  - Uses standard pads (I2C uses special pads) with 4 mA drive
  - Slave addresses are dynamically assigned, and slaves do not require a static address. However, slaves may have an I2C static address assigned at start-up, so that the slave can operate naturally on an I2C bus.
  - Slaves may use the inbound SCL clock as the peripheral clock, which means that devices can have slow or inaccurate clocks internally.
  - Simple slaves can have no internal clock; for example, like a temperature sensor.
  - For reads from a slave, the slave normally ends the read, but the I3C master can also terminate the read. For I2C and SPI, the master must know the length of the data that is being read, but for I3C the master does not have to know the length of the data being read.
- In-Band interrupts (IBI) are allowed, which allow slaves to notify a master.
  - Can be both equivalent to a separate GPIO, but can also be directly data-bearing.
  - In-Band interrupts are prioritized, so that if multiple Slaves want to interrupt a master at the same time, then the order is resolved. dynamic addresses are used to establish the priority of the slaves, which means that the master controls the priority of the slaves.
  - Interrupts can be started even when the master is not active on the bus, and yet no free-running clock is needed (for that situation).
  - A time-stamping option allows the resolution of an initial event, not just when an interrupt gets through
- Built-in commands are in separate space, so that these commands do not collide with normal Master to Slave messages.
  - Controls bus behavior, modes and states, low-power state, inquiries, and more
  - Has additional room for new built-in commands to be used by other groups
- Organized forms of multi-master modes:
  - Secondary masters that can use clean handoffs between different Masters
- Hot-join onto I3C bus allows devices to connect to the bus later than when the bus starts.
  - Enables a device or module to get onto the I3C bus, because it woke up after power-up, or was physically inserted onto the I3C bus.
  - Also provides a clean method for notification when new devices or modules get onto the I3C bus.
- Capable of using both I2C and I3C buses:
  - I3C supports specific legacy I2C devices on the bus
  - I3C Slave devices can operate on I2C buses
  - Supports bridging to I2C, SPI, UART, and other buses
- Higher data rate modes are optionally available
  - Only the master and the specific slave have to support the higher data rate; the other slaves are able to ignore the higher data rate.

  - Has an HDR-DDR mode (High Data Rate - Double Data Rate), which is about 2x the data rate of SDR (so about 20 Mbps)

- Slaves can be as small as 2 K gates (or less), which allows the I3C to be fully state-machine driven, as well as using a processor (to control the I3C).
- Masters can be as small as 2.5 K gates, but rely on the processor to handle the I3C.

The I3C peripheral supports the full I3C feature set, except for the ternary data rates (HDR-TSP, HDR-TSL).

49.3 Functional description

The following sections describe functional details of the I3C module.

49.3.1 Operating modes

This section describes all functional operation modes of the I3C module.

49.3.1.1 Master vs. slave roles for I3C

The I3C protocol defines 5 roles for devices on the I3C bus:

- **Main Master**: controls the I3C bus
- **Secondary Master**: controls the I3C with permission from the Main Master, and returns control of the bus back to the Main Master when it (Secondary Master) has finished with its tasks
- **Slave**: responds to commands from any I3C master
- **Peer-to-Peer Slave**: can read or write to other peer-to-peer slaves without any help from the I3C master
- **I2C Slave**: responds to commands from any I3C master

The I3C peripheral contains both a master and slave component, and can be parameterized to be either master or slave, or both master and slave. However, if the I3C is chosen to be a master, then the I3C peripheral should generally support slave mode, to make handoffs to multiple masters easier to do.

In general, any I3C master should be able to be a master or a slave, because a master becomes a slave when giving over control to another master. The only exception to this rule would be when using a point-to-point master or when using a master that never shares mastership.

Master requirements

Master mode uses software that supports the various requirements of the master (including as a Secondary Master):

- Special handling of Enter Dynamic Address Assignments (ENTDAA): assigning dynamic addresses to each slave. This is a process that is supported by the I3C peripheral, but requires the software to make choices.
- Building up a table of slaves and their capabilities, which is used to control what kinds of actions and commands may be sent to the slaves.
- Handling requests such as In-band interrupts, peer-to-peer slave, and master request (handoff).
- Adjusting clock speed or write-to-read timing to match the slave's limitations. This can be done in hardware using dividers and uneven duty cycles, but the software must make the decisions.
- Adjusting the maximum data length.
- Being a slave after a master handoff to another master

Additionally, a master needs 3 pins normally, unless a very precise, high strength pullup is included in the SDA pad. The 3-pin model allows 1 pad/pin to enable a system-provided pullup, which is sized to system requirements.

The master needs a reasonably accurate clock, normally capable of a frequency that is a multiple of a frequency between 11 MHz and 12.5 MHz. For example:

- 24 MHz (multiple of 12 MHz)
- 48 MHz (multiple of 12 MHz)
- 25 MHz (multiple of 12.5 MHz)
- 50 MHz (multiple of 12.5 MHz)
- 33 MHz (multiple of 11 MHz)
- 66 MHz (multiple of 11 MHz)

Higher ratios can also be used.

Slave requirements

The I3C slave mode is intended to allow a much simpler module to be used, allowing the device implementation to use fewer logic circuits when space on the device is limited. For example, when the slave minimum requirements are very small (just I3C SDR mode and a few Common Command Code (CCC) commands). Conversely, slave functionality in the module logic can be increased, increasing the module's area on the device, but saving software development costs. What is important is that the Slave can be scaled for system requirements, by doing more in software or by doing more in hardware. This decision is made when the module is integrated into the device.

I3C slave acting as a normal I2C slave on I3C buses

The I3C slave, if assigned an I2C static address, acts like a normal I2C device when the I3C slave first comes up. If the I3C slave is placed on an I2C bus with an I2C master, then the I3C slave will simply stay in I2C mode and operate normally. The software knows that the I3C slave is in I2C mode, because:

- There has not been a DACHG indicating that a dynamic address was assigned
- The SDYNADDR register contains 0x0

If full I2C support for Fast Mode (FM) and Fast Mode Plus (FM+) is desired, then the pads should also support a 50ns spike filter, which must be turned off when the I3C 7'h7E broadcast address is seen (indicating an I3C master). Turning off the spike filters can be done by hardware (using the raw net indicating that the address was seen) or can be done by software. A 50ns spike filter is not needed for the I3C to operate on an I2C bus; therefore the spike filter is not a requirement for the I3C peripheral.

How a slave re-joins the I3C bus

When a slave powers up or after a hard reset, when the slave tries to rejoin the I3C bus, the slave needs a new Dynamic Address (DA). The slave provides ways to rejoin the I3C bus:

- If the dynamic address is lost, then Hot-Join is used.
- If the dynamic address is retained in the peripheral (for example, with SRFFs), then the SCONFIG.OFFLINE bit is used (see below).
- If the dynamic address is retained in separate always-on memory, then the SDYNADDR register (as a writable mechanism) can be used with the SCONFIG.OFFLINE bit.

When SLVENA is set to 1, the OFFLINE bit of the SCONFIG register may be set. This causes the peripheral to safely rejoin the bus, by ensuring that the I3C bus is not in High Data Rate (HDR) mode, using the same approach as S0/S1 exit does: waiting for the first of the HDR Exit Pattern, or waiting for 60 µs of SCL and SDA lines not changing.

After using OFFLINE, the I3C peripheral still cannot safely use IBI until it sees a STOP (SSTATUS register), which ensures that the next START is safe to use for IBI).

If the application needs to do an IBI right away, then the application should wait for the first STOP (SSTATUS register), or should wait for 200 µs of SCL and SDA lines being High. This can be done using the SSTATUS and SINTSET controls.

- If the SSTATUS indicates that the bus is not busy and the peripheral interrupts on START or STOP, then use a timer to measure 200 µs. If the timer goes off with no START or STOP, then it is safe to use IBI.
- If a START causes an interrupt, then the timer should be turned off and the application should wait for a STOP.

- If a STOP causes an interrupt, then it is safe to use IBI.

49.3.1.2 Using the I3C Master for I2C and I3C

The I3C Master operates with a set of built-in capabilities mixed with the application flow:

- Built-in Enter Dynamic Address Assignment (ENTDAA) mechanism to simplify assignment of DAs to slaves (when Set Dynamic Address from Static Address (SETDASA) is not available).
- Request for START+Address with IBI support, including both I2C and I3C modes
- SDR Write flow via FIFO, with automatic parity in I3C and ACK/NACK detect in I2C
- SDR Read flow via the FIFO, with an automatic NACK generator for I2C, and optional use of a terminate generator for I3C
- Request for repeated START+Address or STOP when finished with previous, including both I2C and I3C
- Auto-IBI mode which responds immediately to a Slave-initiated IBI; can be used when in sleep or deep sleep
- Special message mode for SDR and DDR to simplify for DMA use
- All SCL, SDA, Pull-up, and High-Keeper controls are automated
- I2C and I3C Frequency and duty cycle configurations from functional clock

Note the MCONFIG register and the MIBIRULES register should be configured before using the Master.

49.3.2 Operations

This section describes the I3C module's operations.

49.3.2.1 Reading and writing I2C messages using normal method

The normal method:

1. Set up interrupts. Normally:
    a. MCTRLDONE: optional
    b. COMPLETE: to fire when end of data
    c. RXPEND if read; this can be used with the MDATACTRL register to set the FIFO trigger. The alternative is for DMA to read out bytes.
    d. TXNOTFULL if write; this can be used with the MDATACTRL register to set the FIFO trigger. The alternative is for DMA to supply bytes.
    e. IBIWON: so the software knows if an IBI has occurred
    f. MERRWARN: in case of an error
2. Write the MCTRL register with:
    a. REQUEST set to 1 (EmitStartAddr)
    b. TYPE set to 1 (I2C)
    c. IBIRESP set depending on how you want IBIs handled
    d. DIR set to 1 if Read, or set to 0 if Write
    e. ADDR set to the static address of the I2C slave
    f. If read, then RDTERM may be set for the length, or may be set as the data is read out (for example, set to 1 (with REQUEST=0) when you want it to stop next).
3. If Write: Write the MWDATAB register for each byte before the last byte, then write the MWDATABE register for the last byte.
    a. This can be done or started before step 1 **Set up interrupts**

b. If there is more data than the FIFO can hold, use the TXNOTFULL interrupt based on the trigger level, to allow the application to provide more, or use DMA.

4. If Read: wait for RXPEND, and then read out data via the MRDATAB register. DMA may also be used
5. On COMPLETE, the message may be ended with a STOP, or a new message started with a repeated START.
   a. Write MCTRL with REQUEST of 2 (EmitStop to STOP)
   b. Write MCTRL with REQUEST of 1 (EmitStartAddr to start another message).

      Note that IBI is not possible in this case.

49.3.2.2 Reading/writing I3C messages using normal methods (SDR and HDR-DDR)

The normal method for I3C is the same as for I2C with a few differences. Note that **Option 2: From stopped and not in HDR-DDR mode** below is preferred from stopped (bus free condition) when in Single Data Rate mode (SDR) [and not in High Data Rate - Double Data Rate mode (HDR-DDR)], because it allows any slave to issue an IBI, it avoids collisions with IBI addresses, and it is faster (when MSB of dynamic addresses are always 0).

1. Set up interrupts. Normally:
   - MCTRLDONE: optional
   - COMPLETE: to fire when end of data
   - RXPEND if read; this can be used with the MDATACTRL register to set the FIFO trigger. The alternative is for DMA to read out bytes.
   - TXNOTFULL if Write; this can be used with the MDATACTRL register to set the FIFO trigger. The alternative is for DMA to supply bytes.
   - IBIWON: so the software knows if an IBI has occurred
   - MERRWARN: in case of an error
2. Write the MCTRL register:
   - **Option 1:** Write the MCTRL register with:
     a. REQUEST set to 1 (EmitStartAddr) (cannot have pre-written TX data in the FIFO)
     b. TYPE set to 0 (if I3C) or set to 2 (if DDR)
     c. IBIRESP set depending on how you want IBIs handled
     d. DIR set to 1 (if Read) or set to 0 (if Write)
     e. ADDR set to the dynamic address of the I3C slave
     f. If read, then optionally RDTERM is set for the maximum length to auto-terminate.
     g. If write, then pre-writing the data (MWDATAB or MWDATAW) is preferred, to ensure that there are no time delays waiting on the data.
   - **Option 2:** From stopped and not in HDR-DDR mode, write MCTRL register with;
     a. REQUEST set to 1 (EmitStartAddr)
     b. TYPE set to 0 (I3C)
     c. IBIRESP set depending on how you want IBIs to be handled
     d. DIR set to 0
     e. ADDR set to 0x7E
     f. Wait for MCTRLDONE (for example, by interrupt), then proceed with **Option 1:**. This Option 2 method has advantages for IBIs when 7E is emitted on START (but not on repeated STARTs).

NOTE

The Option 2 method would not allow an immediate switch to read; the normal I3C process is to write index, then read data. So, if doing a blind read (no index is written), do not use Option 2 method.

3. If Write: then write the MWDATAB register for each byte before the last byte, then write the MWDATABE register for the last byte.
   - This can be done or started before step 1 [REQUEST set to 1 (EmitStartAddr)]) of **Option 1: Write the MCTRL register with:**. It should not be before **Option 2: From stopped and not in HDR-DDR mode**.
   - If there is more data than the FIFO can hold, use the TXNOTFULL interrupt based on the trigger level, to allow the application to provide more; or use DMA.
4. If Read: wait for RXPEND, and then read out data using the MRDATAB register. DMA may also be used.
5. On COMPLETE, the message may be ended with STOP, or a new message started with a repeated START.
   - Write MCTRL with REQUEST of 2 (EmitStop to STOP)
   - Write MCTRL with REQUEST of 1 (EmitStartAddr to start another message).

     Note that IBI is not possible in this case.

49.3.2.3 Sending a CCC to one or all I3C slaves

The normal Common Command Code (CCC) method is to use an I3C Write with an address of 0x7E. The 1st byte will be the CCC.

- If Broadcast, then any remaining bytes are the bytes that go with the Common Command Code (CCC). This would end with a STOP or a repeated START and 0x7E normally.
- If Direct, then only the CCC byte is sent, followed by a repeated START and the address of the I3C Slave (for SETDASA, this is its I2C Static address). This may be repeated with more repeated START and addresses until done. Then, it may end in STOP or a repeated START and 0x7E.

NOTE

Each repeated START is just a new EmitStart request. This can be chained by interrupt or pushed by message model using DMA.

49.3.2.4 In-band interrupt (IBI) handling

An in-band interrupt occurs when a slave sends its address after a START, and the slave's address is numerically lower than the address that the master sent (and any other slaves trying to send their addresses). When the master sends a 0x7E, the master will always lose, which is the intention.

The in-band interrupt (IBI) can happen unexpectedly when any new START (vs. repeated START) is emitted, but the in-band interrupt can also be in response to a slave pulling SDA low, which can happen in one of two ways:

- The slave has set the request to AutoIBI mode, and so it happens automatically (the engine emits 0x7E to allow the slave to win).
- The application gets the SLVSTART (slave START request) interrupt and so emits 0x7E (normally).

In either of these cases, the application can decide whether to:

- Always accept (ACK) the IBI
- Always reject (NACK) the IBI
- Allow the decision to be made by the application on a case-by-case basis (manual).

How the IBI is handled is configured by the MCTRL.IBIRESP field, which can be set to ACK, NACK, or manual.

- If manual is selected, then the application rewrites it when stopped, pending on an IBI. The application can ACK or NACK based on the IBI address (which is in the MSTATUS register). Note that manual mode chooses if there is an IBI byte or not when doing ACK.

- If always ACK was selected in the IBIRESP field, then the MIBIRULES register must be configured so that the engine knows if bytes will follow.
- If IBI bytes will follow (also known as IBI Mandatory byte), then the COMPLETE bit is not set when IBIWON is set, and RXPEND is set for 1 or more bytes. When the last byte is received, then the COMPLETE status is set.

49.3.2.5 Assigning dynamic addresses to I3C devices

If Dynamic Addresses (DAs) are all assigned below 0x40 (7-bit values from 0x3F down to 0x03, except where this is not allowed), then the MSB0 bit can be set in the Master In-Band Interrupt Registry and Rules register (MIBIRULES). This optimizes the START timing. When dynamic addresses are assigned, the MIBIRULES register should be programmed based on which I3C slave uses IBI bytes (known from Bus Capabilities Register (BCR)).

Any SETDASA (Set Dynamic Address from Static Address) assignments can be done using the normal Common Command Code (CCC) model (except when using the static address for the directed part).

There is a built-in mechanism to process the Dynamic Address Assignment (DAA) mode:

1. Set up interrupts. Normally:
   - MCTRLDONE: need to know when a slave has sent its ID and BCR/DCR and a new DA is needed.
   - COMPLETE: to fire when DAA done (NACKed by all slaves).
   - RXPEND to read the IDs of the slaves. The alternative is for DMA to read out bytes.
   - IBIWON: so the software knows if an IBI happened, which should not be possible normally.
   - MERRWARN: in case of an error
2. Write the MCTRL register with:
   - REQUEST set to 4 - ProcessDAA
   - IBIRESP set to IBI response, if that is possible (if not the 1st Slave assignment)
3. Wait for the MCTRLDONE interrupt, while reading in ID using the RXPEND interrupt. If MSTATUS indicates in DAA mode (STATE=5) and BETWEEN (bit 4=1), then it is waiting for a dynamic address for the slave whose ID was read in.
   - Write the dynamic address into MWDATAB using bits 6:0, such as 0x14 for dynamic address=7'h14.
   - Write MCTRL REQUEST to 4 (ProcessDAA again). This writes the dynamic address and then move on to the next dynamic address.
   - If MSTATUS indicates all is done via the COMPLETE bit being set and STATE=0, then all slaves have been assigned.
   - If MSTATUS indicates NACK after having written a new dynamic address, then the dynamic address was not accepted by the slave. The normal next step is REQUEST set to EmitStop and start over. However, it is also OK to set REQUEST to 4 (ProcessDAA again).

49.3.2.6 Using Master Message mode

Master Message mode is really intended for use with DMA, although message mode can also be used by the processor. The message mode concept is that all writes are to the same location, including the control and then the data; the read back is from an associated location.

NOTE

The data writes for message mode work exactly in the same way as the half-word access registers MWDATAH and MRDATAH.

To send a message via Single Data Rate (SDR), the following steps are used (from DMA or from processor):

1. Write to the MWMSG_SDR register with the control request, which includes the address, I2C vs. I3C, read or write, the count of bytes to process, and how to end (on STOP or ready for repeated START).

2. Process the Data:
   - If Write: then write the rest of the data to MWMSG, using the DMA trigger (or interrupt) to keep the TX FIFO full. Will stop asking when count is down to 0.
   - If Read: then a DMA trigger (or interrupt) indicates when the RX FIFO is to be read out via the MRMSG_SDR.
3. In-band interrupt (IBI) behavior is selected in the MCTRL register.
4. Use END type STOP to exit MSG mode. This can be done with the original message, with a 0 length message, or by using the MCTRL register.

To send a message via Double Data Rate (DDR), the following steps are used (from DMA or from processor):

1. Write to the MWMSG_DDR register with the control request, which includes the count of byte-pairs and how to end (on High Data Rate (HDR) Exit or ready for HDR Restart).
2. Write the 2nd control data to MWMSG_DDR, which includes the address, read or write, and the 7-bit command value.
3. Process the Data:
   - If Write: then write the rest of the data to same register, using the DMA trigger (or interrupt) to keep the TX FIFO full. Will stop asking when count is down to 0.
   - If Read: then a DMA trigger (or interrupt) indicates when the RX FIFO is to be read out.
4. In-band interrupt (IBI) behavior is selected in the MCTRL register.
5. Use END type Exit to exit DDR MSG mode. This can be done with the original message, with a 0 length message, or by using the MCTRL register.

49.3.2.7 Handing off mastership to another slave and getting it back

To hand off mastership, the master either:

- Waits for an Master Request (MR) (an IBIWON interrupt with MSTATUS indicating that an MR is using the IBITYPE field)
- Or pushes the request manually

In either case, the master sends a GETACCMST request. This is a directed GET that tells the slave that the slave is being assigned mastership (if the slave wants it). If the slave accepts (and sends back its own dynamic address in bits 7:1 and the negative parity of the dynamic address in bit 0), then a STOP should be issued and the MCONFIG.MSTENA field should be set to 2 (switching to slave mode).

To gain mastership, the slave sends an MR using the SCTRL register.

- If the MSTENA field is 2, then the GETMSTACC CCC (Common Command Code) will accept
- If the MSTENA field is not 2, then the GETMSTACC CCC will refuse

After mastership has granted, the MSTATUS.NOWMASTER bit is set. The application must enable the NOWMATER bit in the MINTSET register, so the application will be interrupted when a mastership transfer happens.

49.4 External signals

This table describes the I3C module signals.

Signal	I/O	Description
SCL	I/O	Serial clock
SDA	I/O	Serial data

Table continues on the next page...

Table continued from the previous page...

Signal	I/O	Description
PUR	O	Pull up resistance. There is internal pull up resistance on SDA, which is contolled by the I3C master. PUR can be used to actively control an external pull up resistance on SDA, if the internal pull up is not enough.

49.5 Initialization

49.5.1 Configuration initialization

The configuration is handled once (normally) when initializing the I3C module. Configuration is done using the MCONFIG register, which controls the frequencies, duty cycle, optimizations for performance, and other parameters.

Table 298. Configuration parameters used to initialize the I3C module

Configuration Parameter		Description
MSTENA	Master Enable	Determines whether the I3C peripheral starts in Master mode (ie. the “Main Master” in I3C terms) or starts in slave mode (and will switch to Master later).
HKEEP	High Keeper	Determines how the high-keeper (weak pullup) is to be implemented, depending on the device capabilities.
PPBAUD	Push-Pull BAUD	Sets the push-pull frequency as a divider from the FCLK (alternative clock fed to the peripheral). This sets the half-clock period baseline (used at least for the high time of SCL). • If FCLK = 24 MHz, then a PPBAUD = 0 yields 12 MHz (42.67 ns per half period) • If FCLK = 50 MHz, then a PPBAUD = 1 yields 12.5 MHz (20+20= 40 ns per half period)
PPLOW	Push-Pull Low	Changes the duty cycle for push-pull. It indicates how many more FCLKs to use for low. For example, a 50 MHz FCLK, a PPBAUD of 1, and a PPLOW of 1, yields 20+20= 40 ns high and 20+20+20= 60 ns low. This would be equivalent of 10 MHz SCL timing, but maintaining the 40 ns high needed, so that I2C devices do not see the high periods.
ODBAUD	Open Drain BAUD	The number of PPBAUD periods to make up one I3C open-drain half-clock baseline. For example, if PPBAUD yields 12 MHz (40 ns per PPBAUD period), then 5 PPBAUD can be used to get 200 ns. See also ODHPP for details about short high and long low.
ODHPP	Open Drain High Push-Pull	Optional field that allows for the I3C open drain to be long low and short high. The high period of SCL will be the PPBAUD period. This leaves enough time for the pull-up resistor to pull the SDA high when SCL is low, but is quick when SCL is high and there are no changes happening.
I2CBAUD	I2C Baud	Indicates how many ODBAUD periods are needed to communicate with I2C devices. For example, if ODBAUD gives 200 ns, and the goal is FM+ (Fast Mode, 1 MHz), then the sum needs to be 1 us. If odd vs. even, then I2CBAUD acts differently. For example, if I2CBAUD= 3, it will give 3 ODBAUD periods low and 2 ODBAUD periods high. • If I2CBAUD= 4, then it will give 3 ODBAUD periods for low and 3 ODBAUD periods for high.

Table continues on the next page...

Table 298. Configuration parameters used to initialize the I3C module (continued)

Configuration Parameter		Description
		• Also, if I2CBAUD= 3, you get 200*3= 600 ns and 200*2= 400 ns, with the sum 600 + 400 = 1000ns = 1us.
SKEW	Skew	The normal SDA skew from SCL is handled by using the time for the SCL to reach its pad and come back to the design. This is normally 2 ns to 5 ns (or sometimes worse). If the SKEW is too fast, then to add more delay, the SKEW allows specifying the number of FCLKs to insert.

Additonal optimizations:

- Use MIBIRULES.MSB0 to get much faster START header times. If the master application assigns all I3C Dynamic Addresses to be less than 0x40 (it does not have MSB set), then this bit (MSB0) can be set. This means that when the master emits 0x7E (broadcast) and the 1st bit is not driven low by a slave, the rest of the header can be at push-pull speeds. This is about 2x faster (or more, depending on optimizations above).
- Auto-emit 0x7E speeds up the frame when used in conjunction with MSB0, because it allows the processor to be sleeping when the frame starts automatically (in response to a slave).

49.6 Application information

This section describes applications supported by the I3C module.

49.6.1 Using registers when the System clock is much faster than the Functional clock

The Master block has 2 basic clocks:

- System clock: which controls the access into the memory-mapped registers.
- Functional clock (FCLK): which is used to generate the SCL clock rate on the I2C/I3C bus.

Because there are two clocks, requests made to MCTRL and MWMSG_xxx registers have to cross over the clock domains. This is also true of data reads and writes, but there are certain aspects of MCTRL that require consideration.

The normal use is to write MCTRL and wait for an interrupt indicating DONE and/or COMPLETE. Once that interrupt arrives, the interrupt handler likely writes a new request (like a new message or a STOP).

- **When the System clock is less than or equal to 8x faster than the FCLK**, there are no special actions needed. The servicing of the interrupt takes long enough to ensure that all clock-crossing details are settled. For example, if the FCLK is 25 MHz and the system clock is 150 MHz, there are no problems.
- **When the System clock is more than 8x faster than FCLK (or if the code is using a polling spin loop on MSTATUS)**, then special considerations may apply:
  - The MSTATUS sticky bits for DONE and COMPLETE are set, and optionally an interrupt is triggered.
  - To complete the clock crossing, the internal state goes through a handshake process.
  - If a new request posts before 2 FCLKs have completed, then the new request may be lost.
    - For example, if the FCLK is 25 MHz and the System clock is 400 MHz, then 2 FCLKs is 16 beats of the System clock, or really 17 beats (since the clocks are not aligned). If the interrupt handler is entered in under 16 clocks and the interrupt handler tries to write the MCTRL register immediately, then the new request is lost.
    - In reality, most processors need around 12 clocks to enter an interrupt handler, and then the handler code needs to read MSTATUS and make decisions, so this will not be an issue; but if the processor is very fast, then an extra delay is needed.
    - Likewise, if using a polling spin loop, then the timing from detecting MSTATUS DONE or COMPLETE to writing the next MCTRL would need to consider that time required (2 FCLKs).

49.6.2 Master registers summary

The Master registers are integrated with the Slave registers. Other than the configuration registers, the Master registers are above all of the Slave registers, starting at 0x80. The mapping is designed to work for both types of registers, and many Master registers are just aliases of Slave registers, but with different meanings.

- When Master operation is enabled (MCONFIG.MSTENA = 1), the Master registers should be used.
- When Slave operation is enabled (MCONFIG.MSTENA = 0), the Slave registers should be used.

Offset	Type	Register		Description
0x000	RW	MCONFIG	Master Configuration	Configuration for the master
0x084	RW	MCTRL	Master Control	Master main control. Starts actions on the bus (see Using Master Message mode).
0x088	RO and R/W1C	MSTATUS	Master Status	Status for the master, including interrupt causes.
0x08C	RW	MIBIRULES	Master In-Band Interrupts Register and Rules	Rules for IBI use, and registry of Slaves which use an IBI byte.
0x09C	RW	MERRWARN	Master Errors and Warnings	Error and Warning state from the misuse of registers and detected errors on the bus. Related to MSTATUS.ERRWARN bit.
0x0A0	RW	MDMACTRL (alias)	Master DMA Control	DMA control register, if DMA is enabled in the I3C module. Alias of Slave DMACTRL (SDMACTRL).
0x0AC	RW	MDATACTRL (alias)	Master Data Control	Controls data buffering and indicates the current buffer state. Alias of Slave DATACTRL (SDATACTRL). This is also controls the FIFO.
0x0B0	WO	MWDATAB (alias)	Master Write Data Byte	Write a byte of data, possibly the last byte. Alias of Slave WDATAB (SWDATAB).
0x0B4	WO	MWDATABE (alias)	Master Write Last Data Byte	Write the last byte of data. Alias of Slave WDATABE (SWDATABE).
0x0B8	WO	MWDATAH (alias)	Master Write Data Half-Word	Write a half-word of data, possibly the last half-word of data. Alias of Slave WDATAH (SWDATAH).
0x0BC	WO	MWDATAHE (alias)	Master Write Data Half-Word as End	Write the last half-word of data. Alias of Slave WDATAHE (SWDATAHE).
0x0C0	RO	MRDATAB (alias)	Master Read Data Byte	Read a byte of data. Alias of Slave RDATAB (SRDATAB).

Table continues on the next page...

Table continued from the previous page...

Offset	Type	Register		Description
0x0C4	RO	MRDATAH (alias)	Master Read Data Half-Word	Read a half-word of data. Alias of Slave RDATAH (SRDATAH).
0xD0	WO	MWMSG_SDR (semi-alias)	Master Write SDR Message	Set up and push through a message in Single Data Rate (SDR) mode. Written with 16b words.
0xD4	RO	MRMSG_SDR (alias)	Master Read SDR Message	Read content from Slave in message mode. Read as 16b words.
0xD8	WO	MWMSG_DDR	Master Write DDR Message	Set up and push through a message in DDR mode. Written with 16b words.
0xDC	RO	MRMSG_DDR (alias)	Master Read DDR Message	Read content from a slave in Double Data Rate (DDR) message mode. Read as 16b words.
0xE4	RW	MDYNADDR	Master Writable Dynamic Address	Allows writing its own Dynamic Addresswhen switching to slave mode

49.6.3 Slave registers summary

Offset	Type	Register		Description
0x000	RW	Reserved		Reserved for the master
0x004	RW	SCONFIG	Configuration	Configuration fields to set up before a block is activated
0x008	RO	SSTATUS	Status	Status for master and slave. Not all bits used if only slave mode is used.
0x00C	RW	SCTRL	Control	Control for active use, usually event generation (interrupts to the master)
0x010	R/W1S	SINTSET	Interrupts Set	Interrupt enables
0x014	W1C	SINTCLR	Interrupts Clear	Interrupt disables
0x018	RO	SINTMASKED	Interrupts Masked	Mask of sourced interrupts (SSTATUS ANDed with SINTSET)
0x01C	RW	SERRWARN	Errors and Warnings	Error and Warning state from protocol errors and issues. Related to SERRWARN status and interrupt.
0x020	RW	SDMACTRL	DMA Control	DMA control register
0x02C	RW	SDATACTRL	Data Control	Controls data buffering and indicates the current buffer state. This register also controls the FIFO.
0x030	WO	SWDATAB	Write Data Byte	Write a byte of data, including using the 9th bit to mark the end (of the last byte)

Table continues on the next page...

Table continued from the previous page...

Offset	Type	Register		Description
0x034	WO	SWDATABE	Write Last Data Byte	Write a byte of data, which is the end (of the last byte).
0x038	WO	SWDATAH	Write Data Half-Word	Write a half-word of data, using the 16th bit to mark as the end (the last byte of a half-word is the end).
0x03C	WO	SWDATAHE	Write Data Half-Word as End	Write a half-word of data, which is the end (the last byte of a half-word is the end).
0x040	RO	SRDATAB	Read Data Byte	Read a byte of data
0x048	RO	SRDATAH	Read Data Half-Word	Read a half-word of data
0x060	RO	SCAPABILITIES	Capabilities	Indicates what is available/supported in this module, including master and/or slave, HDR modes, and others.
0x064	RO	SDYNADDR	Writable Dynamic Address	The dynamic address once assigned; otherwise this is 0.
0x068	RO	SMAXLIMITS	Maximum Limits	Indicates the maximum read and write limits set by the master (or the original requested limits).
0x06C	RW	SIDPARTNO	ID Part Number	Enables the application to write the ID part-number.
0x070	RW	SIDEXT	ID Extensions	Enables the application to write the ID extension of DCR and/or BCR and/or instance.
0x074	RW	SVENDORID	Vendor ID	Enables the application to write the Vendor ID.
0x078	RW	STCCLOCK	Time Control Clock	Enables the application to dynamically set the time control clock and accuracy information.
0x07C	RO	SMSGMAPADDR	Message Mapped Address	Returns the index of the matching Dynamic address or Static address.
0xFFC	RO	SID	Block ID	Shows the block ID (module ID) and revision.

49.7 I3C register descriptions

Table 299. Register Types

Type		
R	Read	
RO	Read-Only	
RW	Read/Write	
W1C	Write 1 to Clear	W1S and W1C registers are readable (they can be read).
W1S	Write 1 to Set	
WO	Write-Only	

NOTE

Writing a Read-Only (RO) register or reading a Write-Only (WO) register can cause bus errors. This module will not check if programmed values in the registers are correct; the application software must ensure that valid programmed values are being written.

However, the I3C peripheral will ignore writes to RO registers, and the I3C peripheral will return 0 for reads from WO or non-existent registers. It requires all 32-bit regs to be read and written as 32-bit and aligned to 32 bits; the peripheral uses the Advanced Peripheral Bus (APB), so the peripheral would not know if partial read or write operations (less than 32 bits) are used.

49.7.2 Master Configuration Register (MCONFIG)

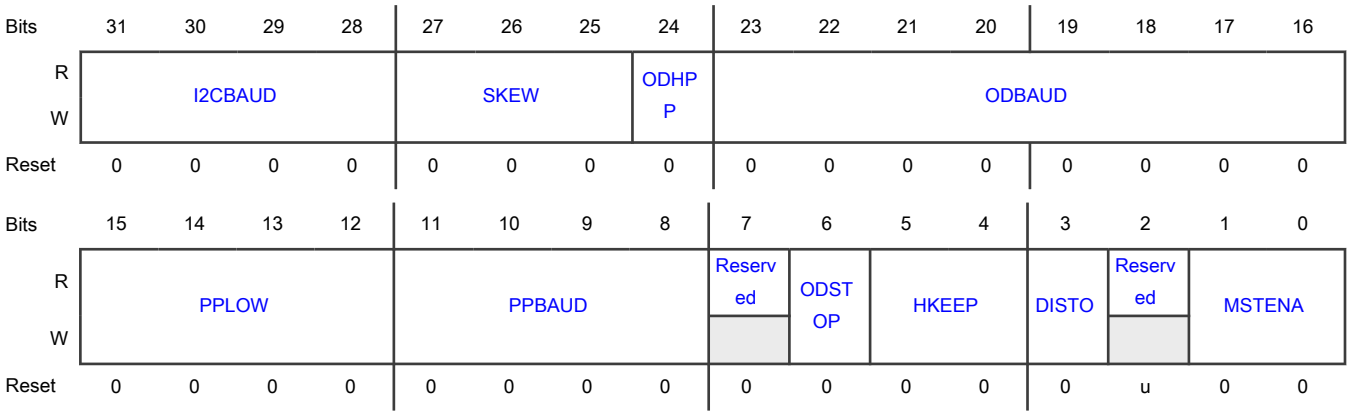
Offset

Register	Offset
MCONFIG	0h

Function

The MCONFIG register controls all Master states when Master operation is enabled. The MCONFIG register should not be changed when an active transaction is happening.

Diagram



Fields

Field	Function
31-28 I2CBAUD	I2C baud rate The I2C low and high times in ODBAUD counts. • I2CBAUD > 1 is the main count load, and it is *count-1*. Therefore, for I2CBAUD > 1: I2CBAUD==0 is 1 ODBAUD beat, and I2CBAUD==1 is 2 ODBAUD beats. • If I2CBAUD[28] is 1, then low will be 1 extra ODBAUD beat. This means that the I2CBAUD field is normally 3, where ODBAUD gives 200 ns; therefore, this means that for I2CBAUD > 1 I2CBAUD==1, which means 2 ODBAUD. Therefore, (2+1)*200=600ns low, with 2*200=400ns high for 1 us period, to match Fast Mode Plus (FM+). For Fast Mode (FM), I2CBAUD is normally 11 (giving 2.6 us) or is 6 (giving 2.4 us).
27-25 SKEW	Skew Number of FCLK counts for an SDA change after SCL for I3C push-pull; this is in addition to the roundtrip of the SCL line from the pad back to the module (3 ns to 4 ns or more). • SKEW is normally not needed, so assign SKEW=0. • SKEW is only used if SDA is not naturally skewing from an SCL change. • I2C automatically skews SDA (but not PUR) to match I2C rules.
24 ODHPP	Open drain high push-pull If ODHPP=1, then Open-Drain High should be 1 PPBAUD count for I3C messages; otherwise ODHPP should be the same value as ODBAUD. Using an ODHPP that is the same value as ODBAUD is commonly used so that I2C devices do not see high.
23-16 ODBAUD	Open drain baud rate ODBAUD= (number of PPBAUD counts) - 1. ODBAUD should not be 0 (not the same as push-pull). This would normally go for 200 ns (see I2CBAUD for I2C counts). When used with ODHPP, this gives 250 ns

Table continues on the next page...

Table continued from the previous page...

Field	Function
	per clock in I3C. Therefore, if PPBAUD gives 12 MHz, then 1 PPBAUD is ½ of 12MHz or 41.67 ns, and then to get around 200 ns, use 5-1=4 for ODBAUD.
15-12 PPLOW	Push-Pull low Adder for push-pull low, to create a duty-cycle with a longer low period, with up to 15 more FCLKs low than high. PPLOW=0 means a 50:50 duty cycle.
11-8 PPBAUD	Push-pull baud rate The FCLK Counter for each push-pull low and normally high period. So, PPBAUD=0 if run at ½ input FCLK speed (for example, a 24 MHz FCLK yields a 12 MHz SCL, because each FCLK is SCL Low or SCL High). Note the use of duty-cycle via Push-Pull Low (PPLOW). For example, 24 MHz with 50:50 duty cycle is 12 MHz, but with PPLOW adding 3 more low beats, the push-pull baud rate becomes 4.8 MHz (from 24 MHz/5 beats).
7 —	Reserved
6 ODSTOP	Open drain stop If ODSTOP=1, then STOP will be emitted at open-drain speeds even for I3C messages. This can be useful for legacy devices, to ensure that the legacy devices see the STOP.
5-4 HKEEP	High-Keeper Indicates how High-Keeper is to be supported. **NOTE** Your specific device may not support any or all of these High-Keeper methods. Refer to the chip-specific section for this module, at the beginning of this chapter. 00b - NONE. Use PUR (Pull-Up Resistor). Hold SCL High. 01b - WIRED_IN. Wired-in High Keeper controls; use pin_HK (High Keeper) controls. 10b - PASSIVE_SDA. Can Hi-Z (high impedance) for Bus Free (IDLE) and hold. 11b - PASSIVE_ON_SDA_SCL. Can Hi-Z (high impedance) both for Bus Free (IDLE), and can Hi-Z SDA for hold.
3 DISTO	Disable Timeout This timeout detects application errors. • If DISTO=1, then it disables the timeout (if the timeout is configured). • If the master has been left in a state other than STOPped for more than 100 us (because 10 KHz is the slowest allowed I3C speed), then the timeout will send an MERRWARN (interrupt). • To prevent the MERRWARN interrupt when doing development or testing, write 1 to DISTO to disable the timeout. • In systems that support timeouts, timeout will be disabled automatically during debug.
2	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
1-0 MSTENA	Master enable Indicates if the master is enabled and what “states” are allowed for it (the master). 00b - MASTER_OFF. Master is off (is not enabled). If MASTER_OFF is enabled, then the I3C module can only use slave mode. 01b - MASTER_ON. Master is on (is enabled). When used from start-up, this I3C module is master by default (the main master). The module will control the bus unless the master is handed off. If the master is handed off, then MSTENA must move to 2 after that happens. The handoff means emitting GETACCMST and if accepted, the module will emit a STOP and set the MSTENA bit to 2 (or 0). 10b - MASTER_CAPABLE. The I3C module is master-capable; however the module is operating as a slave now. When used from the start, the I3C module will start as a slave, but will be prepared to switch to master mode. To switch to master mode, the slave emits an Master Request (MR), or gets a GETACCMST CCC command and accepts it (to switch on the STOP). 11b - Reserved

49.7.3 Slave Configuration Register (SCONFIG)

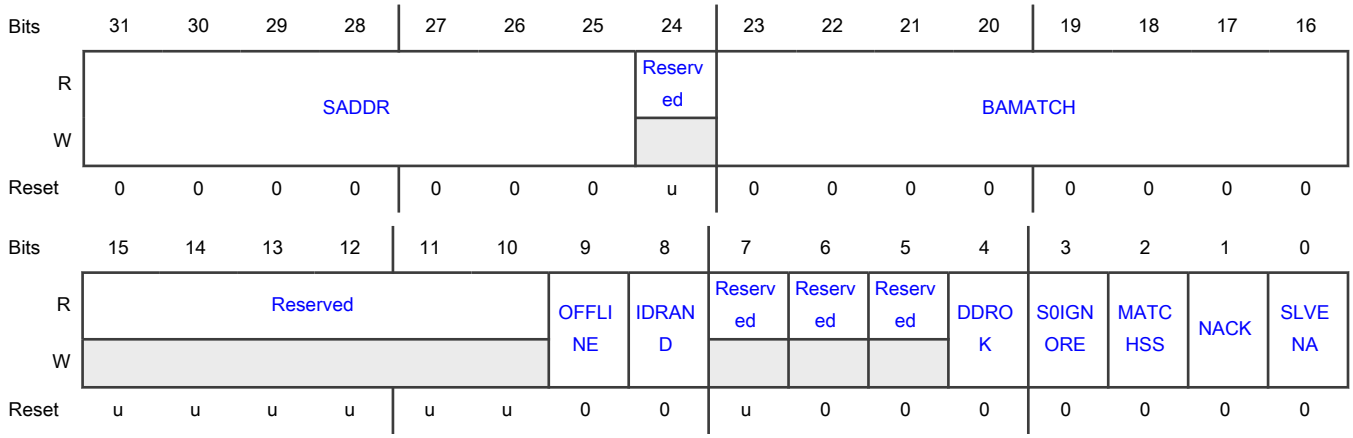
Offset

Register	Offset
SCONFIG	4h

Function

Contains fields that must be configured before the module is activated.

Diagram



Fields

Field	Function
31-25 SADDR	Static address SADDR sets the I2C 7-bit static address.
24 —	Reserved
23-16 BAMATCH	Bus available match This is the Bus Available condition match value for the current slow clock. BAMATCH provides the count of the slow clock to count out 1 us (or more), to allow an In-Band Interrupt (IBI) to drive SDA low when the master is not doing so. The maximum width and maximum values are controlled by the I3C module.
15-10 —	Reserved
9 OFFLINE	Offline If OFFLINE=1 when the slave enable (SCONFIG.SLVENA) is set to 1, then the I3C module will wait for either 60 us of bus quiet or a High Data Rate (HDR) Exit Pattern. This ensures that the bus is not in High Data Rate (HDR) mode, and so can safely track Single Data Rate (SDR) mode.
8 IDRAND	ID random • If IDRAND=1, then SIDPARTNO.PARTNO is a random value. • If IDRAND=0, then SIDPARTNO.PARTNO is a part number and an instance.
7 —	Reserved
6 —	Reserved
5 —	Reserved
4 DDROK	Double Data Rate OK If DDROK=1, then HDR-DDR messaging is allowed; set the corresponding SIDEXT.BCR bit (Bus Characteristics Register bit in Slave ID Extension Register) to say that High Data Rate (HDR) is available, and configure the corresponding HDRCAP HDR-DDR bit to allow using Double Data Rate (DDR) mode. **NOTE** The DDROK bit must be set before the Slave can connect to the I3C bus; the Slave peripheral will indicate to the Master whether it (the slave) can support the feature during dynamic address assignment.
3	S0/S1 errors ignore

Table continues on the next page...

Table continued from the previous page...

Field	Function
S0IGNORE	If S0IGNORE=1, then the slave will not detect S0 or S1 errors, and therefore the slave will not lock up, and will wait for an exit pattern. S0IGNORE=1 should only be used when the I3C bus will not use a High Data Rate (HDR) mode.
2 MATCHSS	Match START or STOP If MATCHSS=1, then the START and STOP sticky STATUS bits will only be set if SSTATUS.MATCHED is set. This allows START and STOP to be used to detect the end of a message to/from this slave.
1 NACK	Not acknowledge If NACK=1, then the slave will NACK all requests to it, except a Common Command Code (CCC) broadcast. NACK=1 should be used with caution, because the master may decide that the slave is missing, if NACK is overused.
0 SLVENA	Slave enable • If SLVENA=1, then a slave can operate on the I2C or I3C bus. • If SLVENA=0, then a slave will ignore the I2C or I3C bus. SLVENA should not be set before registers like SCONFIG (SIDPARTNO, SIDEXT, and others) are set, because these registers affect the data to/from the master. Slave enable is normally only configured just one time before the I3C bus comes up. If slave enable is used at other times, see Hot-Join. In the case of Hot-Join, the Hot-Join bit (SCAPABILITIES.IBI_MR_HJ])should be set before setting the slave enable bit (SLVENA), so that the device does not see a START or STOP incorrectly.

49.7.4 Slave Status Register (SSTATUS)

Offset

Register	Offset
SSTATUS	8h

Function

Not all bits are used if the module only acts as a slave. The Slave Status register is used to indicate both sticky status for interrupts, as well as “states” and “modes” related to the I3C bus. The fields are divided into current activity, interrupt maskable actions, then states and modes on the bus.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	1	0	0	0	0	u	0	0	0	0	0	0	0

Fields

Field	Function
31-30 TIMECTRL	Time control Indicates if time control is currently enabled. 00b - NO_TIME_CONTROL. No time control is enabled 01b - Reserved 10b - ASYNC_MODE. Asynchronous standard mode (0) is enabled 11b - Reserved
29-28 ACTSTATE	Activity state from Common Command Codes (CCC) 00b - NO_LATENCY. Normal bus operations 01b - LATENCY_1MS. 1 ms of latency 10b - LATENCY_100MS. 100 ms of latency 11b - LATENCY_10S. 10 seconds of latency
27 HJDIS	Hot-Join is disabled HJDIS=1 if Hot-Join is disabled at this time. While Hot-Join is disabled, CTRL requests will be held off (not responded to).
26 —	Reserved
25 MRDIS	Master requests are disabled MRDIS=1 if Master Requests are disabled at this time. While Master Requests are disabled, CTRL requests will be held off (not responded to).
24 IBIDIS	In-Band Interrupts are disabled IBIDIS=1 if In-Band Interrupts are disabled at this time. While In-Band Interrupts are disabled, CTRL requests will be held off (not responded to).

Table continues on the next page...

Table continued from the previous page...

Field	Function
23-22 —	Reserved
21-20 EVDET	Event details Current details of the last (EVENT=1) or pending event. 00b - NONE. No event or no pending event 01b - NO_REQUEST. Request not sent yet. Either there was no START yet, or is waiting for Bus-Available or Bus-Idle (HJ). 10b - NACKED. Not acknowledged(Request sent and NACKed); the module will try again. 11b - ACKED. Acknowledged (Request sent and ACKed), so Done (unless the time control data is still being sent).
19 —	Reserved
18 EVENT	Event For a Slave, a pending In-Band Interrupt (IBI), P2P (peer-to-peer), MR (Master Request), or Hot-Join (HJ) has been sent as requested. See the upper status register fields for details. Note that for an in-band interrupt, this occurs on the ACK if no IBI byte is present, and after the 1 IBIDATA byte has been sent. So, if time control is used, those time control bytes (in IBI) will go out after this EVENT is signaled.
17 CHANDLED	Common-Command-Code handled A Common Command Code (CCC) is being handled by the module. This is a notification only, but the result may be an updated SSTATUS register.
16 HDRMATCH	High Data Rate command match An HDR command matched this device's I3C Dynamic Address. The HDR command will be available as the 1st byte and RXPEND will be set (whether the command is read or write, the MSb of that command byte indicates if it is a read or a write command). If the HDR command is a read, and there are to-bus bytes waiting, then the command will be ACKed and the data sent back; otherwise the HDR command will be NACKed. Note that when HDRMATCH is set, the ERRWARN bit should be checked, because the HPAR error may have be encountered after signaling this HDR command (the parity is after the destination address and command).
15 ERRWARN	Error warning An error or warning has occurred, such as data underrun, data overrun, parity error, HDR-DDR CRC error, or other error or warning condition. See the Slave Errors and Warnings Register (SERRWARN).
14 CCC	Common Command Code A Common-Command-Code (CCC) has been received, and is not handled by the I3C module. There are 2 types of Common Command Codes: • Broadcasted CCC, which will then also correspond with RXPEND and the 1st byte will be the CCC (command).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Direct CCC, which may never be directed to this device. If Direct CCC are directed to this device, then the TXSEND or RXPEND will be triggered, and the RXPEND will contain the command.
13 DACHG	DACHG The Slave Dynamic Address has been assigned, re-assigned, or reset (lost) and is now in that state of being valid or none.
12 TXNOTFULL	Transmit buffer is not full TXNOTFULL=1 when the To-bus buffer/FIFO can accept more data to go out. For all but External FIFO, this uses SDATACTRL.TXTRIG, which defaults to not-full. If DMA is enabled for TX, then it will also be signaled to provide more data.
11 RX_PEND	Received message pending Receiving a message from master, which is not being handled by the I3C module (not a Common Command Code (CCC), so is internally processed by the module). For all but External FIFO, this uses SDATACTRL.RXTRIG, which defaults to not-empty. If DMA is enabled for RX, then DMA will be signaled as well. RX_PEND will self-clear if data is read (from FIFO and non-FIFO sources).
10 STOP	Stop The STOP bit is from a stopped state being detected, meaning that a STOP state was present on the bus since the bus was last cleared. The STNOTSTOP state will also indicate if the I3C module is in stop mode. A fast STOP/START combination may not trigger the STOP status; for that case, START will always be set.
9 MATCHED	Matched An incoming header matched this device's I3C Dynamic or I2C Static address (if any) since the bus was last cleared.
8 START	Start START=1 if a START or repeated START was seen after the START bit was last cleared. This is not usually needed, but can be used for wake events.
7 —	Reserved
6 STHDR	Status High Data Rate STHDR=1 if the I3C bus is in HDR-DDR, HDR-TSP, or HDR-TSL modes, regardless of whether HDR mode is supported by this module or not, and regardless of whether the message is to this module or to some other module.
5 STDAA	Status Dynamic Address Assignment STDAA=1 if the I3C bus is in Enter Dynamic Address Assignment (ENTDAA) mode, regardless of whether this bus slave has or does not have a Dynamic Address.
4	Status request write

Table continues on the next page...

Table continued from the previous page...

Field	Function
STREQWR	STREQWR=1 if the request (REQ) in process is SDR write data from the master to this bus slave (or all I3C slaves), but not in Enter Dynamic Address Assignment (ENTDAA) mode. See Status High Data Rate (STHDR) for Double Data Rate (DDR) handling.
3 STREQRD	Status required STREQRD=1 • if the REQ in process is an SDR read from this slave • or if an In-Band Interrupt (IBI) is being pushed out Also see Status High Data Rate (STHDR) for Double Data Rate (DDR) handling.
2 STCCCH	Status Common Command Code Handler STCCCH=1 if a Common Command Code (CCC) message is being handled automatically.
1 STMSG	Status message STMSG=1 if this bus slave is listening to the bus traffic or responding. If STNOSTOP=1, then STMSG will be 0 when a non-matching address is seen, until the next repeated START or STOP occurs.
0 STNOTSTOP	Status not stop • when the bus is busy (has activity), STNOTSTOP=1 • when the I3C module is in a STOP condition, STNOTSTOP=0 Other SSTATUS bits may also be set when busy. Note that STNOTSTOP can also be true (=1) after an S0 or S1 error, where the I3C module is waiting for an Exit Pattern.

49.7.5 Slave Control Register (SCTRL)

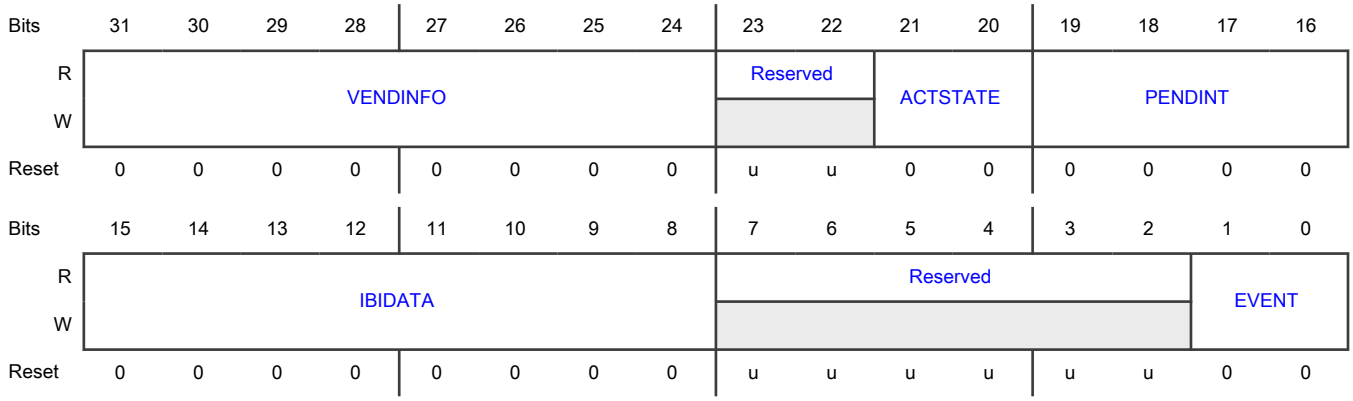
Offset

Register	Offset
SCTRL	Ch

Function

Contains controls for the active use of the I3C bus, like event generation (for example, interrupts to the master). The Slave Control register is used to activate various special operations for the Slave, but only if the module is configured to support those operations. This includes events such as IBI and GETSTATUS fields (except the Protocol error, which is automatically set).

Diagram



Fields

Field	Function
31-24 VENDINFO	Vendor information Should be set to the Vendor Reserved field that the GETSTATUS CCC will return. The vendor information should be maintained by the application, because the master will read this field. If VENDINFO is not configured, then the GETSTATUS field will always return 0.
23-22 —	Reserved
21-20 ACTSTATE	Activity state (of slave) Should be set to the slave's activity state that the GETSTATUS CCC (command code) will return as activity mode. The activity state should be maintained by the application, because the master will read this field. If the activity state is not configured, then the GETSTATUS command will always return 0.
19-16 PENDINT	Pending interrupt Should be set to the pending interrupt that the GETSTATUS CCC (command code) will return. The pending interrupt should be maintained by the application, because the master will read this field. If PENDINT=0 and • if an IBI interrupt is pending, then the GETSTATUS command will return 1. • if an IBI interrupt is not pending, then the GETSTATUS field will return 0.
15-8 IBIDATA	In-Band Interrupt Data Data byte to go with an In-Band Interrupt (IBI), if the module is enabled for in-band interrupts. If SCTRL.IBIDATA is enabled, then in-band interrupts are required.
7-2 —	Reserved
1-0 EVENT	EVENT • If EVENT is set to non-0, it will request an event.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• After being requested, SSTATUS.EVENT and SSTATUS.EVDET will show the status as it progresses. • After completion, the EVENT field will automatically return to 0. • After EVENT is non-0, only 0 can be written to EVENT (to cancel), until the event processing is done (finished). 00b - NORMAL_MODE. If EVENT is set to 0 after was a non-0 value, event processing will cancel if the event processing has not yet started; if event processing has already been started, then event processing will not be be cancelled. 01b - IBI. Start an In-Band Interrupt. This will try to push an IBI interrupt onto the I3C bus. If data is associated with the IBI, then the data will be read from the SCTRL.IBIDATA field. If time control is enabled, then this data will also include any time control-related bytes; additionally, the IBIDATA byte will have bit 7 set to 1 automatically (as is required for time control). The IBI interrupt will occur after the 1st (mandatory) IBIDATA, if any. 10b - MASTER_REQUEST. Start a Master-Request. 11b - HOT_JOIN_REQUEST. Start a Hot-Join request. A Hot-Join Request should only be used when the device is powered on after the I3C bus is already powered up, or when the device is connected using hot insertion methods (the device is powered up when it is physically inserted onto the powered-up I3C bus). The hot join will wait for Bus Idle, and SCTRL.EVENT=HOT_JOIN_REQUEST must be set before the slave enable (SCONFIG.SLVENA).

49.7.6 Slave Interrupt Set Register (SINTSET)

Offset

Register	Offset
SINTSET	10h

Function

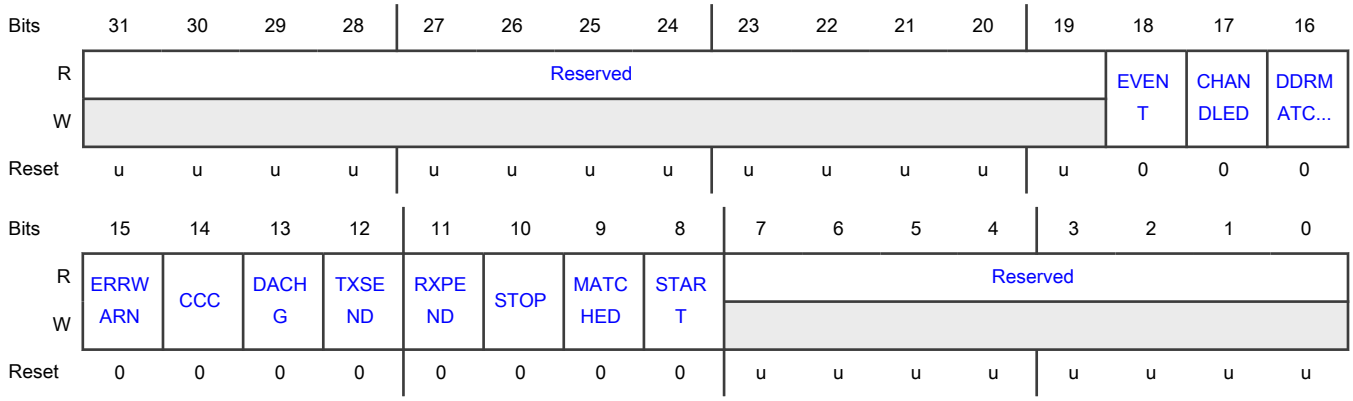
Sets interrupt enables for select STATUS bits. Reading this register (SINTSET) returns the status of the interrupt enables.

- To activate an interrupt enable, write 1 to its field in this register (SINTSET).
- To disable an interrupt enable, write 1 to the appropriate bit in the Interrupt Clear Register (SINTCLR). Writing 0 to the interrupt enable in this register (SINTSET) does not disable the interrupt.

The Interrupt registers allow masking interrupt sources, as well as checking which interrupts have activated. The normal method is to enable an interrupt, and then once the interrupt fires, the interrupt is either cleared by writing the SSTATUS register or cleared by action on the corresponding data register. The Interrupt is level held, meaning the interrupt stays set until the cause is cleared by some method. The module prevents races, so that if a new event comes in, that new event will not be lost.

- SINTSET sets interrupt enables for STATUS bits. Reading the SINTSET register returns the status of the interrupt enables.
- SINTCLR clears interrupt enables for STATUS bits.
- SINTMASKED returns the value of the STATUS bits ANDed with their interrupt enables.

Diagram



Fields

Field	Function
31-19 —	Reserved
18 EVENT	Event interrupt enable
17 CHANDLED	Common Command Code (CCC) (that was handled by I3C module) interrupt enable
16 DDRMATCHED	Double Data Rate (DDR) interrupt enable
15 ERRWARN	Error/warning interrupt enable
14 CCC	Common Command Code (CCC) (that was not handled by I3C module) interrupt enable
13 DACHG	Dynamic address change interrupt enable
12 TXSEND	Transmit interrupt enable
11 RXPEND	Receive interrupt enable
10 STOP	Stop interrupt enable

49.7.9 Slave Errors and Warnings Register (SERRWARN)

Offset

Register	Offset
SERRWARN	1Ch

Function

Contains errors and warnings from I3C/I2C protocol, which includes internal issues such as overrun and underrun, detected errors and conditions like parity errors, CRC errors, and read terminations by the Master. Related to SSTATUS.ERRWARN bit and SINTSET.ERRWARN interrupt.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved														OWRITE	OREAD

W																
Reset	u	u	u	u	0	0	0	0	u	u	u	0	0	0	0	0

Fields

Field	Function
31-18 —	Reserved
17 OWRITE	Over-write error The SWDATAB/BE register was written when FULL.
16 OREAD	Over-read error The SRDATAB register was read for more bytes than were available by the application.
15-12 —	Reserved
11 S0S1	S0 or S1 error A S0 or S1 error has occurred and the slave is locked and waiting for an HDR Exit Pattern. Writing 1 to S0S1 will cause the module to release the lock, but that should be used with great care. Normally, S0S1 will clear automatically when an Exit Pattern is detected. Therefore, writing 1 to S0S1 should only be used under controlled circumstances, to avoid problems. Before starting to operate normally, the module will then wait for a START (or repeated START) or STOP.
10 HCRC	HDR-DDR CRC error HDR-DDR Cyclic Redundancy Check (CRC) error on a message from the master. This calls into question the data from the whole DDR command frame. Note that this includes an HDR Restart or Exit being issued before an HDR-DDR message from master has finished.
9 HPAR	HDR parity error HDR Parity error or framing error on a message from the master. Note that the corresponding command or data that had the error will normally be in the RX buffer (which can be read using the Slave Read Data Byte Register (SRDATAB)).
8 SPAR	SDR parity error SDR Parity error on a message from the master. This will also set the GETSTATUS Protocol Error sticky bit (which is cleared after a GETSTATUS read).
7-5 —	Reserved
4 INVSTART	Invalid start error Invalid start with SCL falling while SDA=1 is in a STOP condition.
3 TERM	Terminated error The master terminated a read from a slave when an END was not set (on the same or previous read).
2 URUNNACK	Underrun and Not Acknowledged (NACKed) error The internal to-bus buffer/FIFO was underrun in the read header and so the module NACKed the header.

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 URUN	Underrun error The internal to-bus buffer/FIFO was underrun during data read (the application did not provide the data fast enough). The END bit or register should be used if that was the last one.
0 ORUN	Overrun error The internal from-bus buffer/FIFO was overrun (too many characters are coming in and cannot be processed by the the user application fast enough).

49.7.10 Slave DMA Control Register (SDMACTRL)

Offset

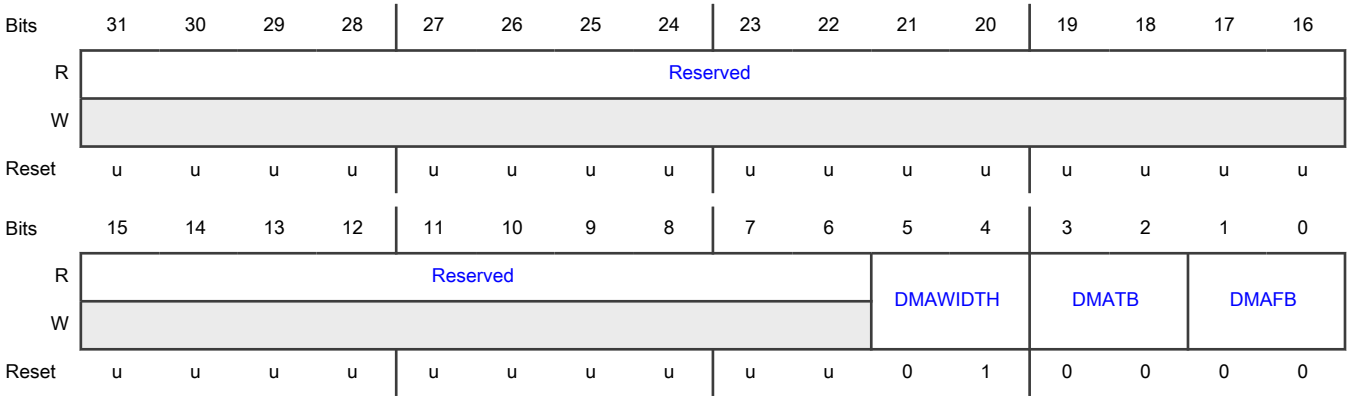
Register	Offset
SDMACTRL	20h

Function

The DMA Control register allows for DMA to be used for inbound messages and outbound messages. The DMA Control register is limited in value for Slave use, because the Slave has to be reactive to what happens. Two common use models:

- From-bus collection to avoid being overrun: The SCONFIG.MATCHSS bit is set, and then the processor enables the interrupts for START, and STOP, as well as enabling the DMA to collect the data. The START or STOP interrupt will only occur after a message is directed to the Slave (MATCHED bit set), and the DMA copied data can then be examined.
- To-bus for larger reads: Because I3C and I2C reads are preceded by a write that indicates what will be read (or in response to an IBI from the Slave), the DMA can be used to push through the data.
  - For I3C, the last value needs to be handled by the processor, unless the DMA moves wider words and is able to set the END bit (i.e., 16-bit values when in byte mode or 32-bit values when in half-word mode).
  - For I2C, the last value is determined by the Master, so the DMA may end early or may run out when the Master still wants more.

Diagram



Fields

Field	Function
31-6 —	Reserved
5-4 DMAWIDTH	Width of DMA operations The width of DMA operations, if configured to allow half-word data access. 00b - BYTE 01b - BYTE_AGAIN 10b - HALF_WORD: Half word (16 bits). This will make sure that 2 bytes are free/available in the FIFO. 11b - Reserved
3-2 DMATB	DMA Write (To-bus) trigger If enabled with 1 or 2, DMATB will start a request DMA on a TX trigger; see the Slave Data Control Register (SDATACTRL). DMATB will request until full unless the DMA is set up as a trigger. DMATB will cancel on MSTATUS.ERRWARN. 00b - NOT_USED. DMA is not used 01b - ENABLE_ONE_FRAME. DMA is enabled for 1 Frame (ended by DMA or terminated). DMATB auto-clears on a STOP or START (see the Match START or STOP bit (SCONFIG.MATCHSS). 10b - ENABLE. DMA is enabled until turned off. Normally, ENABLE should only be used with Master Message mode.
1-0 DMAFB	DMA Read (From-bus) trigger If enabled with 1 or 2, DMAFB will request DMA on RX trigger (see Slave Data Control Register (SDATACTRL)). It will request until empty unless the DMA is set up as a trigger. DMAFB will cancel on SSTATUS.ERRWARN. 00b - DMA not used 01b - DMA is enabled for 1 frame. Auto-clears on STOP or repeated START. See the Match START or STOP bit (SCONFIG.MATCHSS). 10b - DMA enable. DMA is enabled until it is turned off.

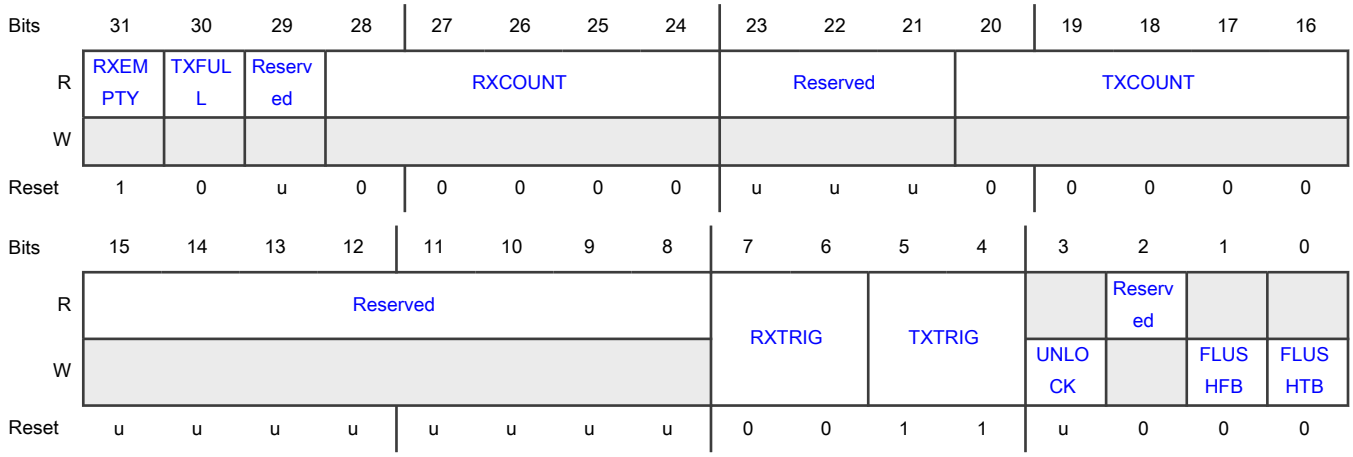
49.7.11 Slave Data Control Register (SDATACTRL)

Offset

Register	Offset
SDATACTRL	2Ch

Function
Controls data buffering and FIFO behavior.

Diagram



Fields

Field	Function
31 RXEMPTY	RX is empty 0b - RX is not empty 1b - RX is empty
30 TXFULL	TX is full 0b - TX is not full 1b - TX is full
29 —	Reserved

23-21 —	Reserved
20-16 TXCOUNT	Count of bytes in TX
15-8 —	Reserved
7-6 RXTRIG	Trigger level for RX FIFO fullness Affects interrupts and DMA (if enabled). 00b - Trigger on not empty

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01b - Trigger on ¼ or more full 10b - Trigger on ½ or more full 11b - Trigger on 3/4 or more full
5-4 TXTRIG	Trigger level for TX FIFO emptiness Affects interrupts and DMA (if enabled). The default is Trigger on 1 less than full or less (=3). 00b - Trigger on empty 01b - Trigger on ¼ full or less 10b - Trigger on ½ full or less 11b - Trigger on 1 less than full or less (Default)
3 UNLOCK	Unlock • If 0 is written to UNLOCK, then the RXTRIG and TXTRIG fields cannot be changed on a write. • If 1 is written to UNLOCK, then the RXTRIG and TXTRIG fields can be changed on a write.
2 —	Reserved
1 FLUSHFB	Flushes the from-bus buffer/FIFO Not normally used.
0 FLUSHTB	Flush the to-bus buffer/FIFO Used when the master terminates a to-bus (read) message prematurely.

49.7.12 Slave Write Data Byte Register (SWDATAB)

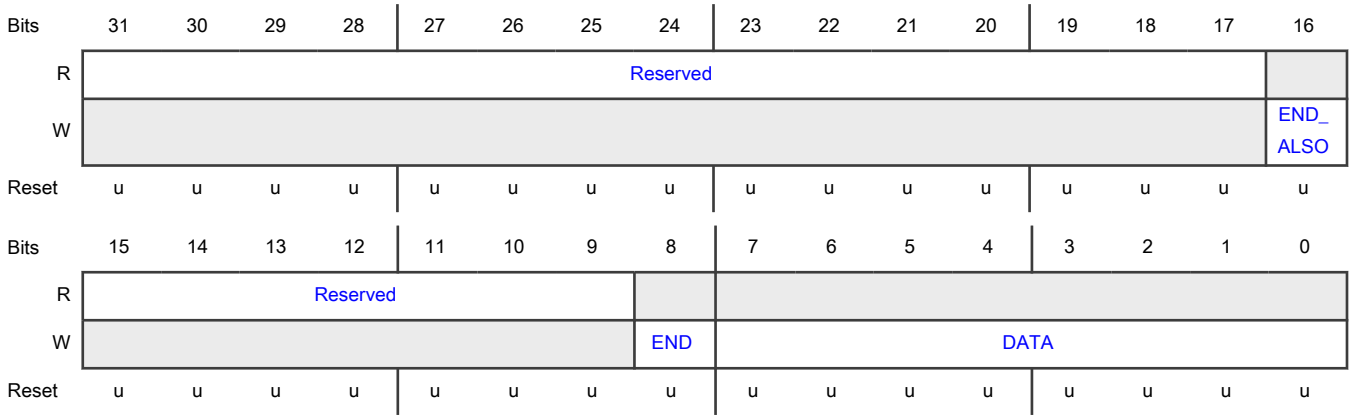
Offset

Register	Offset
SWDATAB	30h

Function

Write a byte of data, using the 9th bit to mark as the end (the last byte of the message). This register allows writing a byte to the bus (to Master) unless an external FIFO is used. This takes a byte and an end-of-data (last) marker bit. A byte should not be written unless there is room, as indicated by the TXNOTFULL bit being set in the SSTATUS register.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END_ALSO	End also • If END_ALSO=1, then this bit marks the last byte of the message • If END_ALSO=0, then there are more bytes in the message END_ALSO is required to be used in I3C, but is optional in I2C. For HDR-DDR (Double Data Rate), the byte with the END_ALSO must be an even byte (2nd, 4th, 6th, etc.) because DDR uses byte-pairs.
15-9 —	Reserved
8 END	End • If END=1, then this bit marks the last byte of the message • If END=0, then there are more bytes in the message END is required to be used in I3C, but is optional in I2C. For HDR-DDR (Double Data Rate), the byte with the END must be an even byte (2nd, 4th, 6th, etc.) because DDR uses byte-pairs.
7-0 DATA	The data byte to send to the master

49.7.13 Slave Write Data Byte End (SWDATABE)

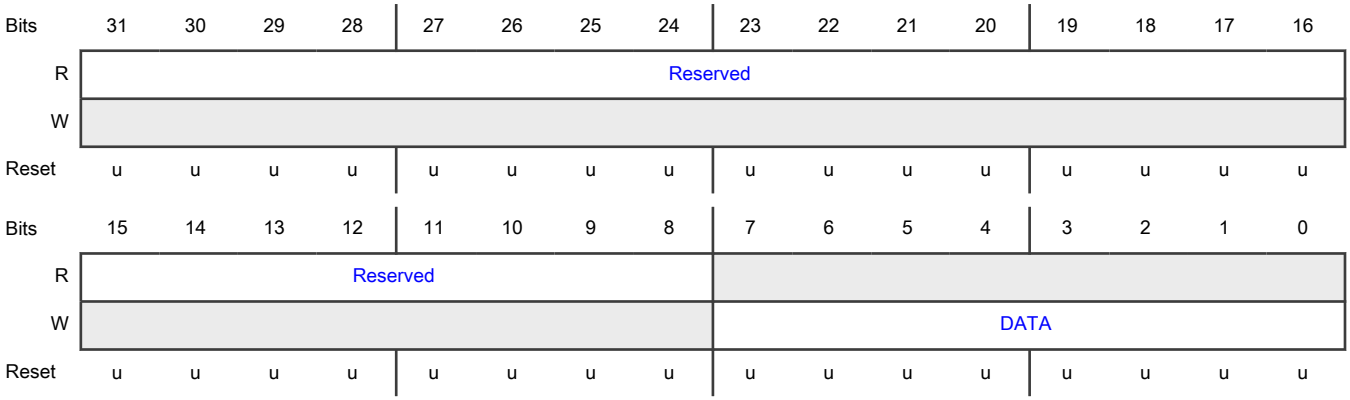
Offset

Register	Offset
SWDATABE	34h

Function

Write a byte of data, which is the end (the last byte of the message). Write a byte just like SWDATAB, but mark as end-of-data (last byte). For HDR-DDR, the byte with the END must be an even (2nd, 4th, 6th, etc) because DDR uses byte-pairs. A byte should not be written unless there is room, as indicated by the TXNOTFULL bit being set in the SSTATUS register.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 DATA	The data byte to send to the master

49.7.14 Slave Write Data Half-word Register (SWDATAH)

Offset

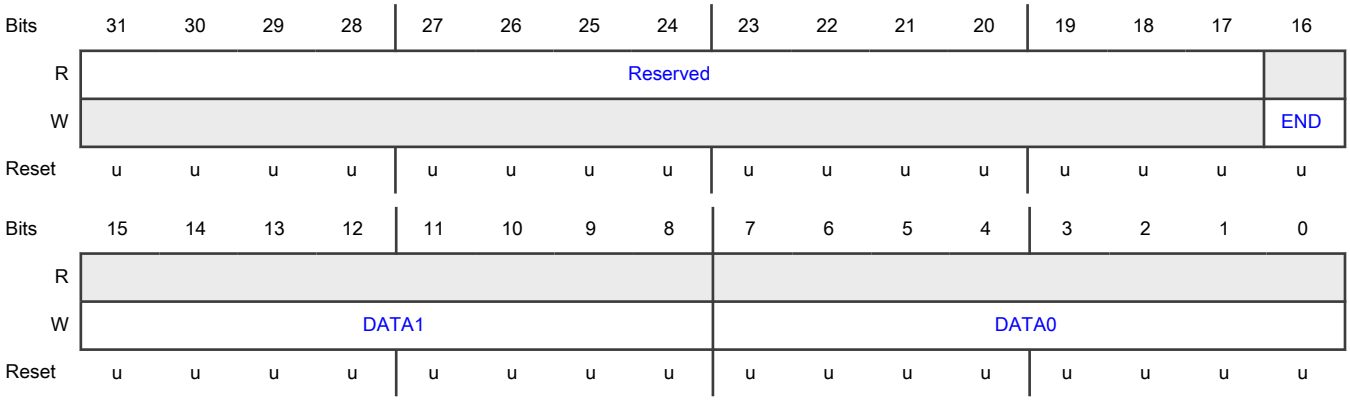
Register	Offset
SWDATAH	38h

Function

Write a half-word of data, using the 16th bit to mark as the end (the last byte of the half-word is the end). This register allows writing a half-word (pair of bytes) to the bus unless an external FIFO is used. This takes a half-word, which will send out the Low byte and then the High byte. An end-of-data (last) marker bit is allowed (or must be 0). A half-word should not be written

unless there is room for both, as indicated by use of TX FIFO level trigger or TXCOUNT available space in the SDATACTRL register.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END	End of message • If END=1, then END bit marks the last byte of the message • If END=0, then there are more bytes in the message For this register, this always marks DATA1 as the end. END is required to be used in I3C, but is optional in I2C. For HDR-DDR (Double Data Rate), the byte with the END must be an even byte (2nd, 4th, 6th, etc.) because DDR uses byte-pairs.
15-8 DATA1	The 2nd byte to send to the master
7-0 DATA0	The 1st byte to send to the master

49.7.15 Slave Write Data Half-word End Register (SWDATAHE)

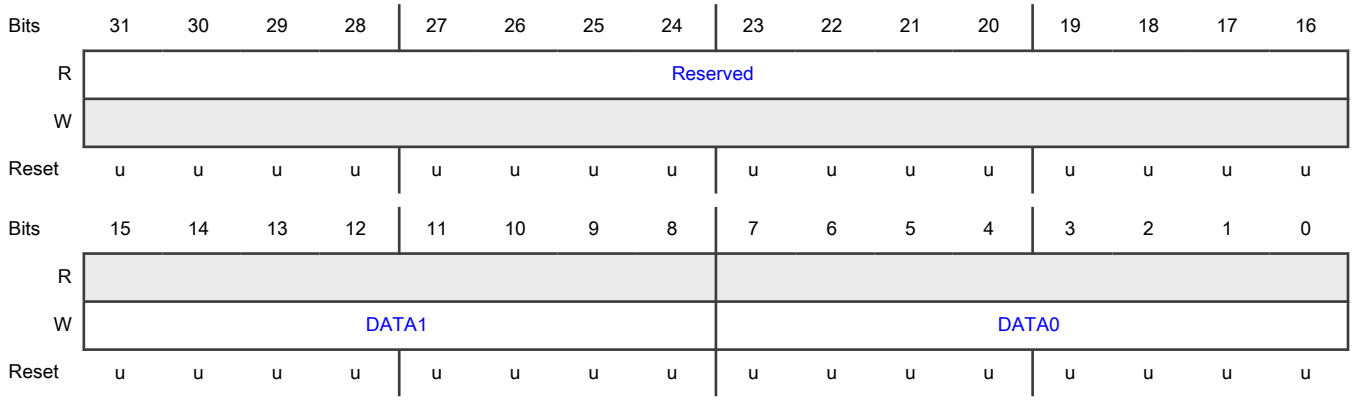
Offset

Register	Offset
SWDATAHE	3Ch

Function

Write a half-word of data, which is the end (the last byte of the half-word is the end). Write a half-word (byte pair) just like MWDATAH, but mark the 2nd bytes as end-of-data (last byte). For HDR-DDR, the byte with the END must be an even (2nd, 4th, 6th, etc) because DDR uses byte-pairs. A half-word should not be written unless there is room for both, as indicated by use of TX FIFO level trigger or TXCOUNT available space in the SDATACTRL register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 DATA1	The 2nd byte to send to the master
7-0 DATA0	The 1st byte to send to the master

49.7.16 Slave Read Data Byte Register (SRDATAB)

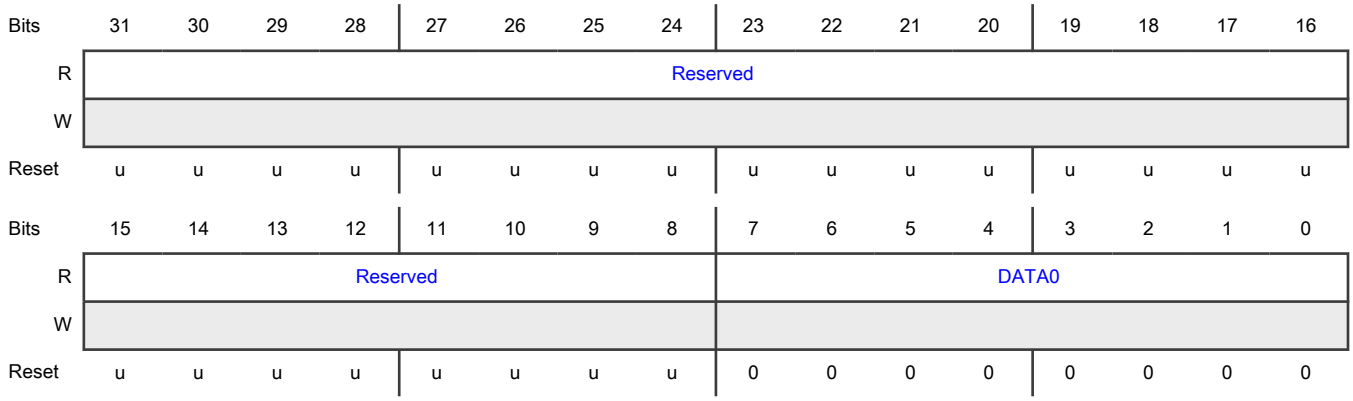
Offset

Register	Offset
SRDATAB	40h

Function

Read a byte of data. This register allows reading a byte from the bus (Master). A byte should not be read unless there is data waiting, as indicated by the RXPEND bit being set in the SSTATUS register.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 DATA0	Byte read from the master

49.7.17 Slave Read Data Half-word Register (SRDATAH)

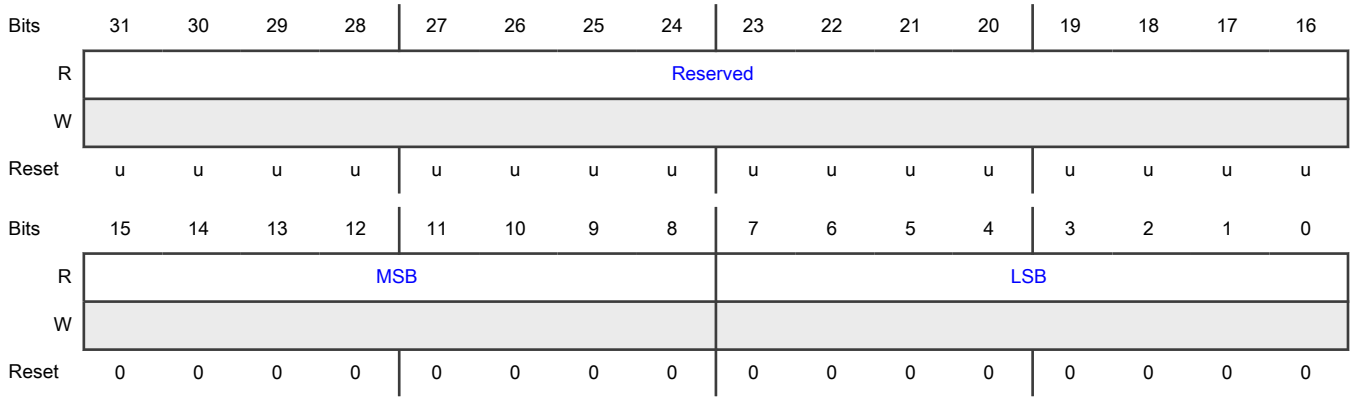
Offset

Register	Offset
SRDATAH	48h

Function

Read a half-word of data. This register allows reading a half-word (byte pair) written by the Slave on an SDR Read or DAA or DDR. This is only used when using MCTRL to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively. A half-word should not be read unless there is at least 2 bytes of data waiting, as indicated the RX FIFO level trigger or RXCOUNT available space in the SDATACTRL register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 MSB	The 2nd byte read from the slave
7-0 LSB	The 1st byte read from the slave

49.7.18 Slave Capabilities Register (SCAPABILITIES)

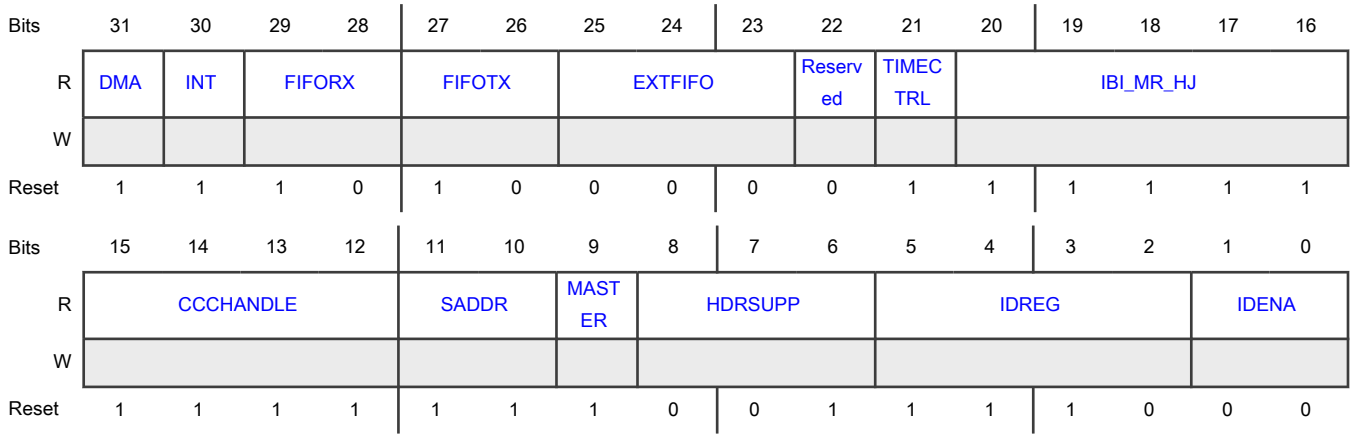
Offset

Register	Offset
SCAPABILITIES	60h

Function

Indicates which features are available and supported in this I3C module, including master and/or slave capabilities, HDR modes, and others.

Diagram



Fields

Field	Function
31 DMA	DMA 0b - DMA is not supported 1b - DMA is supported
30 INT	Interrupt 0b - Interrupts are not supported 1b - Interrupts are supported.
29-28 FIFORX	FIFO receive Indicates if RX (from-bus) is enabled and what size it is. 00b - FIFO_2BYTE. 2 (or 3)-byte RX FIFO, the default FIFO receive value (FIFORX) 01b - FIFO_4BYTE. 4-byte RX FIFO 10b - FIFO_8BYTE. 8-byte RX FIFO 11b - FIFO_16BYTE. 16-byte RX FIFO
27-26 FIFOTX	FIFO transmit Indicates if TX (to-bus) is enabled and what size it is. 00b - FIFO_2BYTE. 2-byte TX FIFO, the default FIFO transmit value (FIFOTX) 01b - FIFO_4BYTE. 4-byte TX FIFO 10b - FIFO_8BYTE. 8-byte TX FIFO 11b - FIFO_16BYTE. 16-byte TX FIFO
25-23 EXTFIFO	External FIFO Indicates whether External FIFOs are enabled. If External FIFOs are not enabled, then check FIFOTX and FIFORX for the internal FIFO.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	000b - NO_EXT_FIFO. No external FIFO is available 001b - STD_EXT_FIFO:. Standard available/free external FIFO 010b - REQUEST_EXT_FIFO. Request track external FIFO 011b - Reserved
22 —	Reserved
21 TIMECTRL	Time control Specifies if any time-control type is supported or not. 0b - NO_TIME_CONTROL_TYPE. No time control is enabled 1b - NO_TIME_CONTROL_TYPE. ATLEAST1_TIME_CONTROL: at least one time-control type is supported
20-16 IBI_MR_HJ	In-Band Interrupts, Master Requests, Hot Join events Indicates which events (In-Band Interrupts, Master Requests, Hot Join) are to be allowed. For example, if this field is set to 00011b, it means that IBI (bit 0) and IBI_HAS_DATA (bit 1) functionality are both enabled. • Bit 0: IBI: supports the application generating an In-Band Interrupt (IBI) • Bit 1: IBI_HAS_DATA: when bit 0=1, the In-Band Interrupt (IBI) has data from the SCTRL register • Bit 2: MASTER_REQUEST: supports the application generating a Master Request for a secondary master or a Peer-to-Peer • Bit 3: HOT_JOIN: supports the application generating Hot-Join • Bit 4: BAMATCH_FOR_BUS: use the BAMATCH register for bus-available timing
15-12 CCCHANDLE	Common Command Codes (CCC) handling Indicates who handles Common Command Codes (CCC) between I3C module and the user application. • Bit 0: BLOCK_HANDLE: the block (I3C module) handles events, activities, status, HDR, and if enabled for it, ID and static address related things • Bit 1: MAX_READ_WRITE: the block handles maximum read and write lengths, and max data speed • Bit 2: PENDINT_ACTSTATE: GETSTATUS CCC (command code) will return the SCTRL register's Pending interrupt (PENDINT) and activity state (ACTSTATE) fields • Bit 3: VENDINFO: GETSTATUS CCC will return the SCTRL register's VENDINFO (vendor info) bits
11-10 SADDR	Static address Indicates how the static address is handled. 00b - NO_STATIC. No static address 01b - STATIC. Static address is fixed in hardware

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - HW_CONTROL. Hardware controls the static address dynamically (for example, from the pin strap) 11b - CONFIG. SCONFIG register supplies the static address
9 MASTER	Master Specifies if a master capability is supported or not. 0b - MASTERNOTSUPPORTED. Master capability is not supported. 1b - MASTERSUPPORTED. Master capability is supported.
8-6 HDRSUPP	HDR support Indicates which High Data Rate (HDR) modes are supported. • Bit 0: DDR: Double Data Rate • Bit 1: TSP: Ternary Symbol for pure bus (no I2C devices) - NOT SUPPORTED • Bit 2: TSL: Ternary Symbol for legacy-inclusive-bus - NOT SUPPORTED
5-2 IDREG	ID register Bits indicate what is in the registers vs. what is in the hardware. • Bit 0: ID_INSTANCE: ID Instance is a register, and is used if there is no PARTNO register. • Bit 1: IDRAND: an ID Random field is available • Bit 2: DCR: a Device Characteristic Register (DCR) is available • Bit 3: BCR: a Bus Characteristics Register (BCR) is available
1-0 IDENA	ID 48b handler Indicates who handles the ID 48b value. 00b - APPLICATION. Application handles ID 48b 01b - HW. Hardware handles ID 48b 10b - HW_BUT. In hardware but the I3C module instance handles ID 48b. 11b - PARTNO. A part number register (PARTNO) handles ID 48b

49.7.19 Slave Dynamic Address Register (SDYNADDR)

Offset

Register	Offset
SDYNADDR	64h

Function

Contains the dynamic address after being assigned; otherwise =0.

The Slave Dynamic Address register is filled in with the assigned address once the Master has assigned it via SETDASA or ENTDAA CCC commands. It will clear if the RESETDAA CCC is used. The current validity state is also indicated via the SSTATUS.DAVALID bit, which can be used to interrupt the processor

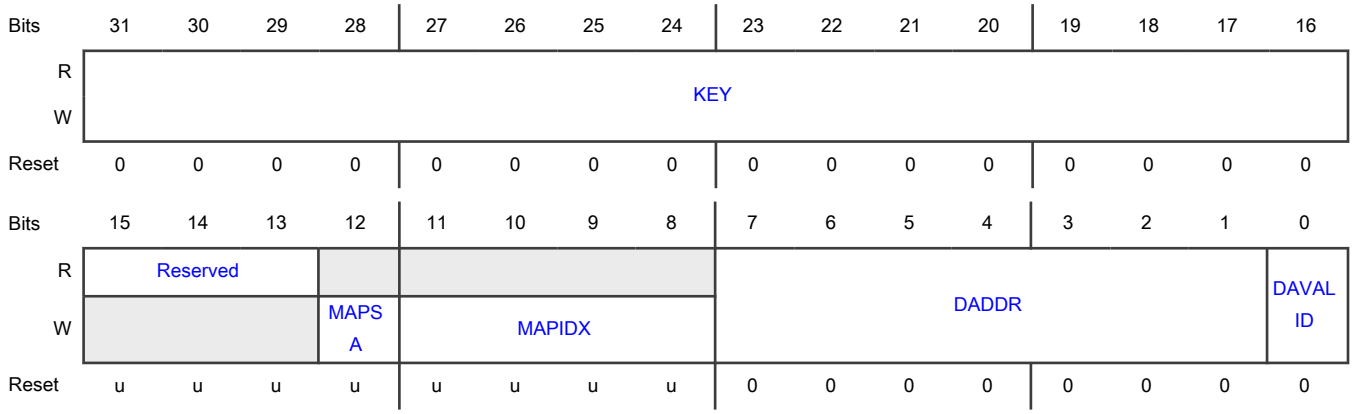
If configured to allow write, this is normally only used to restore the DA after a power-down (an ultra-low power state that loses power to peripherals but retains the DA somewhere else). This is not needed if state-retention flops are used for the DA. This mechanism only allows writes when Slave is disabled (and it will be ignored otherwise). If the Master uses RSTDAA or SETNEWDA, then it will over-ride this mechanism and cede (yield) to the master-assigned DA. Note that when when enabling the Slave, the SCONFIG.OFFLINE bit should also be set. This will wait for evidence that the bus is not in I3C HDR mode; and will exit when an HDR Exit pattern is seen or when 60 usec has expired. This makes it safe to monitor START and STOP. If the application needs to do an IBI, then the application should either wait for a STOP (see STATUS) or make sure that 200 usec have gone by with no activity (no START or STOP) before the app emits the IBI.

The MAPIDX/MAPSA model allows writing additional DAs (and SAs) into a list (the number in the list is pre-configured); any DA or SA with DAVALID=0 are never matched. The additional DAs may be based on the bridge target CCC, or done by a move (read current DA and then copy into upper map, then invalidate the 0 map) when matching ENTDAA over and over. Any mapped location can be invalidated by writing the MAPIDX and DAVALID=0. The mapped ones are not reset by the RSTDA CCC. See the SMSGMAPADDR register.

To copy the base DA to the mapped set, the configuration has to be set up to allow it, otherwise they are distinct mechanisms.

- If used for the copy model, then a special reset feature is allowed. In this case, the SDYNADDR register is written with KEY=CB19 and the rest 0. This will clear the DA and then self-clear.
- If used in I3C mode, a base DA is required, so the last one should not be cleared (or writing one with DAVALID=1 is necessary).

Diagram



Fields

Field	Function
31-16 KEY	Key Must set to 0xA4D9 to write DADDR field (and set DAVALID bit to 1). Only writable when a slave is not enabled (for restoring after power-down sleep with auto-restore). The mapped locations and base may be written when a slave is enabled, but care should be taken to not do that when there are transactions on the I3C bus. KEY reads back as 1 if overwritten, else KEY is 0 if assigned by the master, including when the master changes it. If address mapping is allowed, then writing with KEY=0xCB19 is used to clear the base DA.
15-13	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
12 MAPSA	Map a Static Address If MAPSA=1 on a write with MAPIDX!=0, then this sets a static address into the list;, otherwise a dynamic address is used.
11-8 MAPIDX	Mapped Dynamic Address Selects which mapped DA to write to, with MAPIDX=0 meaning the DA is not mapped (which is the normal use of write SDYNADDR if allowed). This allows for a list of matching DAs or SAs (I2C static addresses). Note that the mechanism is write-only.
7-1 DADDR	Dynamic address This is the assigned Dynamic Address, when DAVALID is 1.
0 DAVALID	DAVALID Determines if a Dynamic Address is assigned. 0b - DANOTASSIGNED. A Dynamic Address is not assigned 1b - DAASSIGNED. A Dynamic Address is assigned

49.7.20 Slave Maximum Limits Register (SMAXLIMITS)

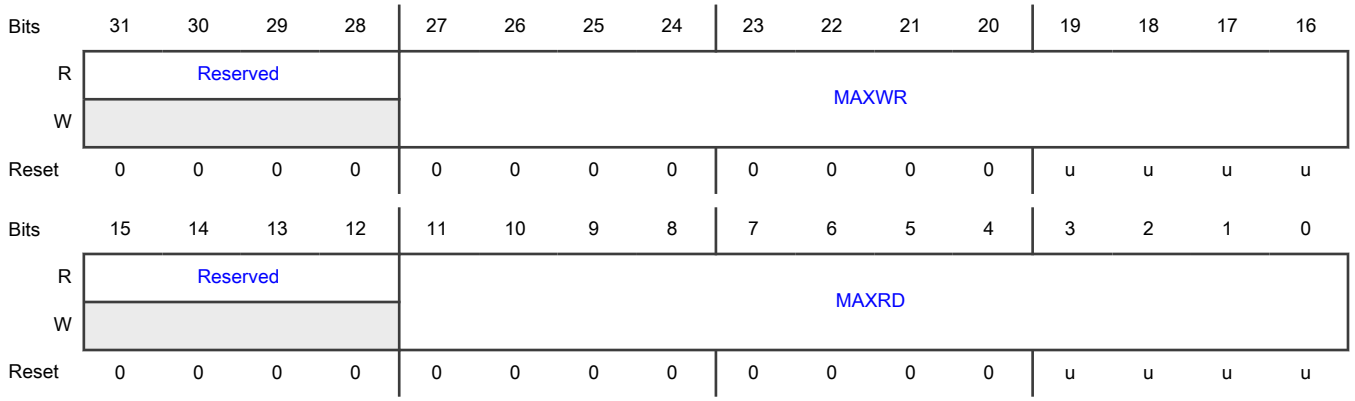
Offset

Register	Offset
SMAXLIMITS	68h

Function

Indicates the limits set by the master (or the original requested limits). The maximum limits may or may not be enabled in the hardware design, including maximum read and write lengths. If those maximum read/write lengths are enabled, then the current setting (including default request) shows up in this register (SMAXLIMITS).

Diagram



Fields

Field	Function
31-28 —	Reserved
27-16 MAXWR	Maximum write length The maximum write length must be between 8 to 4095 (saturation). The application should not set the maximum write length longer than what the master sets the maximum write length to; the application should set the maximum write length to be less than what the master sets the maximum write length to
15-12 —	Reserved
11-0 MAXRD	Maximum read length The maximum read length must be between 16 to 4095 (saturation). The application should not set the maximum read length longer than what the master sets the maximum read length to; the application should set the maximum read length to be less than what the master sets the maximum read length to.

49.7.21 Slave ID Part Number Register (SIDPARTNO)

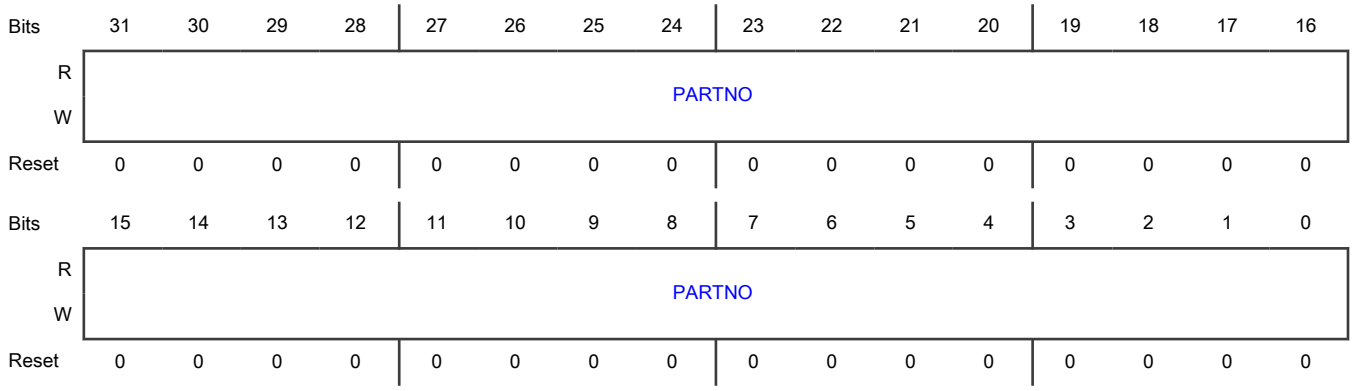
Offset

Register	Offset
SIDPARTNO	6Ch

Function

Allows an application to write the ID part-number. The application must write a value into the PARTNO field, because normally, 0 is not valid.

Diagram



Fields

Field	Function
31-0 PARTNO	Part number

49.7.22 Slave ID Extension Register (SIDEXT)

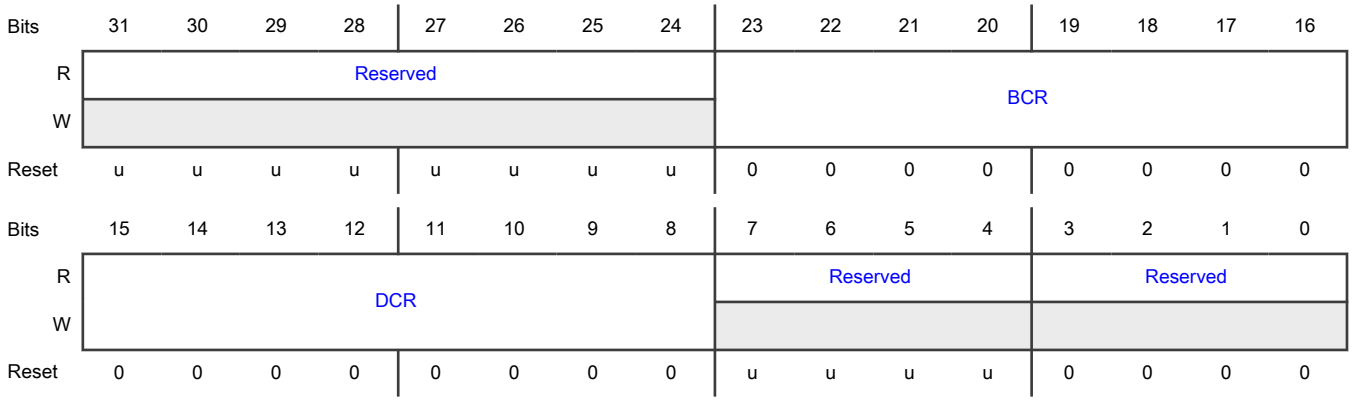
Offset

Register	Offset
SIDEXT	70h

Function

Allows an application to write the ID extension of the Device Characteristic Register (DCR) and/or the Bus Characteristics Register (BCR).

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 BCR	Bus Characteristics Register Set the Bus Characteristics Register (BCR) if configured for it. This controls features like Peer-to-Peer or Secondary Master, slow speed requirements, and others.
15-8 DCR	Device Characteristic Register Set the Device Characteristic Register (DCR) if configured for it.
7-4	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
3-0 —	Reserved

49.7.23 Slave Vendor ID Register (SVENDORID)

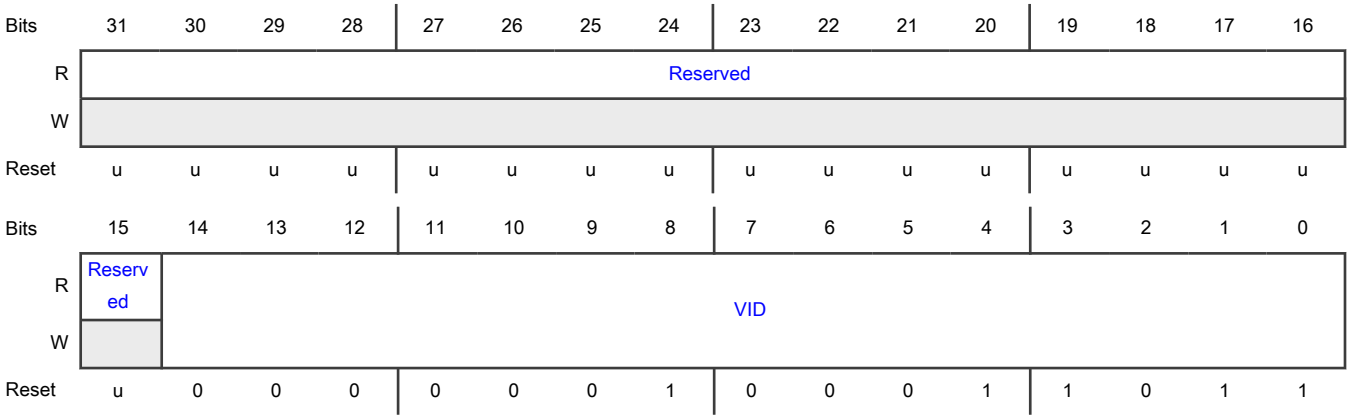
Offset

Register	Offset
SVENDORID	74h

Function

Allows an application to write the Vendor ID. The default will be set from the constant field and so usually will be the chip vendor. If using the chip vendor ID, the PARTNO must then not collide with other uses. The MIPI Vendor ID is available to all companies (MIPI membership is not required); to get a vendor ID, make a request at the mipi.org website.

Diagram



Fields

Field	Function
31-15 —	Reserved
14-0 VID	Vendor ID May be set to the 15-bit MIPI Vendor ID, if used.

49.7.24 Slave Time Control Clock Register (STCCLOCK)

Offset

Register	Offset
STCCLOCK	78h

Function

Allows an application to dynamically set the time control clock and accuracy information. The clock frequency and accuracy is normally a constant set by the hardware. But if the clock can be adjusted (i.e., divided) or if the accuracy could vary with knowable information, then the clock may be set via this register. This register should be updated whenever the clock source is changed.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-16 —	Reserved
15-8 FREQ	Clock frequency Clock frequency in 0.5-MHz steps. For example, 10 MHz is FREQ= 20. Default: set by parameters if configured.
7-0 ACCURACY	Clock accuracy Clock accuracy in 1/10ths of %. For example, 1.5% is 15. Default: set by parameters if configured.

49.7.25 Slave Message-Mapped Address Register (SMSGMAPADDR)

Offset

Register	Offset
SMSGMAPADDR	7Ch

Function

Allows an application to dynamically set the time control clock and accuracy information. When the SDYNADDR register is used to build a list of extra DAs or SAs to match, then the SMSGMAPADDR register enables the software to determine which address was matched when the SSTATUS.MATCHED bit is set. The SMSGMAPADDR register holds the last 3 matches (MAPLAST, MAPLASTM1, MAPLASTM2).

Fields

Field	Function
31-20 —	Reserved
19-16 MAPLASTM2	Previous match index 2 0 for the base address.
15-12 —	Reserved
11-8 MAPLASTM1	Previous match index 1 0 for the base address.
7-4 —	Reserved
3-0 MAPLAST	Matched address index Matched address index for current or last matched message. 0 for the base address. Only valid if mapped address list is enabled.

49.7.26 Master Main Control Register (MCTRL)

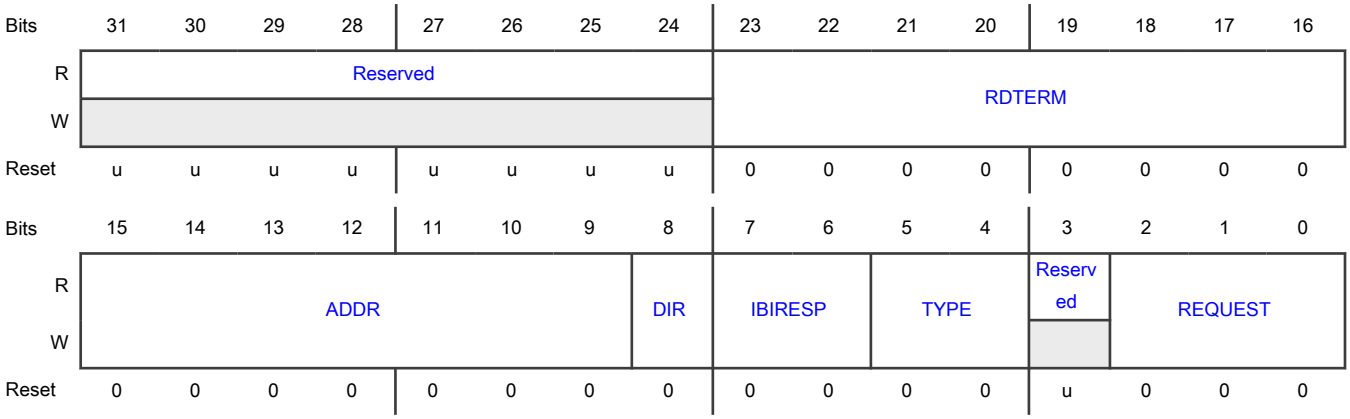
Offset

Register	Offset
MCTRL	84h

Function

Starts activities on the I3C or I2C bus.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 RDTERM	Read terminate The termination counter for reads. • For I2C, RDTERM controls when to NACK the read. • For I3C, RDTERM can be use to terminate (end) a read that is too long. — RDTERM=0 has no effect — RDTERM=1 will terminate after the next character — RDTERM=2 will terminate after the next 2 characters Supports up to 255 characters. If in Double Data Rate (DDR) mode, then RDTERM will terminate the read, based on word counts (for DDR) vs. byte counts (for SDR).
15-9 ADDR	ADDR Address with START for I3C or I2C
8	DIR

Table continues on the next page...

Table continued from the previous page...

Field	Function
DIR	0b - DIRWRITE: Write 1b - DIRREAD: Read
7-6 IBIRESP	In-Band Interrupt (IBI) response The response to use when you get an In-Band Interrupt (IBI) from START, and to force using a IbiAckNack request when completing a manual In-Band Interrupt. Completion of a manual In-Band Interrupt means that the slave Dynamic Address (DA) is known, and so the mandatory byte (or not) is specified by the application when ACKing. MIBIRESP register is also used when a message is emitted in Message Mode using the MWMSG_SDR or MWMSG_DDR registers. 00b - ACK. Acknowledge. A mandatory byte (or not) is decided by the Master In-band Interrupt Registry and Rules Register (MIBIRULES). To limit the maximum number of IBI bytes, configure the Read Termination field (MCTRL.RDTERM). 01b - NACK. Not acknowledge 10b - ACK_WITH_MANDATORY. Acknowledge with mandatory byte (ignores the MIBIRULES register). Acknowledge with mandatory byte should not be used, unless only slaves *with a mandatory byte* can cause an In-Band Interrupt. 11b - MANUAL. Stop and wait for a decision using the IBIAckNack request
5-4 TYPE	Bus type with START 00b - I3C. Normally the SDR mode of I3C. For ForceExit, the Exit pattern. 01b - I2C. Normally the Standard I2C protocol. 10b - DDR. (Double Data Rate): Normally the HDR-DDR mode of I3C. Enter DDR mode (7E and then ENTHDR0), if the module is not already in DDR mode. The 1st byte written to the TX FIFO should be a command, and should already be in the FIFO. To end DDR mode, use ForceExit. For ForceExit, the normal IBHR (In-Band Hardware Reset). 11b - For ForcedExit, this is forced IBHR.
3 —	Reserved
2-0 REQUEST	Request Emits the requested operation when doing in pieces vs. doing by message. The MSTATUS register should be checked because the state of the Master must be such that the request makes sense; for example, the system cannot do SDR from DDR (but can do DDR from SDR since it enters), cannot use an incorrect request if in DAA mode, and other similar situations. 000b - NONE. Returns to this when finished with any request. The MSTATUS register indicates the master's state. See also AutoIBI mode. NONE is only written as 0: when setting RDTERM to 1 (to stop a read in progress) or when setting IBI reponse field (IBIRESP) for MSG use. 001b - EMITSTARTADDR. Emit START with address and direction from a stopped state or in the middle of a Single Data Rate (SDR) message. If from a stopped state (IDLE), then emit start may

Table continues on the next page...

Table continued from the previous page...

Field	Function
	be prevented by an event (like IBI, MR, HJ), in which case the appropriate interrupt is signaled; note that Emit START can be resubmitted. 010b - EMITSTOP. Emit a STOP on bus. Must be in Single Data Rate (SDR) mode. If in Dynamic Address Assignment (DAA) mode, Emit stop will exit DAA mode. 011b - IBIACKNACK. Manual In-Band Interrupt (IBI) Acknowledge (ACK) or Not Acknowledge (NACK). When IBIRESP has indicated a hold on an In-Band Interrupt to allow a manual decision, this request completes it. Uses IBIRESP to provide the information. 100b - PROCESSDAA. If not in Dynamic Address Assignment (DAA) mode now, will issue START, 7E, ENTDAA, and then will emit 7E/R to process first Slave. Will stop just before the new Dynamic Address (DA) is to be emitted. The DA is written using MWDATAB bits 6:0 and then ProcessDAA is requested again to write the new address, and then starts the next; an MSTATUS indicating NACK means DA was not accepted (e.g. parity error). If Process DAA is NACKed on the 7E/R, the interrupt will indicate so and this will emit a STOP. 101b - Reserved 110b - FORCEEXIT and IBHR. Emit an Exit Pattern from any state, but end Double Data Rate (DDR) (including MSGDDR), if in DDR mode now. Includes a STOP afterward. If TYPE != 0, then it will perform an IBHR (In-Band Hardware Reset). If TYPE=2, then it does a normal reset (DEFRST can prevent the reset). If TYPE=3, it does a forced reset (will always reset). 111b - AUTOIBI. Hold in a stopped state, but auto-emit START,7E when the slave is holding down SDA to get an In-Band Interrupt (IBI). Actual In-Band Interrupt handling is defined by IBIRESP.

49.7.27 Master Status Register (MSTATUS)

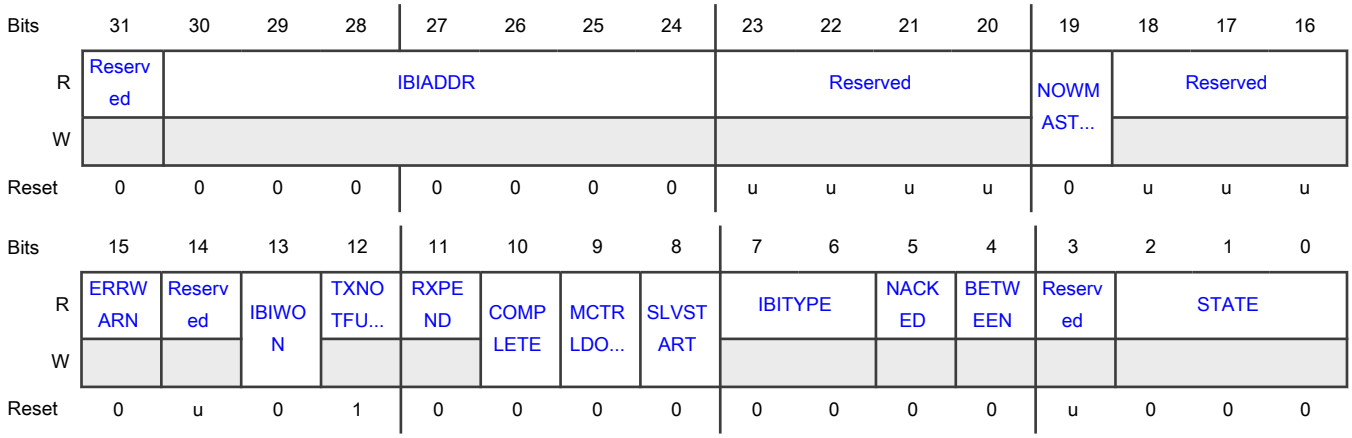
Offset

Register	Offset
MSTATUS	88h

Function

Status for the master, including which events caused the interrupts. The peripherals share the IRQ (called Parallel-to-Slave status). Because a peripheral can only be in a Master or Slave mode, but not be in both modes at the same time, then only one (Slave or Master peripheral) can be the cause of the IRQ. So, if there is an IRQ and the peripheral is a Master, then this register (MSTATUS) has the status. If there is an IRQ and the peripheral is a Slave, then the SSTATUS register has the status.

Diagram



Fields

Field	Function
31 —	Reserved
30-24 IBIADDR	IBI address The address of the In-Band Interrupt (while IBITYPE=1) or the Master Request (MR)(while IBITYPE=2) or is 7'h2 if Hot-Join (while IBITYPE=3).
23-20 —	Reserved
19 NOWMASTER	Now master (now this module is a master) NOWMASTER=1 if the module is now a master (it was previously a slave, acceptance was requested from the previous master and it was accepted). Note that the reverse operation (master becomes a slave) does not need an interrupt, because the application is granting it via the Common-Command-Code status bit MSTATUS.CCC.
18-16 —	Reserved
15 ERRWARN	Error or warning ERRWARN=1, if an error occurred (like improper register use, overrun or underrun of FIFO/buffer, invalid parity or CRC in DDR read, and others). See the Master Errors and Warnings Register (MERRWARN).
14 —	Reserved
13 IBIWON	In-Band Interrupt (IBI) won IBIWON is set to 1 if IBI or MR or HJ won the arbitration on a header address, regardless of whether it was NACKed or ACKed.

Table continues on the next page...

Table continued from the previous page...

Field	Function
12 TXNOTFULL	TX buffer/FIFO not yet full TXNOTFULL=1 if TX buffer/FIFO or message register can accept another byte or half-word.
11 RXPEND	RXPEND The receiving message from a slave and byte(s) are in the input buffer/FIFO. • If using a FIFO, this is one FIFO trigger's worth. • If DMA is enabled for RX, then DMA will be signaled. RXPEND will self-clear when the data is read.
10 COMPLETE	COMPLETE A message has completed: • With MWMSG_SDR or MWMSG_DDR, this is count to 0. • With MCTRL using EmitStartAddr, this is the end of write or read by terminate or end. • With IBI (AutoIBI or EmitStartAddr), this is the end of IBI data (if any).
9 MCTRLDONE	Master control done After the module completes an MCTRL request, MCTRLDONE is set to 1 . MCTRLDONE self-clears when writing a new control; otherwise write to MCTRLDONE to clear it (MCTRLDONE). • When MCTRL.REQUEST=EmitStartAddr, MCTRLDONE fires (sets to 1) when the address went out (and was ACKed or NACKed or ended in an IBI). However if ACKed, it will then fire COMPLETE when the write or read data has completed (finished). • When MCTRL.REQUEST=ProcessDAA, this fires when the module is ready to emit the Dynamic Address (DA) for the slave, or when no more slaves are ACKing. This can be determined using the MSTATUS.BETWEEN and MSTATUS.STATE fields.
8 SLVSTART	Slave start If a slave is/was requesting a START by holding SDA low, SLVSTART is set to 1. Handling will start automatically if MCTRL.REQUEST=AutoIBI.
7-6 IBITYPE	In-Band Interrupt (IBI) type Indicates the type of In-Band Interrupt (IBI) of the last event that won the arbitration (whether the interrupt is ACKed or NACKed or pending) 00b - NONE. cleared when IBI Won bit (MSTATUS.IBIWON) is cleared 01b - IBI. In-Band Interrupt 10b - MR. Master Request 11b - HJ. Hot-Join
5 NACKED	Not acknowledged If NACKED=1, then the last Start and Address was NACKed (was not ACKed by the addressed slave).
4	Between

Table continues on the next page...

Table continued from the previous page...

Field	Function
BETWEEN	Between messages or Dynamic Address Assignments (DAA) Active if: • STATE is MSGSDR, DDR, or DAA, the state is between messages/DAAs and so is expecting a new messages/DAAs to start (or STOP or Exit). • STATE is NORMACT, the module is stuck waiting on the TX FIFO to be not-empty or the RX FIFO to be not full. 0b - Inactive. For other cases. 1b - Active. If STATE is MSGSDR, DDR, or DAA; or if STATE is NORMACT.
3 ——	Reserved
2-0 STATE	State of the master Indicates the current master state 000b - IDLE. The bus has STOPped. 001b - SLVREQ. (Slave Request state) The bus has STOPped but a slave is holding SDA low. If using auto-emit IBI (MCTRL.AutoIBI), then the master will not stay in the Slave Request state. 010b - MSGSDR. In Single Data Rate (SDR) Message state (from using MWMSG_SDR) 011b - NORMACT. Normal active Single Data Rate (SDR) state (from using MCTRL and MWDATAn and MRDATAn registers). The master will stay in the NORMACT state until a STOP is issued. 100b - MSGDDR. In Double Data Rate (DDR) Message mode (from using MWMSG_DDR or using the normal method with DDR). The master will stay in the DDR state, until the master exits using EXIT (emits the Exit pattern). 101b - DAA. In Enter Dynamic Address Assignment (ENTDAA) mode 110b - IBIACK. Waiting for an In-Band Interrupt (IBI) ACK/NACK decision 111b - IBIRCV. Receiving an In-Band Interrupt (IBI); this IBIRCV state is used after IBI/MR/HJ has won the arbitration, and IBIRCV state is also used for IBI mandatory byte (if any) and any bytes that follow.

49.7.28 Master In-band Interrupt Registry and Rules Register (MIBIRULES)

Offset

Register	Offset
MIBIRULES	8Ch

Function

Contains the rules for using In-band Interrupts, and keeps a registry of the slaves who use the IBI byte.

Concerning ADDRn fields: The address is 6 bits, and assuming that IBIRULES.MSB0=1, then each address has its most significant bit = 0. This means is that each address is 7 bits (usually written as A7 to A1), and the A7 must be 0. If the application does not use that optimal convention, then the Manual method of IBI ACK handling must be used (see MCTRL).

- The default is that the ADDRn values indicate the slaves with a mandatory byte.
- If MIBIRULES.NOBYTE is set, then the ADDRn values indicate slaves that do not have a mandatory IBI byte.

NOTE

A7=0 is only needed for Slaves that use IBI. For legacy I2C devices, A7 can use any valid value, because I2C devices cannot cause an IBI.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	NOBYTE	MSB0	ADDR4						ADDR3				ADDR2			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR2				ADDR1				ADDR0							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 NOBYTE	No IBI byte • If NOBYTE=1, then the ADDRx fields refer to slaves without a mandatory IBI byte. • If NOBYTE=0, then the ADDRx fields refer to slaves with a mandatory IBI byte.
30 MSB0	Set Most Significant address Bit to 0 If MSB0=1, then all I3C dynamic addresses will be assigned with the MSb==0 (most significant bit); this allows the START header to be optimized.
29-24 ADDR4	ADDR4 Address of slave with or without Mandatory IBI byte. See ADDR0 field description for more details.
23-18 ADDR3	ADDR3 Address of slave with or without Mandatory IBI byte. See ADDR0 field description for more details.
17-12 ADDR2	ADDR2 Address of slave with or without Mandatory IBI byte. See ADDR0 field description for more details.
11-6 ADDR1	ADDR1 Address of slave with or without Mandatory IBI byte. See ADDR0 field description for more details.

Table continues on the next page...

Table continued from the previous page...

Field	Function
5-0 ADDR0	ADDR0 Address of slave with or without Mandatory IBI byte. If 0, then the address does not apply.

49.7.29 Master Interrupt Set Register (MINTSET)

Offset

Register	Offset
MINTSET	90h

Function

Set interrupt enables for select bits in MSTATUS. Reading the MINTSET register returns the status of the interrupt enables.

- To activate an interrupt enable, write 1 to it.
- To disable an interrupt enable, write 1 to the appropriate bit in the Interrupt Clear Register (MINTCLR). Writing 0 to the interrupt enable in this register (MINTSET) does not disable the interrupt.

The Interrupt registers allow masking interrupt sources, as well as checking which interrupts have activated in the MSTATUS register. The normal method is to enable an interrupt and then once that interrupt fires, the interrupt is either cleared (by writing the MSTATUS register) or cleared by action (on the corresponding data register). The interrupt is level held, meaning that the interrupt stays set until the cause is cleared, by some method. The module prevents races, so that if a new event comes in, that new event will not be lost.

These interrupts are parallel to the Slave INTSET/INTCLR set, and only one interrupt set is active depending on state (Master or Slave operation).

- MINTSET: sets interrupt enables for MSTATUS bits. Reading MINTSET register returns the status of the interrupt enables.
- MINTCLR: clears interrupt enables for MSTATUS bits.
- MINTMASKED: returns the value of the MSTATUS bits ANDed with their interrupt enables.

49.7.32 Master Errors and Warnings Register (MERRWARN)

Offset

Register	Offset
MERRWARN	9Ch

Function

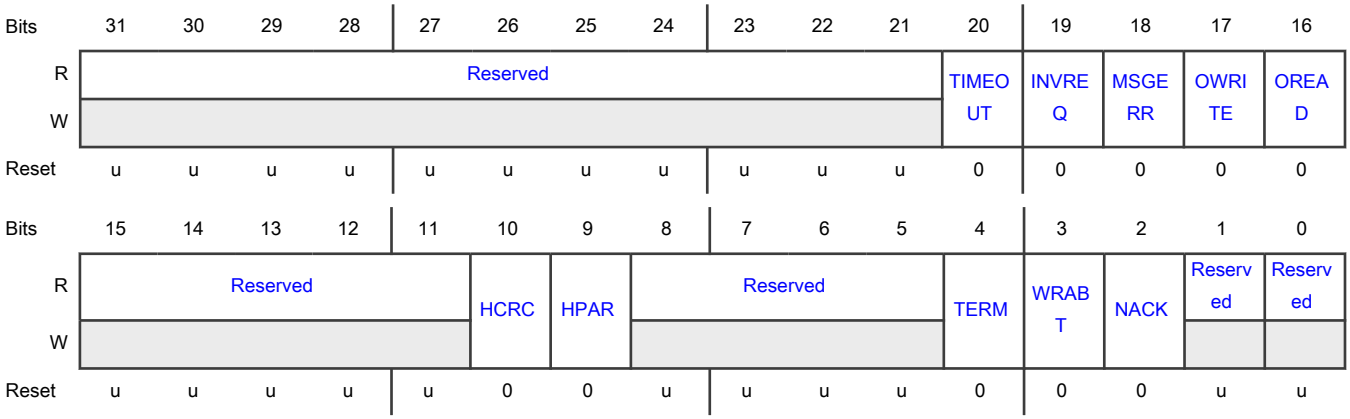
Contains errors and warnings from I3C/I2C protocol. When any errors or warnings are not 0, then the MSTATUS.ERRWARN bit will be set.

Parallel-to-slave ERRWARN:

- In Master mode, use this register (MERRWARN).
- In Slave mode, use the slave register SERRWARN.

The error bits in both registers (MERRWARN and SERRWARN) are similar in meaning.

Diagram



Fields

Field	Function
31-21 —	Reserved
20 TIMEOUT	TIMEOUT error The module has stalled too long in a frame. This happens: • When the TX FIFO or RX FIFO is not handled and the bus is stuck in the middle of a message, • When no STOP was issued and between messages, • When IBI manual is used and no decision was made. The maximum stall period is 10 KHz or 100 us.
19 INVREQ	Invalid request error Invalid use of a request: • Not using IBIAckNack when stopped in manual hold for IBI acknowledge. • Using other than ForceStop or ForceExit while in a message. Others are OK when the message is done. • Other mismatched uses (for example, IBIAckNack when in normal states).
18 MSGERR	Message error • Trying to write to or read from MWMSG_SDR register when in a DDR message (double data rate). • Trying to write to or read from MWMSG_DDR register when in a SDR message (single data rate). • Trying to read from HRMSG_SDR or HRMSG_DDR registers when no message has yet started.

Table continues on the next page...

Table continued from the previous page...

Field	Function
17 OWRITE	Over-write error Trying to write to the Master Write Data Byte Register (MWDATAB) when the FIFO is full.
16 OREAD	Over-read error Trying to read from the Master Read Data Byte Register (MRDATAB) when the FIFO is empty.
15-11 —	Reserved
10 HCRC	High data rate CRC error A Cyclic Redundancy Check (CRC) error occurred from a Double Data Rate (DDR) read.
9 HPAR	High data rate parity • Parity error from a Double Data Rate (DDR) read; this includes a bad preamble on a read. • Does not stop the read, because it is not safe to terminate (because the read data may get mis-framed). • Will end on a run of 1 second.
8-5 —	Reserved
4 TERM	Terminate error • This master terminated a slave read because athe read exceeded the count for the message; only valid when using the MWMSG_SDR or MWMSG_DDR register. • TERM self-clears if the MWMSG_SDR or MWMSG_DDR register is written.
3 WRABT	WRABT (Write abort) error • The I2C slave NACKed the write data, terminating the message. • WRABT self-clears if the MCTRL register is written. For example, the Master is writing in I2C and the Slave NACKed the write.
2 NACK	Not acknowledge (NACK) error • The slave or slaves NACKed (not acknowledged) the last address. • If 7E was the address, then all slaves NACKed the last address. • NACK self-clears if the MCTRL register is written.
1 —	Reserved
0 —	Reserved

49.7.33 Master DMA Control Register (MDMACTRL)

Offset

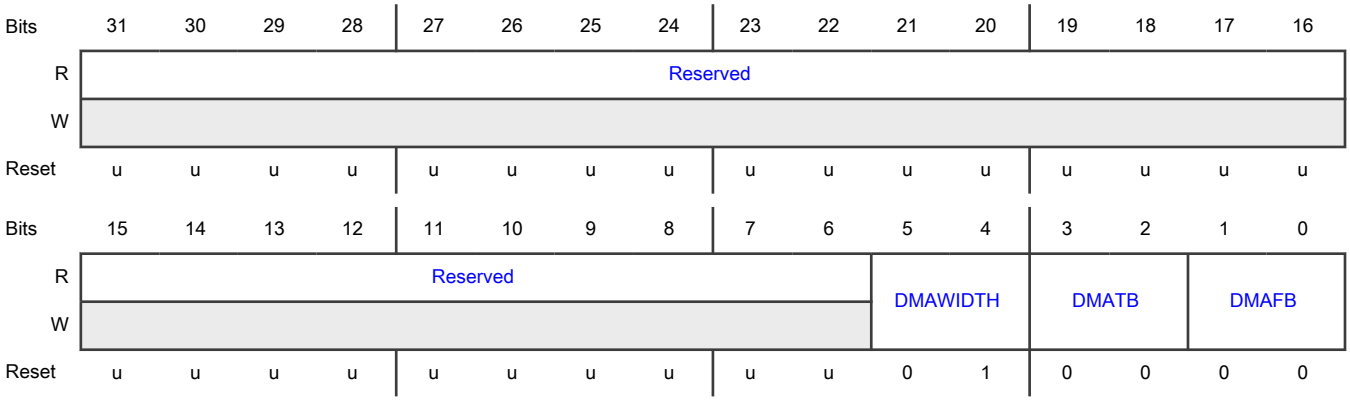
Register	Offset
MDMACTRL	A0h

Function

The DMA Control register allows for DMA to be used for inbound and outbound messages. DMA is much more useful for a Master than for a Slave, because the Master is directing the bus traffic and actions, so setting up DMA is more natural for a Master. DMA can be used with a Master in one of two ways:

- Push or Pull data to go with an MCTRL.REQUEST=EMITSTARTADDR request written by the processor.
- Implementing a message mode, to be completely DMA-controlled.

Diagram



Fields

Field	Function
31-6 —	Reserved
5-4 DMAWIDTH	DMA width Specifies the data width of DMA operations. 00b - BYTE 01b - BYTE_AGAIN 10b - HALF_WORD. Half-word (16 bits). This will make sure that 2 bytes are free/available in FIFO. 11b - Reserved
3-2 DMATB	DMA to bus

Table continues on the next page...

Table continued from the previous page...

Field	Function
	DMA Write (to-bus) trigger. If enabled with DMATB=1 or 2, then the I3C module will start request DMA on TX trigger. See the Master Data Control Register (MDATACTRL). The I3C module will request until full, unless DMA is set up as a trigger. DMAFB will cancel on MSTATUS.ERRWARN. 00b - NOT_USED. DMA is not used 01b - ENABLE_ONE_FRAME. DMA is enabled for 1 frame (ended by DMA or Terminated). DMATB auto-clears on STOP or START. See MCONFIG.MATCHSS. 10b - ENABLE. DMA is enabled until DMA is turned off. Normally DMA ENABLE should only be used in Master Message mode.
1-0 DMAFB	DMA from bus DMA Read (from-bus) trigger. If enabled with DMAFB=1 or 2, then the I3C module will request DMA on a RX trigger (see MDATACTL register). The I3C module will request until empty, unless the DMA is set up as a trigger. DMAFB will cancel on MSTATUS.ERRWARN. 00b - NOT_USED. DMA is not used 01b - ENABLE_ONE_FRAME. DMA is enabled for 1 frame. DMAFB auto-clears on STOP or repeated START. See MCONFIG.MATCHSS. 10b - ENABLE. DMA is enabled until the DMA is turned off.

49.7.34 Master Data Control Register (MDATACTRL)

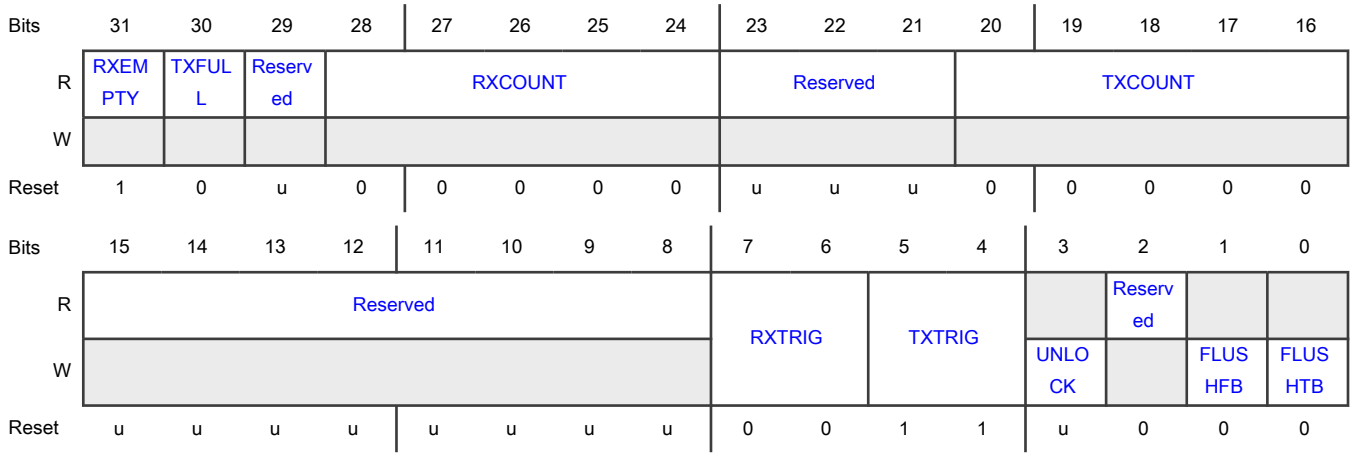
Offset

Register	Offset
MDATACTRL	ACh

Function

Controls data buffering and indicates the current buffer state. The MDATACTRL register is the alias of slave DATACTRL register (SDATACTRL). The MDATACTRL register is also the FIFO control.

Diagram



Fields

Field	Function
31 RXEMPTY	RX is empty • RXEMPTY=1 if RX is empty • RXEMPTY=0 if RX is not yet empty
30 TXFULL	TX is full • TXFULL=1 if TX is full • TXFULL=0 if TX is not yet full
29 —	Reserved
28-24 RXCOUNT	RX byte count The count of bytes in RX
23-21 —	Reserved
20-16 TXCOUNT	TX byte count The count of bytes waiting in the TXFIFO. This is how many bytes the application has written to the TXFIFO, that have not yet gone onto the I3C bus.
15-8 —	Reserved
7-6 RXTRIG	RX trigger level Trigger level for RX fullness when using a FIFO. Affects interrupts and DMA (if enabled). The default is off, and it triggers on any byte in the RXFIFO (meaning that the RXFIFO is not empty).

Table continues on the next page...

Table continued from the previous page...

Field	Function
5-4 TXTRIG	TX trigger level Trigger level for TX emptiness when using a FIFO. Affects interrupts and DMA (if enabled). The default is 3.
3 UNLOCK	Unlock • If 0 is written to UNLOCK, then the RXTRIG and TXTRIG fields cannot be changed on a write. • If 1 is written to UNLOCK, then the RXTRIG and TXTRIG fields can be changed on a write.
2 —	Reserved
1 FLUSHFB	Flush from-bus buffer/FIFO Flushes the from-bus buffer/FIFO. FLUSHFB is not normally used.
0 FLUSHTB	Flush to-bus buffer/FIFO Flush the to-bus buffer/FIFO. Used when the master terminates a to-bus message (read) prematurely.

49.7.35 Master Write Data Byte Register (MWDATAB)

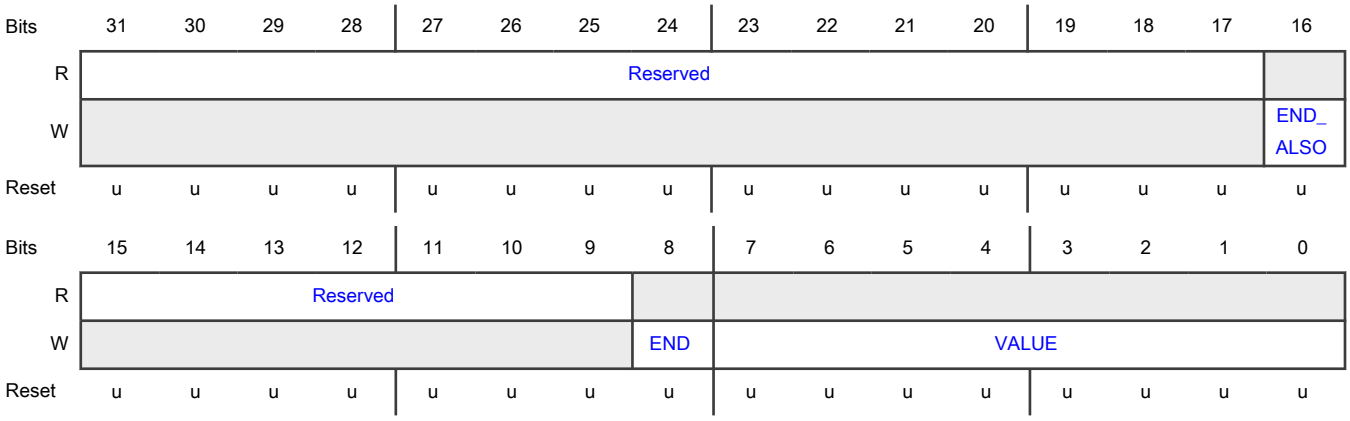
Offset

Register	Offset
MWDATAB	B0h

Function

Write a byte of data, possibly the last byte. The MWDATAB register is the alias of the WDATAB register. The MWDATAB register allows writing bytes to send onto the bus. This is only used when using MCTRL to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END_ALSO	End of message also End outbound message normally. Any message has to end, this just indicates that it is the last message to go out. This method can be used, and also the MDATABE register. • If END_ALSO=1, this marks the last byte of the message. • If END_ALSO=0, it is assumed there are more bytes. This is required to be used in I3C and is optional in I2C. For HDR-DDR (High Data Rate, Double Data Rate), the byte with the END_ALSO must be an even byte (2nd, 4th, 6th, etc) because DDR uses byte-pairs.
15-9 —	Reserved
8 END	End of message • If END=1, then the END bit marks the last byte of the message. • If END=0, then it is assumed there are more bytes. This is required to be used in I3C and is optional in I2C. For HDR-DDR (High Data Rate, Double Data Rate), the byte with the END must be an even byte (2nd, 4th, 6th, etc) because DDR uses byte-pairs.
7-0 VALUE	Data byte The byte to send to (write to) the master. • If I3C, the block will compute the parity. • If I2C, the block will handle the ACK/NACK.

49.7.36 Master Write Data Byte End Register (MWDATABE)

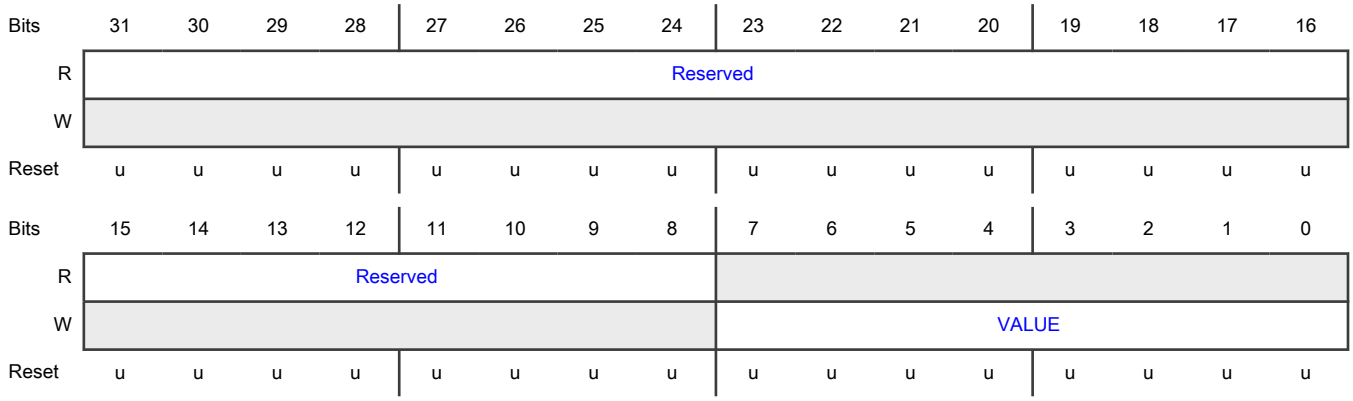
Offset

Register	Offset
MWDATABE	B4h

Function

The MWDATABE register is the alias of the Slave WDATABE register (SWDATABE). The MWDATABE register allows writing the last byte to send onto the bus. This is only used when using MCTRL to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively. Note that MWDATAB can also indicate END using bit 8.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 VALUE	Data The last byte to send to (write to) the master. • If I3C, the block will compute the parity. • If I2C, the block will handle the ACK/NACK.

49.7.37 Master Write Data Half-word Register (MWDATAH)

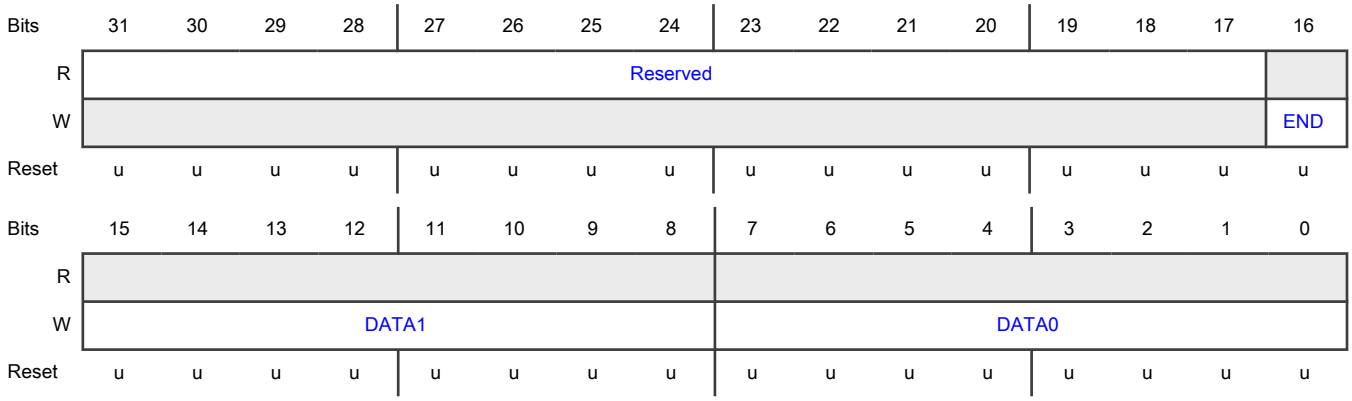
Offset

Register	Offset
MWDATAH	B8h

Function

Write a half-word of data, possibly the last half-word. The MWDATAH register is the alias of the WDATAH register. Thes Master Write Data Half-word register allows writing a half-word (pair of bytes) to the bus, unless an external FIFO is used. This takes a half-word, which will send out the Low byte and then the High byte. An end-of-data (last) marker bit is allowed (or must be 0). A half-word should not be written unless there is room for both, as indicated by use of TX FIFO level trigger or TXCOUNT available space in the MDATACTRL register.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END	End of message • If END=1, then END bit marks the last byte of the message. • If END=0, then there are more bytes in the message. For this register, this always marks DATA1 as the end. END is required to be used in I3C, but is optional in I2C. For HDR-DDR, the byte with the END must be an even byte (2nd, 4th, 6th, etc.) because DDR uses byte-pairs.
15-8 DATA1	Data byte 1 The 2nd byte to send to the master.
7-0 DATA0	Data byte 0 The 1st byte to send to the master.

49.7.38 Master Write Data Byte End Register (MWDATAHE)

Offset

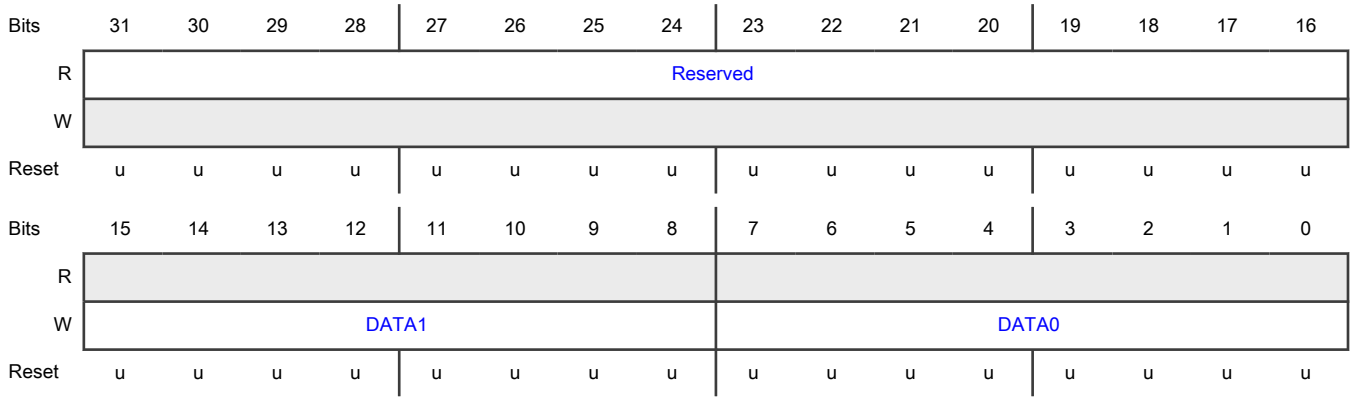
Register	Offset
MWDATAHE	BCh

Function

Write the last half-word of data. The MWDATAHE register is the alias of the Slave WDATAHE register (SWDATAHE). Write a half-word (byte pair) just like the MWDATAH register, but mark the 2nd byte as end-of-data (last byte). Note that for HDR-DDR, the byte with the END must be an even (2nd, 4th, 6th, etc) because DDR uses byte-pairs. A half-word should not

be written unless there is room for both half-words, as indicated by use of TX FIFO level trigger or TXCOUNT available space in the MDATACTRL register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 DATA1	DATA 1 The 2nd byte to send to the master.
7-0 DATA0	DATA 0 The 1st byte to send to the master.

49.7.39 Master Read Data Byte Register (MRDATAB)

Offset

Register	Offset
MRDATAB	C0h

Function

Read a byte of data. The MRDATAB register is the alias of the Slave RDATAB register (SRDATAB). The MRDATAB register is used to read bytes written by the Slave on an SDR Read or DAA or DDR. This is only used when using MCTRL to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

31-8 —	Reserved
7-0 VALUE	VALUE The byte read from the master (and written by the Slave).

49.7.40 Master Read Data Half-word Register (MRDATAH)

Offset

Register	Offset
MRDATAH	C8h

Function

Read a half-word of data. The MRDATAH register is the alias of the RDATAH register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7-0 LSB	LSB The 1st byte read from the master.

49.7.41 Write Byte Data 1 (to bus) (MWDATAB1)

Offset

Register	Offset
MWDATAB1	CCh

Function

The MWDATAB1 register allows writing bytes to send onto the bus, and is intended for DMAs, which do not clear the upper bits of the word – MWDATAB1 does not have the END bits. MWDATAB1 is only used when using MCTRL to start the message. If MWMSG_SDR or MWMSG_DDR starts a message, that interface must be used exclusively.

Diagram

Table continued from the previous page...

Field	Function
7-0 VALUE	Value Byte to write out. The block computes the parity if I3C, or handles the ACK/NACK if I2C.

49.7.42 Master Write Message in SDR mode (MWMSG_SDR_CONTROL)

Offset

Register	Offset
MWMSG_SDR_CONTROL	D0h

Function

Set up and write 16-bit words in Single Data Rate (SDR) mode. The MWMSG_SDR_ register is modal, and has 2 modes: control and data.

- On the first write to set up a new message, this register functions as the MWSMSG_SDR_CONTROL register.
- On subsequent writes, this register functions as the MWMSG_SDR_DATA register.

When not in the middle of a message, the MWMSG_SDR_CONTROL register is used to start a new message (or emit a STOP). After starting a message, the MWMSG_SDR_DATA register is used until the Length (see LEN field) counts down, or until data with END = 1 is used.

The MWMSG_SDR_CONTROL register is written with the 16-bit Control word if currently stopped or past the end of the previous message. If MSTATUS.STATE is MSGSDR and MSTAT.BETWEEN is 0, then the register (at this offset address) is functioning as the MWMSG_SDR_DATA register; otherwise, this register (at this offset address) is functioning as the MWMSG_SDR_CONTRL register, as long as MSTATUS.STATE is not in another mode. The control word contains the byte length (LEN), the address (ADDR), the direction (DIR), and how it ends (END). Note that if START and if an event (IBI, MR, HJ) occurs, the MCTRL register's IBIRESP field will be used to determine action, and the corresponding interrupt will occur. The message will be restarted in that case.

The MWMSG_SDR_CONTROL and MWMSG_SDR_DATA registers are oriented to DMA operations; but the MWMSG_SDR_CONTROL register can also be written by the processor if desired (instead of using MCTRL and MxDATAB).
