31-16 —	Reserved
15-11 LEN	Length The byte length of the message. If LEN=0, then only END is used (and it will not use the address if STOPped). LEN=1 should not be used; the minimal LEN size is 2 bytes (LEN=2).
10 I2C	I2C Specifies if the message is I2C or I3C. 0b - I3C message 1b - I2C message
9 —	Reserved
8 END	End of SDR message • If END=1, then the single data rate message ends on STOP. • If END=0, then the single data rate message ends waiting for a new SDR message (will issue a repeated START for a new message). Sets MSTATUS.COMPLETE when done. This can be happen before LEN bytes are read in I3C if a slave ends sooner; or this can happen before LEN bytes are written in I2C if a slave NACKs.
7-1 ADDR	Address to be written to
0 DIR	Direction 0b - Write 1b - Read

49.7.43 Master Write Message Data in SDR mode (MWMSG_SDR_DATA)

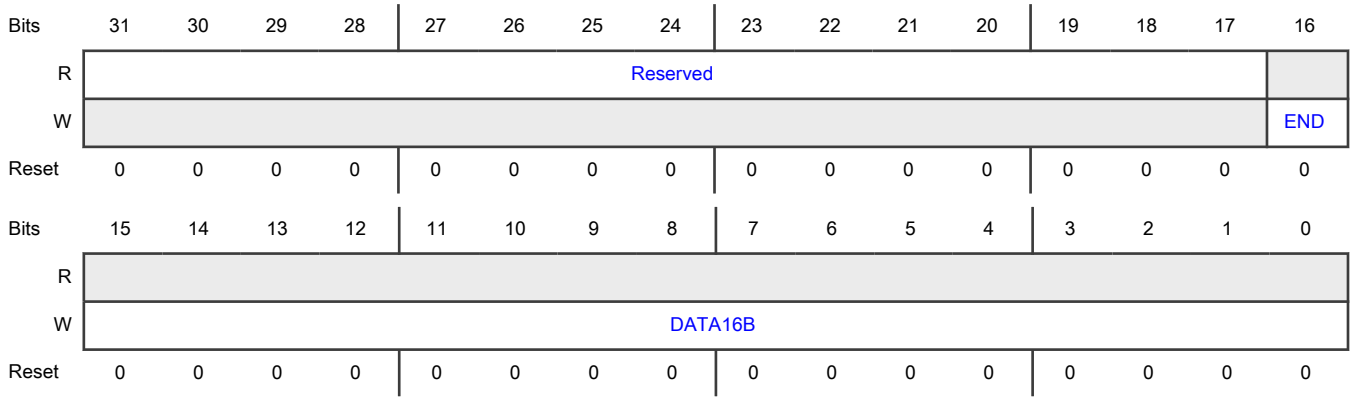
Offset

Register	Offset
MWMSG_SDR_DATA	D0h

Function

This is the 16-bit word to be written in Single Data Rate (SDR) mode. This register also functions as the MWMSG_SDR_CONTROL register.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END	End of message • If END=1, then END bit marks the last byte of the message. • If END=0, then the normal message count is used. The default is to use END=0 and let the header count count down normally. END allows terminating a write earlier than MWMSG_SDR_CONTROL.LEN field does.
15-0 DATA16B	Data

49.7.44 Master Read Message in SDR mode (MRMSG_SDR)

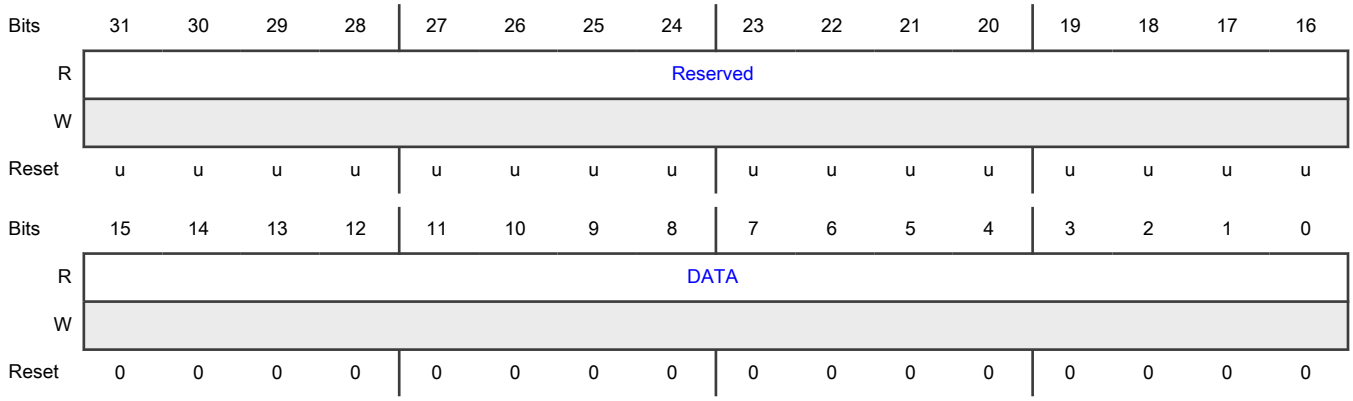
Offset

Register	Offset
MRMSG_SDR	D4h

Function

Read 16-bit words from a slave in Single Data Rate (SDR) message mode. The MRMSG_SDR register is used to read 16-bit words from an active message started with MWMSG_SDR. These words are intended to be read by DMA.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 DATA	Data DATA is the 16-bit word read from the slave. • If the length (LEN) was an uneven number, then the upper byte will be 0. • If the slave ends before LEN is finished, then it will treat the read as completed. • If the slave is not done before LEN is finished and END is not a continuation, then the read will be terminated.

49.7.45 Master Write Message in DDR mode (MWMSG_DDR_CONTROL)

Offset

Register	Offset
MWMSG_DDR_CONTROL	D8h

Function

Set up and write 16-bit words in Double Data Rate (DDR) mode. The MWMSG_DDR_ register is modal, and has 2 modes: control and data.

- On the first write to set up a new message, this register functions as the MWSMSG_DDR_CONTROL register.
- On subsequent writes, this register functions as the MWMSG_DDR_DATA register.

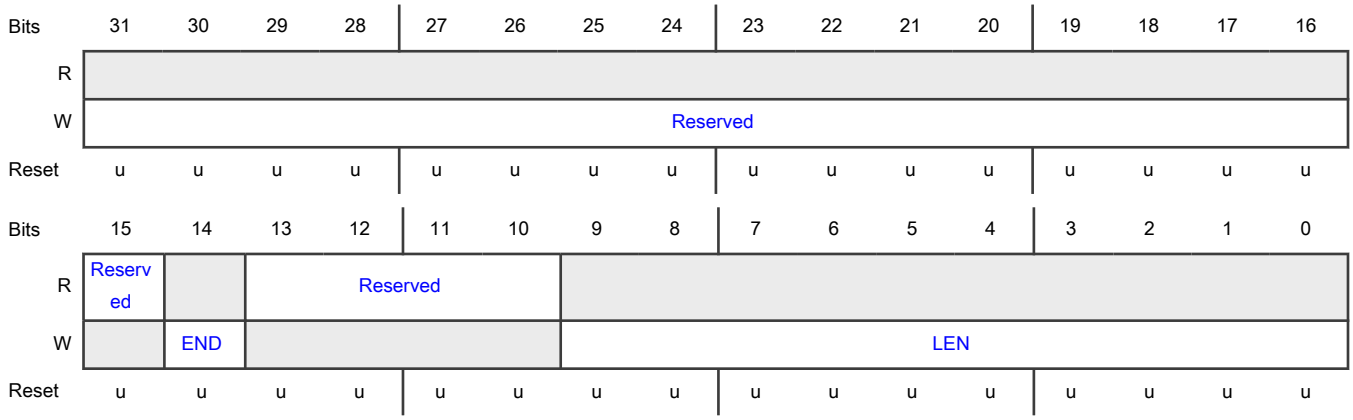
When not in the middle of a message, the MWMSG_DDR_CONTROL register is used to start a new message (or emit a STOP). After starting a message, the MWMSG_DDR_DATA register is used until the Length (see LEN field) counts down, or until data with END=1 is used.

The MWMSG_DDR_CONTROL register is written with the 16-bit Control word if currently stopped or past the end of the previous message. If MSTATUS.STATE is MSGDDR and MSTAT.BETWEEN is 0, then the register (at this offset address) is functioning as

the MWMSG_DDR_DATA register; otherwise, this register (at this offset address) is functioning as the MWMSG_DDR_CONTRL register, as long as MSTATUS.STATE is not in another mode. The main control word contains the 16-bit word length, and how it ends (stop, ready for next, continuation with more length). Then the 1st data word has the command and address for read or write. Note that if START and if an event (IBI, MR, HJ) occurs, then the MCTRL register's IBIRESP field will be used to determine action, and the corresponding interrupt will occur. The message will be restarted in that case. Note that the module handles preamble, parity, and CRC.

The MWMSG_DDR_CONTROL and MWMSG_DDR_DATA registers are oriented to DMA operations; but the MWMSG_DDR_CONTROL register can also be written by the processor if desired (instead of using MCTRL and MxDATAB).

Diagram



Fields

Field	Function
31-16 —	Reserved
15 —	Reserved
14 END	End of message • If END=1, then the double data rate message ends on HDR Exit. • If END=0, then the double data rate message ends waiting for a new DDR message (will issue a HDR Restart for the new message). Sets MSTATUS.COMPLETE when done. This can be happen before LEN bytes are read if the slave ends sooner.
13-10 —	Reserved
9-0 LEN	Length of message The length of the message (including the command) in half-words, so up to 2046 bytes. If LEN=0, then END is applied only. For Read, +1 for the CRC; for example, to read 4 bytes, use 1+2+1 for CMD + 2 halves + CRC.

49.7.46 Master Write Message Data in DDR mode (MWMSG_DDR_DATA)

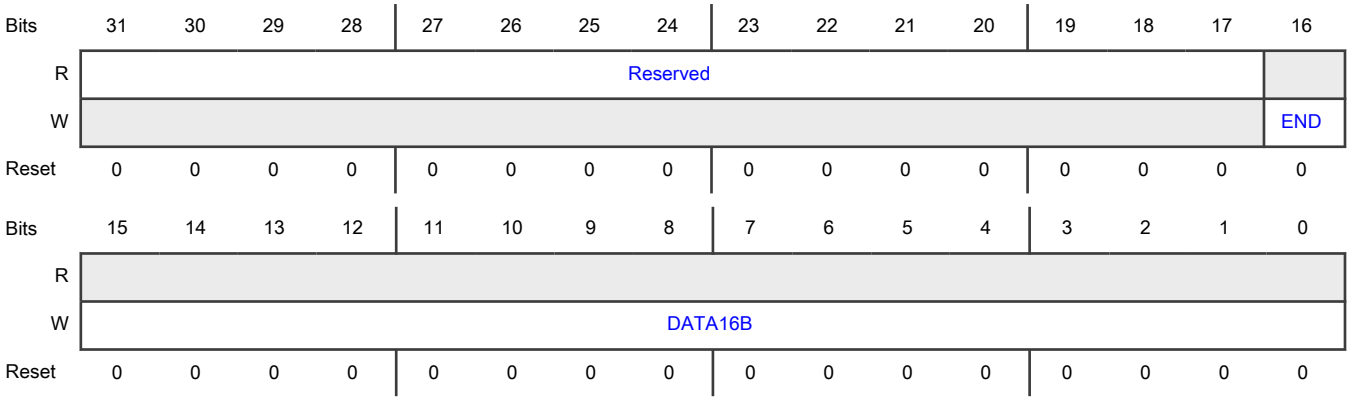
Offset

Register	Offset
MWMSG_DDR_DATA	D8h

Function

This is the 16-bit word to be written in Double Data Rate (DDR) mode. This register also functions as the MWMSG_DDR_CONTROL register.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END	End of message • If END=1, then END bit marks the last byte of the message. • If END=0, then the normal message count is used. The default is to use END=0 and let the header count count down normally. END allows terminating a write earlier than MWMSG_DDR_CONTROL.LEN field does.
15-0 DATA16B	Data

49.7.47 Master Read Message in DDR mode (MRMSG_DDR)

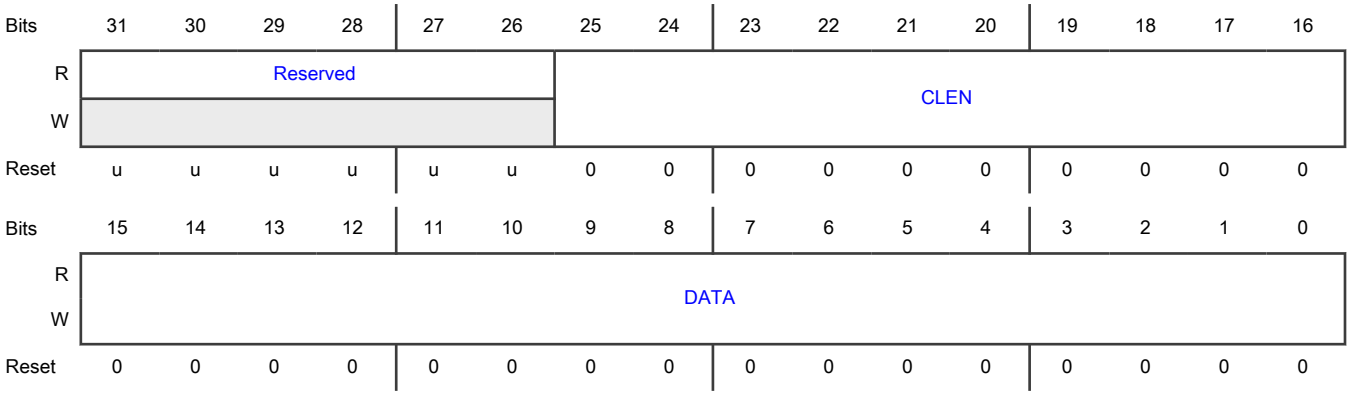
Offset

Register	Offset
MRMSG_DDR	DCh

Function

Read 16-bit words from a slave in Double Data Rate (DDR) message mode. The MRMSG_DDR register is used to read 16-bit words from an active message started with MWMSG_DDR. This is intended to be read by DMA.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 CLEN	Current length Current length. The DMA would normally only read 16 bits, and so not use the CLEN field. However, a processor can read CLEN to determine the current message length (for example, to see what the message ended on).
15-0 DATA	Data DATA is the 16-bit word read from a slave: the 1st byte is the LSB and the 2nd byte is the MSB. The 1st byte is in DATA[7:0] and the 2nd byte is in DATA[15:8]. • If the slave ends before the entire length of the message (MWMSG_DDR.LEN) is read, then the module will consider the DATA read as completed. In I3C, the slave can indicate the end of message (the last byte); otherwise, the master would terminate the message if the message is more than the master will accept. • If the slave has not yet finished sending DATA before the entire length of the message (MWMSG_DDR.LEN) is read and END is not a continuation, then the DATA read will be terminated.

49.7.48 Master Dynamic Address Register (MDYNADDR)

Offset

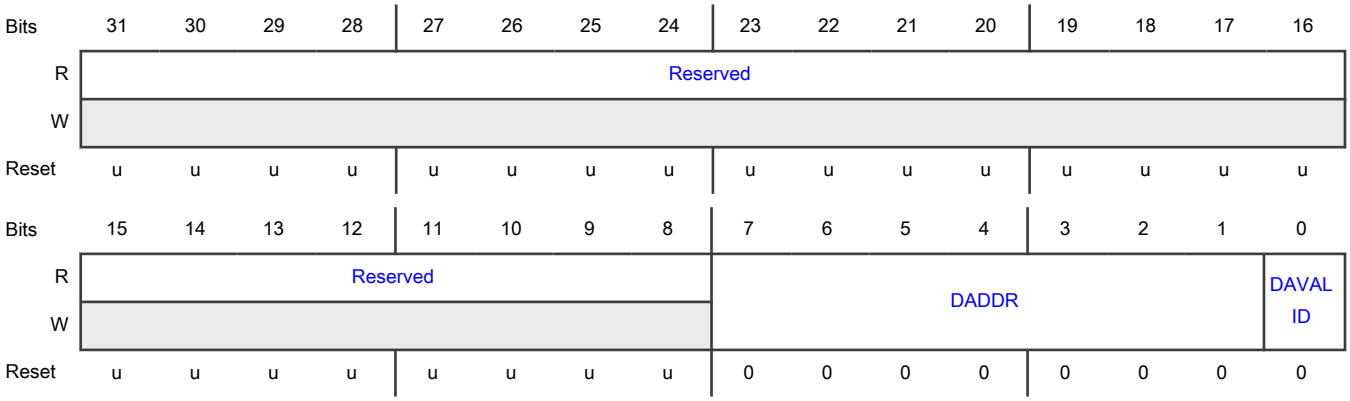
Register	Offset
MDYNADDR	E4h

Function

Allows an I3C module to write its own Dynamic Address when the I3C module changes from master mode to slave mode.

If this device is the Main Master (the Master at bus initialization), then this device may use this mechanism to assign itself its own Dynamic Address, for cases where the device hands off control to a secondary Master, and so becomes a Slave itself. This should be written before switching to Slave mode and should not be changed once in Slave mode (it is not clock safe for that). It should only be written with a valid address value in DADDR if DAVALID=1. Note that the Main master will also use DEFSLVS to define the slave addresses, including itself; this is how secondary Masters know this address. If the Master is not the Main Master, then this should not be used. If this peripheral needs to retain its DA for use during power cycle (when this peripheral is Slave), then the Slave DYNADDR register (SDYNADDR) should be used.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-1 DADDR	Dynamic address The assigned Dynamic Address when DAVALID is 1.
0 DAVALID	Dynamic address valid DAVALID=1 if a Dynamic Address is assigned.

49.7.49 Slave Module ID (SID)

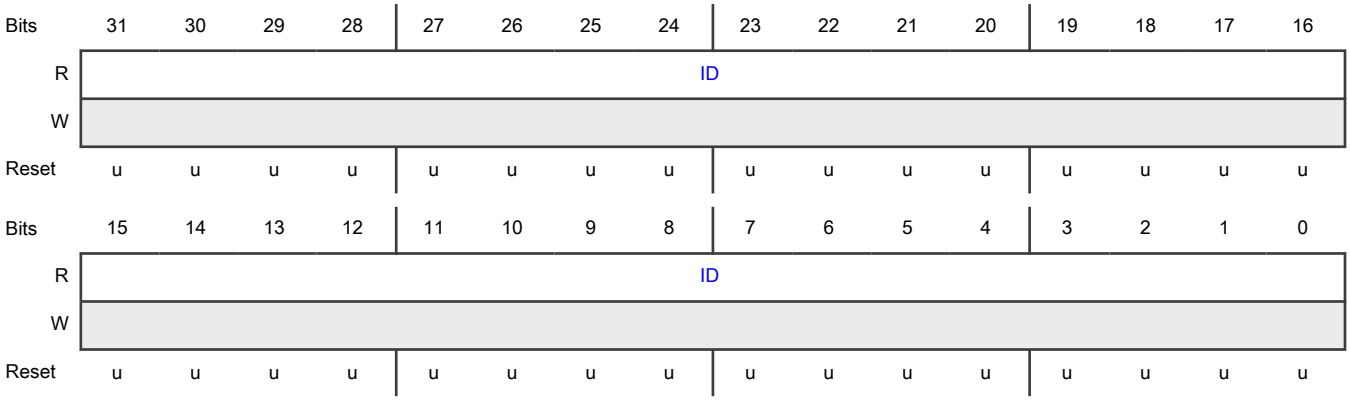
Offset

Register	Offset
SID	FFCh

Function

Allows software to detect the module and its version information.

Diagram



Fields

Field	Function
31-0 ID	ID The ID meaning is specific to each use of the I3C module.

Chapter 50
Low Power Serial Peripheral Interface (LPSPI)

50.1 Chip-specific LPSPI information

Table 300. Reference links to related information

Topic	Related module	Reference
Full description	LPSPI	LPSPI
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

50.1.1 Module instances

This device has two instances of the LPSPI module, LPSPI0, and LPSPI1.

50.1.2 Host request configuration

Both of the LPSPI0 and LPSPI1 support host request feature.

LPSPI0 does not have PCS1/HREQ pin, the related fields in CFGR0 are reserved which include LPSPI0_CFGR0[HRDIR] and 0b of the LPSPI0_CFGR0[HRSEL].

The input trigger that can be used as host request input is from TRGMUX, refer to Trigger multiplexer (TRGMUX) for more details.

50.2 Overview

LPSPI provides an efficient interface to a SPI bus, either as a master or slave. A SPI bus is a synchronous serial communication interface used in embedded systems. It is typically used to perform short distance communications between microcontrollers and peripheral devices, on printed circuit boards. Typical applications include interfacing to Secure Digital cards and LCD displays.

50.2.1 Block diagram

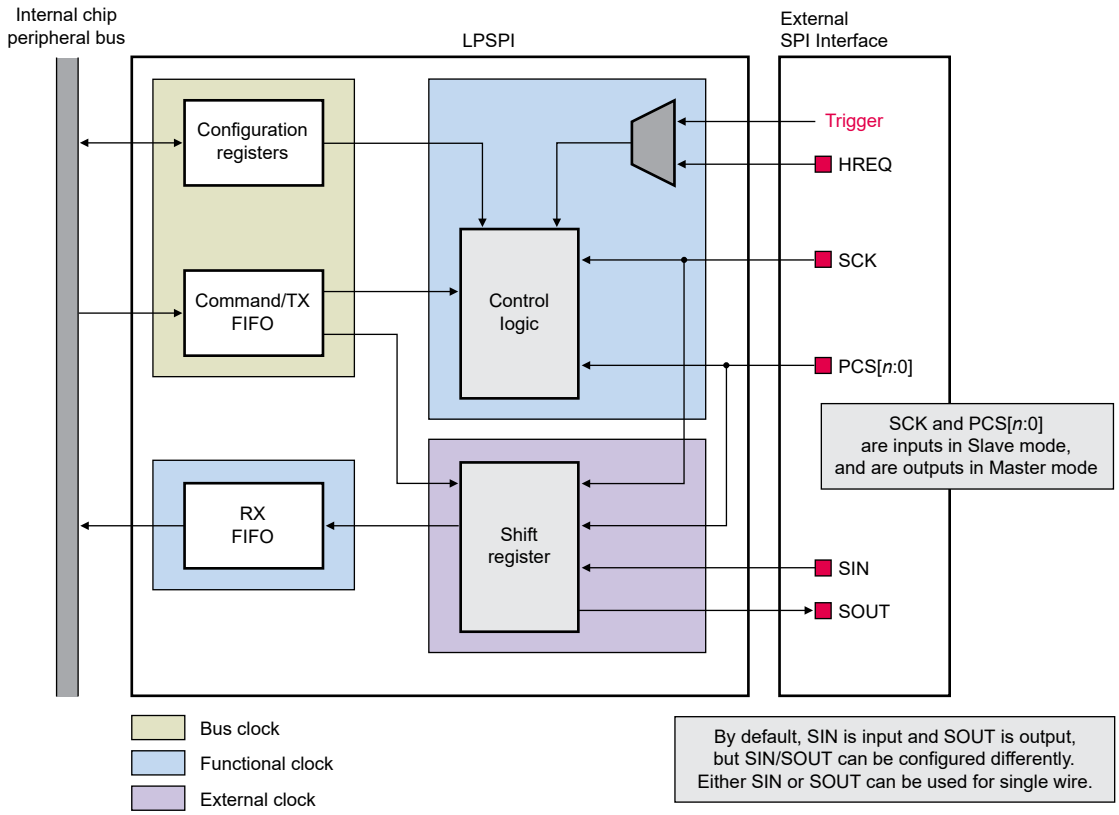


Figure 179. Block diagram

50.2.2 Features

- Requires minimal CPU overhead, with DMA offloading of FIFO register accesses
- Continues operating in Sleep mode, if configured to do so and an appropriate clock is available
- Supports DMA accesses and generates DMA requests
- 32-bit word size
- Configurable clock polarity and phase
- Master mode—supports 4 peripheral chip selects
- Slave mode
- 8-word transmit and command FIFO
- 8-word receive FIFO
- Flexible timing parameters in Master mode, including SCK frequency and duty cycle, and delays between PCS and SCK edges
- Continuous transfer option to keep PCS asserted across multiple frames
- Full-duplex transfers support 1-bit transmit and receive on each clock edge
- Half-duplex transfers support:
  - 1-bit transmit or receive on each clock edge
  - 2-bit transmit or receive on each clock edge

— 4-bit transmit or receive on each clock edge

- Can use host request to control the start of a SPI bus transfer
- Receive data match logic supports discard of non-matching data and interrupt on data match

50.3 Functional description

50.3.1 Master mode

50.3.1.1 Transmit and command FIFO commands

The transmit and command FIFO is a combined FIFO that includes both transmit data words and command words.

- You store transmit data words to the transmit and command FIFO, by writing to Transmit Data (TDR).
- You store command words to the transmit and command FIFO, by writing to Transmit Command (TCR).

When a command word is at the top of the transmit and command FIFO, the actions that can occur depend upon whether the LPSPI module is busy or between frames. See TCR[CONT] and TCR[CONTC].

Table 301. Possible actions when a command word is at the top of the transmit and command FIFO

Condition	Action
LPSPI is enabled and idle	The command word is pulled from the FIFO, and that command word controls all subsequent transfers.
LPSPI is busy and the Continuing Command field (TCR[CONTC]) is 0	The SPI frame completes at the end of the existing word, ignoring TCR[FRAMESZ]. The command word is then pulled from the FIFO and that command word controls all subsequent transfers (or until the next update to the command word). Note that a command word with TCR[CONTC] = 0 always terminates the existing transfer regardless of the previous TCR[CONT] value.
LPSPI is busy, the existing TCR[CONT] value is 1 and the new TCR[CONTC] value is 1	The command word must be updated at the frame boundary. The command word is pulled from the FIFO during the last SCK pulse of the existing frame (based on the FRAMESZ value), and the frame continues using the new command value for the rest of the frame (or until the next update to the command word). When TCR[CONTC] = 1, only the lower 24-bits of the command word are updated. If the command word is updated at a word boundary, then the transfer halts (stops) after that word. TCR[CONTC] is ignored when not at a frame boundary, so the frame ends prematurely.

About TCR[CONT] and TCR[CONTC]:

- TCR[CONT] = 1 keeps PCS asserted at end of frame, allowing the transfer to continue.
- TCR[CONTC] = 1 specifies that this command word should not terminate the existing frame, and the transfer can continue using the new command word.

TCR[CONTC] = 1 is restricted in the sense that the new command must load on a frame boundary, and the only way for a transfer to continue from a frame boundary is when the previous command has TCR[CONT] = 1.

You can read the current state of the existing command word from Transmit Command (TCR). It requires at least 3 LPSPI functional clock cycles for TCR to update after TCR is written (assuming an empty FIFO), and LPSPI must be enabled (CR[MEN] = 1).

Writing the TCR does not initiate a SPI bus transfer, unless the TCR[TXMSK] = 1. When the TCR[TXMSK] = 1, a new command word is not loaded until the end of the existing frame (based on the TCR[FRAMESZ] value); at the end of the transfer, TCR[TXMSK] transitions to 0.

In Master mode, the LPSPI command word in TCR controls SPI attributes based on selections in register fields.

Table 302. Command word in Master mode

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
CPOL	Clock polarity	Specifies the polarity of the SCK pin. Any change of CPOL value causes a transition on the SCK pin.	N
CPHA	Clock phase	Specifies the clock phase of the transfer.	N
PRESCALE	Prescaler value	Specifies a prescaler used to divide the LPSPI functional clock, to generate the timing parameters of the SPI bus transfer. Changing PRESCALE in conjunction with PCS enables the LPSPI module to connect to different slave devices at different frequencies.	N
PCS	Peripheral chip select	Specifies which PCS pin asserts for the transfer; the polarity of PCS is static and specified by CFGR1[PCSPOL]. If CFGR1[PCSCFG] = 1, do not select PCS[3:2].	N
LSBF	LSB first	Specifies whether LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.	Y
BYSW	Byte swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing to devices that organize data as big-endian.	Y
CONT	Continuous transfer	Configures LPSPI for a continuous transfer that keeps PCS asserted between frames (as specified by FRAMESZ). You must write a new command word to cause PCS to negate. Also supports changing the command word at the frame size boundaries.	Y
CONTC	Continuing command	Indicates that this is a new command word for the existing continuous transfer. When CONTC = 1, the command word must only be written to the transmit and command FIFO on a frame boundary.	Y
RXMSK	Receive data mask	Masks the receive data and does not store the masked receive data to the receive FIFO or perform receive data matching. This option is useful for half-duplex transfers or to specify which fields are compared during receive data matching.	Y
TXMSK	Transmit data mask	Masks the transmit data; masked transmit data is not pulled from the transmit FIFO, and the output data pin is 3-stated (unless otherwise configured by CFGR1[OUTCFG]). This option is useful for half-duplex transfers.	Y
WIDTH	Transfer width	Specifies the number of bits shifted on each SCK pulse. • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit half-duplex transfers are useful for interfacing to QuadSPI memory devices, and either TXMSK or RXMSK must also be 1.	Y
FRAMESZ	Frame size	Configures the frame size in number of bits equal to (FRAMESZ + 1).	Y

Table continues on the next page...

Table 302. Command word in Master mode (continued)

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
		• The minimum frame size is 8 bits. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remaining bits. For example, a 72-bit transfer consists of 3 words: the first and second words are 32 bits, and the third word is 8 bits.	

50.3.1.1.1 SPI bus transfers

LPSPI initiates a SPI bus transfer when all of the following conditions are true:

- Data is written to the transmit FIFO.
- The HREQ pin is asserted (or the HREQ function is disabled).
- LPSPI is enabled.

To perform the SPI bus transfer, LPSPI uses the attributes configured in Transmit Command (TCR) and uses the timing parameters in Clock Configuration (CCR).

The SPI bus transfer ends after the number of bits indicated by the FRAMESZ value have been transferred (provided CONT = 0), or at the end of a word when a new transmit command word is at the top of the transmit and command FIFO. When LPSPI is disabled, the SPI bus transfers end after the transmit FIFO is empty and LPSPI is idle.

The HREQ input is only checked when PCS is negated.

50.3.1.1.2 Circular FIFO

The transmit and command FIFO supports a circular FIFO feature. This feature enables the LPSPI master to (periodically) repeat a short data transfer that fits within the transmit and command FIFO, without requiring additional FIFO accesses. When the circular FIFO is enabled (CFGR0[CIRFIFO] = 1), the current state of the FIFO read pointer is saved and the status flags do not update. After the FIFO is empty and LPSPI is idle, the FIFO read pointer is restored with the saved version, so the contents of the transmit and command FIFO are not permanently pulled from the FIFO while Circular FIFO mode is enabled.

50.3.1.2 Receive FIFO and data match

The receive FIFO stores received data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of being stored in the receive FIFO.

- Received data is written to the receive FIFO when the last bit of the word is sampled.
- If the transmit FIFO is empty during a multiple-word or continuous transfer, then the receive data is written to the receive FIFO before the transfer stalls (assuming CFGR1[NOSTALL] = 0) while waiting for new transmit data or for a command word to be written.

LPSPI provides a receive data match function that can match received data against one of two words in DMR0 and DMR1, or against a masked data word. The received data match function can also be configured to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded due to the TCR[RXMSK] field cannot cause the data match flag to set, and delays the receive data match on the first received data word, until all discarded data is received.

- You can configure the receive data match function to discard all received data until a data match is detected, using CFGR0[RDMO].
- After a receive data match, to allow all subsequent data to be received, write 0 to the CFGR0[RDMO] field, then write 0 to SR[DMF].

50.3.1.3 Timing parameters

The timing parameters that are used for all SPI bus transfers are relative to the LPSPI functional clock divided by the TCR[PRESCALE] selection. Although you cannot change Clock Configuration (CCR) when the LPSPI module is busy, to support interfacing to different slave devices at different frequencies, you can change the TCR[PRESCALE] selection between SPI bus transfers using Transmit Command (TCR).

NOTE

The minimum value below is the minimum counter value, but the clock configuration register values must also satisfy the data sheet specs based on the LPSPI functional clock frequency and prescaler value.

Table 303. Timing parameters

Clock Configuration (CCR) Clock Configuration 1 (CCR1)		Description	Min	Max
Field	Name			
SCKSET	SCK setup phase	Configures the SCK setup phase to (SCKSET + 1) cycles. The setup phase is the SCK high period when either CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. Otherwise, it is the SCK low period. The SCK period is defined as (SCKSET + SCKHLD + 2) and the duty cycle is the difference between SCKSET and SCKHLD.	0 (1 cycle)	255 (256 cycles)
SCKHLD	SCK hold phase	Configures the SCK hold phase to (SCKHLD + 1) cycles. The hold phase is the SCK low period when either CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. Otherwise, it is the SCK high period. The SCK period is defined as (SCKSET + SCKHLD + 2) and the duty cycle is the difference between SCKSET and SCKHLD.	0 (1 cycle)	255 (256 cycles)
PCSPCS	PCS-to-PCS delay	Configures the minimum delay between PCS negation and the next PCS assertion to (PCSPCS + PCSPCS + 2) cycles. When the command word is updated between transfers, there is a minimum of (PCSPCS + 1) cycles between the command word update and any change on PCS pins.	0 (2 cycles)	255 (512 cycles)
SCKSCK	SCK-to-SCK delay	Configures the delay during a continuous transfer between the last SCK edge of a frame and the first SCK edge of the continuing frame to (SCKSCK + 1) cycles. This is useful when the external slave requires a large delay between different words of an SPI bus transfer.	0 (1 cycle)	255 (256 cycles)

Table continues on the next page...

Table 303. Timing parameters (continued)

Clock Configuration (CCR) Clock Configuration 1 (CCR1)		Description	Min	Max
Field	Name			
PCSSCK	PCS-to-SCK delay	Configures the minimum delay between PCS assertion and the first SCK edge to (PCSSCK + 1) cycles.	0 (1 cycle)	255 (256 cycles)
SCKPCS	SCK-to-PCS delay	Configures the minimum delay between the last SCK edge and the PCS negation to (SCKPCS + 1) cycles.	0 (1 cycle)	255 (256 cycles)

This figure shows the timing settings controlled by:

- TCR[CPHA]
- TCR[CPOL]
- CCR[SCKPCS]
- CCR[PCSSCK]
- CCR1[SCKSET]
- CCR1[SCKHLD]

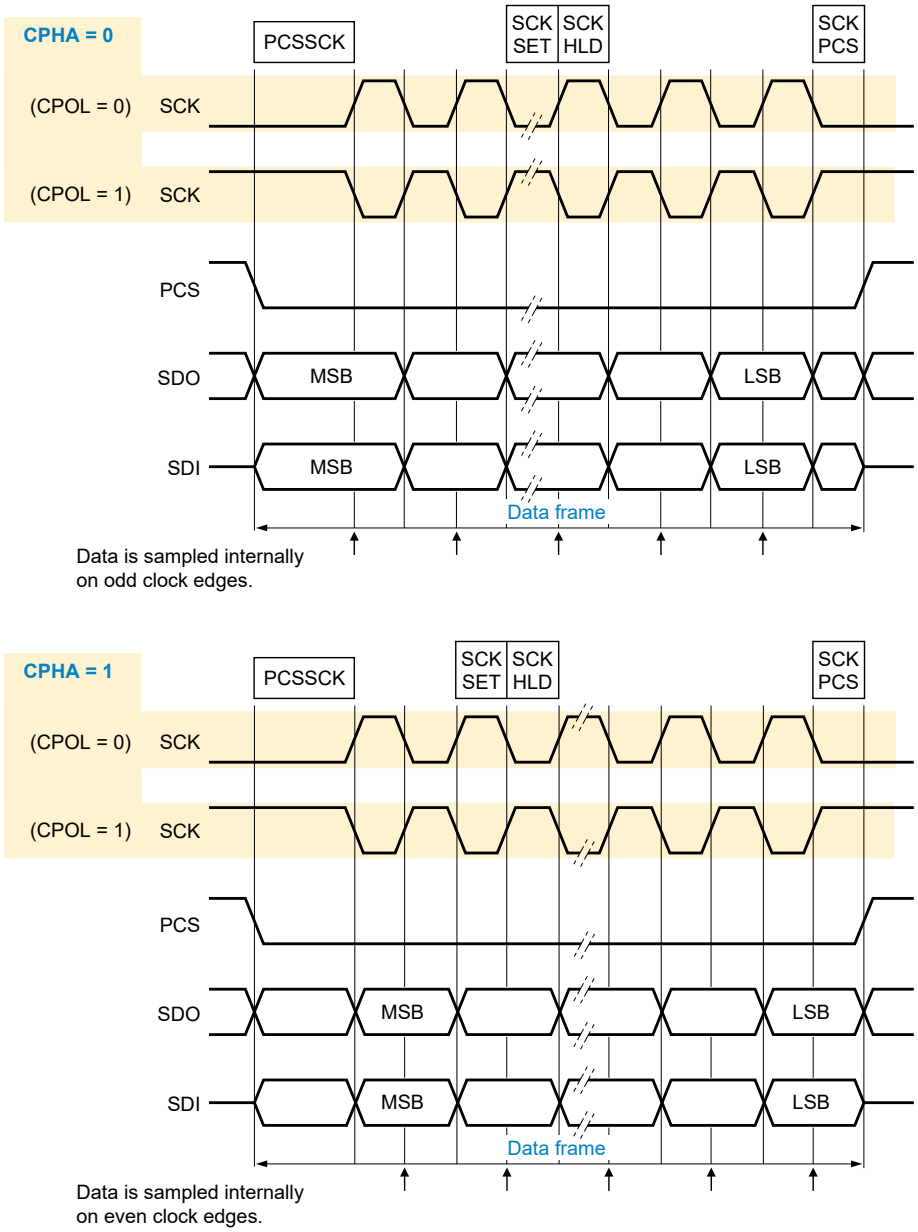

Figure 180. Clock phase (TCR[CPHA]) timing diagram example

50.3.1.4 Pin configuration

- To swap directions or support half-duplex transfers on the same pin, you can configure the SIN and SOUT pins using CFGR1[PINCFG].
- To specify whether an output data pin (SOUT, for example) 3-states when PCS is negated, or if the output data pin retains the last value, use CFGR1[OUTCFG].
- When configuring for half-duplex transfers, you must configure the output data pins to 3-state when PCS is negated (CFGR1[OUTCFG] = 1).
- When performing half-duplex 2-bit transfers, you can set CFGR1[PCSCFG] to any value.
- When performing half-duplex 4-bit transfers, you must set CFGR1[PCSCFG] to 1h.

50.3.1.5 Clock loopback

Configure the LPSPI master to use one of the following clocks to sample the input data:

- The SCK output clock
- A delayed version of the SCK output clock

The delayed version of the SCK is chosen by the SCK pin output delay, plus the SCK pin input delay, and is selected by writing 1 to CFGR1[SAMPLE]. Enabling the loopback version of the SCK can improve the setup time of the input data from the slave.

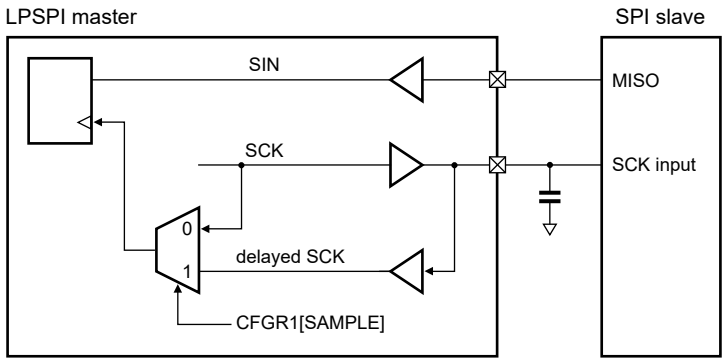

Figure 181. Clock loopback

See the chip data sheet for the specific input setup time in Master Loopback mode.

50.3.2 Slave mode

LPSPI slave mode:

- Uses the same shift register and logic that master mode uses.
- Does not use Clock Configuration Register (CCR).
- Requires that Transmit Command (TCR) remain static (unchanging) during SPI bus transfers.

50.3.2.1 Transmit and command FIFO commands

Before enabling LPSPI in Slave mode, initialize Transmit Command (TCR), although TCR does not update until after LPSPI is enabled. After LSPI is enabled, only change TCR when LPSPI is idle. In Slave mode, the LPSPI command word in TCR controls SPI attributes. Before the PCS input asserts, the transmit FIFO must be filled with transmit data, or the transmit error flag sets.

Table 304. Command word in Slave mode

Transmit Command (TCR)		Description
Field	Name	
CPOL	Clock polarity	Specifies the polarity of the external SCK input.
CPHA	Clock phase	Specifies the clock phase of transfer.
PRESCALE	Prescaler value	Specifies the LPSPI functional clock prescaler.
PCS	Peripheral chip select	Specifies which PCS is used. The polarity of PCS is static and configured by CFGR1[PCSPOL]. If CFGR1[PCSCFG] is not equal to zero, then do not select the PCS[3:2] pins.

Table continues on the next page...

Table 304. Command word in Slave mode (continued)

Transmit Command (TCR)		Description
Field	Name	
LSBF	LSB first	Specifies whether LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.
BYSW	Byte swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing to devices that organize data as big-endian.
CONT	Continuous transfer	When continuous transfer is selected in Slave mode, after the number of bits indicated by FRAMESZ are transferred, the LPSPI will passthrough and transmit the received data until the next PCS negation. Whatever is shifted in on the receive data is shifted out as transmit data as if there were a 32-bit shift register.
CONTC	Continuing command	When continuing command is enabled in Slave mode, after the number of bits indicated by FRAMESZ are transferred, then RXMSK is considered equal to 1 and TXMSK is considered equal to 0 until the next PCS negation. CONTC can be used to change the direction of a transfer after the number of bits indicated by FRAMESZ.
RXMSK	Receive data mask	Masks the receive data; LPSPI does not store masked receive data to the receive FIFO or perform receive data matching. This option is useful for half-duplex transfers or to specify which fields are compared during receive data matching.
TXMSK	Transmit data mask	Masks the transmit data, so that the masked transmit data is not pulled from transmit FIFO, and the output data pin is 3-stated (unless otherwise specified by CFGR1[OUTCFG]). This option is useful for half-duplex transfers.
WIDTH	Transfer width	Specifies the number of bits shifted on each SCK pulse. • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit half-duplex transfers are useful for interfacing to QuadSPI memory devices, and at least one of TCR[TXMSK] or TCR[RXMSK] must be 1.
FRAMESZ	Frame size	Specifies the frame size in number of bits equal to (FRAMESZ + 1). • The minimum frame size is 8 bits. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contain the remainder bits. For example, a 72-bit transfer consists of 3 words: the first and second words are 32 bits, and the third word is 8 bits.

50.3.2.2 Receive FIFO and data match

The receive FIFO stores receive data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of storing the received data in the receive FIFO.

Receive data supports a receive data match function that can match received data against one of two words in the DMR0 and DMR1 registers or against a masked data word. The data match function can also be configured to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded because TCR[RXMSK] = 1 cannot cause the data match to set, and delays the match on the first received data word, until all discarded data is received.

- The receiver match function can also be configured to discard all received data until a data match is detected, using the CFGR0[RDMO] bit.
- After a receive data match, to allow all subsequent data to be received, first clear the CFGR0[RDMO] bit, then clear the SR[DMF] bit.

50.3.2.3 Partial received word

When the PCS pin deasserts and the receive shift register has shifted in a partial word, the receive shift register can be configured to either discard the partial word or to store it in the receive FIFO. You specify this using CFGR1[PARTIAL].

A partial word is defined as less than FRAMESZ bits (when FRAMESZ is equal or less than 32 bits, or it is the last word in a multi-word frame) or less than 32 bits (when FRAMESZ is greater than 32 bits and not the last word in a multi-word frame).

A single-bit frame is not supported. A partial received word of 1 bit is fine, but a partial received frame of 1 bit is not supported.

50.3.2.4 Clocked interface

LPSPI supports interfacing to external masters that provide only clock and data pins (PCS is not required). This interface requires:

- Writing 1 to TCR[CPHA] (data is changed on the leading edge of SCK and captured on the following edge).
- Configuring the PCS input to be always asserted (CFGR1[PCSPOLn] = 1). For example, to configure PCS[0] to be always asserted, write 1 to PCSPOL[0], and do not configure PCS[0] in the pin muxing. The chip-level drives PCS to a certain value (ideally 1), CFGR1[PCSPOL*n*] could be used to invert that value.
- Writing 1 to CFGR1[AUTOPCS] to enable automatic PCS generation. When CFGR1[AUTOPCS] = 1, a minimum of four LPSPI functional clock cycles (divided by the TCR[PRESCALE] selection) is required between the last SCK edge of one word and the first SCK edge of the next word.

50.3.3 Low-power modes

Table 305. Low-power modes

Chip mode	LPSPI operation
Run	Normal operation
Sleep/Wait	Can continue operating in Sleep mode if CR[DOZEN] = 0 and LPSPI is using an external or internal clock source that remains operating during Sleep/Wait modes
Low Power Stop (also called Deep Sleep)	Before entering Low Power Stop mode, LPSPI waits for the current transfer to finish any pending operation, temporarily ignoring CR[DOZEN].

50.3.4 Debug mode

Table 306. Debug mode

Chip mode	LPSPI operation
Debug (the core is in Debug/ Halted mode)	Can continue operating in Debug mode, if the CR[DBGEN] = 1.

50.3.5 Interrupts and DMA requests

The following table lists the Slave mode sources (status flags) that can generate LPSPI interrupts and LPSPI slave transmit and receive DMA requests.

Table 307. Interrupts and DMA requests

Status (SR)		Description	Can generate		
Status flag	Name		Interrupt?	DMA request?	Low-power wake-up?
TDF	Transmit data flag	Data can be written to transmit FIFO, as configured by the transmit FIFO watermark FCR[TXWATER]	Y	TX	Y
RDF	Receive data flag	Data can be read from the receive FIFO, as configured by the receive FIFO watermark FCR[RXWATER]	Y	RX	Y
WCF	Word complete flag	Word is complete, the last bit of the word has been sampled	Y	N	Y
FCF	Frame complete flag	Frame is complete, and PCS has deasserted	Y	RX	Y
TCF	Transfer complete flag	Transfer is complete, PCS has deasserted, and the transmit and command FIFO is empty	Y	N	Y
TEF	Transmit error flag	Indicates a transmit and command FIFO underrun. In Master mode when CFGR1[NOSTALL] = 0 (transfers stall when transmit FIFO is empty), the Transmit Error Flag cannot set.	Y	N	Y
REF	Receive error flag	Indicates a receive FIFO overflow. In Master mode when CFGR1[NOSTALL] = 0 (transfers stall when receive FIFO is full), the Receive Error Flag cannot set.	Y	N	Y
DMF	Data match flag	Indicates that the received data has matched the configured data match value	Y	N	Y
MBF	Module busy flag	LPSPI is busy performing a SPI bus transfer	N	N	N

50.3.5.1 End of packet DMA transfer

The end of packet functionality is designed for serial interfaces where the size of the transfer may not be known by software in advance and the data is being pushed by an external device. Examples include UART receive, I2C Slave mode and SPI Slave mode. The end of packet processing is intended to ensure data does not become stranded in either the receive FIFO or the DMA receive buffer. Support for end of packet processing must be implemented in both the serial interfaces and the DMA controller.

The condition that signals the end of packet is different for each serial interface but is processed by the serial peripheral and DMA in the same way. For example, UART end of packet is signaled by idle line condition, I2C end of packet by STOP and/or Repeated START condition, and SPI end of packet by PCS negation.

When the serial peripheral is configured to signal end of packet condition to the DMA and an end of packet condition is detected by the serial interface, it asserts the DMA request for the receive FIFO irrespective of the watermark configuration. For larger watermark configurations, this ensures the last few words of the transfer are first flushed from the receive FIFO.

The DMA then reads the contents of the receive FIFO, depending on the first word in the FIFO:

- If the receive FIFO is empty, the serial interface signals an end of packet condition to the DMA controller.
- If the receive FIFO is not empty, but the first word in the FIFO is the start of a new packet, then data is not pulled from the receive FIFO and the serial interface signals an end of packet condition to the DMA controller.

- If the receive FIFO is not empty, and the first word in the FIFO is not the start of a new packet, the DMA will transfer the receive data as normal.

Since the DMA may be transferring multiple words on each request, the end of packet condition persists until the DMA minor loop has completed and no additional data is pulled from the receive FIFO. The status flag that triggered the end of packet condition is cleared when the minor loop completes following end of packet being signaled to the DMA controller.

When the DMA detects the end of packet condition, it writes all received words up to the end of packet into system memory and saves the destination address for the word after the last valid data. The DMA then terminates the channel as if the major loop completed, including final offsets and optional interrupts, channel linking and scatter/gather. The final destination address can optionally be saved to system memory or is available in the destination address register.

Since the DMA terminates the major loop, no servicing of the receive FIFO occurs until the DMA is reconfigured through either software or hardware (for example, channel linking or scatter-gather). This delay should be minimized to avoid receiver FIFO overrun. The automatic DMA end of packet processing is not recommended when there are only a few words transferred between end of packet conditions since the DMA will spend more time processing the end of packet than transferring the data. For example, the UART idle line length should be increased as needed to avoid an excessive number of idle conditions.

50.3.6 Clocks

Table 308. LPSPI clocks

LPSPI functional clock	• Asynchronous to the bus clock. • If the LPSPI functional clock remains enabled in low-power modes, then LPSPI can perform SPI bus transfers and low-power wakeups, in both Master and Slave modes. • LPSPI divides the functional clock by a prescaler; the resulting frequency must be at least 2 times faster than the SPI external clock frequency (SCK).
External clock	• The LPSPI shift register is clocked directly by the SCK clock. • How the SCK clock is generated or supplied depends upon the mode (Master or Slave): — In Master mode: the SCK clock is generated internally. — In Slave mode: the SCK clock is supplied externally.
Bus clock	The bus clock is only used for bus accesses to the LPSPI control and configuration registers. The bus clock frequency must be high enough to support the data bandwidth requirements of the LPSPI registers, including the FIFOs.

See the chip-specific LPSPI information.

50.3.7 Resets

Table 309. Resets

Chip reset	Resets the LPSPI logic and registers to their default state.
Software reset	• Resets the LPSPI logic and registers to their default state, except for the Control Register. • The LPSPI software reset is controlled using CR[RST].
FIFO resets	• Resets the transmit and command FIFO and the receive FIFO. • The Reset Transmit FIFO field, CR[RTF], and the Reset Receive FIFO field, CR[RRF], are write only. • After being reset, a FIFO is empty.

50.3.8 Peripheral triggers

The connection of the LPSPI peripheral triggers to other peripherals depend upon the specific device being used.

Table 310. Peripheral triggers

Trigger	Description	Notes
Frame output trigger	The frame output trigger: • Asserts at the end of each frame (when PCS deasserts) • Remains asserted for one cycle of LPSPI functional clock divided by the PRESCALE configuration	LPSPI generates two output triggers that can be connected to other peripherals on the chip.
Word output trigger	The word output trigger: • Asserts at the end of each received word • Remains asserted for one cycle of LPSPI functional clock divided by the PRESCALE configuration	
Input trigger	To control the start of an LPSPI bus transfer, the LPSPI input trigger can be selected instead of the HREQ input. • The LPSPI input trigger is synchronized, and must assert for at least 2 cycles of the LPSPI functional clock divided by the PRESCALE configuration, so that the input trigger can be detected. • When the LPSPI module is busy, the HREQ input (and therefore the LPSPI input trigger) is ignored. • Both HREQ and the LPSPI input trigger are ignored when the module is busy. They are used to start a new transfer when the module is idle.	

50.4 Signals

Table 311. Signals

Signal	Name	Description	I/O
SCK	Serial clock	• Input in Slave mode • Output in Master mode	I/O
PCS[0]	Peripheral chip select	• Input in Slave mode • Output in Master mode	I/O
PCS[1] / HREQ	Peripheral chip select or host request	Host request pin is selected when CFGR0[HREN] = 1 and CFGR0[HRSEL] = 0 • Input in either Slave mode or when used as master host request • Output in either Master mode or when used as slave host request	I/O
PCS[2] / DATA[2]	Peripheral chip select or data pin 2 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Slave mode	I/O

Table continues on the next page...

Table 311. Signals (continued)

Signal	Name	Description	I/O
		• Output in Master mode When CFGR1[PCSCFG] = 1: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	
PCS[3] / DATA[3]	Peripheral chip select or data pin 3 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Slave mode • Output in Master mode When CFGR1[PCSCFG] = 1: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
SOUT / DATA[0]	Serial data output	Can be configured as serial data input signal • Used as data pin 0 in half-duplex parallel data transfers	I/O
SIN / DATA[1]	Serial data input	Can be configured as serial data output signal • Used as data pin 1 in half-duplex parallel data transfers	I/O

50.5 Memory map and registers

NOTE

- Writing to a read-only register or reading a write-only register can cause bus errors.
- LPSPI does not check values programmed in registers for validity, so you must take care to write valid values only.

50.5.1 LPSPI register descriptions

50.5.1.2 Version ID (VERID)

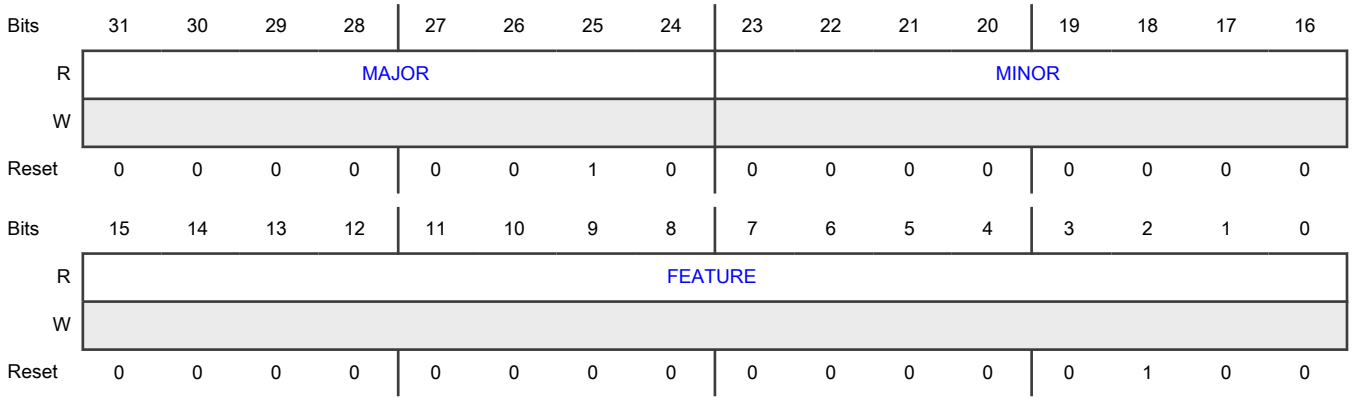
Offset

Register	Offset
VERID	0h

Function

Contains version numbers for the module design and feature set.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Indicates the major version number for the module specification.
23-16 MINOR	Minor Version Number Indicates the minor version number for the module specification.
15-0 FEATURE	Module Identification Number Indicates the feature set number. 0000_0000_0000_0100b - Standard feature set supporting a 32-bit shift register. All other values are reserved.

50.5.1.3 Parameter (PARAM)

Offset

Register	Offset
PARAM	4h

Function

Contains:

- Number of PCS pins
- Receive FIFO size
- Transmit FIFO size

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 —	Reserved
23-16 PCSNUM	PCS Number Indicates the number of PCS pins supported.
15-8 RXFIFO	Receive FIFO Size Indicates the maximum number of words in the receive FIFO. The maximum number of words is 2^{RXFIFO}.
7-0 TXFIFO	Transmit FIFO Size Indicates the maximum number of words in the transmit FIFO. The maximum number of words is 2^{TXFIFO}.

50.5.1.4 Control (CR)

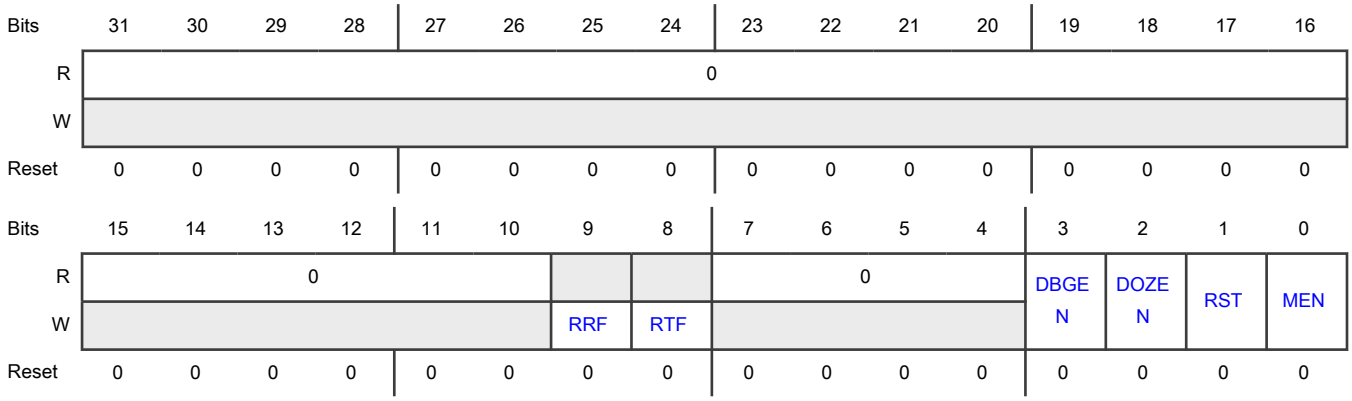
Offset

Register	Offset
CR	10h

Function

Contains fields that control module operation.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RRF	Reset Receive FIFO Deletes all entries in the receive FIFO. This field always reads zero. 0b - No effect 1b - Reset
8 RTF	Reset Transmit FIFO Deletes all entries in the transmit FIFO. This field always reads 0. 0b - No effect 1b - Reset
7-4 —	Reserved
3 DBGEN	Debug Enable Enables LPSPI in when the CPU is in Debug mode. When this field is 0, LPSPI is disabled when the CPU is halted; the PCS pin is deasserted after the transmit FIFO is empty regardless of the state of Transmit Command (TCR). Update this field only when the LPSPI module is disabled (MEN = 0). 0b - Disable 1b - Enable
2 DOZEN	Doze Mode Enable Enables LPSPI when the chip is in Doze mode. Update this field only when the LPSPI module is disabled (MEN = 0).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Enable 1b - Disable
1 RST	Software Reset Resets all internal logic and registers, except Control (CR). The reset takes effect immediately and remains asserted until you write 0 to it. There is no minimum delay required before clearing the software reset by writing 0. 0b - Not reset 1b - Reset
0 MEN	Module Enable After writing 0, MEN remains set until the LPSPI has completed the current transfer and is idle. 0b - Disable 1b - Enable

50.5.1.5 Status (SR)

Offset

Register	Offset
SR	14h

Function
Contains data flow status.

Diagram

Fields

Field	Function
31-25 —	Reserved
24 MBF	Module Busy Flag In Master mode, indicates that there is data to transmit and LPSPI is able to transmit (for example, HREQ is asserted). It deasserts after the PCS pin deasserts and the LPSPI master has waited half the CCR[DBT] time with no new data to transmit. Slave mode asserts this flag when LPSPI is enabled and PCS is asserted. 0b - LPSPI is idle 1b - LPSPI is busy
23-14 —	Reserved
13 DMF	Data Match Flag Indicates that received data matches DMR0[MATCH0] and/or DMR1[MATCH1] (as configured by CFGR1[MATCFG]). 0b - No match 1b - Match
12 REF	Receive Error Flag Indicates a receive FIFO overflow error. When this flag is set: 1. End the transfer. 2. Empty the Receive FIFO. 3. Clear this flag. 4. Restart the transfer from the beginning. 0b - No overflow 1b - Overflow
11 TEF	Transmit Error Flag Indicates a Transmit FIFO underrun error. When this flag is set: 1. End the transfer. 2. Clear this flag. 3. Restart the transfer from the beginning. 0b - No underrun 1b - Underrun
10	Transfer Complete Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
TCF	In Master mode, indicates that all transfers have completed and that LPSPI has returned to Idle state and the transmit FIFO is empty. 0b - Not complete 1b - Complete
9 FCF	Frame Complete Flag Indicates that a frame transfer has completed, when the PCS deasserts. 0b - Not complete 1b - Complete
8 WCF	Word Complete Flag Indicates that the last bit of a received word is sampled. 0b - Not complete 1b - Complete
7-2 —	Reserved
1 RDF	Receive Data Flag Indicates that the number of words in the receive FIFO is greater than the value in FCR[RXWATER]. 0b - Receive data not ready 1b - Receive data is ready
0 TDF	Transmit Data Flag Indicates that the number of words in the transmit FIFO is equal to or less than the value in FCR[TXWATER]. 0b - Transmit data not requested 1b - Transmit data is requested

50.5.1.6 Interrupt Enable (IER)

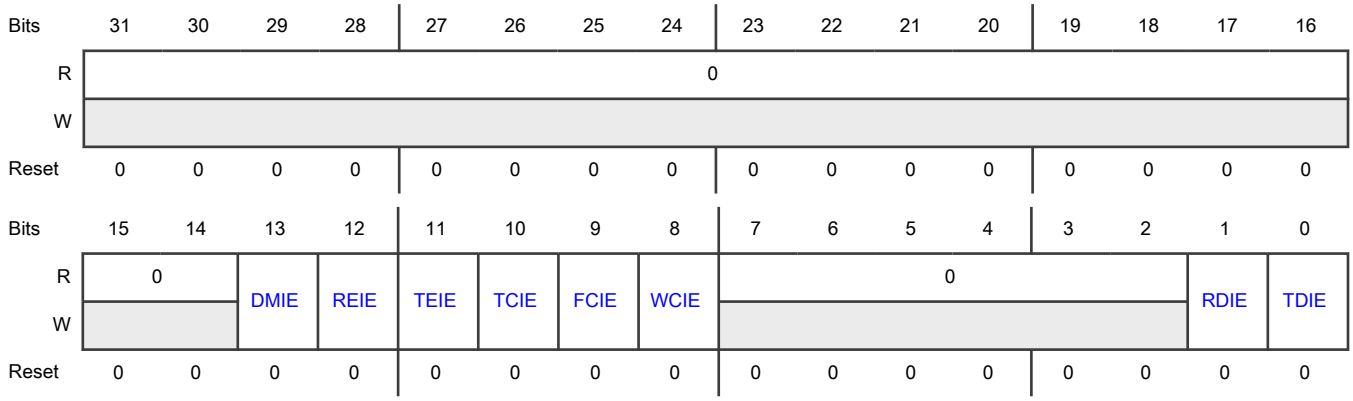
Offset

Register	Offset
IER	18h

Function

Enables interrupts based on data flow and errors.

Diagram



Fields

Field	Function
31-14 —	Reserved
13 DMIE	Data Match Interrupt Enable 0b - Disable 1b - Enable
12 REIE	Receive Error Interrupt Enable 0b - Disable 1b - Enable
11 TEIE	Transmit Error Interrupt Enable 0b - Disable 1b - Enable
10 TCIE	Transfer Complete Interrupt Enable 0b - Disable 1b - Enable
9 FCIE	Frame Complete Interrupt Enable 0b - Disable 1b - Enable
8 WCIE	Word Complete Interrupt Enable 0b - Disable 1b - Enable
7-2 —	Reserved

0 TDIE	Transmit Data Interrupt Enable 0b - Disable 1b - Enable

50.5.1.7 DMA Enable (DER)

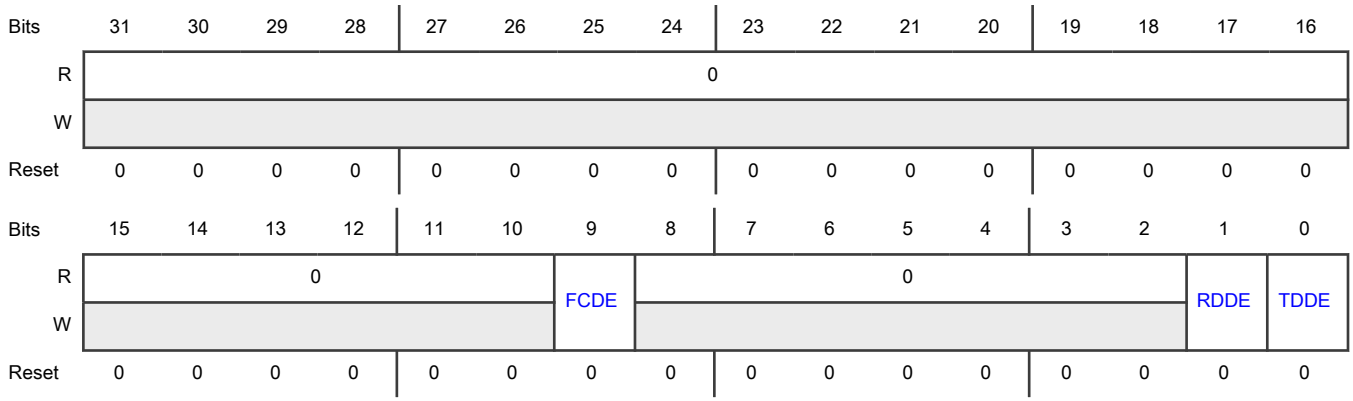
Offset

Register	Offset
DER	1Ch

Function

Enables DMA data flow.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 FCDE	Frame Complete DMA Enable Enables DMA end-of-packet processing. After the last word of a frame is read from the receive data FIFO, reading the receive data FIFO returns an end-of-packet signal with the receive data forced to

Table continues on the next page...

Table continued from the previous page...

Field	Function
	FFFF_FFFFh. This continues until the DMA minor loop completes, and then SR[FCF] deasserts if the receive FIFO is empty or if LPSPI is busy (SR[MBF] = 1). 0b - Disable 1b - Enable
8-2 —	Reserved
1 RDDE	Receive Data DMA Enable 0b - Disable 1b - Enable
0 TDDE	Transmit Data DMA Enable 0b - Disable 1b - Enable

50.5.1.8 Configuration 0 (CFGR0)

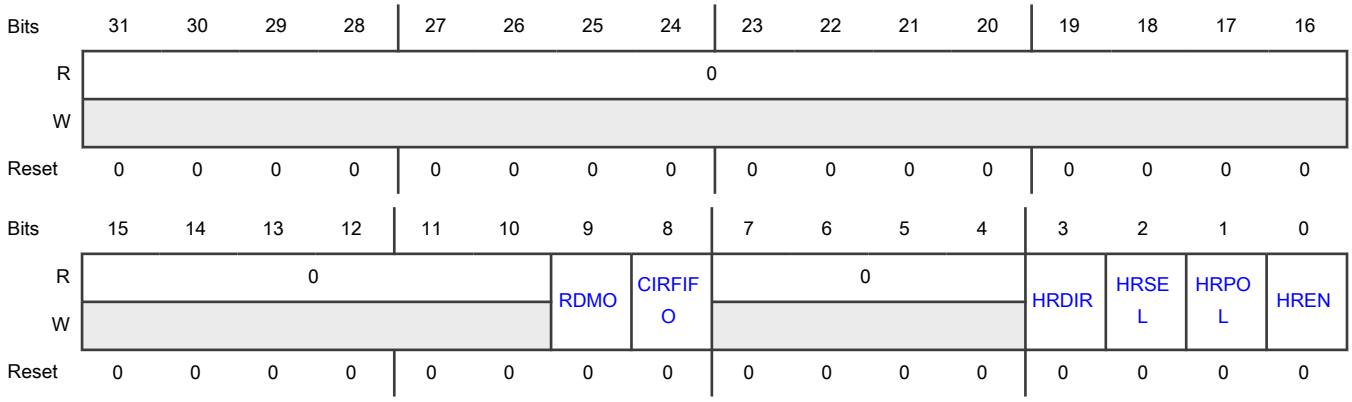
Offset

Register	Offset
CFGR0	20h

Function

Includes fields to configure LPSPI.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RDMO	Receive Data Match Only When enabled, all received data that does not cause the Data Match Flag (SR[DMF]) to assert is discarded. • Write 1 to this field when LPSPI is idle and SR[DMF] = 0. • After SR[DMF] = 1, this field is ignored. • To ensure that no receive data is lost when disabling RDMO, write 0 to this field before clearing SR[DMF]. See CFGR1[MATCFG] for the received data matching options. When disabled, all received data is stored in the receive FIFO. 0b - Disable 1b - Enable
8 CIRFIFO	Circular FIFO Enable When enabled, the transmit FIFO read pointer is saved to a temporary register. The transmit FIFO is emptied as in normal operation, but when LPSPI is idle and the transmit FIFO is empty, the read pointer value is restored from the temporary register. This restoring of the read pointer causes the contents of the transmit FIFO to be cycled through repeatedly. **NOTE** The read pointer is restored for as long as this field is 1. Writing additional words to the FIFO when this field is 1 adds them to the end of the FIFO, up to the size of the transmit FIFO. 0b - Disable 1b - Enable
7-4 —	Reserved
3 HRDIR	Host Request Direction Specifies the direction of the HREQ pin. Only configure the HREQ pin as an output when LPSPI is in Slave mode. The HREQ pin direction must be an input for Master mode. 0b - Input 1b - Output
2 HRSEL	Host Request Select Specifies the source of the host request input. When the host request function is enabled with the HREQ pin, the PCS[1] function is disabled. 0b - HREQ pin 1b - Input trigger

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 HRPOL	Host Request Polarity Specifies the polarity of the HREQ pin or input trigger. 0b - Active high 1b - Active low
0 HREN	Host Request Enable In Master mode, allows LPSPI to start a new SPI bus transfer only if the host request input is asserted. When LPSPI is busy, the host request input is ignored. In Slave mode, causes the HREQ output pin to assert when data is available to be transmitted. 0b - Disable 1b - Enable

50.5.1.9 Configuration 1 (CFGR1)

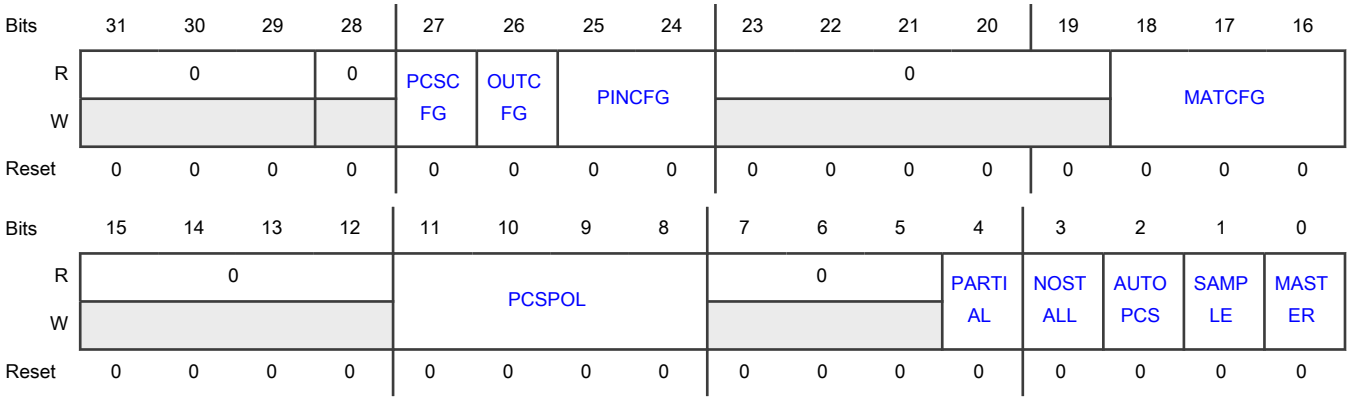
Offset

Register	Offset
CFGR1	24h

Function

Includes fields to configure LPSPI. Write to this register only when LPSPI is disabled.

Diagram



Fields

Field	Function
31-29	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function

28 —	Reserved
27 PCSCFG	Peripheral Chip Select Configuration Specifies the PCS pin configuration. When performing parallel transfers, this field must be configured to enable the desired transfer. 0b - PCS[3:2] are configured for chip select function 1b - PCS[3:2] are configured for half-duplex 4-bit transfers (PCS[3:2] = DATA[3:2])
26 OUTCFG	Output Configuration Specifies whether the output data is 3-stated between accesses (when PCS is deasserted). When performing half-duplex transfers, this field must be 1. 0b - Output data retains last value. 1b - Output data is 3-stated.
25-24 PINCFG	Pin Configuration Specifies the pins used for input and output data during serial transfers. This field is ignored when performing parallel transfers. 00b - SIN is used for input data; SOUT is used for output data. 01b - SIN is used for both input and output data. Only half-duplex serial transfers are supported. 10b - SOUT is used for both input and output data. Only half-duplex serial transfers are supported. 11b - SOUT is used for input data; SIN is used for output data.
23-19 —	Reserved
18-16 MATCFG	Match Configuration Specifies the condition that causes SR[DMF] to assert.

Condition	Description
Match first data word with compare word	Match if first data word equals MATCH0 logically ORed with MATCH1 *first_data_word* == (MATCH0 || MATCH1)
Match any data word with compare word	Match if any data word equals MATCH0 logically ORed with MATCH1 *any_data_word* == (MATCH0 || MATCH1)

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>
<table>
<tr><th>Condition</th><th>Description</th></tr>
<tr><td>Sequential match, first data word</td><td>Match if first data word equals MATCH0, and second data word equals MATCH1
(first_data_word == MATCH0) && (second_data_word == MATCH1)</td></tr>
<tr><td>Sequential match, any data word</td><td>Match if any data word equals MATCH0, and the next data word equals MATCH1
(any_data_word == MATCH0) && (next_data_word == MATCH1)</td></tr>
<tr><td>Match first data word (masked) with compare word (masked)</td><td>Match if first data word logically ANDed with MATCH1 equals MATCH0 logically ANDed with MATCH1
(first_data_word && MATCH1) == (MATCH0 && MATCH1)</td></tr>
<tr><td>Match any data word (masked) with compare word (masked)</td><td>Match if any data word logically ANDed with MATCH1 equals MATCH0 logically ANDed with MATCH1
(any_data_word && MATCH1) == (MATCH0 && MATCH1)</td></tr>
</table>
000b - Match is disabled
001b - Reserved
010b - Match first data word with compare word
011b - Match any data word with compare word
100b - Sequential match, first data word
101b - Sequential match, any data word
110b - Match first data word (masked) with compare word (masked)
111b - Match any data word (masked) with compare word (masked)
</td></tr>
<tr><td>15-12
—</td><td>Reserved</td></tr>
<tr><td>11-8
PCSPOL</td><td>Peripheral Chip Select Polarity
Specifies the polarity of each PCS pin. Bit n in this field (the least-significant bit is bit 0) corresponds to PCS[n].
For each PCSPOL bit:
0b – PCS[n] pin is active low
1b – PCS[n] pin is active high
NOTE
The entire PCSPOL field is not fully supported in every LPSPI module instance. See the LSPI chip-specific information.</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-5 —	Reserved
4 PARTIAL	Partial Enable Specifies whether LSPI, when in Slave mode, stores a partial received word in the receive FIFO, or discards it, when PCS deasserts. 0b - Discard 1b - Store
3 NOSTALL	No Stall Disables a normal operating feature that causes LSPI, when in Master mode, to stall transfers when the transmit FIFO is empty or when the receive FIFO is full. This feature prevents transmit FIFO underruns and receive FIFO overruns. Writing 1 to this field disables this functionality. 0b - Disable 1b - Enable
2 AUTOPCS	Automatic PCS Enables automatic PCS generation. For correct operation in Slave mode, LPSPI requires the PCS signal to deassert between frames. Writing 1 to this field generates an internal PCS signal at the end of each transfer word when TCR[CPHA] = 1. When this field is 1, SCK must remain idle for at least 4 LPSPI functional clock cycles, divided by the prescaler selected (see TCR[PRESCALE]) between each word, to ensure correct operation. This field is ignored in Master mode. 0b - Disable 1b - Enable
1 SAMPLE	Sample Point Specifies the SCK clock edge on which LSPI, when in Master mode, samples input data. Writing 1 to this field causes LSPI to sample input data on a delayed loopback SCK clock edge, which improves the setup time when sampling data (see Clock loopback). In this configuration. The input data setup time in Master mode is equal to the input data setup time in Slave mode. In Slave mode, this field is ignored. 0b - SCK edge 1b - Delayed SCK edge
0 MASTER	Master Mode Specifies the LPSPI operating mode—either Master or Slave. This field directly controls the direction of the SCK and PCS pins. 0b - Slave mode 1b - Master mode

50.5.1.10 Data Match 0 (DMR0)

Offset

Register	Offset
DMR0	30h

Function

Specifies match data to be used when data matching is enabled. See CFGR1[MATCFG] for the received data matching options.

NOTE

Do not change the value in this register while CFGR0[RDMO] = 1.

Diagram

Fields

Field	Function
31-0 MATCH1	Match 1 Value MATCH1 value to be compared against received data.

50.5.1.12 Clock Configuration (CCR)

Offset

Register	Offset
CCR	40h

Function

Contains clock configuration fields. These fields are only used in Master mode and you can only change them when LPSPI is disabled (CR[MEN] = 0).

Warning

Writing a 32-bit value to this register overwrites Clock Configuration 1 (CCR1); DBT and SCKDIV always read 0.

To avoid overwriting CCR1:

- Either write all 4 CCR register fields simultaneously and only once in a 32-bit data.
- Or to modify SCKPCS and/or PCSSCK values, write only these 2 upper bytes in a 16-bit data or one of them in an 8-bit data.
- Or to modify CCR1[PCSPCS] and CCR1[SCKSCK] fields only or CCR1[SCKSET] and CCR1[SCKHLD] fields only, write respectively CCR[DBT] or CCR[SCKDIV] in 8-bit data

Diagram

Fields

Field	Function
31-24 SCKPCS	SCK-to-PCS Delay In Master mode: configures the delay from the last SCK edge to the PCS negation. • The delay is equal to (SCKPCS + 1) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum delay is 1 cycle. See Figure 180.
23-16 PCSSCK	PCS-to-SCK Delay In Master mode: configures the delay from the PCS assertion to the first SCK edge. • The delay is equal to (PCSSCK + 1) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum delay is 1 cycle. See Figure 180.
15-8 DBT	Delay Between Transfers Writing this field updates the contents of CCR1[PCSPCS] and CCR1[SCKSCK].
7-0 SCKDIV	SCK Divider Writing this field updates the contents of CCR1[SCKSET] and CCR1[SCKHLD].

50.5.1.13 Clock Configuration 1 (CCR1)

Offset

Register	Offset
CCR1	44h

Function

Contains clock configuration fields. These fields are only used in Master mode and you can only change them when LPSPI is disabled (CR[MEN] = 0).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	SCKSCK								PCSPCS

R W	SCKHLD								SCKSET							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 SCKSCK	SCK Inter-Frame Delay In Master mode: • Configures the delay from the last SCK pulse of a frame and the first SCK pulse of the following frame, in a continuous transfer. • The delay is equal to (SCKSCK + 1) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum delay is 1 cycle. **NOTE** For backward compatibility, writing CCR[DBT] updates CCR1[SCKSCK] with the value written.
23-16 PCSPCS	PCS to PCS delay In Master mode: • Configures the delay from the PCS negation to the next PCS assertion. • The delay is equal to (PCSPCS + PCSPCS + 2) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum delay is 2 cycles. • Half of the delay (PCSPCS + 1) occurs before PCS assertion and the other half of the delay (PCSPCS + 1) occurs after PCS negation. If the command word is updated between 2 transfers, then the command word is updated halfway between the PCS negation of the last transfer and PCS assertion of the next transfer. • The command word specifies which PCS signal is used, the polarity and phase of the SCK signal, and the prescaler selected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE For backward compatibility, writing CCR[DBT] updates this field with (DBT÷2) rounded up.
15-8 SCKHLD	SCK Hold In Master mode, this field configures the hold phase of the SCK pin. • The hold phase is the delay between the SCK edge that samples the receive data and the SCK edge that drives the transmit data. • This is the SCK low period when CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. This is the SCK high period when CPHA = 0, CPOL = 0 and CPHA = 1, CPOL = 1. • The SCK hold phase delay is equal to (SCKHLD + 1) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum delay is 1 cycle. • The SCK period is equal to (SCKSET + SCKHLD + 2) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The SCK duty cycle is based on the difference between SCKSET and SCKHLD. Configure both fields to the same value for 50/50 duty cycle. See Figure 180. **NOTE** For backward compatibility, writing CCR[SCKDIV] updates this field with (SCKDIV ÷ 2) rounded down.
7-0 SCKSET	SCK Setup In Master mode, the SCK Setup configures the setup phase of the SCK pin. • The setup phase is the delay between the SCK edge that drives the transmit data and the SCK edge that samples the receive data. • This is the SCK high period when CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. This is the SCK low period when CPHA = 0 and CPOL = 0, or CPHA = 1 and CPOL = 1. • The SCK setup phase delay is equal to (SCKSET + 1) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The minimum delay is 1 cycle. • The SCK period is equal to (SCKSET + SCKHLD + 2) cycles of the LPSPI functional clock divided by the prescaler selected (see TCR[PRESCALE]). • The SCK duty cycle is based on the difference between SCKSET and SCKHLD, configure both fields to the same value for 50/50 duty cycle. See Figure 180. **NOTE** For backward compatibility, writing CCR[SCKDIV] updates this field with (SCKDIV ÷ 2) rounded up.

50.5.1.14 FIFO Control (FCR)

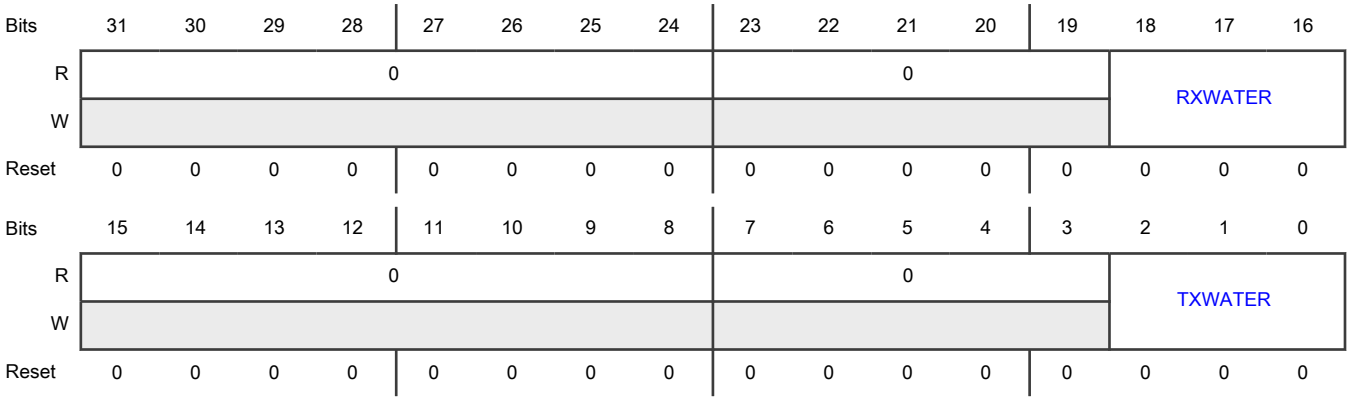
Offset

Register	Offset
FCR	58h

Function

Contains the receive FIFO and transmit FIFO watermark values.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-19 —	Reserved
18-16 RXWATER	Receive FIFO Watermark Causes LPSPI to set the Receive Data Flag (SR[RDF]) when the number of words in the receive FIFO is greater than RXWATER. Writing a value equal or greater than the FIFO size truncates the written value.
15-8 —	Reserved
7-3 —	Reserved
2-0 TXWATER	Transmit FIFO Watermark Causes LPSPI to set the Transmit Data Flag (SR[TDF]) when the number of words in the transmit FIFO is equal or less than TXWATER. Writing a value equal or greater than the FIFO size truncates the written value.

50.5.1.15 FIFO Status (FSR)

Offset

Register	Offset
FSR	5Ch

Function

Contains fields that indicate the number of words currently stored in the receive FIFO and transmit FIFO.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 —	Reserved
23-20 —	Reserved
19-16 RXCOUNT	Receive FIFO Count Indicates the number of words currently stored in the receive FIFO.
15-8 —	Reserved
7-4 —	Reserved
3-0 TXCOUNT	Transmit FIFO Count Indicates the number of words currently stored in the transmit FIFO.

50.5.1.16 Transmit Command (TCR)

Offset

Register	Offset
TCR	60h

Function

Writes to either this register or Transmit Data (TDR) push the data into the transmit FIFO, in the order written. Only write to this register using 32-bit writes. Writes are tagged and cause the command register to update, after that entry reaches the top of the FIFO and the LPSPI is enabled. This allows changes to the command word and the transmit data itself to be interleaved. That is, the writes to the two registers can be interleaved (write command word, then data word, then command word, and so on). Changing the command word causes all subsequent SPI bus transfers to be performed using the new command word.

- **In Master mode,** writing a new command word does not initiate a new transfer, unless TXMSK is 1. Transfers are initiated by transmit data in the transmit FIFO, or by a new command word (with TXMSK = 1). Hardware writes 0 to TXMSK when the PCS deasserts.
- **In Master mode,** if the command word is changed before an existing frame has completed, then the existing frame terminates and the command word then updates. The command word can be changed during a continuous transfer, if CONTC of the new command word is 1 and the command word is written on a frame size boundary.
- **In Slave mode,** the command word should be changed only when LPSPI is idle and there is no SPI bus transfer.

Avoid resetting the Transmit FIFO after writing to the Transmit Command Register, wait for the command register to update from the FIFO first.

Avoid register reading problems: Reading the Transmit Command Register returns the current state of the command register. Reading the Transmit Command Register at the same time that the Transmit Command Register is loaded from the transmit FIFO, can return an incorrect Transmit Command Register value. It is recommended to:

- Read the Transmit Command Register when the transmit FIFO is empty,
- Read the Transmit Command Register more than once and then compare the returned values.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31 CPOL	Clock Polarity Specifies the value of SCK when it is idle. This field can only be updated when PCS deasserted. See Figure 180. 0b - Inactive low 1b - Inactive high
30 CPHA	Clock Phase This field can only be updated when PCS deasserted. See Figure 180. 0b - Captured. Data is captured on the leading edge of SCK and changed on the following edge of SCK 1b - Changed. Data is changed on the leading edge of SCK and captured on the following edge of SCK
29-27 PRESCALE	Prescaler Value For all SPI bus transfers, this value is applied to Clock Configuration (CCR) clock. This field can only be updated when PCS deasserted. 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64 111b - Divide by 128
26 —	Reserved
25-24 PCS	Peripheral Chip Select Configures the peripheral chip select used for the transfer. The Peripheral Chip Select field is only updated when PCS deasserted. **NOTE** The entire PCS field is not fully supported in every LPSPI module instance. See the chip-specific LPSPI information. 00b - Transfer using PCS[0] 01b - Transfer using PCS[1]

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - Transfer using PCS[2] 11b - Transfer using PCS[3]
23 LSBF	LSB First 0b - Data is transferred MSB first 1b - Data is transferred LSB first
22 BYSW	Byte Swap Swaps the contents of [31:24] with [7:0] and [23:16] with [15:8] for each transmit data word read from the FIFO and for each received data word stored to the FIFO (or compared with match registers). 0b - Disabled 1b - Enabled
21 CONT	Continuous Transfer • In Master mode, CONT keeps the PCS asserted at the end of the frame size, until a command word is received that starts a new frame. • In Slave mode, when CONT is enabled, LPSPI only transmits the first FRAMESZ bits; after which LPSPI transmits received data (assuming a 32-bit shift register) until the next PCS negation. 0b - Continuous transfer is disabled 1b - Continuous transfer is enabled
20 CONTC	Continuing Command In Master mode, this field enables the command word to be changed within a continuous transfer. • The initial command word must enable continuous transfer (CONT = 1). • The continuing command must have CONTC = 1. • The continuing command word must be loaded on a frame size boundary. For example, if the continuous transfer has a frame size of 64-bits, then a continuing command word must be loaded on a 64-bit boundary. In Slave mode, the Continuing Command bit modifies the internal RXMSK/TXMSK configuration after the first FRAMESZ bits and until the PCS negation. • Receive data is discarded after the first FRAMESZ bits. If CONT is also 1 this does not block the transmission of received data. • Transmit data is not masked after the first FRAMESZ bits, this allows the first FRAMESZ bits to be received and a response transmitted. 0b - Command word for start of new transfer 1b - Command word for continuing transfer
19 RXMSK	Receive Data Mask Masks receive data (receive data is not stored in receive FIFO).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Normal transfer 1b - Receive data is masked
18 TXMSK	Transmit Data Mask Masks transmit data (no data is loaded from transmit FIFO and the output pin is 3-stated). In Master mode, TXMSK initiates a new transfer which cannot be aborted by another command word. TXMSK automatically transitions to 0 at the end of the transfer. 0b - Normal transfer 1b - Mask transmit data
17-16 WIDTH	Transfer Width Configures serial (1-bit) or parallel transfers. For half-duplex parallel transfers, either Receive Data Mask (RXMSK) or Transmit Data Mask (TXMSK) must be 1. 00b - 1-bit transfer 01b - 2-bit transfer 10b - 4-bit transfer 11b - Reserved
15-12 —	Reserved
11-0 FRAMESZ	Frame Size Configures the frame size in number of bits equal to (FRAMESZ + 1). • The minimum frame size is 8 bits • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remainder bits. For example, a 72-bit transfer consists of 3 words: the first and second words are 32 bits, and the third word is 8 bits.

50.5.1.17 Transmit Data (TDR)

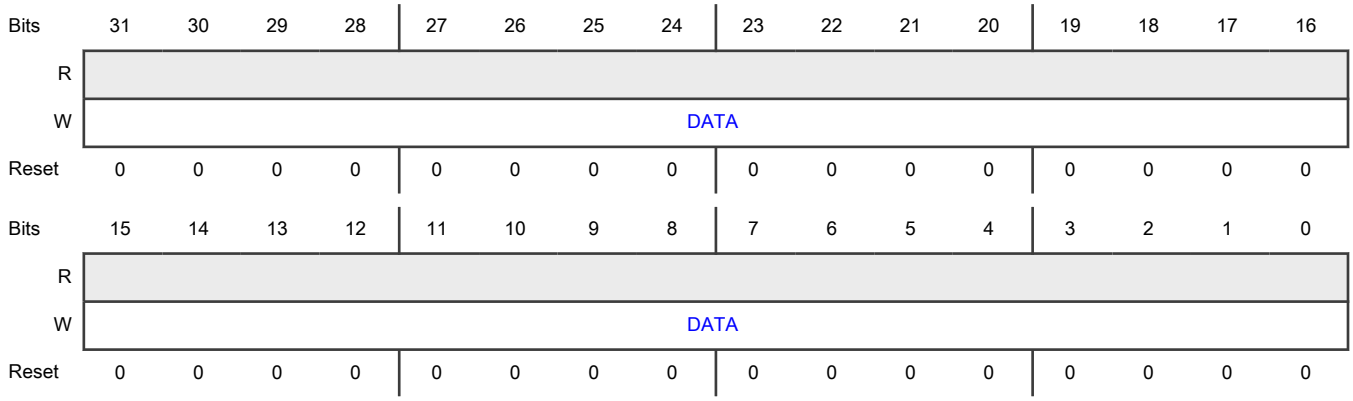
Offset

Register	Offset
TDR	64h

Function

Writes to either Transmit Command (TCR) or this register push the data into the transmit FIFO, in the order that the data is written. You can write to TDR using 32-, 16-, or 8-bit writes, but each write pushes data into the FIFO with zero pushed in unwritten bytes.

Diagram



Fields

Field	Function
31-0 DATA	Transmit Data Both 8- and 16-bit writes of transmit data zero-extend the data written and push the data into the transmit FIFO. To zero-extend 8- and 16-bit writes (to 32 bits), means that the higher order (most significant) empty parts of the 8-bit and 16-bit writes are filled with zeroes.

50.5.1.18 Receive Status (RSR)

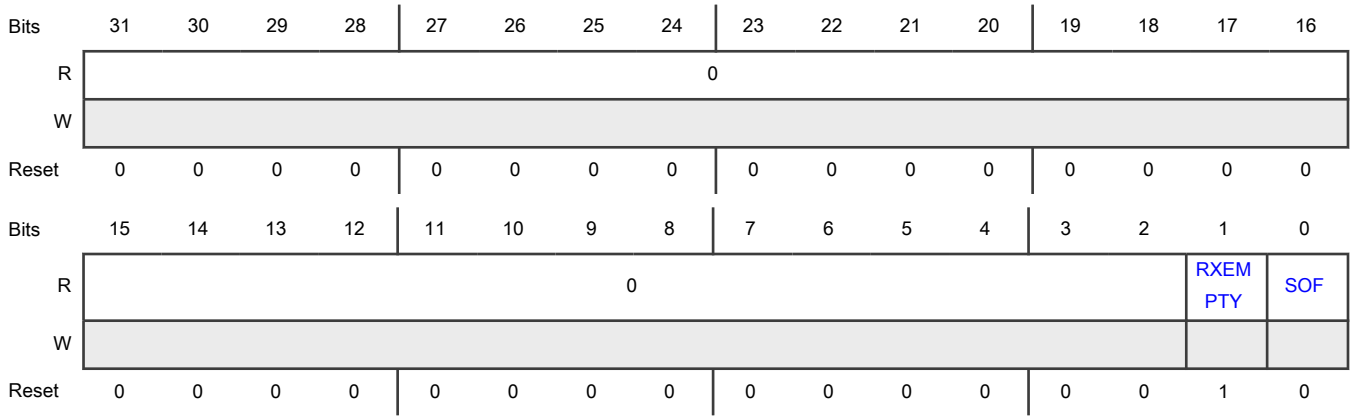
Offset

Register	Offset
RSR	70h

Function

Contains data flow status fields for receive FIFO.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RXEMPTY	RX FIFO Empty 0b - Not empty 1b - Empty
0 SOF	Start Of Frame Indicates that this is the first data word received after PCS assertion. 0b - Subsequent data word 1b - First data word

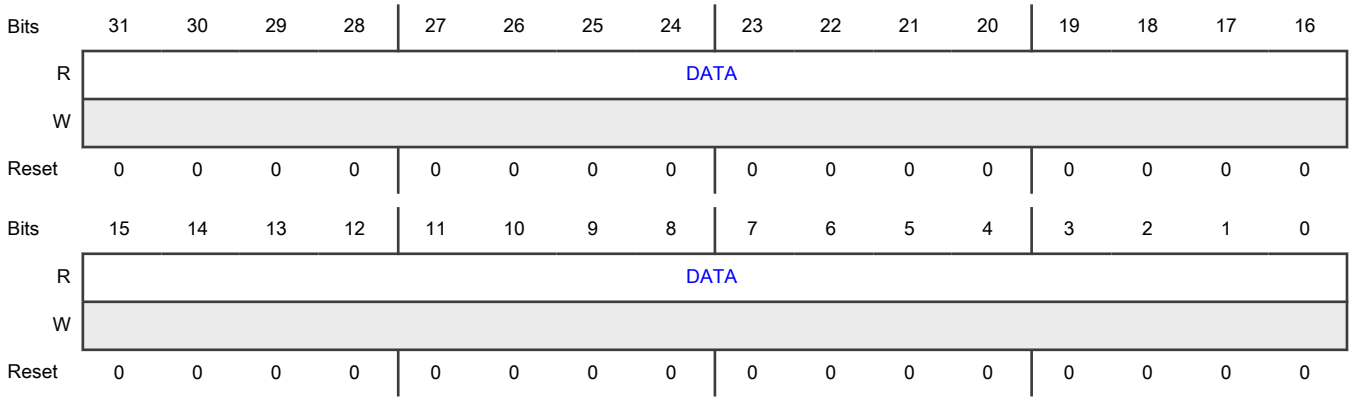
50.5.1.19 Receive Data (RDR)

Offset

Register	Offset
RDR	74h

Function
Reading this register pulls the first entry from the receive FIFO.

Diagram



Fields

Field	Function
31-0 DATA	Receive Data

50.5.1.20 Receive Data Read Only (RDROR)

Offset

Register	Offset
RDROR	78h

Function
Returns the first entry in the receive FIFO, but does not remove the data from the FIFO.

50.5.1.23 Receive Data Burst (RDBR0 - RDBR127)

Offset

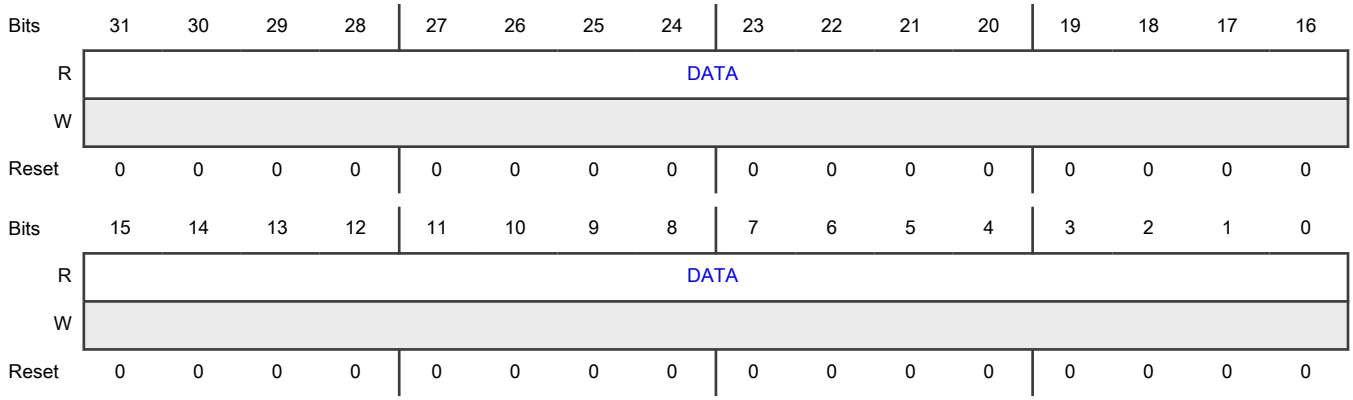
For n = 0 to 127:

Register	Offset
RDBRn	600h + (n × 4h)

Function

Supports burst transfers of data from the receive FIFO. The size of this register is 512 bytes.

Diagram



Fields

Field	Function
31-0 DATA	Data Data is read from the Receive Data Register.

Chapter 51
Low Power Universal Asynchronous Receiver/ Transmitter (LPUART)

51.1 Chip-specific LPUART information

Table 312. Reference links to related information

Topic	Related module	Reference
Full description	LPUART	LPUART
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

51.1.1 Module instances

This device has two instances of the LPUART module, LPUART0, and LPUART1.

51.2 Overview

LPUART provides asynchronous, serial communication capabilities with external devices. It supports the non-return-to-zero (NRZ) encoding format and IrDA-compatible, low-speed serial infrared (SIR) protocol. LPUART can continue operating when the processor is in Low-Power mode, if an appropriate peripheral clock is available.

51.2.1 Block diagram

The following figure shows the transmitter portion of LPUART.

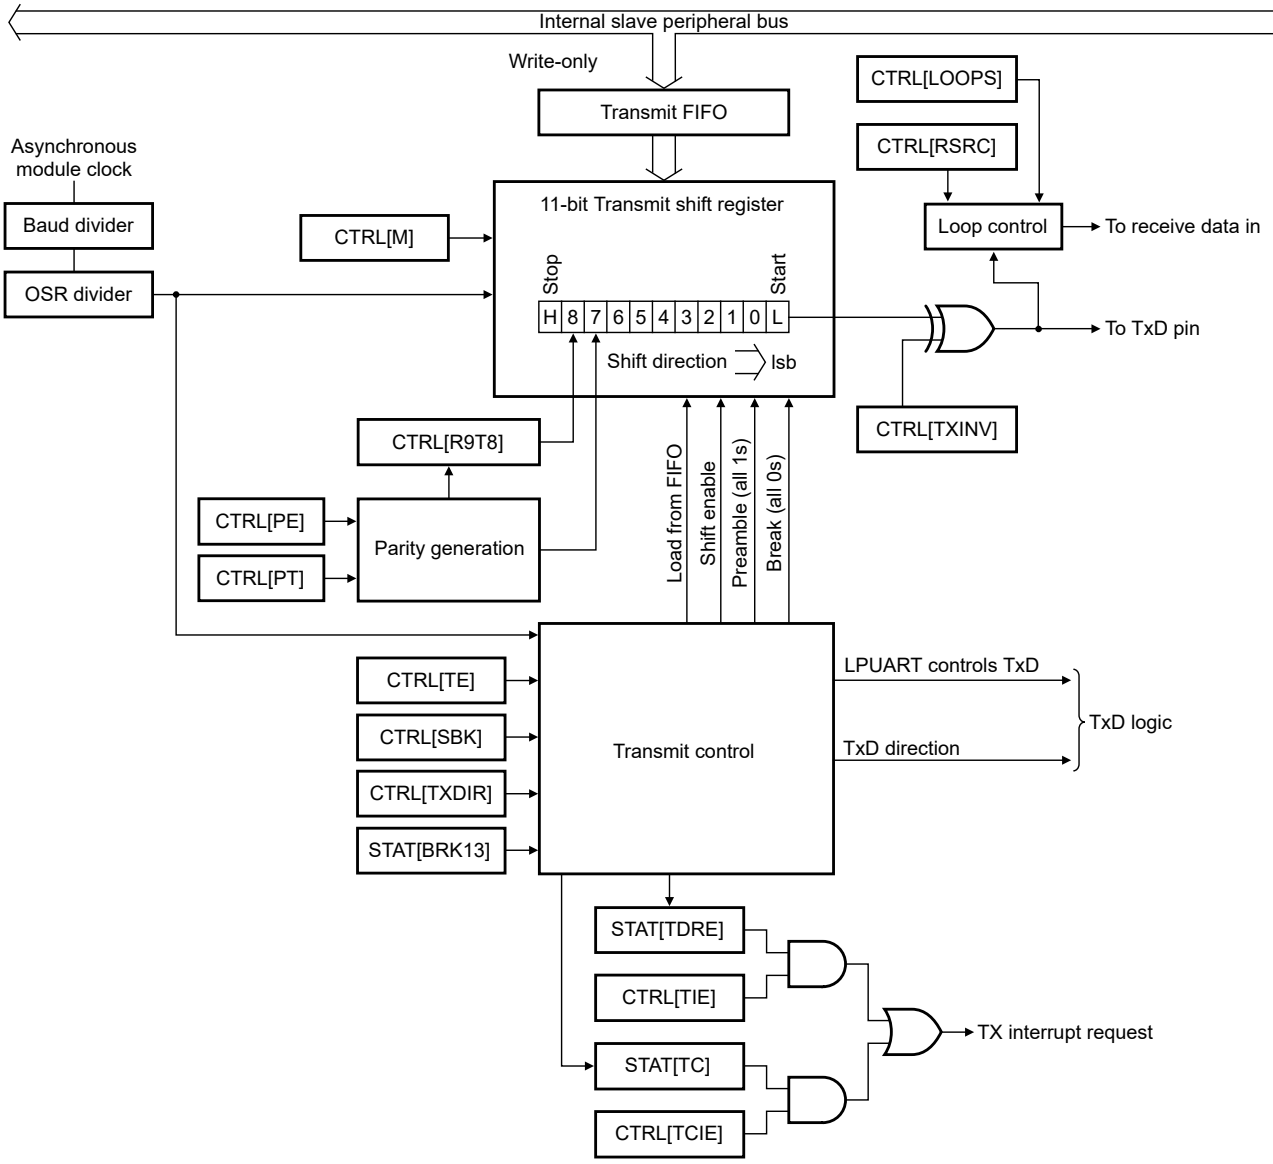


Figure 182. LPUART transmitter block diagram

The following figure shows the receiver portion of LPUART.

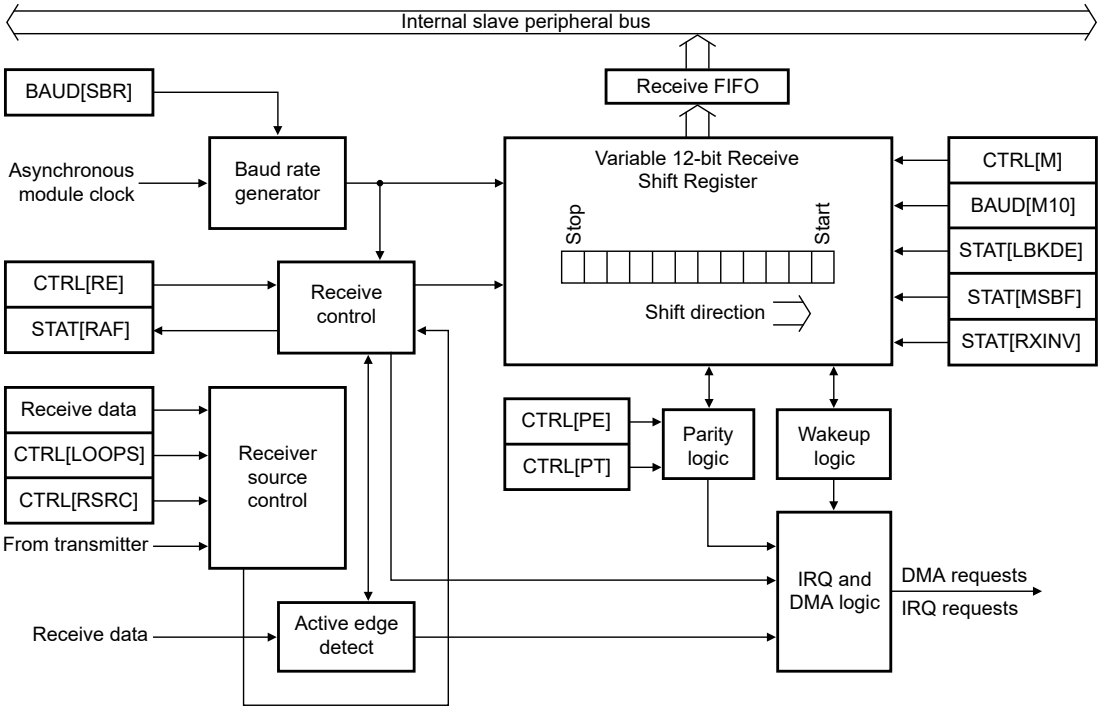

Figure 183. LPUART receiver block diagram

51.2.2 Features

- Full-duplex, standard NRZ format
- Programmable baud rates (13-bit modulo divider) with a configurable oversampling ratio (OSR) of 4× to 32×
- Asynchronous operations of transmit and receive baud rates with respect to the bus clock:
  - Baud rate can be configured independently of the bus clock frequency.
  - Operation in Low-Power modes is supported.
- Interrupt, DMA, or polled operations:
  - Transmit data empty and transmission complete
  - Receive data full
  - Receive overrun, parity error, framing error, and noise error
  - Idle receiver detect
  - Active edge on receive pin
  - Break detect supporting LIN
  - Receive data match
- Hardware parity generation and checking
- Programmable 7-bit, 8-bit, 9-bit, or 10-bit character length
- Programmable 1-bit or 2-bit stop bits
- Support for three receiver wakeup methods:
  - Idle line wakeup

  - Address mark wakeup
  - Receive data match
- Automatic address matching to reduce ISR overhead:
  - Address mark matching
  - Idle line address matching
  - Address match start, address match end
- Optional 13-bit and 11-bit break character generation
- Configurable idle length detection supporting 1, 2, 4, 8, 16, 32, 64, or 128 idle characters
- Selectable transmitter output and receiver input polarity
- Hardware flow control support for request to send (RTS) and clear to send (CTS) signals
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with a programmable pulse width
- Independent FIFO structure for transmit and receive functions:
  - Separate configurable watermarks for receive and transmit requests
  - Option for receiver to assert request after a configurable number of idle characters, if receive FIFO is not empty

51.3 Register definition

LPUART includes registers to control baud rate, select options, report status, and store transmit and receive data. Access to an address outside the valid memory map generates a bus error.

NOTE

Writing to a read-only (RO) register or reading a write-only (WO) register can cause bus errors. This module does not check if programmed values in the registers are correct; you must write valid values to them.

51.3.1 LPUART register descriptions

51.3.1.1 LPUART memory map

31 MAEN1	Match Address Mode Enable 1 Enables automatic address matching or data matching mode for MATCH[MA1]. If this field = 0, normal operation takes place. 0b - Disables 1b - Enables
30 MAEN2	Match Address Mode Enable 2 Enables automatic address matching or data matching mode for MATCH[MA2]. If this field = 0, normal operation takes place. 0b - Disables 1b - Enables
29 M10	10-Bit Mode Select Causes the tenth bit to be a part of the serial transmission. You must change the value of this field only when both the transmitter and receiver are disabled. 0b - Receiver and transmitter use 7-bit to 9-bit data characters 1b - Receiver and transmitter use 10-bit data characters
28-24 OSR	Oversampling Ratio (OSR) Configures the OSR of the receiver. You must change the value of this field only when both the transmitter and receiver are disabled. **NOTE** BAUD[OSR] in this bit field results an OSR of BAUD[OSR]+1, for example, BAUD[OSR] = 0_0101b results in final divide by 6. 0_0000b - Results in an OSR of 16 0_0001b - Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0_0010b - Reserved 0_0011b - Results in an OSR of 4 (requires BAUD[BOTHEDGE] to be 1) 0_0100b - Results in an OSR of 5 (requires BAUD[BOTHEDGE] to be 1) 0_0101b - Results in an OSR of 6 (requires BAUD[BOTHEDGE] to be 1) 0_0110b - Results in an OSR of 7 (requires BAUD[BOTHEDGE] to be 1) 0_0111b - Results in an OSR of 8 0_1000b - Results in an OSR of 9 0_1001b - Results in an OSR of 10 0_1010b - Results in an OSR of 11 0_1011b - Results in an OSR of 12 0_1100b - Results in an OSR of 13 0_1101b - Results in an OSR of 14 0_1110b - Results in an OSR of 15 0_1111b - Results in an OSR of 16 1_0000b - Results in an OSR of 17 1_0001b - Results in an OSR of 18 1_0010b - Results in an OSR of 19 1_0011b - Results in an OSR of 20 1_0100b - Results in an OSR of 21 1_0101b - Results in an OSR of 22 1_0110b - Results in an OSR of 23 1_0111b - Results in an OSR of 24 1_1000b - Results in an OSR of 25 1_1001b - Results in an OSR of 26 1_1010b - Results in an OSR of 27 1_1011b - Results in an OSR of 28 1_1100b - Results in an OSR of 29 1_1101b - Results in an OSR of 30 1_1110b - Results in an OSR of 31 1_1111b - Results in an OSR of 32
23 TDMAE	Transmitter DMA Enable Configures STAT[TDRE] to generate a DMA request. 0b - Disables DMA request

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enables DMA request
22 —	Reserved
21 RDMAE	Receiver Full DMA Enable Configures STAT[RDRF] to generate a DMA request. 0b - Disables DMA request 1b - Enables DMA request
20 RIDMAE	Receiver Idle DMA Enable Configures STAT[IDLE] to generate a DMA request. If the value of this field = 1, reading Data (DATA) when either DATA[RXEMPT] or DATA[IDLINE] is 1 generates an end-of-packet response until the completion of the DMA minor loop. During an end-of-packet response, reading Data (DATA) returns 0000_33FFh and does not pull data from the receive FIFO. STAT[IDLE] becomes 0 on completion of the minor loop, provided an end-of-packet response is generated and either the receive FIFO is empty or the receiver is active. 0b - DMA request disabled 1b - DMA request enabled
19-18 MATCFG	Match Configuration Configures the match addressing mode used. You must change the value of this field only when both the transmitter and receiver are disabled. 00b - Address match wakeup 01b - Idle match wakeup 10b - Match on and match off 11b - Enables RWU on data match and match on/off for the transmitter CTS input
17 BOTHEDGE	Both Edge Sampling Enables sampling of the received data on both edges of the baud rate clock, effectively doubling the number of times the receiver samples the input data for a given OSR. This field must be 1 for OSRs between x4 and x7 and is optional for higher OSRs. You must change the value of this field only when the receiver is disabled. 0b - Receiver samples input data using the rising edge of the baud rate clock 1b - Receiver samples input data using the rising and falling edges of the baud rate clock
16 RESYNCDIS	Resynchronization Disable Disables resynchronization of the received data word when a data one followed by data zero transition is detected. You must change the value of this field only when the receiver is disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Enables resynchronization 1b - Disables resynchronization
15 LBKDIE	LIN Break Detect Interrupt Enable Enables STAT[LBKDIF] to generate interrupt requests. 0b - Disables hardware interrupts from STAT[LBKDIF] (uses polling) 1b - Requests hardware interrupt when STAT[LBKDIF] is 1
14 RXEDGIE	RX Input Active Edge Interrupt Enable Enables STAT[RXEDGIF] to generate interrupt requests. Changing the value of CTRL[LOOPS] or CTRL[RSRC] when this field (RXEDGIE) is 1 can cause STAT[RXEDGIF] to become 1. 0b - Disables hardware interrupts from STAT[RXEDGIF] 1b - Requests hardware interrupts when STAT[RXEDGIF] is 1
13 SBNS	Stop Bit Number Select Determines whether data characters include one or two stop bits. You must change the value of this field only when both the transmitter and receiver are disabled. 0b - One stop bit 1b - Two stop bits
12-0 SBR	Baud Rate Modulo Divisor Sets the modulo divide rate for the baud rate generator. If SBR is 1 - 8191, baud rate = baud clock ÷ ((OSR + 1) × SBR). You must update the 13-bit baud rate setting [SBR12:SBR0] only when both the transmitter and receiver are disabled (both CTRL[RE] and CTRL[TE] are 0).

Fields

Field	Function
31 LBKDIF	LIN Break Detect Interrupt Flag Specifies whether a LIN break character is detected. This field becomes 1 when the LIN break detect circuitry is enabled and a LIN break character is detected. 0b - Not detected 1b - Detected
30 RXEDGIF	RXD Pin Active Edge Interrupt Flag Specifies whether an active edge on the receive pin has occurred. This field becomes 1 whenever the receiver is enabled and an active edge (falling if STAT[RXINV] = 0, rising if STAT[RXINV] = 1) on the RXD pin occurs. 0b - Not occurred 1b - Occurred
29 MSBF	MSB First Specifies the first bit that is transmitted after the start bit. If the value of this field = 0, LSB (bit 0) is the first bit transmitted after the start bit (which means, the first bit received after the start bit is identified as bit 0). If the value of this field = 1, MSB (identified as bit 9, bit 8, bit 7, or bit 6) is the first bit that is transmitted, after the start bit, depending on the settings of CTRL[M], CTRL[PE], and BAUD[M10]. Writing 1 to this field reverses the order of the bits that are transmitted and received on the wire. This field does not affect the polarity of the bits, the location of the parity bit, or the location of the start or stop bits. You must change the value of this field only when both the transmitter and receiver are disabled. 0b - LSB 1b - MSB
28	Receive Data Inversion

Table continues on the next page...

Table continued from the previous page...

Field	Function
RXINV	Specifies whether receive data is inverted. Writing 1 to this field reverses the polarity of the received data input. You must change the value of this field only when the receiver is disabled. **NOTE** Writing 1 to this field inverts the RXD input for all cases: data bits, start and stop bits, break, and idle. 0b - Inverted 1b - Not inverted
27 RWUID	Receive Wake Up Idle Detect Controls, for CTRL[RWU] on idle character detection, whether the idle character that wakes up the receiver writes 1 to STAT[IDLE]. For address match wakeup, this field controls whether STAT[IDLE] = 1 when the address does not match. You must change the value of this field only when the receiver is disabled. If the value of this field = 0, during the Receive Standby state (CTRL[RWU] = 1), STAT[IDLE] does not become 1 upon detection of an idle character. During address match wakeup, STAT[IDLE] does not become 1 when an address does not match. If the value of this field = 1, during the Receive Standby state (CTRL[RWU] = 1), STAT[IDLE] becomes 1 upon detection of an idle character. During address match wakeup, STAT[IDLE] becomes 1 when an address does not match. 0b - STAT[IDLE] does not become 1 1b - STAT[IDLE] becomes 1
26 BRK13	Break Character Generation Length Selects the longer transmitted break character length. The state of this field does not affect the detection of a framing error. You must change the value of this field only when the transmitter is disabled. You can send a break character by writing 1 to CTRL[SBK], or by writing the transmit FIFO when DATA[FRETSC] = 1 and DATA[R9T9] = 0. 0b - 9 to 13 bit times 1b - 12 to 15 bit times
25 LBKDE	LIN Break Detection Enable Enables LIN break detection. When the value of this field is 1, LIN break detect is enabled and the LIN break character is detected at a length of 11 bit times (if CTRL[M] = 0), 12 bit times (if CTRL[M] = 1), or 13 bit times (if BAUD[M10] = 1). When the value of this field is 0, LIN break detect is disabled, and only a normal break character can be detected. This field selects a longer break character detection length. While the field is 1, receive data is not stored in the receive FIFO.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field enables the LIN break detect circuit and disables writing receive data to FIFO. Therefore, it essentially ignores all characters except a LIN break. 0b - Disables 1b - Enables
24 RAF	Receiver Active Flag Specifies whether the LPUART receiver is idle or active. This field becomes 1 when the receiver detects the beginning of a valid start bit, and the field becomes 0 automatically when the receiver detects an idle line. 0b - Idle, waiting for a start bit 1b - Receiver active (RXD pin input not idle)
23 TDRE	Transmit Data Register Empty Flag Specifies whether the transmit FIFO level is greater than, equal to, or less than the watermark. After the transmit FIFO is enabled, this field becomes 1 when the number of datawords in the transmit FIFO is equal to, or less than the number that WATER[TXWATER] indicates. To make the value of this field 0, write to it until the number of words in the transmit FIFO is greater than the number that WATER[TXWATER] indicates. After the transmit FIFO is disabled, this field becomes 1 to indicate that the FIFO level is less than the watermark. To make the value of this field 0, write to Data (DATA). This register is not affected by a character that is in the process of being transmitted; it is updated at the start of each transmitted character. 0b - Greater than watermark 1b - Equal to or less than watermark
22 TC	Transmission Complete Flag Specifies whether the transmitter is active. This field becomes 0 when a transmission is in progress or a preamble or break character is loaded. The field becomes 1 when the transmit buffer is empty and no data, preamble, or break character is being transmitted. When this happens, the transmit data output signal becomes idle (logic 1). This field becomes 0 after you write to Data (DATA) to transmit new data, queuing a preamble by first writing 0 and then writing 1 to CTRL[TE], queuing a break character by writing 1 to CTRL[SBK]. 0b - Transmitter active (sending data, a preamble, or a break) 1b - Transmitter idle (transmission activity complete)
21 RDRF	Receive Data Register Full Flag Specifies whether the receive FIFO level is less than, equal to, or greater than the watermark. This field becomes 1 when the number of datawords in the receive buffer is greater than the number that WATER[RXWATER] indicates and the receive FIFO is enabled. To write 0 to this field, read Data (DATA) until the number of datawords in the receive FIFO is equal to, or less than the number that

Table continues on the next page...

Table continued from the previous page...

Field	Function
	WATER[RXWATER] indicates. When the receive FIFO is disabled, this field (RDRF) becomes 1 if the receive buffer (Data (DATA)) is full. To make this field 0, read Data (DATA). A character that is in the process of being received does not cause a change in this field until the entire character is received. Even if this field is 1, the character continues to be received until an overrun condition occurs after the entire character is received. 0b - Less than watermark 1b - Equal to or greater than watermark
20 IDLE	Idle Line Flag Specifies whether an idle line is detected. This field becomes 1 when the LPUART receive line becomes idle for a full character time after a period of activity. When CTRL[ILT] = 0, the receiver starts counting idle bit times after the start bit. If the receive character is all 1s, these bit times and the stop bit time count towards the full character time of logic high, 10 to 13 bit times, needed for the receiver to detect an idle line. After CTRL[ILT] becomes 1, the receiver does not start counting idle bit times until after the stop bits. The stop bits and any logic high bit times at the end of the previous character do not count towards the full character time of logic high needed for the receiver to detect an idle line. For this field to become 0, write 1 to it. After the field becomes 0, you cannot write 1 to it again until after a new character is stored in the receive buffer or a LIN break character writes 1 to STAT[LBKDIF]. This field becomes 1 only once, even if the receive line remains idle for an extended period. 0b - No idle line detected 1b - Idle line detected
19 OR	Receiver Overrun Flag Specifies whether there is receive overrun. This field becomes 1 when you cannot prevent STAT[RDRF] from overflowing with data. The field becomes 1 immediately after the stop bit is completely received for the dataword that overflows the buffer and all the other error fields (STAT[FE], STAT[NF], and STAT[PF]) are prevented from becoming 1. The data in the shift register is lost, but the data already in the LPUART data registers is not affected. If STAT[LBKDE] is enabled and a LIN break is detected, this field becomes 1 if STAT[LBKDIF] is not 0 before the next data character is received. When this field is 1, no additional data is stored in the receive FIFO even if sufficient room exists. 0b - No overrun 1b - Receive overrun (new LPUART data lost)
18 NF	Noise Flag (NF) Specifies whether noise is detected in the received character of Data (DATA). The advanced sampling technique used in the receiver takes three samples in each of the received bits. If any of these samples disagrees with the rest of the samples within any bit time in the frame, then noise is detected for that character. This field becomes 1 whenever the next character to be read from Data (DATA) is received with noise detected within the character.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No noise detected 1b - Noise detected
17 FE	Framing Error Flag (FE) Specifies whether a framing error is detected. This field becomes 1 whenever the next character to be read from Data (DATA) is received with logic 0 detected where a stop bit was expected. 0b - No framing error detected (this does not guarantee that the framing is correct) 1b - Framing error detected
16 PF	Parity Error Flag (PF) Specifies whether a parity error is detected. This field becomes 1 whenever the next character to be read from Data (DATA) received when parity is enabled (CTRL[PE] = 1) and the parity bit in the received character does not agree with the expected parity value. 0b - No parity error detected 1b - Parity error detected
15 MA1F	Match 1 Flag Specifies whether the received data is equal to MATCH[MA1]. This field becomes 1 whenever the next character to be read from Data (DATA) matches the value of MATCH[MA1]. 0b - Not equal to MA1 1b - Equal to MA1
14 MA2F	Match 2 Flag Specifies whether the received data is equal to MATCH[MA2]. This field becomes 1 whenever the next character to be read from Data (DATA) matches the value of MATCH[MA2]. 0b - Not equal to MA2 1b - Equal to MA2
13-10 —	Reserved
9-8 —	Reserved
7-2 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 AME	Address Mark Enable Configures the location of the address mark when configured for MSB first transfers. This field has no effect when configured for LSB first and you must change the value of this field only when both the transmitter and receiver are disabled. If the value of this field = 1, the address mark is stored in Data (DATA) at MSB (or MSB-1 when the parity bit is enabled). 0b - Address mark in character is MSB 1b - Address mark in character is the last bit before the stop bit (or parity bit when enabled)
0 LBKFE	LIN Break Flag Enable Enables the LIN break flag to assert whenever a LIN break character is detected. Unlike STAT[LBKDE], this does not impact data being stored in the receive data buffer, but does cause STAT[LBKDIF] to become 1 whenever a LIN break is detected. Because a LIN break is longer than a normal character, the LIN break triggers a write to STAT[RDRF] with the data fields as 0 and STAT[FE] = 1. The character following the LIN break has DATA[LINBRK] = 1 to indicate that the previous character was a LIN break. You must change the value of this field only when both the transmitter and receiver are disabled. If the value of this field = 1, the LIN break character is detected at a length of 11-bit times (if CTRL[M] = 0), 12 (if CTRL[M] = 1), or 13 (if BAUD[M10] = 1). 0b - Disables LIN break detect 1b - Enables LIN break detect

51.3.1.8 Control (CTRL)

Offset

Register	Offset
CTRL	18h

Function

Controls various optional features of the LPUART system.

You must write to the fields of this register only when both the transmitter and receiver are disabled.

Fields

Field	Function
31 R8T9	Receive Bit 8 Transmit Bit 9 Contains R8 and T9 that correspond to different functions. R8 is the ninth data bit received after you configure LPUART for 9-bit or 10-bit data formats. When reading 9-bit or 10-bit data, read R8 before reading Data (DATA). T9 is the tenth data bit transmitted after you configure LPUART for 10-bit data formats. When writing 10-bit data, write T9 before writing to Data (DATA). If T9 does not need to change from its previous value, such as when it is used to generate address mark or parity, then you need not write to it each time you write to Data (DATA). **NOTE** R8 is a read-only bit and T9 is a write-only bit; the value read is different from the value written.
30 R9T8	Receive Bit 9 Transmit Bit 8 Contains R9 and T8 that correspond to different functions. R9 is the tenth data bit received after you configure LPUART for 10-bit data formats. When reading 10-bit data, read R9 before reading Data (DATA). T8 is the ninth data bit transmitted after you configure LPUART for 9-bit or 10-bit data formats. When writing 9-bit or 10-bit data, write T8 before writing to Data (DATA). If T8 does not need to change from its previous value, such as when it is used to generate address mark or parity, then you need not write to it each time you write to Data (DATA). **NOTE** R9 is a read-only field and T8 is a write-only field; the value read is different from the value written.
29 TXDIR	TXD Pin Direction in Single-Wire Mode Determines the direction of data at the TXD pin when LPUART is configured for a single-wire half-duplex operation, (CTRL[LOOPS] = CTRL[RSRC] = 1). When writing 0 to this field, the transmitter finishes transmitting the current character (if any) before the receiver starts receiving data from the TXD pin.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - TXD pin is an input in Single-Wire mode 1b - TXD pin is an output in Single-Wire mode
28 TXINV	Transmit Data Inversion Specifies whether transmit data is inverted. Writing 1 to this field reverses the polarity of the transmitted data output. This action inverts the TXD output for all cases: data bits, start and stop bits, break, and idle. 0b - Not inverted 1b - Inverted
27 ORIE	Overrun Interrupt Enable Enables STAT[OR] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when OR interrupts are disabled. 0b - Disables 1b - Enables
26 NEIE	Noise Error Interrupt Enable Enables STAT[NF] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when NF interrupts are disabled. 0b - Disables 1b - Enables
25 FEIE	Framing Error Interrupt Enable Enables STAT[FE] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when FE interrupts are disabled. 0b - Disables 1b - Enables
24 PEIE	Parity Error Interrupt Enable Enables STAT[PF] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when PF interrupts are disabled. 0b - Disables 1b - Enables
23 TIE	Transmit Interrupt Enable Enables STAT[TDRE] to generate interrupt requests if STAT[TDRE] = 1. 0b - Disables 1b - Enables
22	Transmission Complete Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
TCIE	Enables STAT[TC] to generate interrupt requests if STAT[TC] = 1. 0b - Disables 1b - Enables
21 RIE	Receiver Interrupt Enable Enables STAT[RDRF] to generate hardware interrupt requests if STAT[RDRF] = 1. 0b - Disables 1b - Enables
20 ILIE	Idle Line Interrupt Enable Enables hardware interrupts. This field enables STAT[IDLE] to generate interrupt requests. 0b - Disables hardware interrupts from STAT[IDLE]; use polling 1b - Enables hardware interrupts when STAT[IDLE] = 1
19 TE	Transmitter Enable Enables the LPUART transmitter. Using this field, you can also queue an idle preamble by first writing 0 and then writing 1 to this field. After this field becomes 0, the field reads 1 until the transmitter has completed the current character and the TXD pin is tristated. You can also queue a single idle character by writing to the transmit FIFO with DATA[FRETSC] = 1 and DATA[R9T9] = 1. 0b - Disables 1b - Enables
18 RE	Receiver Enable Enables the LPUART receiver. After you write 0 to this field, this field becomes 1 until the receiver finishes receiving the current character (if any). 0b - Disables 1b - Enables
17 RWU	Receiver Wakeup Control Specifies whether the LPUART receiver in standby is waiting for a wakeup condition. You can write 1 to this field to place the LPUART receiver in a Standby state. The field becomes 0 automatically when an RWU event occurs, that is, in case of an idle event when CTRL[WAKE] = 0 or an address match when CTRL[WAKE] = 1 and STAT[RWUID] = 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE You must write 1 to this field only when CTRL[WAKE] = 0 (wakeup on idle), if the channel is currently not idle. You can determine this by the value of STAT[RAF]. If the field is 1 to wake up an idle event and the channel is already idle, LPUART, possibly, discards the data. This is because the data must be received or a LIN break is detected after an IDLE is detected before IDLE is allowed to be reasserted. 0b - Normal receiver operation 1b - LPUART receiver in standby, waiting for a wakeup condition
16 SBK	Send Break Specifies whether queue break character(s) are to be sent. Writing a 1 and then a 0 to this field queues a break character in the transmit data stream. Additional break characters of 9 to 13 bits, or 12 to 15 bits if STAT[BRK13] = 1, and bit times of logic 0 are queued as long as this field is 1. Depending on the timing when this field is 1 and 0, relative to the character currently being transmitted, a second break character may be queued before you write 0 to this field. If the time taken to write 0 to this field is too long, for example, if the field does not become 0 by the end of the first break character, a second break character is sent. This is compared to queuing a break character through the transmit FIFO that guarantees only one break character is sent. You can also queue a single break character by writing to the transmit FIFO when DATA[FRETSC] = 1 and DATA[R9T9] = 0. 0b - Normal transmitter operation 1b - Queue break character(s) to be sent
15 MA1IE	Match 1 (MA1F) Interrupt Enable Enables the MA1F interrupt. 0b - Disables 1b - Enables
14 MA2IE	Match 2 (MA2F) Interrupt Enable Enables the MA2F interrupt. 0b - Disables 1b - Enables
13-12 —	Reserved
11 M7	7-Bit Mode Select Specifies the data characters that the receiver and transmitter use. You must change the value of this field only after both the transmitter and receiver are disabled. 0b - 8-bit to 10-bit data characters

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - 7-bit data characters
10-8 IDLECFG	Idle Configuration Configures the number of idle characters that must be received before you write 1 to STAT[IDLE]. 000b - 1 001b - 2 010b - 4 011b - 8 100b - 16 101b - 32 110b - 64 111b - 128
7 LOOPS	Loop Mode Select Selects Loop mode. After this field becomes 1, the RXD pin is disconnected from LPUART and the transmitter output is internally connected to the receiver input. The transmitter and receiver must be enabled to use the loop function. In Loop mode or Single-Wire mode, the transmitter outputs are internally connected to the receiver input (see CTRL[RSRC]). 0b - Normal operation: RXD and TXD use separate pins 1b - Loop mode or Single-Wire mode
6 DOZEEN	Enables LPUART in Doze mode. If this field is 1, LPUART remains active when not in Doze mode. 0b - Enables 1b - Disables
5 RSRC	Receiver Source Select Determines the source of the receiver shift register input if CTRL[LOOPS] = 1. This field has no effect unless CTRL[LOOPS] = 1. If the value of this field is 0, internal Loopback mode is selected. LPUART does not use the RXD pin. If the value of this field is 1, single-wire LPUART mode is selected where the TXD pin is connected to the transmitter output and receiver input. 0b - Internal Loopback mode 1b - Single-wire mode
4 M	9-Bit Or 8-Bit Mode Select Specifies the mode that the receiver and transmitter use. 0b - 8-bit data characters

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - 9-bit data characters
3 WAKE	Receiver Wakeup Method Select Determines which condition wakes up LPUART when CTRL[RWU] = 1 and BAUD[MATCFG] = 0 (this field must be 1 when BAUD[MATCFG] = 11): • Address mark in the bit preceding the stop bit (or bit preceding the parity bit when parity is enabled) of the received data character • An idle condition on the receive pin input signal 0b - Configures CTRL[RWU] for idle-line wakeup 1b - Configures CTRL[RWU] with address-mark wakeup
2 ILT	Idle Line Type Select Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or the stop bit. If the count begins after the start bit, a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions. **NOTE** In case you write 1 to this field, a logic 0 is automatically shifted after a received stop bit, therefore resetting the idle count. 0b - After the start bit 1b - After the stop bit
1 PE	Parity Enable Enables hardware parity generation and checking. If parity is enabled, the bit immediately before the stop bit is treated as the parity bit. 0b - Disables 1b - Enables
0 PT	Parity Type Selects the type of parity, even or odd, if parity is enabled (CTRL[PE] = 1): • Odd parity means that the total number of logic 1 bits in the data character, including the parity bit, is odd. • Even parity means that the total number of 1s in the data character, including the parity bit, is even. 0b - Even parity 1b - Odd parity

51.3.1.9 Data (DATA)

Offset

Register	Offset
DATA	1Ch

Function

Supports 8-bit, 16-bit, or 32-bit writes, each type of write performing a separate function. An 8-bit write to DATA[7:0] pushes {CTRL[R8T9], CTRL[R9T8], DATA[7:0]} the transmit FIFO with TSC clear. A 16-bit or 32-bit write pushes the data written into the FIFO and does not update the value of CTRL[R8T9] or CTRL[R9T8].

Reads and writes of this register are also involved in the automatic flag clearing mechanisms for some of the LPUART status fields.

NOTE

Reads return the contents of the read-only receive FIFO and writes go to the write-only transmit FIFO, making this register work as a set of two separate registers.

Fields

Field	Function
31-16 —	Reserved
15 NOISY	Noisy Data Received Indicates whether the current received dataword contained in DATA[R9:R0] is received with noise. 0b - Received without noise 1b - Received with noise
14 PARITYE	Parity Error

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates whether the current received dataword contained in DATA[R9:R0] is received with a parity error. 0b - Received without a parity error 1b - Received with a parity error
13 FRETSC	Frame Error Transmit Special Character Indicates the way the dataword is received. For reads, this field indicates that the current received dataword contained in DATA[R9:R0] is received with a frame error. For writes, the field indicates that a break or idle character is to be transmitted instead of the contents in DATA[T9:T0]. T9 indicates a break character when it is 0 and indicates an idle character when it is 1. The contents of DATA[T8:T0] must be 0. 0b - Received without a frame error on reads or transmits a normal character on writes 1b - Received with a frame error on reads or transmits an idle or break character on writes
12 RXEMPT	Receive Buffer Empty Indicates whether the receive buffer contains valid data. This field becomes 1 when there is no data in the receive buffer. The field does not consider data in the receive shift register. 0b - Contains valid data 1b - Contains invalid data and is empty
11 IDLINE	Idle Line Indicates whether the receiver line was idle before receiving the character in DATA[9:0]. Unlike STAT[IDLE], you can write 1 to this field for the first character received when the receiver is first enabled. 0b - Received was not idle 1b - Receiver was idle
10 LINBRK	LIN Break Indicates whether the receiver line detected a LIN break before receiving the character in DATA[9:0]. This field requires the value of STAT[LBKDIF] to be 1. 0b - LIN break not detected or LIN break detect circuitry disabled 1b - LIN break detected
9 R9T9	Read Receive FIFO Bit 9 Or Write Transmit FIFO Bit 9
8 R8T8	Read Receive FIFO Bit 8 Or Write Transmit FIFO Bit 8
7	Read Receive FIFO Bit 7 Or Write Transmit FIFO Bit 7

Table continues on the next page...

Table continued from the previous page...

Field	Function
R7T7	
6 R6T6	Read Receive FIFO Bit 6 Or Write Transmit FIFO Bit 6

Fields

Field	Function
31-19 —	Reserved
18 IREN	IR Enable Enables IR modulation and demodulation. You must change the value of this field only when both the transmitter and receiver are disabled. 0b - Disables 1b - Enables
17-16 TNP	Transmitter Narrow Pulse Indicates whether LPUART transmits a 1 ÷ OSR, 2 ÷ OSR, 3 ÷ OSR, or 4 ÷ OSR narrow pulse when the IR pulse is enabled. You must change the value of this field only when both the transmitter and receiver are disabled. The IR pulse width must be configured to less than half of the OSR. Common pulse widths are 3 ÷ 16, 1 ÷ 16, 1 ÷ 32, or 1 ÷ 4 of the bit length. You can configure these by selecting the appropriate OSR and pulse width. 00b - 1 ÷ OSR 01b - 2 ÷ OSR 10b - 3 ÷ OSR 11b - 4 ÷ OSR
15-11 —	Reserved
10-8 RTSWATER	Receive RTS Configuration Configures the assertion and negation of the receiver's RTS_B output. The receiver's RTS_B output negates when the number of empty words in the receive FIFO is greater or equal to the value of this field. If this field is 0, the RTS_B pin negates when the receive FIFO is full. For the purpose of receive RTS_B generation, the number of words in the receive FIFO updates when a start bit is detected. This supports additional latency between RTS_B negation and the external transmitter ceasing transmission. If both receive RTS_B and address or data matching is enabled, RTS_B could assert at the end of a character if there exists no match. You must change the value of this field only when the receiver is disabled.
7-6 —	Reserved
5 TXCTSSRC	Transmit CTS Source Configures the source of the CTS input. 0b - The CTS_B pin 1b - An internal connection to the receiver address match result

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 TXCTSC	Transmit CTS Configuration Configures whether the CTS state or input is checked or sampled at the start of each character or only when the transmitter is idle. 0b - Sampled at the start of each character 1b - Sampled when the transmitter is idle
3 RXRTSE	Receiver RTS Enable Allows the RTS output to control the CTS input of the transmitting device to prevent receiver overrun. You must change the value of this field only when the receiver is disabled. If the value of this field = 0, the receiver has no effect on RTS. If the value of this field = 1, RTS is deasserted if STAT[RDRF] = 1 or a start bit is detected that causes STAT[RDRF] to become 1. RTS is asserted if STAT[RDRF] = 0 and has not detected a start bit that causes STAT[RDRF] to become 1. **NOTE** Do not write 1 to both MODIR[RXRTSE] and MODIR[TXRTSE]. 0b - Disables 1b - Enables
2 TXRTSPOL	Transmitter RTS Polarity Controls the polarity of the transmitter RTS. This field does not affect the polarity of the receiver RTS that remains negated in the active-low state unless MODIR[TXRTSE] = 1. You must change the value of this field only when the transmitter is disabled. 0b - Transmitter RTS is active low 1b - Transmitter RTS is active high
1 TXRTSE	Transmitter RTS Enable Controls the operation of RTS before and after a transmission. You must change the value of this field only when the transmitter is disabled. When the value of this field = 1, a character is placed into an empty transmit shift register. RTS asserts 1-bit time before the start bit is transmitted and deasserts 1-bit time after all characters in the transmitter FIFO and shift register are completely sent, including the last stop bit. If the value of this field = 0, the transmitter has no effect on RTS. 0b - Disables 1b - Enables
0 TXCTSE	Transmitter CTS Enable Enables the operation of the transmitter. You can write 1 to this field irrespective of the states of MODIR[TXRTSE] and MODIR[RXRTSE]. If the value of this field = 1, the transmitter checks the state of the CTS signal each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the signal TXD remains in the mark state and

Table continues on the next page...

Table continued from the previous page...

Field	Function
	transmission is delayed until CTS is asserted. Changes in CTS, when a character is being sent, do not affect its transmission. 0b - Disables 1b - Enables

51.3.1.12 FIFO (FIFO)

Offset

Register	Offset
FIFO	28h

Function

Provides you the ability to turn on and turn off the FIFO functionality.

This register also provides you the size of the FIFO that has been implemented. You can read this register at any time and must write to it only when CTRL[RE] and CTRL[TE] are 0 and the FIFO is empty.

Table continues on the next page...

Table continued from the previous page...

Field	Function
27-24 RXCOUNT	Receive Counter Indicates the number of datawords in the receive FIFO or buffer. If a dataword is being received in the receive shift register, it is not included in the count. This value may be used in conjunction with FIFO[RXFIFOSIZE] to calculate the room left in the receive FIFO or buffer.
23-19 —	Reserved
18-16 RXWATER	Receive Watermark Generates a DMA request if the number of datawords in the receive FIFO or buffer is greater than the value of this field. For proper operation, the value of this field must be less than the size of the receive FIFO or buffer, as indicated by FIFO[RXFIFOSIZE] and FIFO[RXFE].
15-12 —	Reserved
11-8 TXCOUNT	Transmit Counter Indicates the number of datawords in the transmit FIFO or buffer. If a dataword is being transmitted to the transmit shift register, it is not included in the count. This value may be used in conjunction with the value of FIFO[TXFIFOSIZE] to calculate the room left in the transmit FIFO or buffer.
7-3 —	Reserved
2-0 TXWATER	Transmit Watermark Generates a DMA request when the number of datawords in the transmit FIFO or buffer is equal to or less than the value of this field. For proper operation, the value of this field must be less than the size of the transmit buffer or FIFO, as indicated by FIFO[TXFIFOSIZE] and FIFO[TXFE].

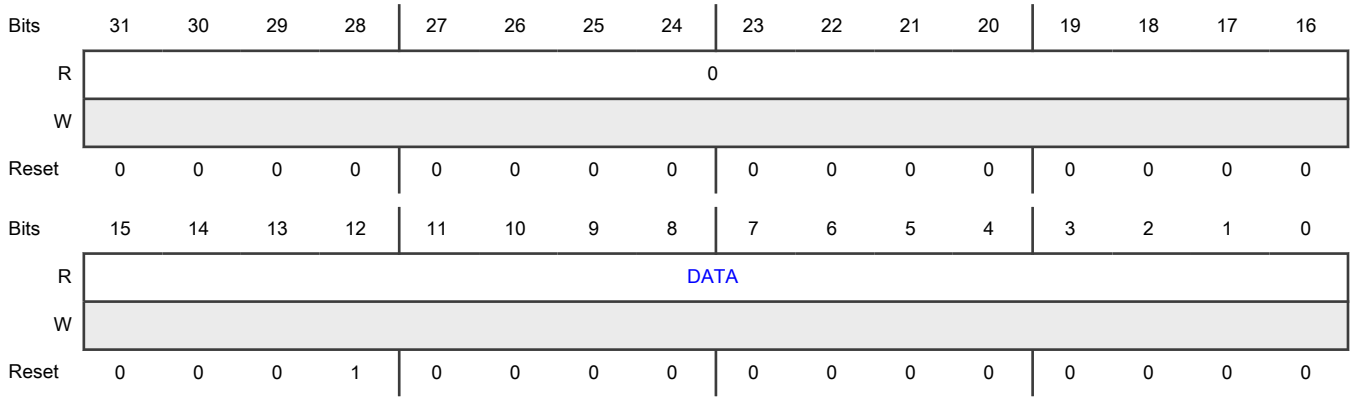
51.3.1.14 Data Read-Only (DATARO)

Offset

Register	Offset
DATARO	30h

Function
Returns the first entry in the receive FIFO, but does not pull data from the FIFO.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 DATA	Receive Data Returns the first entry from the receive FIFO. This register has the same functionality as that of Data (DATA).

51.4 Functional description

LPUART supports full-duplex, asynchronous, NRZ serial communication and comprises a baud rate generator, transmitter, and receiver block. The transmitter and receiver operate independently, although they use the same baud rate generator. The following sections describe all LPUART blocks.

51.4.1 Low-Power modes

LPUART remains functional during Low-Power modes, provided CTRL[DOZEEN] = 0 and the LPUART functional clock is enabled. LPUART can generate an interrupt or DMA request to cause a wakeup from Low-Power modes.

You can configure LPUART to be disabled in Low-Power modes, when CTRL[DOZEEN] = 1. In this case, the transmitter and receiver finish transmitting and receiving the current word.

If LPUART is disabled in Low-Power modes, it can generate a wakeup via STAT[RXEDGIF] if the receiver detects an active edge.

NOTE

See the chip-specific information for specific Low-Power modes available on your chip.

51.4.2 Debug mode

LPUART remains functional in Debug mode.

51.4.3 Baud rate generation

A 13-bit modulus counter in the baud rate generator derives the baud rate for both the receiver and transmitter. The value, ranging from 1 to 8191, written to BAUD[SBR] determines the baud clock divisor for the asynchronous LPUART baud clock. The baud rate clock drives the receiver, while a bit clock, generated from the baud rate clock divided by the OSR, drives the transmitter. Depending on the OSR, the receiver has an acquisition rate of 4 to 32 samples per bit time.

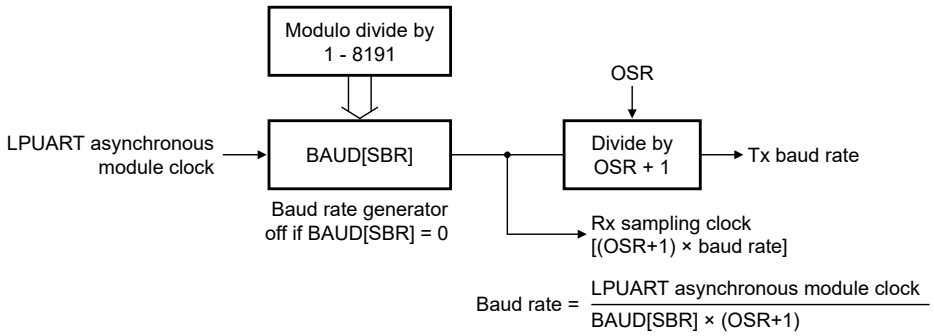


Figure 184. Baud rate generation

Baud rate generation is subject to two sources of error:

- Integer division of the asynchronous LPUART baud clock may not give the exact target frequency.
- Synchronization with the asynchronous LPUART baud clock can lead to a phase shift.

Baud rate generation is a free-running counter that continues whenever the transmitter or receiver is enabled. The transmitter bit clock continues whenever the transmitter is enabled; each transmitted character aligns to the next edge of the transmit bit clock.

In general, configuring OSR for a higher ratio and/or sampling on both edges of the clock slightly improves LPUART's tolerance to baud rate mismatch between the received data and LPUART configured baud rate. However, the three data samples in each bit are also closer together, which may impact noise sensitivity.

51.4.4 Transmitter functional description

This section discusses the functioning of the LPUART transmitter, as shown in the transmitter portion of Block diagram, as well as specialized functions for sending break and idle characters.

The transmitter output (TXD) idle state defaults to logic high; the transmitter output is inverted when you write 1 to CTRL[TXINV], which becomes 0 following reset. You can enable the transmitter by writing 1 to CTRL[TE]. This queues a preamble character that is one full character frame of the idle state. The transmitter then remains idle until data is available in the transmit FIFO. Programs store data in the transmit FIFO by writing to Data (DATA).

The central element of the LPUART transmitter is the transmit shift register that is 9-bit to 13-bit long depending on the settings of CTRL[M], CTRL[M7], BAUD[M10], and BAUD[SBNS]. Going forward in this discussion, assume that CTRL[M], CTRL[M7], BAUD[M10], and BAUD[SBNS] are 0, selecting the normal 8-bit Data mode, in which the shift register holds a start bit, eight data bits, and a stop bit. When the transmit shift register is available for a new character, the value waiting in STAT[TDRE] is transferred to the transmit shift register, synchronized with the baud rate clock, and STAT[TDRE] becomes 1 to indicate that another character may be written to the transmit FIFO at Data (DATA).

If no new character is waiting in the transmit FIFO after a stop bit is shifted out of the TXD pin, the transmitter sets the transmit complete flag and enters an idle mode, with TXD high, waiting for more characters to transmit.

Writing 0 to CTRL[TE] does not immediately disable the transmitter. The current transmit activity in progress must first be completed (that could include a data character, idle character, or break character), although the transmitter does not start transmitting another character.

51.4.4.1 Send break and queued idle

CTRL[SBK] sends break characters, originally used to gain the attention of old teletype receivers. Break characters are a full character time of logic 0, 9-bit to 12-bit times, including the start and stop bits. You can enable a longer break of 13-bit times by writing 1 to STAT[BRK13]. Normally, a program waits for STAT[TDRE] to become 1 to indicate that the last character of a message has moved to the transmit shifter. Next, the program writes 1 and then writes 0 to CTRL[SBK]. This action queues a break character to be sent as soon as the shifter is available. If CTRL[SBK] remains 1 when the queued break moves into the shifter,

synchronized with the baud rate clock, an additional break character is queued. When LPUART is the receiving module, it receives a break character as 0s in all data bits and a framing error (STAT[FE] = 1) is detected.

You can also transmit a break character by writing to Data (DATA) with DATA[FRETSC] = 1 and the data bits clear. This supports transmitting the break character as part of the normal data stream and also allows DMA to transmit a break character.

When idle-line wakeup is used, a full character time of idle (logic 1) is needed between messages to wake up any sleeping receivers. Normally, a program waits for STAT[TDRE] to become 1 to indicate that the last character of a message has moved to the transmit shifter. Next, the program writes 0 and then writes 1 to CTRL[TE]. This action queues an idle character to be sent as soon as the shifter is available. As long as the character in the shifter does not finish while CTRL[TE] becomes 0, the LPUART transmitter does not release control of the TXD pin.

You can also write to Data (DATA) to transmit an idle character, with DATA[FRETSC] and DATA[R9T9] = 1 and the values of all the other fields = 0. This supports transmitting the idle character as part of the normal data stream and also allows DMA to transmit an idle character.

As shown in the following table, STAT[BRK13], CTRL[M], CTRL[M7], BAUD[M10], and BAUD[SBNS] affect the length of the break character.

Table 313. Break character length

STAT[BRK13]	CTRL[M]	BAUD[M10]	CTRL[M7]	BAUD[SBNS]	Break character length (in bit times)

1	1	0	—	0	14
1	1	0	—	1	14
1	—	1	—	0	15
1	—	1	—	1	15

51.4.4.2 Hardware flow control

The transmitter supports hardware flow control by gating the transmission with the value of CTS_B. If the CTS operation is enabled, the character is transmitted when CTS_B is asserted. If CTS_B is deasserted in the middle of a transmission with characters remaining in the transmitter FIFO, the character in the transmit shift register is complete. Any characters in the FIFO wait for CTS_B to assert again, and TXD remains in the mark state (idle state) until CTS_B is reasserted. The CTS_B pin must assert for longer than one bit period to guarantee that a new transmission is started when the transmitter is idle with DTS.

If the CTS operation is disabled, the transmitter ignores the state of CTS_B.

The transmitter's CTS_B signal can be enabled even if the same LPUART receiver's RTS_B signal is disabled.

51.4.4.3 Transceiver driver enable

The transmitter can use RTS_B as an enable signal for the driver of an external transceiver. See Transceiver driver enable using RTS_B for details. If the RTS operation is enabled, when a character is placed into an empty transmit shift register, RTS_B asserts 1-bit time before the start bit is transmitted. RTS_B remains asserted for the whole time that the transmit shift register has any characters. RTS_B deasserts 1-bit time after all characters in the transmit FIFO and shift register are completely sent, including the last stop bit. In other words, when RTS_B is used as a transceiver enable, RTS_B asserts 1-bit time before the transmitter starts transmitting and negates 1-bit time after the transmitter goes idle.

Transmitting a break character also asserts RTS_B, with the same assertion and deassertion timing as having a character in the transmit shift register.

The transmitter's RTS_B signal asserts only when the transmitter is enabled. However, the transmitter's RTS_B signal is unaffected by its CTS_B signal. RTS_B remains asserted until the transfer is complete, even if the transmitter is disabled mid-way through a data transfer.

51.4.4.4 Transceiver driver enable using RTS_B

RS-485 is a multiple drop communication protocol in which the LPUART transceiver's driver is three-stated unless the LPUART is driving. The transmitter can use the RTS_B signal to enable the driver of a transceiver. The polarity of RTS_B can be matched to the polarity of the transceiver's driver enable signal.

In the following figure, the receiver enable signal is asserted. Another option for this connection is to connect RTS_B to both DE and RE_B. The transceiver's receiver is disabled while driving. A pullup can pull RXD to a non-floating value during this time. You can refine this option further by operating LPUART in Single-Wire mode, freeing the RXD pin for other uses.

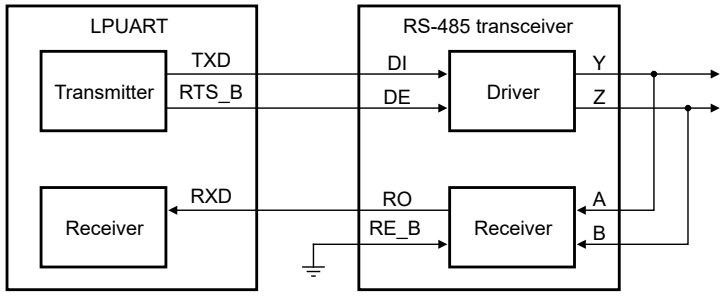

Figure 185. Transceiver driver enable using RTS_B

51.4.5 Receiver functional description

This section discusses the functioning of the LPUART receiver, as shown in the receiver portion of Block diagram. The section also discusses:

- The data sampling technique used to reconstruct receiver data
- Different variations of the receiver wakeup function

You can invert the receiver input by writing 1 to STAT[RXINV] and enable the receiver by writing 1 to CTRL[RE]. Character frames consist of a start bit of logic 0, sever to 10 data bits (MSB or LSB first), and one or two stop bits of logic 1. For information about 7-bit, 9-bit, or 10-bit Data mode, see Data modes. Going forward in this discussion, assume that LPUART is configured for a normal 8-bit Data mode.

After receiving the stop bit into the receive shifter, and provided STAT[RDRF] = 0, the data character is transferred to STAT[RDRF] resulting into its value becoming 1. However, if STAT[RDRF] is already 1, indicating that the receive data buffer is already full, STAT[OR] becomes 1 and the new data is lost.

Because the LPUART receiver is separate from the receive FIFO, the receive shift register can receive the next word when the receive FIFO is full, and it is only at the end of the character that the next data is written into the receive FIFO, potentially triggering the overrun flag if the FIFO is full.

When a program detects that STAT[RDRF] = 1, it gets the data from STAT[RDRF] by reading Data (DATA). See Interrupts and status fields for details about flag clearing.

51.4.5.1 Data sampling technique

The LPUART receiver supports a configurable oversampling rate of between 4× and 32× of the baud rate clock for sampling. The receiver starts by considering logic level samples at the oversampling rate times the baud rate to search for a falling edge on the RXD serial data input pin. A falling edge is defined as a logic 0 sample after three consecutive logic 1 samples. The oversampling baud rate clock divides the bit time into 4 to 32 segments from 1 to OSR (where OSR is the configured oversampling ratio). When a falling edge is located, three more samples are taken at (OSR ÷ 2), (OSR ÷ 2) + 1, and (OSR ÷ 2) + 2 to ensure that this is a real start bit and not merely noise. If at least two of these three samples are 0, the receiver assumes it is synchronized to a received character. If another falling edge is detected before the receiver is considered synchronized, the receiver restarts sampling from the first segment.

The receiver then samples each bit time, including the start and stop bits, at (OSR ÷ 2), (OSR ÷ 2) + 1, and (OSR ÷ 2) + 2, to determine the logic level for that bit. The logic level is interpreted to be that of the majority of the samples taken during the bit time. If any sample in any bit time, including the start and stop bits, in a character frame fails to agree with the logic level for that bit, STAT[NF] becomes 1 when the received character is transferred to the receive FIFO.

When the LPUART receiver is configured to sample on both edges of the baud rate clock (that is, when BAUD[BOTHEDGE] = 1), the number of segments in each received bit is effectively doubled (from 1 to OSR× 2). The start and data bits are then sampled at OSR, OSR + 1, and OSR + 2. You must enable sampling on both edges of the clock for oversampling rates of 4× to 7×. This sampling is optional for higher oversampling rates.

The synchronization feature of LPUART synchronizes the internal oversampling counter with a detected falling edge on the receive signal, and to adjust the data sampling window. The falling edge detection needs three consecutive 1s prior to the 1->0 transition. After the initial falling edge detection for the start bit, the circuit continuously monitors the next falling edge, and resets the counter after another falling edge is detected. This is called resynchronization.

When BAUD[RESYNCDIS] = 0, you perform this falling edge detection and resynchronization not only for the start bit but also for the rest of the character reception after the start bit.

When BAUD[RESYNCDIS] = 1, you perform the falling edge detection and resynchronization only for the start bit. The use case for disabling the resynchronization is protocols that require this (for example, LIN 2.1 prohibits resynchronization within a byte).

The following table and figure explain LPUART resynchronization.

Table 314. LPUART resynchronization settings

Resynchronization	BAUD[RESYNCDIS] = 0	BAUD[RESYNCDIS] = 1
For the starting bit falling edge	Yes	Yes
For all falling edges after the start bit	Yes	No

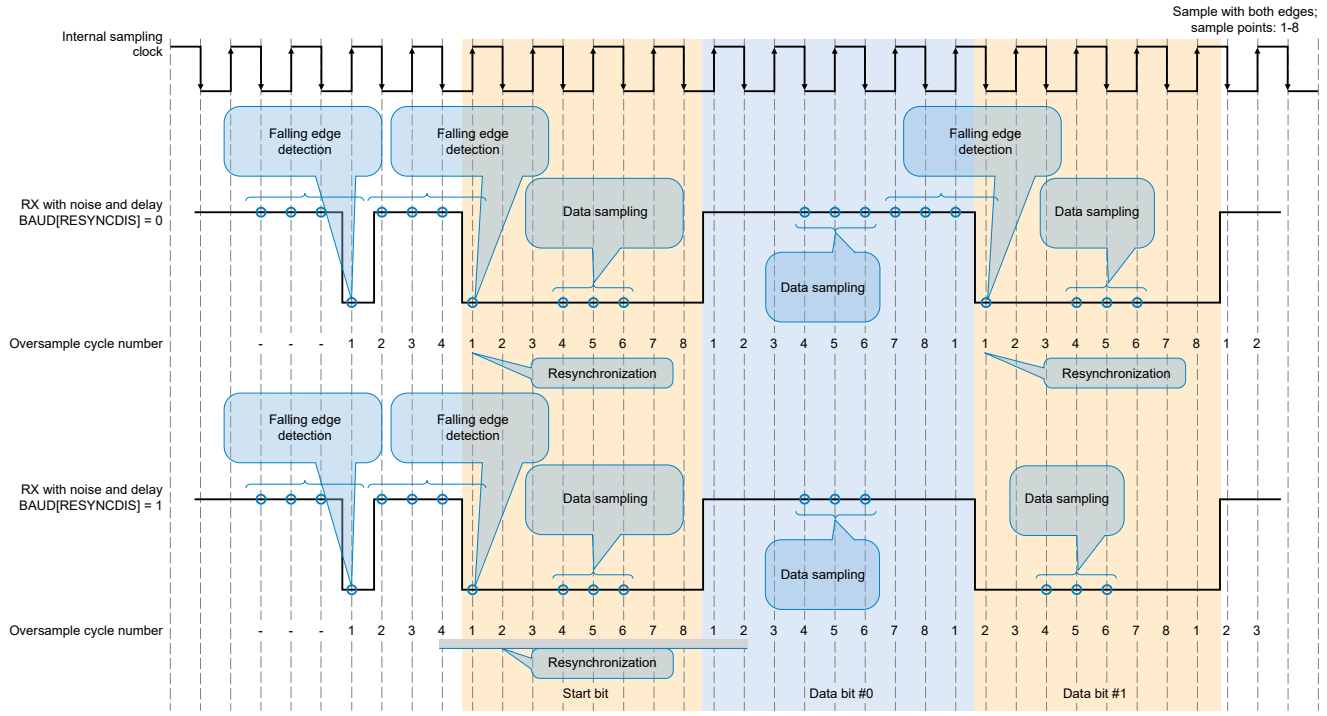

Figure 186. LPUART resynchronization diagram

51.4.5.2 Receiver wakeup operation

Receiver wakeup and receiver address matching are hardware mechanisms that allow an LPUART receiver to ignore the characters in a message intended for a different receiver.

During receiver wakeup, all receivers evaluate the first character(s) of each message, and as soon as they determine the message is intended for a different receiver, they write 1 to CTRL[RWU].

When CTRL[RWU] and STAT[RWUID] are 1, the status fields associated with the receiver, with the exception of STAT[IDLE], are inhibited from becoming 1, thus eliminating the software overhead for handling the unimportant message characters. At the end of a message, all receivers automatically force CTRL[RWU] to become 0. This results in all receivers waking up in time to look at the first character(s) of the next message.

During receiver address matching, the address matching is performed in hardware and the LPUART receiver ignores all characters that do not meet the address match requirements.

Table 315. Receiver wakeup options

CTRL[RWU]	BAUD[MAEN1] | BAUD[MAEN2]	BAUD[MATCFG]	CTRL[WAKE]: STAT[RWUID]	Receiver wakeup
0	0	X	X	Normal operation
1	0	00	00	Receiver wakeup on idle line, STAT[IDLE] = 0
1	0	00	01	Receiver wakeup on idle line, STAT[IDLE] = 1

Table continues on the next page...

Table 315. Receiver wakeup options (continued)

CTRL[RWU]	BAUD[MAEN1] | BAUD[MAEN2]	BAUD[MATCFG]	CTRL[WAKE]: STAT[RWUID]	Receiver wakeup
1	0	00	10	Receiver wakeup on address mark
1	1	11	10	Receiver wakeup on data match
0	1	00	X0	Address mark address match, STAT[IDLE] = 0 for discarded characters
0	1	00	X1	Address mark address match, STAT[IDLE] = 1 for discarded characters
0	1	01	X0	Idle line address match
0	1	10	X0	Match on and match off, STAT[IDLE] = 0 for discarded characters
0	1	10	X1	Match on and match off, STAT[IDLE] = 1 for discarded characters

51.4.5.2.1 Idle-line wakeup

When CTRL[WAKE] = 0, you can configure the receiver for an idle-line wakeup. In this mode, CTRL[RWU] becomes 0 automatically when the receiver detects a full character time of the idle-line level.

CTRL[M], CTRL[M7], and BAUD[M10] select 7-bit to 10-bit Data mode and BAUD[SBNS] selects a 1-bit or 2-bit stop bit number that determines how many bit times of idle are needed to constitute a full character time, 9 to 13 bit times because of the start and stop bits.

When CTRL[RWU] = 1 and STAT[RWUID] = 0, the idle condition that wakes up the receiver does not lead to STAT[IDLE] becoming 1. The receiver wakes up and waits for the first data character of the next message that leads to STAT[RDRF] becoming 1 and generates an interrupt if enabled. When STAT[RWUID] = 1, any idle condition leads to STAT[IDLE] becoming 1 and generates an interrupt if enabled, regardless of whether CTRL[RWU] is 0 or 1.

The following are ways to detect an idle line:

- When CTRL[ILT] = 0, the idle bit counter starts after the start bit so that the stop bit and any logic 1s at the end of a character count to calculate the full character time of idle.
- When CTRL[ILT] = 1, the idle bit counter does not start until after the stop bit time so that the data in the last character of the previous message does not impact the idle detection.

51.4.5.2.2 Address-mark wakeup

When CTRL[WAKE] = 1, you can configure the receiver for an address-mark wakeup. In this mode, CTRL[RWU] becomes 0 automatically when the receiver detects a logic 1 in the most significant bit of the received character. When parity is enabled, the second most significant bit is used for address-mark wakeup.

Address-mark wakeup allows messages to contain idle characters, but requires one bit to be reserved for use in address frames. The logic 1 in the most significant bit (or second most significant bit when parity is enabled) of an address frame writes 0 to

CTRL[RWU] and writes 1 to STAT[RDRF]. In this case, the character with the address-mark bit is received even if the receiver is sleeping during most of this character time.

51.4.5.2.3 Data-match wakeup

When CTRL[RWU] and CTRL[WAKE] are 1, and BAUD[MATCFG] equals 11, the receiver is configured for a data-match wakeup. In this mode, CTRL[RWU] becomes 0 automatically when the receiver detects a character that matches MATCH[MA1] when BAUD[MAEN1] = 1, or that matches MATCH[MA2] when BAUD[MAEN2] = 1.

51.4.5.2.4 Address match operation

You can enable the address match operation when either BAUD[MAEN1] or BAUD[MAEN2] = 1 and BAUD[MATCFG] = 0. In this function, a character that the RXD pin receives with a logic 1 in the most significant bit (or second most significant bit when parity is enabled) is considered an address and is compared to the associated MATCH[MA1] or MATCH[MA2] field. The character is only transferred to the receive buffer, and STAT[RDRF] becomes 1, if the comparison matches. All subsequent characters received with a logic 0 in the most significant bit (or second most significant bit when parity is enabled) are considered to be data associated with the address and are transferred to the receive FIFO. If no marked address match occurs, no transfer is made to the receive FIFO, and all the characters that follow, with logic 0 in the most significant bit (or second most significant bit when parity is enabled), are also discarded. If both BAUD[MAEN1] and BAUD[MAEN2] are 0, the receiver operates normally, and all the received data is transferred to the receive FIFO.

The address match operation functions in the same way for both MATCH[MA1] and MATCH[MA2]:

- If either BAUD[MAEN1] or BAUD[MAEN2] is 1, a marked address is compared only to the associated Match Address (MATCH) field and data is transferred to the receive FIFO only on a match.
- If both BAUD[MAEN1] and BAUD[MAEN2] are 1, a marked address is compared to both MATCH[MA1] and MATCH[MA2] and data is transferred only on a match with either of these fields.

51.4.5.2.5 Idle match operation

You can enable the idle match operation when either BAUD[MAEN1] or BAUD[MAEN2] = 1 and BAUD[MATCFG] = 1. In this function, the first character that the RXD pin receives after an idle line condition is considered an address and is compared to the associated MATCH[MA1] or MATCH[MA2] field. The character is transferred only to the receive buffer, and STAT[RDRF] becomes 1, if the comparison matches. All subsequent characters are considered to be data associated with the address and are transferred to the receive FIFO until the next idle line condition is detected. If no address match occurs, no transfer is made to the receive FIFO, and all the frames that follow, until the next idle condition, are also discarded. If both BAUD[MAEN1] and BAUD[MAEN2] are 0, the receiver operates normally, and all the received data is transferred to the receive FIFO.

An idle match operation functions in the same way for both MATCH[MA1] and MATCH[MA2]:

- If either BAUD[MAEN1] or BAUD[MAEN2] is 1, the first character after an idle line is compared only to the associated Data (DATA) field and data is transferred to the receive FIFO only on a match.
- If both BAUD[MAEN1] and BAUD[MAEN2] are 1, the first character after an idle line is compared to both MATCH[MA1] and MATCH[MA2] and data is transferred only on a match with either of these fields.

51.4.5.2.6 Match on, match off operation

The match on, match off operation is enabled when both BAUD[MAEN1] and BAUD[MAEN2] are 1 and BAUD[MATCFG] = 10. In this function, a character that the RXD pin receives matches MATCH[MA1] and is transferred to the receive buffer, and STAT[RDRF] becomes 1. All subsequent characters are considered to be data and are also transferred to the receive FIFO, until a character that matches MATCH[MA2] is received. The character that matches MATCH[MA2], along with all subsequent characters, is discarded; and this continues until another character that matches MATCH[MA1] is received. If both BAUD[MAEN1] and BAUD[MAEN2] are 0, the receiver operates normally, and all the received data is transferred to the receive FIFO.

NOTE

The match on, match off operation requires both BAUD[MAEN1] and BAUD[MAEN2] to be 1.

51.4.5.3 Hardware flow control

To support hardware flow control, you can program the receiver to automatically assert and deassert RTS_B:

- RTS_B remains asserted until the transfer is complete, even if the transmitter is disabled midway through a data transfer. See Transceiver driver enable using RTS_B for more information.
- If the receiver RTS functionality is enabled, the receiver automatically deasserts RTS_B if STAT[RDRF] = 1 or a start bit is detected that causes STAT[RDRF] to become 1.
- The receiver asserts RTS_B when STAT[RDRF] = 0 and has not detected a start bit that causes STAT[RDRF] to become 1. There is no impact if STAT[RDRF] = 1 already.
- Even if RTS_B is deasserted, the receiver continues to receive characters until the receive FIFO is overrun.
- If the receiver RTS functionality is disabled, the receiver's RTS_B remains deasserted.

51.4.6 Additional LPUART functions

51.4.6.1 Data modes

The LPUART transmitter and receiver can be configured to operate in 7-bit Data mode by writing 1 to CTRL[M7], 9-bit Data mode by writing 1 to CTRL[M], or 10-bit Data mode by writing 1 to BAUD[M10]. In 9-bit Data mode, there exists a ninth data bit and in 10-bit mode, there exists a tenth data bit.

When performing 8-bit writes to the transmit FIFO, the ninth and tenth bits are pushed into the FIFO from CTRL[T8] and CTRL[T9]. For coherent 8-bit writes, you must write to CTRL[T8] and CTRL[T9] before writing to Data (DATA)[7:0]. However, if the values in CTRL[T8] or CTRL[T9] do not need to change, it is not necessary to update CTRL[T8] and CTRL[T9] before every 8-bit write to Data (DATA).

When performing 16-bit or 32-bit writes to the transmit FIFO, all 10 bits are pushed into the transmit FIFO from the write data.

When performing 8-bit reads of the receive FIFO, the ninth and tenth bits are held in CTRL[R8] and CTRL[R9] but should be read before reading Data (DATA). A 16-bit or 32-bit read of the receive FIFO returns all 10 bits in Data (DATA).

The 9-bit Data mode is typically used with parity to allow eight bits of data plus the parity in the ninth bit, or it is used with the address-mark wakeup so that the ninth data bit can serve as the wakeup bit. The 10-bit Data mode is typically used with parity and address-mark wakeup so that the ninth data bit can serve as the wakeup bit and the tenth bit can serve as the parity bit. In custom protocols, the ninth and/or tenth bits can also serve as software-controlled markers.

51.4.6.2 Idle length

An idle character is one where the start bit, all data bits, and stop bits are in the mark position (idle state, generally logic 1). You can configure CTRL[ILT] to start detecting an idle character from the previous start bit (any data bits and stop bits count for idle character detection) or from the previous stop bit.

You can also use CTRL[IDLECFG] to configure the number of idle characters that must be received before an idle line condition is detected. This field configures the number of idle characters that must be received before STAT[IDLE] becomes 1, STAT[RAF] becomes 0, and DATA[IDLINE] becomes 1 with the next received character.

CTRL[IDLECFG] also affects the idle-line wakeup and idle match operations. When either the address match or match on/off operation is enabled, writing 1 to STAT[RWUID] causes any discarded characters to be treated as idle characters.

51.4.6.3 Loop mode

When CTRL[LOOPS] = 1, CTRL[RSRC] selects between Loop mode (CTRL[RSRC] = 0) or Single-Wire mode (CTRL[RSRC] = 1). You, sometimes, use Loop mode to check software, independent of connections in the external system, to help isolate system problems. In this mode, the transmitter output is internally connected to the receiver input and LPUART does not use the RXD pin.

51.4.6.4 Single-Wire mode

When CTRL[LOOPS] = 1, CTRL[RSRC] selects either Loop mode (CTRL[RSRC] = 0) or Single-Wire mode (CTRL[RSRC] = 1). Single-Wire mode implements a half-duplex serial connection. The receiver is internally connected to the transmitter output and to the TXD pin (the RXD pin is not used).

In Single-Wire mode, CTRL[TXDIR] controls the direction of serial data on the TXD pin. When CTRL[TXDIR] becomes 0, the TXD pin is an input to the receiver and the transmitter is temporarily disconnected from the TXD pin so that an external device can send serial data to the receiver. When CTRL[TXDIR] = 1, the TXD pin is an output that the transmitter drives. The internal loop back connection is disabled, and as a result, the receiver is unable to receive characters that the transmitter sends out.

51.4.7 Infrared (IR) interface

LPUART provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses, transforming them to serial bits, which are then sent to LPUART. The IrDA physical layer specification defines a half-duplex IR communication link for exchanging data. The full standard includes data rates up to 16 Mbit/s. The LPUART IrDA support is limited to SIR mode that supports data rates only between 2.4 kbit/s and 115.2 kbit/s.

LPUART has an infrared transmit encoder and a receive decoder. The infrared decoder converts the received character from the IrDA format to the NRZ format, which the receiver uses. It also has an OSR oversampling baud rate clock counter that filters noise and indicates when a 1 is received. LPUART transmits serial bits of data, which the infrared submodule encodes, to transmit a narrow pulse for every zero bit. No pulse is transmitted for every single bit. When receiving data, an IR photo diode (external to LPUART) detects the IR pulses. The IR receive decoder transforms them to CMOS levels. The infrared receive decoder then stretches the narrow pulses to get back to a serial bit stream that LPUART receives. You can invert the polarity of transmitted pulses and expected receive pulses so that a direct connection can be made to external IrDA transceiver modules that use active-high pulses.

The IR submodule receives its clock sources from LPUART. The submodule selects one of these clocks to generate either 1 ÷ OSR, 2 ÷ OSR, 3 ÷ OSR, or 4 ÷ OSR narrow pulses during transmission.

51.4.7.1 Infrared transmit encoder

The infrared transmit encoder converts serial bits of data from the transmit shift register to the TXD signal. A narrow pulse is transmitted for a 0 bit and no pulse is transmitted for a 1 bit. The narrow pulse is sent at the start of the bit with a duration of 1 ÷ OSR, 2 ÷ OSR, 3 ÷ OSR, or 4 ÷ OSR of a bit time. A narrow low pulse is transmitted for a 0 bit when CTRL[TXINV] = 0, while a narrow high pulse is transmitted for a 0 bit when CTRL[TXINV] = 1.

51.4.7.2 Infrared receive decoder

The infrared receive block converts data from the RXD signal to the receive shift register. A narrow pulse is expected for each 0 received and no pulse is expected for each 1 received. A narrow low pulse is expected for a 0 bit when STAT[RXINV] = 0, while a narrow high pulse is expected for a 0 bit when STAT[RXINV] = 1. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared physical layer specification.

51.4.7.3 Start bit detection

When STAT[RXINV] = 0, the first falling edge of the received character corresponds to the start bit. The infrared decoder resets its counter. At this time, the receiver also begins its start bit detection process. After the start bit is detected, the receiver synchronizes its bit times to this start bit time. For the rest of the character reception, the infrared decoder's counter and the receiver's bit time counter count independently of each other.

51.4.7.4 Noise filtering

The decoder ignores any rising edges detected during the first half of the infrared decoder counter, and can leave any pulses less than one oversampling baud clock as undetected. This is regardless of whether the pulse is seen in the first or second half of the count.

51.4.7.5 Low-bit detection

During the second half of the decoder count, a rising edge is decoded as 0, which is sent to the receiver. The decoder counter is also reset.

51.4.7.6 High-bit detection

At OSR oversampling baud rate clocks after the previous rising edge, if a rising edge is not seen, the decoder sends a 1 to the receiver.

If the next bit is 0, which arrives late, a low bit is detected according to Low-bit detection. The value sent to the receiver is changed from 1 to 0. Then, if a noise pulse occurs outside the receiver's bit time sampling period, the delay of a 0 is not recorded as noise.

51.4.8 Interrupts and status fields

The LPUART transmitter has two status fields that can optionally generate hardware interrupt requests. STAT[TDRE] = 1 indicates that there is room in the transmit FIFO to write another transmit character to Data (DATA). If CTRL[TIE] = 1, a hardware interrupt is requested when STAT[TDRE] = 1.

STAT[TC] indicates that the transmitter is finished transmitting all data, preamble, and break characters and is idle with TXD at the inactive level. This field is often used in systems with modems to determine when it is safe to turn off the modem. If CTRL[TCIE] = 1, a hardware interrupt is requested when STAT[TC] = 1. Instead of hardware interrupts, software polling may be used to monitor STAT[TDRE] and STAT[TC] if the corresponding CTRL[TIE] or CTRL[TCIE] are 0.

When a program detects that STAT[RDRF] = 1, it gets the data from this field by reading Data (DATA). The field becomes 0 by reading Data (DATA).

STAT[IDLE] includes logic that prevents it from becoming 1 repeatedly when the RXD line remains idle for an extended period of time. STAT[IDLE] becomes 0 when you write 1 to it, and cannot become 1 again until the receiver has received at least one new character and has STAT[RDRF] = 1.

If the associated error is detected in the received character that caused STAT[RDRF] to become 1, STAT[NF], STAT[FE], and STAT[PF] become 1 at the same time STAT[RDRF] becomes 1. These flags do not become 1 in overrun cases.

If STAT[RDRF] is already 1 when a new character is ready to be transferred from the receive shifter to the receive FIFO, STAT[OR] becomes 1, instead of the data along with any associated STAT[NF], STAT[FE], or STAT[PF] condition is lost.

If the received character matches the contents of MATCH[MA1] and/or MATCH[MA2], then STAT[MA1F] and/or STAT[MA2F] become 1 at the same time that STAT[RDRF] becomes 1.

At any time, an active edge on the RXD serial data input pin causes STAT[RXEDGIF] to become 1. STAT[RXEDGIF] becomes 0 when you write 1 to it. This function depends on the receiver being enabled (CTRL[RE] = 1).

51.4.8.1 End-of-packet DMA transfers

The end-of-packet functionality is designed for serial interfaces where you may not know the size of the transfer in advance and the data is being pushed by an external device. Examples include UART receive, I2C Slave mode, and SPI Slave mode. The end of packet processing ensures that data does not become stranded in either the receive FIFO or the DMA receive buffer. Support for end-of-packet processing must be implemented in both the serial interfaces and DMA controller.

The condition that signals the end of packet is different for each serial interface, but the serial peripheral and DMA process it in the same way. For example, an idle line condition signals the UART end of packet, the Stop and/or Repeated Start condition signals the I2C end of packet, and PCS negation signals the SPI end of packet.

When the serial peripheral is configured to signal the end-of-packet condition to the DMA and the serial interface detects an end-of-packet condition, it asserts the DMA request for the receive FIFO irrespective of the watermark configuration. For larger watermark configurations, this ensures that the last few words of the transfer are first flushed from the receive FIFO.

The DMA then reads the contents of the receive FIFO, depending on the first word in the FIFO:

- If the receive FIFO is empty, the serial interface signals an end of packet condition to the DMA controller.

- If the receive FIFO is not empty, but the first word in the FIFO is the start of a new packet, data is not pulled from the receive FIFO and the serial interface signals an end-of-packet condition to the DMA controller.
- If the receive FIFO is not empty, and the first word in the FIFO is not the start of a new packet, the DMA transfers the receive data as normal.

Because the DMA may be transferring multiple words on each request, the end-of-packet condition persists until the DMA minor loop has completed and no additional data is pulled from the receive FIFO. The field that triggered the end-of-packet condition becomes 0 when the minor loop completes following the end of packet being signaled to the DMA controller.

When the DMA detects the end-of-packet condition, it writes all received words up to the end of packet into the system memory and saves the destination address for the word after the last valid data. The DMA then terminates the channel as if the major loop completed, including final offsets and optional interrupts, channel linking, and scatter-gather. You can, optionally, save the final destination address to system memory. The final destination address is also available in the destination address register.

Because the DMA terminates the major loop, no servicing of the receive FIFO occurs until you or the hardware reconfigures the DMA (for example, channel linking or scatter-gather). You must minimize this delay to avoid receiver FIFO overrun. The automatic DMA end-of-packet processing is not recommended when there are only a few words transferred between end-of-packet conditions. This is because the DMA spends more time processing the end of packet than transferring the data. For example, the UART idle line length must be increased as needed to avoid an excessive number of idle conditions.

51.4.9 Peripheral triggers

The connection of the LPUART peripheral triggers with other peripherals is chip-specific.

Output triggers

LPUART generates the following output triggers that can be connected to other peripherals on the chip:

- The transmit word trigger asserts at the end of each transmitted word and negates after 1-bit period.
- The transmit data trigger is identical to the TXD pin output, but without support for input trigger modulation.
- The receive word trigger asserts at the end of each received word that is written to the receive FIFO, for one oversampling clock period.
- The receive idle trigger asserts when STAT[IDLE] becomes 1, for one oversampling clock period.

Input trigger

LPUART supports one peripheral input trigger that you can configure in one of the following ways:

- By enabling the CTS function: You can connect the input trigger instead of the CTS_B pin input. The input trigger must assert for longer than 1-bit clock period when the transmitter is idle, with data to send, to guarantee a new transmission.
- By making the input trigger modulate the transmit data output (trigger is logically ANDed with the TXD output): The input trigger is expected to be a free running clock (carrier signal) that generates from a timer or PWM source with a frequency that is greater than the bit-clock frequency. The carrier signal must not toggle faster than the maximum supported bit time.
- By connecting the input trigger instead of the RXD pin input: The input trigger is expected to be generated from a receive data source, such as an analog comparator or external pin.

51.5 Clocking and resets

Table 316. Clocks

LPUART functional clock	Is asynchronous to the bus clock and can remain enabled in Low-Power modes to support transmit and/or receive functions, including low-power wakeups.
Bus clock	Is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPUART transmit and receive registers, including the FIFOs.

Table 317. Resets

Chip reset	Enables the logic and registers for the LPUART transmitter and receiver to reset to their default states.
Software reset	Resets the LPUART logic and registers to their default states, except for Global (GLOBAL). GLOBAL[RST] controls the LPUART software reset.
FIFO reset	Implements write-only control fields that reset the transmit FIFO (FIFO[TXFLUSH]) and receive FIFO (FIFO[RXFLUSH]). After a FIFO is reset, that FIFO becomes empty.

51.6 External signals

Table 318. External signals

Signal	Description	I/O
TXD	Transmit data: This pin is normally an output, but is an input (tristated) in Single-Wire mode whenever the transmitter is disabled or transmit direction is configured for receive data.	I/O
RXD	Receive data	I
CTS_B	Clear-to-send	I
RTS_B	Request-to-send	O

52.1.1 Module instances

The parts with CAN module have one instance: CAN0. Refer to Ordering information for parts have CAN module.

52.1.2 Enhanced Rx FIFO under DMA operation

In order to use the DMA feature, the ERFCR[ERFWM] must be configured as 0b.

ERFSR[ERFDA] is set by the hardware when there is at least one frame available to be read from the Enhanced Rx FIFO, and ERFSR[ERFWMI] is set by the hardware when the number of frames stored in the FIFO is greater than 0 (the watermark defined by ERFCR[ERFWM]). A DMA request is generated when ERFSR[ERFWMI] is set. Upon receiving the request, the DMA controller can read the message in the Enhanced Rx FIFO output. The DMA controller performs one read loops in the FIFO output defined by ERFCR[ERFWM]. Also, each message reading process must end by the address defined in ERFCR[DMALW].

52.1.3 Maximum data rate

The maximum data rate for CAN in this device is 8 Mbps. Refer to device's Data sheet for more information.

52.1.4 Wakeup source from low-power mode on 40-pin package

In the 40-pin HVQFN package that supports FlexCAN interface, the pins PTC5 and PTC6 are tied together inside the device. The PTC5 works as a CAN interface while the PTC6 pin works as a wake-up source only. In order to wake up from low-power mode, the user uses PTC5 as CAN0_RX interface and must configure the PTC6 signal as input and wake up source in the target wake-up domain. When a CAN frame is received in pin PTC5, a wake-up interrupt will be triggered asserting PTC6.

NOTE

Do not configure PTC5 and PTC6 pins as output at the same time in 40-pin HVQFN packages. When not in use, they must be configure as disabled (ALT0).

NOTE

In 40-pin HVQFN package, PTC6 shall only be configured as an input wake up source if in use.

52.1.5 FlexCAN reset

The chip level hard reset input of FlexCAN is controlled by MRCC_CANn[RSTB], therefore a FlexCAN hard reset leads to reset all the module which results in all registers being affected by this reset. The chip level soft reset input is not supported on this device, use MCR[SOFTRST] to initiate a soft reset of the FlexCAN.

52.2 Overview

FlexCAN is a communication controller implementing the CAN protocol according to the ISO 11898-1:2015 standard and CAN 2.0 Part B protocol specifications.

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific real-time processing and reliable operation requirements in the electromagnetic interference (EMI) environment of a vehicle. FlexCAN is a full implementation of the CAN protocol specification, the CAN with flexible data rate (CAN FD) protocol, and the CAN version 2.0 Part B protocol. It supports both standard and extended message frames and long payloads.

NOTE

Legacy Receive (RX) FIFO cannot be used in Flexible Data (FD) mode.

NOTE

In CAN FD mode, use the Enhanced Receive FIFO feature instead of the Legacy Receive FIFO.

52.2.1 Block diagram

Figure 187 shows the main submodules implemented in FlexCAN.

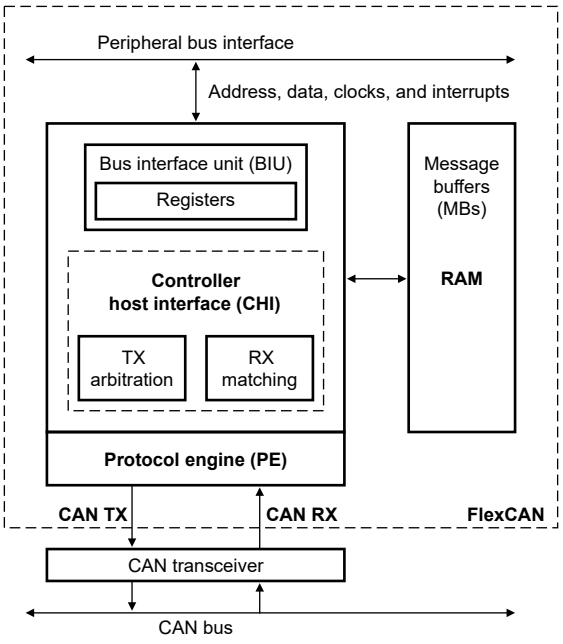

Figure 187. Block diagram

The Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- RAM access for receiving and transmitting message frames
- Receive message validation
- Error handling.
- CAN FD message detection

The Controller Host Interface (CHI) submodule manages:

- Message buffer (MB) selection for reception and transmission
- Arbitration and ID matching algorithms for both CAN FD and non-CAN FD message formats

The Bus Interface Unit (BIU) submodule controls access to and from the internal interface bus to establish connection to the CPU and to other blocks. The BIU manages access to:

- Clocks
- Address and data buses
- Interrupt outputs
- DMA
- Test signals

52.2.2 Features

- Full implementation of *CAN with Flexible data rate (CAN FD) protocol specification* and *CAN Specification Version 2.0, Part B*
  - Standard data frames
  - Extended data frames
  - Data length of 0–64 bytes
  - Programmable bit rate (see chip-specific FlexCAN information for specific maximum rate configuration)
  - Content-related addressing
- Compliance with ISO 11898-1:2015 standard
- Flexible message buffers that can be configured to store a payload of 0, 8, 16, 32, or 64 bytes
  - Increasing the payload size decreases the number of supported message buffers (see FlexCAN memory partition for CAN FD).
  - Message buffers are configurable as receive or transmit, supporting standard and extended messages.
- Individual Receive Mask registers for each message buffer
- Full-featured Legacy RX FIFO with storage capacity for six frames and automatic internal pointer handling with DMA support
- Full-featured Enhanced RX FIFO with storage capacity of 12 CAN FD frames and automatic internal pointer handling with DMA support
- Transmission abort capability
- Optional general purpose RAM space, using RAM not used by reception or transmission structures
- Listen-Only mode
- Programmable loopback mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Timestamp based on 16-bit free-running timer
- Global network time, synchronized by specific message
- Maskable interrupts
- Independence from transmission medium (external transceiver is assumed)
- Short latency time due to arbitration scheme for high-priority messages
- Low-power modes, with programmable wake-up on bus activity or matching with received frames (Pretended Networking)
- Transceiver delay compensation when transmitting CAN FD messages at faster data rates
- Management of remote request frames, automatically or by software
- Restriction only to write CAN bit time settings and configuration bits in Freeze mode
- Transmit message buffer status (lowest-priority buffer or empty buffer)

- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- ESR1[SYNCH] to indicate module is synchronous with CAN bus
- CRC status for transmitted message
- Legacy RX FIFO Global Mask register
- Selectable priority between message buffers and receive FIFO during matching process
- Powerful Legacy RX FIFO ID filtering, capable of matching incoming IDs against either 128 extended IDs, 256 standard IDs, or 512 partial (8-bit) IDs, with 32 individual masking capability
- Powerful Enhanced RX FIFO ID filtering, capable of matching incoming IDs against either 16 extended or 32 standard ID filter elements with three filtering schemes: mask plus filter, range, and two filters without mask.
- Complete backward compatibility with previous FlexCAN version
- Pretended Networking functionality in low power: Doze mode, Stop mode

52.3 Functional description

FlexCAN is a CAN protocol engine with a flexible message buffer system for transmitting and receiving CAN frames. The system is a set of message buffers (MBs) that stores configuration and control data, timestamp, message ID, and data (see Message buffer structure).

For classical CAN frames, FlexCAN supports simultaneous reception through Legacy FIFO and message buffer. For CAN FD frames, FlexCAN supports reception through message buffer and enhanced receive FIFO.

For message buffer reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed in the ID field. A masking scheme makes it possible to match the ID programmed on the message buffer with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of message buffers to be transmitted based on the message ID (optionally augmented by three local priority bits) or the message buffer ordering.

A message buffer is active at a given time if it can participate in both the matching and arbitration processes. A receive message buffer with a 0b code is inactive (see Table 354). A transmit message buffer with a 1000b or 1001b code is also inactive (see Table 355).

FlexCAN can receive and transmit messages in CAN FD format. The message buffers are sized to store the quantity of data bytes selected by FDCTRL[MBDSRn]. The quantity of FD message buffers available for a given quantity of data bytes is described in the CAN FD Control (FDCTRL) register. See also FlexCAN memory partition for CAN FD.

52.3.1 Modes of operation

FlexCAN has these functional modes:

Table 320. Functional modes

Mode	Description
Normal	In Normal mode, FlexCAN receives and transmits message frames, manages errors normally, and enables all CAN Protocol functions.
Freeze	Freeze mode is enabled when MCR[FRZ] = 1. If enabled, FlexCAN enters Freeze mode when MCR[HALT] is 1 or when is requested at chip level and FlexCAN writes 1 to MCR[FRZACK]. In this mode, no transmission or reception of frames is done, and synchronicity to the CAN bus is lost. See Freeze mode.
Loopback	FlexCAN enters this mode when CTRL1[LPB] becomes 1. In this mode, FlexCAN performs an internal loopback that can be used for self-test. The bit stream output of the transmitter is internally fed back to the receiver input. The receiving CAN input pin is ignored and the transmitting CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting and treats its own

Table continues on the next page...

Table 320. Functional modes (continued)

Mode	Description
	transmitted message as a message received from a remote node. To ensure proper reception of its own message, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field. Both transmit and receive interrupts are generated.
Listen-Only	FlexCAN enters this mode when CTRL1[LOM] becomes 1. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station are received. If FlexCAN detects an unacknowledged message, it flags a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.
CAN FD Active	In this mode, FlexCAN can transmit and receive all messages formatted according to the CAN FD Standard (2.0) and 2.0B Protocol in an interleaved fashion. The CPU can put FlexCAN into CAN FD Active mode by configuring MCR[FDEN] in Freeze mode.

Some features available in classical CAN are unavailable in CAN FD mode.

Table 321. Differences between classical CAN and CAN FD

Feature	Classical CAN	CAN FD
Legacy RX FIFO DMA	Yes	No
Legacy RX FIFO	Yes	No
Enhanced RX FIFO DMA	Yes	Yes
Enhanced RX FIFO	Yes	Yes
Pretended network support	Yes	No

FlexCAN can operate in these low-power modes:

Table 322. Low-power modes

Mode	Description
Module Disable	FlexCAN enters this mode when the CPU writes 1 to MCR[MDIS] and FlexCAN writes 1 to MCR[LPMACK]. After FlexCAN is disabled, it issues a request to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Writing 0 to MCR[MDIS] exits this mode. See Module Disable mode.
Doze	FlexCAN enters this mode when MCR[DOZE] is 1, Doze mode is requested at chip level, and FlexCAN writes 1 to MCR[LPMACK]. When in Doze mode, FlexCAN issues a request to disable the clocks to the CAN Protocol Engine and the CAN Controller-Host Interface submodules. This mode is exited when: • MCR[DOZE] becomes 0 • The chip is removed from Doze mode • Or activity is detected on the CAN bus and the Self-Wake-up mechanism is enabled. See Doze mode.
Stop	FlexCAN enters this mode when Stop mode is requested at chip level and FlexCAN writes 1 to MCR[LPMACK]. When in Stop mode, FlexCAN puts itself in an inactive state and then informs the CPU that the clocks can be shut down globally. Exit from this mode occurs when the Stop mode request is

Table continues on the next page...

Table 322. Low-power modes (continued)

Mode	Description
	removed, or when activity is detected on the CAN bus and the Self-Wake-up mechanism is enabled. See Stop mode.
Pretended Network (PN)	FlexCAN can operate in this mode with Doze mode or Stop mode. Before entering one of these low-power modes, you must write 1 to MCR[PNET_EN]. When in a low-power mode, CHI subblock clocks are shut down and CAN_PE subblock remains clocked. The receive process remains active to filter incoming messages (see Receive process in Pretended Networking mode) as defined by the configuration registers (see Pretended Networking Control 1 (CTRL1_PN)). Upon detecting a wake-up event, a wake-up interrupt is issued to the system. When MCR[PNET_EN] becomes 1, the CPU must disable Self-Wake-up by writing 0 to MCR[SLFWAK] (see Module Configuration (MCR).

52.3.1.1 Modes of operation details

FlexCAN has functional modes and low-power modes. See Modes of operation for an introductory description of all the modes of operation. The following subsections contain functional details about Freeze mode and low-power modes.

CAUTION

FlexCAN does not support "Permanent Dominant" failure on the CAN bus line. If a Low-Power request or Freeze mode request occurs during a "Permanent Dominant" condition, the corresponding acknowledgment field can never be 1.

52.3.1.1.1 Freeze mode

This mode is requested either by the CPU writing 1 to MCR[HALT] or when the chip is put into Debug mode. MCR[FRZ] must be 1 and the module must not be in a low-power mode.

To obtain acknowledgment, FlexCAN writes 1 to MCR[FRZACK]. The CPU must only consider FlexCAN to be in Freeze mode when both request and acknowledgment conditions are satisfied.

When Freeze mode is requested, FlexCAN:

1. Waits to be in either Intermission, Error Passive, Bus Off, or Idle state.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in does not prevent entering Freeze mode.
3. Ignores the receive input pin and drives the transmit pin as recessive.
4. Stops the prescaler, halting all CAN protocol activities.
5. Grants write access to the Error Counters register, which is read-only in other modes.
6. Writes 1 to MCR[NOTRDY] and MCR[FRZACK].

After requesting Freeze mode, you must wait for MCR[FRZACK] to become 1 before executing any other action, otherwise FlexCAN may operate unpredictably. In Freeze mode, all memory-mapped registers are accessible.

Freeze mode is exited in one of these conditions:

- CPU writes 0 to MCR[FRZ].
- The chip is removed from Debug mode or the MCR[HALT] becomes 0.

MCR[FRZACK] becomes 0 after the protocol engine recognizes the negation of the freeze request. After leaving Freeze mode, FlexCAN tries to resynchronize to the CAN bus by waiting for 11 consecutive recessive bits.

52.3.1.1.2 Module Disable mode

This low-power mode is normally used to disable a complete FlexCAN block temporarily, with no power consumption. The CPU requests this mode by writing 1 to MCR[MDIS], and FlexCAN acknowledges the request by writing 1 to MCR[LPMACK]. The CPU must only consider FlexCAN to be in Disable mode when both the request and acknowledgment conditions are satisfied.

If FlexCAN is disabled during Freeze mode, the module requests to disable the clocks to the PE and CHI submodules, writes 1 to MCR[LPMACK] and writes 0 to MCR[FRZACK].

It is not recommended to use Module Disable mode under Pretended Networking mode. Write 0 to MCR[MDIS] and wait for MCR[LPMACK] to become 0 before writing 1 to MCR[PNET_EN].

If the module is disabled during transmission or reception, FlexCAN:

1. Waits to be in either Idle or Bus Off state, or waits for the third bit of Intermission and then checks that it is recessive.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. FlexCAN does not take a pending move-in into account.
3. Ignores its receive input pin and drives its transmit pin as recessive.
4. Shuts down the clocks to the PE and CHI submodules.
5. Writes 1 to MCR[NOTRDY] and MCR[LPMACK].

In this mode, the Bus Interface Unit continues to operate, enabling the CPU to access memory-mapped registers, except for:

- The Receive Message Buffers Global Mask registers
- The Receive Buffer 14 Mask register
- The Receive Buffer 15 Mask register

When in Disable mode, these items may not be accessed:

- The message buffers
- The Receive Individual Mask registers
- The reserved words within RAM

To exit this mode, the CPU writes 0 to MCR[MDIS], causing FlexCAN to request to resume the clocks and write 0 to MCR[LPMACK]. This write occurs after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

52.3.1.1.3 Doze mode

This is a system low power mode in which the CPU bus is kept alive and a global Doze mode request is sent to all peripherals asking them to enter low-power mode. When Doze mode is globally requested, MCR[DOZE] needs to have been asserted previously for Doze mode to be triggered. The acknowledgement is obtained through the assertion by the FlexCAN of MCR[LPMACK]. The CPU must only consider the FlexCAN to be in Doze mode when both request and acknowledgement conditions are satisfied.

If Doze mode is triggered during Freeze mode, FlexCAN requests to shut down the clocks to the PE and CHI submodules, sets MCR[LPMACK] and negates MCR[FRZACK]. If Doze mode is triggered during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Shuts down the clocks to the PE and CHI submodules.
- Sets MCR[NOTRDY] and MCR[LPMACK].

The Bus Interface Unit continues to operate, enabling the CPU to access memory-mapped registers, except the Rx Mailboxes Global Mask registers, the Rx Buffer 14 Mask register, the Rx Buffer 15 Mask register. The message buffers, the Rx Individual Mask registers, and the reserved words within RAM may not be accessed when the module is in Doze mode.

Exiting Doze mode is done in one of the following ways:

- CPU removing the Doze mode request
- CPU negating MCR [DOZE]
- Self Wake mechanism

In the Self Wake mechanism, if MCR[SLFWAK] was set at the time FlexCAN entered Doze mode, then upon detection of a recessive to dominant transition on the CAN bus, FlexCAN negates the DOZE bit, requests to resume its clocks and negates the LPMACK after the CAN protocol engine recognizes the negation of the Doze mode request. It also sets ESR [WAKINT] and, if enabled by MCR[WAKMSK], generates a Wake-Up interrupt to the CPU. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up. The following table details the effect of SLFWAK and WAKMSK upon wakeup from Doze mode.

Table 323. Wakeup from Doze mode

SLFWAK	WAKINT	WAKMSK	FlexCAN clocks enabled	Wakeup interrupt generated
0	-	-	No	No
0	-	-	No	No
1	0	0	No	No
1	0	1	No	No
1	1	0	Yes	No
1	1	1	Yes	Yes

52.3.1.1.4 Stop mode

In this low-power mode for the system, all chip clocks can be stopped for maximum power savings. Stop mode is globally requested by the CPU and FlexCAN writes 1 to a Stop Acknowledgment signal to indicate acknowledgment. The CPU must only consider FlexCAN to be in Stop mode when both request and acknowledgment conditions are satisfied.

If FlexCAN receives the global Stop mode request during Freeze mode, it shuts down the clocks globally by:

1. Writing 1 to MCR[LPMACK].
2. Writing 0 to MCR[FRZACK].
3. Sending the Stop Acknowledge signal to the CPU.

If Stop mode is requested during transmission or reception, FlexCAN:

1. Waits to be in either Idle or Bus Off state, or waits for the third bit of Intermission and verifies that it is recessive.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. FlexCAN does not take a pending move-in into account.
3. Ignores its receive input pin and drives its transmit pin as recessive.
4. Writes 1 to MCR[NOTRDY] and MCR[LPMACK].
5. Sends a Stop Acknowledge signal to the CPU, so that the CPU can shut down the clocks globally.

FlexCAN exits Stop mode when the CPU resumes the clocks and removes the Stop mode request. This exit can occur as a result of the Self-Wake mechanism.

In Self-Wake, if MCR[SLFWAK] = 1 when FlexCAN enters Stop mode, then upon detecting a recessive-to-dominant transition on the CAN bus, FlexCAN writes 1 to ESR1[WAKINT]. If enabled by MCR[WAKMSK], FlexCAN generates a wake-up interrupt to the CPU. Upon receiving the interrupt, the CPU should resume the clocks and remove the Stop mode request. FlexCAN waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, FlexCAN does not receive the frame that woke it up. Table 324 details the effect of MCR[SLFWAK] and MCR[WAKMSK] upon wakeup from Stop mode. Waking from Stop mode only works when both fields are 1.

After the CAN protocol engine recognizes the negation of the Stop mode request, FlexCAN writes 0 to MCR[LPMACK]. FlexCAN then waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, FlexCAN does not receive the frame that woke it up.

Table 324. Waking from Stop mode

SLFWAK	WAKINT	WAKMSK	Chip clocks enabled	Wake-up interrupt generated
0	—	—	No	No
0	—	—	No	No
1	0	0	No	No
1	0	1	No	No
1	1	0	No	No
1	1	1	Yes	Yes

NOTE

When FlexCAN is in the Bus Off state and Low-Power mode, FlexCAN may take an extra 128 IDLE cycles to leave the Bus Off state after exiting Low-Power mode.

52.3.1.1.5 Pretended Networking (PN) mode

This special low-power mode receives wake-up messages with low power consumption. This mode can be selected to operate together with Doze mode or Stop mode. Before entering a low-power mode, MCR[PNET_EN] must be 1. After entering a low-power mode, the CHI subblock is shut down and the CAN_PE subblock is kept active. The receive process is still active to filter incoming messages (see Receive process in Pretended Networking mode) as defined by the configuration registers (see Pretended Networking Control 1 (CTRL1_PN)). Upon detecting a wake-up event, FlexCAN issues a wake-up interrupt to the system.

To enter Pretended Networking mode, FlexCAN must be in Normal mode, not in Freeze or Module Disable mode. In Pretended Networking mode, FlexCAN keeps itself synchronized with the CAN bus in Doze or Stop mode. Then, when either Doze or Stop mode is requested, FlexCAN:

1. Waits to be in the Idle state, or waits for the third bit of Intermission, then verifies that it is recessive.
2. Writes 1 to MCR[LPMACK].
3. Requests the shutdown of the CHI submodule clock, while keeping the PE submodule clock active.

FlexCAN can exit Pretended Networking mode in one of these ways:

- The CPU removes the Doze mode request.
- The CPU writes 0 to MCR[DOZE].
- The CPU removes the Stop mode request.
- FlexCAN waits until Bus Idle, or until the third bit of Intermission state, to write 0 to MCR[LPMACK].

The above exit events can be triggered:

- By FlexCAN, after detecting a wake-up event and issuing the respective interrupt.
- By the CPU itself, when another method wakes it up.

Consequently, FlexCAN waits until the Bus Idle state, or until the third bit of the Intermission state, to write 0 to MCR[LPMACK] and resume Normal mode. This procedure ensures that FlexCAN is synchronized to the CAN bus after exiting Pretended Networking mode. The CPU must wait for MCR[LPM_ACK] to become 0 before performing any access to FlexCAN.

When MCR[PNET_EN] becomes 1, the CPU must disable the self-wake-up by writing 0 to MCR[SLFWAK] (see Module Configuration (MCR)).

NOTE

For more information about the difference between FD and non-FD regarding this feature, see Table 321.

52.3.2 Transmission process

NOTE

Instances of MB_CS in this topic refer to items in message buffers. See Message buffer structure for details.

To transmit a CAN frame, the CPU must prepare a message buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt flag is set, and clear it if necessary.
2. If the message buffer is active (transmission pending), request an abort of the transmission. Write the ABORT code (1001b) to the CODE field of the Control and Status word.
3. Poll the IFLAG register until the corresponding IFLAG flag is set, or wait for the interrupt request (if enabled by the respective IMASK field).
4. Read the CODE field to identify whether the transmission was aborted or transmitted (see Transmission abort mechanism).
5. Clear the corresponding interrupt flag.
6. Write the ID register (containing the local priority if enabled via MCR[LPRIOEN]).
7. Write payload data bytes.
8. Configure the Control and Status word as needed.
    a. Set ID type via MB_CS[IDE].
    b. Set Remote Transmission Request (if needed) via MB_CS[RTR].
    c. If MCR[FDEN] = 1, configure MB_CS[EDL] and MB_CS[BRS]. For details about the relationship between the written value and transmitted value of MB_CS[ESI], see Table 335.[2]
    d. Configure Data Length Code in bytes via MB_CS[DLC]. See Table 357 for detailed information.
    e. To transmit the CAN frame, activate the message buffer by writing Ch to MB_CS[CODE].

NOTE

To maximize software performance, configure all the fields in the MB_CS word in a single 32-bit write operation. If the fields are configured in separate writes, MB_CS[CODE] must be the last write in the Control and Status word.

When the MB is activated, it participates in the arbitration process and its contents are eventually transmitted according to its priority. When the DLC value stored in the MB selected for transmission exceeds the MB payload size, FlexCAN completes the expected DLC by adding a constant CCh pattern.

[2] There is no need to write the ESI field; it is automatically transmitted as dominant by error active nodes and as recessive by error passive nodes. If FlexCAN is operating as a network gateway, however, the CPU writes MB_CS[ESI] according to the error status of the node that sent the message.

After a successful transmission:

1. The value of the free-running timer is written into the timestamp field.
2. The CODE field in the Control and Status word is updated.
3. Both Cyclic Redundancy Check (CRCR) and CAN FD CRC (FDCRC) are updated.
4. A status flag is set in the Interrupt Flag register.
5. If allowed by the corresponding Interrupt Mask Register field, an interrupt is generated.

After transmission, the new CODE field depends on the code used to activate the message buffer (see Table 354 and Table 355 in Message buffer structure).

When the Abort feature is enabled (MCR[AEN] is 1), after the Interrupt flag is set for an MB configured as transmit buffer, the message buffer is blocked. The CPU cannot update the message buffer until the Interrupt Flag is cleared by the CPU. The CPU must clear the corresponding IFLAG flag before preparing this MB for a new transmission or reception.

NOTE

For backward compatibility (MCR[AEN] is 0), write the INACTIVE code (1000b) to the CODE field to deactivate the MB. In this case, the pending frame may be transmitted without notification (see Message buffer inactivation).

52.3.3 Arbitration process

The arbitration process scans the message buffers, searching for the transmission MB that holds the message to be sent at the next opportunity. This MB is called the arbitration winner. The scan starts from the lowest number MB and continues to the higher ones.

The arbitration process is triggered when at least one of the following occur:

- CRC field of the CAN frame arrives. The starting point depends on the value of CTRL2[TASD].
- Error Delimiter field of a CAN frame is in progress.
- Overload Delimiter field of a CAN frame is in progress.
- The winner of the arbitration is deactivated, and the CAN bus has not reached the first bit of the Intermission field.
- CPU writes to the Control and Status word of a winner MB, and the CAN bus has not reached the first bit of the Intermission field.
- CHI is in the Idle state and the CPU writes to the Control and Status word of any message buffer.
- FlexCAN exits Bus Off state.
- FlexCAN leaves Freeze mode or a low-power mode.

If the arbitration process does not evaluate all message buffers before the CAN bus reaches the first bit of the Intermission field, the temporary arbitration winner is invalidated. FlexCAN will not compete for the CAN bus at the next opportunity.

The arbitration process selects the winner among the active transmission message buffers at the end of the scan according to the values of CTRL1[LBUF] and MCR[LPRIOEN].

See Arbitration process (continued) for more information about this process.

52.3.3.1 Lowest-number message buffer first

If CTRL1[LBUF] is 1, the first (lowest number) active transmission message buffer found is the arbitration winner. MCR[LPRIOEN] has no effect when CTRL1[LBUF] is 1.

52.3.3.2 Highest-priority message buffer first

If CTRL1[LBUF] is 0, the arbitration process searches for the active transmission message buffer with the highest priority. The frame of this message buffer has a higher probability of winning the arbitration on the CAN bus when multiple external nodes compete for the bus simultaneously.

The sequence of bits considered for this arbitration is called the arbitration value of the message buffer. The transmission message buffer with the lowest arbitration value among all transmission message buffers has the highest priority.

If two or more message buffers have equivalent arbitration values, the message buffer with the lowest number is the arbitration winner.

The composition of the arbitration value depends on MCR[LPRIOEN].

52.3.3.2.1 Local priority disabled

If MCR[LPRIOEN] = 0, the arbitration value is built using the exact sequence of bits that would be transmitted in a CAN frame where local priority is disabled.

Table 325. Composition of the arbitration value when local priority is disabled

Format	Message buffer arbitration value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	— (18 bits)	— (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

52.3.3.2.2 Local priority enabled

To enable local priority, MCR[LPRIOEN] must be 1. In this case, the message buffer PRIO field (see Message buffer structure) is included at the very left of the arbitration value.

Table 326. Composition of the arbitration value when local priority is enabled

Format	Message buffer arbitration value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	— (18 bits)	— (1 bit)
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

Because the PRIO field is the most significant part of the arbitration value, message buffers with low PRIO values have higher priority than message buffers with high PRIO values. This priority is maintained regardless of the rest of their arbitration values.

The PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

52.3.3.3 Arbitration process (continued)

After the arbitration winner is found (see Arbitration process), its content is copied to a hidden auxiliary message buffer called a transmit serial message buffer (TX SMB). The TX SMB has the same structure as a normal message buffer, but is not user-accessible. This copy operation is called move-out. After it is done, write access to the Control and Status word of the corresponding MB is blocked (if MCR[AEN] = 1). Write access is restored in one of the following events:

- The CPU clears the corresponding IFLAG flag after the message buffer is transmitted.
- FlexCAN enters Freeze mode or Bus Off state.
- FlexCAN loses the bus arbitration, or there is an error during the transmission.

At the first opportunity window on the CAN bus, the message on the TX SMB is transmitted according to the CAN protocol rules.

The arbitration process can be triggered under the following conditions:

- During RX and TX frames from CAN CRC field to end of frame. The value of CTRL2[TASD] may be changed to optimize the arbitration start point.

- During CAN Bus Off state from TX_ERR_CNT = 124 to 128. The value of CTRL2[TASD] may be changed to optimize the arbitration start point.
- During Control and Status write by CPU in Bus Idle. The first Control and Status write starts the arbitration process, and a second Control and Status write during this same arbitration restarts the process. If other Control and Status writes are performed, the transmission arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, then the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and Bus Idle state starts, then an arbitration process is triggered. In this case, the first and second Control and Status writes in Bus Idle do not restart the arbitration process. If there is not enough time to finish arbitration in the Wait For Bus Idle state and the next state is Idle, the scan is not interrupted. That scan is completed during Bus Idle state. During this arbitration, a Control and Status write does not cause an arbitration restart.
- Deactivation of an arbitration winner during a valid arbitration window.
- Upon exiting Freeze mode (first bit of the Wait For Bus Idle state). If a resynchronization occurs during Wait For Bus Idle, the arbitration process is restarted.

The arbitration process stops when:

- All message buffers are scanned.
- A transmission message buffer is found (if lowest buffer feature is enabled).
- An arbitration winner deactivates or aborts during any arbitration process.
- There is not enough time to finish the transmission arbitration process (for instance, when a deactivation is performed near the end of frame). In this case, the arbitration process is pending.
- An error or overload flag occurs in the bus.
- A low-power or Freeze mode request occurs in Idle state.

Arbitration is considered pending when:

- It is not possible to finish arbitration process in time.
- A Control and Status write occurs during arbitration, when that write is performed in an MB whose number is lower than the transmission arbitration pointer.
- Any Control and Status write occurs when there is no transmission arbitration process in progress.
- RX Match has updated an RX code to TX code.
- FlexCAN enters the Bus Off state.

If a Control and Status write is performed in the arbitration winner, a new process is restarted immediately.

If a Control and Status write is performed in an MB whose number is higher than the transmission arbitration pointer, the ongoing arbitration process scans this MB as normal.

52.3.4 Receive process

To be able to receive CAN frames into a message buffer, the CPU must prepare it for reception by executing the following steps:

1. If the message buffer is active (either TX or RX), deactivate it (see Message buffer inactivation), preferably with a safe deactivation (see Transmission abort mechanism).
2. Write the ID word into the message buffer.
3. To activate the message buffer, write the EMPTY code (0100b) to the CODE field of the Control and Status word. No setup is required for EDL, BRS, and ESI fields. The respective fields in the received message overwrite these fields.

After the MB is activated, it can receive frames that match the programmed filter. At the end of a successful reception, the move-in process updates the message buffer (see Move-in) as follows:

1. The received data field (up to eight bytes for Classical CAN message format and up to 64 bytes for CAN FD message format) is stored.

2. The received Identifier field is stored.
3. The value of the free-running timer when the second bit of the Identifier field of the frame is written into the Timestamp field of the MB.
4. The received SRR, IDE, RTR, EDL, BRS, ESI, and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see Table 354 and Table 355 in Section Message buffer structure).
6. If allowed by the corresponding Interrupt Mask field, a status flag is set in the Interrupt Flag register and an interrupt is generated.

The recommended way for the CPU to service (read) the frame received in a message buffer is:

1. Read the Control and Status word of that message buffer.
2. Verify that the BUSY bit is 0, indicating that the message buffer is locked. If it is not 0, repeat step 1 until it becomes 0. See Message buffer lock mechanism.
3. Read the contents of the message buffer. After the message buffer is locked, FlexCAN move-in processes do not modify its contents. See Move-in.
4. Acknowledge the proper flag in the IFLAG registers.
5. Unlock the message buffer by reading the free-running timer.

To verify frame reception, the CPU should poll the status flag bit for that specific message buffer in one of the IFLAG registers, not the CODE field of that message buffer. Polling the CODE field does not work in this case. After a frame is received and the CPU services the message buffer (by reading the Control and Status word and unlocking the message buffer), the CODE field does not return to EMPTY. It remains FULL, as explained in Table 354. If the CPU tries to work around this behavior by writing to the Control and Status word to force an EMPTY code after reading the message buffer without a prior safe deactivation, a newly received frame matching the filter of that message buffer may be lost.

CAUTION

In summary: never poll by reading the Control and Status word of the message buffers directly. Instead, read the IFLAG registers.

The Identifier field of the received frame is always stored in the matching message buffer. If the match was due to masking, the contents of the ID field in a message buffer may change. When MCR[SRXDIS] becomes 1, FlexCAN does not store frames transmitted by itself in any MB, even if it contains a matching receive MB. Also, no interrupt flag or interrupt signal is generated. Otherwise, when MCR[SRXDIS] becomes 0, if a matching receive MB exists, FlexCAN can receive frames transmitted by itself.

When MCR[DMA]) becomes 1, upon receiving a frame in the Legacy FIFO, IFLAG1[BUF5I] generates a DMA request and does not generate a CPU interrupt (see Legacy RX FIFO in DMA Operation). The IMASK1 fields in the Legacy RX FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the Control and Status word (read 80h address, optional).
2. Read the ID field (read 84h address, optional).
3. Read all data bytes (start read at 88h address, optional).

52.3.5 Matching process

The matching process scans the message buffer memory for RX MBs programmed with the same ID as the one received from the CAN bus. The matching starts from the lowest number message buffer and continues toward the higher-numbered ones.

For enhanced RX FIFO, see Enhanced RX FIFO.

For legacy RX FIFO, see Legacy RX FIFO.

As the frame is received, it is stored in a hidden auxiliary MB called Receive Serial Message Buffer (RX SMB).

The starting point of the matching process depends on the following conditions:

- If the received frame is a remote frame, the starting point is the CRC field of the frame.
- If the received frame is a data frame with DLC field equal to zero, the starting point is the CRC field of the frame.
- If the received frame is a data frame and the DLC field has a nonzero value, the starting point is the DATA field of the frame.

If a matching ID is found in one of the message buffers, the move-in process transfers the contents of the RX SMB to the matched MB. If any CAN protocol error is detected, no match results are transferred to the matched MB at the end of reception.

The matching process scans all matching elements of the active receive MBs (CODE is EMPTY, FULL, OVERRUN, or RANSWER). The process searches for a successful comparison to the matching elements of the RX SMB that is receiving the frame on the CAN bus. The RX SMB has the same structure as a message buffer. The reception structures (message buffers) associated with the matching elements that had a successful comparison are the matched structures. The matching winner is selected at the end of the scan among those matched structures. The matching winner depends on conditions described in Table 327.

Table 327. Matching architecture

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID[1]]	MB[CODE]
Message buffer	0	—	0	cmp[2]	no_cmp[3]	cmp_msk[4]	EMPTY, FULL, or OVERRUN
Message buffer	0	—	1	cmp_msk	cmp_msk	cmp_msk	EMPTY, FULL, or OVERRUN
Message buffer	1	0	—	cmp	no_cmp	cmp	RANSWER
Message buffer	1	1	0	cmp	no_cmp	cmp_msk	EMPTY, FULL, or OVERRUN
Message buffer	1	1	1	cmp_msk	cmp_msk	cmp_msk	EMPTY, FULL, or OVERRUN

1. For message buffer structure, if SMB[IDE] is 1, the ID is 29 bits (ID Standard plus ID Extended). If SMB[IDE] is 0, the ID is 11 bits (ID Standard). For Legacy RX FIFO structure, the ID depends on IDAM.
2. cmp: Compares the RX SMB contents to the MB contents regardless of masks.
3. no_cmp: The RX SMB contents are not compared to the MB contents.
4. cmp_msk: Compares the RX SMB contents to MB contents, accounting for masks.

NOTE

For Enhanced RX FIFO, see Enhanced RX FIFO matching process.

A reception structure is free-to-receive when any of the following conditions is satisfied:

- The CODE field of the message buffer is EMPTY.
- The CODE field of the message buffer is either FULL or OVERRUN, and it has already been serviced (the CPU has read the Control and Status word and unlocked it as described in Message buffer lock mechanism).
- The CODE field of the message buffer is either FULL or OVERRUN and an inactivation (see Message buffer inactivation) is performed.

The scan order for message buffers is from the matching element with the lowest number to the higher ones.

52.3.5.1 Matching priority

MCR[IRMQ] affects the matching winner search for MBs. If the field is 0, the matching winner is the first matched MB whether it is free-to-receive or not. If it is 1, the matching winner is selected according to this priority:

1. The first free-to-receive matched message buffer
2. The last non-free-to-receive matched message buffer

52.3.5.2 Special cases

If a non-safe MB inactivation (see Message buffer inactivation) occurs during the matching process and the inactivated MB is the temporary matching winner, the temporary matching winner is invalidated. The matching elements scan is not stopped and not restarted; it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist. In this case, a message may be lost.

Consider an example where:

- MCR[IRMQ] is 1.
- There are two message buffers with the same ID: the second and fifth MBs in the array.
- FlexCAN starts receiving messages with that ID.

When the first message arrives, the matching algorithm finds the first match in message buffer number 2. The code of this message buffer is EMPTY, so the message is stored in that MB. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive." It continues looking, finds MB number 5, and stores the message in that MB. If yet another message with the same ID arrives, the matching algorithm finds no matching free-to-receive MBs, so it overwrites the last matched message buffer (MB number 5). In doing so, it updates the CODE field of the message buffer to OVERRUN.

The ability to match the same ID in more than one MB can be used to implement a reception queue to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages are queued into the message buffers. The CPU can examine the Timestamp field of the message buffers to determine the order in which the messages arrived.

Matching a range of IDs is possible via ID acceptance masks. FlexCAN supports individual masking per message buffer (see Receive Individual Mask (RXIMR0 - RXIMR31)). During the matching algorithm, if a mask field is 1, the corresponding ID bit is compared. If the mask field is 0, the corresponding ID bit is a "don't care". Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed when the module is in Freeze mode; otherwise, the module blocks them.

FlexCAN also supports an alternate masking scheme with only RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), and Receive 15 Mask (RX15MASK) for backward compatibility with legacy applications. This alternate masking scheme is enabled when the MCR[IRMQ] = 0.

52.3.6 Receive process in Pretended Networking mode

Pretended Networking mode adds specific wake-up functionality in low-power modes (Doze and Stop mode). When Pretended Networking (PN) mode is enabled by writing 1 to MCR[PNET_EN], FlexCAN continues processing received CAN messages in low-power mode. FlexCAN is able to detect specific wake-up messages by filtering them against identifier (ID) and payload target values using preselected matching criteria.

NOTE

Wake-up functionality is not available for messages in CAN FD format. When in PN mode, CAN FD format messages are ignored.

PN registers are located in the 0B00h–0B7Ch address range and can be written only in Freeze mode. These registers are used for writing PN configuration (both control and target values) prior to entering PN mode. They are also used for reading wake-up flags and the received message ID and data when returning to Normal mode after wake-up. The CPU must wait for MCR[LPMACK] to become 0 before performing any access to FlexCAN PN registers.

PN control registers are described in Pretended Networking Control 1 (CTRL1_PN) and Pretended Networking Control 2 (CTRL2_PN). The control fields that configure the filtering criteria are:

- Payload filtering selection: CTRL*n*_PN[PLFS]
- ID filtering selection: CTRL*n*_PN[IDFS]
- Filtering combination selection: CTRL*n*_PN[FCS]

Table 328. PN target values

Value	Description
FLT_IDE	IDE target value used to filter the incoming message by its format (standard or extended)
FLT_RTR	RTR target value used to filter the incoming message by its type (data or remote frame)
FLT_DLC_HI and FLT_DLC_LO	Target DLC range used to filter the size of the payload of an incoming message
FLT_ID1	ID target value used to filter the incoming message ID (equal to, smaller than or equal to, greater than or equal to, or the lower limit value in an ID range)
FLT_ID2	ID target value used as the upper limit in an ID range
PL1	Payload target value used to filter the incoming message payload (equal to, smaller than or equal to, greater than or equal to, or the lower limit value in a payload range)
PL2	Payload target value used as the upper limit in a payload range

IDE, RTR, ID, and payload filters have their respective masks. The ones in these masks determine which bits are considered in equality comparisons. The zeroes in these masks determine which bits are don't care. ID and payload masks are used only for exact ID and exact payload comparisons.

52.3.6.1 ID filtering

The IDs of incoming messages can be filtered based on the following criteria:

- Match the exact ID value, found by comparing the ID field of the incoming message to the content of target Pretended Networking ID Filter 1 (FLT_ID1). The ID mask is used.
- Less than or equal to the maximum range of ID. That is, any message with ID value smaller than or equal to the content of target FLT_ID1 is accepted. The ID mask is not used.
- Greater than or equal to the minimum range of ID. That is, any message with ID value greater than or equal to the content of target FLT_ID1 is accepted. The ID mask is not used.
- Inside a range of IDs. Any message with an ID value greater than or equal to the content of target FLT_ID1 and smaller than or equal to the content of target Pretended Networking ID Filter 2 or ID Mask (FLT_ID2_IDMASK) is accepted. The ID mask is not used.

See CTRL1_PN[IDFS].

The above criteria for ID filtering must be coherent with FLT_IDE and FLT_RTR target values in Pretended Networking ID Filter 1 (FLT_ID1). Only RX frames that match the respective IDE and RTR bits to the contents of FLT_ID1[FLT_IDE] and FLT_ID1[FLT_RTR] are compared. When a range of IDs is selected (CTRL1_PN[IDFS] = 11), both FLT_ID1 and FLT_ID2 are referred to the same FLT_IDE and FLT_RTR fields in FLT_ID1.

The ID mask is applied only to the exact ID comparison filtering option (CTRL1_PN[IDFS] = 00) to determine which bits are considered in the comparison. For the exact match option, the mask can select any bit within the ID field. For maximum range, minimum range, and inside range comparisons, the ID mask is not considered.

The IDE and RTR masks are applied in both exact and range ID comparison filtering options to determine which bits are considered in comparison.

52.3.6.2 Payload filtering

Similar to the ID criteria, 64-bit data or payloads (PL) of incoming messages can be filtered based on the following criteria:

- A match with the exact payload value, found by comparing the payload field of the incoming message to the content of PL1. The payload mask is used.
- Less than or equal to the maximum range of payload. That is, any message with payload value smaller than or equal to the content of PL1 is accepted. The payload mask is not used.
- Greater than or equal to the minimum range of payload. That is, any message with payload value greater than or equal to the content of PL1 is accepted. The payload mask is not used.
- Inside a range of payloads. Any message with a payload value greater than or equal to the content of PL1 and smaller than or equal to the content of PL2 is accepted. The payload mask is not used.

See CTRL1_PN[PLFS].

The above criteria for payload filtering must be coherent with upper and lower limit values in Pretended Networking Data Length Code (DLC) Filter (FLT_DLC). The payload of an incoming message is filtered using the selected criteria only if the DLC value of the incoming message is inside a DLC range:

- Greater than or equal to FLT_DLC[FLT_DLC_LO] (lower limit)
- Lower than or equal to FLT_DLC[FLT_DLC_HI] (upper limit)

A DLC value outside the specified range results in a mismatch. If you configure FLT_DLC_LO = FLT_DLC_HI, only payloads of the specified quantity of bytes are filtered. DLC is not maskable.

When the inside range of payloads option is selected (CTRL1_PN[PLFS] = 11), both PL1 and PL2 are considered with the 8-byte data length. All data bytes excluded by the DLC of the received message are considered to have value zero.

The payload mask is only used in the exact match option (CTRL1_PN[PLFS] = 00). This mask determines which bits or bytes in the 8-byte data field of both incoming message and the contents of PL1 register are used for matching. Mask length must meet the expected range of DLC values. For maximum range, minimum range, and inside range comparisons, the payload mask is not considered.

When FlexCAN receives a remote frame and CTRL1_PN[FCS] is configured to select payload comparison, payload filtering is not considered and the comparison results in a mismatch.

52.3.6.3 Other filtering

Incoming messages can also be filtered based on the quantity and rate of message reception, specifically:

- Several messages that match the filtering criteria for ID or payload for a predefined number of times. This number can be from 1 to 255. See Pretended Networking Control 1 (CTRL1_PN).
- No message matching the filtering criteria for ID or payload up to a timeout trigger. That is, non-reception of a matching message for a defined quantity of time. See Pretended Networking Control 2 (CTRL2_PN).

When the counter reaches the predefined timeout value, FlexCAN can generate a wake-up timeout event from an internal timer with associated comparator circuitry capable of generating a timeout flag. This behavior is specified in CTRL2_PN[MATCHTO].

The above filtering criteria can be used together as follows:

- Message ID filtering only
- Message ID filtering and Payload filtering
- Message ID filtering only occurring *n* times
- Message ID filtering and Payload filtering occurring *n* times

The timeout counter runs concurrently with the reception filtering process. Both engines (timeout counter and message filtering) are independent. If an incoming message matches the selected filter criteria, the timeout counter continues counting until the CPU wakes up. If the timeout counter reaches the target value, the message filtering process continues to filter incoming messages until the CPU wakes up. WU_MTC[MCOUNTER] reports the number of matched messages that occurred in Pretended Networking mode up to the moment the CPU wakes up.

In Pretended Networking mode, the wake-up event that may occur sets the respective wake-up flag (see Pretended Networking Wake-Up Match (WU_MTC)):

- WU_MTC[WUMF] indicates a successful match meeting the selected filtering criteria.
- WU_MTC[WTOF] indicates a timeout trigger.

Any of these flags generates interrupts to the CPU, provided the respective mask bits are enabled (CTRL1_PN[WUMF_MSK] = 1 or CTRL1_PN[WTOF_MSK] = 1).

There are four Wake-up Message Buffers (WMBs) used to store incoming messages in Pretended Networking mode. Up to four messages can be stored (see Wake-Up Message Buffer (WMB0_CS - WMB3_CS)).

When CTRL1_PN[NMATCH] = 1, only one message is received if the filtering criteria are matched. This message is stored in WMB0.

If CTRL1_PN[NMATCH] is between two and four, WMB1, WMB2, and WMB3 store the second, third, and fourth matching messages, respectively.

If CTRL1_PN[NMATCH] is greater than four, the last four matching messages are stored in the WMBs. The WMB index indicates the arrival order. The last message is stored in WMB3.

Only the valid data bytes of the incoming match message are stored in the data field of WMBs. The non-valid data bytes are read as zero. If DLC = 0 and RTR = 1, the data field is filled with zeroes. In any of the above cases, the wake-up interrupt is generated only when the filtering criteria are completed and CTRL1_PN[WUMF_MSK] = 1.

When a non-match wake-up event occurs (timeout or external) and WU_MTC[MCOUNTER] ≥ 4, the message stored in WMB0 does not have valid content. WMB0 is used as a buffer for the current message in the CAN bus. Messages received during Pretended Networking mode do not have time stamps, and the respective field in the WMB structure must be ignored.

In low-power mode (Doze or Stop), all processes are shut down except for the PN functionality inside the CAN_PE subblock, which remains clocked by the oscillator clock (see Clock domains and restrictions). FlexCAN continues to receive incoming messages, but only compares them to the predefined target values according to the selected filtering criteria. The matching, arbitration, move-in, and move-out processes, normally available in Normal mode, are not performed in Pretended Networking mode.

FlexCAN in Pretended Networking reacts to messages on the CAN bus in the same manner as in Normal mode. It generates acknowledge bits, detect and count errors, and so on.

52.3.7 Move process

There are two types of move process: move-in and move-out.

52.3.7.1 Move-in

The move-in process is the copying of a message received by an RX SMB to an RX message buffer that has matched it. Each RX SMB has its own move-in process, but only one is performed at a given time. The move-in starts only when the message held by the RX SMB has a corresponding match (see Matching process) and all of the following conditions are true:

- The CAN bus has reached or already gone past:
  - The second bit of Intermission field next to the frame that carried the message that is in the RX SMB.
  - The first bit of an overload frame next to the frame that carried the message in the RX SMB.
- There is no ongoing matching process.
- The CPU is not locking the destination message buffer.
- No move-in process from another RX SMB is ongoing. If more than one move-in process is to be started at the same time, both are performed and the newest process substitutes for the oldest.

The term "pending move-in" is used throughout the documentation and stands for a move-to-be that does not satisfy all of the above conditions.

If any of the following conditions is satisfied, the move-in is canceled and the RX SMB is able to receive another message:

- The destination message buffer is inactivated after the CAN bus has reached the first bit of the Intermission field next to the frame that carried the message. Also, its matching process has finished.
- There is a previous pending move-in to the same destination message buffer.
- The RX SMB is receiving a frame transmitted by FlexCAN itself and self-reception is disabled (MCR[SRXDIS] = 1).
- Any CAN protocol error is detected.

If the module enters Freeze or Low-Power mode, the pending move-in is not canceled. It remains on hold, waiting for Freeze and Low-Power mode to be exited and for the module to be unlocked. If a message buffer is unlocked during Freeze mode, the move-in occurs immediately.

The move-in process is FlexCAN executing the following steps:

1. Read all data words from the RX SMB in accordance with the selected payload size for the RX storage element.
2. Write all data words to the RX message buffer according to the selected payload size for the RX storage element. If the data size of the storage element is smaller than the original payload size described in the DLC field of the message, the payload is truncated. The high-order bytes that do not fit the destination size are lost.
3. Read the Control and Status and ID words from the RX SMB.
4. Write the Control and Status and ID words to the RX message buffer, and update the CODE field.

The move-in process is not atomic; the inactivation of the destination message buffer immediately cancels it (see Message buffer inactivation). In this case, the message buffer may remain partially updated, and therefore incoherent.

To alert the CPU that the message buffer content is temporarily incoherent, the BUSY Bit (least significant bit of the CODE field) of the destination message buffer becomes 1 during move-in.

52.3.7.2 Move-out

The move-out process is the copying of content from a TX message buffer to the TX SMB when a message for transmission is available (see Arbitration process). The move-out occurs in the following conditions:

- In the first bit of Intermission field
- During the Bus Off state, when TX Error Counter is in the 124 to 128 range
- During the Bus Idle state
- During the Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently outside the Bus Idle state. In Bus Idle, the move-out has the lowest priority of the concurrent memory accesses.

52.3.8 Data coherence

In order to maintain data coherency and proper FlexCAN operation, the CPU must obey the rules described in Transmission process and Receive process.

52.3.8.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the CPU whether the transmission was aborted or the frame could not be aborted and was transmitted instead.

These primary conditions must be fulfilled in order to abort a transmission:

- MCR[AEN] must be 1.
- The first CPU action must be the writing of abort code (1001b) into the CODE field of the Control and Status word.

Active message buffers configured for transmission must be aborted before they can be updated. The write operation is blocked and the transmission is not disturbed when the abort code is written to:

- A message buffer currently being transmitted.

- A message buffer that was already loaded into the TX SMB for transmission.

In this case, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The module loses the bus arbitration.
- There is an error during the transmission.
- The module is put into Freeze mode.
- The module enters the Bus Off state.
- There is an overload frame.

If none of the conditions above are reached:

1. The message buffer is transmitted correctly.
2. The interrupt flag is set in the proper IFLAG register.
3. If enabled, an interrupt to the CPU is generated.

The abort request is automatically cleared when the interrupt flag is set. If only one of the above conditions is reached, the frame is not transmitted. In this case:

1. The abort code is written into the CODE field.
2. The interrupt flag is set in the proper IFLAG register.
3. Optionally, an interrupt is generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, the write operation is not blocked. The MB is updated and the interrupt flag is set. In this way, the CPU only needs to read the abort code to verify that the active MB was safely inactivated. In this case, although MCR[AEN] = 1 and the CPU wrote the abort code, the MB is inactivated and not aborted, because the transmission did not start yet. A message buffer is aborted only when the abort request is captured and kept pending until one of the previous conditions is satisfied.

52.3.8.2 Message buffer inactivation

Inactivation protects the message buffer against updates by FlexCAN internal processes. It allows the CPU to rely on message buffer data coherence after having updated it, even in Normal mode.

Inactivation of transmission message buffers must be performed only when MCR[AEN] = 0.

If a message buffer is inactivated, it does not participate in the arbitration process or the matching process until it is reactivated. See Transmission process and Receive process for detailed instructions on how to inactivate and reactivate a message buffer.

To inactivate a message buffer, the CPU must update its CODE field to INACTIVE (either 0b or 1000b).

Because you cannot synchronize the CODE field update with FlexCAN internal processes, an inactivation can have the following consequences:

- A frame in the bus that matches the filtering of an inactivated RX message buffer may be lost without notice. This loss can occur even if there are other message buffers with the same filter.
- A frame containing the message within an inactivated TX message buffer may be transmitted without setting the respective IFLAG flag.

To perform a safe inactivation and avoid the above consequences for TX message buffers, the CPU must use the transmission abort mechanism (see Transmission abort mechanism).

The inactivation automatically unlocks the message buffer (see Message buffer lock mechanism).

52.3.8.3 Message buffer lock mechanism

In addition to message buffer inactivation, FlexCAN uses a message buffer lock mechanism to maintain data coherence for the receive process. When the CPU reads the Control and Status word of an RX message buffer with codes FULL or OVERRUN,

FlexCAN is configured to allow the CPU to read the whole message buffer in an atomic operation. FlexCAN sets an internal lock flag for that message buffer.

The lock is released in any of the following events:

- The CPU reads the free-running timer (global unlock operation).
- The CPU reads the Control and Status word of another message buffer, regardless of its code.
- The CPU writes into the Control and Status word. This procedure is not recommended for normal unlocking, because it cancels a pending move and may lose a received message.

The message buffer lock prevents a new frame from being written into the message buffer when the CPU is reading it.

NOTE

The locking mechanism applies only to RX message buffers that have a code other than INACTIVE (0b) or EMPTY[1] (0100b). TX message buffers cannot be locked.

Consider an example where:

- The second and the fifth message buffers of the array are programmed with the same ID.
- FlexCAN has already received and stored messages into these two message buffers.
- The CPU reads message buffer number 5 while another message with the same ID is arriving.

When the CPU reads the Control and Status word of message buffer number 5, this message buffer is locked. The new message arrives and the matching algorithm finds no free-to-receive message buffers, so it overrides message buffer number 5. This message buffer is locked, so the new message cannot be written to it. The message remains in the RX SMB until the message buffer is unlocked, and only then is it written to the message buffer.

If the message buffer remains locked and another new message with the same ID arrives, the new message overwrites the one in the RX SMB. There is no indication of lost messages in the CODE field of the message buffer or in Error and Status 1 (ESR1).

When the message is moved from the RX SMB to the message buffer, the BUSY bit on the CODE field becomes 1. If the CPU reads the Control and Status word and identifies that the BUSY bit is 1, it must wait until the BUSY bit becomes 0 to access the MB.

NOTE

If the BUSY bit is 1 or the message buffer is empty, reading the Control and Status word does not lock the message buffer.

Inactivation takes precedence over locking. If the CPU inactivates a locked receive message buffer, then its lock status is negated and the message buffer is marked as invalid for the current matching round. Any pending message on the RX SMB is not transferred to the message buffer. A message buffer is unlocked when the CPU reads Free-Running Timer (TIMER) or the Control and Status word of another message buffer.

The lock and unlock mechanisms have the same functionality in Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. If unlocking occurs during a low-power mode, however, the move-in is postponed (see Modes of operation). Move-in takes place only when the module returns to Normal or Freeze mode.

52.3.9 Enhanced RX FIFO

FlexCAN supports an enhanced RX FIFO engine which can store up to 12 CAN FD messages. The region 2000h– 204Bh contains the output of the FIFO, which the CPU should read. To enable the enhanced RX FIFO, write 1 to ERFCR[ERFEN]. FlexCAN has two FIFO options, Legacy RX FIFO and Enhanced RX FIFO, but both options cannot be enabled at the same time. See Legacy RX FIFO for additional information.

To configure the enhanced RX FIFO watermark, write a value to ERFCR[ERFWM]. If ERFCR[ERFWM] is configured, the CPU is notified only if a minimum number of messages is stored in the FIFO. When the number of stored messages is greater than the

[1] In previous FlexCAN versions, reading the Control and Status word locked the message buffer even when CODE indicates it is EMPTY. This behavior is maintained when the IRMQ bit is 0.

value in ERFCR[ERFWM], the module sets ERFSR[ERFWMI]. Optionally, if MCR[DMA] or ERFIER[ERFWMIIE] are enabled, a DMA transfer or an interrupt can be triggered, respectively.

For the enhanced RX FIFO to receive, the CPU must execute the configuration procedure below. If the CPU must change any configurations of the Enhanced RX FIFO, the same procedure must be followed.

Prerequisites

MCR[RFEN] must be 0.

Procedure

Step	Purpose	Programming	Notes
1	Enter Freeze mode.	See Freeze mode.	—
2	If enhanced RX FIFO is not already enabled, enable it.	Write 1 to ERFCR[ERFEN].	—
3	Reset enhanced RX FIFO engine.	Write 1 to ERFSR[ERFCLR].	—
4	If the enhanced RX FIFO error flags are set, clear them.	Write 1 to these flags: • ERFSR[ERFUFW] • ERFSR[ERFOVF] • ERFSR[ERFWMI] • ERFSR[ERFDA]	—
5	Specify the total number of enhanced RX FIFO filter elements to be used in Enhanced RX FIFO reception.	Write the number to ERFCR[NFE].	—
6	Specify the number of extended ID and standard ID filter elements to be used in Enhanced RX FIFO reception.	Write the number to ERFCR[NEXIF].	ERFCR[NEXIF] ≤ ERFCR[NFE] + 1.
7	If you are using DMA, enable DMA.	Write 1 to MCR[DMA].	—
8	If you are using DMA, specify the number of words to transfer for each Enhanced RX FIFO data element.	Write the number to ERFCR[DMALW].	—
9	Specify the Enhanced RX FIFO watermark.	Write the number to ERFCR[ERFWM].	If MCR[DMA] = 1, ERFCR[ERFWM] should be 0h.
10	If you are using interrupts, enable the interrupts.	Write 1 to the interrupt enables in Enhanced RX FIFO Interrupt Enable (ERFIER).	—
11	Configure the filter elements.	Write to the ERFFEL*n* registers.	ERFFEL*n* registers are implemented in RAM; you must explicitly initialize them before prior any reception.
12	Exit Freeze mode.	See Freeze mode.	—

There are two types of enhanced RX FIFO filter elements that can be stored in ERFFEL*n* registers: extended-ID filter elements and standard-ID filter elements. Each extended-ID filter element is stored in two ERFFEL*n* registers, and each standard-ID filter element is stored in one ERFFEL*n* register. ERFCR[NFE] defines the total number of Enhanced RX FIFO filter elements.

In addition, the filter memory space can be split into two regions: one for extended-ID filter elements and another for standard-ID filter elements, according to ERFCR[NEXIF]. Figure 188 shows how the enhanced RX filter elements are defined. See Enhanced RX FIFO matching process for information about the Enhanced RX FIFO matching process and filter element formats.

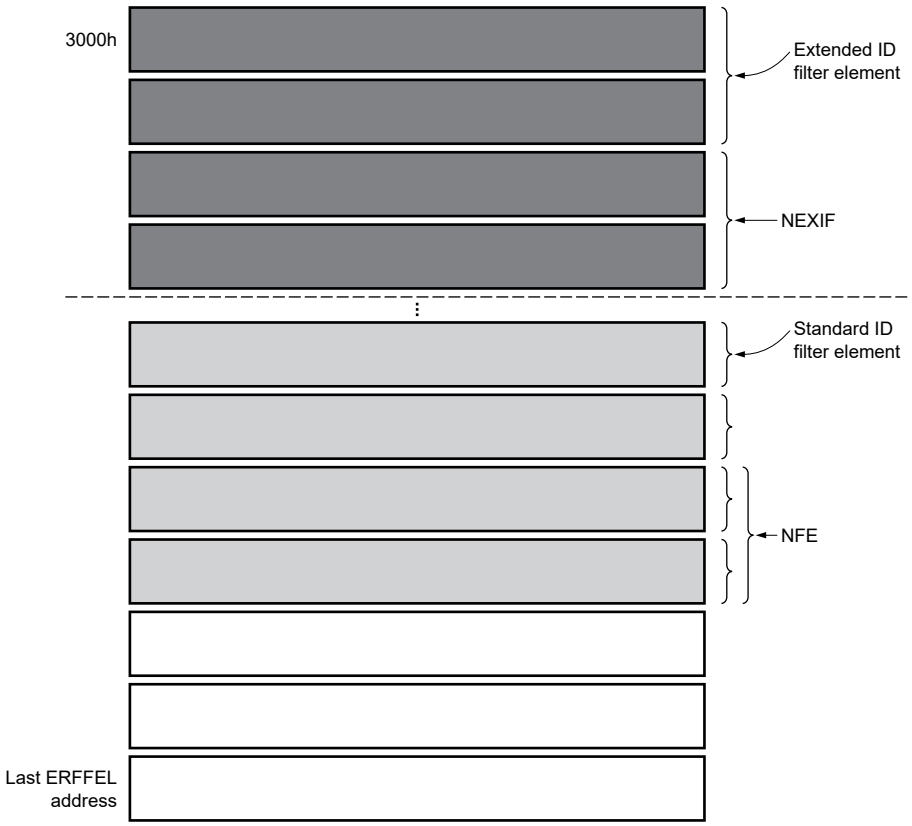

Figure 188. Number of enhanced RX FIFO filter elements

52.3.9.1 Enhanced RX FIFO matching process

When ERFCR[ERFEN] = 1, FlexCAN scans the ERFFEL*n* memory region. If at least one filter element satisfies the matching criteria, the CAN message content is transferred to the enhanced RX FIFO memory. If multiple filters match the incoming message ID, the first matching filter found by the matching process must be indicated in IDHIT.

Each ERFFEL*n* register can store one standard filter element. ERFFEL*n*[FEL][31:30], also called FSCH, determines the matching criteria in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base-frame format (IDE = 0).
  2. (ID[*n*] = STD ID filter [*n*]) or (STD ID Mask[*n*] = 0) for each bit *n* from 0 to 10.
  3. (RTR = RTR Filter) or (RTR MASK = 0).

In this explanation, RTR and ID are the Remote Transmit Request field and the ID from a CAN message, respectively.

If FSCH = b00, the filters and masks are defined as shown in Table 329.

Table 329. Standard ID filter element with filter and mask scheme (FSCH = b00)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH = b00		Reserved		RTR Filter	STD ID Filter		Reserved		RTR MASK	STD ID MASK	

- If FSCH = b01, the filter scheme is based on range. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0).
  2. ID ≥ STD ID Filter1.
  3. ID ≤ STD ID Filter2.
  4. (RTR = RTR filter) or (RTR MASK = 0).

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b01, the filters and mask are defined as shown in Table 330.

Table 330. Standard ID filter element with range scheme (FSCH = b01)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH = b01		Reserved		RTR Filter	STD ID Filter2		Reserved		RTR MASK	STD ID Filter1	

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0).
  2. (ID[*n*] = STD ID Filter1[*n*]) or (ID[*n*] = STD ID Filter2[*n*]) for each bit *n* from 0 to 10.
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2).

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b10, the filters are defined as shown in Table 331.

Table 331. Standard ID filter element with two-filter scheme (FSCH = b10)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH = b10		Reserved		RTR Filter 2	STD ID Filter2		Reserved		RTR Filter 1	STD ID Filter1	

Each pair of ERFFEL*n* registers can store one extended filter element. ERFFEL*n*[FSCH] determines the matching criteria in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. (ID[*n*] = EXT ID filter [*n*]) or (EXT ID Mask[*n*] = 0) for each bit *n* from 0 to 28.
  3. (RTR = RTR Filter) or (RTR MASK = 0).

If FSCH = b00, the filters and masks are defined as shown in Table 332.

Table 332. Extended ID filter element with filter + mask scheme (FSCH = b00)

31	30	29	28	0
FSCH		RTR Filter	EXT ID Filter	
Reserved		RTR MASK	EXT ID MASK	

- If FSCH = b01, the filter scheme is based on range. A CAN message matches an extended ID filter element only if the following criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. ID ≥ EXT ID Filter1.
  3. ID ≤ EXT ID Filter2.
  4. (RTR = RTR Filter) or (RTR MASK = 0).

If FSCH = b01, the filters and masks are defined as shown in Table 333.

Table 333. Extended ID filter element with range scheme (FSCH = b01)

31	30	29	28	0
FSCH		RTR Filter	EXT ID Filter2	
Reserved		RTR MASK	EXT ID Filter 1	

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. (ID[*n*] = EXT ID Filter1[*n*]) or (ID[*n*] = EXT ID Filter2[*n*]) for each bit *n* from 0 to 28.
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2).

If FSCH = b10, the filters are defined as shown in Table 334.

Table 334. Extended ID filter element with two-filter scheme (FSCH = b10)

31	30	29	28	0
FSCH		RTR Filter2	EXT ID Filter2	
Reserved		RTR Filter1	EXT ID Filter 1	

52.3.9.2 Enhanced RX FIFO under DMA operation

You can enable the DMA feature by writing 1 to both ERFCR[ERFEN] and MCR[DMA]. The DMA controller can read the received message by reading a message buffer structure at the enhanced FIFO output port at the address range defined in Enhanced RX FIFO structure.

NOTE

FlexCAN supports 32-bit access only for DMA transfers.

For proper FIFO engine operation, the CPU should not access the Enhanced FIFO output port address range during DMA operation. Before writing 1 to MCR[DMA], the CPU must service Enhanced RX FIFO status bits. Otherwise, these bits may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before writing 0 to MCR[DMA], the CPU must first clear the ERFSR[ERFUFW], ERFSR[ERFOVF], ERFSR[ERFWMI], and ERFSR[ERFDA] flags. It must then clear the enhanced RX FIFO engine by writing one to ERFSR[ERFCLR].

When there is one frame available to be read from the Enhanced RX FIFO, FlexCAN sets ERFSR[ERFDA]. Upon receiving the request, the DMA controller can read the message in the Enhanced RX FIFO output. Each message reading process must end by the address defined in ERFCR[DMALW].

Follow these rules for Enhanced RX FIFO DMA operation:

- Because a DMA transfer cannot be changed dynamically, program ERFCR[DMALW] so the enhanced RX FIFO element can store the largest CAN message present on the CAN bus.
- Data bytes are valid according to the DLC field. See Table 357.

Each time the DMA controller reads one message from the FIFO, FlexCAN clears ERFSR[ERFDA]. If there is at least one message stored in the FIFO, FlexCAN sets it again.

Consider an example where the maximum number of bytes in the data field of a CAN frame for a certain application is eight. In that case, the last enhanced RX FIFO address offset can be found in Table 367 and Table 368. Using this address offset, ERFCR[DMALW] can be determined in this way:

- Maximum number of data bytes = 8
- Last address offset = TS_OFF = 2010h
- DMALW = 4

52.3.9.3 Enhanced RX FIFO clear operation

When ERFCR[ERFEN] is 1, the CPU can clear the Enhanced RX FIFO by writing 1 to ERFSR[ERFCLR]. The clear operation resets the internal FIFO pointers, but the FIFO content stored in RAM is not changed. This operation can only be performed in Freeze mode; the module blocks the operation in other modes. This operation does not clear ERFSR[ERFUFW], ERFSR[ERFOVF], ERFSR[ERFDA], or ERFSR[ERFWMI]. The CPU must service all these fields before executing the clear FIFO operation.

52.3.10 Legacy RX FIFO

The Legacy RX FIFO is receive-only. To enable it, write 1 to MCR[RFEN]. To maintain software backward compatibility with previous versions of FlexCAN that did not have the Legacy FIFO feature, the reset value of this field is zero.

CAUTION

Do not enable Legacy RX FIFO when the CAN FD feature is enabled.

The Legacy FIFO is six messages deep. The memory region the Legacy FIFO structure occupies (both message buffers and Legacy FIFO engine) is described in Legacy RX FIFO structure. The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a message buffer structure at the output of the Legacy FIFO.

IFLAG1[BUF5I] (Frames Available in Legacy RX FIFO) is set when at least one frame is available to be read from the Legacy FIFO. If the corresponding mask bit enables it, an interrupt is generated. Upon receiving the interrupt, the CPU can read the message (accessing the output of the Legacy FIFO as a message buffer) and Legacy RX FIFO Information (RXFIR), then clear the interrupt. If there are more messages in the Legacy FIFO, clearing the interrupt:

1. Updates the output of the Legacy FIFO with the next message.
2. Updates RXFIR with the attributes of that message.
3. Reissues the interrupt to the CPU.

Otherwise, the flag remains cleared. The output of the Legacy FIFO is valid only when IFLAG1[BUF5I] is set.

IFLAG1[BUF6I] (Legacy RX FIFO Warning) is set when the Legacy RX FIFO receives a new message that increases the number of unread messages from four to five. This change means that the Legacy RX FIFO is almost full. The flag remains set until the CPU clears it.

IFLAG1[BUF7I] (Legacy RX FIFO Overflow) is set when an incoming message is lost because the Legacy RX FIFO is full. The flag is not set when the Legacy RX FIFO is full and a message buffer captures the message. The flag remains set until the CPU clears it.

Clearing one of the three flags above does not affect the state of the other two.

If an IFLAG flag is set and the corresponding mask bit is 1, an interrupt is generated.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing workload. The filtering criteria are specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN]. This table can be configured to one of the following formats (see also Legacy RX FIFO structure):

- Format A: 128 Identifier Acceptance Filters (IDAFs) — extended or standard IDs including IDE and RTR
- Format B: 256 IDAFs — standard IDs or extended 14-bit ID slices including IDE and RTR
- Format C: 512 IDAFs — standard or extended 8-bit ID slices

NOTE

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the Legacy RX FIFO has a corresponding Identifier Acceptance Filter Hit Indicator (IDHIT). The IDHIT can be read in the IDHIT field in the Control and Status word, as shown in the Legacy RX FIFO Structure description. The CPU can also obtain this information by accessing Legacy RX FIFO Information (RXFIR). RXFIR[IDHIT] refers to the message at the output of the Legacy FIFO, and is valid when IFLAG1[BUF5I] is set. RXFIR must be read only before clearing the flag, guaranteeing that the information refers to the correct frame within the Legacy FIFO.

The Individual Mask Registers (RXIMR*n*) individually affect up to 32 elements of the filter table, according to the value of CTRL2[RFFN]. This configuration allows very powerful filtering criteria to be defined. If MCR[IRMQ] is 0, the Legacy RX FIFO filter table is affected by Legacy RX FIFO Global Mask (RXFGMASK).

NOTE

See Table 321 for information about the difference between FD and non-FD regarding this feature.

52.3.10.1 Legacy RX FIFO in DMA Operation

The receive-only Legacy FIFO can support DMA. To enable this feature, write 1 to both MCR[RFEN] and MCR[DMA]. To maintain backward compatibility with previous versions of the module that did not have the DMA feature, the reset value of MCR[DMA] is zero.

The DMA controller can read the received message by reading a message buffer structure at the Legacy FIFO output port in the 80h–8Ch address range.

NOTE

FlexCAN supports 32-bit access only for DMA transfers.

When MCR[DMA] = 1, the CPU must not access the Legacy FIFO output port address range. Before writing 1 to MCR[DMA], the CPU must service the IFLAG flags set in the Legacy RX FIFO region. Otherwise, these flags may indicate that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before writing 0 to MCR[DMA], the CPU must perform a clear Legacy FIFO operation.

When at least one frame available to be read from the FIFO, IFLAG1[BUF5I] (Frames available in Legacy RX FIFO) is set. A DMA request is generated simultaneously. Upon receiving the request, the DMA controller can read the message (accessing the output of the Legacy FIFO as a message buffer). The DMA reading process must end by reading address 8Ch. This read operation:

- Clears IFLAG1[BUF5I].
- Updates the FIFO output with the next message (if the FIFO is not empty).
- Updates Legacy RX FIFO Information (RXFIR) with the attributes of the new message.

If there are more messages stored in the FIFO, IFLAG1[BUF5I] is reasserted and another DMA request is issued. Otherwise, the flag remains cleared.

IFLAG1[BUF6I] and IFLAG1[BUF7I] are not used when the DMA feature is enabled.

When FlexCAN is working with DMA, the CPU does not receive any Legacy RX FIFO interruption and must not clear the related IFLAG flags. The related IMASK bits are not used to mask the generation of DMA requests.

NOTE

See Table 321 for information about the difference between FD and non-FD regarding this feature.

52.3.10.2 Clear Legacy FIFO

When MCR[RFEN] = 1, you can use the clear Legacy FIFO operation to empty Legacy FIFO contents. When the CPU writes 1 to IFLAG1[BUF0I], the clear FIFO operation occurs. This operation can only be performed in Freeze mode; FlexCAN blocks it in other modes. This operation does not clear the FIFO IFLAG flags; the CPU must service all FIFO IFLAG flags before executing the clear FIFO operation.

When Legacy RX FIFO is working with DMA, the clear FIFO operation clears IFLAG1[BUF5I], and the DMA request is canceled.

CAUTION

The clear Legacy FIFO operation does not clear IFLAG flags, except when MCR[DMA] = 1; in this case, only IFLAG1[BUF5I] is cleared.

52.3.11 Fault reaction

This situation is catastrophic, and in response to the fault reaction, FlexCAN goes into a safe state (Freeze) and drives a safe value (recessive bit) on the bus.Either CTRL2[FLT_RXN] or an input "fault reaction" signal from another module can trigger a fault reaction. FlexCAN remains in a safe state as long as CTRL2[FLT_RXN] = 1 or the "fault reaction" signal is asserted and MCR[FRZ] = 1.

A fault can occur at any time, including during frame transmission, reception, and BUS IDLE. If a fault occurs during frame transmission, FlexCAN stops the frame transmission and goes into a safe state.

If a fault occurs during frame reception, FlexCAN stops receiving the frame and goes into a safe state. If FlexCAN is in loopback or self-reception mode, the effect of the fault reaction is the same as described above.

When the fault condition is removed, FlexCAN remains in Freeze mode until the CPU writes 0 to MCR[FRZ].

52.3.12 Retransmission

If a message transmission is unsuccessful due to a reason other than a loss of arbitration or being aborted by the host, FlexCAN attempts to retransmit the message a number of times determined by the value of CTRL2[RETRY].

When a message transmission is unsuccessful, a counter is decremented. When that counter reaches zero, FlexCAN aborts the message. FlexCAN sets the IFLAG for the aborted message and an interrupt is generated (if enabled). FlexCAN sets the IFLAG and updates the CODE field of the control and status word by abort code. The host can read the IFLAG flag and CODE field to identify which message FlexCAN aborted due to retransmission attempts greater than the value of CTRL2[RETRY].

52.3.13 CAN protocol-related features

52.3.13.1 CAN FD ISO compliance

The CAN FD protocol has been improved to increase the failure-detection capability that was in the original CAN FD protocol. This original protocol is also called non-ISO CAN FD, by CAN in Automation (CiA). A three-bit stuff counter and a parity bit have been introduced in the improved CAN FD protocol, now called ISO CAN FD. The CRC calculation has also been modified. All these improvements make the ISO CAN FD protocol incompatible with the non-ISO CAN FD protocol. FlexCAN still supports non-ISO CAN FD, so it can be used during an intermediate phase, for evaluation and development purposes.

It is recommended that you configure FlexCAN with the ISO CAN FD protocol by writing 1 to CTRL2[ISOCANFDEN].

52.3.13.2 CAN FD frames

ISO 11898-1:2015 specifies the Classical Frame format compliant to ISO 11898-1:2003 (2003) and introduces the CAN Flexible Data Rate Frame format (CAN FD). The Classical Frame format allows bit rates up to one Mbit/s and payloads up to eight bytes per frame. The Flexible Data Rate Frame format allows bit rates faster than one Mbit/s and payloads longer than eight bytes per frame. FlexCAN can receive and transmit CAN FD messages interleaved with Classical CAN messages.

There are additional control bits in the CAN FD frame:

- The Extended Data Length (EDL) bit enables a longer data payload with different data length coding.
- The Bit Rate Switch (BRS) bit decides whether the bit rate is switched inside a CAN FD format frame.
- The Error State Indicator (ESI) flag is transmitted dominant by error active nodes, and recessive by error passive nodes.

There are no Remote Frames (see Remote frames) in the CAN FD format. A message configured to transmit a Remote Frame is always sent out in Classical CAN format. When an FD frame is received and matches a message buffer, the RTR bit in the receiving message buffer becomes 0. The RTR bit must be considered in classical frames only.

52.3.13.2.1 CAN FD messages

CAN FD messages may be formatted as long frames where the data field exceeds eight bytes, and may range from 12 up to 64 bytes. They can also be configured to support bit rate switching. In this case, the control field, data field, and CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and end of the frame. Messages in Classical CAN format are limited to transport a maximum payload of eight bytes at nominal rate. Figure 189 illustrates the message formats for Classical and FD frames with either standard or extended ID.

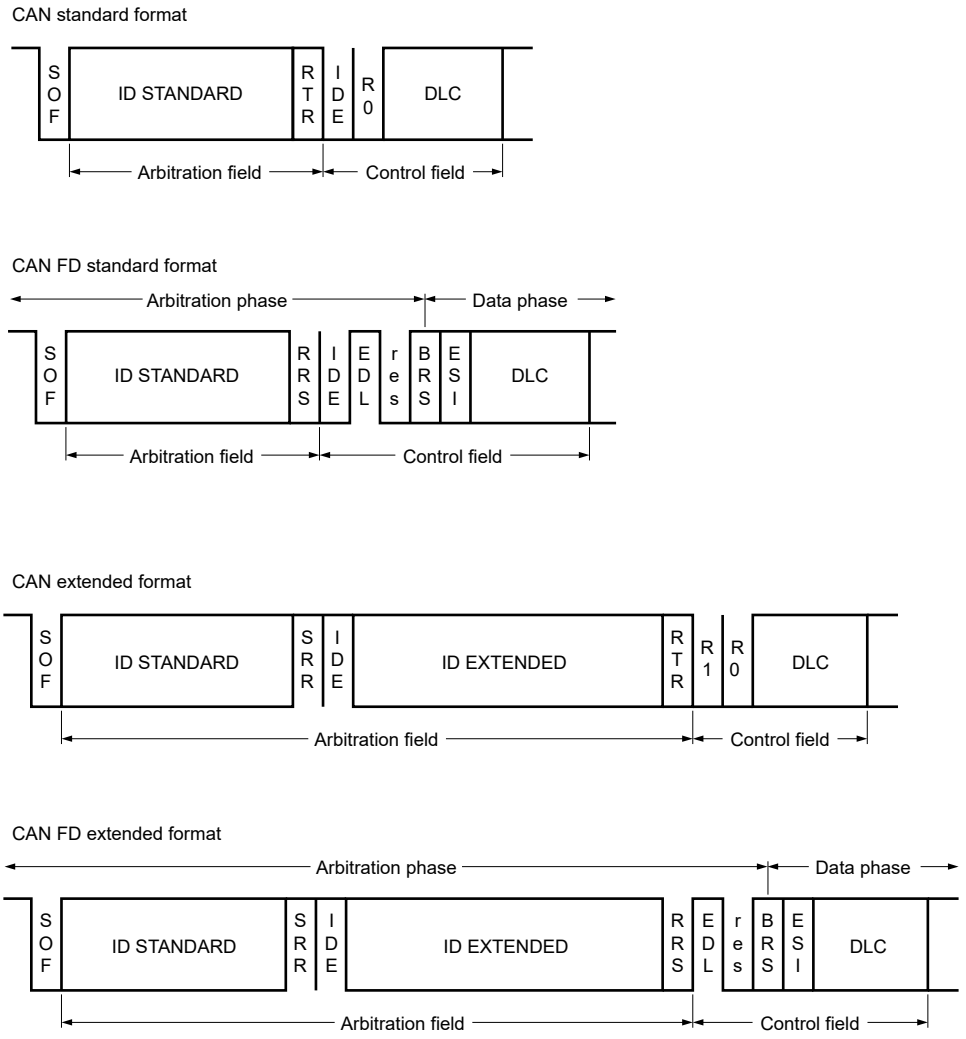

Figure 189. CAN message formats

MCR[FDEN] enables the ability to receive and transmit CAN FD messages. A recessive R0 bit in CAN frames with 11-bit identifiers, or a recessive R1 bit in CAN frames with 29-bit identifiers, is decoded as an EDL bit (not a reserved one). A recessive EDL bit identifies a CAN FD frame, and a dominant EDL bit identifies a Classical CAN frame. The BRS bit specifies whether this frame switches the bit rate in its data phase. A long frame is decoded according to the DLC field value (see DLC definition in Message buffer structure).

CAN FD messages can be transmitted with two different bit rates. The first part of a CAN FD frame, from the Start of Frame (SOF) bit until the Bit Rate Switch (BRS) bit is called the arbitration phase. This part is transmitted with the nominal bit rate based on a set of nominal CAN bit timing configuration values. The second part, from the BRS bit until the CRC Delimiter bit, is called the data phase. When this second part is transmitted, a second set of CAN data bit timing configuration values determines the data bit rate. Finally, from the CRC delimiter until the Intermission bits, the transmission returns to nominal bit rate.

52.3.13.2.2 BRS in CAN FD

In CAN FD frames with bit rate switching, the bit timing changes inside the frame at the sample point of the BRS bit if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by CAN Bit Timing (CBT). (Control 1 (CTRL1) also defines this timing for backward compatibility.) Upon detecting a recessive BRS bit, the CAN data bit timing is used as defined by CAN FD Bit Timing (FDCBT).

NOTE

If the time quantum length in nominal bit timing and in the data bit timing are not identical, a quantization error of up to one time quantum of the arbitration phase may be present as a phase error. This situation can occur after the switch from arbitration to data phase, and it lasts until the next synchronization event. The length of the time quantum should be the same in nominal and data bit timing. This configuration minimizes the chance of error frames on the CAN bus, and optimizes the clock tolerance in networks that use FD frames.

If BRS = 1 in the selected TX MB, FDCTRL[FDRATE] enables the transmission of all frames with bit rate switching. If FDCTRL[FDRATE] = 0, the transmission is performed at nominal rate regardless of the BRS bit value. FDCTRL[FDRATE] can be written at any time but takes effect only for the next message transmitted or received.

Nominal bit timing is resumed at the sample point of the CRC Delimiter bit or when an error is detected, whichever occurs first. Figure 190 describes the mechanism for entering and leaving the data phase when the BRS bit is recessive.

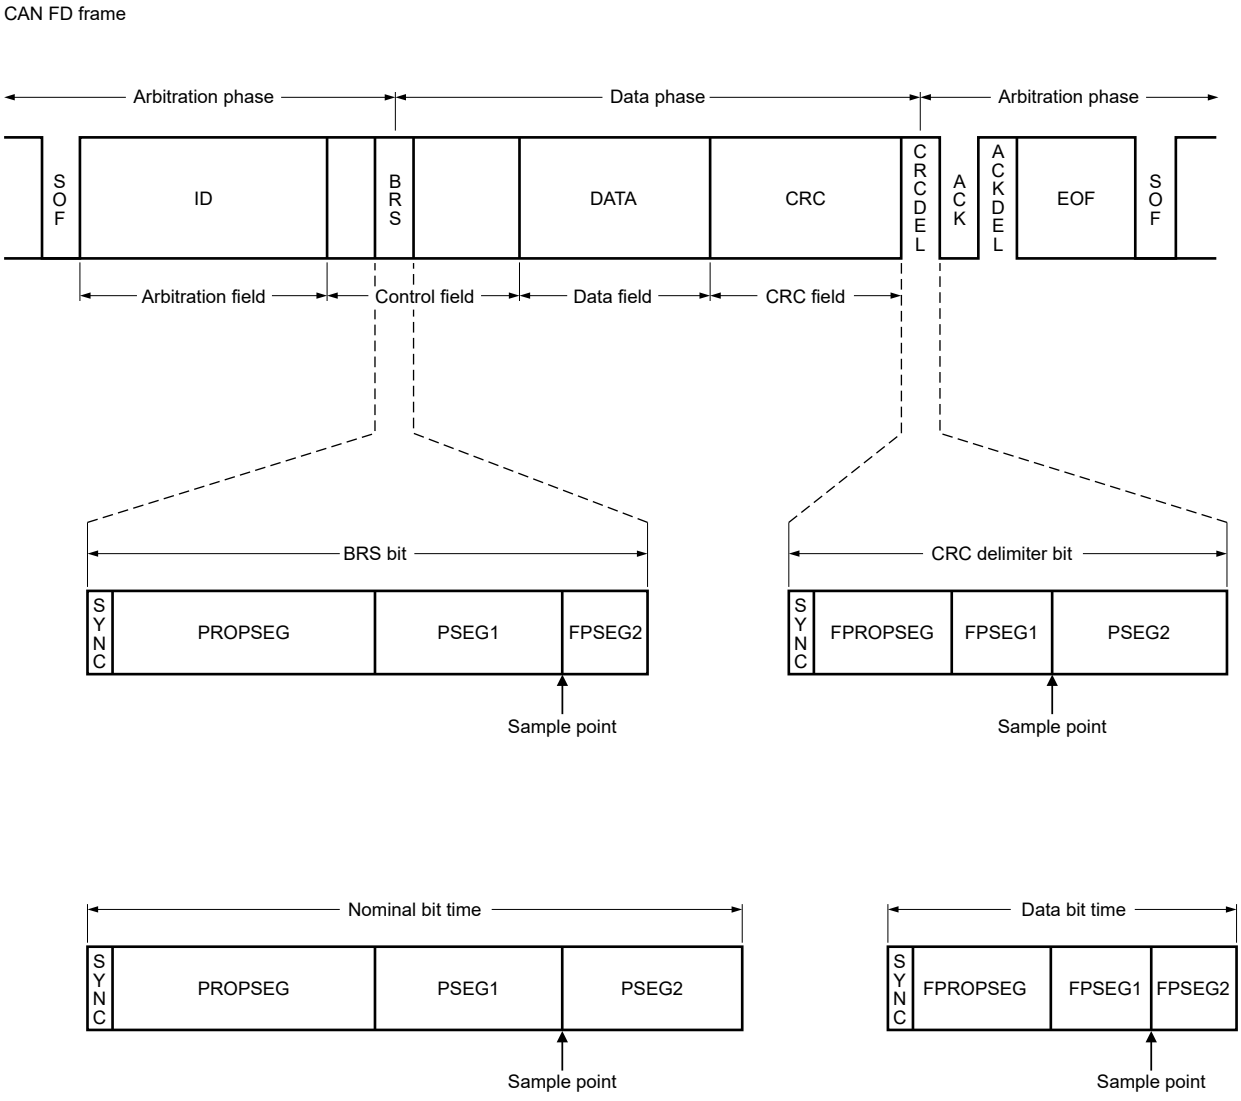

Figure 190. Bit rate switching mechanism for CAN FD messages

NOTE

In Classical CAN frames, the CRC delimiter is one recessive bit. In CAN FD frames, the CRC delimiter may consist of one or two recessive bits. FlexCAN sends only one recessive bit as the CRC delimiter. It accepts two recessive bits before the recessive-to-dominant edge that starts the acknowledge slot. As a receiver, FlexCAN sends its acknowledge bit after the first CRC delimiter bit. In CAN FD frames, FlexCAN accepts a two-bit dominant ACK slot as a valid ACK to compensate for phase shifts between the receivers.

The maximum configurable bit rate in the CAN FD data phase depends on the clock frequency of the CAN_PE subblock. For example, for a CAN_PE clock frequency of 40 MHz and the shortest configurable bit time of 5 time quanta, the bit rate in the data phase is 8 Mbit/s.

NOTE

The frequency used in this example may not be supported on this chip. It is shown only to demonstrate how the maximum configurable bit rate is calculated.

52.3.13.2.3 ESI in CAN FD

The value of the ESI bit is determined:

- By the error state of the transmitter at the start of the transmission, if the frame is originated in the FlexCAN node,
- Or by the original transmitting node when FlexCAN is acting as a gateway for the message.

If the transmitter is error-passive, ESI is transmitted recessive; otherwise, it is transmitted dominant. The permutations of the relationship between the written value and the transmitted value of the ESI are shown in Table 335.

Table 335. Written versus transmitted values of ESI field

FlexCAN fault confinement status at start of frame	ESI bit of TX MB	Transmitted ESI
Error active	0	0 (Error Active)
Error passive	0	1 (Error Passive)
Error active	1	1 (Error Passive)
Error passive	1	1 (Error Passive)

52.3.13.2.4 CRC calculations in CAN FD

Different CAN frame formats have different CRC polynomials. The first polynomial, CRC_15, is used for all frames in Classical CAN format. The second, CRC_17, is used for frames in CAN FD format with a data field up to 16 bytes long. The third, CRC_21, is used for frames in CAN FD format with a data field longer than 16 bytes. Each polynomial results in a Hamming distance of 6. At the start of the frame, all three CRC polynomials are calculated concurrently. The values of the EDL bit and the DLC field select the CRC sequence to be transmitted. When receiving a message, FlexCAN decodes EDL and DLC to select the adequate CRC polynomial to check for a CRC error.

In CAN FD format frames, stuff bits are included in the bit stream for CRC calculation. In Classical CAN format frames, stuff bits are not included. After the transmission of the last bit relevant to the CRC calculation, CAN FD CRC (FDCRC) stores the calculated CRC for the transmitted message. This storage is performed with adequate length for the type of message, for CAN FD and non-FD messages. Cyclic Redundancy Check (CRCR) reports a valid CRC for Classical CAN messages only.

In CAN FD format frames, the CAN bit stuffing method changes for the CRC sequence, so the stuff bits are inserted at fixed positions. When FlexCAN is transmitting a CAN FD frame, a fixed stuff bit is inserted just before the first bit of the CRC sequence. This insertion occurs even if the last bits of the preceding field do not fulfill the CAN stuff condition. Additional stuff bits are inserted after each fourth bit of the CRC sequence. The value of any fixed stuff bit is the inverse value of its preceding bit. When FlexCAN receives a CAN FD frame, it discards the fixed stuff bits from the bit stream for the CRC check. A stuff error is detected if the fixed stuff bit has the same value as its preceding bit.

52.3.13.2.5 CAN FD errors

FlexCAN detects errors in CAN FD frames the same way as in Classical CAN frames. The error counters ECR[RXERRCNT] and ECR[TXERRCNT] accumulate the counts of RX and TX errors, respectively, for both FD and non-FD frames indiscriminately. Two extra error counters, ECR[RXERRCNT_FAST] and ECR[TXERRCNT_FAST], accumulate RX and TX errors occurring in the data phase of CAN FD frames with BRS = 1 only. The rules for updating the error counters are the same for both CAN FD and non-FD frames (see Error Counter (ECR)).

These error flags report errors in both CAN FD and non-FD frames:

- ESR1[BIT1ERR]
- ESR1[BIT0ERR]
- ESR1[ACKERR]
- ESR1[CRCERR]
- ESR1[FRMERR]
- ESR1[STFERR]

If CTRL1[ERRMSK] = 1, they also generate the ERRINT interrupt.

These additional error flags indicate the occurrence of errors in the data phase of CAN FD frames with BRS = 1:

- ESR1[BIT1ERR_FAST]
- ESR1[BIT0ERR_FAST]
- ESR1[CRCERR_FAST]
- ESR1[FRMERR_FAST]
- ESR1[STFERR_FAST]

No ACKERR is detected in the data phase of a CAN FD frame. Fault confinement status reported in ESR1[FLTCONF] is the same for both CAN FD and Classical CAN frames, and is based on ECR[RXERRCNT] and ECR[TXERRCNT] only. Information in ECR[RXERRCNT_FAST] and ECR[TXERRCNT_FAST] may be considered as status to help detect the error nature related to the bit rate value.

When FlexCAN detects an error while transmitting or receiving a CAN FD message in the data phase, it immediately switches:

- Back to the arbitration phase, and
- Back to the nominal rate to start an error flag.

52.3.13.2.6 CAN FD synchronization

Resynchronization and hard synchronization occur in CAN FD frames in the same way as in Classical CAN ones. A hard synchronization is also performed at the recessive-to-dominant edge from EDL to R0 in CAN FD format frames. FlexCAN does not resynchronize when transmitting in the CAN FD data phase.

52.3.13.3 Transceiver delay compensation

The CAN FD protocol allows the transmission and reception of data at a higher bit rate than the nominal rate used in the arbitration phase, when BRS = 1 in the message. This feature enables the use of rates up to 8 Mbit/s.

During the data phase of a CAN FD frame, if the transmitter cannot receive its own latest transmitted bit at the sample point of that bit, it detects a bit error. When bit rate switching is enabled (BRS = 1), the CAN bit time in the data phase can become shorter than the loop delay of the transceiver. This condition impedes the correct comparison between the transmitted bit and the received bit within the current CAN bit time interval.

The transceiver delay compensation (TDC) process defines a secondary sample point where the transmitted bit is correctly compared to the received bit to check for bit errors.

You can enable the TDC mechanism via FDCTRL[TDCEN] or ETDC[ETDCEN]. The TDC mechanism is effective only during the data phase of FD frames with BRS = 1. It has no effect on either non-FD frames or FD frames transmitted at the normal bit rate. When the transmitted message has BRS = 1, TDC is active from the sample point of the BRS bit until the sample point of the CRC Delimiter bit. When TDC is active, the real received bit is compared to the delayed transmitted bit, where the delay is calculated based on the measured transceiver loop delay.

NOTE

The transmitters using TDC disregard the value of the CRC delimiter bit. A global error at the end of the CRC field causes the receivers to send error frames that the transmitter detects during Acknowledge or End of Frame.

For every transmitted FD frame with BRS = 1, the transition from the recessive EDL bit to the dominant R0 bit triggers the delay measurement (as shown in Figure 191). The loop delay is measured in Protocol Engine (PE) clock periods (CANCLK, see Protocol timing), from the transmitted EDL-R0 edge to the received EDL-R0 edge. The measured loop delay time added to an offset value specified in FDCTRL[TDCOFF] or ETDC[ETDCOFF] determines the position of the secondary sample point. FDCTRL[TDCVAL] or ETDC[ETDCVAL] stores the result of this calculation. The TDCVAL and ETDCVAL value saturates at its maximum value of 63 CANCLK and 255 CANCLK when the delay measurement is too long.

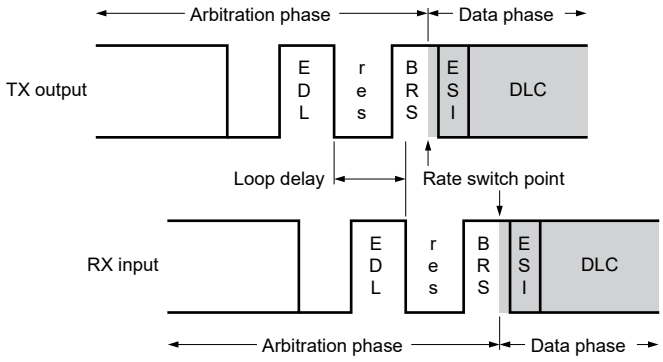

Figure 191. Transceiver loop delay measurement

The measured loop delay is not enough to define the secondary sample point, because it relates to the CAN bit edges. The transceiver delay compensation offset FDCTRL[TDCOFF] or ETDC[ETDCOFF] is used to shift the secondary sample point to an intermediate point inside the bit time, far away from its edges. The value of FDCTRL[TDCOFF] or ETDC[ETDCOFF] cannot be larger than the CAN bit duration in the data phase.

If the secondary sample point is set very near the CAN bit edge (SYNC field), problems may occur during the bit sampling in the data phase. For the TDC to work reliably, the offset must use optimal settings. To ensure that bit sampling is performed in the best region, configure the TDC offset as shown in this equation:

$$Offset = (FPSEG1 + FPROPSEG + 2) \times (FPRESDIV + 1)$$
or
$$Offset = (DTSEG1 + 2) \times (EDPRESDIV + 1), \textit{ if ETDCEN}$$

Equation 1. TDC offset calculation

Figure 192 shows the SSP position when these settings are used.

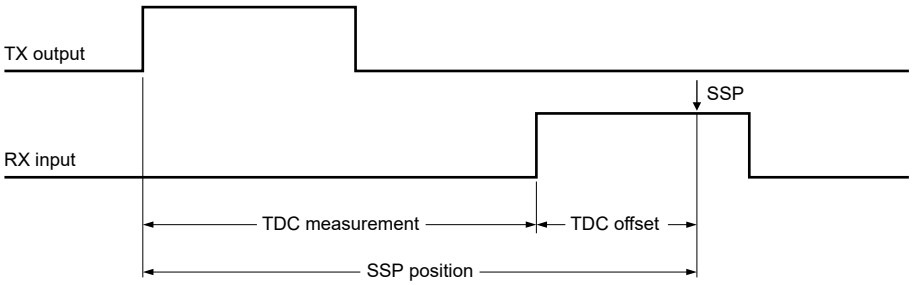

Figure 192. SSP position with optimal values

Alternatively, if CTRL2[BTE] and ETDC[ETDCEN] are 1, you can write 1 to ETDC[TDMDIS] to disable the transceiver delay measurement. In this case, only ETDC[ETDCOFF] defines the SSP position. Figure 193 shows the secondary sample point position when the transceiver delay measurement is disabled.

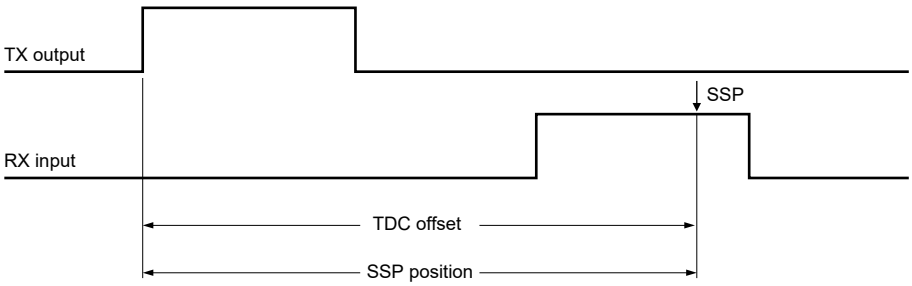

Figure 193. SSP position with TDC measurement disabled by ETDCEN and TDMDIS

During the data phase of CAN FD frames with bit rate switching enabled, at the onset of every TX CAN bit:

- The transmitted TX bit value is temporarily stored in a buffer.
- A time countdown based on FDCTRL[TDCVAL] or ETDC[ETDCVAL] is started. This countdown ends with the comparison of the received RX bit (delayed by the external loop delay plus the specified offset) to the stored TX bit.

If a bit error is detected at the secondary sample point, FlexCAN issues an error flag to the CAN bus at the next sample point.

During the arbitration phase, delay compensation is always disabled. During the data phase, the TDC mechanism of FlexCAN can compensate a maximum delay of 3 CAN bit times − 2 Tq. Beyond this limit, the FDCTRL[TDCFAIL] or ETDC[ETDCFAIL] flag is set. The flag indicates when the TDC mechanism is out of range and is unable to compensate the transceiver loop delay.

52.3.13.4 Remote frames

A remote frame is a special type of frame. You can program a message buffer to be a remote request frame by configuring the message buffer as Transmit with the RTR = 1. After the remote request frame is transmitted successfully, the message buffer becomes a receive message buffer, with the same ID as before.

When FlexCAN receives a remote request frame, the frame can be treated in different ways, depending on remote request storing (CTRL2[RRS]) and RX FIFO Enable (MCR[RFEN]):

- If RRS = 0, the ID of the frame is compared to the IDs of the transmit message buffers with the CODE field 1010b. If a matching ID exists, this message buffer frame is transmitted. If the matching message buffer has the RTR = 1, FlexCAN transmits a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response.

  The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. If a remote request frame is received and matches a message buffer, this message buffer immediately enters the internal arbitration process. However, it is considered a normal TX message buffer, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.

- If CTRL2[RRS] = 1, the ID of the frame is compared to the IDs of the receive message buffers with the CODE field 0100b, 0010b, or 0110b. If a matching ID exists, this message buffer stores the remote frame in the same fashion as a data frame. No automatic remote response frame is generated. The mask registers are used in the matching process.
- If MCR[RFEN] = 1, FlexCAN does not generate an automatic response for remote request frames that match the Legacy FIFO filtering criteria. If the remote frame matches one of the target IDs, it is stored in the Legacy FIFO and presented to the CPU.

  For filtering formats A and B (see Legacy RX FIFO structure), it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted if they match the ID. Remote request frames are considered as normal frames. They generate a Legacy FIFO overflow when a successful reception occurs and the Legacy FIFO is already full.
- If ERFCR[ERFEN] = 1, FlexCAN does not generate an automatic response for remote request frames that match the Enhanced RX FIFO filtering criteria. Remote Request Frames are considered normal frames. They generate an Enhanced RX FIFO overflow when a successful reception occurs and the enhanced RX FIFO is already full.

NOTE

There is no remote frame in the CAN FD format. A fixed dominant RRS bit replaces the RTR bit. FlexCAN receives and transmits remote frames in the Classical CAN format.

52.3.13.5 Overload frames

When a dominant bit is detected on the CAN bus in these locations, FlexCAN transmits overload frames:

- The first or second bit of Intermission.
- The seventh bit (last) of End of Frame field (RX frames).
- The eighth bit (last) of Error Frame Delimiter or Overload Frame Delimiter.

52.3.13.6 Timestamp

The value of the free-running timer is sampled at the beginning of the Identifier field on the CAN bus. This value is stored at the end of move-in in the TIME_STAMP field, providing network behavior regarding time.

The FlexCAN bit clock clocks the free-running timer, which defines the baud rate on the CAN bus. During a message transmission or reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The free-running timer is not incremented during Disable, Doze, Stop, and Freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization. See CTRL1[TSYN].

52.3.13.7 Protocol timing

Figure 194 shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule.

NOTE

To identify the proper clock source, see the clock distribution chapter (module clocks table).

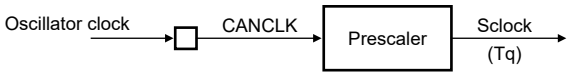

Figure 194. CAN engine clocking scheme

52.3.13.7.1 Bit timing configuration

FlexCAN supports various means to configure bit timing parameters required by the CAN protocol. Control 1 (CTRL1) has various fields to control bit timing parameters:

- CTRL1[PRESDIV]

- CTRL1[PROPSEG]
- CTRL1[PSEG1]
- CTRL1[PSEG2]
- CTRL1[RJW]

CAN Bit Timing (CBT) extends the range of the CAN bit timing variables in CTRL1. Enhanced Data Phase CAN Bit Timing (EDCBT) provides a second set of CAN bit timing variables to be applied at the data phase of CAN FD frames with the Bit Rate Switch (BRS) = 1.

Enhanced Nominal CAN Bit Timing (ENCBT) extends the range of CAN bit timing variables in CBT. Enhanced Nominal CAN Bit Timing (ENCBT) extends the range of CAN bit timing variables in FDCBT. When using ENCBT and EDCBT, you must program the nominal bit timing and data phase serial clock (Sclock) dividers in Enhanced CAN Bit Timing Prescalers (EPRS).

NOTE

When the CAN FD feature is enabled, always write 1 to CBT[BTF] or CTRL2[BTE] and specify the CAN bit timing variables in CBT or ENCBT. See CAN Bit Timing (CBT) or Enhanced Nominal CAN Bit Timing (ENCBT).

CTRL1[PRESDIV], and its extended range CBT[EPRESDIV] (or EPRS[ENPRESDIV]) and FDCBT[FPRESDIV] (or EPRS[EDPRESDIV]) for the data phase bits of CAN FD messages, defines the prescaler value that generates the serial clock (Sclock). (See Equation 2.) The period of Sclock defines the time quantum used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time managed by the CAN engine. It is the smallest time unit for all configuration values.

$$Tq = \frac{(PRESDIV + 1)}{f_{CANCLK}}$$

Equation 2. Time quantum

The bit rate, which defines the rate the CAN message is received or transmitted, is calculated with the formula:

$$CAN\ bit\ time = (Number\ of\ time\ quanta\ in\ 1\ bit\ time) \times Tq$$

$$Bit\ rate = \frac{1}{CAN\ bit\ time}$$

Equation 3. CAN bit time and baud rate

52.3.13.7.2 Bit time segments

A bit time is subdivided into three segments as shown in Figure 195. See also Figure 196 , Figure 197, and Table 336.

NOTE

For further explanation of the underlying concepts, see ISO 11898-1:2015. See also *CAN Specification Version 2.0, Part A and Part B* for bit timing.

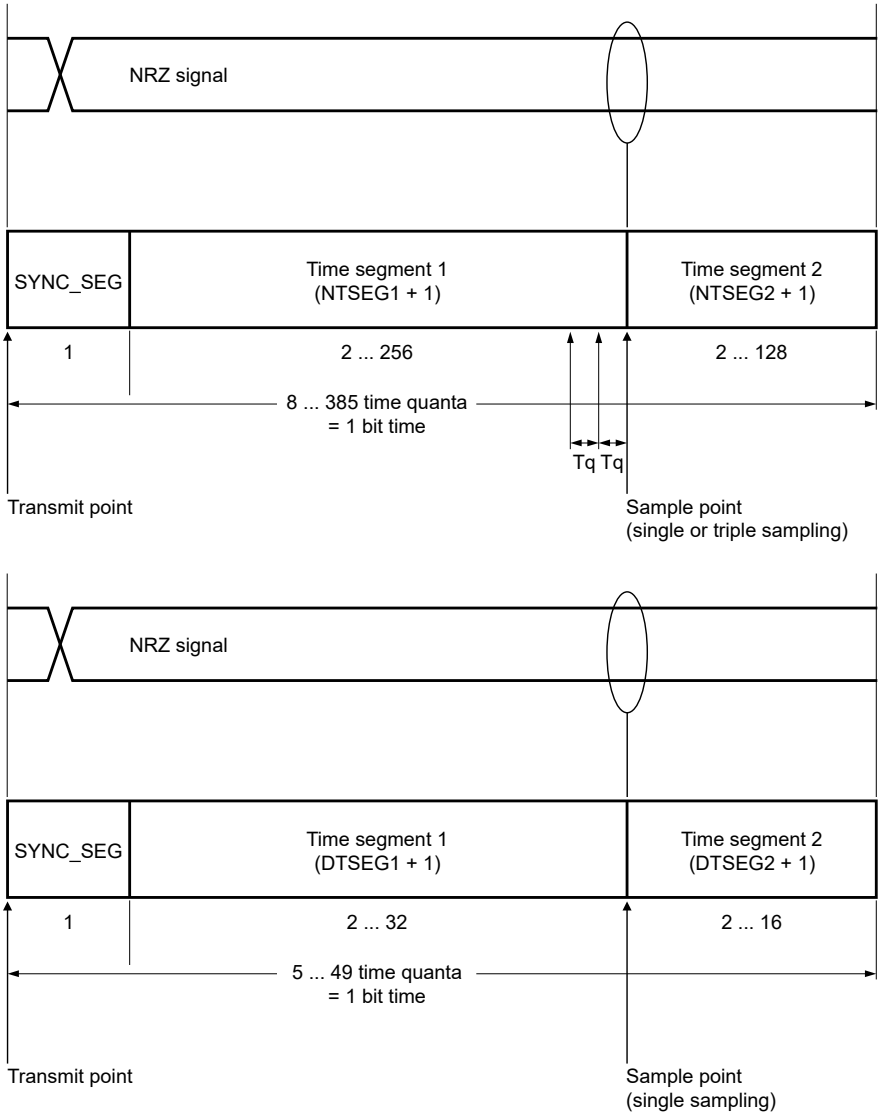

Figure 195. Segments within the bit timing (example using ENCBT and EDCBT bit timing variables)

The three bit time segments are:

- SYNC_SEG—this segment has a fixed length of one time quantum. Signal edges are expected to occur within this section.
- Time Segment 1—this segment includes the propagation segment and the phase segment 1 of the CAN standard.

  It can be programmed by configuring CTRL1[PROPSEG] and CTRL1[PSEG1] so that the sum (plus 2) is 2–16 time quanta. When CBT[BTF] = 1, FlexCAN uses CBT[EPROPSEG] and CBT[EPSEG1] so that the sum (plus 2) is 2–96 time quanta. For messages in CAN FD format with the BRS = 1, FlexCAN uses FDCBT[FPROPSEG] and FDCBT[FPSEG1] so that the sum (plus 1) is 2–39 time quanta.

  If CTRL2[BTE] = 1, FlexCAN uses ENCBT[NTSEG1] to configure time segment 1 to 2–256 time quanta. For the data phase in CAN FD messages with BRS = 1, EDCBT[DTSEG1] must be used for configuring time segment 1 to 2–32 time quanta.
- Time Segment 2—this segment represents the phase segment 2 of the CAN standard.

  It can be programmed by configuring CTRL1[PSEG2] (plus 1) to be 2–8 time quanta. When CBT[BTF] = 1, FlexCAN uses CBT[EPSEG2] so that its value (plus 1) is 2–32 time quanta. For messages in CAN FD format with the BRS = 1, FlexCAN uses

FDCBT[FPSEG2] instead, so that its value (plus 1) is 2–8 time quanta. Time segment 2 cannot be smaller than the Information Processing Time (IPT), which is 2 time quanta in FlexCAN.

If CTRL2[BTE] = 1, FlexCAN uses ENCBT[NTSEG2] to configure time segment 2 to 2–128 time quanta. For the data phase in CAN FD messages with BRS = 1, EDCBT[DTSEG2] must configure time segment 2 to 2–16 time quanta.

NOTE

The bit time defined by the above time segments must not be smaller than five time quanta. For bit time calculations, use an Information Processing Time (IPT) of two, which is the value implemented in the FlexCAN module.

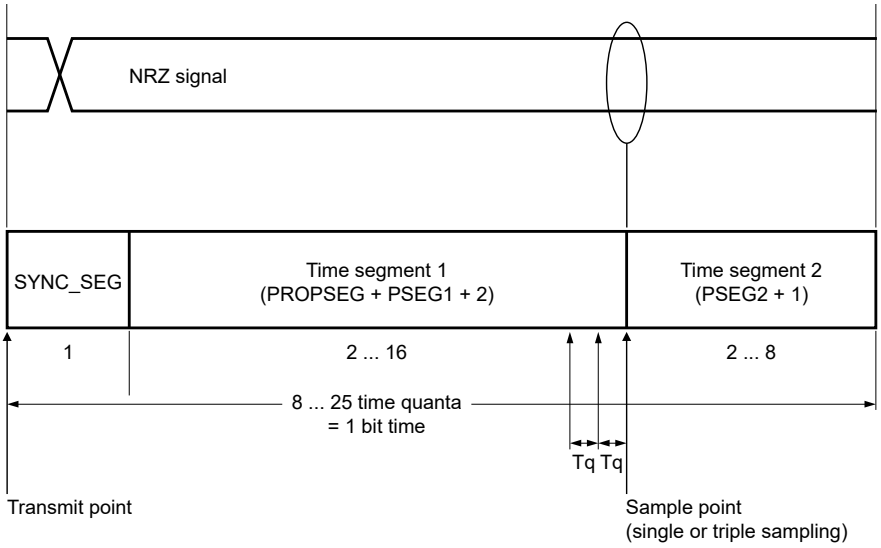

Figure 196. Segments within the bit time (example using CTRL1 bit timing variables for Classical CAN format)

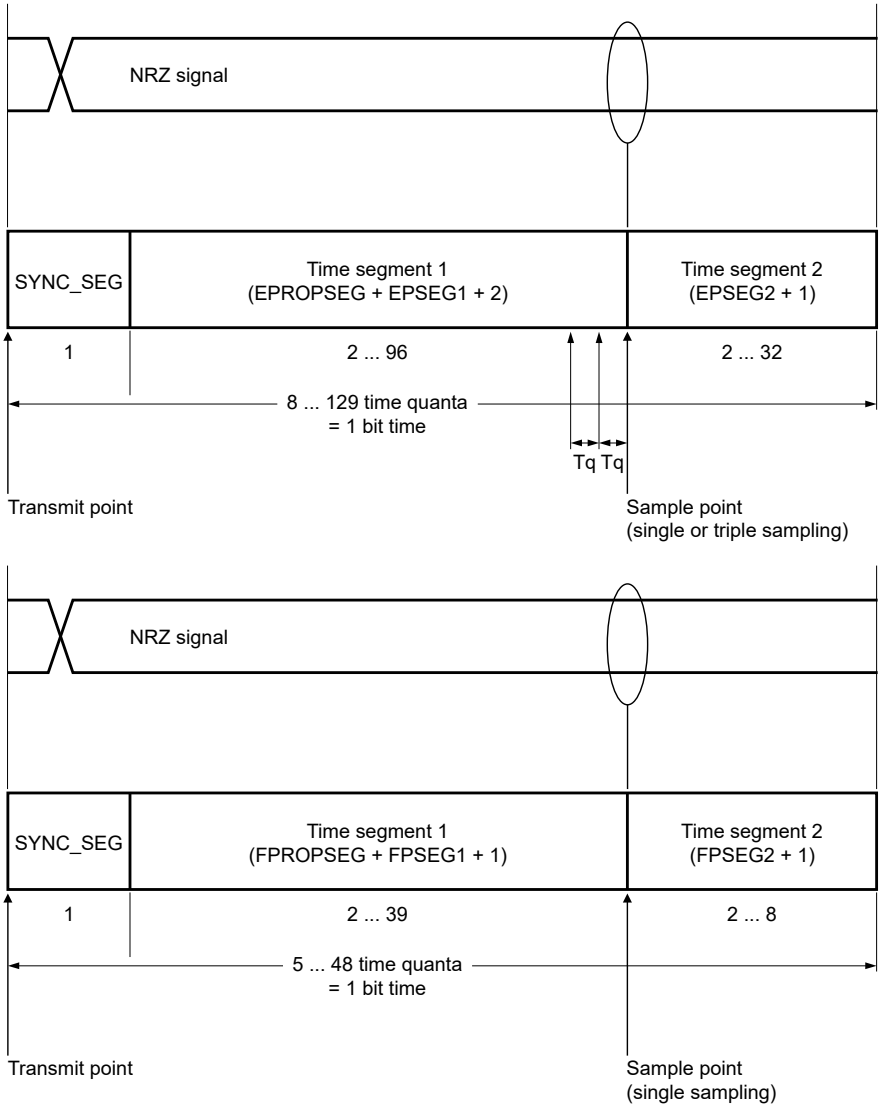

Figure 197. Segments within the bit time (example using CBT and FDCBT bit timing variables for CAN FD format)

Table 336. Time segment syntax

Syntax	Description
SYNC_SEG	Period during which the system expects transitions to occur on the bus
TSEG1	Period corresponding to the sum of PROPSEG and PSEG1
TSEG2	Period corresponding to the PSEG2 value
Transmit point	Point at which a node in Transmit mode transfers a new value to the CAN bus
Sample point	Point at which a node samples the bus. If the option of three samples per bit is selected, this point marks the position of the third sample.

Table 337 gives some examples of the CAN-compliant segment settings for Classical CAN format (Bosch CAN 2.0B) (non-FD) messages.

Table 337. Bosch CAN 2.0B standard compliant bit time segment settings

Time segment 1	Time segment 2	Resynchronization jump width
5 to 10	2	1 to 2
4 to 11	3	1 to 3
5 to 12	4	1 to 4
6 to 13	5	1 to 4
7 to 14	6	1 to 4
8 to 15	7	1 to 4
9 to 16	8	1 to 4

NOTE

You must ensure the bit time settings comply with the CAN Protocol standard (ISO 11898-1:2015).

52.3.13.7.3 Calculating peripheral clocks

A CAN bit can be used as a measure of duration (for example, estimating the occurrence of a CAN bit event in a message). When a CAN bit is used in this way, the number of peripheral clocks in one CAN bit (NumClkBit) can be calculated as:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (PRESDIV + 1) \times (PROPSEG + PSEG1 + PSEG2 + 4)$$

Equation 4. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 0

Or, if CTRL2[BTE] = 1:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (ENPRESDIV + 1) \times (NTSEG1 + NTSEG2 + 3)$$

Equation 5. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 1

Where:

- NumClkBit is the number of peripheral clocks in one CAN bit.
- f_{CANCLK} is the Protocol Engine (PE) Clock (see Figure 194), in Hz.
- f_{SYS} is the frequency of operation of the system (CHI) clock, in Hz.
- PSEG1 is the value of CTRL1[PSEG1].
- PSEG2 is the value of CTRL1[PSEG2].
- PROPSEG is the value of CTRL1[PROPSEG].
- PRESDIV is the value in CTRL1[PRESDIV].
- ENPRESDIV is the value of EPRS[ENPRESDIV].
- NTSEG1 is the value of ENCBT[NTSEG1].
- NTSEG2 is the value of ENCBT[NTSEG2].

The formula above is also applicable to the alternative CAN bit timing variables described in:

- CAN Bit Timing (CBT)

- Enhanced Nominal CAN Bit Timing (ENCBT)
- CAN FD Bit Timing (FDCBT)
- Enhanced Nominal CAN Bit Timing (ENCBT)

For example, 180 CAN bits = (180 × NumClkBit) peripheral clock periods.

52.3.13.8 Arbitration and matching timing

During normal reception and transmission, the matching, arbitration, move-in, and move-out processes are executed during certain time windows inside the CAN frame. These windows are shown in the following figures.

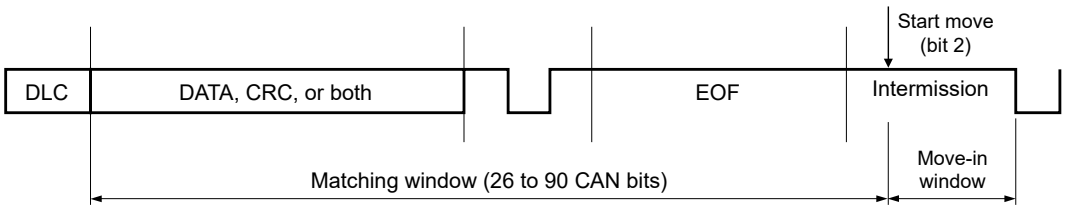

Figure 198. Matching and move-in time windows

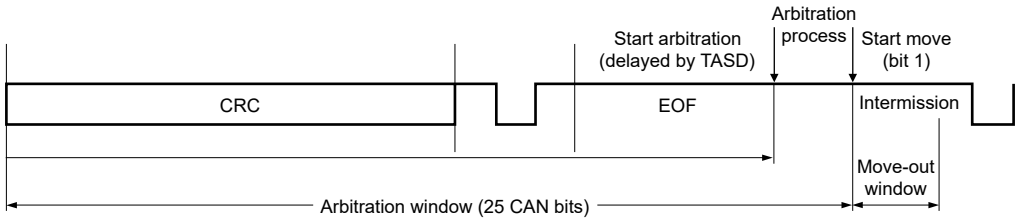

Figure 199. Arbitration and move-out time windows

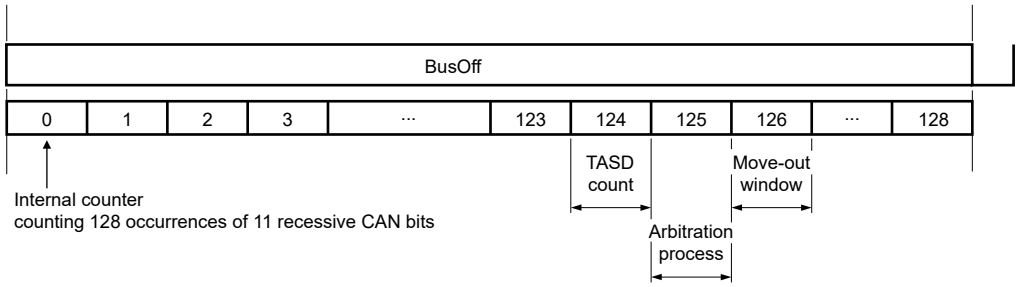

Figure 200. Arbitration at the end of bus off and move-out time windows

NOTE

In these figures, the matching and arbitration timing do not consider delays caused by concurrent memory access due to the CPU or other internal FlexCAN subblocks.

52.3.13.9 TX arbitration start delay

TX Arbitration Start Delay (CTRL2[TASD]) indicates the number of CAN bits that FlexCAN uses to delay the TX arbitration process starting point from the first bit of the CRC field of the current frame. This variable can be written only in Freeze mode; FlexCAN blocks it in other modes.

The ability of the CPU to reconfigure message buffers for transmission after the end of the internal arbitration process impacts transmission performance. In the arbitration process, FlexCAN finds the winner MB for transmission (see Arbitration process). If

the arbitration ends too early (before the first bit of the Intermission field) the CPU may reconfigure some TX message buffers. It is possible that the winning message buffer is no longer the best candidate to be transmitted.

TASD can optimize the transmission performance by defining the arbitration start point, as shown in Figure 201, based on factors such as:

- Peripheral-to-oscillator clock ratio
- CAN bit timing variables that determine the CAN bit rate
- Number of message buffers in use by the matching and arbitration processes

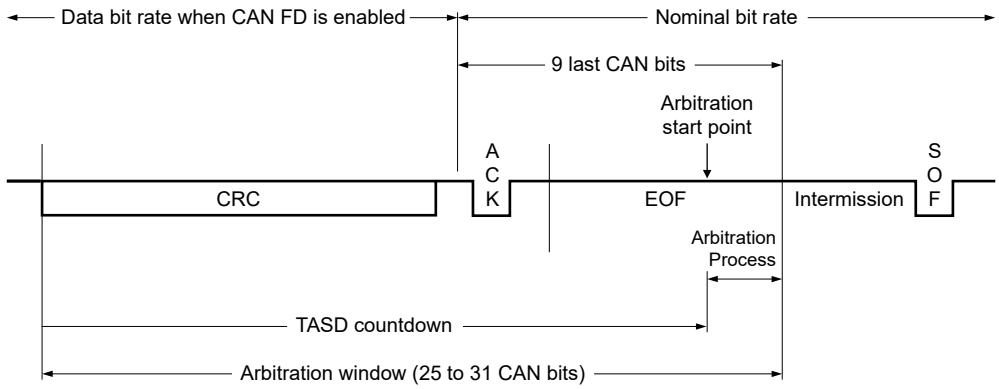

Figure 201. Optimal TX arbitration start point

The duration of an arbitration process, in terms of CAN bits, is:

- Directly proportional to the number of available message buffers
- Directly proportional to the CAN bit rate
- Inversely proportional to the peripheral clock frequency

The optimal arbitration timing occurs when the last message buffer is scanned immediately before the first bit of the Intermission field of a CAN frame. For instance, if the following are true:

- There are few message buffers.
- The peripheral-to-oscillator clock ratio is high.
- The CAN baud rate is low.

Then the arbitration can be placed closer to the end of the frame, adding more delay to its starting point, and vice versa.

If CTRL2[TASD] = 0, the arbitration start is not delayed, and more time is reserved for arbitration. Alternatively, if CTRL2[TASD] is close to 24, the CPU can configure a TX message buffer later, and less time is reserved for arbitration. If too little time is reserved for arbitration, FlexCAN may not be able to find a winner MB in time. The transmitted arbitration winner may not have the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal TASD value can be calculated as follows:

For CAN FD frames and (MAXMB + 1) ≤ NMB_{END}

$$TASD = 31 - \frac{2 * (MAXMB + 1) + 4}{CPCB_N}$$

For CAN FD frames and (MAXMB + 1) > NMB_{END}

$$TASD = 22 - \frac{2 * (MAXMB + 1) - NMB_{END}}{CPCB_F}$$

For non-FD frames

$$TASD = 25 - \frac{2 * (MAXMB + 1) + 4}{CPCB}$$

Equation 6. Optimal value for TASD

Where:

$$NMB_{END} = \frac{(9 \times CPCB_N) - 4}{2}$$

$$BITRATE_N = \left(\frac{f_{CANCLK}}{[1 + (EPSEG1 + 1) + (EPSEG2 + 1) + (EPROPSEG + 1)] \times (EPRESDIV + 1)} \right)$$

$$BITRATE_F = \left(\frac{f_{CANCLK}}{[1 + (FPSEG1 + 1) + (FPSEG2 + 1) + FPROPSEG] \times (FPRESDIV + 1)} \right)$$

$$CPCB_N = \frac{f_{SYS}}{BITRATE_N}$$

$$CPCB_F = \frac{f_{SYS}}{BITRATE_F}$$

$$CPCB = CPCB_N$$

Equation 7. Variables used in TASD calculation

- MAXMB is the value in MCR[MAXMB].
- NMB_{END} is the number of message buffers that the arbitration process can scan during the last nine CAN bits at the end of a frame. (See Equation 7.)
- $BITRATE_N$ is the CAN bit rate in bits per second calculated by the nominal CAN bit time variables.
- $BITRATE_F$ is the CAN bit rate in bits per second calculated by the data CAN bit time variables.
- $CPCB_N$ is the number of peripheral clocks per CAN bit in nominal bit rate for CAN FD frames.
- $CPCB_F$ is the number of peripheral clocks per CAN bit in data bit rate for CAN FD frames.
- CPCB is the number of peripheral clocks per CAN bit for non-FD frames.
- f_{CANCLK} is the oscillator clock, in Hz.
- f_{SYS} is the peripheral clock, in Hz.
- EPSEG1 is the value in CBT[EPSEG1] (CTRL1[PSEG1] can also be used).
- EPSEG2 is the value in CBT[EPSEG2] (CTRL1[PSEG2] can also be used).
- EPROPSEG is the value in CBT[EPROPSEG] (CTRL1[PROPSEG] can also be used).
- EPRESDIV is the value in CBT[EPRESDIV] (CTRL1[PRESDIV] can also be used).
- FPSEG1 is the value in FDCBT[FPSEG1].

- FPSEG2 is the value in FDCBT[FPSEG2].
- FPROPSEG is the value in FDCBT[FPROPSEG].
- FPRESDIV is the value in FDCBT[FPRESDIV].
- NTSEG1 is the value in ENCBT[NTSEG1].
- NTSEG2 is the value in ENCBT[NTSEG2].
- ENPRESDIV is the value in EPRS[ENPRESDIV].
- DTSEG1 is the value in EDCBT[DTSEG1].
- DTSEG2 is the value in EDCBT[DTSEG2].
- EDPRESDIV is the value in EPRS[EDPRESDIV].

If CTRL2[BTE] = 1, then:

$$BITRATE_N = \frac{f_{CANCLK}}{[1 + (NTSEG1 + 1) + (NTSEG2 + 1)] \times (ENPRESDIV + 1)}$$

Equation 8. Nominal baud rate when CTRL2[BTE] = 1

$$BITRATE_F = \frac{f_{CANCLK}}{[1 + (DTSEG1 + 1) + (DTSEG2 + 1)] \times (EDPRESDIV + 1)}$$

Equation 9. Fast baud rate when CTRL2[BTE] = 1

See also Protocol timing for more details.

52.3.13.9.1 TASD configuration examples

The following tables show the TASD value calculated for some configuration cases.

Case 1:

- Clock ratio = 2:1 (for example, peripheral clock 80 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 338. TASD values in Case 1

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	24	8.0

Case 2:

- Clock ratio = 1:1 (for example, peripheral clock 40 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 339. TASD values in Case 2

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	23	6.67

Case 3:

- Clock ratio = 2:1 (for example, peripheral clock 40 MHz and oscillator clock 20 MHz)

- Bit rate in arbitration phase = 1 Mbaud

Table 340. TASD values in Case 3

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	23	4.0

52.3.14 Clocks

The following table describes the clock sources for FlexCAN. See the chip clocking chapter for clock setting, configuration, and gating information.

Table 341. FlexCAN clocks

Clock name	Description
MODULE_CLK (system_clk)	Peripheral clock
MODULE_CLK_CHI (host_clock)	Control Host Interface (CHI) clock
MODULE_CLK_PE (protocol_engine_clock)	Protocol Engine (PE) clock
MODULE_CLK_PE_NOGATE (protocol_engine_clock_nogate)	Protocol Engine clock (no gating)
MODULE_CLK_S (system_clock_nogate)	Peripheral access clock

52.3.14.1 Clock domains and restrictions

FlexCAN has two clock domains asynchronous to each other:

- The bus domain feeds the Control Host Interface (CHI) submodule.
- The oscillator domain feeds the CAN Protocol Engine (PE) submodule.

When the two domains are connected to clocks with different frequencies or phases, the frequency relationship between the two clock domains is restricted. In asynchronous operation, the bus domain clock frequency must always be greater than the oscillator domain clock frequency.

NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

When performing matching and arbitration, FlexCAN must scan the whole message buffer memory during the time slot of one CAN frame, comprised of a number of CAN bits. To provide sufficient time for the scan, observe the following requirements:

- The peripheral clock frequency cannot be less than the oscillator clock frequency.
- There must be a minimum number of peripheral clocks per CAN bit, as specified in Table 342.

Table 342. Minimum number of peripheral clocks per CAN bit for Classical CAN format

Number of message buffers	Value of MCR[RFEN]	Value of ERFCR[ERFEN]	Minimum number of peripheral clocks per CAN bit
16	0	0	16
32	0	0	16

Table continues on the next page...

Table 342. Minimum number of peripheral clocks per CAN bit for Classical CAN format (continued)

Number of message buffers	Value of MCR[RFEN]	Value of ERFCR[ERFEN]	Minimum number of peripheral clocks per CAN bit
16	1	0	16
32	1	0	17
16	0	1	16
32	0	1	19

For classical frame format, the minimum number of peripheral clocks per CAN bit specified in Table 342 determines the minimum peripheral clock frequency for a given number of message buffers and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit. This number can be defined by adjusting one or more of the bit timing values contained in:

- Control 1 (CTRL1)
- CAN Bit Timing (CBT)
- Enhanced Nominal CAN Bit Timing (ENCBT)

The time quantum (Tq) is defined in Protocol timing. The minimum number of time quanta per CAN bit must be eight, so the oscillator clock frequency should be at least eight times the CAN bit rate.

52.3.14.1.1 Clock restrictions for CAN FD

For CAN FD frame format, some constraints must be satisfied. The equation below calculates the number of peripheral clocks per CAN bit in nominal bit rate (NumClkNomBit).

$$NumClkNomBit = \frac{f_{SYS}}{f_{CANCLK}} \times (PRESDIV + 1) \times (PROPSEG + PSEG1 + PSEG2 + 4)$$

$$= \frac{f_{SYS}}{NomBitRate}$$

Equation 10. Number of peripheral clocks per nominal CAN bit

Where PRESDIV, PSEG1, and PSEG2 are CAN bit time values in Control 1 (CTRL1). Alternatively, EPRESDIV, EPSEG1, and EPSEG2 values in CAN Bit Timing (CBT) or the values of EPRS[ENPRESDIV], ENCBT[NTSEG1], and ENCBT[NTSEG2] can be used instead. NumClkNomBit can also be calculated as a function of the expected nominal bit rate used in the arbitration phase (NomBitRate), as shown in the equation above.

The number of CAN bits in the data phase of an FD frame with BRS = 1 (fast CAN bits) depends on the number of data bytes in the payload. The number of fast CAN bits (NumOfFastBits) can be determined in Table 343. Having fewer data bytes means having fewer fast CAN bits. It also means that less time is available for FlexCAN to scan the whole message buffer memory during the internal matching and arbitration processes.

Table 343. Number of fast CAN bits in a CAN FD frame

Minimum number of data bytes	DLC field	NumOfFastBits
0	0h	21
1	1h	29
2	2h	37
3	3h	45
4	4h	53

Table continues on the next page...

Table 343. Number of fast CAN bits in a CAN FD frame (continued)

Minimum number of data bytes	DLC field	NumOfFastBits
5	5h	61
6	6h	69
7	7h	77
8	8h	85
12	9h	117
16	Ah	149
20	Bh	186
24	Ch	218
32	Dh	282
48	Eh	410
64	Fh	538

The critical part of a CAN FD frame is during the data phase, where the CAN bit rate is faster than in the arbitration phase. The minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated to guarantee that enough time is available for FlexCAN to scan the message buffer memory during reception and transmission. The equation below calculates this constraint.

$$MinNumClkFastBit_A = \frac{(8.5 \times MaxNumOfMb) + [ERFEN \times (2 \times NFE + 4)] + 64 - (9 \times NumClkNomBit)}{NumOfFastBits}$$

Equation 11. Minimum number of peripheral clocks per fast CAN bit for FlexCAN scan process

Where MaxNumOfMb is the maximum number of available message buffers defined in MCR[MAXMB]. NFE and ERFEN are the fields defined in Enhanced RX FIFO Control (ERFCR).

The clock-domain-crossing circuit between the CHI and PE subblocks also imposes a minimum number of peripheral clocks per fast CAN bit. This minimum is required for the handshake mechanism to work properly without losing status information through the interface, as shown in the equation below.

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{f_{SYS}}{f_{CANCLK}}\right)$$

Equation 12. Minimum number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface

Therefore, the larger of the two values calculated above determines the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit).

$$MinNumClkFastBit = Maximum\ (MinNumClkFastBitA, MinNumClkFastBitB)$$

Equation 13. Minimum number of peripheral clocks per fast CAN bit

Then, the maximum CAN bit rate in the data phase of CAN FD frames (DataBitRateMAX) can be calculated as below.

$$DataBitrate_{MAX} = \frac{f_{CANCLK}}{ROUNDUP\left(\frac{MinNumClkFastBit \times f_{CANCLK}}{f_{SYS}}\right)}$$

Equation 14. Maximum achievable baud rate for data phase

These factors affect the maximum data bit rate attainable by FlexCAN in CAN FD mode:

- The peripheral and oscillator clock frequencies
- The maximum number of message buffers
- The expected nominal bit rate

Also, the data bit rate depends on the minimum payload size of FD frames used in a given application.

To illustrate how the configuration of FlexCAN variables affects the CAN FD bit rate, consider this application example:

- The peripheral clock frequency is set to 50 MHz
- The oscillator clock frequency is set to 40 MHz

1. Considering the nominal bit rate as 1 Mbit/s, the number of peripheral clocks per CAN bit in nominal bit rate is calculated as below.

$$NumClkNomBit = \frac{50 \times 10^6}{1 \times 10^6} = 50$$

Equation 15. Calculation example for number of peripheral clocks per nominal CAN bit

2. The number of fast CAN bits (NumOfFastBits) is determined in Table 343. For example, if the minimum payload in FD frames is 8 bytes, there are 85 CAN bits in the data phase.
3. Assuming the maximum number of message buffers is 96, and Enhanced RX FIFO is disabled, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated.

$$MinNumClkFastBit_A = \frac{(8.5 \times 96) + 64 - (9 \times 50)}{85} = 5.06$$

Equation 16. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN scan process

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{50}{40}\right) = 6.75$$

Equation 17. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface

$$MinNumClkFastBit = Maximum\ (\ 5.06, 6.75\ ) = 6.75$$

Equation 18. Calculation example for number of peripheral clocks per fast CAN bit

4. The maximum CAN bit rate in the data phase can finally be found.

$$DataBitRate_{MAX} = \frac{40 \times 10^6}{ROUNDUP\left(\frac{6.75 \times 40 \times 10^6}{50 \times 10^6}\right)} = 6.667\ Mbps$$

Equation 19. Calculation example for maximum achievable baud rate

Even though the oscillator clock frequency (40 MHz) is adequate to generate a data rate of 8 Mbit/s in CAN FD mode, the specific FlexCAN configuration limits this rate to 6.667 Mbit/s. This limitation is mainly due to the low peripheral clock frequency that imposes the MinNumClkFastBitB bound.

Table 344 shows the maximum data rate for CAN FD with Enhanced RX FIFO disabled according to clock frequencies, payload size, and number of available message buffers. For some cases, if the number of available message buffers is reduced, FlexCAN can then achieve a data rate up to 8 Mbit/s.

Table 344. Maximum CAN bit rate in data phase on CAN FD frames with Enhanced RX FIFO disabled

Peripheral clock frequency (MHz)	Payload size	Number of available message buffers	Maximum data rate (Mbit/s)
40	8	94	6.667
40	8	114	>5.0
40	12	>117	6.667
40	12	128	5.714
50	12–64	128	6.667
60	8	126	8.0
60	12	128	8.0
67	6	128	8.0
80	3	128	8.0
100	0	128	8.0

52.3.15 Reset

You can reset FlexCAN in the following ways:

- Soft reset, in one of two ways:
  - MCR[SOFTRST], which resets some of the memory-mapped registers synchronously. To see which registers soft reset affects, see Table 347.
  - Chip-level soft reset, which has the same effect as MCR[SOFTRST].

Soft reset is synchronous and must follow an internal request-and-acknowledge procedure across clock domains. Therefore, it may take some time to propagate its effects fully. MCR[SOFTRST] remains 1 when soft reset is pending, so software can poll this field to identify when the reset has completed. Soft reset cannot be applied when clocks are shut down in a low-power mode. The low-power mode should be exited and the clocks resumed before applying soft reset.

When the module is enabled (MCR[MDIS] becomes 0), FlexCAN automatically enters Freeze mode. In Freeze mode:

1. FlexCAN is unsynchronized to the CAN bus.
2. MCR[HALT] and MCR[FRZ] become 1.
3. The internal state machines are disabled.
4. MCR[FRZACK] and MCR[NOTRDY] become 1.

The TX pin is in the recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Reset does not affect the message buffers and the RX Individual Mask registers, so they are not automatically initialized.

52.3.16 Interrupts

FlexCAN has many interrupt sources:

- Interrupts due to message buffers

- Interrupts due to interrupts combined via an OR operator from:
  - Message buffers
  - Bus Off
  - Bus Off Done
  - Error
  - Error Fast (errors detected in the data phase of CAN FD format messages with BRS = 1)
  - Wake Up
  - Wake Up Match
  - Wake Up Timeout
  - TX Warning
  - RX Warning

If its corresponding IMASK bit is 1, each message buffer can be an interrupt source. There is no distinction between TX and RX interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each buffer has an assigned flag bit in the IFLAG registers. When the corresponding buffer completes a successful transfer, the flag is set. When the CPU writes 1 to it, the flag is cleared (unless another interrupt is generated at the same time).

NOTE

The CPU must clear only the bit causing the current interrupt. For this reason, do not use bit manipulation instructions (BSET) to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt handler.

If the Legacy RX FIFO is enabled (MCR[RFEN] = 1) and DMA is disabled (MCR[DMA] = 0), the interrupts corresponding to message buffers 0–7 have different meanings.

- Bit of Interrupt Flags 1 (IFLAG1) becomes the Legacy FIFO Overflow flag
- Bit becomes the Legacy FIFO Warning flag
- Bit becomes the Frames Available in Legacy FIFO flag
- Bits are unused.

See Interrupt Flags 1 (IFLAG1) for more information.

If both Legacy RX FIFO and DMA are enabled (MCR[RFEN] = 1 and MCR[DMA] = 1), FlexCAN does not generate any Legacy FIFO interrupt. Bit of IFLAG1 still indicates Frames Available in Legacy FIFO and generates a DMA request. Bits are unused.

CAUTION

Legacy FIFO cannot be enabled when CAN FD is enabled.

When multiple message buffer interrupt sources are combined via an OR operator into a single interrupt, the interrupt is generated when any associated message buffer (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which message buffer or FIFO source caused the interrupt.

These interrupt sources generate interrupts like the message buffer interrupt sources, and can be read from Error and Status 1 (ESR1):

- Bus Off
- Bus Off Done
- Error
- Error Fast
- Wake Up
- TX Warning

- RX Warning

The Bus Off, Error, TX Warning, and RX Warning interrupt masks are located in Control 1 (CTRL1); the wake-up interrupt mask is located in Module Configuration (MCR).

The interrupt sources for Pretended Networking (Wake-up by Match Flag and Wake-up by Timeout Flag) can be read in Pretended Networking Wake-Up Match (WU_MTC). The respective interrupt mask bits are located in Pretended Networking Control 1 (CTRL1_PN).

52.3.17 Bus interface

CPU access to FlexCAN registers is subject to the following rules:

- Read and write access to implemented reserved address space results in an access error.
- Write access to positions whose bits are all currently read-only results in an access error. If at least one of the bits is not read-only, no access error is issued. Write permission to specific positions or some of their bits can change depending on the mode of operation or transitory state. See register and field descriptions for details.
- Read and write access to unimplemented address space results in an access error.
- Read and write access to RAM-located positions during Low-Power mode results in an access error.
- The RXIMR memory region can be considered as general-purpose memory and available for access via these methods:
  - If you write 0 to MCR[IRMQ], the individual masks (RXIMR) are disabled. In this case, the RXIMR memory region is considered general-purpose memory.
  - If MCR[MAXMB] is programmed with a value smaller than the available number of message buffers, the unused memory space can be used as general-purpose RAM space. Reserved words within RAM cannot be used.
    For example, suppose the RAM in FlexCAN can support up to 16 message buffers, CTRL2[RFFN] = 0h, and MCR[MAXMB] = 0.
    - In this case, the maximum number of message buffers becomes one.
    - The RAM starts at 0080h, and the space 0080h–008Fh is used by the one message buffer.
    - The memory space 0090h–017Fh is available.
    - The space 0180h–087Fh is reserved.
    - The space 0880h–0883h is used by the one individual mask and the available memory in the mask register space is 0884h–08BFh.
    - In the space from 08C0h–09DFh, there are reserved words for internal use which cannot be used as general-purpose RAM.

    As a rule, free memory space for general purpose depends only on MCR[MAXMB].
  - If MCR[FDEN] = 1, general-purpose memory can be used only outside Freeze mode.

Reserved space (empty)[1]	Bus error	Bus error	Bus error

1. Access in low power is only possible if RAM_clk and MODULE_CLK are enabled.
2. If MCR[RFEN] = 1, see Legacy FIFO access rules below.
3. Write operation has no effect.
4. If MCR[RFEN] = 1, do not access Enhanced RX FIFO.

52.4 External signal descriptions

FlexCAN has two I/O signals connected to the external chip pins. These signals are summarized in Table 346 and described in the following subsections.

Table 346. FlexCAN signal descriptions

Signal	Description	I/O
CAN RX	CAN receive pin	Input
CAN TX	CAN transmit pin	Output

52.4.1 CAN RX

This pin is the receive pin from the CAN bus transceiver. Logic level 0 represents its dominant state. Logic level 1 represents its recessive state.

52.4.2 CAN TX

This pin is the transmit pin to the CAN bus transceiver. Logic level 0 represents its dominant state. Logic level 1 represents its recessive state.

52.5 Memory map and register definition

This section describes the registers and data structures in FlexCAN. The base address of the module depends on the particular memory map of the chip.

52.5.1 FlexCAN memory mapping

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address offset 0080h.

Each individual register is identified by its complete name and corresponding mnemonic.

NOTE

An invalid register access results in a bus error. Invalid accesses include reading a write-only register, writing a read-only register, and accessing an invalid address.

NOTE

To update the parity bits in memory properly, all FlexCAN memory must be initialized before reading registers which are implemented in memory. You must also initialize RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), Receive 15 Mask (RX15MASK) and Legacy RX FIFO Global Mask (RXFGMASK). MCR[RFEN] and ERFCR[ERFEN] must not be 1 during memory initialization.

Table 347. Register reset information

Register	Affected by soft reset

Enhanced RX FIFO Status (ERFSR)	Yes
Enhanced RX FIFO	No
Enhanced RX FIFO Filter Element (ERFFEL)	No

FlexCAN can store CAN messages for transmission and reception using message buffers and RX FIFO structures.

52.5.2 CAN register descriptions

The table below shows the FlexCAN memory map.

The address range from offset 80h–27Fh allocates the thirty-two 128-bit message buffers. The memory maps for the message buffers are in FlexCAN message buffer memory map.

The address range from offset 2000h–2048h allocates the Enhanced RX FIFO output, and the address range from offset 204Ch–238Ch allocates the rest of Enhanced RX FIFO 11 elements. The memory map for the Enhanced RX FIFO is in Enhanced RX FIFO structure.

Fields

Field	Function
31 MDIS	Module Disable Disables FlexCAN. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Soft reset does not affect this field. See the chip-specific FlexCAN information for reset value of MCR[MDIS] and state of FlexCAN (enabled or disabled). 0b - Enable 1b - Disable
30 FRZ	Freeze Enable Specifies FlexCAN behavior when MCR[HALT] = 1 or when Debug mode is requested at chip level. When this field becomes 1, FlexCAN can enter Freeze mode. Writing 0 to this field causes FlexCAN to exit from Freeze mode. 0b - Disable 1b - Enable
29 RFEN	Legacy RX FIFO Enable Enables the Legacy RX FIFO feature. When this field is 1, message buffers 0–5 cannot be used for normal reception and transmission. The corresponding memory region (80h–DCh) is used by the FIFO engine and additional message buffers (up to 32, depending on CTRL2[RFFN]). These message buffers are used as Legacy RX FIFO ID filter table elements. This field also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 342. This field can be written in Freeze mode only; the module blocks it in other modes. **NOTE** When CAN FD operation is enabled (see MCR[FDEN]), you cannot write 1 to this field. **NOTE** This field must not be 1 if ERFCR[ERFEN] = 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
28 HALT	Halt FlexCAN Puts FlexCAN into Freeze mode. The CPU should write 0 to this field after initializing the message buffers and Control 1 (CTRL1) and Control 2 (CTRL2). FlexCAN performs no reception or transmission before this field becomes 0. Freeze mode cannot be entered when FlexCAN is in a low-power mode. 0b - No request 1b - Enter Freeze mode, if MCR[FRZ] = 1.
27 NOTRDY	FlexCAN Not Ready Indicates whether FlexCAN is in Disable mode, Doze mode, Stop mode or Freeze mode. When FlexCAN has exited these modes, this field becomes 0. Soft reset does not affect this field. 0b - FlexCAN is in Normal mode, Listen-Only mode, or Loopback mode. 1b - FlexCAN is in Disable mode, Doze mode, Stop mode, or Freeze mode.
26 WAKMSK	Wake-up Interrupt Mask Enables the wake-up interrupt generation under the Self Wake-Up mechanism. 0b - Disabled 1b - Enabled
25 SOFTRST	Soft Reset Resets internal state machines of FlexCAN and some memory-mapped registers. The CPU can write 1 to this field directly. This field also becomes 1 when global soft reset is requested at the chip level. Because soft reset is synchronous and must follow a request-and-acknowledge procedure across clock domains, it may take some time to propagate its effect fully. When reset is pending, this field remains 1; it automatically becomes 0 when reset completes. You can poll this field to know when the soft reset has completed. Soft reset cannot be applied when clocks are shut down in a low-power mode. Transfer the module out of the low-power mode before applying soft reset. Soft reset does not affect this field. **NOTE** This field becomes 0 within 2 CAN bits after assertion of this bit. 0b - No reset 1b - Soft reset affects reset registers
24 FRZACK	Freeze Mode Acknowledge Indicates whether FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore you can poll this field to know when FlexCAN has entered Freeze mode. If the Freeze mode request is negated, this field becomes 0 after the FlexCAN prescaler is running again. If Freeze mode is requested when FlexCAN is in

Table continues on the next page...

Table continued from the previous page...

Field	Function
	a low-power mode, this field becomes 1 only when the low-power mode is exited. See Freeze mode. Soft reset does not affect this field. **NOTE** This field becomes 1 within 180 CAN bits if current transmission or reception is ongoing for classical frames and 730 CAN bits if current transmission or reception is ongoing for FD frames after the low-power mode requested by CPU. This field becomes 0 within 2 CAN bits after the Freeze mode request removal (see Protocol timing). 0b - Not in Freeze mode, prescaler running. 1b - In Freeze mode, prescaler stopped.
23 —	Reserved
22 SLFWAK	Self Wake-up Enables the Self Wake-up feature when FlexCAN is in a low-power mode other than Disable mode. When this feature is enabled, the FlexCAN module monitors the bus for a wake-up event (that is, a recessive-to-dominant transition). If a wake-up event is detected during Doze mode, FlexCAN requests to resume its clocks. If enabled to do so, it also generates a wake-up interrupt to the CPU. If a wake-up event is detected during Stop mode, FlexCAN generates, if enabled to do so, a wake-up interrupt to the CPU. The CPU can exit Stop mode globally and FlexCAN can request to resume the clocks. When FlexCAN is in a low-power mode other than Disable mode, this field cannot be written, as the module blocks it. When MCR[PNET_EN] = 1, this feature must be disabled. 0b - Disable 1b - Enable
21 WRNEN	Warning Interrupt Enable Enables the generation of the flags ESR1[TWRNINT] and ESR1[RWRNINT]. When this field is 1, TWRNINT and RWRNINT flags are set when the respective error counter transitions from less than 96 to greater than or equal to 96. When this field is 0, the TWRNINT and RWRNINT flags are always zero, independent of the values of the error counters. No warning interrupt is generated. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Disable 1b - Enable
20 LPMACK	Low-Power Mode Acknowledge Indicates whether FlexCAN is in a low-power mode (Disable mode, Doze mode, Stop mode). A low-power mode cannot be entered until all current transmission and reception processes have finished. The CPU can poll this field to know when FlexCAN has entered low-power mode. Soft reset does not affect this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field becomes 1 within 180 CAN bits if current transmission or reception is ongoing for classical frames and 730 CAN bits if current transmission or reception is ongoing for FD frames after the low-power mode requested by CPU. This field becomes 0 within 2 CAN bits after the low-power mode request removal (see Protocol timing). When FlexCAN is in Pretended Networking mode, this field becomes 0 within 180 CAN bits after the low-power mode request removal. 0b - Not in a low-power mode 1b - In a low-power mode
19 WAKSRC	Wake-Up Source Determines whether the integrated low-pass filter is applied to the RX input that FlexCAN uses to detect recessive-to-dominant edges on the CAN bus. This filter can protect the RX CAN input from spurious wake-up. This field can be written only in Freeze mode. The module blocks it in other modes. 0b - No filter applied 1b - Filter applied
18 DOZE	Doze Mode Enable Determines whether FlexCAN can enter low-power mode when Doze mode is requested at chip level. This field is automatically reset when FlexCAN wakes from Doze mode upon detecting activity on the CAN bus (self wake-up enabled). 0b - Disable 1b - Enable
17 SRXDIS	Self-Reception Disable Determines whether FlexCAN can receive frames transmitted by itself. If 1, frames transmitted by the module are not stored in any MB, regardless of whether the MB is programmed with an ID that matches the transmitted frame. No interrupt flag or interrupt signal is generated due to the frame reception. This field can be written only in Freeze mode; the module blocks it in other modes. 0b - Enable 1b - Disable
16 IRMQ	Individual RX Masking and Queue Enable Indicates whether RX matching process is based on individual masking and queue, or based on a masking scheme with RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), Receive 15 Mask (RX15MASK), and Legacy RX FIFO Global Mask (RXFGMASK). When this field is disabled, for backward compatibility with legacy applications, reading the Control and Status word locks the MB even if it is empty. This field can be written in Freeze mode only. The module blocks it in other modes. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
15 DMA	DMA Enable Enables DMA. The DMA feature can only be used in Legacy RX FIFO or Enhanced RX FIFO, so MCR[RFEN] or ERFCR[ERFEN] must be 1. When DMA and RFEN are 1, IFLAG1[BUF5I] generates the DMA request, and no RX FIFO interrupt is generated. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Disable 1b - Enable
14 PNET_EN	Pretended Networking Enable Enables Pretended Networking functionality. When in Doze mode or Stop mode, the PE subblock is kept operational. It can process RX message filtering as defined by the Pretended Networking configuration registers. See Receive process in Pretended Networking mode. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Disable 1b - Enable
13 LPRIOEN	Local Priority Enable Enables the local priority feature. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word. However, the actual transmitted ID is 11 bits for standard frames and 29 bits for extended frames. This field can be written only in Freeze mode; the module blocks it in other modes. This bit is provided for backward compatibility with legacy applications. 0b - Disable 1b - Enable
12 AEN	Abort Enable Enables the TX abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This field can be written only in Freeze mode; the module blocks it in other modes. **NOTE** When this field is 1, only use the abort mechanism (see Transmission abort mechanism) to update message buffers configured for transmission. **CAUTION** Writing the abort code into RX message buffers can cause unpredictable results when this field is 1. 0b - Disabled 1b - Enabled
11	CAN FD Operation Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
FDEN	Enables the CAN with flexible data rate (CAN FD) operation. This field can be written in Freeze mode only. FlexCAN can receive and transmit messages in CAN 2.0 format. If this field is enabled, FlexCAN can also receive and transmit messages in CAN FD format. FlexCAN can transmit FD frame format according to ISO 11898-1:2015. **NOTE** If the value of this field is 1, the Legacy RX FIFO Enable (MCR[RFEN]) field cannot be 1. 0b - Disable 1b - Enable
10 TPOV	TX Pin Override Value Indicates forced value on the TX pin. This bit is affected by soft reset. 0b - TX pin is forced to be dominant 1b - TX pin is forced to be recessive
9-8 IDAM	ID Acceptance Mode Identifies the format of the Legacy RX FIFO ID filter table elements. This field configures all elements of the table at the same time; they are all the same format. See Legacy RX FIFO structure. This field can be written only in Freeze mode; the module blocks it in other modes. 00b - Format A: One full ID (standard and extended) per ID filter table element. 01b - Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID filter table element. 10b - Format C: Four partial 8-bit standard IDs per ID filter table element. 11b - Format D: All frames rejected.
7 TPOE	TX Pin Override Enable Enables forcing of TX pin to recessive or dominant. This bit is affected by soft reset. **NOTE** This bit must not be enabled during the functional mode. 0b - TX pin forcing is disabled 1b - TX pin forcing is enabled
6-0 MAXMB	Number of the Last Message Buffer Defines the number of the last message buffer that takes part in the matching and arbitration processes. The reset value (0Fh) is equivalent to a 16-MB configuration. This field can be written only in Freeze mode; the module blocks it in other modes. **NOTE** You must write a value smaller than or equal to the number of available message buffers to this field, as described in FlexCAN memory partition for CAN FD.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Additionally, the MAXMB value must consider the region of message buffers occupied by Legacy RX FIFO and its ID filters table space defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit, as described in Table 342.

52.5.2.3 Control 1 (CTRL1)

Offset

Register	Offset
CTRL1	4h

Function

Contains specific FlexCAN control features related to the CAN bus. These features include bit rate, programmable sampling point within an RX bit, Loopback mode, Listen-Only mode, Bus Off recovery behavior, and interrupt enabling (Bus-Off, Error, Warning). It also determines the division factor for the clock prescaler.

The CAN bit timing variables (CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW]) can also be configured in CAN Bit Timing (CBT), which extends the range of all these variables. If CBT[BTF] = 1, CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] become read-only.

If CTRL2[BTE] = 1, CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] are not used by the module. Instead, these fields are read as zero, and a write operation to them has no effect.

NOTE

When the CAN FD feature is enabled, do not use CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] for CAN bit timing. Instead use CBT[EPRESDIV], CBT[ERJW], CBT[EPSEG1], CBT[EPSEG2], and CBT[EPROPSEG].

The CAN bit variables in CTRL1 and in CBT are stored in the same internal register.

Soft reset does not affect the contents of this register.

Diagram

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 PRESDIV	Prescaler Division Factor Determines the ratio between the PE clock frequency and the serial clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The maximum value of this field is FFh, which gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Sclock frequency = PE clock frequency ÷ (PRESDIV + 1).
23-22 RJW	Resync Jump Width Defines the maximum number of time quanta that one resynchronization can change a bit time. One time quantum is equal to one Sclock period. The valid programmable values are 0–3. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Resync Jump Width = RJW + 1.
21-19 PSEG1	Phase Segment 1 Defines the length of phase segment 1 in the bit time. The valid programmable values are 0–7. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 1 = (PSEG1 + 1) × Time Quanta.
18-16 PSEG2	Phase Segment 2 Defines the length of phase segment 2 in the bit time. The valid programmable values are 1–7. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 2 = (PSEG2 + 1) × Time Quanta.
15 BOFFMSK	Bus Off Interrupt Mask Provides a mask for the Bus Off interrupt ESR1[BOFFINT]. 0b - Interrupt disabled 1b - Interrupt enabled
14 ERRMSK	Error Interrupt Mask Provides a mask for the Error interrupt ESR1[ERRINT]. 0b - Interrupt disabled 1b - Interrupt enabled
13 —	Reserved **NOTE** Writeable only if the module is disabled. Otherwise the access type is read-only.
12	Loopback Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
LPB	Configures FlexCAN to operate in Loopback mode. In this mode, FlexCAN performs an internal loopback that can be used for self-test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The RX CAN input pin is ignored and the TX CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field. It generates an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This field can be written only in Freeze mode; the module blocks it in other modes. **NOTE** In this mode, MCR[SRXDIS] cannot become 1, because it would impede the self-reception of a transmitted message. **NOTE** FDCTRL[TDCEN] and MCR[ETDCEN] must be 0 when this field is 1. 0b - Disabled 1b - Enabled
11 TWRNMSK	TX Warning Interrupt Mask Provides a mask for the TX Warning interrupt associated with the ESR1[TWRNINT] flag. When MCR[WRNEN] = 0, this field is read as 0. This field can be written only if MCR[WRNEN] = 1. 0b - Disabled 1b - Enabled
10 RWRNMSK	RX Warning Interrupt Mask Provides a mask for the RX Warning interrupt associated with the ESR1[RWRNINT] flag. When MCR[WRNEN] = 0, this field is read as 0. This field can be written only if MCR[WRNEN] = 1. 0b - Disabled 1b - Enabled
9 —	Reserved
8 ROM	Restricted Operation Mode Enables restricted operation mode. In restricted operation mode, FlexCAN is able to receive and acknowledge CAN messages, but it cannot send error frames and overload frames. If an error or overload condition is detected, FlexCAN treats it as a protocol exception and enters an integrating state. In restricted operation mode, FlexCAN does not increment or decrement the error counters. Besides, FlexCAN is able to transmit time reference messages of potential time masters in a network, but other types of frames must not be configured to be transmitted.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field can be written in freeze mode only. 0b - Restricted operation is disabled 1b - Restricted operation is enabled
7 SMP	CAN Bit Sampling Determines the sampling mode of CAN bits at the RX input. This field can be written in Freeze mode only; the module blocks it in other modes. **NOTE** For proper operation, to write 1 to this field, you must guarantee a minimum value of two time quanta in CTRL1[PSEG1] (or CBT[EPSEG1]).This bit cannot become 1 when CAN FD is enabled (MCR[FDEN] = 1). 0b - One sample is used to determine the bit value. 1b - Three samples are used to determine the value of the received bit: the regular one (sample point) and two preceding samples. A majority rule is used.
6 BOFFREC	Bus Off Recovery Determines how FlexCAN recovers from Bus Off state. If 0, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If 1, automatic recovering from Bus Off is disabled. The module remains in Bus Off state until you write 1 to this field. If this field becomes 0 before 128 sequences of 11 recessive bits are detected on the CAN bus, Bus Off recovery happens as if this field had never become 1. If this field becomes 0 after 128 sequences of 11 recessive bits occurred, FlexCAN resynchronizes to the bus. It waits for 11 recessive bits before joining the bus. After this field becomes 0, it can become 1 again during Bus Off, but it will only be effective the next time the module enters Bus Off. If this field becomes 0 when the module is in Bus Off, writing 1 to this field is not effective for the current Bus Off recovery. **NOTE** See Bus Off in the CAN Protocol standard (ISO 11898-1:2015) for details. 0b - Enabled 1b - Disabled
5 TSYN	Timer Sync Enables a mechanism that resets the free-running timer each time a message is received in message buffer 0. This feature provides the means to synchronize multiple FlexCAN stations with a special "SYNC" message (that is, global network time). If MCR[RFEN] = 1 (Legacy RX FIFO enabled), the first available message buffer, according to CTRL2[RFFN], is used for timer synchronization instead of MB0. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 LBUF	Lowest Buffer Transmitted First Determines the ordering mechanism for message buffer transmission. When 1, MCR[LPRIOEN] does not affect the priority arbitration. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Buffer with highest priority is transmitted first. 1b - Lowest number buffer is transmitted first.
3 LOM	Listen-Only Mode Configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters described in Error Counter (ECR) are frozen, and the module operates in CAN Error Passive mode. Only messages acknowledged by another CAN station are received. If FlexCAN detects an unacknowledged message, it flags a BIT0 error without changing the receive error counter (ECR[RXERRCNT]), as if it is trying to acknowledge the message. FlexCAN acknowledges Listen-Only mode when ESR1[FLTCONF] = 1, indicating the Error Passive state. There can be some delay between the Listen-Only mode request and its acknowledgment. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Listen-Only mode is deactivated. 1b - FlexCAN module operates in Listen-Only mode.
2-0 PROPSEG	Propagation Segment Defines the length of the propagation segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation segment time = (PROPSEG + 1) × Time Quanta. One Time Quantum = one Sclock period.

52.5.2.4 Free-Running Timer (TIMER)

Offset

Register	Offset
TIMER	8h

Function

Represents a 16-bit free-running counter that the CPU can read and write. The timer starts from 0h after reset, counts linearly to FFFFh, and wraps around.

The CAN bit clock increments the timer, which defines the baud rate on the CAN bus. During a message transmission or reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable, Doze, Stop, Pretended Networking, and Freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the timestamp entry in a message buffer after a successful reception or transmission of a message.

If CTRL1[TSYN] = 1, the timer is reset whenever a message is received in the first available message buffer, according to CTRL2[RFFN].

The CPU can write to this register anytime. However, if the write occurs simultaneously with the timer being reset by a reception in the first message buffer, the write value is discarded.

Reading this register affects the message buffer unlocking procedure (see Message buffer lock mechanism).

Field	Function
31-16 —	Reserved
15-0 TIMER	Timer Value Contains the free-running counter value.

52.5.2.5 RX Message Buffers Global Mask (RXMGMASK)

Offset

Register	Offset
RXMGMASK	10h

Function

Masks the filter bits of all RX message buffers, excluding MB14 and MB15, which have individual mask registers.

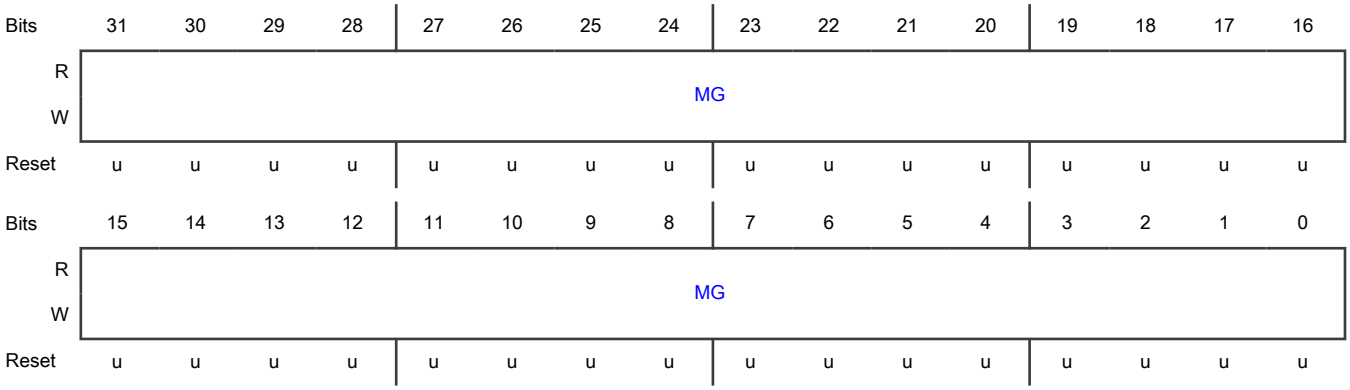
This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When MCR[IRMQ] is 0, RXMGMASK is always in effect. The bits in RXMGMASK[MG] mask the MB filter bits.
- When MCR[IRMQ] is 1, RXMGMASK has no effect. The bits in RXMGMASK[MG] do not mask the MB filter bits.

This register can only be written in Freeze mode; the module blocks it in other modes.

Diagram



Fields

Field	Function
31-0 MG	Global Mask for RX Message Buffers Masks the message buffer filter bits. The alignment with the ID word of the message buffer is imperfect. The two most significant MG bits affect the fields RTR and IDE, which are located in the Control and Status word of the MB. The following table shows which MG bits mask each MB filter field.

SMB[RTR] [1]	CTRL2[RRS]	CTRL2[EACEN]	Message buffer filter fields			
			MB[RTR]	MB[IDE]	MB[ID]	Reserved
0	-	0	Note [2]	Note [3]	MG[28:0]	MG[31:29]
0	-	1	MG[31]	MG[30]	MG[28:0]	MG[29]
1	0	-	-	-	-	MG[31:0]
1	1	0	-	-	MG[28:0]	MG[31:29]
1	1	1	MG[31]	MG[30]	MG[28:0]	MG[29]

1. RTR bit of the incoming frame. It is saved into an auxiliary MB called RX serial message buffer (RX SMB).
2. If CTRL2[EACEN] is 0, the RTR bit of MB is never compared with the RTR bit of the incoming frame.
3. If CTRL2[EACEN] is 0, the IDE bit of MB is always compared with the IDE bit of the incoming frame.

0b - The corresponding bit in the filter is "don't care."

1b - The corresponding bit in the filter is checked.

52.5.2.6 Receive 14 Mask (RX14MASK)

Offset

Register	Offset
RX14MASK	14h

Function

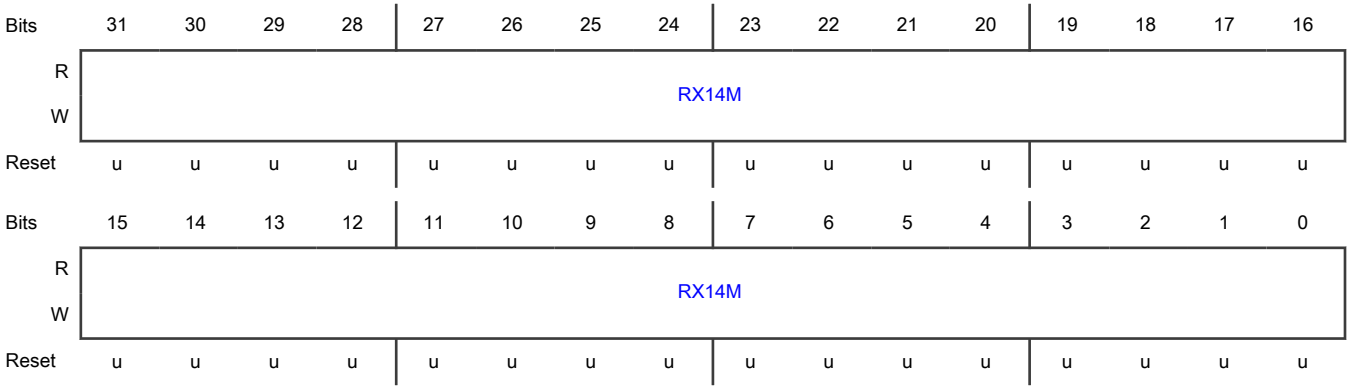
Masks the filter fields of MB14.

This register is located in RAM.

RX14MASK is provided for legacy application support. When MCR[IRMQ] = 1, RX14MASK has no effect.

This register can only be programmed when the module is in Freeze mode; the module blocks it in other modes.

Diagram



Fields

Field	Function
31-0 RX14M	RX Buffer 14 Mask Bits Masks the corresponding MB14 filter field in the same way that RX Message Buffers Global Mask (RXMGMASK) masks the filters of the other message buffers. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

52.5.2.7 Receive 15 Mask (RX15MASK)

Offset

Register	Offset
RX15MASK	18h

Function

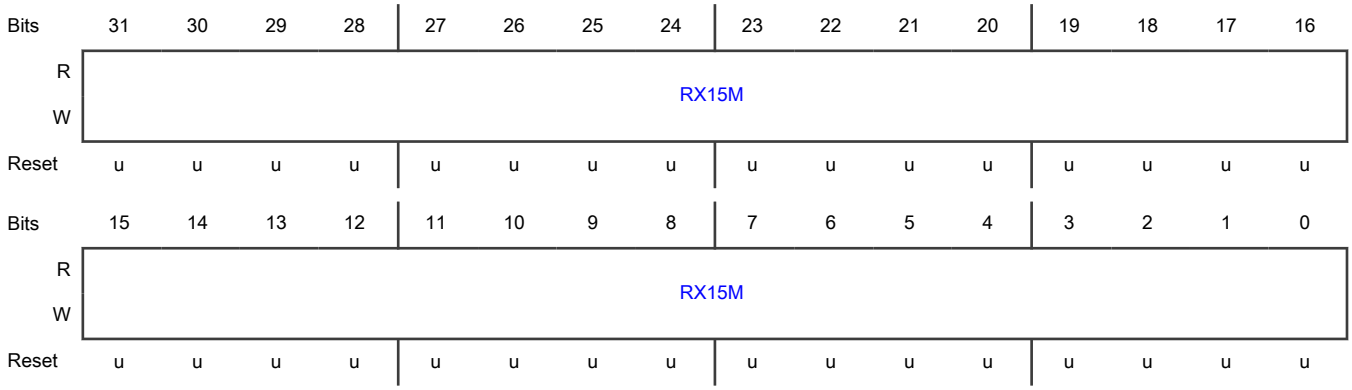
Masks the filter fields of MB15.

This register is located in RAM.

RX15MASK is provided for legacy application support. When MCR[IRMQ] = 1, RX15MASK has no effect.

This register can be programmed only when the module is in Freeze mode; the module blocks it in other modes.

Diagram



Fields

Field	Function
31-0 RX15M	RX Buffer 15 Mask Bits Masks the corresponding MB15 filter field in the same way that RX Message Buffers Global Mask (RXMGMASK) masks the filters of other message buffers. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

52.5.2.8 Error Counter (ECR)

Offset

Register	Offset
ECR	1Ch

Function

Contains error counters for received and transmitted messages.

TXERRCNT and RXERRCNT consider all errors in both CAN FD and non-FD message formats. TXERRCNT_FAST and RXERRCNT_FAST count only the errors that occur in the data phase of CAN FD frames that have BRS = 1.

The Fault Confinement state (ESR1[FLTCONF]) is updated based on TXERRCNT and RXERRCNT counters only. The rules for increasing and decreasing these counters are described in the CAN protocol and are entirely implemented in FlexCAN.

The basic rules for FlexCAN bus state transitions are:

- If the value of TXERRCNT or RXERRCNT becomes greater than or equal to 128, ESR1[FLTCONF] is updated to reflect Error Passive state.
- If the state of FlexCAN is Error Passive, and TXERRCNT or RXERRCNT decrements to a value less than 128 when the other already satisfies this condition, ESR1[FLTCONF] is updated to reflect Error Active state.
- If the value of TXERRCNT becomes greater than 255, ESR1[FLTCONF] is updated to reflect Bus Off state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in Bus Off, TXERRCNT is cascaded with another internal counter to count the occurrences of 11 consecutive recessive bits on the bus. TXERRCNT is reset to zero. It counts in a manner where the internal counter

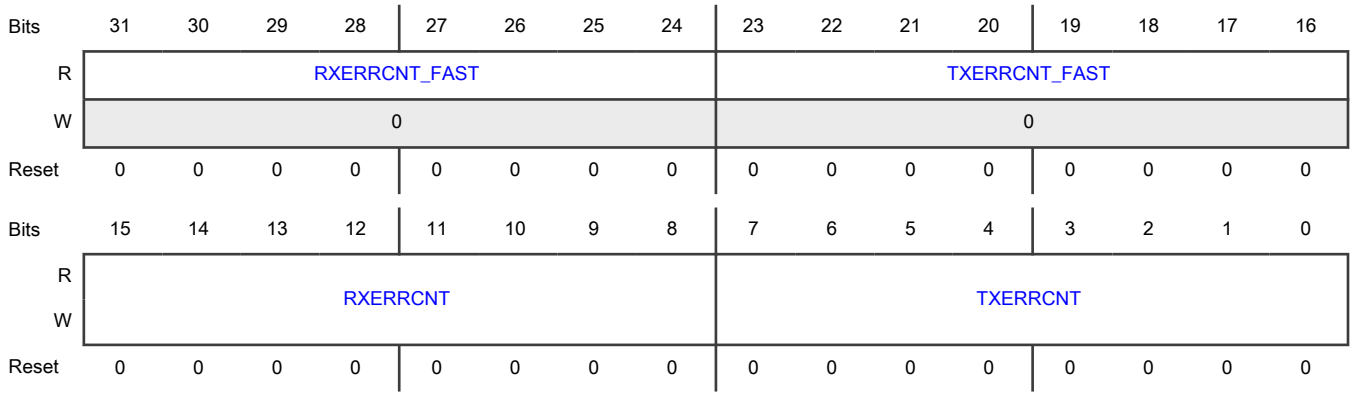
counts 11 such bits and then wraps around when incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, ESR1[FLTCONF] is updated to Error Active, and both error counters are reset to zero. Upon any instance of a dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value. The TXERRCNT_FAST counter is frozen during Bus Off.

- If only one node is operating during system startup, its TXERRCNT increases upon each attempted message transmission, as a result of acknowledge errors (indicated by ESR1[ACKERR]). After the transition to Error Passive state, TXERRCNT no longer increments upon acknowledge errors. The chip never goes into the Bus Off state.
- If RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected when being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to return to the Error Active state.
- TXERRCNT_FAST and RXERRCNT_FAST error counter values increment and decrement based on errors detected only in the data phase of CAN FD frames that have BRS = 1. These counters follow the same increment and decrement rules as TXERRCNT and RXERRCNT. These counters do not wrap around and get stuck at their maximum value (255). They stop counting and keep their values frozen when FlexCAN is in the Bus Off state. They are reset when FlexCAN leaves the Bus Off state and resume counting after FlexCAN returns to the Error Active state.
- When FlexCAN is in Pretended Networking mode, RXERRCNT and RXERRCNT_FAST keep counting errors, and error flags are stored. TXERRCNT and TXERRCNT_FAST preserve their values and do not change, because no transmission occurs in Pretended Networking mode. Error counters and error flags that changed values in Pretended Networking mode are updated in this register and in Error and Status 1 (ESR1) when FlexCAN returns to Normal mode. If FlexCAN is in Pretended Networking mode, the FAST error flags in ESR1 are not set.

NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1:2015) for details.

Diagram



Fields

Field	Function
31-24 RXERRCNT_FAST	Receive Error Counter for Fast Bits Counts errors detected in the data phase of received CAN FD messages that have BRS = 1. This field is read-only except in Freeze mode, when the CPU can write an 8-bit zero value only.
23-16 TXERRCNT_FAST	Transmit Error Counter for Fast Bits Counts errors detected in the data phase of transmitted CAN FD messages that have BRS = 1. This field is read-only except in Freeze mode, when the CPU can write an 8-bit zero value only.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-8 RXERRCNT	Receive Error Counter Counts all errors detected in received messages. This field is read-only except in Freeze mode, when the CPU can write to it.
7-0 TXERRCNT	Transmit Error Counter Counts all errors detected in transmitted messages. This field is read-only except in Freeze mode, when the CPU can write to it.

52.5.2.9 Error and Status 1 (ESR1)

Offset

Register	Offset
ESR1	20h

Function

Reports various error conditions detected in the reception and transmission of a CAN frame. This register provides status information about the chip, and is the source of some interrupts to the CPU. The reported error conditions are:

NOTE

Reading host can clear these fields.

- Errors detected in CAN frames of any format:
  - BIT1ERR
  - BIT0ERR
  - ACKERR
  - CRCERR
  - FRMERR
  - STFERR
- Errors detected in the data phase of CAN FD frames with the BRS bit set only:
  - BIT1ERR_FAST
  - BIT0ERR_FAST
  - CRCERR_FAST
  - FRMERR_FAST
  - STFERR_FAST

One or more error flags may report an error detected in a single CAN frame. To account for more error events occurring in subsequent frames when the CPU does not attempt to read this register, error reporting is cumulative.

Status flags:

- TXWRN
- RXWRN

- IDLE
- TX
- FLTCONF
- RX
- SYNCH

Interrupt flags:

- BOFFINT
- BOFFDONEINT
- ERRINT
- ERRINT_FAST
- WAKINT
- TWRNINT
- RWRNINT

The CPU should follow this procedure when servicing interrupt requests generated by these flags:

1. Read this register to capture all error condition and status flags. This action clears the respective flags that were set since the last read access.
2. Write 1 to clear the interrupt flag that triggered the interrupt request.
3. Write 1 to clear the ERROVR flag, if it is set.

Starting from all error flags cleared, a first error event sets either ERRINT or ERRINT_FAST (provided the corresponding mask bit is 1). If other error events in subsequent frames occur before the CPU serves the interrupt request, the ERROVR flag is set to indicate that errors from different frames have accumulated.

Table 348. CAN bus status

SYNCH	IDLE	TX	RX	FlexCAN state
0	0	0	0	Not synchronized to CAN bus
1	1	X	X	Idle
1	0	1	0	Transmitting
1	0	0	1	Receiving

NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1:2015) for details.

Fields

Field	Function
31 BIT1ERR_FAST	Fast Bit1 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit transmitted as recessive is received as dominant.
30 BIT0ERR_FAST	Fast Bit0 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit transmitted as dominant is received as recessive.
29 —	Reserved
28 CRCERR_FAST	Fast Cyclic Redundancy Check Error Flag Indicates that the receiver node has detected a CRC error in the CRC field of CAN FD frames that have BRS = 1. This error means that the calculated CRC is different from the received CRC. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A CRC error occurred since last read of this register.
27	Fast Form Error Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
FRMERR_FAST	Indicates whether the receiver node has detected a form error in the data phase of CAN FD frames that have BRS = 1. This error means that a fixed-form bit field contains at least one illegal bit. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A form error occurred since last read of this register.
26 STFERR_FAST	Fast Stuffing Error Flag Indicates that a stuffing error has been detected in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A stuffing error occurred since last read of this register.
25-24 —	Reserved
23 PTA	Passive to Active State If this field is 1, controller is transitioned from passive to active error state. If this field is 0, controller is not transitioned from passive to active error state. Interrupt signals are asserted if enabled from FLTCONF_IE when the controller is transitioned from passive to active error state. 0b - Does not transition 1b - Transitions
22 ATP	Active to Passive State If this field is 1, controller is transitioned from active to passive error state. If this field is 0, controller is not transitioned from active to passive error state. Interrupt signals are asserted if enabled from FLTCONF_IE when the controller is transitioned from active to passive error state. 0b - Does not transition 1b - Transitions
21 ERROVR	Error Overrun Flag Indicates that an error condition occurred when any error flag is already set. 0b - No overrun 1b - Overrun
20 ERRINT_FAST	Fast Error Interrupt Flag Indicates that at least one error flag detected in the data phase of CAN FD frames that have BRS = 1 (BIT1ERR_FAST, BIT0ERR_FAST, CRCERR_FAST, FRMERR_FAST, or STFERR_FAST) is set. If CTRL2[ERRMSK_FAST] = 1, an interrupt is generated to the CPU. 0b - No such occurrence. 1b - Error flag set in the data phase of CAN FD frames that have BRS = 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
19 BOFFDONEINT	Bus Off Done Interrupt Flag Indicates whether ECR[TXERRCNT] has finished counting 128 occurrences of 11 consecutive recessive bits on the CAN bus and is ready to leave Bus Off. If CTRL2[BOFFDONEMSK] = 1, an interrupt is generated to the CPU. 0b - No such occurrence 1b - FlexCAN module has completed Bus Off process.
18 SYNCH	CAN Synchronization Status Flag Indicates whether FlexCAN is synchronized to the CAN bus and able to participate in the communication process. FlexCAN sets and clears this flag. See the table in Error and Status 1 (ESR1). 0b - Not synchronized 1b - Synchronized
17 TWRNINT	TX Warning Interrupt Flag Indicates whether TX error counter changed from less than 96 to greater than or equal to 96. If MCR[WRNEN] = 1, this flag is set when the TXWRN flag transitions from 0 to 1, meaning that the TX error counters reached 96. If CTRL1[TWRNMSK] = 1, an interrupt is sent to the CPU. When MCR[WRNEN] = 0, this flag is masked. The CPU must clear this flag before writing 0 to MCR[WRNEN]. Otherwise, this flag is set when MCR[WRNEN] = 1 again. Writing 0 has no effect. This flag is not generated when in the Bus Off state. This flag is not updated during Freeze mode. When FlexCAN returns to Normal mode from Pretended Network mode (see Receive process in Pretended Networking mode), this bit is not updated. 0b - No such occurrence 1b - TX error counter changed from less than 96 to greater than or equal to 96.
16 RWRNINT	RX Warning Interrupt Flag Indicates whether the RX error counter changed from less than 96 to greater than or equal to 96. If MCR[WRNEN] = 1, this flag is set when the RXWRN flag transitions from 0 to 1, meaning that the RX error counters reached 96. If CTRL1[RWRNMSK] = 1, an interrupt is sent to the CPU. When MCR[WRNEN] = 0, this flag is masked. The CPU must clear this flag before writing 0 to MCR[WRNEN]. Otherwise, this flag is set when MCR[WRNEN] = 1 again. Writing 0 has no effect. This flag is not updated during Freeze mode. When FlexCAN returns to Normal mode from Pretended Network mode (see Receive process in Pretended Networking mode), this bit is updated to reflect the RX error counter state. 0b - No such occurrence 1b - RX error counter changed from less than 96 to greater than or equal to 96.
15 BIT1ERR	Bit1 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This flag is updated when FlexCAN returns to Normal mode from Pretended Network mode. **NOTE** A transmitter does not set this flag for an arbitration field or ACK slot. It is not set for a node sending a error passive flag that detects dominant bits. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as recessive is received as dominant.
14 BIT0ERR	Bit0 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. This field is updated when FlexCAN returns to Normal mode from Pretended Network mode. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as dominant is received as recessive.
13 ACKERR	Acknowledge Error Flag Indicates whether the transmitter node has detected an acknowledge error. This error means that a dominant bit has not been detected during the ACK SLOT. This flag is updated when FlexCAN returns to Normal mode from Pretended Network mode. After a read operation, the field's value clears to 0. 0b - No error 1b - Error occurred since last read of this register.
12 CRCERR	Cyclic Redundancy Check Error Flag Indicates whether the receiver node has detected a cyclic redundancy check (CRC) error either in a non-FD message or in the arbitration or data phase of a frame in CAN FD format. This error means that the calculated CRC is different from the received. This flag is updated when FlexCAN returns to Normal mode from Pretended Network mode. After a read operation, the field's value clears to 0. 0b - No error 1b - Error occurred since last read of this register.
11 FRMERR	Form Error Flag Indicates whether a form error has been detected in a non-FD message or in the arbitration or data phase of an FD message by the receiver node. This error means that a fixed-form field contains at least one illegal bit. This flag is updated when FlexCAN returns to Normal mode from Pretended Network mode. After a read operation, the field's value clears to 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No error 1b - Error occurred since last read of this register.
10 STFERR	Stuffing Error Flag Indicates that a stuffing error has been detected in a non-FD message or in the arbitration or data phase of an FD message by the receiver node. This flag is updated when FlexCAN returns to Normal mode from Pretended Network mode. After a read operation, the field's value clears to 0. 0b - No error 1b - Error occurred since last read of this register.
9 TXWRN	TX Error Warning Flag Indicates when repetitive errors occur during message transmission. Only the value of ECR[TXERRCNT] affects this flag. This flag is not updated during Freeze mode. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - TXERRCNT is 96 or greater.
8 RXWRN	RX Error Warning Flag Indicates when repetitive errors occur during message reception. Only the value of ECR[RXERRCNT] affects this flag. This flag is not updated during Freeze mode. Additionally, this flag is updated when FlexCAN returns to Normal mode from Pretended Networking mode. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - RXERRCNT is greater than or equal to 96.
7 IDLE	Idle Indicates whether CAN bus is in IDLE state. See Table 348. 0b - Not IDLE 1b - IDLE
6 TX	FlexCAN In Transmission Indicates whether FlexCAN is transmitting a message. See Table 348. 0b - Not transmitting 1b - Transmitting
5-4 FLTCONF	Fault Confinement State Indicates the confinement state of FlexCAN.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If CTRL1[LOM] = 1, after a delay that depends on the CAN bit timing, this field indicates Error Passive. The same delay affects the way that this field reflects an update to ECR register by the CPU. It may be necessary to wait up to one CAN bit time for coherence to be restored. Soft reset affects this field, but if CTRL1[LOM] = 1, its reset value lasts for only one CAN bit. After that time, this field reports Error Passive. 00b - Error Active 01b - Error Passive 1xb - Bus Off
3 RX	FlexCAN in Reception Flag Indicates whether FlexCAN is receiving a message. See the table in Error and Status 1 (ESR1). 0b - Not receiving 1b - Receiving
2 BOFFINT	Bus Off Interrupt Flag Indicates whether FlexCAN has entered Bus Off state. If CTRL1[BOFFMSK]) = 1, an interrupt is generated to the CPU. Writing 0 to this field has no effect. 0b - No such occurrence. 1b - FlexCAN module entered Bus Off state.
1 ERRINT	Error Interrupt Flag Indicates that at least one of the error flags (ESR1[BIT1ERR], ESR1[BIT0ERR], ESR1[ACKERR], ESR1[CRCERR], ESR1[FRMERR], or ESR1[STFERR]) is set. If the corresponding mask CTRL1[ERRMSK] = 1, an interrupt is generated to the CPU. Writing 0 to this field has no effect. 0b - No such occurrence. 1b - Indicates setting of any error flag in the Error and Status register.
0 WAKINT	Wake-up Interrupt Flag Generates an interrupt to the CPU when a recessive-to-dominant transition is detected on the CAN bus and MCR[WAKMSK] = 1. This field applies when FlexCAN is in low-power mode during Self Wake-up: • Doze mode • Stop mode When MCR[SLFWAK] = 0, this flag is masked. The CPU must clear this flag before disabling the field. Otherwise, it is set when MCR[SLFWAK] becomes 1 again. Writing 0 has no effect. 0b - No such occurrence. 1b - Indicates that a recessive-to-dominant transition was received on the CAN bus.

52.5.2.10 Interrupt Masks 1 (IMASK1)

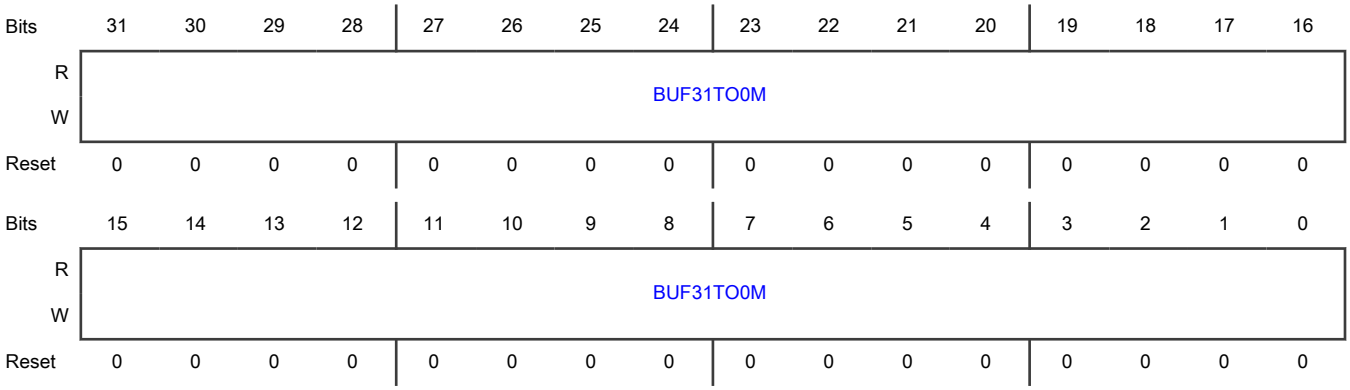
Offset

Register	Offset
IMASK1	28h

Function

Masks interrupt flags. This register allows any of the 32 message buffer interrupts to be enabled or disabled for MB31–MB0. It contains one interrupt mask bit per buffer. This configuration allows the CPU to determine which buffer generates an interrupt after a successful transmission or reception when the corresponding Interrupt Flags 1 (IFLAG1) flag is set.

Diagram



Fields

Field	Function
31-0 BUF31TO0M	Buffer MBi Mask Enables or disables the corresponding FlexCAN message buffer interrupt for MB31–MB0. **NOTE** If the corresponding Interrupt Flags 1 (IFLAG1) flag is set, writing 1 or 0 to a field in IMASK1 can set or clear an interrupt request. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

52.5.2.11 Interrupt Flags 1 (IFLAG1)

Offset

Register	Offset
IFLAG1	30h

Function

Contains the flags for the 32 message buffer interrupts for MB31–MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding Interrupt Masks 1 (IMASK1) bit is set, an interrupt is generated. There is an exception when DMA for Legacy RX FIFO is enabled, as described below.

The BUF7I–BUF5I flags also represent Legacy FIFO interrupts when the Legacy RX FIFO is enabled. When MCR[RFEN] is 1 and MCR[DMA] is 0, the function of the eight least significant interrupt flags changes:

- BUF7I, BUF6I, and BUF5I indicate operating conditions of the Legacy FIFO.
- BUF4I–BUF1I fields are reserved.
- BUF0I empties the Legacy FIFO.

Before writing 1 to MCR[RFEN], the CPU must service the IFLAG flags set in the Legacy RX FIFO region; see Legacy RX FIFO. Otherwise, these IFLAG flags mistakenly show the related message buffers now belonging to Legacy FIFO as having contents to be serviced. When MCR[RFEN] is 0, the Legacy FIFO flags must be cleared. The same care must be taken when a CTRL2[RFFN] value is selected, extending Legacy RX FIFO filters beyond MB7. For example, when RFFN is 8h, Legacy RX FIFO filters occupy the MB23–MB0 range, and related IFLAG flags must be cleared.

When MCR[RFEN] and MCR[DMA] are 1 (DMA feature for Legacy RX FIFO enabled), the function of the eight least significant interrupt flags (BUF7I–BUF0I) changes to support DMA operation. BUF7I, BUF6I, and BUF4I–BUF1I are not used.

BUF5I indicates the operating condition of the Legacy FIFO, and BUF0I empties the Legacy FIFO. Moreover, BUF5I does not generate a CPU interrupt, but it does generate a DMA request. IMASK1 bits in the Legacy RX FIFO region are not considered when bit MCR[DMA] = 1. In addition, the CPU must not clear the BUF5I flag when DMA is enabled. Before writing 1 to MCR[DMA], the CPU must service the IFLAG flags set in the Legacy RX FIFO region. When MCR[DMA] is 0, the Legacy FIFO must be empty. Legacy FIFO must be disabled when MCR[FDEN] = 1.

Before updating MCR[MAXMB], the CPU must service the IFLAG1 flags whose MB value is greater than the MCR[MAXMB] to be updated. Otherwise, those flags remain set and are inconsistent with the number of message buffers available.

Diagram

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-8 BUF31TO8I	Buffer MBi Interrupt Flags the corresponding FlexCAN message buffer interrupt for MB31–MB8. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - The corresponding buffer has successfully completed transmission or reception.
7 BUF7I	Buffer MB7 Interrupt or Legacy RX FIFO Overflow Flags the interrupt for MB7 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, this flag represents a Legacy RX FIFO overflow. In this case, the flag indicates that a message was lost because the Legacy RX FIFO is full. When the Legacy RX FIFO is full and a message buffer captures the message, this flag is not set. 0b - No occurrence of MB7 completing transmission or reception, or no FIFO overflow. 1b - MB7 completed transmission or reception, or FIFO overflow.
6 BUF6I	Buffer MB6 Interrupt or Legacy RX FIFO Warning Flags the interrupt for MB6 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, this flag represents a Legacy RX FIFO warning. In this case, the flag indicates when the number of unread messages within the Legacy RX FIFO is increased to five from four due to the reception of a new message. In other words, the Legacy RX FIFO is almost full. If this flag is cleared when there are more than four unread messages, it does not set again until the number of unread messages in the Legacy RX FIFO decreases to four or fewer. 0b - No occurrence of MB6 completing transmission or reception, or FIFO not almost full. 1b - MB6 completed transmission or reception, or FIFO almost full.
5 BUF5I	Buffer MB5 Interrupt or Frames available in Legacy RX FIFO Flags the interrupt for MB5 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, the BUF5I flag represents frames available in Legacy RX FIFO. In this case, the flag indicates that at least one frame is available to be read from the Legacy RX FIFO. When MCR[DMA] = 1, this flag generates a DMA request. The CPU must not clear this field by writing 1 to BUF5I. 0b - No occurrence of completed transmission or reception, or no frames available 1b - MB5 completed transmission or reception, or frames available
4-1 BUF4TO1I	Buffer MBi Interrupt or Reserved Flags the interrupts for MB4–MB1 when MCR[RFEN] = 0 (Legacy RX FIFO disabled).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When a CPU write changes the value of MCR[RFEN], FlexCAN clears these flags. When MCR[RFEN] = 1, the BUF4TO1I flags are reserved. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.
0 BUF0I	Buffer MB0 Interrupt or Clear Legacy FIFO bit Flags the interrupt for MB0 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). If MCR[RFEN] = 1, this field is used to trigger the clear Legacy FIFO operation. This operation empties the Legacy FIFO contents. Before performing this operation, the CPU must service all Legacy FIFO-related IFLAG flags. When MCR[DMA] = 1, this operation also clears the BUF5I flag, aborting the DMA request. The clear Legacy FIFO operation occurs when the CPU writes 1 to BUF0I. This operation is only allowed in Freeze mode; the module blocks it in other conditions. 0b - MB0 has no occurrence of successfully completed transmission or reception. 1b - MB0 has successfully completed transmission or reception.

52.5.2.12 Control 2 (CTRL2)

Offset

Register	Offset
CTRL2	34h

Function

Complements Control 1 (CTRL1), providing control bits for memory write-access in Freeze mode. This register extends Legacy FIFO filter quantity, and adjusts the operation of internal FlexCAN processes such as matching and arbitration.

Soft reset does not affect the contents of this register.

Table 349 shows how the value of CTRL2[RFFN] determines the Legacy RX FIFO filter structure.

Table 349. Possible Legacy RX FIFO filter structures

RFFN[3:0]	Number of Legacy RX FIFO filter elements	Message buffers occupied by Legacy RX FIFO and ID filter table	Remaining available message buffers	Legacy RX FIFO ID filter table elements affected by RX individual masks	Legacy RX FIFO ID filter table elements affected by Legacy RX FIFO global mask

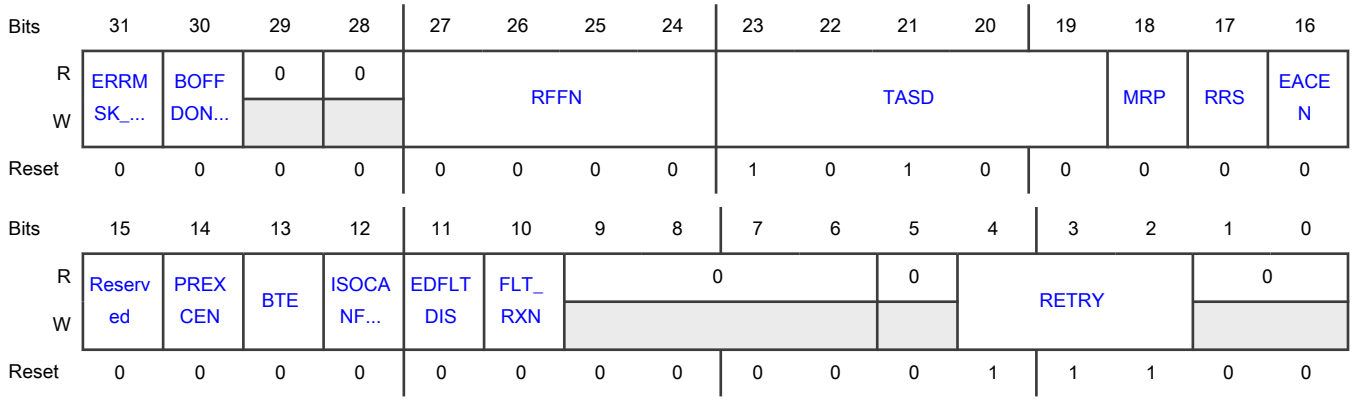
Diagram



Fields

Field	Function
31 ERRMSK_FAST	Error Interrupt Mask for Errors Detected in the Data Phase of Fast CAN FD Frames Enables the ESR1[ERRINT_FAST] interrupt. 0b - Disable 1b - Enable
30	Bus Off Done Interrupt Mask Enables the Bus Off Done interrupt, ESR1[BOFFDONEINT].

Table continues on the next page...

Table continued from the previous page...

Field	Function
BOFFDONEMSK	0b - Disable 1b - Enable
29 —	Reserved
28 —	Reserved
27-24 RFFN	Number of Legacy Receive FIFO Filters Defines the number of Receive Legacy FIFO filters, as shown in Table 349. The chip determines the maximum selectable number of filters. Do not program this field with values that cause the number of message buffers occupied by Legacy RX FIFO and Legacy RX FIFO ID Filter to exceed MCR[MAXMB]. MCR[MAXMB] defines the number of message buffers present. This field can only be written in Freeze mode; the module blocks it in other modes. Each group of eight filters occupies a memory space equivalent to two message buffers. The more filters are implemented, the fewer message buffers are available. The Legacy RX FIFO occupies the memory space originally reserved for MB5–MB0. This field should be programmed with a value corresponding to a number of filters less than the number of available memory words. The number of available words can be calculated as follows: (SETUP_MB - 6) × 4 Where SETUP_MB is the smaller of the parameter NUMBER_OF_MB and MCR[MAXMB]. The number of remaining message buffers available is: (SETUP_MB - 8) - (RFFN × 2) If the number of Legacy RX FIFO filters programmed through RFFN exceeds the SETUP_MB value (memory space available), the exceeding ones are not functional. **NOTE** • The number of the last remaining available message buffers is the smaller of (NUMBER_OF_MB - 1) and MCR[MAXMB]. • If RX Individual Mask registers are not enabled, the Legacy RX FIFO Global Mask affects all Legacy RX FIFO filters.
23-19 TASD	Transmission Arbitration Start Delay Indicates by how many CAN bits the transmission arbitration process start point can be delayed from the first bit of CRC field on CAN bus. See TX arbitration start delay for details. This field can be written only in Freeze mode; the module blocks it in other modes.
18 MRP	Message Buffers Reception Priority Sets the priority for the matching process. This field can be written only in Freeze mode; the module blocks it in other modes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Matching starts from Legacy RX FIFO or Enhanced RX FIFO and continues on message buffers. 1b - Matching starts from message buffers and continues on Legacy RX FIFO or Enhanced RX FIFO.
17 RRS	Remote Request Storing Determines what the module does with a remote request. The remote request frame is submitted to a matching process. If this field is 1, the frame is stored in the corresponding message buffer in the same fashion as a data frame. No automatic remote response frame is generated. If this field is 0, an automatic remote response frame is generated if a message buffer with CODE = 1010b is found with the same ID. You can only write to this field in Freeze mode. The module blocks it in other modes. 0b - Generated 1b - Stored
16 EACEN	Entire Frame Arbitration Field Comparison Enable for RX Message Buffers Controls the comparison of IDE and RTR fields within RX message buffer filters with their corresponding bits in the incoming frame by the matching process. If enabled, the IDE and RTR fields of the RX message buffer are compared to their corresponding bits within the incoming frame (mask bits apply). If disabled, the IDE field of the RX message buffer filter is always compared and RTR is never compared despite mask bits. This field does not affect matching for Legacy RX FIFO or Enhanced RX FIFO. You can only write to this field in Freeze mode; the module blocks it in other modes. 0b - Disable 1b - Enable
15 —	Reserved When writing to this field, always write the reset value.
14 PREXCEN	Protocol Exception Enable Enables the protocol exception feature. You can only write to this field in Freeze mode. **NOTE** See Protocol exception event in the CAN Protocol standard (ISO 11898-1:2015) for details. 0b - Disabled 1b - Enabled
13 BTE	Bit Timing Expansion Enable

Table continued from the previous page...

Field	Function
	Enables the use of Enhanced CAN Bit Timing Prescalers (EPRS), Enhanced Data Phase CAN Bit Timing (EDCBT), and Enhanced Nominal CAN Bit Timing (ENCBT) to configure the CAN bit timing segments, instead of using the bit timing fields of CAN Bit Timing (CBT), CAN FD Bit Timing (FDCBT), and Control 1 (CTRL1). If this field is 1: • CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] are read as zero. A write operation to these fields has no effect. • CBT[EPRESDIV], CBT[ERJW], CBT[EPROPSEG], CBT[EPSEG1], and CBT[EPSEG2], and the corresponding fields in CAN FD Bit Timing (FDCBT), are read as zero. A write operation to these fields has no effect. • ETDC[ETDCOFF], ETDC[ETDCEN], ETDC[ETDCFAIL], and ETDC[ETDCVAL] are used by FlexCAN instead of FDCTRL[TDCOFF], FDCTRL[TDCEN], FDCTRL[TDCFAIL], and FDCTRL[TDCVAL]. These fields are read as zero, and a write operation to them has no effect. • ETDC[TDMDIS] can be used to disable transceiver delay measurement. 0b - Disable 1b - Enable
12 ISOCANFDEN	ISO CAN FD Enable Enables the CAN FD protocol according to ISO specification (ISO 11898-1:2015) (see CAN FD ISO compliance). When disabled, FlexCAN operates using the non-ISO CAN FD protocol. You can only write to this field in Freeze mode. **NOTE** FlexCAN is able to transmit FD frame format according to CAN Protocol standard (ISO 11898-1:2015). 0b - Disable 1b - Enable
11 EDFLTDIS	Edge Filter Disable Disables the edge filter used during the Bus Integration state. When the Edge Filter is enabled, two consecutive nominal time quanta with dominant bus states are required to detect an edge that causes synchronization. When synchronization occurs, the counting of the sequence of 11 consecutive recessive bits is restarted. The edge filter prevents dominant pulses that are shorter than a nominal bit time (present during the data phase of an FD frame) from being mistaken for an idle condition. You can only write to this field in Freeze mode. **NOTE** See Bus Integration state in the CAN Protocol standard (ISO 11898-1:2015) for details. 0b - Enabled 1b - Disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
10 FLT_RXN	Fault reaction Indicates fault reaction during the functional mode. Setting this bit makes the TX pin to recessive state. 0b - Fault reaction is disabled 1b - Fault reaction is enabled
9-6 —	Reserved
5 —	Reserved
4-2 RETRY	Number of Retransmission Requests The message is discarded in case of a re-transmission counter exhausted. **NOTE** You can only write to this field in Freeze mode. 000b - No retransmission 001b - Count of re-transmission attempts 010b - Count of re-transmission attempts 011b - Count of re-transmission attempts 100b - Count of re-transmission attempts 101b - Count of re-transmission attempts 110b - Count of re-transmission attempts 111b - Unlimited number of retransmission
1-0 —	Reserved

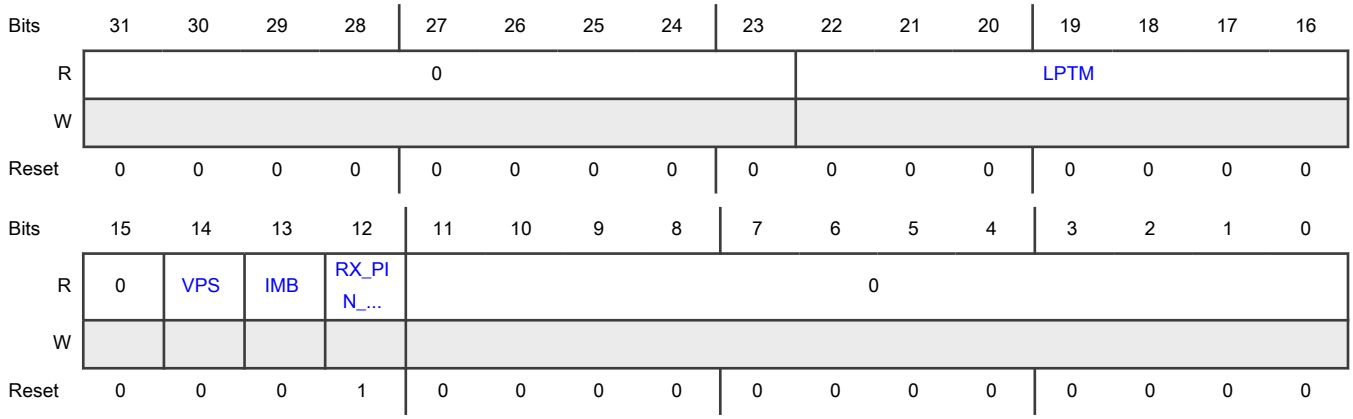
52.5.2.13 Error and Status 2 (ESR2)

Offset

Register	Offset
ESR2	38h

Function
Reports general status information.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-16 LPTM	Lowest Priority TX Message Buffer Indicates the lowest number inactive message buffer when ESR2[VPS] = 1 (see ESR2[IMB]). If no message buffer is inactive, the message buffer indicated depends on the value of CTRL1[LBUF]. If CTRL1[LBUF] = 0, the message buffer indicated is the one with the greatest arbitration value (see Highest-priority message buffer first). If CTRL1[LBUF] = 1, the message buffer indicated is the active TX message buffer with the highest number. If a TX message buffer is being transmitted, it is not considered in the LPTM calculation. If ESR2[IMB] is not 0 and a frame is transmitted successfully, the value of LPTM is updated with its message buffer number.
15 —	Reserved
14 VPS	Valid Priority Status Indicates whether the contents of ESR2[IMB] and ESR2[LPTM] are valid. It becomes 1 upon every complete TX arbitration process, unless the CPU writes to the Control and Status word of a message buffer already scanned. In other words, it is behind the TX Arbitration Pointer, during the TX arbitration process. If there is no inactive message buffer and only one TX message buffer that is being transmitted, this field remains 0. This field becomes 0 upon the start of every TX arbitration process or upon a write to the Control and Status word of any message buffer. **NOTE** No CPU write to the Control and Status of a message buffer that the abort mechanism blocks affects this field. When MCR[AEN] = 1, the abort code write to the Control and Status of an MB being transmitted (pending abort) is blocked. Any write attempt to a TX MB with its IFLAG flag set is also blocked. 0b - Invalid 1b - Valid

Table continues on the next page...

Table continued from the previous page...

Field	Function
13 IMB	Inactive Message Buffer Indicates whether any message buffer is inactive (CODE field is either 1000b or 0b) when ESR2[VPS] = 1. This field becomes 1 when: • A lowest-priority TX message buffer (ESR2[LPTM]) is found and it is inactive during arbitration. • This field is not 1, and a frame is transmitted successfully. This field always becomes 0 at the start of arbitration (see Arbitration process). If a message buffer is successfully transmitted and this field is 0 (no inactive message buffer), ESR2[VPS] and this field both become 1. The index related to the MB transmitted is loaded into ESR2[LPTM]. In this case, the value of ESR2[LPTM] is the number of the first inactive message buffer. 0b - Message buffer indicated by ESR2[LPTM] is not inactive. 1b - At least one message buffer is inactive.
12 RX_PIN_ST	RX Pin Status Indicates the current state of the RX pin. This bit is affected by soft reset. **NOTE** IP takes a few clock cycles to propagate the value of RX pin to this status bit. 0b - RX pin is in the dominant state 1b - RX pin is in a recessive state
11-0 —	Reserved

52.5.2.14 Cyclic Redundancy Check (CRCR)

Offset

Register	Offset
CRCR	44h

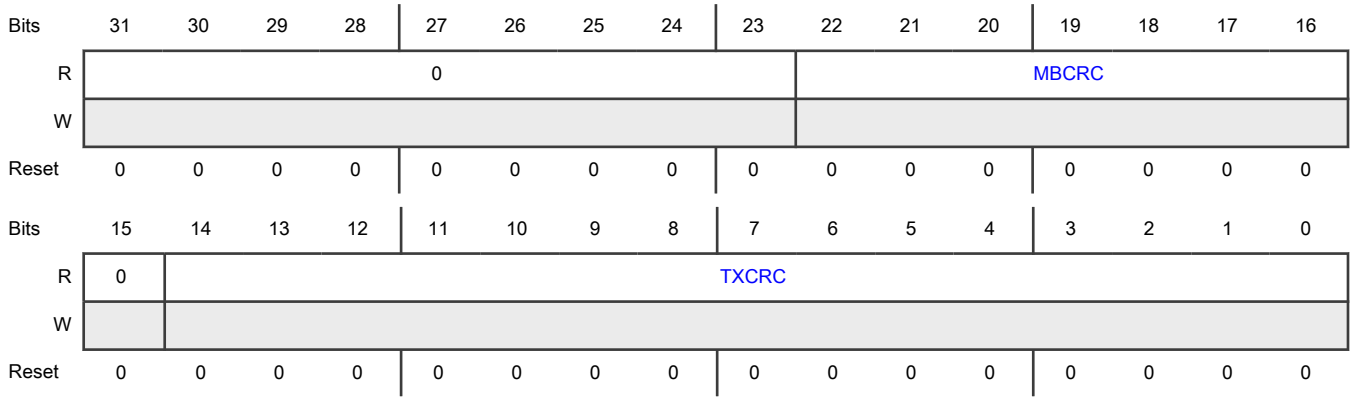
Function

Provides information about the CRC of transmitted messages for non-FD messages. This register only reports the 15 low-order bits of CRC calculations for messages in CAN FD format that require either 17 or 21 bits. For CAN FD format frames, you must use the CAN FD CRC (FDCRC). This register is updated at the same time that the TX interrupt flag is set.

NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1:2015) for details.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-16 MBCRC	CRC Message Buffer Indicates the number of the message buffer corresponding to the value in CRCR[TXCRC].
15 —	Reserved
14-0 TXCRC	Transmitted CRC value Indicates the CRC value of the last transmitted message for non-FD frames. For FD frames, CRC value is reported in CAN FD CRC (FDCRC).

52.5.2.15 Legacy RX FIFO Global Mask (RXFGMASK)

Offset

Register	Offset
RXFGMASK	48h

Function

Masks the Legacy RX FIFO ID filter table elements that do not have a corresponding RXIMR according to CTRL2[RFFN], when Legacy RX FIFO is enabled.

This register is located in RAM.

You can only write to this register in Freeze mode; the module blocks it in other modes.

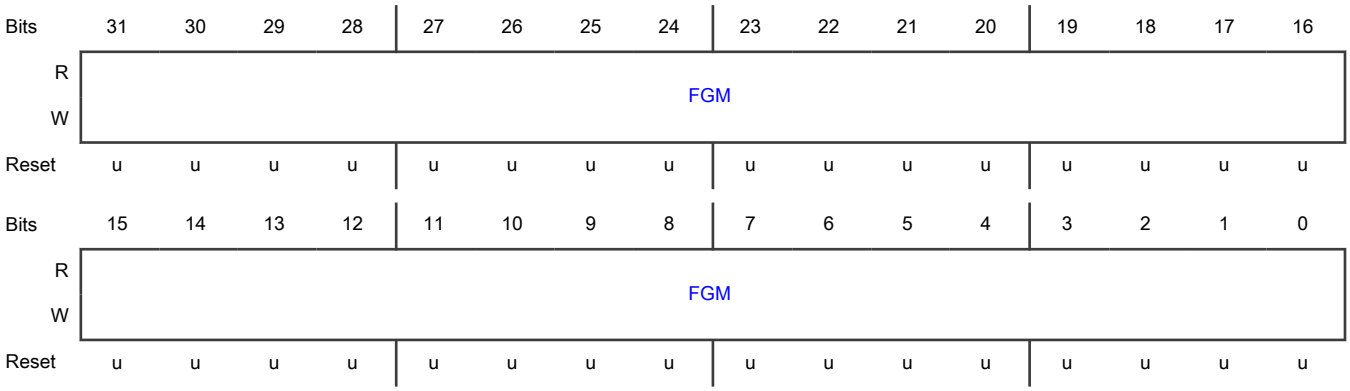
The following table shows how the FGM bits correspond to each IDAF field.

Table 350. Correspondence of Legacy RX FIFO global mask bits to IDF fields

Legacy RX FIFO ID filter table elements format (MCR[IDAM])	Identifier acceptance filter fields					
	RTR	IDE	RXIDA	RXIDB [1]	RXIDC [2]	Reserved
A	FGM[31]	FGM[30]	FGM[29:1]	—	—	FGM[0]
B	FGM[31], FGM[15]	FGM[30], FGM[14]	—	FGM[29:16], FGM[13:0]		—
C	—	—		—	FGM[31:24], FGM[23:16], FGM[15:8], FGM[7:0]	

1. If MCR[IDAM] is equivalent to format B, only the 14 most significant bits of the identifier of the incoming frame are compared with the Legacy RX FIFO filter.
2. If MCR[IDAM] is equivalent to format C, only the eight most significant bits of the identifier of the incoming frame are compared with the Legacy RX FIFO filter.

Diagram



Fields

Field	Function
31-0 FGM	Legacy RX FIFO Global Mask Bits Masks the ID filter table elements bits in a perfect alignment. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

52.5.2.16 Legacy RX FIFO Information (RXFIR)

Offset

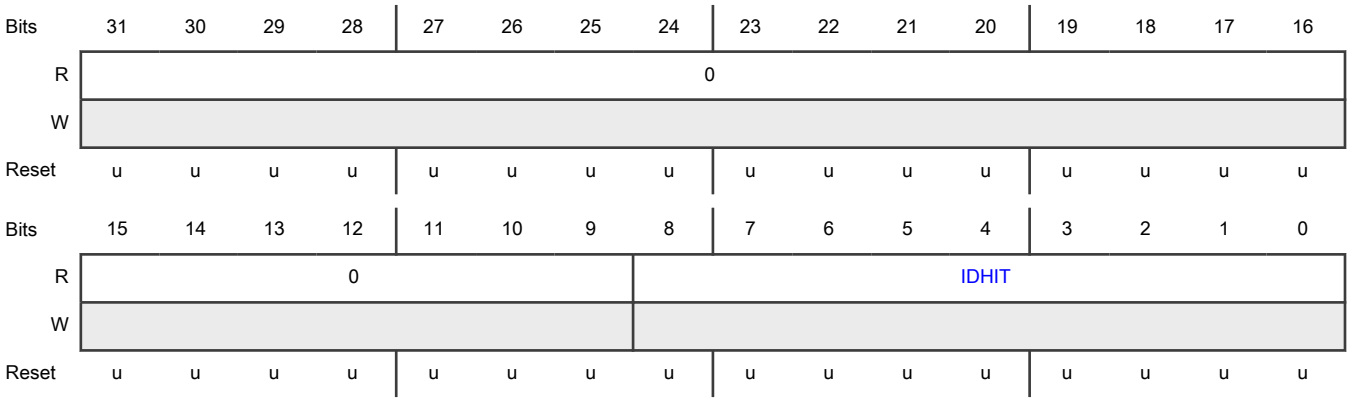
Register	Offset
RXFIR	4Ch

Function

Provides information about Legacy RX FIFO.

This register is the port through which the CPU accesses the output of the Legacy RXFIR FIFO located in RAM. FlexCAN writes to the Legacy RXFIR FIFO when a new message is moved into the Legacy RX FIFO. Also, its output is updated whenever the output of the Legacy RX FIFO is updated with the next message. See Legacy RX FIFO for instructions on reading this register.

Diagram



Fields

Field	Function
31-9 —	Reserved
8-0 IDHIT	Identifier Acceptance Filter Hit Indicator Indicates which Identifier Acceptance filter that the received message hit in the output of the Legacy RX FIFO. If multiple filters match the incoming message ID, the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only when IFLAG1[BUF5I] is set.

52.5.2.17 CAN Bit Timing (CBT)

Offset

Register	Offset
CBT	50h

Function

Provides an alternative way to store the CAN bit timing variables described in Control 1 (CTRL1). EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW are extended versions of CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] respectively.

NOTE

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

CBT[BTF] selects the use of the timing variables defined in this register.

When the CAN FD feature is enabled (MCR[FDEN] = 1), always write 1 to CBT[BTF].

Soft reset does not affect the contents of this register.

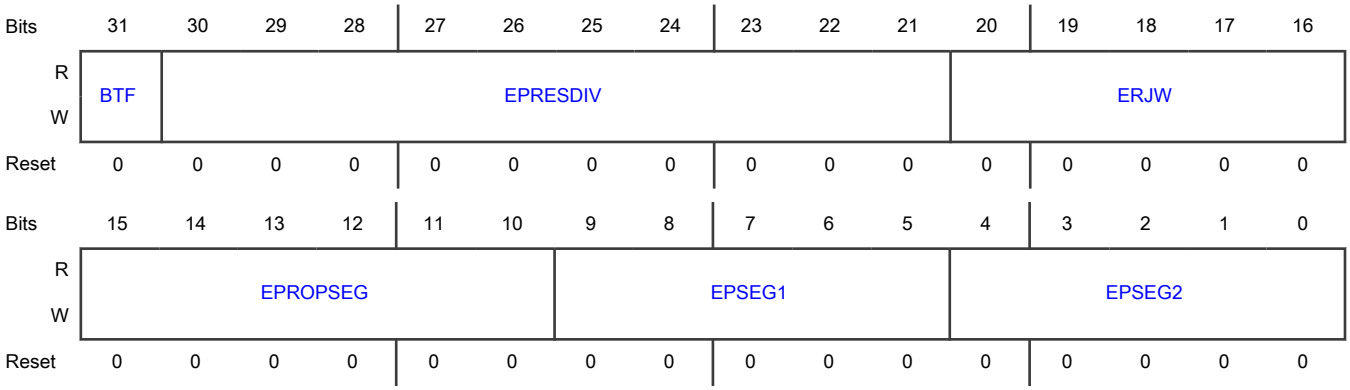
NOTE

Ensure that bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

NOTE

If CTRL2[BTE] = 1, EPRESDIV, ERJW, EPROPSEG, EPSEG1, and EPSEG2 are read as zero. A write operation to them has no effect.

Diagram



Fields

Field	Function
31 BTF	Bit Timing Format Enable Enables the use of extended CAN bit timing fields EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW. These fields replace the CAN bit timing variables defined in Control 1 (CTRL1). This field can be written in Freeze mode only. 0b - Disable 1b - Enable
30-21 EPRESDIV	Extended Prescaler Division Factor Defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PRESDIV] value range. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). This field can be written only in Freeze mode; the module blocks it in other modes. Sclock frequency = PE clock frequency ÷ (EPRESDIV + 1)
20-16 ERJW	Extended Resync Jump Width Defines the maximum number of time quanta that one resynchronization can change a bit time when CBT[BTF] = 1. Otherwise, it has no effect. It extends the CTRL1[RJW] value range.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field can be written only in Freeze mode; the module blocks it in other modes. Resync Jump Width = ERJW + 1. One Time Quantum = one Sclock period.
15-10 EPROPSEG	Extended Propagation Segment Defines the length of the propagation segment in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PROPSEG] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation Segment Time = (EPROPSEG + 1) × Time Quanta. One Time Quantum = one Sclock period.
9-5 EPSEG1	Extended Phase Segment 1 Defines the length of phase segment 1 in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PSEG1] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 1 = (EPSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.
4-0 EPSEG2	Extended Phase Segment 2 Defines the length of phase segment 2 in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PSEG2] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 1 = (EPSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.

52.5.2.18 External Timer (ET)

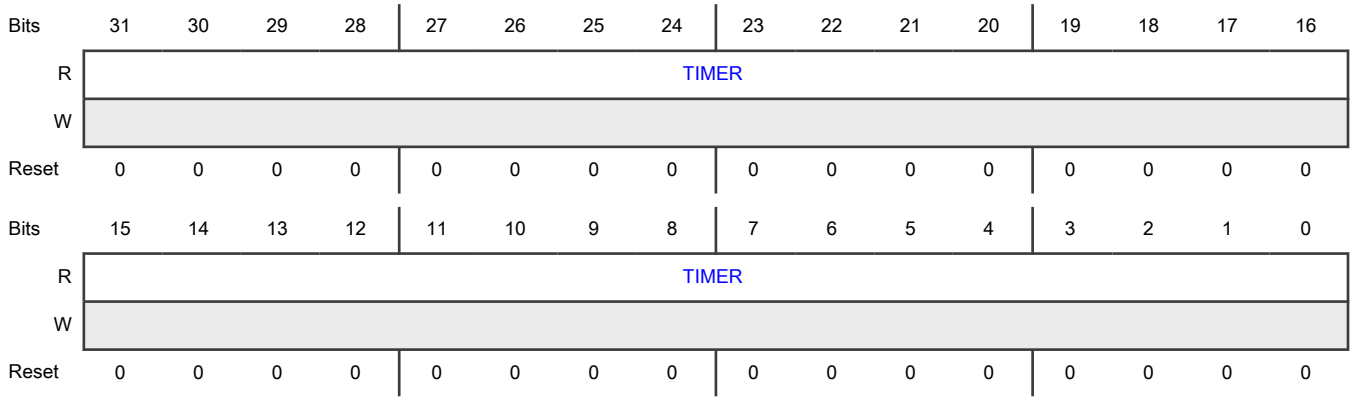
Offset

Register	Offset
ET	78h

Function

This register captures the value of external timer.

Diagram



Fields

Field	Function
31-0 TIMER	Timer Indicates the current value of the external timer. This field is affected by soft reset.

52.5.2.19 Fault Confinement Interrupt Enable (FLTCONF_IE)

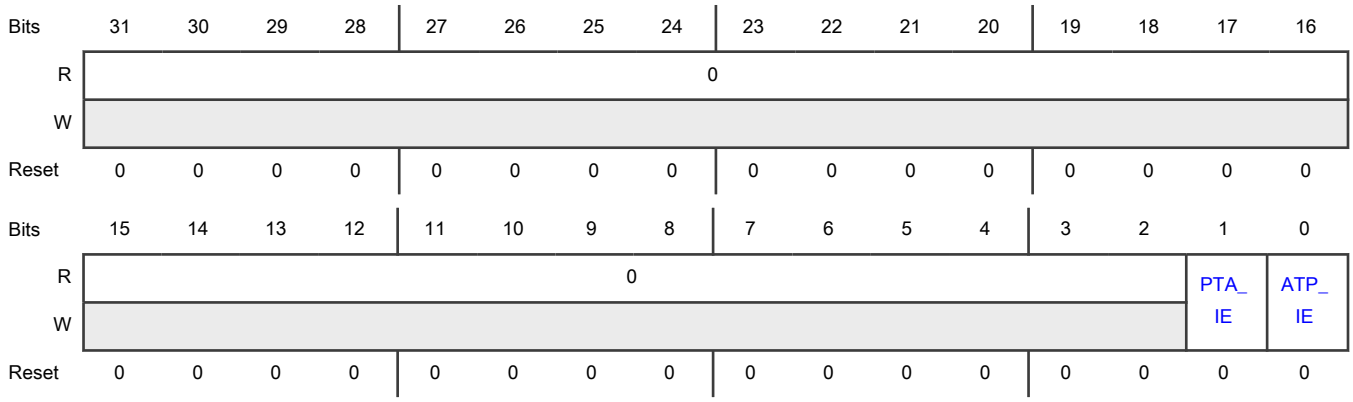
Offset

Register	Offset
FLTCONF_IE	7Ch

Function

Interrupt enables for active to passive and passive to active state transitions.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 PTA_IE	Passive to Active Interrupt Enable Enables passive to active error state interrupt. When this field is 1, passive to active error state interrupt is enabled. When this field is 0, passive to active error state interrupt is not enabled. 0b - Disable 1b - Enable
0 ATP_IE	Active to Passive Interrupt Enable Enables active to passive error state interrupt. When this field is 1, active to passive error state interrupt is enabled. When this field is 0, active to passive error state interrupt is not enabled. 0b - Disable 1b - Enable

52.5.2.20 Receive Individual Mask (RXIMR0 - RXIMR31)

Offset

For n = 0 to 31:

Register	Offset
RXIMRn	880h + (n × 4h)

Function

Stores the acceptance masks for ID filtering in RX message buffers and the Legacy RX FIFO.

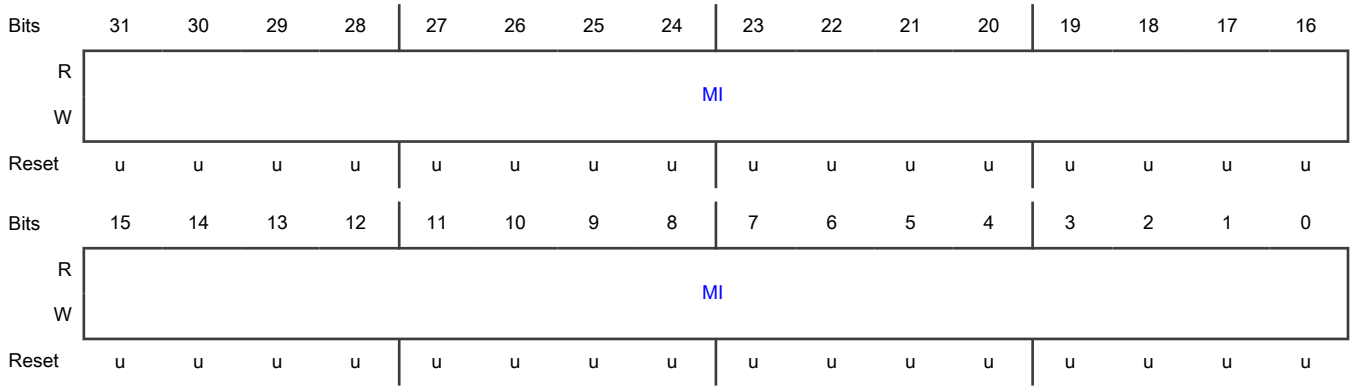
When the Legacy RX FIFO is disabled (MCR[RFEN] = 0), an individual mask is provided for each available RX message buffer on a one-to-one correspondence. When the Legacy RX FIFO is enabled (MCR[RFEN] = 1), an individual mask is provided for each Legacy RX FIFO ID filter table element on a one-to-one correspondence. This correspondence depends on the setting of CTRL2[RFFN] (see Legacy RX FIFO).

RXIMR0 stores the individual mask associated with either MB0 or ID filter table element 0. RXIMR1 stores the individual mask associated with either MB1 or ID filter table element 1, and so on.

The CPU can only access the RXIMR registers when the module is in Freeze mode; otherwise, the module blocks them. Reset does not affect these registers. They are located in RAM and must be explicitly initialized prior to any reception.

It is possible for the RXIMR memory region to be accessed as general-purpose memory. See Bus interface for more information.

Diagram



Fields

Field	Function
31-0 MI	Individual Mask Bits Masks the corresponding bit in both the message buffer filter and Legacy RX FIFO ID filter table element in distinct ways. For message buffer filters, see RX Message Buffers Global Mask (RXMGMASK). For Legacy RX FIFO ID filter table elements, see Legacy RX FIFO Global Mask (RXFGMASK). 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

52.5.2.21 Pretended Networking Control 1 (CTRL1_PN)

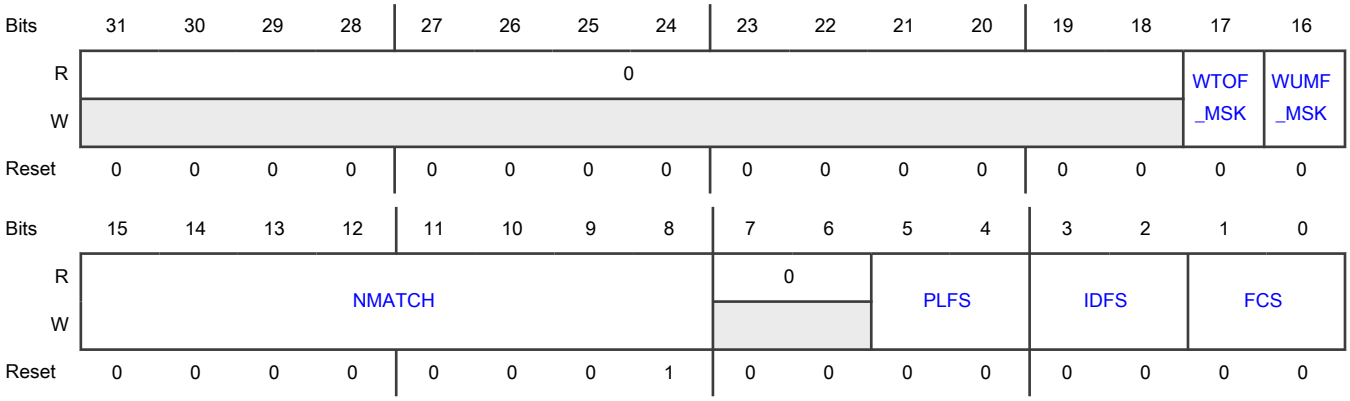
Offset

Register	Offset
CTRL1_PN	B00h

Function

Contains control bits for Pretended Networking mode filtering selection. Configure this register with the filter criteria to be used to receive wake-up messages. Fields in this register can be written in Freeze mode only, except for CTRL1_PN[WTOF_MSK] and CTRL1_PN[WUMF_MSK].

Diagram



Fields

Field	Function
31-18 —	Reserved
17 WTOF_MSK	Wake-up by Timeout Flag Mask Enables the generation of a wake-up event originated by a timeout. 0b - Disable 1b - Enable
16 WUMF_MSK	Wake-up by Matching Flag Mask Enables the generation of a wake-up event originated by a successful filtered RX message. 0b - Disable 1b - Enable
15-8 NMATCH	Number of Messages Matching the Same Filtering Criteria Defines the number of times a given message must match the predefined filtering criteria for ID or payload before generating a wake-up event. You can configure this quantity in the 1–255 range by using values 01h–FFh, respectively. 0000_0001b - Once 0000_0010b - Twice 1111_1111b - 255 times
7-6 —	Reserved
5-4 PLFS	Payload Filtering Selection Selects the level of payload filtering to be applied when FlexCAN is in Pretended Networking mode. When payload filtering is active, filtering does not accept remote messages (RTR = 1).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - Match payload contents to an exact target value 01b - Match a payload value greater than or equal to a specified target value 10b - Match a payload value smaller than or equal to a specified target value 11b - Match upon a payload value within a range of values, inclusive
3-2 IDFS	ID Filtering Selection Selects the level of ID filtering to be applied when FlexCAN is in Pretended Networking mode. In ID filtering, if FLT_ID2_IDMASK[IDE_MSK] = 1 and FLT_ID2_IDMASK[RTR_MSK] = 1, the IDE and RTR bits are considered part of the reception filter. 00b - Match ID contents to an exact target value 01b - Match an ID value greater than or equal to a specified target value 10b - Match an ID value smaller than or equal to a specified target value 11b - Match an ID value within a range of values, inclusive
1-0 FCS	Filtering Combination Selection Selects the filtering criteria to be applied when FlexCAN is in Pretended Networking mode. See Receive process in Pretended Networking mode for more details. 00b - Message ID filtering only 01b - Message ID filtering and payload filtering 10b - Message ID filtering occurring a specified number of times 11b - Message ID filtering and payload filtering a specified number of times

52.5.2.22 Pretended Networking Control 2 (CTRL2_PN)

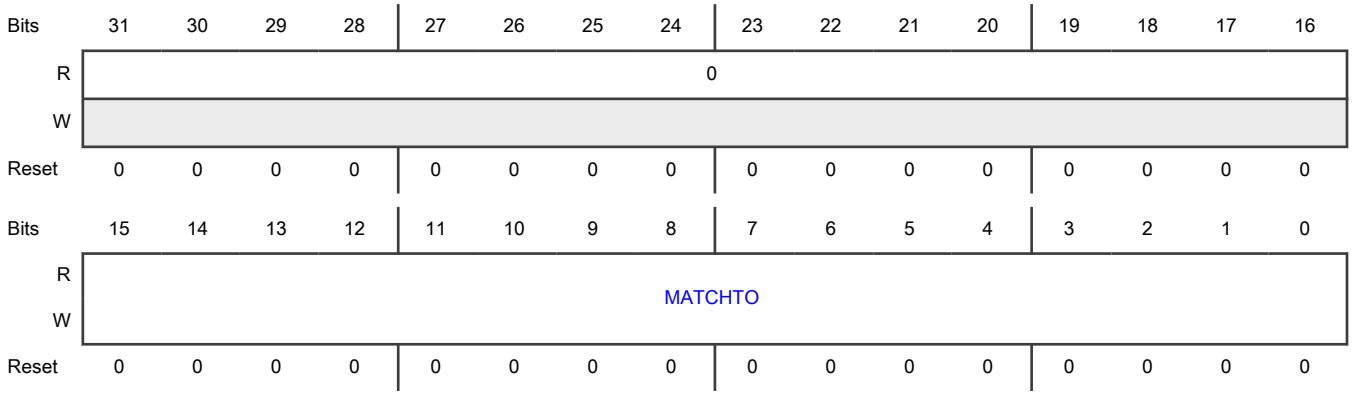
Offset

Register	Offset
CTRL2_PN	B04h

Function

Contains the configuration for the timeout value in Pretended Networking mode. You can only write to this register in Freeze mode.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 MATCHTO	Timeout for No Message Matching the Filtering Criteria Defines a timeout value that generates a wake-up event if MCR[PNET_EN] = 1. If the timeout counter reaches the target value when FlexCAN is in Pretended Networking mode, a wake-up event is generated. The timeout limit can be configured from 1 to 65535 to control an internal 16-bit incrementing timer to produce a trigger upon reaching this configured value. The internal timer is incremented based on periodic time ticks, where the period is 64 times the CAN Bit Time unit. Writing 0000h to this field disables the timeout.

52.5.2.23 Pretended Networking Wake-Up Match (WU_MTC)

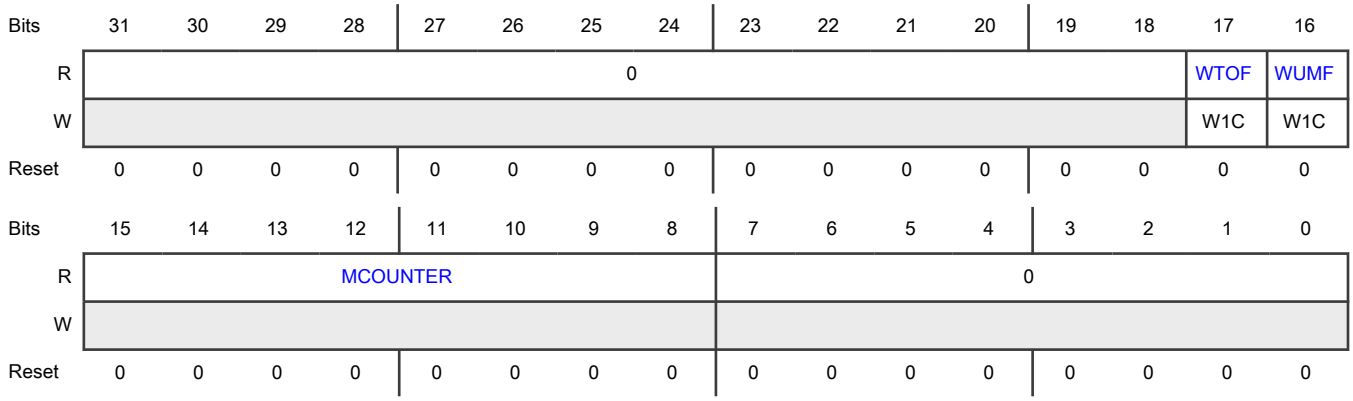
Offset

Register	Offset
WU_MTC	B08h

Function

Contains wake-up information related to the matching processes performed when FlexCAN receives frames in Pretended Networking mode.

Diagram



Fields

Field	Function
31-18 —	Reserved
17 WTOF	Wake-up by Timeout Flag Bit Identifies whether FlexCAN has detected a timeout event during a time interval defined by CTRL2_PN[MATCHTO]. If CTRL1_PN[WTOF_MSK] = 1, this flag generates a wake-up event. 0b - No event detected 1b - Event detected
16 WUMF	Wake-up by Match Flag Identifies whether FlexCAN has detected a matching RX incoming message that meets the filtering criteria specified in Pretended Networking Control 1 (CTRL1_PN). If CTRL1_PN[WUMF_MSK] = 1, this flag generates a wake-up event. 0b - No event detected 1b - Event detected
15-8 MCOUNTER	Number of Matches in Pretended Networking Contains the number of times a given message has matched the predefined filtering criteria for ID or payload before a wake-up event. When FlexCAN enters Pretended Networking mode, this register is reset; soft reset does not affect it.
7-0 —	Reserved

52.5.2.24 Pretended Networking ID Filter 1 (FLT_ID1)

Offset

Register	Offset
FLT_ID1	B0Ch

Function

Contains FLT_ID1 target value, as well as IDE and RTR target values used to filter an incoming message ID. The FLT_ID1 is used for comparisons or as the lower limit value in an ID range detection. It can be written in Freeze mode only.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	FLT_ID1															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 —	Reserved
30 FLT_IDE	ID Extended Filter Identifies whether the frame format is standard or extended. It is used as part of the ID reception filter. 0b - Standard 1b - Extended
29 FLT_RTR	Remote Transmission Request Filter Identifies whether the frame is remote. It is used as part of the ID reception filter. 0b - Reject remote frame (accept data frame) 1b - Accept remote frame
28-0 FLT_ID1	ID Filter 1 for Pretended Networking filtering Defines either the 29 bits of an extended frame format, considering all bits, or the 11 bits of a standard frame format, considering only the leftmost 11 bits.

52.5.2.25 Pretended Networking Data Length Code (DLC) Filter (FLT_DLC)

Offset

Register	Offset
FLT_DLC	B10h

Function

Contains the DLC inside a range of target values (FLT_DLC_LO and FLT_DLC_HI) used to filter an incoming message. The DLC range is used only for payload filtering. It can be written in Freeze mode only.

When a fixed quantity of data bytes is required, write the same value to FLT_DLC[FLT_DLC_LO] and FLT_DLC[FLT_DLC_HI]. See Receive process in Pretended Networking mode.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-20 —	Reserved
19-16 FLT_DLC_LO	Lower Limit for Length of Data Bytes Filter Specifies the lower limit for the number of data bytes considered valid for payload comparison. It is used as part of payload reception filter.
15-4 —	Reserved
3-0 FLT_DLC_HI	Upper Limit for Length of Data Bytes Filter Specifies the upper limit for the number of data bytes considered valid for payload comparison. It is used as part of payload reception filter.

52.5.2.26 Pretended Networking Payload Low Filter 1 (PL1_LO)

Offset

Register	Offset
PL1_LO	B14h

Function

Contains the low-order bits of the target value used to filter incoming message payload for payload filter 1. It is used for comparisons or as the lower limit value in a payload range detection. It can be written in Freeze mode only.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Data_byte_0								Data_byte_1

R W	Data_byte_2								Data_byte_3							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 Data_byte_0	Data byte 0 Contains payload filter 1 low-order bits for PN payload filtering corresponding to data byte 0.
23-16 Data_byte_1	Data byte 1 Contains payload filter 1 low-order bits for PN payload filtering corresponding to data byte 1.
15-8 Data_byte_2	Data byte 2 Contains payload filter 1 low-order bits for PN payload filtering corresponding to data byte 2.
7-0 Data_byte_3	Data byte 3 Contains payload filter 1 low-order bits for PN payload filtering corresponding to data byte 3.

52.5.2.27 Pretended Networking Payload High Filter 1 (PL1_HI)

Offset

Register	Offset
PL1_HI	B18h

Function

Contains the high-order bits of the target value used to filter incoming message payload for payload filter 1. It is used either for comparisons or as the lower limit value in a payload range detection. It can be written in Freeze mode only.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Data_byte_4								Data_byte_5							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Data_byte_6								Data_byte_7							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 Data_byte_4	Data byte 4 Contains payload filter 1 high-order bits for PN payload filtering corresponding to data byte 4.
23-16 Data_byte_5	Data byte 5 Contains payload filter 1 high-order bits for PN payload filtering corresponding to data byte 5.
15-8 Data_byte_6	Data byte 6 Contains payload filter 1 high-order bits for PN payload filtering corresponding to data byte 6.
7-0 Data_byte_7	Data byte 7 Contains payload filter 1 high-order bits for PN payload filtering corresponding to data byte 7.

52.5.2.28 Pretended Networking ID Filter 2 or ID Mask (FLT_ID2_IDMASK)

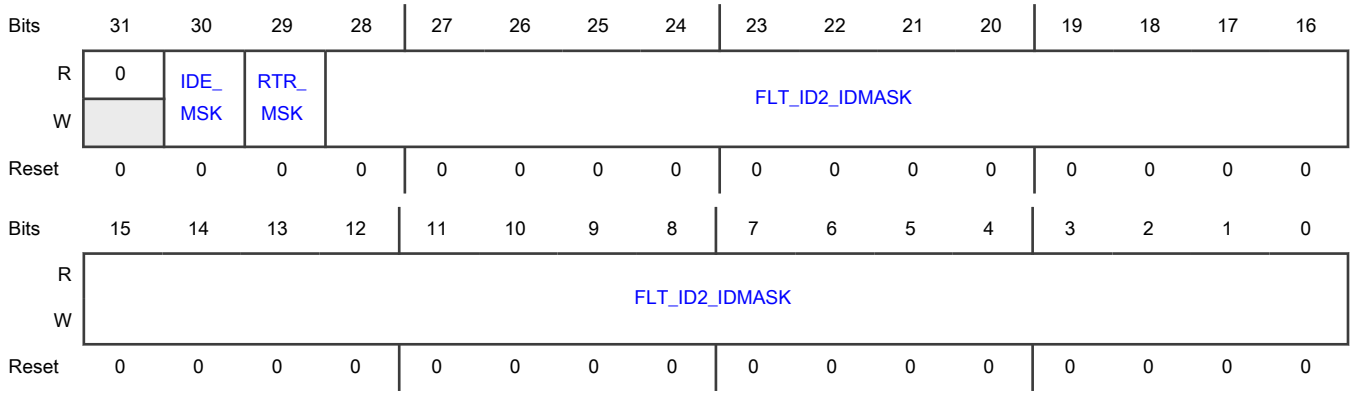
Offset

Register	Offset
FLT_ID2_IDMASK	B1Ch

Function

Contains FLT_ID2 target value used only as the upper limit value in ID range detection. When an exact ID filtering criterion is selected, this register stores the ID mask. IDE_MSK and RTR_MSK are used in both types of ID filtering (exact and range). These fields enable FLT_ID1[FLT_IDE] and FLT_ID1[FLT_RTR] to be used as part of the ID reception filter. This register can be written in Freeze mode only.

Diagram



Fields

Field	Function
31 —	Reserved
30 IDE_MSK	ID Extended Mask Indicates whether the frame format (standard or extended) is used as part of the ID reception filter. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.
29 RTR_MSK	Remote Transmission Request Mask Indicates whether the frame type (data or remote) is part of the ID reception filter. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.
28-0 FLT_ID2_IDMASK	ID Filter 2 for Pretended Networking Filtering or ID Mask Bits for Pretended Networking ID Filtering Defines filter values in range ID filtering: • Value in extended frame format (29 bits), considering FLT_ID2[28:0] • Value in standard frame format (11 bits), considering the FLT_ID2[28:18]. In this case, bits [17:0] are meaningless. Or, defines the mask values in exact ID filtering: • Values for extended frame format (29 bits), considering IDMASK[28:0] • Values for standard frame format (11 bits), considering IDMASK[28:18]. In this case, bits [17:0] are meaningless.

52.5.2.29 Pretended Networking Payload Low Filter 2 and Payload Low Mask (PL2_PLMASK_LO)

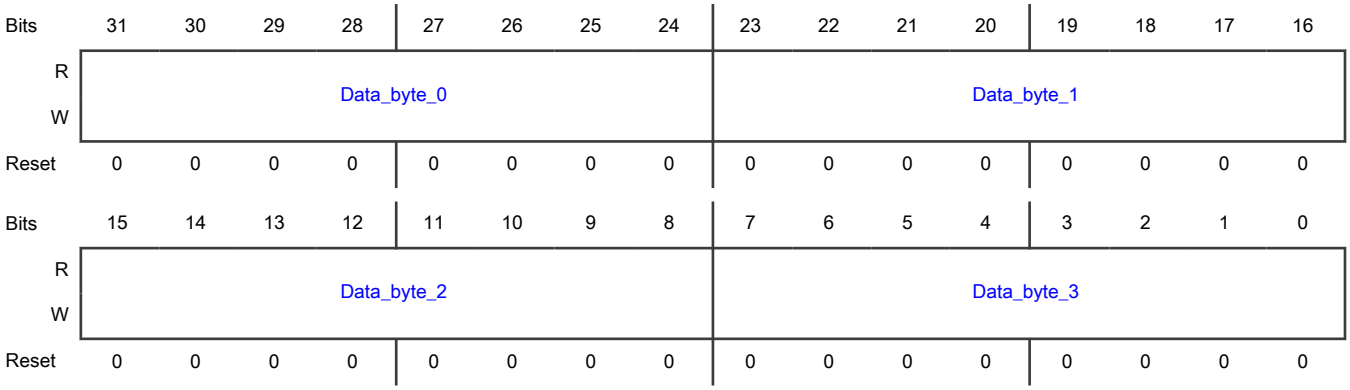
Offset

Register	Offset
PL2_PLMASK_LO	B20h

Function

Contains the low-order bits for Payload Filter 2, used only as the upper limit value in a payload range detection. Also, when an exact payload filtering criterion is selected, this register is used as payload mask for the low-order bits. Otherwise, this register is unused. It can be written in Freeze mode only.

Diagram



Fields

Field	Function
31-24 Data_byte_0	Data Byte 0 Contains payload filter 2 low-order bits, or Payload Mask low-order bits for PN payload filtering, corresponding to data byte 0
23-16 Data_byte_1	Data Byte 1 Contains payload filter 2 low-order bits, or Payload Mask low-order bits for PN payload filtering, corresponding to data byte 1
15-8 Data_byte_2	Data Byte 2 Contains payload filter 2 low-order bits, or Payload Mask low-order bits for PN payload filtering, corresponding to data byte 2
7-0 Data_byte_3	Data Byte 3 Contains payload filter 2 low-order bits, or Payload Mask low-order bits for PN payload filtering, corresponding to data byte 3

52.5.2.30 Pretended Networking Payload High Filter 2 and Payload High Mask (PL2_PLMASK_HI)

Offset

Register	Offset
PL2_PLMASK_HI	B24h

Function

Contains the high-order bits for the Payload Filter 2, used only as the upper limit value in a payload range detection. Also, when an exact payload filtering criterion is selected, this register is used as payload mask for the high-order bits. Otherwise, this register is unused. It can be written in Freeze mode only.

Diagram

7-0 Data_byte_7	Data Byte 7 Contains payload filter 2 high-order bits, or Payload Mask high-order bits for PN payload filtering, corresponding to data byte 7.

52.5.2.31 Wake-Up Message Buffer (WMB0_CS - WMB3_CS)

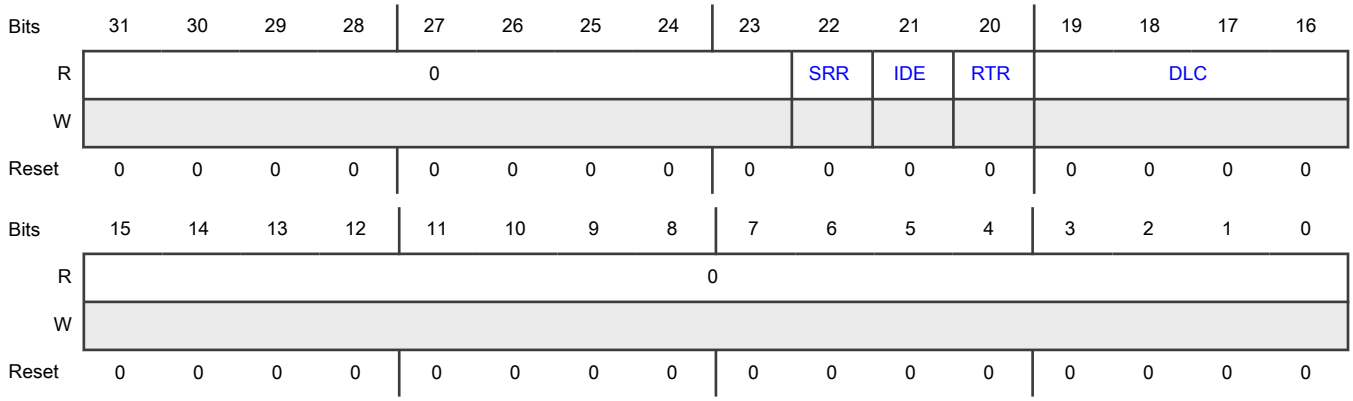
Offset

Register	Offset
WMB0_CS	B40h
WMB1_CS	B50h
WMB2_CS	B60h
WMB3_CS	B70h

Function

Stores the Control and Status information (IDE, RTR, and DLC fields) of an incoming RX message.

Diagram



Fields

Field	Function
31-23 —	Reserved
22 SRR	Substitute Remote Request Identifies whether the request is dominant or recessive. This field is used only in extended format. You must write 1 to this field for transmission buffers. The value of this field is stored with the value received on the CAN bus for receiving buffers. If FlexCAN receives this field as dominant, it is interpreted as an arbitration loss. 0b - Dominant 1b - Recessive
21 IDE	ID Extended Bit Identifies whether the frame format is standard or extended.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Standard 1b - Extended
20 RTR	Remote Transmission Request Identifies whether the frame is remote or data 0b - Data 1b - Remote
19-16 DLC	Length of Data in Bytes Contains the length (in bytes) of the RX data received when FlexCAN is in Pretended Networking mode. FlexCAN writes this field, copied from the DLC (Data Length Code) field of the received frame. The DLC field indicates which data bytes are valid.
15-0 —	Reserved

52.5.2.32 Wake-Up Message Buffer for ID (WMB0_ID - WMB3_ID)

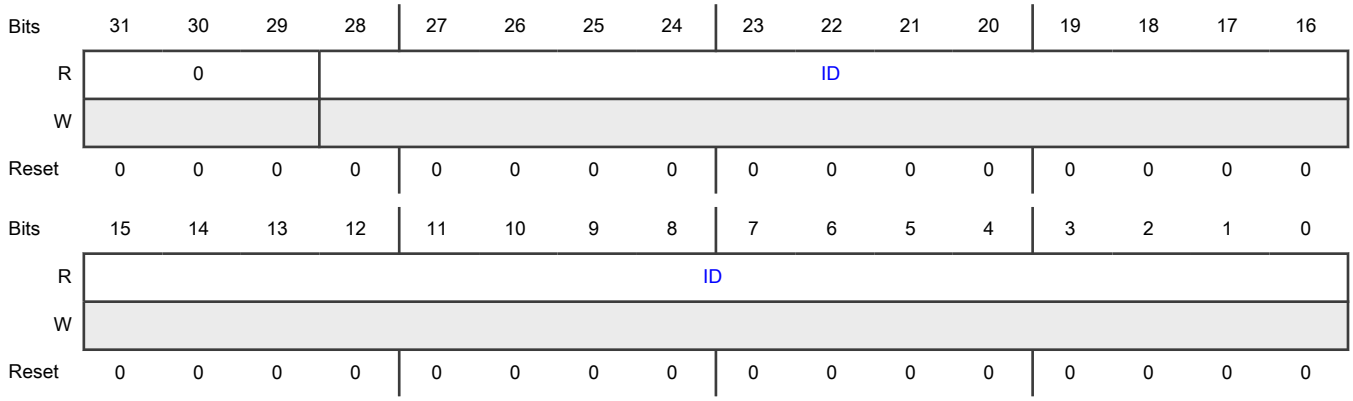
Offset

Register	Offset
WMB0_ID	B44h
WMB1_ID	B54h
WMB2_ID	B64h
WMB3_ID	B74h

Function

Stores the ID information of an incoming RX message.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-0 ID	Received ID in Pretended Networking Mode Stores the received ID, which is: • The 29 bits of the extended frame format (considering) • The 11 bits of the standard frame format (considering only; the remaining bits in the range are meaningless).

52.5.2.33 Wake-Up Message Buffer for Data 0–3 (WMB0_D03 - WMB3_D03)

Offset

Register	Offset
WMB0_D03	B48h
WMB1_D03	B58h
WMB2_D03	B68h
WMB3_D03	B78h

Function

Stores data bytes 0–3 of the payload information of an incoming RX message. The content of each register is cleared when the incoming matched message is either a remote frame (RTR = 1) or a data frame with DLC = 0.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Function
31-24 Data_byte_0	Data Byte 0 Contains received payload corresponding to data byte 0 in Pretended Networking mode
23-16 Data_byte_1	Data Byte 1 Contains received payload corresponding to data byte 1 in Pretended Networking mode
15-8 Data_byte_2	Data Byte 2 Contains received payload corresponding to data byte 2 in Pretended Networking mode
7-0 Data_byte_3	Data Byte 3 Contains received payload corresponding to data byte 3 in Pretended Networking mode

52.5.2.34 Wake-Up Message Buffer Register Data 4–7 (WMB0_D47 - WMB3_D47)

Offset

Register	Offset
WMB0_D47	B4Ch
WMB1_D47	B5Ch
WMB2_D47	B6Ch
WMB3_D47	B7Ch

Function

Stores the data bytes 4–7 of the payload information of an incoming RX message. The content of each register is cleared when the incoming matched message is either a remote frame (RTR = 1) or a data frame with DLC = 0.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 Data_byte_4	Data Byte 4 Contains received payload corresponding to data byte 4 in Pretended Networking mode
23-16 Data_byte_5	Data Byte 5 Contains received payload corresponding to data byte 5 in Pretended Networking mode
15-8 Data_byte_6	Data Byte 6 Contains received payload corresponding to data byte 6 in Pretended Networking mode
7-0 Data_byte_7	Data Byte 7 Contains received payload corresponding to data byte 7 in Pretended Networking mode

52.5.2.35 Enhanced CAN Bit Timing Prescalers (EPRS)

Offset

Register	Offset
EPRS	BF0h

Function

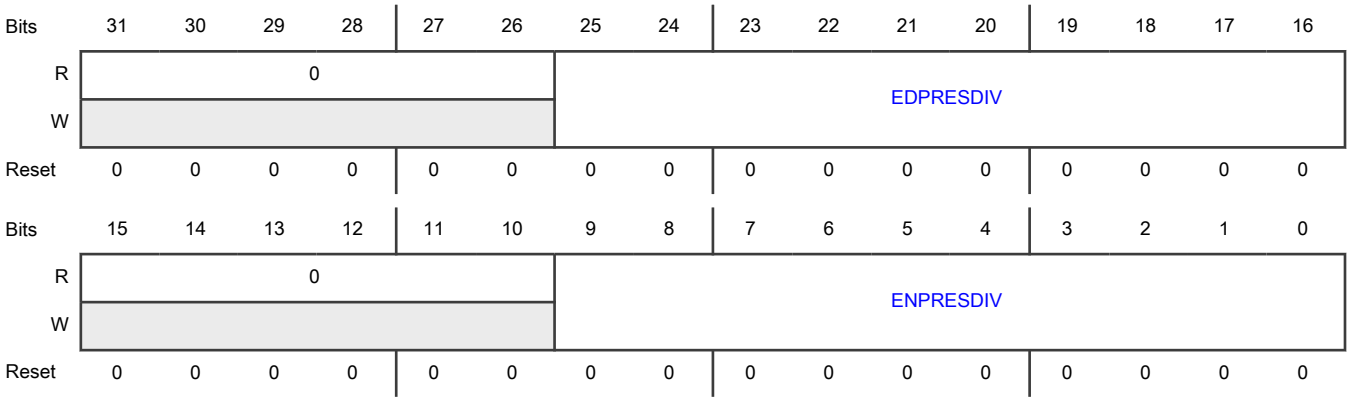
Defines the CAN bit timing prescalers for the nominal phase and data phase when CTRL2[BTE] = 1.

Used by the module only if CTRL2[BTE] = 1; otherwise a write operation has no effect and all fields are read as zero.

This register can be written only in Freeze mode; the module blocks it in other modes.

Soft reset does not affect the contents of this register.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 EDPRESDIV	Extended Data Phase Prescaler Division Factor Defines the ratio between the PE clock frequency and the Sclock frequency in the data phase of a CAN FD message when CTRL2[BTE] = 1. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. Sclock frequency = PE clock frequency ÷ (EDPRESDIV + 1) **NOTE** To minimize errors when processing FD frames, use the same value for this field and for EPRS[ENPRESDIV]. See the first note in CAN FD frames for details.
15-10 —	Reserved
9-0 ENPRESDIV	Extended Nominal Prescaler Division Factor Defines the ratio between the PE clock frequency and the Sclock frequency when CTRL2[BTE] = 1. Otherwise, it reads as 0 and a write operation has no effect. The Sclock period defines the time quantum of the CAN protocol in the nominal phase. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). Sclock frequency = PE clock frequency ÷ (ENPRESDIV + 1)

52.5.2.36 Enhanced Nominal CAN Bit Timing (ENCBT)

Offset

Register	Offset
ENCBT	BF4h

Function

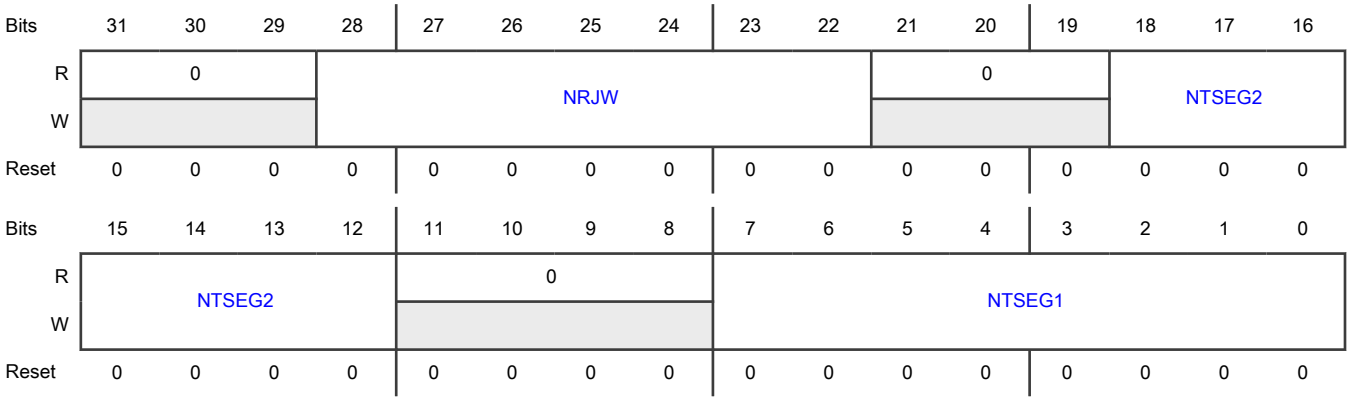
Provides an alternative way to store the CAN bit timing variables described in Control 1 (CTRL1) and CAN Bit Timing (CBT), to get higher CAN bit timing resolution.

This register is used by the module only if CTRL2[BTE] = 1. Otherwise, a write operation has no effect and all fields are read as zero.

Soft reset does not affect the contents of this register.

This register can be written only in Freeze mode; the module blocks it in other modes.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-22 NRJW	Nominal Resynchronization Jump Width Defines the maximum number of time quanta that one resynchronization can change a nominal bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. One time quantum = one Sclock period Nominal Resync Jump Width = NRJW + 1
21-19 —	Reserved
18-12 NTSEG2	Nominal Time Segment 2 Defines the length of Time Segment 2 in the nominal bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Nominal Time Segment 2 = (NTSEG2 + 1) × Time Quanta One time quantum = one Sclock period
11-8 —	Reserved
7-0 NTSEG1	Nominal Time Segment 1 Defines the length of Time Segment 1 in the bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Nominal Time Segment 1 = (NTSEG1 + 1) × Time Quanta One time quantum = one Sclock period

52.5.2.37 Enhanced Data Phase CAN Bit Timing (EDCBT)

Offset

Register	Offset
EDCBT	BF8h

Function

Provides an alternative way to store the data phase CAN bit timing variables described in CAN FD Bit Timing (FDCBT) to achieve higher CAN bit timing resolution.

This register is used by the module only if CTRL2[BTE] = 1; otherwise a write operation has no effect and all fields are read as zero.

Soft reset does not affect the contents of this register.

This register can be written only in Freeze mode; the module blocks it in other modes.

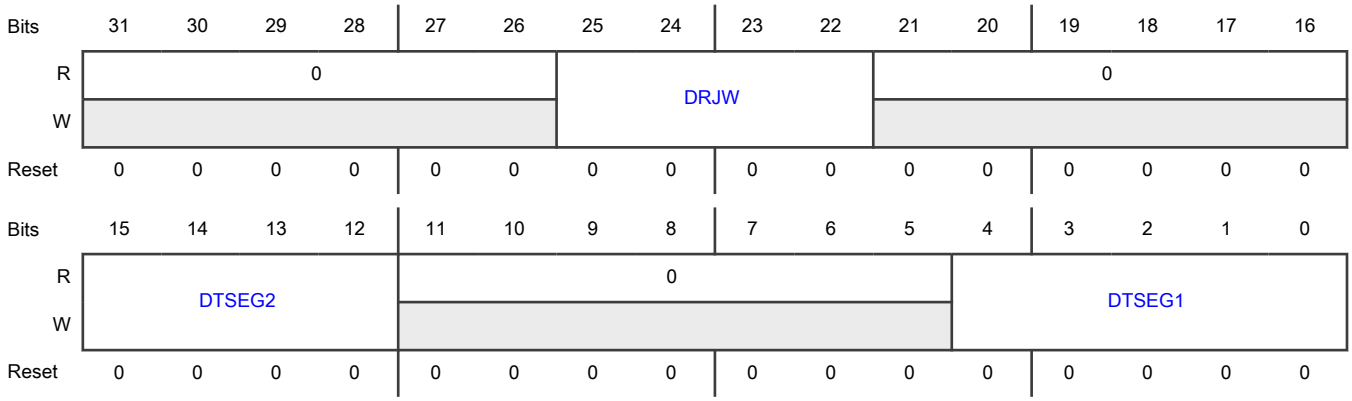
NOTE

Ensure that bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

NOTE

DTSEG1 must be at least two time quanta.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-22 DRJW	Data Phase Resynchronization Jump Width Defines the maximum number of time quanta that one resynchronization can change a data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Data Phase Resync Jump Width = DRJW + 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
21-16 —	Reserved
15-12 DTSEG2	Data Phase Time Segment 2 Defines the length of time segment 2 in the data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Data Phase Time Segment 2 = (DTSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.
11-5 —	Reserved
4-0 DTSEG1	Data Phase Segment 1 Defines the length of time segment 1 in the data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Data Phase Time Segment 1 = (NTSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.

52.5.2.38 Enhanced Transceiver Delay Compensation (ETDC)

Offset

Register	Offset
ETDC	BFCh

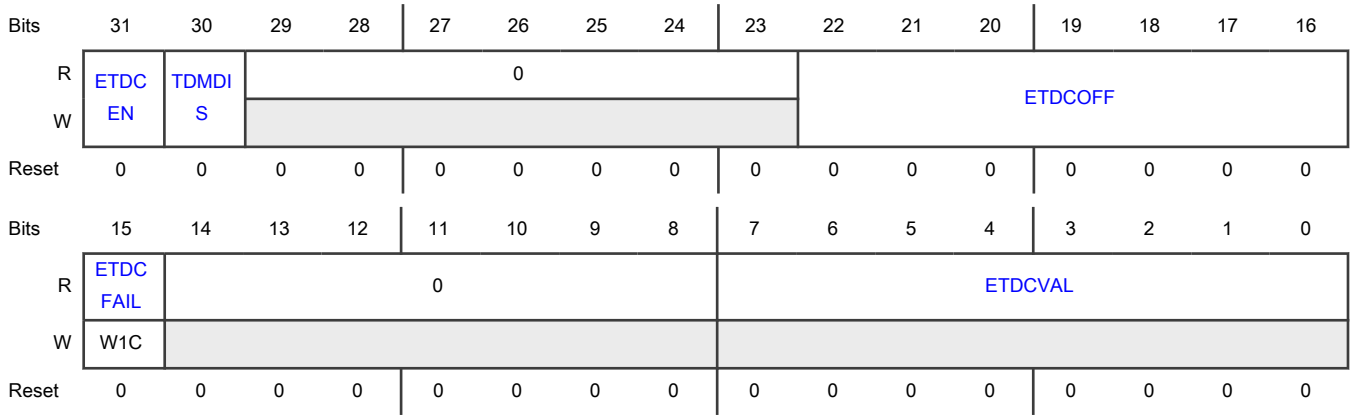
Function

Contains extended versions of FDCTRL[TDCOFF] and FDCTRL[TDCVAL]. This register is used by the module only if CTRL2[BTE] = 1. Otherwise, a write operation has no effect and all fields are read as zero.

NOTE

See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1:2015) for details.

Diagram



Fields

Field	Function
31 ETDCEN	Transceiver Delay Compensation Enable Enables the TDC feature. It can be written in Freeze mode only. **NOTE** See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1:2015) for details. **NOTE** TDC must be disabled when the Loop Back Mode is enabled. See CTRL1[LPB]. 0b - Disable 1b - Enable
30 TDMDIS	Transceiver Delay Measurement Disable Disables the transceiver delay measurement. When the TDC measurement is disabled, only ETDC[ETDCOFF] determines the secondary sample point position. If TCD measurement is enabled, the sum of the transceiver delay measurement plus the enhanced TDC offset determines the secondary sample point position. Soft reset does not affect this field. **NOTE** This bit can be enabled only if CTRL2[BTE] = 1. 0b - Enable 1b - Disable
29-23 —	Reserved
22-16	Enhanced Transceiver Delay Compensation Offset

Table continues on the next page...

Table continued from the previous page...

Field	Function
ETDCOFF	Contains the offset value to be added to the loop delay of the measured transceiver. This value defines the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for details on how the loop delay measurement is performed. This field can be written in Freeze mode only. Its value can be defined in protocol engine (PE) clock periods (CANCLK, see Protocol timing for more details). It must be smaller than the CAN bit duration in the data bit rate for proper operation. Do not write 0 to this field. **NOTE** If CTRL2[BTE] becomes 1 after a chip-level hard reset, this field is read as 1h.
15 ETDCFAIL	Transceiver Delay Compensation Fail Indicates whether the transceiver delay compensation (TDC) mechanism is out of range. In this case, it is unable to compensate the loop delay of the transceiver and successfully compare the delayed received bits to the transmitted ones. (See Transceiver delay compensation.) This field becomes 0 the first time FlexCAN detects the out of range condition. 0b - In range 1b - Out of range
14-8 —	Reserved
7-0 ETDCVAL	Enhanced Transceiver Delay Compensation Value Contains ETDC[ETDCOFF] added to the measured value of the transceiver loop delay in the latest transmitted CAN FD frame, with BRS = 1. The module only updates this field when ETDC[ETDCEN] = 1. Soft reset affects this field. **NOTE** If ETDC[TDMDIS] = 1, this field stores ETDC[ETDCOFF] only.

52.5.2.39 CAN FD Control (FDCTRL)

Offset

Register	Offset
FDCTRL	C00h

Function

Contains control bits for CAN FD operation. It also defines the data size of message buffers allocated in different partitions of RAM (memory blocks) as described in Table 351.

When an 8-byte payload is selected:

- Block R0 allocates MB0–MB31.
- Block R1 allocates MB32–MB63.

When a payload larger than eight bytes is selected, the maximum number of message buffers in a block is limited as described below.

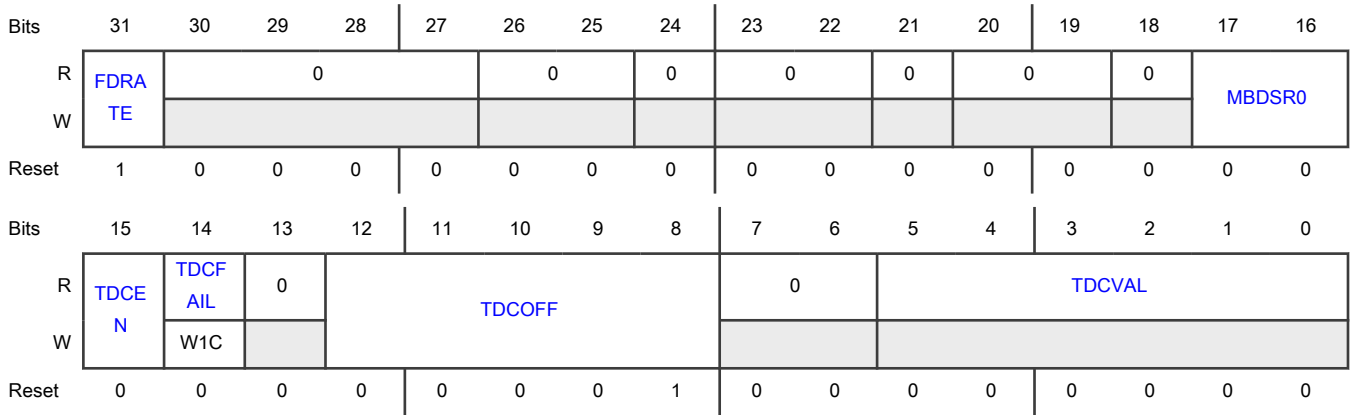
Table 351. Number of message buffers

Payload size	Maximum number of message buffers per RAM block
8 bytes	32
16 bytes	21
32 bytes	12
64 bytes	7

One memory block fits exactly 32 message buffers with an 8-byte payload. For other possible payload sizes, empty memory may exist between the last message buffer in a block and the beginning of the next block. This empty memory corresponds to less than one message buffer, and must not be used.

Soft reset does not affect the contents of this register.

Diagram



Fields

Field	Function
31 FDRATE	Bit Rate Switch Enable Enables the effect of the Bit Rate Switch (BRS bit) during the data phase of TX messages. When 1, if BRS = 1 in the TX message buffer, frames are transmitted with bit rate switching. When 0, frames are transmitted at a nominal rate, and the BRS bit in the TX MB has no effect. The CPU can write to this field at any time. However, its effect becomes active only under one of these conditions: • The CAN bus is in the Wait for Bus Idle state. • The CAN bus is in the Bus Idle state. • The CAN bus is in the Bus Off state.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• The current frame under reception or transmission reaches the interframe space. By writing 0 to FDCTRL[FDRATE], the CPU can force all bits in CAN FD messages to be transmitted at nominal bit rate. This transmission occurs regardless of the value in the BRS bit of the TX message buffers. 0b - Disable 1b - Enable
30-27 —	Reserved
26-25 —	Reserved
24 —	Reserved
23-22 —	Reserved
21 —	Reserved
20-19 —	Reserved
18 —	Reserved
17-16 MBDSR0	Message Buffer Data Size for Region 0 Selects the data size per message buffer for region R0 of message buffers allocated in RAM. This field can be written in Freeze mode only. 00b - 8 bytes 01b - 16 bytes 10b - 32 bytes 11b - 64 bytes
15 TDCEN	Transceiver Delay Compensation Enable Enables the TDC feature. It can be written in Freeze mode only. See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1:2015) for details. TDC must be disabled when Loopback mode is enabled (see CTRL1[LPB]).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE If CTRL2[BTE] = 1, this field is read as 0 and a write operation has no effect. 0b - Disable 1b - Enable
14 TDCFAIL	Transceiver Delay Compensation Fail Indicates whether the Transceiver Delay Compensation (TDC) mechanism is out of range. In this case, the mechanism cannot compensate for the loop delay of the transceiver and successfully compare the delayed received bits to the transmitted ones (see Transceiver delay compensation). The first time that FlexCAN detects the out-of-range condition, this field becomes 1. **NOTE** If CTRL2[BTE] = 1, this field is read as 0 and a write operation has no effect. 0b - In range 1b - Out of range
13 —	Reserved
12-8 TDCOFF	Transceiver Delay Compensation Offset Contains the offset value to be added to the loop delay of the measured transceiver. This value defines the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for details about loop delay measurement. This field can be written in Freeze mode only. Its value can be defined in Protocol Engine Clock periods (CANCLK, see Protocol timing for more details). The value must be smaller than the CAN bit duration in the data bit rate for proper operation. **NOTE** If CTRL2[BTE] = 1, TDCOFF is read as 0 and a write operation has no effect. Do not write 0 to this field.
7-6 —	Reserved
5-0 TDCVAL	Transceiver Delay Compensation Value Contains the value of the transceiver loop delay measured from the transmitted EDL-to-R0 transition edge to the respective received one added to FDCTRL[TDCOFF]. This value is an integer multiple of the Protocol Engine Clock period (CANCLK). If CTRL2[BTE] = 1, this field is read as 0. See Protocol timing for details on the loop delay measurement.

52.5.2.40 CAN FD Bit Timing (FDCBT)

Offset

Register	Offset
FDCBT	C04h

Function

Stores the CAN bit timing variables used in the data phase of CAN FD messages when the FDCTRL[FDRATE] = 1, compatible with the CAN FD specification. Fields in this register define:

- The time quantum duration
- The number of time quanta per CAN bit
- The sample point position for the data bit rate portion of a CAN FD message with BRS = 1

Soft reset does not affect the contents of this register.

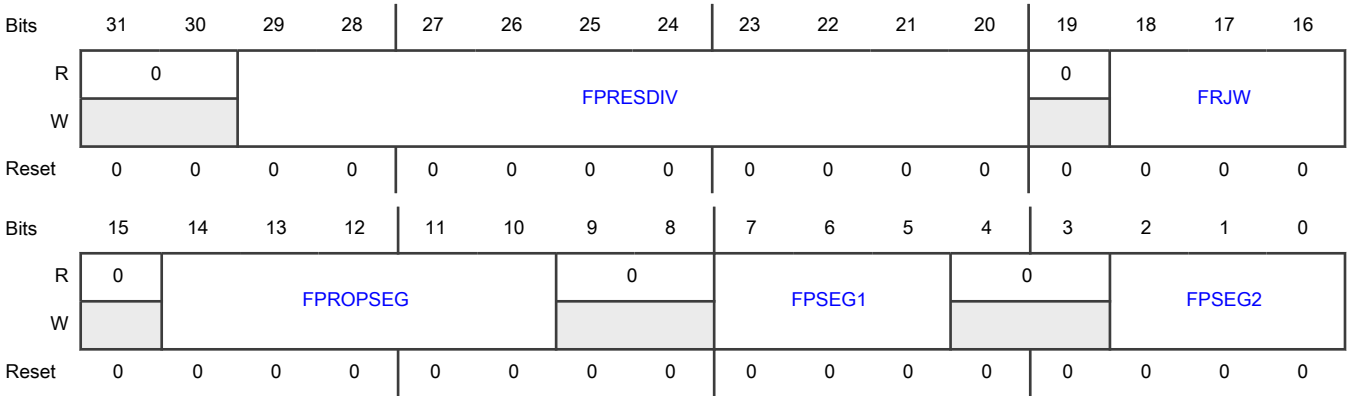
The sum of the Fast Propagation Segment (FPROPSEG) and Fast Phase Segment 1 (FPSEG1) must be at least two time quanta.

Ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

NOTE

If CTRL2[BTE] = 1, this register is read as zero and a write operation has no effect.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-20 FPRESDIV	Fast Prescaler Division Factor Defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency in the data bit rate portion of a CAN FD message with BRS = 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. This field can be written only in Freeze mode; the module blocks it in other modes. Sclock frequency = PE clock frequency ÷ (FPRESDIV + 1). **NOTE** To minimize errors when processing FD frames, use the same value for this field and for CTRL1[PRESDIV] or CBT[EPRESDIV]. See the first note in CAN FD frames for details.
19 —	Reserved
18-16 FRJW	Fast Resync Jump Width Defines the maximum number of time quanta that one resynchronization can change a bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Resync Jump Width = FSJW + 1. One Time Quantum = one Sclock period.
15 —	Reserved
14-10 FPROPSEG	Fast Propagation Segment Defines the length of the propagation segment in the bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation Segment Time = FPROPSEG × Time Quanta. One Time Quantum = one Sclock period.
9-8 —	Reserved
7-5 FPSEG1	Fast Phase Segment 1 Defines the length of phase segment 1 in the bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Segment 1 = (FPSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.
4-3 —	Reserved
2-0 FPSEG2	Fast Phase Segment 2 Defines the length of phase segment 2 in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Phase Segment 2 = (FPSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.

52.5.2.41 CAN FD CRC (FDCRC)

Offset

Register	Offset
FDCRC	C08h

Function

Provides information about the cyclic redundancy check (CRC) of transmitted messages.

FlexCAN uses different CRC polynomials for different frame formats.

- The CRC_15 polynomial is used for all frames in CAN format.
- The CRC_17 polynomial is used for frames in CAN FD format with a DATA FIELD up to 16 bytes.
- The CRC_21 polynomial is used for frames in CAN FD format with a DATA FIELD longer than 16 bytes.

Each polynomial shown below results in a Hamming distance of 6. This register is updated at the same time that the TX Interrupt flag is set.

$$\text{CRC\_15} = \text{C599h}: \ (x^{15} + x^{14} + x^{10} + x^{8} + x^{7} + x^{4} + x^{3} + 1)$$

$$\text{CRC\_17} = \text{3685Bh}: \ (x^{17} + x^{16} + x^{14} + x^{13} + x^{11} + x^{6} + x^{4} + x^{3} + x^{1} + 1)$$

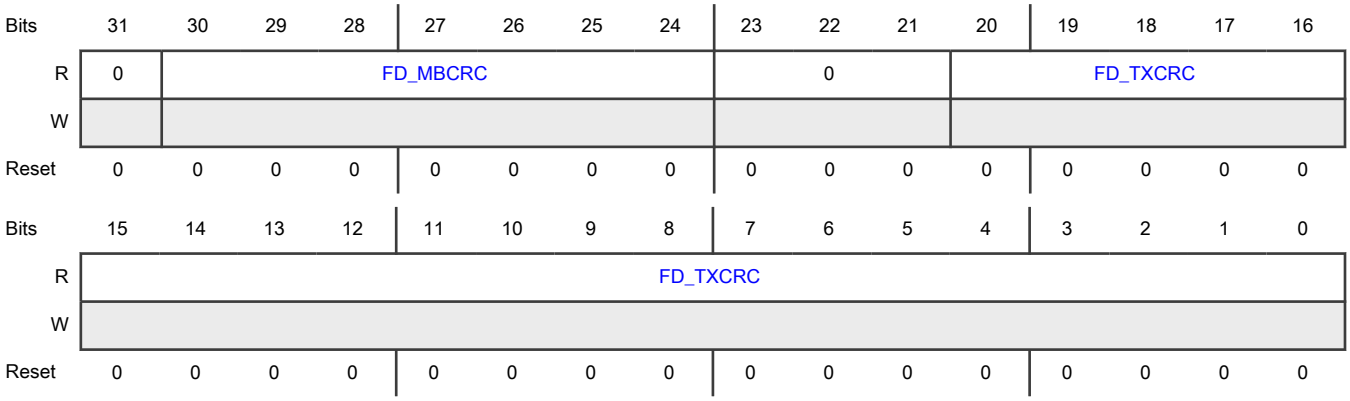
$$\text{CRC\_21} = \text{302899h}: \ (x^{21} + x^{20} + x^{13} + x^{11} + x^{7} + x^{4} + x^{3} + 1)$$

Equation 20. CRC polynomial used on CAN frame

NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1:2015) for details.

Diagram



Fields

Field	Function
31 —	Reserved
30-24 FD_MBCRC	CRC Message Buffer Number for FD_TXCRC Indicates the number of the message buffer corresponding to the value in FDCRC[FD_TXCRC], for both FD and non-FD frames. It reports the same information as in CRCR[MBCRC].
23-21 —	Reserved
20-0 FD_TXCRC	Extended Transmitted CRC value Contains the CRC value calculated over the most recent transmitted message. Different CRC polynomials are used for different frame formats. For CRC_15 and CRC_17, the six most significant bits and the four most significant bits are reported as zeroes, respectively. For CRC_15, this field has the same content as Cyclic Redundancy Check (CRCR).

52.5.2.42 Enhanced RX FIFO Control (ERFCR)

Offset

Register	Offset
ERFCR	C0Ch

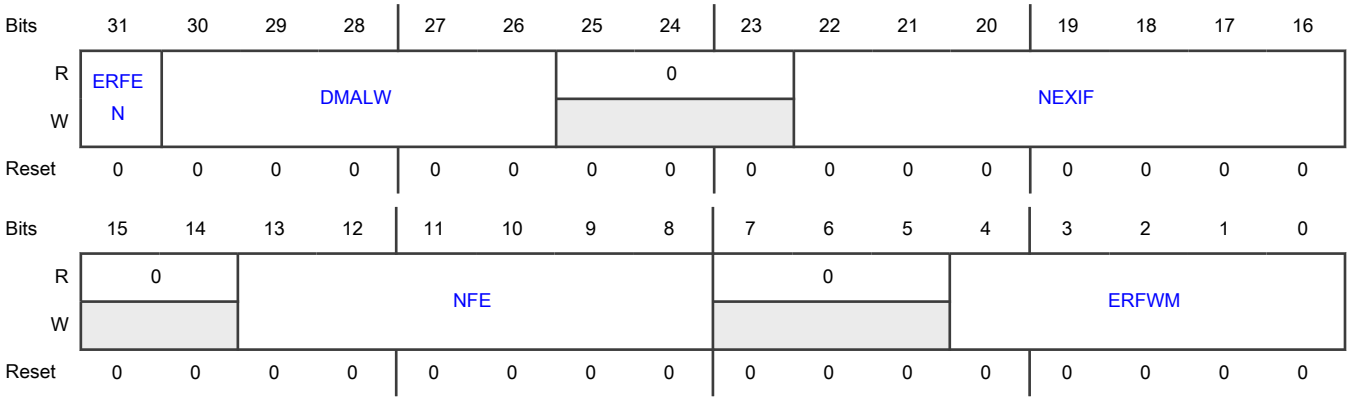
Function

Defines the Enhanced RX FIFO configuration.

This register can be written only in Freeze mode.

Soft reset does not affect any of the contents of this register.

Diagram



Fields

Field	Function
31 ERFEN	Enhanced RX FIFO enable Enables the Enhanced RX FIFO. **NOTE** If MCR[RFEN] = 1, do not write 1 to this field. 0b - Disable 1b - Enable
30-26 DMALW	DMA Last Word Defines the last DMA address for each Enhanced RX FIFO element. This table shows the number of elements and the last address for each Enhanced RX FIFO element according to the value of DMALW.

DMALW	Number of 32-bit words transferred	Last FIFO address
0	1	2000h
1	2	2004h
2	3	2008h
3	4	200Ch

Fields

Field	Function
31 ERFUFW	Enhanced RX FIFO Underflow Flag Indicates whether an underflow condition occurred in the enhanced RX FIFO. If ERFIER[ERFUFWIE] = 1, this field generates an interrupt. 0b - No such occurrence 1b - Underflow
30 ERFOVF	Enhanced RX FIFO Overflow Flag Indicates whether an overflow condition occurred in the Enhanced RX FIFO. If ERFIER[ERFOVFIE] = 1, this field generates an interrupt. 0b - No such occurrence 1b - Overflow
29	Enhanced RX FIFO Watermark Indication Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
ERFWMI	Indicates whether the number of messages available in the Enhanced RX FIFO is greater than the watermark defined in ERFCR[ERFWM]. If ERFIER[ERFWMIIE] = 1, this field generates an interrupt. 0b - No such occurrence 1b - Number of messages in FIFO is greater than the watermark
28 ERFDA	Enhanced RX FIFO Data Available Flag Indicates whether there is at least one message stored in the ERX FIFO. If ERFIER[ERFDAIE] = 1, this field generates an interrupt. 0b - No such occurrence 1b - At least one message stored in Enhanced RX FIFO
27 ERFCLR	Enhanced RX FIFO Clear Writing 1 to this field during Freeze mode resets the internal FIFO pointers, but the FIFO content stored in RAM is not changed. Writing to this field outside Freeze mode, or writing 0 to this field, has no effect. 0b - No effect 1b - Clear enhanced RX FIFO content
26-18 —	Reserved
17 ERFE	Enhanced RX FIFO Empty Flag Indicates whether Enhanced RX FIFO is empty. 0b - Not empty 1b - Empty
16 ERFF	Enhanced RX FIFO Full Flag Indicates whether enhanced RX FIFO is full. 0b - Not full 1b - Full
15 —	Reserved
14-6 —	Reserved
5-0	Enhanced RX FIFO Elements

Table continues on the next page...

Table continued from the previous page...

Field	Function
ERFEL	Indicates the number of CAN messages stored in the Enhanced RX FIFO.

52.5.2.45 Enhanced RX FIFO Filter Element (ERFFEL0 - ERFFEL31)

Offset

For n = 0 to 31:

Register	Offset
ERFFELn	3000h + (n × 4h)

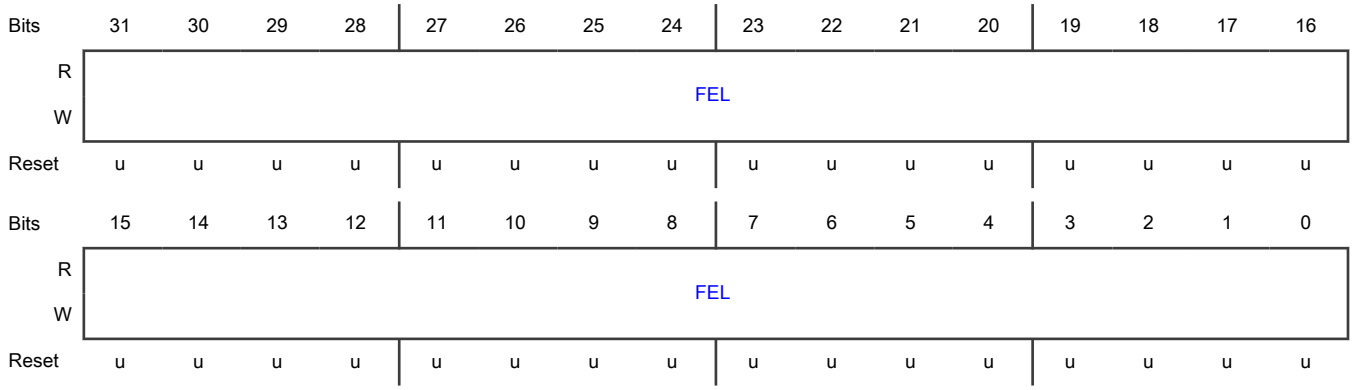
Function

Stores the filter elements of the Enhanced RX FIFO.

For standard ID filtering, each ERFFEL register stores one filter element. For extended ID filtering, each pair of ERFFEL registers stores one filter element.

ERFFEL registers can be written only in Freeze mode; otherwise, the module blocks them. Reset does not affect these registers. They are located in RAM and must be explicitly initialized prior to any reception.

Diagram



Fields

Field	Function
31-0 FEL	Filter Element Bits Stores filter elements. Each filter element is used during the match process. If the matching criteria are met, a message is stored in the Enhanced RX FIFO.

52.5.3 Message buffer structure

The message buffer structure used by FlexCAN is represented in the following figure. Both extended (29-bit identifier) and standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual message

buffer is 16, 24, 40, or 72 bytes, depending on the quantity of data bytes allocated for the message payload: 8, 16, 32, or 64 data bytes, respectively.

The memory area 80h–27Fh is used by the message buffers. When CAN FD is enabled, the exact address for each message buffer depends on the size of its payload. See FlexCAN memory partition for CAN FD.

Table 352. Message buffer structure example with 64-byte payload

0h	EDL	BRS	ESI		CODE		SRR	IDE	RTR	DLC	TIMESTAMP
4h	PRIO			ID (standard/extended)						ID (extended)	
8h	Data byte 0				Data byte 1					Data byte 2	Data byte 3

44h	Data byte 60				Data byte 61					Data byte 62	Data byte 63
		= Unimplemented or reserved									

Table 353. Field descriptions

Mnemonic	Field	Description
EDL	Extended Data Length	Distinguishes between CAN format and CAN FD format frames. EDL must not be 1 for message buffers configured to RANSWER with code field 1010b (see Table 354).
BRS	Bit Rate Switch	Defines whether the bit rate is switched inside a CAN FD format frame.
ESI	Error State Indicator	Indicates whether the transmitting node is error-active or error-passive.
CODE	Message Buffer Code	Can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in Table 354 and Table 355. See Functional description.

Table 354. Message buffer code for RX buffers

CODE description	RX code BEFORE RX new frame	SRV[1]	RX code AFTER successful reception[2]	RRS[3]	Comment
0000b: INACTIVE. Message buffer is not active.	INACTIVE	—	—	—	Message buffer does not participate in the matching process.
0100b: EMPTY. Message buffer is active and empty.	EMPTY	—	FULL	—	When a frame is received successfully (after Move-in), CODE is automatically updated to FULL.
0010b: FULL. Message buffer is full.	FULL	Yes	FULL	—	The act of reading the Control and Status word followed by unlocking the message buffer (SRV) does not make CODE return to EMPTY. It remains FULL. If a new frame is moved to the message buffer after the message buffer is serviced, the code remains FULL. See Matching process for matching details related to FULL code.
		No	OVERRUN	—	If the message buffer is FULL and a new frame is moved to this message buffer before the CPU services it, CODE is automatically updated to OVERRUN. See Matching process for details about overrun behavior.
0110b: OVERRUN. Message buffer is being overwritten into a full buffer.	OVERRUN	Yes	FULL	—	If CODE indicates OVERRUN and the CPU has serviced the message buffer, when a new frame is moved to the message buffer, CODE returns to FULL.
		No	OVERRUN	—	If CODE already indicates OVERRUN, and another new frame must be moved, the message buffer is overwritten

Table continues on the next page...

Table 354. Message buffer code for RX buffers (continued)

CODE description	RX code BEFORE RX new frame	SRV[1]	RX code AFTER successful reception[2]	RRS[3]	Comment
					again, and CODE remains OVERRUN. See Matching process for details about overrun behavior.
1010b: RANSWER[4]. A frame was configured to recognize a Remote Request frame and transmit a Response frame in return.[5]	RANSWER	—	TANSWER (1110b)	0	A Remote Answer was configured to recognize a Remote Request frame received. After that, a message buffer is set to transmit a response frame. CODE is automatically changed to TANSWER (1110b). See Matching process for details. If CTRL2[RRS] = 0, transmit a response frame when a remote request frame with the same ID is received.
		—	—	1	This code is ignored during matching and arbitration process. See Matching process for details.
CODE[0] = 1: BUSY. FlexCAN is updating the contents of the message buffer. The CPU must not access the message buffer.	BUSY[6]	—	FULL	—	Indicates that the message buffer is being updated. It automatically becomes 0 and does not interfere with the next CODE.
		—	OVERRUN	—	

1. SRV: Serviced message buffer. Message buffer was read and unlocked by reading TIMER or other message buffer.
2. A frame is considered a successful reception after the frame is moved to a message buffer (move-in process). See Move-in.
3. Remote Request Stored field. See Control 2 (CTRL2).
4. Code 1010b is not considered TX and a message buffer with this code should not be aborted.
5. Code 1010b must be used in message buffers configured in CAN FD format, with EDL = 1.
6. For TX message buffers, the BUSY bit should be ignored upon read, except when MCR[AEN] = 1. If this field is 1, the corresponding message buffer does not participate in the matching process.

Table 355. Message buffer code for TX buffers

CODE Description	TX Code BEFORE TX frame	MB RTR	TX Code AFTER successful transmission	Comment
1000b: INACTIVE. Message buffer is not active.	INACTIVE	—	—	Message buffer does not participate in arbitration process.
1001b: ABORT. Message buffer is aborted.	ABORT	—	—	Message buffer does not participate in arbitration process.
1100b: DATA. Message buffer is a TX data frame (MB RTR must be 0).	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the message buffer automatically returns to the INACTIVE state.
1100b: REMOTE. Message buffer is a Transmit Remote Request frame (MB RTR must be 1).	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the message buffer automatically becomes an RX Empty message buffer with the same ID.
1110b: TANSWER. Message buffer is a Transmit Response frame from an incoming Remote Request frame.	TANSWER	—	RANSWER	This intermediate code is automatically written to the message buffer by the CHI as a result of a match to a Remote Request frame. The Remote Response frame is transmitted unconditionally once, then the code automatically returns to RANSWER (1010b). The CPU can also write this code with the same effect. The Remote Response frame can be a data frame or another remote request frame, depending on the value of RTR. See Matching process and Arbitration process for details.

Table 356. RX and TX message buffer field descriptions

Mnemonic	Field	Description
SRR	Substitute Remote Request	Fixed recessive bit, used only in extended format. Write 1 to SRR for transmission (TX Buffers). SRR is stored with the value received on the CAN

Table continues on the next page...

Table 356. RX and TX message buffer field descriptions (continued)

Mnemonic	Field	Description
		bus for RX receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, it is interpreted as an arbitration loss. 1: Recessive value is compulsory for transmission in extended format frames. 0: Dominant is not a valid value for transmission in extended format frames.
IDE	ID Extended Bit	Identifies whether the frame format is standard or extended. 1: Frame format is extended 0: Frame format is standard
RTR	Remote Transmission Request	Affects the behavior of remote frames and is part of the reception filter. See Table 354, Table 355, and CTRL2[RRS]. If FlexCAN transmits this field as 1 (recessive) and receives it as 0 (dominant), it is interpreted as an arbitration loss. If this field is transmitted as 0 (dominant) and it is received as 1 (recessive), FlexCAN treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission. 1: If message buffer is TX, indicates that the current message buffer may have a Remote Request frame to be transmitted. If the message buffer is RX, incoming remote request frames may be stored. 0: Indicates that the current message buffer has a Data frame to be transmitted. In an RX message buffer, it may be considered in matching processes. **NOTE** When configuring CAN FD frames, this field must be 0.
DLC	Data Length Code	Indicates the length (in bytes) of the RX or TX data, which is located in offset 8h–Fh of the message buffer space (see Table 352). In reception, this field is written by FlexCAN, copied from the DLC field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see Table 357).
TIMESTAMP	Free-Running Counter Timestamp	Provides a copy of the Free-Running Timer, captured for TX and RX frames when the beginning of the Identifier field appears on the CAN bus.
PRIO	Local priority	Used only when MCR[LPRIOEN] = 1, and only makes sense for transmit message buffers. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See Arbitration process.
ID	Frame Identifier	In standard frame format, only the 11 most significant bits are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.

Table continues on the next page...

Table 356. RX and TX message buffer field descriptions (continued)

Mnemonic	Field	Description
DATA BYTE 0–63	Data Field	Up to 64 bytes can be used for a data frame, depending on the size of payload selected for the message buffers. For RX frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC, as shown in Table 357.

Table 357. DATA BYTE validity

DLC	Valid data bytes
0	None
1	DATA BYTE 0
2	DATA BYTE 0–1
3	DATA BYTE 0–2
4	DATA BYTE 0–3
5	DATA BYTE 0–4
6	DATA BYTE 0–5
7	DATA BYTE 0–6
8	DATA BYTE 0–7
9	DATA BYTE 0–11
10	DATA BYTE 0–15
11	DATA BYTE 0–19
12	DATA BYTE 0–23
13	DATA BYTE 0–31
14	DATA BYTE 0–47
15	DATA BYTE 0–63

52.5.4 FlexCAN memory partition for CAN FD

When CAN FD is enabled, FlexCAN RAM can be partitioned into blocks of 512 bytes each. Each block can accommodate a number of message buffers depending on the configuration provided by FDCTRL[MBDSR*n*] as shown in Table 358.

Table 358. RAM partition

RAM block	Number of MBs with 8 bytes (default range)	Size control field in FDCTRL	Number of MBs of different sizes, per block
0	0 to 31	MBDSR0	MBDSR0 = 00, 32 MBs with 8-byte payload MBDSR0 = 01, 21 MBs with 16-byte payload MBDSR0 = 10, 12 MBs with 32-byte payload MBDSR0 = 11, 7 MBs with 64-byte payload

Payload sizes of 16, 32, or 64 bytes may be configured in some or all of RAM blocks. In those cases, the total number of MBs and their respective number order may differ from the default configuration of 8 bytes. Consider an example where:

- Block0 is configured to an 8-byte payload
- Block1 is configured to a 16-byte payload

In this case, Table 359 indicates how the message buffers are arranged in RAM.

Table 359. RAM partition example

RAM block	Payload size	Number of MBs in the RAM block	Message buffer range
0	FDCTRL[MBDSR0] = 00, 8-byte payload	32	0 to 31

52.5.5 FlexCAN message buffer memory map

The FlexCAN memory buffers are allocated in memory according to the tables below.

52.5.6 Legacy RX FIFO structure

When MCR[RFEN] = 1, the memory area 80h–DCh (which is normally occupied by MBs 0–5) is used by the reception Legacy FIFO engine.

The region 80h–8Ch contains the output of the Legacy RX FIFO, which the CPU must read as a message buffer. This output contains the oldest message that has been received but not yet read. The region 90h–DCh is reserved for internal use of the Legacy RX FIFO engine.

An additional memory area, which starts at E0h and may extend up to 2DCh (normally occupied by MBs 6–37) depending on the value of CTRL2[RFFN], contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the Legacy RX FIFO.

Out of reset, the ID filter table flexible memory area defaults to E0h and extends only to FCh, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Legacy RX FIFO data structure.

Table 364. Legacy RX FIFO structure

80h	IDHIT		SRR	IDE	RTR	DLC	TIMESTAMP
84h		ID standard				ID extended	
88h	Data byte 0		Data byte 1			Data byte 2	Data byte 3
8Ch	Data byte 4		Data byte 5			Data byte 6	Data byte 7
90h–DCh	Reserved						
E0h	ID filter table element 0						
E4h	ID filter table element 1						
E8h–2D4h	ID filter table elements 2 to 125						
2D8h	ID filter table element 126						
2DCh	ID filter table element 127						
		= Unimplemented or reserved					

Each ID filter table element occupies an entire 32-bit word. One, two, or four Identifier Acceptance Filters (IDAF) can compound each element, depending on MCR[IDAM]. The following tables show the IDAF indexing.

Table 365 shows the three different formats of the ID table elements. All elements of the table must have the same format. See Legacy RX FIFO for more information.

Table 365. ID table structure

A	RTR	IDE	RXIDA				
B	RTR	IDE	RXIDB_0	RTR	IDE	RXIDB_1	
C	RXIDC_0		RXIDC_1	RXIDC_2		RXIDC_3	
		= Unimplemented or Reserved					

Table 366. Field descriptions

Mnemonic	Field	Description
RTR	Remote Frame	Specifies whether remote frames are accepted into the Legacy FIFO if they match the target ID. 1: Remote frames can be accepted and data frames are rejected. 0: Remote frames are rejected and data frames can be accepted.
IDE	Extended Frame	Specifies whether extended or standard frames are accepted into the Legacy FIFO if they match the target ID. 1: Extended frames can be accepted and standard frames are rejected. 0: Extended frames are rejected and standard frames can be accepted.
RXIDA	RX Frame Identifier (Format A)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, only the 11 most significant bits (to) are used for frame identification. In the extended frame format, all bits are used.
RXIDB_0, RXIDB_1	RX Frame Identifier (Format B)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (to and to) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.
RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3	RX Frame Identifier (Format C)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.
IDHIT	Identifier Acceptance Filter Hit Indicator	Indicates which identifier acceptance filter the received message in the output of the Legacy RX FIFO hit. See Legacy RX FIFO for more information.

52.5.7 Enhanced RX FIFO structure

When ERFCR[ERFEN] = 1, the Enhanced RX FIFO is enabled. The region 2000h–2048h contains the output of the Enhanced RX FIFO, which the CPU must read as a message buffer. This output contains the oldest message that has been received but not yet read.

Table 369. Field descriptions

Mnemonic	Field	Description
EDL	Extended Data Length	Distinguishes between classical CAN format and CAN FD format frames. 0: Classical CAN frame format 1: CAN FD frame format
BRS	Bit Rate Switch	Defines whether the bit rate is switched inside a CAN FD format frame. 0: Bit rate is not switched in a CAN FD frame. 1: Bit rate is switched in a CAN FD frame.
ESI	Error State Indicator	Indicates whether the transmitting node is error-active or error-passive. This field is meaningful only if EDL = 1. 0: Error-active 1: Error-passive
SRR	Substitute Remote Request	Fixed recessive bit, used only in extended format. Transmitting nodes always send it as recessive and receiving nodes can receive it as either recessive or dominant. If FlexCAN receives this bit as dominant, it is interpreted as an arbitration loss.
IDE	ID Extended Bit	Identifies whether the frame format is standard or extended. 0: Standard 1: Extended
RTR	Remote Frame	Identifies whether the current frame is a data frame or a remote request. 0: Data frame 1: Remote request
DLC	Data Length Code	Defines the number of bytes in the data field of a CAN frame (Data byte 0 to Data byte 63). When RTR = 1, the frame is a remote request and does not include the data field, regardless of the DLC field. See Table 357 for more details.
TIMESTAMP	16-bit Timestamp	Provides a copy of the Free-Running Timer, captured during the CAN frame.
ID	Frame Identifier	In base frame format, only the 11 most significant bits are used for frame identification. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification.
DATA BYTE 0–63	Data Field	Up to 64 bytes can be stored in the data field.
IDHIT	Identifier Acceptance Filter Hit Indicator	Indicates which Enhanced RX FIFO Filter Element (ERFFEL0 - ERFFEL31) the received message in the output of the Enhanced RX FIFO hit. For each filter region, standard-ID filter space, and extended-ID filter space, there is an independent index starting from zero. Table 370 shows how FlexCAN writes IDHIT according to each filter element.

Table 370. IDHIT for Enhanced RX FIFO

Enhanced RX FIFO filter element - ERFFEL	IDHIT value	Filter element type
ERFFEL0	0	Extended-ID
ERFFEL1	1	Extended-ID
. . .	. . .	Extended-ID
ERFFEL(m-1)	m-1	Extended-ID
ERFFEL(m)	0	Standard-ID
ERFFEL(m+1)	1	Standard-ID
. . .	. . .	Standard-ID
ERFFEL(2n-m+1)	2x(n-m)+1	Standard-ID

NOTE

Where m = NEXIF and n = NFE. If NEXIF = 0, only standard-ID filter elements exist. If NEXIF > NFE, only extended-ID filter elements exist.

52.6 Initialization and application information

52.6.1 FlexCAN initialization sequence

For any configuration change or initialization, you must put FlexCAN into Freeze mode (see Freeze mode). The module must be initialized after every reset. FlexCAN memory must be initialized before switching to functional mode.

The following is a generic initialization sequence applicable to FlexCAN:

1. Initialize Module Configuration (MCR).
    a. Enable the individual filtering per message buffer and reception queue features by writing 1 to MCR[IRMQ].
    b. Enable the warning interrupts by writing 1 to MCR[WRNEN].
    c. If required, disable frame self-reception by writing 1 to MCR[SRXDIS].
    d. Enable the Legacy RX FIFO by writing 1 to MCR[RFEN] or enable the Enhanced RX FIFO by writing 1 to ERFCR[ERFEN].
    e. If Legacy RX FIFO or Enhanced RX FIFO is enabled and DMA is required, write 1 to MCR[DMA].
    f. If Pretended Networking mode is required, write 1 to MCR[PNET_EN].
    g. Enable the abort mechanism by writing 1 to MCR[AEN].
    h. Enable the local priority feature by writing 1 to MCR[LPRIOEN].
2. Initialize Control 1 (CTRL1) and CAN FD Bit Timing (FDCBT). Optionally initialize CAN Bit Timing (CBT).
    a. Determine the bit timing parameters: CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW].

b. Optionally determine the bit timing parameters: CBT[EPROPSEG], CBT[EPSEG1], CBT[EPSEG2], and CBT[ERJW].

c. Determine the CAN FD bit timing parameters: FDCBT[FPROPSEG], FDCBT[FPSEG1], FDCBT[FPSEG2], and FDCBT[FRJW].

d. Determine the bit rate by programming CTRL1[PRESDIV] and optionally programming CBT[EPRESDIV].

e. Determine the CAN FD bit rate by programming FDCBT[FPRESDIV].

f. Determine the internal arbitration mode by programming CTRL1[LBUF].

3. Initialize the message buffers. (See Message buffer structure for message buffer details.)

   a. The control and status word of all message buffers must be initialized.

   b. If RX FIFO is enabled, the ID filter table must be initialized.

   c. Other entries in each message buffer should be initialized as required.

4. Initialize Receive Individual Mask (RXIMR0 - RXIMR31).

5. Write 1 to required interrupt mask bits in:

   - IMASK registers (for all message buffer interrupts)
   - Module Configuration (MCR) (for wake-up interrupt)
   - Control 1 (CTRL1) and Control 2 (CTRL2) (for Bus Off and Error interrupts)

6. If Pretended Networking mode is enabled, configure the necessary registers for selective wake-up.

7. Write 0 to MCR[HALT].

After the last step listed above, FlexCAN attempts to synchronize to the CAN bus.

52.7 Glossary

Active message buffer	A message buffer is active if it can participate in the current matching or arbitration process.
Bus interface unit	FlexCAN submodule responsible for the interface to the CPU.
Bus off	See CAN Specification.[3]
CAN	Controller Area Network, a serial communication protocol defined in CAN Specification[3] and ISO International Standard.[4]
CHI	Controller-host interface, a FlexCAN submodule responsible for message buffer matching and arbitration algorithms.
CRC	Cyclic redundancy check
Dominant bit	A dominant bit wins the arbitration on the CAN bus. It is transmitted as 0.
Doze mode	A system low-power mode where the CPU bus remains active and a global Doze mode request is sent to all peripherals asking them to enter low power mode.
Error active	See CAN Specification.[3]
Error frame	See CAN Specification.[3]
Error passive	See CAN Specification.[3]
Form error	See CAN Specification.[3]

[3] Controller Area Network - CAN Specification Version 2.0 Part A, Part B, Robert Bosch GmbH, 1991.
[4] ISO International Standard - ISO 11898 First Edition 1993 Road Vehicles - Interchange of Digital Information - Controller Area Network (CAN) for high-speed Communication.

Hard reset	A reset coming from an external pin and/or following power-on. It resets everything.
Idle	See CAN Specification.[3]
Information processing time	See CAN Specification.[3]
Intermission	See CAN Specification.[3]
Matching elements	Data used in the matching process, such as ID, filter, mask, etc.
MB	See Message buffer.
Message buffer	Internal FlexCAN data structure containing bytes received from, or to be transmitted to, the CAN line, as well as information about this data.
Overload frame	See CAN Specification.[3]
Phase buffer segment	See CAN Specification.[3]
Recessive bit	A recessive bit loses the arbitration on the CAN bus. It is transmitted as 1.
Sclock	Serial clock. Obtained by dividing the clock feeding the CAN engine (oscillator or bus clock) by a prescaler factor. The Sclock period defines the time quantum for CAN protocol timing.
Soft reset	Global reset typically used by peripherals to reinitialize some of its registers, but not all of them.
Stop mode	A system low-power mode in which all chip clocks are stopped for maximum power savings.
Stuffing error	See CAN Specification.[3]
Time quantum	This is equal to the Sclock period. It is the minimum time period used to compose the CAN protocol bit timing.

53.1.1 Module instances

This device has one FlexIO module, FLEXIO0.

53.2 Overview

Flexible I/O (FlexIO) is a highly configurable module providing a wide range of functionality including:

- Emulation of various serial or parallel communication protocols
- Flexible 16-bit timers with support for various trigger, reset, enable, and disable conditions
- Programmable logic blocks allowing the implementation of digital logic functions on-chip, and configurable interaction of internal and external modules
- Programmable state machine for offloading basic system control functions from CPU

53.2.1 Block Diagram

The following diagram gives a high-level overview of the FlexIO timers and shifters configuration.

FlexIO uses shifters, timers, and external triggers to shift data into or out of the FlexIO. Timers control the timing of the data shift, as shown in the block diagram. The timers can be configured to use generic timer functions, external triggers, or various other conditions to determine this control.

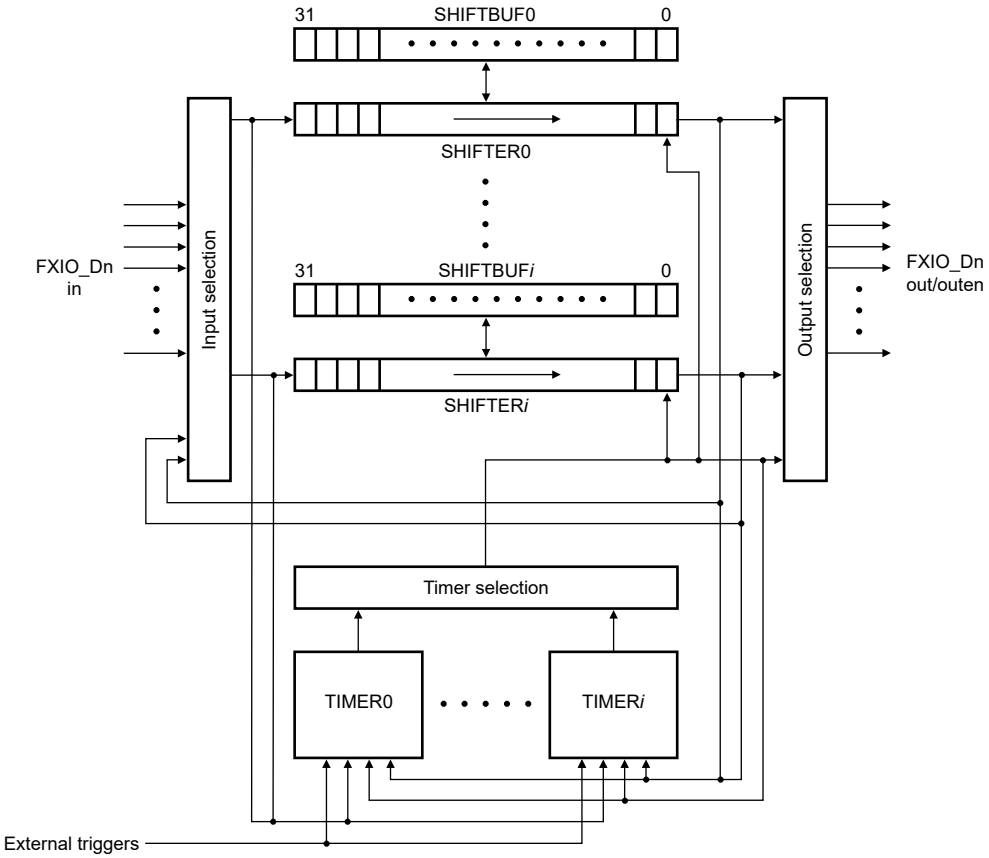

Figure 202. FlexIO block diagram

53.2.2 Features

FlexIO can support a wide range of protocols including, but not limited to:

- UART
- I2C
- SPI
- I2S
- Camera IF
- Motorola 68K or Intel 8080 bus
- PWM or waveform generation
- Input-capture (pulse edge interval measurement), such as SENT

FlexIO includes the following features:

- Array of 32-bit shift registers with transmit, receive, data match, logic, and state modes
- Double-buffered shifter operation for continuous data transfer
- Shifter concatenation to support large transfer sizes
- Automatic start and stop bit generation
- 1, 2, 4, 8, 16, or 32 multi-bit shift widths for parallel interface support

- Interrupt, DMA, or polled transmit and receive operation
- Programmable baud rates independent of bus clock frequency, with support for asynchronous operation during stop modes
- Highly flexible 16-bit timers with support for various internal or external trigger, reset, enable, and disable conditions
- Programmable logic mode for integrating external digital logic functions on-chip or combining pin, shifter, or timer functions to generate complex outputs
- Programmable state machine for offloading basic system control functions from CPU with support for up to eight states, eight outputs, and three selectable inputs per state
- Integrated general purpose input/output registers and pin rising or falling edge interrupts to simplify software support

53.3 Functional description

53.3.1 Shifter operation

Shifters are responsible for buffering and shifting data into or out of the FlexIO. The timing of shift, load and store events are controlled by the Timer assigned to the Shifter via the SHIFTCTL[TIMSEL] register. The Shifters are designed to support either DMA, interrupt or polled operation. The following block diagram provides a detailed view of the Shifter microarchitecture.

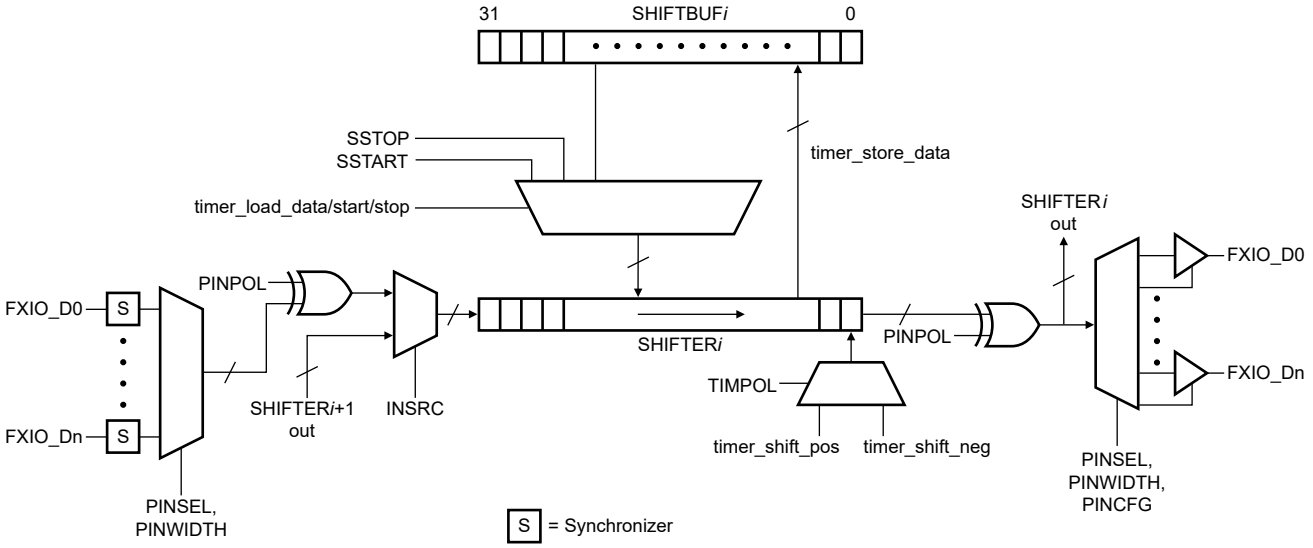

Figure 203. Shifter Microarchitecture

Transmit Mode

When configured for Transmit mode (SHIFTCTL[SMOD]=Transmit), the shifter loads data from the SHIFTBUF register and shift data out when a load event is signalled by the assigned Timer. An optional start/stop bit can also be automatically loaded before/ afterSHIFTBUFdata by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer.

NOTE

The shifter immediately loads a stop bit when the Shifter is initially configured for Transmit mode if a stop bit is enabled.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data has been loaded from the SHIFTBUF register into the Shifter or when the Shifter is initially configured into Transmit mode. The flag clears when new data has been written into the SHIFTBUF register or a logic 1 is written to this flag. In transmit mode, any write of the SHIFTBUF

register clears the corresponding Shifter Status Flag. It does not matter what is writing or the state of the DMA/interrupt enables, the flag is cleared. How the flag is set/cleared for each mode is documented in the SSF register description.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to load data from an empty SHIFTBUF register occurs (buffer underrun). The flag can be cleared by writing it with logic 1.

Receive Mode

When configured for Receive mode (SHIFTCTL[SMOD]=Receive), the shifter shifts data in and store data into the SHIFTBUF register when a store event is signalled by the assigned Timer. Checking for a start/stop bit can be enabled before/after shifter data is sampled by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data has been stored into the SHIFTBUF register from the Shifter. The flag clears when the data has been read from theSHIFTBUF register or a logic 1 is written to this flag. Any read of the SHIFTBUF register clears the corresponding Shifter Status Flag when Shifter is configured in Receive mode. It does not matter what is reading or the state of the DMA/interrupt enables, the flag is cleared. How the flag is set/clear for each mode is documented in the SSF register description.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to store data into a fullSHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start/stop bit check. The flag can be cleared by writing it with logic 1.

Match Store Mode

When configured for Match Store mode (SHIFTCTL[SMOD]=Match Store), the shifter shifts data in, check for a match result and store matched data into the SHIFTBUF register when a store event is signalled by the assigned Timer. Checking for a start/stop bit can be enabled before/after shifter data is sampled by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer. Up to 16-bits of data can be compared using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs and matched data has been stored into the SHIFTBUF register from the Shifter. The flag clears when the matched data has been read from the SHIFTBUF register or a logic 1 is written to this flag. Any read of the SHIFTBUF register clears the corresponding Shifter Status Flag when Shifter is configured in Match Store mode. It does not matter what is reading or the state of the DMA/interrupt enables, the flag is cleared. How the flag is set/clear for each mode is documented in the SSF register description.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to store matched data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start/stop bit check. The flag can be cleared by writing it with logic 1.

Match Continuous Mode

When configured for Match Continuous mode (SHIFTCTL[SMOD]=Match Continuous), the shifter shifts data in and continuously check for a match result whenever a shift event is signalled by the assigned Timer. Up to 16-bits of data can be compared using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs. The flag clears automatically as soon as there is no longer a match between Shifter data and SHIFTBUF register. **The flag cannot be cleared by reading the SHIFTBUF register.**

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when a match occurs. The flag clears when there is a read from the SHIFTBUF register or it written with logic 1.

State Mode

Using State mode enables the user to implement any state machine with up to 8 states, 8 outputs and 3 selectable inputs per state. This feature allows basic control functions to be offloaded from the CPU, which could potentially remain in a low power mode.

When configured for State mode (SHIFTCTL[SMOD]=State), the SHIFTBUF register is used to drive the output and compute next state values when the Shifter has been selected by the current state pointer (SHIFTSTATE[STATE]). The following diagram provides a detailed view of Shifter microarchitecture when configured for State mode.

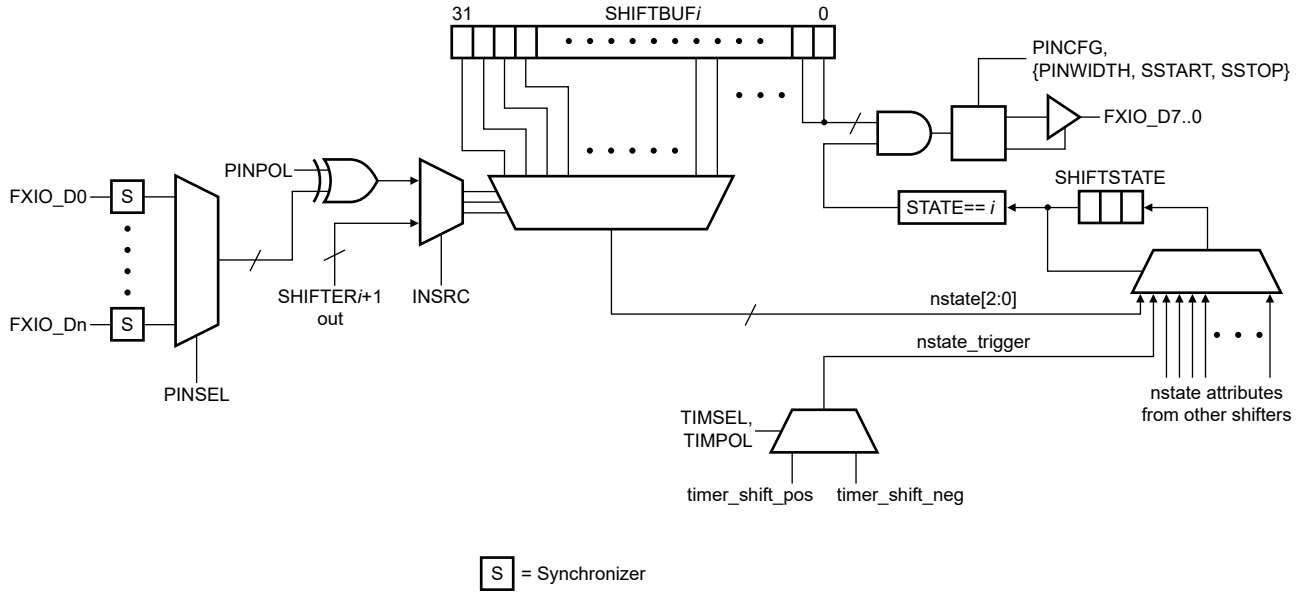

Figure 204. State Microarchitecture

When Shifter i has been selected by the current state pointer, output pins FXIO_D[7:0] are driven by SHIFTBUFi[31:24] using the configuration set by SHIFTCTLi[PINCFG]. When set, SHIFTCFGi{PWIDTH[3:0],SSTOP[1:0],SSTART[1:0]} are respectively used to disable the output drive on pins FXIO_D[7:0] for state machine applications which require less than 8 output pins.

The next state value is computed using the 3 input pins selected by SHIFTCTLi[PINSEL] together with SHIFTBUFi[23:0].

NOTE

Each state could potentially use a different set of 3 input pins.

The following table details how the next state value is computed when the current state pointer is pointing to Shifter i.

Table 372. Next State computation for SHIFTSTATE[STATE]=i

FXIO_D[PINSEL+2]	FXIO_D[PINSEL+1]	FXIO_D[PINSEL]	Next State Value
0	0	0	SHIFTBUFi[2:0]
0	0	1	SHIFTBUFi[5:3]
0	1	0	SHIFTBUFi[8:6]
0	1	1	SHIFTBUFi[11:9]
...	...	...	...
1	1	1	SHIFTBUFi[23:21]

Note that other shifters/timers could potentially be configured to drive the input pins of a given state, allowing the user to create complex combinations of shifters/timers as desired e.g. the output of a Shifter configured for logic mode could potentially be used to drive a state machine input.

The next state transition is triggered using the Timer output selected by SHIFTCTLi[TIMSEL] with polarity controlled by SHIFTCTLi[TIMPOL]. Note that each state could potentially use a different Timer to trigger each next state transition, allowing a variety of internal/external trigger sources and clocking configurations to be used (see Timer section for more detail).

The current state pointer defaults to Shifter 0 at reset, however it can be written by the user to select a different Shifter for the initial state. If the current state pointer selects a Shifter which is not configured for State mode, then outputs are not driven and a next state transition is never triggered.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set whenever the Shifter has been selected by the current state pointer. The flag clears when the current state pointer is updated to a different Shifter.

Logic Mode

Using logic mode enables the user to implement a small amount of programmable digital logic within a FlexIO Shifter.

When configured for Logic mode (SHIFTCTL[SMOD]=Logic), theSHIFTBUF register is used to implement a 5-input, 32-bit programmable logic look-up table. The following diagram provides a detailed view of Shifter microarchitecture when configured for Logic mode.

The SHIFTBUFi configures the lookup table for the 4 pin inputs and the SHIFTERi can optionally be used to configure a feedback or delayed pin source as the 5th input to the look up table.

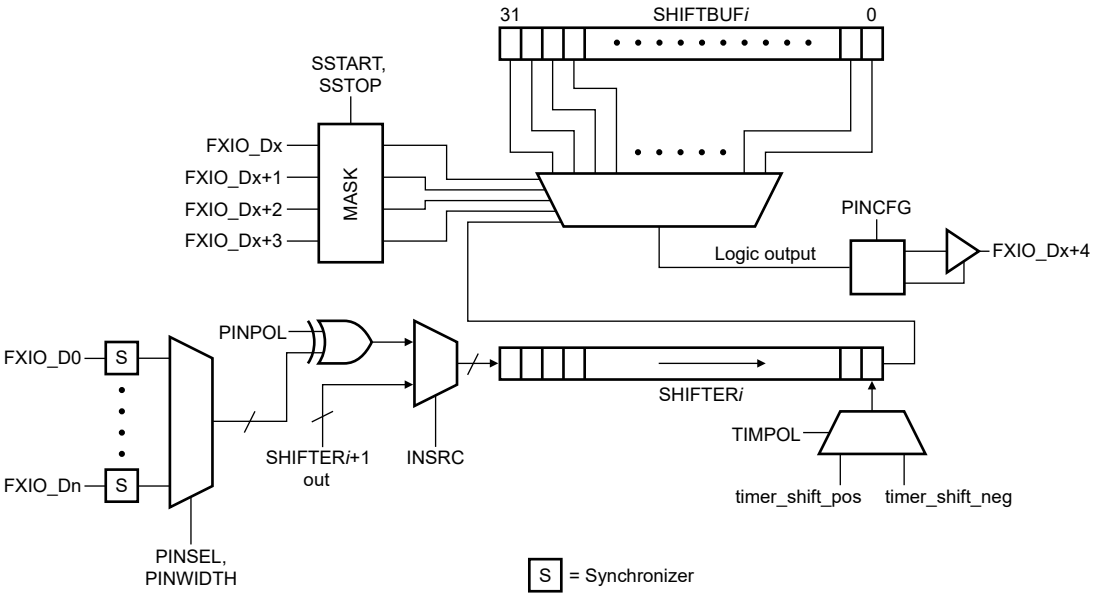

Figure 205. Logic Microarchitecture

The look-up table is driven using 4 pin inputs (maskable using SHIFTCFG[SSTOP] and SHIFTCFG[SSTART]) plus 1 input from the internal shifter and can be configured to drive an output pin using the SHIFTCTL[PINCFG] field. Pin inputs and outputs are fixed for each logic look-up table and are not selectable. The following table lists the logic output value selected by the look-up table for Shifter 'i'.

Table 373. Logic Look-up table for Shifter 'i'

SHIFTERi[0]	FXIO_D[x+3][1]	FXIO_D[x+2]	FXIO_D[x+1]	FXIO_D[x]	Logic Output to FXIO_D[x+4]
0	0	0	0	0	SHIFTBUFi[0]
0	0	0	0	1	SHIFTBUFi[1]
0	0	0	1	0	SHIFTBUFi[2]
0	0	0	1	1	SHIFTBUFi[3]

Table continues on the next page...

Table 373. Logic Look-up table for Shifter 'i' (continued)

...	...	...	...	...	...
1	1	1	1	1	SHIFTBUFi[31]

1. for Shifter i=0...3, x=i

   for Shifter i=4...7, x=i+4

To minimize output glitches, SHIFTCFG[SSTOP] and SHIFTCFG[SSTART] can be used to mask unused input pins. When set, {SSTOP[1:0], SSTART[1:0]} mask FXIO_D[x+3]...FXIO_D[x] inputs respectively, so that any transitions on these pins does not cause the logic output to glitch.

Note that other shifters/timers could potentially be configured to drive the input pins of a given look-up table, allowing the user to concatenate look-up tables or create complex combinations of shifters/timers as desired.

SHIFTCFG[PWIDTH] controls the number of delay stages introduced by the internal shifter input (SHIFTERi[0]). For example, when configured for 1-bit shift (PWIDTH=0), the internal shifter introduces a 32 Shift clock delay before passing its input (selected by SHIFTCTL[PINSEL]) to the look-up table. When configured for 32-bit shift (PWIDTH=16...31), the internal shifter introduces a 1 Shift clock delay to its input.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set whenever the output pin allocated to the logic look-up table has a value of 1 (after being synchronized to the FlexIO clock). The flag clears when the output pin has a value of 0. This also allows the SSF flag to be used as a trigger to a Timer if desired.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts are set when the output pin allocated to the logic look-up table has asserted. The flag can be cleared by writing it with logic 1.

The logic mode input pins (including pins driven by other shifters/timers) are first synchronized to the FlexIO functional clock before they are input to the programmable logic look-up table.

53.3.2 Timer Operation

The FlexIO 16-bit timers control the loading, shifting, and storing of the shift registers. The counters load the contents of the compare register and decrement down to zero on the FlexIO clock. The counters can perform generic timer functions such as generating a clock or select output or a PWM waveform. Timers can be configured to:

- enable in response to a trigger, pin, or shifter condition,
- decrement always or only on a trigger or pin edge,
- reset in response to a trigger or pin condition, or
- disable on a trigger or pin condition or on a timer compare.

Timers can optionally include a start condition and a stop condition.

Although each timer operates independently, a timer can be configured to enable or disable at the same time as the previous timer (for example, timer1 can enable or disable at the same time as timer 0) and a timer output can be used to trigger any other timer. The trigger used by each timer is configured independently and can be configured to be a timer output, shifter status flag, pin input, or an external trigger input. The trigger configuration is separate from the pin configuration which can be configured for input, output data, or output enable. See the chip-specific FlexIO information for details on the external trigger connections.

The Timer Configuration Register (TIMCFGn) should be configured before setting the Timer Mode (TIMOD).

Timer 8-bit Baud Counter mode

In 8-bit Baud Counter Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the baud rate of the shift clock and the upper 8-bits are used to configure the number of shift clock edges in the transfer. When the lower 8-bits decrement to zero, the timer output is toggled and the lower 8-bits reload from the compare register. The upper 8-bits decrement when the lower 8-bits equal zero and decrement.

Note that a timer reset event in 8-bit Baud Counter Mode only resets the lower 8-bit counter, the upper 8-bit counter is not affected and can decrement if the timer reset is configured to update the state of the timer output, and the timer output toggles as a result of the timer reset event.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

Timer 8-bit High PWM Mode

In 8-bit High PWM Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the timer output high period and the upper 8-bits are used to configure the timer output low period. The lower 8-bits decrement when the output is high. When the lower 8-bits equal zero and decrement, the timer output is cleared and the lower 8-bits are reloaded from the compare register. The upper 8-bits decrement when the output is low. When the upper 8-bits equal zero and decrement, the timer output is set and the upper 8-bits are reloaded from the compare register.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

Timer 16-bit Counter Mode

In 16-bit Counter Mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (eg: TIMDEC[1:0] != 10 or 11) or the number of shift clock edges in the transfer (eg: TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer compare event.

Timer 16-bit Counter Disable Mode

In 16-bit Counter Disable Mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (eg: TIMDEC[1:0] != 10 or 11) or the number of shift clock edges in the transfer (eg: TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer disable event.

Timer 8-bit Word Counter Mode

In 8-bit Word Counter Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the number of shift clock edges in each word and the upper 8-bits are used to configure the number of words in the transfer. When the lower 8-bits decrement to zero, the timer output is toggled and the lower 8-bits reload from the compare register. The upper 8-bits only decrement when the lower 8-bits equal zero and decrement.

A timer compare event occurs when the lower 8-bits equal zero and decrements. The timer status flag is set when the upper 8-bits equal zero and decrements.

Timer 8-bit Low PWM Mode

In 8-bit Low PWM Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the timer output low period and the upper 8-bits are used to configure the timer output high period. The lower 8-bits decrement when the output is low. When the lower 8-bits equal zero and decrement, the timer output is set and the lower 8-bits are reloaded from the compare register. The upper 8-bits decrement when the output is high. When the upper 8-bits equal zero and decrement, the timer output is cleared and the upper 8-bits are reloaded from the compare register.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

Timer 16-bit Input Capture Mode

In 16-bit Input Capture Mode, the 16-bit counter uses a fixed initial value of 0xFFFF to load the counter. Whenever a timer counter disable condition is detected (as configured by TIMDIS), the timer status flag is set and the inverted timer counter value is stored in the timer compare register, then the timer counter is immediately restarted from 0xFFFF. The timer output is always output on the FlexIO trigger outputs (which can also be used by other timers as an input trigger) and can also be output to a pin (PINCFG/PINPOL/PINSEL) or a shifter.

If the timer status flag is already set, then the input capture event is missed. When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads with 0xFFFF. The timer output can be used to count the number of counter overflows between two input capture events. Input capture mode is not intended to be used to control shift registers, it is to enable software to count the number of bits in a variable length transfer or to monitor the period or frequency of an input.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer disable event. Whenever the status flag asserts, the inverted timer counter value is stored in the timer compare register.

Timer Enable and Start Bit

When the TIMOD is configured for the desired mode, and the condition configured by timer enable (TIMENA) is detected then the following events occur. When ONETIM is set, then the timer status flag must also be clear to generate a timer enable event, otherwise the timer enable event is blocked. This can be used to enforce software intervention after each timer iteration.

- Timer counter loads the current value of the compare Register and start decrementing as configured by TIMDEC.
- Timer output may update to its initial state depending on the TIMOUT configuration. Shifters that are controlled by this timer do not see this as a rising edge on the timer shift clock.
- Transmit shifters controlled by this timer either output their start bit value, or load the shift register from the shift buffer and output the first bit, as configured by SSTART.

If the Timer start bit is enabled, the timer counter reloads with the compare register on the first rising edge of the shift clock after the timer starts decrementing. If there is no falling edge on the shift clock before the first rising edge (for example, when TIMOUT=1), a shifter that is configured to shift on falling edge and load on the first shift does not load correctly.

Timer Decrement and Reset

The Timer then generates the timer output and timer shift clock depending on the TIMOD and TIMDEC fields. The shifter clock is either equal to the timer output (when TIMDEC != 10 or 11) or equal to the decrement clock (when TIMDEC = 10 or 11). When TIMDEC is configured to decrement from a pin or trigger, the timer decrements on both rising and falling edges.

If a Timer is configured to decrement on the FlexIO functional clock divided by 16 or 256 (when TIMDEC = 100 or 101), then a common prescaler that is shared by all Timers is used to generate the two divide ratios. This prescaler is reset when all Timers are either idle or configured to not use the prescaler (TIMDEC != 100 or 101).

When the Timer is configured to reset as configured in the TIMRST field then the Timer counter loads the current value of the compare register again. The timer output and timer shift clock can be configured to update on timer reset, as configured by TIMOUT. This can result in a timer shift clock edge if the timer output toggles as a result of the timer reset. In 8-bit Baud Counter mode this would also decrement the upper 8-bits of the counter.

In general, when the timer counter decrements to zero a timer compare event is triggered. The timer compare event causes the timer counter to load the contents of the timer compare register, the timer output to toggle, any configured transmit shift registers to load, and any configured receive shift registers to store. Depending on the timer mode, the timer status flag may also be set.

Timer Disable and Stop Bit

When the is Timer is configured to add a stop bit on each compare, the following additional events occur.

- Transmit shifters controlled by this timer output their stop bit value (if configured by SSTOP).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SSTOP.

- On the first rising edge of the shifter clock after the compare, the timer counter reloads the current value of the Compare Register.

Transmit shifters must be configured to load on the first shift when the timer is configured to insert a stop bit on each compare.

When the condition configured by timer disable (TIMDIS) is detected, the following events occur.

- Timer counter reloads the current value of the Compare Register and start decrementing as configured by TIMDEC.
- Timer output clears. Shifters that are controlled by this timer do not see this as a falling edge on the timer shift clock, but can generate a shift event if the timer shift clock would otherwise generate one.
- Transmit shifters controlled by this timer output their stop bit value (if configured by SSTOP).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SSTOP.

If the timer stop bit is enabled, the timer counter continues decrementing until the next rising edge of the shift clock is detected, at which point it finishes. Although the timer output is forced low during the stop bit, the timer shift clock can toggle during the stop bit, but does not generate shift events.

A timer enable condition can be detected in the same cycle as a timer disable condition (if timer stop bit is disabled), or on the first rising edge of the shift clock after the disable condition (if stop bit is enabled). When ONETIM is set, the timer status flag must be clear before the next timer enable condition is detected. Receive shift registers with stop bit enabled store the contents of the shift register into the shift buffer and verify the state of the input data on the configured shift edge while the timer is in the stop state condition. If there is no configured edge between the timer disable and the next rising edge of the shift clock then the final store and verify do not occur.

53.3.3 Pin operation

The pin configuration for each timer and shifter can be configured to use any FlexIO pin with either polarity. Each timer and shifter can be configured as an input, output data, output enable or bidirectional output. A pin configured for output enable can be used as an open drain (with inverted polarity, since the output enable assertion would cause logic zero to be output on the pin) or to control the enable on the bidirectional output. Any timer or shifter could be configured to control the output enable for a pin where the bidirectional output data is driven by another timer or shifter.

Parallel Interface

Shifters can be configured to use multiple FlexIO pins in parallel using the SHIFTCFG[PWIDTH] field. PWIDTH is used to configure the following settings of a shifter:

1. Number of bits shifted per Shift clock.
2. Number of pins driven by the shifter per Shift clock (only on shifters supporting parallel transmit i.e. SHIFTER0, SHIFTER4).
3. Number of pins sampled by the shifter per Shift clock (only on Shifter supporting parallel receive i.e. SHIFTER3, SHIFTER7).

When configured for parallel shift, either 4, 8, 16 or 32-bits can be shifted on every Shift clock. If an adjacent shifter is selected as the input source (SHIFTCFG[INSRC]=1), the least significant 4, 8, 16 or 32-bits from the adjacent shifter is sampled on each Shift clock.

For shifters supporting parallel receive (SHIFTER3, SHIFTER7), the shifter can be configured to sample multiple pins (SHIFTCFG[INSRC]=0), with PWIDTH and PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL]. Note that if PWIDTH is less than the number of bits being shifted on each Shift clock, then the most significant bits are masked with 0 e.g. if PINSEL=7 and PWIDTH=6, then SHIFTER[31:24] samples {0,0,FXIO_D[12:7]} on each Shift clock.

For shifters supporting parallel transmit (SHIFTER0, SHIFTER4), the shifter can be configured to drive multiple pins using SHIFTCTL[PINCFG], with PWIDTH and PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL]. Note that if PWIDTH is less than the number of bits being shifted on each Shift clock, then the most significant pins are not driven e.g. if PINSEL=7 and PWIDTH=6, then SHIFTER[5:0] drives only FXIO_D[12:7] on each Shift clock.

Pin Synchronization

When configuring a pin as an input (this includes a timer trigger configured as a pin input), the input signal is first synchronized to the FlexIO clock before the signal is used by a timer or shifter. This introduces a small latency of between 0.5 to 1.5 FlexIO clock cycles when using an external pin input to generate an output or control a shifter. This sets the maximum setup time at 1.5 FlexIO clock cycles.

If an input is used by more than one timer or shifter then the synchronization occurs once to ensure any edge is seen on the same cycle by all timers and shifters using that input.

Note that FlexIO pins are also connected internally, configuring a FlexIO shifter or timer to output data on an unused pin makes an internal connection that allows other shifters and timer to use this pin as an input. This allows a shifter output to be used to trigger a timer or a timer output to be shifted into a shifter. This path is also synchronized to the FlexIO clock and therefore incurs a 1 cycle latency.

So when using a Pin input as a Timer Trigger, Timer Clock or Shifter Data Input, the following synchronization delays occur:

1. 0.5 to 1.5 FlexIO clock cycles for external pin
2. 1 FlexIO clock cycle for an internally driven pin

For timing considerations such as output valid time and input setup time for specific applications (SPI Master, SPI Slave, I2C Master, I2S Master, I2S Slave) refer to the FlexIO Application Information Section.

Pin Override

The state of any FlexIO pin can be changed at any time by software. The Pin Output Enable register configures any pin as an output and drives that pin with the value in the Pin Output Data Register.

Alias registers for the Pin Output Enable/Data Registers also exist, writing a logic one to an alias register updates the corresponding register bits in both the Pin Output Enable Register and the Pin Output Data Register as follows.

- Pin Output Disable Register clears Output Enable Register and clear Output Data Register.
- Pin Output Clear Register sets Output Enable Register and clear Output Data Register.
- Pin Output Set Register sets Output Enable Register and set Output Data Register.
- Pin Output Toggle Register sets Output Enable Register and toggle Output Data Register.

Pin Interrupt

The state of any FlexIO pin can be read by software at any time. Software can also configure any pin to set a status flag when either a rising and/or falling edge is detected on that pin. The pin status flag can also be configured to generate an interrupt.

53.3.4 Low power modes

The FlexIO remains functional during low power modes, provided the Doze Enable field (CTRL[DOZEN]) is clear and the FlexIO functional clock remains enabled.

The exception to this is in Deep Sleep mode. In this case, the Doze Enable (CTRL[DOZEN]) field is ignored and the FlexIO waits for all timers to complete any pending operation before acknowledging Deep Sleep mode entry.

53.3.5 Debug mode

The FlexIO remains functional in debug mode, provided the Debug Enable field (CTRL[DBGE]) is set.

53.3.6 Clocks

Functional clock

The FlexIO functional clock is asynchronous to the bus clock and can remain enabled in low power modes. The FlexIO functional clock must be enabled before accessing any FlexIO registers. Provided the FlexIO functional clock is at least equal to the bus clock, the CTRL[FASTACC] field can be set to support fast register accesses.

Bus clock

The bus clock is only used for bus accesses to the control and configuration registers.

53.3.7 Reset

Chip reset

The logic and registers for the FlexIO are reset to their default state on chip reset.

Software reset

The FlexIO implements a software reset field in its Control Register. CTRL[SWRST] resets all logic and registers to their default state, except for the CTRL itself.

53.3.8 Interrupts and DMA requests

The following table shows the status flags that generate the FlexIO interrupt and DMA requests.

Table 374. FlexIO interrupts and DMA requests

Flag	Description	Interrupt	DMA request	Low power wakeup
SSF	Shifter Status Flag.	Y	Y	Y
SEF	Shifter Error Flag.	Y	N	Y
TSF	Timer Status Flag.	Y	Y	Y
PSF	Pin Status Flag.	Y	N	Y
ETSF	External Trigger Status Flag.	Y	N	Y

53.3.9 Peripheral triggers

The connection between the FlexIO peripheral triggers and other peripherals is device-specific.

Output triggers

Each FlexIO timer generates an output trigger equal to the timer output. The output trigger is not affected by the timer pin polarity configuration.

Input trigger

FlexIO supports multiple external trigger inputs that can be used to trigger one or more FlexIO timers. If a rising edge is detected on an external trigger when FlexIO is enabled, then the external trigger status flag is set. The external triggers are synchronized to the FlexIO functional clock and must assert for at least two cycles of the FlexIO functional clock to be sampled correctly.

53.4 Application information

This section provides examples for a variety of FlexIO module applications. See the register descriptions for further details.

53.4.1 UART transmit

UART transmit can be supported using one Timer, one Shifter, and one Pin (two Pins if supporting CTS). The start and stop bit insertion is handled automatically and multiple transfers are supported using DMA controller. The timer status flag is used to indicate when the stop bit of each word is transmitted.

Break and idle characters require software intervention. Before transmitting a break or idle character, the SSTART and SSTOP fields must be altered to transmit the required state, and the data to transmit must equal FFh or 00h. Supporting a second stop bit requires the stop bit to be inserted into the data stream using software (and increasing the number of bits to transmit). When performing byte writes to SHIFTBUFn (or SHIFTBUFBIS for transmitting MSB first), the rest of the register remains unaltered. This allows an address mark bit or additional stop bit to remain undisturbed.

NOTE

FlexIO does not support automatic insertion of parity bits.

Table 375. UART transmit configuration

Register	Value	Comments
SHIFTCFGn	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0003_0002h	Configure transmit using Timer 0 on posedge of clock with output data on Pin 0. Can invert output data by setting PINPOL, or can support open-drain by setting PINPOL=1h and PINCFG=1h.
TIMCMPn	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0000_2222h	Configure start bit, stop bit, enable on trigger asserted and disable on compare. Can support CTS by configuring TIMEN=3h.
TIMCTLn	01C0_0001h	Configure dual 8-bit counter using Shifter 0 status flag as inverted internal trigger source. Supports CTS by configuring PINSEL=1h (for Pin 1) and PINPOL=1h.
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer. Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Supports MSB first transfer by writing to the SHIFTBUFBBS[7:0] register instead.

The following table shows an alternative configuration that supports slower baud rates. This configuration requires two Timers.

Table 376. UART transmit configuration for slow baud rate

Register	Value	Comments
SHIFTCFGn	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0003_0002h	Configure transmit using Timer 0 on posedge of clock with output data on Pin 0. Invert output data by setting PINPOL. Support open-drain by setting PINPOL=1h and PINCFG=1h.
TIMCMPn	0000_000Fh	Configure for 8-bit transfer. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFGn	0030_2622h	Configure start bit, stop bit, enable on trigger rising edge, decrement on trigger and disable on compare.
TIMCTLn	0740_0003h	Configure 16-bit counter using Timer 1 output as internal trigger source.
TIMCMP(n+1)	0000_0001h	Configure baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:0] = (baud rate divider / 2) - 1.
TIMCFG(n+1)	0000_1200h	Configure enable on trigger asserted and disable on Timer 0 disable. Can support CTS by configuring TIMEN=3h.
TIMCTL(n+1)	01C0_0003h	Configure 16-bit counter using Shifter 0 status flag as inverted internal trigger source. Support CTS by configuring PINSEL=1h (for Pin 1) and PINPOL=1h.
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer. Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Support MSB first transfer by writing to SHIFTBUFBBS[7:0] register instead.

53.4.2 UART receive

UART receive can be supported using one Timer, one Shifter, and one Pin (two Timers and two Pins if supporting RTS). The start and stop bit verification is handled automatically and multiple transfers are supported using the DMA controller. The timer status flag is used to indicate when the stop bit of each word is received.

Triple voting of the received data is not supported by FlexIO; data is sampled only once in the middle of each bit. A separate timer can be used to implement a glitch filter on the incoming data, and a different Timer can be used to detect an idle line of programmable length. Break characters cause the error flag to set and the shifter buffer register returns 00h.

NOTE

FlexIO does not support automatic verification of parity bits.

Table 377. UART receiver configuration

Register	Value	Comments
SHIFTCFGn	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0080_0001h	Configure receive using Timer 0 on negedge of clock with input data on Pin 0. Can invert input data by setting PINPOL.
TIMCMPn	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0204_2422h	Configure start bit, stop bit, enable on pin posedge and disable on compare. Enable resynchronization to received data with TIMOUT=2h and TIMRST=4h.
TIMCTLn	0000_0081h	Configure dual 8-bit counter using inverted Pin 0 input.
SHIFTBUFn	Data to receive	Received data can be read from SHIFTBUFBYS[7:0]. Use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Supports MSB first transfer by reading from the SHIFTBUFBIS[7:0] register instead.

The UART receiver with RTS configuration uses a second Timer to generate the RTS output. The RTS asserts when the start bit is detected and negates when the data is read from the shifter buffer register. If no start bit is detected while the RTS is asserted, the received data is ignored.

Table 378. UART receiver with RTS configuration

Register	Value	Comments
SHIFTCFGn	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTLn	0080_0001h	Configure receive using Timer 0 on negedge of clock with input data on Pin 0. Invert input data by setting PINPOL.
TIMCMPn	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0204_2522h	Configure start bit, stop bit, enable on pin posedge with trigger asserted and disable on compare. Enable resynchronization to received data with TIMOUT=2h and TIMRST=4h.

Table continues on the next page...

Table 378. UART receiver with RTS configuration (continued)

Register	Value	Comments
TIMCTLn	02C0_0081h	Configure dual 8-bit counter using inverted Pin 0 input. Trigger is internal using inverted Pin 1 input.
TIMCMP(n+1)	0000_FFFFh	Never compare.
TIMCFG(n+1)	0030_6100h	Enable on Timer N enable and disable on trigger falling edge. Decrement on trigger to ensure no compare.
TIMCTL(n+1)	0143_0003h	Configure 16-bit counter and output on Pin 1. Trigger is internal using Shifter 0 flag.
SHIFTBUFn	Data to receive	Received data can be read from SHIFTBUFBYS[7:0]. Use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Supports MSB first transfer by reading from the SHIFTBUFBIS[7:0] register instead.

53.4.3 SPI Leader

SPI Leader mode can be supported using two Timers, two Shifters, and four Pins. Either CPHA=0 or CPHA=1 can be supported and transfers can be supported using the DMA controller. For CPHA=1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The stop bit is used to guarantee a minimum of one clock cycle between the follower select negating and before the next transfer. Writing to the transmit buffer by either core or DMA is used to initiate each transfer.

NOTE

Due to synchronization delays, the setup time for the serial input data is 1.5 FlexIO clock cycles. This means the maximum baud rate is divide by 4 of the FlexIO clock frequency.

Table 379. SPI leader (CPHA=0) configuration

Register	Value	Comments
SHIFTCFGn	0000_0000h	Start and stop bit disabled.
SHIFTCTLn	0083_0002h	Configure transmit using Timer 0 on negedge of clock with output data on Pin 0.
SHIFTCFG(n+1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(n+1)	0000_0101h	Configure receive using Timer 0 on posedge of clock with input data on Pin 1.
TIMCMPn	0000_3F01h	Configure 32-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1.

Table continues on the next page...

Table 379. SPI leader (CPHA=0) configuration (continued)

Register	Value	Comments
		Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0100_2222h	Configure start bit, stop bit, enable on trigger high and disable on compare, initial clock state is logic 0.
TIMCTLn	01C3_0201h	Configure dual 8-bit counter using Pin 2 output (shift clock), with Shifter 0 flag as the inverted trigger. Set PINPOL to invert the output shift clock.
TIMCMP(n+1)	0000_FFFFh	Never compare.
TIMCFG(n+1)	0000_1100h	Enable when Timer 0 is enabled and disable when Timer 0 is disabled.
TIMCTL(n+1)	0003_0383h	Configure 16-bit counter (never compare) using inverted Pin 3 output (as follower select).
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUF. Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Supports MSB first transfer by writing to the SHIFTBUFBIS register instead.
SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUF. Use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Supports MSB first transfer by reading from the SHIFTBUFBIS register instead.

Table 380. SPI leader (CPHA=1) configuration

Register	Value	Comments
SHIFTCFGn	0000_0021h	Start bit loads data on first shift.
SHIFTCTLn	0003_0002h	Configure transmit using Timer 0 on posedge of clock with output data on Pin 0.
SHIFTCFG(n+1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(n+1)	0080_0101h	Configure receive using Timer 0 on negedge of clock with input data on Pin 1.
TIMCMPn	0000_3F01h	Configure 32-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1.

Table continues on the next page...

Table 380. SPI leader (CPHA=1) configuration (continued)

Register	Value	Comments
		Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0100_2222h	Configure start bit, stop bit, enable on trigger high and disable on compare, initial clock state is logic 0.
TIMCTLn	01C3_0201h	Configure dual 8-bit counter using Pin 2 output (shift clock), with Shifter 0 flag as the inverted trigger. Set PINPOL to invert the output shift clock. Set TIMDIS=3 to keep follower select asserted for as long as there is data in the transmit buffer.
TIMCMP(n+1)	0000_FFFFh	Never compare.
TIMCFG(n+1)	0000_1100h	Enable when Timer 0 is enabled and disable when Timer 0 is disabled.
TIMCTL(n+1)	0003_0383h	Configure 16-bit counter (never compare) using inverted Pin 3 output (as follower select).
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUF. Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Supports MSB first transfer by writing to the SHIFTBUFBIS register instead.
SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUF. Use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Supports MSB first transfer by reading from SHIFTBUFBIS register instead.

53.4.4 SPI follower

SPI Follower mode can be supported using one Timer, two Shifters, and four Pins. Either CPHA=0 or CPHA=1 can be supported and transfers can be supported using the DMA controller. For CPHA=1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The transmit data must be written to the transmit buffer register before the external follower select asserts, otherwise the shifter error flag is set.

NOTE

Due to synchronization delays, the output valid time for the serial output data is 2.5 FlexIO clock cycles. This means the maximum baud rate is divide by 6 of the FlexIO clock frequency.

Table 381. SPI follower (CPHA=0) configuration

Register	Value	Comments
SHIFTCFGn	0000_0000h	Start and stop bit disabled.
SHIFTCTLn	0083_0002h	Configure transmit using Timer 0 on falling edge of shift clock with output data on Pin 0.
SHIFTCFG(n+1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(n+1)	0000_0101h	Configure receive using Timer 0 on rising edge of shift clock with input data on Pin 1.
TIMCMPn	0000_003Fh	Configure 32-bit transfer. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFGn	0120_0600h	Configure enable on trigger rising edge. Initial clock state is logic 0 and decrements on pin input.
TIMCTLn	06C0_0203h	Configure 16-bit counter using Pin 2 input (shift clock), with Pin 3 input (follower select) as the inverted trigger.
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUF. Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Supports MSB first transfer by writing to SHIFTBUFBIS register instead.
SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUF. Use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Supports MSB first transfer by reading from the SHIFTBUFBIS register instead.

53.4.5 I2C controller

I2C Controller mode can be supported using two Timers, two Shifters, and two Pins. One timer is used to generate the SCL output and one timer is used to control the shifters. The two shifters are used to transmit and receive for every word when receiving the transmitter must transmit FFh to 3-state the output. FlexIO inserts a stop bit after every word to generate and verify the ACK or NACK. FlexIO waits for the first write to the transmit data buffer before enabling SCL generation. Data transfers can be supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The first timer generates the bit clock for the entire packet (START to Repeated START or STOP), so the compare register must be programmed with the total number of clock edges in the packet (minus one). The timer supports clock stretching using the reset counter when pin is equal to output. However, this increases both the clock high and clock low periods by at least 1 FlexIO clock cycle each. The second timer uses the SCL input pin to control the transmit and receive shift registers. This enforces an SDA data hold time by an extra 2 FlexIO clock cycles.

Both the transmit and receive shifters must be serviced for each word in the transfer. The transmit shifter must transmit FFh when receiving and the receive shifter returns the data present on the SDA pin. The transmit shifter loads one additional word on the last falling edge of SCL pin. If generating a STOP condition or a repeated START condition, this word must be 00h or FFh, respectively. During the last word of a controller-receiver transfer, you must set the transmit SSTOP bit to generate a NACK.

The receive shift register asserts an error interrupt if a NACK is detected, but you are responsible for generating the STOP or repeated START condition. If a NACK is detected during master-transmit, the interrupt routine must immediately write 00h (if generating STOP) or FFh (if generating repeated START) to the transmit shifter register. You must wait for the next rising edge on SCL before disabling both timers. The transmit shifter should be disabled after waiting the setup delay for a repeated START or STOP condition.

NOTE

Due to synchronization delays, the data valid time for the transmit output is two FlexIO clock cycles. This means the maximum baud rate is divide by 6 of the FlexIO clock frequency.

To guarantee SDA hold time, the I2C controller data valid is delayed two cycles because the clock output is passed through a synchronizer before clocking the transmit or receive shifter. Because the SCL output is synchronous with FlexIO clock, the synchronization delay is one cycle and then one cycle to generate the output.

Table 383. I2C controller configuration

Register	Value	Comments
SHIFTCFGn	0000_0032h	Start bit enabled (logic 0) and stop bit enabled (logic 1).
SHIFTCTLn	0101_0082h	Configure transmit using Timer 1 on rising edge of clock with inverted output enable (open-drain output) on Pin 0.
SHIFTCFG(n+1)	0000_0020h	Start bit disabled and stop bit enabled (logic 0) for ACK or NACK detection.
SHIFTCTL(n+1)	0180_0001h	Configure receive using Timer 1 on falling edge of clock with input data on Pin 0.
TIMCMPn	0000_2501h	Configure 2 word transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of words x 18) + 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0102_2222h	Configure start bit, stop bit, enable on trigger high, disable on compare, reset if output equals pin. Initial clock state is logic 0 and is not affected by reset.
TIMCTLn	01C1_0101h	Configure dual 8-bit counter using Pin 1 output enable (SCL open-drain), with Shifter 0 flag as the inverted trigger.
TIMCMP(n+1)	0000_000Fh	Configure 8-bit transfer. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFG(n+1)	0020_1112h	Enable when Timer 0 is enabled, disable when Timer 0 is disabled. Enable start bit and stop bit at end of each word and decrement on pin input.
TIMCTL(n+1)	01C0_0183h	Configure 16-bit counter using inverted Pin 1 input (SCL).
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUFBBS[7:0]. Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.
SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUFBIS[7:0]. Use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.

53.4.6 I2S controller

I2S Controller mode can be supported using two Timers, two Shifters, and four Pins. One timer is used to generate the bit clock and control the shifters and one timer is used to generate the frame sync. FlexIO waits for the first write to the transmit data buffer before enabling bit clock and frame sync generation. Data transfers are supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The bit clock frequency is an even integer divide of the FlexIO clock frequency. The initial frame sync assertion occurs at the same time as the first bit clock edge. The timer uses the start bit to ensure that the frame sync is generated one clock cycle before the first output data.

NOTE

Due to synchronization delays, the setup time for the receiver input is 1.5 FlexIO clock cycles. This means the maximum baud rate is divide by 4 of the FlexIO clock frequency.

Table 384. I2S controller configuration

Register	Value	Comments
SHIFTCFGn	0000_0001h	Load transmit data on first shift and stop bit disabled.
SHIFTCTLn	0003_0002h	Configure transmit using Timer 0 on rising edge of clock with output data on Pin 0.
SHIFTCFG(n+1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(n+1)	0080_0101h	Configure receive using Timer 0 on falling edge of clock with input data on Pin 1.
TIMCMPn	0000_3F01h	Configure 32-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFGn	0000_0202h	Configure start bit, enable on trigger high and never disable. Initial clock state is logic 1.
TIMCTLn	01C3_0281h	Configure dual 8-bit counter using inverted Pin 2 output (bit clock), with Shifter 0 flag as the inverted trigger. Clear PINPOL to invert the polarity of the output shift clock.
TIMCMP(n+1)	0000_007Fh	Configure 32-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:0] = (number of bits x baud rate divider) - 1.
TIMCFG(n+1)	0000_0100h	Enable when Timer 0 is enabled and never disable.
TIMCTL(n+1)	0003_0383h	Configure 16-bit counter using inverted Pin 3 output (as frame sync). Clear

Table continues on the next page...

Table 384. I2S controller configuration (continued)

Register	Value	Comments
		PINPOL to invert the polarity of the output frame sync
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUFBIS. Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Supports LSB first transfer by writing to SHIFTBUF register instead.
SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUFBIS. Use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Supports LSB first transfer by reading from SHIFTBUF register instead.

53.4.7 I2S target

I2S Target mode can be supported using three Timers, two Shifters, and four Pins. For single transmit and single receive, other combinations of transmit and receive are possible.

The transmit data must be written to the transmit buffer register before the external frame sync asserts, otherwise the shifter error flag is set.

NOTE

Due to synchronization delays, the output valid time for the serial output data is 2.5 FlexIO clock cycles. This means the maximum baud rate is divide by 6 of the FlexIO clock frequency.

The output valid time of I2S follower is max 2.5 cycles because there is a maximum 1.5 cycle delay on the clock synchronization, plus 1 cycle to output the data

Timer 2 detects the falling edge of frame sync (start of new frame) and asserts output until rising edge of bit clock (when the frame sync is normally sampled). Timer 0 detects rising edge of bit clock with Timer 2 output asserted and asserts output for length of frame. Timer 1 detects falling edge of bit clock with Timer 0 output asserted and controls shift registers for 32-bit transfers.

Table 385. I2S follower configuration

Register	Value	Comments
SHIFTCFGn	0000_0000h	Start and stop bit disabled.
SHIFTCTLn	0103_0002h	Configure transmit using Timer 1 on rising edge of shift clock with output data on Pin 0.
SHIFTCFG(n+1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(n+1)	0180_0101h	Configure receive using Timer 1 on falling edge of shift clock with input data on Pin 1.
TIMCMPn	0000_007Fh	Configure two 32-bit transfers per frame. Set TIMCMP[15:0] = (number of bits x 4) - 1.

Table continues on the next page...

Table 385. I2S follower configuration (continued)

Register	Value	Comments
TIMCFGn	0020_2500h	Configure enable on pin rising edge (inverted bit clock) with trigger high (Timer 2) and disable on compare. Initial clock state is logic 1 and decrement on pin input (bit clock).
TIMCTLn	0B40_0203h	Configure 16-bit counter using Pin 2 input (bit clock), with Timer 2 output as the trigger.
TIMCMP(n+1)	0000_003Fh	Configure 32-bit transfers. Set TIMCMP[15:0] = (number of bits x 2) - 1.
TIMCFG(n+1)	0020_2500h	Configure enable on pin (bit clock) rising edge with trigger (Timer 0) high and disable on compare. Initial clock state is logic 1 and decrement on pin input (bit clock).
TIMCTL(n+1)	0340_0283h	Configure 16-bit counter using inverted Pin 2 input (bit clock), with Timer 0 output as the trigger.
TIMCMP(n+2)	0000_0000h	Compare on zero (first edge).
TIMCFG(n+2)	0020_6400h	Configure enable on inverted pin (frame sync) rising edge and disable on trigger falling edge (bit clock). Initial clock state is logic 1 and decrement on inverted pin input (frame sync).
TIMCTL(n+2)	04C0_0383h	Configure 16-bit counter using inverted Pin 3 input (frame sync), with Pin 2 inverted input (bit clock) as the trigger.
SHIFTBUFn	Data to transmit	Transmit data can be written to SHIFTBUFBIS. Use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Supports LSB first transfer by writing to SHIFTBUF register instead.
SHIFTBUF(n+1)	Data to receive	Received data can be read from SHIFTBUFBIS. Use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Supports LSB first transfer by reading from SHIFTBUF register instead.

53.4.8 SENT receiver

SENT receiver can be supported by using one timer and one pin. The timer is configured as Input-Capture mode, and captures the counter value at falling edge of the pin input. After the counter value is captured, the counter is automatically restarted from counter value 0. Therefore, the captured value always indicates the period between previous falling edge and current falling edge.

The CPU interrupt or DMA trigger can be configured at each capture of the counter. The entire SENT frame decoding with the latest tick width adjustment is performed by CPU software.

Table 386. SENT receiver configuration

Register	Value	Comments
TIMCMPn	-	Stores counter value at the falling edge of the pin.
TIMCFGn	0x0000_6000	Timer is always enabled. Timer is disabled on trigger falling edge, decrement counter on FlexIO clock.
TIMCTLn	0xnn40_0007	Single 16-bit input capture mode. Timer pin input and output are selected by PINSEL. Timer pin output disabled, internal trigger selected, select pin nn as trigger.

53.4.9 Camera interface

Camera interface can be supported using one Timer, one or more Shifters, and multiple pins. Multiple transfers can be supported using DMA controller.

The example below describes the FlexIO configuration for interfacing to an 8-bit CMOS sensor with PCLK, VSYNC, HREF, and D[7:0] outputs. The example uses a 128-bit buffer to capture 16-pixels of image data before interrupt or DMA transfer. You can use a bigger or smaller buffer depending on system DMA performance and FlexIO resource usage by other applications.

NOTE

You can use additional timers to track the number of pixels per row and number of rows per frame, or HREF or VSYNC can be assigned as GPIO interrupts for software tracking.

Table 387. Camera interface configuration for 8-bit CMOS sensor

Register	Value	Comments
SHIFTCFGn...n+2[1]	0007_0100h	Configure 8-bit parallel shift in from adjacent shifter.
SHIFTCFGn+3	0007_0000h	Configure 8-bit parallel shift in from pins FXIO_D[7:0] (D[7:0]).
SHIFTCTLn...n+3	0080_0001h	Configure receive using Timer 0 on negedge of clock.
TIMCMPn	0000_001Fh	Configure 16-pixel (8 bits/pixel x 16 pixels = 128-bits) transfer. Set TIMCMP[15:0] = (number of pixels x 2) - 1.
TIMCFGn	0120_6600h	Configure enable on trigger (HREF) rising edge and disable on trigger falling edge. Initial Shift clock state is logic 0 and decrement on PCLK input.
TIMCTLn	12C0_0803h	Configure 16-bit counter using FXIO_D[8] input (PCLK), with

1. n=0 or 4

53.4.10 Motorola 68K and Intel 8080 bus interface

The Motorola 68K and Intel 8080 bus are two parallel interfaces commonly used by Smart/Asynchronous LCD controllers. With GPIO, FlexIO can drive these interfaces using one Timer and one Shifter. Additional Shifters can be used to support large transfers via the DMA controller.

The table below provides an example of how to drive a 16-bit 68K or 8080 bus. For an 8080 bus, two GPIOs are used to drive the nCS and RS pins. For a 68K bus, an additional GPIO is required to drive the RDWR pin.

Table 388. Motorola 68K and Intel 8080 write configuration

Register	Value	Comments
SHIFTCFG0...7	000F_0100h	Configure 16-bit parallel shift in from adjacent shifter.
SHIFTCTL0	0003_0002h	Configure transmit using Timer 0 on posedge of clock with data output to FXIO_D[15:0].
SHIFTCTL1...7	0000_0002h	Configure transmit using Timer 0 on posedge of clock.
TIMCMP0	0000_0101h (1-beat) 0000_1F01h (16-beats)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of beats x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG0	0000_2200h	Configure enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	01C3_1001h (Motorola 68K, 1-beat) 1DC3_1001h (Motorola 68K, 16-beats) 01C3_1081h (Intel 8080, 1-beat) 1DC3_1081h (Intel 8080, 16-beats)	Configure dual 8-bit counter using FXIO_D[16] output (EN pin for 68K, nWR pin for 8080), with Shifter 0 (1-beat) or Shifter 7 (16-beats) flag as the inverted trigger.
SHIFTBUF0...7	Data to transmit	Transmit data can be written to SHIFTBUF0 (1-beat) or SHIFTBUF0...7 (16-beats) to initiate a transfer, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request.

Table 389. Motorola 68K 8080 Read Configuration

Register	Value	Comments
SHIFTCFG0...6	000F_0100h	Configure 16-bit parallel shift in from adjacent shifter.
SHIFTCFG7	000F_0000h	Configure 16-bit parallel shift in from pin.
SHIFTCTL0...7	0080_0001h	Configure receive using Timer 0 on negedge of clock with data input from FXIO_D[15:0].
TIMCMP0	0000_0101h (1-beat) 0000_1F01h (16-beats)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of beats x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG0	0000_2220h	Configure stop_bit. Enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	1DC3_1001h (Motorola 68K, 1 beat) 01C3_1001h (Motorola 68K, 16 beats) 1DC3_1181h (Intel 8080, 1 beat) 01C3_1181h (Intel 8080, 16 beats)	Configure dual 8-bit counter using either FXIO_D[16] output (EN pin for 68K) or FXIO_D[17] output (nRD pin for 8080), with Shifter 7 flag (1-beat) or Shifter 0 flag (16-beats) as the inverted trigger.
SHIFTBUF0...7	Data received	Received data can be read from SHIFTBUF0 (1-beat) or SHIFTBUF0...7 (16-beats). Use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request.

In general, any operation to a 68K or 8080 bus follower begins with a register write cycle followed by one or more data read or write cycles. To accomplish this, the following program flow must be used:

1. Configure FlexIO with 1-beat write configuration
2. Configure GPIO to assert nCS, RS pins (and deassert RDWR pin for 68K)
3. Write register index data to SHIFTBUF0[15:0]
4. Configure GPIO to deassert RS pin (and assert RDWR pin for 68K data read)
5. Configure FlexIO with desired read or write configuration (1 or 16-beats)
6. Use the Shifter Status Flag to trigger interrupt or DMA driven data transfers to and from SHIFTBUF registers
7. Configure GPIO to deassert nCS pin

53.4.11 Low-power state machine

The table below shows an example of a hypothetical state machine in order to illustrate the flexibility allowed in Shifter State mode.

In this example, FlexIO waits for the FXIO_D[2] pin to assert and then drives a complementary square wave output at a frequency of FLEXIO_CLK/131072 on the FXIO_D[1:0] pins while the comparator output is asserted. This assumes that the comparator isthat connected to external trigger 15. See the chip-specific FlexIO information for actual FlexIO trigger mappings. Throughout this operation, the CPU can be kept in a STOP or VLPS mode by clearing the CTRL[DOZEN] field and ensuring the FLEXIO_CLK is enabled. The state diagram below shows the states and transitions implemented by this example.

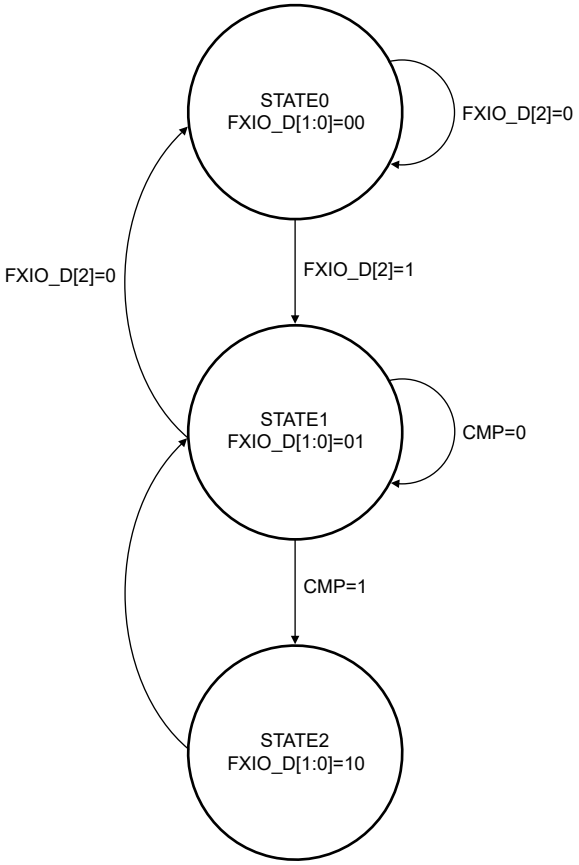

Figure 206. State diagram

Table 390. State machine configuration

Register	Value	Comments
SHIFTCFG0...2	0000_0003h	Enable FXIO_D[1:0] as outputs.
SHIFTCTL0	0080_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output low to trigger next state.
SHIFTBUF0	0020_8208h	State0: Drive FXIO_D[1:0]=00, transition to State0 if FXIO_D[2]=0, State1 if FXIO_D[2]=1.
SHIFTCTL1	0000_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output high to trigger next state.
SHIFTBUF1	0140_8408h	State1: Drive FXIO_D[1:0]=01, transition to State0 if FXIO_D[2]=0, State1 if CMP=0, State2 if CMP=1 (FXIO_D[3]=1)

Table continues on the next page...

Table 390. State machine configuration (continued)

Register	Value	Comments
SHIFTCTL2	0080_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output low to trigger next state.
SHIFTBUF2	0224_9249h	State2: Drive FXIO_D[1:0]=10, transition to State1 when Timer0 output low
TIMCMP0	0000_FFFFh	Configure baud rate of divide by 131072 of the FlexIO clock. Set TIMCMP[7:0] = (baud rate divider / 2) - 1.
TIMCFG0	0000_0000h	Configure timer always enabled.
TIMCTL0	0000_0003h	Configure single 16-bit counter.
TIMCFG1	0010_7600h	Configure timer enabled on trigger rising edge, disabled on trigger falling edge, decrement on trigger edge.
TIMCTL1	0F03_0303h	Configure timer output enabled on FXIO_D[3], external trigger 15 (comparator output) selected.

53.4.12 Keypad interface

The keypad interface can support a 3 × 4 keypad matrix using three timers and three shifters, although a larger matrix can be supported using additional shifters. The configuration is designed for four columns configured as active low open-drain pins and three rows configured as input pins with pull-up resistors enabled.

One shifter is configured in logic mode to assert its output when any of the row inputs are low, indicating a key is pressed. Use a timer to filter the shifter output to ensure that the key is pressed for a minimum amount of time before performing the column scan.

A different shifter is configured for parallel transmit. Use this shifter to scan each column when a keypress is detected. When not scanning, the shifter output is configured to assert all active low open-drain column outputs to detect any keypress. Use a dedicated timer to control the transmit shifter.

The last shifter is configured for parallel receive. Use this shifter to capture the result of the column scanning for software to decode which key (or keys) was pressed. This configuration captures the state of both row and column pins for each scan, although the row state can also be deduced by the shift order. Use a dedicated timer to control the receive shifter, which shifts at half the frequency of the transmit shifter.

When the result of the key scan is available in the receive shifter register, FlexIO continues to monitor the row inputs and can trigger multiple scans from the one keypress. To support debouncing, you can decide how many consecutive scans should be considered a single keypress.

Because the pins used in logic mode are fixed per shifter and the shifters that support parallel shifts are limited, this configuration is restricted in what pins and shifters it can use. Increasing the matrix beyond four-row inputs requires multiple shifters in logic mode. Increasing beyond four-column outputs requires concatenating transmit shifters to create a larger shift register.

Table 391. Keypad interface configuration

Register	Value	Comments
SHIFTCFG0	0003_0032h	Start bit enabled (logic 0) and stop bit enabled (logic 1), configured for 4-bit shift.
SHIFTCTL0	0101_0402h	Configure transmit using Timer 1 on rising edge of clock generating open-drain output on Pins [7:4] (column outputs).
SHIFTBUF0	0804_0201h	Static data containing the column scan pattern, each column is scanned one-hot with dead time in between.
SHIFTCFG1	0000_0020h	In logic mode, mask input 3.
SHIFTCTL1	0000_0007h	Configure logic mode.
SHIFTBUF1	07FF_07FFh	Static data configuring logic mode LUT. Output asserts if pins [3:1] are logic 0.
SHIFTCFG3	0007_0000h	Configured for 8-bit shift.
SHIFTCTL3	0280_0001h	Configure receive using Timer 2 on falling edge of clock with input data on Pins [7:0] (both rows and columns, pin 0 is don't care).
TIMCMP0	0000_00ffh	Configures pre-scanning glitch filter to 256 FlexIO clock cycles. For different filter cycles, set TIMCMP[15:0] = (filter cycles) - 1.
TIMCFG0	0103_6600h	Configure enable on trigger rising edge and disable on trigger falling edge. Initial clock state is logic 0 and is not affected by reset.
TIMCTL0	0540_0003h	Configure 16-bit counter using Shifter 1 flag (logic state) as trigger.
TIMCMP1	0000_0F3Fh	Configure 8 shifts (twice for each column) at column scan rate of divide by 128. For different scan frequency, set TIMCMP[7:0] = (scan divider / 2) - 1.
TIMCFG1	0020_2622h	Enable on trigger rising edge, disable on compare. Start and stop bits are enabled.
TIMCTL1	0340_0001h	Configure dual 8-bit counter using Timer 0 output as the trigger.
TIMCMP2	0000_0801h	Configure 4 shifts at half the frequency of Timer 1 trigger.
TIMCFG2	0110_2100h	Enable on Timer 1 enable, disable on compare, decrement on trigger input

Fields

Field	Function
31-24	Trigger Number

Table continues on the next page...

Table continued from the previous page...

Field	Function
TRIGGER	Number of external triggers implemented.
23-16 PIN	Pin Number Number of Pins implemented.
15-8 TIMER	Timer Number Number of Timers implemented.
7-0 SHIFTER	Shifter Number Number of Shifters implemented.

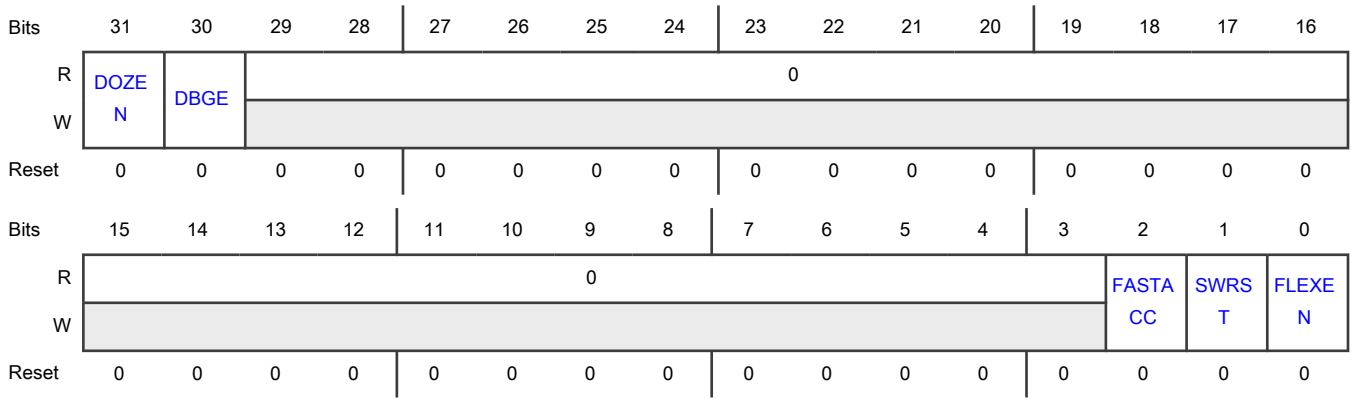
53.6.1.4 FlexIO Control Register (CTRL)

Offset

Register	Offset
CTRL	8h

Function
Control register.

Diagram



Fields

Field	Function
31 DOZEN	Doze Enable Disables FlexIO operation in Doze modes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - FlexIO enabled in Doze modes. 1b - FlexIO disabled in Doze modes.
30 DBGE	Debug Enable Enables FlexIO operation in Debug mode. 0b - FlexIO is disabled in debug modes. 1b - FlexIO is enabled in debug modes
29-3 —	Reserved
2 FASTACC	Fast Access Enables fast register accesses to FlexIO registers, but requires the FlexIO functional clock to be at least equal to the frequency of the bus clock. 0b - Configures for normal register accesses to FlexIO 1b - Configures for fast register accesses to FlexIO
1 SWRST	Software Reset The FlexIO Control Register is not affected by the software reset, all other logic in the FlexIO is affected by the software reset and all other register accesses are ignored until this bit is cleared. This register bit remains set until cleared by software, and the reset has cleared in the FlexIO clock domain. 0b - Software reset is disabled 1b - Software reset is enabled, all FlexIO registers except the Control Register are reset.
0 FLEXEN	FlexIO Enable Determines if the FlexIO is enabled or disabled. 0b - FlexIO module is disabled. 1b - FlexIO module is enabled.

53.6.1.5 Pin State Register (PIN)

Offset

Register	Offset
PIN	Ch

Function
Reports status of the Pin Data Input.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0								SSF							
W									W1C							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-8 —	Reserved
7-0 SSF	Shifter Status Flag The shifter status flag is updated when one of the following events occurs: For SMOD=Receive, the status flag is set when SHIFTBUF has been loaded with data from Shifter (SHIFTBUF is full), and the status flag is cleared when SHIFTBUF register is read. For SMOD=Transmit, the status flag is set when SHIFTBUF data has been transferred to the Shifter (SHIFTBUF is empty) or when initially configured for SMOD=Transmit, and the status flag is cleared when the SHIFTBUF register is written. For SMOD=Match Store, the status flag is set when a match has occurred between SHIFTBUF and Shifter, and the status flag is cleared when the SHIFTBUF register is read. For SMOD=Match Continuous, returns the current match result between the SHIFTBUF and Shifter. The status flag cannot be cleared by reading SHIFTBUF. For SMOD=State, the status flag for a shifter sets when it is selected by the current state pointer. For SMOD=Logic, returns the current value of the programmable logic block output. The status flag can also be cleared by writing a logic one to the flag for all modes except Match Continuous/ State /Logic. 0b - Status flag is clear. 1b - Status flag is set.

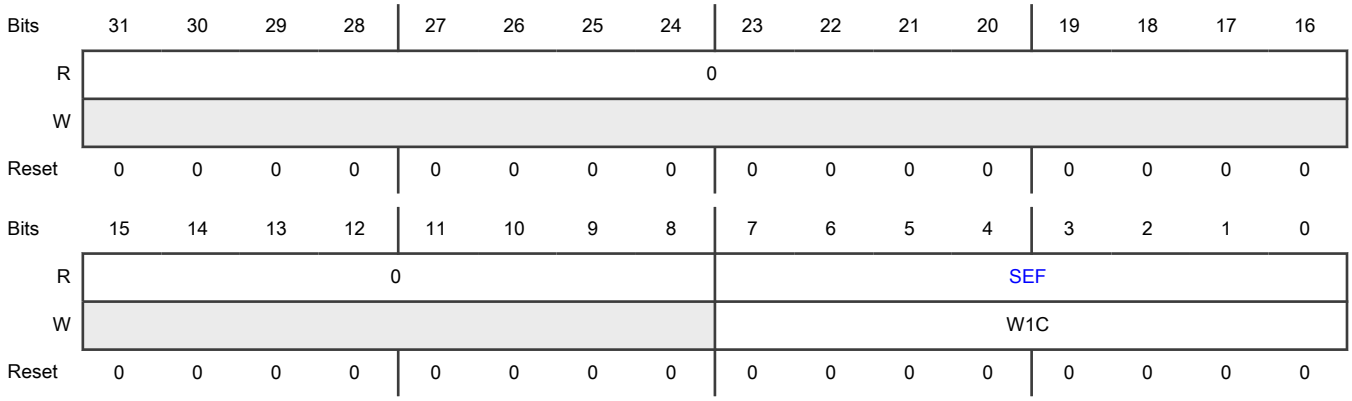
53.6.1.7 Shifter Error Register (SHIFTERR)

Offset

Register	Offset
SHIFTERR	14h

Function
This register reports shifter error flags. Write one to clear.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SEF	Shifter Error Flags The shifter error flag is set when one of the following events occurs: For SMOD=Receive, indicates Shifter was ready to store new data into SHIFTBUF before the previous data was read from SHIFTBUF (SHIFTBUF Overrun), or indicates that the received start or stop bit does not match the expected value. For SMOD=Transmit, indicates Shifter was ready to load new data from SHIFTBUF before new data had been written into SHIFTBUF (SHIFTBUF Underrun). For SMOD=Match Store, indicates a match event occurred before the previous match data was read from SHIFTBUF (SHIFTBUF Overrun). For SMOD=Match Continuous, the error flag is set when a match has occurred between SHIFTBUF and Shifter. For SMOD=Logic, the error flag is set when the output of the programmable logic block has asserted. Can be cleared by writing logic one to the flag. For SMOD=Match Continuous, can also be cleared when the SHIFTBUF register is read. 0b - Shifter Error Flag is clear. 1b - Shifter Error Flag is set.

53.6.1.8 Timer Status Register (TIMSTAT)

Offset

Register	Offset
TIMSTAT	18h

Function

This register reports timer status flags. Write one to clear.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0								TSF							
W									W1C							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-8 —	Reserved
7-0 TSF	Timer Status Flags The timer status flag sets depending on the timer mode, and can be cleared by writing logic one to the flag. In 8-bit baud counter mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements. In 8-bit high PWM mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements. In 16-bit counter mode, the timer status flag is set when the 16-bit counter equals zero and decrements. In 16-bit counter disable mode, the timer status flag is set when a timer disable event is detected. In 8-bit word counter mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements. In 8-bit low PWM mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements. In 16-bit input capture mode, the timer status flag is set when a timer disable event is detected and the timer status flag is clear. In this mode, the timer compare register should only be read when the timer status flag is set. 0b - Timer Status Flag is clear. 1b - Timer Status Flag is set.

53.6.1.9 Shifter Status Interrupt Enable (SHIFTSIEN)

Offset

Register	Offset
SHIFTSIEN	20h

Function
Enables for Shifter Status Interrupts.

Diagram

Fields

Field	Function
31-8 —	Reserved
7-0 SSIE	Shifter Status Interrupt Enable Enables interrupt generation when corresponding SSF is set. 0b - Shifter Status Flag interrupt disabled. 1b - Shifter Status Flag interrupt enabled.

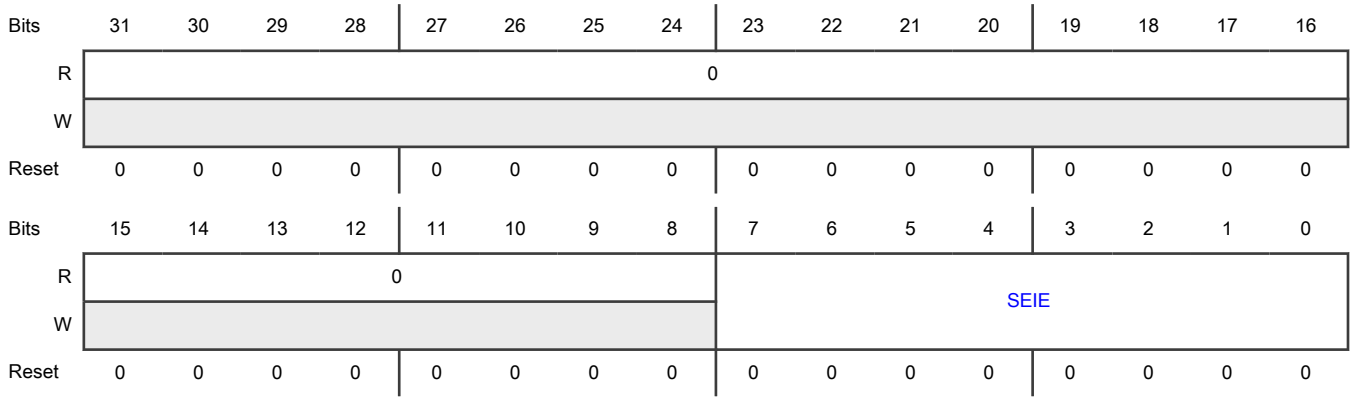
53.6.1.10 Shifter Error Interrupt Enable (SHIFTEIEN)

Offset

Register	Offset
SHIFTEIEN	24h

Function
Enables for Shifter Error Interrupts.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SEIE	Shifter Error Interrupt Enable Enables interrupt generation when corresponding SEF is set. 0b - Shifter Error Flag interrupt disabled. 1b - Shifter Error Flag interrupt enabled.

53.6.1.11 Timer Interrupt Enable Register (TIMIEN)

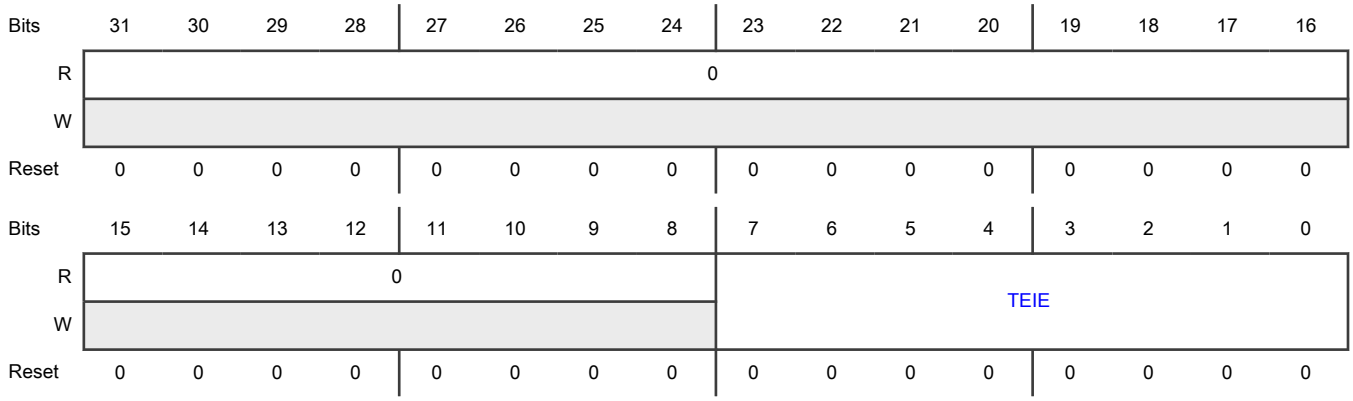
Offset

Register	Offset
TIMIEN	28h

Function

Enables for Timer Status Interrupts.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 TEIE	Timer Status Interrupt Enable Enables interrupt generation when corresponding TSF is set. 0b - Timer Status Flag interrupt is disabled. 1b - Timer Status Flag interrupt is enabled.

53.6.1.12 Shifter Status DMA Enable (SHIFTSDEN)

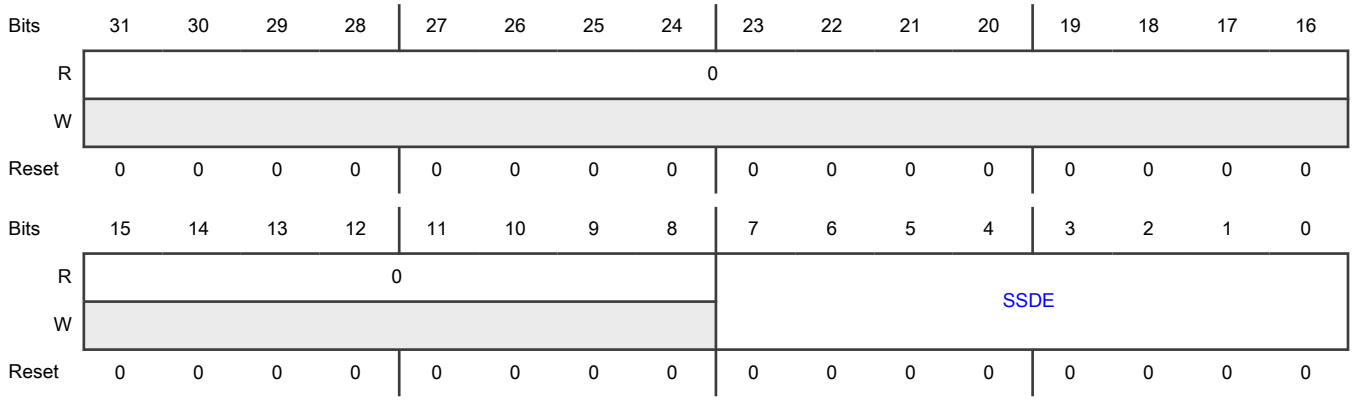
Offset

Register	Offset
SHIFTSDEN	30h

Function

Enables for Shifter DMA requests.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SSDE	Shifter Status DMA Enable Enables DMA request generation when corresponding SSF is set. 0b - Shifter Status Flag DMA request is disabled. 1b - Shifter Status Flag DMA request is enabled.

53.6.1.13 Timer Status DMA Enable (TIMERSDEN)

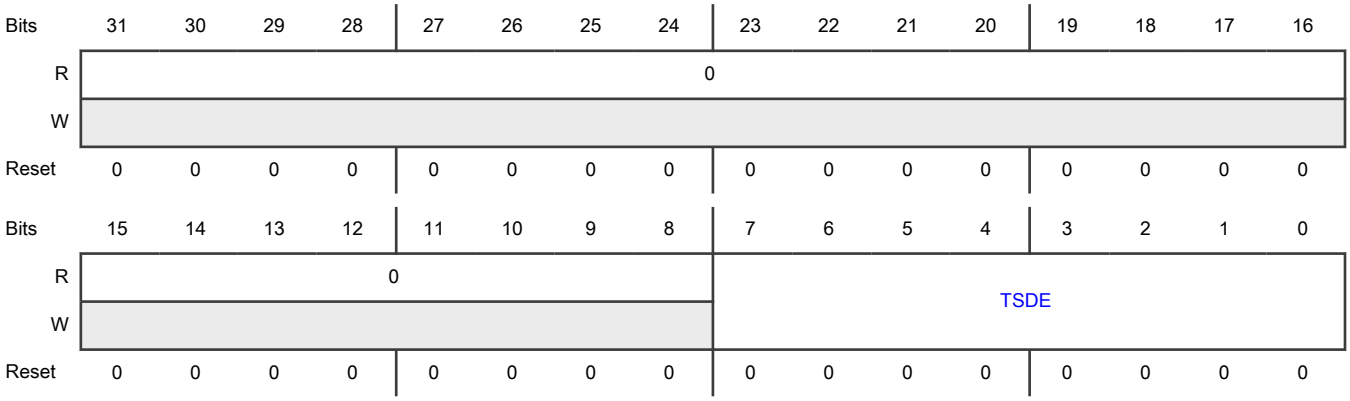
Offset

Register	Offset
TIMERSDEN	38h

Function

Enables for DMA requests when Timer Status Flag is set.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 TSDE	Timer Status DMA Enable Enables DMA request generation when corresponding TSF is set. When the Timer Status DMA request is enabled, reading or writing a Timer Compare Register clears the corresponding Timer Status Register. The DMA must therefore read or write the Timer Compare Register as part of the DMA transfer, otherwise the DMA request remains asserted. 0b - Timer Status Flag DMA request is disabled. 1b - Timer Status Flag DMA request is enabled.

53.6.1.14 Shifter State Register (SHIFTSTATE)

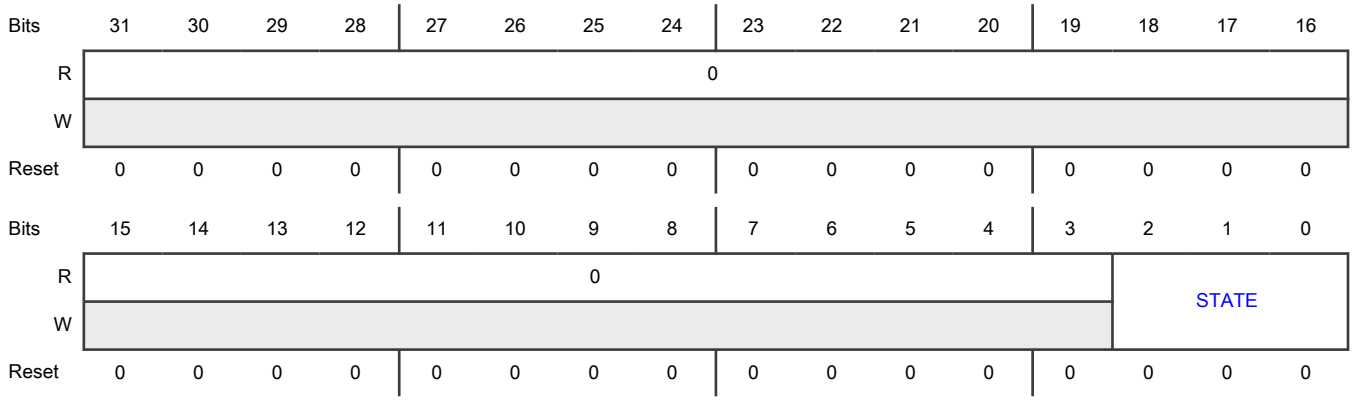
Offset

Register	Offset
SHIFTSTATE	40h

Function

Contains the pointer to keep track of the current shifter.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 STATE	Current State Pointer The current state field maintains a pointer to keep track of the current Shifter (configured for State mode) enabled to drive outputs and compute the next state. Reading this register when the state pointer is updating can result in the incorrect state returned. This field is writable and the value written overrides the current state.

53.6.1.15 Trigger Status Register (TRGSTAT)

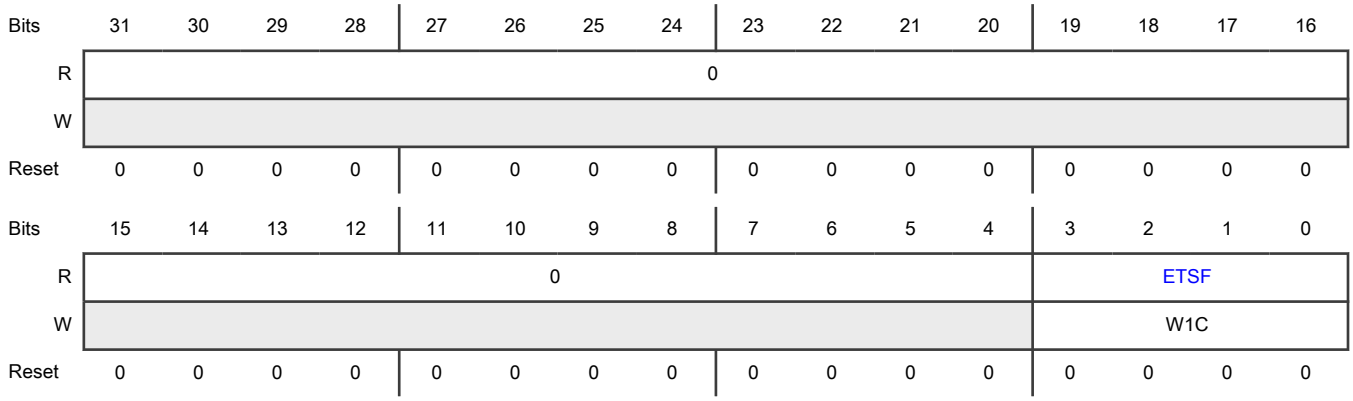
Offset

Register	Offset
TRGSTAT	48h

Function

External Trigger Status Flags. Write one to clear.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 ETSF	External Trigger Status Flags The external trigger status flag is set when a rising edge is detected on the corresponding external trigger input. 0b - External Trigger Status Flag is clear 1b - External Trigger Status Flag is set

53.6.1.16 External Trigger Interrupt Enable Register (TRIGIEN)

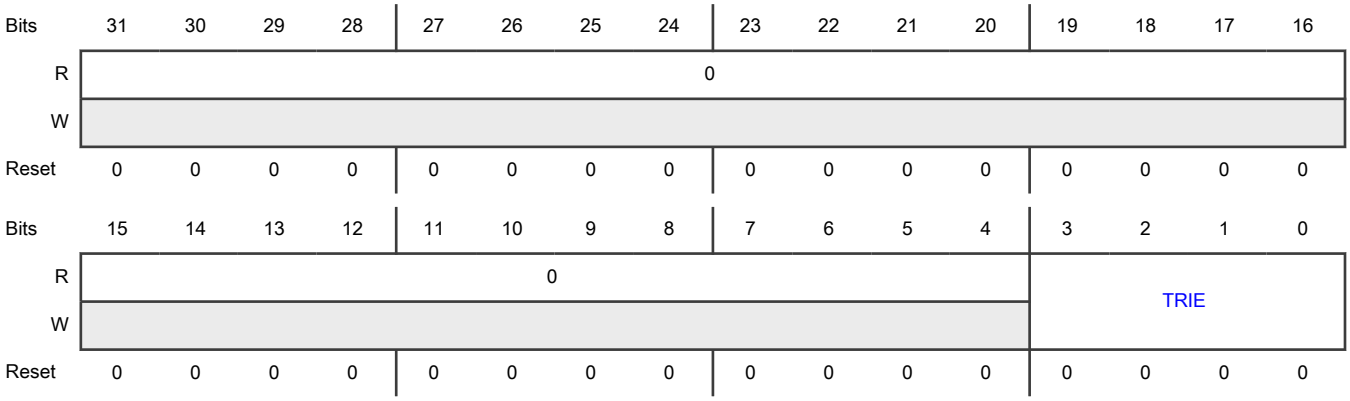
Offset

Register	Offset
TRIGIEN	4Ch

Function

Enables for external trigger interrupts.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 TRIE	External Trigger Interrupt Enable Enables interrupt generation when corresponding ETSF is set. 0b - External Trigger Status Flag interrupt is disabled. 1b - External Trigger Status Flag interrupt is enabled.

53.6.1.17 Pin Status Register (PINSTAT)

Offset

Register	Offset
PINSTAT	50h

Function

Pin Status Flags. Write one to clear.

Diagram

R W	OUTE															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 OUTE	Output Enable Enables direct output on the corresponding pin. 0b - Pin is controlled by timer/shifter configuration. 1b - Pin is an output and driven with value of PINOUTD register.

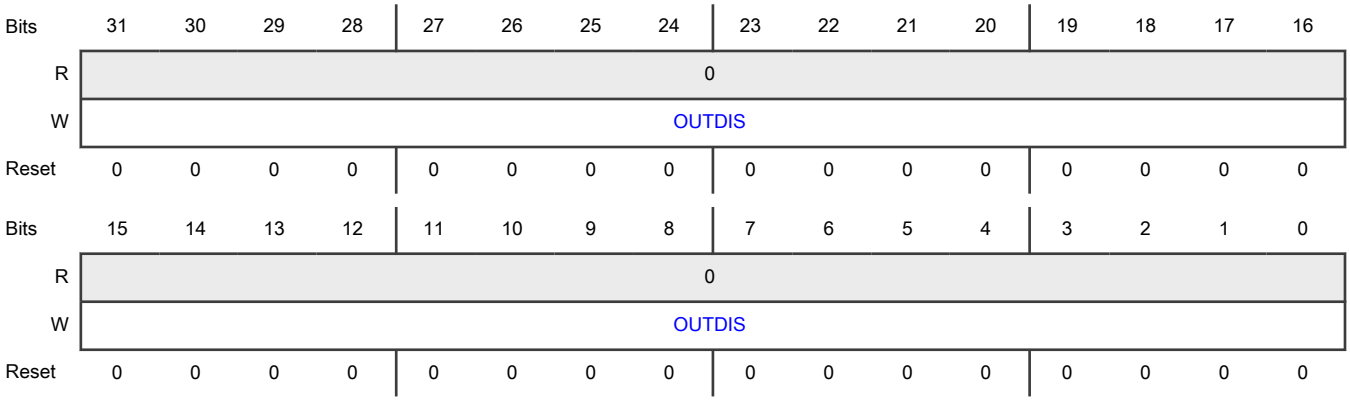
53.6.1.23 Pin Output Disable Register (PINOUTDIS)

Offset

Register	Offset
PINOUTDIS	68h

Function
Disable for pin output.

Diagram



Fields

Field	Function
31-0 OUTDIS	Output Disable Configures corresponding pins to disable direct output. 0b - No effect. 1b - Corresponding PINOUTD and PINOUTE bits are cleared.

53.6.1.24 Pin Output Clear Register (PINOUTCLR)

Offset

Register	Offset
PINOUTCLR	6Ch

Function
Clears pin output.

Diagram

Fields

Field	Function
31-0 OUTTOG	Output Toggle Configures corresponding pins to toggle. 0b - No effect. 1b - Corresponding PINOUTD is inverted and PINOUTE is set.

53.6.1.27 Shifter Control N Register (SHIFTCTL0 - SHIFTCTL7)

Offset

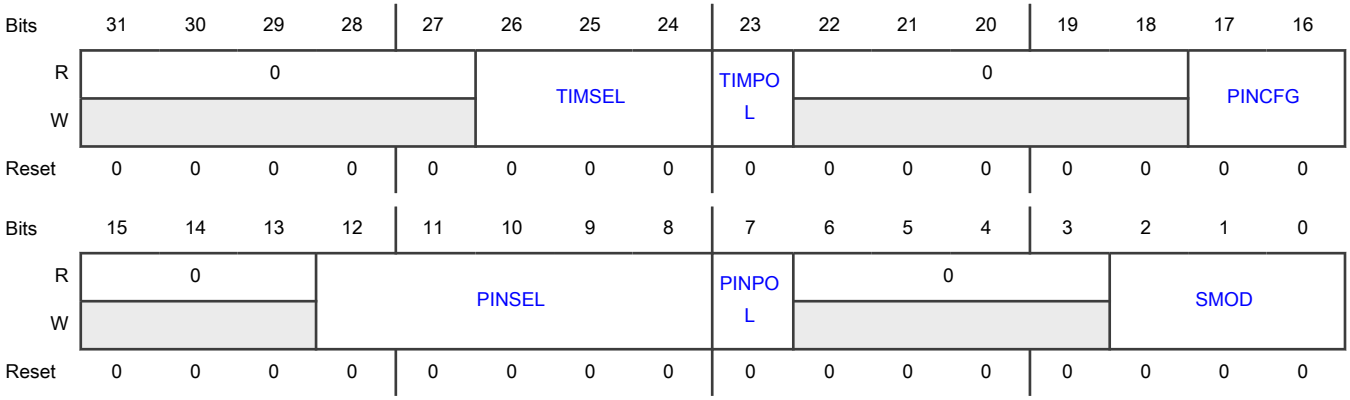
For a = 0 to 7:

Register	Offset
SHIFTCTLa	80h + (a × 4h)

Function

Control for Shift Register N

Diagram



Fields

Field	Function
31-27 —	Reserved
26-24 TIMSEL	Timer Select Selects which Timer is used for controlling the logic/shift register and generating the Shift clock. TIMSEL=i selects TIMERi.
23	Timer Polarity

Table continues on the next page...

Table continued from the previous page...

Field	Function
TIMPOL	Determines the shift occurs on the positive edge or negative edge of the shift clock. 0b - Shift on posedge of Shift clock 1b - Shift on negedge of Shift clock
22-18 —	Reserved
17-16 PINCFG	Shifter Pin Configuration For pins configured as an output (PINCFG=11), this field takes effect when the register is written. **NOTE** When initially configuring PINCFG=0x11, FlexIO may briefly drive the pin low. To avoid this, software can configure PINCFG=0x10 along with the rest of the control register and then perform a subsequent write to set PINCFG=0x11. 00b - Shifter pin output disabled 01b - Shifter pin open drain or bidirectional output enable 10b - Shifter pin bidirectional output data 11b - Shifter pin output
15-13 —	Reserved
12-8 PINSEL	Shifter Pin Select Selects which pin is used by the Shifter input or output. PINSEL=i selects the FXIO_Di pin. For pins configured as an output (PINCFG=11), this field takes effect when the register is written.
7 PINPOL	Shifter Pin Polarity For pins configured as an output (PINCFG=11), this field takes effect when the register is written. 0b - Pin is active high 1b - Pin is active low
6-3 —	Reserved
2-0 SMOD	Shifter Mode Configures the mode of the Shifter. 000b - Disabled. 001b - Receive mode. Captures the current Shifter content into the SHIFTBUF on expiration of the Timer. 010b - Transmit mode. Load SHIFTBUF contents into the Shifter on expiration of the Timer.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	011b - Reserved. 100b - Match Store mode. Shifter data is compared to SHIFTBUF content on expiration of the Timer. 101b - Match Continuous mode. Shifter data is continuously compared to SHIFTBUF contents. 110b - State mode. SHIFTBUF contents are used for storing programmable state attributes. 111b - Logic mode. SHIFTBUF contents are used for implementing programmable logic lookup table.

53.6.1.28 Shifter Configuration N Register (SHIFTCFG0 - SHIFTCFG7)

Offset

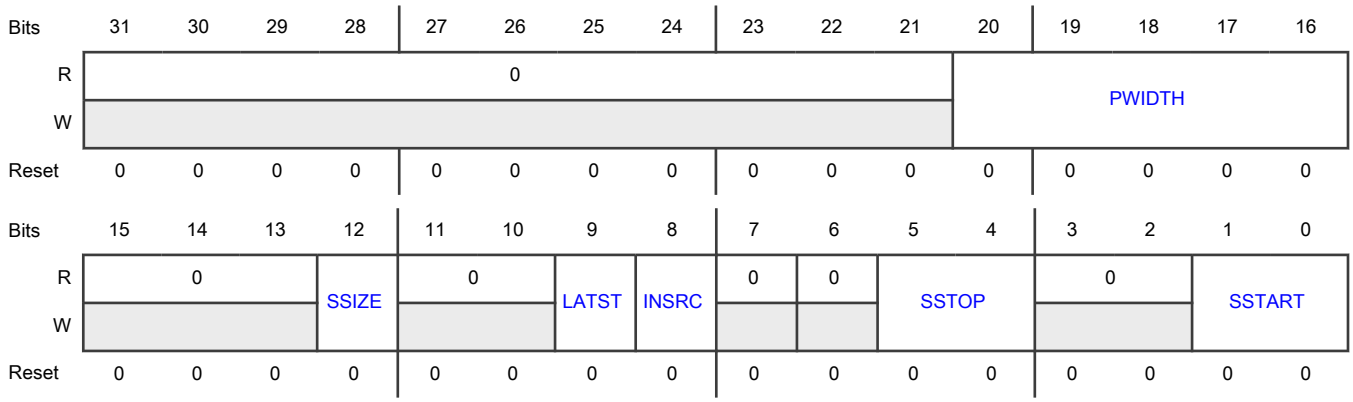
For a = 0 to 7:

Register	Offset
SHIFTCFGa	100h + (a × 4h)

Function

Contains configuration bit fields for Shifter Register N.

Diagram



Fields

Field	Function
31-21 —	Reserved
20-16	Parallel Width

Table continues on the next page...

Table continued from the previous page...

Field	Function
PWIDTH	For all Shifters, this register field configures the number of bits to be shifted on each Shift clock as follows: 1-bit shift for PWIDTH=0 2-bit shift for PWIDTH=1 4-bit shift for PWIDTH=2...3 8-bit shift for PWIDTH=4...7 16-bit shift for PWIDTH=8...15 32-bit shift for PWIDTH=16...31 For Shifters which support parallel transmit (SHIFTER0, SHIFTER4, ...) or parallel receive (SHIFTER3, SHIFTER7, ...), this register field, together with SHIFTCTL[PINSEL], also selects the pins to be driven or sampled on each Shift clock as follows: • FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL] Shifters which do not support parallel transmit or parallel receive only support parallel shift when INSRC=1. For SMOD=State, this field is used to disable state outputs. See State Mode for more details.
15-13 —	Reserved
12 SSIZE	Shifter Size Configures the size of the Shift Registers. A 24-bit shift register shifts data into bits [23:0] only and does not update bits [31:24] during shift operations. When shift register is configured for 24-bit, configuring PWIDTH=8..15 performs a 12-bit shift and PWIDTH=16..31 performs a 24-bit shift. 0b - Shift register is 32-bit. 1b - Shift register is 24-bit.
11-10 —	Reserved
9 LATST	Late Store Configures what happens when a receive or match shift register is configured to both shift and store on the same cycle. 0b - Shift register stores the pre-shift register state. 1b - Shift register stores the post-shift register state.
8 INSRC	Input Source Selects the input source for the shifter. Configuring INSRC=1 is not supported for the last shifter. 0b - Pin 1b - Shifter N+1 Output

Table continues on the next page...

Table continued from the previous page...

Field	Function
7 —	Reserved
6 —	Reserved
5-4 SSTOP	Shifter Stop bit For SMOD=Transmit, this field allows automatic stop bit insertion if the selected timer has also enabled a stop bit. For SMOD=Receive or Match Store, this field allows automatic stop bit checking if the selected timer has also enabled a stop bit. For SMOD=State, this field is used to disable state outputs. See 'State Mode' section for more detail. For SMOD=Logic, this field is used to mask logic pin inputs. See 'Logic Mode' section for more detail. 00b - Stop bit disabled for transmitter/receiver/match store 01b - Stop bit disabled for transmitter/receiver/match store, receiver/match store will store receive data on the configured shift edge when timer in stop condition 10b - Transmitter outputs stop bit value 0 on store, receiver/match store sets error flag if stop bit is not 0, receiver/match store will also store receive data on the configured shift edge when timer in stop condition 11b - Transmitter outputs stop bit value 1 on store, receiver/match store sets error flag if stop bit is not 1, receiver/match store will also store receive data on the configured shift edge when timer in stop condition
3-2 —	Reserved
1-0 SSTART	Shifter Start bit For SMOD=Transmit, this field allows automatic start bit insertion if the selected timer has also enabled a start bit. For SMOD=Receive or Match Store, this field allows automatic start bit checking if the selected timer has also enabled a start bit. For SMOD=State, this field is used to disable state outputs. See 'State Mode' section for more detail. For SMOD=Logic, this field is used to mask logic pin inputs. See 'Logic Mode' section for more detail. 00b - Start bit disabled for transmitter/receiver/match store, transmitter loads data on enable 01b - Start bit disabled for transmitter/receiver/match store, transmitter loads data on first shift 10b - Transmitter outputs start bit value 0 before loading data on first shift, receiver/match store sets error flag if start bit is not 0 11b - Transmitter outputs start bit value 1 before loading data on first shift, receiver/match store sets error flag if start bit is not 1

53.6.1.29 Shifter Buffer N Register (SHIFTBUF0 - SHIFTBUF7)

Offset

For a = 0 to 7:

Register	Offset
SHIFTBUFa	200h + (a × 4h)

Function

Contains Shift buffer data.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	SHIFTBUF															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 SHIFTBUF	Shift Buffer Shift buffer data is used for various functions depending on the SHIFTCTL0[SMOD] setting: For SMOD=Receive, Shifter data is transferred into SHIFTBUF at the expiration of Timer. The SHIFTBUF register should only be read when the corresponding shifter status flag is set, indicating new Shifter data is available. For SMOD=Transmit, SHIFTBUF data is transferred into the Shifter before the Timer begins. For SMOD=Match Store, SHIFTBUF[31:16] contains the data to be matched with the Shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1=mask, 0=no mask). The Match is checked when the Timer expires and Shifter data [31:16] is written to SHIFTBUF[31:16] whenever a match event occurs. The SHIFTBUF register should only be read when the corresponding shifter status flag is set, indicating new Shifter data is available. For SMOD=Match Continuous, SHIFTBUF[31:16] contains the data to be matched with the Shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1=mask, 0=no mask). For SMOD=Logic, SHIFTBUF[31:0] is used to implement a 5-input, 32-bit programmable logic look-up table. See Logic Mode for more details. For SMOD=State, SHIFTBUF[31:24] is used to drive the output value when this shifter is selected by the current state pointer and SHIFTBUF[23:0] is used to configure the value of the next state transition. See State Mode for more detail.

53.6.1.30 Shifter Buffer N Bit Swapped Register (SHIFTBUFBIS0 - SHIFTBUFBIS7)

Offset

For a = 0 to 7:

Register	Offset
SHIFTBUFBISa	280h + (a × 4h)

Function

SHIFTBUF register contents, but contents of this register are bit swapped.

Fields

Field	Function
31-0 SHIFTBUFBBS	Shift Buffer Alias to SHIFTBUF register, except reads/writes to this register are bit swapped within each byte. Reads return { SHIFTBUF[24:31], SHIFTBUF[16:23], SHIFTBUF[8:15], SHIFTBUF[0:7] }.

53.6.1.33 Timer Control N Register (TIMCTL0 - TIMCTL7)

Offset

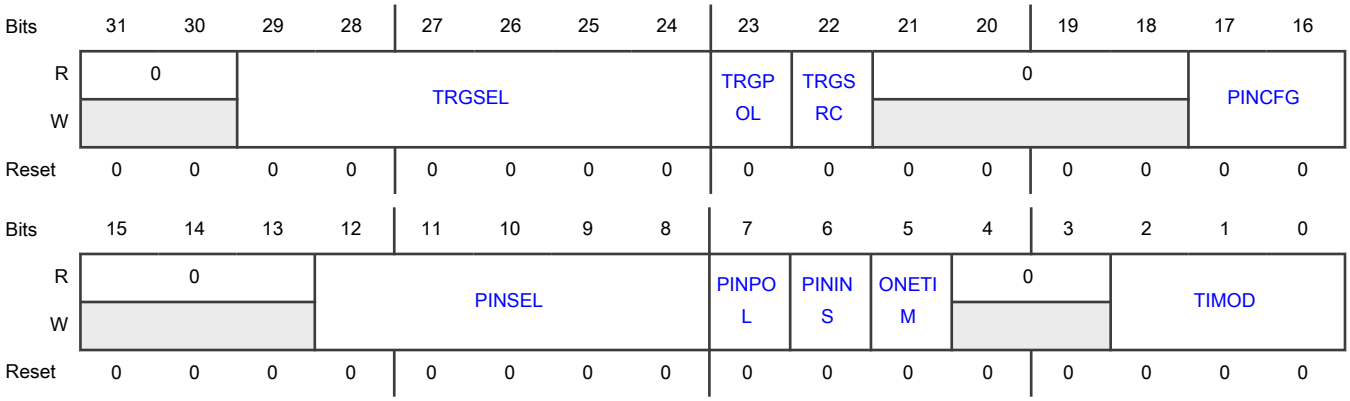
For a = 0 to 7:

Register	Offset
TIMCTLa	400h + (a × 4h)

Function

Timer Control for Timer N.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 TRGSEL	Trigger Select The valid values for TRGSEL depend on the FLEXIO_PARAM register. • When TRGSRC = 1, the valid values for N depend on PIN, TIMER, SHIFTER fields in the FLEXIO_PARAM register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• When TRGSRC = 0, the valid values for N depend on TRIGGER field in FLEXIO_PARAM register. Refer to the chip-specific FlexIO information for external trigger selection. **NOTE** For a pin, N=0 to 31. For a Shifter, N=0 to 7. For a Timer, N=0 to 7. When TRGSRC = 0 the trigger selection is configured as follows: • N - External trigger N input When TRGSRC = 1 the internal trigger can be configured to select an input pin as follows: • 2*N - Pin N input When TRGSRC = 1 the internal trigger can be configured to select a shifter/timer signal as follows: • 4*N+1 - Shifter N status flag • 4*N+3 - Timer N trigger output In other words, the expanded internal trigger selection (TRGSRC = 1) is as follows: • 0000 = Pin 0 • 0001 = Shifter 0 Flag • 0010 = Pin 1 • 0011 = Timer 0 Trigger • 0100 = Pin 2 • 0101 = Shifter 1 Flag • 0110 = Pin 3 • 0111 = Timer 1 Trigger • ... • This continues up to the Pin 31, Shifter 7 and Timer 7.
23 TRGPOL	Trigger Polarity Determines if the trigger is active high or active low. 0b - Trigger active high 1b - Trigger active low
22 TRGSRC	Trigger Source Determines if the trigger source is external or internal. 0b - External trigger selected 1b - Internal trigger selected
21-18 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
17-16 PINCFG	Timer Pin Configuration Configures the direction of the Timer pin. For pins configured as an output (PINCFG=11), this field takes effect when the register is written. **NOTE** When initially configuring PINCFG=0x11, FlexIO may briefly drive the pin low. To avoid this, software can configure PINCFG=0x10 along with the rest of the control register and then perform a subsequent write to set PINCFG=0x11. 00b - Timer pin output disabled 01b - Timer pin open drain or bidirectional output enable 10b - Timer pin bidirectional output data 11b - Timer pin output
15-13 —	Reserved
12-8 PINSEL	Timer Pin Select Selects which pin is used by the Timer input or output. PINSEL=i selects the FXIO_Di pin. For pins configured as an output (PINCFG=11), this field takes effect when the register is written.
7 PINPOL	Timer Pin Polarity For pins configured as an output (PINCFG=11), this field takes effect when the register is written. 0b - Pin is active high 1b - Pin is active low
6 PININS	Timer Pin Input Select When set, the timer input pin is a different pin from the timer output pin. PINSEL must select an even-numbered pin when this bit is set, so the output pin is even-numbered and input pin is odd-numbered. 0b - Timer pin input and output are selected by PINSEL. 1b - Timer pin input is selected by PINSEL+1, timer pin output remains selected by PINSEL.
5 ONETIM	Timer One Time Operation When set, configures the timer to perform a single enable/disable iteration, after which software must clear the timer status flag for the timer to be enabled again. 0b - The timer enable event is generated as normal. 1b - The timer enable event is blocked unless timer status flag is clear.
4-3 —	Reserved
2-0	Timer Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
TIMOD	In 8-bit baud counter mode, the lower 8-bits of the counter and compare register are used to configure the baud rate of the timer shift clock, and the upper 8-bits are used to configure the shifter bit count. In 8-bit PWM high mode, the lower 8-bits of the counter and compare register are used to configure the high period of the timer shift clock, and the upper 8-bits are used to configure the low period of the timer shift clock. The shifter bit count is configured using another timer or external signal. In 16-bit counter mode, the full 16-bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count. In 16-bit counter disable mode, the full 16-bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count. In 8-bit word counter mode, the lower 8-bits of the counter and compare register are used to configure the shifter bit count, and the upper 8-bits are used to configure the shifter word count. In 8-bit PWM low mode, the lower 8-bits of the counter and compare register are used to configure the low period of the timer shift clock and the upper 8-bits are used to configure the high period of the timer shift clock. The shifter bit count is configured using another timer or external signal. In 16-bit input capture mode, the inverted value of 16-bit counter is latched into the compare register when a timer counter disable condition is detected (as configured by TIMDIS). This also sets the timer status flag. The timer counter is immediately restarted from 0xFFFF 000b - Timer Disabled. 001b - Dual 8-bit counters baud mode. 010b - Dual 8-bit counters PWM high mode. 011b - Single 16-bit counter mode. 100b - Single 16-bit counter disable mode. 101b - Dual 8-bit counters word mode. 110b - Dual 8-bit counters PWM low mode. 111b - Single 16-bit input capture mode.

53.6.1.34 Timer Configuration N Register (TIMCFG0 - TIMCFG7)

Offset

For a = 0 to 7:

Register	Offset
TIMCFGa	480h + (a × 4h)

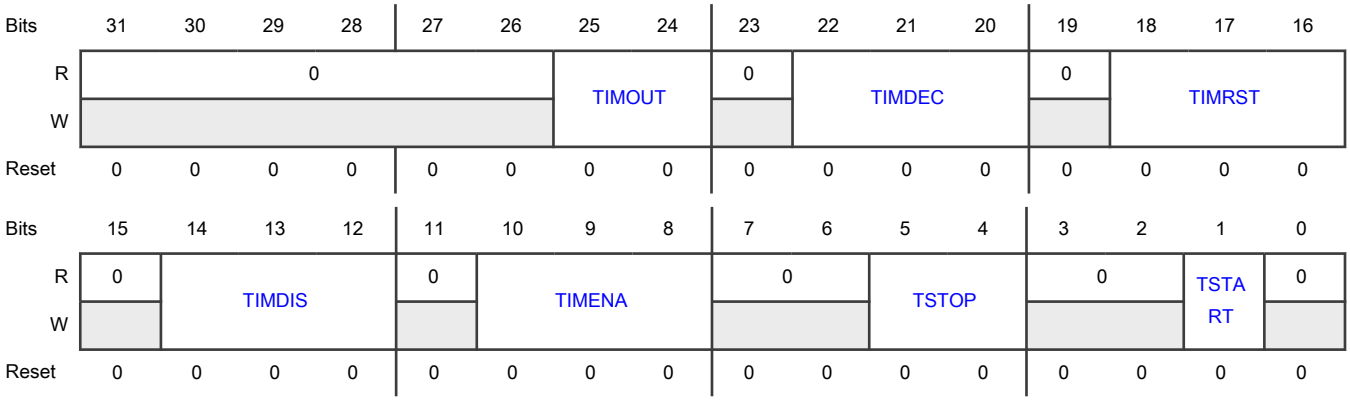
Function

The options to enable or disable the timer using the Timer N-1 enable or disable are reserved when N is evenly divisible by 4 (for example: Timer 0).

NOTE

The pin and trigger level/edges specified below refer to the signal state after being modified by the PINPOL or TRGPOL setting in the TIMCTL register. For example, "Trigger low" means that a trigger is actually at logic level 1 if the TRGPOL is set to 1 (active low).

Diagram



Fields

Field	Function
31-26 —	Reserved
25-24 TIMOUT	Timer Output Configures the initial state of the Timer Output and whether it is affected by the Timer reset. 00b - Timer output is logic one when enabled and is not affected by timer reset 01b - Timer output is logic zero when enabled and is not affected by timer reset 10b - Timer output is logic one when enabled and on timer reset 11b - Timer output is logic zero when enabled and on timer reset
23 —	Reserved
22-20 TIMDEC	Timer Decrement Configures the source of the Timer decrement and the source of the Shift clock. 000b - Decrement counter on FlexIO clock, Shift clock equals Timer output. 001b - Decrement counter on Trigger input (both edges), Shift clock equals Timer output. 010b - Decrement counter on Pin input (both edges), Shift clock equals Pin input. 011b - Decrement counter on Trigger input (both edges), Shift clock equals Trigger input. 100b - Decrement counter on FlexIO clock divided by 16, Shift clock equals Timer output. 101b - Decrement counter on FlexIO clock divided by 256, Shift clock equals Timer output.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	110b - Decrement counter on Pin input (rising edge), Shift clock equals Pin input. 111b - Decrement counter on Trigger input (rising edge), Shift clock equals Trigger input.
19 —	Reserved
18-16 TIMRST	Timer Reset Configures the condition that causes the timer counter (and optionally the timer output) to be reset. In 8-bit counter mode, the timer reset only resets the lower 8-bits that configure the baud rate. In all other modes, the timer reset resets the full 16-bits of the counter. 000b - Timer never reset 001b - Timer reset on Timer Output high. 010b - Timer reset on Timer Pin equal to Timer Output 011b - Timer reset on Timer Trigger equal to Timer Output 100b - Timer reset on Timer Pin rising edge 101b - Reserved 110b - Timer reset on Trigger rising edge 111b - Timer reset on Trigger rising or falling edge
15 —	Reserved
14-12 TIMDIS	Timer Disable Configures the condition that causes the Timer to be disabled and stop decrementing. 000b - Timer never disabled 001b - Timer disabled on Timer N-1 disable 010b - Timer disabled on Timer compare (upper 8-bits match and decrement) 011b - Timer disabled on Timer compare (upper 8-bits match and decrement) and Trigger Low 100b - Timer disabled on Pin rising or falling edge 101b - Timer disabled on Pin rising or falling edge provided Trigger is high 110b - Timer disabled on Trigger falling edge 111b - Reserved
11 —	Reserved
10-8 TIMENA	Timer Enable Configures the condition that causes the Timer to be enabled and start decrementing.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	000b - Timer always enabled 001b - Timer enabled on Timer N-1 enable 010b - Timer enabled on Trigger high 011b - Timer enabled on Trigger high and Pin high 100b - Timer enabled on Pin rising edge 101b - Timer enabled on Pin rising edge and Trigger high 110b - Timer enabled on Trigger rising edge 111b - Timer enabled on Trigger rising or falling edge
7-6 —	Reserved
5-4 TSTOP	Timer Stop Bit The stop bit can be added on a timer compare (between each word) or on a timer disable. When stop bit is enabled, configured shifters output the contents of the stop bit when the timer is disabled. When stop bit is enabled on timer disable, the timer remains disabled until the next rising edge of the shift clock. If configured for both timer compare and timer disable, only one stop bit is inserted on timer disable. 00b - Stop bit disabled 01b - Stop bit is enabled on timer compare 10b - Stop bit is enabled on timer disable 11b - Stop bit is enabled on timer compare and timer disable
3-2 —	Reserved
1 TSTART	Timer Start Bit When start bit is enabled, configured shifters outputs the contents of the start bit when the timer is enabled and the timer counter reloads from the compare register on the first rising edge of the shift clock. 0b - Start bit disabled 1b - Start bit enabled
0 —	Reserved

53.6.1.35 Timer Compare N Register (TIMCMP0 - TIMCMP7)

Offset

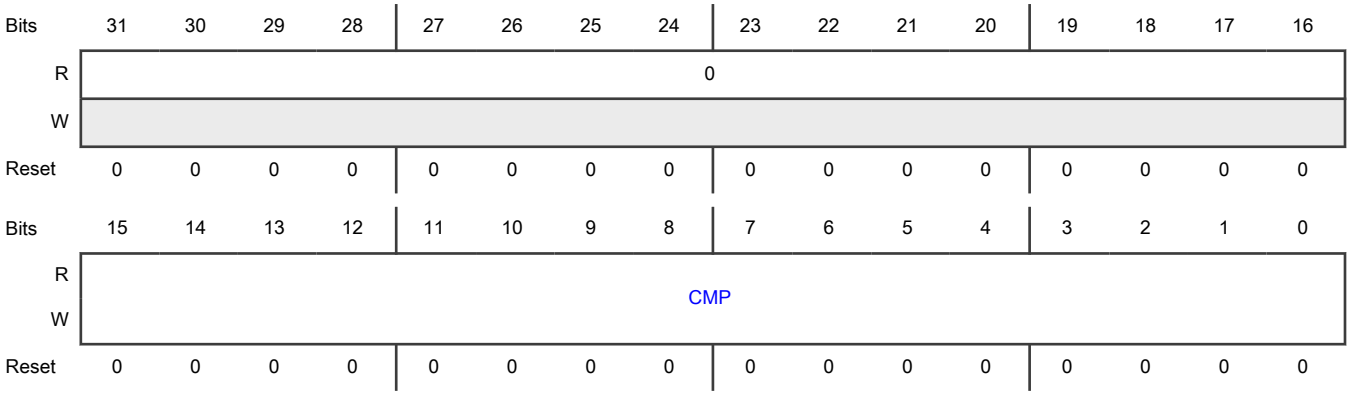
For a = 0 to 7:

Register	Offset
TIMCMPa	500h + (a × 4h)

Function

Contains the timer compare value.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 CMP	Timer Compare Value The timer compare value is loaded into the timer counter when the timer is first enabled, when the timer is reset and when the timer decrements down to zero. In 8-bit baud counter mode, the lower 8-bits configure the baud rate divider equal to (CMP[7:0] + 1) * 2. The upper 8-bits configure the number of bits in each word equal to (CMP[15:8] + 1) / 2. In 8-bit PWM high mode, the lower 8-bits configure the high period of the output to (CMP[7:0] + 1) and the upper 8-bits configure the low period of the output to (CMP[15:8] + 1). In 16-bit counter mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) to equal (CMP[15:0] + 1) * 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word equal to (CMP[15:0] + 1) / 2. In 16-bit counter disable mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) to equal (CMP[15:0] + 1) * 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word equal to (CMP[15:0] + 1) / 2. In 8-bit word counter mode, the lower 8-bits configure the number of bits in each word equal to (CMP[7:0] + 1) / 2. The upper 8-bits configure the number of words to transfer equal to (CMP[15:8] + 1) / 2. In 8-bit PWM low mode, the lower 8-bits configure the low period of the output to (CMP[7:0] + 1) and the upper 8-bits configure the high period of the output to (CMP[15:8] + 1).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	In 16-bit input capture mode, the compare register is updated with the inverse of the timer counter value whenever the timer status flag is set. The timer compare register should only be read when the timer status flag is set.

54.1.1 Module instances

This device has one instance of the SEMA42 module.

54.1.2 Domain ID

The following table lists modules assigned to each domain.

Table 394. SEMA42 domain ID assignment

Domain ID	Modules
0	CM33 Code and Data in normal functional mode
1	CM33 Code and Data in Debug mode
2	DMA0
3	EdgeLock Secure Enclave
4	Data Stream
5	Radio NBU

54.2 Overview

SEMA42 is a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve "lock and unlock" operations via a single - write access. The hardware semaphore module provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

54.2.1 Block diagram

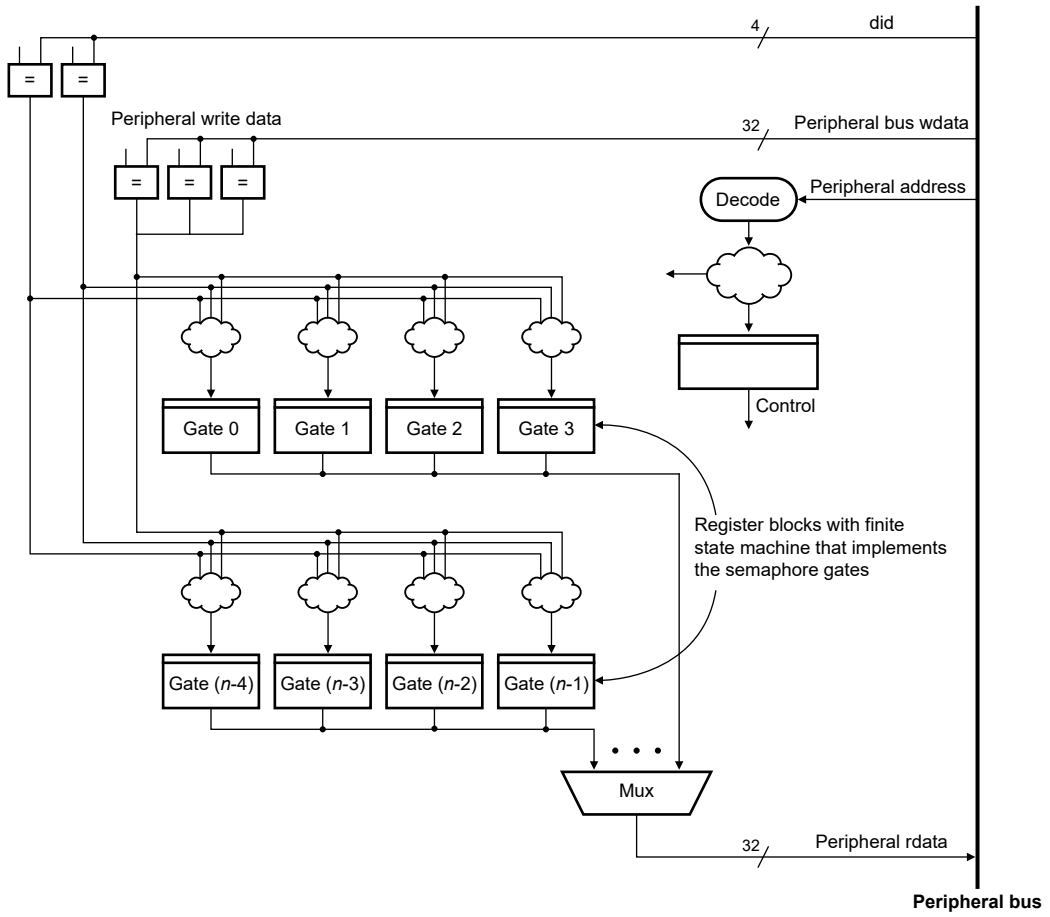

Figure 207. SEMA42 block diagram

54.2.2 Features

SEMA42 implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:

- Support for 16 hardware-enforced gates in a multi-domain configuration that supports up to 15 domains.
- Each hardware gate appears as a 16-state, 4-bit state machine.
- Support for secure reset mechanisms to clear the contents of individual gates, as well as a clear-all capability.
- Memory-mapped slave peripheral that offers programming-model accesses.

54.3 Memory map/register definition

You can access these registers only in Supervisor mode. User accesses terminate with an error.

54.3.1 SEMA42 register descriptions

54.3.1.1 SEMA42 memory map

SEMA42 base address: 4003_F000h

Offset	Register	Width (In bits)	Access	Reset value
0h - Fh	Gate (GATE0 - GATE15) [1]	8	RW	00h
42h	Reset Gate Read (RSTGT_R)	16	R	0000h
42h	Reset Gate Write (RSTGT_W)	16	W	See section

1. In this array, the index and offset values of the registers do not increment in direct alignment. For details, see the register description.

54.3.1.2 Gate (GATE0 - GATE15)

Offset

For n = 0 to 15:

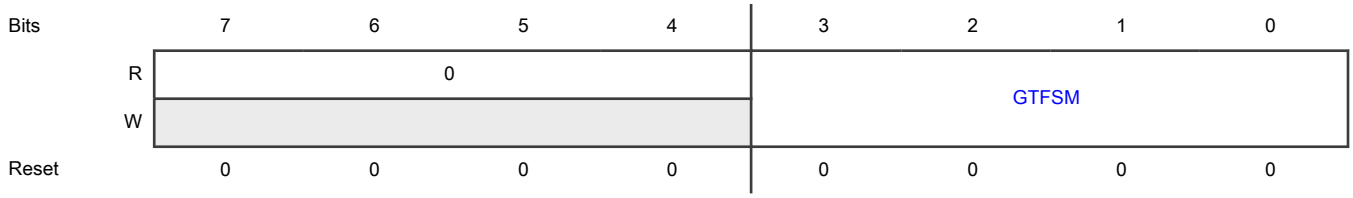
Register	Offset
GATEn	0h + (n + 3 - 2 × (n mod 4))

Function

Implements each semaphore gate in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical domain-identifier number in conjunction with the data patterns to validate all attempted write operations. Only domain masters can modify the gate registers. After a gate locks, only the locking domain must open (unlock) the gate.

You can read multiple gate values in a single access. However, you can update only a single gate at a time, via a write operation. If you attempt to write a byte-wide value that is neither the unlock value (00h) nor the appropriate lock value (domainID_number + 1), SEMA42 considers this as "no operation" and does not change any gate state. Attempts to write multiple gates in a single-aligned access with a size larger than 8 bits (byte) generate an error termination and do not allow any gate state changes.

Diagram



Fields

Field	Function
7-4 —	Reserved
3-0 GTFSM	Gate Finite State Machine Indicates the state of the gate for the last domain that locked the gate. This can be useful during system debug.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The hardware gate has a 16-state implementation, defined as: 0000b - The gate is unlocked (free). 0001b - Domain 0 locked the gate. 0010b - Domain 1 locked the gate. 0011b - Domain 2 locked the gate. 0100b - Domain 3 locked the gate. 0101b - Domain 4 locked the gate. 0110b - Domain 5 locked the gate. 0111b - Domain 6 locked the gate. 1000b - Domain 7 locked the gate. 1001b - Domain 8 locked the gate. 1010b - Domain 9 locked the gate. 1011b - Domain 10 locked the gate. 1100b - Domain 11 locked the gate. 1101b - Domain 12 locked the gate. 1110b - Domain 13 locked the gate. 1111b - Domain 14 locked the gate.

54.3.1.3 Reset Gate Read (RSTGT_R)

Offset

Register	Offset
RSTGT_R	42h

Function

Describes the specific hardware gate to be reset and records the logic number of domain. Reset Gate Write (RSTGT_W) also describe the same register showing the fields when you write it.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0		RSTGSM		RSTGMS				RSTGTN							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-14 —	Reserved
13-12 RSTGSM	Reset Gate Finite State Machine Indicates the encoded state machine value when you read the register. RSTGSM = 10b is valid for only a single machine cycle, so a read can never return this value. SEMA42 maintains the reset state machine in a 2-bit, 3-state implementation, defined as follows: 00b - Idle, waiting for the first data pattern write. 01b - Waiting for the second data pattern write 10b - The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. 11b - This state encoding is never used and therefore reserved.
11-8 RSTGMS	Reset Gate Domain Records the logical number of the domain performing the gate reset function. To succeed, this function requires that the same domain initiate the two consecutive writes to this register. SEMA42 updates the field each time a write to this register occurs.
7-0 RSTGTN	Reset Gate Number Specifies the specific hardware gate to be reset. The second write updates this field. If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates.

54.3.1.4 Reset Gate Write (RSTGT_W)

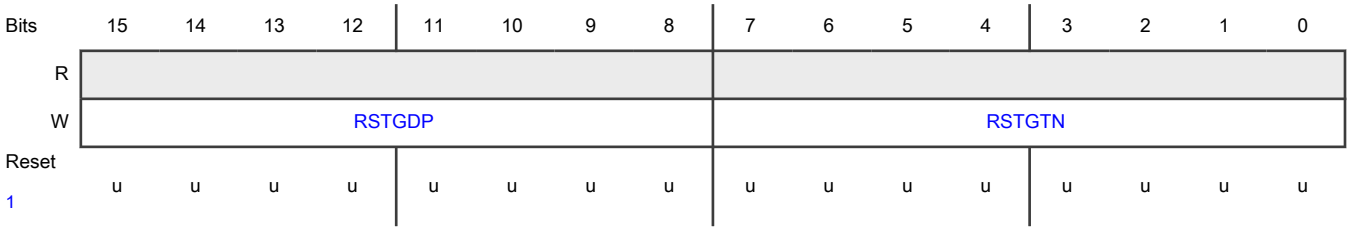
Offset

Register	Offset
RSTGT_W	42h

Function

Specifies the hardware gate to reset when data patterns are specified.

Diagram



1. Reset value is not applicable for writes.

Fields

Field	Function
15-8 RSTGDP	Reset Gate Data Pattern You access this field with the specified data patterns on the two consecutive writes to enable the gate-reset mechanism. For the first write, RSTGDP must be E2h. For the second write, RSTGDP must be 1Dh.
7-0 RSTGTN	Reset Gate Number Specifies the specific hardware gate to be reset. The second write updates this field. If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates.

54.4 Functional description

The intent of the hardware gate implementation is to specify a protocol where the locking domain must unlock the gate. However, some systems may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset. To support this special gate reset requirement, SEMA42 implements a secure reset mechanism that allows you to initialize a hardware gate (or all the gates) by following a specific dual-write access pattern. The secure-gate reset:

- Uses a technique similar to that required for the servicing of a software watchdog timer
- Requires two consecutive writes with pre-defined data patterns from the same domain

You must do this to force the clearing of the specified gate(s). The required access pattern as follows:

1. A domain performs a 16-bit write to the RSTGT memory location. The most significant byte (RSTGT_W[RSTGDP]) must be E2h. The value of least significant byte is irrelevant for this reference and can be anything.
2. The same domain then performs a second 16-bit write to the RSTGT location. For this write, the upper byte (RSTGT_W[RSTGDP]) is the logical complement of the first data pattern (1Dh) and the lower byte (RSTGT_W[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate or all gates to be cleared. If the same domain writes incorrect data on the second access or another domain performs the second write access, SEMA42 aborts the special gate reset sequence and does not assert an error signal.
3. Reads of the RSTGT location return information on the 2-bit reset state machine (RSTGT_R[RSTGSM]) that implements these functions:
   - The domain performing the reset (RSTGT_R[RSTGMS])
   - The last-cleared gate number(s) (RSTGT_R[RSTGTN])

   Reads of the RSTGT register do not affect the secure-reset finite state machine in any manner.

54.4.1 Multi-core programming: software gates

Multi-processor systems require a function that can be used to safely and easily provide a locking mechanism for system software to control access to shared data structures, shared hardware resources, and so on. The software uses the gating mechanisms to serialize (and synchronize) accesses to shared data and/or resources to prevent race conditions and preserve memory coherency between different processes and domains.

Consider the following description of a typical use-case: domain*X* enters a section of code. where shared data values are to be updated. The domain must first acquire a semaphore. Think of this as the locking (or closing) of a software gate. After the gate locks, a properly-architected software system does not allow other processes (or domains) to execute the same code segment or modify the shared data structure protected by the gate. In other words, the system locks out other processes/domains. Many software implementations include a spin-wait loop within the lock function until the gate locks. After domain X obtains the lock, domain X continues execution and updates the data values protected by the particular lock. After domain X completes the updates, it unlocks (or opens) the software gate, allowing other processes/domains access to the updated data values.

A correctly-implemented system solution must follow these important rules:

- A gate variable must protect all writes to shared data values or shared hardware resources.
- After a domain locks a gate, the system must block other processes/domains from accessing the shared data or resources. Software conventions enforce this.
- The domain that locks a particular gate is the only domain that can open (unlock) that gate.

Information in the hardware gate identifying the locking domain can be extremely useful for system-level debugging.

54.4.2 16 Hardware-enforced gates

Gates appear as a 16-entry byte-size array with read and write accesses.

Domains lock gates by writing "domainID_number+1" to the appropriate gate and must read back the gate value to verify that the lock operation succeeded.

After the gate locks, the locking domain unlocks the gate by writing zeroes.

- 16-state implementation

  If gate = 0h, then state = unlocked

  if gate = 1h, then state = locked by domain (master) 0

  if gate = 2h, then state = locked by domain (master) 1

  …

  if gate = Fh, then state = locked by domain (master) 14

SEMA42 uses the logical domain number and the specified data patterns as reference attributes to validate all write operation.

After a gate locks, the locking domain must unlock the gate by writing zeroes.

54.4.3 State machine of the GATE*n* registers

This section describes more about the SEMA42 functional operation and specific details of the state machines of the GATE*n* registers.

As described previously, each of the GATE*n* registers implements a 4-bit, 16-state machine. The following figure shows a simplified diagram of the state transitions for each gate.

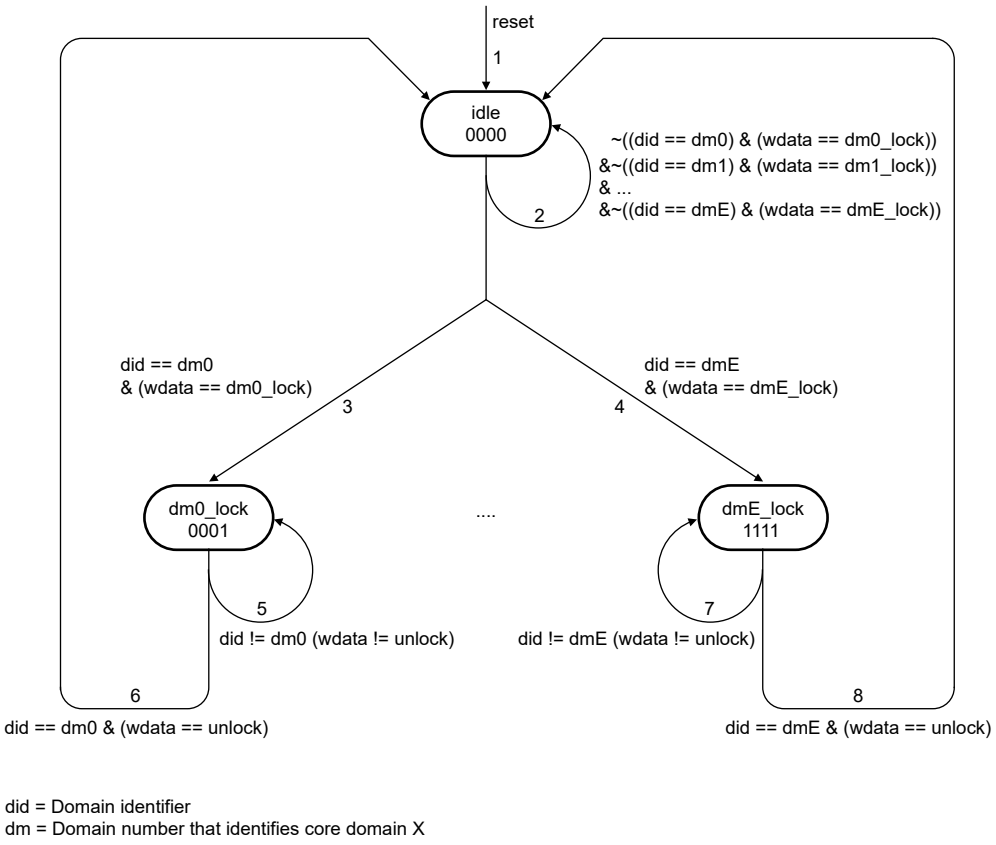


Figure 208. GATE*n* state machine

In the figure above, "dmE" represents domain 14 (E in hexadecimal). The platform passes the domain number to SEMA42.

The following table defines the GATE*n* state transitions.

Table 395. GATE*n* state transitions

Current state	Next state	Transition	Description
–	idle	1	Any reset, whether a system reset or a software-initiated gate reset, unconditionally forces the gate into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding domain occurs, the gate remains in the idle state.
idle	dm0_lock	3	When domain 0h initiates a write of the dm0_lock data value, the gate transitions into the dm0_lock state.
idle	dmE_lock	4	When domain Eh initiates a write of the dmE_lock value, the gate transitions into the dmE_lock state.
dm0_lock	dm0_lock	5	When in this state, the gate remains here if any attempted write is not from domain 0h with the unlock data value.
dm0_lock	idle	6	The gate returns to the idle (unlocked) state after a write from domain 0h with the unlock data value occurs.

Table continues on the next page...

Table 395. GATE*n* state transitions (continued)

Current state	Next state	Transition	Description
dmE_lock	dmE_lock	7	When in this state, the gate remains here if any attempted write is not from domain Eh with the unlock data value.
dmE_lock	idle	8	The gate returns to the idle (unlocked) state after a write from domain Eh with the unlock data value occurs.

SEMA42 uses these gate data values:

- The lock data value is (domain number) + 1.
- The unlock data value is 00h.

54.4.4 Clocking

This module has no clocking considerations.

54.4.5 Interrupts

This module has no interrupts.

54.5 External signals

This module has no external signals.

54.6 Initialization

This module does not require initialization.

Chapter 55
Radio Platform

55.1 Chip-specific Radio Platform information

55.1.1 XTAL_OUT_EN

The XTAL_OUT_EN in this chapter is the RF_XTAL_OUT_ENABLE in the #unique_1319.

55.2 Introduction

55.2.1 Introduction

The 2.4GHz C40 Multi-Protocol Radio supports concurrent operation in the 2.4GHz bands.

The 2.4GHz band radio covers 2.36-2.4835GHz and is built to support multiple protocols.

- Bluetooth Low Energy v5.0 with support for all optional features
  - 1Mbps (legacy mode)
  - 2Mbps (new for v5.0)
  - Long Range 125kbps & 500kbps (new for v5.0)
- IEEE 802.15.4-2006 compliant PHY & MAC
  - Zigbee
  - Thread
- IEEE 802.15.4j-2012 Medical Body Area Network (MBAN) frequency bands spanning from 2360-2400MHz.
- Generic 2-level FSK/GFSK/MSK/GMSK
  - 250kbps
  - 500kbps
  - 1000kbps
  - 2000kbps
- Concurrent 802.15.4 and BluetoothLE operation

The Radio block diagram is provided for illustration of the internal organization of the radio.

The Narrowband Unit (NBU) is a dedicated compute subsystem for the Narrowband Radio. The NBU is comprised of an Arm Cortex-M3 and associated peripherals that, in conjunction with the Bluetooth Unit, support the BluetoothLE protocol. Among the supporting peripherals are timers, a messaging unit, and dedicated flash (distinct from the SoC flash). While the NBU allows for flexibility for evolving requirements, firmware to implement radio protocols is intended to be developed and delivered by NXP.

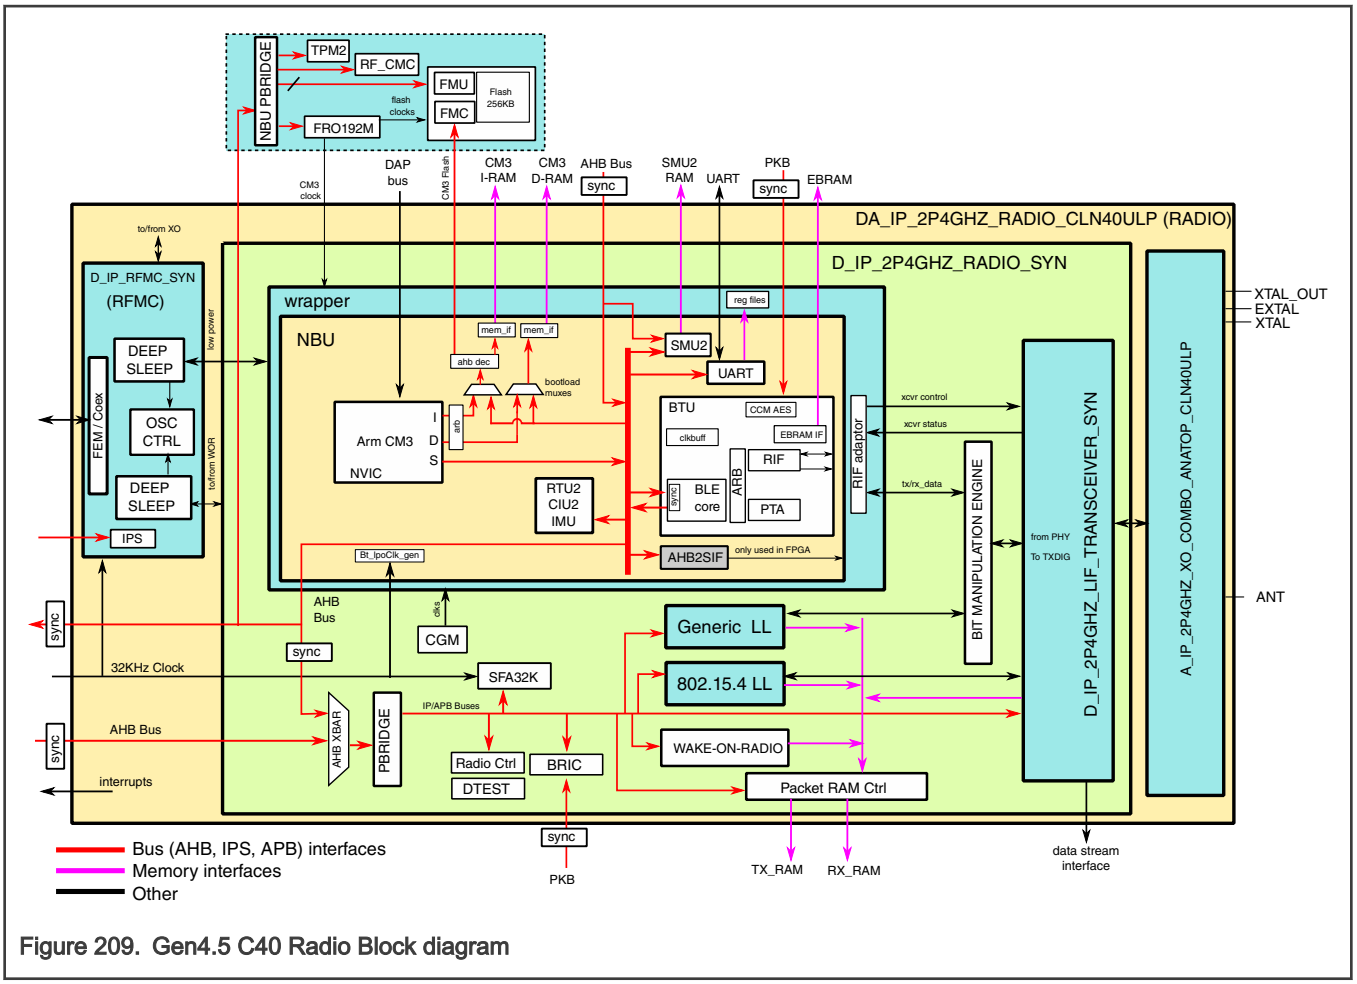

Figure 209. Gen4.5 C40 Radio Block diagram

55.3 RFMC

55.3.1 Introduction

The Radio Mode Controller (RFMC) is responsible for sequencing the power mode of the 2.4GHz radio domain and controlling the radio crystal oscillator (XO). Specifically, it supports the following features:

- Support for Deep Sleep and Power Down modes.
- Low power mode entry/exit for the 2.4GHz radio power domain.
- Enable of XO supported from both internal and external sources.
- Support for external coexistence interface for 2.4GHz frequency band
- 32kHz timer to control low power entry/exit times via Wake on Radio (WOR) or Manual (MAN) counters.
- Timer offsets to ensure XO and radio power restored prior to WOR/MAN exit event.
- Interrupts supported for XO and low power radio wakeup events.

55.3.2 Block Diagram

The following diagram gives a high-level overview of the RFMC.

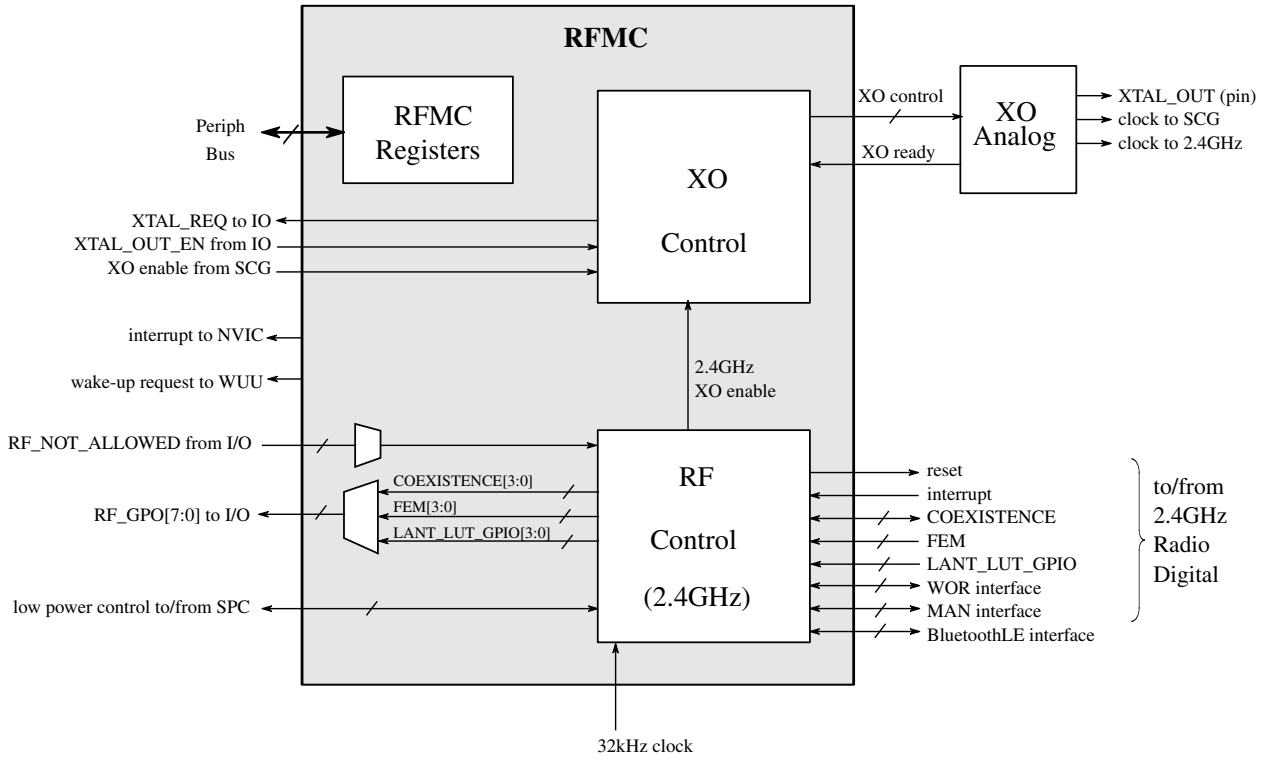

Figure 210. RFMC Block Diagram

55.3.3 Signals

Table 396. RFMC external I/O

Signal	Description	I/O
XO Interface		
XTAL_REQ	Request to enable an external crystal when internal XO is bypassed.	O
XTAL_OUT_EN	Enable from an external source to activate internal XO.	I
Radio Coexistence, FEM Control, and Localization Antenna Select Interfaces		
RF_GPO[7:0]	Software can select any two of {4 Coexistence signals, 4 FEM Control signals, 4 Localization Antenna Select signals} on this 8bit output.	O
RF_NOT_ALLOWED[4:0]	Software can select 1 of 5 input pins to use for the "RF not allowed" Coexistence signal, which blocks radio activity when asserted.	I

17-16 LDO_TRIM	XO LDO Output Voltage Trim 00b - 0.92V 01b - 0.885V 10b - 0.955V 11b - 1.011V
15 —	Reserved
14 DYN_CAP	XO On-chip Load Capacitor: enable switching during startup
13 DYN_ISEL	XO Amplifier: enable current switching during startup
12 AMP_FORCE	XO Amplifier Force PTAT Startup
11 AUX_PD	XO CLK_AUX_DRV Powerdown Also referred to as CLK_AUX_DRV_PDN_FORCE.
10 CAP_OFF	XO Load Capacitor Disable
9-4 CDAC	XO On-chip Load Capacitor Trim These values are per simulation and they are not guaranteed. The parasitic capacitance vary from silicon process and temperature. It only takes into account the internal capacitances including pin, packaging/ wire bond, pads and parasitic component in the chip. It does not consider parasitic capacitance added in the PCB 00_0000b - 5.2pF 11_1111b - 14.3pF
3-0 ISEL	XO Amplifier Current Select Selectable from 40uA to 640uA, with 40uA step size. Example programming shown below

Fields

Field	Function
31 RST	S/W Reset for 2.4GHz Radio When set, the RST bit will cause a reset of the 2.4GHz radio domain. Note, setting this bit has no effect on the RFMC's registers and this bit remains functional even when the RFMC_CTRL[RST_MSK] bits is set. 0b - Release the 2.4GHz radio from reset 1b - Hold the 2.4GHz radio in reset
30 RF_POR	S/W Power-on-Reset for 2.4GHz Radio When set, the RF_POR bit will cause a power-on-reset of the 2.4GHz radio domain. Note, setting this bit has no effect on the RFMC's registers and this bit remains functional even when the RFMC_CTRL[RST_MSK] bits is set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Release the 2.4GHz radio from power-on-reset 1b - Hold the 2.4GHz radio in power-on-reset
29 CPU_RST	S/W Reset for 2.4GHz Radio CPU When set, the CPU_RST bit will cause a reset of the 2.4GHz radio CPU. Note that this bit is set after a system reset, so SOC Core software will have to clear it to bring the 2.4GHz radio CPU out of reset. Setting this bit has no effect on the RFMC's registers and this bit remains functional even when the RFMC_CTRL[RST_MSK] bits is set. 0b - Release the 2.4GHz radio CPU from reset 1b - Hold the 2.4GHz radio CPU in reset
28 CPU_RST_LOCK	LOCK for CPU_RST When set, the CPU_RST bit will be locked and unable to be reprogrammed until the next system reset. Note that this bit is not affected by the RST bit in this register, or by the RFMC CTRL[RFMC_RST] bit. This bit remains functional even when the RFMC_CTRL[RST_MSK] bits is set. 0b - CPU_RST bit is not locked 1b - CPU_RST bit is locked
27-24 CLK_OVR	Clock Gating Override Controls whether low power mode controller clocks are gated off when the logic is not enabled (default), or whether the clocks are on regardless of whether the logic is enabled. 0xxxb - Bluetooth LE power controller clock (and 32kHz clock used by Bluetooth LE link layer) only enabled when BLE_LP_EN=1 (default) 1xxxb - Bluetooth LE power controller clock (and 32kHz clock used by Bluetooth LE link layer) always enabled x0xxb - WOR power controller clock only enabled when WOR_EN=1 (default) x1xxb - WOR power controller clock always enabled xx0xb - MAN power controller clock only enabled when MAN_EN=1 (default) xx1xb - MAN power controller clock always enabled xxx0b - TIMER clock only enabled when TIM_EN=1 xxx1b - TIMER clock always enabled
23 XO_EN	XO Enable for 2.4GHz Radio Software enable of the XO analog and output to the 2.4GHz radio domain. Note that this software enable is logically or'd with enables from the 2.4GHz MAN/WOR/Bluetooth LE power controllers. 0b - XO software enable deasserted 1b - XO software enable asserted
22	XO_EN Glitch Disable for 2.4GHz Radio

Table continues on the next page...

Table continued from the previous page...

Field	Function
XO_EN_GLITCH_DIS	If set, this disables logic added to suppress potential glitches on the xo_en signal to the analog when both MAN and WOR power controllers are enabled.
21 LP_STOP_REQ_GLITCH_DIS	LP_STOP_REQ Glitch Disable for 2.4GHz Radio If set, this disables logic added to suppress potential glitches on the lp_stop_req signal to the SPC when both MAN and WOR power controllers are enabled.
20-18 SFA_TRIG_EN	SFA Trigger Enable Selects which low power controllers can cause an SFA trigger on transition from WKUP to ACTIVE state 0xxb - Bluetooth LE Low Power Controller is not allowed to cause an SFA trigger. 1xxb - Bluetooth LE Low Power Controller is allowed to cause an SFA trigger. x0xb - WOR Low Power Controller is not allowed to cause an SFA trigger. x1xb - WOR Low Power Controller is allowed to cause an SFA trigger. xx0b - MAN Low Power Controller is not allowed to cause an SFA trigger. xx1b - MAN Low Power Controller is allowed to cause an SFA trigger.
17-12 LP_WKUP_DLY	LP Wakeup Delay Configures number of 32kHz reference clocks following enable of the XO to initiate SPC recovery for a MAN/WOR/Bluetooth LE wakeup event. Note, LP_WKUP_DLY should always be set to a value less than or equal to XO_CTRL[WKUP_OFFSET].
11-8 LP_MODE	Radio Low Power Mode Configures the radio low power mode entered after any request is asserted e.g. from S/W, MAN or WOR. The mode bits should not be changed while the radio is in or transitioning through power modes (LP_REQ_STAT and LP_ACK_STAT status bits should be clear). 0000b - Active: clock gating only (only intended for debug) 0001b - Sleep: clock gating, PMC in low power mode(only intended for debug) 0011b - Deep Sleep: low power static mode with retention of digital logic and SRAMs. 0111b - Power Down: power down of radio digital logic, optional SRAM retention. 1111b - Deep Power Down: power down of radio digital logic and SRAMs.
7 LP_ENTER	S/W Low Power Entry Request Software initiated request to enter low power mode. Note that the LP_ENTER bit is clear after a POR/LVD event, resulting in the radio defaulting to a powered up state. 0b - Deassert S/W request for low power mode entry 1b - Assert S/W request for low power mode entry
6 BLE_LP_EN	Bluetooth LE Low Power Enable Enable the Bluetooth LE power controller's wakeup output to initiate Radio low power mode entry/ wakeup.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Bluetooth LE wakeup request disabled 1b - Bluetooth LE wakeup request enabled
5 BLE_WKUP	Bluetooth LE Wakeup Force early Bluetooth LE wakeup from low power mode. 0b - Bluetooth LE low power mode wakeup deasserted 1b - Bluetooth LE low power mode wakeup asserted
4 LP_WKUP_IE	Low Power Wakeup Interrupt Enable Configures the radio to generate an interrupt when the LP_WKUP_FLAG is set. 0b - Low Power wakeup interrupt disabled 1b - Low Power wakeup interrupt enabled
3 RFACT_IE	RF_ACTIVE Interrupt Enable Configures the radio to generate an interrupt when the RFACT_FLAG is set. (It is not recommended to use RFACT_IE or RFACT_FLAG except when RFACT_SRC=2'b00.) 0b - RF_ACTIVE interrupt disabled 1b - RF_ACTIVE interrupt enabled
2 BLE_WKUP_IE	Bluetooth LE Wakeup Interrupt Enable Configures the radio to generate an interrupt when the BLE_WKUP_FLAG is set. 0b - Bluetooth LE wakeup interrupt disabled 1b - Bluetooth LE wakeup interrupt enabled
1 MAN_WKUP_IE	MAN Wakeup Interrupt Enable Configures the radio to generate an interrupt when the MAN_WKUP_FLAG is set. 0b - MAN wakeup interrupt disabled 1b - MAN wakeup interrupt enabled
0 WOR_WKUP_IE	WOR Wakeup Interrupt Enable Configures the radio to generate an interrupt when the WOR_WKUP_FLAG is set. 0b - WOR wakeup interrupt disabled 1b - WOR wakeup interrupt enabled

	010b - SLEEP state (XO disabled, RF_ACTIVE deasserted, LP request asserted). 011b - WAKEUP state (XO enabled, RF_ACTIVE asserted after RFACT_WKUP_DLY, LP request deasserted after LP_WKUP_DLY).
14-12 WOR_STATE	WOR Low Power State Returns the current state of the WOR low power controller. 000b - RESET state (WOR_EN=0). 001b - ACTIVE state (XO enabled, RF_ACTIVE asserted, LP request deasserted). 010b - SLEEP state (XO disabled, RF_ACTIVE deasserted, LP request asserted). 011b - WAKEUP state (XO enabled, RF_ACTIVE asserted after RFACT_WKUP_DLY, LP request deasserted after LP_WKUP_DLY).
11 —	Reserved
10 BLE_WKUP_STAT	Bluetooth LE Wakeup Status Returns the current status of the Bluetooth LE wakeup request (bt_clk_req) to the RFMC.
9 LP_ACK_STAT	Low Power Acknowledge Status Returns the current status of the Radio low power acknowledge from the SPC. Note that the LP_ACK_STAT bit will be set after a POR/LVD event
8 LP_REQ_STAT	Low Power Request Status Returns the current status of the Radio low power request to the SPC. Note that the LP_REQ_STAT bit will be set after a POR/LVD event
7 FRO_CLK_VLD_STAT	FRO Clock Valid Status Returns the current status of the FRO Clock Valid signal.
6 RST_STAT	Reset Status Returns the current status of the RF_CMC's reset output. 0b - Reset is not asserted. 1b - Reset is asserted.
5 SLP_RDY_STAT	RF_CMC Sleep Ready Status Returns the current status of the Sleep Ready signal from RF_CMC.
4	Low Power Wakeup Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
LP_WKUP_FLAG	Flag which sets after deassertion of the Radio low power acknowledge from the SPC, indicating radio power domain wakeup is complete (write 1 to clear). Note, this flag will assert for all sources of radio wakeup e.g. MAN/WOR/Bluetooth LE controller or software clear of LP_ENTER bit.
3 RFACT_FLAG	RF_ACTIVE Flag This flag is associated with the RF_ACTVE pin, but only when RFACT_SRC=2'b00. (It is not recommended to use this flag for other settings of RFACT_SRC.) Write 1 to clear.
2 BLE_WKUP_FLAG	Bluetooth LE Wakeup Flag Flag which sets when Bluetooth LE low power controller transitions to WAKEUP state during a Bluetooth LE wakeup event (write 1 to clear).
1 MAN_WKUP_FLAG	MAN Wakeup Flag Flag which sets when MAN low power controller transitions to ACTIVE state after a MAN wakeup event (write 1 to clear).
0 WOR_WKUP_FLAG	WOR Wakeup Flag Flag which sets when WOR low power controller transitions to ACTIVE state after a WOR wakeup event (write 1 to clear).

23-0 WKUP_TIME_CAPT	MAN Low Power Wakeup Time Captured Captured Time stamp for MAN exit from low power. The value of WKUP_TIME is captured when the man_sleep_req asserts. However, if MAN_WKUP bit is set, the value is updated when that occurs to reflect the early exit time.

55.3.5 Functional description

55.3.5.1 XO Control

The XO Control sub-module is responsible for enabling the XO analog oscillator in response to a request from either the 2.4GHz radio, System Clock Generator (SCG) or an external request (XTAL_OUT_EN pin asserted). The clock output from the XO analog oscillator can be independantly driven to 3 different clocking domains under RFMC control: 2.4GHz radio digital, SCG and XTAL_OUT pin. (Additional XO clock output(s) to the 2.4GHz radio analog blocks are not shown in the figures; this is enabled by TSM.) The figure below illustrates the logic implemented by the XO control sub-module to drive each of these domains.

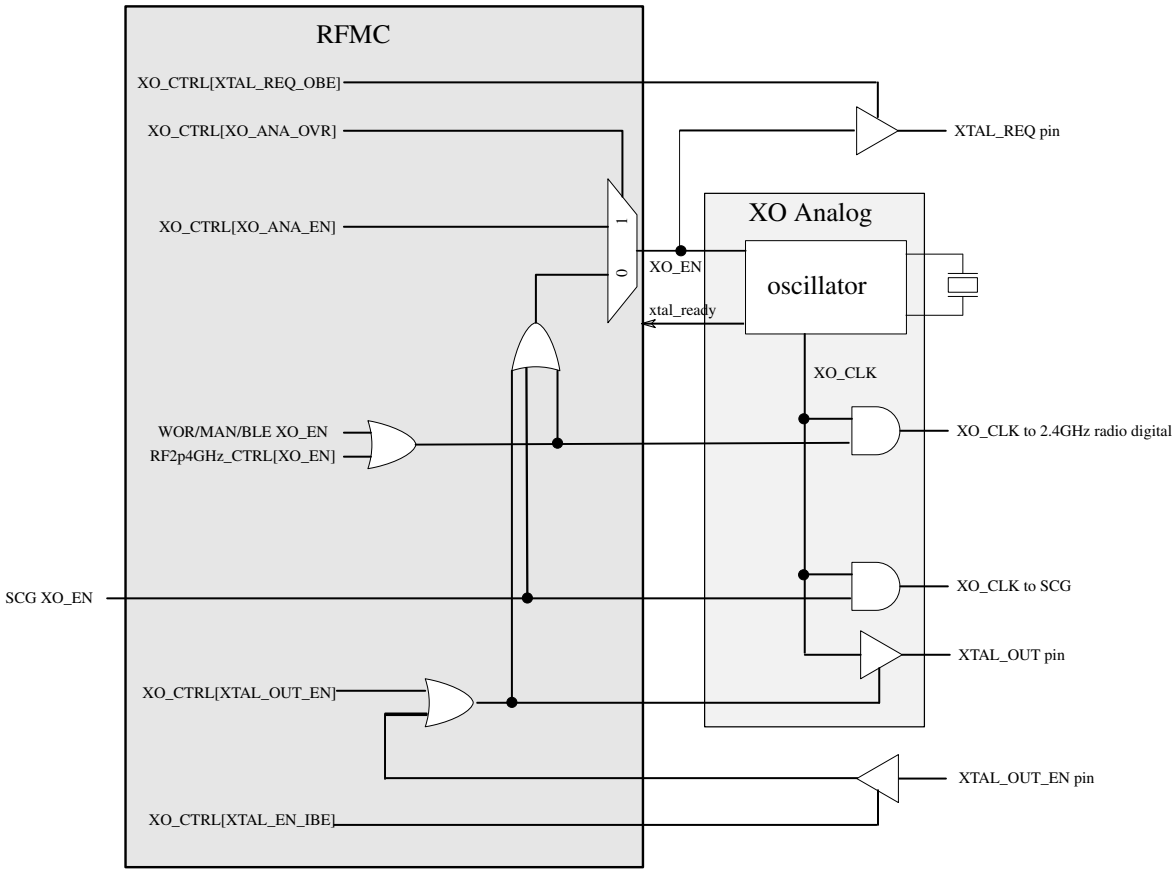

Figure 211. XO Control logic

The XO_CTRL[WKUP_OFFSET] can be used to pre-emptively enable the XO during a MAN/WOR wakeup sequence. This ensures the XO is ready and stable before the link layer begins operation at the designated MAN/WOR wakeup time.

Three flags with optional interrupts can be generated by the XO Control sub-module:

- RDY_FLAG: sets after the XO output is ready.
- INT_FLAG: sets when an internal source (SCG, 2.4GHz radio) has requested the XO.
- EXT_FLAG: sets when an external source (XTAL_OUT_EN pin) has requested the XO.

55.3.5.2 Low Power Mode Controllers

A major function of the RFMC is to control the power mode of the 2.4GHz radio . The RFMC itself resides in the system power domain and remains fully functional in all power modes except for Deep Power Down.

The 2.4GHz sub-module within the RFMC contains the following power controllers, any of which can be used to control low power entry/exit for the 2.4GHz radio:

- The MAN power controller can be used in conjunction with the Generic Link Layer or the 802.15.4 Link Layer. This controller is used to control the low power mode entry/exit time by programming the entry and wakeup time in the RFMC.
- The WOR power controller can be used in conjunction with the Generic Link Layer or the 802.15.4 Link Layer. This controller enters low power mode when directed -- and for the duration specified -- by the radio's WOR scheduler. The WOR scheduler is capable of scheduling multiple low power entry/exit and radio events.
- The Bluetooth LE power controller can only be used in conjunction with the Bluetooth LE Link Layer in the 2.4GHz radio. This power controller enters and exits low power as directed by the Bluetooth LE link layer in the radio. (Note that the Bluetooth LE link layer controls a small amount of logic residing in the system power domain and which uses the 32kHz clock to keep track of time during low power mode.)

In addition to the power controllers, software can also set/clear the RF*_CTRL[LP_ENTER] bit to enter/exit low power mode.

When software or the power controller directs the radio to enter low power, the low power mode will be as selected as programmed by the RF*_CTRL[LP_MODE] bit field, which selects between the following:

- Deep Sleep: low power static mode with clocks gated, but all radio digital logic and SRAM state is retained.
- Power Down: full power down of all radio digital logic and SRAM.

Following a POR/LVD event, RF*_CTRL[LP_ENTER] is set and RF*_CTRL[LP_MODE] is configured such that both radios will initially be in Power Down mode until the RF*_CTRL[LP_ENTER] field is cleared.

The MAN, WOR and Bluetooth LE power controllers in the RFMC each implement its own state machine to sequence the radio in and out of low power modes. Each state machine implements the following states, which are also observable by reading the RF*_STAT[MAN/WOR/BLE_STATE] register fields:

- RESET: controller reset, waiting for controller to be enabled. Outputs set to XO_EN=0, RF_ACTIVE=0, LP_REQ=0.
- ACTIVE: radio in active mode. Outputs set to XO_EN=1, RF_ACTIVE=1, LP_REQ=0.
- SLEEP: radio in low power mode. Outputs set to XO_EN=0, RF_ACTIVE=0, LP_REQ=1.
- WKUP: radio begins transition to active mode. Outputs set to XO_EN=1, RF_ACTIVE=1 (after RF*_COEXT[RFACT_WKUP_DLY]), LP_REQ=0 (after RF*_CTRL[LP_WKUP_DLY]).

The following diagram shows the transitions between states for the power controllers.

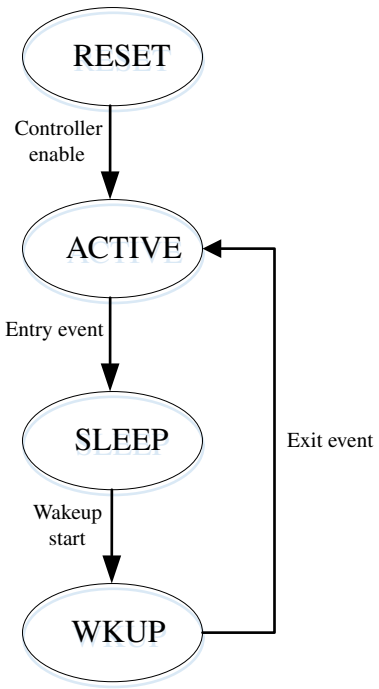

Figure 212. MAN/WOR/Bluetooth LE power control state diagram

Note that the transition from ACTIVE to SLEEP also depends on a "sleep ready" signal from the RF_CMC module, which ensures that other logic in the radio (especially the flash) is ready for the RFMC to put the radio is low power mode. This RF_CMC signal is reflected in the RF*_STAT[SLP_RDY_STAT] bit.

On transition from WKUP state to ACTIVE state, each power controller selected via RF*_CTRL[SFA_TRIG_EN] asserts a trigger to the SFA in the radio for one 32kHz clock cycle which will (if the SFA is properly configured) start a calibration cycle for the FRO32K clock.

To ensure correct sequencing of the radio power modes, it is recommended that only one of the power controllers be enabled at any given time. However, the RFMC does allow the MAN and WOR power controllers to be concurrently enabled in which case the radio will only enter low power when MAN and WOR power controllers both request low power.

The MAN/WOR/Bluetooth LE power controllers operate using the 32kHz OSC clock, and this clock must be available before enabling any of the power controllers for low power entry/exit.

55.3.5.2.1 MAN Power Controller

To enable the MAN power controller, the RF*_MAN2[MAN_EN] bit must be set. The RF*_TIMER[TIM_EN] must also be set to enable the 32kHz timer used by the MAN power control. For the 2.4GHz radio, the MAN must be assigned to a specific link layer in the 2.4GHz radio. In the WOR, the ENTER_TIME and WKUP_TIME for MAN should be programmed with the desired low power entry and exit time, respectively.

The low power entry/exit sequence is illustrated in the figure below. After the link layer has requested deep sleep entry (man_sleep_req in figure below, and reflected in the RF*_MAN1[ENTER_REQ] status bit) a MAN low power entry event is triggered when the RF*_TIMER[TIME] counter matches ENTER_TIME. Low power exit is scheduled to complete when the RF*_TIMER[TIME] counter matches WKUP_TIME. Prior to the WKUP_TIME, the MAN controller will enable the XO (xo_en) at XO_CTRL[WKUP_OFFSET] 32kHz cycles before WKUP_TIME, and request the SPC to wake the radio domain from low power mode (lp_stop_req de-assertion) at RF*_CTRL[LP_WKUP_DLY] 32kHz cycles after XO is enabled. It is expected that the WKUP_OFFSET is programmed to allow sufficient time for the XO to warmup and assert the xtal_ready signal. Likewise, the LP_WKUP_DLY is programmed to allow enough time for the SPC to bring the radio out of low power mode before

WKUP_TIME. RF_ACTIVE can also be programmed to assert at RF*_COEXT[RFACT_WKUP_DLY] after XO is enabled. Flags RF*_STAT[LP_WKUP_FLAG] and RF*_STAT[MAN_WKUP_FLAG] (with optional interrupts) are set after the lp_stop_ack (from SPC) de-asserts and at WKUP_TIME, respectively. Before the MAN power controller will enter ACTIVE state, TIME must reach WKUP_TIME and man_sleep_req must be de-asserted. If properly configured in RF*_CTRL[SFA_TRIG_EN], a trigger (sfa_meas) will be issued to the radio SFA after the MAN power controller reaches the ACTIVE state. The MAN power controller's state is reflected in RF*_STAT[MAN_STATE] for use as needed by software.

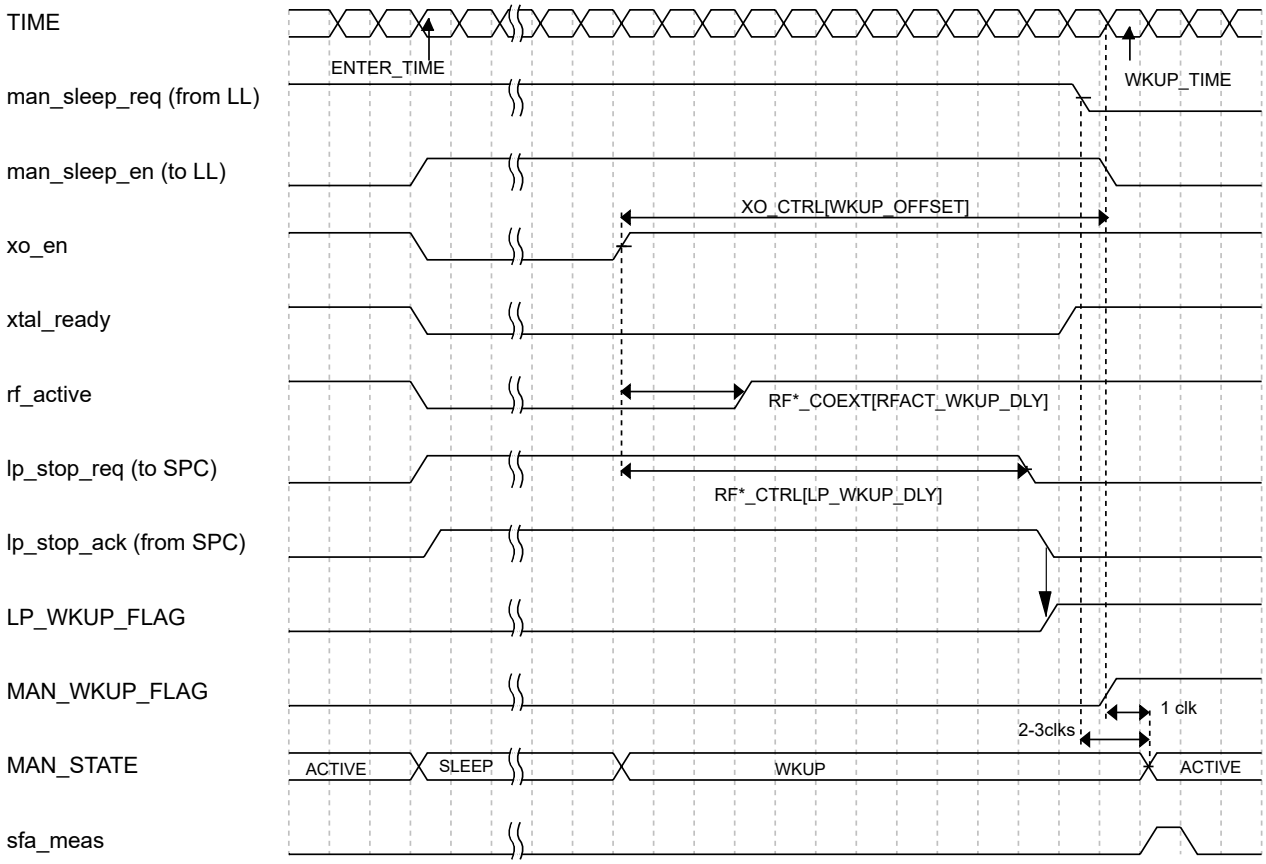

Figure 213. Low Power entry/exit for MAN Power Controller

If for some reason the radio needs to be woken before WKUP_TIME has been reached, the RF*_MAN2[MAN_WKUP] bit can be set by software to wake the radio prematurely.

55.3.5.2.2 WOR Power Controller

To enable the WOR power controller, the RF*_WOR2[WOR_EN] bit must be set. For the 2.4GHz radio, the WOR must be assigned to a specific link layer by programming the WOR_CTRL[WOR_PROTOCOL] in the 2.4GHz radio. The WOR low power entry is controlled by wor_sleep_req (reflected in RF*_WOR1[ENTER_REQ] bit) from the "WOR scheduler" (the WOR logic in the radio domain), and the desired low power duration (wor_sleep_duration -- reflected in RF*_WOR1[DURATION_TGT]) is also an input to the RFMC from the WOR scheduler.

The low power entry/exit sequence is illustrated in the figure below. Prior to low power entry, the WOR scheduler pulses the wor_sleep_duration_clr to clear the DURATION counter (RF*_WOR2[DURATION]) in the WOR power controller, then asserts wor_sleep_req. The WOR power controller needs to synchronize this request to the 32kHz clock domain, so after 2-3 cycles, low power mode is entered. Low power exit is scheduled to complete when the DURATION counter matches wor_sleep_duration. Prior to this time, the WOR controller will enable the XO (xo_en) at XO_CTRL[WKUP_OFFSET] 32kHz cycles

before wor_sleep_duration, and request the SPC to wake the radio domain from low power mode (lp_stop_req de-assertion) at RF*_CTRL[LP_WKUP_DLY] 32kHz cycles after XO is enabled. It is expected that the WKUP_OFFSET is programmed to allow sufficient time for the XO to warmup and assert the xtal_ready signal. Likewise, the LP_WKUP_DLY is programmed to allow enough time for the SPC to bring the radio out of low power mode before WKUP_TIME. RF_ACTIVE can also be programmed to assert at RF*_COEXT[RFACT_WKUP_DLY] after XO is enabled. Flags RF*_STAT[LP_WKUP_FLAG] and RF*_STAT[WOR_WKUP_FLAG] (with optional interrupts) are set after the lp_stop_ack (from SPC) de-asserts and at wor_sleep_duration, respectively. The WOR power controller does not move to ACTIVE state until after the WOR scheduler de-asserts the wor_sleep_req signal. If properly configured in RF*_CTRL[SFA_TRIG_EN], a trigger (sfa_meas) will be issued to the radio SFA after the WOR power controller reaches the ACTIVE state. The WOR power controller's state is reflected in RF*_STAT[WOR_STATE] for use as needed by software.

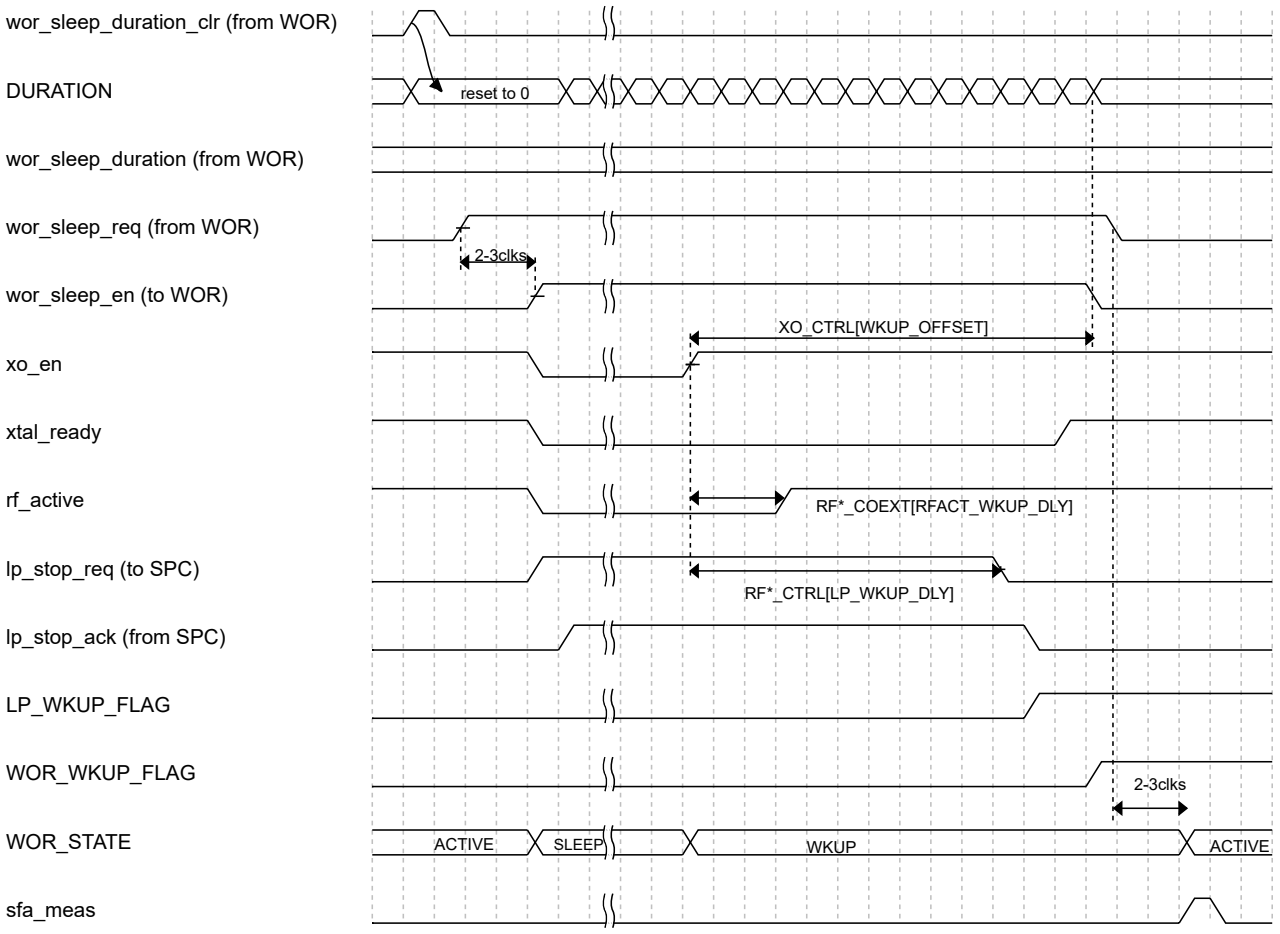

Figure 214. Low Power entry/exit for WOR Power Controller

If for some reason the radio needs to be woken before wor_sleep_duration has been reached, the RF*_WOR2[WOR_WKUP] bit can be set by software to wake the radio prematurely.

55.3.5.2.3 Bluetooth LE Power Controller

To enable the Bluetooth LE power controller, the RF2p4GHz_CTRL[BLE_LP_EN] bit must be set. A Bluetooth LE low power entry and exit event is then controlled by the Bluetooth LE link layer (see Bluetooth LE link layer programming model).

NOTE

The 32kHz clock used by both the Bluetooth LE power controller and the Bluetooth LE link layer is enabled by setting RF2p4GHz_CTRL[BLE_LP_EN]. If for some reason the Bluetooth LE link layer needs this clock to be active while the Bluetooth LE power controller is not enabled (BLE_LP_EN bit not set), software can program RF2p4GHz_CTRL[CLK_OVR] to force the clock to be enabled.

The low power entry/exit sequence is illustrated in the figure below. When the Bluetooth LE link layer wants to enter low power, it de-asserts the bt_clk_req input to RFMC (this signal is reflected in RF*_STAT[BLE_WKUP_STAT]). When the Bluetooth LE link layer wants to exit low power, it asserts bt_clk_req. At that time, the Bluetooth LE power controller will enable the XO (xo_en), and after RF*_CTRL[LP_WKUP_DLY] 32kHz cycles it will request the SPC to wake the radio domain from low power mode (lp_stop_req de-assertion). It is expected that the LP_WKUP_DLY is programmed such that the SPC will complete bringing the radio out of low power mode near the time when the XO becomes ready (xtal_ready). RF_ACTIVE can also be programmed to assert at RF*_COEXT[RFACT_WKUP_DLY] after XO is enabled. Flags RF*_STAT[LP_WKUP_FLAG] and RF*_STAT[BLE_WKUP_FLAG] (with optional interrupts) are set after the lp_stop_ack (from SPC) de-asserts and at xo_en, respectively. The Bluetooth LE power controller moves to ACTIVE state in the cycle after lp_stop_req is de-assrted. If properly configured in RF*_CTRL[SFA_TRIG_EN], a trigger (sfa_meas) will be issued to the radio SFA after the Bluetooth LE power controller reaches the ACTIVE state. The Bluetooth LE power controller's state is reflected in RF*_STAT[BLE_STATE] for use as needed by software.

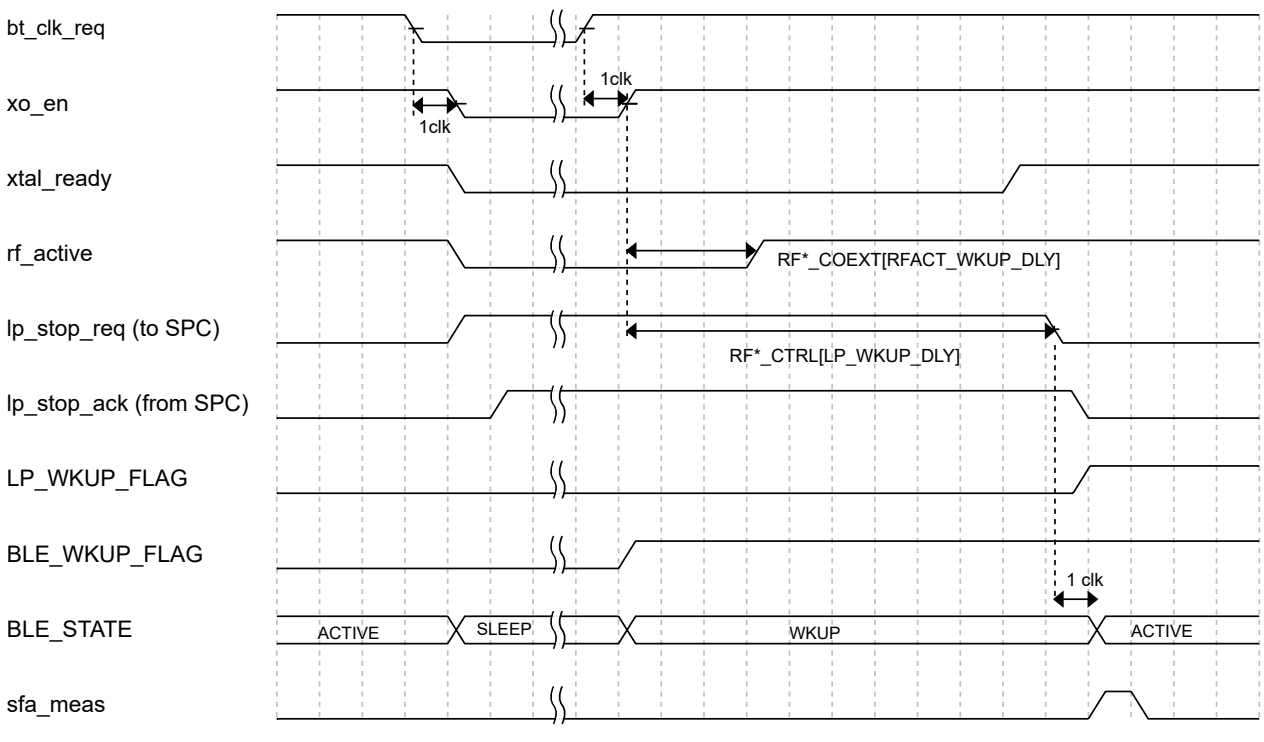

Figure 215. Low Power entr/exit for Bluetooth LE Power Controller

If for some reason the radio needs to be woken before the Bluetooth LE link layer is scheduled to assert bt_clk_req, the RF2p4GHz_CTRL[BLE_WKUP] bit can be set by software to wakeup the radio prematurely.

The Bluetooth LE power controller behavior is a bit different than the MAN and WOR power controllers. In particular

- The XO_CTRL[WKUP_OFFSET] bitfield is not used by the Bluetooth LE power controller. Instead the Bluetooth LE link layer has its own programmable bitfield "Osc_startup_delay" which is used to delay when the Bluetooth LE link layer switches timing control from the low power clock to the XO

- The Bluetooth LE power controller does not have a counter to keep track of the low power duration; that is handled in the Bluetooth LE link layer
- The BLE_WKUP_FLAG asserts at WKUP state, whereas the MAN_WKUP_FLAG and WOR_WKUP_FLAG assert at the end of the requested low power duration

55.3.5.3 Radio Coexistence

The 2.4GHz radio implements external IO signals to support coexistence with an external RF device operating within the same frequency band. The RFMC provides mux control (via RFMC's RF_GPO[7:0] output) for the coexistence outputs {RF_ACTIVE, RF_STATUS, and RF_PRIORITY[1:0]} from the 2.4GHz radio, provides additional control for the RF_ACTIVE signal, and provides control for the RF_NOT_ALLOWED coexistence input. The next few paragraphs discuss RFMC control of the RF_NOT_ALLOWED and RF_ACTIVE signals. For more information on coexistence refer to the Coexistence Interface and Coexistence/FEM/LANT connections sections of the Radio Control chapter.

For RF_NOT_ALLOWED, the RFMC provides programmable control (RF*_COEXT[RFNA_IE] bitfield) so that this coexistence signal can be sourced from any of 5 device pins, or disabled.

For RF_ACTIVE, the RFMC provides programmable control (RF*_COEXT[RFACT_SRC] bitfield) to select whether this coexistence output is sourced by the RFMC, the Bluetooth LE bt_clk_req signal, or a mux of the TSM's RF_ACTIVE signal and the active link layer's REQUEST signal. If RF_ACTIVE is sourced by the RFMC (RF*_COEXT[RFACT_SRC]=00), this signal relies on the RFMC’s low power controllers (one of the RFMC’s low power controllers should be enabled); in this configuration the RF_ACTIVE behavior is as follows:

- If RF*_COEXT[RFACT_IDIS]=0
  - Asserts during the RFMC low power controller's wakeup sequence, RF*_COEXT[RFACT_WKUP_DLY] 32kHz clock cycles after the XO is enabled
  - De-asserts when the RFMC low power controller requests that the radio enters a low power mode
  - Software can cause RF_ACTIVE to be asserted during a low power mode by setting the RF*_COEXT[RFACT_EN] bitfield
- If RF*_COEXT[RFACT_IDIS]=1
  - Asserts when the TSM is busy
  - De-asserts when the TSM is idle

Also related to RF_ACTIVE are the QUIET_REQ outputs. These also indicate when the radios are active, but are used inside the SOC to suppress SOC Core flash and/or RF Core flash activity if needed. These outputs have configurable behavior using the RF*_COEXT register's QREQ_SRC, QREQ_SOC_EN and QREQ_RF_EN bits.

55.3.5.4 Radio FEM Control

The RFMC provides mux control (via RFMC's RF_GPO[7:0] output) for the FEM (front-end module) signals {ANT_A, ANT_B, RX_SWITCH, and TX_SWITCH} from the 2.4GHz radio, but does not otherwise make use of, or affect these signals. For more information on these signals, refer to the Transceiver Localization and Antenna Control section of the Transceiver chapter and Coexistence/FEM/LANT connections sections of the Radio Control chapter.

55.3.5.5 Radio Localization Antenna Select

The RFMC provides mux control (via RFMC's RF_GPO[7:0] output) for the LANT_LUT_GPIO[3:0] (localization antenna select) signals from the 2.4GHz radio, but does not otherwise make use of, or affect these signals. For more information on these signals, refer to the Transceiver Localization and Antenna Control section of the Transceiver chapter and Coexistence/FEM/LANT connections sections of the Radio Control chapter.

55.3.5.6 Reset

The RFMC and 2.4GHz radio are reset on any system reset event or by setting the RFMC_CTRL[RFMC_RST] bit, with the exception of the following registers bits which are only reset on a POR/LVD event: RFMC_CTRL[RFMC_RST] (resets to 0) and RFMC_CTRL[RST_MSK] (resets to 0).

The RFMC can also generate software resets for the 2.4GHz radio via the RF*_CTRL[RF_POR], RF*_CTRL[RST] and RF*_CTRL[CPU_RST] bits. Setting RF*_CTRL[RF_POR], RF*_CTRL[RST], or RF*_CTRL[CPU_RST] will have no effect on the RFMC itself however. The reset associated with RF*_CTRL[CPU_RST], ipg_async_cpu_reset_lv, is used primarily to hold the CM3 core in reset for flash loading. The reset associated with RF*_CTRL[RF_POR], ipg_async_por_2p4GHz_b_lv, provides POR for the LV domain logic. On exit from Power Down or Deep Power Down low power modes, a signal from the SPC (spc_pd_pwrdwn_exit) asserts all of the LV resets.

There is also a RF*_CTRL[CPU_RST_LOCK] bit associated with the RF*_CTRL[CPU_RST]. If the CPU_RST_LOCK bit is set, the CPU_RST bit cannot be cleared until the next system reset (ipg_async_reset_1p8v). The lock bit is used by boot ROM code to force the radio CPU to remain in reset if the radio flash verification fails.

The radio also needs to be held off until the flash has finished its initialization (its IFR outputs are valid, and it is ready to accept read requests) after a reset. The radio flash output signal msf_core_hold is used by the RF_CMC module for this purpose: the RF_CMC delays de-assertion of the non-POR resets used by the radio.

For testing purposes, the RFMC and radio power domains can be isolated from system reset events by setting the RFMC_CTRL[RST_MSK] register bit. Note that the RFMC_CTRL[RFMC_RST] and RF*_CTRL[RST] register bits are still functional when the RFMC_CTRL[RST_MSK] bit is set.

The figure below illustrates reset bits and signals for the RFMC, RF_CMC and radio. The ipg_async_reset_rfmc_1p8v is an output from the RFMC to use to reset any other 1.8v logic in the radio power domain.

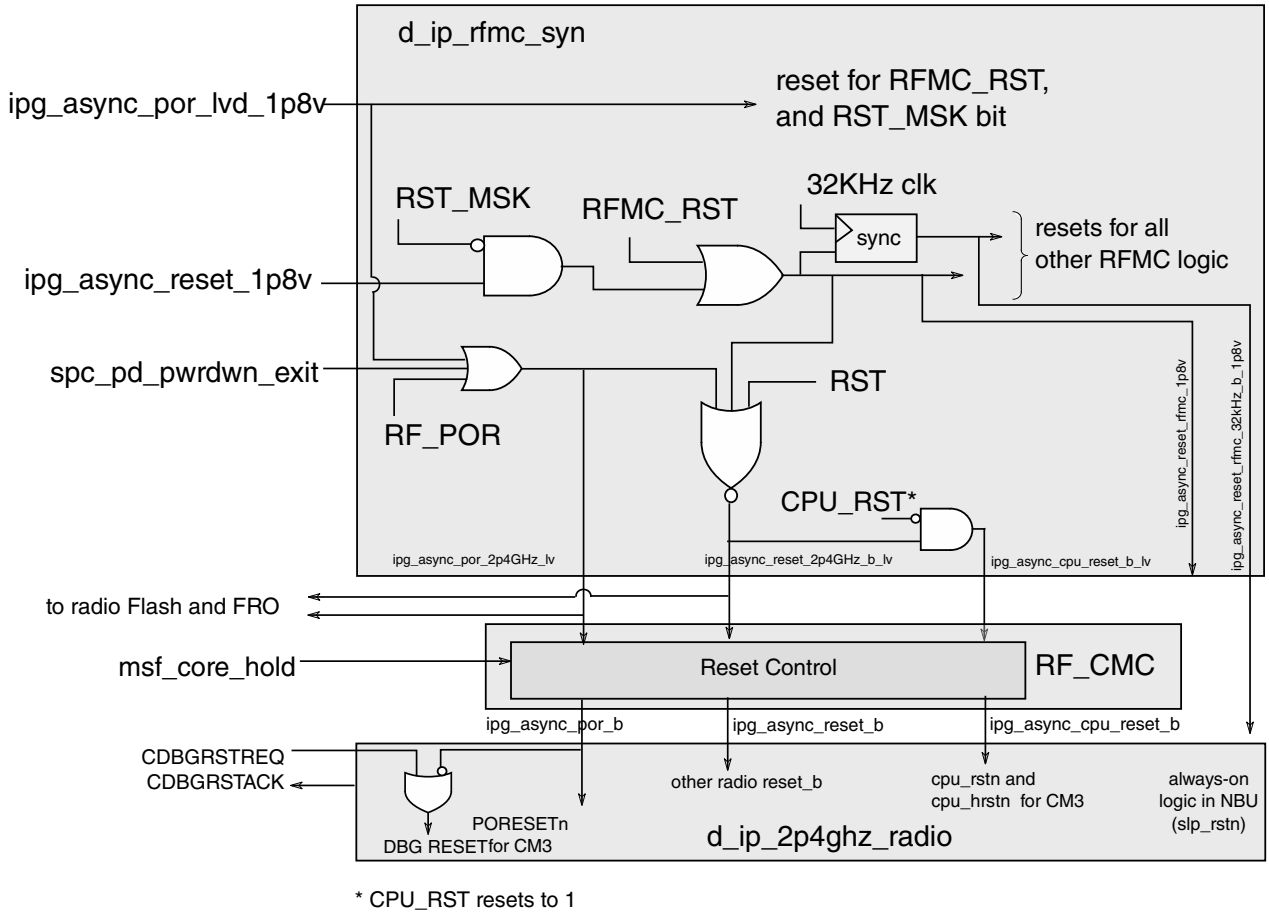

Figure 216. Reset

55.3.5.7 Interrupt and wake-up request

The RFMC generates an output for the SOC's interrupt controller (NVIC) and a wake-up request for the SOC's wake-up unit (WUU). As shown in the figure below, all enabled interrupt sources within the RFMC -- from the XO control and the 2.4GHz low power controllers -- are combined to generate the rfmc interrupt. The wake-up request for the WUU combines enabled interrupt requests from the Bluetooth LE, WOR and MAN low power controllers within the RFMC with interrupt requests from the 2.4GHz radio .

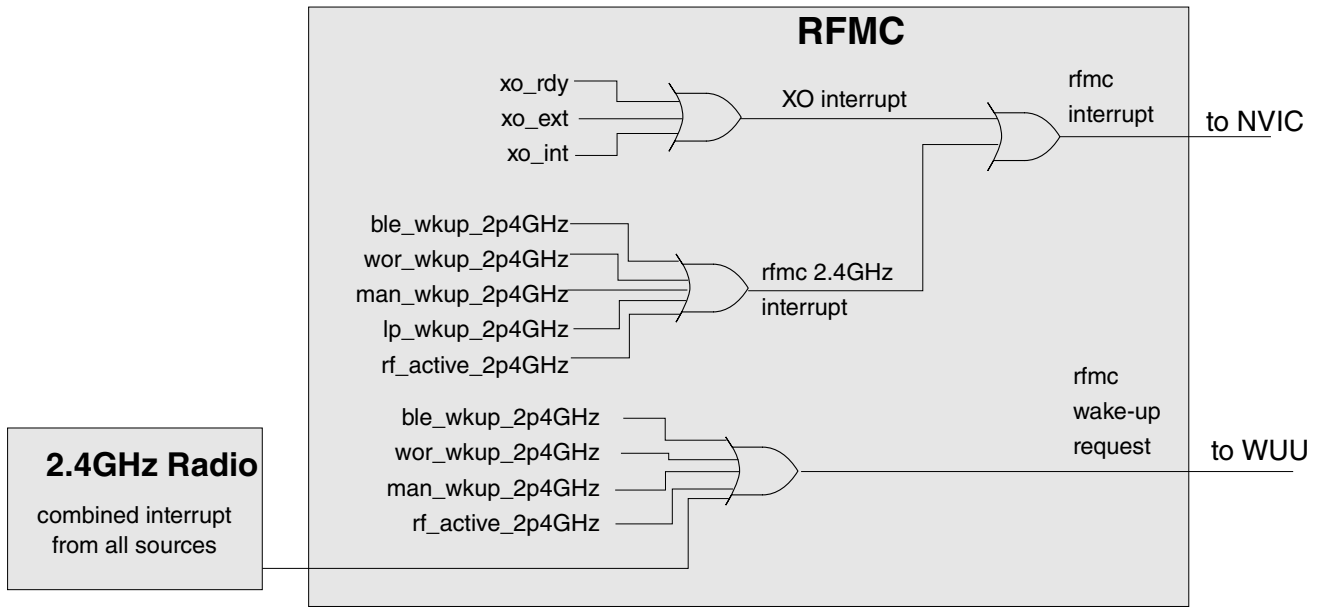

Figure 217. Interrupt and wake-up request

55.3.5.8 Power-on Sequence

After a POR/LVD event, the RFMC is released from reset, the 2.4GHz radio is powered up and released from reset, but the the XO is disabled and the NBU CPU is held in reset . The following steps are needed by software. (Note that steps 1-3 may optionally be supported by the SOC boot ROM.)

1. Configure the XO. Program the EXT_MODE, XTAL_REQ_OBE and other bits in the XO_CTRL register as needed
2. Set RF*_CTRL[XO_EN] to enable the XO, or enable of the RFMC's low power controllers to allow it to enable the XO.
3. Clear the RF*_CTRL[CPU_RST] bit to release the NBU CPU from reset.
4. Wait for XO_STAT[RDY_FLAG] to be set. An RFMC interrupt is also associated with this event. Software can access the radio modules which use the XO clock after the XO is ready. (Software can access the radio modules which use the radio FRO clock before the XO is ready.)

55.4 2.4GHz Radio

55.4.3 Bus Interfaces and Memory Map

The radio supports the following bus interfaces to allow software access to radio peirpherals and memories:

1. CM3 interface to the CM3 memories, the memory-mapped peripherals inside the NBU, access to the radio resources (Generic LL, XCVR, etc.) outside of the NBU via the radio's PBRIDGE, access to resources (radio flash, TPM2, RF_CMC, radio FRO192M) related to -- but outside of -- the radio via NBU PBRIDGE, and access to CM33 peripherals (e.g., DSB, EdgeLock Secure Enclave, SEMA42, and RFMC) via AXBS PBRIDGE0. (For a detailed list of peripherals accessible via PBRIDGE0, refer to the Peripheral Bridge section of the Core overview chapter of this Reference Manual.)
2. CM33 access some NBU resources, and NBU PBRIDGE resources. Note that this path only allows access to certain regions of the NBU/CM3 memory space, and (unlike #1 above) it is not allowed acess to the radio PBRIDGE or the AXBS's PBRIDGE0.
3. CM33 access to the radio PBRIDGE to access radio resources (Generic LL, XCVR, etc.) outside of the NBU
4. CM33 and CM3 access to RFMC registers. The CM3 access is via AXBS PBRIDGE0 (#1 above).

These buses are highlighted in the figure below.

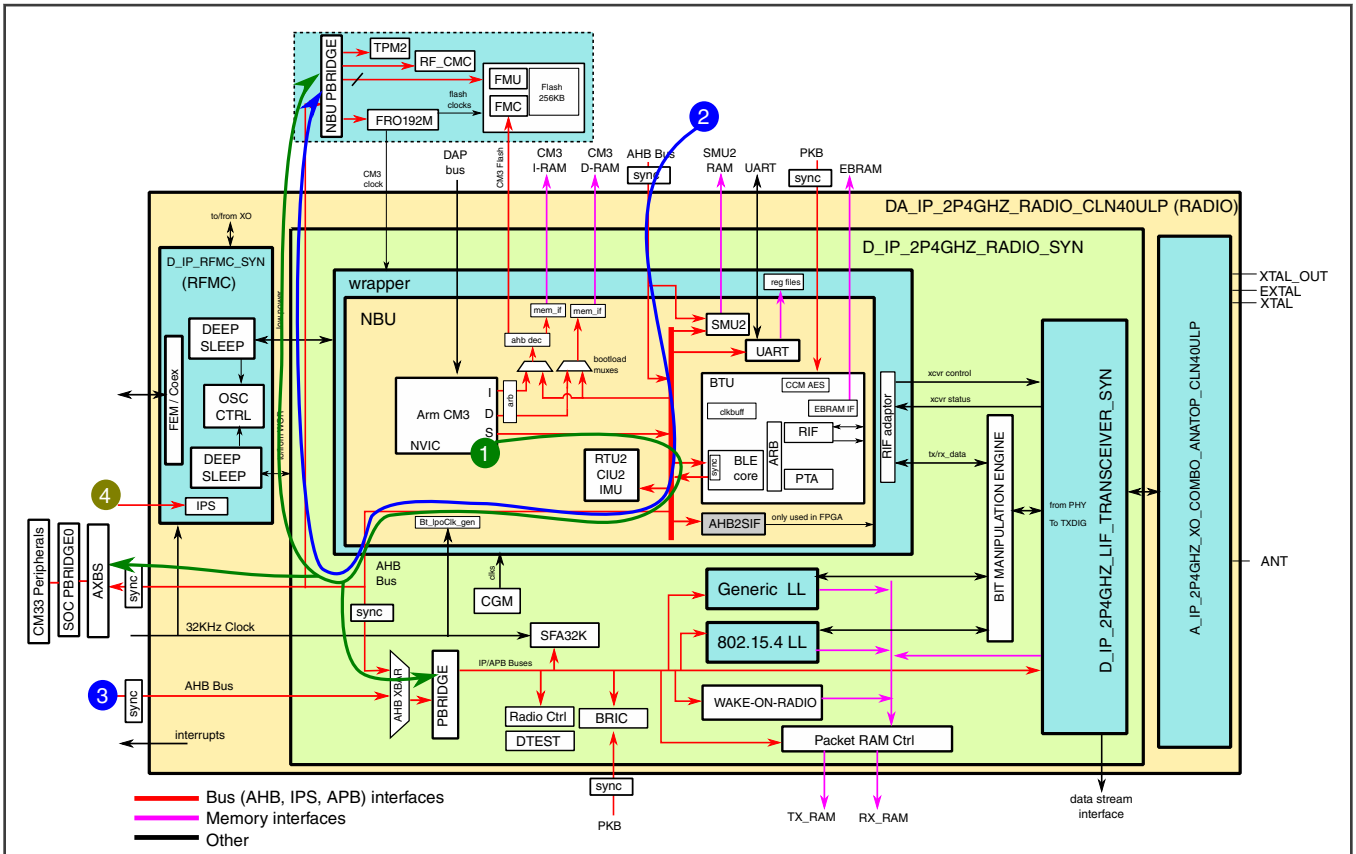

Figure 218. Radio Bus

The table below shows the radio memory space (excluding CM33 access to RFMC). The left columns show the CM3 memory space (#1 in previous figure). Columns to the right of that show the CM33 access via NBU (#2 in previous figure) and via the radio PBRIDGE (#3 in previous figure).

2. The CM3 Start Addr for the peripheral assigned to PBRIDGE0 slot "n" is 0xA9180000 + n * 0x1000. For a detailed list of peripherals accessible via PBRIDGE0, refer to the Peripheral Bridge section of the Core overview chapter of this Reference Manual.

55.4.4 Clocking

The radio uses the following clock sources:

- Radio XO: A 32MHz or 26MHz crystal is normally connected to the radio's XTAL and EXTAL pins, but a 32MHz or 26MHz clock input to EXTAL is also supported.
- Radio FRO192M: This 192MHz clock source is used to derive the clocks for the radio CM3, the radio flash and buses related to the NBU and radio flash.
- SOC 32.768kHz. This clock, from the SOC's CCM32K module, is used by the radio's "always on" logic and by the radio's SFA32K module.

The figure below shows the clock distribution, with focus on the NBU clocks. For the FRO clock outputs, the default output frequency to the NBU and PD_RF AHB, etc. is 32MHz, and the default output frequency for the flash APB and RF_CMC clock is 16MHz (with a maximum supported frequency of 24MHz).

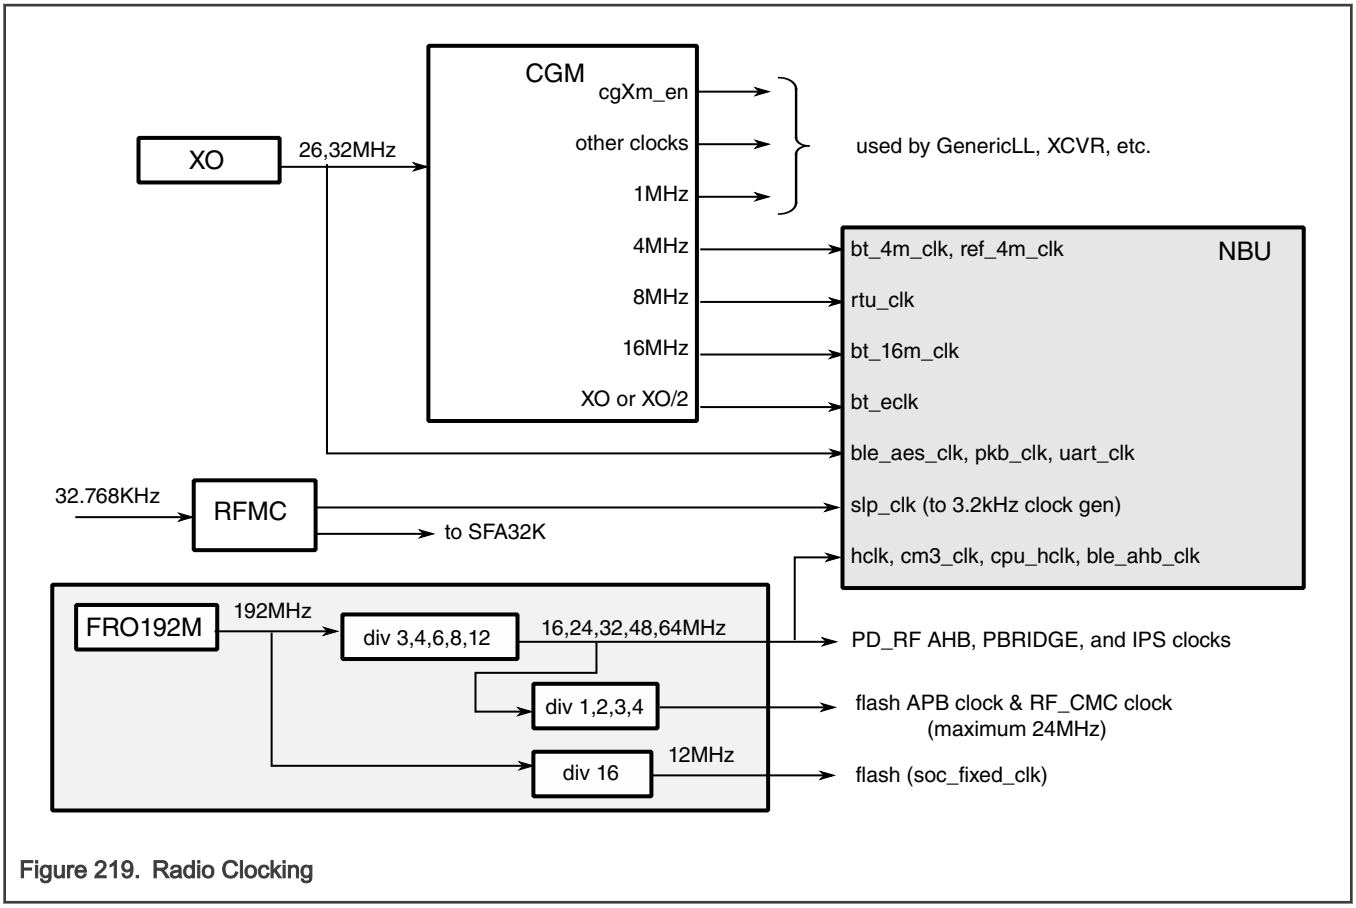

Figure 219. Radio Clocking

Inside the NBU, there is a module (bt_lpoClk_gen) which generates a 3.2KHz clock: in low power modes, this clock is derived from slp_clk (32.768KHz), while when not in low power mode the clock is derived from bt_4m_clk (4MHz).

The NBU's clock inputs are further described in the table below.

Table 398. NBU Clocks

NBU clock input	Source	Used in NBU by	Clock enabled by
cm3_hclk	FRO divider	CM3	RF_CLK_CTRL[CM3_HCLK_EN] & !cpu_sleeping & nbu_cm3_clock_en_mask[1]
cpu_hclk		flash/IMEM/ DMEM/buses	RF_CLK_CTRL[NBU_AHB_CLK_EN] & ((bt_clk_req & RF_CLK_CTRL[BT_CLK_REQ_EN]) || (!man_deep_sleep_enable & RF_CLK_CTRL[MAN_DS_EN]) || (!wor_deep_sleep_enable & RF_CLK_CTRL[WOR_DS_EN]) || ! cpu_cp15_sleep) & nbu_ahb_clock_en_mask[1]
hclk		AHB subsystem clock, SMU2, CIU2

rtu_clk	XO divider (8MHz)	RTU	RF_CLK_CTRL[RTU_CLK_EN] & bt_clk_req & btll[3]

Table continues on the next page...

Table 398. NBU Clocks (continued)

NBU clock input	Source	Used in NBU by	Clock enabled by
bt_4m_clk	XO divider (4MHz)	BTU	RF_CLK_CTRL[BT_4M_CLK_EN] & bt_clk_req & btll[3]
ref_4m_clk		lpoClk_gen	RF_CLK_CTRL[BT_REF_4M_CLK_EN] & btll[3]
ble_aes_clk	XO	AES	RF_CLK_CTRL[BLE_AES_CLK_REQ] & ble_aes_clk_req & btll[3]
nbu_pkb_clk		Private Key Bus	RF_CLK_CTRL[NBU_PKB_CLK_EN]
uart_clk		UART	RF_CLK_CTRL[UART_CLK_EN] & btll[3]
slp_clk	32.768kHz	lpoClk_gen	RFMC: RF2p4GHz_CTRL register: BLE_LP_EN | CLK_OVR[3]

1. from RF_CMC
2. selected by RF_CLK_CTRL[BT_ECLK_DIV]. Should be >=16MHz, so for XO=26MHz select XO while for XO=32MHz XO/2 can be selected
3. btll = btll_en & (LL_CTRL[ACTIVE_LL]==Bluetooth LE) | RF_CLK_CTRL[BTLL_CLK_EN_OVRD], where btll_en is an IFR bit

The other radio peripherals outside of the NBU use only clocks derived from the XO. The following table describes the 802.15.4 LL, Generic LL, and WOR clocks

Table 399. Link Layer and WOR Clocks

Module	Clock	Clock enabled by
802.15.4 LL	zigbee_tsm	(tsm_clk_en | zig_force_clk_on) & zbll[1]
802.15.4 LL	zigbee	!dsm_zig_deep_sleep_enable & zbll[1]
Generic LL	generic_tmr (1MHz)	generic_tmrload & !dsm_gen_deep_sleep_en & genll[2]
Generic LL	generic_500k (500kHz)	!dsm_gen_deep_sleep_en & genll[2]
Generic LL	generic_1m (1MHz or XO when requested for tmrload)	!dsm_gen_deep_sleep_en & genll[2]
WOR	clk_wor	wor_en
WOR	clk_wor_1m (1MHz)	(wor_en | wor_clk_xtend)
WOR	clk_wor_comp (1MHz or XO when requested for computing)	(wor_en | wor_clk_xtend)
WOR	clk_wor_timestamp	(wor_en | wor_clk_xtend) & wor_timstamp_clk_en
WOR	clk_wor_ww_1m (1MHz)	(wor_en | wor_clk_xtend) & ! wor_deep_sleep_enable

1. zbll = zbll_en & (LL_CTRL[ACTIVE_LL]==ZIGBEE) | RF_CLK_CTRL[ZBLL_CLK_EN_OVRD], where zbll_en is an IFR bit
2. genll = genll_en & (LL_CTRL[ACTIVE_LL]==GENERIC) | RF_CLK_CTRL[GENLL_CLK_EN_OVRD], where genll_en is an IFR bit

55.4.5 Radio interrupts and Wake-up request

The Radio can generate some asynchronous interrupts and one asynchronous MCU wakeup signal.

The interrupt configurations are illustrated in the diagram below and detailed in the following sections.

55.4.5.1 Interrupts and Wake-up request Diagram

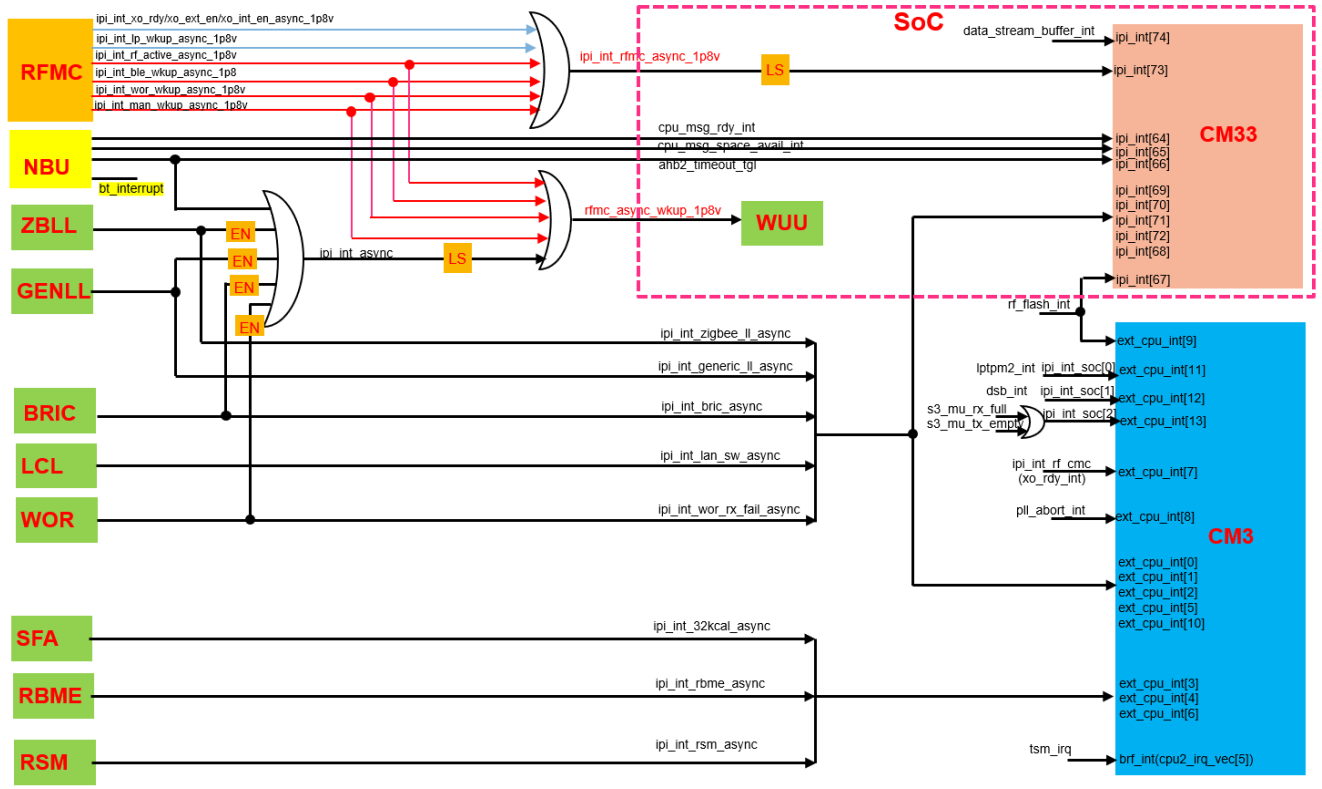

Figure 220. Radio Interrupts

55.4.5.2 Interrupt sources and connections

The radio interrupt sources and connections are summarized in the table below.

Table 400. Radio Interrupts

Interrupt Source	to NBU/CM3 NVIC	to SOC
sources inside the NBU used exclusively by CM3	connected inside the NBU	
NBU IMU interrupt to SOC Core (cpu_msg_rdy_int)		radio output to SOC Core NVIC
NBU IMU interrupt to SOC Core (cpu_msg_space_avail_int)		radio output to SOC Core NVIC
NBU timeout (ahb2_timeout_tgl)		radiout output to SOC Core NVIC *or* SOC RESET
Transceiver: TSM	connected inside radio to brf_int	
15.4 LL	connected inside radio to ext_cpu_int[0]	radio output to SOC Core NVIC
Generic LL	connected inside radio to ext_cpu_int[1]	radio output to SOC Core NVIC
BRIC	connected inside radio to ext_cpu_int[2]	radio output to SOC Core NVIC

Table continues on the next page...

Table 400. Radio Interrupts (continued)

Interrupt Source	to NBU/CM3 NVIC	to SOC
SFA32K	connected inside radio to ext_cpu_int[3]	
Transceiver: RBME	connected inside radio to ext_cpu_int[4]	
Transceiver: LCL_CTRL (lant_sw)	connected inside radio to ext_cpu_int[5]	radio output to SOC Core NVIC
Transceiver: Ranging Sequence Manager	connected inside radio to ext_cpu_int[6]	
RFMC		radio output to SOC Core NVIC
RF_CMC (XO ready)	connected inside radio to ext_cpu_int[7]	
Transceiver: PLL abort	connected inside radio to ext_cpu_int[8]	
Radio Flash FMU	radio input from PD_RF domain to ext_cpu_int[9]	PD_RF domain output to SOC Core NVIC
WOR (RX failure)	connected inside radio to ext_cpu_int[10]	radio output to SOC Core NVIC
TPM2 (in PD_RF domain)	radio input from PD_RF domain to ext_cpu_int[11]	
Data Stream Buffer (in SOC domain)	radio input from SOC domain to ext_cpu_int[12]	
EdgeLock Secure Enclave (in SOC domain) rx_full || tx_empty	radio input from SOC domain to ext_cpu_int[13]	
RFMC WUU_MxIF (OR of radio interrupts assigned to SOC Core)		radio output to SOC Core WWU

55.4.6.2 Wake On Radio

55.4.6.2.1 Introduction

The 2.4GHz Wake-On-Radio (WOR) Scheduler, is a new hardware automation block, intended to reduce radio and SoC dynamic power consumption, and facilitate radio frequency hopping.

55.4.6.2.1.1 Overview

The 2.4GHz Radio Wake-On-Radio Scheduler provides hardware automation for the insertion of the radio digital logic into Deep Sleep Mode (DSM), and subsequent DSM exit, as well as the sequencing of RF operations, both TX and RX, between DSM cycles, without MCU intervention. Wake-On-Radio (WOR) substantially increases the autonomy of the radio within the SoC, taking advantage of the separated power domains for the MCU and the Radio in the SoC, by providing sufficient hardware automation to ensure very long MCU low-power intervals, encompassing multiple RF operations, whenever possible. Two different scheduling methods are supported: Timeslot-based scheduling, and Constant-Interval scheduling. WOR also includes hardware automation for RF Frequency Hopping. WOR supports the radio's 802.15.4, and GENERIC_FSK protocol engine(s), and interfaces to the radio's RFMC (Radio Mode Controller) for the scheduling of DSM entry/exit. WOR divides future RF operations into "timeslots", which can occur at regularly-, or non-regularly-scheduled intervals. WOR provides a descriptor-based format for software to program timeslot information. WOR interacts with the protocol engines to dynamically manage radio interrupts, allowing link layer interrupts to propagate only when it is necessary to notify the MCU of required action.

55.4.6.2.1.2 Block Diagram

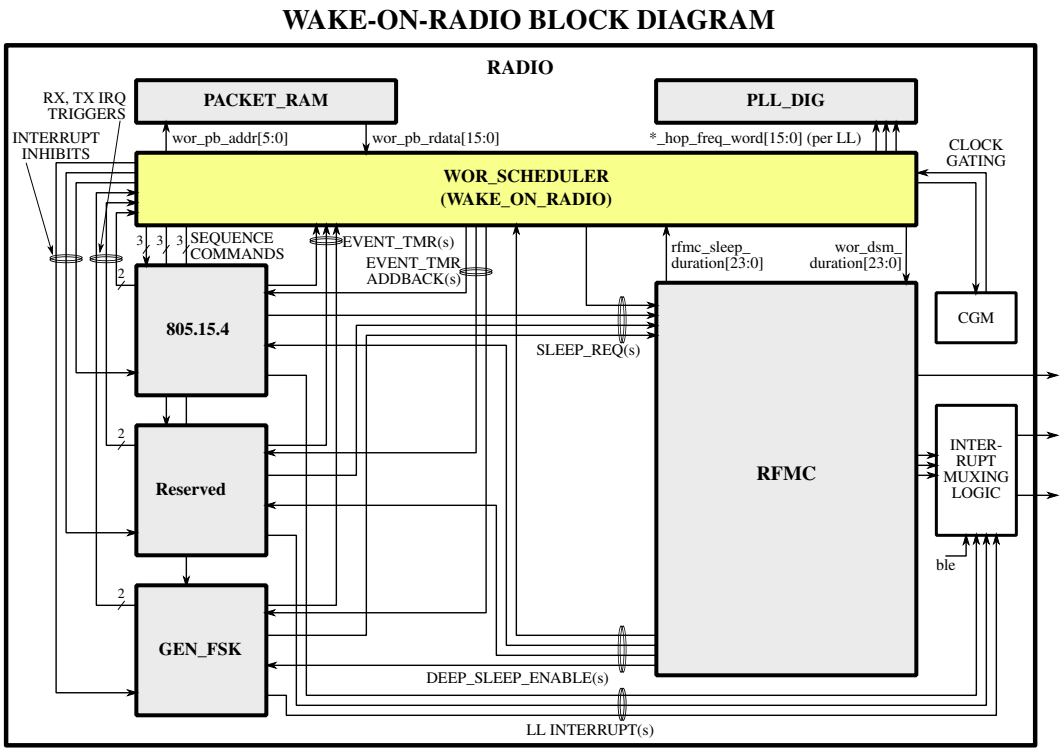

Figure 221. WAKE-ON-RADIO BLOCK DIAGRAM

55.4.6.2.2 Memory Map and Register Definition

Programmable registers to provide configuration and status for the Wake-On-Radio Scheduler are mapped into Transciever Address Space. WOR registers are described in the table below.

55.4.6.2.2.1 WOR register descriptions

55.4.6.2.2.1.1 WOR_ADDR memory map

WOR_REGS base address: 48A0_6100h

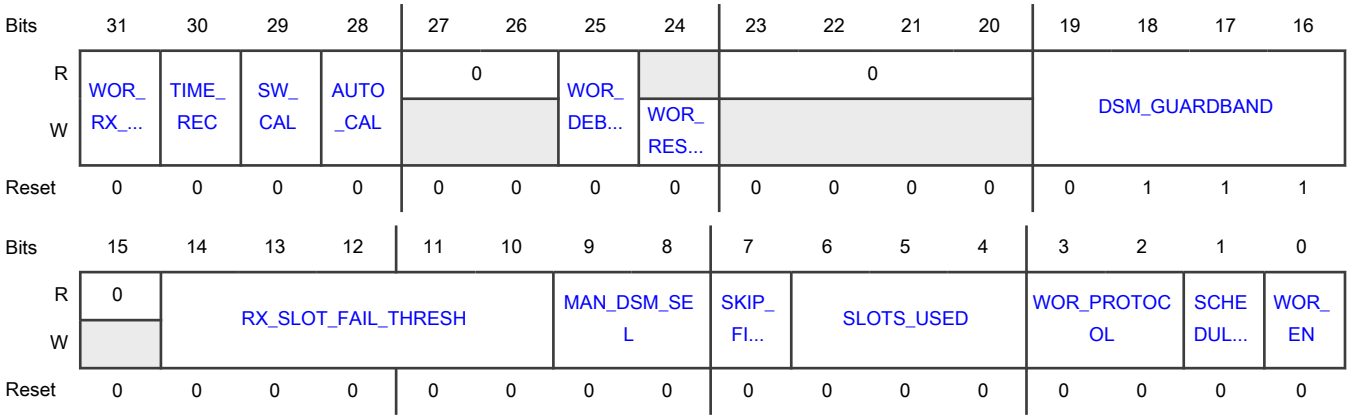
Register	Offset
CTRL	0h

Diagram



Fields

Field	Function
31 WOR_RX_FAIL_IRQ_EN	WOR_RX_FAIL_IRQ Enable 1: WOR_RX_FAIL_IRQ interrupt is enabled 0: WOR_RX_FAIL_IRQ interrupt is not enabled
30 TIME_REC	Enable the WOR HW to record the timing information to the Packet RAM. 1: Record the timing information to the Packet RAM 0: Do not record the timing information to the Packet RAM.
29 SW_CAL	Enable the WOR SW to calculate the drift. Only when AUTO_CAL is set. Software can calculate the drift based on the timing information stored in the Packet RAM. When AUTO_CAL is enabled, this calculated drift can override the HW result. 1: Enable the software drift override. 0: Disable the software drift override.
28 AUTO_CAL	Auto calculate and track the drift enable Enable the WOR HW to auto calculate the drift. For Constant-Interval mode only. 1: Enable the drift auto calculation. 0: Disable the drift auto calculation.

Table continues on the next page...

Table continued from the previous page...

Field	Function
27-26 —	Reserved
25 WOR_DEBUG_REG	WAKE-ON-RADIO Debug Register Enable WOR_DEBUG_REG alters the readback values of several read-only registers, for debug purposes. The registers which have a different readback value when WOR_DEBUG_REG=1 are: • TIMESTAMP1 • TIMESTAMP2 • TIMESTAMP3 See the description of those registers, which indicates their nominal, and debug-mode readback values.
24 WOR_RESUME	WAKE-ON-RADIO Resume This bit causes the WOR state machine to advance from its WAIT_RESUME state. The state machine will enter WAIT_RESUME on any slot in which an MCU wakeup occurs (based on descriptor WAKE_ON_COMPLETE and/or WAKE_ON_TIMEOUT fields). After waking up (interrupting) the MCU, WOR will hold in WAIT_RESUME, giving software whatever time it needs to complete all required activity. Software then sets WOR_RESUME=1, causing the state machine to break out of WAIT_RESUME, advance to the next slot, and enter DSM. This bit is write-only. Writes of '0' have no effect. Readback value is always 0. Setting WOR_RESUME has no effect if WOR state machine is not in WAIT_RESUME. 1: Causes WOR state machine to advance out of WAIT_RESUME state, and begin the next slot 0: No effect.
23-20 —	Reserved
19-16 DSM_GUARDBAND	WAKE-ON-RADIO DSM Guardband Determines the number of 32.768KHz clock cycles of guardband used by the WOR state machine in computing duration of the DSM for any slot. Increasing this setting by 1 LSB causes WOR to shorten the DSM duration by 1 32.768KHz clock cycle. This guardband takes into account synchronization, and other, delays within the RFMC, and ensures that DSM will wakeup will never occur "too late" with respect to the slot descriptor's START_TIME field. The current default setting is 7. Values below 7 should not be used.
15 —	Reserved
14-10 RX_SLOT_FAIL_THRESH	RX Slot Fail Thresh When the number of missed slot is equal to (RX_SLOT_FAIL_THRESH + 1), the WOR_RX_FAIL_IRQ is set.
9-8 MAN_DSM_SEL	Manual DSM Selector Assigning Manual DSM to a protocol is done by way of the MAN_DSM_SEL[1:0] register, as shown in the following table:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0: Manual DSM Not Assigned 1: Manual DSM Assigned to 802.15.4 2: Manual DSM Assigned to GENERIC_FSK
7 SKIP_FIRST_DSM	WAKE-ON-RADIO Skip DSM On First Slot Setting this bit causes the WOR State Machine to skip the DSM entry/exit cycle for the first SLOT (SLOT 0) encountered after setting SLOTS_USED > 0, regardless of the setting of the NO_DSM field of the slot's descriptor. Subsequent slots, including SLOT 0 when it is re-encountered, will enter/exit DSM based on the descriptor NO_DSM. The SKIP_FIRST_DSM feature is useful, especially in Constant Interval Scheduling mode, when the desire is to begin RF operations immediately (at the start of the first EVENT_INTERVAL), as programmed in the descriptor START_TIME, without waiting out a DSM cycle 1: WOR skips DSM entry/exit on the first SLOT 0 after setting SLOTS_USED > 0, regardless of descriptor NO_DSM 0: WOR always obeys descriptor NO_DSM **Note:** SKIP_FIRST_DSM should not be used if the SLOT 0 descriptor FUNCTION is set to "NO_RF".
6-4 SLOTS_USED	WAKE-ON-RADIO Number Of Slots Used Determines the number of timeslots used to schedule future DSM and RF operations, for either scheduling mode. Up to 4 timeslots can be enabled. Increasing the number of timeslots used decreases average power consumption. Valid values are 0 ≤ SLOTS_USED ≤ 4. The SLOTS_USED register is the mechanism by which the WOR state machine is activated and de-activated. Setting SLOTS_USED to 0 disables the WOR state machine and puts the WOR functionality in an IDLE state. A subsequent write of a non-zero value to SL0TS_USED activates the state machine, initializing to SLOT 0, and starts a new WOR "session".
3-2 WOR_PROTOCOL	WAKE-ON-RADIO Protocol Selector Assigns the Wake-On-Radio function to one of the radio's protocol engines. 0: Not assigned 1: Assigned to 802.15.4 2: Assigned to GENERIC_FSK 3: Reserved
1 SCHEDULING_MODE	WAKE-ON-RADIO Scheduling Mode Determines the scheduling mode used by the WOR HW to organize future DSM and RF operations. 1: Constant-Interval Scheduling mode. 0: Timeslot Scheduling mode.
0 WOR_EN	WAKE-ON-RADIO Enable Wake-On-Radio Master Enable. In addition to enabling the block function, this bit gates the clock to the WOR module. This bit should be set, and remain set, whenever WOR is in use. 1: Wake-On-Radio is enabled. 0: Wake-On-Radio is disabled, and clocks to the module are gated off.

55.4.6.2.2.1.3 WAKE-ON-RADIO TIMEOUT REGISTER (TIMEOUT)

Offset

Register	Offset
TIMEOUT	4h

R	RECEIVE_TIMEOUT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 WOR_SLOT_COUNT	WAKE-ON-RADIO Absolute Slot Count This read-only register indicates the number of slots that have elapsed since SLOTS_USED was set to a non-zero value to activate the WOR state machine. WOR_SLOT_COUNT can be considered an Absolute Slot Number. WOR_SLOT_COUNT counts slots up to a maximum of 255. If the number of elapsed slots exceeds 255, WOR_SLOT_COUNT will remain at 255. WOR_SLOT_COUNT is "sticky" in the sense that it will hold its value after the WOR session has ended by setting SLOTS_USED=0; WOR_SLOT_COUNT will clear to 0 when a new WOR session is started by taking SLOTS_USED from 0 to any non-zero value.
23-16 WAKE_ON_NTH_SLOT	WAKE-ON-RADIO Force Wake On Nth Slot If the WAKE_ON_COMPLETE bit is not set in any descriptor, WOR will not awaken the MCU even after a number of good packets are received. Additionally, if WAKE_ON_TIMEOUT is also not set in any descriptor, WOR will not wake up the MCU under any circumstances, which would not be desirable. This register provides a backup method to awaken the MCU, after *N+1* slots have elapsed, where *N* = WAKE_ON_NTH_SLOT[7:0], regardless of whether or not any good packets have been received, and regardless of the setting of the WAKE_ON_* descriptor bits. Applies to Constant-Interval Mode only. (For Timeslot mode, at least one slot *must* have a WAKE_ON_* bit set in its descriptor).
15-0 RECEIVE_TIMEOUT	WAKE-ON-RADIO Receive Timeout For any RX slot, determines how long RX stays on after the descriptor's START_TIME is reached, in microseconds. A timeout is declared if a good packet is not received before the expiration of this time period (START_TIME + RECEIVE_TIMEOUT + WINDOW_WIDENING). Applies to TIMESLOT mode only.

55.4.6.2.2.1.4 WAKE-ON-RADIO TIMESTAMP 1 (TIMESTAMP1)

Offset

Register	Offset
TIMESTAMP1	8h

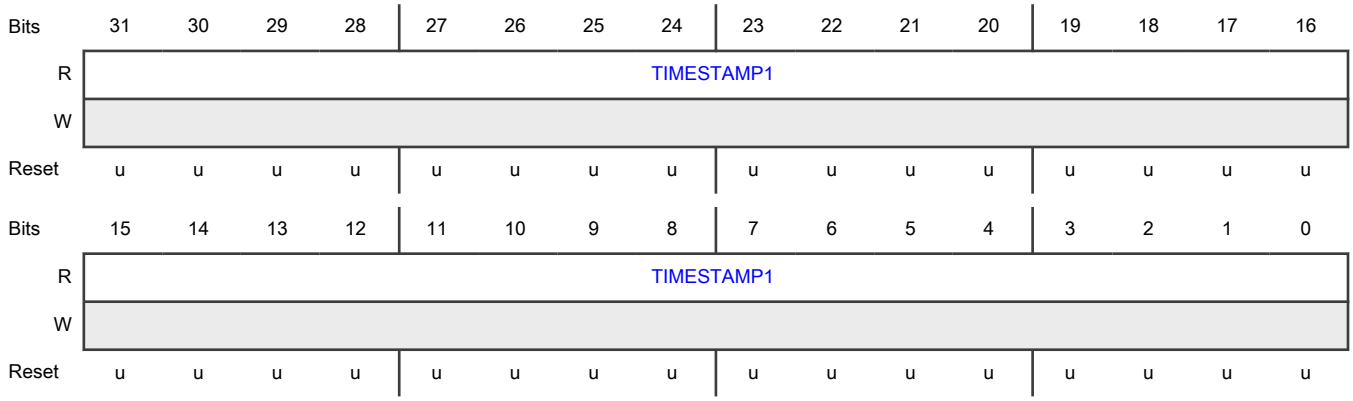
Function

Timestamp captured for a packet received on SLOT 1. During SLOT 1, any valid Access Address or SFD detection will result in the contents of the respective Link Layer's Event Timer being captured into this register at the instant of detection (there is no offset applied). TIMESTAMP1 remains "sticky" until a new AA or SFD detection occurs, during either the same, or a subsequent, SLOT 1.

Note: Timestamp for SLOT 0 is captured into the respective Link Layer's TIMESTAMP register (external to WOR), and can be read from that Link Layer's address space.

Note: If WOR_DEBUG=1, this register instead reads back WOR_ADDBACK[27:0], which is the number of microseconds that the WOR state machine "added back" to the assigned Link Layer's Event Timer, to correct for the amount of time that Link Layer was in DSM (Event Timer frozen). The WOR_ADDBACK readback value applies to the most recently-completed DSM cycle.

Diagram



Fields

Field	Function
31-0 TIMESTAMP1	WAKE-ON-RADIO TIMESTAMP1 Timestamp captured for a packet received on SLOT 1. During SLOT 1, any valid Access Address or SFD detection will result in the contents of the respective Link Layer's Event Timer being captured into this register at the instant of detection (there is no offset applied). TIMESTAMP1 remains "sticky" until a new AA or SFD detection occurs, during either the same, or a subsequent, SLOT 1.

55.4.6.2.2.1.5 WAKE-ON-RADIO TIMESTAMP 2 (TIMESTAMP2)

Offset

Register	Offset
TIMESTAMP2	Ch

Function

Timestamp captured for a packet received on SLOT 2. During SLOT 2, any valid Access Address or SFD detection will result in the contents of the respective Link Layer's Event Timer being captured into this register at the instant of detection (there is no offset applied). TIMESTAMP2 remains "sticky" until a new AA or SFD detection occurs, during either the same, or a subsequent, SLOT 2.

Note: Timestamp for SLOT 0 is captured into the respective Link Layer's TIMESTAMP register (external to WOR), and can be read from that Link Layer's address space.

Note: If WOR_DEBUG=1, this register instead reads back WW_DSM_ADJUST[23:0], which is the accumulated DSM component of the Window Widening adjustment value that is used to offset the start and end of receive operations during the timeslot.

Diagram

Field	Function
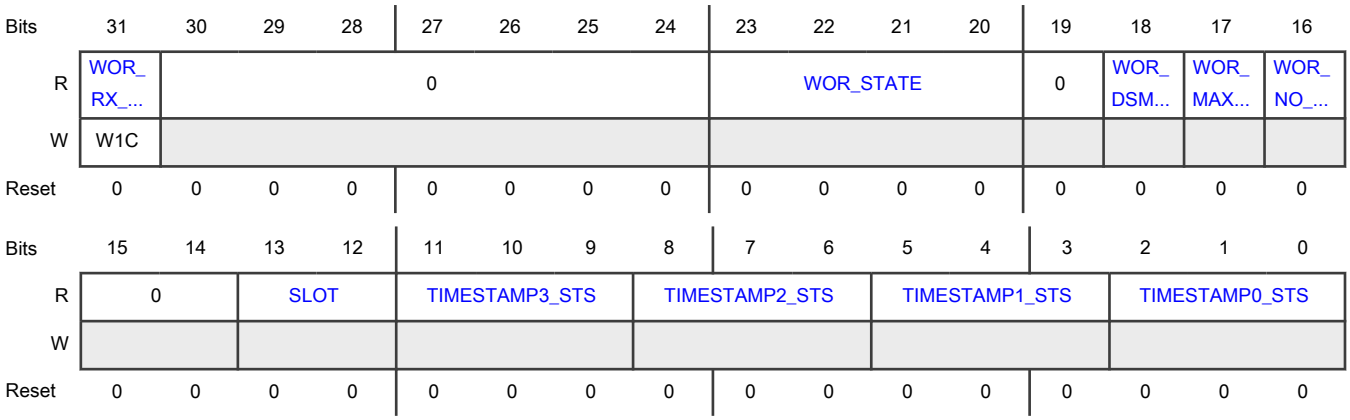
31-0 TIMESTAMP3	WAKE-ON-RADIO TIMESTAMP3 Timestamp captured for a packet received on SLOT 3. During SLOT 3, any valid Access Address detection or SFD detection will result in the contents of the respective Link Layer's Event Timer being captured into this register at the instant of detection (there is no offset applied). TIMESTAMP3 remains "sticky" until a new AA or SFD detection occurs, during either the same, or a subsequent, SLOT 3.

55.4.6.2.2.1.7 WAKE-ON-RADIO STATUS REGISTER (STATUS)

Offset

Register	Offset
STATUS	14h

Diagram



Fields

Field	Function
31 WOR_RX_FAIL_IRQ	WOR RX Fail Interrupt Flag Will assert when the number of missed slot is equal to RX_SLOT_FAIL_THRESH.
30-24 —	Reserved
23-20 WOR_STATE	WAKE-ON-RADIO Current State This read-only register reflects the instantaneous state of the Wake-On-Radio state vector. A listing of the Wake-On-Radio states, along with the associated state vector, is below: • DISABLED (0) • COMP_DURATION1 (1) • COMP_DURATION2 (2) • COMP_DURATION3 (10) • SLEEP_REQ (3) • IN_DSM (4) • COMP_ADDBACK (5) • COMP_WW (6)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• WAIT_SEQ_START (7) • WAIT_SEQ_END (8) • WAIT_RESUME (9)
19 —	Reserved
18 WOR_DSM_EXIT_FLAG	WAKE-ON-RADIO Early DSM Exit Flag This read-only flag indicates that, in the current slot, an event external to the radio has forced an early exit from DSM, before the WOR-computed DSM duration has expired. The WOR_IRQ (WAKE_IRQ) interrupt inside the assigned Link Layer will become set under these conditions, and this flag indicates that the reason for WOR_IRQ was due to an "DSM Early Exit wakeup", as described by the conditions above. The WOR_IRQ will become set, and the MCU awakened, even if the slot descriptor's WAKE_ON_COMPLETE and WAKE_ON_TIMEOUT bits are both set to 0. The WOR state machine is holding in the WAIT_RESUME state, and once software has completed all activities pursuant to the "DSM Early Exit wakeup", software must set WOR_RESUME to advance to the next slot.
17 WOR_MAX_SLOT_FLAG	WAKE-ON-RADIO Maximum Slot Count Reached Flag This read-only flag indicates that, in the current slot, the following conditions have all been met: 1. SCHEDULING_MODE is set to 1 (Constant Interval) 2. WOR_SLOT_COUNT[7:0] (absolute slot number) has matched WAKE_ON_NTH_SLOT[7:0] The WOR_IRQ (WAKE_IRQ) interrupt inside the assigned Link Layer will become set under these conditions, and this flag indicates that the reason for WOR_IRQ was due to a "Maximum Slot Reached wakeup", as described by the conditions above. The WOR_IRQ will become set, and the MCU awakened, even if the slot descriptor's WAKE_ON_COMPLETE and WAKE_ON_TIMEOUT bits are both set to 0. The WOR state machine is holding in the WAIT_RESUME state, and once software has completed all activities pursuant to the "Maximum Slot Reached wakeup", software must set WOR_RESUME to advance to the next slot
16 WOR_NO_RF_FLAG	WAKE-ON-RADIO NO_RF Slot Flag This read-only flag indicates that, in the current slot, the following conditions have all been met: 1. The slot's descriptor FUNCTION is set to "NO_RF" 2. A DSM cycle has just completed (exited) during the slot 3. The slot's descriptor WAKE_ON_COMPLETE bit was set (or the WOR_SLOT_COUNT matched WAKE_ON_NTH_SLOT), requiring an MCU wakeup. The WOR_IRQ (WAKE_IRQ) interrupt inside the assigned Link Layer will become set under these conditions, and this flag indicates that the reason for WOR_IRQ was due to a "NO_RF wakeup", as described by the conditions above. The WOR state machine is holding in the WAIT_RESUME state, and once software has completed all activities pursuant to the "NO_RF wakeup", software must set WOR_RESUME to advance to the next slot
15-14	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
13-12 SLOT	WAKE-ON-RADIO Current Slot This read-only register reflects the instantaneous state of the WOR's SLOT counter, indicating which SLOT is currently in service by the WOR state machine. Software can determine which of the 4 descriptors is currently in effect based on this register.
11-9 TIMESTAMP3_STS	WAKE-ON-RADIO Timestamp 3 Status This read-only register comprises 3 bits which convey information about the validity of the TIMESTAMP3 register contents: **TIMESTAMP3_STS[0]** -- "AA/SFD Status". If set, this bit indicates at least 1 AA or SFD detection occured during the current, or most recent, SLOT 3 RX operation, and therefore a timestamp, valid or not, was captured into the TIMESTAMP3 register. **TIMESTAMP3_STS[1]** -- "CRC Status". If set, this bit indicates a packet was received which passed CRC verification during the current, or most recent, SLOT 3 RX operation **TIMESTAMP3_STS[2]** -- "Filter Status". If set, this bit indicates a packet was received which passed Packet Filtering rules during the current, or most recent, SLOT 3 RX operation
8-6 TIMESTAMP2_STS	WAKE-ON-RADIO Timestamp 2 Status This read-only register comprises 3 bits which convey information about the validity of the TIMESTAMP2 register contents: **TIMESTAMP2_STS[0]** -- "AA/SFD Status". If set, this bit indicates at least 1 AA or SFD detection occured during the current, or most recent, SLOT 2 RX operation, and therefore a timestamp, valid or not, was captured into the TIMESTAMP2 register. **TIMESTAMP2_STS[1]** -- "CRC Status". If set, this bit indicates a packet was received which passed CRC verification during the current, or most recent, SLOT 2 RX operation **TIMESTAMP2_STS[2]** -- "Filter Status". If set, this bit indicates a packet was received which passed Packet Filtering rules during the current, or most recent, SLOT 2 RX operation
5-3 TIMESTAMP1_STS	WAKE-ON-RADIO Timestamp 1 Status This read-only register comprises 3 bits which convey information about the validity of the TIMESTAMP1 register contents: **TIMESTAMP1_STS[0]** -- "AA/SFD Status". If set, this bit indicates at least 1 AA or SFD detection occured during the current, or most recent, SLOT 1 RX operation, and therefore a timestamp, valid or not, was captured into the TIMESTAMP1 register. **TIMESTAMP1_STS[1]** -- "CRC Status". If set, this bit indicates a packet was received which passed CRC verification during the current, or most recent, SLOT 1 RX operation **TIMESTAMP1_STS[2]** -- "Filter Status". If set, this bit indicates a packet was received which passed Packet Filtering rules during the current, or most recent, SLOT 1 RX operation
2-0	WAKE-ON-RADIO Timestamp 0 Status This read-only register comprises 3 bits which convey information about the validity of the TIMESTAMP0 register contents:

Table continues on the next page...

Table continued from the previous page...

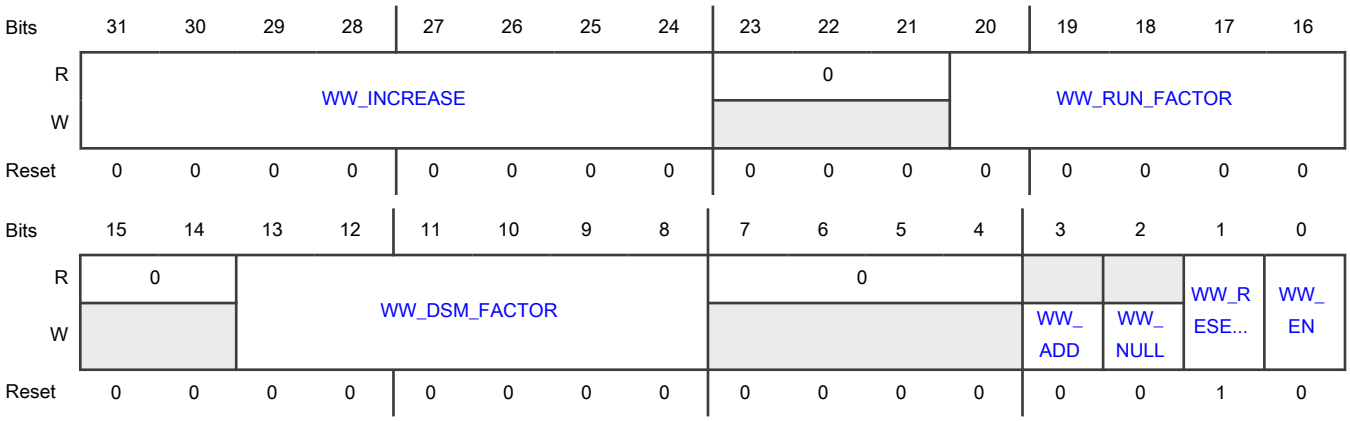
Field	Function
TIMESTAMP0_STS	**TIMESTAMP0_STS[0]** -- "AA/SFD Status". If set, this bit indicates at least 1 AA or SFD detection occured during the current, or most recent, SLOT 0 RX operation, and therefore a timestamp, valid or not, was captured into the TIMESTAMP0 register. **TIMESTAMP0_STS[1]** -- "CRC Status". If set, this bit indicates a packet was received which passed CRC verification during the current, or most recent, SLOT 0 RX operation **TIMESTAMP0_STS[2]** -- "Filter Status". If set, this bit indicates a packet was received which passed Packet Filtering rules during the current, or most recent, SLOT 0 RX operation **Note:** TIMESTAMP0 register (timestamp for SLOT 0) is captured into the assigned Link Layer's TIMESTAMP register (external to WOR), and can be read from that Link Layer's address space. However TIMESTAMP0_STS[2:0], which applies to that register, resides in WOR address space.

55.4.6.2.2.1.8 WINDOW-WIDENING CONTROL REGISTER (WW_CTRL)

Offset

Register	Offset
WW_CTRL	18h

Diagram



Fields

Field	Function
31-24 WW_INCREASE	Window-widening Manual Increase Amount This register allows software to increase (add to) the HW-computed window-widening adjustment. This incremental amount is added whenever a 1 is written to the WW_ADD register bit. The units of WW_INCREASE[7:0] are microseconds. It is an unsigned (positive only) addition. This is a one-time only addition (whever WW_ADD is set), and the window-widening adjustment value continues to accumulate

Table continues on the next page...

Table continued from the previous page...

Field	Function
	after the increment. The capability to add to the HW-computed adjustment is intended for contingency or debug purposes only, as the HW-computed value should be accurate.
23-21 —	Reserved
20-16 WW_RUN_FACTOR	Window-widening Runtime Factor Determines the rate of Window-widening that applies during RUNTIME (Reference Oscillator On). This setting should be based on the combined Sleep Clock Accuracy (SCA) of the Master + Slave. Each LSB is worth 64ppm of SCA drift. Valid values are 0 -> 16. The lower this factor, the greater the power savings.
15-14 —	Reserved
13-8 WW_DSM_FACTOR	Window-widening DSM Factor WW_DSM_FACTOR[5:0]: Determines the rate of Window-widening that applies during DSM (Reference Oscillator Off). This setting should be based on the combined Sleep Clock Accuracy (SCA) of the Master + Slave. Each LSB is worth 16ppm of combined SCA drift. Valid values are 0 -> 63. The lower this factor, the greater the power savings.
7-4 —	Reserved
3 WW_ADD	Window-widening Add Command This bit allows software to increase (add to) the HW-computed window-widening adjustment. The incremental amount is determined by the WW_INCREASE[7:0] register. The capability to add to the HW-computed adjustment is intended for contingency or debug purposes only, as the HW-computed value should be accurate. This bit is write-only. Readback value is always 0. 1: Increase the HW-computed window-widening adjustment by amount WW_INCREASE[7:0]. 0: No effect
2 WW_NULL	Window-widening Null Command This bit allows software to reset the accumulated window-widening adjustment to 0. This bit is write-only. Readback value is always 0. 1: Reset the accumulated window-widening adjustment to 0. 0: No effect.
1 WW_RESET_ON_RX	Window-widening Reset on Received Good Packet Enable a good packet reception to reset the accumulated window-widening adjustment to 0. A good packet is one that passes CRC verification, and passes packet filtering rules. Filtering rules vary by protocol. 1: Allow good packet reception to reset window-widening adjustment. This is the default. 0: Block good packet reception from resetting window-widening adjustment.

Table continues on the next page...

Table continued from the previous page...

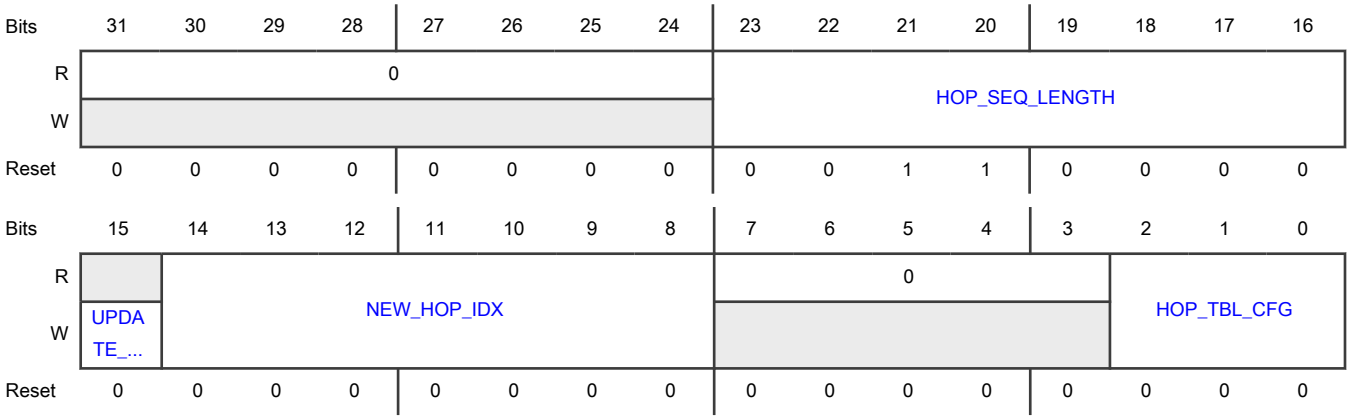
Field	Function
0 WW_EN	Window-widening Enable Master Enable for Window Widening. Typically, only slave devices employ window widening. 1: Window Widening is enabled. 0: Window Widening is disabled.

55.4.6.2.2.1.9 FREQUENCY HOP CONTROL REGISTER (HOP_CTRL)

Offset

Register	Offset
HOP_CTRL	1Ch

Diagram



Fields

Field	Function

55.4.6.2.3 Functional Description

55.4.6.2.3.1 Assign To Protocol

The 2.4GHz radio supports multiple protocols, each with its own protocol engine. All protocols can benefit from scheduling in advance several RF operations and DSM cycles, with the radio conducting the successive operations autonomously, allowing the MCU to remain in low power state for the duration. This is the concept behind Wake-On-Radio (WOR).

The WOR function can be assigned to any one of the following protocol(s): 802.15.4, GENERIC_FSK. (Bluetooth LE has its own, internal DSM and wake-on-radio control scheme, as well as hardware-controlled frequency hopping, built into the IP, so it does not interact with the WOR Scheduler).

Assigning WOR to a protocol is done by way of the WOR_PROTOCOL register, as shown in the following table:

WOR_PROTOCOL[2:0]	ASSIGNED PROTOCOL ENGINE
0	Not Assigned

Table continues on the next page...

Table continued from the previous page...

WOR_PROTOCOL[2:0]	ASSIGNED PROTOCOL ENGINE
1	802.15.4
2	GENERIC_FSK
3	Reserved

Assigning to protocol means that the assigned Link Layer's WOR interface signals are routed, exclusively, to and from the WOR state machine. WOR interface signals include the event timers, sequence start- and stop-command signals, interrupt inhibits, and event timer addback commands. These interface signals are covered in more details in later sections.

The following diagram illustrates how 1 of the 3 WOR-capable Link Layers is assigned to the WOR function:

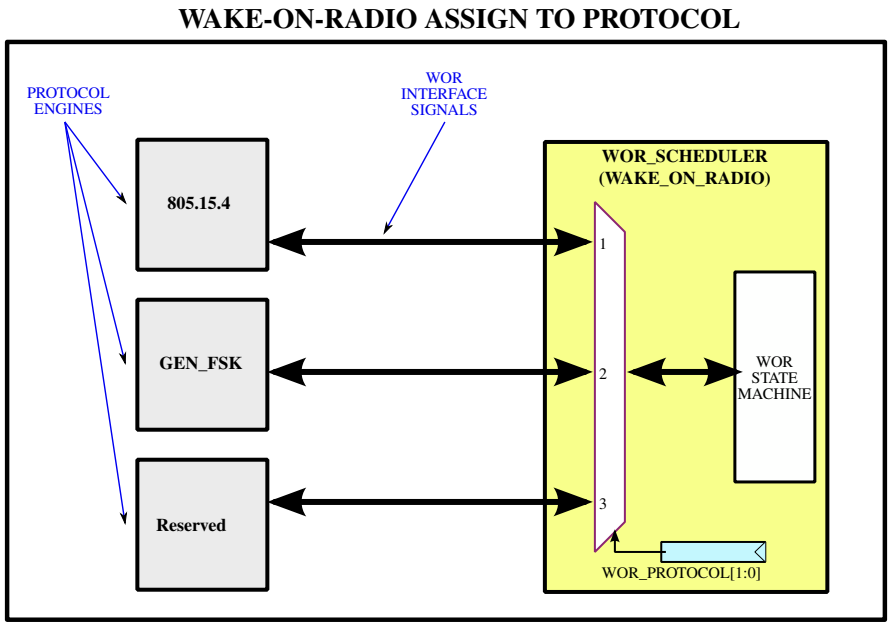

Figure 222. WAKE-ON-RADIO ASSIGN TO PROTOCOL

In a multi-protocol setting, assigning a protocol to Wake-On-Radio does not mean that unassigned protocols are incapable of DSM. There is a back-up method, Manual DSM, which uses software-driven DSM entry and exit. In a multi-protocol setting, any 2 of the radio's protocols can be assigned to different DSM control scheme, with the control schemes being Wake-On-Radio, Manual DSM, and Bluetooth LE DSM.

55.4.6.2.3.2 Scheduling Modes

For maximum flexibility in scheduling future RF operations and Deep Sleep cycles, Wake-On-Radio (WOR) defines 2 scheduling modes: Timeslot Mode, and Constant Interval Mode. These modes are described in the sections below.

Timeslot Mode

Timeslot mode is desirable when the schedule for RF transactions is sporadic, varies over time, or is otherwise non-periodic. Timeslot mode is based loosely on the TSCH (Timeslotted Channel Hopping) concept, first defined in IEEE Std 802.15.4-2015. Key principles of TSCH are adopted by WOR, but far short of full adherence.

In TSCH, time is divided into slots of fixed duration. Slots are grouped into slotframes, containing fixed number of slots. Once a TSCH PAN (network) is established, slotframes will repeat forever, back-to-back. Devices can be assigned to 1 or more slots

within a slotframe. For any given device on any given slot, the assigned slot can be TX or RX. One device can be assigned to transmit in a given slot; another device can be assigned to receive in the same slot. Assigning Device A to Transmit, and Device B to Receive, in the same slot, creates a link. Links can be dedicated (one TX and one RX device assigned). Or, links can be shared (multiple TX devices, using CSMA, and multiple RX devices). Typically, each slot uses a different hop frequency.

Slotframes are TDMA structures, with time on one axis and hop frequency on the other. The diagram below shows one "row" of a typical slotframe, with links established for Devices A, B, and C, all on the same hop frequency. This slotframe consists of 3 timeslots: TS0, TS1, and TS2.

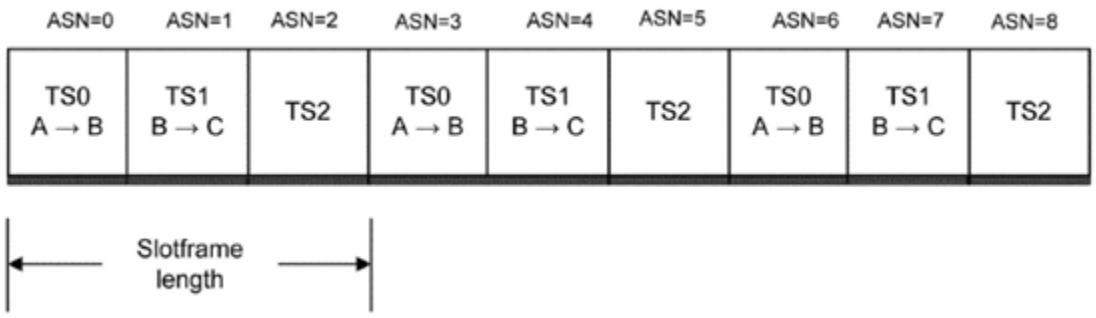

Figure 223. IEEE Std 802.15.4 TSCH 1-D SLOTFRAME

Another diagram below, shows a slotframe of 2 dimensions. The time axis has 100 slots, and the frequency axis has 4 indices into a table of available hop frequencies. Devices A, B, C, and D are assigned to various slots, and links are created amongst them.

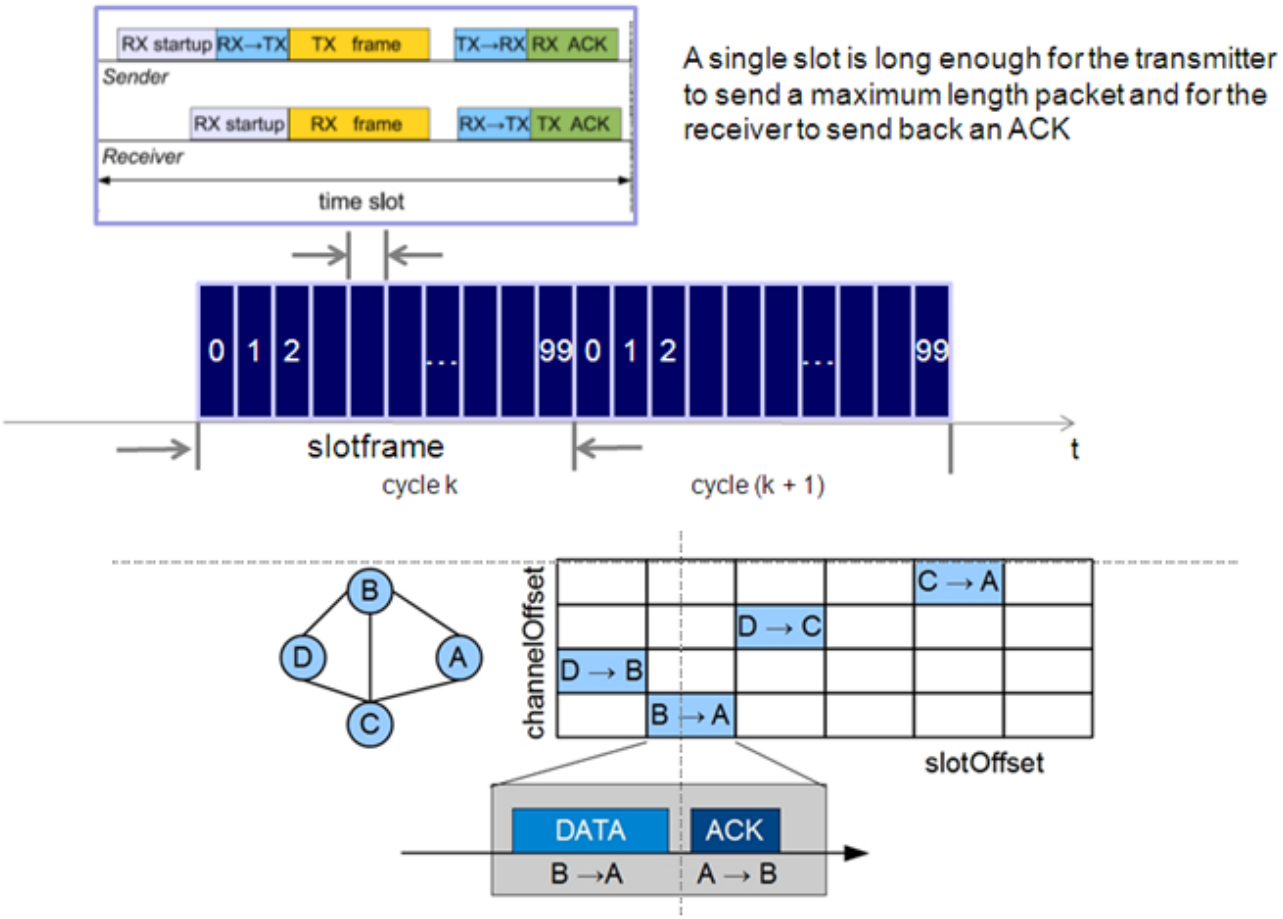

Figure 224. IEEE Std 802.15.4 TSCH 2-D SLOTFRAME

When RF operations are to be scheduled using Wake-On-Radio in a TIMESLOT context, the start times for the next *N* operations are programmed into the descriptor table to assign them to slots. One field of each slot descriptor, START_TIME, holds this information for WOR. See Section Descriptor Format for more information on the descriptor fields, and how they are packed into the descriptor. *N* is the number of slots used, and can be any integer from 2 to 4. The register SLOTS_USED is programmed with this value. The start times programmed into the descriptors, are relative to the Event Timer of the assigned Link Layer. WOR software will read the Event Timer, add to this value the desired time-to-next-event, and write the sum into the descriptor START_TIME. WOR hardware will monitor the assigned Link Layer's Event Timer; when it matches the START_TIME field of the current slot's descriptor, WOR hardware will initiate an RF sequence. The type of sequence is determined by the descriptor's FUNCTION field, and can be TX or RX or RT or TR. The RF operation will be allowed to continue, until it either self-terminates, or a timeout is reached. The timeout period for TIMESLOT scheduling mode is determined by the RECEIVE_TIMEOUT[15:0] register. The units of this register are microseconds. If a timeout is reached, i.e.,

EVENT_TMR = START_TIME + RECEIVE_TIMEOUT,

WOR hardware will terminate the sequence. Timeout applies to RX sequences only. RX sequences may result in no packet being received, a packet being received which is not addressed to the device, or a packet which is received corruptly. Any of these scenarios will result in a timeout and a WOR shutdown of the sequence. A correctly received packet addressed to the device will self-terminate the RX sequence before the timeout is reached. Timeout is not relavent to TX sequences, since these always self-terminate. The following diagram depicts how the WOR hardware processes the descriptor table, the assigned Event Timer, and the RECEIVE_TIMEOUT register, to start and terminate an RF operation.

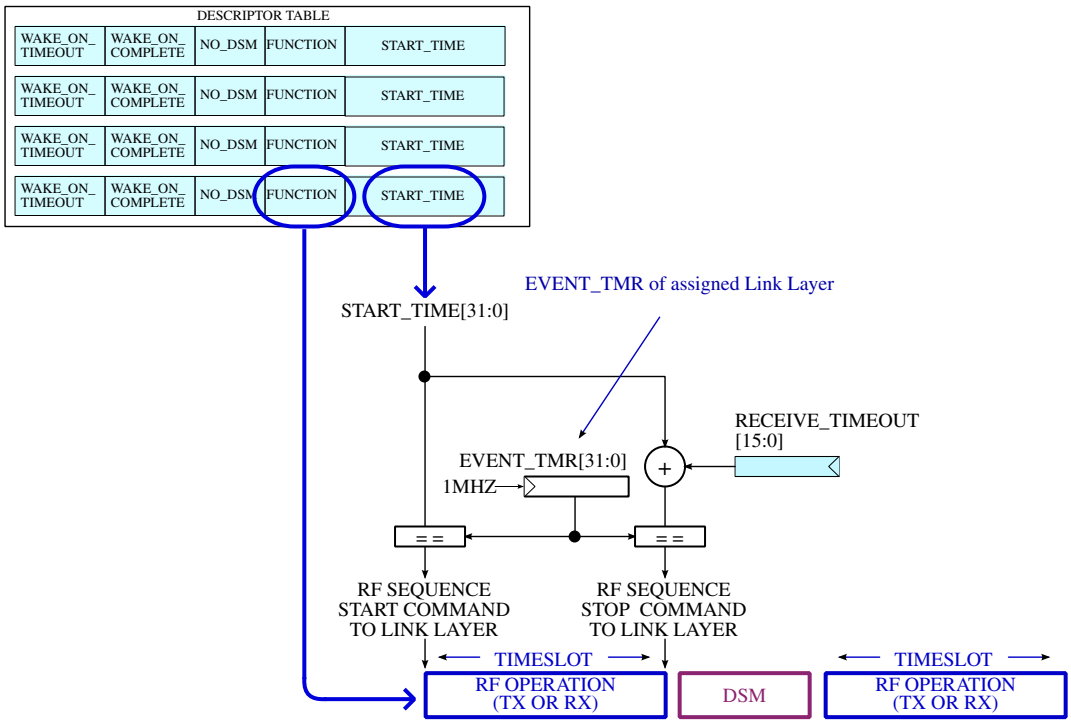

Figure 225. EVENT SCHEDULING IN TIMESTLOT SCHEDULING MODE

If the assigned protocol engine is 802.15.4 or GENERIC_FSK, an autosequence is available which is a TX sequence preceded by a CCA (Clear Channel Assessment). If the CCA results in a busy channel, the autosequence terminates without transmission; otherwise the transmission proceeds. This autosequence can be used in WOR Timeslot mode by appropriately configuring the 802.15.4 or GENERIC_FSK Link Layer.

In any timeslot, if the assigned FUNCTION is RX or RT, a TIMESTAMP can be captured to record the instant the packet's Access Address or SFD arrives at the Link Layer packet processor. There are 4 TIMESTAMP registers, once for each slot; hence, timestamps for the last 4 slots during which packets are received, can be recorded. See Section Timestamps for more details.

To execute the function RT, Link Layer should be configured with **AUTOACK** set. When Event Timer match, WOR will assert **wor_rx_start_ext signal** to Link Layer to start the RX sequence. After Link Layer completes the Auto-ACK sequence, it will send the signal **tx_irq_trig** to WOR to advance to the next state. If the RX operation timeout occurs, either nominal or delayed, WOR will assert **wor_seq_stop_ext** to the assigned Link Layer, causing an immediate abort of the RX sequence. RT function is effected by the window widening feature. A TIMESTAMP is captured in the RT sequence.

To execute the function TR, when Event Timer match, WOR will assert **wor_tx_start_ext** signal as well as **wor_function_is_tr** signal to Link Layer to start the TR sequence. After Link Layer completes the TR sequence, it will send signal **rx_irq_trig** to WOR to advance to the next state. If the RX operation timeout occurs, either nominal or delayed, WOR will **assert wor_seq_stop_ext** to the assigned Link Layer, causing an immediate abort of the RX sequence. TR function is not effected by the window widening feature. A TIMESTAMP is captured in the TR sequence.

Typically, for RX timeslots, it is desirable to wake the MCU on good packets only. Thus, the slot descriptor's WAKE_ON_COMPLETE field should be set to 1. If it is desired to wake the MCU on no-packet, or on incorrecty-received packets, the WAKE_ON_TIMEOUT descriptor field can be set to 1. If WAKE_ON_TIMEOUT is set to 1 on any slot's descriptor, the WAKE_ON_COMPLETE field is *implied* to be set to 1 as well, regardless of its actual programmed value.

Typically, for TX timeslots, it is desirable to wake the MCU after each transmission, to service the Packet Buffer. In such scenarios, WAKE_ON_COMPLETE should be set to 1. If it is required to transmit the same packet repeatedly, across multiple slots, such that the Packet Buffer does not require regular service, WAKE_ON_COMPLETE can be set to 0, to skip the MCU wakeup, on any slot.

In Timeslot Scheduling mode, the MCU *must* be awakened at least once every *N* slots, to refresh the descriptor table (or at least, to refresh the START_TIME's), with *N* being the value of SLOTS_USED. This periodic wakeup requirement must be enforced by

appropriate setting of the WAKE_ON_COMPLETE and WAKE_ON_TIMEOUT fields of the 4 slot descriptors. This is a requirement imposed on WOR software. (The same period wakeup requirement does not necessarily apply to Constant Interval scheduling mode. See next section.)

Constant-Interval Mode

Constant-Interval mode is appropriate when the schedule for RF transactions is perfectly periodic. A good example of such a scheduling regime, is the Bluetooth Low Energy Scanning State. In this state, a SCAN_INTERVAL is defined, which sets the interval between receive operations, and a SCAN_WINDOW is defined, which sets the duration of receiver "ON" time within the SCAN_INTERVAL. Wake-On-Radio adopts the principles of Bluetooth LE SCAN_INTERVAL and SCAN_WINDOW, broadening their scope to apply to any type of RF operation (TX or RX), and modifying the nomenclature to better represent the nature of the operations, to WOR_EVENT_INTERVAL and WOR_EVENT_WINDOW.

Instead of programming timeslot START_TIME's into the slot descriptors, Contant-Interval requires that WOR_EVENT_INTERVAL and WOR_EVENT_WINDOW be programmed instead. An additional parameter, WOR_EVENT_START, determines the instant of the first RF operation of the Constant-Interval WOR session, in case the desired start time is not immediate. WOR_EVENT_START is also programmed into the descriptor table. In Constant-Interval scheduling mode, WOR hardware processes the descriptors, and uses WOR_EVENT_INTERVAL, WOR_EVENT_WINDOW, and WOR_EVENT_START, to calculate the start time (Event Timer match), for the first RF operation, as well as all subsequent RF operations, on a rolling basis. WOR software is not required to refresh the descriptor table on a periodic basis, and would only intervene in the descriptors if a change was required to any parameter (e.g., a Bluetooth LE "Anchor Point Move" during a connection would require descriptor updates). In Constant-Interval mode, the start of WOR_EVENT_WINDOW always aligns to the start of WOR_EVENT_INTERVAL.

Aside from replacing the Timeslot descriptor START_TIME parameters with WOR_EVENT_INTERVAL, WOR_EVENT_WINDOW, and WOR_EVENT_START, the descriptor format is identical across the 2 scheduling modes, and the descriptor storage space (registers) is completely shared, since only 1 scheduling mode can be in effect at any given time. See Section Descriptor Format for more information on the descriptor fields, and how they are packed into the descriptor, and how the descriptor table is shared between the 2 scheduling modes.

A diagram depicting an example of Constant-Interval scheduling mode is shown below. In this diagram, the scanning device is in Constant-Interval mode, with the WOR_EVENT_INTERVAL and WOR_EVENT_WINDOW indicated.

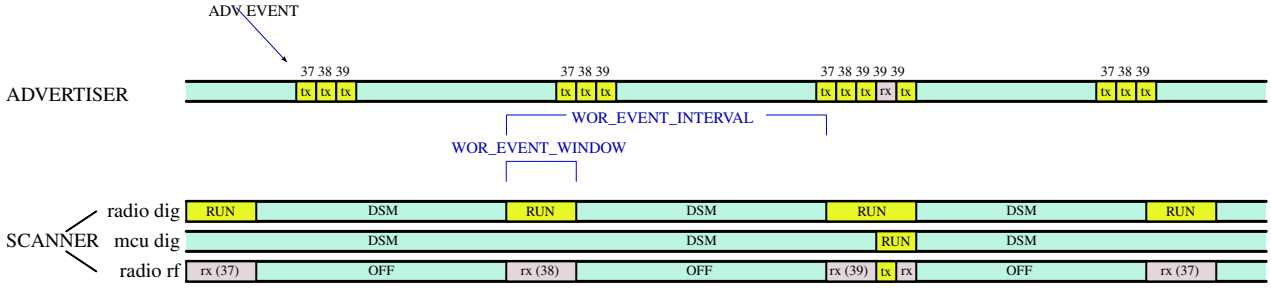

Figure 226. CONSTANT-INTERVAL SCHEDULING MODE EXAMPLE

When RF operations are to be scheduled using Wake-On-Radio in a Constant-Interval context, the WOR_EVENT_START, WOR_EVENT_INTERVAL, and WOR_EVENT_WINDOW parameters for the Constant-Interval operation are programmed into the descriptor table. These need be programmed only once, unless a change in network timing require an on-the-fly change to one of these parameters. The units for all 3 WOR_EVENT parameters are microseconds. See Section Descriptor Format for more information on the descriptor fields, and how they are packed into the descriptor. WOR hardware will process these 3 parameters to calculate the initial start time, and all subsequent start times, on a rolling basis. The start times computed by WOR hardware, are relative to the Event Timer of the assigned Link Layer. WOR hardware will monitor the assigned Link Layer's Event Timer; when it matches the next computed start time, WOR hardware will initiate an RF sequence. The type of sequence is determined by the current slot descriptor's FUNCTION field, and can be TX or RX. The RF operation will be allowed to continue, until it either self-terminates, or a timeout is reached. The timeout period for Constant-Interval scheduling mode is determined by the WOR_EVENT_WINDOW descriptor field. If a timeout is reached, i.e.,

EVENT_TMR = START_TIME (computed) + WOR_EVENT_WINDOW (descriptor),

WOR hardware will terminate the sequence. Timeout applies to RX sequences only. RX sequences may result in no packet being received, a packet being received which is not addressed to the device, or a packet which is received corruptly. Any of these scenarios will result in a timeout and a WOR shutdown of the sequence. A correctly received packet addressed to the device will self-terminate the RX sequence before the timeout is reached. Timeout is not relavent to TX sequences, since these always self-terminate. The concept of slots still applies to Constant-Interval Mode. The number of slots used can be any integer from 3 to 4 for Constant-Interval mode. The register SLOTS_USED is programmed with this value. Consecutive RF operations are assigned to consecutive slots, with the slot descriptor's parameters (e.g. FUNCTION, or WAKE_ON_COMPLETE) applying to the current slot. As in Timeslot mode, in Constant-Interval mode, WOR hardware will increment the slot number for each new RF operation, modulo SLOTS_USED.

In any timeslot, the assigned FUNCTION is a simple TX or RX operation. There is no automatic acknowledgement of packets. If acknowledgement is required during a timeslot, the MCU must be awakened (by setting the WAKE_ON_COMPLETE bit of the slot's descriptor), and the software must handle the acknowledgement, using standard Link Layer (not WOR) resources, within the turnaround time requirement (if any). WOR hardware will hold its state and wait for software to complete the acknowledgement, and other required tasks, before advancing to the next slot on software command.

If the assigned protocol engine is 802.15.4 or GENERIC_FSK, an autosequence is available which is a TX sequence preceded by a CCA (Clear Channel Assessment). If the CCA results in a busy channel, the autosequence terminates without transmission; otherwise the transmission proceeds. This autosequence can be used in WOR Timeslot mode by appropriately configuring the 802.15.4 or GENERIC_FSK Link Layer.

In any timeslot, if the assigned FUNCTION is RX, a TIMESTAMP can be captured to record the instant the packet's Access Address or SFD arrives at the Link Layer packet processor. There are 4 TIMESTAMP registers, once for each slot; hence, timestamps for the last 4 slots during which packets are received, can be recorded. See Section Timestamps for more details.

Typically, for RX timeslots, it is desirable to wake the MCU on good packets only. Thus, the slot descriptor's WAKE_ON_COMPLETE field should be set to 1. If it is desired to wake the MCU on no-packet, or on incorrecty-received packets, the WAKE_ON_TIMEOUT descriptor field can be set to 1. If WAKE_ON_TIMEOUT is set to 1 on any slot's descriptor, the WAKE_ON_COMPLETE field is *implied* to be set to 1 as well, regardless of its actual programmed value.

Typically, for TX timeslots, it is desirable to wake the MCU after each transmission, to service the Packet Buffer. In such scenarios, WAKE_ON_COMPLETE should be set to 1. If it is required to transmit the same packet repeatedly, across multiple slots, such that the Packet Buffer does not require regular service, WAKE_ON_COMPLETE can be set to 0, to skip the MCU wakeup, on any slot.

Unlike Timeslot mode, in Constant-Interval mode, it is not required to wake up the MCU at least every *Nth* slot to refresh the descriptor start times, because WOR hardware is able to compute all future start times on a rolling basis. If all slots are of the same type (same FUNCTION, TX or RX, and same descriptor information), there is no hard limit on the number of consecutive slots that can be executed between MCU wakeups. To set such a upper limit, the WAKE_ON_NTH_SLOT[7:0] register can be programmed with a value. When the number of slots elapsed after setting SLOTS_USED to a non-zero value to begin a WOR session, reaches the value of WAKE_ON_NTH_SLOT, the MCU will automatically be awakened at the end of the current slot, regardless of the setting of the WAKE_ON_COMPLETE and WAKE_ON_TIMEOUT bits in the descriptor. The WAKE_ON_NTH_SLOT register is only relavent to Constant-Interval scheduling mode, and has no effect in Timeslot mode. In Constant-Interval mode, if automatic wake on *Nth* slot is not desired, set WAKE_ON_NTH_SLOT=0 to disable this wakeup upper-limit. However, if a zero setting is used, software *must* program at least one of the slot descriptors to schedule an MCU wakeup by setting the either WAKE_ON_COMPLETE or WAKE_ON_TIMEOUT fields of the descriptor to 1; otherwise a situation could arise where the MCU is never awakened by WOR.

55.4.6.2.3.3 Descriptor Format

As mentioned in previous sections, Wake-On-Radio allows the next several RF operations to be scheduled in advance. For scheduling purposes, each of the next, several RF operations is assigned to a slot. Each slot is associated with a descriptor, which is a hardware-based data structure containing information about the characteristics of the slot, and instructions for how WOR hardware should execute it. Characterisics include start time of the RF operation, and type (function) or operation to be conducted by WOR. Software schedules the next *N* RF operations (slots) by programming the next *N* descriptors with the slots' characteristics. Software then sets the SLOTS_USED register to *N* to begin a WOR session. WOR hardware includes a 2-bit slot counter that cycles through the slots, in order, starting with SLOT 0; the slot counter is used to select the "current descriptor". The current descriptor's slot characteristics are forwarded to the WOR state machine, which executes the RF operation per the

instructions in the descriptor. After the RF operation is complete, the slot counter is incremented by 1 (modulo SLOTS_USED), and the next slot's descriptor becomes the "current" one. The process repeats indefinitely until the WOR session is ended by setting SLOTS_USED=0. WOR hardware automaticlly inserts (unless instructed otherwise in the descriptor) a DSM cycle, after the current slot's RF operation completes, with a DSM duration that lasts until the start time of the *next* slot, so that time between RF operations is always filled with DSM, for maximum power savings. After setting SLOTS_USED to a non-zero value to begin a WOR session, the MCU can be put into a low power state, and remain there, until the last (*Nth*) slot completes, assuming Timeslot scheduling mode. (For Constant Interval mode, MCU wake up on the *Nth* slot is not required. See Section Scheduling Modes for information on when and how the MCU is to be awakened for Constant-Interval mode.)

The descriptor format for Timeslot scheduling mode is shown in the diagram below, indicating the various fields in the descriptor, and the bits assigned to each field:

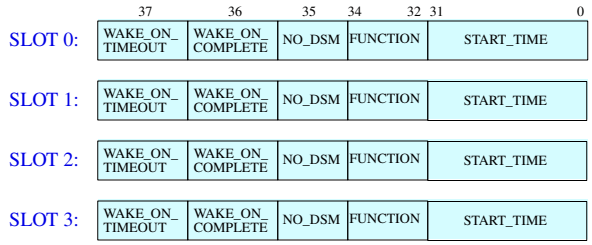

Figure 227. DESCRIPTOR FORMAT (TIMESLOT MODE)

The descriptor format for Constant-Interval scheduling mode is shown in the diagram below, indicating the various fields in the descriptor, and the bits assigned to each field:

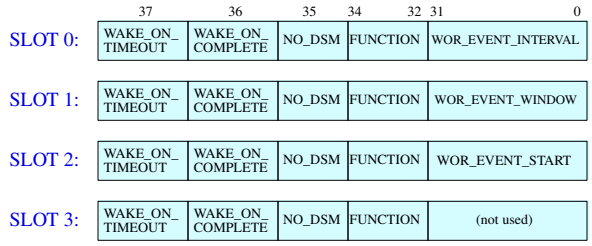

Figure 228. DESCRIPTOR FORMAT (CONSTANT-INTERVAL MODE)

The descriptor formats for Timeslot and Constant-Interval scheduling modes are almost identical, and so the desciptor hardware is almost completely shared by the 2 scheduling modes, as shown in the diagram below:

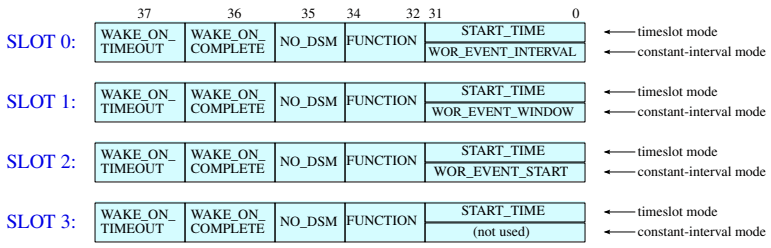

Figure 229. DESCRIPTOR FORMAT (SHARED)

Descriptor fields are described in the table below:

FIELD	DESCRIPTION
START_TIME	The instant at which to begin the current slot's RF operation. START_TIME is relative to the assigned Link Layer's Event Timer. Units are microseconds. Because the Event Timers' bit widths vary with protocol, see START_TIME programming information later in this section. Applies to Timeslot mode only. WOR hardware will automatically adjust this value with window-widening, if enabled.
WOR_EVENT_INTERVAL	Sets the interval between the start of RF operations for consecutive slots. Units are microseconds. Applies to Constant-Interval mode only. WOR hardware will automatically adjust this value with window-widening, if enabled.
WOR_EVENT_WINDOW	Maximum duration of the transceiver "ON" time for the current slot. "ON" time will be less than this if the RF operation self-terminates. Units are microseconds. Applies to Constant-Interval mode only. The start of the WOR_EVENT_WINDOW aligns to the start of the WOR_EVENT_INTERVAL. WOR hardware will automatically adjust this value with window-widening, if enabled.
WOR_EVENT_START	The instant at which to begin the RF operation for the first SLOT 0 of the WOR session. WOR_EVENT_START is relative to the assigned Link Layer's Event Timer. Units are microseconds. Because the Event Timers' bit widths vary with protocol, see WOR_EVENT_START programming information later in this section. Applies to Constant-Interval mode only. WOR hardware will automatically adjust this value with window-widening, if enabled.
FUNCTION	This 3 -bit field defines the RF function of the slot: 0: No RF 1: TX 2: RX 3: RT 4: TR 5~7: Reserved
NO_DSM	By default, a DSM cycle is automatically entered at the end of the current slot's RF operation, and the DSM cycle is timed to expire just before the start time of the next consecutive slot. If this field is set to 1, DSM is not entered, and the WOR state machine holds the radio in RUN state until the start time of the next slot is reached. NO_DSM can be used to execute back-to-back, or closely spaced RF operations, such as a Bluetooth LE 3-channel advertising event.
WAKE_ON_COMPLETE	Instructs the WOR state machine to permit an interrupt to wake up the MCU at the end of a succesfully completed

Table continues on the next page...

Table continued from the previous page...

FIELD	DESCRIPTION
	RF operation. RX operations are successfully completed if a packet is received before the timeout, which passes CRC and packet filtering rules. TX operations are always successfully completed. A successfully completed operation with WAKE_ON_COMPLETE=1 will cause the WOR state machine to temporarily remove its Link Layer interrupt inhibits, allowing the assigned Link Layer's RF interrupts (RXIRQ, TXIRQ, and/or SEQ_END_IRQ) to propagate, resulting in an MCU wakeup. If WAKE_ON_TIMEOUT=1, WAKE_ON_COMPLETE is *implied* to be 1 as well, regardless of the setting of this field.
WAKE_ON_TIMEOUT	Instructs the WOR state machine to permit an interrupt to wake up the MCU at the point of timeout of an RX operation. For Timeslot mode, timeout is determined by the RECEIVE_TIMEOUT[15:0] register; for Constant-Interval mode, timeout is determined by WOR_EVENT_WINDOW descriptor field. In either case, window-widening will automatically adjust the timeout instant, if enabled. A timeout which occurs with WAKE_ON_TIMEOUT=1 will cause the WOR state machine to temporarily remove its Link Layer interrupt inhibits, allowing the assigned Link Layer's SEQ_END_IRQ to propagate, resulting in an MCU wakeup, with a notification of timeout.

Event Timer bit width various across protocols. For 802.15.4, Event Timer is 28 bits; for GENERIC_FSK, Event Timer is 32 bits. In all cases, the Event Timer clock rate is 1MHz.

When FUNCTION is set to "NO_RF", no RF operation is performed during the slot. In this scenario, the WOR state machine will wait until the slot's programmed (or computed) START_TIME, and then automatically re-enter DSM until the next consecutive slot's START_TIME is reached. This allows multiple (up to 4) DSM-only slots which effectively extends the maximum DSM duration fourfold, to 1073 seconds (about 18 minutes), for the 802.15.4 and GENERIC_FSK protocol. However the RF Oscillator is activated breifly at each slot's START_TIME so that the WOR can process the current slot descriptor, and update the assigned Link Layer's Event Timer. Extending the DSM duration using the "NO_RF" method is referred to as "DSM cascading".

During an RX operation on any slot, if an AA or SFD has been detected at the point of timeout, the timeout (and the automatic shudown of the sequence by the WOR state machine) is *deferred* until either:

1: The packet is fully received and determined to be good. In this case the WAKE_ON_COMPLETE bit determines if the MCU is to be awakened.

2: The packet is fully received and determined not to be good. In this case the WAKE_ON_TIMEOUT bit determines if the MCU is to be awakened.

There are no time restrictions on programming the descriptor table. All descriptor fields can be modified at any time. Needless to say, caution should be exercised with modifying descriptor START_TIME, and other parameters, for the *current* slot; START_TIME (or WOR_EVENT_START) must be in the future, and FUNCTION should not be modified once the START_TIME has been reached.

55.4.6.2.3.4 State Machine

In Wake-On-Radio, future RF operations are scheduled by programming instructions into the WOR Descriptor table. Based on descriptor specifications, WOR hardware organizes the scheduled RF operations into slots, with one RF operation per slot. The slot includes more than just the RF operation. Idle time between the current time, and the start of the RF operation, is filled

with DSM. WOR hardware must compute the required DSM duration, and request DSM from RFMC (Radio Mode Controller). A diagram showing how WOR hardware processes the descriptor table, and organizes the required operations into consecutive slots, encompassing both DSM and RF, is shown below.

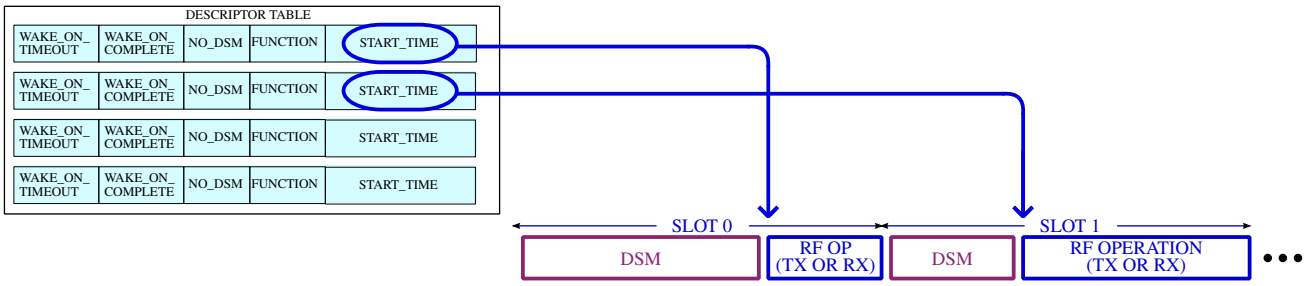

Figure 230. TIMELINE OF CONSECUTIVE SLOTS

Once a WOR session has been initiated by setting SLOTS_USED to a non-zero value, the timeline of consecutive slots shown, will repeat indefinitely, with the slot number increasing by 1 after each slot, modulo SLOTS_USED.

During each slot, WOR hardware must perform a series of tasks, e.g., computing the DSM duration, commanding the the assigned Link Layer to start and stop the RF sequence, etc. Some of the required WOR hardware tasks are superimposed on the slot timeline, in the diagram below.

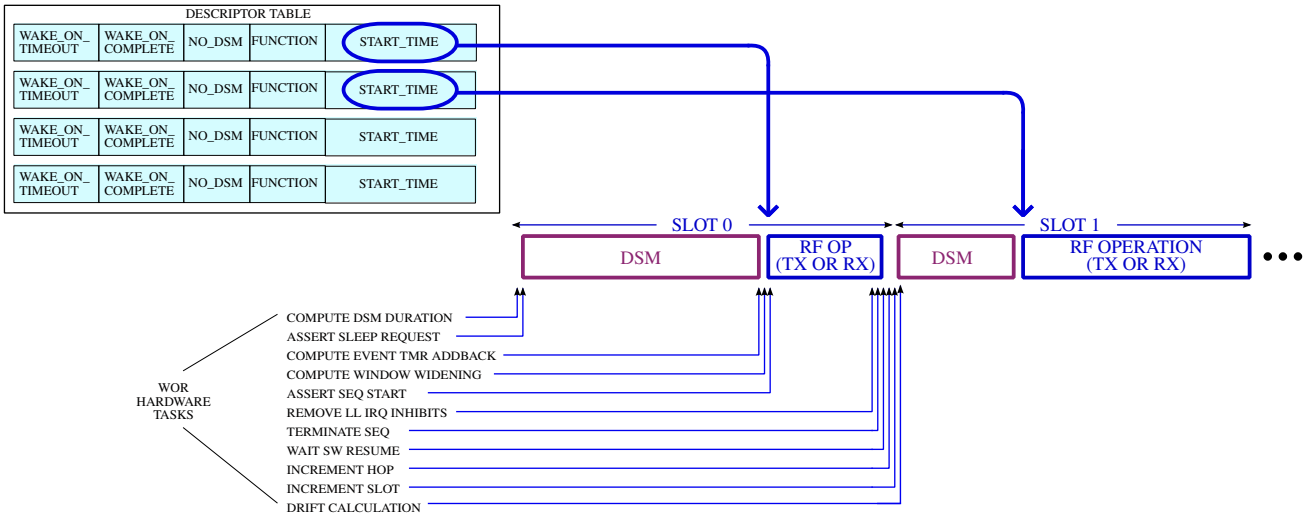

Figure 231. SLOT TIMELINE WITH HARDWARE TASKS

The WOR state machine is responsible for processing the descriptor table, and performing all the required tasks during each slot. The 11 -state machine interfaces with the assigned Link Layer for sequence operations, and with RFMC for DSM operations. The state machine also controls the incrementing of the the slot counter, and the frequency hop table index. A state diagram of the WOR state machine is shown below.

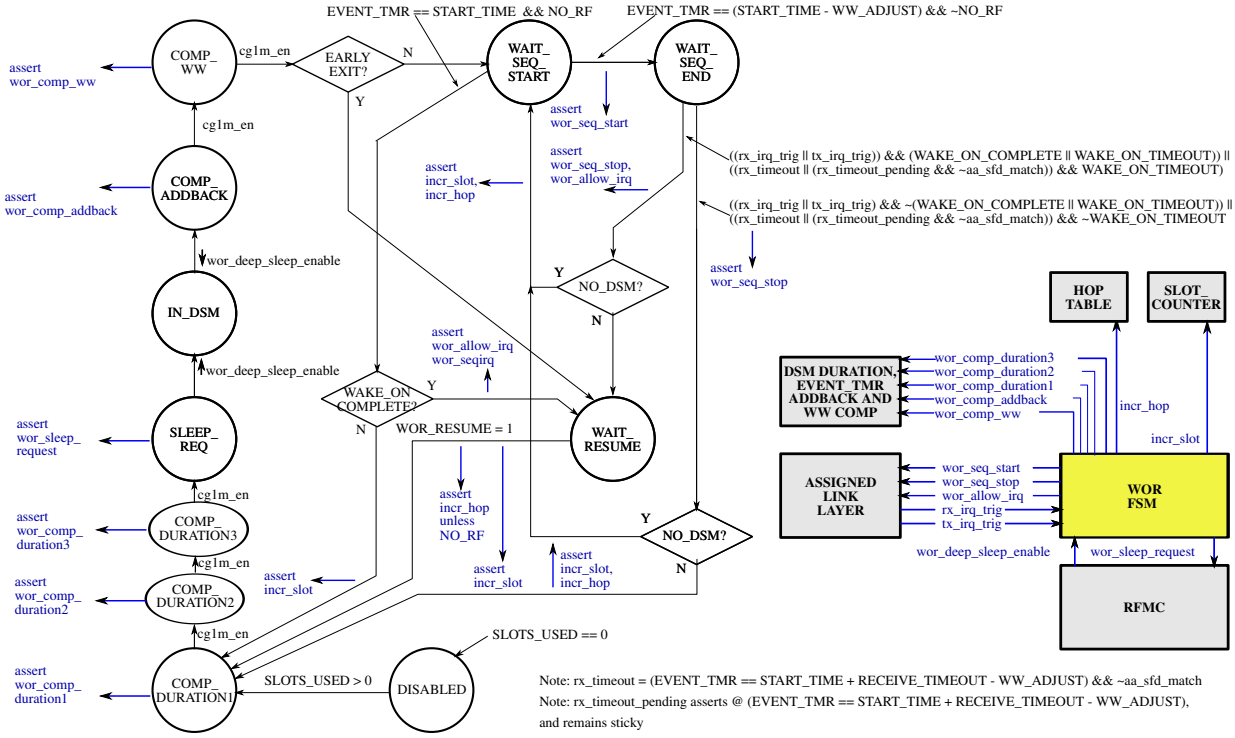

Figure 232. WAKE-ON-RADIO STATE DIAGRAM

A description of the WOR states follows.

DISABLED

WOR is in its disabled state whenever SLOTS_USED=0. WOR can be taken to "DISABLED" from any state by setting SLOTS_USED=0. WOR can be enabled by setting SLOTS_USED to a non-zero value, which initiates a new WOR "session".

COMP_DURATION1

WOR must compute the duration of the upcoming DSM cycle. This is done in 3 stages (states). COMP_DURATION1 is the first stage. Whenever the slot counter is incremented to begin a new slot, the slot's (descriptor's) START_TIME is in the future. In most cases, the START_TIME is distant enough that DSM is justified. During COMP_DURATION1, WOR computes the time to the next START_TIME, by subtracting both the current time (the assigned Link Layer's Event Timer) and the time-accumulated window-widening (if enabled) from the slot descriptor's START_TIME. (See Section Window Widening for more details on this feature.) The result of this subtraction is MICROSECONDS_TO_START_TIME[27:0]. This value must be converted to 32.768KHz cycles to be of use to RFMC. The multiplier is (549755 / 2^24), which is an approximation to the ideal conversion factor. The product is truncated to integer, the result represents the number of 32.768KHz cycles to remain in DSM prior to the next START_TIME. The hardware computations which take place during COMP_DURATION1 are shown in the following diagram.

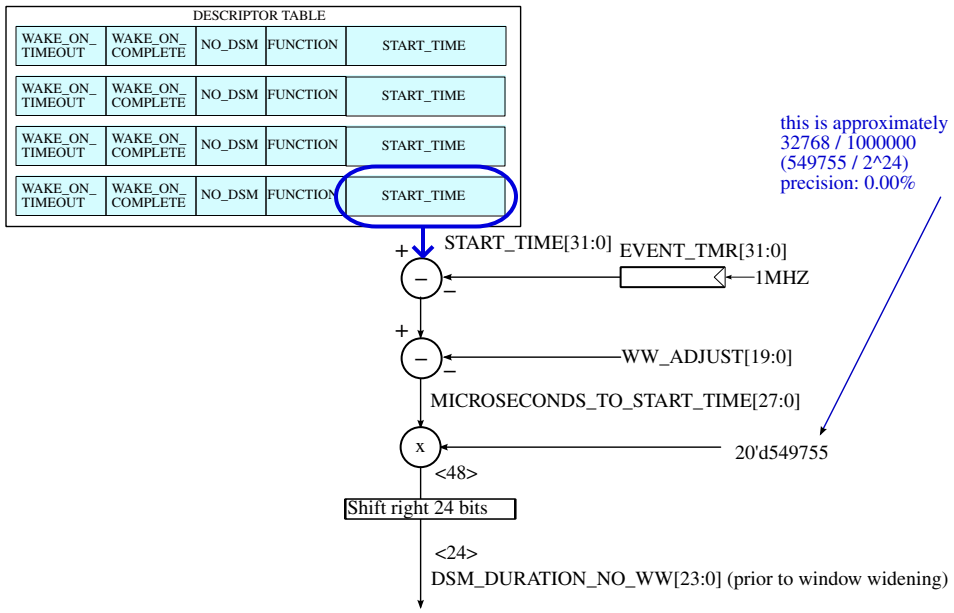

Figure 233. COMP_DURATION1

However this intermediate result does not account for the fact that window-widening for the upcoming DSM cycle itself, must be subtracted from this product. This is separate from the "accumulated" window-widening which has built up during the WOR session so far, which has already been accounted for. The estimate for the next DSM cycle's window widening is handled in the next state, COMP_DURATION2

The WOR output wor_clr_dsm_duration is asserted in this state, which is sent to the RFMC to proactively clear the DSM Duration Counter, which becomes active in the IN_DSM state (see below). The wor_clr_dsm_duration is an active-high, registered (glitch-proof) output signal.

COMP_DURATION2 and COMP_DURATION3

If window-widening is enabled, the DSM duration computed during COMP_DURATION1 may be long enough that it will need to be shortened slightly to account for window-widening which will accumulate during the DSM cycle itself. The computation for this window-widening is performed during this state. (See Section Window Widening for more details on this computation, and the usage of WW_DSM_FACTOR.) The (intermediate) duration from COMP_DURATION1 is multiplied by the DSM window-widening factor, and the product is subtracted from the duration estimate. The difference is a more accurate duration that accounts for window-widening during the DSM cycle. In a final step, a guardband is subtracted from the DSM duration. The guardband, with units of 32.768KHz clock cycles, guarantees that the DSM will complete on time before the next START_TIME is reached, accounting for RFMC synchronization and other delays in processing the WOR's sleep request. The guardband, which applies to all DSM cycles initiated by WOR, is determined by the register DSM_GUARDBAND[3:0]. The result of this step, is the final DSM duration (wor_dsm_duration[23:0]) which is then sent to the RFMC, which is responsible for radio DSM entry and exit. The hardware computations which take place during COMP_DURATION2 and COMP_DURATION3(alongside those covered by COMP_DURATION1) are shown in the following diagram.

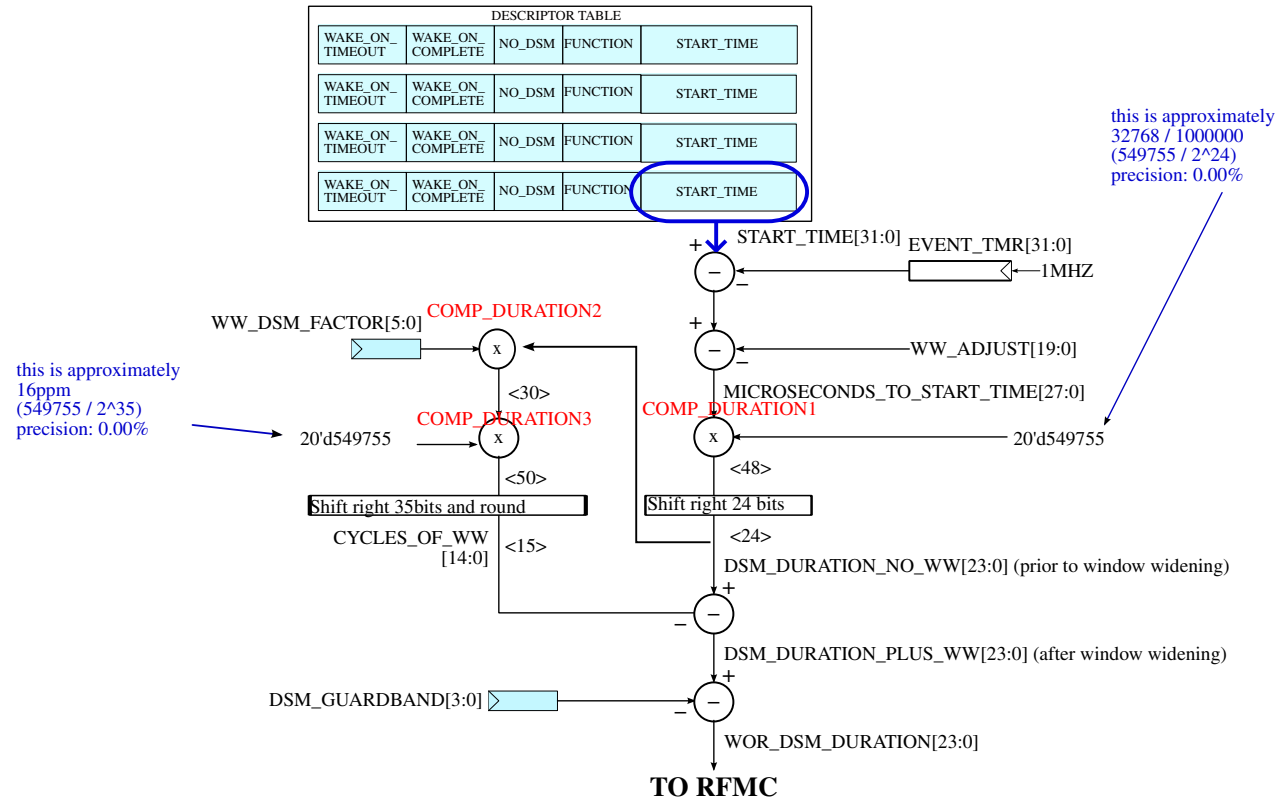

Figure 234. COMP_DURATION2 and COMP_DURATION3

SLEEP_REQ

In this state, WOR asserts its sleep request (wor_sleep_request) to the RFMC. This is a level, active-high, and registered (glitch-proof) signal to RFMC to indicate a DSM cycle is being requested of precise duration wor_dsm_duration[23:0], which was computed during the prior 2 WOR states. The units of wor_dsm_duration[23:0] are 32.768KHz clock cycles. RFMC shall synchronize wor_sleep_request into the 32.768KHz clock domain, and use it to activate the RFMC's DSM state machine. The RFMC DSM state machine shall place the radio in DSM, and simultaneously assert the output: wor_deep_sleep_enable. This signal is the precise indicator of DSM being "in effect", and is used to gate the assigned Link Layer's clocks and freeze its Event Timer.

IN_DSM

DSM is in effect during this state. Because the RF Oscillator has been disabled, there are no clocks to WOR, including its state machine, or the Link Layer, in this state. This is merely a holding state that prevails until DSM exits and the clocks to WOR and Link Layer are restarted. During this state, RFMC will use wor_deep_sleep_enable to enable a 24-bit counter which counts out the precise number of cycles in wor_dsm_duration[23:0]. When this counter reaches wor_dsm_duration, RFMC shall exit DSM and de-assert wor_deep_sleep_enable. RFMC shall provide the final count of the 24-bit counter which was used to time the DSM, using output signal rfmc_sleep_duration[23:0]. In most cases, rfmc_sleep_duration will be an exact match to wor_dsm_duration; the exceptional case is an unscheduled, early exit of DSM (see Section DSM Early Exit.) The interface signals between WOR and RFMC, and a high-level description of the hardware tasks performed by RFMC during IN_DSM state, is shown in the following diagram.

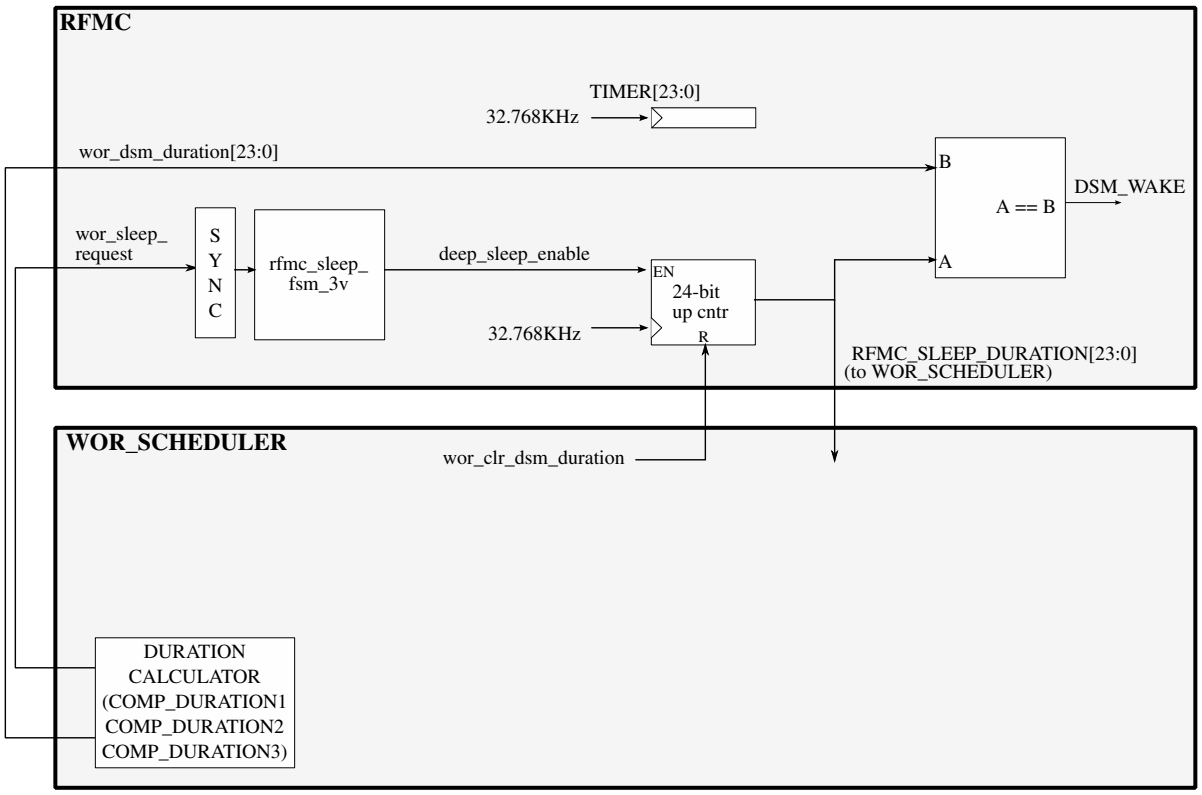

Figure 235. IN_DSM

COMP_ADDBACK

During the previous state, IN_DSM, the Reference Oscillator was disabled, and so the Event Timer of the assigned Link Layer was frozen. After DSM completes, clocks are restored and Event Timer resumes counting, but it is "behind" by the amount of time that the radio was in DSM. WOR hardware must compute the amount of DSM time, convert it to microseconds, and "add it back" to the Event Timer, so that after the addback, the Event Timer timebase is restored to where it would have been, had there been no DSM. (Note: there is a maximum of 1us of "loss of precision" upon every DSM exit; this timebase error is random and will not accumulate, it will average out over many DSM cycles). In this state, WOR computes the addback value by multiplying the rfmc_sleep_duration[23:0] (the precise number of 32.768KHz clock cycles during which RFMC held the radio in DSM) by 30.517578125 (the number of microseconds per 32.768KHz clock cycle). The 30.517578125 is an unsigned 14-bit value with 5 integer bits. The other multipicand, rfmc_sleep_duration is an unsigned integer. The product is the DSM elapsed time in microseconds, a 38 unsigned bit value with 29 integer bits. The product is rounded to the nearest integer and the 1 MSB's are discarded, resulting in the final wor_addback[27:0] value. At the end of this state, this result is sent to the assigned Link Layer's Event Timer, along with the wor_addback command (pulse), indicating to the Link Layer that it must add this amount to the current state of its Event Timer. After this point the protocol's timebase has been restored and operations can now be performed referencing the Event Timer. The following diagram depicts the hardware tasks performed in the COMP_ADDBACK state.

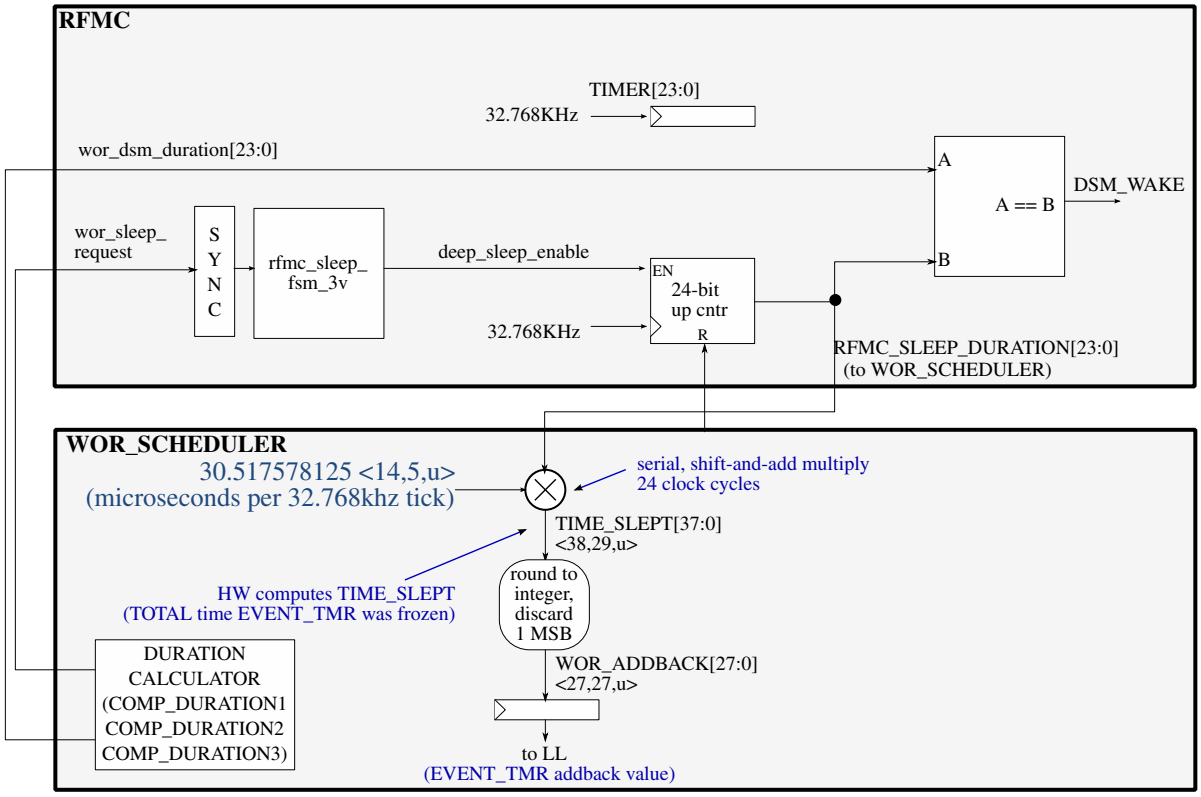

Figure 236. COMP_ADDBACK

COMP_WW

If window-widening is enabled, WOR must compute how much to increase the receive window by, based on the duration of the just-completed DSM cycle, so that this early-start offset to the receive window is ready in advance of the slot descriptor's START_TIME. The window-widening increment is computed during this state. Details of this hardware task are described in Section Window Widening.

WAIT_SEQ_START

After COMP_WW state, the WOR is ready to command an RF operation, and is only waiting for the slot descriptor's START_TIME to arrive. This start time will be in the near future since the DSM duration was timed to wake up "just in time" to start the RF operation, with sufficient guardband to guarantee that a DSM wake up can never occur too late. The WAIT_SEQ_START state merely waits for the assigned Event Timer to match the current slot descriptor's START_TIME. If the slot's FUNCTION is RX or RT, and window widening is enabled, START_TIME is modified by the hardware to be:

START_TIME - ww_adjust[19:0],

where ww_adjust[19:0] is the time-accumulated window-widening "early start" amount for the RX operation (see Section Window Widening.) If the FUNCTION is not RX or if window-widening is disabled, START_TIME is unmodified. Once a START_TIME match to the Event Timer occurs, WOR asserts the Link Layer interface signal wor_tx_start_ext (if FUNCTION is TX or TR), or wor_rx_start_ext (if FUNCTION is RX or RT). Neither interface signal is asserted if FUNCTION is NO_RF. The assigned Link Layer will commence an RF operation, TX or RX, based on this WOR command. At this point, the WOR state machine arrives at a fork:

- If FUNCTION = NO_RF and the descriptor WAKE_ON_COMPLETE=1, the next state is WAIT_RESUME
- Else if FUNCTION = NO_RF and WAKE_ON_COMPLETE=0, the next state returns to COMP_DURATION1 to begin the next slot. The slot counter and hop table index are incremented.
- Else, this is an RF operation that must be waited for. The state machine advances to the WAIT_SEQ_END state.

WAIT_SEQ_END

This state has been reached because an RF operation was launched during the previous state, and WOR is waiting for that operation to end. There are 3 ways for an RF operation to end:

- A TX operation self-terminates, indicated when the Link Layer asserts tx_irq_trig to WOR.
- A RX operation self-terminates due to a good packet reception, indicated when the Link Layer asserts rx_irq_trig to WOR.
- A RXor RT or TR operation times out. The rx_irq_trig is not asserted before the timeout. See Section Scheduling Modes for a description on the 2 methods WOR uses to compute the point-of-timeout, based on Scheduling Mode.

If either tx_irq_trig or rx_irq_trig is asserted, WOR advances to the next state (see below). If a point-of-timeout is reached without an rx_irq_trig, WOR hardware checks to see if Access Address Match has occurred or if SFD has been detected. If either is the case, timeout is deferred until either:

- The rx_irq_trig is ultimately asserted to indicate a good packet was received. This is a delayed good packet reception.
- The packet reception underway at point-of-timeout ultimately results in a CRC- or filtering-violation. This will automatically trigger a Link Layer RX recycle which will negate the AA-match or SFD-match indicator. WOR will detect this negation and declare a delayed timeout at this point.

If a timeout occurs, either nominal or delayed, WOR will assert wor_seq_stop_ext to the assigned Link Layer, causing an immediate abort of the RX sequence. This abort shall be handled by the protocol engine like a software abort. The wor_seq_stop_ext will not assert for a deferred timeout which results in a delayed good packet reception.

Nominally, WOR blocks the assigned Link Layer's RF-related interrupts from propagating to the MCU, to prevent unintended MCU wakeups during a WOR session. The RF-related interrupts for the supported protocol engines, are nearly identical in function across a 3 protocols, and are called RXIRQ, TXIRQ, and SEQ_END_IRQ. At the conclusion of an RF operation on a slot, WOR must decide whether to temporarily remove the Link Layer interrupt inhibits, to allow the Link Layer interrupt to be asserted to wake the MCU, based on which of the 5 outcomes to the RF operation occurred, and the state of the WAKE_ON_COMPLETE and WAKE_ON_TIMEOUT descriptor fields. The following table specifies whether WOR blocks, or allows, the RF interrupts to propagate, at the conclusion of the RF operation.

RF OPERATION OUTCOME	WAKE_ON_TIMEOUT=0, WAKE_ON_COMPLETE=0	WAKE_ON_TIMEOUT=0, WAKE_ON_COMPLETE=1	WAKE_ON_TIMEOUT=1, WAKE_ON_COMPLETE=x
tx_irq_trig	BLOCK	ALLOW	ALLOW
rx_irq_trig (nominal)	BLOCK	ALLOW	ALLOW
rx_irq_trig (delayed)	BLOCK	ALLOW	ALLOW
no rx_irq_trig @ nominal timeout	BLOCK	BLOCK	ALLOW
no rx_irq_trig @ delayed timeout	BLOCK	BLOCK	ALLOW

At the conclusion of the RF operation, the WOR next state is a function of whether the Link Layer RF interrupts were BLOCKED or ALLOWED (see previous table), as well as the NO_DSM descriptor field as illustrated in the following table.

RF OPERATION OUTCOME	INTERRUPTS BLOCKED, NO_DSM=0	INTERRUPTS ALLOWED, NO_DSM=0	NO_DSM=1
tx_irq_trig	COMP_DURATION1 (increment slot, hop idx)	WAIT_RESUME	WAIT_SEQ_START (increment slot, hop idx)
rx_irq_trig (nominal)	COMP_DURATION1 (increment slot, hop idx)	WAIT_RESUME	WAIT_SEQ_START (increment slot, hop idx)

Table continues on the next page...

Table continued from the previous page...

RF OPERATION OUTCOME	INTERRUPTS BLOCKED, NO_DSM=0	INTERRUPTS ALLOWED, NO_DSM=0	NO_DSM=1
rx_irq_trig (delayed)	COMP_DURATION1 (increment slot, hop idx)	WAIT_RESUME	WAIT_SEQ_START (increment slot, hop idx)
no rx_irq_trig @ nominal timeout	COMP_DURATION1 (increment slot, hop idx)	WAIT_RESUME	WAIT_SEQ_START (increment slot, hop idx)
no rx_irq_trig @ delayed timeout	COMP_DURATION1 (increment slot, hop idx)	WAIT_RESUME	WAIT_SEQ_START (increment slot, hop idx)

WAIT_RESUME

If WOR has allowed the MCU to be awakened (interrupted) by temporarily negating the RF interrupt inhibits, WOR must enter a state which permits the MCU executing WOR or Link Layer software, to complete all its assigned tasks on the slot. These tasks may include processing and decrypting a received packet, servicing the packet buffer, and formulating and transmitting an acknowledge packet. The WAIT_RESUME state serves that purpose. The WAIT_RESUME state is reached whenever all of the following conditions are met:

- Current state is WAIT_SEQ_END
- FUNCTION is TX or RXor RT or TR
- RF operation completes with any outcome (rx_irq_trig, tx_irq_trig, nominal, or delayed timeout)
- NO_DSM=0
- RF Interrupts are ALLOWED (see table, WAIT_SEQ_END state)

WAIT_RESUME is also reached whenever all of these following conditions are met:

- Current state is WAIT_SEQ_START
- FUNCTION is NO_RF
- START_TIME match to the assigned Link Layer's Event Timer
- WAKE_ON_COMPLETE=1

Once WAIT_RESUME is reached, WOR software must authorize WOR hardware to resume the WOR session and advance to the next slot, by setting the WOR_RESUME register bit to 1. When WOR_RESUME is set to 1 in WAIT_RESUME state, WOR hardware takes the following steps:

1. Advances to the next slot (slot counter++ % SLOTS_USED)
2. Increments the frequency hop table index *unless* FUNCTION = NO_RF
3. Enters COMP_DURATION1 state on the new slot
4. Reimposes Link Layer interrupt inhibits

55.4.6.2.3.5 Window Widening

OVERVIEW

Because a device in a connected state is not receiving all the time, its timebase will invariably drift with respect to the timebase of other device(s) in the network, due to finite crystal oscillator tolerances amongst the networked devices. Reducing the duty cycle of the receiver, albeit necessary to achieve power savings, exacerbates the drift problem.

To compensate for drift, Receive Window Widening can be employed. As time elapses in a network connection between successful packet receptions, the window-widening algorithm gradually moves future receiver turn-on times to the left (advance) and the turn-off time to the right (retard) to allow the transmitted packet to fall within the receiver's window in the presence of a

drifting timebase. The effect of window-widening on successive receive cycles, none of which result in a good packet reception, is illustrated in the following diagram.

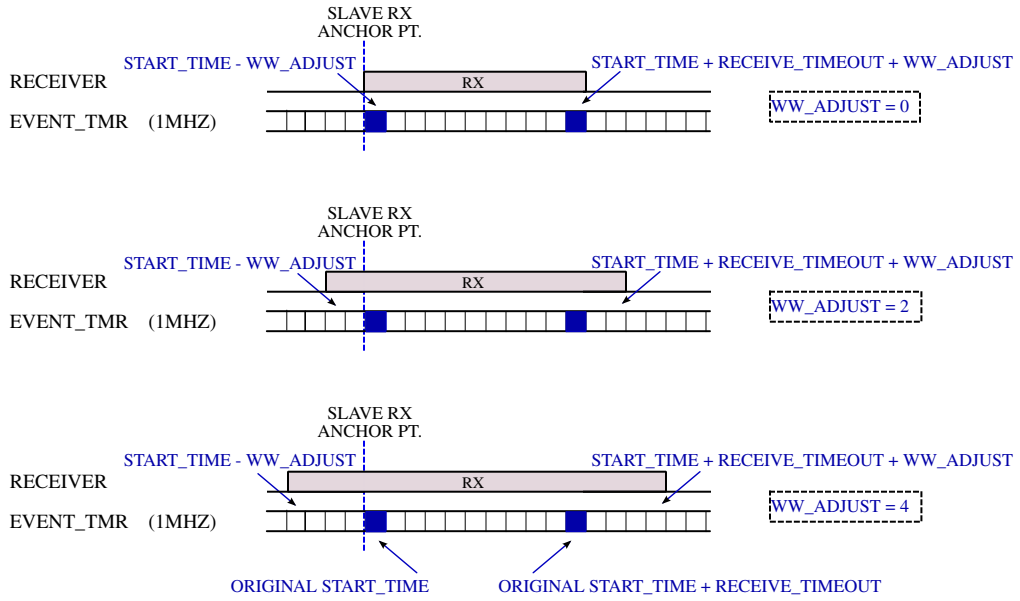

Figure 237. EFFECT OF WINDOW WIDENING ON RECEIVE WINDOW

Window widening is typically applicable only to the slave device(s) in a network, as the master (coordinator) of the network is normally the master of network timing. Thus, in Wake-On-Radio, window widening is optional, enabled by the by setting the WW_EN register bit to 1.

The Window widening algorithm needs to take into account the "Sleep Clock Accuracy" of the devices in the network. Sleep Clock Accuracy (SCA) is a *Bluetooth Low Energy* concept, and the Bluetooth LE nomenclature is adopted by Wake-On-Radio, and extrapolated to all supported protocols.

In Bluetooth LE, drift encountered by a slave device must be compensated by accounting for the SCA of both the master and the slave (self). The master transmits its SCA to the slave in the connection request (CONNECT_REQ), an advertising channel packet which informs an advertising slave of the master's desire to form a connection with it; the parameters on the CONNECT_REQ include the master's SCA. The slave device knows its own SCA, so the composite SCA is known at the point of connection establishment. Wake-On-Radio adopts this concept, although the precise method of informing the slave of Master SCA is protocol-dependent and takes place at a higher level, beyond the scope of this document.

Bluetooth LE subdivides the allowed Master SCA into coarse ranges, to reduce the number of over-the-air bits required to inform the slave. The ranges are shown in the following diagram.

SCA	masterSCA
0	251 ppm to 500 ppm
1	151 ppm to 250 ppm
2	101 ppm to 150 ppm
3	76 ppm to 100 ppm
4	51 ppm to 75 ppm
5	31 ppm to 50 ppm
6	21 ppm to 30 ppm
7	0 ppm to 20 ppm

Figure 238. SCA RANGES

The slave SCA must be accounted for as well, so the maximum composite SCA is 1000ppm. For Wake-On-Radio, this is the maximum allowed drift as well, and window-widening programmability will allow for drift amounts within these ranges to be compensated.

FACTS

In the WOR hardware, the window-widening adjustment, is a value, ww_adjust[19:0], that is subtracted from the receiver START_TIME, and added to the receiver TIMEOUT, when the slot's FUNCTION = RX, as shown in the diagram below.

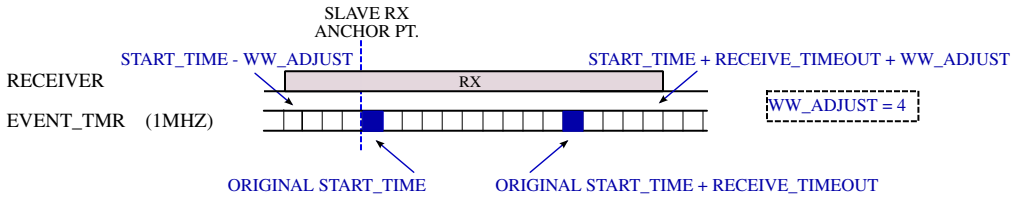

Figure 239. WINDOW WIDENING EFFECT ON RX SEQUENCE

The ww_adjust[19:0] adjustment, has no effect on START_TIME for slots using FUNCTION TX or NO_RF.

After system reset, if window-widening is enabled using WW_EN, ww_adjust[19:0] will increase linearly over time.

The adjustment, ww_adjust[19:0], will be reset to 0 under any of the following conditions:

1. system reset
2. good packet received (CRC verified and packet filtering passes)
3. Software writes a 1 to WW_NULL register bit

The reset-on-good-packet (item #2 above), can be inhibited by setting register bit WW_RESET_ON_RX=0. By default this bit is set.

The adjustment, ww_adjust[19:0], consists of 2 components, which are summed together:

1. **DSM adjustment:** computed at the conclusion of every DSM cycle based on rfmc_sleep_duration[23:0]
2. **RUNTIME adjustment:** computed by periodically incrementing a binary counter by 1 every *N* EVENT_TMR ticks whenever NOT in DSM

The rates at which window-widening accumulates during DSM and RUNTIME, are controlled by 2 programmable registers. The programmed values of these registers should be informed by the combined (master + slave) SCA.

The 2 components of the window-widening adjustment, and the reset conditionality, are illustrated in the following diagram:

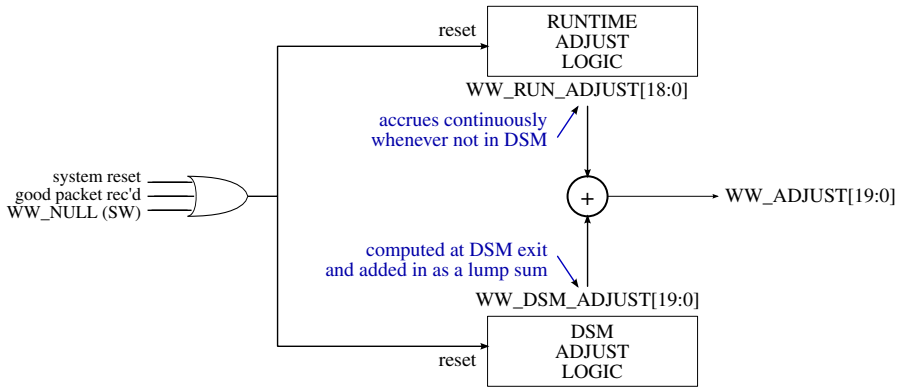

Figure 240. WINDOW WIDENING COMPONENTS AND RESET CONDITIONALITY

WINDOW WIDENING DSM ADJUSTMENT

In Wake-On-Radio, every slot includes a DSM cycle (unless NO_DSM=1 in the descriptor). WOR hardware computes the window-widening DSM adjustment after the DSM cycle completes, during the WOR COMP_WW state. This state immediately follows the COMP_ADDBACK state which updates the Event Timer for time-slept. The WW DSM adjustment, ww_dsm_adjust[19:0], is computed, and then added to the composite, accumulated adjustment, ww_adjust[19:0], as a lump sum. During COMP_WW state, WOR hardware multiplies rfmc_sleep_duration[23:0], which is the precise number of 32.768KHz cycles for which the RFMC held the radio in DSM, by a programmable factor which represents the number of microseconds per 32.768KHz clock cycle, scaled by the combined SCA of the master and slave (drift), i.e.,

DSM_DURATION (from RFMC) * (masterSCA + slaveSCA), converted to µs

Programmable register WW_DSM_FACTOR maps the composite SCA (masterSCA + slaveSCA), in parts per million, to a multiplicand which represents

N *** 16ppm * 30.5178125µs,**

where *N* = WW_DSM_FACTOR, and

30.5178125 is the *precise* number of microseconds per 32.768KHz tick, not an approximation.

Register WW_DSM_ADJUST allows SCA to be applied in coarse ranges, as described earlier in this section. Each LSB of WW_DSM_ADJUST is worth 16ppm of 30.5178125µs. Valid values are 0 ≤ WW_DSM_FACTOR ≤ 63. Consider the table below as a guide for selecting WW_DSM_FACTOR based on composite SCA:

masterSCA + slaveSCA	Use this WW_DSM_FACTOR
251 ppm to 500 ppm	16 (256ppm) - 32(512ppm)
151 ppm to 250 ppm	10 (160ppm) - 16(256ppm)
101 ppm to 150 ppm	7 (112ppm) - 10(160ppm)
76 ppm to 100 ppm	5 (80ppm) - 6 (96ppm)
51 ppm to 75 ppm	4 (64ppm)
31 ppm to 50 ppm	3 (48ppm)
21 ppm to 30 ppm	2 (32ppm)
0 ppm to 20 ppm	1 (16ppm)

Figure 241. WW_DSM_FACTOR BASED ON COMPOSITE SCA

A summary of all the hardware tasks performed to compute ww_dsm_adjust[19:0] during the COMP_WW state, is shown in the diagram below.

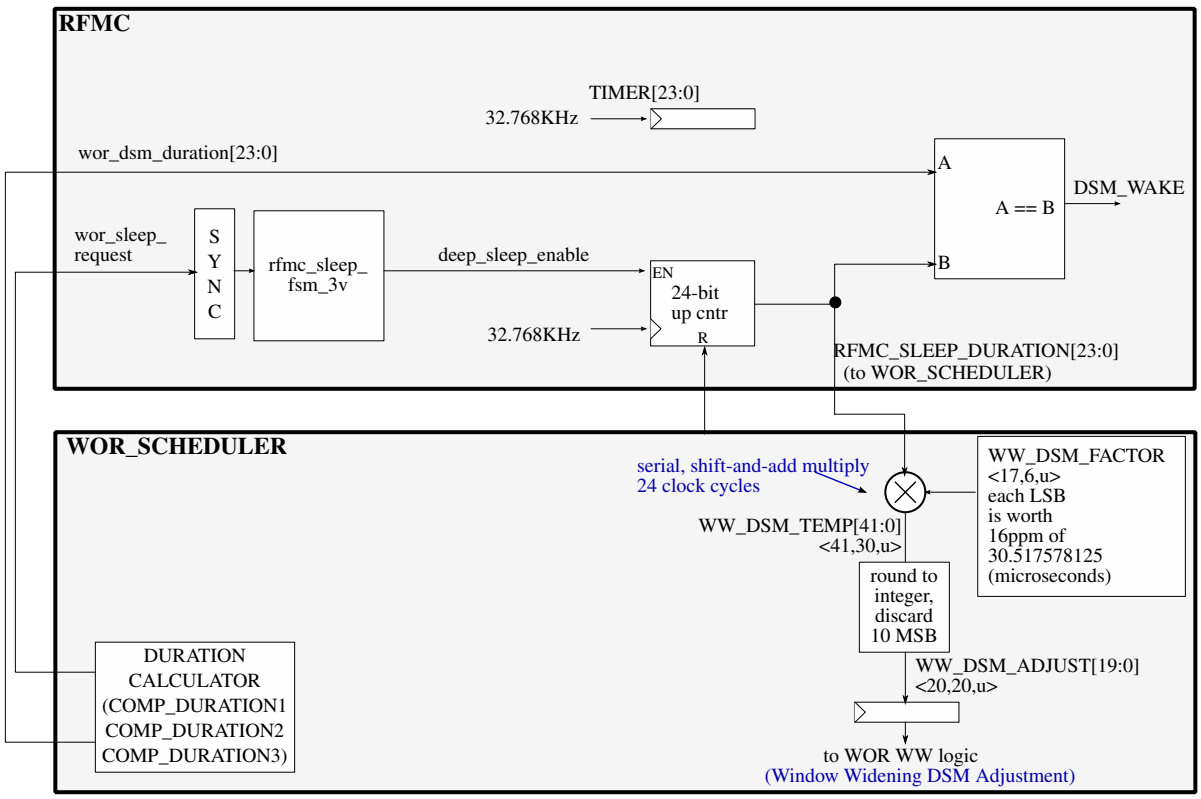

Figure 242. HARDWARE TASKS DURING COMP_WW STATE

WINDOW WIDENING RUNTIME ADJUSTMENT

The window-widening RUNTIME adjustment is computed by incrementing a binary counter every *N* EVENT_TMR ticks whenever NOT in DSM (i.e., EVENT_TMR is running). *N* is a variable based on programmable register WW_RUN_ADJUST[4:0]. The programmable resolution, or granularity, of the DSM adjustment (16ppm), will be matched by the RUNTIME adjustment. Unlike the DSM adjustment, the RUNTIME adjustment is an approximation to the ideal value of *N*, since *N* is the result of a division operation whose quotient is not always an integer number of microseconds. However, the objective in Wake-On-Radio is to spend as little time in RUN between events as possible, so the DSM adjustment will dominate the sum. Therefore, additional resolution in the RUNTIME adjustment, although acheivable, would have little benefit in overall power savings.

N is a modulo for the binary counter which tracks the runtime adjustment, and represents the ideal number of microseconds between each increment to the adjustment, which is simply the reciprocal of the composite SCA, i.e.,

***N* = 1 / (master SCA + slave SCA)**

Using an example of composite SCA = 192ppm,

***N* = 1 / 192e-6 = 5208.333**

For implementation, each SCA range (the same table of ranges defined for the DSM adjustment) becomes an input to a look-up table (LUT) which approximates this division, rounding the quotient to the nearest integer. SCA range is represented by the WW_RUN_FACTOR. If WW_RUN_FACTOR=0, the RUNTIME adjustment never increments (special case). Valid values are 0 ≤ WW_RUN_FACTOR ≤ 16.

Every time the modulo *N* is reached, the binary counter resets to 0, and the RUNTIME adjustment is incremented by 1, meaning that the start of the next receive operation, has been advanced by 1µs. The hardware which implements the window widening RUNTIME adjustment is shown in the following diagram.

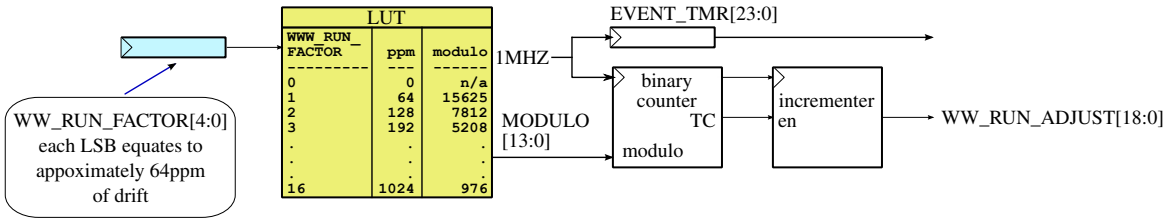

Figure 243. WINDOW WIDENING RUNTIME ADJUSTMENT

COMPENSATING DSM DURATION FOR WINDOW WIDENING

In executing each slot as specified by the WOR descriptor, there is one other instance where window widening must be accounted for. During the COMP_DURATION1 state, WOR computes the DSM duration based on descriptor START_TIME and current (Event Timer) time. This duration is timed to complete the DSM cycle as close as possible to the desired START_TIME, but with sufficient guardband to ensure wakeup can never occur too late. But the duration computed during this state may be sufficiently long that the desired START_TIME needs to be advanced, due to drift within the DSM cycle itself. Thus, window widening needs to be estimated and subtracted from this computation. This window widening estimation is used only for the purpose of the duration estimation, and does not accumulate from one DSM cycle to the next (i.e., from one slot to the next). This window widening compensation to DSM duration occurs during the COMP_DURATION2 and COMP_DURATION3 state. See Section State Machine for a description of WOR states.

The difference between this window widening computation, and the computation during COMP_WW, is that the result must be in units 32.768KHz clock cycles, because it is targetted for RFMC, instead of microseconds for an Event Timer offset. The COMP_DURATION2 and COMP_DURATION3 computation multiplies the DSM duration (in 32K cycles) computed in COMP_DURATION1 by an estimate of the SCA (drift), to arrive at a product which represents the number of 32.768KHz cycles by which to foreshorten the upcoming DSM cycle due to the widening requirement. So there is no conversion of units.

CYCLES_OF_WW[14:0] = DSM_DURATION_NO_WW[23:0] (result of COMP_DURATION1, neglecting widening) * *WW_DSM_FACTOR* * 549755 / 2^35

This product is subtracted from the DSM duration estimate, along with the DSM_GUARDBAND[3:0], to arrive at the final wor_dsm_duration[23:0] sent to RFMC for execution:

WOR_DSM_DURATION[23:0] = DSM_DURATION_NO_WW[23:0] - CYCLES_OF_WW[14:0] - DSM_GUARDBAND[3:0].

The following diagram illustrates all of the hardware tasks performed during COMP_DURATION2 and COMP_DURATION3 state:

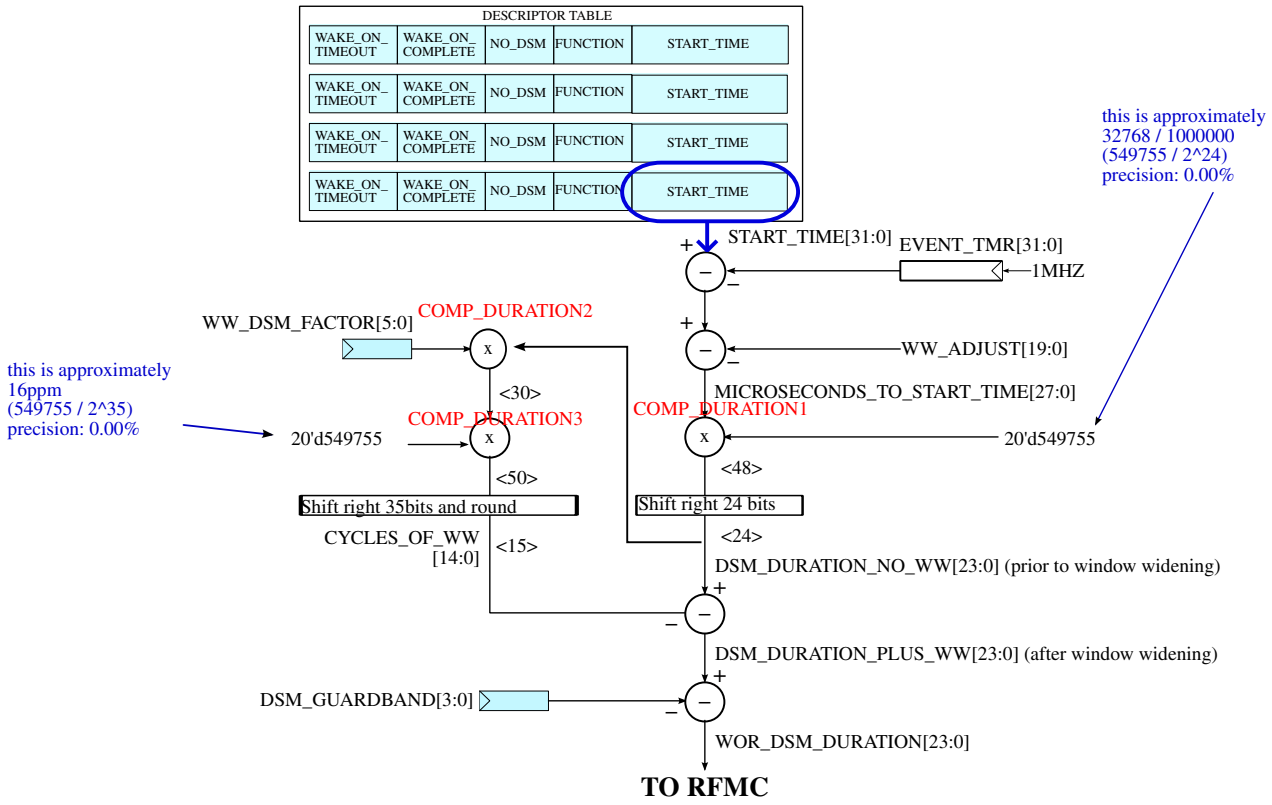

Figure 244. COMP_DURATION2

APPLYING THE WINDOW WIDENING

Now that the window-widening adjustment has been computed, it must be put into effect, by modifying the START_TIME of the RF operation to advance it by the number of microseconds in ww_adjust[19:0], which is the combined DSM and RUNTIME window widening adjustment. This occurs during the WAIT_SEQ_START state. The same adjustment is applied again, by modifying the TIMEOUT of the RF operation (assuming timeout is reached), by delaying it by the same number of microseconds that START_TIME was advanced by. This occurs during the WAIT_SEQ_END state. The following diagram illustrates how window-widening is applied in Timeslot Scheduling mode.

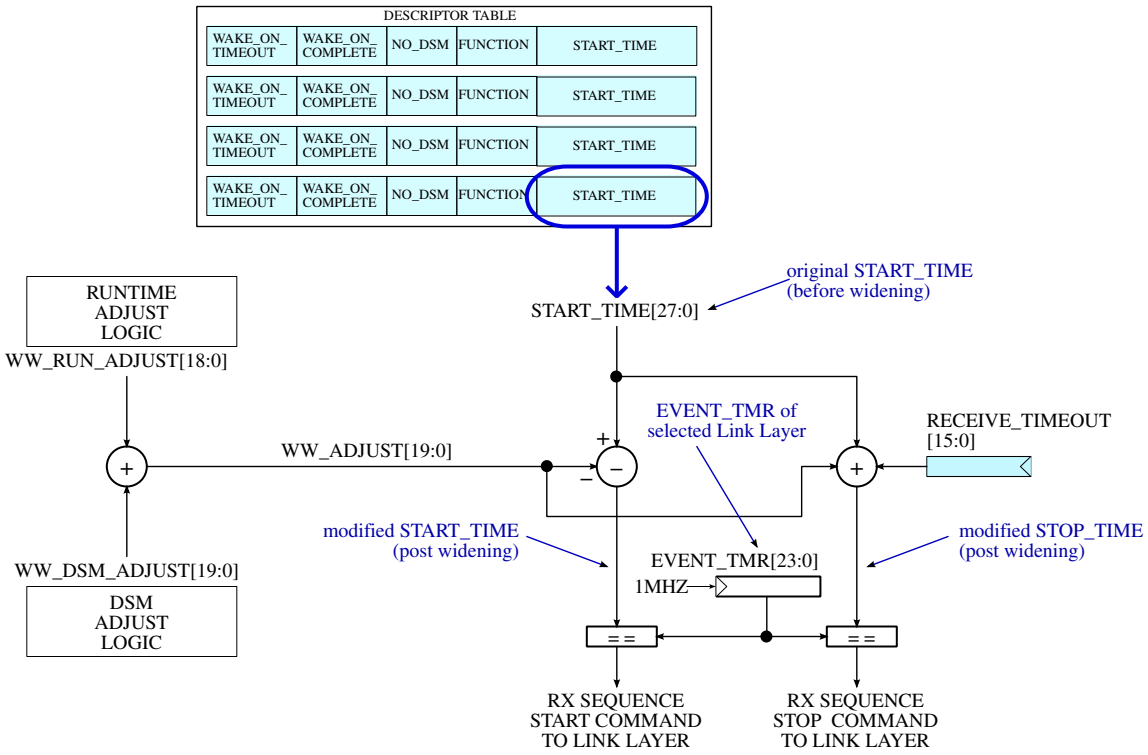

Figure 245. APPLYING WINDOW WIDENING (TIMESLOT MODE)

The application of window-widening in Constant-Interval scheduling mode, is largely the same as Timeslot mode; however the way the WOR hardware determines START_TIME and TIMEOUT is different, these need to be computed by WOR on a slot-by-slot basis. The following diagram illustrates how window-widening is applied in Constant-Interval Scheduling mode.

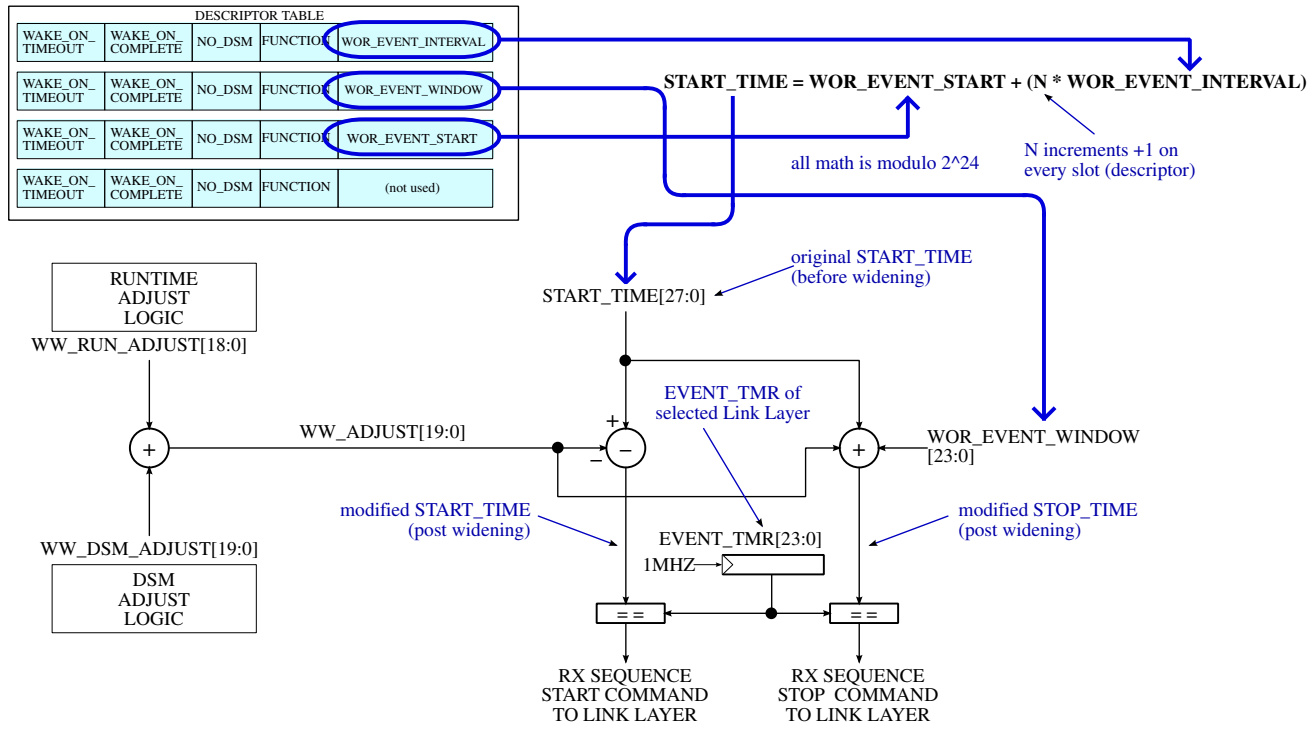

Figure 246. APPLYING WINDOW WIDENING (CONSTANT-INTERVAL MODE)

NOTE

When dealing with the combination of high SCA (Sleep Clock Accuracy) as well as long requested DSM intervals, it is the responsibility of software to guarantee that the accumulation of window widening does not become excessively large. Window widening should not be allowed to accumulate to such an extent that the adjusted START_TIME is advanced so much that it moves to the left of the *previous* slot's START_TIME, or that the TIMEOUT is retarded so much that is moves to the right of the *next* slot's START_TIME, especially in scenarios where no good packets are received for an extended period of time. Software should periodically monitor window widening accumulation using mandatory MCU wakeups after every third or fourth slot (timeslot mode), or WAKE_ON_NTH_SLOT (constant interval mode), and use caution when scheduling long DSM intervals (distance between START_TIME on consecutive slots) with high WW_DSM_FACTOR values.

55.4.6.2.3.6 Auto DSM Drift Calculation

Usually, the combination of SCA (Sleep Clock Accuracy) is hard to get, so for Window Widening, user has to set a big enough WW_DSM_FACTOR to cover the worst case. This makes the window larger enough to receive the packets but also wastes power. And also, the accumulation of window widening may become excessively large after many slots.

The "Auto Drift Calculation" feature is used to solve these shortcomings. This feature can only be used in Constant-Interval mode and it is enabled by register AUTO_CAL set when WW_EN is also enabled.

Its basic concept is that (the timestamp of the packet arrives - expected) is proportional to (the set drift - the actual drift). Based on this theory, hardware can calculate the actual drift after received a packet and then apply the calculated drift to the next slot to get the optimized window to save power. The detailed process is as follows.

1. Theory of Drift Calculation

Below figure shows a 4 slots receive case in Constant-Interval mode. After the reception of the first packet which is called the synchronization packet, software configures the WOR to the Constant-Interval mode and enables the Window Widening feature.

The term Rx(x=sync, 0~3) denotes the timestamp recorded in the link layer's Event Timer when the packet actually arrives, and Sx(x=0~3) denotes the expected timestamp which is calculated by the WOR hardware. RX_ENx(x=0~3) denotes the RX_EN signal assertion time.

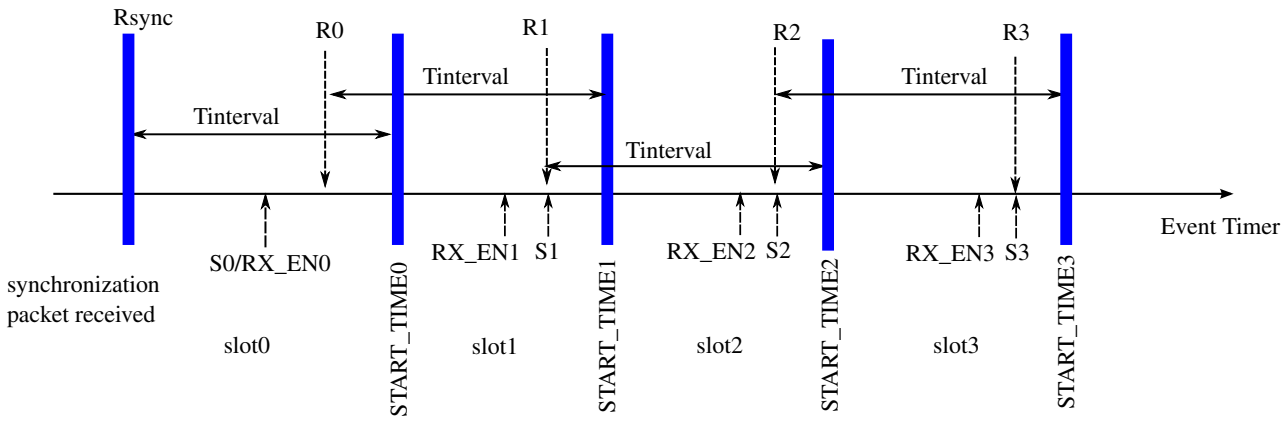

Figure 247. Auto Drift Calculation Algorithm

Software programs the START_TIME(WOR_EVENT_START) of the slot0 as

START_TIME0 = Rsync + Tinterval, Tinterval is WOR_EVENT_INTERVAL,

because if there is no clock drift, this is the next packet arrive time.

Since the START_TIME is the time which WOR hardware informs the Link Layer to assert the RX_EN signal, so it should consider the RX warm up time and the Preamble-SFD delay. The precise START_TIME should be

START_TIME0 = Rsync + Tinterval - AA_SFD_DLY,

where AA_SFD_DLY is a programmable regiter which counts for the RX warm up time and the Preamble-SFD delay.

AA_SFD_DLY does not effect the drift calculation, so for simplicity, it is ignored in the discussion below.

In this example, at slot0, user will set an initial WW_DSM_FACTOR to cover the worst case drift. If ignore the RUNTIME adjustment, the window will open WW_DSM_ADJUST0(Tsleep0 * drift_set0) earlier before the START_TIME. Due to the combination of SCA, the real packet arrive time is R0, it is (Tsleep0 * drift_real0) earlier than the START_TIME. That is to say,

the expected packet arrive time is:

S0 = START_TIME0 - WW_DSM_ADJUST0

= START_TIME0 - Tsleep0 * drift_set0 / 1000000, where drift_set0 = WW_DSM_FACTOR * 16 (ppm), Tsleep0 is the sleep time in slot0,

the real packet arrive time is:

R0 = START_TIME0 - Tsleep0 * drift_real0 / 1000000, where drift_real0 is the real drift during slot0, the unit is ppm

Hardware uses the delta time between S0 and R0, delta_time0, to get the drift_real0 as:

delta_time0 = R0 -S0

= Tsleep0 * (drift_set0 - drift_real0) / 1000000 (us)

drift_real0 = drift_set0 - (delta_time0 / Tsleep0 * 1000000) (ppm)

In the above formula, It is difficult for the hardware to calculate the division, so an approximate method is using Tinterval instead of Tsleep0:

drift_real0 = drift_set0 - (delta_time0 / Tinterval * 1000000) (ppm)

Convert drift_real0 to 16ppm unit as:

drift_real0_factor = drift_real0 / 16

= drift_set0_factor - (delta_time0 / Tinterval * 1000000 / 16) (LSB), where drift_set0_factor = WW_DSM_FACTOR

If user calculates the 1000000/Tinterval/16 and programs the result into register TINT_DIV_MILLION, hardware can simplify division into multiplication as,

drift_real0_factor = drift_set0_factor - (delta_time0 * TINT_DIV_MILLION) (LSB)

To cover the whole range of Tinterval, which is about 500 us to 2^28 us, the actual value programmed to the TINT_DIV_MILLION is

TINT_DIV_MILLION = (1000000 / Tinterval / 16) * 2^17

The hardware will take this extension into account and handle it accordingly.

The calculated drift_real_factor is readable by register **CAL_DSM_FACTOR** which is a signed register of two's complement value. A negetive value means the packet comes later than expected.

2. START_TIME Calculation for Each Slot

To calculate and track the drift in each slot, the START_TIME calculation is different with the normal Constant Interval Mode.

In normal Constant Interval Mode, the slot1's START_TIME is calculated as,

START_TIME1 = START_TIME0 +Tinterval

When AUTO_CAL is set, and if Link Layer received a packet in slot0, WOR calculates the next START_TIME as

START_TIME1 = R0 + Tinterval,

and the expected packet arrive time is:

S1 = START_TIME1 - WW_DSM_ADJUST1

= START_TIME1 - Tsleep1 * drift_set1 / 1000000, where drift_set1 = drift_real0, Tsleep1 is the sleep time in slot1,

and the real packet arrive time is:

R1 = START_TIME1 - Tsleep1 * drift_real1 / 1000000, where drift_real1 is the real drift during slot1, the unit is ppm

So, drift_real1 can be calculated as:

drift_real1 = drift_set1 - (delta_time1 / Tsleep1 * 1000000)

By this way, at each slot, hardware repeats to calculate and track the drift.

Ideally, the drift_real in slot0 and slot1 is same, so S1 is equal to R1. This means the packet may come at the exact time when the window opens. This achieves the longest sleep time.

But due to the drift calcuation error in slot0 or/and drift change between the slots, the packet may come a little bit earlier(like in slot2) or later than the expected time. To make sure that the packet is received, the real window open time is TIME_MGN earlier than the calculated point, Sx, where TIME_MGN is a user programmable register with us unit.

TIME_MGN can be calculated as:

TIME_MGN = (drift_calculation_err + inter_slot_drift_change) * Tinterval

The real Winodw Open time for slot 1 is

RX_EN1 = S1 - TIME_MGN

and the real STOP_TIME, i.e., Window Close time is

STOP1 = S1 + WOR_EVENT_WINDOW + TIME_MGN

For summary, for slot n, if there is a packet received in the previous slot n-1,

START_TIME(n) = R(n-1) + Tinterval

S(n) = START_TIME(n) - WW_DSM_ADJUST(n)

RX_EN(n) = S(n) - TIME_MGN

STOP(n) = S(n) + WOR_EVENT_WINDOW + TIME_MGN

3. Packet Missed Case

When a slot missed a packet due to some reasons, like drift sudden changes or RF signal is blocked, it will impact the drift calculation process.

Below figure shows the case that a packet is missed at slot 0. The basical idea is to apply the initial WW_DSM_FACTOR to slot 1, after received in slot 1, then apply the initial WW_DSM_FACTOR to slot2, after received in slot 2, the drift_real2 is calculated.

Since packet is missed in slot0, the initial WW_DSM_FACTOR is still used in slot1 and there is no margin time applied to START/STOP_TIME.

For slot1,

START_TIME1 = S0+Tinterval

RX_EN1 = START_TIME1 - WW_DSM_ADJUST1

STOP1 = RX_EN1 + WOR_EVENT_WINDOW + 2 * WW_DSM_ADJUST

WW_DSM_ADJUST is the accumulated DSM adjust,

WW_DSM_ADJUST = WW_DSM_ADJUST0 + WW_DSM_ADJUST1

WW_DSM_ADJUST0 is the DSM adjust of slot0,

WW_DSM_ADJUST0 = Tsleep0 * drift_set0 / 1000000, drift_set0 = WW_DSM_FACTOR * 16 (ppm)

WW_DSM_ADJUST1 is the DSM adjust of slot1,

WW_DSM_ADJUST1 = Tsleep1 * drift_set1 / 1000000, drift_set1 = WW_DSM_FACTOR * 16 (ppm)

For slot2,

START_TIME2 = R1+Tinterval

RX_EN2(S2) = START_TIME2 - WW_DSM_ADJUST2,

STOP2 = RX_EN2 + WOR_EVENT_WINDOW + 2 * WW_DSM_ADJUST2,

WW_DSM_ADJUST2 is the DSM adjust of slot2,

WW_DSM_ADJUST2 = Tsleep2 * drift_set2 / 1000000, drift_set2 = WW_DSM_FACTOR * 16 (ppm)

R2 = START_TIME2 - Tsleep2 * drift_real2 / 1000000

Using R2 and S2, we can get the drift_real2 and apply it to slot3.

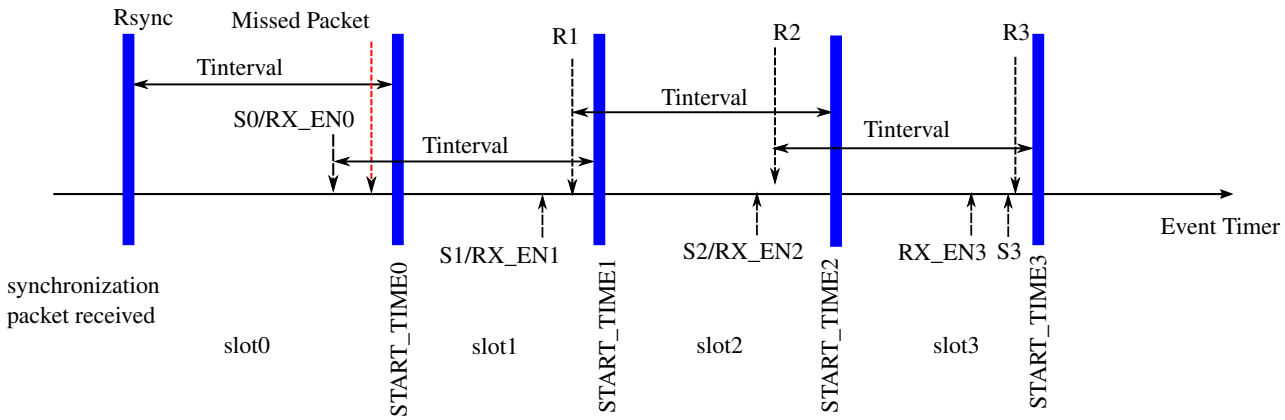

Figure 248. Handle of Missed Packet(Example 1)

As another example below, in slot0 packet is received, but in slot1, the packet is missed. The basical idea is to apply the drift_real0 to slot 2, after received in slot 2, then apply the initial WW_DSM_FACTOR to slot3, after received in slot 3, the drift_real3 is calculated..

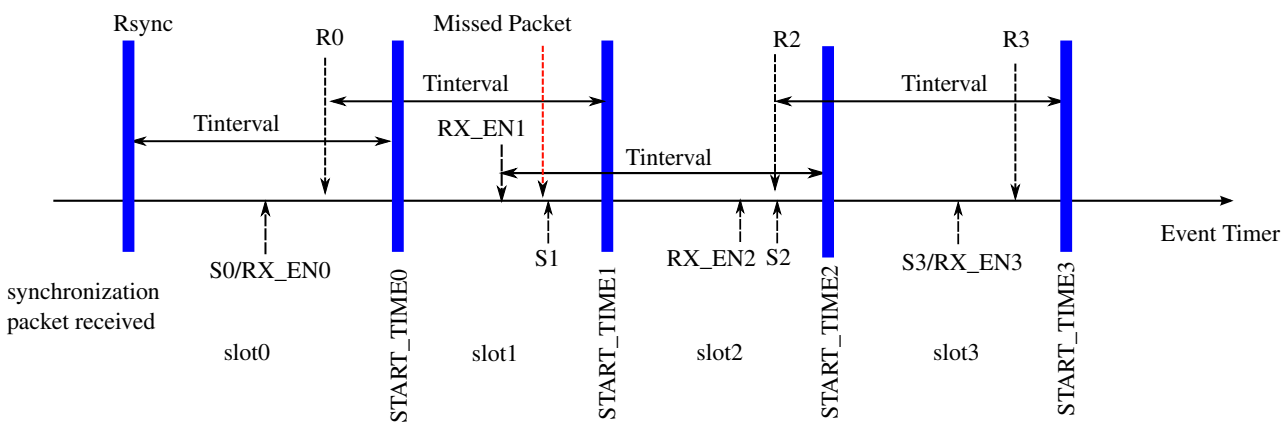

Figure 249. Handle of Missed Packet(Example 2)

Since packet is received in slot0, drift_real0 can be calculated.

For slot1,

START_TIME1 = R0+Tinterval

RX_EN1 = START_TIME1 - Tsleep1 * drift_real0 / 1000000 - TIME_MGN

STOP1 = RX_EN1 + WOR_EVENT_WINDOW + 2 * TIME_MGN

For slot2,

Then the START_TIME is calculated as:

START_TIME2 = RX_EN1+Tinterval

And hardware still applies the calculated drift_real0 to slot 2. Consider the drift change between slot0 and slot1, slot1 and slot2, the real window open point is TIME_MGN us before S2.

RX_EN2 = START_TIME2 - Tsleep2 * drift_real0 / 1000000 - TIME_MGN

and the real STOP_TIME, i.e., Window Close time is

STOP2 = RX_EN2 + WOR_EVENT_WINDOW + 4 * TIME_MGN

For summary, for slot n, if there is no packet received in the previous slot n-1,

START_TIME(n) = RX_EN(n-1) + Tinterval

RX_EN(n) = START_TIME(n) - Tsleep(n) * drift_set(n) / 1000000 - TIME_MGN

STOP(n) = RX_EN(n) + WOR_EVENT_WINDOW + 2 * (k+1) * TIME_MGN, where k is the number of missed slots since last reveived

In this example, in slot2, the packet is received. At this point, hardware does not calculate the drift_real for the next slot, because the calculation may be not correct since two slots passed. So hardware uses the initial WW_DSM_FACTOR for the next slot, slot3. and

START_TIME3 = R2 + Tinterval

So, if slot3 received a packet, the situation is like slot0, hardware get the drift_real for the next slot again.

S3 = START_TIME3 - Tsleep3 * drift_set3 / 1000000, where drift_set3 = WW_DSM_FACTOR * 16 (ppm)

R3 = START_TIME3 - Tsleep3 * drift_real3 / 1000000

drift_real3 = drift_set3 - (delta_time3 / Tsleep3 * 1000000) (ppm)

4. Slot with Function TX/TR/NO_RF

For slots with function TX/TR/NO_RF, they are not effected by the window widening. That is to say, for TX/TR, the TX_EN is asserted at the START_TIME_T:

START_TIME_T(n) = START_TIME_T(n-1) + Tinterval

START_TIME_T(0) = WOR_EVENT_START

For NO_RF, at the START_TIME_T, the WoR state machine jumps to next slot.

There is the case that TX/TR/NO_RF may be mixed with RX/RT function. In this case, the slot with TX/TR/NO_RF function is treated as "missed slot" since there is no packet received.

5. Handle of Missing Many Slots

In WoR operation, there may be some cases that many slots missed packets. The window will become larger and larger if missed so many packets and it is responsible for the WoR to wake up the MCU to check the fail condition and re-configure the radio block again.

WoR block provides a register **RX_SLOT_FAIL_THRESH**. When the number of missed slot is equal to this value plus 1, the WOR_RX_FAIL_IRQ is set. And when WOR_RX_FAIL_IRQ_ EN is set, the related interrupt will be sent to the MCU.

6. Software Do the Drift Calculation

Because the hardware uses Tinterval to approximate Tsleep, there is error. The WoR hardware provides a software interface that uses the MCU to calculate drift_real. When register **TIME_REC** is set with AUTO_CAL, some timing information is recorded to the Packet RAM. There can be at most 8 slots timing information can be recorded. WOR uses 160 bytes of Packet RAM for the timing information.

The timing information for one slot is as shown in below table.

Basically the drift_real can be calculated with:

drift_real_factor = drift_set_factor - (aa_match_time_delta_signed / Tsleep * 1000000 / 16) (LSB)

Where

Tsleep = rfmc_sleep_duration * 1000 / 32.768 (us)

Note, the calculation is only make sense when received a packet in a slot with the previous slot also received, or received a packet in the first slot.

This calculated drift factor can be programmed into register **SW_DRIFT_SET**, which is a two's complement value and each LSB is worth 16ppm.

Table 401. Timing Information for One Slot

Timing information word #	Timing information
Timing information word 0	{16'h0, packet_received, NO_DSM, 3'h0, wor_function[2:0], wor_slot_count[7:0]}
Timing information word 1	{{8{1'b0}}, rfmc_sleep_duration[23:0]}
Timing information word 2	TX_EN or RX_EN assert time
Timing information word 3	Packet arrived time, TimeStamp
Timing information word 4	{{11{1'b0}}, aa_match_time_delta_signed[20:0]} (aa_match_time_delta_signed is the delta time between Sx and Rx, two's complement value)

7. Calculation Error

There are many cases which will cause the calculation error. All these error can be covered by properly setting the register **TIME_MGN.**

7.1 Using Tinterval as Tsleep

Since the hardware are using Tinterval as Tsleep during the drift calculation, this will cause error.

7.2 Using 16ppm granularity

Since the hardware finally calculates the drift in 16ppm granularity, due to the round function, there may be 0.5 LSB(8 ppm) error

7.3 Drift change during slots

Due to the voltage or temperature change, the drift may change during slots.

7.4 The Event Timer Jitter after sleep

The event timer has a random ±1 us error after sleep. This error is caused and cannot be avoided by the fact that the 1MHz clock and the 32KHz clock are async. As shown in below waveform.

This will cause the delta_time ±1 us error, so will cause the calculation has error as:

When the Tinterval is 1ms, this 1us error will cause the calculated drift ±1000ppm error;

When the Tinterval is 10ms, ±100ppm error

When the Tinterval is 100ms, ±10ppm error

When the Tinterval is 1s, ±1ppm error

So the register TIME_MGN should be set to also consider this ±1 us error.

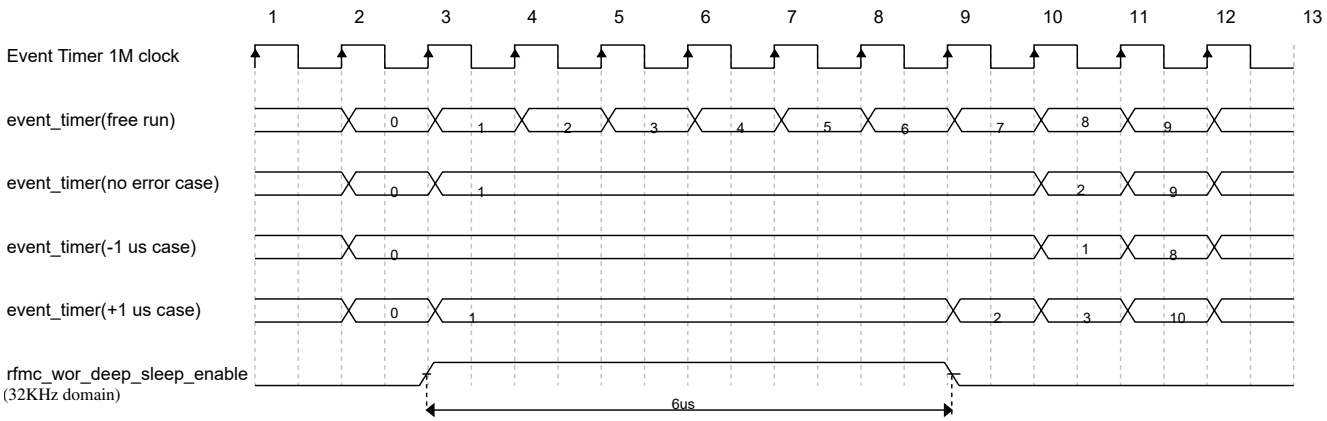

Figure 250. Event Timer Jitter

55.4.6.2.3.7 Timestamps

In Wake-On-Radio, every slot with FUNCTION=RX can capture a timeslot associated with any packet that is received in the slot. Any receive slot which results in an Access Address or an SFD detection will capture a timestamp into a register. Timestamps assist Link Layer software in maintaining and fine-tuning the network timebase across 2 or more networked devices.

Timestamp Capture

In Wake-On-Radio, each descriptor is associated with a slot. Any slot can be assigned an RX operation. RX operations require a timestamp to be captured. So, the timestamp can be thought of as being associated with the descriptor. The bit width of the timestamp is the same as the bit-width of the assigned Link Layer; i.e., 32 bits for GENERIC_FSK, and 28 bits for 802.15.4. Association of timestamps to descriptors is illustrated in the following diagram.

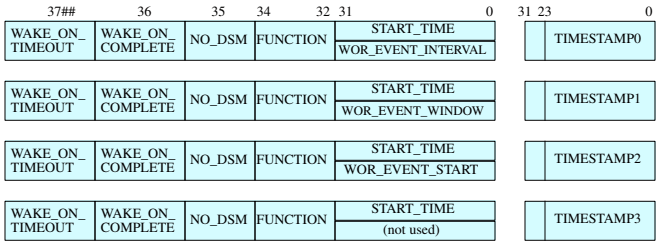

Figure 251. TIMESTAMP CAPTURE

Capture occurs at the instant AA or SFD is detected, and results in the current state of the assigned Link Layer's Event Timer being transferred to a TIMESTAMP register. WOR hardware does not apply any offset to the captured timestamp. A timestamp is captured for the last *N* RX operations, which result in (at least) one AA or SFD detection, where *N* = SLOTS_USED (typically 4).

Timestamp capture is area-intensive, due to:

- wide bit-width
- multiplicity (per descriptor)

Each of the supported protocol engines already has a TIMESTAMP register of the required bit-width. It is used for non-WOR (legacy) operations. To save area, when WOR is engaged, the TIMESTAMP register indigenous to the Link Layer, is used to capture the timestamp for WOR SLOT 0. Thus, in WOR mode (WOR_EN=1), the assigned Link Layer's TIMESTAMP register will only capture a timestamp when WOR SLOT=0, and will not change otherwise. If WOR is not engaged, the Link Layer TIMESTAMP register will capture all timestamps, the legacy behaviour. When WOR_EN, timestamps associated with SLOTS 1, 2, and 3 are captured in the TIMESTAMP1, TIMESTAMP2, and TIMESTAMP3 registers, respectively, which are new, and resident in the WOR scheduler. This distribution of timestamp register resources is illustrated in the following diagram.

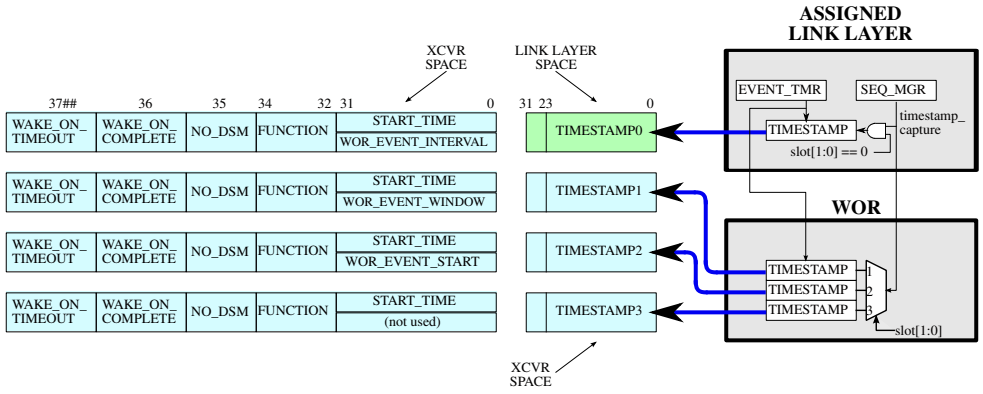

Figure 252. TIMESTAMP REGISTER DISTRIBUTION

Software should be aware of the fact that the designating the SLOT 0 timestamp to reside in the assigned Link Layer's TIMESTAMP register means that the TIMESTAMP regsters in Wake-On-Radio, are not all in one address space: TIMESTAMP0 resides in the assigned Link Layer's address space, while TIMESTAMP1-3 register reside in XVCR address space, alongside all the other WOR registers.

TIMESTAMP STATUS

A timestamp will be captured into a TIMESTAMPx register on any slot assigned to FUNCTION RX, whenever an Access Address or SFD is detected during the receive window. Whenever a timestamp is captured as described above, a 3-bit read-only status register is updated with information regarding status of the reception which occured during the slot. The timestamp status, TIMESTAMPx_STS[2:0], becomes valid, and final (for the current slot), at the end of the receive window, and is made available to MCU when it is next awakened, along with the TIMESTAMP itself. The status information can be used by software to ascertain the validity of the timestamp. The following diagram describes timestamp status.

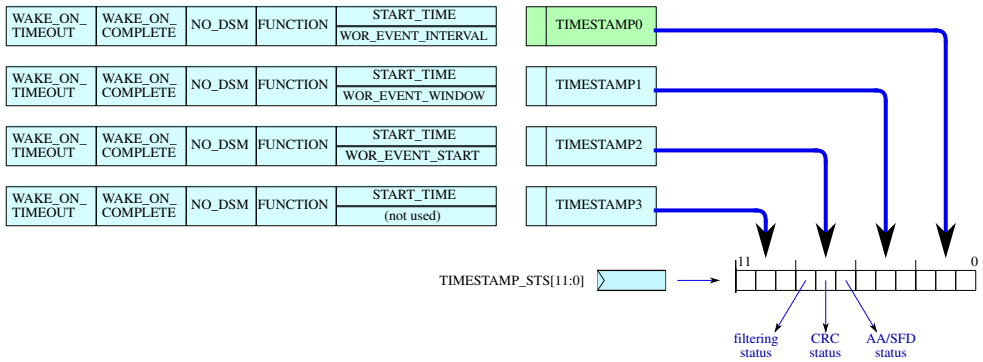

Figure 253. TIMESTAMP STATUS

A breakdown of the 3-bit status field, per timestamp, follows in the table below.

- 0: AA/SFD status
- 1: CRC status
- 2: Packet Filtering status

For any WOR slot assigned to RX, the 3-bit timestamp status field for that slot is cleared to 000 at the instant that WOR state WAIT_SEQ_START is reached. This is prior to the launch of the receive operation. (The bits are not cleared if the slot's function is not RX.) Once reception begins, the individual timestamp status bits are updated in realtime as the circumstances of the reception warrant. The 3-bit timestamp status is considered valid at the end of the receive window, and the bits reflect reception status per the following table.

TIMESTAMPx_STS bit	Meaning if 0	Meaning if 1
[0] AA/SFD status	No AA or SFD was detected during the receive window.	At least one AA or SFD was detected. RX recycles can lead to multiple occurrences.
[1] CRC status	For the packet associated with last (most recently) detected AA or SFD, CRC verification failed.	For the packet associated with last (most recently) detected AA or SFD, CRC verification passed.
[2] Packet Filter status	For the packet associated with last (most recently) detected AA or SFD, at least 1 packet filtering rule was violated.	For the packet associated with last (most recently) detected AA or SFD, all packet filtering rules passed.

Packet filtering rules, and hence the meaning of the TIMESTAMPx_STS[2] bit, vary across protocols, as summarized in the following table.

PROTOCOL	MEANING OF TIMESTAMP_STSx[2] (PACKET FILTER)
802.15.4	Reflects the Packet Processor FILTERFAIL flag
GENERIC_FSK	There are 3 packet filter criteria: 1. H0 matching 2. H1 matching 3. LENGTH_MAX compliance (maximum packet length verification)

Timestamp status bits are sticky. Once they become valid at the end of the receive window (end of WAIT_SEQ_END state), they remain valid until the *next* time the same slot number comes up again, and WOR reaches WAIT_SEQ_START state on that slot number.

In general, the MCU does not need to be notified on "bad packets." However, timestamp status may still be of value to WOR software even without Data Indication on any given slot. Notification policy can be modified at the protocol level, to enable RXIRQ on bad packets, mainly for debug purposes. If notification policy is modified by configuring the assigned Link Layer accordingly, this will affect Wake-On-Radio was well, as an rx_irq_trig will be generated on otherwise "bad" packets. See Section State Machine, specifically the WAIT_SEQ_END state, for details on how WOR responds to rx_irq_trig during this state, to determine how modifying notification rules would affect WOR response.

WOR software can use timestamp status to gauge the validity of the timestamp in any given slot. The following tables provides some guidelines.

TIMESTAMPx_STS	TIMESTAMPx REGISTER VALIDITY	MEANING
0b000	stale	No AA or SFD was received during this timeslot. The TIMESTAMPx register was not updated by HW and continues to hold the timestamp captured after the last AA or SFD detection on this slot number.
0bX01	invalid	At least 1 AA or SFD was detected during this timeslot. For the last (most recent) AA or SFD detected, CRC verification failed. TIMESTAMP register holds the EVENT_TMR captured for

Table continues on the next page...

Table continued from the previous page...

TIMESTAMPx_STS	TIMESTAMPx REGISTER VALIDITY	MEANING
		this reception. Because CRC failed, the TIMESTAMP should be deemed invalid, but this decision is left to the application.
0b011	valid	At least 1 AA or SFD was detected during this timeslot. For the last (most recent) AA or SFD detected, CRC verification passed. TIMESTAMP register holds the EVENT_TMR captured for this reception, and can be deemed valid. However Packet Filtering failed, so typically there would be no Data Indication.
0b111	valid	At least 1 AA or SFD was detected during this timeslot. For the last (most recent) AA or SFD detected, CRC verification passed. TIMESTAMP register holds the EVENT_TMR captured for this reception, and is valid. Packet Filtering passed.

55.4.6.2.3.8 Interrupt Management

WOR hardware utilizes the assigned Link Layer's interrupts for all MCU wakeups and notifications. In Wake-On-Radio, the MCU is in a low-power state most of the time. So, interrupts are allowed to assert only when it is mandatory to wake the MCU out of its low power state, to tend to required Link Layer or WOR tasks. WOR hardware modifies the interrupt activity of the assigned Link Layer by dynamically blocking and/or allowing Link Layer interrupts to propagate to the MCU, under control of the current slot descriptor specifications. Each of the 3 supported protocol engines have been modified to allow WOR to manage its RF-related interrupts. The RF-related interrupts have nearly identical functions and meanings across the 3 protocols:

- TXIRQ (or TX_IRQ)
- RXIRQ (or RX_IRQ)
- SEQ_END_IRQ (or SEQIRQ)

The modifications to the protocol engines, involve an AND gate inserted between each interrupt trigger, and the interrupt status bit, allowing or blocking the trigger from asserting the status bit. A gating signal, wor_allow_irq, is provided by WOR to each protocol engine to enable/disable the AND gate. The gating signal is updated dynamically by the WOR state machine based on state, RF operation status, and the current descriptor's WAKE_ON_* fields. See Section State Machine, specifically the description of the WAKE_SEQ_END state, for more details on how and when WOR allows and blocks RF-related interrupts. For protocols not assigned to WOR, interrupts are always allowed.

The raw interrupt triggers themselves (the inputs to the AND gates), namely, tx_irq_trig and rx_irq_trig, are passed directly to WOR hardware, so that WOR state machine can react to RF operation status in realtime, and sequence through the states as specified by the current slot's descriptor.

WOR manages one other Link Layer interrupt, for non-RF-related notifications. Each protocol engine has an existing interrupt, WAKE_IRQ, to notify MCU on wakeup from Manual DSM mode (not Wake-On-Radio). See Section Manual DSM for more details on this DSM control scheme. For any protocol, Wake-On-Radio and Manual DSM are mutually-exclusive control schemes, so when a protocol is assigned to WOR, its WAKE_IRQ is re-purposed, and re-named, to WOR_IRQ.

Like the "allow/block" gating WOR uses to manage the RF-related interrupts, WOR uses 2 signals to either block or *force* a WAKE_IRQ / WOR_IRQ:

- **wor_block_wake_irq:** prevents the (legacy) WAKE_IRQ from asserting at DSM exit, this is *mandatory* for Manual DSM, but is *conditional* for WOR.
- **wor_force_wake_irq:** WOR needs to assert WOR_IRQ under 3 conditions (see below)

There are 3 conditions for which WOR needs to compel the Link Layer to assert WOR_IRQ. WOR maintains 3 read-only status flags to indicate each of these conditions. The status flags exist in XCVR (WOR) address space, even though the WOR_IRQ resides in the protocol-specific address space. The 3 conditions, and the associated status flag for each, are described in the following table.

- **WOR_NO_RF_FLAG:** START_TIME has been reached on a slot with FUNCTION = NO_RF and WAKE_ON_COMPLETE=1
- **WOR_MAX_SLOT_FLAG:** In Constant-Interval scheduling mode, the WOR_SLOT_COUNT[7:0] has reached WAKE_ON_NTH_SLOT[7:0]
- **WOR_DSM_EXIT_FLAG:** An unscheduled, asynchronous DSM "Early Exit" has occurred

To service an WOR_IRQ, the interrupt service routine should query the 3 read-only status flags to determine the cause of the MCU wake up. At least one of these flags will be set. It is possible that more than 1 of the flags is set. For the WOR_NO_RF_FLAG, WAKE_ON_COMPLETE would typically not be set on a NO_RF slot, since the purpose of NO_RF is to allow "DSM cascading"; only for debug purpose has this flag been provided. Servicing of the other 2 flags is beyond the scope of this document.

Clear the WOR_IRQ by writing a 1 to this bit in the protocol-specific address space. However the 3 WOR flags are "sticky". Any flag which is set will remain set until a new WOR session has begun, which means taking WOR to DISABLED by setting SLOTS_USED=0, followed by re-enabling by setting SLOTS_USED>0.

In initializing the assigned Link Layer for WOR operation, it is *essential* that software enable (unmask) the 3 RF-related interrupts, as well as WAKE_IRQ / WOR_IRQ. It is equally essential that all non-WOR related interrupt sources are *disabled* when a protocol is assigned to WOR, to prevent unnecessary MCU wakeups. The following tables describe all the Link Layer interrupts, their controllability (or lack of) by WOR, and the required enabling/unmasking by software.

INTERRUPT CONFIGURATION (802.15.4)

INTERRUPT	WOR CONTROL	SW INIT	COMMENTS
TXIRQ	gated by wor_irq_allow	ENABLE	Asserted after packet transmission when: WAKE_ON_COMPLETE || WAKE_ON_TIMEOUT
RXIRQ	gated by wor_irq_allow	ENABLE	Asserted after good packet reception when: WAKE_ON_COMPLETE || WAKE_ON_TIMEOUT
SEQIRQ	gated by wor_irq_allow	ENABLE	1. Asserted after any good packet transmission or reception when: WAKE_ON_COMPLETE || WAKE_ON_TIMEOUT 2. Asserted after bad (or no) packet reception when: WAKE_ON_TIMEOUT

55.4.6.2.3.9 Channel Hop Table

Typically, in either Timeslot or Constant-Interval scheduling mode, RF operations on consecutive slots use different RF channels. Using Wake-On-Radio to program slot specifications for the next few RF operations in advance, would be of little value if the MCU had to wake up on every slot to program the assigned Link Layer's CHANNEL_NUM register. Thus, Wake-On-Radio provides hardware automation for channel hopping on a slot-by-slot basis.

A table of channel hop frequencies is maintained by hardware. The number of entries in the table (hop sequence length) is programmable. Prior to starting a WOR session, software will program the desired sequence of channel numbers into the table. After WOR is activated by setting SLOTS_USED>0, The WOR state machine controls the index (read pointer) into the table. The index is typically incremented at the end of every slot, when the slot counter is incremented. The increment is +1 modulo "hop sequence length". The RF operation on the current slot, is then carried out on the RF channel pointed to by the hop table index. If necessary, WOR or Link Layer software can update the hop table index at any time.

Rather than adding a channel number field to the descriptor, to save area, the hop table is decoupled from the descriptor table. The hop tables utilizes a small section of Packet RAM which is not otherwise used by the supported WOR protocols. WOR uses 128 bytes of Packet RAM for the channel hop table.

The channel information entered into the hop table, can use the (legacy) 7-bit "mapped channel" format, which allows channels to be specified on a 1MHz boundary; or one of 2 new 16-bit formats that allows channel frequency of higher resolution. The option for the legacy format, provides backwards compatability to existing software, which does not use WOR, to program RF channel information the way it does today, without any changes. The inclusion of the new formats allows additional flexibility for programming channels which deviate from a 1MHz boundary, coupled with the automation built in to WOR. The format selected, determines:

1. how the hop table is organized in RAM
2. how software programs the hop table
3. how the WOR parses the table during execution of the current slot
4. and how the PLL digital block interprets the frequency word extracted from the table.

Selecting the hop table configuration is by way of the HOP_TBL_CFG[2:0] register. Based on this setting, the source of channel information, can either be the CHANNEL_NUM[6:0] bit register that exists in each protocol engine today (legacy), or the new hop table, according to the following table:

Source of RF channel information, based on HOP_TBL_CFG[2:0]:

0: Assigned Link Layer's CHANNEL_NUM register (legacy)

1: WOR Hop Table

2: WOR Hop Table

3: WOR Hop Table

4-7: Reserved

To allow for the legacy option, the 3 protocol-specific CHANNEL_NUM registers are now routed to WOR, which multiplexes them with the hop table output based on HOP_TBL_CFG and WOR_PROTOCOL settings. WOR then outputs 3 16 bit frequencies words, one per protocol, to PLL Digital, conveying the required channel information.

Hop table organization is determined by HOP_TBL_CFG, as per the following table:

Hop Table Organization, based on HOP_TBL_CFG[2:0]:

0: N/A

1: Table size is 128 entries. Two 7-bit CHANNEL_NUM fields are packed into a 16-bit hop frequency word for RAM storage

2: Table size is 128 entries. Each 16-bit hop frequency word in RAM contains a specification for a single RF channel

3: Table size is 128 entries. Each 16-bit hop frequency word in RAM contains a specification for a single RF channel

4-7: Reserved

The content of the hop frequency word provided to PLL Digital, and how it is interpreted by that block, also varies with HOP_TBL_CFG, as per the following table:

PLL Digital Interpretation of Hop Frequency Word, based on HOP_TBL_CFG[2:0]:

0: Lower 7 bits of hop frequency word contain a mapped channel (legacy format). Upper 9 bits are 0

1: Lower 7 bits of hop frequency word contain a mapped channel (legacy format). Upper 9 bits are 0

2: All 16 bits are valid. See Chapter *PLL Digital* for interpretation

3: All 16 bits are valid. See Chapter *PLL Digital* for interpretation

4-7: Reserved

The following diagram summarizes the routing of channel hop signalling amongst the supported protocol engines, the WOR scheduler, the PLL Digital, and Packet RAM. It also shows the 2 hop table configurations, and hop frequency word generation, based on HOP_TBL_CFG. The existing (legacy) configuration is on the left, and the new, WOR-based configuration is on the right.

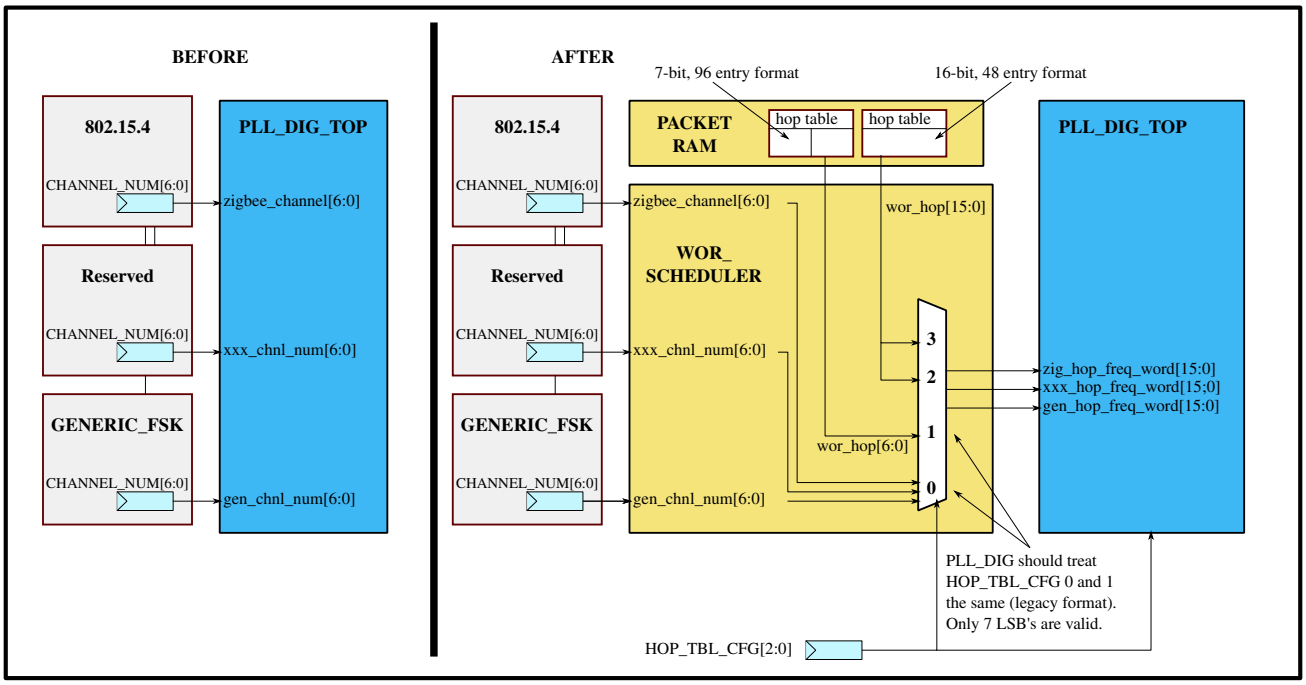

Figure 254. CHANNEL HOP SIGNAL ROUTING AND CONFIGURATION

The number of entries in the table is determined by programmable register HOP_SEQ_LENGTH[7:0]. If HOP_TBL_CFG=1, HOP_SEQ_LENGTH determines the number of 7-bit CHANNEL_NUM entries in the Packet RAM table, which are packed 2 per RAM word. HOP_SEQ_LENGTH must not exceed 128 in this case. If HOP_TBL_CFG=2 or HOP_TBL_CFG=3, HOP_SEQ_LENGTH determines the number of 16-bit format entries in the Packet RAM table, one per RAM word. HOP_SEQ_LENGTH must not exceed 128 in this case.

At the start of new WOR "session" (setting SLOTS_USED to a non-zero value), WOR hardware initalizes the table index (read pointer) to 0. (Software can modify this index, see below.) After slot execution completes, as the WOR state machine increments the slot counter to service the next slot, the hop table index is incremented by +1 (modulo HOP_SEQ_LENGTH). An exception is made to this rule, if the FUNCTION field of the slot descriptor is set to NO_RF, the hop index is *not* incremented when the slot counter is incremented to advance to the next slot. The NO_RF function is used for "DSM cascading".

Software can take control of the hop table index at any time, by writing a new desired index to the NEW_HOP_IDX[6:0], and with the UPDATE_HOP_IDX register set to 1. These 2 steps can be performed as a single, atomic IPS bus write. WOR hardware will update the index accordingly. From this point forward, the hop-table hardware incrementing rules, discussed in the previous paragraph, apply. This way, software can execute a one-time "jump" in the hop table indexing.

The read-only register WOR_HOP_IDX[6:0] allows software to read the instantaneous, hardware-controlled hop table index at any time. Similarly, the read-only register WOR_HOP_FREQ_WORD[15:0] allows software to read the instantaneous, hardware-generated frequency word sent to PLL digital. This word is the output of the hop table configuration selection mux shown in the diagram above, the protocol-specific word currently selected by WOR_PROTOCOL.

A diagram showing the RAM-based, 128-entry hop table (HOP_TBG_CFG=1), where it is situated in Packet RAM space, how the channel information is organized in the table, and how WOR hardware indexes the table, is shown below.

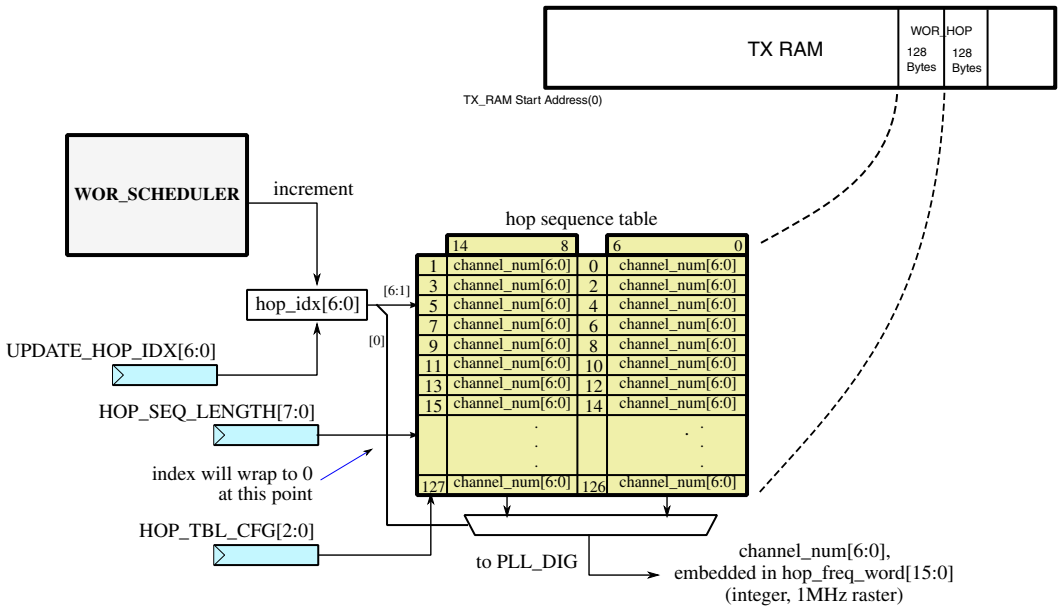

Figure 255. 128-ENTRY HOP TABLE

A diagram showing the RAM-based, 128-entry hop table (HOP_TBG_CFG=2 or 3), where it is situated in Packet RAM space, how the channel information is organized in the table, and how WOR hardware indexes the table, is shown below.

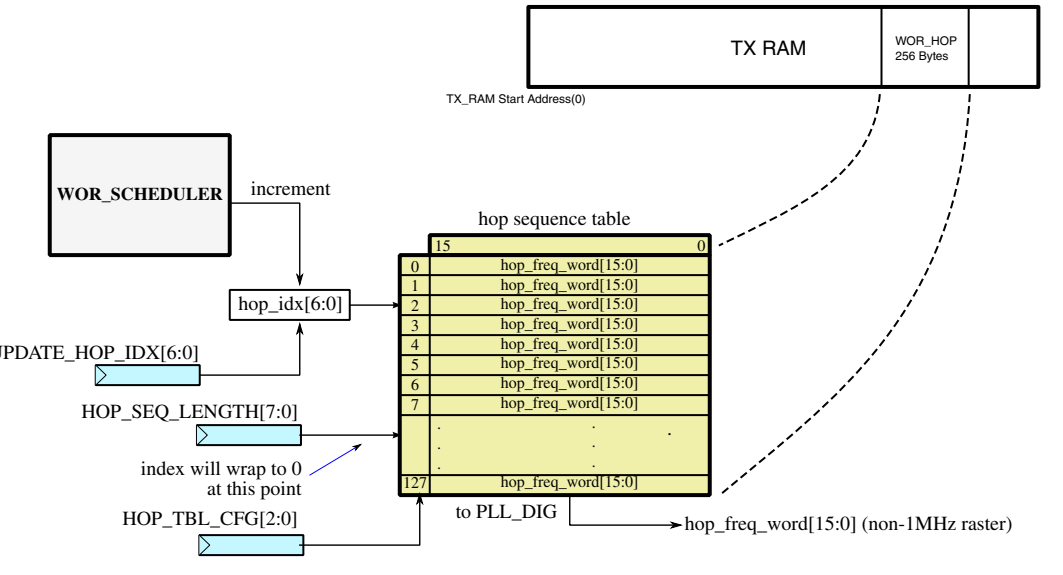

Figure 256. 128-ENTRY HOP TABLE

The 256 bytes of Packet RAM are reserved for the WOR hop table. The table is fixed in this position, and does not move based on HOP_TBL_CFG.

The WOR hop table should not be accessed (no writes or reads) while an RF operation is underway. There is no hardware to de-conflict RAM accesses with those originating in the protocol engines. Aside from this restriction, the hop table can be accessed at any time. A convenient time to modify the hop table, if required, would be during the WOR WAIT_RESUME state.

Follow the instructions below to program the WOR hop table.

1. Program the hop table

2. Program HOP_CTRL[HOP_SEQ_LENGTH] with the desired size of the hop sequence
3. Program HOP_CTRL[HOP_TBL_CFG] to select the desired table configuration and enable hopping during WOR

55.4.6.2.3.10 DSM Early Exit

As described in Section State Machine, for every slot, WOR hardware computes the duration of the upcoming DSM cycle based on descriptor START_TIME, current time, and window-widening, during the COMP_DURATION1 and COMP_DURATION2 states. WOR outputs the desired duration on wor_dsm_duration[23:0]. The Radio Mode Controller (RFMC) then executes this DSM for the prescribed number of 32.768KHz clock cycles, and when complete, sends the actual duration back to WOR using rfmc_sleep_duration[23:0]. Normally, these 2 durations will match precisely.

Conditions exist where the DSM cycle may occasionally need to be cut short, due to circumstances beyond the control of the radio. The SoC, starting with the MCU, must be awakened out of its low power state before the WOR DSM duration expires. When this happens, software handling the event which triggered the wakeup, will determine if the radio needs to be awakened as well. If this is the case, software will set the RFMC_WOR_WKUP bit. This will trigger an unscheduled wakeup process out of DSM by the RFMC deep sleep state machine. The wakeup will complete before the wor_dsm_duration[23:0] time has expired. RFMC will capture the *actual* DSM duration, cut short by the early exit, into rfmc_sleep_duration[23:0]

After DSM wakeup, WOR hardware always performs this check during the COMP_WW state:

rfmc_sleep_duration[23:0] == wor_dsm_duration[23:0]

If this check fails, WOR hardware declares an "DSM Early Exit", and takes the following steps:

1. Forces the assigned Link Layer to assert its WAKE_IRQ / WOR_IRQ (see Section Interrupt Management)
2. Sets the WOR_DSM_EXIT_FLAG in WOR space
3. Transitions to the WAIT_RESUME state and waits for software to service the WOR_IRQ.

Software should then take whatever steps are necessary to configure the radio to respond to the conditions which triggered the early exit. Servicing of a DSM early exit interrupt is beyond the scope of this document.

55.4.6.2.3.11 Manual DSM

Prior to Wake-On-Radio, implementation of the 2.4GHz used a software-driven, "manual" DSM. This DSM control scheme does not have any of the hardware automation associated with WOR, and software must perform such tasks as computing the Event Timer addback time, window-widening, etc.

Manual DSM still exists as an alternative to Wake-On-Radio. Manual mode can be of value in a multiprotocol setting. See Section Multiprotocol for more details.

Any of the 3 protocols supported by Wake-On-Radio, can utilize Manual DSM as an alternative to Wake-On-Radio. In short, Manual DSM works by programming a desired DSM start time into the ENTER_TIME register, and a desired DSM wake time into the WKUP_TIME register. The ENTER_TIME and WKUP_TIME registers are referenced to the 32.768KHZ TIMER, the radio's low-power (DGO) timer. ENTER_TIME, WKUP_TIME, and TIMER reside in RFMC address space.

When a match on TIMER to ENTER_TIME occurs, RFMC places the radio in deep sleep mode. The RF Oscillator is shut off, and the Link Layer's Event Timer is frozen in place. When a match on TIMER to WKUP_TIME occurs, the Event Timer resumes from where it left off. The RF Oscillator, is re-started as part of the DSM wake up process, and is running before WKUP_TIME is reached. At the instant the Event Timer resumes, the Link Layer asserts its WAKE_IRQ. The MCU should use the WAKE_IRQ ISR to compute the precise amount of time the radio was in DSM, convert this value to microseconds, and add this value to the current Link Layer Event Timer, to restore the timer to where it would have been, had DSM not occurred. There is a 1us loss-of-precision in the Event Timer timebase incurred on every DSM wakeup. This timebase error is random, and averages out over many DSM cycles.

Regarding the DSM wakeup process, there is additional programmability to configure the lead time for power-domain wakeup and oscillator re-start, relative to DSM exit (WKUP_TIME). This configurability is covered by the RFMC register. See the *Radio Mode Controller* chapter for more details.

55.4.6.2.3.12 Multiprotocol

The 2.4GHz radio supports 4 protocols, any 2 of which can be enabled for multiprotocol use on an alternating, time-shared basis. Both of the active protocols may require DSM. The following section describes the rules to be applied when assigning a protocol to a DSM control scheme.

The radio has 3 DSM control schemes:

1. Bluetooth LE-internal
2. Wake-On-Radio
3. Manual DSM

The Bluetooth LE-internal DSM controller applies to the Bluetooth LE protocol engine only, and is the only DSM option for Bluetooth LE.

Wake-On-Radio can be assigned to any one of the following protocols (see Section *Assign To Protocol*):

1. 802.15.4
2. GENERIC_FSK

Manual DSM can be assigned to any one of the following protocols (see Section *Manual DSM*):

1. 802.15.4
2. GENERIC_FSK

55.4.6.2.3.13 Hardware Multiplier

Wake-On-Radio requires 6 multiplies while executing each slot. The multiplications take place in the following WOR states (See Section State Machine):

1. COMP_DURATION1: to compute the upcoming DSM duration, excluding window widening
2. COMP_DURATION2 and COMP_DURATION3: to compute the subtractor to the upcoming DSM duration, for window widening
3. COMP_ADDBACK: to compute the Event Timer addback value based on RFMC-provided DSM duration
4. COMP_WW: to compute the DSM-component of window-widening incurred during the just-completed DSM cycle
5. DRIFT_CAL: to compute the clock drift

For maximum area and power saving, there is 1 hardware multiplier instance, which is timeshared for the 6 multiplies. Also, because the state machine has been architected to allow sufficient time to perform these computations before the results are needed, the multiplier uses a serial, add-and-accumulate construction. The multiplicands are 30 bits and 20 bits. The 30 bit operand is appropriately sized for the DSM_DURATION_NO_WW[23:0] * WW_DSM_FACTOR[5:0]. The 20 bit operand is appropriately sized to achieve the precision of the required calculations, as described in the earlier sections.

For each calculation, the multiplier requires 20 clocks (20 shifts). Each multiply takes place within the confines of a single state of duration 1µs. There are 32 periods of the reference oscillator during that period (26 for a 26MHz crystal), more than enough to complete the multiply. The clock to the multiplier runs at the reference oscillator rate, but runs only during the 6 1µs states listed above, to maximize power savings.

Depending on the calculation, the required precision, the positioning of the integer bits within the product, etc., the bits of the product tapped for each calculation varies. Also, depending on the calucation, combinational rounding or truncation of the product occurs, external to the multiplier.

55.4.6.2.3.14 Clocks and Gating

Because of the intensive interaction between Wake-On-Radio and 3 protocol engines it supports, the WOR hardware runs at 1MHz. This facilitates signalling between the WOR and the assigned Link Layers, with no additional pulse-stretching or signal-conditioning required. Like the protocol engines and the TSM, the CGM's cg1m_en gating signal is used to generate the common 1MHz, so the phasing of the clocks across all the communicating modules remains in sync.

All WOR clocks are conditioned on WOR_EN=1. This bit should be set, and remain set, whenever Wake-On-Radio is in use (it should not be toggled or modified dynamically by software, since module clock-gating is based on it). This bit should not be set if WOR is not in use; that way, the WOR hardware block will consume zero dynamic power.

In total, there are 4 clocks used by WOR hardware:

1. **ipg_clk_wor_1m**: Most of the WOR hardware runs off this 1MHz clock, including the state machine, descriptor processing, and hop table indexing. All link layer interface outputs are generated with this clock, and link layer inputs sampled by it.
2. **ipg_clk_wor_ww_1m**: Identical in timing to ipg_clk_wor_1m, but used only by functions that require window widening to be enabled. The additional clock gating granularity saves power when widening is disabled.
3. **ipg_clk_wor_comp**: This is the "compute clock" used by the serial multilier. This clock runs at the reference oscillator frequency (derivative of xcvr_ref_clk_gated), but only during the 4 1µs-long states (per slot) during which the multiplier is in use; See Section Hardware Multiplier)
4. **ipg_clk_wor_timestamp**: This is the "timestamp clock". Because the protocol engines determine the timestamp-capture timing, based on AA/SFD detection, the clock-gate enable for the capture is sent to the CGM, which routes the resulting timetamp clock itself to WOR so that it can update its TIMESTAMP1,2, and 3 registers. This clock will typically pulse once per RX slot, and not at all for slots of other types.

All gating for the WOR clocks is performed in CGM. WOR provides the gating-enable signal, and CGM provides the clock.

All WOR clocks are in the Reference Oscillator domain. There are no clock domain crossings inside the module.

No WOR critical timing paths are anticipated, nor any timing exceptions (e.g., multicycle paths).

55.4.6.3 Radio Bit Manipulation Engine

55.4.6.3.1 Introduction

This section provides an introduction to the Radio Bit Manipulation Engine (RBME) module. The RBME module is a group of configurable bit manipulation modules.

55.4.6.3.1.1 Features

- FEC: Forward Error Correction
  - Support for Bluetooth LE and Bluetooth LE LR
    - Requires a two pass FEC, over the AA+CI and over the payload + CRC
    - These are called FECBlock1 and FECBlock2 respectively
- Spreading
  - Hard Spreader
  - Inclusive of hard Manchester encode and decode
- Configurable CRC and Whiten (CRCW)
  - CRC
    - Supports direct method only
    - Supports input byte reflection
    - Final XOR and checksum byte reflection
    - Multiple CRCs per packet is not currently supported
    - Programable polynomial and seed values
  - Whitening Block
    - Hard whitening and de-whitening modes only
    - Programable polynomial and seed values

- Galois or Fibonacci type LFSR

— CRC can switch on before or after the second whitening module

- RAM interface

— Debug

— Frame processing

NOTE

The RBME is fully functional with GEN-LL, while totally bypassed when 15p4-LL is activated. If the NBU is the active link-layer, the RBME only be enabled for receiving long-range (coded) packets. In this case, the RBME responsible for despreading and do FEC decode. The de-whitening and CRC calculation should be done inside the NBU

55.4.6.3.1.2 TX-RBME Diagram

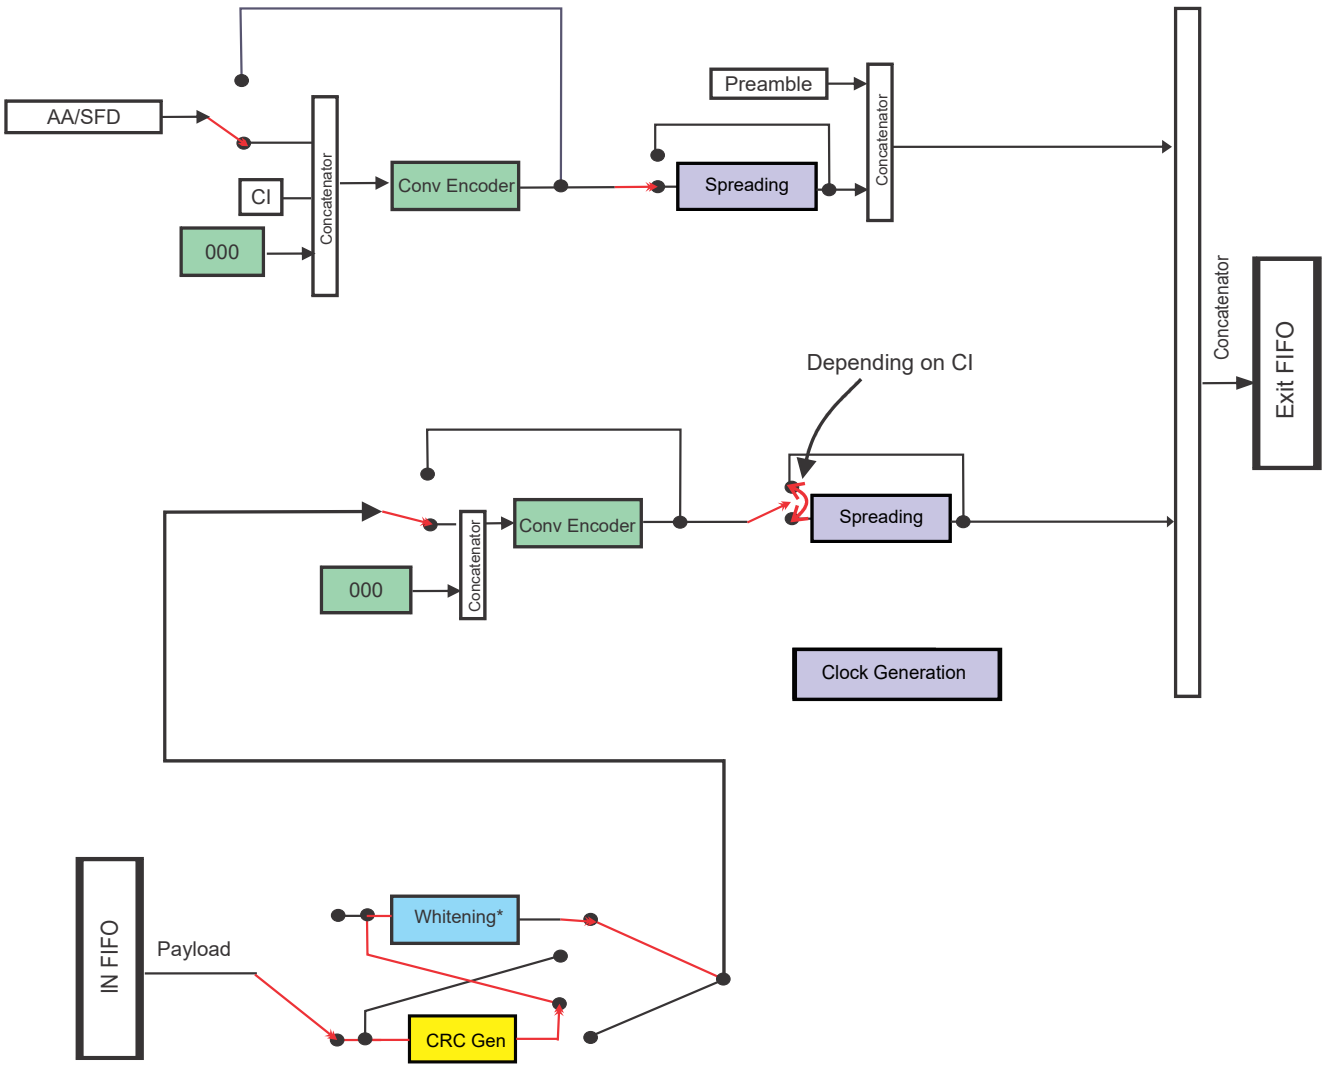

Figure 257. TX Diagram

55.4.6.3.1.3 RX-RBME Diagram

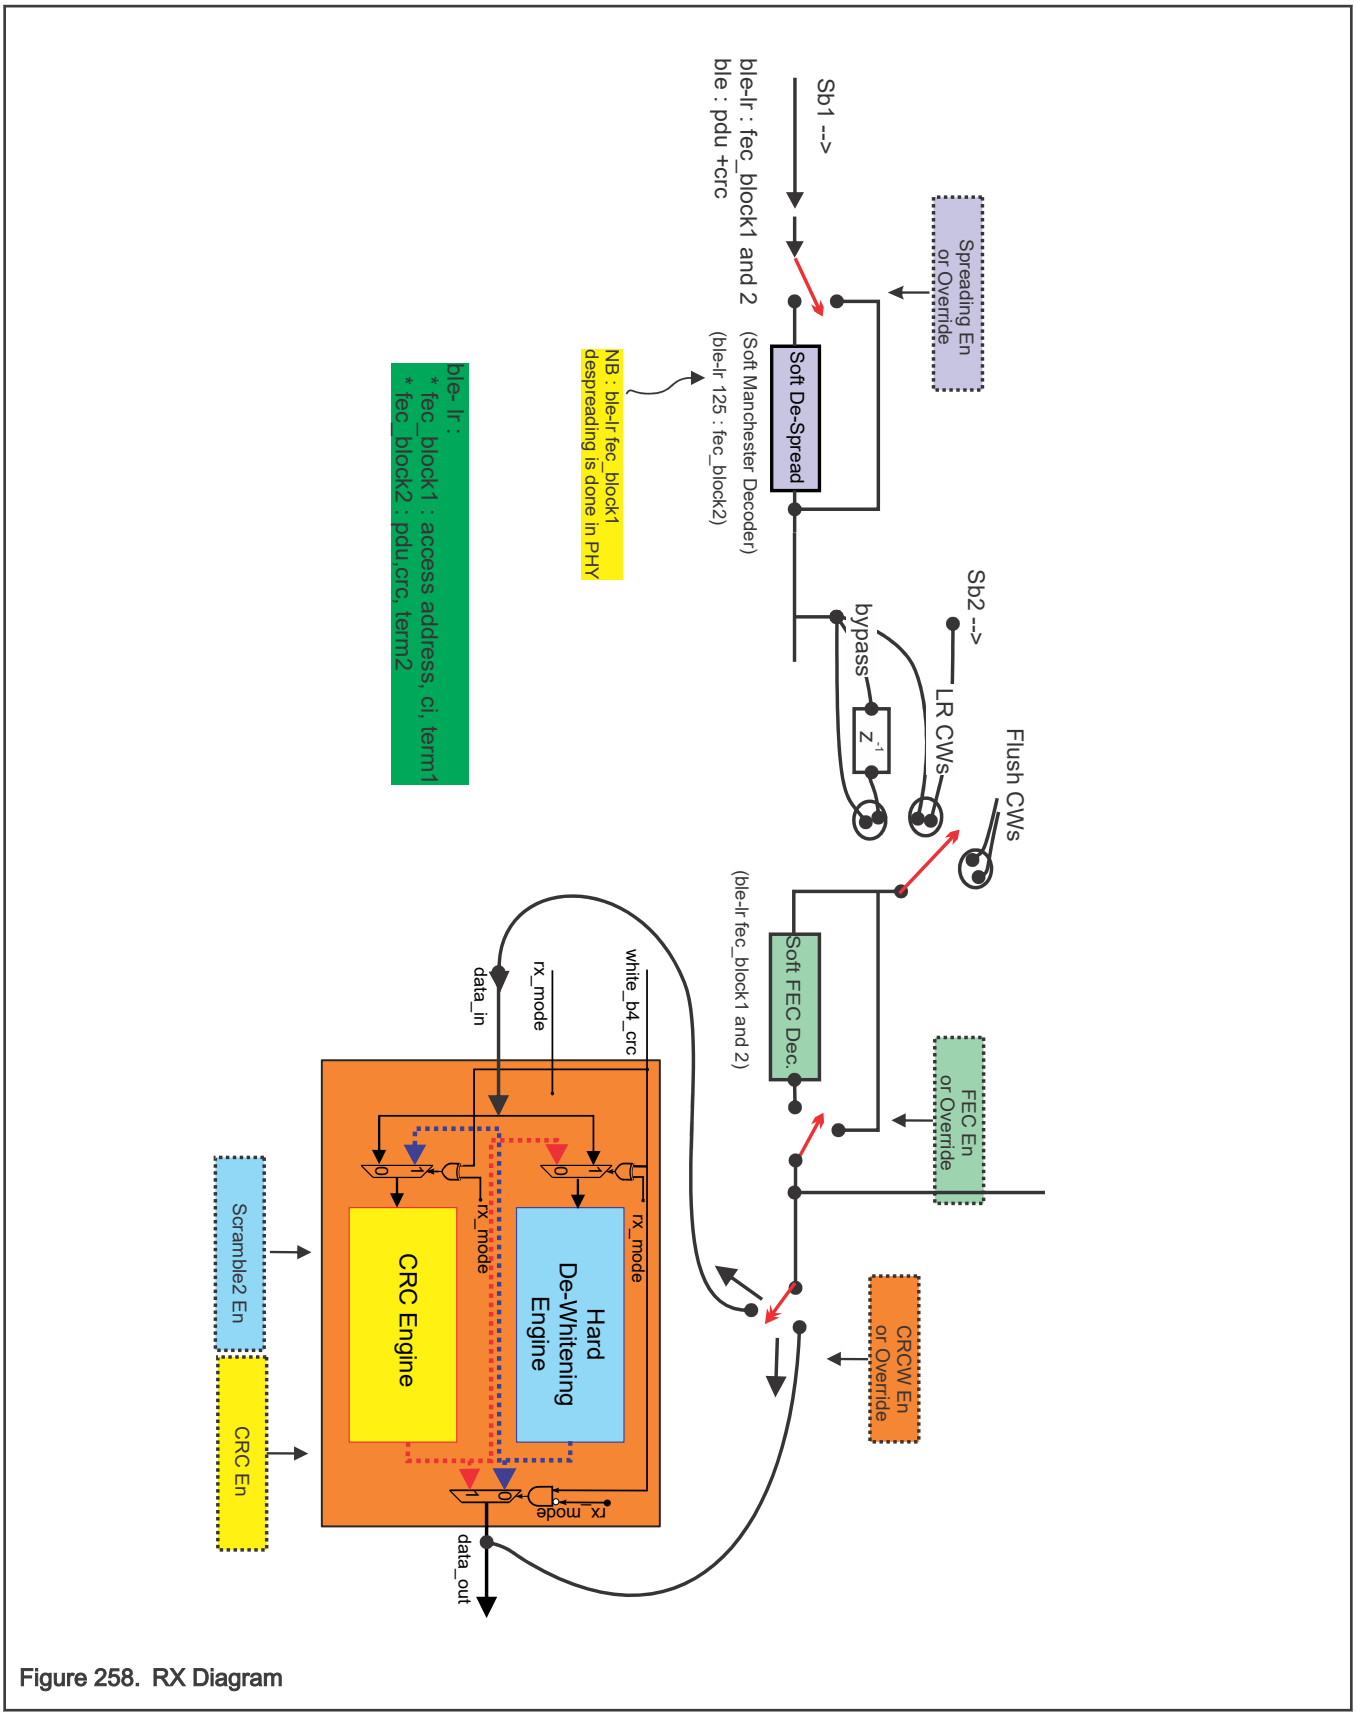

Figure 258. RX Diagram

55.4.6.3.2 Processing Order

TX-RBME Diagram shows the order of processing for the Transceiver (TX). The Receiver (RX) has the reverse order of processing shown in RX-RBME Diagram. The order of processing and the number of modules involved depends on:

1. The enable register for the block
   - Used to configure a block statically
   - Allows for configurability for a pre-known setup of the RBME
   - All TX modules only require a static enable as the configurations are known in advance
2. Override of the block (RX only)
   - Allows a dynamic override of the block enabling it regardless of the enable register
   - It requires that the appropriate override enable register be asserted
   - It does not disable the block: if a block is to be enabled dynamically
     - Set enable register off
     - Set override enable on
3. Bypass of the (RX only)
   - It has the highest priority
   - It is used only internally
   - It is dynamic

55.4.6.3.2.1 RX Bluetooth LE LR Example

When the Coding Indicator (CI) bits are demodulated and decoded, the mode of Bluetooth LE LR is known. Therefore, dynamic override needs to be used for de-spreading. For this reason, the spreading is disabled and the override is enabled for the RX. Furthermore, the receive for Bluetooth LE LR requires special handling as the FEC is required twice. The following steps describe the RX flow.

1. RBME input mode from link layer has been set to 1 to let RBME prepare for a long range (LR) configuration before AAFound.
2. RBME_en is asserted once AAFound, from the PHY acquisition, has been asserted.
3. After reading the decoded CI bits, the PHY sends a one-bit CI indication.
   - CI_indicator NOT asserted for 125 ksps reception
   - CI_indicator asserted for 500 ksps reception
4. The FEC processing must have the packet length from the link layer before the end of the packet for the CRC to be applied correctly. The processing counts the soft bits till Cnt = FECCounter2.
   a. FECCounter2 equals MaxPacketSize register until the LL updates the Frame length
   b. FECCounter2 = FrameLengthBits + NPHRBits + NCRCBits + FineTuneFECFlushBits
      i. FrameLengthBits is the number of bits from the link layer
      ii. NPHRbits = 16 for Bluetooth LE LR
      iii. NCRCbits = length of the CRC
      iv. FineTuneFECFlushBits is a register that allows for customization of the decoder length

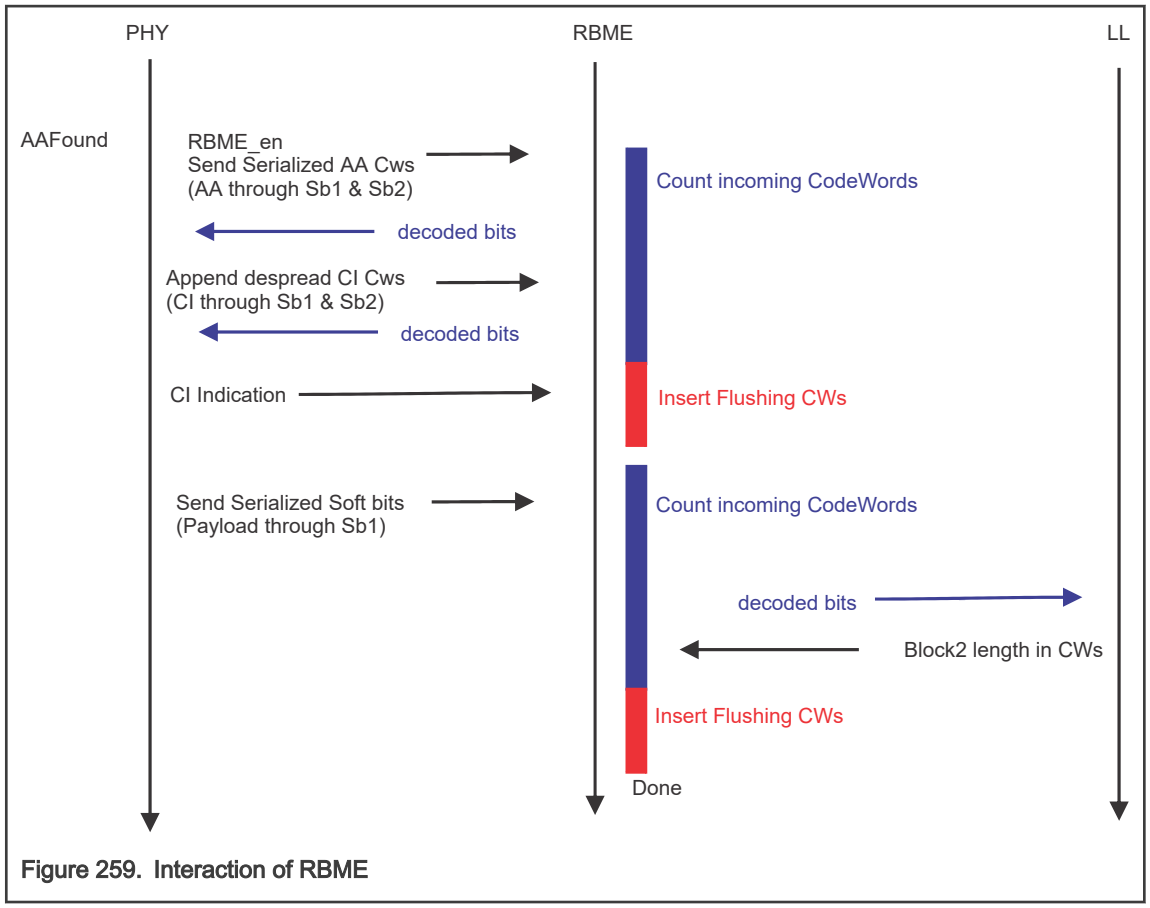

Figure 259. Interaction of RBME

The above figure (Interaction of RBME) shows the interaction among link layer, RBME, and PHY. The following table illustrates the Bluetooth LE LR packet format that RBME RX must account for. Note the separation into FEC Block1 and FEC Block2. Other important aspects are:

- AA+CI are spread with a spreading pattern of length 4
- AA+CI+TERM1 are combined as FECBlock1 as they need to be decoded together
- Header+Payload+CRC+TERM2 are combined as FECBlock2 as they need to be decoded together
- The de-spreading of AA+CI is done in the PHY for speed
- FECBlock2 may or may not need de-spreading depending on whether 125 ksps or 500 ksps are transmitted

Table 402. Standard Bluetooth LE LR Frame Format

10 Octets	4 Octets	2 bits	3 bits	Variable in Octets			24 bits	3 bits
Pre	AA	CI	TERM1	PDU			CRC	TERM2
				Header (16 bits)		Payload		
					Length (8 bits) L0:L7 Payload field length in octets. LSB first	ADV => 1:255 octets Data => 0:251 octets		
	FEC BLOCK 1			FEC BLOCK 2				

55.4.6.3.2.2 Frame delimiter before CRC Protocol (FCP) Example

An example of FCP frame packet is shown in the table below. It has the distinct characteristic that the Start Frame Delimiter (SFD) is passed through the CRC. This complicates the processing for the RX as there are two possibilities:

1. The ideal SFD is assumed for processing the CRC.
2. The decoded SFD is provided by the PHY.

   RBME assumes option 1, that is, the CRC presumes an ideal SFD. That ideal SFD is injected at the CRC buffer for processing, so no SFD bit errors will ever be caught. Another important feature of FCP is that whitening from a TX perspective is done before the CRC.

Table 403. FCP Frame Packet

1 octet	2 octets	5 octets		Variable in octets (8 -25)	2 octets
		RBME PHR		RBME Payload	
Pre	Net add	Device Address	Control (1 octet)	Data	CRC

55.4.6.3.3 RBME RAM And Interface

55.4.6.3.3.1 RAM Interface for RBME

RAM interface for RBME is important for debug and pre/post process frame. The only interrupt of RBME is generted by RAM interface. When packet RAM is filled completely with payload, the interrupt is sent to MCU in case of RAM_IF_IE set. The following figure (RBME TX RAM Interface) shows all the options, however, for simplicity the implementation of the RAM interface is in two developmental stages:

1. RAM-RBME-RAM only

   This interface is the simplest as it presumes that data into RBME and out of RBME comes and returns to the packet RAM.
2. RAM-RBME TX

   This interface writes single bit data from the packet RX RAM into RBME TX. The interface is like that of the generic LL using fast clock implicitly for the data rate and then switching internally to OTA derived clocks. For example, if FEC encoding alone is done, the input buffer is normally read at twice the OTA rate. TX_DIG normally dictates the OTA rate that is desired for the implementation. For the RAM equivalent, the read rate can be higher. The rate of RBME output may be higher than the equivalent OTA rate for the use case but must be smaller or equal to ref_clk/encoding_factor. The values for encoding factor are for example:

   a. For FEC encoding only

   b. 32 if a spreading factor of 16 was required and FEC was also required

   In Step2 of next figure (RBME RX RAM Interface), the data from TX RAM pre-processed is sent to link layer as normal case without RAM interface. Then RBME does the same way as usual.

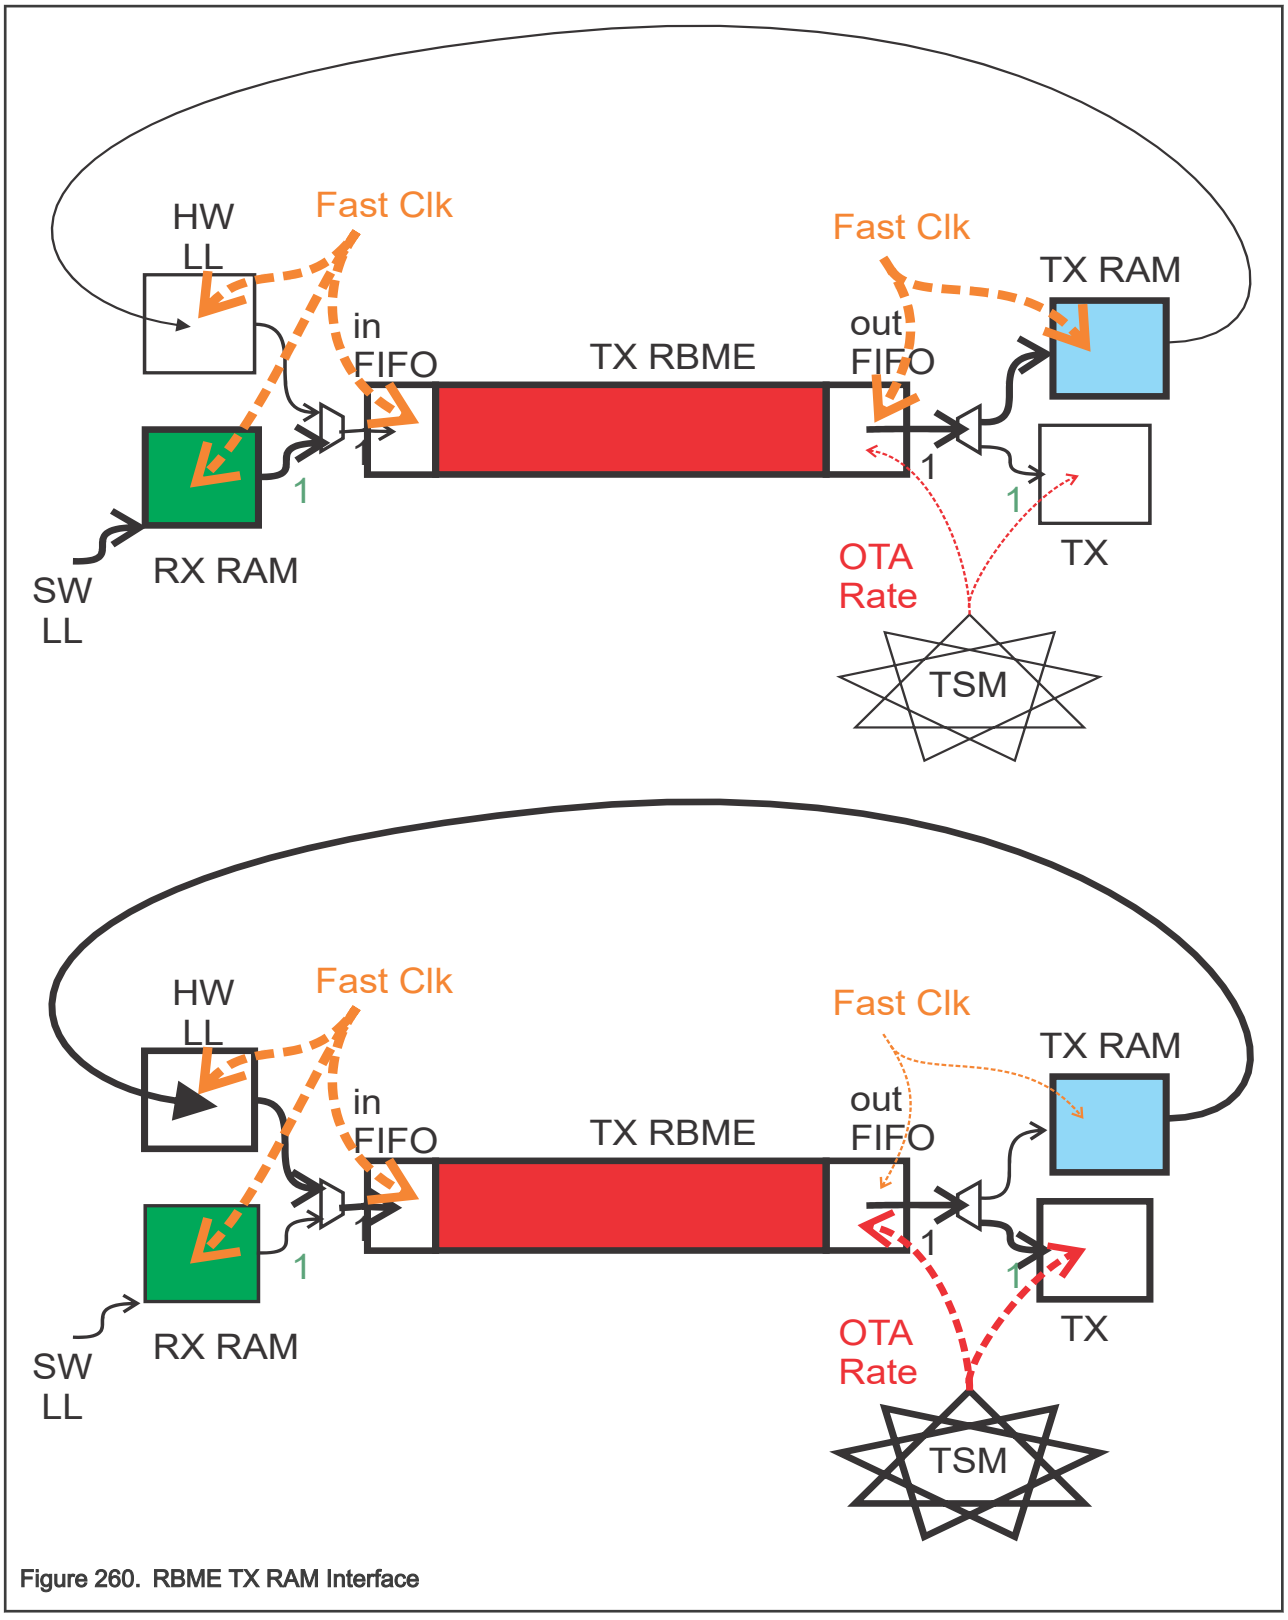

Figure 260. RBME TX RAM Interface

3. RAM-RBME RX

RBME RX processing: PHY ->[Despreading->FEC decoding->CRC & hard de-whitening]->LL Example: unsupported hard de-whitener with a different polynomial, interleaving and FEC plus soft de-spreading and CRC processing can be done in RBME RX.

1. First Pass: Use the PHY to RBME interface to process the data as normal but save the data to TX packet RAM before the de-whitener
    a. FEC decoding is enabled
    b. CRCW is bypassed
    c. Use software processing to do the soft de-whitening data
2. Second-Pass: Use the RAM interface to write 7-bit softbit words into RBME
    a. Do CRC decoding in RBME
    b. Use the RX RAM interface to read the CRC processed hard bit data

NOTE

A bypass from the PHY directly into packet RAM is needed if the de-spreader must be bypassed.

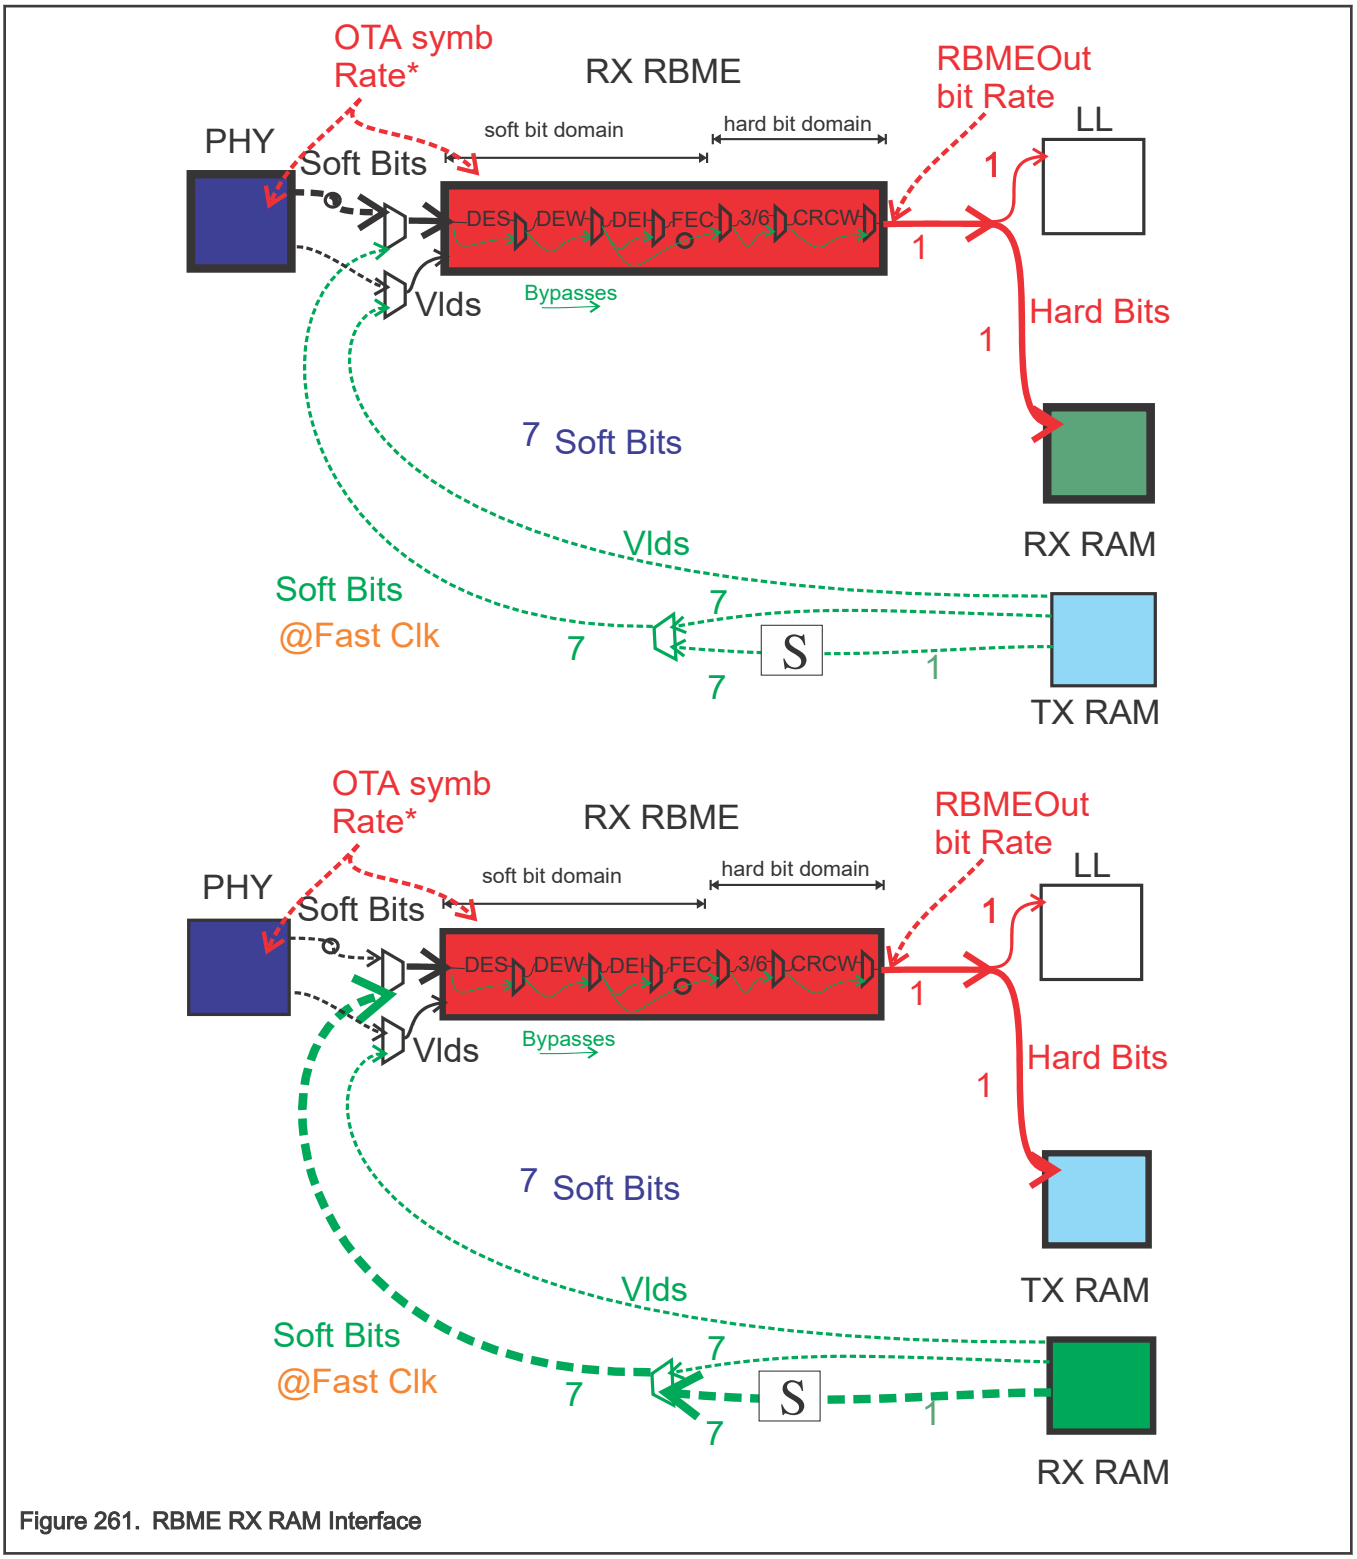

Figure 261. RBME RX RAM Interface

55.4.6.3.3.2 Internal Interfaces, Word Sizes, and Internal State Machines

For the TX, data and dataVld are single bits; for the RX and before the FEC, the data is in 7-bit words to describe softbits. The data format for CRCW for both TX and RX needs to be Boolean. In terms of clock valid management, every module internally

controls its output clock valid (as opposed to a central control). This methodology makes the modules easier to interact with each other. Examples:

1. When bypassing a module, the data valid is equally bypassed.
2. If de-spreading by four is used, the output data valid(s) are four times slower at the output.

The FEC Decoder input is in codeword (CW) pairs. This is normal for a rate ½ FEC. For Bluetooth LE LR, the de-spreading is done at the PHY so that the input to RBME is CW pairs at FrefFreq/2 for speed. This means that a second seven-bit input word needs to be separately added to the input. In summary, the input to the RBME RX is either a seven-bit input or two seven-bit inputs (both associated with the same input data valid signal). For Bluetooth LE LR only, the two seven-bit inputs are expected during the decoding of the AA and CI. For all other cases, there is a single seven-bit input. The RBME may also decode data from external memory, such data are expected to be serialized outside the RBME. The single Sb1 input can be used for this, alternatively, both Sb1 and Sb2 inputs can be used for faster processing. The enable control for a module is tabulated in Table 404. Note that a bypass signal has priority. Block bypasses are internal to the RBME. External override access on the other hand, that is, for the Soft-Whitening module and the FEC module, is allowed as long as the corresponding override enable register is set.

Table 404. RBME Module Enable Truth Table

Enable (Register)	OverrideEnable (Register)	Override	Bypass*	Block Enabled

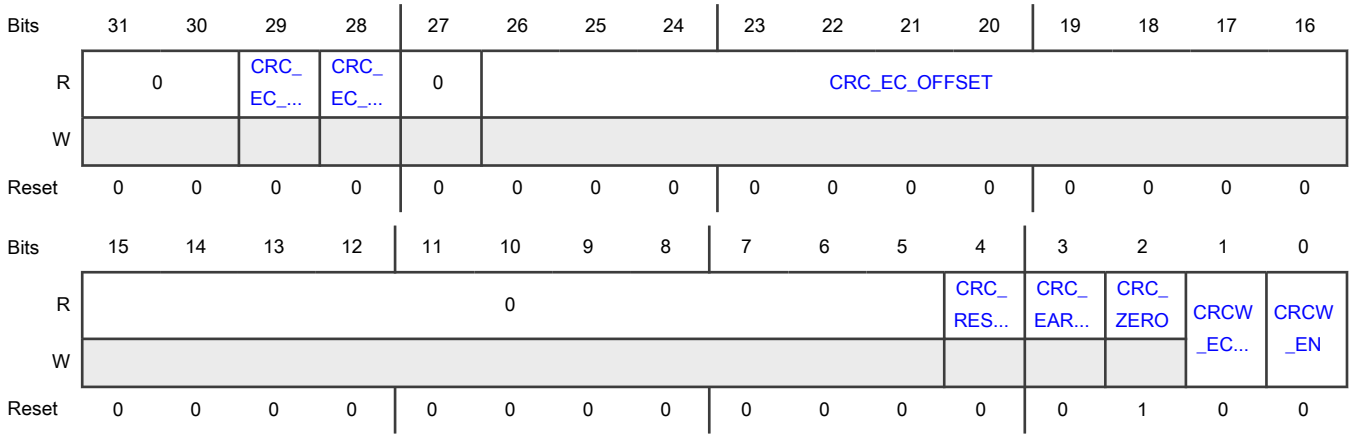
Offset

Register	Offset
CRCW_CFG	0h

Diagram



Fields

Field	Function
31-30 —	Reserved
29 CRC_EC_FAIL	CRC error correction fail This signal is cleared when *crc_init* is asserted. It is set after the completion of a CRC error correction calculation that does not find a valid data correction solution or if error correction was disabled and the CRC check found an error.
28 CRC_EC_DONE	CRC error correction done This signal is cleared when *crc_init* is asserted. It is set after the error correction logic completes processing the syndrome. It is immediately set after a packet is received if no error was detected or if error correction is disabled. Otherwise, it can take up to N system clocks after the packet is received to assert, with N = number of bits used in the CRC calculation, including the CRC value.
27 —	Reserved
26-16 CRC_EC_OFFSET	CRC error correction offset This value provides the byte offset within the data packet to which the CRC error correction mask should be XOR-ed. This value is valid if the *crc_ec_done* signal is asserted and the *crc_ec_fail* signal is not asserted. The offset includes only the bytes used in the CRC calculation, including the CRC value.
15-5 —	Reserved
4 CRC_RES_OUT_VLD	CRC result output valid CRC result output valid
3	CRC error correction fail

Table continues on the next page...

Table continued from the previous page...

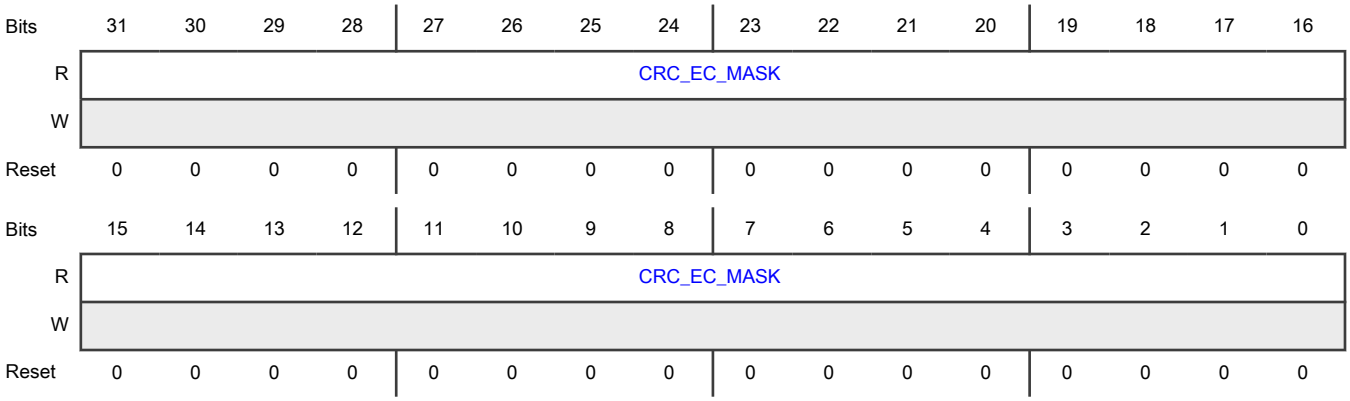
Field	Function
CRC_EARLY_FAIL	This signal is cleared when *crc_init* is asserted. It is set after the completion of a CRC error correction calculation that does not find a valid data correction solution or if error correction was disabled and the CRC check found an error.
2 CRC_ZERO	CRC zero This signal is asserted at any time when the CRC shift register contains a value of zero.
1 CRCW_EC_EN	CRC Error Correction Enable CRC Error Correction Enable
0 CRCW_EN	CRC calculation enable Input data bits loaded with this signal asserted are used in the CRC calculation.

55.4.6.3.4.3 CRC ERROR CORRECTION MASK (CRC_EC_MASK)

Offset

Register	Offset
CRC_EC_MASK	4h

Diagram



Fields

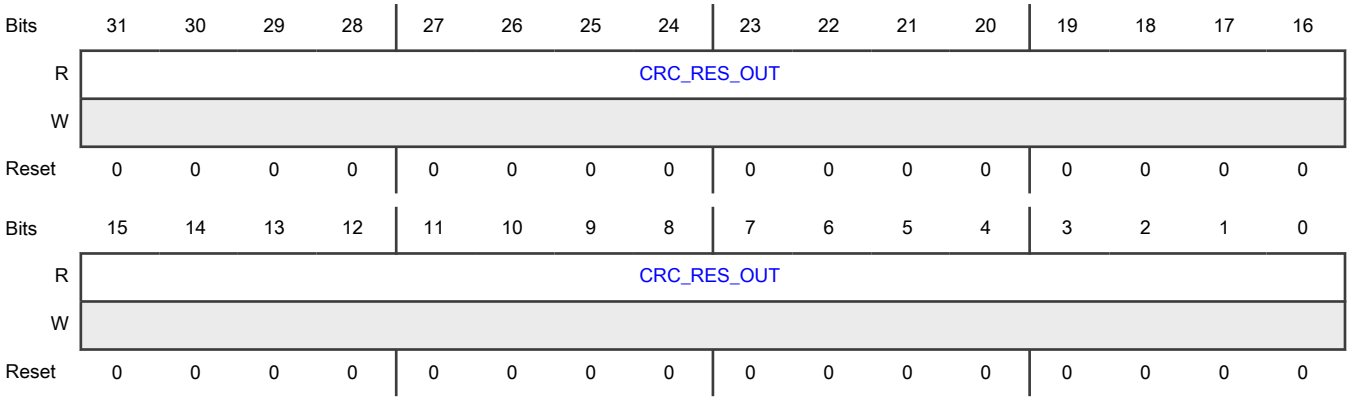
Field	Function
31-0 CRC_EC_MASK	CRC error correction mask This value provides a 32-bit XOR mask that must be applied to the input data packet to correct the burst errors detected by the error correction calculation. This value is valid if the *crc_ec_done* signal is asserted and the *crc_ec_fail* signal is not asserted.

55.4.6.3.4.4 CRC RESULT (CRC_RES_OUT)

Offset

Register	Offset
CRC_RES_OUT	8h

Diagram



Fields

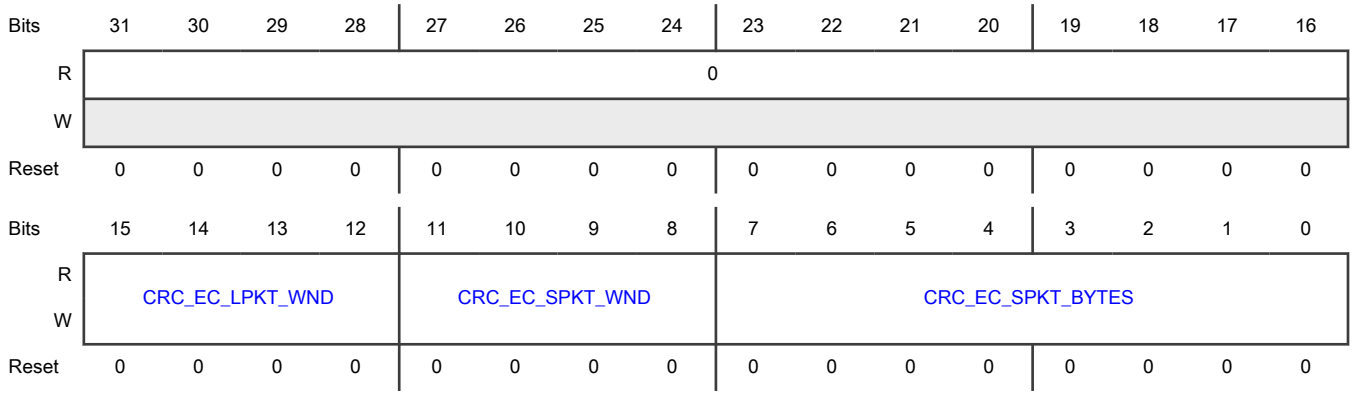
Field	Function
31-0 CRC_RES_OUT	CRC result output This bus provides the instantaneous value of the CRC shift register.

55.4.6.3.4.5 CRC/WHITENER CONFIG 2 REGISTER (CRCW_CFG2)

Offset

Register	Offset
CRCW_CFG2	Ch

Diagram



Fields

Field	Function
31-16 —	Reserved
15-12 CRC_EC_LPKT_WND	Error correction long packet burst error window This value determines the largest burst error corrected when long packets are processed. A value of zero will disable long packet error correction. The maximum value is 15.
11-8 CRC_EC_SPKT_WND	Error correction short packet burst error window This value determines the largest burst error corrected when short packets are processed. A value of zero will disable short packet error correction. The maximum value is 15.
7-0 CRC_EC_SPKT_BYTES	Error Correction Short Packet Bytes Short packets are defined as those where the number of bytes used in the CRC calculation, including the CRC value, do not exceed this value. The maximum value is 255.

55.4.6.3.4.6 CRC CONFIGURATION (CRCW_CFG3)

55.4.6.3.5 FEC

The initial FEC originates from BL5 specifications related to the long-range feature. It is a part of 2.4 GHz Radio IP. The convolutional FEC encoder uses:

1. A non-systematic, non-recursive design
2. Code rate ½ with constraint length 4
3. The generator polynomials are:

$$G0(x) = 1 + x + x^2 + x^3$$

$$G1(x) = 1 + x^2 + x^3$$

55.4.6.3.5.1 Two-Pass FEC

The FEC encoder and decoder can run twice on a packet. For the TX and Bluetooth LE long range, it must encode the AA, CI + termination bits (FECBlock1), and then encode the payload and CRC (FECBlock2), see section "RX Bluetooth LE LR Example".

For the RX, it must decode the two differently. To reduce latency, FECBlock1 is decoded with a fast clock once the AA is detected. FECBlock2 is decoded at the symbol rate.

55.4.6.3.5.2 TX FEC

FEC Encoder: Bluetooth LE-LR use case A shift register based representation of convolutional encoder is shown in the following figure.

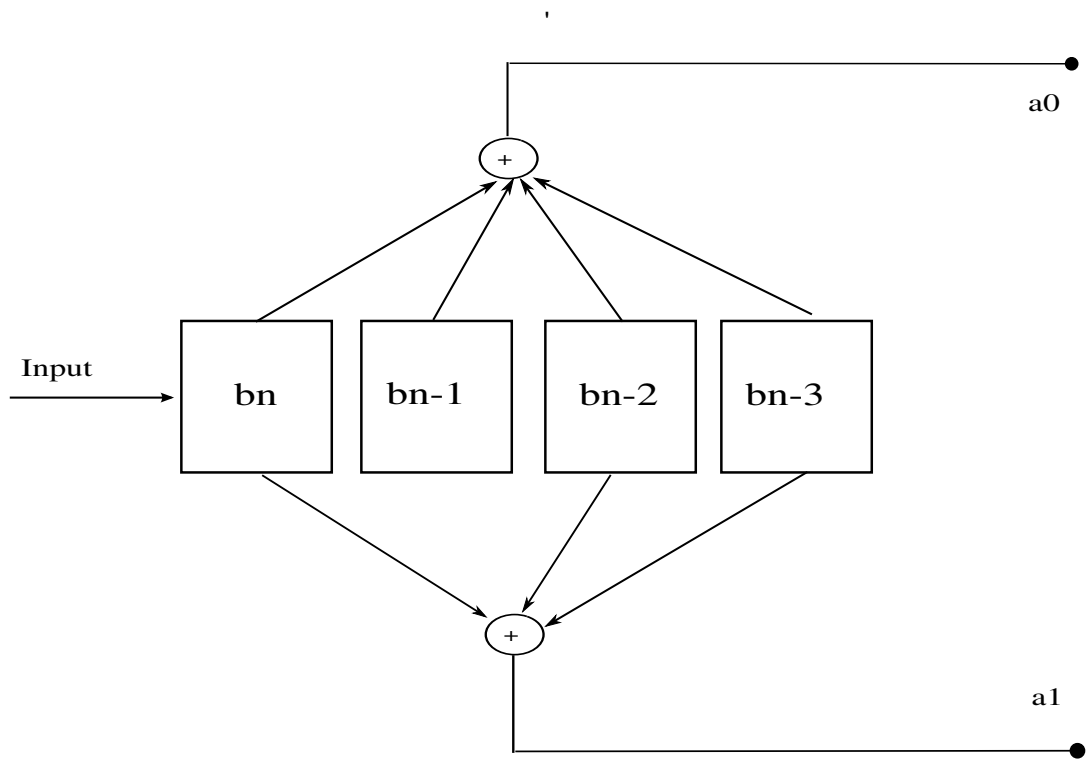

Figure 262. Bluetooth LE-LR FEC Encoder

Where:

- bn denotes the current bit, this is the input for the shift register.
- bn-i (i=1..3) are the previous bits sequence, they are referred to as the state or the memory of the encoder. The encoder produces two bits for each input bit.

The bit from generator polynomial G0 (a0) is transmitted first; the bit from generator polynomial G1 (a1) is transmitted second. The initial state of the convolutional FEC encoder is set to all zeros. An input sequence of three consecutive zeros always brings the convolutional FEC encoder back to its original state. This sequence is known as the termination sequence.

55.4.6.3.6 Spreader

TX Spreading

The spreading maps each input bit to P output bits (P = 2,4,8,16) symbols. The following table shows an example of Bluetooth LE LR where the choice for M is 4, depending on the coding scheme of protocols in use.

Table 405. Pattern Mapper inputs and outputs for Bluetooth LE LR spreading

Input from FEC encoder	Output sequence when P=1 (no spreading)	Output sequence when P=4
0	0	0011*
1	1	1100*
*The entries in the table are transmitted MSB first		

Manchester encoding is a subset of spreading with just two bits per input bit — see below figure. As the Manchester example illustrates, the clock rates (actually, clock valid signal rates) are affected by the Manchester encoding and decoding. The same applies to the spreader and de-spreader modules but with data rates changing by P = 2, 4, 8 or 16. Up to 16 are necessary to support all the 802.15.4 standards. The use of spreading means that output bits are serialized at P times the rate of the input bits. This is an important consideration as a clock valid on the output must be P times more often. That is, the data rate after the spreader is P times higher than that before the spreader. The data rate after the de-spreader in the RX is up to 16x smaller.

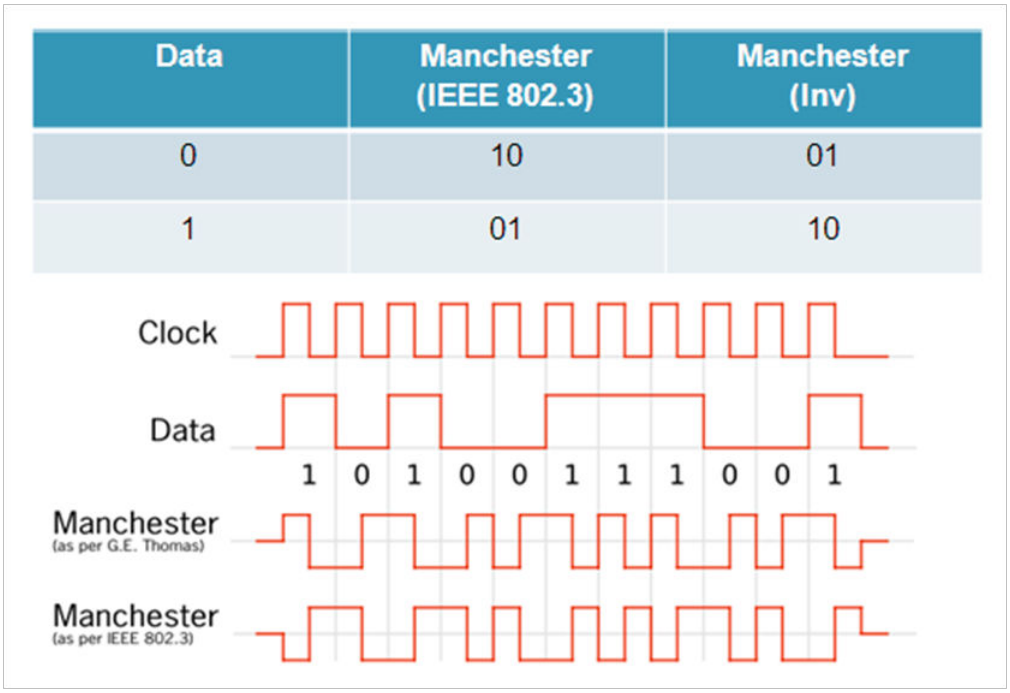

Figure 263. Manchester Encoding option for the Spreading Module

RX DE-Spreading

De-spreading is the dual of the spreading operation. De-spreading means correlating the soft bits provided by the demodulator with the reference sequence. This correlation needs to be done in a timely manner, that is, it has specific timing. For example, with a de-spreading of 4, four samples of the input generate the first output, the next four samples generate the second output and so on. The boundaries of de-spreading are fixed in the PHY.

55.4.6.3.7 Operation

The CRCW module contains the functionality to perform transmit CRC insertion, receive CRC checking, and data whitening. Additionally, the module can perform data error correction on received packets using the CRC syndrome if configured appropriately.

55.4.6.3.7.1 CRC Calculation

The CRC value is calculated using a configurable LFSR as depicted in Figure 264. The CRC calculation polynomial value is loaded into register *P*. The seed is loaded into register *SR* at initilization. The result is in register *SR* after all bits have been processed.

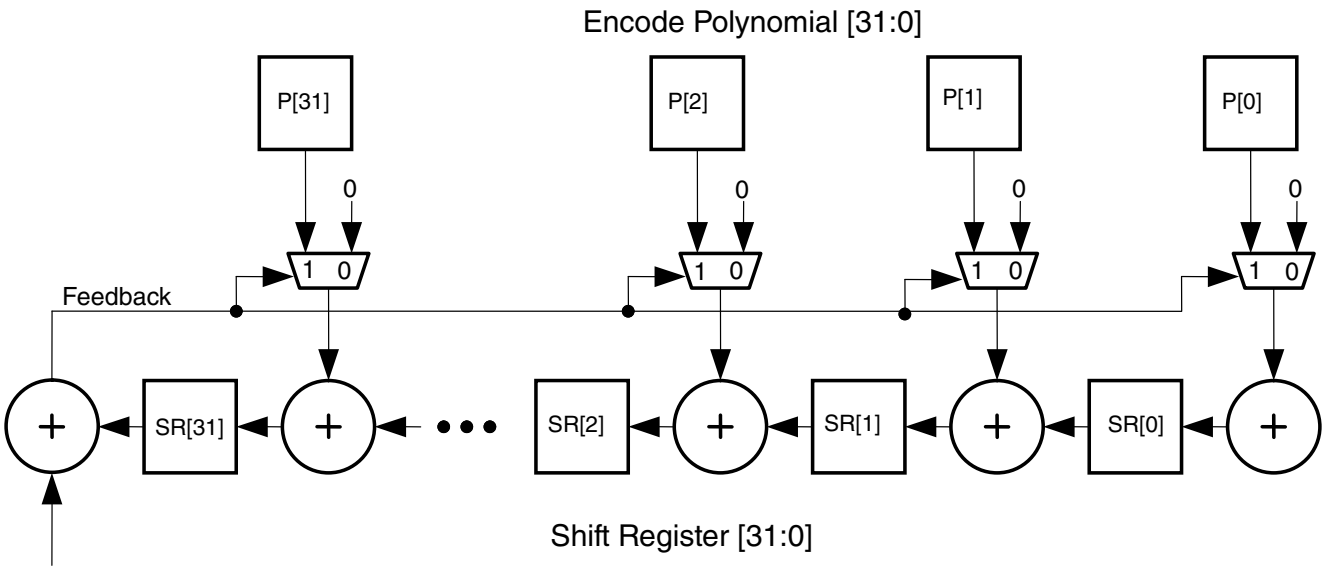

Figure 264. CRC Calculation Shift Register

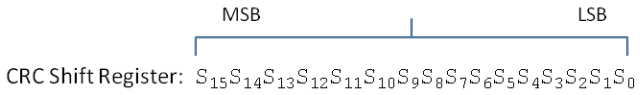
Data flows from the link layer function to the CRCW module during transmit before being sent to the radio physical layer. All bits in each packet are provided by the link layer function, including placeholder bits for the CRC value. The link layer function marks the CRC calculation start and stop points in the bit stream. The link layer also indicates the start of the CRC placeholder bits. The CRCW module overwrites the placeholder CRC bits with the CRC result, ordered as specified by the configuration options. Figure 265 is a list of example 16-bit CRC output modes.



REF IN	BYTE ORDER	REF OUT	Order of Transmitted Bits (shifted out first ..... shifted out last)
X	0	0	$P_0P_1P_2P_3P_4P_5P_6P_7P_8P_9P_{10}P_{11}P_{12}P_{13}P_{14}P_{15}$ $S_{15}S_{14}S_{13}S_{12}S_{11}S_{10}S_9S_8S_7S_6S_5S_4S_3S_2S_1S_0$

Figure 265. CRC Output Bit Order

55.4.6.3.7.2 CRC Check

During reception, data flows from the radio physical layer to the CRCW module before being sent to the link layer function. All bits in each packet are provided by the radio physical layer. Just as in transmit, the link layer function marks the CRC calculation start and stop points in the bit stream. The link layer also indicates the start of the received CRC bits.

The CRCW calculates the expected CRC result just as in transmit, but compares the received CRC bits as they arrive, ordered as specified by the configuration options, instead of inserting them into the packet. An early fail signal is asserted if a CRC bit miscompare is detected.

The CRC register contains the expected CRC when either of the *config_crc_byte_order* or *config_crc_ref_in* CRC configuration options are set. The CRC register contains the syndrome of the CRC error calculation when both options are not set.

Figure 266. CRC Input Bit Order

55.4.6.3.7.3 Data Whitening

The data whitener behaves identically in both transmit (whiten) and receive (de-whiten) operating modes. The LFSR used in this operation is designed to use either Fibonacci or Galois types of calculations. In either case, the LSB of the shift register is used to whiten each data bit as they are streamed through the CRCW.

An initialization signal for the data whiten logic loads the shift register with the seed value. The initialization signal can be used to re-initialize the shift register during a packet. A protocol-specific state machine controls a signal to mark the start and stop points for data whitening in the data stream.

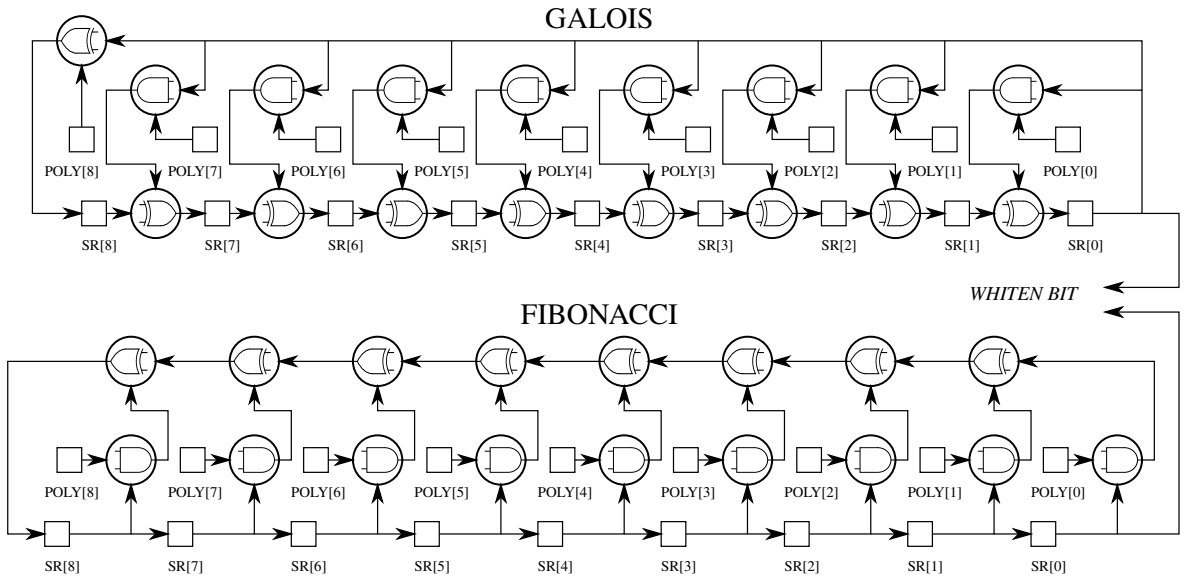

Figure 267. Data Whitening Shift Register

55.4.6.4 SFA32K(Signal Frequency Analyser of 32KHz Clock)

55.4.6.4.1 Overview

The 32KHz clock source is used as the sleep timer clock source inside RFMC and Bluetooth LE Link Layer. So accuracy of the sleep timer depends on the accuracy of the 32KHz clock in the chip. In order to achieve a higher accuracy 32KHz clock source, the SFA module is used to measure the 32KHz clock source with RF OSC clock. The measurement result can be used by software to calibrate the 32KHz clock source.

The radio SFA module can be configured to measure the 32KHz clock source by a hardware trigger when radio exists from low power mode.

55.4.6.4.2 Radio SFA

Refer to SoC Signal Frequency Analyser (SFA) chapter.

55.4.6.5 Basic Radio Integrated Crypto (BRIC)

55.4.6.5.1 BRIC

55.4.6.5.1.1 Introduction

The Basic Radio Integrated Crypto (BRIC) module is a wrapper, with control logic around the Low Tier Crypto (LTC) block and PKB (Private Key Bus) Slave that interfaces with EdgeLock Secure Enclave. This module provides the legacy interface (IPS + DMA) to the LTC module, contains additional logic to enable direct hardware interfacing for simple AES functions and a PKB interface with the EdgeLock Secure Enclave to receive KEYS securely over the PKB interface. Essentially, the logic takes control of the IPS interface so that another HW entity can easily interface.

55.4.6.5.1.1.1 Overview

The BRIC module allows for legacy behavior of the LTC. The IPS bus and relevant DMA signals are brought out to be used by the system. When in isolated mode, the control of these signals comes from the internal logic using a dedicated hardware interface. For example, RPA checking can be performed by a direct hardware connection as opposed to using a bus master to interface with the LTC.

55.4.6.5.1.1.2 Features

- Supports all LTC functions (See LTC block guide)
- IPS and DMA interface for use by the system as needed
- Dedicated HW interface that overrides the IPS interface
- HW interface simplified for easy integration
- PKB Slave that interfaes directly with EdgeLock Secure Enclave for secure KEY Transfer
- No RAM footprint

55.4.6.5.1.2 External Signal Descriptions

Signal	Width	I/O	Function
ipg_clk	1	I	IP Bus Clock, Free-running
ipg_hard_async_reset_b	1	I	asynchronous HW reset
ipt_se_gatedclk	1	I	Scan enable for gated clocks
ipg_soft_reset	1	I	synchrounous soft reset
ipg_stop	1	I	IPG stop mode
ipg_sop_ack	1	O	IPG stop acknowledge
bric_busy	1	O	BRIC/LTC busy
IPS Bus Interface			
ips_module_en	1	I	IPS module enable
ips_rwb	1	I	IPS read/write
ips_addr [15:0]	16	I	IPS address
ips_wdata [31:0]	32	I	IPS write data
ips_byte_en [3:0]	4	I	IPS byte enable
ips_rdata [31:0]	32	O	IPS read data
ips_xfr_wait	1	O	IPS transfer wait
ips_xfr_err	1	O	IPS transfer error
DMA/Interrupt			
ipd_done_idata	1	I	IPD done in data
ipd_done_odata	1	I	IPD done out data
ipd_req_idata	1	O	IPD request in data
ipd_req_odata	1	O	IPD request out data
ipi_bric_int	1	O	Interrupt
Direct HW Interface			
key_in [127:0]	128	I	Key input

Table continues on the next page...

Table continued from the previous page...

Signal	Width	I/O	Function
prand [23:0]	24	I	PRAND input for creating hash
hash [23:0]	24	O	Hash output from AES
lock_bric	1	I	Lock LTC IPS interface for direct Hardware access (Multiple RPA resolution) • **0 :** Legacy IP interface can be used to access LTC • **1 :** Legacy IPS bus disabled, direct HW Interface is active
hi_mode	1	I	Request hash operation (high pulse of one clock cycle) through Hardware interface. key_in and prand inputs has to be valid at the time of assertion hi_mode. hi_ready will be 1 while a hash operation is performed. • **0 :** Legacy IPS interface is available, HW Interface is not • **1 :** IPS bus disabled, direct HW Interface to be used
hi_ready	1	O	HW interface ready • **0 :** HW Interface ready to accept command, safe to change hi_mode • **1 :** HW Interface busy, no inputs should be changed
hash_req	1	I	Not used
hash_comp	1	O	Hash operation complete. Asserts for one clock cyclewhen 'hash' is valid and can be read.
Private Key Bus (PKB) Interface			
pkb_psel	1	I	PKB APB select
pkb_penable	1	I	PKB APB Enable
pkb_paddr	32	I	PKB APB address
pkb_pwrite	1	I	PKB APB write enable (1= write, read not supported)
pkb_pwdata	32	I	PKB APB write data
pkb_pwdata_mask	32	I	PKB APB write data mask
pkb_pready	1	O	PKB APB ready
pkb_pslverr	1	O	PKB APB slave error

55.4.6.5.1.3 Block Diagram

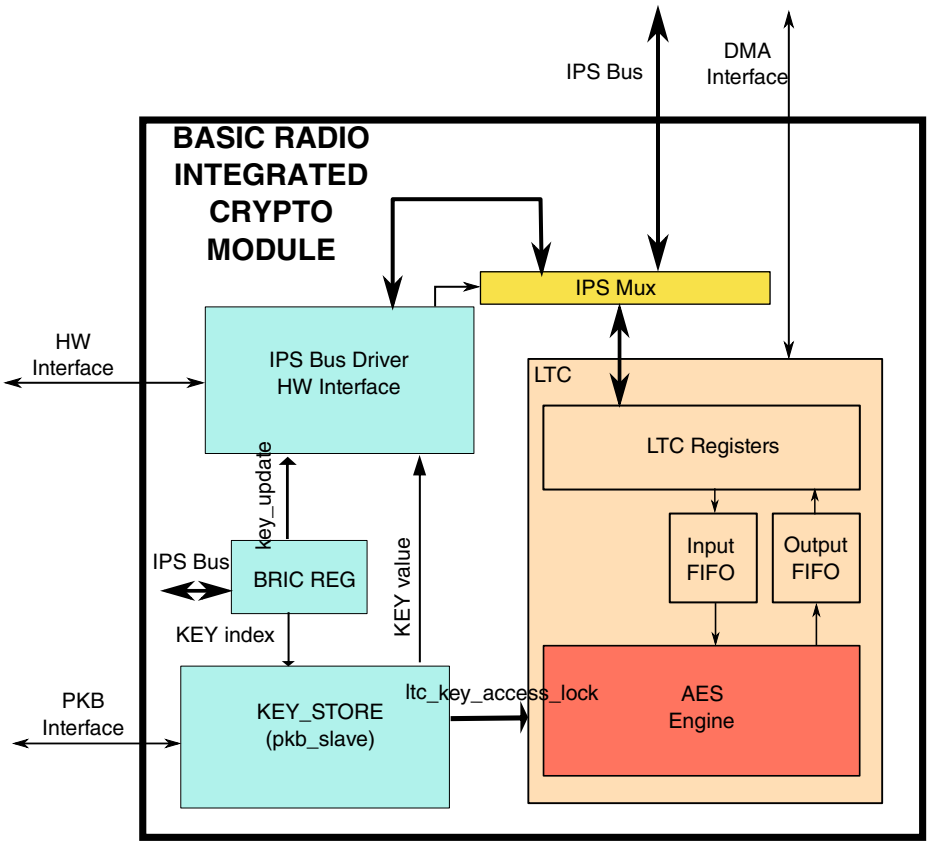

Figure 268. BRIC Block Diagram

55.4.6.5.1.4 Functional Description

The BRIC module provides following functionalities:

- Legacy LTC mode
- Hardware Interface mode
- Secure key transfer

55.4.6.5.1.4.1 Legacy LTC mode

If the HW interface mode is not selected. The BRIC module simply passes through the IPS and DMA signals. Is this configuration the core, or any bus master for that matter, can access the LTC in the traditional manner and use its capabilities as described in the LTC block guide.

55.4.6.5.1.4.2 Hardware interface mode

If the HW interface is selected, the BRIC module will take over control of the LTC.

The first part of this is to check that no process is pending by checking the AB bit in LTC_STA. If this bit is clear, the IPS module enable is then checked to confirm that no accesses are in progress on the IPS bus. When the module enable is low, the xfr_wait will be asserted until the HW interface is disabled. This will effectively block any bus master from accessing the LTC until the HW interface has completed its activity. **NOTE: There is a possibility that SW could be interrupted while configuring the LTC. The BRIC module will not maintain such configuration and SW should take care to resolve this situation if it happens by re-configuring.**

In addition to blocking the system IPS bus, the DMA signals will also be blocked to avoid any spurious requests during HW interface operation. This completes the interface isolation and hi_ready will be asserted.Once the external interfaces have been isolated as per above, the HW interface will begin operation according to the following sequence (HWM indicates HW master below):

1. HWM waits for hi_ready = 0
2. HWM asserts lock_bric for continuous BRIC access for multiple key resolution
3. HWM sets key_in[127:0] and prand[23:0] to desired values
4. HWM asserts hi_mode
5. BRIC uses key_in[127:0] and prand[23:0] to configure and execute ah(key_in,prand) using the LTC as per the Bluetooth Low Energy privacy specification.
6. BRIC sets resultant hash value on hash[23:0] when the LTC is complete, then asserts hash_comp.
7. HWM waits until hash_comp is asserted
8. HWM captures the hash
9. HWM repeats steps **3-8** as needed
10. HWM de-asserts lock_bric

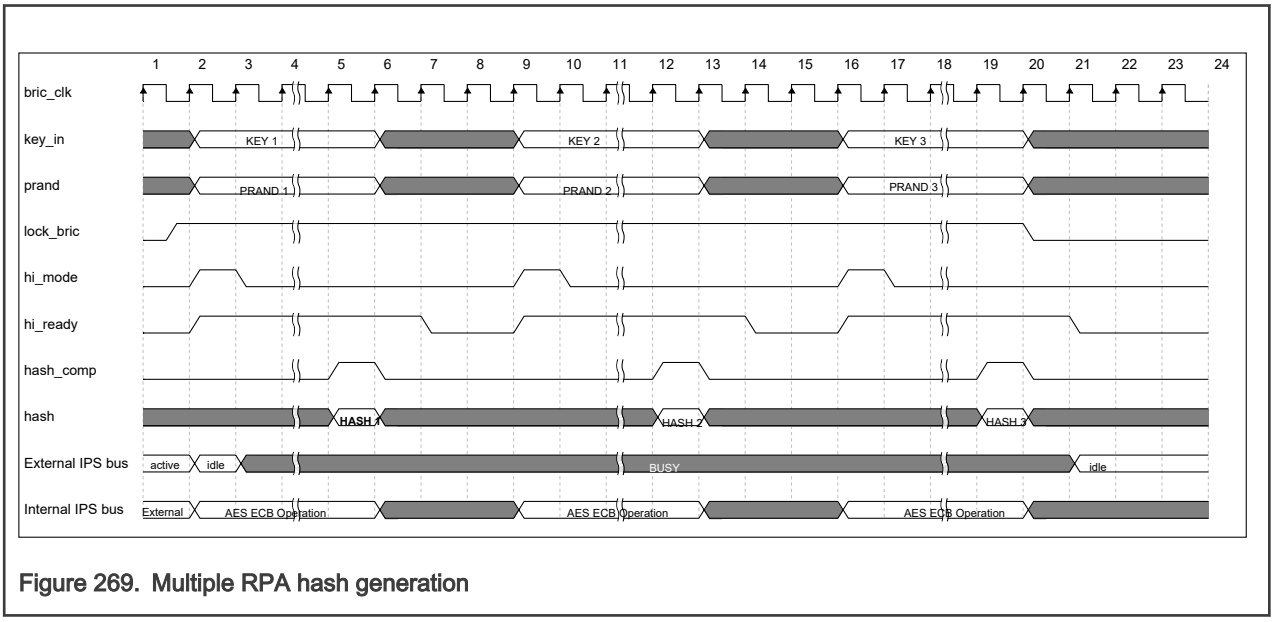

Figure 269. Multiple RPA hash generation

55.4.6.5.1.4.3 Software Access duing HW mode

To avoid any unexpected results due to software access through IPS bus during HW mode the following response methods are implemented.

IPS_XFR_WAIT is asserted through out the HW mode to inform that SW that BRIC is busy. Hence any SW access wull have to wait till the HW access is over.

IPS_XFR_ERR is asserted whenever there is a SW access during ongoign HW mode. This is to avoid SW waiting for longer time till the end of HW operation.

Both the above signal behavior can be controlled individually through register bits in BRIC_CONFIG register.

A few SW-HW access scenarios are listed in below timing diagrams.

1. HW request is asserted while SW access is ongoing - HW waits for SW access to be over
2. SW access start and HW request at the same clock - HW waits for SW access to be over

3. SW access during HW mode - respond with WAIT/ERROR/WAIT & ERROR based on the configuration

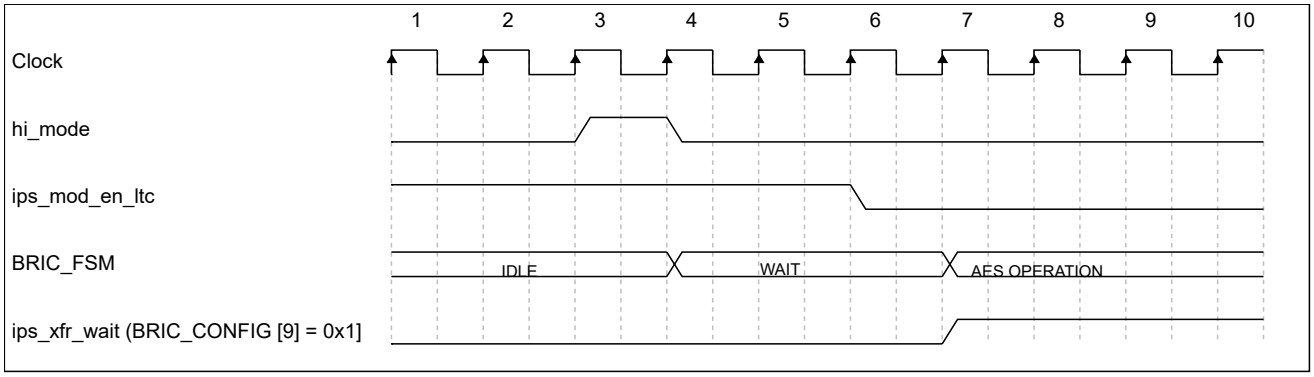

Figure 270. HW request asserted during SW access

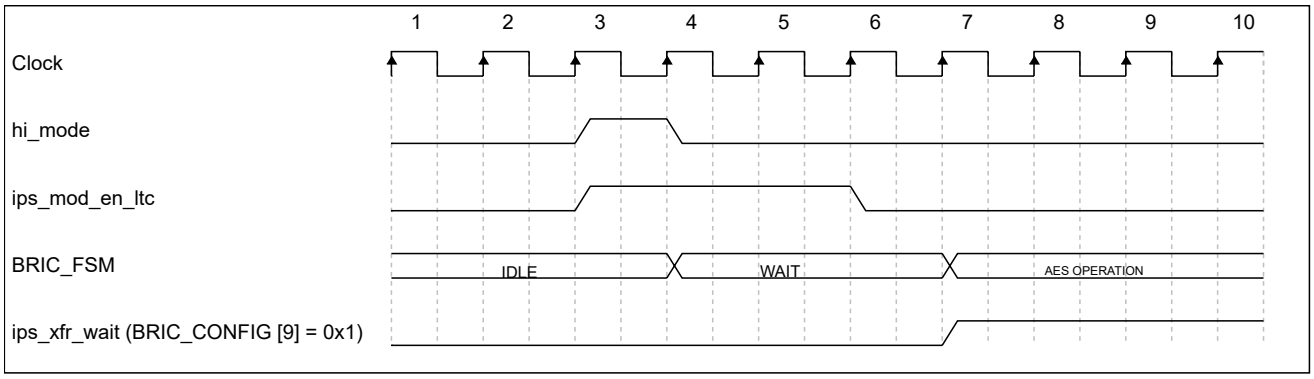
Figure 271. SW access and HW request at same clock



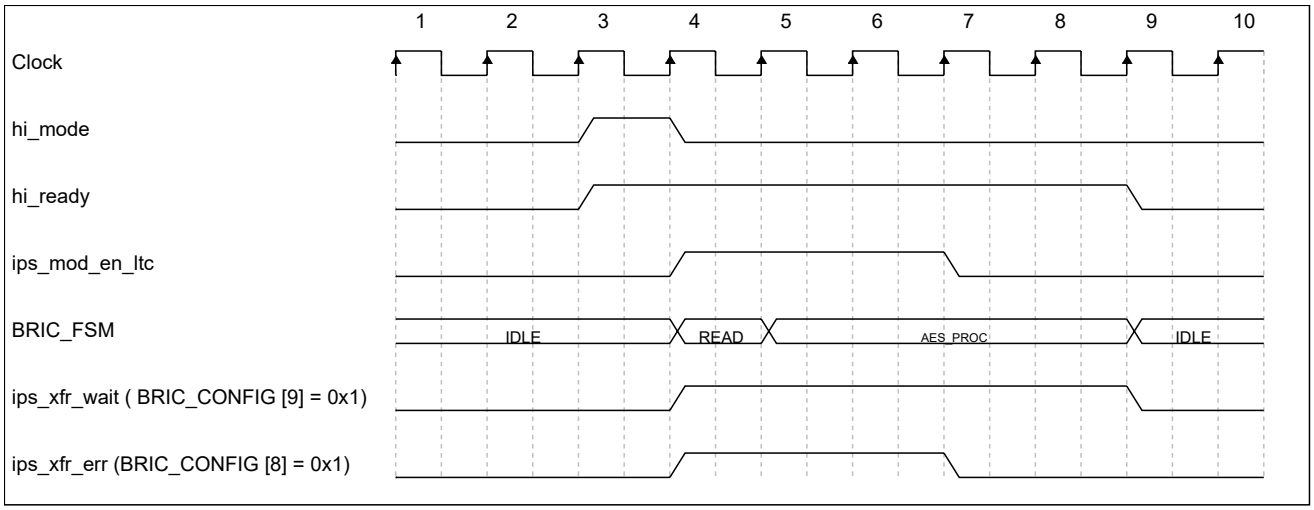


Figure 272. SW access during HW mode

55.4.6.5.1.4.4 Secure KEY transfer

The PKB master (EdgeLock Secure Enclave) can write the KEY securely over a PKB interface to any of the two KEY registers present in the BRIC. Any one of these KEYs (transferred over PKB interface) can be selectively transferred to the LTC by writing the index 0/1 to the KEY_INDEX_REGISTER.

The BRIC key_store module can accept and store two 128 bit keys from security module over the secure PKB interface. The written KEYs are no more readable from BRIC.

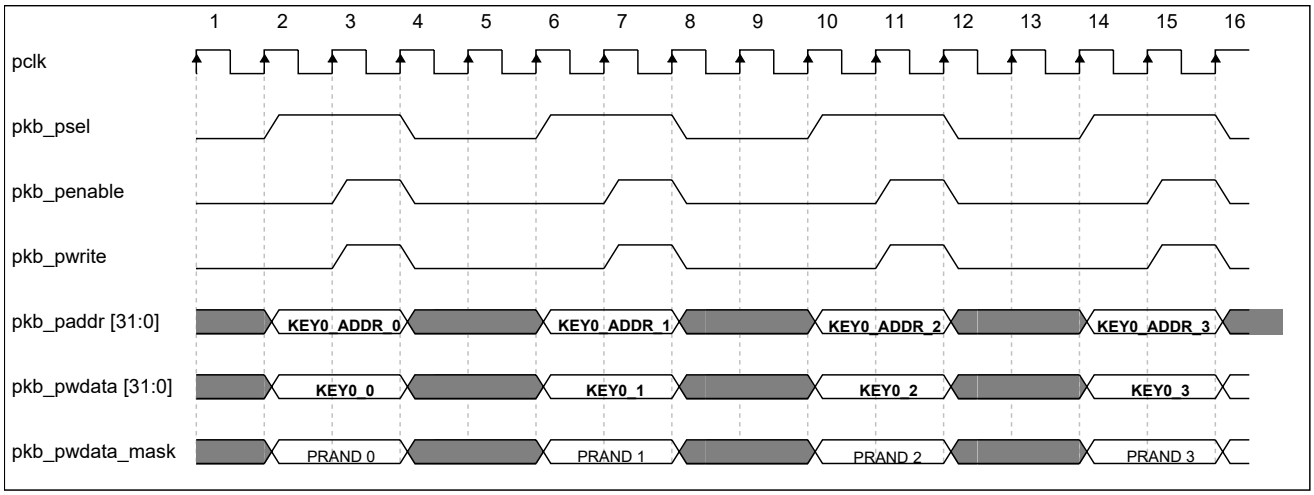

Figure 273. KEY write through PKB

Once KEYs are written by the secutiry IP t to the BRIC the procesor can initiate a KEY transfer by writing a valid value to the BRIC KEY_INDEX register. The below transactions indicate the steps involved in transferring a KEY from PKB master (security IP) to LTC module.

1. Write KEY value to BRIC key_store module through PKB interface securely. PKB bus is write only.
2. To transfer the KEY from BRIC key_store to LTC update the KEY_INDEX register with intended value
3. KEY_INDEX register update triggers KEY value write to LTC through the HW IPS interface

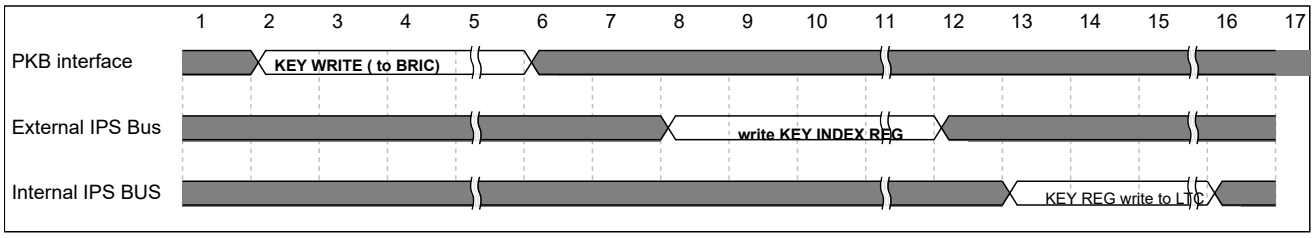

Figure 274. PKB KEY transfer to LTC

55.4.6.5.1.4.5 LTC KEY read access

LTC legacy module has a provisoin to disable the KEY read access by asserting the input signal "ltc_key_access_lock". In the BRIC this input signal has to be tied to "high" (KEY read is locked/disabled) always. To ensure a read path for the LTC KEY for special requirements like debug a different method is implemented and available for the debug software. This is by writing a key value of all 1's to KEY0 REGISTER or KEY1 REGISTER in the BRIC key store through the PKB interface. The KEY register in LTC will be readable as long as the value is retained in any of the KEYx Registers.

55.4.6.5.1.4.6 Interrupts

The LTC interrupt is passed through to the BRIC output in all modes of operation except HW interface mode.

During HW interface mode the LTC module generates a done_interrupt once encryption is complete. BRIC state machine clears this itnerrupt internally and hence this interrupt is masked from the output during HW interface mode.

55.4.6.5.1.5 Memory Map and register definition

The BRIC memory map and register description is included in the following section.

55.4.6.5.1.5.1 BRIC register descriptions

55.4.6.5.1.5.1.1 BRIC Base Address memory map

BRIC base address: 48A0_6700h

Offset	Register	Width (In bits)	Access	Reset value
0h - Ch	KEY0 Registers (PKB) (KEY0_0 - KEY0_3)	32	W	0000_0000h
10h - 1Ch	KEY1 Registers (PKB) (KEY1_0 - KEY1_3)	32	W	0000_0000h
20h	BRIC CONFIG register (BRIC_CONFIG)	32	RW	0000_0200h

55.4.6.5.1.5.1.2 KEY0 Registers (PKB) (KEY0_0 - KEY0_3)

Offset

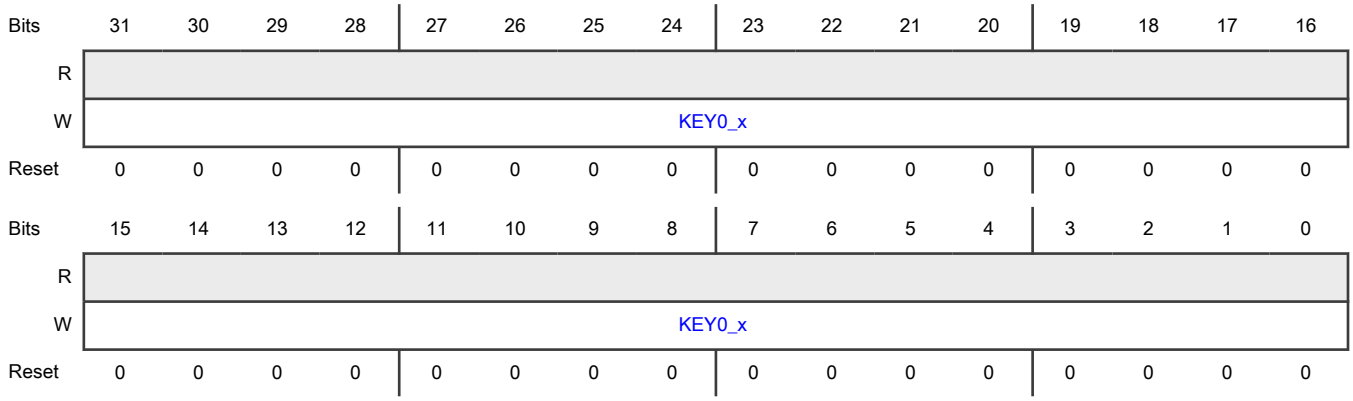
Register	Offset
KEY0_0	0h
KEY0_1	4h
KEY0_2	8h
KEY0_3	Ch

Function

The KEY0 Register normally holds the left-aligned key for the internal crypto engine written by the EdgeLock Secure Enclave. The MSB "KEY0_3" is in offset 0Ch. The Key is 128 bits in length and is written as four PKB masked write access.

The value in the Key0 Register can be transferred to the crypto engine by writing the KEY_INDEX_CONFIG register with value 00h.

Diagram



Fields

Field	Function
31-0 KEY0_x	KEY0 written through PKB interface

55.4.6.5.1.5.1.3 KEY1 Registers (PKB) (KEY1_0 - KEY1_3)

Offset

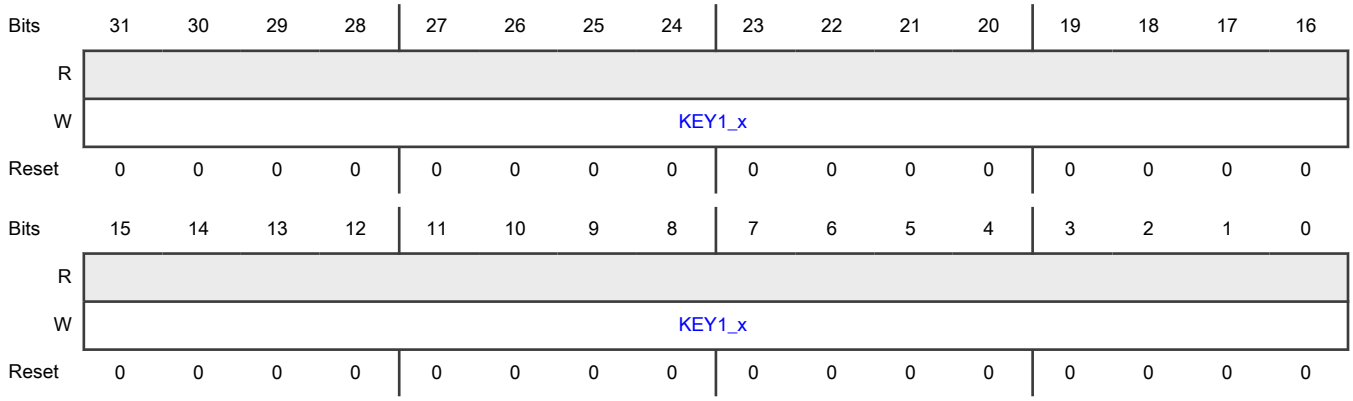
Register	Offset
KEY1_0	10h
KEY1_1	14h
KEY1_2	18h
KEY1_3	1Ch

Function

The KEY1 Register normally holds the left-aligned key for the internal crypto engine written by the EdgeLock Secure Enclave. The MSB "KEY1_3" is in offset 1Ch. The Key is 128 bits in length and is written as four PKB masked write access.

The value in the "KEY1" Register can be transferred to the crypto engine by writing the KEY_INDEX register with value 01h.

Diagram



Fields

Field	Function
31-0 KEY1_x	KEY1 written through PKB interface

55.4.6.5.1.5.1.4 BRIC CONFIG register (BRIC_CONFIG)

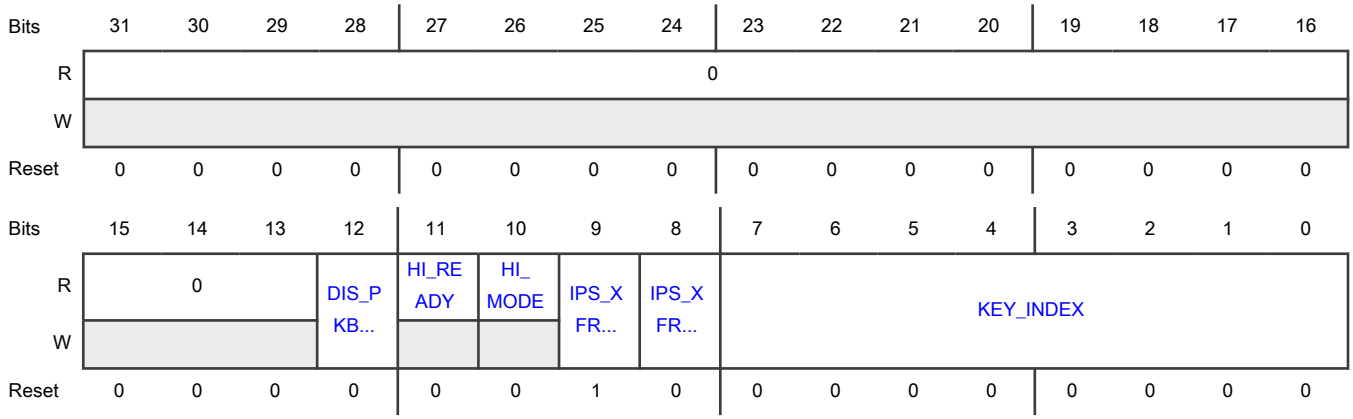
Offset

Register	Offset
BRIC_CONFIG	20h

Function

Configuration and Status register in BRIC

Diagram



Fields

Field	Function
31-13 —	This bit is reserved and should not be set.
12 DIS_PKB_ERR_RESP	Disable (0x1) PKB error response (Error response will be forced to zero)
11 HI_READY	Indicates HW mode is in progress and any SW access during this time is responded with an IPS_ERROR or IPS_WAIT depending on the configuration
10 HI_MODE	Indicates HW mode request to BRIC is active. BRIC may be in HW mode or waiting for a SW access to be over to start the HW mode when this bit is 0x1
9 IPS_XFR_WAIT_EN	Enable (0x1) ips_xfr_wait generation on IPS access during HW mode
8 IPS_XFR_ERR_EN	Enable (0x1) ips_xfr_err generation on IPS access during HW mode
7-0 KEY_INDEX	KEY INDEX KEY INDEX value for selecting the KEY from the PKB slave key array to be transferred to LTC. Writing this field with a valid value (0x0 or 0x1) triggers the KEY transfer from the PKB Slave KEY array to the LTC. To initiate KEY transfer to LTC a write has to be done to this register even if there is no change in KEY value

55.4.6.5.2 LTC

55.4.6.5.2.1 LP Trusted Cryptography Block Diagram

LP Trusted Cryptography is an architecture that allows multiple cryptographic hardware accelerator engines to be instantiated and share common registers. This version of LTC only supports AES. The following figure presents a top-level diagram of the LP Trusted Cryptography module with an AES engine.

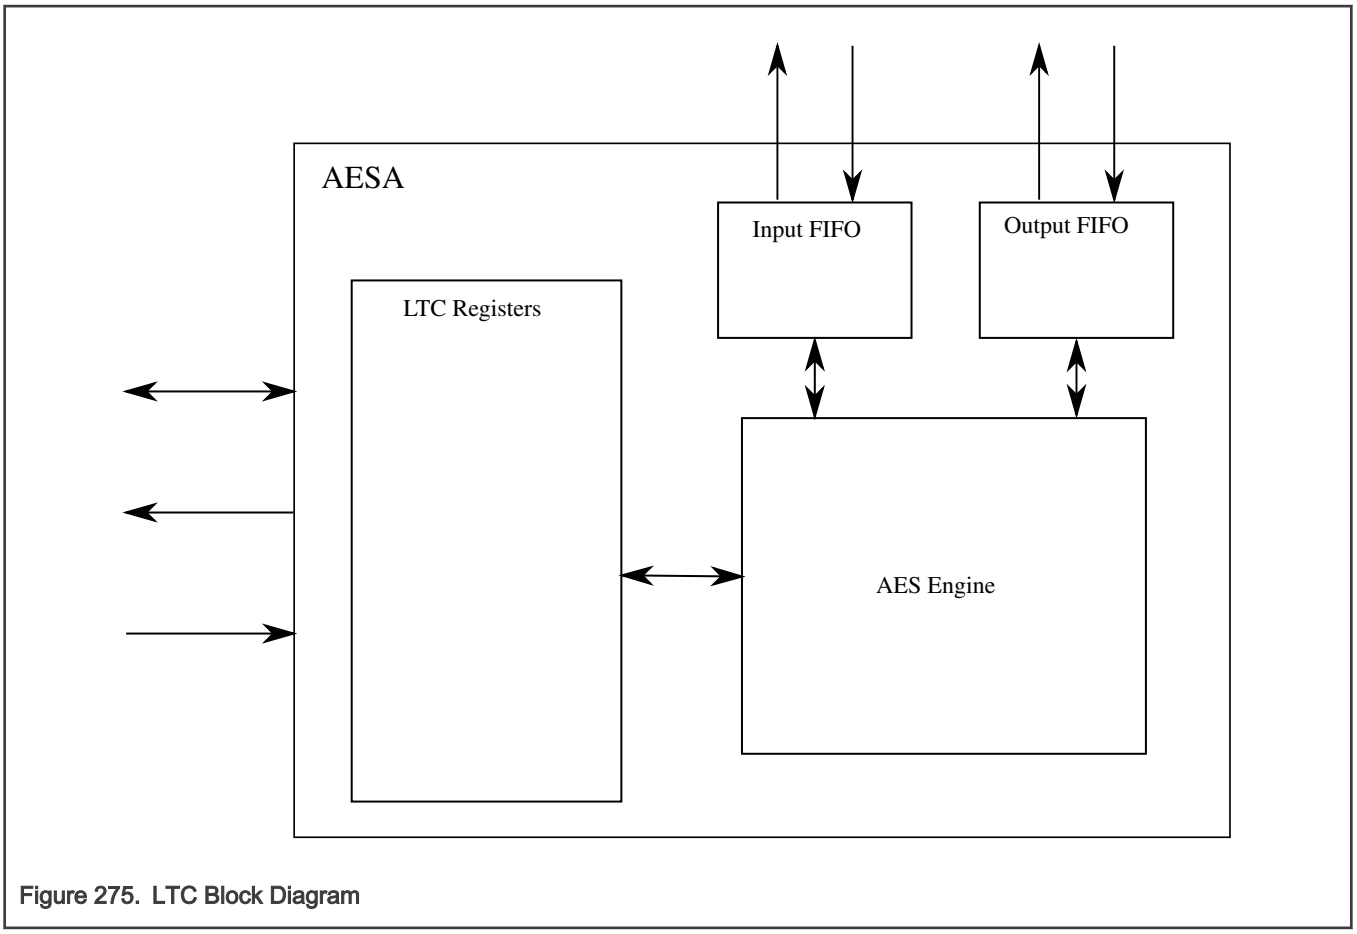


Figure 275. LTC Block Diagram

55.4.6.5.2.2 Feature summary

LTC includes the following actives:

- Cryptographic authentication
  - Message authentication codes (MAC)
    - AES-CMAC
    - AES-XCBC-MAC
- Authenticated encryption algorithms
  - AES-CCM (counter with CBC-MAC)
- Symmetric key block ciphers
  - AES (128-bit keys)
  - Cipher modes
    - ECB, CBC, CTR for AES
- Secure Scan

55.4.6.5.2.3 AES accelerator (AESA) functionality

The advanced encryption standard accelerator (AESA) module is a hardware co-processor capable of accelerating the advanced encryption standard (AES) cryptographic algorithm.

55.4.6.5.2.3.1 Differences between the AES encrypt and decrypt keys

The decrypt form of the key is different from the encrypt form of the key, because AES successively modifies the cryptographic key during the steps of the cryptographic operation. The decryption operation yields the correct result only if the modified form of the key (the decrypt key) is used at the beginning of the decryption operation. Unless told otherwise (via the DK bit in the Mode Register), AES assumes that a key loaded from memory is the encrypt key, that is, the form appropriate for encryption. If a decryption operation is specified and DK = 0, AES first goes through the steps required to derive the decrypt key from the encrypt key, and then performs the decryption operation. If a decryption operation is specified and DK = 1, the steps required to derive the decrypt key are skipped and the decryption operation is performed immediately, significantly improving performance for small data blocks.

Note that the difference between the encrypt key and the decrypt key must be taken into account when sharing keys between jobs. When an AES decryption job loads a key from memory, it is probably an encrypt key, so the DK bit in the Mode Register should be set to 0 so that AES derives the decrypt key from the encrypt key before beginning the decryption operation. But when a subsequent AES decryption job shares the key from a previous decryption job, the key that is shared is a decrypt key. In that case, the DK bit should be set to 1, which tells AES to skip the key derivation steps. If DK were set to 0 in this case, the decrypt key would be modified as if it were an encrypt key, and consequently, the wrong key value would be used in the decryption operation.

55.4.6.5.2.3.2 AESA modes of operation

The following modes are supported by AESA:

- Electronic codebook (ECB)
- Cipher block chaining (CBC)
- Counter (CTR)
- Extended cipher block chaining message authentication code (XCBC-MAC)
- Cipher-based MAC (CMAC)
- CTR and CBC-MAC (CCM)

AES modes can be classified into these categories:

- Confidentiality (ECB, CBC, CTR)
- Authenticated Confidentiality (CCM, CCM*)
- Authentication (XCBC-MAC, CMAC)

CBC Mode can also be viewed as an authentication mode when used to encrypt data, because it provides CBC-MAC in the context registers.

55.4.6.5.2.3.3 AESA use of registers

Note the following regarding the AESA's use of registers:

- For all modes, if AES is selected and the mode code written to the Mode Register does not correspond to any of the implemented AES modes, the illegal-mode error is generated.
- If ICV-only(Integrity Check Value, Final MAC) jobs are created (no data to be processed, only ICV to be checked) in modes that support ICV check, the AS mode field should be reset.

55.4.6.5.2.3.4 AES ECB mode

The electronic codebook (ECB) mode is a confidentiality mode that features, for a given key, the assignment of a fixed, ciphertext block to each plaintext block, analogous to the assignment of code words in a codebook. In ECB encryption, the forward cipher function is applied directly and independently to each block of the plaintext. The resulting sequence of output blocks is the ciphertext. In ECB decryption, the inverse cipher function is applied directly and independently to each block of the ciphertext. The resulting sequence of output blocks is the plaintext.

55.4.6.5.2.3.4.1 AES ECB mode use of the Mode Register

AES ECB mode uses the Mode Register as follows:

- The Encrypt (ENC) field should be 1 for ECB encryption and 0 for ECB decryption.
- The Algorithm State (AS) field in not used in ECB mode.
- The Additional Algorithm Information (AAI) field must be set with value 20h that activates ECB mode. Setting the MSB in the AAI field (interpreted as the Decrypt Key or DK bit for AES operations) specifies that the key loaded to the Key Register is the decryption form of the key, rather than the encryption form of the key. If DK = 0, when a decryption operation is requested AES processes the content of the Key Register to yield the decryption form of the key. If DK = 1, AES skips this processing. The illegal-mode error is generated if DK = 1 and ENC=1.
- The Algorithm (ALG) field is used to activate AESA by setting it to 10h.

55.4.6.5.2.3.4.2 AES ECB mode use of the Context Register

ECB does not use Context Registers.

55.4.6.5.2.3.4.3 AES ECB Mode use of the Data Size Register

The length of the message to be processed in bytes must be written to the Data Size register. If this value is not divisible by 16, the Data Size error is generated.

55.4.6.5.2.3.4.4 AES ECB Mode use of the Key Register

ECB keys must be written to the Key Register and can have only 16 bytes.

55.4.6.5.2.3.4.5 AES ECB Mode use of the Key Size Register

The number of bytes in the ECB key must be written to the Key Size register. Any value other than 16 causes the key-size error to be generated.

55.4.6.5.2.3.5 AES CBC mode

The CBC mode is described in this table.

Table 406. AES CBC, OFB, CFB128 modes

Name	Abbreviation	Function
Cipher-block chaining mode	CBC	Confidentiality mode whose encryption process features the combining ("chaining") of the plaintext blocks with the previous ciphertext blocks. The CBC mode requires an IV (Initialization Vector) to combine with the first plaintext block **NOTE** CBC mode uses both forward and inverse AES cipher. OFB and CFB use only forward AES cipher.

55.4.6.5.2.3.5.1 AES CBC mode use of the Mode Register

The AES CBC mode use the Mode Register as follows:

- The Encrypt (ENC) field should be 1 for encryption and 0 for decryption
- The ICV/TEST bit is not used in these modes.
- The Algorithm State (AS) field is used only in CBC mode to prevent IV update in the context for the last data block when set to "Finalize" (2h).

- The Additional Algorithm Information (AAI) field must be set with value 10h that activates CBC mode. The Decrypt Key [DK] (AAI field MSB) bit specifies that the key loaded to the Key Register is the decrypt key. The illegal mode error is generated if DK=1 and ENC=1.
- The Algorithm (ALG) field is used to activate AESA by setting it to 10h.

55.4.6.5.2.3.5.2 AES CBC mode use of the Context Register

The AES CBC mode use the Context Register as follows:

- CBC use the Context Registers to provide IV, which is updated with every processed block of a message. When a message is split into chunks and processed in multiple sessions, the IV must be saved and later restored for the next chunk to be processed correctly. At the end of CBC processing, IV is also the MAC of the message.
- If the AS field of the Mode Register is set to "Finalize" (2h) in the CBC mode, the last IV update is not written to the context. This enables CBC encryption to effectively perform ECB encryption transformation of a single-block message located in the context in place of IV, and with an all-zero block provided as input data through the FIFO without overwriting the context.

Table 407. Context usage in CBC mode

Context Word	Definition
0	IV [127:96]
1	IV [95:64]
2	IV [63:32]
3	IV [31:0]

55.4.6.5.2.3.5.3 AES CBC mode use of the Data Size Register

The AES CBC mode use the Data Size Register as follows:

- The byte length of the message to be processed must be written to the Data Size Register.
- The first write to this register initiates processing. It can also be written during processing in which case the value written is accumulated to the current state of the register.
- After the Data Size Register is written for the last time, its value must be divisible by 16 in CBC mode, otherwise the data-size error is generated.

55.4.6.5.2.3.5.4 AES CBC mode use of the Key Register

The AES CBC mode use the Key Register as follows:

- A CBC key must be written to the Key Register.
- Keys must be 16 bytes.

55.4.6.5.2.3.5.5 AES CBC mode use of the Key Size Register

The AES CBC mode use the Key Size Register as follows:

- The number of bytes in a key must be written to the Key Size register.
- Any value other than 16 causes a key-size error to be generated.

55.4.6.5.2.3.6 AES CTR mode

The counter (CTR) mode is a confidentiality mode that features the application of the forward cipher to a set of input blocks, called counters, to produce a sequence of output blocks that are exclusive-ORed with the plaintext to produce the ciphertext, and vice versa. Note that the counter value must be unique for each data block that is encrypted with the same key. CAAM uses a 128-bit counter to ensure that the counter value will not overflow and wrap around.

NOTE

It is the user's responsibility to ensure that the same key value is not used again following a reset.

55.4.6.5.2.3.6.1 AES CTR mode use of the Mode Register

The AES CTR mode uses the Mode Register as follows:

- The Additional Algorithm Information (AAI) field should be set to 00h to activate CTR mode. If the Decrypt Key [DK] (AAI field MSB) bit is set, the illegal-mode error is generated, because CTR uses only forward AES cipher requiring encryption rather than decryption keys.
- The Algorithm State (AS) field when set to "Finalize" (2h) prevents counter update in the context for the last data block.
- The Algorithm (ALG) field is used to activate AESA by setting it to 10h.

55.4.6.5.2.3.6.2 AES CTR mode use of the Context Register

The AES CTR mode uses the Context Register as follows:

- CTR uses context words 4,5,6 and 7 to provide initial counter value (CTR0). This value is incremented with every processed block of a message. When a message is split into chunks and processed in multiple sessions, the CTRi field of context has to be saved and later restored for the next chunk to be processed correctly.
- If the AS field of the Mode Register is set to Finalize (2h) in the CTR mode, the last counter update is not written to the context. This enables CTR encryption to effectively perform ECB encryption transformation of a single-block message located in the context words 4,5,6 and 7 in place of CTR0 and with all-zero block provided as input data through the FIFO without overwriting the context.

Table 408. Context usage in CTR mode

Context Word	Initial-input definition	Context-switching definition
0	-	-
1	-	-
2	-	-
3	-	-
4	CTR0 [127:96]	CTRi [127:96]
5	CTR0 [95:64]	CTRi [95:64]
6	CTR0 [63:32]	CTRi [63:32]
7	CTR0 [31:0]	CTRi [31:0]

55.4.6.5.2.3.6.3 AES CTR mode use of the Data Size Register

The byte-length of the message to be processed must be written to the Data Size register. CTR decrements the value in this register with every processed block.

55.4.6.5.2.3.6.4 AES CTR mode use of the Key Register

- CTR key must be written to the Key Register.
- The Key Register only supports 16 byte keys.

55.4.6.5.2.3.6.5 AES CTR mode use of the Key Size Register

The number of bytes in a key must be written to the Key Size register by the time that MODE and DATA SIZE have been written. Any value other than 16 will cause Key Size error to be generated.

55.4.6.5.2.3.7 AES XCBC-MAC and CMAC modes

The AES XCBC-MAC and CMAC modes are described together because of their similarities. They are extensions of the AES CBC mode that produces a key-dependent, one--way hash (or message authentication code (MAC)) in a secure fashion across messages of varying lengths. They also provide data-integrity and data-origin authentication regarding the original message source.

55.4.6.5.2.3.7.1 AES XCBC-MAC and CMAC modes use of the Mode Register

The AES XCBC-MAC and CMAC modes use the Mode Register as follows:

- The Encrypt (ENC) bit is ignored.
- The ICV bit must be set for computed MAC to be compared with the received MAC. The received MAC must be written to the Input Data FIFO after message data and the FIFO data type must be set to ICV. If this bit is not set, XCBC-MAC and CMAC do not expect received ICV to be supplied after message data.
- The Algorithm State (AS) field is defined for XCBC-MAC as shown in this table.

Table 409. Mode Register[AS] operation selections in AES XCBC-MAC

Operation	Description
INITIALIZE	Message is processed in multiple sessions and the current session is the first one. During initialization, derived keys K3 and K2 that are XOR-ed with the last message block are computed and stored in the context to be used in the last processing session. The derived key K1 used as an AES key is computed and written back to the Key Register over the original key
INITIALIZE/FINALIZE	Message is processed in a single XCBC session and the final MAC is computed
UPDATE	Message is processed in multiple sessions and the current session is neither the first nor the last. Derived keys K2 and K3 are provided in the context and the derived key K1 is provided in the Key Register. If decryption is requested, and data size is not written or is set to 0, and ICV bit is 1 - AS = UPDATE means that Check ICV (CICV) job is requested. The CICV-only job does not process any data, it just pops received ICV/MAC from the Input Data FIFO, and compares it to the computed MAC that is restored with the rest of the context from the previous session.
FINALIZE	Message is processed in multiple sessions and the current session is the last one. Derived keys K2 and K3 are provided in the context and the derived key K1 is provided in the Key Register. The final MAC is computed

- The Algorithm State (AS) field is defined for CMAC as shown in this table.

Table 410. Mode Register[AS] operation selections in CMAC

Operation	Function
INITIALIZE	Message is processed in multiple sessions and the current session is the first one. During initialization, the constant L = E(K, 0) is computed as encrypted block of zeros using key K and stored in the context to be used in the last processing session for derivation of keys K1 and K2. One of these keys will be XOR-ed with the last message block.
INITIALIZE/ FINALIZE	Message is processed in a single session and the final MAC is computed
UPDATE	Message is processed in multiple sessions and the current session is neither the first nor the last. The constant L used for key derivation is provided in the context. If decryption is requested, and data size is not written or is set to 0, and ICV bit is 1 - AS = UPDATE means that Check ICV (CICV) job is requested. The CICV-only job does not process any data, it just pops received ICV/MAC from the Input Data FIFO, and compares it to the computed MAC that is restored with the rest of the context from the previous session
FINALIZE	Message is processed in multiple sessions and the current session is the last one. The constant L used for key derivation is provided in the context. The final MAC is computed

- If the AS field is not set to either "Initialize/Finalize" or "Finalize" and the ICV bit is set to 1, the illegal-mode error is generated, except for CICV-only jobs.
- The Additional Algorithm Information (AAI) field must be set to 70h for XCBC and 60h for CMAC to be activated. Setting the DK bit (AAI field MSB) will cause the Illegal Mode error.
- The Algorithm (ALG) field is used to activate AESA by setting it to 10h.

55.4.6.5.2.3.7.2 AES XCBC-MAC and CMAC Modes use of the Context Register

The AES XCBC-MAC and CMAC modes use the Context Register as follows:

- No data needs to be provided in the context when starting a new XCBC or CMAC session.
- The computed MAC and the derived keys K2 and K3 are written back to the context by XCBC.
- The computed MAC and the constant L = E(K,0), computed as encrypted block of zeros using key K, are written back to the context by CMAC.
- When a message is split into chunks and processed in multiple sessions, these values need to be saved before context switch and restored before the next chunk of a message is to be processed. At the end of message processing the first 2 words of the context contain the MAC value.

Table 411. Context usage in XCBC-MAC and CMAC modes

Mode	Context word	Context-switching definition	Final-result definition
XCBC-MAC	0	MAC[127:96]	MAC[127:96]
	1	MAC[95:64]	MAC[95:64]
	2	MAC[63:32]	MAC[63:32]
	3	MAC[31:0]	MAC[31:0]

Table continues on the next page...

Table 411. Context usage in XCBC-MAC and CMAC modes (continued)

Mode	Context word	Context-switching definition	Final-result definition
	4	K3[127:96]	-
	5	K3[95:64]	-
	6	K3[63:32]	-
	7	K3[31:0]	-
	8	K2[127:96]	-
	9	K2[95:64]	-
	10	K2[63:32]	-
	11	K2[31:0]	-
CMAC	0	MAC[127:96]	MAC[127:96]
	1	MAC[95:64]	MAC[95:64]
	2	MAC[63:32]	MAC[63:32]
	3	MAC[31:0]	MAC[31:0]
	4	L[127:96]	-
	5	L[95:64]	-
	6	L[63:32]	-
	7	L[31:0]	-

55.4.6.5.2.3.7.3 AES XCBC-MAC and CMAC modes use of the ICV Size Register

The AES XCBC-MAC and CMAC modes use the ICV Size Register as follows:

- This ICV register is used to provide received ICV/MAC byte-size when it is other than 16 bytes.
- The computed ICV/MAC written to the context in the XCBC mode is always 16 bytes.
- In CMAC mode, this register determines also the computed MAC size-the remaining bytes are cleared.
- Supported values for ICV size are 4 to 16 bytes. If this register is 0, the size of ICV is 16 bytes.

55.4.6.5.2.3.7.4 AES XCBC-MAC and CMAC modes use of the Data Size Register

The AES XCBC-MAC and CMAC modes use the Data Size Register as follows:

- The byte-length of the message to be processed must be written to the Data Size register.
- XCBC-MAC and CMAC decrement the value in this register with every processed block.

55.4.6.5.2.3.7.5 AES XCBC-MAC and CMAC modes use of the Key Register

The AES XCBC-MAC and CMAC modes use the Key Register as follows:

- The key must be written to this register.
- For XCBC-MAC, if the AS mode field is set to either "Initialize" or "Initialize/Finalize", it is the original XCBC key (K) that must be written here. Otherwise, the derived key (K1) must be restored to this register. CMAC only uses original key K as an AES key.

55.4.6.5.2.3.7.6 AES XCBC-MAC and CMAC modes use of the Key Size Register

The AES XCBC-MAC and CMAC modes use the Key Size Register as follows:

- The total number of key bytes must be written to the Key Size register.
- For XCBC-MAC, any value other than 16 causes a key-size error to be generated. For CMAC, this error is generated only if any value other than 16 is written.

55.4.6.5.2.3.7.7 ICV checking in AES XCBC-MAC and CMAC modes

Automatic ICV checking is enabled by setting the ICV bit of the Mode Register to 1. When ICV is set to 1, the AS mode field must be set to either "Finalize" or "Initialize/Finalize"; otherwise the illegal-mode error is generated, except for CICV-only (Check-ICV-only) jobs.

The received ICV must be provided on the FIFO after the message data. The FIFO data type must be set to ICV when it is put on the FIFO. The size of the received and computed ICV is provided in the ICV Size register.

If the ICV check detects a mismatch between the decrypted received ICV and the computed ICV, the ICV error is generated.

55.4.6.5.2.3.8 AESA CCM and CCM modes*

CCM and CCM* consists of two related processes: generation encryption and decryption verification, which combine two cryptographic primitives: counter mode encryption (CTR) and cipher-block chaining based authentication (CBC-MAC). Only the forward cipher function of the block cipher algorithm is used within these primitives. Note that the counter value must be unique for each data block that is encrypted with the same key. AES uses a 128-bit counter to ensure that the counter value does not overflow and wrap around.

NOTE

It is the user's responsibility to ensure that the same key value is not used again following a reset.

55.4.6.5.2.3.8.1 Generation encryption

A cipher-block chaining is applied to the payload, the associated data (AAD), and the nonce to generate a message authentication code (MAC); then counter mode encryption is applied to the MAC and the payload to transform them into an unreadable form, called the ciphertext. Thus, CCM generation encryption expands the size of the payload by the size of the MAC.

55.4.6.5.2.3.8.2 Decryption verification

Counter-mode decryption is applied to the purported ciphertext to recover the MAC and the corresponding payload; then cipher block chaining is applied to the payload, the received associated data, and the received nonce to verify the correctness of the MAC.

55.4.6.5.2.3.8.3 AES CCM and CCM* mode use of the Mode Register

The AES CCM and CCM* mode uses the Mode Register as follows:

- The Encrypt (ENC) bit must be set to 1 for encryption and 0 for decryption.
- The ICV bit must be set for CCM and CCM* to compare computed MAC with the received MAC when decryption is requested.
- The received MAC must be written to the input-data FIFO after message data and the FIFO data type must be set to ICV.
- Setting the ICV bit causes the received MAC to be decrypted and compared with the computed MAC.
- The number of MSBs to be compared is defined by the MAC size in the CCM and CCM* IV (B_0) as described in the CCM specification.

- If the AS field is set to FINALIZE, but ICV = 0, AESA does not expect received ICV to be put on the input-data FIFO. In that case, MAC is computed and truncated to the specified size for decryption.
- For encryption, the computed MAC is encrypted and truncated to size. The illegal-mode error is generated if ICV = 1 and ENC = 1.
- If ICV = 1 and the decrypted received MAC do not match computed MAC, the ICV error is generated.
- The Algorithm State (AS) field is defined for CCM and CCM* as follows:

Table 412. Mode Register[AS] operation selections in AES CCM and CCM*

Operation	Description
INITIALIZE	Message is processed in multiple sessions and the current session is the first one. During initialization, the initial counter CTR0 is encrypted in the CTR mode and the B0 is processed with the CBC-MAC mode. The resulting values are stored in the context. Also, the size of MAC is decoded from B0 and written to the context. This AS setting must be used whenever the first part (or whole) AAD is being processed
INITIALIZE/ FINALIZE	Message is processed in a single CCM or CCM* session and the final MAC is computed and encrypted. The initial counter CTR0 and B0 must be provided in the context
UPDATE	Message is processed in multiple sessions and the current session is neither the first nor the last. All context data is restored from the previous session and the key is written to the Key Register. If decryption is requested, and data size is not written or is set to 0, and ICV bit is 1 - AS=UPDATE means that a CICV-only job is requested. The CICV-only job does not process any data, it just pops received ICV/MAC from the Input Data FIFO, decrypts it and compares it to the computed MAC that is restored with the rest of the context from the previous session
FINALIZE	Message is processed in multiple sessions and the current session is the last one. All context data is restored from the previous session and the key is written to the Key Register. The final MAC is computed and encrypted

- Whenever AS is set to Initialize or Initialize/Finalize, context registers must be zero.
- If the AS field is not set to either Initialize/Finalize or Finalize and the ICV bit is set to 1, the illegal-mode error is generated. This does not apply in case when only ICV check is requested as described for AS = UPDATE.
- The Additional Algorithm Information (AAI) field must be set to 80h for both CCM and CCM* to be activated. The C2K bit is used to select a key register. If C2K = 0, CCM and CCM* uses the key in the Key Register. Setting the DK bit causes the illegal-mode error.
- The Algorithm (ALG) field is used to activate AESA by setting it to 10h.

55.4.6.5.2.3.8.4 AES CCM and CCM* modes use of the Context Register

The AES CCM and CCM* mode uses the Context Register as follows:

- B0 and the initial counter CTR0 must be provided in the context before the first chunk of the message is to be processed. During initialization, the initial counter CTR0 is encrypted in the CTR mode and B0 (which functions like a CBC-MAC IV in CCM and CCM*) is processed with the CBC-MAC mode. The resulting values are stored in the context. Also, the size of MAC is decoded from B0 and written to context word 13.
- If there is AAD, the first block of it defines its size, and that value is decoded and written to context word 12. All of the context data must be restored before the next chunk of the message is to be processed in multi-session processing.
- For CCM and CCM* encryption, the ICV (encrypted final MAC) is written to context words 8-11. For CCM and CCM* decryption, the ICV (received MAC), which is always encrypted, is decrypted to words 8-11. The final computed MAC is written (in clear) to context words 0-3.

Table 413. Context usage in CCM and CCM* mode encryption

Context Word	Initial-input definition	Intermediate definition	Final-output definition
0	B0[127:96]	-	MAC[127:96]
1	B0[95:64]	-	MAC[95:64]
2	B0[63:32]	-	MAC[63:32]
3	B0[31:0]	-	MAC[31:0]
4	CTR0[127:96]	CTR[127:96]	-
5	CTR0[95:64]	CTR[95:64]	-

Table 416. Format of Context Word 13 for AES-CCM and AES-CCM* mode

Bits 31-3	Bits 2-0
0	Encoded MAC Size

55.4.6.5.2.3.8.5 AES CCM and CCM* mode use of the Data Size Register

The AES CCM and CCM* mode uses the Data Size Register as follows:

- The byte-length of the message to be processed must be written to the Data Size register.
- CCM and CCM* decrements the value in this register with every processed block.
- The content of the Data Size register must be divisible by 16 if the AS mode field is set to either "Update" or "Initialize". Otherwise, the data-size error is generated. In other words, message splitting can be done only on a 16-byte boundary.

55.4.6.5.2.3.8.6 AES CCM and CCM* mode use of the Key Register

CCM and CCM* key must be written to this register; it is always an encryption key.

55.4.6.5.2.3.8.7 AES CCM and CCM* mode use of the Key Size Register

The AES CCM and CCM* mode uses the Key Size Register as follows:

- The total number of key bytes must be written to the Key Size register.
- Any value other than 16 causes a key-size error to be generated.

55.4.6.5.2.3.8.8 AES CCM and CCM* mode use of the ICV check

The AES CCM and CCM* mode uses ICV checking as follows:

- Automatic ICV checking is enabled by setting the ICV bit of the Mode Register to 1. When ICV is set to 1, the AS mode field must be set to either "Finalize" or "Initialize/Finalize"-otherwise the illegal-mode error is generated, unless data size is 0 indicating ICV check is only requested. Also, if ICV = 1, the ENC bit must be 0.
- The received ICV(MAC) must be provided on the input data FIFO after the message data. In CCM and CCM*, received ICV(MAC) is always encrypted. The FIFO data type must be set to ICV when it is put on the FIFO. The size of the received and computed ICV(MAC) is for CCM and CCM* encoded in the B0.
- If the ICV check detects mismatch between the decrypted received ICV(MAC) and the computed ICV(MAC), the ICV error is generated.

55.4.6.5.2.4 Standalone AES Examples

Example AES ECB Operation:

1. Write key to Primary Key Register.
2. Write key size to Primary Key Size Register. (00000010h)
3. Write Mode to Primary Mode Register. (0010020Dh)
4. Write Size of data to encrypt/decrypt to Data Size Register.
5. Write data into the Input FIFO.
6. Read data from the Output FIFO.
7. Interrupt is generated after final word is pushed to output FIFO.

Example AES CTR Operation:

1. Write key to Primary Key Register.
2. Write key size to Primary Key Size Register. (00000010h)
3. Write initial counter value to Context Words 4-7 in the Context Register.
4. Write Mode to Primary Mode Register. (0010020Dh)
5. Write Size of data to encrypt/decrypt to Data Size Register.
6. Write data into the Input FIFO.
7. Read data from the Output FIFO.
8. Interrupt is generated after final word is pushed to output FIFO.

Example AES CCM or CCM* Operation:

1. Write key to Primary Key Register.
2. Write key size to Primary Key Size Register. (00000010h)
3. Write B0 value to Context Words 0-3 in the Context Register.
4. Write initial counter value to Context Words 4-7 in the Context Register.
5. Write Mode to Primary Mode Register. (0010080Dh) CCM and CCM* both use the same mode value.
   - CCM and CCM* both use the same mode value.
6. Write Size of Authentication Only Data to the AAD Size Register.
7. Write Authentication Only data to the Input FIFO.
   - Authentication data needs to be padded to a 16 byte boundary with zeros.
   - For example if there is 8 bytes of AAD then (00000008h) should be written to AAD Size register and 8 bytes of AAD data followed by 8 bytes of Zero should be written into the Input FIFO.

8. Write Size of data to encrypt/decrypt and authenticate to Data Size Register.
9. Write data into the Input FIFO.
10. Read data from the Output FIFO.
11. Interrupt is generated after final word is pushed to output FIFO.
12. Read MAC from Context Registers
    - MAC is read from Context Registers 0-3.
    - Encrypted MAC is read from Context Registers 8-11.

Example AES CCM or CCM* Authentication Only Operation:

1. Write key to Primary Key Register.
2. Write key size to Primary Key Size Register. (00000010h)
3. Write B0 value to Context Words 0-3 in the Context Register.
4. Write initial counter value to Context Words 4-7 in the Context Register.
5. Write Mode to Primary Mode Register. (0010080Dh).
    - CCM and CCM* both use the same mode value.
6. Write Size of Authentication Only Data to the AAD Size Register.
    - The AL bit needs to be set in the AAD Size Register. This tells the AES core engine that it will recieve only Authentication Data. Note for encryption only the mechanism is handled automatically.
7. Write Authentication Only data to the Input FIFO.
    - Authentication data needs to be padded to a 16 byte boundary with zeros.
    - For example if there is 8 bytes of AAD then (00000008h) should be written to AAD Size register and 8 bytes of AAD data followed by 8 bytes of Zero should be written into the Input FIFO.
8. Write data into the Input FIFO.
9. Interrupt is generated after final word is processed from input FIFO.
10. Read MAC from Context Registers
    - MAC is read from Context Registers 0-3.
    - Encrypted MAC is read from Context Registers 8-11.

Example AES CCM or CCM* Encryption Only Operation:

1. Write key to Primary Key Register.
2. Write key size to Primary Key Size Register. (00000010h)
3. Write B0 value to Context Words 0-3 in the Context Register.
4. Write initial counter value to Context Words 4-7 in the Context Register.
5. Write Mode to Primary Mode Register. (0010080Dh).
    - CCM and CCM* both use the same mode value.
6. Write Size of data to encrypt/decrypt to Data Size Register.
7. Write data into the Input FIFO.
8. Read data from the Output FIFO.
9. Interrupt is generated after final word is pushed into the output FIFO.

Writing and Reading Data from the FIFOs:

1. Writing and reading by polling operations.

- The FIFO Status Register(LTCFIFOSTA) shows the number of entries in both the input and output FIFOs. It also shows when the FIFOs are full.
- The input and output FIFOs support 4x32bit entries each.
- Whenever there is space in the input FIFO the user can write a word into the Input FIFO.
- Whenever there is a word in the output FIFO then the user can read a word from the Output FIFO.

2. Writing and reading FIFOs by DMA operations.
   - The on chip DMA will handle all reads and writes of the FIFOs.
   - The IDE and ODE bits in the Control Register must be written to enable the DMA handshake.
     - IDE will enable dma transfers to the input FIFO when there is space available.
     - ODE will enable dma transfers from the output FIFO when there are words in the FIFO.
   - The on chip DMA should then be programmed to write data to the input FIFO and read data from the output FIFO.

55.4.6.5.2.5 LTC register descriptions

All reads of write-only addresses always return zero. Writes to read-only addresses are ignored. LTC will generate a transfer error whenever an undefined address is read or written to on the register bus. Although many of the LTC registers hold more than 32 bits, the register addresses shown in the Memory Map below represent how these registers are accessed over the register bus as 32-bit words.

NOTE

The reset value of some registers differs between different versions of LTC. To ensure driver compatibility across different versions of LTC, when updating fields within registers, the registers should first be read, the required fields updated, and then the register should be written. This will avoid inadvertently changing the settings of other fields in the same register.

55.4.6.5.2.5.1 LTC memory map

LTC base address: 48A0_6800h

Offset	Register	Width (In bits)	Access	Reset value

55.4.6.5.2.5.2 Mode Register (MD)

Offset

Register	Offset
MD	0h

Function

The Mode Register is used to tell the cryptographic engines which operation is being requested. The interpretation of this register will be unique for each CHA.

This section defines the format of the Mode Register when used with non-public-key algorithms and non-RNG operations.

Diagram

Field	Function
1 ICV_TEST	ICV Checking / Test AES fault detection. For algorithms other than AES ECB mode: ICV Checking This bit selects whether the current algorithm should compare the known ICV versus the calculated ICV. This bit will be ignored by algorithms that do not support ICV checking. 0 - Don't compare 1 - Compare For AES ECB mode: Test AES fault detection In AES ECB mode, this bit activates fault detection testing by injecting bit level errors into AES core logic as defined in the first 128 bits of the context. 0 - Don't inject bit errors 1 - Inject bit errors
0 ENC	Encrypt/Decrypt. This bit selects encryption or decryption. 0b - Decrypt. 1b - Encrypt.

55.4.6.5.2.5.3 Key Size Register (KS)

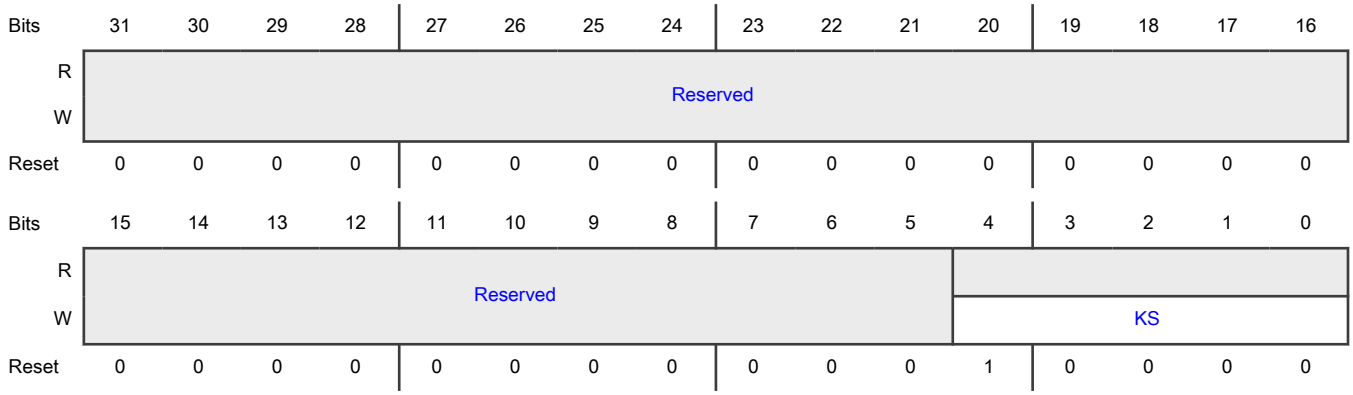
Offset

Register	Offset
KS	8h

Function

The Key Size Register is used to tell the crypto engine(AES) the size of the key that was loaded into the Key Register. The Key Size Register must be written after the key is written into the Key Register. Writing to the Key Size Register will prevent the user from modifying the Key Register. Only 16 byte keys are supported so this register will always read 16 bytes. This register is still required to be written to indicate to the AES engine that the key was loaded.

Diagram



Fields

Field	Function
31-5 —	Reserved
4-0 KS	Key Size This is the size of a Key measured in bytes

55.4.6.5.2.5.4 Data Size Register (DS)

Offset

Register	Offset
DS	10h

Function

The Data Size Register is used to tell a crypto engine the amount of data that will be loaded into the Input Data FIFO. This register should only be written to once during a single operation. Note that writing to the AAD Size Register (AADSZ) , will cause this register to also update. When this register is then written directory to then the new value will be added to the previous value in the register. That is, if the DS field currently has the value 16, writing 2 to the least-significant half of the Data Size register (i.e. the DS field) will result in a value of 18 in the DS field. Note that AES decrements this register, so reading the register may return a value less than sum of the values that were written into it. This register is cleared whenever a key is decrypted or encrypted.

55.4.6.5.2.5.5 ICV Size Register (ICVS)

Offset

Register	Offset
ICVS	18h

Function

The ICV Size Register indicates how much of the last block of ICV is valid when performing AES integrity check modes (e.g. AES-CMAC, AES-XCBC-MAC). This register must be written prior to the corresponding word of data being consumed by AES. In practical terms, this means the register must be written prior to the corresponding data being written to the Input Data FIFO.

AAD flag in B0 =1 and not enough AAD provided - expecting more based on AAD size.) 1111b - Invalid Crypto Engine Selected

55.4.6.5.2.5.11 AAD Size Register (AADSZ)

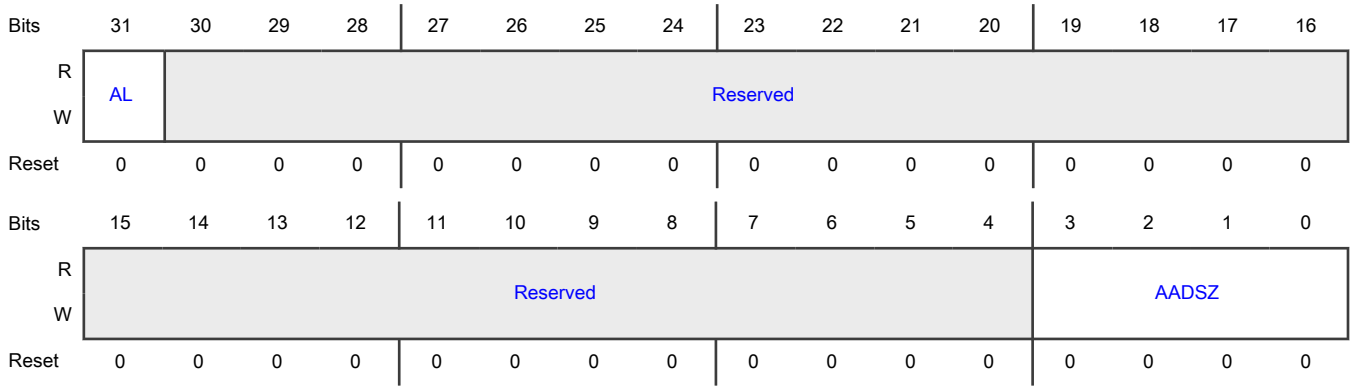
Offset

Register	Offset
AADSZ	58h

Function

The AAD Size Register is used by AESA to determine how much of the last block of AAD is valid. The write to this register should be the entire size of the AAD as it is also added directly to the Data Size Register. The size added to the Data Size Register is the AAD size rounded up to the next 16 byte boundary. For instance a size of 20 bytes written to the AAD size register will cause 32 bytes to be added to the Data Size Register. The size stored in the AADSZ field represents the number of bytes valid in the final block of AAD. However the entire size of AAD should be written to the AAD Size Register (AADSZ) Register address location. When authentication only is being done then the AL bit needs to be written to tell the AES engine that this is the last of the data.

Diagram



Fields

Field	Function
31 AL	AAD Last Only AAD data will be written into the Input FIFO.
30-4 —	Reserved
3-0 AADSZ	AAD size in Bytes, mod 16

55.4.6.5.2.5.12 Context Register (CTX_0 - CTX_13)

Offset

For a = 0 to 13:

Register	Offset
CTX_a	100h + (a × 4h)

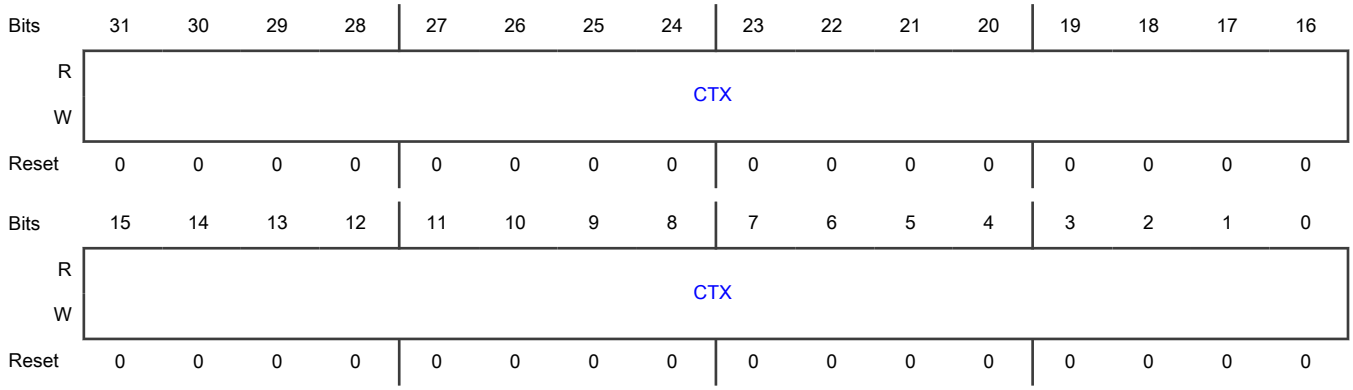
Function

The Context Register holds the context for the internal crypto engine. This register is 448 bits in length. The IP bus write to the Context Register is accessible only as full-word reads or writes to fourteen 32-bit registers. The MSB is located at offset 0100h with respect to the register page.

The bit assignments of this register are dependent on the algorithm, and in some cases the mode of that algorithm. See the appropriate section for the Context Register format used for that algorithm:

- AES ECB: Section AES ECB mode use of the Context Register
- AES CBC: Section AES CBC mode use of the Context Register
- AES CTR: Section AES CTR mode use of the Context Register
- AES CCM: Section AES CCM and CCM* modes use of the Context Register

Diagram



Fields

Field	Function
31-0 CTX	CTX

55.4.6.5.2.5.13 Key Registers (KEY_0 - KEY_3)

Offset

Register	Offset
KEY_0	200h
KEY_1	204h
KEY_2	208h
KEY_3	20Ch

Function

The Key Register normally holds the left-aligned key for the internal crypto engine. The MSB is in offset 200h. The Key Register is 128 bits in length. The IP bus write to the Context Register is accessible only as full-word reads or writes to four 32-bit registers.

Before the value in the Key Register can be used in a cryptographic operation, the size of the key must be written into the Key Size Register. Once the Key Size Register has been written, the Key Register cannot be written again until the Key Size Register has been cleared.

55.4.6.6 WiFi Coexistence Interface

The 2.4GHz radio architecture supports a flexible coexistence interface that enables the narrowband (NB) radio (e.g., Bluetooth, IEEE 802.15.4 and proprietary protocols) to coexist in the same space as a WiFi radio, which shares the same frequency band, or a different IC, with which active synchronization may be required to reduce either power consumption from battery or reduce electro-magnetic interference (EMI). As a simplification, this section primarily showcases the coexistence capabilities of the NB 2.4GHz radio in the context of WiFi radio coexistence. Note that an inter-processor communication (IPC) channel using a serial bus may also be used to augment the capabilities of the HW coexistence interface.

Typical coexistence schemes between a Bluetooth and WiFi designate the WiFi transceiver as the master, and the 2.4GHz transceiver as the slave. However in some cases, an application profile may dictate the opposite. The coexistence strategy is to prevent both the NB 2.4GHz radio and the WiFi radio from transmitting simultaneously; a configuration option exists to prevent the NB 2.4GHz radio from reception when the WiFi radio owns the RF channel. Yet another implementation choice is for the two radios to indicate the nature of their RF activity allowing the coexistence scheme to allow for simultaneous reception on both radios as well as other options when NB and WiFi channels have adequate separation.

55.4.6.6.1 Coexistence Pin Definition

The WiFi coexistence pins are described in the following table.

WiFi Coexist Function	Pin Direction	Pin Description
RF_ACTIVE (REQUEST)	O	An output which is asserted prior to any Radio event and remains asserted for the duration of the event.
RF_STATUS (DIRECTION)	O	An output which indicates when the Radio is in an RX or TX event, software can also control this signal directly.
RF_PRIORITY	O	An output which indicates to the external WiFi device that the Radio event is a high priority and it needs access to the 2.4 GHz antenna.
RF_NOT_ALLOWED (!GRANT)	I	External signal which causes the internal Radio to cease radio activity.
RF_TX_CONF	I	Signal from an external Radio which indicates the availability of the 2.4 GHz antenna to the internal Radio. Note that this signal is not connected to the Radio hardware. Radio software can use any interrupt-capable GPIO which the application assigns for this function.

Behavioral control information for the radio pins is provided below. Refer also to Radio Coexistence/FEM/LANT Connections which illustrates how the signals are connected and muxed in the radio.

55.4.6.6.1.1 RF_NOT_ALLOWED Behavioral Control

The WiFi IC generates a signal, RF_NOT_ALLOWED. If this signal is asserted, then 2.4GHz radio does not perform any communication. When this signal is de-asserted, then 2.4GHz radio is free to perform communications. In case when the signal RF_NOT_ALLOWED is asserted when 2.4GHz radio has already initiated the transmission/reception of a packet then the 2.4GHz radio must stop its activity immediately. Note that a software override of the RF_NOT_ALLOWED signal is also supported by the radio, which can be used for debug as well as enabling the capability to abort radio activity under software control (based on application layer arbitration between a multi-radio system).

The table below describes register bits in the RFMC and RADIO_MISC to enable, control and provide status for RF_NOT_ALLOWED

Field	Type	Description
RFNA_IBE[2:0]	RW	RFMC bitfield to select which (among several) SOC pin to use for RF_NOT_ALLOWED function
RF_NOT_ALLOWED_EN[3:0]	RW	RADIO_MISC (COEX_CTRL register) bitfield to choose which link layers will receive RF_NOT_ALLOWED signal
RF_NOT_ALLOWED_ASSERTED	W1C	RADIO_MISC (COEX_CTRL register) bitfield sets on assertion of RF_NOT_ALLOWED, cleared only by software.
RF_NOT_ALLOWED	R	RADIO_MISC (COEX_CTRL register) bitfield reflects the raw state of the selected RF_NOT_ALLOWED SOC pin
RF_NOT_ALLOWED_OVRD_EN	RW	RADIO_MISC (COEX_CTRL register) bitfield. If set, allows software to control the RF_NOT_ALLOWED signal to the link layers via the RF_NOT_ALLOWED_OVRD bitfield
RF_NOT_ALLOWED_OVRD	RW	RADIO_MISC (COEX_CTRL register) bitfield. If RF_NOT_ALLOWED_OVRD_EN is set, the RF_NOT_ALLOWED signal to the link layers is driven with the value of the RF_NOT_ALLOWED_OVRD bitfield
RF_NOT_ALLOWED_INV	RW	RADIO_MISC (COEX_CTRL register) bitfield. If set, the selected RF_NOT_ALLOWED pin is inverted before being used as the RF_NOT_ALLOWED signal to the link layers

55.4.6.6.1.2 RF_ACTIVE Behavioral Control

The NB radio provides the RF_ACTIVE (REQUEST) output to request coexistence access. This signal can be generated by either the TSM, one of the link layers, or the RFMC.

The table below describes register bits in the TSM, RFMC and RADIO_MISC to enable, control, and provide status for RF_ACTIVE. Refer to the link layer chapters for information on their REQUEST output.

Field	Type	Description
RF_ACTIVE_RX_HI[7:0]	RW	TSM bitfield to control when TSM RF_ACTIVE asserts in the RX sequence
RF_ACTIVE_RX_LO[7:0]	RW	TSM bitfield to control when TSM RF_ACTIVE de-asserts in the RX sequence
RF_ACTIVE_TX_HI[7:0]	RW	TSM bitfield to control when TSM RF_ACTIVE asserts in the TX sequence
RF_ACTIVE_TX_LO[7:0]	RW	TSM bitfield to control when TSM RF_ACTIVE de-asserts in the TX sequence
TSM_RF_ACTIVE_OVRD_EN	RW	TSM bitfield to provide override enable for TSM RF_ACTIVE output
TSM_RF_ACTIVE_OVRD	RW	TSM bitfield to provide override value for TSM RF_ACTIVE output
TSM_SPARE1_EXTEND[7:0]	RW	TSM bitfield to control when how long TSM RF_ACTIVE remains asserted after end of RX or TX sequence. This is intended to close any gaps which may occur between consecutive RX/TX or TX/RX operations
COEX_SEL	RW	RADIO_MISC (COEX_CTRL register) bitfield to select whether the TSM outputs (RF_ACTIVE, RF_STATUS, RF_PRIORITY) or the active Link Layer's outputs are input to the RFMC.
RFACT_SRC[1:0]	RW	RFMC bitfield to select whether RF_ACTIVE radio output is driven by RFMC (2'b00), TSM/LL output from the COEX_SEL mux (2'b01), or Bluetooth LE bt_clk_req signal (2'b10)
RFACT_WKUP_DLY[5:0]	RW	RFMC bitfield. If RFACT_SRC=2'b00, this configures number of 32kHz reference clocks following enable of the XO to assert the RF_ACTIVE pin for a MAN/WOR/Bluetooth LE wakeup event.
RFACT_IDIS	RW	RFMC bitfield. If RFACT_SRC=2'b00, this selects whether the RF_ACTIVE radio output de-asserts when the TSM becomes idle
RFACT_EN	RW	RFMC bitfield. If RFACT_SRC=2'b00, the RF_ACTIVE radio output is asserted while this bit is set
RFACT_FLAG	W1C	RFMC bitfield. Sets when the RF_ACTIVE radio output asserts
RFACT_IE	RW	RFMC bitfield. If set, the RFMC will generate an interrupt to CM33 when the RF_ACTIVE radio output asserts

55.4.6.6.1.3 RF_STATUS Behavioral Control

The NB radio provides the RF_STATUS (DIRECTION) output to indicate when the radio is in an RX or TX event. This signal can be generated by either the TSM or the active link layers.

The table below describes register bits in the TSM and RADIO_MISC to enable and control RF_STATUS. Refer to the link layer chapters for information on their DIRECTION output.

Field	Type	Description
RF_STATUS_RX_HI[7:0]	RW	TSM bitfield to control when TSM RF_STATUS asserts in the RX sequence

Table continues on the next page...

Table continued from the previous page...

RF_STATUS_RX_LO[7:0]	RW	TSM bitfield to control when TSM RF_STATUS de-asserts in the RX sequence
RF_STATUS_TX_HI[7:0]	RW	TSM bitfield to control when TSM RF_STATUS asserts in the TX sequence
RF_STATUS_TX_LO[7:0]	RW	TSM bitfield to control when TSM RF_STATUS de-asserts in the TX sequence
TSM_RF_STATUS_OVRD_EN	RW	TSM bitfield to provide override enable for TSM RF_STATUS output
TSM_RF_STATUS_OVRD	RW	TSM bitfield to provide override value for TSM RF_STATUS output
COEX_SEL	RW	RADIO_MISC (COEX_CTRL register) bitfield to select whether the TSM outputs (RF_ACTIVE, RF_STATUS, RF_PRIORITY) or the active Link Layer's outputs are input to the RFMC.

55.4.6.6.1.4 RF_PRIORITY Behavioral Control

The NB radio provides the RF_PRIORITY[1:0] outputs to indicate the radio access priority. This signal can be generated by either the TSM or the active link layers. Note that if the TSM is chosen, then RF_PRIORITY[1] is always 0.

The table below describes register bits in the TSM and RADIO_MISC to enable and control RF_PRIORITY. Refer to the link layer chapters for information on their PRIORITY output.

Field	Type	Description
RF_PRIORITY_RX_HI[7:0]	RW	TSM bitfield to control when TSM RF_PRIORITY asserts in the RX sequence
RF_PRIORITY_RX_LO[7:0]	RW	TSM bitfield to control when TSM RF_PRIORITY de-asserts in the RX sequence
RF_PRIORITY_TX_HI[7:0]	RW	TSM bitfield to control when TSM RF_PRIORITY asserts in the TX sequence
RF_PRIORITY_TX_LO[7:0]	RW	TSM bitfield to control when TSM RF_PRIORITY de-asserts in the TX sequence
TSM_RF_PRIORITY_OVRD_EN	RW	TSM bitfield to provide override enable for TSM RF_PRIORITY output
TSM_RF_PRIORITY_OVRD	RW	TSM bitfield to provide override value for TSM RF_PRIORITY output
COEX_SEL	RW	RADIO_MISC (COEX_CTRL register) bitfield to select whether the TSM outputs (RF_ACTIVE, RF_STATUS, RF_PRIORITY) or the active Link Layer's outputs are input to the RFMC.

55.4.6.6.2 Coexistence Signaling Options

The figure below illustrates a number of Bluetooth & WiFi coexistence signaling (adapted from WiFi alliance documentation). The interface definition between the two radio has evolved over time targeting improved spectral and antenna control efficiency. Most modern BT & WiFi interfaces utilize 3 or more signals.

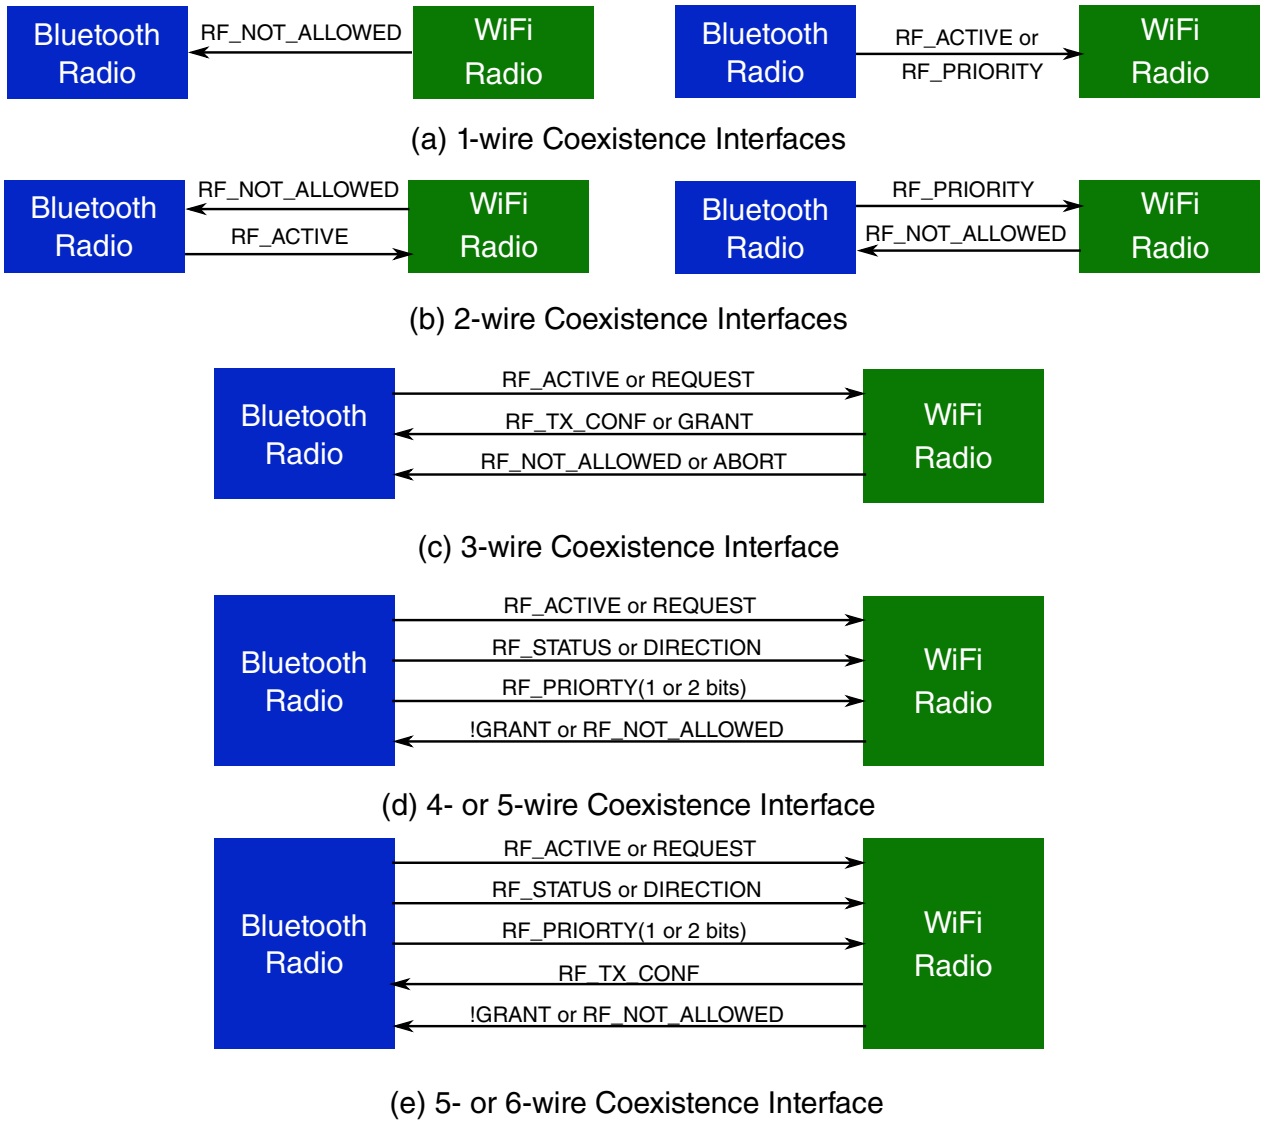

Figure 276. Coexistence signaling options between Bluetooth-LE and WiFi Radios

55.4.6.6.3 Example Coexistence Pin Mapping

The table below shows example mapping of legacy coexistence signals supported by the NB 2.4GHz radio for a few WiFi radios available in the market.

WiFi Co-existence Use Case	RF_ACTIVE	RF_STATUS	RF Priority	RF_NOT_ALLOWED	RF_TX_CONF	WiFi SoC

55.4.6.7 Radio Coexistence/FEM/LANT Connections

The Radio provides flexible mux configuration for 4 coexistence outputs, 4 FEM control outputs and 4 Localization outpus. The detailed connections are shown in below diagram.

NOTE

For the Bluetooth LE use case using the NBU: once asserted the bt_grant_n input should remain asserted until 10us after the bt_request has been de-asserted.

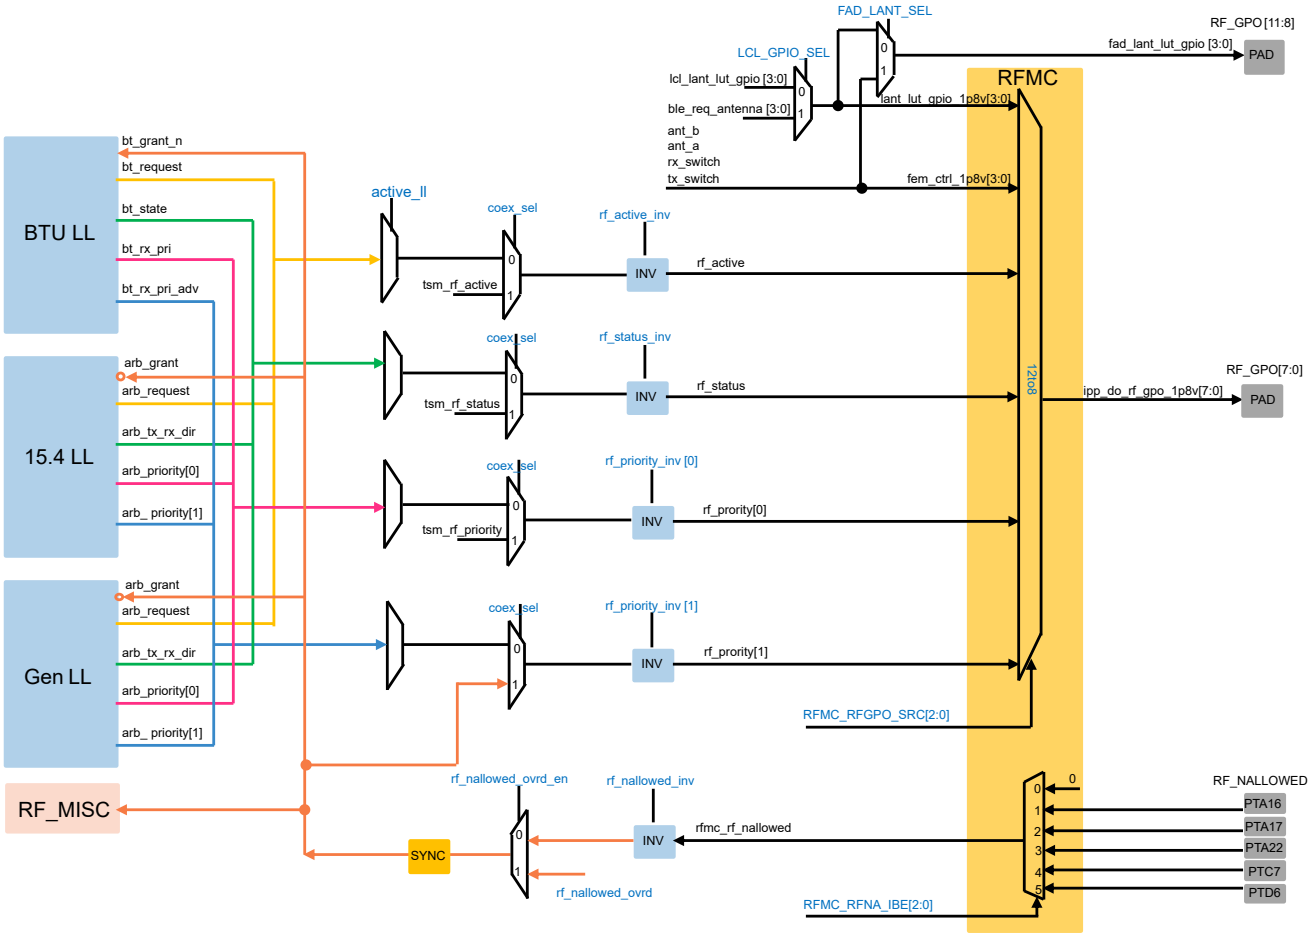

Figure 277. Radio Coexistence/FEM/LANT Mux diagram

55.4.7 Transceiver

55.4.7.1 Introduction

The transceiver uses a constant envelope direct launch transmitter and a low IF quadrature receiver. A high level figure illustrating the digital and analog components and their hierarchy is shown below.

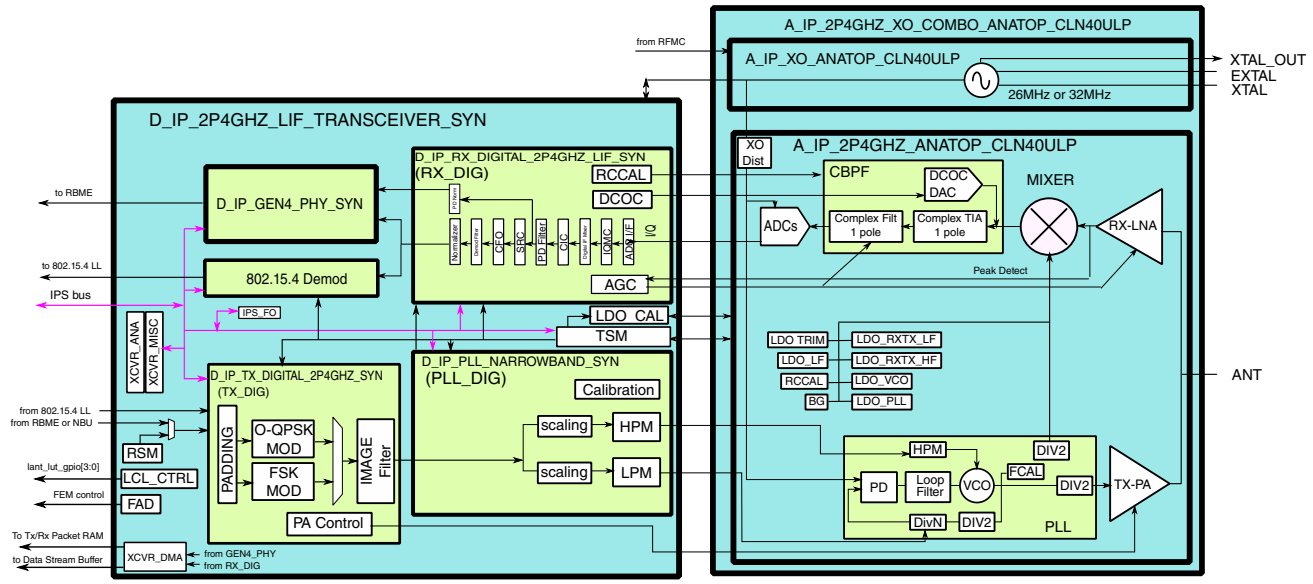

Figure 278. Transceiver Hierarchy

55.4.7.2 Transmitter Digital Module

55.4.7.2.1 About the Transmitter Digital

The Transmitter Digital processes the Transmission Data from the RF Protocol Link Layers and presents the processed data to the PLL Frequency Synthesizer as the Baseband Frequency Word.

PFC_en (Phase to Frequency Conversion) is set when zigbee symbols are to be transmitted.

55.4.7.2.1.1 Block diagram

1. Modulation Type is set using TXDIG:MODULATION_TYPE.
2. Data Rate is set using XCVR_CTRL:DATA_RATE[2:0].
3. Bandwidth Time Product is changed by reprogramming the GFSK Gaussian Filter coefficients.

55.4.7.2.1.3 Data Rates

For other Radio protocols, the Transit Data Rate is set by the DATA_RATE bits in the XCVR_CTRL register.

The supported data rates are shown in the table below.

Table 418. Transmitter Data Rates

XCVR_CTRL: DATA_RATE[2:0] Identifies the data rate at the output of the PHY	TX Data Rate
000	2Mbps
001	1Mbps
010	500Kbps
011	250Kbps
100-111	Reserved

55.4.7.2.1.4 Over-Sampling

The TX Digital uses an Oversample Clock to process the transmission data.

The GFSK, GMSK, and MSK Oversample Ratios are summarized below.

Table 419. Oversample Ratios for GFSK, GMSK, and MSK Modulations

TX Data Rate (kb/s)	Ref Clk Freq (MHz)	OSR Ref Clk Divider	OSR Clk Rate (MHz)	Data Oversample Rate
2000	32	2	16	8
1000	32	4	8	8

Table continues on the next page...

Table 419. Oversample Ratios for GFSK, GMSK, and MSK Modulations (continued)

500	32	8	4	8
250	32	16	2	8
2000	26	1	26	13
1000	26	2	13	13
500	26	4	6.5	13
250	26	8	3.25	13

55.4.7.2.1.5 Frequency Word Adjust

The Transmitter has a frequency adjustment register, FREQ_WORD_ADJ, which is used as a signed 9-bit number that is added to the TX Digital output before it is presented to the PLL as the baseband frequency word. This allows the baseband frequency word to be adjusted, or skewed, by a range of -512 to +511.

This frequency adjustment is applied to the final modulation word from any source (GFSK, FSK, DFT) and there is no protection from a math overflow. So the baseband frequency word range of -4096 to 4095 must be considered when adding this frequency word adjustment.

55.4.7.2.2 Data Pre-Processing

Before the Transmission Data is processed by the GFSK or FSK Modulators, it can be inverted, and it can also have additional preamble-like data pre-pended.

55.4.7.2.2.1 Data Polarity

The Transmission Data that is received by the TX Digital module is mapped to a positive frequency deviation if the data is a 1, and is mapped to a negative frequency deviation if the data is a 0

This mapping can be reversed by setting the TX_CAPTURE_POL register bit.

55.4.7.2.2.2 Data Padding

Transmission Data Padding is done to avoid abrupt steps in On-Air frequency modulation and thereby minimize spectral transients during the transition from a low Power Amplifier setting to a high Power Amplifier setting prior to protocol data packet transmission.

The abrupt step in modulation is avoided by pre-pending frequency words onto the front end of the actual preamble transmission. The Power Amplifier ramp-up is done while modulating these additional frequency words, and then the modulating power ramp-up smoothly transitions into the packet transmission at the Target Power level.

The data-padding starts right after TxDig_en and is applied to the Tx modulator before and during PA ramp-up as well as PA settling time(PAD_DLY plus PA_PUP_ADJ).

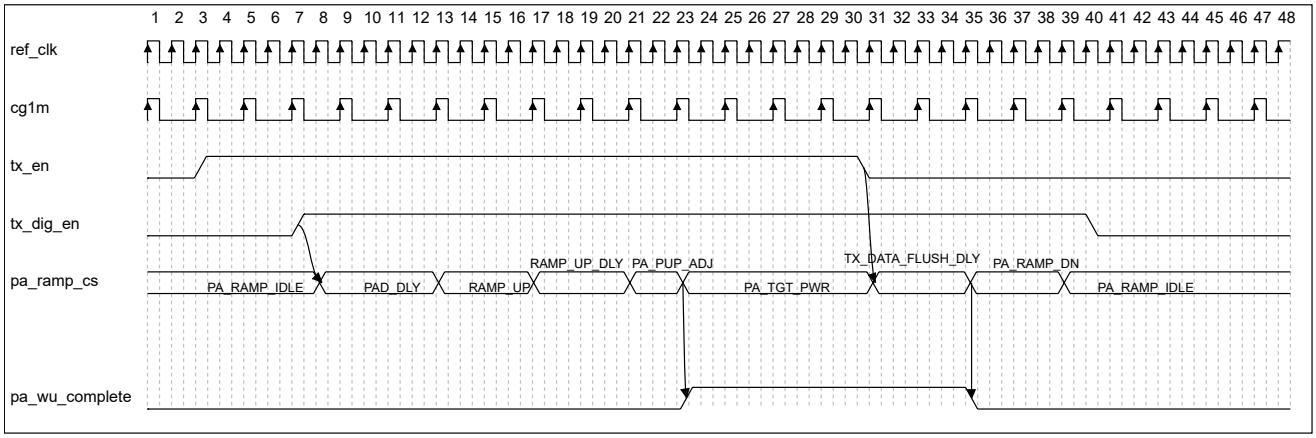

Figure 280. TX padding

There are basically three data padding steps:

- PAD_DLY, if enabled, it adds symbols before rampup.
- RAMP_UP_DLY, smooth transitions to the target power level.
- PA_PUP_ADJ, additional settling time, 2 times ref_clk cycles.
- TX_DATA_FLUSH_DLY, if enabled, it adds symbols before it starts ramping down.

DATA_PADDING_CTRL[PAD_DLY_EN],

- 1'b0, Pad delay is disabled.
- 1'b1:, Pad delay is enabled, and will insert 0-0-0-0... or 1-1-1-1..., based on data_padding_en settings.

DATA_PADDING_CTRL_1[RAMP_UP_DLY]

- It adds the number of cycles after PA ramp-up is completed, up to 31 cg1m cycles.

Table 420. Data Padding Selection

DATA_PADDING_EN[1:0]	Frequency word to PLL
00	13'h000
01	data_pad_pfdev
10	data_pad_mfdev
11	Reserved

55.4.7.2.2.3 Power Amplifier Ramping

PA ramping is included in the 2p4, to prevent abrupt transitions in PA (power amplifier) power, that could cause unwanted spectral transients. During a TX sequence, PA ramping graually ramps up PA power, between a programmable minimum, and the TX target power. The trajectory of the ramp is programmable, and ramping takes place over the course of 1, 2, or 4us (programmable).

During ramp-down of the Power Amplifier the TX Digital holds the TX Modulation Data at the final value until power reaches the minimum level.

Please refer to the section Power Amplifier Ramping in the Transceiver Sequence Manager chapter for more details on the Power Ramping topic.

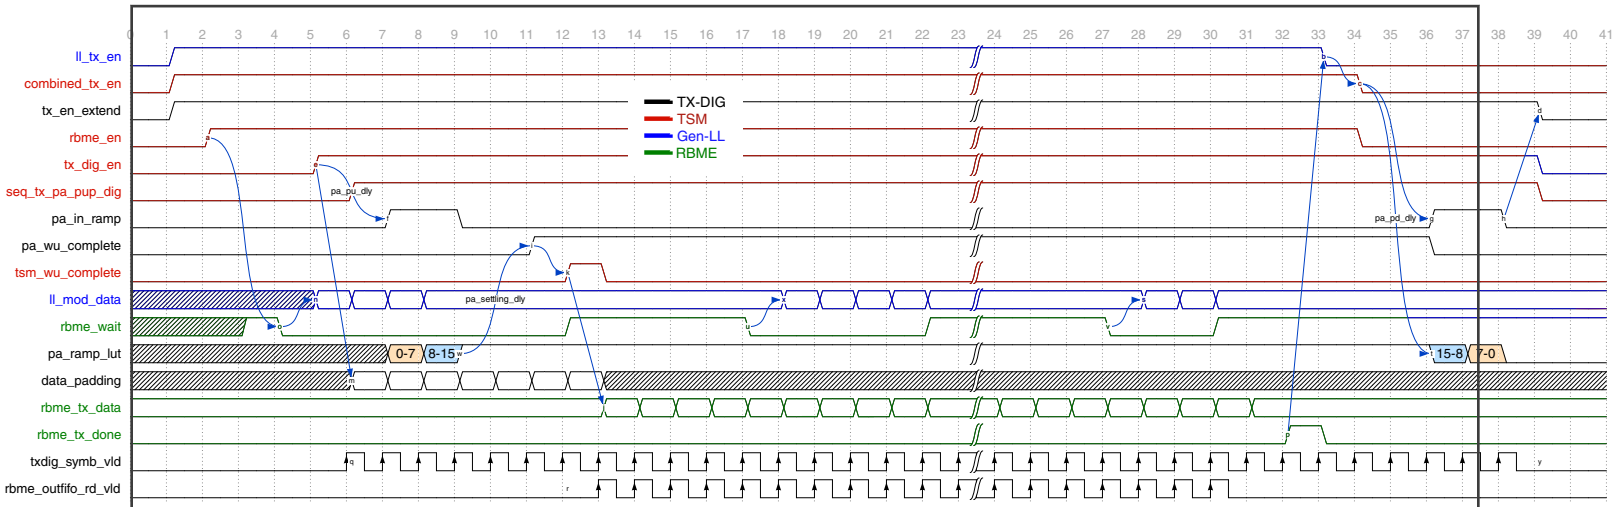

Figure 281. Power Amplifier Ramping

55.4.7.2.3 TX Warmup

When a Link Layer asserts *source*_tx_en (or software sets the FORCE_TX_EN bit) to start a TX burst, the TSM TX warmup sequence will begin. Near the end of the TSM TX warmup sequence, a TSM timing signal (tx_dig_en) will signal to the TXDIG to ramp-up the PA and start sending TX data.

The TXDIG warmup time is the time from tx_dig_en TSM signal assertion to when the TX is ready to send bits on air, which is the assertion of pa_wu_complete by the TXDIG.

The TXDIG warmup time depends on the following:

- pa_ramp_pad
- pa_ramp_up
- pa_ramp_settle

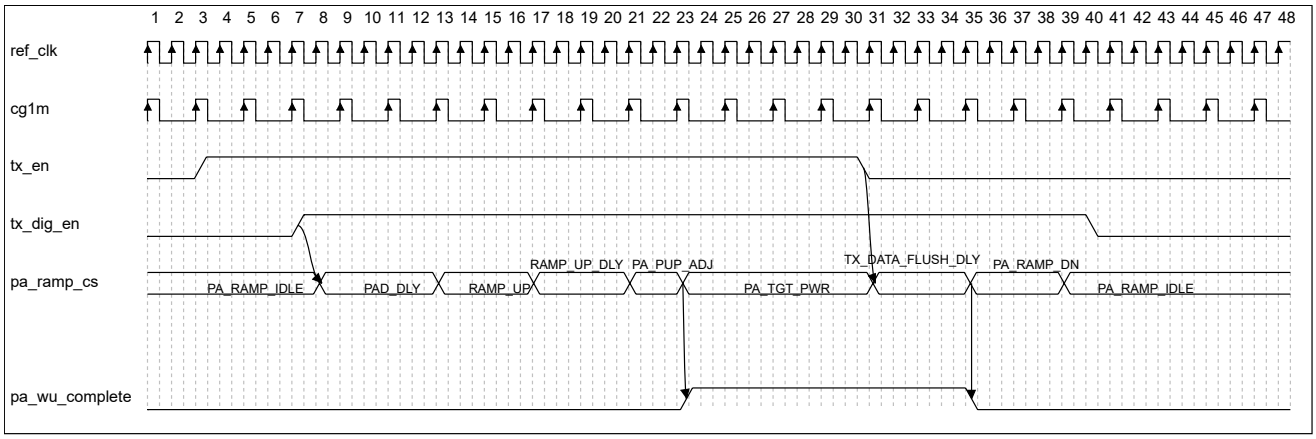

Figure 282. TX warmup delay

So the total TX warmup delay is composed of the following:

- pa_ramp_pad: DATA_PADDING_CTRL[PAD_DLY], number of cg1m cycles of padding before ramp-up.
- pa_ramp_up: PA_CTRL[PA_RAMP_SEL], 0us, 1us, 2us, or 4us.

- pa_ramp_settle: DATA_PADDING_CTRL_1[RAMP_UP_DLY], number of cg1m cycles plus DATA_PADDING_CTRL[PA_PUP_ADJ], 2 times the number of ref_clk cycles.

The total TX warmup delay can be then summarized with the following equation: DATA_PADDING_CTRL[PAD_DLY_EN]*DATA_PADDING_CTRL[PAD_DLY] (cg1m cycles, us).

PA_CTRL[PA_RAMP_SEL] 0x0: 0 us 0x1: 1 us 0x2: 2 us 0x3: 4 us DATA_PADDING_CTRL_1[RAMP_UP_DLY] (cg1m cycles, us). DATA_PADDING_CTRL_1[PA_UP_ADJ]*2 (ref_clk cycles).

55.4.7.2.4 GFSK Modulator

55.4.7.2.4.1 Gaussian Filter

GFSK Modulation is implemented using a Gaussian filter and a lookup table to implement the various reference frequencies, data rates, and modulation index values.

The Gaussian filter is a symmetric 16-tap FIR filter with 9-bit quantized coefficients and supports reference frequencies of 32 and 26 MHz at oversampling ratios of 8 and 13 respectively. There are 2 sets of pre-programmed filter coefficients available as shown in the table below.

Table 421. Gaussian Filter Coefficients BT=0.5

Tap Number(s)	32 MHz Ref	26 MHz Ref
0	9'h001	9'h017
1	9'h004	9'h029
2	9'h00d	9'h044
3	9'h029	9'h067
4	9'h063	9'h090
5	9'h0c0	9'h0ba
6	9'h12c	9'h0dc
7	9'h176	9'h0ef
8	9'h176	9'h0ef
9	9'h12c	9'h0dc
10	9'h0c0	9'h0ba
11	9'h063	9'h090
12	9'h029	9'h067
13	9'h00d	9'h044
14	9'h004	9'h029
15	9'h001	9'h017

The pre-programmed filter coefficients can be manually overridden using the gfsk_coeff_man bit to disable the GFSK Filter Lookup Table. In this case the filter coefficients will be taken from the TX GFSK Filter Coefficients register.

The following tables show the coefficients for BT=0.7 and BT=0.3

Table 422. Gaussian Filter Coefficients BT=0.7

55.4.7.2.4.2 On-Air Frequency Deviation

By default, the GFSK Modulator presents the modulation word to the PLL starting with the Negative Frequency Deviation, this results in the PLL going On-Air at the Carrier Frequency minus the frequency deviation.

The GFSK Modulator can instead be configured to begin modulating at Zero Frequency Deviation, allowing the PLL to go On-Air at the Carrier Frequency. This configuration is used if the ZERO_FDEV bit in the TX Digital Control register is set.

55.4.7.2.5 FSK Modulator

55.4.7.2.5.1 FSK Modulation Word

The default FSK Modulation mapping translates the chips/bits to a frequency modulation of +Frequency Deviation/PLL Minimum Modulation Step for a data 1, and -Frequency Deviation/PLL Minimum Modulation Step for a data 0.

For a 32 MHz reference clock with a PLL Minimum Modulation Step Size of 244.14 Hz, the default FSK Modulation mapping translates to a +/- 500 kHz peak Frequency Deviation, which is a PLL Baseband Frequency Word of +2047/-2047.

55.4.7.2.5.2 802.15.4 Modes, DFT only.

In Gen4p5, the 802.15.4 mode is only implemented for DFT. No Symbol to chip is implemented, only Phase to Frequency Conversion takes place.

To enable 802.15.4 DFT mode the following settings are needed:

- data_stream_sel = 1'b0.
- radio_dft_mode = 4'b0010: for DFT pattern register.

  or radio_dft_mode = 4'b0011: for DFT LFSR register.
- pfc_en = 1'b1.
- modulator_sel = 1'b1.

55.4.7.2.5.3 FSK Modulator

The FSK Modulation is implemented by mapping directly to a frequency modulation.

For most cases, mFdev is equal to minus Fdev.

Fdev = mod_index * Symbol_Rate/2 * TX_Scale.

TX_Scale = LO_DIV/PLL_Scale

PLL_Scale = 2^PLL_Scale_exp

PLL_Scale_exp = floor(log2(LO_Div))

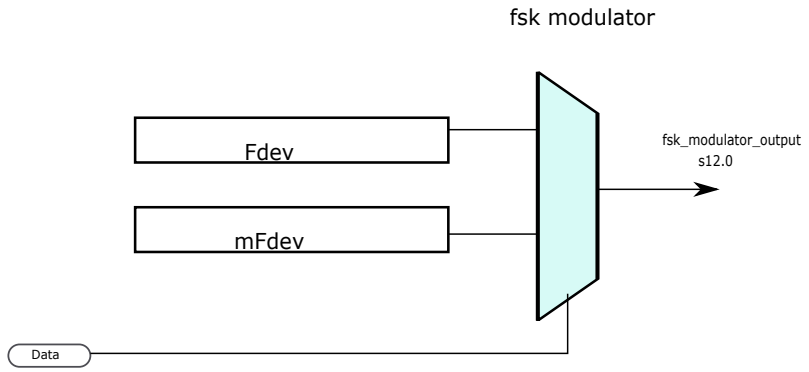

Figure 283. FSK Transmit Modulator

55.4.7.2.6 Data Post-Processing

After the Transmission Data is processed by the GFSK or FSK Modulators, it can be post-processed to remove TX modulation images.

55.4.7.2.6.1 Sample/Hold Images

Power efficient constant envelope transmit modulation is done at a multiple of the symbol clock (Over-Sample Rate), which is chosen as a fraction of the RF Osc reference clock frequency. The transmit modulation signal is then converted to the reference clock rate, at which it is presented to the PLL as the modulation word. This sample/hold (or zero-order hold, ZOH) operation results in TX modulation images that repeat at the fractional reference clock rate at used.

These modulation images are automatically filtered by the sinc ZOH transfer function and the integration (i.e., 1/s) operation of the VCO. These inherent filtering operations result in these modulation images not violating any of the transmit modulation frequency mask. However, to provide additional spectral margin to support using an external power amplifier to boost the transmit power, an image suppression set of FIR filters has been included in the transmit path to suppress the transmit sample/hold images by at least an additional 20 dB.

The transmit image filters are enabled by default in GFSK and GMSK modes and not enabled in IEEE 802.15.4 and MSK modulation modes, but their usage can be overridden using the TX_IMAGE_FILTER_OVRD_EN bit.

55.4.7.2.6.2 Image Filters

The Transmitter uses up to three image filters, by default they are enabled based upon the modulation type and data rate as shown below. There is an option to override the individual filters by programming: sync0_filter_en, sync1_filter_en, and image_fir_filter_en.

Table 424. Default Transmit Image Filter Usage

Ref Clk Freq (MHz)	ModulationType; Data Rate	TX Image Sync0	TX Image Sync1	TX Image FIR

55.4.7.2.6.3 Image Filters Frequency Response

The frequency response of the TX image suppression filters and the reduction in the level of TX images for the 1 Mbps GMSK (BluetoothLE) with the FIR filter are demonstrated in the plots below.

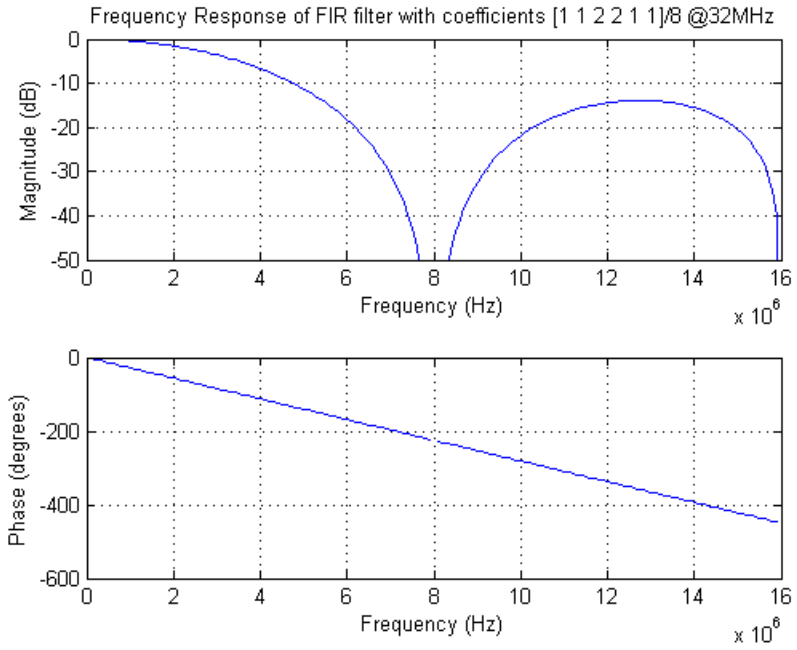

Figure 284. Frequency response of the 6-Tap FIR Transmit Image Suppression filter

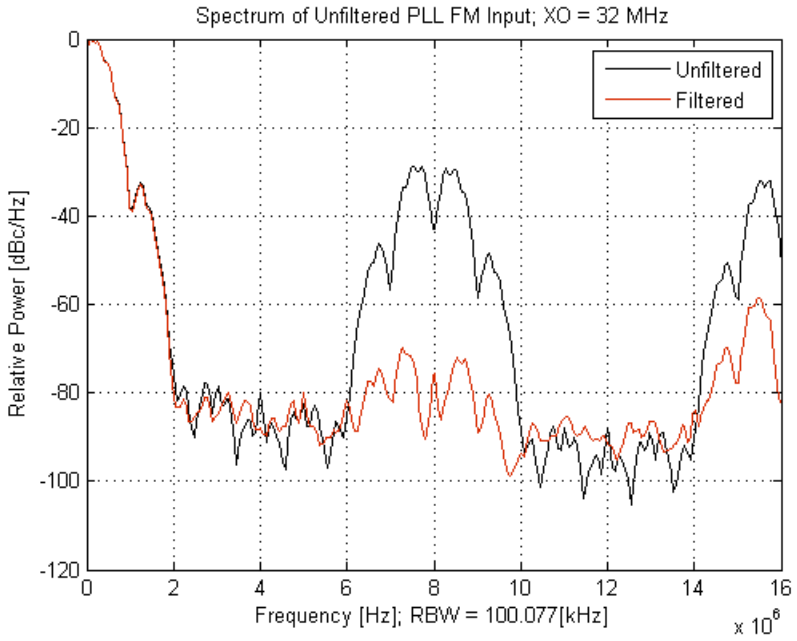

Figure 285. Comparison of Transmit Modulation Images at the PLL Input for BluetoothLE

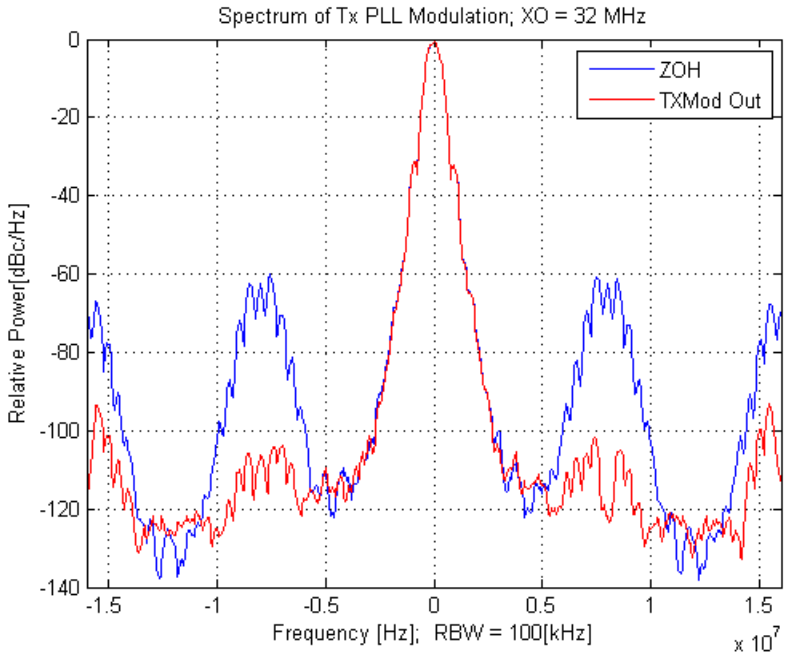

Figure 286. Comparison of Transmit Modulation Images at the PLL Output for BluetoothLE (1 Mbps GMSK)

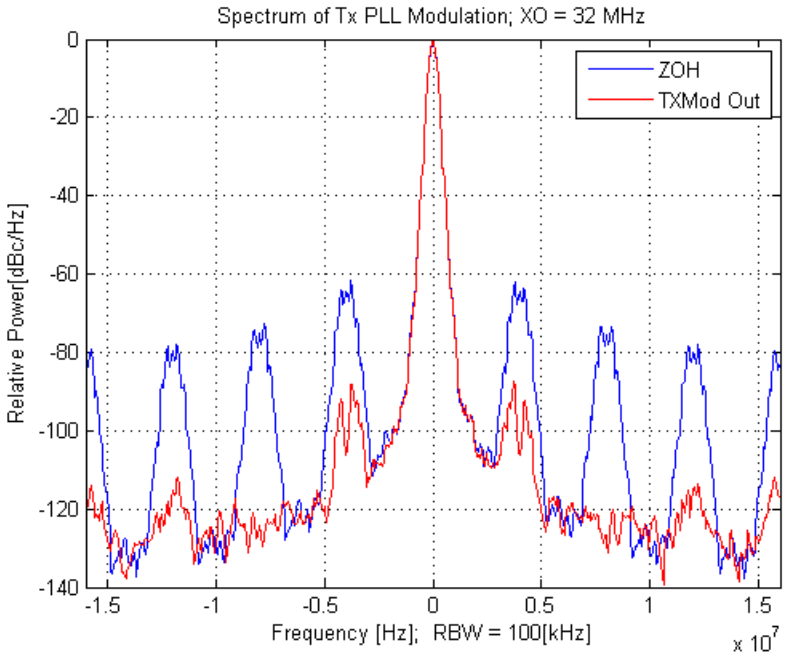

Figure 287. Comparison of Transmit Modulation Images at the PLL Output for 500 kbps GMSK

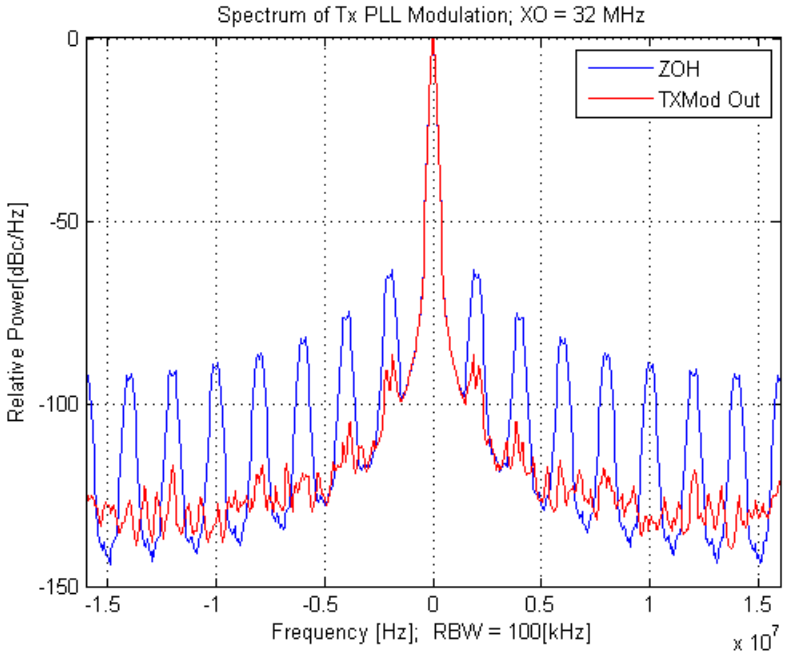

Figure 288. Comparison of Transmit Modulation Images at the PLL Output for 250 kbps GMSK

55.4.7.2.7 CTE (Continuous Tone Extension)

In BluetoothLE 5.1, Constant Tone Extension (CTE) consists of a constantly modulated series of unwhitened 1 symbols (however TX_DIG 2p4 has the option to transmitt 0 symbols as well). The Constant Tone Extension is not included in CRC or MIC calculations and it follows the CRC transmission in the packet. The Constant Tone Extension has a variable length with a minimum duration of 16us.

For direction finding applications, CTE is transmitted during various phases of the programmed antenna switching pattern that compromises of the guard period, the reference period and the switching/sampling slots.

- The Localization Control Module (lcl_ctrl) asserts tx_cte_on (based on cte_dur).
- When tx_en deasserts, TX_DIG looks at the state of tx_cte_on.

  If deasserted, the pa_ramp_cs behaves normally, it will go through the data flush state if a value other than zero is programmed, then it will ramp down.

  If tx_cte_on is asserted, then the pa_ramp_cs state machine keeps the state at target power, then it transmitts 0 if CTE_DATA = 1'b0 or 1 if CTE_DATA = 1'b1 (DATA_PADDING_CTRL[4]).

  When tx_cte_on is deassserted, then the state machine behaves as normal: it will go through data flush if a value other than zero is programmed and then it will enter ramp down.

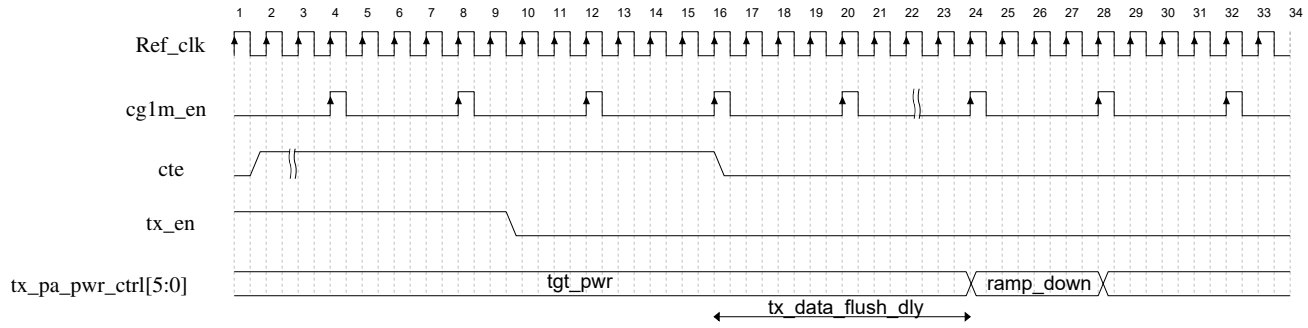

Figure 289. CTE

55.4.7.2.8 Memory Map and Register Definition

The Transmitter Digital memory map and detailed descriptions of all its registers are as follows.

55.4.7.2.8.1 XCVR_TX_DIG register descriptions

55.4.7.2.8.1.1 XCVR_TX_DIG_REGS memory map

XCVR_TX_DIG base address: 48A0_7200h

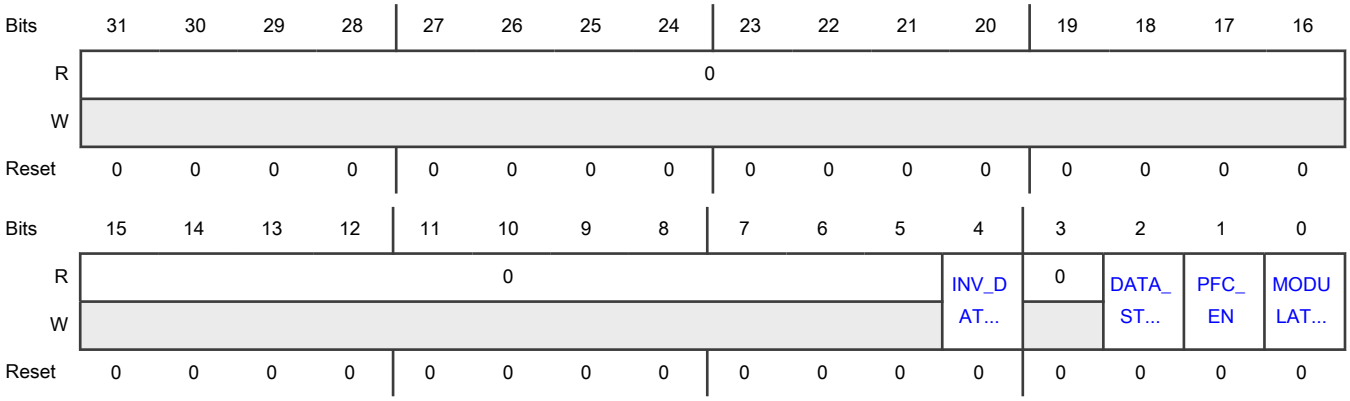
Diagram



Fields

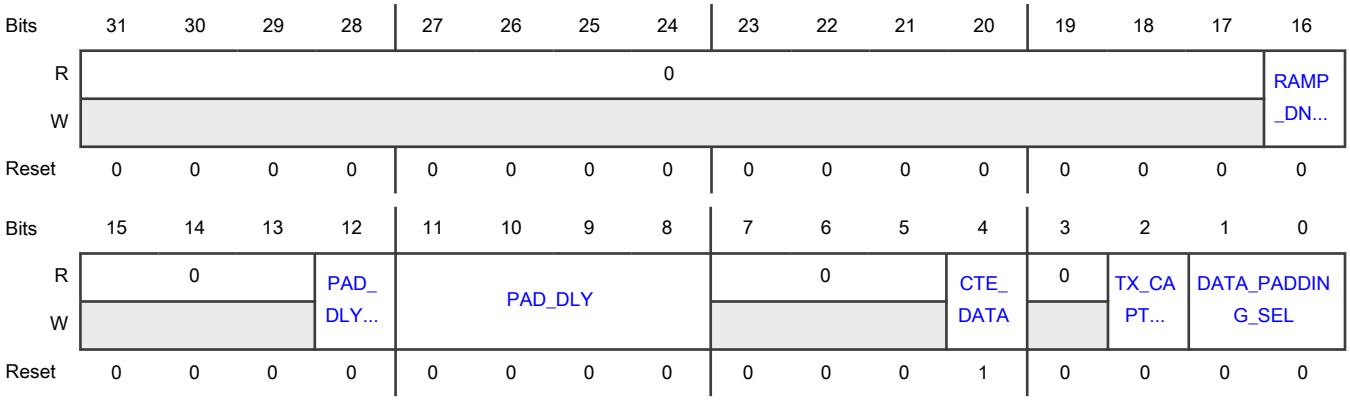
Field	Function
31-5 —	Reserved
4 INV_DATA_OUT	INV_DATA_OUT Inverts the data out.
3 —	Reserved
2 DATA_STREAM_SEL	DATA_STREAM_SEL Selects between symbol_to_chip and tx_data_padding. 1'b0: tx_data_padding 1'b1: symbol_to_chip
1 PFC_EN	PFC_EN Selects between the output of data_stream and tx_data_padding. PFC_en (Phase to Frequency Conversion) is set when zigbee symbols are to be transmitted. The frequency modulation (FM) information is obtained by differentiating the phase using a delay of 1 symbol (for Zigbee is a 1-chip delay). 1'b0: tx_data_padding 1'b1: data_stream
0 MODULATOR_SEL	MODULATOR_SEL Selects between GFSK and FSK modulator. 1'b0: GFSK 1'b1: FSK

55.4.7.2.8.1.3 DATA_PADDING_CTRL (DATA_PADDING_CTRL)

Offset

Register	Offset
DATA_PADDING_CTRL	4h

Diagram



Fields

Field	Function
31-17 —	Reserved
16 RAMP_DN_PAD_EN	RAMP_DN_PAD_EN Enables padding during ramp-down.
15-13 —	Reserved
12 PAD_DLY_EN	PAD_DLY_EN Enable padding before ramp-up.
11-8 PAD_DLY	PAD_DLY Number of Cg1m cycles of padding before ramp-up.
7-5 —	Reserved
4 CTE_DATA	CTE_DATA When CTE (Countinuous Tone Extension) selects the data to be transmitted.

Table continues on the next page...

Table continued from the previous page...

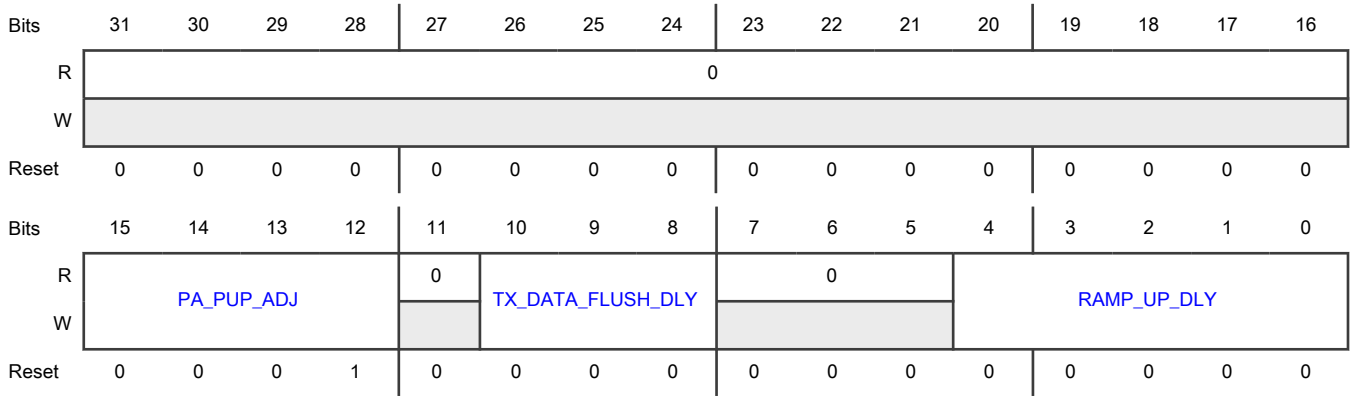
Field	Function
	1'b0: Transmitt 0. 1'b1: Transmitt 1.
3 —	Reserved
2 TX_CAPTURE_POL	TX_CAPTURE_POL Inverts the polarity of the transmitt data. 1'b0: Do not invert transmitt data. 1'b1: Inver transmitt data.
1-0 DATA_PADDING_SEL	DATA_PADDING_SEL Selects data to be used during padding. 2'b00: 0x0000 is sent to the PLL as frequency word (baseband). 2'b01: DATA_PAD_PFDEV is sent to the PLL (1). 2'b10: DATA_PAD_MFDEV is sent to the PLL (0). 2'b11: Reserved.

55.4.7.2.8.1.4 DATA_PADDING_CTRL_1 (DATA_PADDING_CTRL_1)

Offset

Register	Offset
DATA_PADDING_CTRL_1	8h

Diagram



Fields

Field	Function
31-16 —	Reserved
15-12 PA_PUP_ADJ	PA_PUP_ADJ PA Power Up Adjust. This field tells the TX_DIG to assert tx_pa_pup after tx_dig_en is set, then waits for 2 times the number of ref clk cycles programmed in this field (2*PA_PUP_ADJ) before the PA_RAMP state machine enters the RAMP_UP state. If PAD_DLY_EN is set and PAD_DLY is different than zero, the TX_DIG pads for the number of cg1m cycles specified by PAD_DLY, then it asserts tx_pa_pup and waits for the number of ref clk cycles programmed (2xPA_PUP_ADJ) before entering RAMP_UP state.
11 —	Reserved
10-8 TX_DATA_FLUSH_DLY	TX_DATA_FLUSH_DLY TX Data Flush Delay This registers tells the number of cycles (Cg1m) to wait after tx_en de-asserts before ramp-down.
7-5 —	Reserved
4-0 RAMP_UP_DLY	RAMP_UP_DLY This registers indicates the number of cycles (cg1m) to wait after ramp-up before asserting pu_complete, if PA_PUP_ADJ is non zero, assertion of pu_complete takes place after 2 times the number of ref_clk cycles programmed in PA_PUP_ADJ after RAMP_UP_DLY. (ready to start receiving data from the link layer).

55.4.7.3 PLL Digital Module

55.4.7.3.1 About the PLL Frequency Synthesizer

55.4.7.3.1.1 Introduction

The PLL Frequency Synthesizer is a Digital Module that -

1. Selects the Radio Carrier Frequency
2. Coarse Tunes the VCO and Calibrates the High Port DAC
3. Controls the PLL Loop Divider value to lock the VCO at the Carrier Frequency
4. Applies the Baseband Frequency Word as High Port Modulation (HPM) to the VCO High Port DAC
5. Applies the Baseband Frequency Word as Low Port Modulation (LPM) to the PLL Loop Divider
6. Monitors the PLL lock status and flags unlocked conditions
7. Provides DFT features for evaluating the PLL Frequency Synthesizer during factory validation and testing

55.4.7.3.1.2 Block diagram

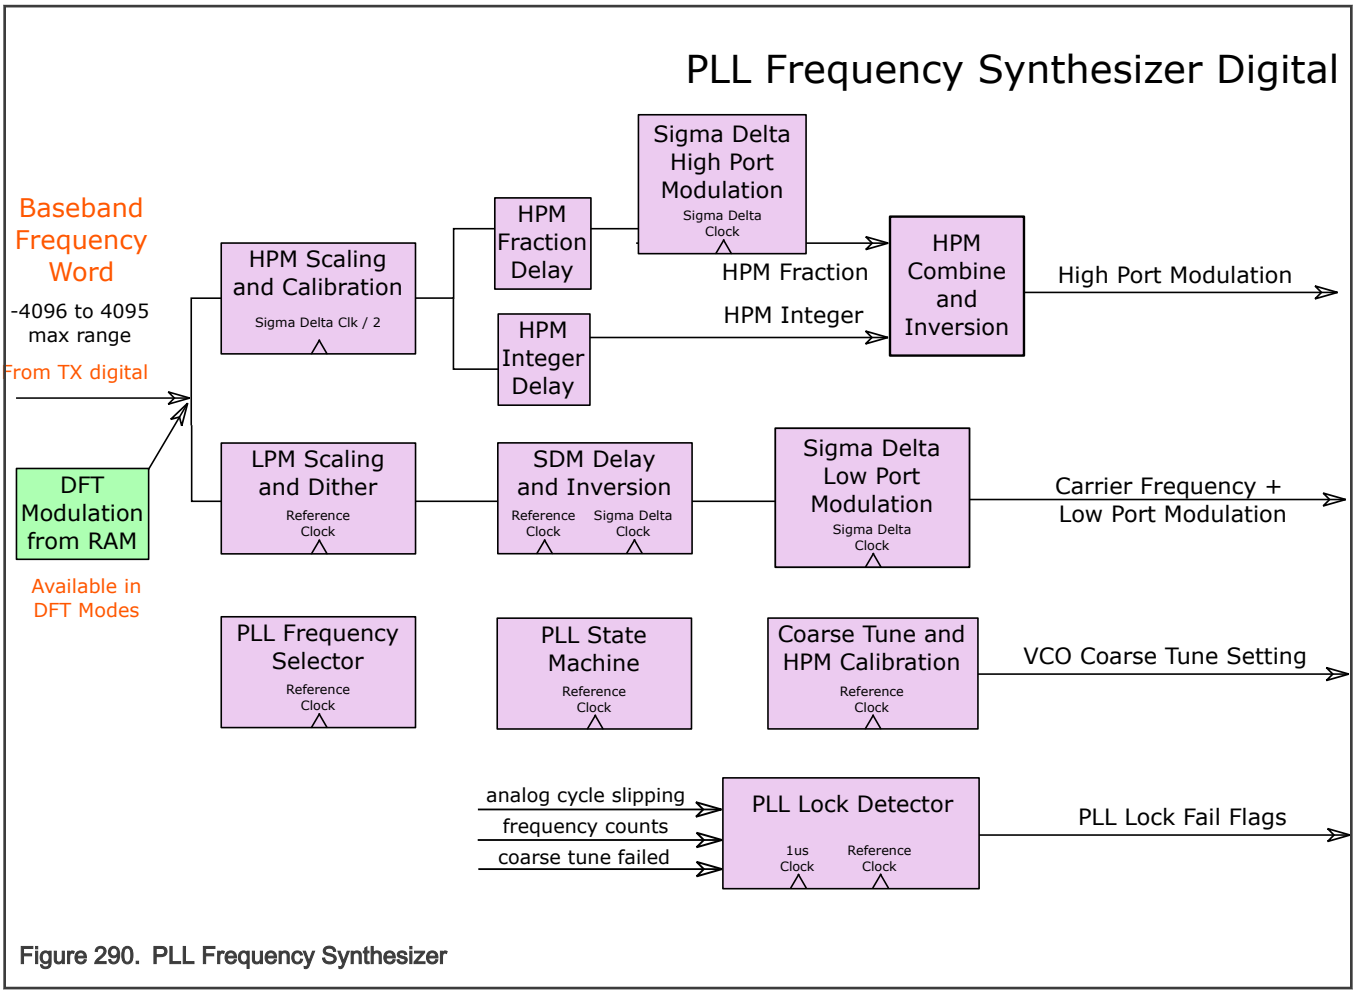

Figure 290. PLL Frequency Synthesizer

55.4.7.3.1.3 Baseband Frequency Word

The Transmitter Digital presents the PLL Frequency Synthesizer with a signed 13-bit Baseband Frequency word to modulate onto the RF Carrier Frequency. The Baseband Frequency Word range is -4096 to 4095, which provides a modulation range of +/- 1000 kHz when using a 32 MHz reference frequency with a PLL Minimum Frequency Step Size of 244.14 Hz. Note, this range can be adjusted using LPM_CTRL[LPM_SCALE] along with LPM_CTRL[HPM_CAL_SCALE] to adjust the PLL Minimum Frequency Step Size.

55.4.7.3.1.3.1 Manual Frequency Word

The Baseband Frequency word can be overridden by software if the MOD_DISABLE bit is set. In this case the PLL Digital will use the MODULATION_WORD_MANUAL register as the source of the modulation.

Note that due to the speeds at which the High Port and Low Port react to changes in the modulation word, and the speed at which software is able to effect such changes, for all practical purposes this can only support low frequency modulation.

55.4.7.3.2 Carrier Frequency Tuning

55.4.7.3.2.1 Radio Frequency Selection

The PLL Digital has hardware support for 128 RF channels in 1 MHz increments spanning the range from 2.360 GHz to 2.487 GHz.

Each supported carrier frequency is derived by Fractional-N Frequency Synthesis using the Low Port Sigma Delta Modulator. Note, the frequency selection registers should be programmed from the perspecive of TX operation. If the PLL is operating in

an RX mode then the CHAN_MAP_S3[NUM_OFFSET] will be utilized to derive the RX channel frequency. The NUM_OFFSET register field represents the IF frequency difference between RX and TX.

These 128 RF channels are mapped to the various supported RF Protocols through two lookup tables as shown in the figure below.

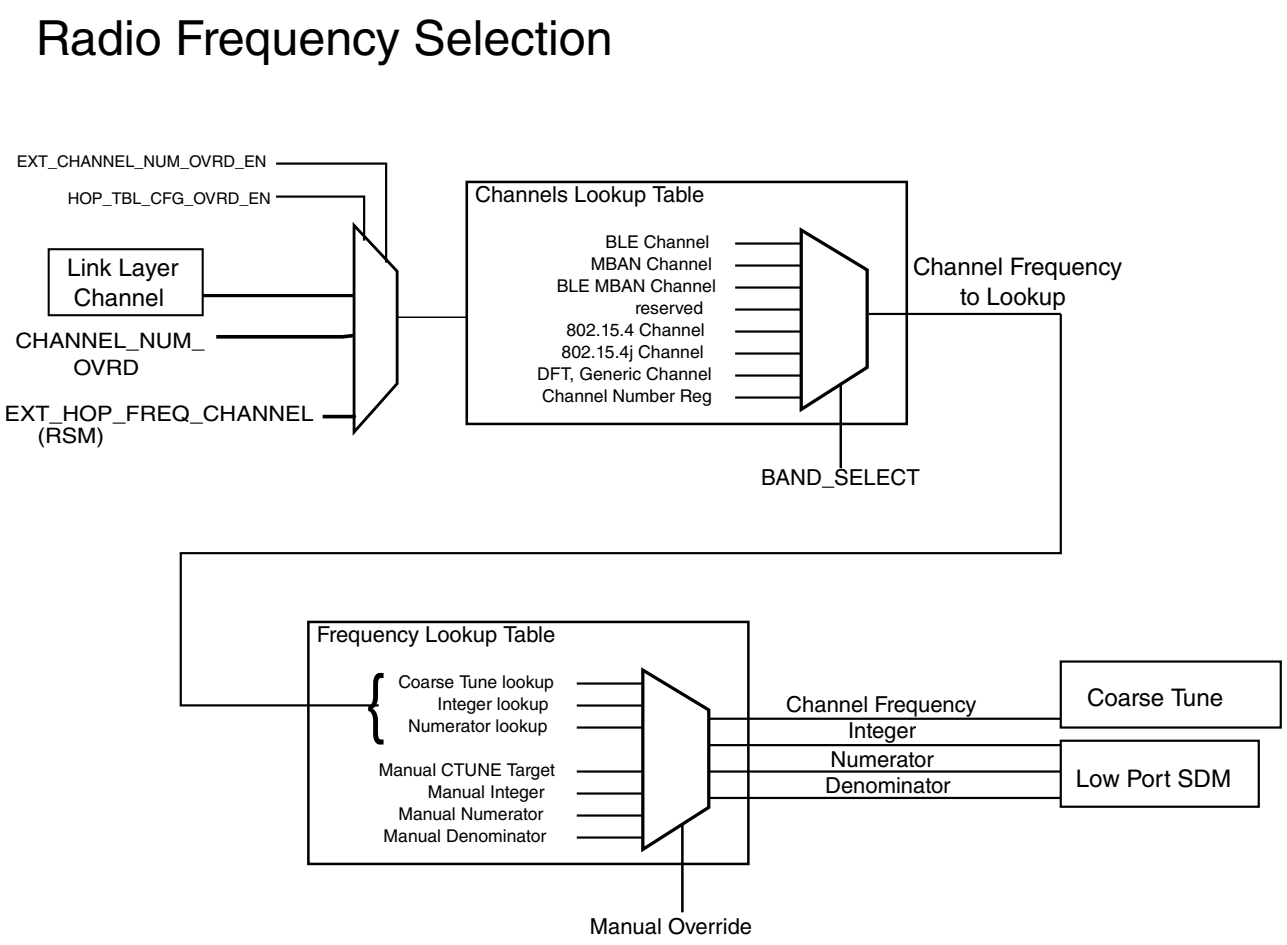

Figure 291. Radio Frequency Selection

55.4.7.3.2.2 RF Channels Supported

The channel frequencies for each protocol are shown in the tables below. The channel mapping is selected based on the register CHAN_MAP[BAND_SELECT].

55.4.7.3.2.3 Channel Selector

During typical Radio usage, the channel selection is done automatically by the Link Layer.

Channel selection can be overridden using the PLL_CHAN_MAP register bits HOP_TBL_CFG_OVRD_EN and HOP_TBL_CFG_OVRD. If HOP_TBL_CFG_OVRD_EN is set then the CHANNEL_NUM_OVRD register selects the Radio Channel Number instead of the Link Layer. In addition, the HOP_TBL_CFG_OVRD selection will determing how the CHANNEL_NUM_OVRD is interpreted.

55.4.7.3.2.4 Manual Carrier Frequency

The internal frequency mapping can be bypassed and software can directly control the Low Port Sigma Delta inputs to select any channel frequency in the VCO's range (in increments of the Low Port Minimum Frequency Step Size).

The Radio Channel Frequency override is manually selected by setting the SDM_MAP_DISABLE bit along with the LPM_INTG, LPM_NUM, and LPM_DENOM register values.

Any modulation from the TX Digital will be added to this manual frequency selection.

The Manual carrier frequency selected can be calculated using the formula below:

Radio Carrier Frequency = ((Reference Clock Frequency x 2) x (LPM_INTG + (LPM_NUM / LPM_DENOM))

WARNING : The fraction (LPM_NUM / LPM_DENOM) must be in the range of -0.55 to +0.55 for valid Sigma Delta Modulator operation.

55.4.7.3.3 VCO Calibration

55.4.7.3.3.1 Coarse Tune

The VCO Coarse Tune is carried out by a Successive Approximation Register method that computes the best coarse tune setting for the VCO in successive steps from MSB to LSB.

This SAR method uses a Frequency Meter count value that is successively compared to expected counts to determine the best coarse tune setting for the VCO.

The coarse tune setting can be overridden for test and validation purposes, and the individual frequency counts used at each successive step for the coarse tune setting are available for viewing in DTEST mode and also as register values in the PLL register space.

55.4.7.3.3.2 High Port DAC Calibration

The objective of the HPM DAC Calibration is to determine the DAC Step Size and estimate the ratio of this DAC unit step to the Low Port Minimum Frequency Step Size.

Once the step size of the High Port DAC is known, a scaling factor is applied to correctly map the baseband frequency word to the High Port modulation.

The length of the calibration time is set using the HPM_CAL_TIME register and the size of the DAC array used is selected using the HPM_CAL_ARRAY_SIZE register.

The register HPM_COUNT_ADJUST[3:0] provides a (-8/+7) range of adjustment to the HPM Calibration Count Difference for the HPM Calibration lookup table to allow for any count error bias that may be present. This adjusted Count Difference is used with a Lookup Table to choose the HPM Calibration Factor

55.4.7.3.3.2.1 HPM CAL Factor

The HPM_CAL_FACTOR register shows the value that is currently being used by High Port Modulation Multiplier. This value is from the most recent High Port calibration unless it is being overridden using the HP_CAL_DISABLE and HPM_CAL_FACTOR_MANUAL registers.

55.4.7.3.4 High Port Modulation

The High Port Modulator multiplies the HPM Calibration Factor and the PLL Baseband Frequency Word to get the High Port Modulation Word.

The High Port Modulation Word is represented by both an Integer and a Fractional portion. The Fraction is processed by the High Port Sigma Delta Modulator and the result is combined with the Integer and used to control the VCO High Port DAC.

55.4.7.3.4.1 High Port DAC

The High Port Digital to Analog Converter is designed to take the High Port Modulation Word and convert it to a control voltage that is applied as modulation to the VCO High Port.

55.4.7.3.4.1.1 HPM DAC Settings

The HPM DAC settings during calibration and normal operation are shown in the table below.

Warning : TX operation with On-Air modulation ranges greater than +/- 250 kHz (+/- 500 kHz at the VCO) require that the VCO Kvm be adjusted using the PLL_VCO_TRIM_KVM[2:0] register.

Table 427. Nominal HPM DAC parameters in various modes

Radio TX Mode		DAC max swing (mV)	DAC output common mode (mV)	DAC swing during operation	Vcm (mV) / HPM_VCM	OPAMP gain setting (R2/R1) / HPM_FDB_RES	Common mode at varactor (mV)	Swing at Varactor input (mV)	Kvm (MHz/Kv)	Deviation at VCO (KHz)[1]
802.15.4/ 2000kHz	HPM calibration	+/-82	82	+/-82	288 / 3'b001	2/ 2'b01	700	+/-164	20	+/-3280
	TX operation	+/-82	82	+/-51.2	391 / 3'b000	1/ 2'b00	700	+/51.2	20	+/-1024

	TX operation	+/-82	82	+/-51.2	391 / 3'b000	1/ 2'b00	700	+/51.2	10	+/-512
500kHz	HPM calibration	+/-82	82	+/-82	288 / 3'b001	2/ 2'b01	700	+/-164	10	+/-1640
	TX operation	+/-82	82	+/-25.6	391 / 3'b000	1/ 2'b00	700	+/25.6	10	+/-256
250kHz	HPM calibration	+/-82	82	+/-82	288 / 3'b001	2/ 2'b01	700	+/-164	10	+/-1640
	TX operation	+/-82	82	+/-12.8	391 / 3'b000	1/ 2'b00	700	+/12.8	10	+/-128

1. On-Air modulation frequency is a divide by 2 of the VCO frequency.

55.4.7.3.4.1.2 HPM DAC Bump

The HPM DAC Calibration is normally done at 2X the On-Air Modulation Range, this is accomplished by writing the PLL HPM Analog Bump Control (PLL_HPM_BUMP) register bits:

- HPM_VCM_CAL, value applied during HPM DAC Calibration
- HPM_FDB_RES_CAL, value applied during HPM DAC Calibration
- HPM_VCM_TX, value applied during Radio Transmissions
- HPM_FDB_RES_TX, value applied during Radio Transmissions

If the registers are written in such a way that the DAC range is not doubled, then the HPM_CAL_NOT_BUMPED bit must be set to change the math in the HPM Calibration.

55.4.7.3.4.1.3 HPM DAC 1 MHz Range

TX operation with On-Air modulation ranges greater than +/- 250 kHz (+/- 500 kHz at the VCO) require that the VCO Kvm be adjusted using the PLL_VCO_TRIM_KVM[2:0] register.

This VCO Kvm setting should be made prior to HPM DAC calibration.

55.4.7.3.4.2 High Port Sigma Delta

The High Port fractional modulation is implemented using a 2nd-order MASH Sigma Delta Modulator (SDM), which converts the 6-bit fractional portion of the high port modulation word to a 3-state thermometric code {-1,0,+1}. The resulting code is then added to the integer portion of the high port modulation word and the final result is applied to the HPM DAC.

55.4.7.3.4.2.1 HPM SDM Dither

In addition to the nominal SDM functionality, the HPM SDM design includes a zero-mean dithering to mitigate idle tones that can occur when modulating a string of ones or zeros.

The Dither is implemented using a Linear-Feedback Shift Register (LFSR) which provides a 1-bit pseudo-randomization that adds or subtracts 1-bit to the 6-bit fractional portion before it is processed by the Sigma Delta Modulator.

The length of the LFSR can be selected using the HPM_LFSR_SIZE register, and the scale can be changed using the HPM_DTH_SCL bit. The Dither can also be disabled by clearing the HPM_DTH_EN bit.

55.4.7.3.4.3 High Port Delay, Disable, Invert

The HPM Integer and Fraction portions each have an array of programmable delays available to allow the HPM modulations to be matched to each other and to the LPM modulation and the delay through the PLL Loop Divider and onto the VCO feedback loop.

The HPM delay steps are in increments of the PLL Sigma Delta Clock divided by 2, and the LPM SDM delay steps are in increments of the PLL Sigma Delta Clock. All three delay step settings are in the range of {0 to 15}.

There are several inversion bits that can be used if needed:

- HPM_CAL_INVERT, Invert the High Port Modulator during Calibration
- HPM_MOD_IN_INVERT, Invert the input word to the High Port Modulator
- HPM_INTEGER_INVERT, Invert the High Port Modulation Integer portion
- HPM_SDM_OUT_INVERT, Invert the HPM SDM Fractional Output

High Port Modulation can be disabled by setting the HPM_MOD_DISABLE bit, in this case the HPM_MOD_MANUAL register value is applied to the VCO High Port. Disabling high port modulation can be useful depending on the modulation range required for the desired data rate. For use cases where no high port modulation is required, the TX warm-up time can be reduced by skipping the HPM Calibration. To skip HPM CAL, the register bit HPMCAL_CTRL[HPM_CAL_SKIP] must be set. In this case, the HPM_MOD_MANUAL register should be set to 0x80. Note, the TSM default warm-up sequence must be overridden if HPM_CAL_SKIP is set to recover the HPM CAL warm-up time.

55.4.7.3.5 Low Port Modulation

The Low Port Modulator uses a 3rd order Sigma-Delta to produce a fractional division (Fractional-N Frequency Synthesis) to control the PLL Loop Divider and tune the VCO to the Radio Carrier Frequency.

The Low Port Baseband Frequency Word is added as modulation to the Sigma-Delta input.

55.4.7.3.5.1 Low Port Resolution

The table below shows the PLL Minimum Frequency Step Sizes for Modulation and Carrier Frequency tuning. Note, the PLL Minimum Carrier Frequency Step size is equivalent to the PLL Numerator LSB resolution. This step size is measuered at the PLL VCO. This table is calculated using the default numerator value of Numerator = 0x400_0000.

Note that the minimum step size for carrier frequency tuning is a divide by 256 of the modulation step sizes.

Table 428. PLL Minimum Frequency Step Size

Ref Clk Freq (MHz)	32	26

Table continues on the next page...

Table 428. PLL Minimum Frequency Step Size (continued)

PLL Minimum Modulation Step (Hz)	244.14	198.36
PLL Minimum Carrier Frequency Step (Hz)	0.9536	0.7749

55.4.7.3.5.2 Low Port Sigma-Delta

The Integer, Numerator, and Denominator are presented at the input to the Sigma-Delta Modulator.

A 3-level quantized Sigma-Delta output signal {-1, 0, +1} is generated and combined with the Integer divide value to produce the Modulus Divide Ratio for the PLL Loop Divider. The resulting RF Frequency can be calculated using the formula below:

RF Frequency = ((Reference Clock Frequency x 2) x (LPM_INTG + (LPM_NUM / LPM_DENOM))

WARNING : The fraction (LPM_NUM / LPM_DENOM) must be in the range of -0.55 to +0.55 for valid Sigma Delta Modulator operation.

55.4.7.3.5.2.1 LPM SDM Dither

While in Transmit mode the input to the SDM is naturally dithered by the Low Port modulation, which keeps the SDM from generating a pseudo-periodic output. However, in Receive mode, the SDM can potentially generate idle tones (dominant frequency modes at its output) when the input to the SDM is a constant. And in either Transmit or Receive mode the LPM SDM can generate idle tones if the Fraction is near zero.

To mitigate these impairments, the Numerator input to the SDM is dithered whenever the Numerator is in the near zero range { -64 to 63 }, or whenever the Radio is in Receive Mode.

This dither operation can also be overridden using the LPM_D_OVRD and LPM_D_CTRL bits.

55.4.7.3.5.3 Low Port Delay, Disable, Invert

The Low Port Modulator has an array of programmable delays available to allow the HPM modulation to be matched to the LPM modulation and the delay through the PLL Loop Divider and onto the VCO feedback loop.

The Low Port Modulation can be delayed at the PLL Loop Divider by delaying the input to the LPM SDM (LPM_SDM_DELAY).

There is an option to invert the Numerator (LPM_SDM_INV) before it is applied to the SDM in order to invert the sigma-delta modulation to the PLL.

The Low Port Modulation of the Loop Divider can be disabled by setting the LPM_DISABLE bit. When the modulation is disabled the LPM SDM will continue to tune the VCO to the Radio Carrier Frequency.

55.4.7.3.6 Lock Detector

The PLL Lock Detector has two methods to measure the stability of the PLL and check that it is tuned to the selected Radio Frequency.

The real-time results of the PLL Lock Detect module can be read as register bits, and flags are set and can be cleared to provide software long-term access to any PLL unlock events.

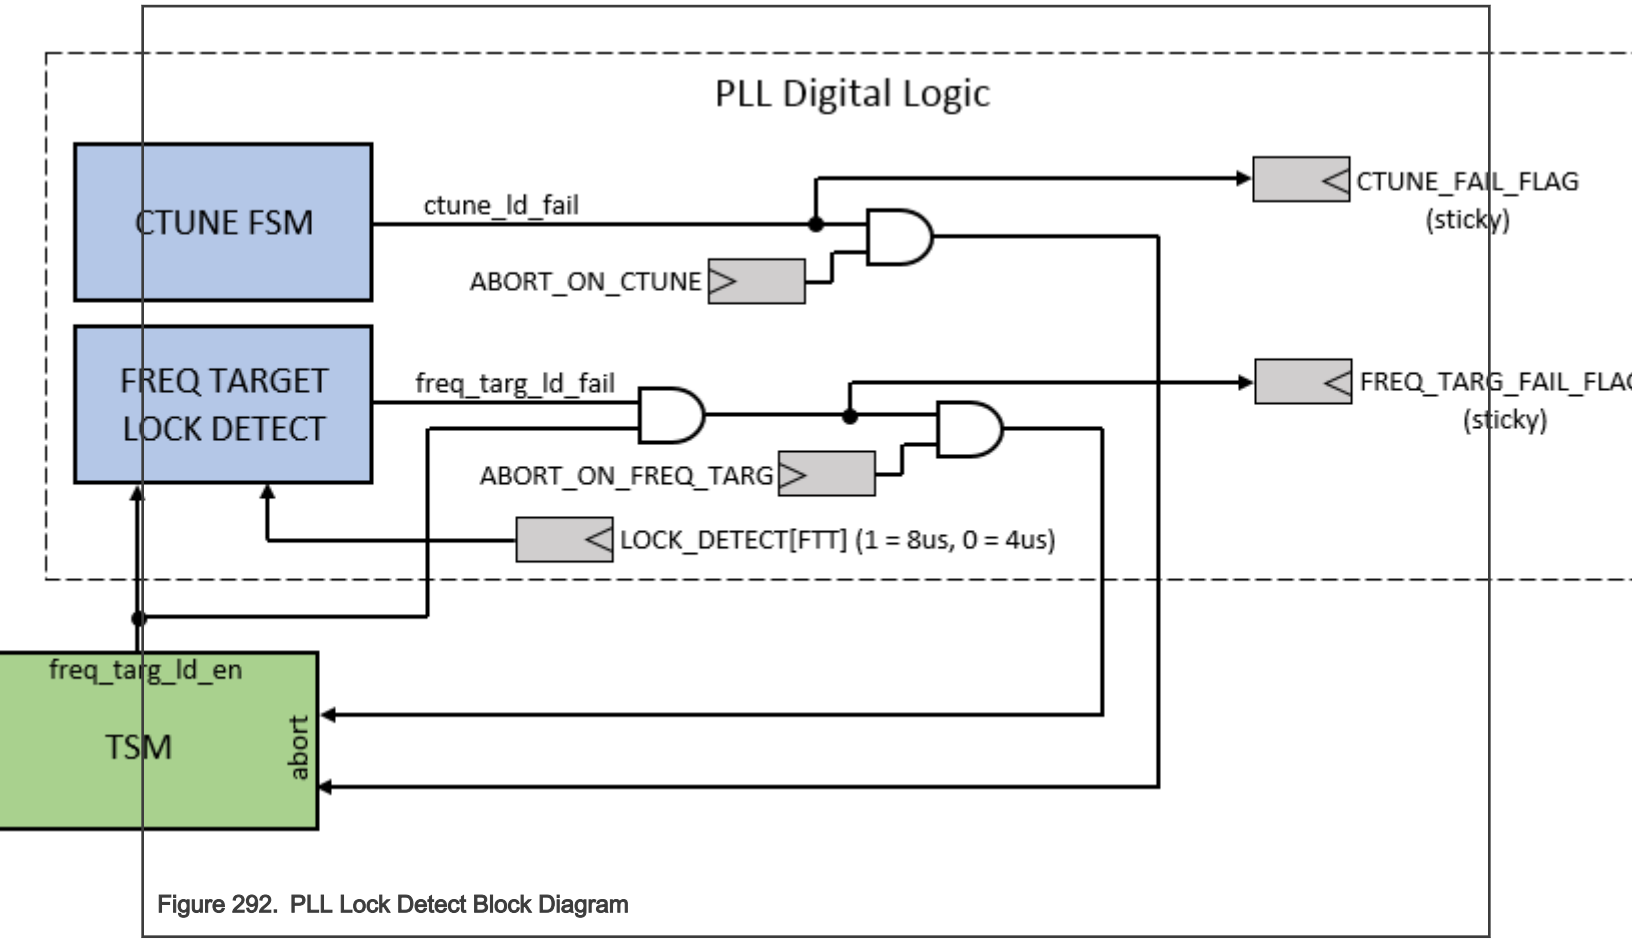

Figure 292. PLL Lock Detect Block Diagram

55.4.7.3.6.1 Coarse Tune Fail

During every Radio start-up sequence the PLL does a Coarse Tune Calibration to select a VCO setting that will allow the PLL to correctly tune and lock the VCO when the PLL/VCO loop is closed.

During the coarse tune calibration a count is maintained that indicates how close the coarse tune is to the targeted Radio Frequency, if this count is outside of the threshold selected by the Coarse Tune Lock Detect Fail Level register (LOCK_DETECT[CTUNE_LDF_LEV]), then the Coarse Tune Failure Flag bit (CTFF) will be set.

The CTFF bit is cleared by writing a 1 to it.

The CT_FAIL bit always shows the real time status of the latest Coarse Tune Calibration. If the absolute count difference was out of the range selected by CTUNE_LDF_LEV, then this bit will be set.

55.4.7.3.6.2 Fine Tune Fail

An additional lock detect method, Fine Tune Lock Detect, can be added to the end of a start-up sequence. The PLL turns on the PLL Frequency Meter for a time that is requested by the Frequency Target Window time select register bits, separately selected for RX (FTW_RX) and TX (FTW_TX).

By default, the pll frequency meter will be turned off after the standard warm-up routine (HPM CAL in TX Mode, CTUNE in RX Mode). THe Fine Tune Lock Detect sequence required that the frequency meter remain on after standard warm-up. To override the default behaviour, the LOCK_DETECT[FCAL_HOLD_EN] bit must be set. This will keep the frequency meter on until the Fine Tune Lock Detect sequence has been ran. Note, to trigger the fine tune lock detect sequence, the TSM will also need to be programmed to insert a lock detect at the end of warm-up.

These bits select either a 4us or an 8us count period and if the frequency counter is outside of the threshold selected by the Frequency Target Fail Threshold registers, FTF_RX_THRSH and FTF_TX_THRSH, then the Frequency Target Fail Flag bit (FTFF) will be set.

The FTFF bit is cleared by writing a 1 to it

The FT_FAIL bit always shows the real time status of the latest Fine Tune Frequency Measurement. If the absolute count difference was out of the range selected by Frequency Target Fail Threshold registers, then this bit will be set.

55.4.7.3.7 Memory Map and Register Definition

Field	Function
31 —	Reserved
30-28 CTUNE_TGT_OFFSET	Coarse Tune Target Frequency Offset In RX Mode, the PLL Coarse Tune Target Frequency will be subtracted from the CTUNE_TGT_OFFSET to form the final CTUNE Target Frequency. Note, if this register field is left as zero, then it will have no effect. A value should only written here if the NUM_OFFSET is large enough to require a CTUNE modification. This value should be written as a 3-bit two's compliment number. Register bit 30 is the CTUNE_TGT_OFFSET sign bit. The unit for CTUNE_TGT_OFFSET is MHz. This register can provide a maximum offset of +3 MHz or -4 MHz from the internally calculated CTUNE Target.
27-0 NUM_OFFSET	Numerator Offset The NUM_OFFSET register field represents the IF frequency difference between RX and TX. To achieve this offset, the NUM_OFFSET value will be subtracted from the internally derived PLL Numerator value. Note that the numerator LSB will change the PLL target frequency according to the table in section Low Port Modulation . This value represents a multiple of the pll minimum frequency step size. In RX Mode, this register holds a signed two's compliment offset which will be subtracted from the PLL Numerator value calculated using the PLL internal channel mapping logic. Warm-up in RX mode will automatically subtract this value from the PLL Numerator. If NUM_OFFSET == 0 then no frequency offset will exist between Tx to Rx. Bit 27 of this register provides the sign bit for RX_NUM_OFSET. The largest positive number supported is 0x3FF_FFFF. The largest negative number supported is 0xC00_0000. Note, manual override mode won't use this register field.

31-30 FREQ_COUNT_TIME	Frequency Meter Count Time This is the length of time that the Frequency Meter will count VCO clocks. 00b - 800 us 01b - 25 us 10b - 50 us 11b - 100 us
29 FREQ_COUNT_FINISHED	Frequency Meter has finished the Count Time This bit is set when the FREQ_COUNT_TIME value is reached, it is cleared when FREQ_COUNT_GO is cleared.
28 FREQ_COUNT_GO	Start the Frequency Meter The Frequency Meter starts when this bit is set and runs until the FREQ_COUNT_TIME value is reached. The bit should not be cleared until after the counting is finished. After the Counting Time finishes, the FREQ_COUNT_FINISHED bit will read as a one. Then the measured frequency can be calculated by reading the frequency counts in the DFT_FREQ_COUNTER register (PLL_DFT_OCR_1[DFT_FREQ_COUNTER]) and dividing by the FREQ_COUNT_TIME. Note that the counting is done at the VCO frequency which is 2X the Carrier Frequency
27-25 FTW_TXRX	TX and RX Frequency Target Window time select In Radio Receive Mode, register field is decoded to select the length of time to count for the estimation of PLL lock frequency, which is compared with the Frequency Target Window, we refer to this decoding as FTW_RX. In Radio Transmit Mode, register field is decoded to select the length of time to count for the estimation of PLL lock frequency, which is compared with the Frequency Target Window, we refer to this decoding as FTW_TX.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	000b - FTW_TX = 4us ; FTW_RX = 4us 001b - FTW_TX = 4us ; FTW_RX = 8us 010b - FTW_TX = 8us ; FTW_RX = 4us 011b - FTW_TX = 8us ; FTW_RX = 8us 100b - FTW_TX = 16us ; FTW_RX = 16us 101b - FTW_TX = 16us ; FTW_RX = 32us 110b - FTW_TX = 32us ; FTW_RX = 16us 111b - FTW_TX = 32us ; FTW_RX = 32us
24 FCAL_HOLD_EN	Frequency Counter Hold Enable This bit controls if the pll ripple counter stays on after the PLL warm-up sequence (TX or RX). By default (FCAL_HOLD_EN==0b0), the ripple counter will be turned off after completing CTUNE in RX mode and HPM CAL in TX mode. If the ripple counter is turned off after the standard warm-up sequence, then a lock detect sequence cannot be inserted during warm-up. To support this lock detect sequence, FCAL_HOLD_EN can be asserted to ensure the PLL ripple counter is maintained in an on state after the default CTUNE or HPM CAL state. In addition, the TSM should be programmed to run the lock detect sequence at the appropriate time during warmup. 0b - The frequency counter is turned off after CTUNE (RX Mode) or HPM CAL (TX Mode) 1b - The frequency counter is held on after CTUNE (RX Mode) or HPM CAL (TX Mode) for an optional lock detect sequence.
23-18 FTF_TX_THRSH	TX Frequency Target Fail Threshold In Radio Transmit Mode, the FT_FAIL and FTFF bits will be set after the Frequency Target Count completes if the absolute value of the count difference from the frequency target count is greater than this register value.
17-12 FTF_RX_THRSH	RX Frequency Target Fail Threshold In Radio Receive Mode, the FT_FAIL and FTFF bits will be set after the Frequency Target Count completes if the absolute value of the count difference from the frequency target count is greater than this register value.
11-8 CTUNE_LDF_LEV	CTUNE Lock Detect Fail Level The CT_FAIL and CTFF bits will be set after Coarse Tune Calibration completes if the absolute value of the Coarse Tune best count difference (CTUNE_BEST_DIFF in the PLL_CTUNE_RESULTS register) is greater than this register value.
7-6 —	Reserved
5 FTFF	Frequency Target Failure Flag This bit is set when FT_FAIL is first set, and this bit is cleared by writing a 1 to it.
4	Real time status of Frequency Target Failure

Table continues on the next page...

Table continued from the previous page...

Field	Function
FT_FAIL	If the Frequency Target Count has completed and the count was out of the range selected by FTW_TX or FTW_RX, then this bit will be set.
3-2 —	Reserved
1 CTFF	CTUNE Failure Flag, held until cleared This bit is set when CT_FAIL is first set, and this bit is cleared by writing a 1 to it.
0 CT_FAIL	Real time status of Coarse Tune Fail signal If the Coarse Tune Calibration has completed and the best count difference is out of the range selected by CTUNE_LDF_LEV, then this bit will be set.

Fields

Field	Function
31 HPM_MOD_IN_INVERT	Invert High Port Modulation If this bit is set then the High Port Modulation Word is inverted before it is multiplied and split into Integer and Fractional values.
30-29	High Port Modulation Calibration Time

Table continues on the next page...

Table continued from the previous page...

Field	Function
HPM_CAL_TIME	This bit selects the length of time to count during HPM Calibration and is used by the math implemented in the HPM Calibration Factor lookup table. 00b - 25 us 01b - 50 us 10b - 100 us 11b - N/A
28 HPM_CAL_INVERT	Invert High Port Modulator Calibration If this bit is set then the order of the High Port Calibration is reversed in order to get a positive count difference between the Maximum and Minimum settings of the HPM DAC.
27 HPM_INTEGER_INVERT	Invert High Port Modulation Integer If this bit is set then the High Port Modulation Integer value, after the multiply and split into Integer and Fractional values, will be inverted before it is applied to the VCO High Port DAC Array.
26-24 HPM_SCALE	High Port Modulation Scale This register controls the scaling of the High Port Modulation word. 000b - No Scaling 001b - Divide by 2 010b - Multiply by 2 011b - Multiply by 4 100b - Divide by 4 101b - Multiply by 8 110b - Divide by 8 111b - N/A
23 HPM_DTH_EN	Dither Enable for HPM LFSR If this bit is set, the High Port Fraction will be Dithered by the High Port LFSR before it is applied to the High Port SDM.
22-21 —	Reserved
20 HPM_DTH_SCL	HPM Dither Scale If this bit is set, the LFSR dithering of the High Port Fraction will be multiplied by 2.
19 RX_HPM_CAL_EN	Receive HPM Calibration Enable If this bit is set, HPM Calibration takes place in receive mode.
18-16	HPM LFSR Length

Table continues on the next page...

Table continued from the previous page...

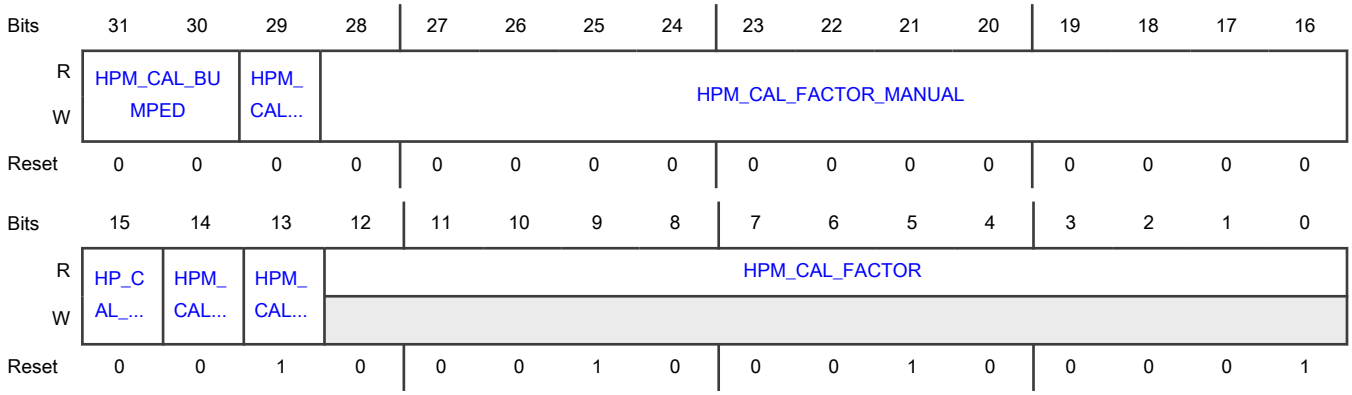
Field	Function
HPM_LFSR_SIZE	This register selects the length of the HPM LFSR and the associated LFSR Tap Mask 000b - LFSR 9, tap mask 100010000 001b - LFSR 10, tap mask 1001000000 010b - LFSR 11, tap mask 11101000000 011b - LFSR 13, tap mask 1101100000000 100b - LFSR 15, tap mask 111010000000000 101b - LFSR 17, tap mask 11110000000000000 110b - Reserved 111b - Reserved
15 HPM_SDM_IN_DISABLE	Disable HPM SDM Input If this bit is set, the Fractional portion of the High Port Modulation to the High Port SDM is disabled, and the High Port SDM input comes from the HPM_SDM_IN_MANUAL register.
14 HPM_SDM_OUT_INVERT	Invert HPM SDM Output If this bit is set the High Port SDM result will be Inverted before it is applied to the VCO High Port DAC Array.
13 HPFF	HPM SDM Invalid Flag This bit is set if the High Port Sigma Delta Modulator output is invalid due to an error in the fraction applied, and this bit is cleared by writing a 1 to it.
12 HPM_CLK_CONFIG	HPM Clock Config When this bit is set, the HPM modulation path including the HPM_SDM operate at the CLK_SDM clock (which is the 2x reference clock derived from PLL loop divider). By default they operate at the reference clock.
11-10 —	Reserved
9-0 HPM_SDM_IN_MANUAL	Manual High Port SDM Fractional value If HPM_SDM_IN_DISABLE is set, this register is the value that is applied as the Fractional value to the input of the High Port SDM.

55.4.7.3.7.1.8 PLL High Port Calibration Control (HPMCAL_CTRL)

Offset

Register	Offset
HPMCAL_CTRL	20h

Diagram



Fields

Field	Function
31-30 HPM_CAL_BUMPED	HPM_CAL_BUMPED This field adjusts the High Port Calibration Value; the default of 0 assumes that the HPM DAC range during the HPM Calibration sequence is equivalent to the range during run mode. 00b - No calibration boost 01b - x2 10b - x4 11b - x8
29 HPM_CAL_SKIP	HPM_CAL_SKIP This bit controls if the high port calibration routine is run during the warm-up sequence. When this bit is set to 1, the warm-up sequence will commence after coarse tune calibration. Note, disabling the coarse tune calibration sequence won't disable high port modulation. The user should set a manual override using either HPM_SDM_IN_DISABLE or HPM_CAL_DISABLE as needed for the application. As an example, the programmer can set HPM_CAL_SKIP = 0b1 and HPM_CAL_DISABLE = 0b1, then provide a manual override of the CAL Factor from external memory. If the CAL Factor is already known for the desired radio configuration, then this will result in a shorter warm-up time. Note that the TSM warm-up sequence will need to be modified to take into account the shorter warm-up time. In addition, if the desired modulation rate only requires single port modulation, setting HPM_CAL_DISABLE = 0b1 will allow shorter warmup time. In this case, the high port modulation path should be disabled by setting a manual override with HPM_MOD_DISABLE and HPM_MOD_MANUAL to half-rail.
28-16 HPM_CAL_FACTOR_MANUAL	Manual HPM Calibration Factor If HP_CAL_DISABLE is set, this register value is the unsigned 13 bit value used by the HPM Multiplier.
15 HP_CAL_DISABLE	Disable HPM Manual Calibration If this bit is set, the lookup table value for the HPM Calibration Factor is overridden by the HPM_CAL_FACTOR_MANUAL register.
14	HPM_CAL_COUNT_SCALE

Table continues on the next page...

Table continued from the previous page...

Field	Function
HPM_CAL_COUNT_SCALE	This bit adjusts the High Port Calibration Value; the default of 0 assumes that the VCO 2x clock (4.8 GHz) has been used by the Frequency Meter counter during the High Port Calibration sequence. If the LO clock (2.4 GHz) has been used instead, then the calibration math can be adjusted by setting this bit
13 HPM_CAL_ARRAY_SIZE	High Port Modulation Calibration Array Size This bit selects the size of the array to be used by the math implemented in the HPM Calibration Factor lookup table. 0b - 128 1b - 256
12-0 HPM_CAL_FACTOR	High Port Modulation Calibration Factor This is the value currently being used by High Port Modulation Multiplier.

20-18 TUNING_RANGE_6	Tuning Range 6 Radio channel between 2450 and 2465 MHz.
17-15 TUNING_RANGE_5	Tuning Range 5 Radio channel between 2435 and 2450 MHz.
14-12 TUNING_RANGE_4	Tuning Range 4 Radio channel between 2420 and 2435 MHz.
11-9 TUNING_RANGE_3	Tuning Range 3 Radio channel between 2405 and 2420 MHz.
8-6 TUNING_RANGE_2	Tuning Range 2 Radio channel between 2390 and 2405 MHz.
5-3 TUNING_RANGE_1	Tuning Range 1 Radio channel between 2375 and 2390 MHz.
2-0 TUNING_RANGE_0	Tuning Range 0 Radio channel less than or equal to 2375 MHz.

55.4.7.3.7.1.21 Max Transmit Frequency For TX Configuration 1 (MAX_TX_CFG1_FREQ)

Offset

Register	Offset
MAX_TX_CFG1_FREQ	58h

Function

Due to regulatory compliance requirements, more than one set of TX configuration settings may be required to meet out-of-band spectral emission requirements for TX frequencies near either the upper or lower limit of a frequency band. The PLL has a built in capability to detect when the TX carrier frequency is below or above a carrier frequency in MHz.

The MAX_TX_CFG1_FREQ register field should be programmed with a frequency threshold to detect when an alternate TX configuration must be utilized. When the PLL center frequency is selected to be greater than this threshold, a signal will be sent to the TX Digital logic indicating the need to use an alternate configuration. Note, to disable this feature, program the MAX_TX_CFG1_FREQ to 12'hFFF. This will ensure the alternatite TX configuration is not selected.

Fields

Field	Function
31 CTUNE_DISABLE	Coarse Tune Disable If this bit is set, the Coarse Tune Setting applied to the VCO comes from the CTUNE_MANUAL register.
30-28 —	Reserved
27-20 CTUNE_MANUAL	Manual Coarse Tune Setting If CTUNE_DISABLE is set, this register is the value that is applied to the VCO as the Coarse Tune Setting.
19-16 CTUNE_ADJUST	Coarse Tune Count Adjustment This register is a signed three bit value that adjusts the PLL Frequency Meter count used in the Coarse Tune Calibration. The range of adjustment is -8 to +7, and the adjustment is only made to the PLL Frequency count used by the Coarse Tune Calibration sequence.
15 CTUNE_TARGET_DISABLE	Disable Coarse Tune Target If this bit is set, the Frequency Target presented to the Coarse Tune Calibrator comes from the CTUNE_TARGET_MANUAL register.
14-12 CTUNE_CNTR_RLS_RST	Coarse Tune Counter Release Reset This field adds up to 7 ref_clk cycles to ctune_counter_release_rst. Right now it is hard coded to 2, so the maximum value could be 9.
11-0 CTUNE_TARGET_MANUAL	Manual Coarse Tune Target If CTUNE_TARGET_DISABLE or LPM_SDM_CTRL1[SDM_MAP_DISABLE] is set, this register is the value that is presented to the Coarse Tune Calibrator as the Frequency Target in MHz.

55.4.7.3.7.1.23 PLL Data Rate Override Control (DATA_RATE_OVRD_CTRL1)

Offset

Register	Offset
DATA_RATE_OVRD_CTRL1	60h

Function

The Bluetooth Low Energy LL defines test cases with asymmetric data rates in multiple connection modes. The PLL configuration must be switched by hardware when a new configuration is requested. The DATA_RATE_SWITCH register is intended to provide an override for various control registers in the PLL. The following register fields will be overridden when the Bluetooth Low Energy LL requests the updated data rate:

```
PLL_LPM_CTRL[LPM_SCALE]
             PLL_LPM_CTRL[HPM_CAL_SCALE]
             HPM_BUMP[HPM_FDB_RES_CAL]
             HPM_BUMP[HPM_FDB_RES_TX]
```

55.4.7.4 Receiver Digital Module

55.4.7.4.1 Introduction

The 2.4GHz Receive Digital Module(RX_DIG) implements the receive digital signal processing functions common to Bluetooth LE, 802.15.4, and Generic Link Layer modes. Generally this includes conditioning the input samples from the ADC and produces a data output for the PHY and an RSSI/LQI for the Link Layers.

55.4.7.4.1.1 Features

The 2.4GHz RX_DIG module includes the following features:

- Automatic Gain Control (AGC)
- CIC Decimation Filtering
- Digital IF mixer
- CFO correction
- IQ Mismatch Correction
- Fractional Correction
- Acquisition Channel Filter(16, 24-tap configurable)
- Demod Channel Filter
- Sample Rate Converter
- DC Offset Calibration and Correction
- DC Residual Correction
- Wide-Band and Narrow-Band RSSI estimator module
- Two instances of Normalizer(Wide-Band, Narrow-Band)
- RC Calibration
- Tone Analyzer
- Multiple Auxiliary Output

55.4.7.4.1.2 Block Diagram

55.4.7.4.1.2.1 Data Path

RX_DIG data path is shown below.

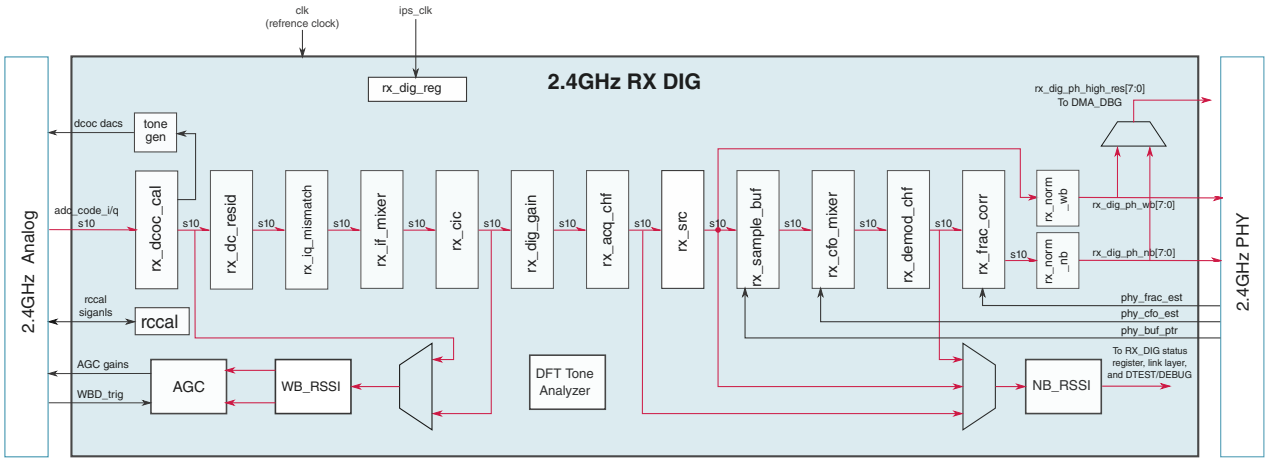

Figure 293. RX_DIG Block diagram

55.4.7.4.1.2.2 Auxiliary Output

RX_DIG has different kinds of auxiliary output for localization applications, test, or debug purposes. The following figure illustrates the structure of RX_DIG auxiliary outputs. The IQ, phase, and magnitude output support window average function, which controlled by the DFT_RX_IQ_OUT_SEL field, and the average window size can be chosen from 1(disabled), 4, 8, 16, 32, 64, 128, and 256. The rx_iq_8b_out is sent to NBU, while other signals mapped to DTEST and/or DMA_DEBUG pages.

NOTE

Check RSSI Estimator section to get the detail information of RSSI and magnitude signals

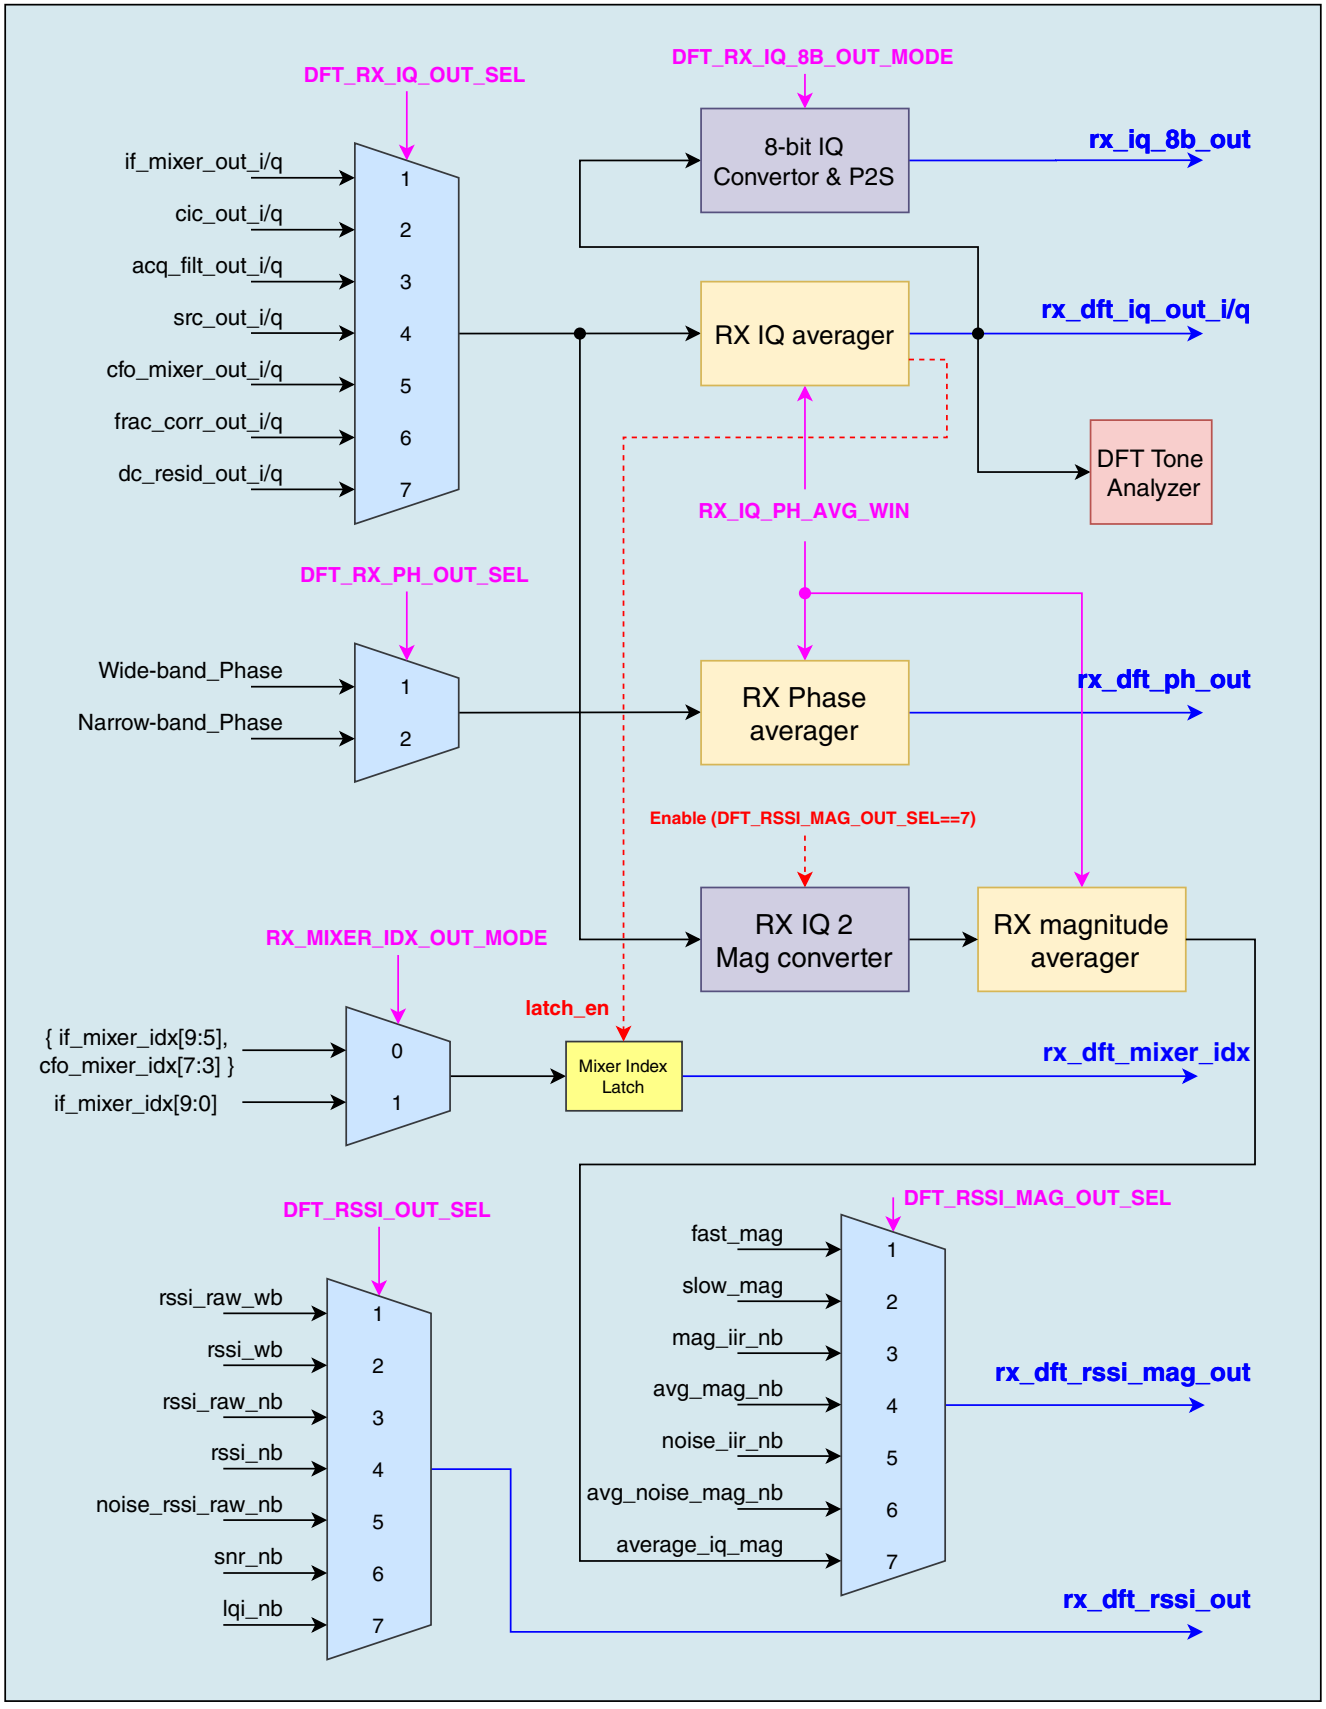

Figure 294. RX_DIG outputs selection diagram

55.4.7.4.1.3 Data Format

The 2.4GHz Radio contains fixed-point data path. In this document, there're two kinds of format to represent the fixed-point data, one is Simulink format [u/s]fix[Nb]_En[Nx], e.g. sfix8_En5, ufix8. And another is the customary format [u/s][N].[M], e.g. s2.5, u8(or u8.0). The below tables show how to parse the fixed point values to real.

Simulink format	
ufix or sfix	Denotes the number is unsigned or singed
Nb	Denotes the total number of bits, including the sign bit if signed
Nx	Denotes the number of bits for fractional

Customary format	
u or s	Denotes the number is unsigned or singed
N	Denotes the number of bits for integer
M	Denotes the number of bits for fractional

Examples	Note: signed values stored as 2's complement.			
Bin	Simulink	Customary	Total bits	Real value
00001111	ufix8	u8 or u8.0	8	15
10000011	ufix8	u8 or u8.0	8	131
0_0011001	sfix8	s7 or s7.0	8	25
1_1111110	sfix8	s7 or s7.0	8	-2
01_011000	ufix8_En6	u2.6	8	1.375
11_000001	ufix8_En6	u2.6	8	3.015625
0_10_11000	sfix8_En5	s2.5	8	2.75
1_11_11100	sfix8_En5	s2.5	8	-0.125

55.4.7.4.2 Functional Description

55.4.7.4.2.1 Reset

All RX_DIG registers that require a reset are reset by a global asynchronous reset. The rx_init signal also synchronously resets the state of various rxdig sub-modules. In addition, a software reset from 2P4Ghz XCVR can reset all RX_DIG modules except RX_DIG control register module.

55.4.7.4.2.2 Clocks

The RX_DIG uses two clocks, the 26 or 32MHz RF reference clock (clk), and the IPS gated clock (ips_clk) that has been synchronized to the reference clock. All programming model registers are clocked by the IPS clock. All other registers are clocked by the RF reference clock.

55.4.7.4.2.3 Datarate Selection

The Gen4 Radio has a hardware feature, called datarate selection, to change TX and RX datarate automatically. When RX_DIG.datarate_config_sel = 0, RX_DIG will use primary configuration values. When RX_DIG.datarate_config_sel = 1, RX_DIG will switch to use another set of configuration values for the secondary datarate. All config registers or register fields with "_DRS" postfix indicate which are using for the secondary datarate.

55.4.7.4.2.4 DC Offset Calibration and Correction

The DCOC block supports the DC offset calibration during RX warmup, and DC correction after RX warmup.

55.4.7.4.2.4.1 DC Calibration

DC calibration is expected to be performed during each RX warmup. A figure illustrating DCOC during DC calibration is shown below.

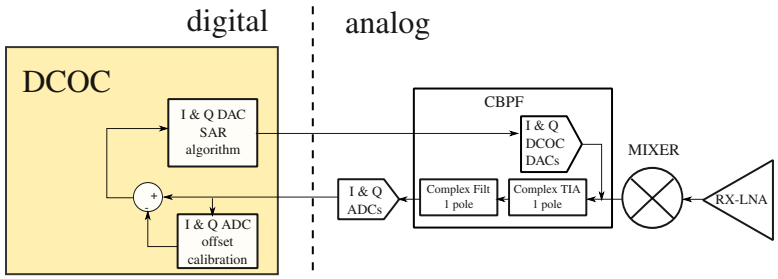

Figure 295. DC Calibration

During DC calibration the following steps are performed

1. The ADC is isolated by putting the CBPF output in a HiZ state, and the ADC inputs are shorted
2. The I and Q ADC outputs are averaged over 4 samples to estimate the DC offset related to the ADCs. These DC offsets are then subtracted from the ADC outputs which are used in steps #4-X below
3. The LNA output is put in HiZ, and the CBPF is put in high gain configuration
4. A SAR algorithm is used to determine the best values for the I DAC. If DCOC_CTRL[DCOC_DAC_ORDER]=1, the Q DAC is used instead in this step.
5. A SAR algorithm is used to determine the best value for the Q DAC. If DCOC_CTRL[DCOC_DAC_ORDER]=1, the I DAC is used instead in this step.
6. Measure the digital correction value on I and Q channel and send the result to the RO register DCOC_DIG_CORR_RESULT. If DCOC_CTRL0.DCOC_DIG_CORR_EN=1(default value), during RX_DIG enabled, the DCOC will compensate the digital correction values on both I and Q channel.

During the SAR for the I DAC, the SAR algorithm evalutates a 4-sample average of the following expression:

SAR_IN = SFIQ * QADC2 + (SFIIP)*(SFII/16) *IADC2

where SFIQ is programmable to be either 0 or 1, SFIIP is programmable to be +1 or -1, SFII is programmable from 0 to 15, IADC2 and QADC2 are the ADC samples corrected by the offsets found in step #2 above.

During the SAR for the I DAC, the SAR algorithm evalutates a 4-sample average of the following expression:

SAR_IN = SFQI * IADC2 + (SFQQP)*(SFQQ/16) *QADC2

where SFQI is programmable to be either 0 or 1, SFQQP is programmable to be +1 or -1, SFQQ is programmable from 0 to 15, and IADC2 and QADC2 are the ADC samples corrected by the offsets found in step #2 above.

After calibration, the ADC offsets and DAC codes determined during calibration can be read in the DCOC_STAT register.

The DCOC has the following additional programmable settings which affect the calibration:

- DCOC_I_CAL_POL. Polarity of the DCOC I DAC
- DCOC_Q_CAL_POL. Polarity of the DCOC Q DAC
- DCOC_CBPF_STL_TIME[3:0]. Settle time in microseconds after estimating the ADC offsets but prior to running the SAR algorithm. This is for the CBPF to be switched from HiZ to high gain.
- DCOC_SAR_STL_TIME[3:0]. Settle time in microseconds during the SAR algorithm, after changing the DAC value
- PULSE_CAPCODE. If this bit is set, then as part of the DCOC calibration sequence, the DCOC calibration logic will direct the RC calibration logic to set its seq_cbpf_ccode output to the maximum value for 3us in order to precharge cap array HiZ nodes.

The programmable values described above are determined through device characterization for the four different CBPF use cases. Preliminary guidance on settings is shown in the table below.

Table 429. DCOC Calibration Settings for 2.4GHz

Programmable Variable	
SFIQ	1
SFQI	1
SFIIP	1
SFQQP	0
SFII	13
SFQQ	9
I_CAL_POL	0
Q_CAL_POL	1
DAC_ORDER	0
CBPF_STL_TIME	3
SAR_STL_TIME	3
PULSE_CAPCODE	0

The total DC calibration duration is a function of the ref clock frequency and some DCOC configs. The referecne clock cycle count during DCOC calibration can be calculated as follows:

dcoc_cycle_count = 34 + (CBPF_STL_TIME + SAR_STL_TIME * 12) * count_in_1us + 14 * AVG_WIN_SIZE

Where, count_in_1us = 32 for 32MHz ref clock, and 26 for 26MHz ref clk. CBPF_STL_TIME and SAR_STL_TIME comes from DCOC_CTRL0. AVG_WIN_SIZE = DCOC_CTRL0.DCOC_AVG_WIN ? 8 : 4.

By default config(CBPF_STL_TIME=SAR_STL_TIME=3, AVG_WIN_SIZE=4), dcoc_cycle_count = (ref clock == 32MHz) ? 1338 : 1104. Thus the DC calibration druation is about 42us for 32MHz ref clock and 43us for 26MHz ref clock.

NOTE: DCOC TSM related timing should be updated if the DCOC calibration configs use non-default value.

For a fast RX warmup, the DC calibration is either mostly or entirely skipped, depending on PULSE_CAPCODE. If PULSE_CAPCODE bit is clear, then the TSM fast RX warmup can be programmed such that the TSM enable for the DCOC calibration remains de-asserted during the RX warmup. If PULSE_CAPCODE bit is set, then the TSM fast RX warmup can be programmed such that the TSM enable for the DCOC calibration should assert for only 3us (precharge time)+ CBPF_STL_TIME (settle time). In either case, for a fast RX warmup none of the DCOC offsets will be updated from those calculated in the previous DCOC calibration.

55.4.7.4.2.4.2 DC Correction

After the RX warmup is complete, the DCOC block handles DC correction. A figure illustrating DCOC operation after RX warmup is shown below.

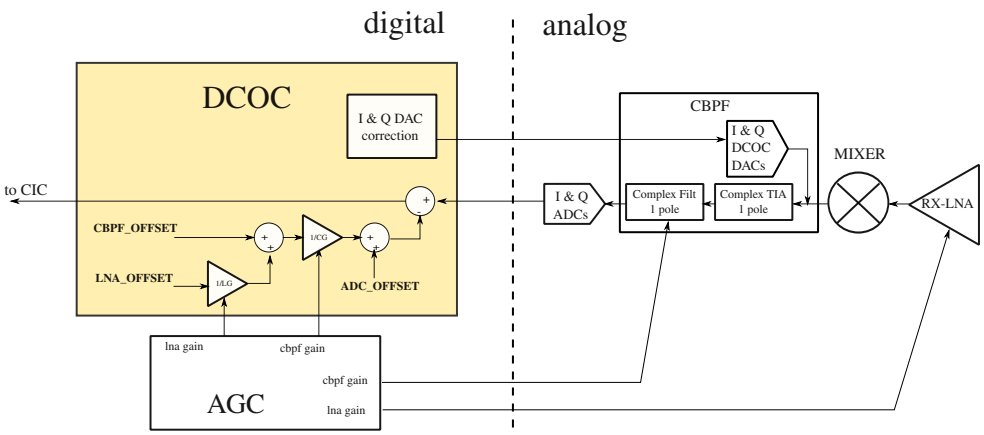

Figure 296. DC Correction

The DAC values and ADC_OFFSETs found during calibration are applied to correct the DC in the receiver. Alternately, the user can override the DAC values by programming DCOC_CTRL2[DCOC_DAC_OVRD_I] and DCOC_CTRL2[DCOC_DAC_OVRD_Q] and setting the DCOC_CTRL0[DCOC_DAC_OVRD_EN] bit. The user can also override the ADC offsets by programming the DCOC_CTRL2[DCOC_ADC_OFFSET_OVRD_I] and DCOC_CTRL2[DCOC_ADC_OFFSET_OVRD_Q] and setting the DCOC_CTRL0[DCOC_ADC_OFFSET_OVRD_EN] bit.

Additionally, the DCOC is capable of correcting for DC offsets which are depednent on the LNA and CBPF gains. These offsets are not determined during the RX warmup calibration. They have to be programmed by the user in the DCOC_CTRL1 register bitfields DCOC_ILNA_OFFSET, DCOC_QLNA_OFFSET, DCOC_ICBPF_OFFSET, and DCOC_QCBPF_OFFSET. These offsets are then scaled based on the AGC gains. In the case of the AGC's LNA gain, the scale factor 1/LG is as follows:

- highest lna gain: 1/LG = 1
- next highest lna gain: 1/LG = 1/4
- next highest lna gain: 1/LG = 1/16
- all other lna gains: 1/LG = 0

In the case of the AGC's CBPF gain, the scale factor 1/CG is as follows:

- high cbpf gain: 1/CG = 1
- low cpbf gain: 1/CG = 1/2

Note that the I & Q DAC correction value is not dependent on the CBPF gain.

55.4.7.4.2.5 DC Residual Correction

This block is used to compensate for the DC offset which is still present after AGC and DCOC calibration/tracking has completed. It estimates the DC offset by measuring the minimum and maximum value and then applies an additive correction factor to the I and Q channels. This block does not change the value of the DCOC DACs.

The DC offset is compensated independently on I and Q channels. The correction loop determines the minimum and maximum values over a specified window of samples (*Nwin*) which are then averaged and used (with an update parameter *Alpha*) to create the DC estimate. This DC estimate is then subtracted from the input samples. The applied DC estimate continues to be updated every *NWIN* samples until *IT_FREEZE* of these windows have elapsed, at which time the DC estimate is frozen.

Some addition capabilities as of Radio 3.6 are not reflected in figure above:

- the 2^{-Alpha} term can assume values of 1, 1/2, 1/4+1/8, 1/4, 1/8+1/16, 1/8, 1/16+1/32, and 1/16
- the 2^{-Alpha} term can be gearshifted using the DC_RESID_GS_EN and DC_RESID_GEARSHIFT bits.
- Further capabilities related to Long Range support. These are described at the end of this DC Residual Correction section.

Multiple modes of operations can be identified for residual DC offset compensation block. They are presented in table below.

Table 430. Residual DC offset compensation operational modes

Mode	Description	DC_RESID_EN	EXT_DC_EN	IT_FREEZE	DLY	NWIN, ALPHA
Bypass	The DC residual is disabled. The input I and Q samples to the DC Residual block are passed directly to the DC Redisdual output without any modifications. .	0	-	-	-	-
Mode 1	In this mode, DC residual has the role of calculating and applying a DC offset without use of an initial estimate from the DCOC. The DC residual processing is restarted at every AGC gain change This mode is suitable for use when an AGC gain change occurs which is not followed by DCOC tracking.	1	0	>1	>0	program as needed
Mode 2	In this mode, DC residual has the role of refining the DC offset estimate provided by the DCOC at the end of the DCOC tracking after the last DCOC DAC update. The DC residual processing is restarted whenever DCOC's tracking hold timer expires. This mode is suitable after AGC gain change followed by DCOC tracking.	1	1	>1	-	program as needed
Mode 3	In this mode, DC residual has the role of applying a correction based on the DC offset estimate provided by the DCOC at the end of the DCOC tracking after the last DCOC DAC update.	1	1	1	-	-

Table continues on the next page...

Table 430. Residual DC offset compensation operational modes (continued)

	The DC residual processing is restarted whenever DCOC's tracking hold timer expires. This mode is suitable after AGC gain change and DCOC tracking when no further refining is desired.					

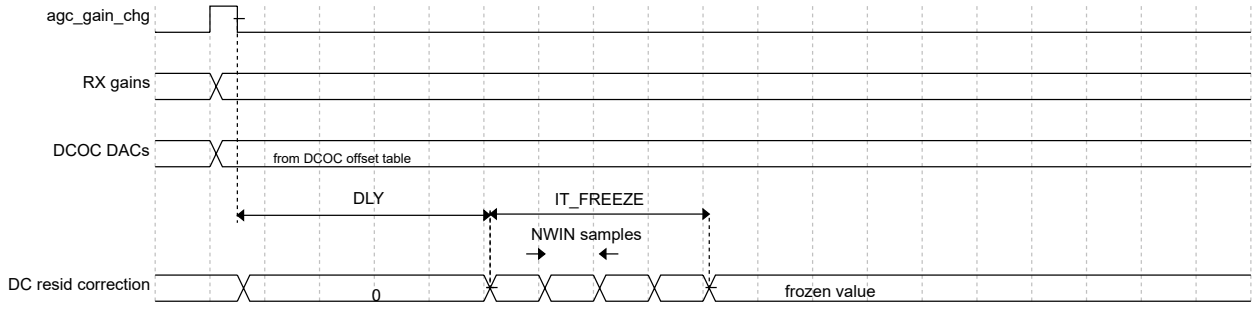

Figure 297. DC residual mode 1 timing

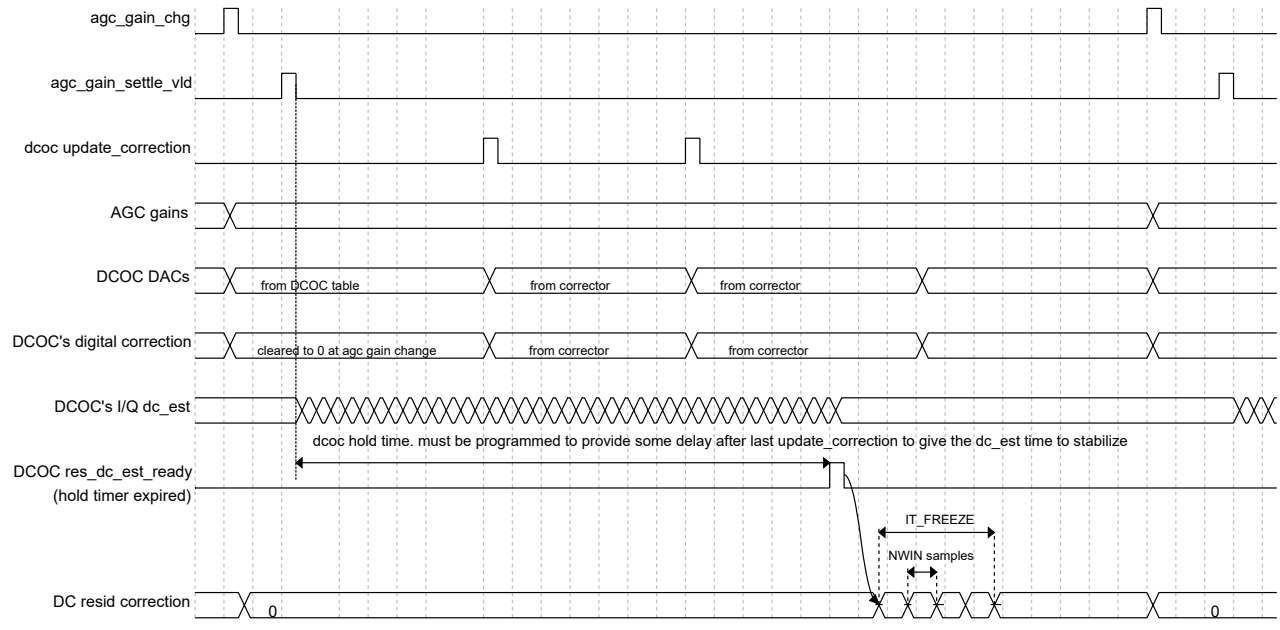

Figure 298. DC residual mode 2 timing

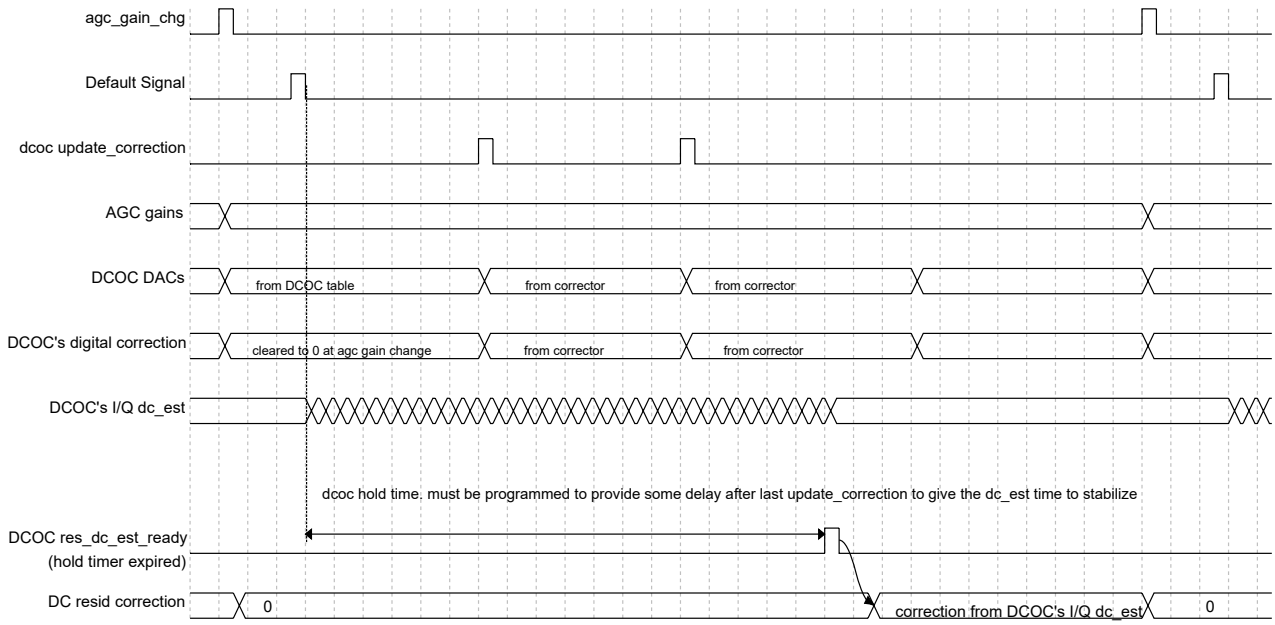

Figure 299. DC residual mode 3 timing

The behavior of the Residual DC block is also dependent on the AGC index and the values programmed for DC_RESID's MIN_AGC_IDX and the DCOC's DCOC_CTRL_1[DCOC_TRK_MIN_AGC_IDX]. This behavior is defined in the table below, which assumes DC_RESID_EN=1.

Table 431. Residual DC offset compensation operation dependency on AGC table index

EXT_DC_EN	MIN_AGC_IDX	DCOC_TRK_MIN_AGC_IDX	Behavior
-	AGC_IDX < MIN_AGC_IDX	-	DC residual is disabled
0	AGC_IDX >= MIN_AGC_IDX	-	DC residual operates in Mode 1 (it does not use an initial estimate from the DCOC)
1		AGC_IDX >= DCOC_TRK_MIN_AGC_IDX	DC residual operates in Mode 2 or 3 (It uses the estimate from the DCOC)
		AGC_IDX < DCOC_TRK_MIN_AGC_IDX	DC residual operates in Mode 1. it does not use the estimate from the DCOC, since the DCOC's tracker is disabled for this AGC gain index

For Long Range, the normal operation of the Residual DC block (as described above) may not reduce the DC level enough to support operation at very low signal levels. The Residual DC block includes an additional feature to handled such cases. If DC_RESID_SECOND_RUN_EN bit is set, then when the AGC index is greater than or equal to DC_RESID_MIN_AGC_IDX2 and the Residual DC block's normal operation has completed, additional DC compensation within the Residual DC block will activate. This "Second Run" DC compensation, when engaged, uses its own set of configuration parameters: DC_RESID_NWIN2, DC_RESID_ALPHA2, DC_RESID_ITER_FREEZE2, DC_RESID_GS2_EN, DC_RESID_GEARSHIFT2. The operation is otherwise similar to the "Mode 2" described above except that the initial DC estimate is the DC offset found at end of Residual DC block's normal operation instead of the estimate from the DCOC module. The following additional features are also supported for "Second Run"

- Slew Rate Control to limit the DC corrections. refer to DC_RESID_SR2_EN and DC_RESID_SLEWRATE2 register descriptions
- Continuous Correction. If DC_RESID_CC_EN bit is set, the DC_RESID_ITER_FREEZ2 is ignored and corrections are applied continuously until the next gain change pulse or initialization
- Operation can be stopped by the PHY. If DC_RESID_PHY_STOP_EN=1, then when the PHY signals that AA found for uncoded has been found, the "Second Run" DC compensation operation is halted (regardless of DC_RESID_ITER_FREEZE2 or DC_RESID_CC_EN bit settings) until the next gain change pulse or initialization.

55.4.7.4.2.6 I/Q Mismatch Correction

The I/Q mismatch block corrects for I/Q gain and phase mismatch. It can correct up to +/- 9 degrees of phase mismatch and +/- 4 dB of gain mismatch. After correction, phase mismatch is reduced to less than 0.5 degree and gain mismatch less than 0.3 dB.

During factory calibration, the I/Q phase adjustment coefficient (iqmc_phase_adj) and the I/Q gain adjustment coefficient (iqmc_gain_adj) are determined. Calibration is enabled by setting the CTRL0[RX_IQMC_EN] and IQMC_CTRL0[IQMC_CAL_EN] bit. The following value should be used for calibration: IQMC_CTRL0[IQMC_NUM_ITER]=0x80. The IQMC_CTRL1 register, which also stores the calibration result, should be set to its default value 0x0000_0400. A CW input with a 250 kHz (+/-75 kHz) offset and -2 dBm (+/- 6 dBm) level at the ADC I channel input is required for calibration, though the calibration should also work with lower signal levels down to -18 dBm.

NOTE

DCOC calibration should be done before doing I/Q mismatch calibration. Also, during the calibration, the AGC should be disabled.

The IQMC_CTRL0[IQMC_CAL_FREQ_SEL] controls the sample clock frequency of the IQMC module. By default IQMC uses 1/2 reference clock(16MHz or 13MHz). Setting the IQMC_CTRL0[IQMC_CAL_FREQ_SEL] bit let IQMC use 1/4 reference clock(8MHz or 6.5MHz). With the standard number of iterations (IQMC_NUM_ITER=0x80), calibration needs 128 * 64(fixed value for each iteration) samples. Thus takes 512 us or 1024 us, based on the IQMC_CAL_FREQ_SEL setting, when using 32MHz ref clock.

After calibration is completed the IQMC_CTRL1 register is updated and the IQMC_CAL_EN bit is cleared automatically. The gain calibration and phase calibration loops are shown in the figures below.

NOTE

For each iteration, the 64 samples(fixed value) should cover at least one full cycle of the CW. That means, suppose using 32MHz ref clock, the MINIMUM CW input freq should be 250KHz(period = 4 us) when IQMC_CAL_FREQ_SEL=0, or 125KHz(period = 8 us) when IQMC_CAL_FREQ_SEL=1.

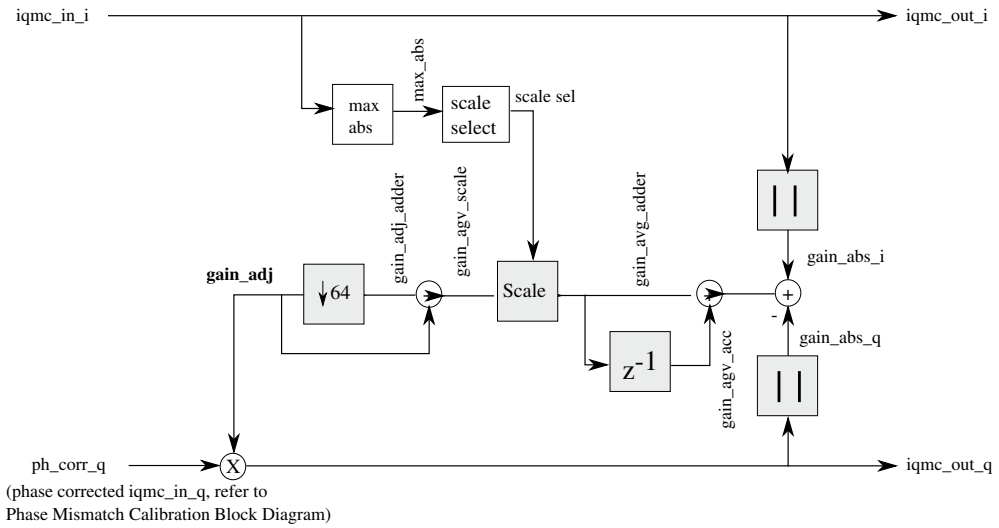

Figure 300. I/Q Gain Mismatch Calibration Block Diagram

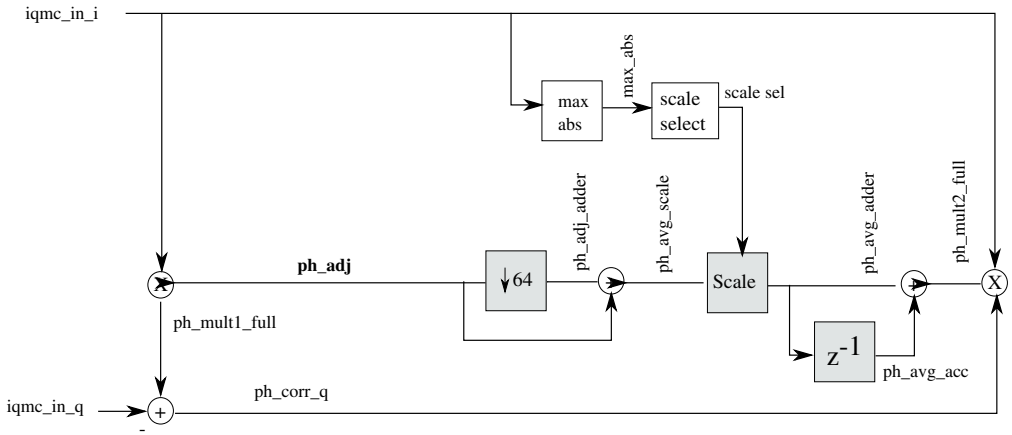

Figure 301. I/Q Phase Mismatch Calibration Block Diagram

Here is the detailed procedures to do I/Q mismatch calibration:

- Do DCOC calibration and apply the result to the input CW signal later
- Disable AGC by clear the CTRL0[AGC_EN]
- Set 0x00000400 for IQMC_CTRL1 register(Default value)
- Set proper values for IQMC_NUM_ITER and IQMC_CAL_FREQ_SEL
- Enter into RX mode and drive the CW tone to the antenna
- Set CTRL0[RX_IQMC_EN]
- Set IQMC_CTRL0[IQMC_CAL_EN]
- Poll IQMC_CTRL0[IQMC_CAL_EN] until it cleared
- Read the calibrited result from IQMC_CTRL2 register

When the receiver is enabled for packet reception, the calibration loops are disabled and the corrections are static. For gain correction, the Q channel is scaled by the gain adjustment coefficient. For phase correction, the I channel is scaled by the phase

adjustment coefficient and subtracted from the Q channel. The gain and phase correction values are stored in programming model registers and may be stored in flash to eliminate the need to run I/Q mismatch calibration after each reset.

The gain and phase corrections are illustrated in the figure below.

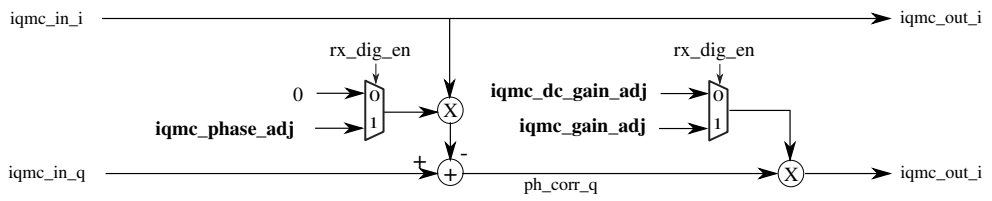

Figure 302. I/Q Mismatch Correction Block Diagram

55.4.7.4.2.7 Digital IF Mixer

The digital IF mixer performs complex mixing from low IF to DC. The mixer operates on samples at the output of the I/Q mismatch correction module. The mixer is implemented with an effective look-up table size of 1024 entries. The programmable mixer frequency is computed as follows:

DIG_MIXER_FREQ = round[1024*desired_mixer_freq/mixer_sample_frequency]

Where supported ratios of desired_mixer_freq/mixer_sample_frequency are within (-0.25, +0.25).

The table below shows the typical DIG_MIXER_FREQ configuration

Table 432. DIG_MIXER_FREQ confugration based on IF and reference clock frequency

	26MHz	32MHz
IF = 1MHz	39	32
IF = 1.5MHz	59	48

55.4.7.4.2.8 CIC Decimation Filter

RX_DIG has an Cascaded Integrator Comb (CIC) decimation filters. The CIC operates on output samples from the Digital IF Mixer at the RF reference clock rate. The order of CIC is 3 or 4 configurable and also the decimation rate can be programmed as needed by the application.

A block diagram of the CIC filter is shown below.

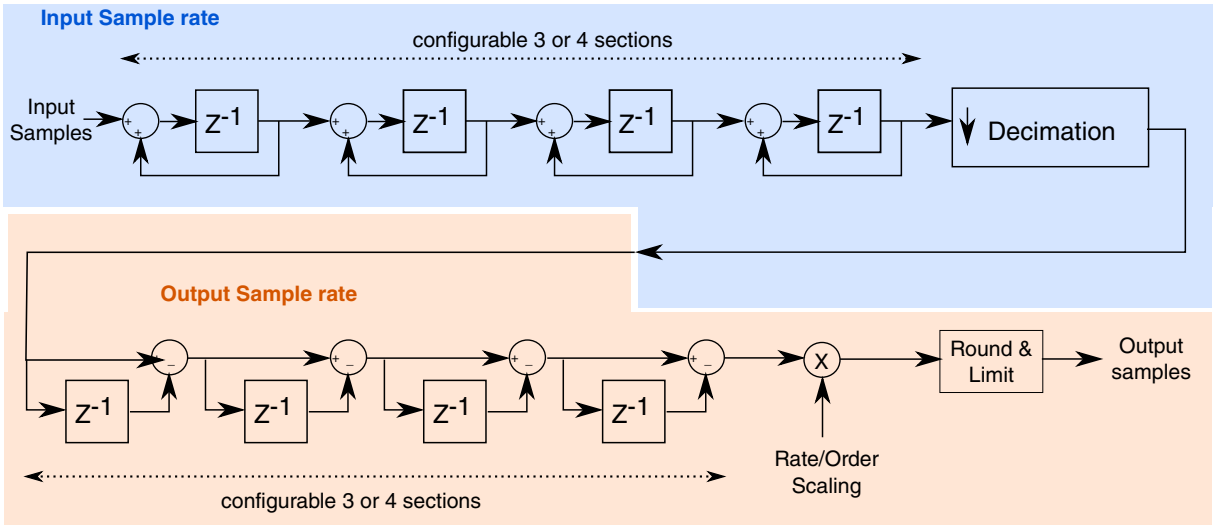

Figure 303. CIC Filter Block Diagram

The table below shows the typical CIC rate configuration.

Table 433. CIC rate confugration base on bitrate and reference clock frequency

	26MHz	32MHz
250Kbps	4	5(Only support 3-order)
500Kbps	3	4
1Mbps	2	3
2Mbps	1	2

55.4.7.4.2.9 Digital Gain

This block is a simple configurable multiplier applied at the output of CIC. The output of this module is computed as follows:

dig_gain_out_i/q = cic_out_i/q * (1 + RX_DIG_GAIN * 1 / 8)

Here the "RX_DIG_GAIN" can be choose from 0 ~ 7, therefore the actual gain value can be 1, 1.125,1.25, 1.375, 1.5, 1.625, 1.75, 1.875.

55.4.7.4.2.10 Acquisition Channel Filter

The acquisition channel filter is a 16/24-tap configurable symmetric FIR filter with real 6-bit to 10-bit coefficients. It operates at the CIC output rate on the output from Digital Gain module.

For 24-tap configuration:

$H(z) = h_0 + h_1z^{-1} + h_2z^{-2} + ... + h_{11}z^{-11} + h_{11}z^{-12} + ... + h_1z^{-22} + h_0z^{-23}$

For 16-tap configuration:

$H(z) = h_3 + h_4z^{-1} + h_5z^{-2} + ... + h_{11}z^{-7} + h_{11}z^{-8} + ... + h_4z^{-14} + h_3z^{-15}$

The filter output is scaled by 1/512, therefore the sum of the 12 or 8(depends on the CTRL0[RX_ACQ_FILT_LEN]) coefficients programmed in register ACQ_FILT_0_3 ~ ACQ_FILT_10_11 is expected to be <=256 in order to avoid saturation.

55.4.7.4.2.11 Sample Rate Conversion (SRC) Filter

The sample rate conversion block is used for a fractional clock rate conversion of the sampled decimated signal, when 26MHz reference clock is used. For the 2.4GHz targeted modulations, the PHY data rate is always 4x the symbol rate (of 2Mbps, 1Mbps, 500kbps or 250kbps) for (G)FSK modes and 4x the 2Mchips/sec rate for IEEE 802.15.4. These desired frequencies are not related to the ADC clock rate by an integer factor, which necessitates the need for a fractional sample rate conversion that is performed by SRC. For a complete list of the fractional conversion modes refer to . The SRC is enabled by setting RX_DIG_CTRL[RX_SRC_EN] to 1, and the conversion factor is selected by RX_DIG_CTRL[RX_SRC_RATE] as described below.

55.4.7.4.2.12 IQ Sample Buffer

This block is a 1~32 depth buffer for storing IQ values output from RX SRC. The sample buffer depth is controlled by Gen4 PHY, but can be bypassed by setting RX_SAMPLE_BUF_BYPASS in CTRL1 register.

NOTE:

1. If RX CFO MIXER bypassed, shuold plus 1 to the original IQ sample buffer pointer config value in PHY(PREPHY_MISC_BUFF_PTR_LR and PREPHY_MISC_BUFF_PTR_GFSK)

2. If RX Fractional Correction bypassed, shuold plus 1 to the original IQ sample buffer pointer config value in PHY(PREPHY_MISC_BUFF_PTR_LR and PREPHY_MISC_BUFF_PTR_GFSK)

3. If both RX CFO MIXER and RX Fractional Correction bypassed, shuold plus 2 to the original IQ sample buffer pointer config value in PHY(PREPHY_MISC_BUFF_PTR_LR and PREPHY_MISC_BUFF_PTR_GFSK)

55.4.7.4.2.13 CFO Mixer

The CFO mixer performs complex mixing to eliminate carrier frequency offset which operates at SRC out clock domain. The mixer is implemented with an effective look-up table size of 256 entries. Tpically the CFO correction coefficient(cfo_est[9:0]) comes from PHY, but can be overrided by RX_CFO_EST_OVRD_EN and RX_CFO_EST_OVRD fields in CTRL1 register. The target CFO mixer frequency computed as follows:

cfo_frequency = round[cic_out_freq*cfo_est/2048]

The supported CFO correction range is +/-0.25 datarate. e.g. for 1Mbps, +/-250KHz CFO can be elimiated

55.4.7.4.2.14 Demodulation Channel Filter

The demodulation channel filter is a 9-tap symmetric FIR filter with real 9-bit to 10-bit coefficients. It operates at the SRC output rate on the output from CFO Mixer module.

$H(z) = h_0 + h_1z^{-1} + h_2z^{-2} + h_3z^{-3} + h_4z^{-4} + h_3z^{-5} + h_2z^{-6} + h_1z^{-7} + h_0z^{-8}$

The filter output is scaled by 1/512, therefore the 5 coefficients programmed in register DEMOD_FILT_0_1 and DEMOD_FILT_2_4 should be meet below formula:

$(h_0 + h_1 + h_2 + h_3) * 2 + h_4 <= 512$

55.4.7.4.2.15 Fractional Correction

This block is responsible with the timing error compensation. The correction factor comes from Gen4 PHY, but can be override by RX_DIG register.

The timing error compensation is realized via linear interpolation using past, current and future samples:

IQOut[k] = IQIn[k] + (IQIn[k+1]-IQIn[k])*abs(FracDly[k]), if FracDly[k]>=0

IQOut[k] = IQIn[k] + (IQIn[k-1]-IQIn[k])*abs(FracDly[k]), if FracDly[k]<0

55.4.7.4.2.16 Normalizer

The normalizer block converts the 11-bit I/Q input signal into phase output as shown in the block diagrams below.The RX_DIG has two instances of normalizer, wide-band and narrow-band, both of them have the same structure. The difference is the wide-band

normalizer connects to the output of RX_SRC, while the narrow-band normalizer uses RX_FRAC_CORR output. In addition, a rounded version, PH_ZB[4:0], of PH_WB[7:0] is sent to ZB_DEMOD.

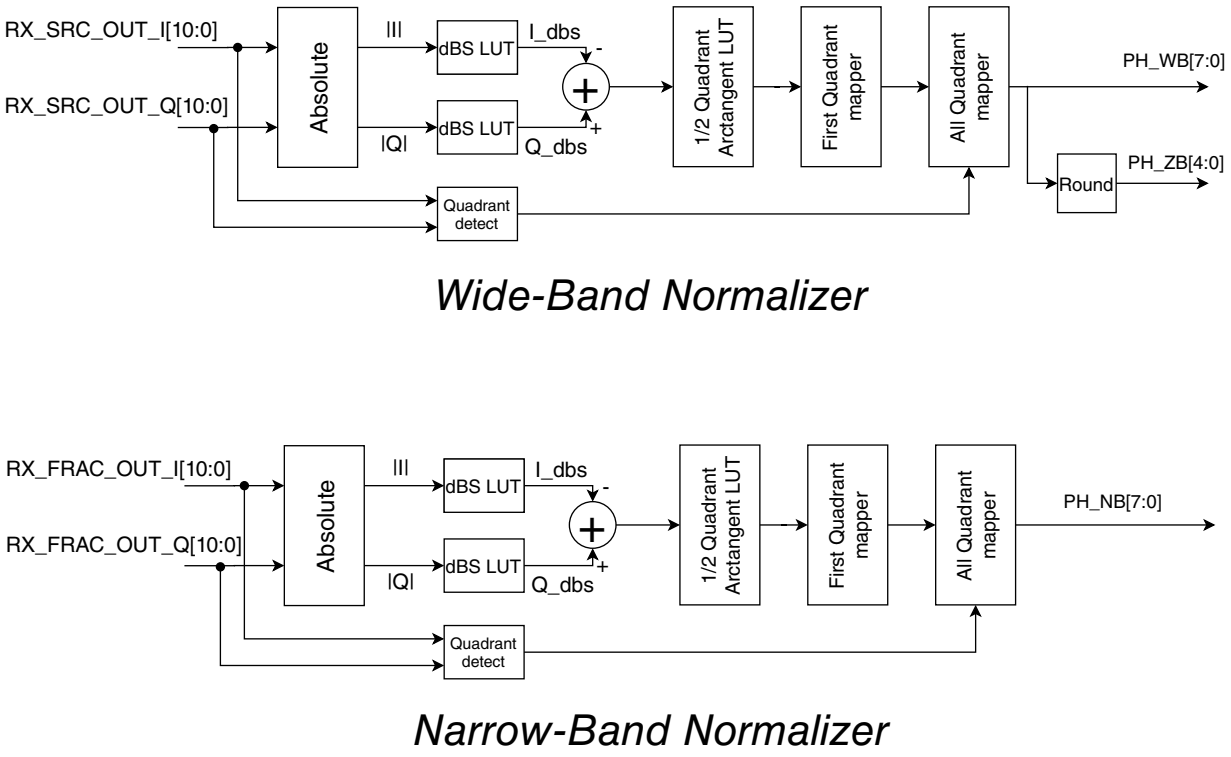

Figure 304. RX_DIG Normalizer Structure

55.4.7.4.2.17 RSSI Estimator

The role of the RSSI (Received Signal Strength Indication) estimator is to measure the energy of an incoming signal. RX_DIG has two RSSI estimator instances called Wide-Band RSSI estimator(WB_RSSI) and Narrow-Band RSSI estimator(NB_RSSI).

WB_RSSI measures the magnitude of ADC(defaule) or CIC output and provids the results to feed AGC. The input of NB_RSSI can be chosen from SRC(default), Acquisition Channel Filter, Demodulation Channel Filter, or Fractional Correction output and the results used by link layer controller or software.

55.4.7.4.2.17.1 Wide-band RSSI

Wide-Band RSSI(WB-RSSI) mainly for generatging fast_mag and slow_mag for AGC. When AGC in magnitude mode, the AGC gain index is determined by fast_mag and slow_mag.

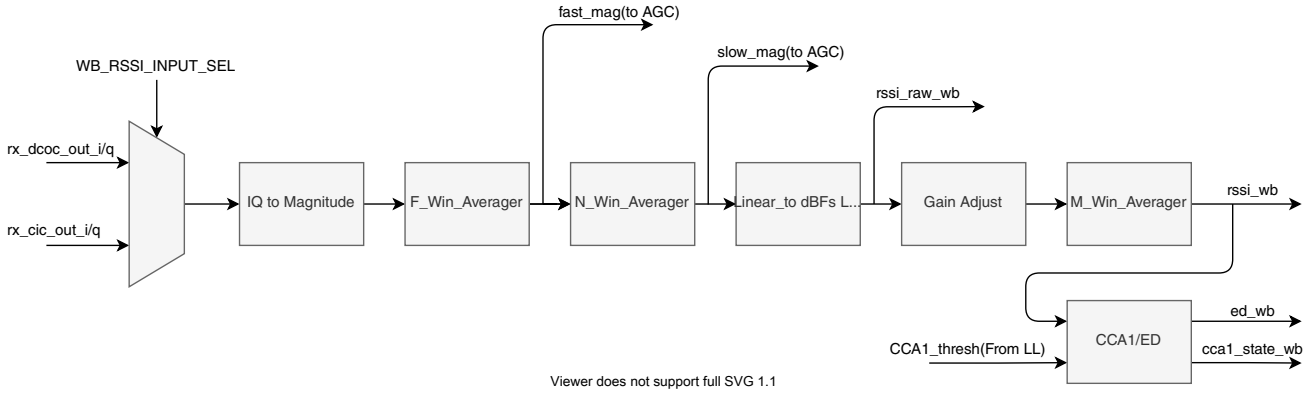

Figure 305. WB-RSSI block diagram

RSSI_WB Calcuation:

rssi_wb = rssi_raw_wb - agc_log_gain + rssi_adj_wb + 13

Where:

1. rssi_raw_wb represent the dBFs result of I/Q signal magnitude. rssi_raw_wb = 20*log10((adc_i^2 + adc_q^2)^0.5/1024) ≈ max(adc_i, adc_q) + 0.375*min(adc_i, adc_q)

2. agc_log_gain indicate current analog gain values, which store in AGC_IDX*_GAIN_VAL[LOG_GAIN_*] and selected by AGC based on current AGC gain index

3. rssi_adj_wb is set by WB_RSSI_CTRL[RSSI_ADJ_WB]

55.4.7.4.2.17.1.1 WB-RSSI Freerun Mode

By default, WB-RSSI working in continuous mode(freerun), until AGC enter into FREEZE state. For debug purpose, by setting WB_CONT_MEAS_OVRD_EN=1 and WB_CONT_MEAS_OVRD=0, the WB-RSSI will stop working once the first rssi_wb calculation done. See RSSI_RDY_WB bit description to get the information about how to get WB-RSSI results continuously.

55.4.7.4.2.17.2 Narrow-Band RSSI

The role of the Narrow-Band RSSI(NB-RSSI) is to estimate and report: narrow band received signal strength, SNR and LQI result to link layer contoller. It also can be chosen for CCA1/ED calculation.

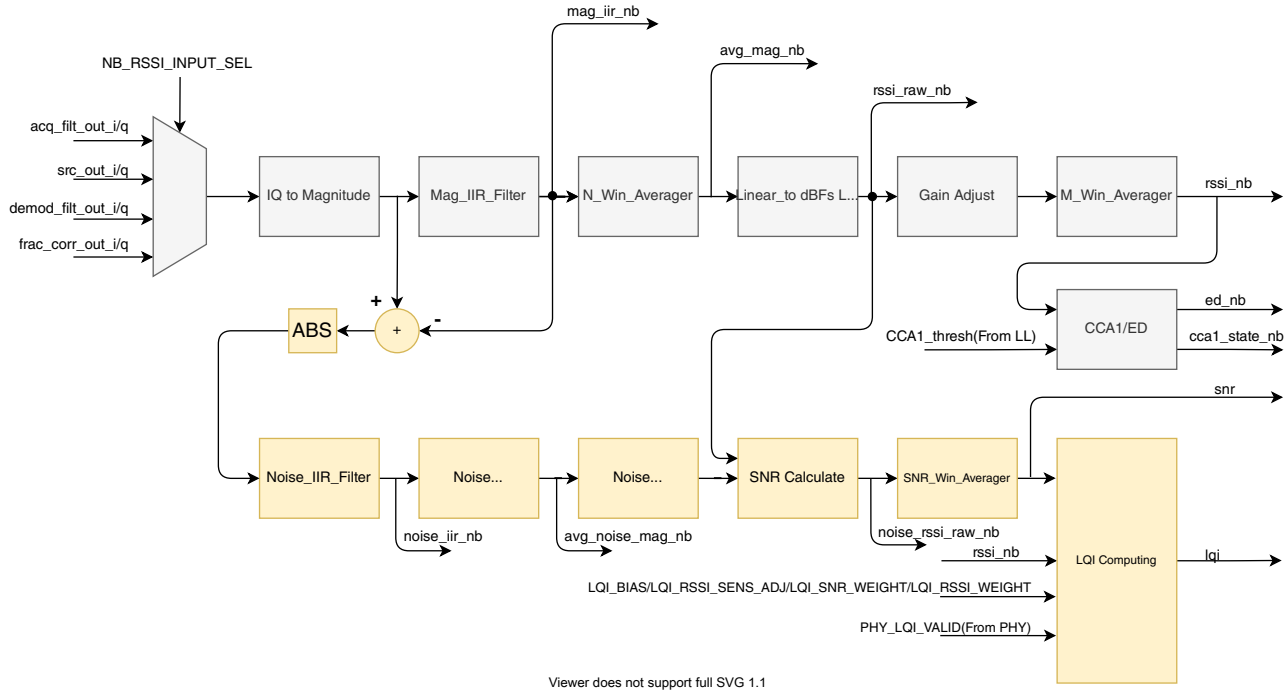

Figure 306. NB-RSSI block diagram

RSSI_NB Calcuation:

rssi_nb = rssi_raw_nb - agc_log_gain + rssi_adj_nb + 13

Where:

1. rssi_raw_nb represent the dBFs result of I/Q signal magnitude. rssi_raw_nb = 20*log10((i^2 + q^2)^0.5/1024) ≈ max(i, q) + 0.375*min(i, q)

2. agc_log_gain indicate current analog gain values, which store in AGC_IDX*_GAIN_VAL[LOG_GAIN_*] and selected by AGC based on current AGC gain index

3. rssi_adj_nb is set by NB_RSSI_CTRL[RSSI_ADJ_NB]. **NOTE**: If CTRL0[RX_DIG_GAIN] set a non-zero value. Should add a negative offset value to NB_RSSI_CTRL[RSSI_ADJ_NB]

55.4.7.4.2.17.2.1 NB-RSSI Freerun Mode

By default, NB-RSSI working in one-time mode. By setting NB_CONT_MEAS_OVRD_EN=1 and NB_CONT_MEAS_OVRD=1 bit, the NB-RSSI will calculate RSSI/LQI/SNR continuously. See RSSI_RDY_NB bit description to get the information about how to get NB-RSSI results continuously.

55.4.7.4.2.17.2.2 NB-RSSI Manually Enable Mode

By default, NB-RSSI starts when PHY AA found. To manually trigger the NB-RSSI(e.g. for software CCA), follow the below steps:

- Make sure XCVR in idle mode
- Clear RSSI_GLOBAL_CTRL[NB_RSSI_AA_MATCH_OVRD]
- Set RSSI_GLOBAL_CTRL[NB_RSSI_AA_MATCH_OVRD_EN]
- Set RSSI_GLOBAL_CTRL[NB_CONT_MEAS_OVRD_EN] and RSSI_GLOBAL_CTRL[NB_CONT_MEAS_OVRD]
- Start RX sequence
- Wait RX warmup done
- Set RSSI_GLOBAL_CTRL[NB_RSSI_AA_MATCH_OVRD], when software get ready

- Poll NB_RSSI_RES0[RSSI_RDY_NB] until 1, which means the NB-RSSI results(

  RSSI_NB/SNR_NB/LQI_NB/ED_NB

) are ready. Check RSSI_RDY_NB bit description for more information
- When measurement done, clear RSSI_GLOBAL_CTRL[NB_RSSI_AA_MATCH_OVRD], GLOBAL_CTRL[NB_RSSI_AA_MATCH_OVRD_EN], RSSI_GLOBAL_CTRL[NB_CONT_MEAS_OVRD_EN], RSSI_GLOBAL_CTRL[NB_CONT_MEAS_OVRD]
- Write 1 to RSSI_RDY_NB to clear this status bit
- Exit RX mode

55.4.7.4.2.17.3 CCA1 and ED Measurement

Both WB and NB RSSI can do CCA1 and ED measurement. The following steps show how to enable the CCA1 and ED function.

- Config CCA1_ED_FROM_NB bit to select use which RSSI instance to do CCA1 and ED measurement
- Set either WB_CCA1_ED_EN or NB_CCA1_ED_EN bit baseed on the value of CCA1_ED_FROM_NB
- Set CCA1 threshold. Note, this config lacated in GEN-LL or 15p4-LL
- Launch CCA1 sequence from GEN-LL or 15p4-LL

NOTE

If 15p4-LL is active, set 15p4_PHY->CCA_LQI_SRC[CCA1_FROM_RX_DIG], or the CCA1 will be measured by 15p4_PHY

55.4.7.4.2.18 Automatic Gain Control (AGC)

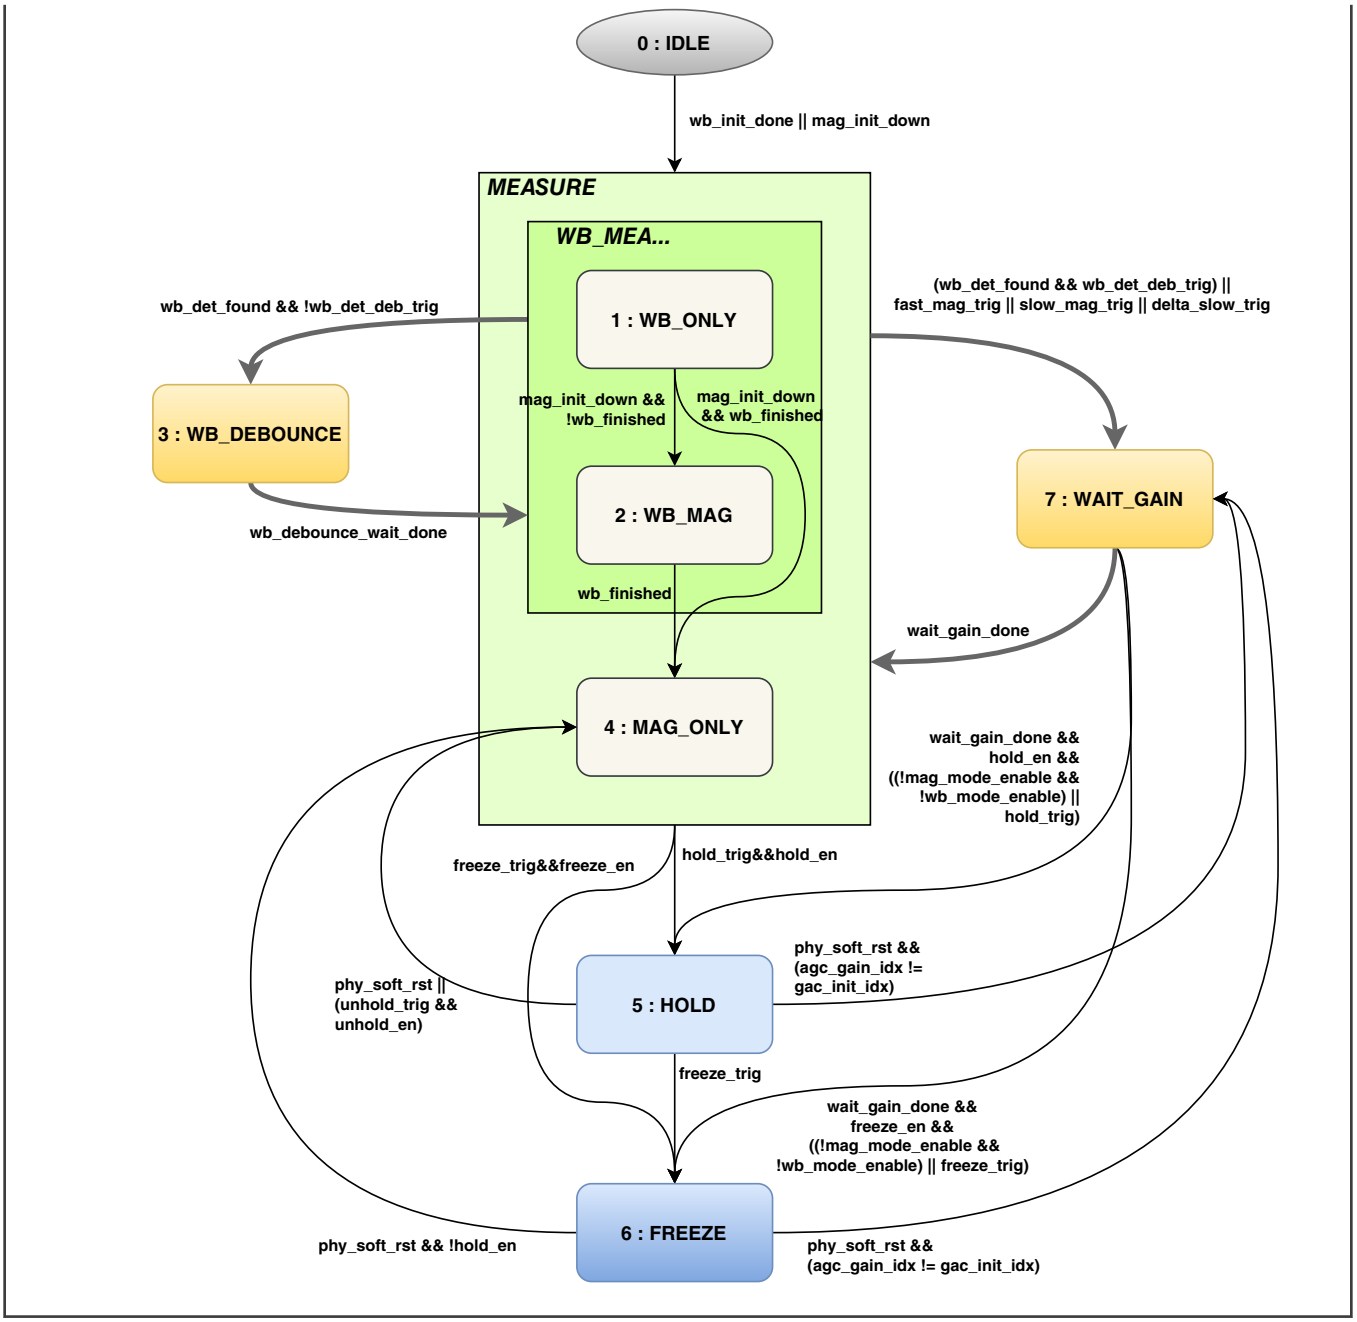
The Automatic Gain Control (AGC) system is designed to ensure that the received signal does not become distorted because of clipping in the analog receive chain, while attempting to maintain an optimal signal level for demodulation. There are two locations where gain may be adjusted: analog LNA, and analog CBPF. The AGC system manipulates these gains to maintain a targeted ADC input signal level. The targeted ADC signal level is chosen as a compromise between receiver linearity, blocker headroom requirements and the goal to maximize the digital signal SNR that is provided to the protocol-specific PHY demodulators.

The AGC sytem operated with a state machine that is depicted in below figure and has the following significant states:

- **IDLE(000b)**: No actions are taken. The system waits for RX_DIG enable and than AGC initial wait done
- **WB_ONLY(001b)**: AGC is working with Wide-Band detector enabled
- **WB_MAG(010b)**: AGC is working with Wide-Band detector and magnitude mode enabled
- **WB_DEBOUNCE(011b)**: AGC is in WB trigger debounce waiting state
- **MAG_ONLY(100b)**: AGC is working with magnitude mode enabled
- **HOLD(101b)**: AGC hold mode
- **FREEZE(110b)**: AGC is freeze
- **WAIT_GAIN(111b)**: Wait analog gain settle state.

55.4.7.4.2.18.1 AGC FSM

Figure 307. AGC FSM state diagram



55.4.7.4.2.18.2 AGC Gain Step Triggers

Gen4 AGC has two kinds of gain step trigger sources. One is from the analog comparator output called wideband detector(WBD) or peak detector, which can only make AGC gain step down. The other is the magnitude output from WB-RSSI, which can make AGC gain step down or up. When WBD enabled, the AGC works in WB_ONLY mode. When magnitude mode enabled, AGC works in MAG_MODE mode. In addition, if both WBD and magnitude mode enabled, AGC works in WB_MAG mode.

In one RX sequence, WBD can trigger once or twice(called WBD step1 and step2), based on the settings of AGC_CTRL[AGC_WBD_EN]. Each step has its own threshold and gain index step down config. In addition, to avoid the WBD triggered by noise or glitch on the antenna, users can enable the WBD dual clip function. When this function enabled, only continually twice trigger occurs can be considered as one WBD trigger. The cooldown(or debounce wait) time can be set by AGC_WBD_STEP1_DUAL_CLIP_WAIT and AGC_WBD_STEP2_DUAL_CLIP_WAIT.

For magnitude mode, AGC compares the FAST_MAG and/or SLOW_MAG value from WB_RSSI with the AGC_THR_FAST and/or AGC_IDX*_THR values to determine gain index step up or step down.

There's a special magnitude trigger called delta slow trigger. To enable delta slow detection, slow magnitude mode also need to be enabled. When the previous Nth(Defined by DELTA_SLOW_WAIT) slow mag value minus the latest slow mag value exceed the value set in DELTA_SLOW_THR, the AGC will issue a big gain index step up, defined by AGC_DELTA_SLOW_STEP.

55.4.7.4.2.18.3 AGC Gains

Gen4 AGC supports up to 12-gear of gain index and enables 11-gear(10~0) by default. Each gain index has its own analog gain control settings and stored in AGC_IDX*_GAIN_CFG register.

The AGC_IDX*_GAIN_VAL registers store the analog gain values for each gain index. The LOG_GAIN is referenced by WB-RSSI and NB-RSSI module to estimate the input power level of RF signal, while LINEAR_GAIN used by Gen4 PHY to determine whether there is RF signal on the antenna.

55.4.7.4.2.18.4 AGC State

55.4.7.4.2.18.4.1 IDLE

This is the default state of AGC. AGC will keep in this state until initialize done. The AGC internal counter will start counting(use reference clock) when RX_DIG enabled. When the AGC counter matches the value of AGC_WBD_INIT_WAIT or AGC_MAG_INIT_WAIT, the AGC will trans to measurement state(WB_ONLY, WB_MAG or MAG_ONLY). Typically, if both WBD and magnitude mode enabled, the programed AGC_WBD_INIT_WAIT should no less than AGC_MAG_INIT_WAIT.

55.4.7.4.2.18.4.2 WB_ONLY

After the AGC initialization done, if AGC_WBD_EN!=0 and AGC_WBD_INIT_WAIT<AGC_MAG_INIT_WAIT, AGC will trans to this mode. In WB_ONLY mode, the AGC only accepts WBD trigger.

If AGC_WBD_AUTO_DIS_CFG != 00, AGC will disable WBD automatically when condition matches. See description of AGC_WBD_AUTO_DIS_CFG for more info. After WBD disabled, AGC will trans to next mode, typically the MAG_ONLY.

If AGC_WBD_STEP*_DUAL_CLI P_EN set, two consecutive WBD triggers treat as one effective AGC gain change trigger. That means the first WBD trigger will make AGC trans to WB_DEBOUNCE mode and wait a moment. After AGC back to WB_ONLY mode, if the WBD trigged again in time, typically less than 5 reference clock cycles, AGC will step down the gain index.

AGC supports WBD gain limit function. If agc_wbd1_gain_limit_en set, after wbd_step1 trig occurs, the AGC max gain will be set as "agc_init_gain – wbd_step1", that means even if mag value is too small, AGC will not increase gain_idx larger than "agc_max_gain – wb_step1"(NOTE: Typically, agc_max_gain = agc_init_gain). Similar function for agc_wb2_gain_limit_en.

55.4.7.4.2.18.4.3 MAG_ONLY

In this state, AGC will compare the magnitude from WB-RSSI with the threshold to determine the AGC gain index. There are two kinks of magnitude called fast_mag and slow_mag and which are using for driven the fast mag trigger(called fast mag mode) and slow mag trigger(called slow mag mode). The difference between fast mode and slow mode is response time and adjustment accuracy. Both fast and slow mag mode can be enabled individually, however, delta slow mode can only work with slow mag mode enabled.

55.4.7.4.2.18.4.4 WB_MAG

This state can be considered as a combination of WB_ONLY and MAG_ONLY. In this state, AGC accepts both WBD and magnitude triggers.

55.4.7.4.2.18.4.5 WAIT_GAIN

After AGC gain index changed, AGC will enter into WAIT_GAIN state and keep a while. At the same time, reset the WBD and WB-RSSI.

55.4.7.4.2.18.4.6 WB_DEBOUNCE

If WBD dual clip(debounce) function enabled, AGC will enter into this state when the first WBD trigger occurs without gain index change and reset the WBD at the same time. After a while(defined by AGC_WBD_DUAL_CLIP_TIMEOUT), AGC will back to WB_ONLY or WB_MAG state.

55.4.7.4.2.18.4.7 HOLD

There are two ways to enter into HOLD state, hold mode timeout(defined by AGC_HOLD_TIMEOUT) matches or hold mode trigger(selected by AGC_PHY_HOLD_TRIG_SEL) occurs.

Note, the hold mode timeout counter will start work when AGC enter into WB_ONLY, WB_MAG or MAG_ONLY and reset when AGC gain index changed.

In HOLD state, AGC will disable WBD and fast mag comparision. However, if AGC_UNHOLD_FEAT_EN[0] and AGC_SLOW_EN set, AGC will be continuing to monitor the slow magnitude values to determine whether exit HOLD and back to MAG_ONLY state.

When AGC_UNHOLD_FEAT_EN[1] set, AGC will exit HOLD mode after N(defined by AGC_UNHOLD _FEAT_TIMEOUT) micro second and back to MAG_ONLY mode.

55.4.7.4.2.18.4.8 FREEZE

In this state, AGC will disable both WBD and mag comparision. Freeze mode timeout(defined by AGC_FREEZE_TIMEOUT) matches or freeze mode trigger(selected by AGC_PHY_FREEZE_TRIG_SEL) occurs can make AGC enter into FREEZE state.

If both HOLD and FREEZE state triggered by timeout, the AGC will enter into HOLD state first, then wait for freeze timeout and finally enter into FREEZE state. However, AGC can trans to FREEZE state immediately when PHY freeze trigger occurs.

When AGC_UNFREEZE_FEAT_EN set, if RX sequence not be finished in N(defined by AGC_UNFREEZE_FEAT_TIMEOUT) micro second, AGC will exit FREEZE mode and back to MAG_ONLY mode.

55.4.7.4.2.18.5 AGC PHY Magnitude Threshold

The 2.4GHz PHY acquisition module needs 2 threshold values, mag_thr and mag_thr_hi, to determine if the current input signal is valid.

When the magnitude of the input signal exceeds the mag_thr(pt_sig_pres=01b), the 2.4GHz PHY acquisition module starts working and use GEN4_PHY->FSK_CFG0[HAMMING_AA_LOW_PWR] to find access address. In addition, if the magnitude exceeds both mag_thr and mag_thr_hi(pt_sig_pres=11b), the acquisition module will use another hamming value (GEN_LL->NTW_ADR_CTRL[NTW_ADR_THR] or GEN4_PHY->FSK_CFG0[BLE_NTW_ADR_THR], depends on which LL is active)to do access address searching.

The mag_thr and mag_thr_hi are AGC gain index dependent, which means for each AGC gain index, there's one pair of mag_thr and mag_thr_hi value. These values are configured by AGC_IDX*_GAIN_VAL[MAG_THR_*] and AGC_IDX*_GAIN_VAL[MAG_THR_HI_*] fields.

Furthermore, when datarate_config_sel = 1, a pair of **signed** offset(AGC_IDX*_GAIN_CFG[MAG_THR_*_DRS_OFS] and AGC_IDX*_GAIN_CFG[MAG_THR_HI_*_DRS_OFS]) values will be added to the AGC_IDX*_GAIN_VAL[MAG_THR_(HI_)*] to calculate the final threshold value.

The below example shows how to determine the mag_thr and mag_thr_hi value when the AGC gain index is 11.

When datarate_config_sel = 0 :

mag_thr = AGC_IDX11_GAIN_VAL[MAG_THR_11]

mag_thr_hi = AGC_IDX11_GAIN_VAL[MAG_THR_HI_11]

When datarate_config_sel = 1 :

mag_thr = AGC_IDX11_GAIN_VAL[MAG_THR_11] + AGC_IDX11_GAIN_CFG[MAG_THR_11_DRS_OFS]

mag_thr_hi = AGC_IDX11_GAIN_VAL[MAG_THR_HI_11] + AGC_IDX11_GAIN_CFG[MAG_THR_11_HI_DRS_OFS]

NOTE: for each AGC gain index, the programmed AGC_IDX*_GAIN_VAL[MAG_THR_*] , AGC_IDX*_GAIN_VAL[MAG_THR_HI*],

AGC_IDX*_GAIN_CFG[MAG_THR_*_DRS_OFS], and AGC_IDX*_GAIN_CFG[MAG_THR_HI*_DRS_OFS] values should let mag_thr and mag_thr_hi meet the following equation:

0 <= mag_thr <= mag_thr_hi <= 2047

55.4.7.4.2.19 RC Calibration

The RX RC Calibration module uses a binary search to find the best 5bit calibration code (rccal_code[4:0]) for the RC calibration circuit in the analog. It is expected that the RC calibration will be performed on each RX warmup. The entire RCCAL sequence requires no more than 8us for all XO reference frequencies supported.

The rccal_code code is then used to calculate a 7bit code for the CBPF circuit, which is dependent on a programmable bandwidth setting (bw_code)and IF setting (sc_code). Also, programmable offsets are provided to allow additional adjustments to the rccal_code or to the computed CBPF code:

cbpf_ccode = round[9 + 2*bw_code)*(2 + sc_code)*(48 + rccal_code + rccal_code_offset)/32] + cpbf_ccode_offset

The figure below illustrates the RC calibration timing. The calibration sequence is initiated by a TSM control signal (seq_rccal_pup). After the seq_rccal_pup asserts, there is a 1.0us settling time followed by a few clock cycles where rccal_code[4:0] = 5'h1_F. Then, 5 calibration stages are performed, each of which requires 1us + 10clks.

Near the end of each calibration stage, the rccal_cmpout signal from the analog is used to determine whether the appropriate bit of rccal_code[4:0] will be set or cleared. By default, the rccal_cmpout is sampled 2 clk cycles after rccal_sample de-asserts, but there are also programmable options for 1clk and 3clk cycles. Also, there is a programmable option to invert the rccal_cmpout signal if needed.

The total calibration time is 1.0us + 5 clks + 5*(1us + 10clks), which is less than 9us for 26MHz and less than 8us for all other XO reference frequencies supported.

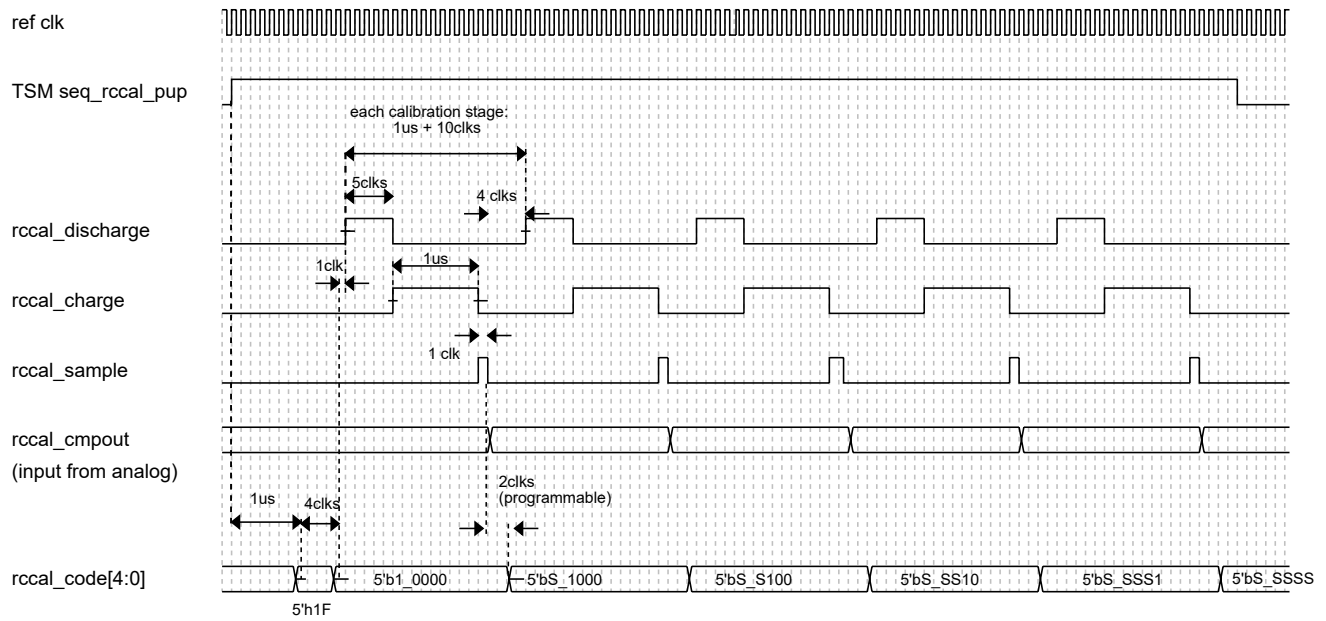


Figure 308. RCCAL timing

55.4.7.4.3 Memory Map and register definition

The 2p4GHz RX_DIG memory map and register description is included in the following section.

55.4.7.4.3.1 2P4GHZ_RX_DIG register descriptions

Fields

Field	Function
31 RX_IQ_PH_OUTPUT_COND	RX IQ or Phase Output Conditioning This field only has effect when DFT_CTRL[DFT_RX_IQ_OUT_SEL], DFT_CTRL[DFT_RX_PH_OUT_SEL] set a non-zero value or DFT_CTRL[DFT_RSSI_MAG_OUT_SEL]=7. When this bit cleared, the RX_DIG will output the selected IQ and/or Phase, Mag signal to DTEST and/or DMA_DEBUG as soon as RX_DIG starts work. For localization application, set this bit can let RX_DIG send the IQ and/or Phase signal to DTEST and/or DMA_DEBUG only during localization(AoA/AoD/HADM/PDE) sample slot. It will reduce the packet buffer usage and software loading. NOTE: When this bit set, should keep DMA_SIGNAL_VALID_MASK_EN and DBG_SIGNAL_VALID_MASK_EN cleared to avoid data capture missing. 0b - Output IQ and/or Phase all-time 1b - Only output IQ and/or Phase during localization sample slot
30-28 RX_IQ_PH_AVG_WIN	RX IQ Phase Output Average Window Config Programing a non-zero value to this field will apply a window averager on RX_DIG output IQ, Phase signal, or Mag. The actual average window size is 2^(RX_IQ_PH_AVG_WIN+1). NOTE: Programing a non-zero value to this field will reduce the RX IQ and/or Phase output rate to 1/2^(RX_IQ_PH_AVG_WIN+1). 000b - Disable RX IQ and/or Phase output average function 001b - Average window size = 4 010b - Average window size = 8 011b - Average window size = 16 100b - Average window size = 32 101b - Average window size = 64 110b - Average window size = 128 111b - Average window size = 256
27	RX_DIG Mixer Index Output Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
RX_MIXER_IDX_OUT_MODE	RX_DIG has 10-bit mixer(s) index output to DMA_DEBUG. By default, the 10-bit output is composed by rx_if_mixer_idx[9:5] and rx_cfo_mixer[7:3]. By setting RX_MIXER_IDX_OUT_MODE, the RX_DIG will send rx_if_mixer_idx[9:0] to DMA_DEBUG.
26 RX_CFO_EST_OVRD_EN	CFO Estimation Override Enable When this bit set, the CFO mixer will use RX_CFO_EST_OVRD value to do CFO compensation. 0b - CFO override is enabled 1b - CFO override is disabled
25-16 RX_CFO_EST_OVRD	CFO Estimation Override Value This field only valid when RX_CFO_EST_OVRD_EN=1
15 RX_FRAC_CORR_OVRD_EN	Fractional Correction Coefficient Override Enable When this bit set, the Fractional correction module will use RX_FRAC_CORR_OVRD value to do correction.
14-12 RX_FRAC_CORR_OVRD	Fractional Correction Coefficient Override Value This field only valid when RX_FRAC_CORR_OVRD_EN=1
11 —	Reserved
10 RX_DEMOD_FILT_BYPASS	Demod Channel Filter Bypass This bit is for test purpose and should not be set in normal mode. 0b - Demod channel filter is enabled. 1b - Demod channel filter is bypassed.
9 RX_HIGH_RES_NORM_SEL	High Resolution Phase Source Select 0b - From RX_NORM_NB 1b - From RX_NORM_WB
8 RX_NB_NORM_EN	Narrow-Band Normalizer Enable 0b - Narrow-Band normalizer is disabled. 1b - Narrow-Band normalizer is enabled.
7 DIS_WB_NORM_AA_FOUND	Disable WB-NORM when AA found When this bit set, RX_DIG will disable the WB-NORM as soon as AA(access address) found by 2.4GHz PHY to save power. NOTE: when using 15p4 PHY, this bit should be cleared.
6 DC_RESID_EN	DC_RESID Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
5 RX_SAMPLE_BUF_AUTO_GATE	Sample Buffer Automatically Gate Off When enabled, after PHY_AA_MATCH asserted, unused taps of sample buffer will be gated off to save power. Here, unused taps is controlled by 2.4GHz PHY.
4 RX_SAMPLE_BUF_BYPASS_IN_CTE	Bypass Sample Buffer During CTE If enabled, during CTE field receiving, sample buffer will be bypassed to save power and reduce latency.
3-1 —	Reserved
0 RX_SAMPLE_BUF_BYPASS	Bypass Sample Buffer This bit is for test or debug purpose, should not be set in normal mode.

55.4.7.4.3.1.5 RXDIG DFT Control (DFT_CTRL)

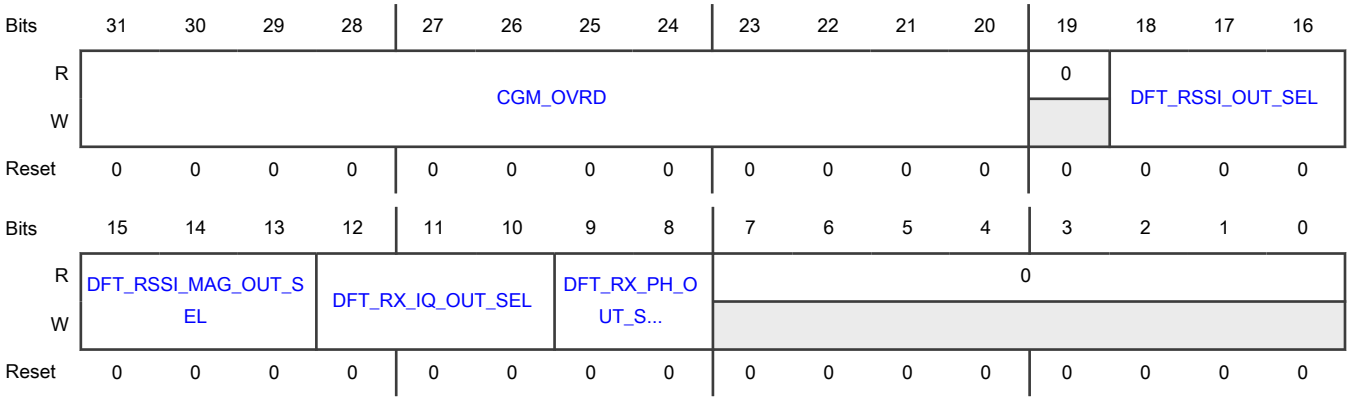
Offset

Register	Offset
DFT_CTRL	Ch

Function

RXDIG test control register.

Diagram



Fields

Field	Function
31-20 CGM_OVRD	CGM Override RXDIG sub-modules clock gating control overrides. If a bit is cleared, the clock is enabled only for the clock cycles when it is required during RX; If the bit is set, the clock is continuously enabled during rx_dig_en=1. 0000_0000_0001b - RCCAL 0000_0000_0010b - DCOC 0000_0000_0100b - IF_MIXER 0000_0000_1000b - CIC 0000_0001_0000b - ACQ_CHF 0000_0010_0000b - SRC 0000_0100_0000b - SAMPLE_BUF and CFO_MIXER 0000_1000_0000b - DEMOD_CHF and FRAC_CORR 0001_0000_0000b - NB_NORM and HIGH_RES_NORM 0010_0000_0000b - AGC 0100_0000_0000b - IQ_MISMATCH 1000_0000_0000b - DIG_GAIN
19 —	Reserved
18-16 DFT_RSSI_OUT_SEL	DFT RSSI Result Output Selection WB-RSSI and NB-RSSI results output to DTEST/DMA_DEBUG selection. 000b - Disable RSSI output 001b - Wide-band RSSI_RAW output 010b - Wide-band RSSI output 011b - Narrow-band RSSI_RAW output 100b - Narrow-band RSSI output 101b - Narrow-band NOISE_RAW output 110b - Narrow-band SNR output 111b - Narrow-band LQI output
15-13 DFT_RSSI_MAG_OUT_SEL	DFT RSSI Magnitude Output Selection WB-RSSI and NB-RSSI magnitude output to DTEST/DMA_DEBUG selection. NOTE: When DFT_RSSI_MAG_OUT_SEL=7, the Mag is calucated based on the IQ signal selected by DFT_RX_IQ_OUT_SEL and send to Mag averager. The typical usecase is select SRC out IQ with WB-Phase or Frac out IQ with NB-Phase to make sure the mag and phase is aligned in the MAG-PHASE page of DMA_DEBUG.

Table continues on the next page...

31-30 AGC_WBD_EN	AGC WBD Enable AGC WBD enable 00b - AGC WBD is disabled 01b - AGC WBD step1 is enabled 10b - AGC WBD step1 and step2 is enabled 11b - Reserved
29-28 AGC_WBD_AUTO_DIS_CFG	AGC WBD Auto Disable If AGC_WBD_AUTO_DIS[0] set and fast or slow magnitude triggers occurs with no WB trigged, WB detect function will be disabled automatically. If AGC_WBD_AUTO_DIS[1] set and WB trigger not occurs in period, specified by AGC_WBD_TIMEOUT, WB detect function will be disabled automatically. NOTE: AGC_WBD_AUTO_DIS = 2'b11 is valid.
27 AGC_WBD_GAIN_LIMIT_EN	AGC WBD Gain Limit When this bit set:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	-- If WBD takes the first step, then the AGC_max_index is set equal to the gain index after the AGC_WBD_det_step -- If WBD takes the 2nd step, then the AGC_max_index is set equal to the gain index after the AGC_WBD_det_step2
26 AGC_WBD_STEP1_DUAL_CLIP_EN	AGC WBD Step1 Dual Clip Enable When this bit set. AGC need two consecutive WB trigger occurs then issue WB stpe 1 gain step down. The cooldown duration is specified by AGC_WBD_STEP1_DUAL_CLIP_WAIT
25 AGC_WBD_STEP2_DUAL_CLIP_EN	AGC WBD Step2 Dual Clip Enable When this bit set. AGC need two consecutive WB trigger occurs then issue WB stpe 2 gain step down. The cooldown duration is specified by AGC_WBD_STEP2_DUAL_CLIP_WAIT
24-21 AGC_WBD_THR1	AGC WBD Step1 threshold Threshold value(unit: mV) for AGC WBD step1. 0000b - 49.31 0001b - 67.56 0010b - 90.98 0011b - 117.42 0100b - 150.66 0101b - 180.98 0110b - 211.87 0111b - 245.2 1000b - 288.31 1001b - 336.02 1010b - 394.34 1011b - 462.71 1100b - 548.04 1101b - 650.13 1110b - 771.65 1111b - 918.12
20-17 AGC_WBD_THR2	AGC WBD Step2 threshold Threshold value(unit: mV) for AGC WBD step2. The actual threshold voltage is as same as the description in AGC_WBD_THR1.
16-14	AGC WBD Step1 Gain Decreas Value

Table continues on the next page...

Table continued from the previous page...

Field	Function
AGC_WBD_STEP1_SZ	Specify the gain index decrease value when AGC WBD step1 triggered. Actual gain step is: AGC_WBD_STEP1_SZ + 1
13-11 AGC_WBD_STEP2_SZ	AGC WBD Step2 Gain Decreas Value Specify the gain index decrease value when AGC WBD step2 triggered. Actual gain step is: AGC_WBD_STEP2_SZ + 1
10 AGC_FAST_EN	AGC Fast Magitude Mode Enable 0b - Disable fast magnitude mode 1b - Enable fast magnitude mode
9 AGC_FAST_STEP_UP_EN	AGC Fast Magitude Mode Step Up Enable AGC step up enable in fast magnitude mode. This bit only take effect with AGC_FAST_EN=1. If this bit cleared, the fast magnitude mode can only make AGC gain index step down. 0b - Fast magnitude mode can only make AGC gain index step down 1b - Fast magnitude mode can make AGC gain index step down or step up
8 AGC_SLOW_EN	AGC Slow Magitude Mode Enable 0b - Disable AGC slow magnitude mode 1b - Enable AGC slow magnitude mode
7 AGC_DELTA_SLOW_EN	AGC Delta Slow Magitude Mode Enable AGC delta slow magnitude mode enable. Note: The AGC delta slow magnitude mode can only work with AGC slow magnitude mode enabled(AGC_SLOW_EN=1). 0b - Disable AGC delta slow magnitude mode 1b - Enable AGC delta slow magnitude mode
6-4 AGC_DELTA_SLOW_STEP	AGC Delta Slow Mode Gain Step Up Value Gain index change for a big step up when delta slow mode triggered
3-2 AGC_HOLD_EN	AGC Hold Mode Enable AGC hold mode enable and control 00b - Disable AGC hold mode 01b - AGC hold when preamble found 10b - AGC hold when AGC hold timeout matched 11b - AGC hold when preamble found or hold timeout matched
1-0	AGC Unhold Enalbe AGC unhold feature enable and config.

Table continues on the next page...

Table continued from the previous page...

Field	Function
AGC_UNHOLD_FEAT_EN	AGC_UNHOLD_FEAT_EN[0]: When AGC in HOLD mode and the selected mag values exceed the range of "agc_hold_mag +/- ipr_hold_mag_margin", AGC will exit from HOLD mode. NOTE: See AGC_TIMING2[AGC_UNHOLD_MAG_SRC_SEL] and AGC_TIMING2[AGC_UNHOLD_MAG_CNT_SEL] for more info AGC_UNHOLD_FEAT_EN[1]: If AGC does not enter into FREEZE mode or receive done in time, AGC will exit HOLD mode. The unhold timeout value is set by AGC_UNHOLD_TMEOUT NOTE: AGC_UNHOLD_FEAT_EN=3 is a valid configuration

Fields

Field	Function
31-29 AGC_STATUS	AGC FSM Status Indicate the current state of AGC state machine. This field will be 0 when RX_DIG or AGC not be enabled. 000b - AGC_IDLE

Table continues on the next page...

Table continued from the previous page...

Field	Function
	001b - AGC_WB_ONLY 010b - AGC_WB_MAG 011b - AGC_WB_DEBOUNCE 100b - AGC_MAG_ONLY 101b - AGC_HOLD 110b - AGC_FREEZE 111b - AGC_WAIT_GAIN_SETTLE
28-26 AGC_GAIN_CHANGE_STATUS	AGC Gain Change Status Indicate the latest AGC gain index change reason. This field will be 0 when RX_DIG or AGC not be enabled. 000b - No gain change 001b - Gain decreased by WBD step1 010b - Gain decreased by WBD step2 011b - Gain decreased by fast mode 100b - Gain increased by fast mode 101b - Gain decreased by slow mode 110b - Gain increased by slow mode 111b - Gain increased by delta slow mode
25 AGC_GAIN_CHANGE	AGC Gain Change Indicate the AGC gain is changing. NOTE: This is a pulse signal, software may not read it correctly. To capture this pulse accurately, please use DTEST function.
24-21 AGC_GAIN_IDX	AGC Gain Index Indicate current AGC gain index. This field will be reset to AGC_INIT_IDX when AGC or RX_DIG disabled(rx_dig_en deassert) . To get the AGC gain index value using for previous packet receiving, enable the AGC gain index store function(set a non-zero value for AGC_GAIN_STORE field) and read the AGC_PREV_GAIN_IDX field.
20-17 AGC_PREV_GAIN_IDX	AGC Previous Gain Index Indicate previous AGC stable gain index. To use this status field, user should set a non-zero value for AGC_GAIN_IDX_STORE. The value of this field will be kept until next AGC gain store trigger occurs. That means RX_DIG disable or RX_DIG initial will not reset this field. See AGC_GAIN_IDX and AGC_GAIN_IDX_STOR for more info.
16-15 AGC_SOFT_RST_SRC_SEL	PHY AGC Soft Reset Sel 00b - Disable PHY AGC soft reset function 01b - Use posedge phy_soft_rst to reset AGC

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - Use negedge phy_soft_rst to reset AGC 11b - Use negedge phy_agc_freeze_trig to reset AGC
14 AGC_SOFT_RST_GAIN_SEL	PHY AGC Soft Reset Gain Sel 0b - AGC keep current gain index when PHY AGC soft reset trigged, 1b - AGC return to AGC_INIT_IDX when PHY AGC soft reset trigged,
13-12 AGC_GAIN_IDX_STORE	Enable and config AGC gain index stroe function. The stored AGC gain index can be read from AGC_PREV_GAIN_IDX field 00b - AGC gain index stroe function is disabled 01b - Store AGC gain index when AGC enter into HOLD mode 10b - Store AGC gain index when AGC enter into FREEZE mode 11b - Store AGC gain index when AA matched
11-10 AGC_FREEZE_EN	AGC Freeze Mode Enable AGC Freeze mode enable and configure 00b - Disable AGC freeze mode 01b - AGC freeze when AA/SFD matched 10b - AGC freeze when AGC freeze timeout matched 11b - AGC freeze when AA/SFD matched or freeze timeout matched
9 AGC_UNFREEZE_FEAT_EN	AGC Unfreeze Feature Enable 0b - AGC unfreeze function is disabled 1b - AGC will exit FREEZE mode when AGC_UNFREEZE_TMEOUT matched and aa_found not be asserted
8 AGC_CALC_MAG_IN_FRZ	AGC Calucate Magnitude In Freeze Mode RXDIG continues to calculate the magnitude value after AGC freezed. NOTE: If NB_RSSI module is expected to start measurement by the asseration of aa_match, pd_found, or sdf_detect, and one of those signal set as AGC Freeze mode trigger, setting this bit is required or the NB-RSSI moudel cannot work when AGC freezed.
7 AGC_PHY_FREEZE_TRIG_SEL	AGC PHY Freeze Trigger Select 0b - PHY_AGC_FREEZE_TRIG is select as AGC freeze trig. 1b - PHY_AGC_HOLD_TRIG is select as AGC freeze trig.
6 AGC_PHY_HOLD_TRIG_SEL	AGC PHY Hold Trigger Select 0b - PHY_AGC_HOLD_TRIG is select as AGC hold trig. 1b - PHY_AGC_FREEZE_TRIG is select as AGC hold trig.
5-2	AGC Initial Gain Index

Table continues on the next page...

Table continued from the previous page...

Field	Function
AGC_INIT_IDX	Initial AGC gain index value. Note: the AGC_INIT_IDX should not greater than 11. Also see AGC_MAX_IDX for more infomation.
1-0 AGC_MAX_IDX	AGC Max Gain Index Actual AGC max gain index is: 11 - AGC_MAX_IDX. When reaches the max gain index AGC will not perform gain index step up.

Reset	0	1	0	0	0	0	1	1	1	0	0	1	1	0	0	0

Fields

Field	Function
31 —	Reserved
30-24 AGC_WBD_INIT_WAIT	AGC WBD Mode Initial Wait Time When RXDIG enabled, the AGC will wait AGC_WBD_INIT_WAIT reference clock cycles than enable WB detect function. NOTE: The programmed value should not less than 2 and not larger than AGC_MAG_INIT_WAIT

Table continues on the next page...

Table continued from the previous page...

Field	Function
23 —	Reserved
22-16 AGC_MAG_INIT_WAIT	AGC Magnitude Mode Initial Wait Time When RXDIG enabled, the AGC will wait AGC_MAG_INIT_WAIT reference clock cycles than enable FAST and/or SLOW mode. NOTE: The programmed value should not less than max(8'd2, AGC_WBD_INIT_WAIT)
15-10 AGC_GAIN_STEP_WAIT	AGC Gain Change Wait Time Determine the duration of AGC WAIT_GAIN_STEL state. That means the number of reference clock cycles to wait for analog stable after AGC gain index changed.
9-7 AGC_WBD_STEP1_TIMEOUT	AGC WBD Timeout WBD step1 timeout value. This timeout counter will start work at the point of AGC WBD initialization done. If AGC_WBD_AUTO_DIS[1]=1 and no WB trigger occurs, AGC will disable WB detect function. The actual timeout duration(Unit is microsecond) is: AGC_WBD_STEP1_TIMEOUT + 1
6-2 AGC_WBD_STEP2_TIMEOUT	AGC WBD Step2 Timeout Indicating the WBD step2 enable duration, counted by reference clock cycles. If no WBD step2 trigger occurs, the AGC will disable WBD function. NOTE: The programmed value should be no less than 2.
1-0 AGC_DELTA_SLOW_WAIT	AGC Delta Slow Mode Timing In delta slow mode, AGC will compare current slow_mag(slow_mag[N]) to the previous Kth(Here K = AGC_DELTA_SLOW_WAIT+1)slow mag(slow_mag[N-k]) and check whether the delta slow mag(slow_mag[N-K] - slow_mag[N]) exceed DELTA_SLOW_THR. If yes, the AGC will issue a delta slow trig and increas the gain index by AGC_DELATA_SLOW_STEP.

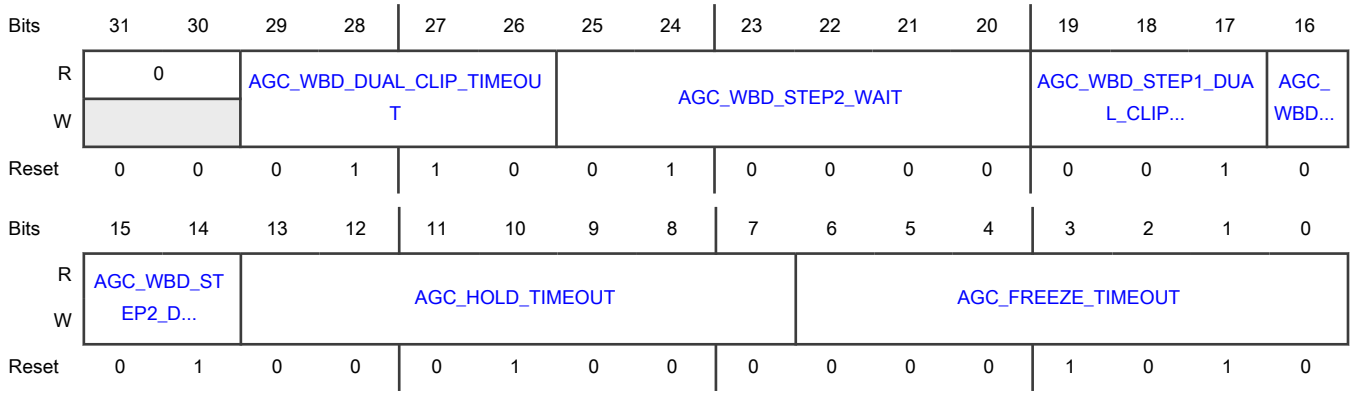
Register	Offset
AGC_TIMING1	9Ch

Function
AGC timing control 1

Diagram



Fields

Field	Function
31-30 —	Reserved
29-26 AGC_WBD_DUAL_CLIP_TIMEOUT	Indicate the max duration, count by reference clk, for WBD debounce. If WBD not be triggered again in this time, debounce failed. If AGC_WBD_EN=2, the programmed AGC_WBD_DUAL_CLIP_TIMEOUT value should be no large than AGC_WBD_STEP2_TIMEOUT. This field has no effect when AGC_WBD_STEP1_DUAL_CLIP_EN || AGC_WBD_STEP2_DUAL_CLIP_EN=0.
25-20 AGC_WBD_STEP2_WAIT	AGC Gain Change Wait For WBD step2 Gain stable wait duration, count by referenct clock, for AGC WBD step2.
19-17 AGC_WBD_STEP1_DUAL_CLIP_WAIT	AGC WBD step1 Debounce Wait Time Cooldown duration for WBD step1.
16-14 AGC_WBD_STEP2_DUAL_CLIP_WAIT	AGC WBD step2 Debounce Wait Time Cooldown duration for WBD step2.
13-7 AGC_HOLD_TIMEOUT	AGC HOLD Mode Wait Time If AGC_HOLD_EN[1] = 1, AGC will trans to hold state when hold timeout matched. The actual hold timeout duration can be calculated as: hold_timeout_duration(microsecond) = AGC_HOLD_TIMEOUT + 1 The hold_timeout counter will start work at the point of AGC initialization done, and which will be reset when every gain index changed.

Table continues on the next page...

Table continued from the previous page...

Field	Function
6-0 AGC_FREEZE_TIMEOUT	AGC FREEZE Mode Wait Time If AGC_FREEZE_EN[1] = 1, AGC will trans to FREEZE state when freeze timeout matched. The actual freeze timeout duration can be calculated as: freeze_timeout_duration(microsecond) = AGC_FREEZE_TIMEOUT + 1 If HOLD function enabled, the freeze_timeout counter will start work when AGC entered into HOLD mode,or it will start counting at the point of AGC initialization done. Similar to the hold_timeout counter, the freeze_timeout counter will be reset when every gain index changes.

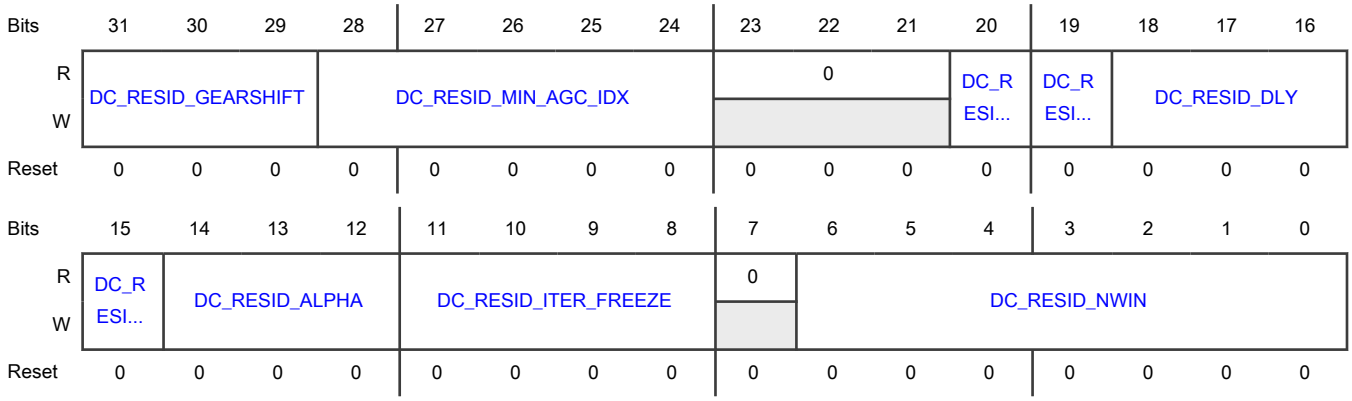
23 AGC_PHY_HOLD_OVRD_EN	PHY_HOLD_TRIG signal override enable
22 AGC_PHY_HOLD_OVRD	PHY_HOLD_TRIG signal override value
21 AGC_GAIN_IDX_OVRD_EN	AGC gain index override enable.
20-17 AGC_GAIN_IDX_OVRD	AGC gain index override value.
16 AGC_GAIN_OVRD_EN	AGC gain config override enable
15-0 AGC_GAIN_OVRD	AGC gain config override values. NOTE: AGC Gain Override function has higher priority than AGC Gain Index override function

55.4.7.4.3.1.87 DC Residual Control (DC_RESID_CTRL)

Offset

Register	Offset
DC_RESID_CTRL	154h

Diagram



Fields

Field	Function
31-29 DC_RESID_GEARSHIFT	DC Residual Gearshift If gearshifting is enabled (DC_RESID_GS_EN = 1), the DC residual will use DC_RESID_ALPHA for DC_RESID_GEARSHIFT windows (DC_RESID_NWIN samples) then will use DC_RESID_ALPHA+1 for the remaining windows.
28-24 DC_RESID_MIN_AGC_IDX	DC Residual Minimum AGC Table Index Specifies the minimum AGC table index value at which DC residual can be enabled. E.g., if this is 5'd0, then the DC residual is enabled for all AGC gain table indexes (assuming RX_DC_RESID_EN is set) if this is 5'd20, then tracking is enabled for AGC gain table indexes 20-26 (assuming RX_DC_RESID_EN is set).
23-21 —	Reserved
20 DC_RESID_EXT_DC_EN	DC Residual External DC Enable 0b - External DC disable. The DC Residual activates at a delay specified by DC_RESID_DLY after an AGC gain change pulse. The DC Residual is initialized with a DC offset of 0. 1b - External DC enable. The DC residual activates after the DCOC's tracking hold timer expires. The DC Residual is initialized with the DC estimate from the DCOC tracking estimator.
19 DC_RESID_SECOND_RUN_EN	DC Residual Second Run Enable This bit enables additional DC residual compensation (primarily intended for Long Range) after the normal DC residual operation has completed. 0b - Second Run disabled 1b - Second Run enabled
18-16 DC_RESID_DLY	DC Residual Delay The delay from activation of the DC residual block to the time when it starts processing. For a 32MHz reference clock, the delay in microseconds matches the value programmed. For other clock frequencies,

Table continues on the next page...

Table continued from the previous page...

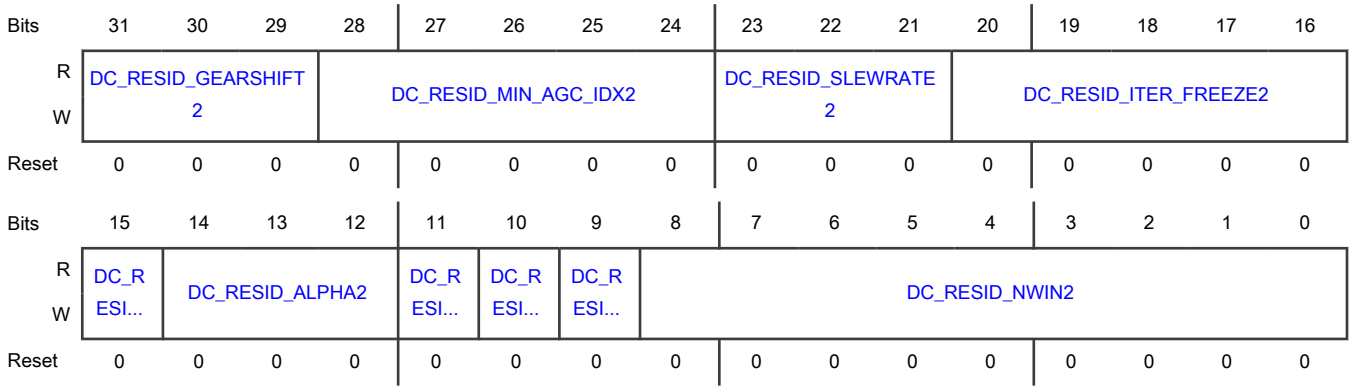
Field	Function
	the delay is scaled based on the clock period. Supported values: 0-7. This delay is only used when EXT_DC_EN=0.
15 DC_RESID_GS_EN	DC Residual Gearshift Enable Controls whether or not gearshifting is enabled. See description of DC_RESID_GEARSHIFT for more information on gearshifting. 0b - Gearshifting disabled 1b - Gearshifting enabled
14-12 DC_RESID_ALPHA	DC Residual Alpha The Alpha parameter controls the rate at which the DC estimate is updated. 000b - Update factor is 1 001b - Update factor is 1/2 010b - Update factor is 1/4 + 1/8 011b - Update factor is 1/4 100b - Update factor is 1/8 + 16 101b - Update factor is 1/8 110b - Update factor is 1/16 + 1/32 111b - Update factor is 1/16
11-8 DC_RESID_ITER_FREEZE	DC Residual Iteration Freeze Number of windows of DC_RESID_NWIN samples before the DC is frozen. Supported values: 1-8
7 —	Reserved
6-0 DC_RESID_NWIN	DC Residual NWIN Number of samples in a window.

55.4.7.4.3.1.88 DC Residual Control2 (DC_RESID_CTRL2)

Offset

Register	Offset
DC_RESID_CTRL2	158h

Diagram



Fields

Field	Function
31-29 DC_RESID_GEARSHIFT2	DC Residual Gearshift, for Second Run If gearshifting is enabled (DC_RESID_GS2_EN = 1) for Second Run, the DC residual will use DC_RESID_ALPHA2 for DC_RESID_GEARSHIFT2 windows (DC_RESID_NWIN2 samples) then will use DC_RESID_ALPHA2+1 for the remaining windows.
28-24 DC_RESID_MIN_AGC_IDX2	DC Residual Minimum AGC Table Index, for Second Run Specifies the minimum AGC table index value at which DC residual can be enabled while Second Run is active. E.g., if this is 5'd0, then the DC residual is enabled for all AGC gain table indexes (assuming RX_DC_RESID_EN is set) if this is 5'd20, then tracking is enabled for AGC gain table indexes 20-26 (assuming RX_DC_RESID_EN is set).
23-21 DC_RESID_SLEWRATE2	DC Residual Slewrate, for Second Run If Slewrate control is enabled (DC_RESID_SR2_EN = 1), changes in the DC correction will be limited to this maximum absolute value, while Second Run is active.
20-16 DC_RESID_ITER_FREEZE2	DC Residual Iteration Freeze, for Second Run Number of windows of DC_RESID_NWIN samples before the DC is frozen. This is used only when Second Run is active.
15 DC_RESID_GS2_EN	DC Residual Gearshift Enable, for Second Run Controls whether or not gearshifting is enabled for Second Run. See description of DC_RESID_GEARSHIFT2 for more information on gearshifting. 0b - Gearshifting disabled for Second Run 1b - Gearshifting enabled for Second Run
14-12 DC_RESID_ALPHA2	DC Residual Alpha, for Second Run The Alpha parameter controls the rate at which the DC estimate is updated. The update factor is shown below. This is used only when the Second Run is active. 000b - Update factor is 1

Table continues on the next page...

Table continued from the previous page...

Field	Function
	001b - Update factor is 1/2 010b - Update factor is 1/4 + 1/8 011b - Update factor is 1/4 100b - Update factor is 1/8 + 16 101b - Update factor is 1/8 110b - Update factor is 1/16 + 1/32 111b - Update factor is 1/16
11 DC_RESID_SR2_EN	DC Residual Slewrate Enable, for Second Run When DC Residual is performing Second Run, if this bit is set, then changes in the DC correction will be limited by DC_RESID_SLEWRATE after Gearshifting.
10 DC_RESID_CC_EN	DC Residual Continuous Correction Enable When DC Residual is performing Second Run, if this bit is set, then the DC_RESID_ITER_FREEZE2 will be ignored and the DC Residual will perform continuous corrections.
9 DC_RESID_PHY_STOP_EN	DC Residual PHY Stop Enable When DC Residual is performing Second Run, if this bit is set, then when the PHY's aa found uncoded signal is asserted, further DC correction updates will be stopped.
8-0 DC_RESID_NWIN2	DC Residual NWIN, for Second Run Number of samples in a window. This is used only when DC_RESID_SECOND_RUN_EN=1.

55.4.7.4.3.1.89 DC Residual Control DataRate1 (DC_RESID_CTRL_DRS)

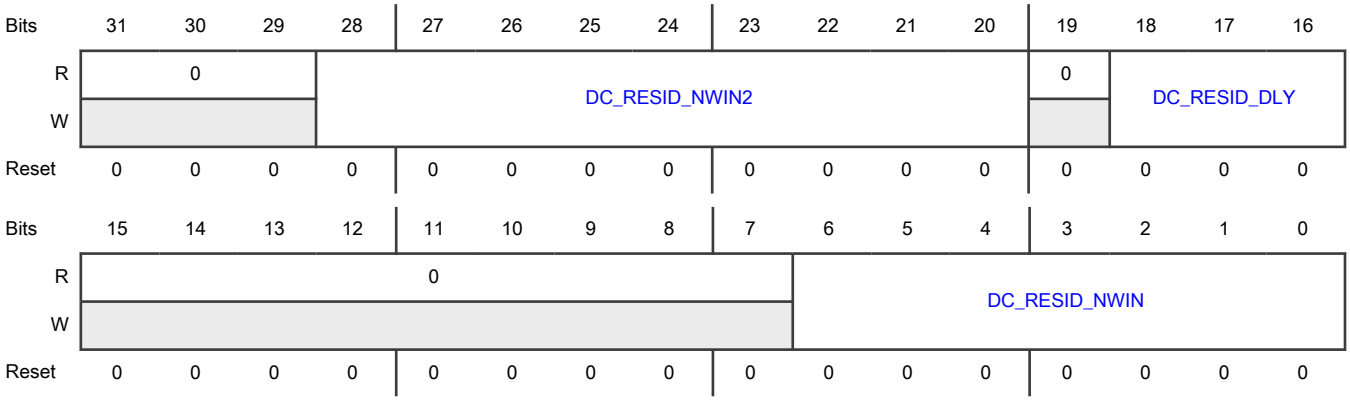
Offset

Register	Offset
DC_RESID_CTRL_DRS	15Ch

Function

The bits in the _DRS registers are only used when the Bluetooth LE signals to request a 2Mbps data rate, or the Generic LL signals using datarate_config_sel to request an alternate data rate.

Diagram



Fields

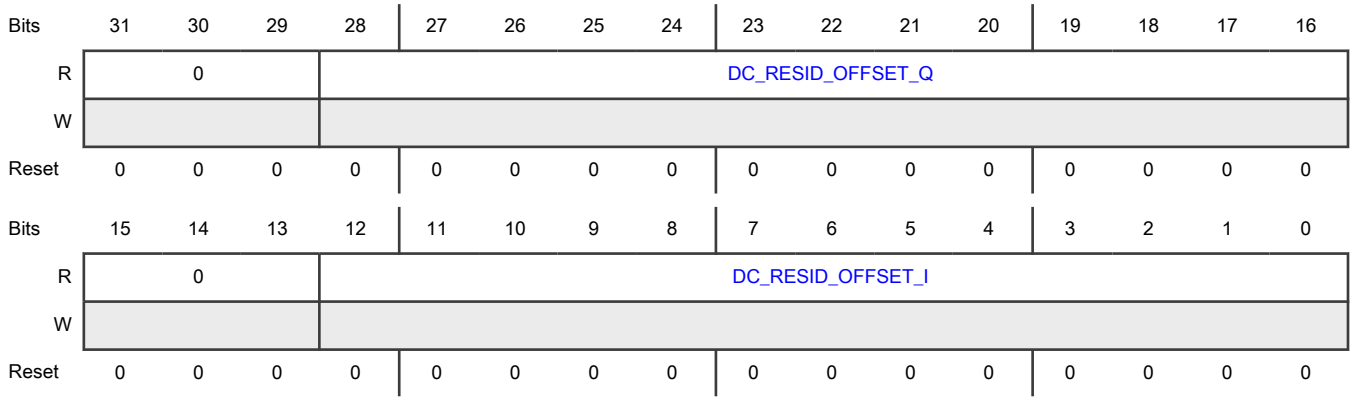
Field	Function
31-29 —	Reserved
28-20 DC_RESID_NWIN2	DC Residual NWIN, for Second Run Number of samples in a window. This is used only when DC_RESID_SECOND_RUN_EN=1.
19 —	Reserved
18-16 DC_RESID_DLY	DC Residual Delay The delay from activation of the DC residual block to the time when it starts processing. For a 32MHz reference clock, the delay in microseconds matches the value programmed. For other clock frequencies, the delay is scaled based on the clock period. Supported values: 0-7. This delay is only used when EXT_DC_EN=0.
15-7 —	Reserved
6-0 DC_RESID_NWIN	DC Residual NWIN Number of samples in a window.

55.4.7.4.3.1.90 DC Residual Estimate (DC_RESID_EST)

Offset

Register	Offset
DC_RESID_EST	160h

Diagram



Fields

Field	Function
31-29 —	Reserved
28-16 DC_RESID_OFFSET_Q	DC Residual Offset Q Reflects the current DC residual offset estimate for Q channel. Format is s11.1. This is provided for debug and characterization purposes only.
15-13 —	Reserved
12-0 DC_RESID_OFFSET_I	DC Residual Offset I Reflects the current DC residual offset estimate for I channel. Format is s11.1. This is provided for debug and characterization purposes only.

55.4.7.4.3.1.91 DfT tone analyzer (DFT_TONE_ANALYZER0)

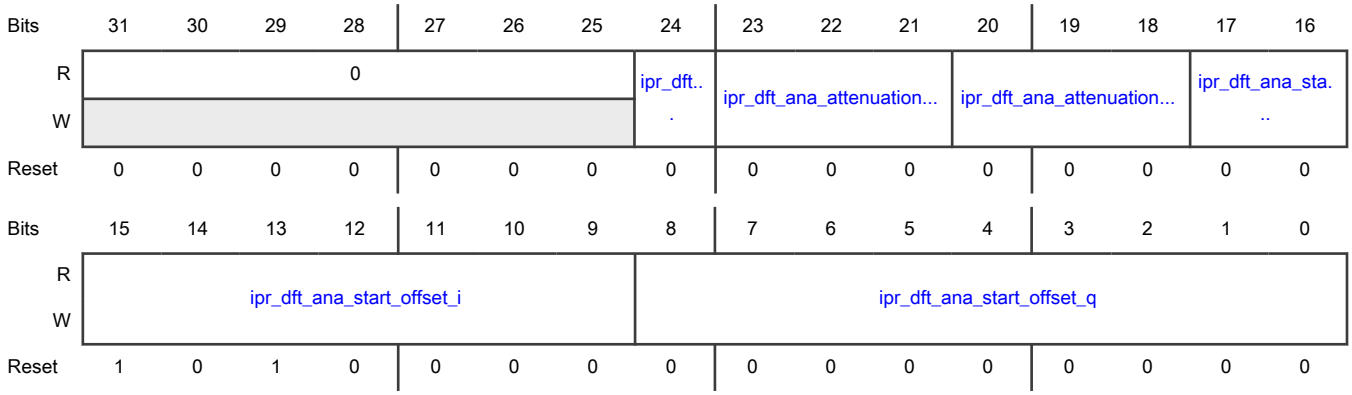
Offset

Register	Offset
DFT_TONE_ANALYZER0	164h

Function

1 of 4 registers required

Diagram



Fields

Field	Function
31-25 —	Reserved
24 ipr_dft_ana_en	Enable for DfT tone analyzer Enable DFT Tone Analyzer module
23-21 ipr_dft_ana_attenuation_i	Check description of ipr_dft_ana_attenuation_q
20-18 ipr_dft_ana_attenuation_q	Tone Attenuation For Q Path Full amplitude of tone generator inside the DFT Tone Analyzer is 1024. By set ipr_dft_ana_attenuation_i and/or ipr_dft_ana_attenuation_q can scale down the amplitude for I and/or Q path. The actual scale factor is calculated as: i_scale = 2^(-ipr_dft_ana_attenuation_i), q_scale = 2^(-ipr_dft_ana_attenuation_q),
17-9 ipr_dft_ana_start_offset_i	I Initial Phase Check description of ipr_dft_ana_start_offset_q
8-0 ipr_dft_ana_start_offset_q	Q Initial Phase ipr_dft_ana_start_offset_i and ipr_dft_ana_start_offset_q are using for control the initial phase of I and Q of tone generator inside the DFT tone analyzer. By setting different phase of I and Q, the tone generator can produce positive freq or negtive freq waveform. Default freq of tone generator is positive. To generage a negtive frequence, set ipr_dft_ana_start_offset_i = 0x50 and ipr_dft_ana_start_offset_q = 0xA0.

55.4.7.4.3.1.92 DfT tone analyzer (DFT_TONE_ANALYZER1)

Offset

Register	Offset
DFT_TONE_ANALYZER1	168h

Function

55.4.7.6 2.4GHz PHY

55.4.7.6.1 About this module

55.4.7.6.1.1 Introduction

This documents describes the PHY and its operation.

modules of the 2.4GHz PHY receiver supporting the demodulation of a wide range of use cases employing FSK modulation:

- acquisition (timing and frequency synchronization)
- symbol demodulation
- interfacing with the PrePHY, RBME and LL

The Following protocols are supported:

- Non-coded Bluetooth LE
- Long range Bluetooth LE
- custom FSK modulation schemes
- MSK

55.4.7.6.1.2 Features

The 2.4GHz PHY includes the following features:

- support preamble detect
- support address match
- support Bluetooth LE long range
- support Bluetooth LE none coded up to 4 address
- support demodulate to RBME/LL
- support custom FSK modulation schemes
- support MSK
- high-accuracy CFO estimation using known sequences embedded in the PDU

55.4.7.6.1.3 Modes and Operations

2.4GHz PHY supports the modes and operations described in the indicated sections:

- Operating modes
- Operations

55.4.7.6.1.4 PHY block diagram and integration

Figure 309 shows the interface signals and the integration of the PHY module with other blocks of the radio:

- Front-end module
- Receiver
- Radio bit manipulation engine
- Link-layer
- Antenna selection logic for the estimation of the angle-of-arrival

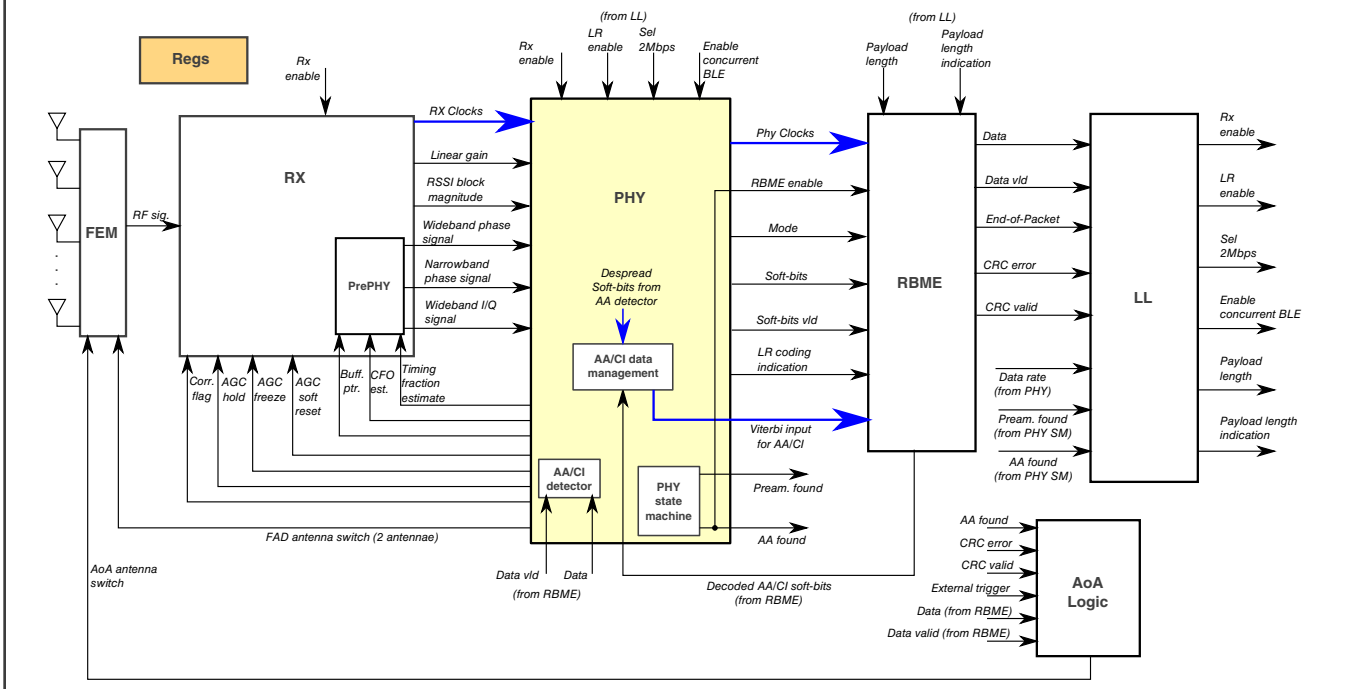

Figure 309. PHY integration block diagram

Figure 310 shows the block diagram of the PHY module. It consists of the following components:

- State-machine and clocks responsible with:
  - generation of control signals
  - generation of clock signals for the PHY processing blocks
- Time/frequency synchronization, responsible with the frame time synchronization and CFO estimation for non-coded packets, that consists of:
  - Power threshold responsible with channel energy sensing
  - Phase domain preamble detection
  - Discriminated phase (FM) domain preamble detection
  - AA detection
- Time/frequency synchronization, responsible with the frame time synchronization and CFO estimation for LR packets, that consists of:
  - LR preamble detection
  - LR AA search
- GFSK demodulator, responsible with the symbol demodulation at the over-the-air baud rate
- AA/CI data parallel to serial conversion, responsible with the data and data valid generation for the RBME module, on the AA/CI portion of the long range Bluetooth LE packets
- AA/CI detection, responsible with the decoded AA matching and CI field extraction for the long range Bluetooth LE packets

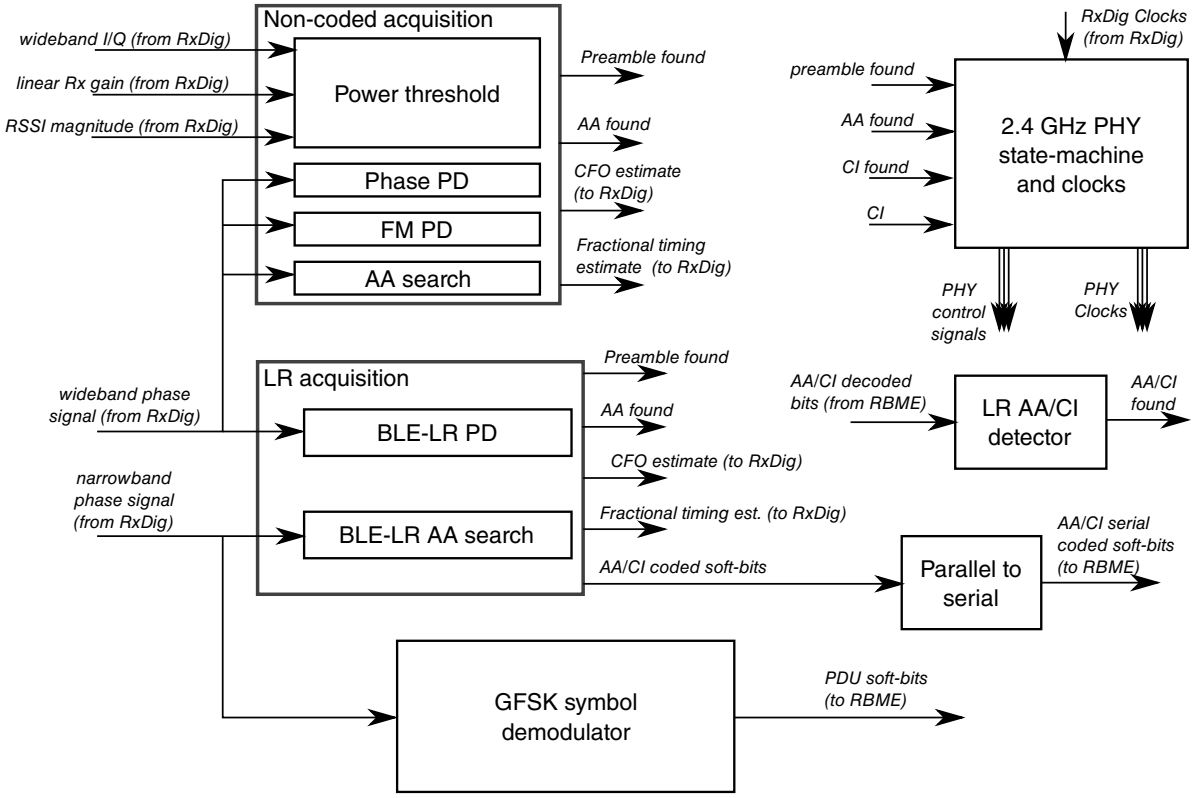

Figure 310. PHY block diagram

A "look-back" buffer provides the required latency of the frequency correction and timing acquisition engines. A pointer is provided from the PHY to the PrePHY via the interface illustrated in Figure 309. The pointer to the IQ buffer has the role of tapping the CFO mixer at the correct sample in the IQ buffer so that the CFO and the fractional timing are properly compensated. The pointer to the buffer is configured by the PHY registers and it is different for different use-cases and configurations. In general the pointer needs to be chosen to account for the following:

- Latency of a detection event, produced by the acquisition block, which is followed by:
  - the enable of the narrowband path
  - the enable of the blocks consuming the output of the narrowband path
- Channel filter pre-filling with enought history samples so that the output is computed using only CFO/fractional timing compensated samples
- The number of history samples has to be equal with at least half of the size of the CHF
- Enough history timing/frequency error compensated samples must be available for the FSK symbol demodulator
- The history needed by the FSK symbol demodulator is 2-symbols worth of samples
- A fine-tune adjustment that accounts for different latencies in the system, intended to ensure a smooth transition when switching from using the wide-band samples to using the narrow-band samples

The size of the IQ buffer needs to be chosen such that it covers for the worst-case scenario. The overall latency of the narrowband path equals the latency of the IQ buffer plus the channel filter latency plus the latencies introduced by the CFO mixer and timing frequency correction interpolator.

55.4.7.6.1.5 Overview

The PHY is made up of several sub-modules. These modules can be viewed as members of two classes: datapath (the flow of the signal and the resultant bits) and control (enable/ disable logic and state control).

55.4.7.6.1.5.1 PHY Datapath

There are two data paths used by the PHY. The wide-band path and the narrow-band path. The PHY uses the one of the two data paths at a time or both of them simultaneously depending on the process(acquisition or payload demodulation) and use-case(coded or non-coded).

The signal of interest is passed through the PHY along the data paths. The overall objective is to process phase samples that are presented and create bits that are sent out. The significant sub-systems are here presented in generally chronological order as the signal passes through.

Initially, the phase samples are input, sequentially, at the sampling rate, one at a time. The first step is to buffer the wide-band samples, so they can be used all at once for certain computations.

The buffer of samples is then presented to the acquisition logic. The acquisition module is responsible for detecting the presence of a signal and then indicating the timing and frequency offset when a signal is detected.

Up to 4 AA's can be searched for in the case of non-coded packets and one AA can be searched for in the case of long range Bluetooth LE packets. When an match occurs, the bit timing (the sample offset at which each bit is optimally demodulated) is recorded.The symbol timing information thus determined is used by the symbol demodulator block to perform payload demodulation.

When a packet is detected, the CFO estimate is presented to the corrector and the correction is applied to the incoming samples. In this fashion, the samples leaving the corrector, which is placed on the narrowband data path, will be optimally corrected for any frequency offset before beginning demodulation.

Demodulation is performed on frequency corrected samples, provided by the narrowband data path, and after a packet is detected, the demodulator produces soft-bits information, at the symbol rate, which is presented to the RBME block. More details are provided in the functional description section.

55.4.7.6.1.5.2 PHY Control

The control of the PHY blocks is realized from a single place denoted the PHY state-machine. the purpose of this block is to provide:

1. triggers(data valid signals)
2. enable/disable signals
3. indications to the processing blocks of the PHY module

Another aspect of the PHY stat machine is to fast antenna diversity(FAD) preamble search feature. FAD is a mechanism that allows antenna selection on fly.

A more detailed description of the PHY control is provided in the functional description section.

55.4.7.6.2 Interface

The PHY interacts with the system in a few distinct ways. The interfaces can be grouped into 5 categories: configuration, signal input, demodulation output, miscellaneous and debug.

55.4.7.6.2.1 PHY Configuration Interface

The PHY is configured by static signals that are observed and used throughout the receive process. It is important that these signals (typically originating from IP registers) remain static during a receive operation to avoid unpredictable behavior. Some examples of these types of configurations are PD thresholds, AA to search for, etc.

55.4.7.6.2.2 Signal Input Interface

The PHY processes the inputs signal from a set of signed, 6-bit phase inputs. There are three class of input data, wide band, narrow band, and raw IQ.

55.4.7.6.2.3 Demodulation Output

The demodulator produces soft bits in fixed-point format which are presented to the RBME block.

55.4.7.6.2.4 Miscellaneous

There are various other outputs from the PHY that are mostly intended for hand shake with other modules. A few significant signals are described here:

- Preamble found: indicates that Preamble was found.
- CFO estimate: Frequency offset as determined by the preamble detect engine.
- FRAC estimate: Fractional timing error estimate computed in the AA detector;
- Data rate:identified received data rate.
- AA found: indicates that an acceptable address synchronization has occurred.
- AA id: indicates which access address was found.
- corr flag: Indicates to the LQI calculator that the correlation magnitude, exceeds a specified threshold value.
- ant_out: indicates the requested antenna when FAD is enabled. May be ignored when FAD is not enabled.

55.4.7.6.2.5 Debug

There are various other outputs from the PHY that are mostly intended for debug. A few significant signals are described here:

- dtest_*: various outputs send to DTEST module, and then send to GPIO pin.
- phy_dma_mux: muxed one of five DMA data send to DMA module, then finially dumped to RAM

55.4.7.6.3 Memory Map and register definition

This section includes the 2.4GHz PHY module memory map and detailed descriptions of all registers.

55.4.7.6.3.1 2.4GHz PHY REGISTERS register descriptions

55.4.7.6.3.1.1 IPR memory map

Fields

Field	Function
31-29 —	Reserved
28-24 AA_ACQ_1_2_3_THRESH_2M	For 2Mbps data rate, correlation threshold applicable to AA detection; uses ufix5_En5 fixed-point format.
23 —	Reserved
22-20 BLE_NTW_ADR_THR	Maximum hamming distance from the given AA pattern that may still be accepted as a match; valid range [0,7]. This threshold value are performed on lower power case.
19-16 HAMMING_AA_LOW_PWR	Maximum hamming distance from the given AA pattern that may still be accepted as a match; valid range [0,7]. This threshold value are performed on lower power case.
15-13 —	Reserved
12-8 AA_ACQ_1_2_3_THRESH_1M	For 1Mbps data rate, Correlation threshold applicable to AA detection; uses ufix5_En5 fixed-point format.
7 —	Reserved
6 MSK2FSK_SEED	Last bit of preamble. It is used as seed of the MSK to FSK transformation to derive the FM access address pattern when MSK is enabled
5 MSK_EN	Configures PHY for MSK decoding.
4 —	Reserved
3 —	Reserved
2	This applies at the demodulator, so it affects both AA and the data portions of the packet. 0b - Normal demodulation. 1b - Invert demodulated bits.

Table continues on the next page...

Table continued from the previous page...

Field	Function
FSK_BIT_INVERT	0b - Normal demodulation 1b - Invert demodulated bits
1 AA_OUT_SEL	Specifies which AA bits to be played-back to the LL: 0b - output the received AA bits 1b - output the programmed AA bits
0 —	Reserved

55.4.7.6.3.1.12 PHY Uncoded Config 1 (FSK_CFG1)

Offset

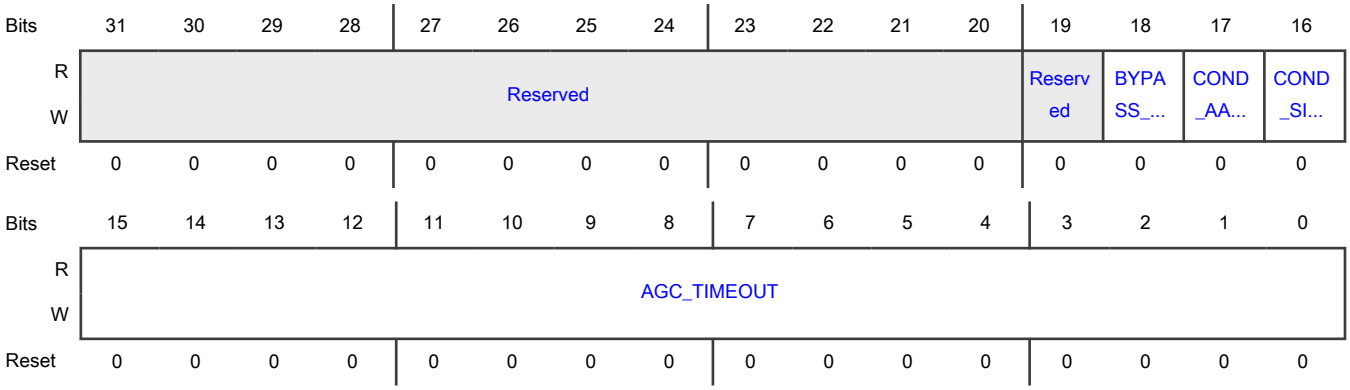
55.4.7.6.3.1.15 PHY Uncoded Power Threshold Config (FSK_PT)

Offset

Register	Offset
FSK_PT	34h

Diagram



Fields

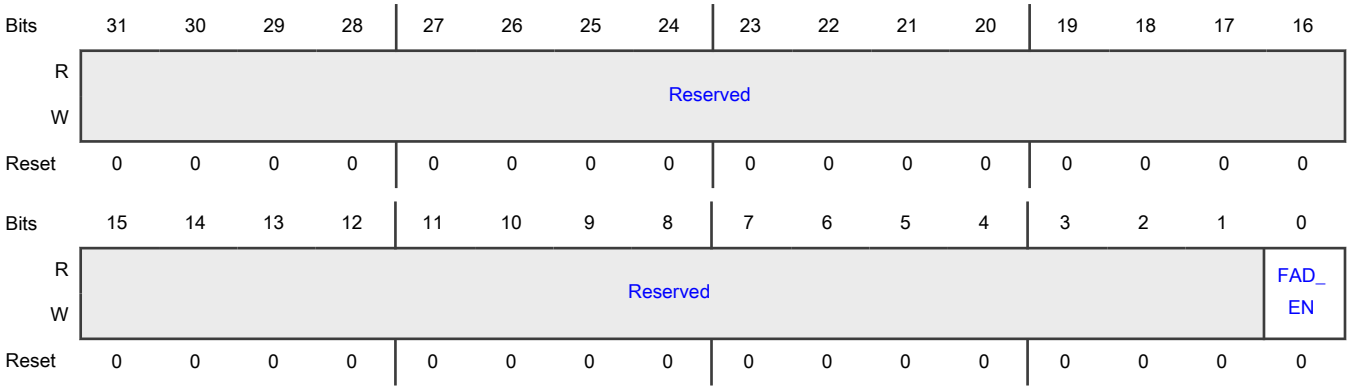
Field	Function
31-20 —	Reserved
19 —	Reserved
18 BYPASS_WITH_RSSI	Bypass signal power measurement with RSSI measurement; 0b - no 1b - yes
17 COND_AA_BUFF_EN	Enables special condition for enabling AA detector buffer; 0b - disable. 1b - enable.
16 COND_SIG_PRST_EN	Enables special conditioning of signal detection; 0b - disable. 1b - enable.
15-0 AGC_TIMEOUT	Time-out, applicable to special conditioning of signal power detection in the Power threshold block, after each AGC gain adjustment. It is expressed in number of samples.

55.4.7.6.3.1.16 PHY Uncoded FAD Control (FSK_FAD_CTRL)

Offset

Register	Offset
FSK_FAD_CTRL	38h

Diagram



Fields

Field	Function
31-1 —	Reserved
0 FAD_EN	Enables FAD; 0b - disable. 1b - enable.

55.4.7.6.3.1.17 PHY Uncoded FAD Config (FSK_FAD_CFG)

Offset

Register	Offset
FSK_FAD_CFG	3Ch

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved	WIN_SEARCH_PD							Reserved	WIN_FAD_SEARCH_PD						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved	WIN_FAD_WAIT_PD							Reserved	WIN_FAD_WAIT_SYNCH						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

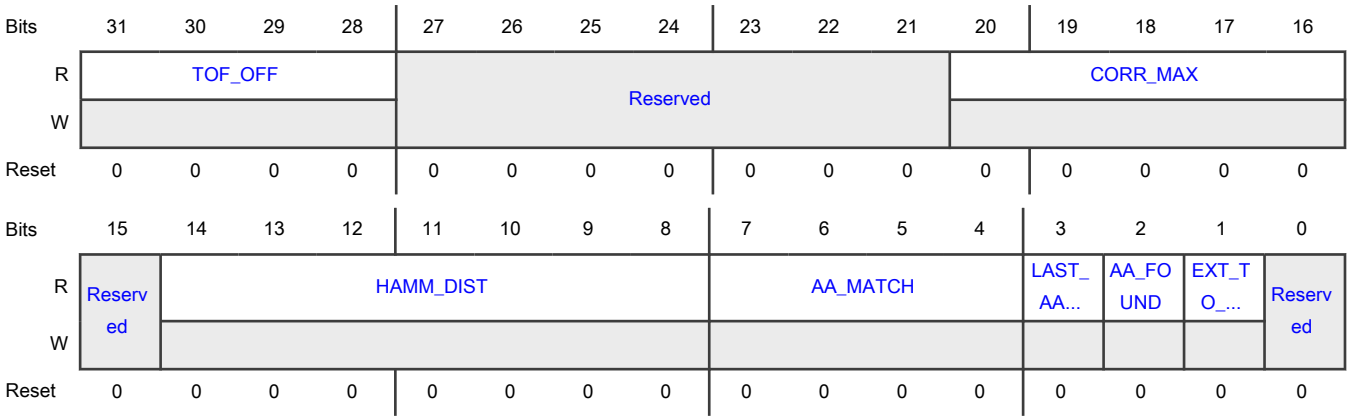
Field	Function
31 —	Reserved
30-24 WIN_SEARCH_PD	Time-window to match preamble pattern on samples coming from the currently selected antenna (refered to as T0 in the PHY state-machine section).
23 —	Reserved
22-16 WIN_FAD_SEARCH_PD	Time-window to match preamble pattern on samples coming from the previously selected antenna (refered to as T1 in the PHY state-machine section).
15 —	Reserved
14-8 WIN_FAD_WAIT_PD	Time-window to wait for clean samples if PD was not found after antenna switch (refered to as T2 in the PHY state-machine section).
7 —	Reserved
6-0 WIN_FAD_WAIT_SYNCH	Time-window to wait for clean samples, before transitioning to AA search PHY state, if PD was found after antenna switch (refered to as T3 in the PHY state-machine section).

55.4.7.6.3.1.18 PHY Uncoded Status (FSK_STAT)

Offset

Register	Offset
FSK_STAT	40h

Diagram



Fields

Field	Function
31-28 TOF_OFF	Timing offset for use in time-of-flight calculation. It is a modulo 16 value which is modified from PHY enabled until AA is found. This provides a fine, sample-time resolution, timing information. Time unit is sample rate, for example, 0.25us for 1M data rate.
27-21 —	Reserved
20-16 CORR_MAX	Indicates the correlation witnessed when AA match occurred {MiHai}In my opinion this should be the maximum AA correlation magnitude, which should be sticky from the moment AA detection occurs until the next PHY reset.
15 —	Reserved
14-8 HAMM_DIST	Indicates the hamming distance witnessed when AA match occurred.
7-4 AA_MATCH	Indicates which non-coded AA has matched. This will clear when the PHY is re-initialized.
3	reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
LAST_AA_BIT	
2 AA_FOUND	Indicates that a uncoded AA detect is active.
1 EXT_TO_MODES_13	Reserved
0 —	Reserved

55.4.7.6.3.1.19 PHY Long Range Preamble Detect Config (LR_PD_CFG)

Offset

Register	Offset

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
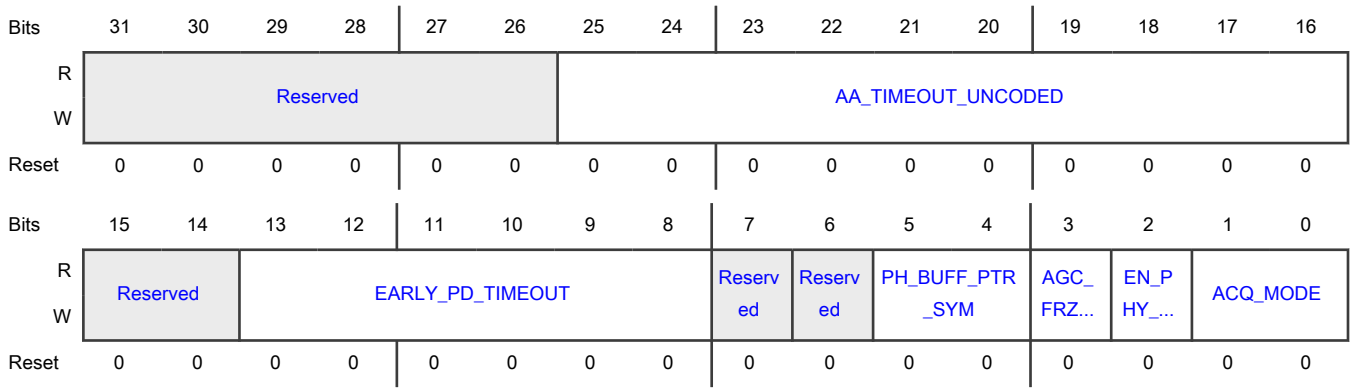
31-24 CMAG_MAX	Indicates the maximum preamble correlation magnitude during preamble found
23-16 AA_CORR_MAX	Indicates the AA correlation magnitude witnessed when AA match occurred
15 —	Reserved
14-8 CODED_HAMM_DIST	Hamming distance between the coded reference sequence and the coded received sequence. This hamming distance is computed in the "Bluetooth LE long range AA correlator" block.
7 CI	CI received.
6 AA_FOUND	Indicates that a AA detect is active for both LR and uncoded.
5-0 DECODED_HAMM_DIST	Hamming distance between the reference sequence and the Viterbi decoded received sequence This is computed in the "AA/CI Detector" block

55.4.7.6.3.1.39 PHY State Machine Config (SM_CFG)

Offset

Register	Offset
SM_CFG	94h

Diagram



Fields

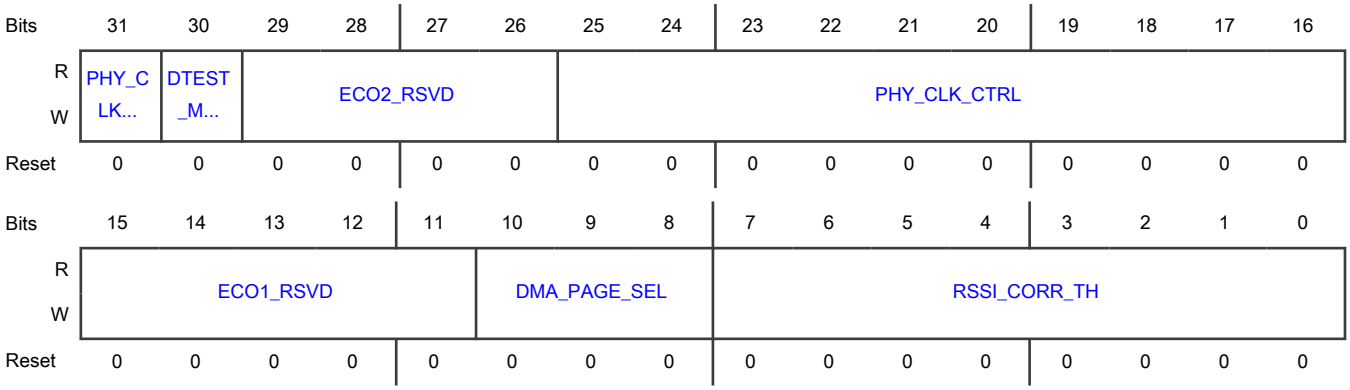
Field	Function
31-26 —	Reserved
25-16 AA_TIMEOUT_UNCODED	Time-out value for access address search for uncoded packets
15-14 —	Reserved
13-8 EARLY_PD_TIMEOUT	Time-out used to reset the AGC state-machine for the eventuality that an "PD found early" event occurs but it is not followed by an "PD found" event
7 —	Reserved
6 —	Reserved
5-4 PH_BUFF_PTR_SYM	Phase buffer size to demodulator, long range only. for system 32MHz case, it should be 0, for system 26MHz case, it should be 1
3 AGC_FRZ_ON_PD_FOUND_ACQ1_LR	Specfies AGC freeze condition for non-coded acq.1 and Bluetooth LE long range. 0b - AGC freeze on AA found. 1b - AGC freeze asserted on PD found.
2 EN_PHY_SM_EXT_RST	Enable PHY state-machine reset on the external reset port; Reserved, should keep 0. 0b - Reset is not allowed. 1b - Reset is allowed.
1-0 ACQ_MODE	Acquisition mode for non-coded reception 00b - Reserved 01b - Use preamble and verify a correlation peak, the synch at the symbol rate as symbol timing is established by the preamble acquisition 10b - Use synch only (which may incorporate part of the preamble) 11b - Use mainly the sync detection: Use a low threshold on the preamble detector and launch the synch detection only if the preamble has shown a recent peak

55.4.7.6.3.1.40 PHY Misc Config (MISC)

Offset

Register	Offset
MISC	98h

Diagram



Fields

Field	Function
31 PHY_CLK_ON	Force PHY clock ON Forces the system to keep the PHY clock on
30 DTEST_MUX_EN	Reserved Should be programed as reset value 0.
29-26 ECO2_RSVD	Reserved it should be programed as reset value 0
25-16 PHY_CLK_CTRL	Enables various clock gating features. Bits are individually decoded, so any combination is allowable. • 0000000001b - Gate off PHY clock when phy_en is not asserted. • 0000000010b - Gate off uncoded preamble detect clock when pd_enable is not asserted (internal signal). • 0000000100b - Gate off uncoded AA synchronizer clock when synchronizer is not in use. • 0000001000b - Gate off m2n demodulator clock when demodulator is not in use. • 0000010000b - Gate off long range preamble detect clock when pd_enable is not asserted (internal signal). • 0000100000b - Gate off long range AA synchronizer clock when synchronizer is not in use. • 0001000000b - Gate off m3c demodulator clock when demodulator is not in use.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• 0010000000b - Gate off AA CI detect clock when it is not in use • 0100000000b - Gate off Viterbi input formating clock when it is not in use • 1000000000b - Gate off phy state machine clock dynamicly when it is not toggle
15-11 ECO1_RSVD	Reserved Must be programed as reset value 0.
10-8 DMA_PAGE_SEL	Select which DMA page is send out 000b - Select DMA PAGE 0 for M3C with cfo; 001b - Select DMA PAGE 1 for M3C with magnitude; 010b - Select DMA PAGE 2 for un-coded; 011b - Select DMA PAGE 3 for Long Range Preampble Detect; 100b - Select DMA PAGE 4 for Long Range AA Detect;
7-0 RSSI_CORR_TH	Threshold use to compare a correlation magnitude value, computed in the acquisition block, in order to determine the correlation flag value provided by the PHY to the LQI computation block. Format is ufix8_En8

55.4.7.6.4 Functional description

The following sections describe functional details of the 2.4GHz PHY module.

55.4.7.6.4.1 Protocol Configuration

The PHY has several configurable parameters that can be changed based on the desired protocol behavior. The details of these parameters are described in the following sections and a summary table is provided here for quick reference.

Table 434. FSK schemes supported by the demodulator

Scheme	baud rate (kbps) R	Data rate (kbps) DR	modulation index *h*	Frequency pulse	LO error (ppm)
Bluetooth LE	1000	1000	0.50	Gaussian; BT=0.5	62.50
Bluetooth LE LR 125	1000	125	0.50	Gaussian; BT=0.5	62.50
Bluetooth LE LR 500	1000	500	0.50	Gaussian; BT=0.5	62.50
GFSK_05_07-500	500	500	0.70	Gaussian; BT=0.5	41.67
GFSK_03_05-1000	1000	1000	0.50	Gaussian; BT=0.3	41.67
MSK_05-1000	500	500	0.50	MSK	41.67
GFSK_05_05-250	250	250	0.50	Gaussian; BT=0.5	20.83
GFSK_05_10-250	250	250	1.00	Gaussian; BT=0.5	20.83
GFSK_07_05-1000	1000	1000	0.50	Gaussian; BT=0.7	62.50
GFSK_05_05-2000	2000	2000	0.50	Gaussian; BT=0.5	62.50
MSK_05-250	250	250	0.50	MSK	20.83
GFSK_05_032-2000	2000	2000	0.32	Gaussian; BT=0.5	62.5
FSK_05-500	500	500	0.50	Rectangular	41.67

55.4.7.6.4.2 Operating modes

This section describes all functional operation modes of the 2.4GHz PHY module.

55.4.7.6.4.2.1 Scan mode

Scan mode determines the way packets are being search for. As shown three modes of operation are defined for the 2.4 GHz PHY:

- Non-coded FSK search: look only for non-coded packets, while keeping all the Long range Bluetooth LE acquisition blocks disabled;
- Long range Bluetooth LE search: search only for long range Bluetooth LE packets while keeping all the non-coded acquisition blocks disabled;
- Simultaneous Non-coded and long range Bluetooth LE search: simultaneously look for long range and non-coded Bluetooth LE packets by enabling both long range and non-coded acquisition blocks.

Note that the PHY block is capable of performing simultaneous search of any non-code FSK use-case and long range Bluetooth LE but, from an use-cases perspective, this mode of operation is restricted to non-coded Bluetooth LE.

55.4.7.6.4.2.2 Acqusition mode

From a non-coded perspective there are three acquisition modes:

- Acquisition mode 1: both preamble and AA are used for packet detection and synchronization. The preamble detector is used to detect the packet and to realize symbol timing synchronization and, following a preamble detection, AA is being searched at symbol rate in order to get frequency and frame synchronization. This mode is suitable for packets that have long enough preambles (usually more than 6 octets) so that the symbol timing synchronization can be reliably realized;

- Acquisition mode 2: only the AA is used for packet detection and time/frequency synchronization. This acquisition mode is suitable to be used when the packet being searched has a short preamble;
- Acquisition mode 3: both preamble and AA are used for packet detection and synchronization. The preamble detector is used merely to detect the presence of a packet and, following a preamble detection, AA is being searched at sample rate in order to get frequency synchronization and symbol/frame timing synchronization. This acquisition mode is suitable for packets which short preamble, and it provides not only a lower power consumption but also an earlier packet presence indication than mode 2.

55.4.7.6.4.3 Operations

This section describes the 2.4GHz PHY module's operations.

55.4.7.6.4.3.1 PHY state-machine

The state-machine state diagram is depicted in Figure 311. As per the depiction in Scan mode three modes of operation are defined for the 2.4 GHz PHY:

- Non-coded FSK search: look only for non-coded packets, while keeping all the long range Bluetooth LE acquisition blocks disabled
- Long range Bluetooth LE search: search only for long range Bluetooth LE packets while keeping all the non-coded acquisition blocks disabled
- Simultaneous Non-coded and long range Bluetooth LE search: simultaneously look for long range Bluetooth LE and non-coded packets by enabling both long range and non-coded acquisition blocks

Note that the PHY block can simultaneously search for non-coded FSK packets and long range Bluetooth LE packets; however the only tested configurations are for simultaneous non-coded Bluetooth LE with long range Bluetooth LE.

The state-machine has 6 main states:

- State 0: Initialization state
  - Reset state used to recycle all the blocks in the PHY
- State 1: Acquisition state
  - Completely (for non-coded) or partially (for long range Bluetooth LE) responsible with time/frequency synchronization
    - More details about state1 are given in the sequel of this section
  - When the PHY is configured to perform simultaneous non-coded and long range Bluetooth LE search
    - Makes a decision whether to continue treating the packet as a non-coded or as a long range Bluetooth LE
- State 2: long range Bluetooth LE PD/AA
  - Only when a long range Bluetooth LE packet is detected
  - Responsible with the simultaneous LR preamble and AA search
  - It can only be entered following a long range Bluetooth LE preamble detection event
    - Keeps the preamble search to improve the CFO estimate
    - Extends the time used for the AA search process as required
- State 3: Long range Bluetooth LE AA/CI check
  - Only when a long range Bluetooth LE packet is detected
  - Tells the PHY and RBME to unpack the AA despread soft-bits
    - More details about these in the long range Bluetooth LE AA detection section
  - Turns on the Viterbi decoder
  - Looks for a match to the AA bits

- Extracts the CI information
  - The CI is further used to configure RBME for PSDU decoding.

- State 4: Demodulation & Decoding
  - handles the PSDU demodulation and decoding for both non-coded and long range Bluetooth LE packets
- State 5: RTT state
  - This state is used for the RTT operation (for more details please consult the description of the RTT module)
  - This represents an idle state for the PHY to transition to when the reception of an RTT packets is done
  - PHY exists this state following a PHY reset issued at a higher level in the hierarchy
  - (Figures below don't show state 5 as this state is not representative for regular communication packets exchanges)

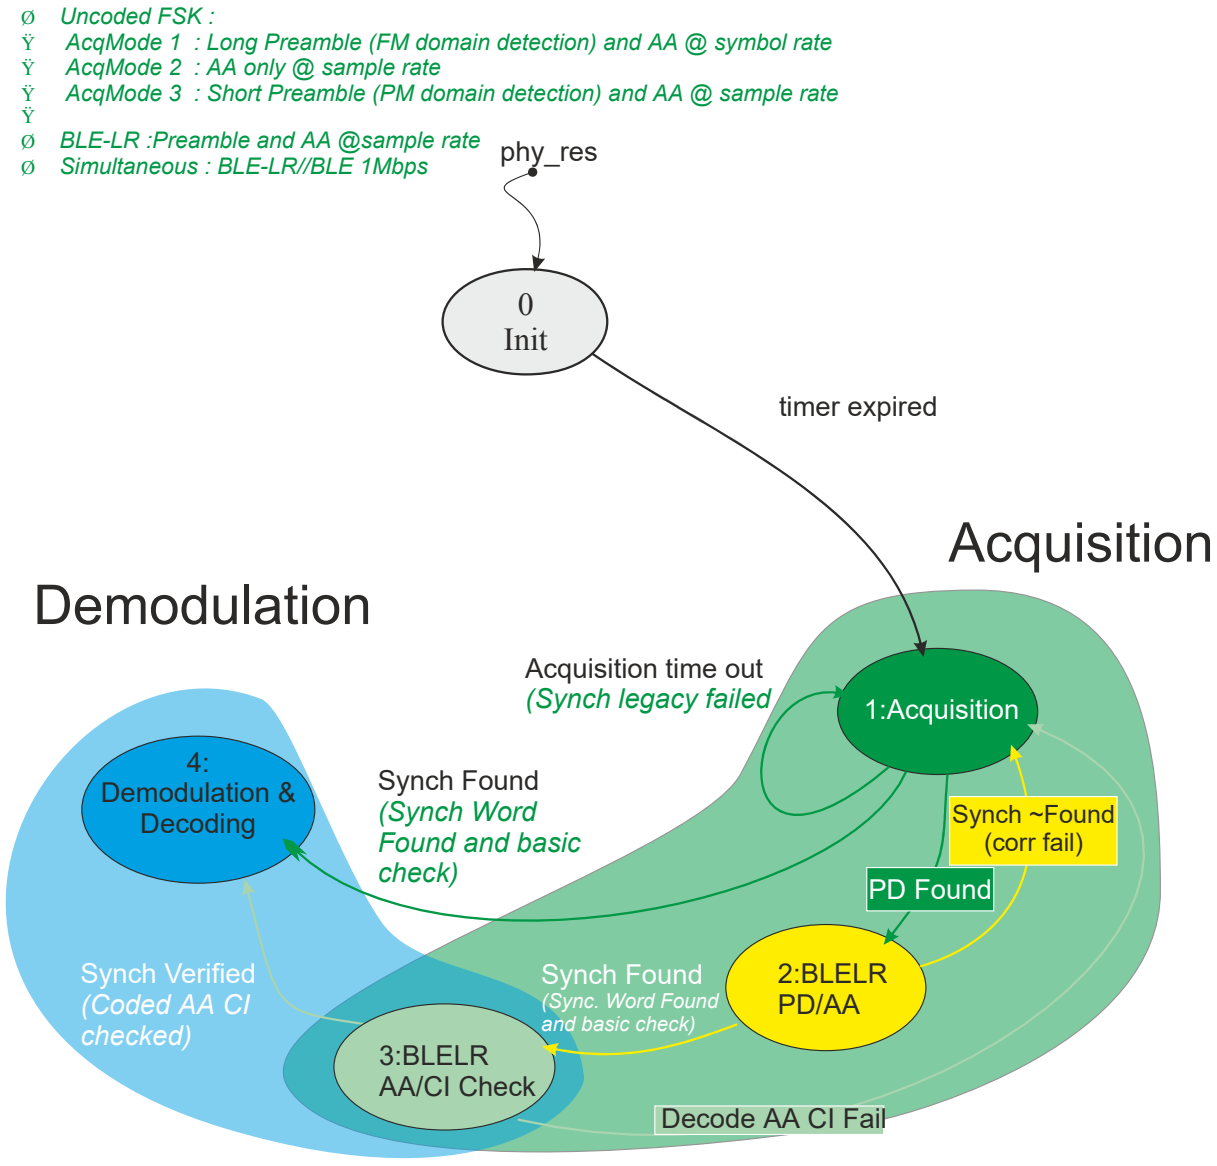

Figure 311. Top level view of the state-machine

A time out is used for the AA detection to allow for a prompt recovery. In long range and non-coded acquisition modes 1 and 3, AA detection runs in parallel with preamble detection in order to: 1) extend the AA search as needed and 2) to update the synchronization information. If neither a preamble detection nor an AA detection occur during the time-out period, the PHY state machine returns to the Acquisition state, disables AA detection and recycles all the PD block memory excepting the samples buffer.

Figure 311 illustrates two functions. The green areas are all about acquisition in a larger sense, meaning that all the processing concerning packets detection are associated to it and the blue region is about demodulation, responsible for PSDU processing and/or decoding in the RBME (Radio Bit Manipulation Engine).

For long range Bluetooth LE packets the preamble detection is responsible for packet acquisition and frequency synchronization (i.e. CFO estimation). Following a preamble found event: 1) the incoming samples are demodulated; 2) the resulting soft bits are correlated to the AA pattern; 3) finally, the correlation peak marks the location of the incoming frame and symbol timing is estimated. The soft-bits are now re-aligned to symbol timing and passed through the Viterbi decoder (State 2 of the SM) . The decoded bits are then matched to the AA pattern and the CI is extracted (State 3 of the SM) .

From a non-coded perspective as the depiction in Acqusition mode there are three acquisition modes:

- Acquisition mode 1
  - Both preamble and AA are used for packet detection and synchronization
  - The preamble detector detects the packet and synchronizes timing
  - Following a preamble detection, the AA is searched at the symbol rate
    - The AA detection outputs frequency and frame synchronization
  - This mode is suitable for packets that have long enough preambles (usually more than 6 octets)
- Acquisition mode 2
  - Only the AA is used for packet detection and time/frequency synchronization
  - This acquisition mode is suitable to be used when the packet being searched has a short preamble
- Acquisition mode 3
  - Both preamble and AA are used for packet detection and synchronization
  - The preamble detector is used merely to detect the presence of a packet
  - Following a preamble detection, the AA is searched at the sample rate
    - The AA detection outputs frequency synchronization and symbol/frame timing synchronization
  - This acquisition mode is
    - Suitable for packets which short preambles
    - Lowers power consumption and an earlier packet detection than mode 2

The figures below show detailed instantiations of the top-level state-machine, considering all the acquisition modes described earlier and all the operation modes. Figure 312 illustrates the state-machine instantiation for non-simultaneous non-coded acquisition modes or long range Bluetooth LE.

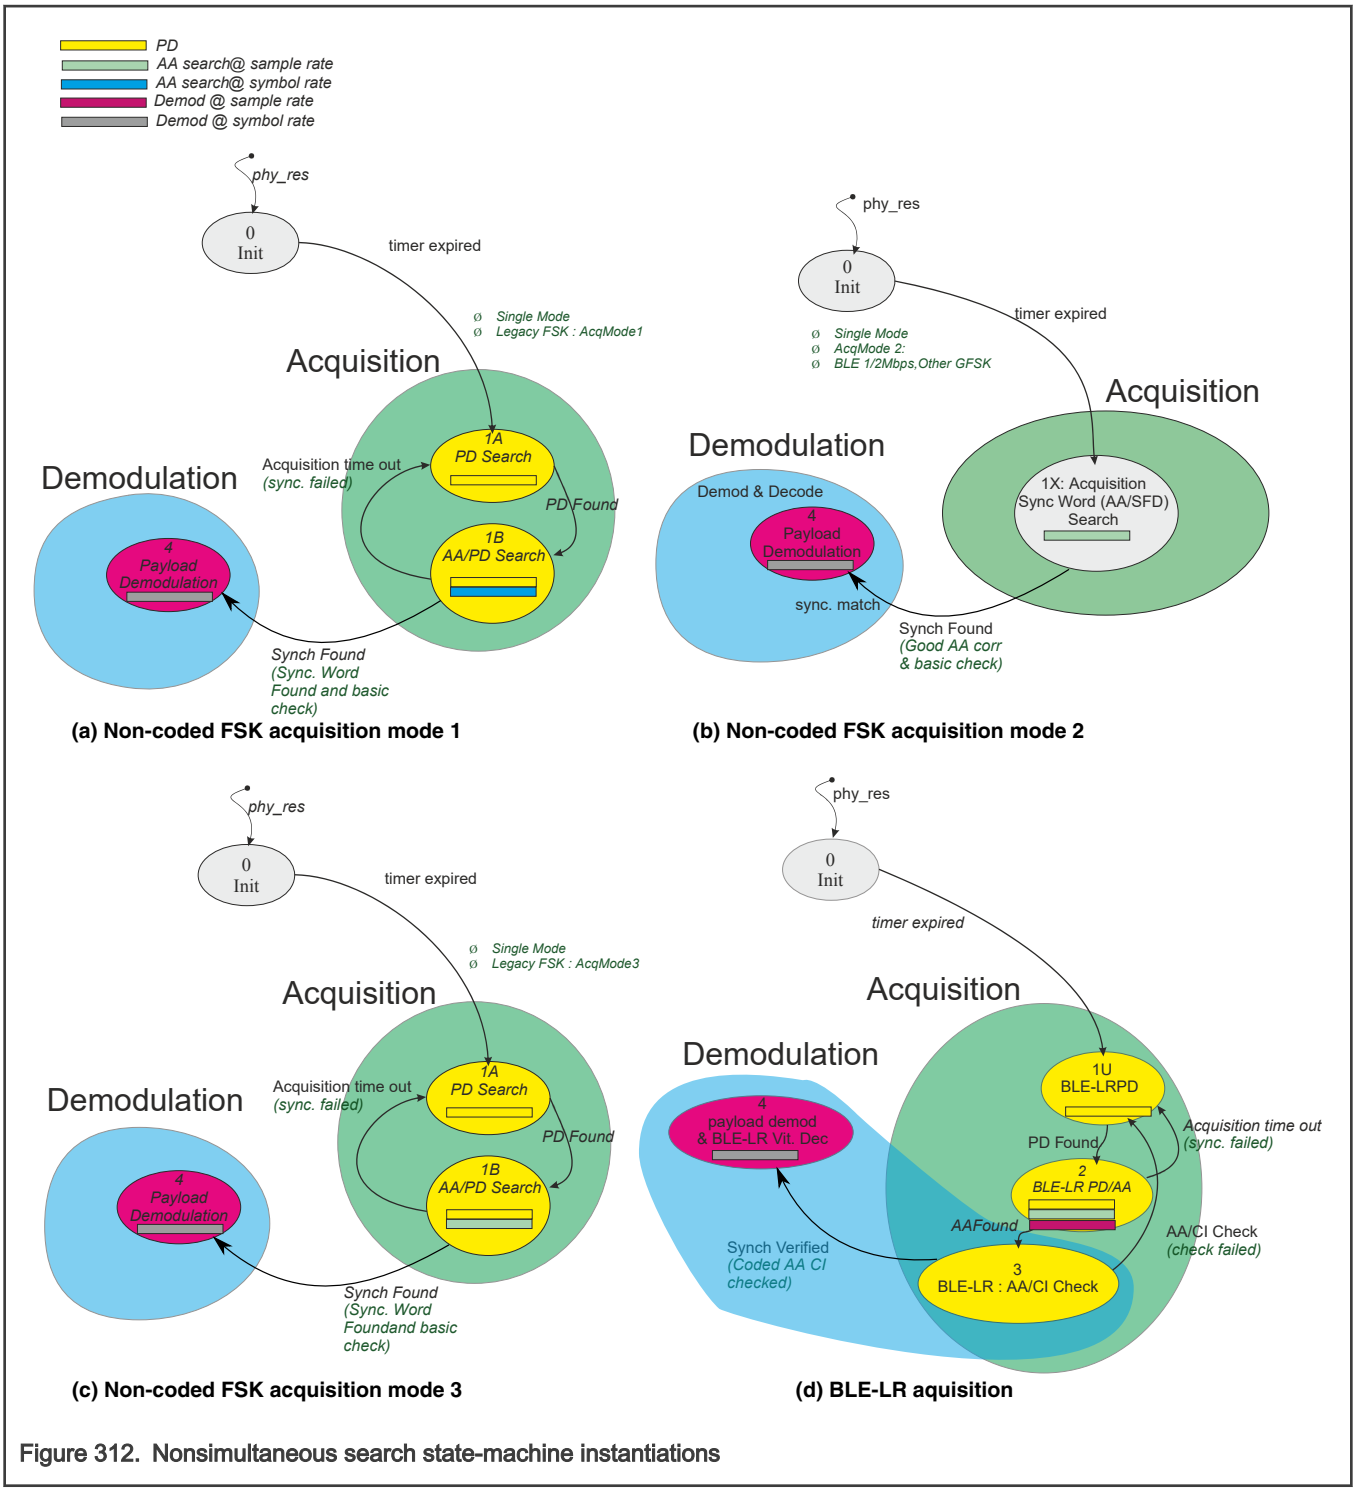

Figure 312. Nonsimultaneous search state-machine instantiations

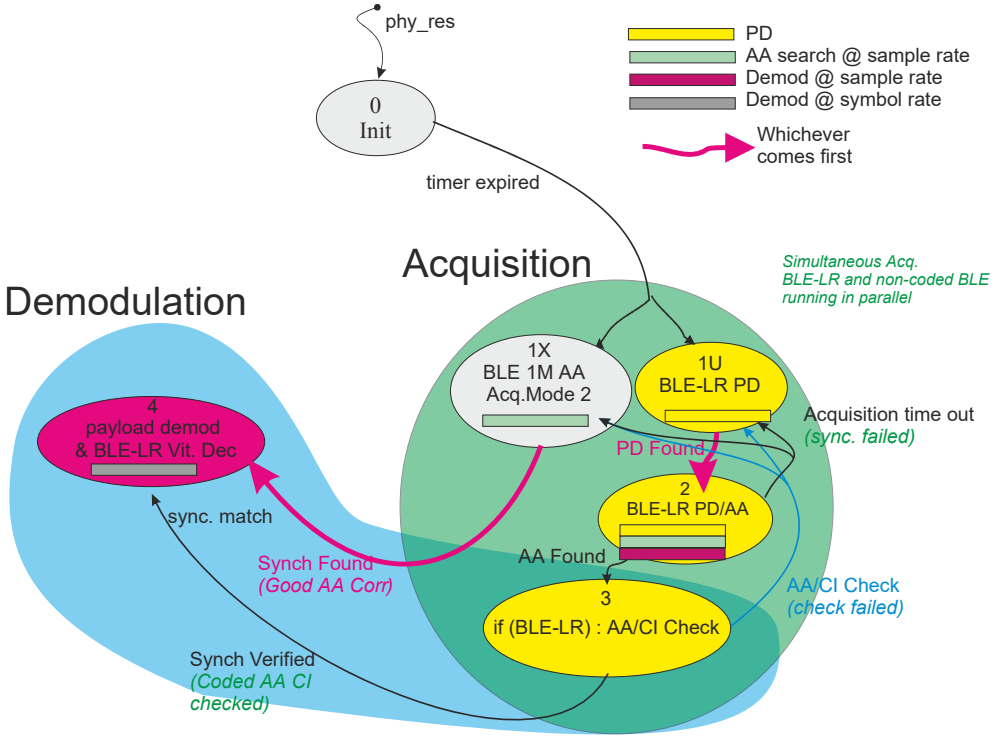
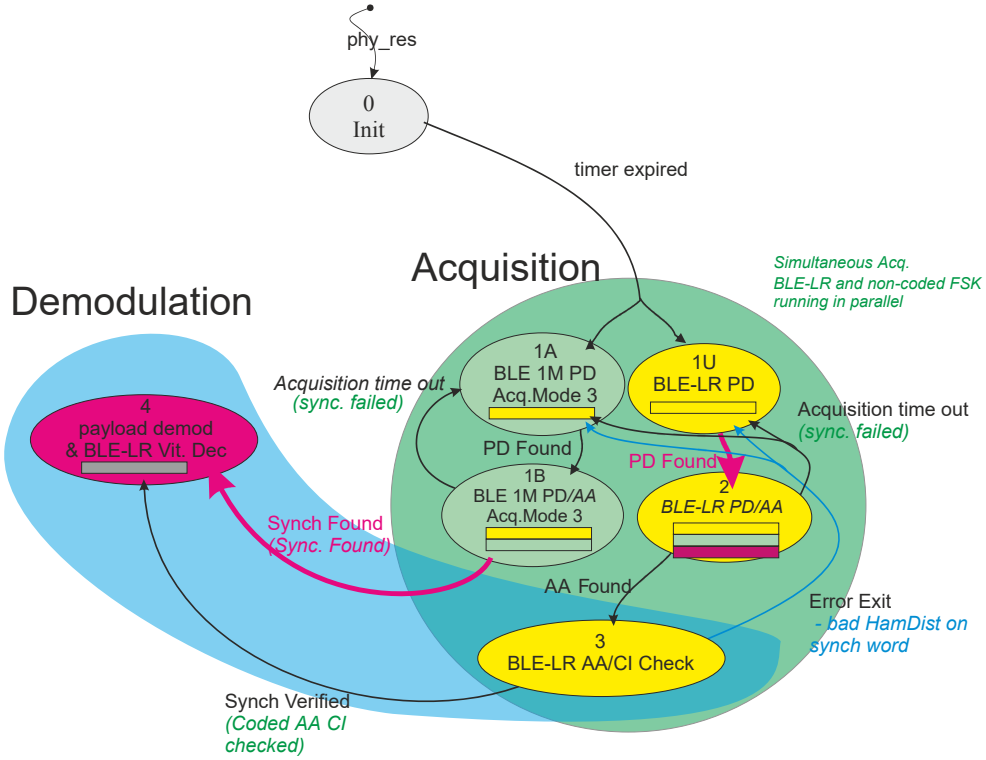
The simultaneous search mode is intended for Bluetooth LE (non-coded or long range) packets. Since the non-coded Bluetooth LE packets have a one octet long preamble, only non-coded acquisition modes 2 and 3 are suitable for the simultaneous search. Figure 313 illustrates the instantiation of the state-machine for simultaneous search of long range Bluetooth LE and non-coded Bluetooth LE 1Mbps in acquisition modes 2 and 3.



(a) Simultaneous BLE-LR and non-coded BLE 1Mbps using acquisition mode 2



(b) Simultaneous BLE-LR and non-coded BLE 1Mbps using acquisition mode 3

Figure 313. Simultaneous search state-machine instantiations

Another aspect of the PHY state machine is the fast antenna diversity (FAD) preamble search feature. FAD is a mechanism that allows antenna selection on the fly. Two antennas and a single receiver chain are used, thus, the receiving chain is used in a time-shared manner. If a detection occurs, the current antenna is immediately selected. FAD involves using the preamble detection mechanism, i.e., one of the two antennas is selected when a preamble is first found. During the FAD process the receiver has to deal with blind spots due to transient behaviour of the different blocks on the receiver chain, so, the preamble must be fairly long to be able to support FAD. The minimal preamble length needed to support FAD depends on a series of factors:

- Receiver latency (without dynamic processes)
- Time required for dynamic control processes (in the sequel AGC only is considered)
- Number of samples needed by the preamble detector to reliably provide detection, timing and CFO estimate

From simulation it has been concluded that the preamble has to be at least 4 octets long. Due to the short preamble portions available for correlation, the FAD feature can only use the preamble detection engine used by acquisition mode 3 in a non-simultaneous search. Note that, the FAD state machine is coded in state 1A, in Figure 312, subfigure (c). A more detailed illustration of the FAD state-machine is provided in Figure 314.

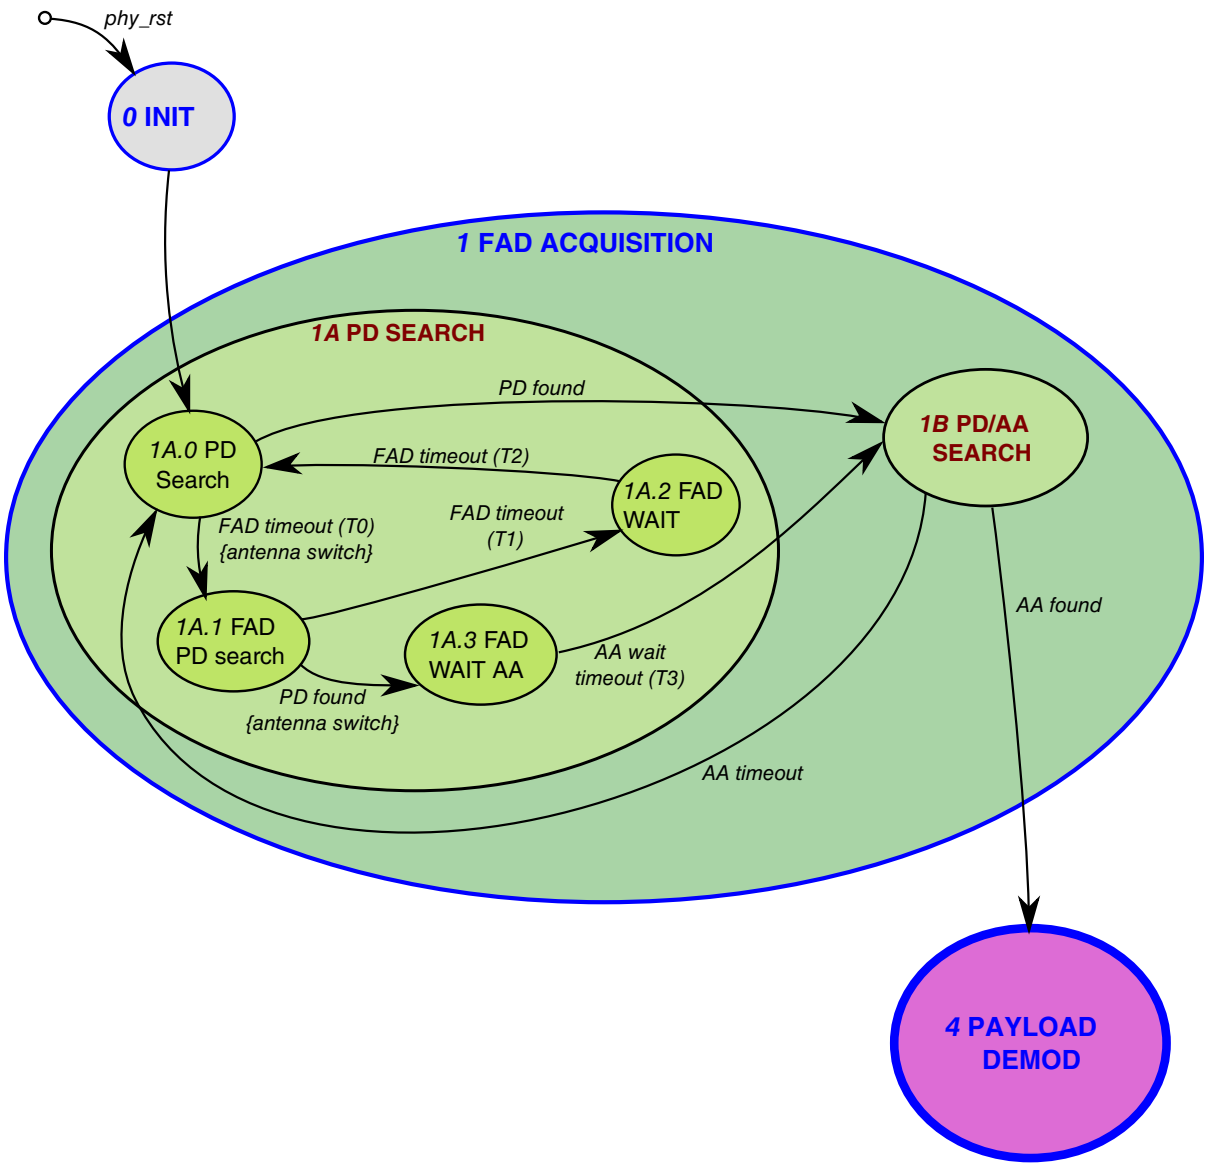


Figure 314. FAD detailed state-machine

The FAD states are:

- FAD sub-state 0 (PD Search)
  - Preamble detection over samples received from the currently selected antenna
    - Note that when the FAD is disabled in acquisition mode 3 this is the only attainable sub-state in "PD search"
- FAD sub-state 1 (FAD PD search)
  - Preamble detection over samples received from the previously selected antenna
    - Note that this is possible due to the propagation latency in the receiver
- FAD sub-state 2 (FAD wait)
  - The state machine waits for transients if a preamble pattern was not detected after antenna switch
- FAD sub-state 3 (FAD wait AA)
  - Before transitioning to AA search PHY state
  - The state machine waits for transients if a preamble pattern was detected after antenna switch

Time constants T_0, T_1 and T_2 from Figure 314 represent the dwell durations the FAD states having the same index and are illustrated in the time diagram from Figure 315. These values are configurable from registers. Figure 315 does not show T_3 because the antenna is not switched after the preamble is found so transition to the PHY state 1B occurs from FAD sub-state 0.

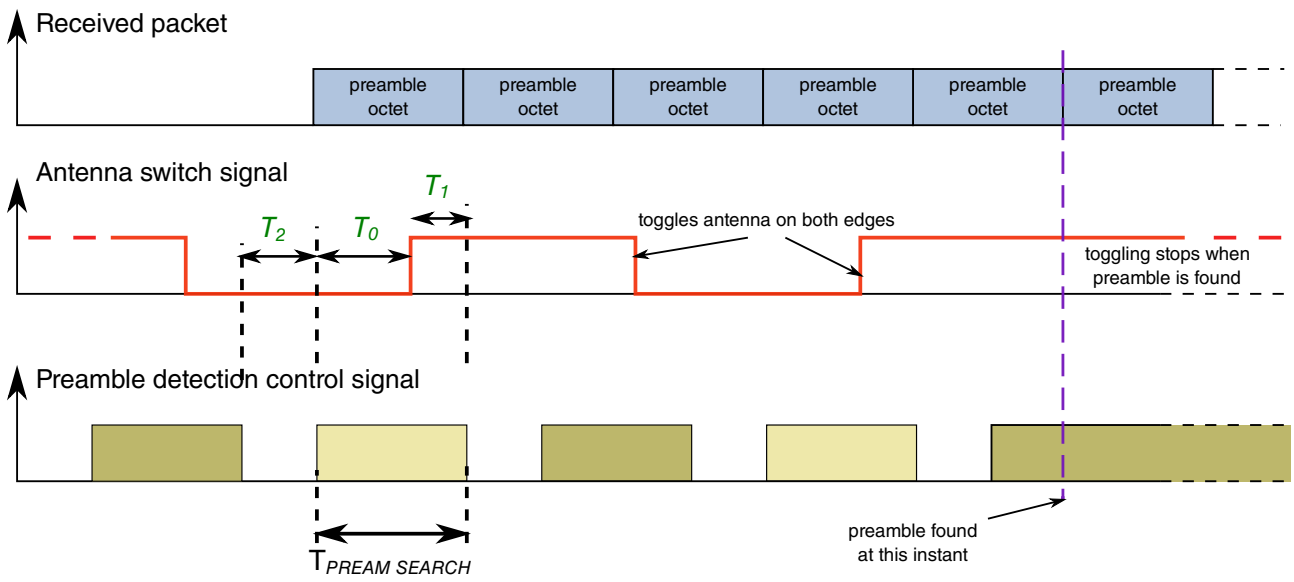

Figure 315. FAD process time diagram

Table 435 presents the recommended settings for FAD.

Table 435. Recommended parameters for FAD

Parameter name	Value
search_pd_window[6:0]	32
fad_search_pd_window[6:0]	12
fad_wait_pd_window[6:0]	12
fad_wait_synch_window[6:0]	12

55.4.7.6.4.3.2 Timing and frequency synchronization

55.4.7.6.4.3.2.1 General description

Figure 316 illustrates the block diagram of the timing/frequency synchronization (acquisition) block. It may be configured to operate in any one of the following three operation modes:

1. Acquisition for non-coded use cases only
2. Acquisition for long range Bluetooth LE only
3. Simultaneous acquisition for non-coded and long range Bluetooth LE use cases

The main inputs to the block are:

1. Wideband phase signal - phase domain signal not compensated for CFO
2. Wideband IQ signal - IQ domain signal not compensated for CFO
3. Narrowband phase signal: phase domain signal compensated for CFO and filtered using the channel filter

Acquisition for non-coded and longe range Bluetooth LE use cases is handled by separate blocks. The *Power Threshold* block provides two outputs that are used by these blocks to:

1. Disqualify any detection events that may occur when the input signal level is below a specified level because they are deemed unreliable
2. Enable Hamming distance check during AA detection when the input signal level is above a specified threshold

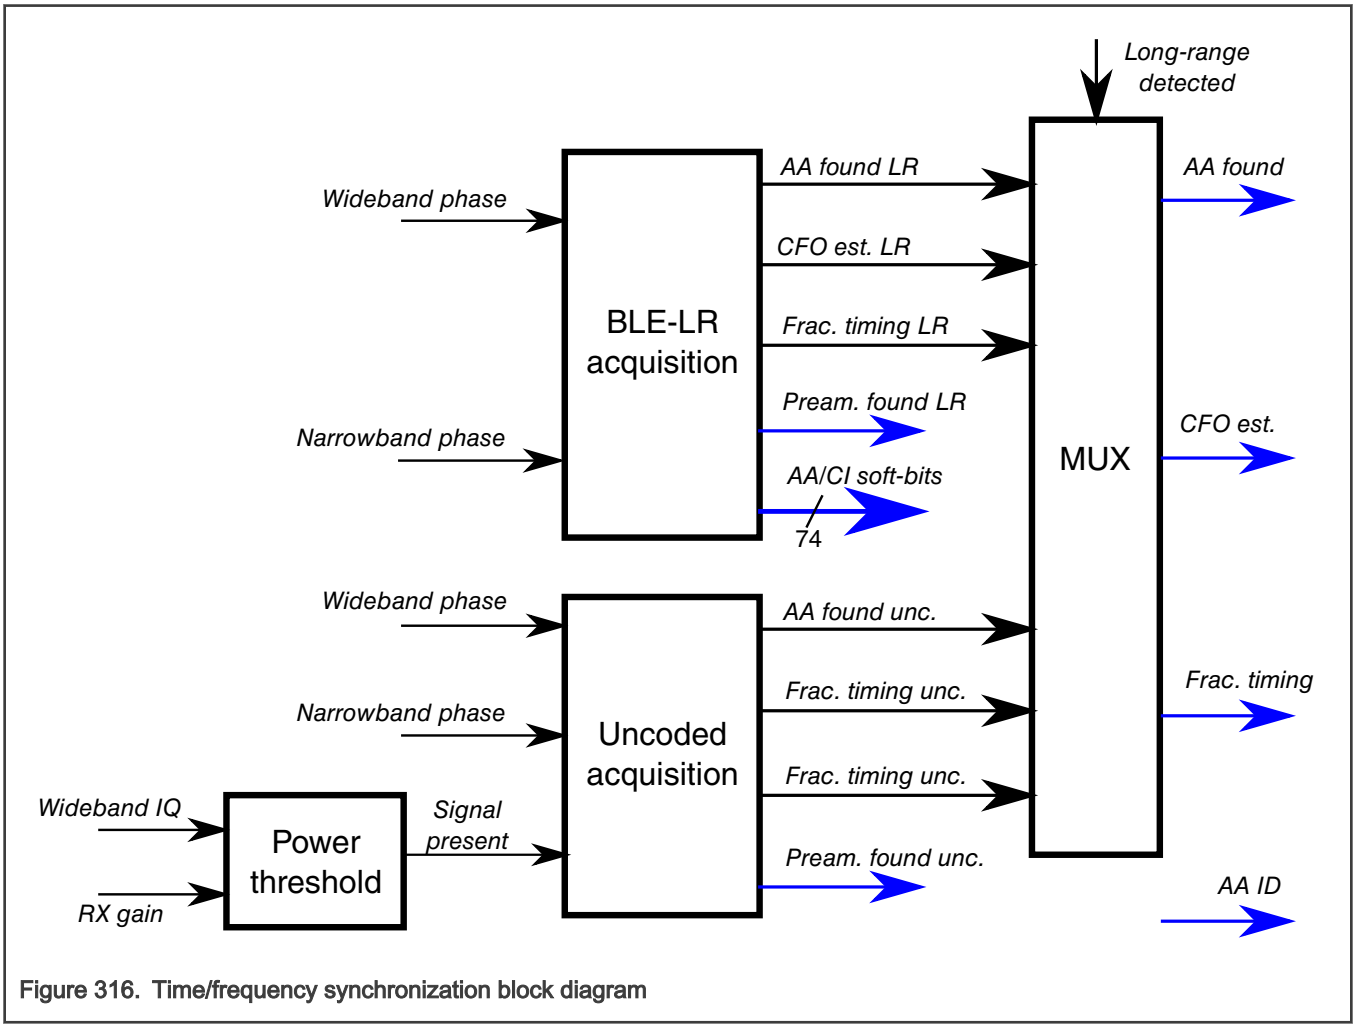

Figure 316. Time/frequency synchronization block diagram

Acquisition for non-coded and longe range Bluetooth LE use cases is described later in this section.

55.4.7.6.4.3.2.2 Acquisition for non-coded use cases

55.4.7.6.4.3.2.2.1 Functional Description

Figure 317 illustrates the three main processing stages involved in the processing of non-coded use cases.

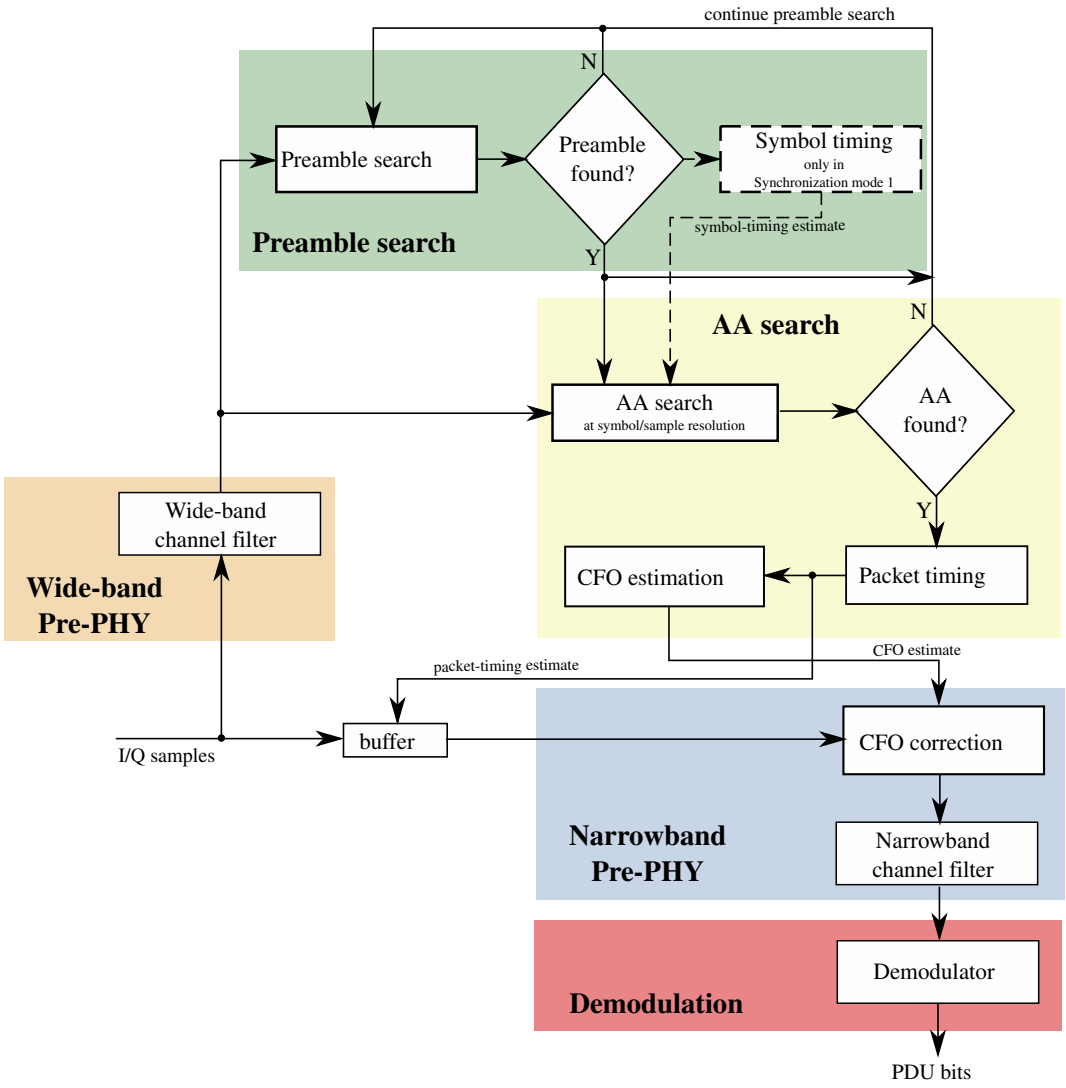

Figure 317. Processing stages of non-coded use cases

55.4.7.6.4.3.2.2.1.1 Preamble detection

During the preamble detection stage, the input phase values are processed to detect the preamble pattern and, if detected, AA search is triggered. No frequency acquisition is performed during this step but a timing estimate may be produced. The process shall continue even after starting AA search and is only terminated when AA is found or if *phy_enable* is de-asserted by the MAC.

55.4.7.6.4.3.2.2.1.2 AA search

During AA search, the PHY searches for one or more AA's to (i) achieve packet timing synchronization, and (ii) produce a CFO estimate. If the preamble detection stage is also active, its symbol timing estimate may be used during this stage to reduce the search complexity. The receiver can simultaneously search for up to four unique AA's of the same size. The number of AA's to be searched and their patterns need to be programmed *a priori* by the MAC.

This stage gets terminated upon either (i) a successful AA detection and synchronization following which the PHY proceeds to the demodulation stage, or (ii) if the *phy_enable* signal is de-asserted by the MAC.

The quality of the timing and CFO estimates obtained from AA search is strongly dependent on the correlation properties of the AA pattern used. So it is important to choose an AA with good correlation properties; refer to AA requirements & guidelines for related notes.

55.4.7.6.4.3.2.2.1.3 Demodulation

During the demodulation stage, using the timing & frequency estimates from the preceding stages, the PHY begins to demodulate the PDU and produces bits which are then sent to the MAC for further processing. In case there is significant timing and/or frequency drift in the PDU, the demodulator can simultaneously perform timing and/or frequency tracking as well.

The demodulator continues its operation until the *phy_enable* signal is de-asserted by the MAC.

55.4.7.6.4.3.2.2.2 AA requirements & guidelines

To ensure good synchronization performance, it is important that the AA used during the connection possesses good auto-correlation and cross-correlation properties. In general terms, if the auto-correlation of a candidate AA pattern, for a non-zero lag, exceeds a pre-defined threshold, then it should not be used. A suggested threshold value is 0.40 but recommended to be no more than 0.50.

For AA's of sizes 3 and 4 octets and For AA's of sizes 1 and 2 octets list some requirements which will reduce the likelihood of generating a candidate AA with poor auto-correlation properties.

55.4.7.6.4.3.2.2.2.1 For AA's of sizes 3 and 4 octets

The following requirements applicable to AA's of sizes 3 and 4 octets are adopted from Bluetooth specification v5.2; vol 6, part B.

The AA shall:

1. have no more than six consecutive 0's or 1's.
2. not be the advertising channel packet's AA.
3. not be a sequence that differs from the advertising channel packet's AA by only one bit.
4. not have all octets identical.
5. have no more than:
   - twenty-four bit transitions in case of 4-octet AA's.
   - eighteen bit transitions in case of 3-octet AA's.
6. have a minimum of two transitions in the most significant six bits.

The following additional requirements ensure better synchronization performance. Each AA shall:

1. contain no more than two contiguous instances of a bit sequence of length seven or more bits.
2. not contain two instances of a bit sequence, contiguous or otherwise, of length
   - thirteen or more bits in case of 4-octet AA's.
   - ten or more bits in case of 3-octet AA's.
3. have no more than four consecutive 0's or 1's within the least significant octet.
4. have no more than 6 transitions in the least significant octet.
5. have at least one transition in the most significant four bits.

55.4.7.6.4.3.2.2.2.2 For AA's of sizes 1 and 2 octets

Below are the requirements applicable to AA's of sizes 1 and 2 octets. Each AA shall:

1. have no more than four consecutive 0's or 1's.
2. not be the advertising channel packet's AA.
3. not be a sequence that differs from the advertising channel packet's AA by only one bit.

4. in case of 2 octets AA's, the two octets shall not be identical.
5. have no more than:
   - eleven bit transitions in case of 2-octet AA's.
   - five bit transitions in case of 1-octet AA's.
6. have a minimum of two transitions in the most significant four bits.
7. contain no more than two contiguous instances of a bit sequence of length five or more bits (not applicable to 1-octet AA's).
8. not contain two instances of a bit sequence, contiguous or otherwise, of length:
   - six or more bits in case of 2-octet AA's.
   - four bits in case of 3-octet AA's.
9. have no more than three consecutive 0's or 1's within the least significant octet.
10. no more than 6 transitions in the least significant octet.

55.4.7.6.4.3.2.2.3 Synchronization for non-coded use cases

For non-coded use cases, three different modes of synchronization are provided to support the general packet structure. Each mode involves one or two of the following three processes.

1. Correlation-based preamble detection in frequency-domain (Freq-PD)
2. Correlation-based preamble detection in phase-domain (Phase-PD)
3. Correlation-based AA detection (AAD)

55.4.7.6.4.3.2.2.3.1 Synchronization modes - functional description, state machines and implementation

55.4.7.6.4.3.2.2.3.1.1 Synchronization mode 1

In ACQ mode 1, the Freq-PD and AAD processes are used to achieve synchronization. This mode is only useful, and is especially recommended, when a long preamble is available because it can significantly reduce power consumption.

55.4.7.6.4.3.2.2.3.1.1.1 Functional description

Figure 318 shows a functional block diagram of the PHY in mode 1. First, the preamble is searched in the frequency-domain (*i.e.*, using phase-discriminated inputs) and when detected, a symbol-timing estimate is produced. The symbol-timing estimate is then used to begin AA search at symbol resolution thereby achieving significant reduction in computational complexity compared to searching the AA at sample resolution. Upon detecting an AA, an AA-based CFO estimate and a packet-timing estimate are generated.

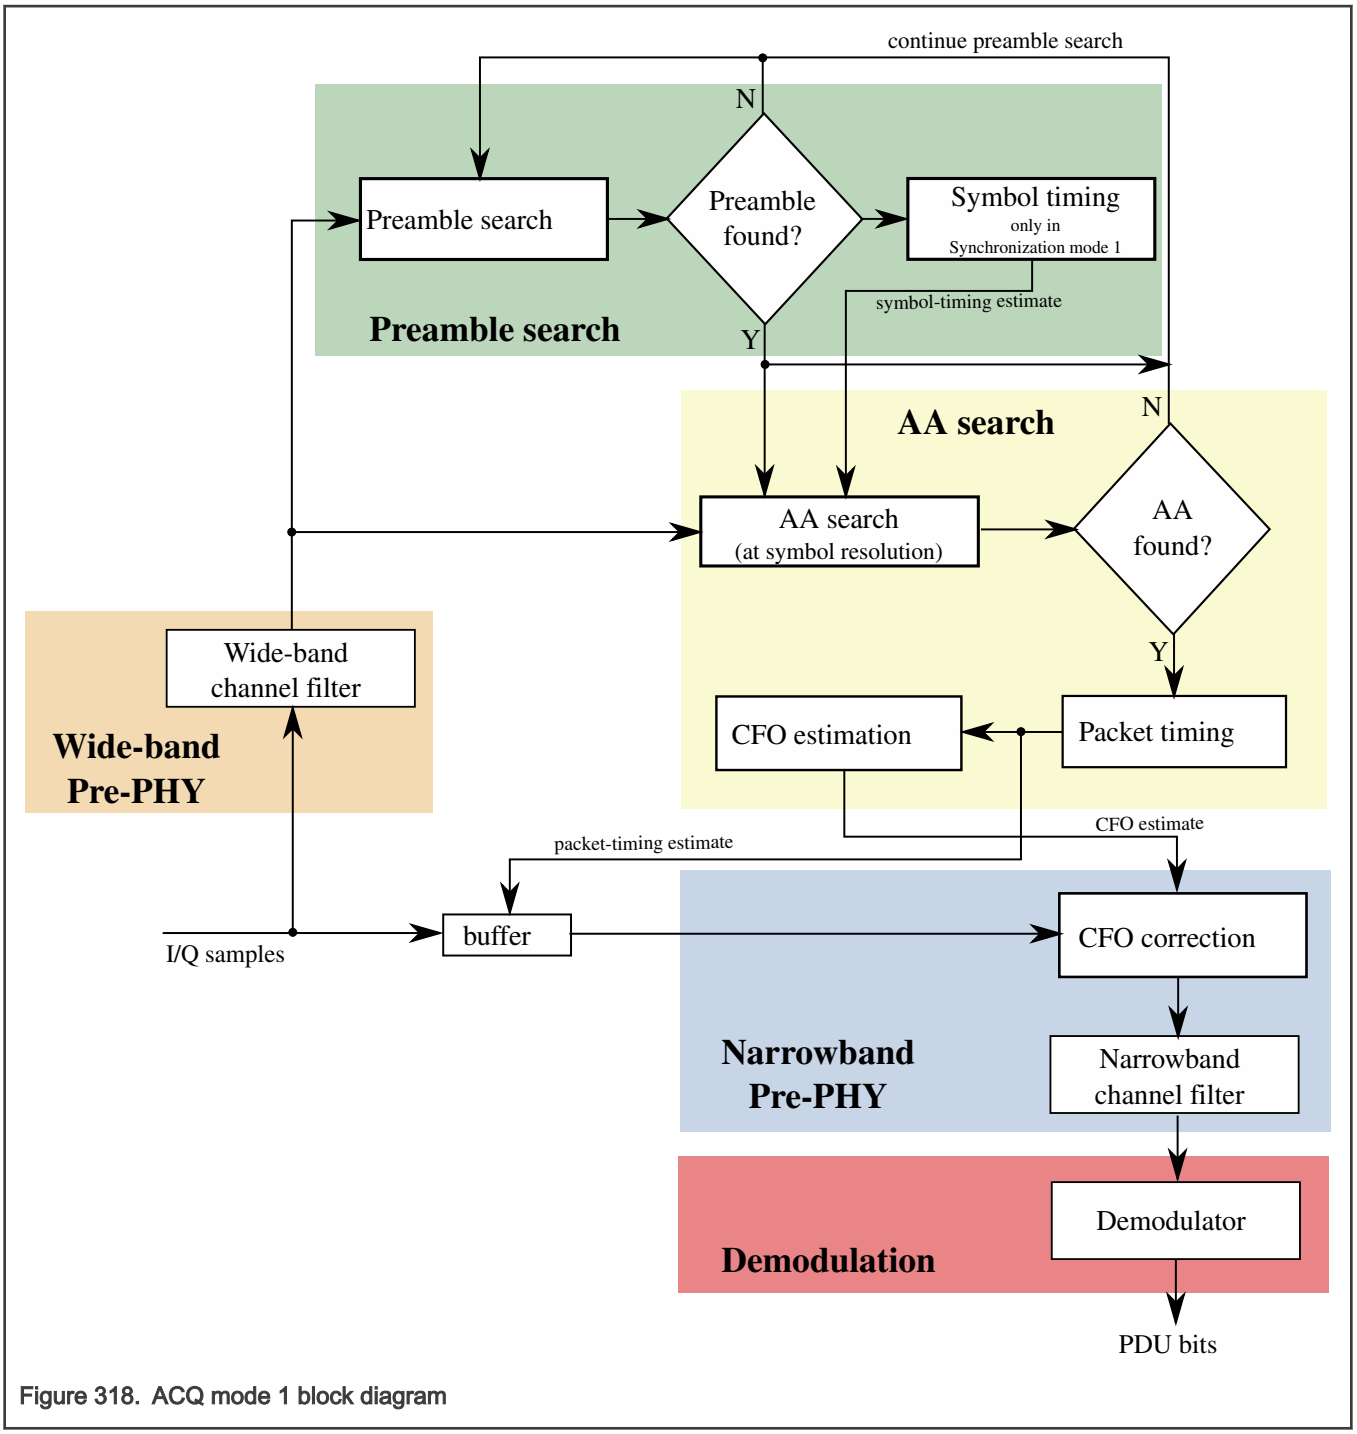

Figure 318. ACQ mode 1 block diagram

55.4.7.6.4.3.2.2.3.1.1.2 State machine

Figure 312 shows the state-machine of the PHY operating in mode 1.

55.4.7.6.4.3.2.2.3.1.2 Synchronization mode 2

In ACQ mode 2, only the AAD process is used to achieve synchronization. This ACQ mode may be used regardless of the length of the preamble but is recommended only when the preamble is short.

55.4.7.6.4.3.2.2.3.1.2.1 Functional description

Figure 319 shows a functional block diagram of the PHY in ACQ mode 2. The receiver begins searching for the AA and, upon detection, produces packet-timing and CFO estimates.

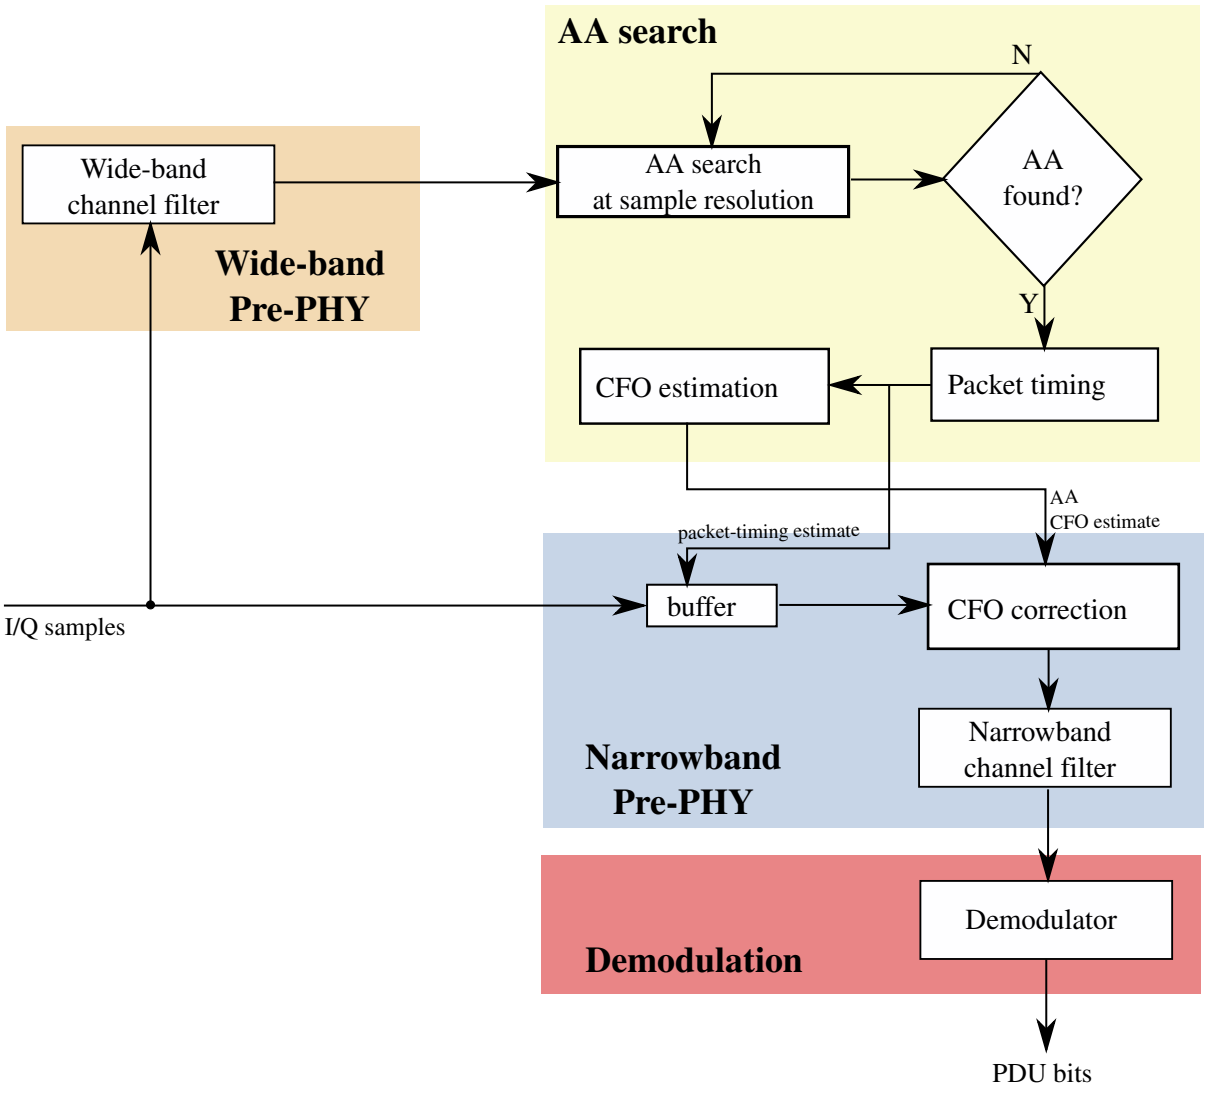

Figure 319. ACQ mode 2 block diagram

55.4.7.6.4.3.2.2.3.1.2.2 State machine

Figure 312 shows the state-machine of the PHY operating in mode 2.

55.4.7.6.4.3.2.2.3.1.3 Synchronization mode 3

In ACQ mode 3, the Phase-PD and AAD processes are used to achieve synchronization. But , unlike ACQ mode 1, this mode can be used when the preamble is short to quickly detect the arrival of a packet.

55.4.7.6.4.3.2.2.3.1.3.1 Functional description

Figure 320 shows a functional block diagram of the PHY in ACQ mode 3. First, the preamble is searched to identify the presence of a packet on the air but no timing or CFO estimate is generated. Like ACQ mode 2, the AA is searched at sample resolution and upon detecting an AA, an AA-based CFO estimate and a packet-timing estimate are generated.

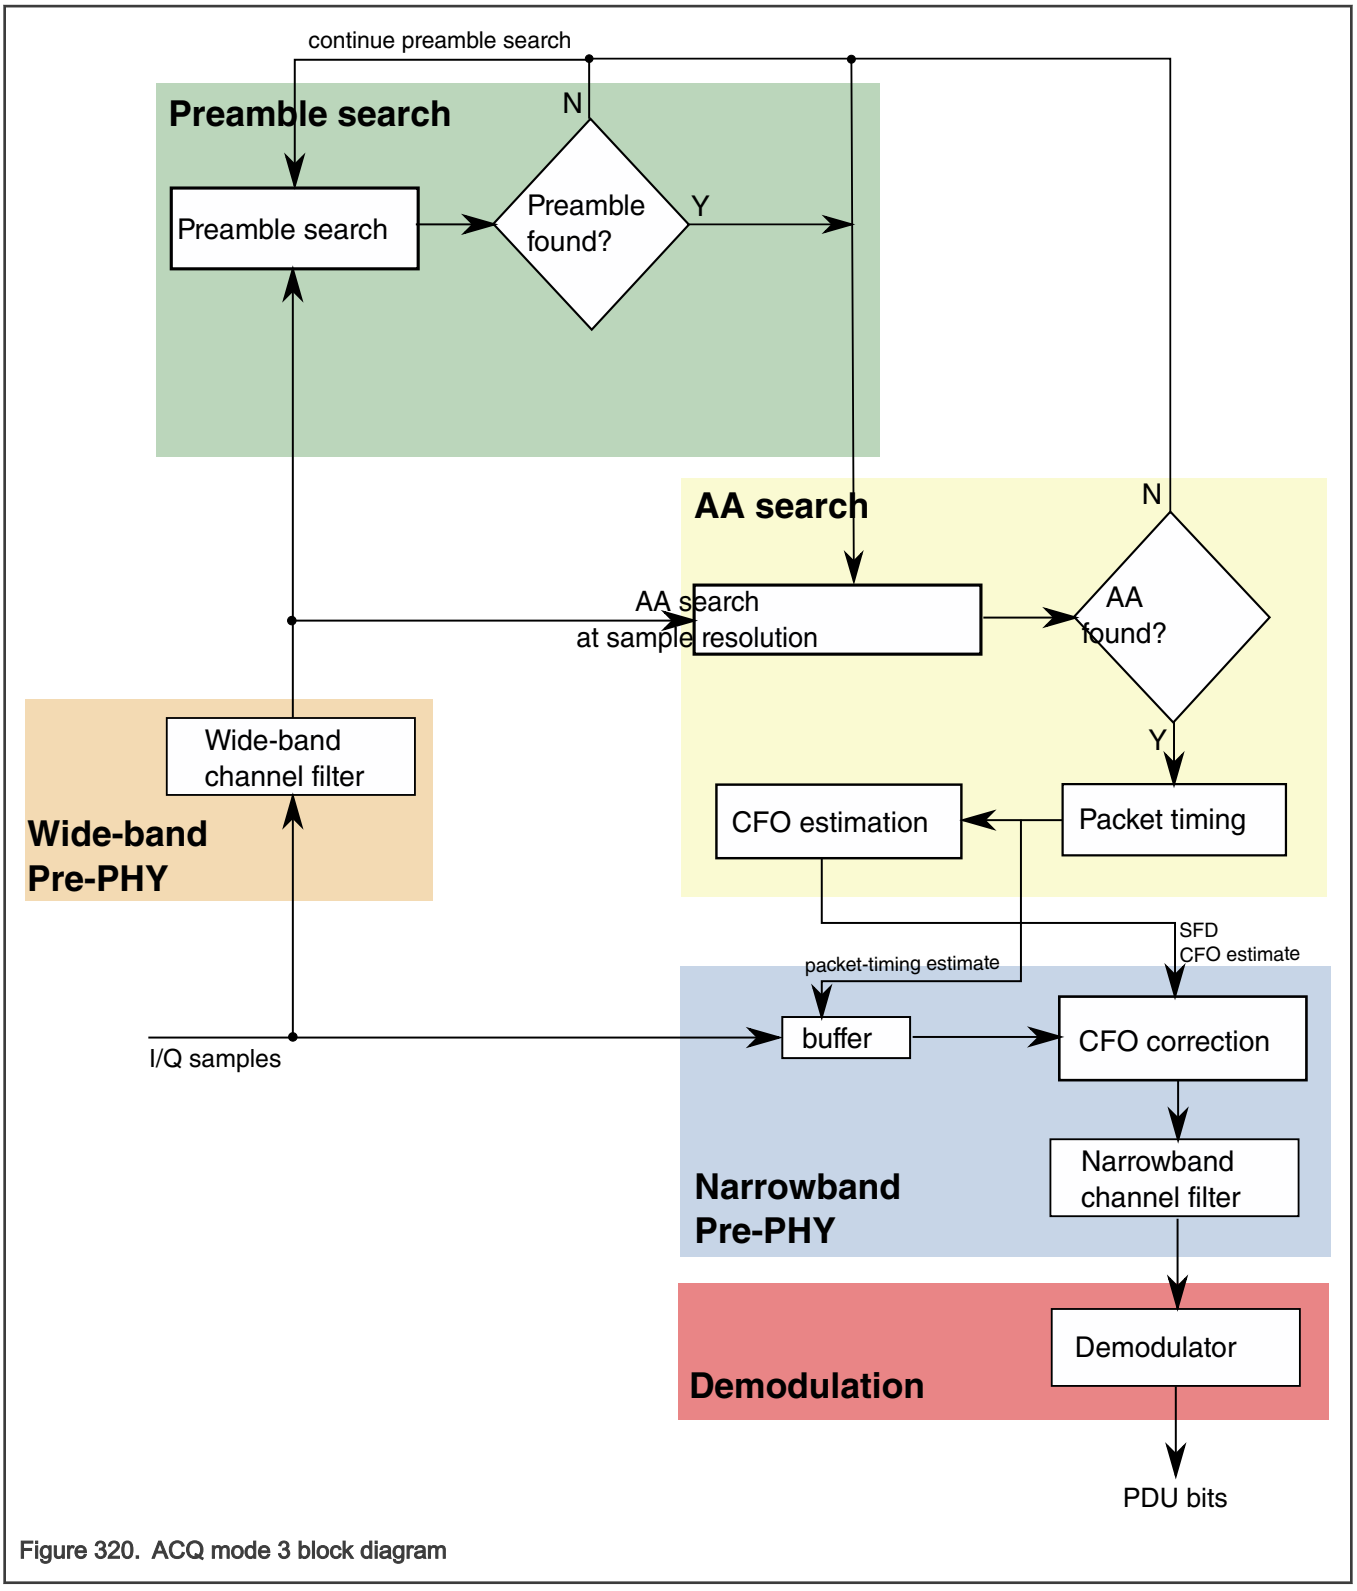

Figure 320. ACQ mode 3 block diagram

55.4.7.6.4.3.2.2.3.1.3.2 State machine

Figure 312 shows the state-machine of the PHY operating in mode 3.

55.4.7.6.4.3.2.2.3.2 Main component blocks

This section presents the details of the main component blocks used as the building blocks for realizing the various ACQ modes. There are six of them as listed below.

1. Power threshold
2. Pre-processor
3. Freq-PD preamble search engine
4. Phase-PD preamble search engine
5. AA search engine
6. Interpolator

55.4.7.6.4.3.2.2.3.2.1 Power threshold

The purpose of this block is to help avoid false preamble/AA detections in the respective search engines when the input signal is purely noise. The fixed-point formats of the block's inputs as well as those used at each internal stage are shown within parentheses.

It measures the input signal magnitude by passing the received I/Q samples through a single-pole IIR filter whose forgetting factor, α, is programmable. This magnitude is compared against two input thresholds - a low power threshold and a high power threshold which are both expected to be adjusted based on the AGC gain setting and the associated NF. If the measured signal magnitude is not less than the low threshold, then the boolean output *signal_present_low* gets asserted; if it is also not less than the high threshold, then both the boolean outputs, *signal_present_low* and *signal_present_high*, get asserted.

The block may alternatively use the narrowband RSSI measured by the RxDIG instead of the signal magnitude computed internally for comparing against the low and high power thresholds. This behavior is configurable through the input parameter BypassWithRSSI.

55.4.7.6.4.3.2.2.3.2.1.1 Register parameters

Table 436 lists the register parameters used by the power threshold block.

Table 436. Registers used by the power threshold block

Parameter	Notes
mag_window[3:0]	Indicates the forgetting factor used in received signal level measurement; forgetting factor used is 2^{-mag_window}. Note that *mag_window* values higher than 8 are not typically used.
pow_th_low[10:0]	Low power threshold specifies a power level below which the signal is considered too weak for reliable aquisition; uses (0,11,11) fixed-point format.
pow_th_high[10:0]	High power threshold specifies a power level above which the signal is considered strong enough that a stricter Hamming tolerance may be applied during acquisition; uses (0,11,11) fixed-point format.
bypass_with_rssi	Bypass signal power measurement with RSSI measurement; 0→no, 1→yes.
cond_sig_prst_enable	Enables special conditioning of signal power detection in the Power threshold block; 0→disable, 1→enable.

55.4.7.6.4.3.2.2.3.2.2 Pre-processor

It is used as the first step, in both Freq-PD and AAD processes, to pre-process the input I/Q samples and its output is then passed on to the respective search block.

55.4.7.6.4.3.2.2.3.2.2.1 Register parameters

Table 437 lists the only register parameter used by the pre-processor. It is used to obtain *1/2h* in the appropriate fixed-point format for providing as input to the pre-processor.

Table 437. Registers used by the pre-processor

Parameter	Notes
recip_mod_idx[8:0]	Reciprocal of modulation index; represented in (0,9,7) format.

55.4.7.6.4.3.2.2.3.2.3 Freq-PD preamble search engine

A block diagram of the Freq-PD preamble search engine is shown in Figure 321. It is used for correlation-based preamble detection in the frequency-domain. The fixed-point formats used at various internal points are also shown within parentheses.

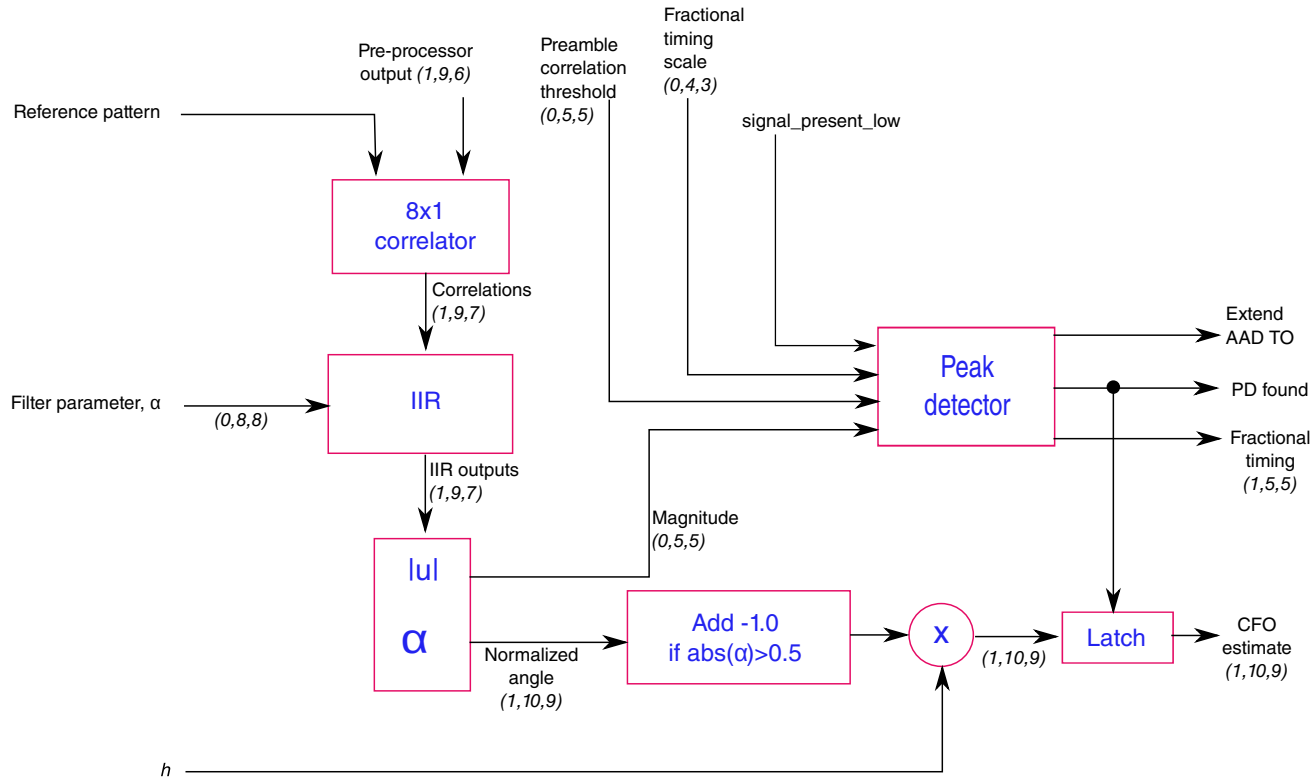

Figure 321. Freq-PD preamble search engine

An 8x1 binary reference pattern along with the pre-processor output phase values is provided as input to the engine. In the first step, each phase value is converted into its equivalent I/Q sample of unit magnitude and a correlation is performed between the I/Q values thus obtained and the reference pattern. The resultant complex correlation values are then passed through a single-pole IIR filter. The outputs of the IIR filter are long-term averages of its inputs and, therefore, are roughly equivalent to much longer correlations. Next, the magnitudes and angles of the complex IIR outputs are obtained using LUTs and passed to the timing detection and CFO estimation circuits respectively.

55.4.7.6.4.3.2.2.3.2.3.1 Register parameters

Table 438 lists the register parameters used by the preamble search engine.

Table 438. Registers used by the Freq-PD preamble search engine

Parameter	Notes
preamble_pattern[7:0]	8-bit preamble pattern used in FM-domain preamble detector.

Table continues on the next page...

Table 438. Registers used by the Freq-PD preamble search engine (continued)

Parameter	Notes
preamble_thresh[7:0]	Correlation threshold applicable to preamble detection; uses (0,5,5) fixed-point format which gets written in (0,8,8) format by zeroing out the LSB's.
preamble_frac_time_scale[3:0]	Scaling factor used for fractional time estimation during preamble search; represented in (0,4,3) format.
iir_alpha[7:0]	IIR filter parameter used during preamble detection; represented in (0,8,8) format.
mod_idx[10:0]	Modulation index; represented in (0,11,7) format.

Table 439 lists a suggested preamble correlation threshold value for each non-coded use case listed in Table 434. The values are applicable to ACQ mode 1 but it should be noted that they were optimized for the specific preamble length of 8 octets and, therefore, may need to be adjusted if a different preamble length is used.

Table 439. Suggested Freq-PD correlation thresholds for ACQ mode 1

Use case	Preamble threshold (fraction)	*preamble_thresh[7:0]* (hexadecimal notation)
Bluetooth LE	12/32	0x60
GFSK_05_07-500	14/32	0x70
GFSK_03_05-1000	12/32	0x60
MSK_05-500	10/32	0x50
GFSK_05_05-250	12/32	0x60
GFSK_05_10-250	16/32	0x80
GFSK_07_05-1000	16/32	0x80
GFSK_05_05-2000	16/32	0x80
MSK_05-250	14/32	0x70
GFSK_05_032-2000	16/32	0x80
FSK_05-500	10/32	0x50

Table 440 lists a suggested value for *preamble_frac_time_scale* applicable to all non_coded use cases. The length of the preamble does not influence this parameter and so the suggested value is applicable regardless of the preamble length.

Table 440. Suggested Freq-PD fractional timing scale for ACQ mode 1

Use case	Preamble frational timing scale (decimal)	*preamble_frac_time_scale[3:0]* (hexadecimal notation)
All use cases	1.50	0xC

Table 441 lists a suggested value for *iir_alpha* for each non-coded use case listed in Table 434. It was optimized for a preamble length of 8 octets and may need to be adjusted if the preamble length is different.

Table 441. Suggested Freq-PD IIR forgetting factor for ACQ mode 1

Use case	IIR parameter, α (fraction)	*iir_alpha[7:0]* (hexadecimal notation)
Bluetooth LE	6/32	0x30
GFSK_05_07-500	6/32	0x30
GFSK_03_05-1000	4/32	0x20
MSK_05-500	3/32	0x18
GFSK_05_05-250	6/32	0x30
GFSK_05_10-250	4/32	0x20
GFSK_07_05-1000	6/32	0x30
GFSK_05_05-2000	6/32	0x30
MSK_05-250	6/32	0x30
GFSK_05_032-2000	6/32	0x30
FSK_05-500	3/32	0x18

55.4.7.6.4.3.2.2.3.2.4 Phase-PD preamble search engine

A block diagram of the Phase-PD preamble search engine is shown in Figure 322. It is used for correlation-based preamble detection in the phase-domain. The fixed-point formats used at various internal points are also shown in the diagram.

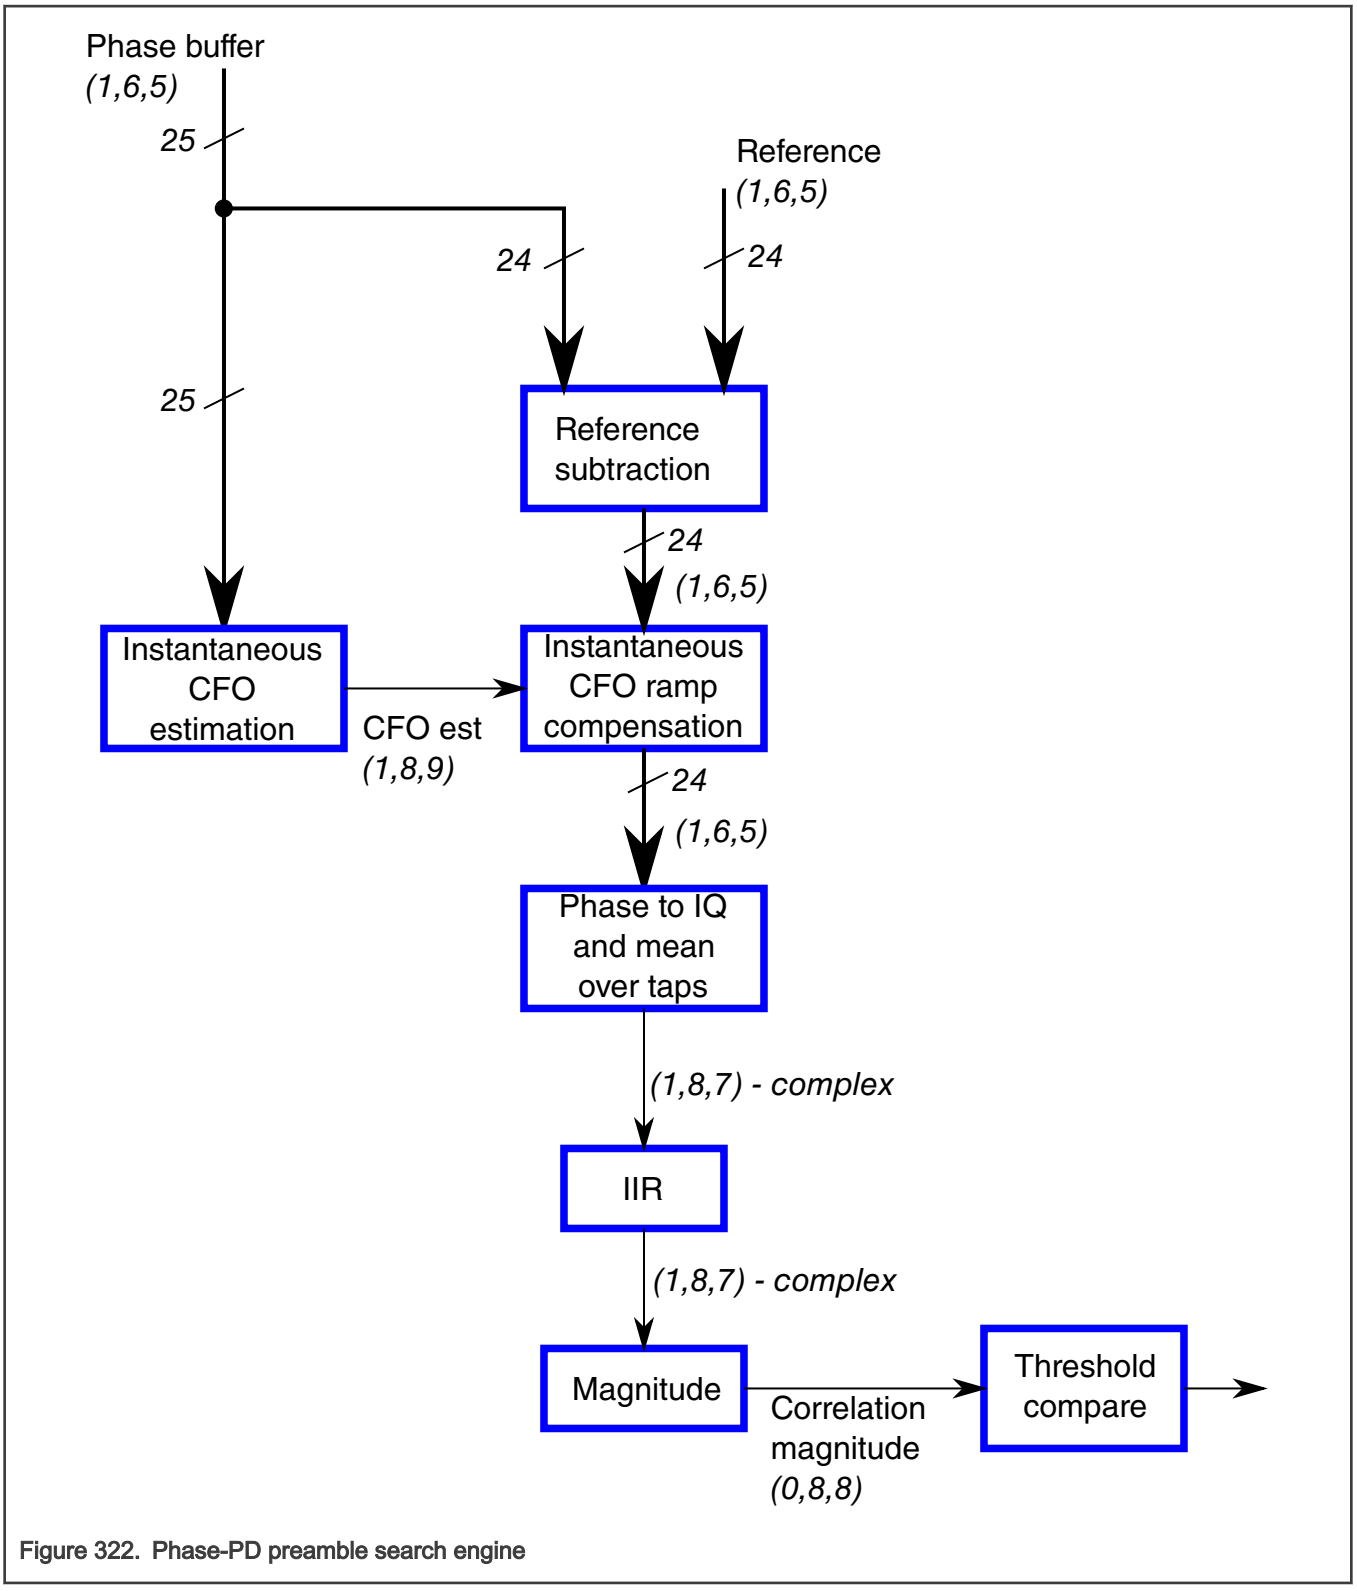

Figure 322. Phase-PD preamble search engine

An 24x1 phase-domain reference pattern along with the pre-processor output phase values is provided as input to the engine. Since the 24x1 vector is periodic with an 8x1 vector repeating three times, only 8 values need to be programmed, as shown in Table 442, in order to save register space. To be able to properly perform phase-domain correlation the phase ramp caused by CFO has to be compensated. In order to achieve that, an instantaneous CFO estimate is computed, by averaging differences between consecutive values in the phase buffer, and all correlation taps are simultaneously compensated by reconstructing the

ramp based upon the estimated CFO. As shown in Figure 322, the CFO is estimated on the input phase vector after the reference is subtracted. After the CFO compensation the phase values are converted to complex values and the taps are averaged over, thus transforming the vector input to a scalar ouput. An IIR can be optionally used, to average the complex correlation values, if preamble is longer. However it is expected that, for the use cases that use acquisition mode 3, the IIR will be bypassed.

Finally the complex correlation values are converted to real values through absolute operation ("Magitude" block) and compared with a threshold. Given the intrinsic behavior of the phase-domain correlator to output a large correlation magnitude when the buffer is filled with zeros (this happens when the preable detector is being reset), a timer is used to gate the output of the block untill the buffer gets filled with non-zeros samples.

55.4.7.6.4.3.2.2.3.2.4.1 Register parameters

Table 442 lists the register parameters used by the preamble search engine.

Table 442. Registers used by the Phase-PD search engine

Parameter	Notes
preamble_pattern[47:0]	8 reference phase values, 6-bits each; uses (1,6,5) fixed-point format.
preamble_thresh[7:0]	Correlation threshold applicable to preamble detection; uses (0,8,8) fixed-point format.
iir_alpha[7:0]	IIR filter parameter used during preamble detection; represented in (0,8,8) format.

Table 439 lists a suggested preamble correlation threshold value for each non-coded use case listed in Table 434.

Table 443. Suggested Phase-PD preamble correlation thresholds for ACQ mode 3

Use case	Preamble threshold (fraction)	*preamble_thresh[7:0]* (hexadecimal notation)
Bluetooth LE	246/256	0xF6
GFSK_05_07-500	215/256	0xD7
GFSK_03_05-1000	246/256	0xF6
MSK_05-500	240/256	0xF0

55.4.7.6.4.3.2.2.3.2.5 AA search engine

A block diagram of the AA search engine is shown in Figure 323. It is used for correlation-based AA detection in AAD. The fixed-point formats used at various stages are also shown within parentheses in the diagram.

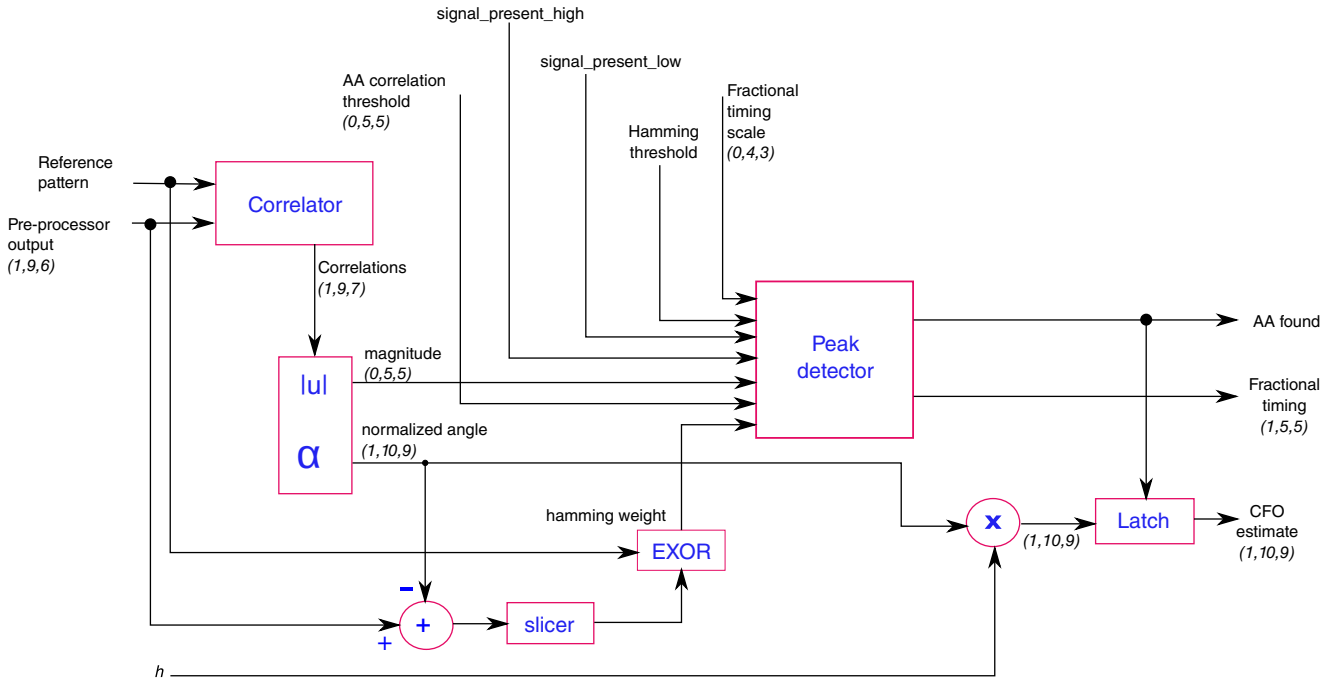

Figure 323. AA search engine

A binary AA reference pattern, along with the pre-processor output phase values, is provided as input to the engine. In the first step, each phase value is converted into its equivalent I/Q sample of unit magnitude and a correlation is performed between the I/Q values thus obtained and the reference pattern. Next, the magnitudes and angles of the complex correlations are obtained using LUTs and passed to the peak detector and CFO estimation circuits respectively. In addition, a hamming weight is also computed between

1. the reference pattern, and
2. the pre-processor output vector (corresponding to the current correlation) after removing the bias due to CFO.

55.4.7.6.4.3.2.2.3.2.5.1 Register parameters

Table 446 lists the register parameters used by the AA search engine.

Table 446. Registers used by the AA search engine

Parameter	Notes
aa_0[31:0]	AA pattern of length 1, 2, 3 or 4 octets used for AA search in ACQ path 0; 1, 2 and 3 octet patterns in bits [7:0], [15:0] and [23:0] respectively.
aa_1[31:0]	AA pattern of length 1, 2, 3 or 4 octets used for AA search in ACQ path 1; 1, 2 and 3 octet patterns in bits [7:0], [15:0] and [23:0] respectively.
aa_2[31:0]	AA pattern of length 1, 2, 3 or 4 octets used for AA search in ACQ path 2; 1, 2 and 3 octet patterns in bits [7:0], [15:0] and [23:0] respectively.
aa_3[31:0]	AA pattern of length 1, 2, 3 or 4 octets used for AA search in ACQ path 3; 1, 2 and 3 octet patterns in bits [7:0], [15:0] and [23:0] respectively.
size_aa[1:0]	Indicates length of active AA's; 0→1 octet, 1→2 octets, 2→3 octets, 3→4 octets.
aa_thresh[4:0]	Correlation threshold applicable to AA detection; uses (0,5,5) fixed-point format.
aa_frac_time_scale[3:0]	Scaling factor used for fractional time estimation during AA search; represented in (0,4,3) format.
search_aa_0	Indicates whether aa_0 should be searched during acquisition; 0→no, 1→yes.
search_aa_1	Indicates whether aa_1 should be searched during acquisition; 0→no, 1→yes.
search_aa_2	Indicates whether aa_2 should be searched during acquisition; 0→no, 1→yes.
search_aa_3	Indicates whether aa_3 should be searched during acquisition; 0→no, 1→yes.
hamming_aa_high_pwr[2:0]	Maximum hamming distance from the given AA pattern that may still be accepted as a match; valid range is [0,7].
hamming_aa_low_pwr[3:0]	Hamming distance tolerance applicable around sensitivity and at low power levels during AA detection; valid range is [0,15].
mod_idx[10:0]	Modulation index; represented in (0,11,7) format.

Table 447 lists the suggested AA correlation threshold values for ACQ modes 2 & 3 while Table 448 lists suggested AA correlation threshold values for ACQ mode 1 for the non-coded use cases listed in Table 434. Note that they are not influenced by the length of the preamble.

Table 447. Suggested AA correlation thresholds for ACQ modes 2 & 3

Use case	AA threshold (fraction)	*aa_thresh[4:0]* (hexadecimal notation)
Bluetooth LE	19/32	0x13
GFSK_05_07-500	16/32	0x10
GFSK_03_05-1000	15/32	0x0F

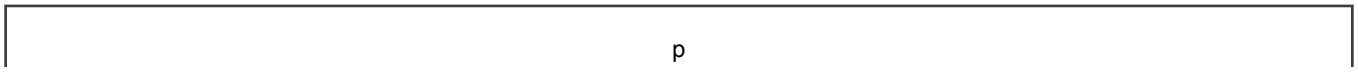
55.4.7.6.4.3.2.2.3.2.6 Interpolator

A block diagram of the interpolator is shown in Figure 324. It is only used in ACQ mode 1 for interpolation in AAD. The fixed-point formats used at various internal stages are also shown within parentheses in the diagram.



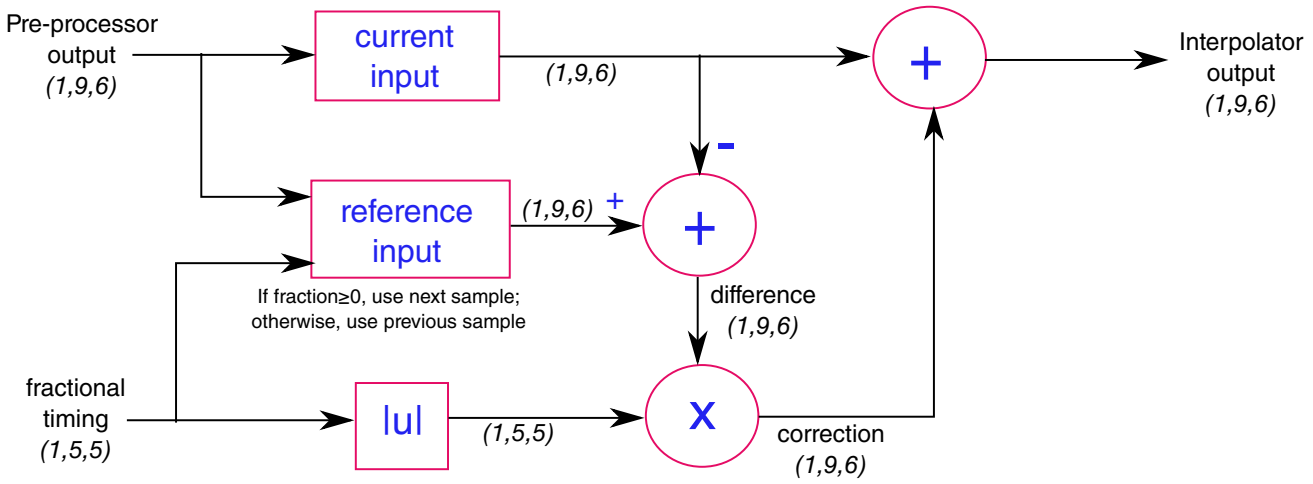


Figure 324. Interpolator

The interpolation in performed by using as reference the immediately preceding sample if the fractional timing estimated in PD is negative or the immediately succeeding sample if the fractional timing is non-negative. For interpolating each input sample, the difference between the itself and the reference is scaled by the fractional timing estimate and added back to itself.

55.4.7.6.4.3.2.3 Acquisition for BluetoothLE-LR

55.4.7.6.4.3.2.3.1 Longe range Bluetooth LE preamble detection

The purpose of the preamble detector is to detect the presence of a longe range Bluetooth LE packet and to estimate the CFO.

55.4.7.6.4.3.2.3.2 Long range Bluetooth LE AA detection

The soft-bits based AA detector performs AA detection for long range Bluetooth LE packets. It consists of the following components:

- Low complexity FSK symbol demodulator which produces the soft-bits, triggered at the sample rate
- Buffer which converts the scalar input to a vector used for correlation
- Long range Bluetooth LE AA correlator, used to perform long range Bluetooth LE AA detection after a long range Bluetooth LE preamble is detected

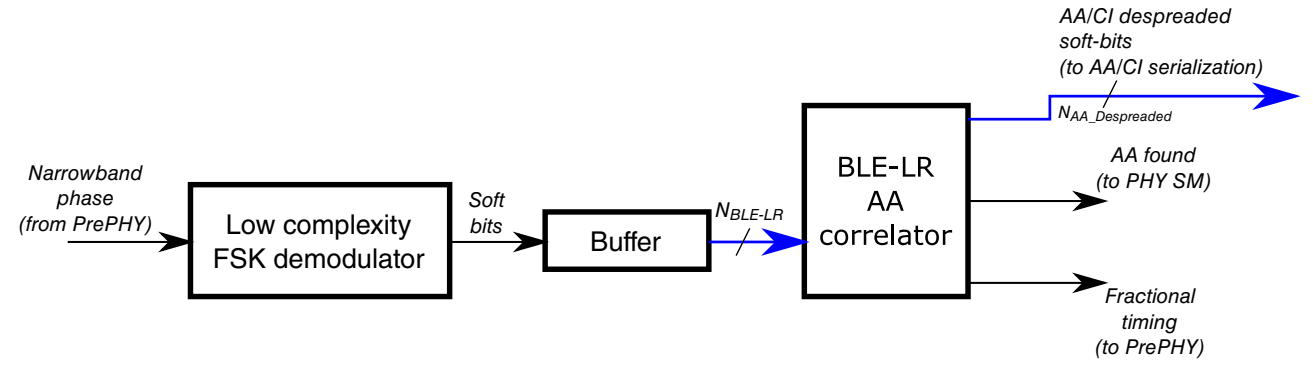

Figure 325. Soft-bits domain AA detector block diagram

It is being recalled here that the AA detection that uses soft-bits is done in parallel with continued preamble detection which has the purpose of improving the CFO estimate and extend the AA search time-out. These details are given in a more detailed manner in the PHY state-machine section. An important aspect to be mentioned is that the long range Bluetooth LE detector supports

detection of a single AA pattern. When AA detection starts, the low complexity FSK demodulator and the buffer are first enabled and the correlator is enabled after enough samples are acquired into the buffer to allow a valid correlation product.

55.4.7.6.4.3.2.3.2.1 Low-Complexity FSK Symbol Demodulation

The soft-bits are generated at the sample rate *i.e.*, $1/T_s$ and they are used during AA detection. The FSK symbol demodulator takes the CFO-corrected phase-domain samples as input and produces soft-bits as described below. Since the PHY has no knowledge of the PDU size, the process continues until the *activate_search* signal is de-asserted by the MAC.

55.4.7.6.4.3.2.3.2.2 Long range Bluetooth LE AA detection

The AA/CI despreaded soft-bits are latched when AA is found and they are further used by the long range Bluetooth LE AA/CI decoding mechanims, which is described in a different section.

In order to match the AA, the despreaded soft-bits are selected in the "Select AA portion" block and 64 despreaded soft bits are provided to the correlation and Hamming distance circuits. The correlator performs real values correlation, against AA corresponding reference waveform, over the input vector and the Hamming distance uses hard-bits to measure the distance between the received vector and the expected, coded AA.

55.4.7.6.4.3.3 Long range Bluetooth LE AA/CI decoding

The AA/CI decoding process is illustrated in Figure 326. This process corresponds to state 3 in the PHY state machine and involves both the PHY and the RBME modules. The chronological steps are indicated by the red arrow. Note that the arrow is meant to show data flow not control. The steps are:

- When AA is detected the detector provides a vector containing the despreaded soft-bits corresponding to the AA and CI portions
- The parallel to serial conversion block in the AA/CI decoding block starts producing codewords (consisting of the pairs of soft-bits {Soft-bit 1, Soft-bit 2}) and data valids
- The RBME engine decodes the inputted codewords and provides back data and data valids to the AA/CI detection block
- AA/CI detection is performing AA matching and CI extraction
  - If AA is matched the CI information is sent to the state-machine together with a CI valid indication
    - Following this event, the PHY state-machine transitions to payload demodulation
  - If AA is not matched the CI valid is not sent and a time-out occurs in the PHY state-machine
    - This further leads to returning to the acquisition state and to RBME disable

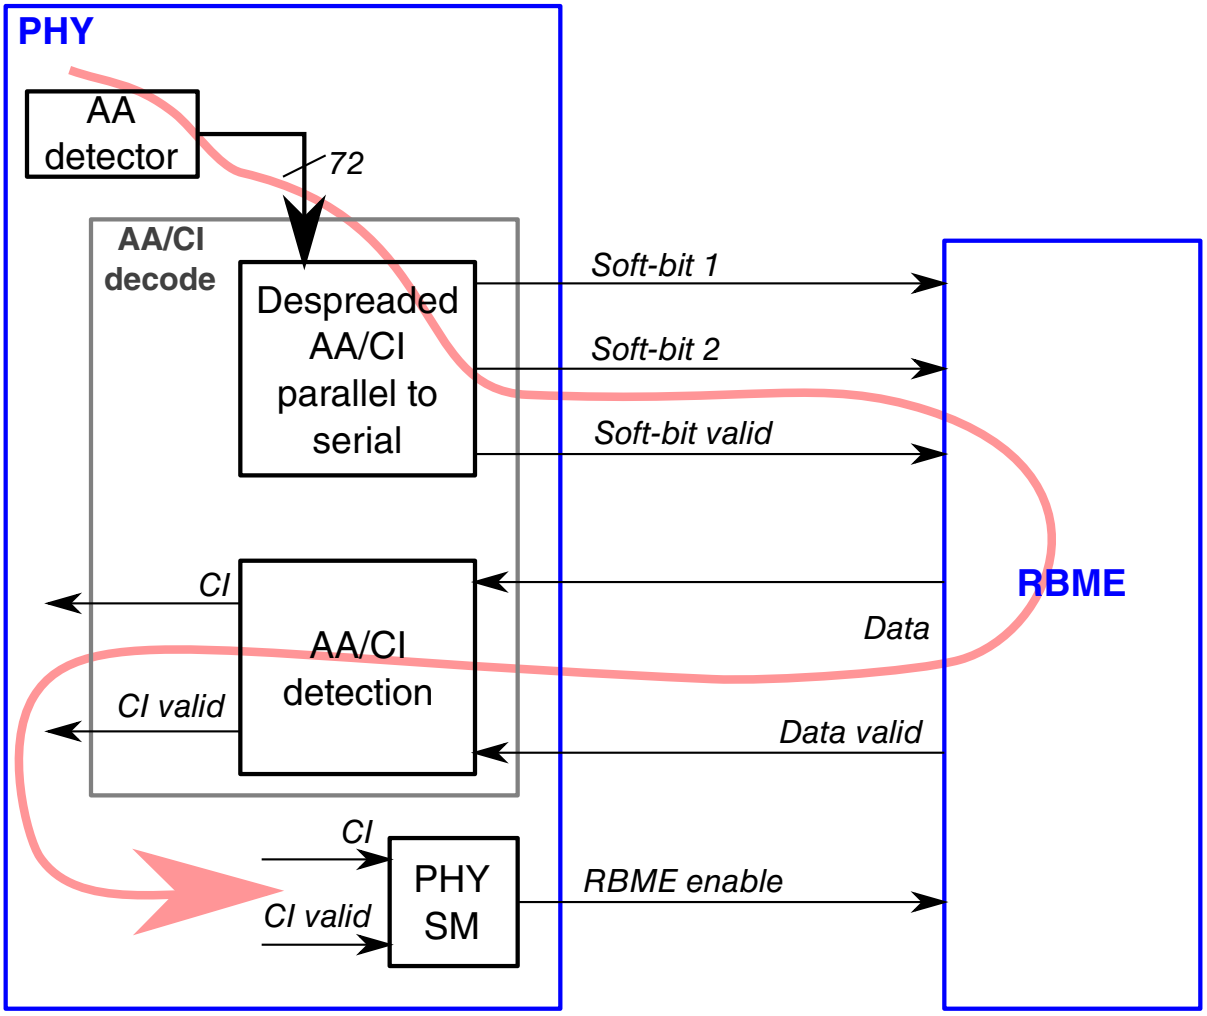

Figure 326. AA/CI decoding process

55.4.7.6.4.3.4 FSK payload demodulation

The demodulator consumes the received samples, at an oversampling rate (OSR) equal to 4, after the symbol timing and frame timing have been determined and after the CFO correction was applied. The I/Q samples are first converted to phase, by using the normalizer block.

The demodulator block supports:

- Symbol demodulation using input phase samples at OSR=4:
- Time tracking to compensate for residual timing error and for timing drift
  - Given that the timing drift needs to cover a various range of use-cases, from a maximum packet length perspective, the range is configurable via registers
- Frequency error detection and compensation to compensate for residual frequency error

Each supported feature will be detailed in the sequel of this section. Figure 327 shows the corresponding block diagram.

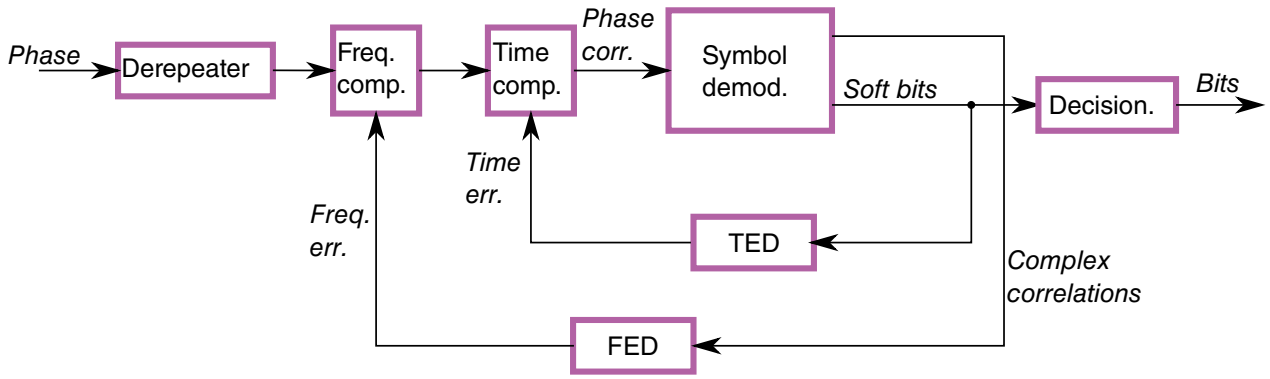

Figure 327. Demodulator block diagram

Symbol demodulation

The symbol demodulation mechanism will be referred to as M3c in the sequel. Figure 328 shows the block diagram of the symbol demodulator.

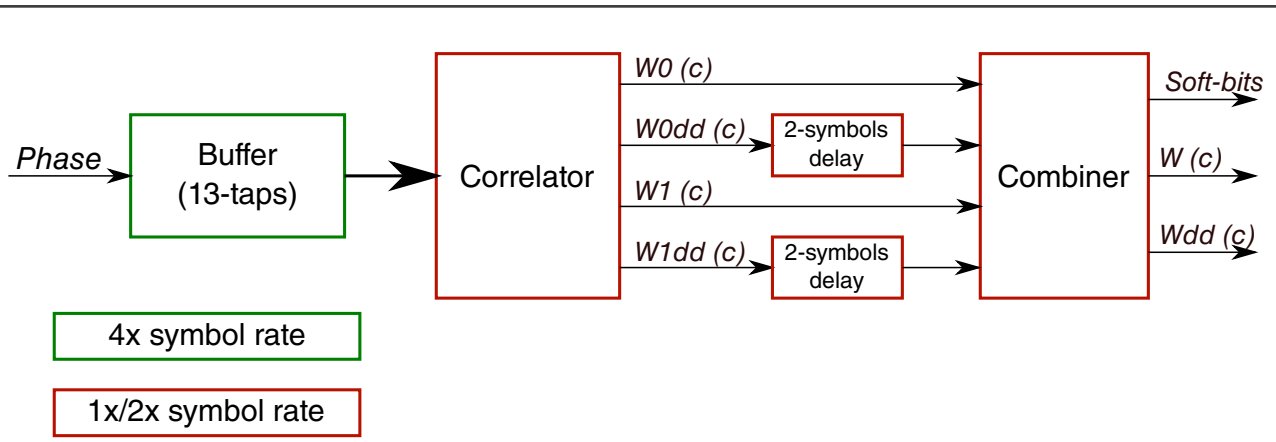

Figure 328. Symbol demodulator block diagram

From a correlation perspective, the symbol demodulator supports four modes:

- Mode 0: uses 12-taps (OSR in the adder tree is 4) and the reference phase vectors are shaped taking into consideration the modulation pulse and the receiver filtering
- Mode 1: uses 4-taps (OSR in the adder tree is 1) and no shaping is performed on the reference phase vectors
- Mode 2: uses 7-taps (OSR in the adder tree is 2) and no shaping is performed on the reference phase vectors
- Mode 4: uses 13-taps (OSR in the adder tree is 4) and no shaping is performed on the reference phase vectors

Some of the modes not only they provide a lower current drain in the correlation circuit but they can also provide a better performance.

Time/frequency error tracking

Following impairments need to be taken into consideration in the demodulator:

- Phase drift which is due to the residual carrier frequency offset, due to imperfect frequency synchronization in the acquisition block (initial frequency error)

- Crystal frequency drift which leads to carrier frequency offset accumulation over time (accumulated frequency error)
- Symbol timing residual error, due to imperfect time synchronization in the acquisition block (initial timing error)
- Timing drift due to misalignment of the frequency of the crystal at the transmitter and at the receiver (accumulated timing error)

The former two impairments are addressed through the frequency tracking mechanism whereas the latter two are handled by the timing tracking loop.

The frequency error tracking algorithm has two components: frequency error detection (FED) and frequency error correction (FED).

The most difficult use-case, from a frequency tracking perspective, is long range Bluetooth LE. This is because no frequency tracking is performed during the AA search. This means that there is a ~300 microseconds period between the moment when the CFO estimate is provided by the preamble detector and the start of the frequency tracking on the PDU portion. Long range Bluetooth LE 500 kbps is particularly affected due to the shorter duration of the informational symbol.

The timing error compensator provides:

1. integer compensation using a buffer
2. fractional compensation using a linear interpolator

The range of the timing error compensator is configurable and determines the latency of this block.

55.4.7.6.4.3.5 AA-confirmation block

The Bluetooth LE specification stipulates that a spec-compliant device be capable of detecting and rejecting a Bluetooth LE packet if the received AA is different from the desired AA even in only one bit position. But the AAD block requires a received powel level which is at least 4-5 dB above sensitivity to fulfil this stipulation as it is a simple correlation-based detector. However, by using a symbol demodulator, a mechanism can be created to meet the stipulation even at 0.2 dB above sensitivity. The AA-confirmation block is a manifestation of such a mechanism.

55.4.7.6.4.3.5.1 Functional description

The AA-confirmation block may be used as a supplementary step with any of the three ACQ modes. It can be enabled/disabled using the parameter *dmd_aa_enable* (see Table 450 for a list of all the parameters used by this block) but will begin its operation only after a successful AA detection has occurred.

A block diagram of the AA-confirmation block is shown in Figure 329. If enabled and a successful AA detection is declared by the AAD block, the AA-confirmation block obtains the symbol timing and CFO estimates produced by the synchronization stage; and simultaneously, a buffer containing the recent history of incoming samples is frozen (or disabled). The buffer then holds all the samples required by the symbol demodulator for a successful demodulation of the AA bits.

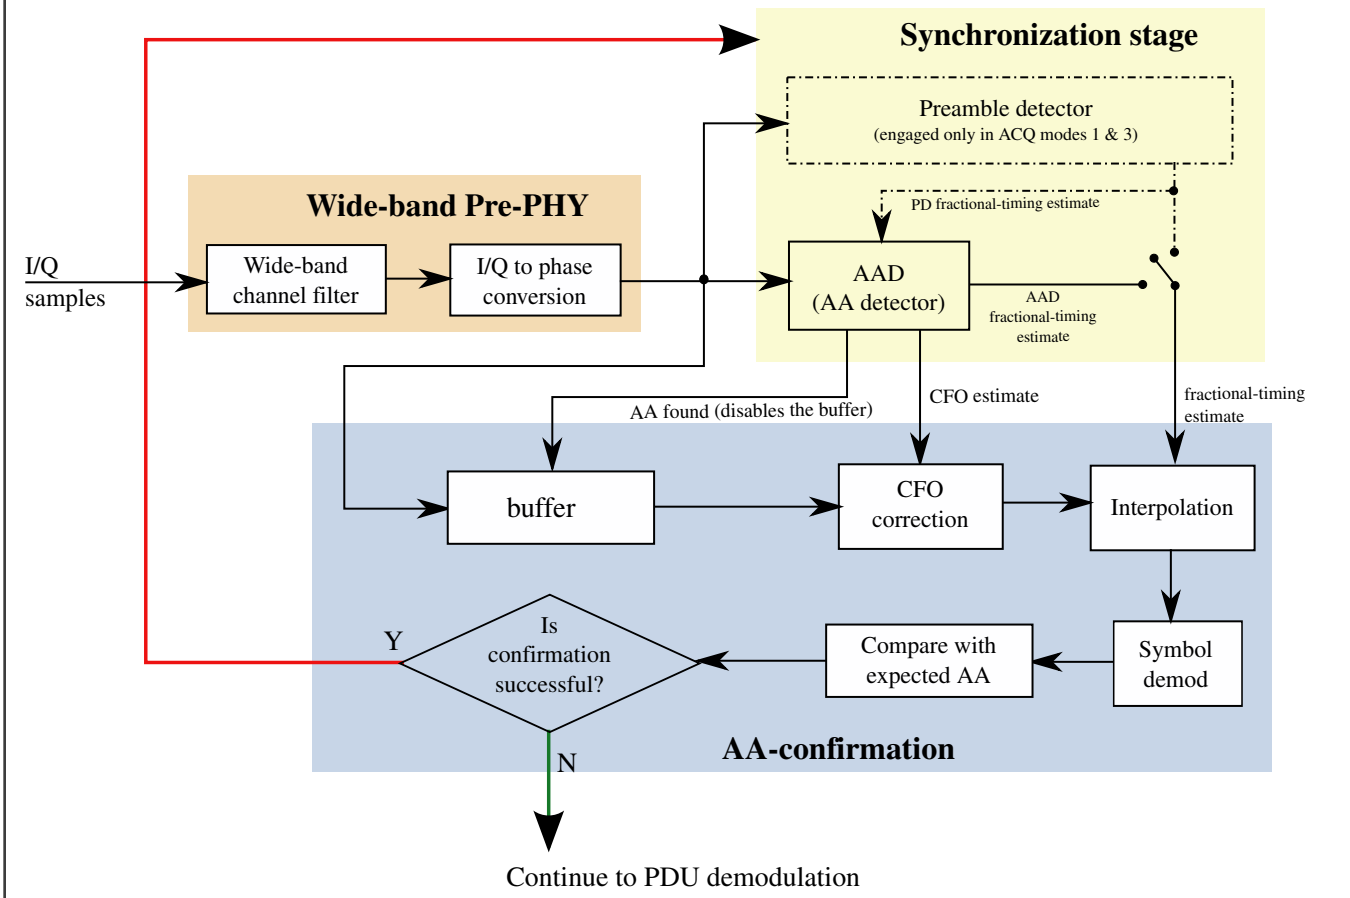

Figure 329. AA-confirmation functional block diagram

Next, the block begins operation by fetching successive samples from the frozen buffer and performs the following steps.

1. First, a CFO correction and timing interpolation is applied to compensate for the frequency offset and timing offset obtained from the synchronization stage.
2. The samples are then passed to a symbol demodulator which processes them and outputs one symbol decision for every *P* input samples.
3. The symbol decisions are then passed to a comparator which compares the demodulated sequence to the desired AA. If they match to within the Hamming distance specified, then AA-confirmation is declared successful and the PHY will continue with PDU demodulation; if not successful, then the AA-confirmation block sends a signal to the PHY state machine to resume acquisition.

55.4.7.6.4.3.5.2 Registers used by the AA-confirmation block

Table 450. AA-confirmation block parameters

Parameter	Notes
aa_0[31:0]	AA pattern of length 1, 2, 3 or 4 octets; 1, 2 and 3 octet patterns in bits [7:0], [15:0] and [23:0] respectively.
aa_1[31:0]	AA pattern of length 1, 2, 3 or 4 octets; 1, 2 and 3 octet patterns in bits [7:0], [15:0] and [23:0] respectively.

Table continues on the next page...

Table 450. AA-confirmation block parameters (continued)

Parameter	Notes
aa_2[31:0]	AA pattern of length 1, 2, 3 or 4 octets; 1, 2 and 3 octet patterns in bits [7:0], [15:0] and [23:0] respectively.
aa_3[31:0]	AA pattern of length 1, 2, 3 or 4 octets; 1, 2 and 3 octet patterns in bits [7:0], [15:0] and [23:0] respectively.
size_aa[1:0]	Indicates length of active AA's; 0→1 octet, 1→2 octets, 2→3 octets, 3→4 octets.
acq_mode[1:0]	Indicates the ACQ mode used for timing & frequency synchronization in non-coded use cases; 1→mode 1, 2→mode 2, 3→mode 3.
dmd_aa_enable	Enables demodulator-based AA-confirmation; 0→disable, 1→enable.
dmd_aa_hamming_high_pwr[2:0]	Hamming distance tolerance allowed at high power level during AA-confirmation; valid range is [0,7].
dmd_aa_hamming_low_pwr[2:0]	Hamming distance tolerance applicable around sensitivity and at low power levels during AA-confirmation; valid range is [0,7].
dmd_aa_hipow_disable_ovrd	Overrides the default disablement of AA-confirmation at high power levels; 0→no override, 1→override.

55.4.7.6.4.3.6 High accuracy RTT (round-trip time) block (HARTT)

The purpose of this block is to determine an accurate estimate of the timing information and also of the CFO, upon detection of an expected GFSK modulated bit pattern. From a detection perspective, it can be used in two possible cases:

1. Regular packets (i.e. packets that are composed of a preamble, an access address and a PDU)
2. RTT packets (i.e. packets that contain only a preamble and a 32 or a 64 bit PN sequence that does not bear any information bits)

The CFO is directly estimated by the HARTT block. On the other hand, from a timing estimation perspective, the time-stamp is not directly determined by the HARTT block. Squared correlation magnitudes around the peak of the main lobe are instead provided to the application, which needs to further use this information to compute the accurate timing.

55.4.7.6.4.3.6.1 Block description

55.4.7.6.4.3.6.1.1 Introduction

In principle, the HARTT block re-uses the arithmetic from the AA detection blocks in the acquisition module. The main difference is that it has a much lower duty-cycle (to save power) and a much higher resolution on the fixed-point formats (to achieve increased time/frequency accuracy). The expected accuracy is <2 ns for the timing estimation and <600 Hz for the CFO. The operation is triggered by an AA found event, provided by the AA detector in the acquisition block. A re-evaluation of the correlation peak is performed, assuming that the peak may not have been correctly detected during acquisition.

55.4.7.6.4.3.6.1.2 I/Os and settings

Note that all the outputs in the input/output signals table are packed in a 31-bit result (rtt_data[30:0]) and provided to the system memory via DMA. The results provided to software are sents as {rtt_data[30:0],1'b1} if a valid RTT pattern was detected and as{rtt_data[30:0],1'b0} when a valid RTT pattern is not detected in the expected time-slot.

Table 451. Input/output signals

Signal name	Type	Dimension	Description
fm_buffer[7:0]	I	134	The content of the FM buffer shared between acquisition and HARTT

Table continues on the next page...

Table 451. Input/output signals (continued)

Signal name	Type	Dimension	Description
rtt_bits	I	64	The bit sequence which is expected by the HARTT block when *overrd_progr_aa* is true
progr_aa	I	32	The AA programmed for the AA0 detector in the acquisition module
aa_found	I	1	Flag that indicates that AA was found in the AA0 detector
cfo_est[9:0]	I	1	The CFO estimate computed by the AA0 detector
PDelta[9:0]	O	1	Difference between the squared correlation magnitude values, *pm-pp*, provided by the HARTT block (format is sfix10En9)
rtt_int_adj[1:0]	O	1	An integer adjustment of the timing which takes a value different of 0 when the early-late mechanism in the HARTT block chooses a peak different of the one chosen in the acquisition module (format is ufix2En0 and possible values are {-1,0,+1})
ham_rtt_dist_sat[1:0]	O	1	Computed Hamming distance saturated to 2 bits (ufix2)
ha_rtt_cfo[15:0]	O	1	The high accuracy CFO computed by the HARTT block through the CORDIC algorithm
ha_rtt_found	O	1	Flag that indicates that the HARTT operation is done and a valid PN pattern was detected

Table 452. HARTT parameters

Parameter	Description
en_hartt	Enables the HARTT block
overrd_progr_aa	Overrides the programmed AA with an input sequence, which is used as reference for both the AA detector and for the HARTT correlation
rtt_seq_len	Specifies the correlation length applicable when *overrd_progr_aa* is true 0 - the correlation width is 32 bits 1 - the correlation width is 64 bits
first_pdu_bit	Allows providing to the HARTT block the value of the first bit of the PDU. This information is used to generate the HARTT correlator reference sequence when *overrd_progr_aa* is false
fm_ref_111[7:0]	Weight applied to the current symbol, in the HARTT correlation sequence, when both the adjacent bits are the same
fm_ref_110[7:0]	Weight applied to the current symbol, in the HARTT correlation sequence, when one of the adjacent bits is the same and the other one is different
fm_ref_010[7:0]	Weight applied to the current symbol, in the HARTT correlation sequence, when both the adjacent bits are different
ha_rtt_threshold[8:0]	Threshold used to compare p0 with in order to validate RTT found

55.4.7.6.4.3.6.1.3 Block diagram

Figure below shows the block diagram of the HARTT block, which has 4 main components:

- Control engine

- it is a state-machine which controls the behaviour of the correlator and of the combiner
- responsible of the generation of the enable/disable signal for the arithmetic
- it manages the generation of the reference sequences used by the correlator

- Correlator
  - responsible with computing the complex correlation values and the Hamming distances
  - the maximum supported correlation width is 32 bits
  - when the HARTT block is programmed to perform a 64-bit correlation, the correlator performs two 32-bits correlations
- Combiner
  - combines the results computed inside the correlator, when a 64-bits correlation is required
  - performs a peak selection based upon an early-late criterion
- IQ to phase conversion
  - determines the CFO using CORDIC algorithm

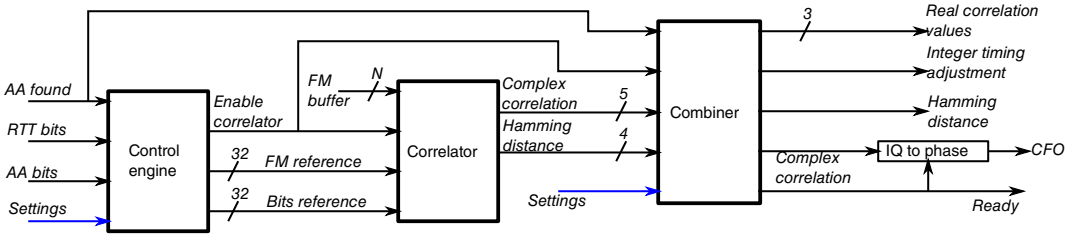

Figure 330. Block diagram

The "Ready" signal is asserted when the result is ready. One example of use of the HARTT block is to interface it with the RSM (ranging sequence manager) block which, when the "Ready" signal is asserted, manages the DMA transfer of the result, packed in a 32-bit word, to the packet RAM. When the HARTT block is used in conjunction with the RSM block, an interrupt is issued to soft-ware for every RSM step (RTT steps included).

More details about each component are provided in the following subsections.

55.4.7.6.4.3.6.1.3.1 Control engine

The state machine consists of 3 states. Two active states and an idle state. When the correlation width is 64 bits (i.e. both *overrd_progr_aa* and *rtt_seq_len* are "1"), both the active states are being used. Otherwise only state 0 is necessary. During each active state, the correlator arithmetic is run for a 5 samples worth of time.

Besides the main states there are secondary states. Their purpose is, they represent transitional states which are meant for preparing the reference sequences or for wait periods. The most complex operation of the state machine is when a 64-bit correlation is required. In this case, after the first 32-bit correlation completes, the state machine manages the change of the reference sequence and also it manages the timing of the second 32-bit chunk correlation.

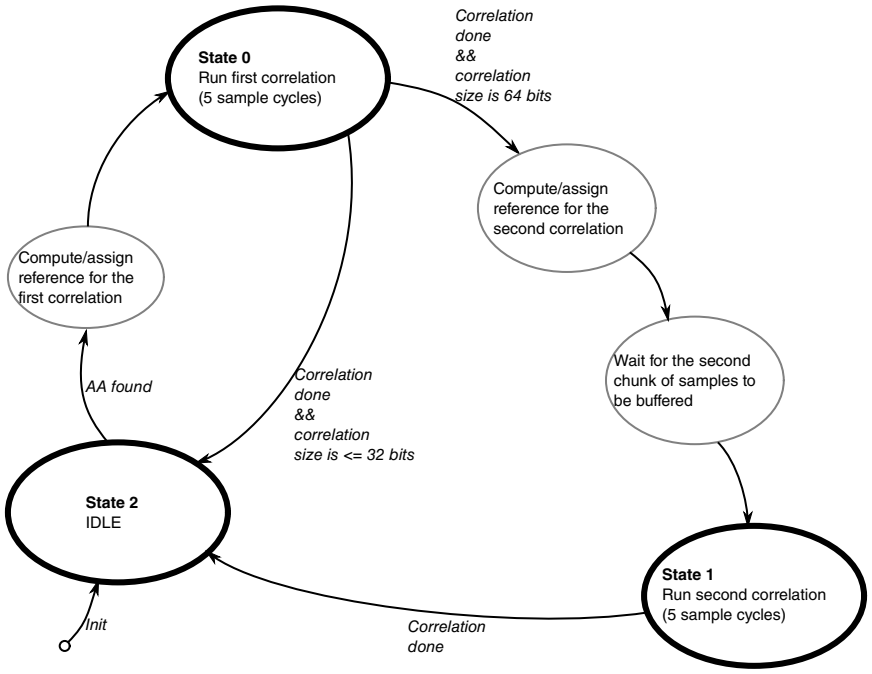

Figure 331. Control engine state-machine diagram

For each active state, an enable signal is sent to the correlator, which drives the computation of 5 complex correlation products at the PHY sampling rate. In order to compute the timing only 3 squared correlation magnitude values are required. However, 5 such values are being computed in order to be able to re-evaluate the position of the correlation peak. Computing 5 values allows moving the estimation of the peak timing by 1 sample at most.

The reference sequence used for correlation is computed by combining the reference symbols with the programmed FM weights. Table below shows an example of how the reference is being derived.

Table 453. Example of FM reference sequence computation

Bit	1	0	1	0	0	0	1	1	1
Bipolar symbol	+1	-1	+1	-1	-1	-1	+1	+1	+1
FM reference value	N/A	*-fm_ref_010*	*+fm_ref_010*	*-fm_ref_110*	*-fm_ref_111*	*-fm_ref_110*	*+fm_ref_110*	*+fm_ref_111*	N/A

A few comments on the reference waveforms:

- Reference values are the result of the multiplication between the bipolar symbols and the programmed weights
- Weights depend on the modulation scheme (more specifically they depend in the BT product and on the modulation index)
- Programmed reference values depend on the context
  - inter-symbol interference is considered negligible from symbols other than the immediate neighbours
  - in order to determine a certain value both the preceding and the succeeding bits need to be known
  - for the reason on the bullet above the values are indeterminate for the first and the last columns of the table above
- When determining an FM reference sequence corresponding to *N* bits, actually (*N*+2) bits need to be known
  - means that the last bit of the preamble and the first bit of the PDU (for regular packets) or the first bit of the post-padding (for the RTT packets) need to be known

— the best timing estimation is obtained when the sequence to be searched for starts and ends with a transition (i.e. the last bit of the preamble is the inverse of the first bit of the searched sequence and the first bit of the PDU/post-padding is the inverse of the last bit of the searched sequence)

- If *N*=64 the correlator needs to perform 2 correlation products of 32-bit width - the correct provisioning of the FM reference sequences, corresponding to the first and the second half, are managed by the control engine

Table below shows an example of FM reference values that correspond to BT=0.5/h=0.5 (RTT 1 Mbps) and BT=2/h=0.5 (RTT 2 Mbps).

Table 454. FM reference values for BT=0.5 / h=0.5

	fm_ref_111	*fm_ref_110*	*fm_ref_010*
Real value [rad]	*π*/2	1.22	0.88
Fixed point value [normalized]	0.5	0.387	0.281
Fixed point value [hex]	0x80	0x63	0x48

Table 455. FM reference values for BT=2 / h=0.5

	fm_ref_111	*fm_ref_110*	*fm_ref_010*
Real value [rad]	*π*/2	1.4	1.2
Fixed point value [normalized]	0.5	0.445	0.382
Fixed point value [hex]	0x80	0x72	0x61

55.4.7.6.4.3.6.1.3.2 Correlator

This sub-block is responsible with computing the complex correlation values and the Hamming distance. It is implemented in a similar fashion as the adder tree in the acquisition AA detectors. The difference is that more resolution is provided to the correlator taps in order to obtain a better timing accuracy.

55.4.7.6.4.3.6.1.3.3 Combiner

This sub-block is responsible with combining the complex correlation and Hamming distance computation results when a 64-bit correlation is required. It is also responsible with the re-evaluation of the correlation peak. The figure below shows a flowchart diagram of the combiner.

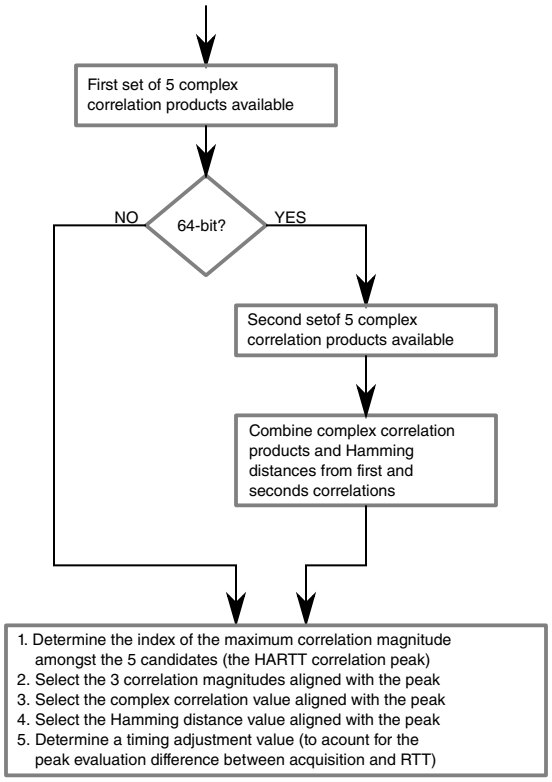

Figure 332. Combiner operation flowchart

The complex magnitude outputted by the combiner is further used by the CFO estimation algorithm.

55.4.7.6.4.3.6.1.3.4 Accurate CFO estimation

For a detailed description of the CFO estimation via CORDIC algorithm please consult the "Radio Frequency Fingerprinting (Fine CFO estimation)" section of the current chapter.

55.4.7.6.4.3.6.2 Integration considerations

As mentioned in the block description there are a few signals provided by the acquisition AA0 detector to the HARTT block. *aa_found* provides the timing reference and triggers the operation of the HARTT block. *cfo_est* is used by the Hamming distance computation for the FM symbols demodulation. Regarding the settings of the AA0 detector, when *overrd_progr_aa* is true the programmed AA is overwritten by the first half of the *rtt_bits* signal and the programmed AA length (a.k.a. SFD length) is overwritten by value 3 (which is the value corresponding to 32-bits).

Impact on other blocks in the PHY is described in the sequel.

55.4.7.6.4.3.6.2.1 Integration with the AA Hamming confirmation block

The purpose of the Hamming confirmation block is to provide a more reliable assessment on the Hamming distance than the one provided by the AA detectors in the acquisition module. When enabled, the operation of the AA Hamming confirmation block is triggered following the assertion of *aa_found*. After a while the AA detection is either confirmed or disconfirmed. When *overrd_progr_aa* is true, the programmed AA used by the AA Hamming confirmation block is overwritten by the first half of the *rtt_bits* signal.

When the operation of the confirmation block is enabled, the *ha_rtt_ready* indication from the HARTT is qualified by the AA confirmation event, which results in *ha_rtt_vld* signal.

55.4.7.6.4.3.6.2.2 Integration with the PHY state-machine

In order to support the reception of RTT packets (which have no PDU) a dedicated state is defined in the PHY state-machine, called RTT state. If *overrd_progr_aa* is true, the PHY SM transitions to the RTT state after AA is detected and confirmed.

RTT state is responsible to providing the control signals to all the blocks in the PHY, after an RTT packet is detected. It also has the role of extending the operation of the FM buffer (in the acquisition module) when *rtt_seq_len*=1 (i.e. the HARTT block searches for a 64-bit sequence).

55.4.7.6.4.3.6.3 Computation of the fractional timing (intended for the application)

The time-stamps, used for the round-trip time computation, are locally determined by the application using the information from HARTT. It has two components:

- an integer component, computed by combining the timing of "AA detection" event (issued by the radio) with the *rtt_int_adj* value provided by HARTT
- a fractional component, computed using the 3 values contained in the *pm_pp_p0* result provided by the HARTT block

Since the determination of the integer part is trivial, the computation of the fractional timing is not. The latter is addressed in the current section.

A few consideration on the main correlation lobe:

- When the data is oversampled it can be approximated by a sinc function
- A property of the sinc function is that peak of the sinc function can be estimated as $p=k*(\alpha-\gamma)$
  - where α and γ are the correlation output samples (squared correlation magnitudes) before and after the peak
  - p is the deviation from the center of the main lobe
  - α and γ are computed by the HARTT block and reported in the *pm_p0_pp* result (they represent the first and the last value of the result)
  - from now on the following notation will be used $\delta=(\alpha-\gamma)$
- k depends on the bit-sequence used for correlation
  - for RTT packets the sequence is randomly generated so it doesn't have to respect strict rules
  - there is a lot of variability of the used sequences leading to variability of k
  - flatter the main lobe larger the required k - sequences close to all-ones or all-zeros lead to very flat lobes
  - some sequences may have a periodical structure which leads to lobe smearing

55.4.7.6.4.3.6.3.1 Modelling of the fractional delay

Modelling of p (which is the fractional delay) as a first order polynomial was not satisfactory. Indeed a third order polynomial is used. In this case, k is replaced by a vector of 3 elements and the equation becomes:

$$p=k_1*\delta+k_2*\delta^2+k_3*\delta^3$$

Usually only the first and the third order terms are significant in the equation above. The coefficients k_1, k_2 and k_3 are related to the structure of the correlation sequence and they are computed for each sequence separately. Different sequences with similar properties will map on the same set of coefficients.

55.4.7.6.4.3.6.3.2 Dependence of the coefficients on the correlation sequence

More specifically, k_1, k_2 and k_3 depend on the context of each composing bit. To formalize this, the following notations are used for a certain sequence:

- c_{010} - count of the bits having both the adjacent neighbours logically inverted
- c_{011} - count of the bits having one of the adjacent neighbours logically inverted
- c_{111} - count of the bits having none of the adjacent neighbours logically inverted

The relation between the coefficients and the count consists in a third order polynomial. This is formalized in the equation below:

$[k_1, k_2, k_3]=[c_{010}, c_{011}, c_{111}, c_{010}^2, c_{011}^2, c_{111}^2, c_{010}^3, c_{011}^3, c_{111}^3]*\Gamma$

where **Γ** is the 9x3 transformation matrix.

This transformation is very useful because it greatly reduces the storage requirements. It also slightly increases the computation requirements because, first, the counts need to be determined for each sequence and second a multiplication is required to determine k_1, k_2 and k_3. **Γ** is unique for all possible sequences and it depends on the modulation scheme (modulation index - BT combination). Matrix **Γ** is pre-determined using intensive simulations and it is made available to the application from memory.

55.4.7.6.4.3.6.3.3 RTT block timing/frequency accuracy at hight SNR

In the figures below each blue "x" dot is the distance estimate corresponding to one RTT measurement. The red line corresponds to the averaging of all the measurements corresponding to a certain fractional delay (i.e. averaging all the dots on the vertical). To determine the red line, which is intended to show that there is no bias in the estimation, 100 distance estimates were used (i.e. 100 distance estimates per fractional delay value). The fractional delay reflects the timing uncertainty due to the sample clock which is 4 MHz for 1Mbps and 8 MHz for 2Mbps. As an example, when the frequency of the sample clock is 4 MHz, a fractional delay of 0.25 corresponds to a timing delay of 0.25/(4 MHz) = 62.5 nanoseconds.

55.4.7.6.4.3.6.4 Methodology for time-stamp determination

Following steps are required to determine the time-stamp for each transaction:

1. Determine the integer component of the time-stamp by capturing the "AA detection" event
2. Adjust the integer value using *rtt_int_adj* value provided in a HARTT status register (note that this value is expressed in PHY sampling rate cycles and it needs to be properly adjusted to the clock frequency)
3. Determine the [c_{010}, c_{011}, c_{111}] that correspond to the PN sequence used for the RTT transaction
4. Determine the [k_1, k_2, k_3] coefficients using the matrix transformation **Γ**
5. Compute the fractional delay using relation $p=k_1*\delta+k_2*\delta^2+k_3*\delta^3$ (δ is reported in the *PDelta* result)

6. Compute the final time-stamp combining the integer and the fractional components (note that the fractional value is expressed in PHY sampling rate cycles and it needs to be properly adjusted to the clock frequency)

55.4.7.6.4.3.6.5 Considerations for the choice of AA patterns

In order to get an accurate RTT estimation the AA pattern must have good autocorrelation properties and a controllable ISI at the beginning and at the end of the over-the-air transmitted waveform. In order to achieve that there are a few measures that can be taken:

- Make sure that there is a transition between the bit preceding the AA pattern and the first bit of AA
- Make sure that there is a transition between the last bit of AA and the first bit that follows after
- Use a scoring mechanism to select AA with good correlation properties
- Take into account the flatness of the main correlation lobe

The BLE protocol already imposes a transition between the last bit of the preamble and the first bit of the AA. For HADM RTT packets a rule was put in place to insure a transition at the end of the AA by defining 4 trailing bits that look like the preamble. However, for legacy packets the AA has to be chosen such that its' last bit is the complement of the first bit of the PDU transmitted over the air. It is important to keep in mind that, if FEC is used (e.g. whitening), the first OTA bit may not be the protocol bit. So, when choosing the AA pattern, the application has to have knowledge of the first protocol bit and the FEC operation that this bit may be subject to.

The BLE AA generation rules are not used in HADM because they can mess-up the entropy and reduce security. This is why a scoring mechanism is required, to achieve a tradeoff between security and correlation properties. The score is computed by summing up the bit autocorrelation of the AA pattern in the vicinity of the main lobe. In HADM, at each RTT transaction, two AA patterns are computed and the one with the best score is used. An alternative would use an AA pattern that has a score less or equal than a threshold. The methodology of computing the score is given in the code below:

```
C = zeros(depth,1);
N = length(aa_pattern);
for m = 1:depth
C(m) = 2*sum(mod(aa_pattern(1:N-m)+aa_pattern((1+m):N),2)) - (N-m);
end
score = sum(abs(C));
```

The value for *depth* used by HADM is 3.

As previously shown in the current section it has been observed that the structure of the AA pattern influences the shape of the correlation (which is used to determine the ToF and thus the distance). To correlate the structure with the correlation a set of counts is being used. The flatness of the main lobe is mainly determined by c_{111}, i.e. higher this count flatter the main autocorrelation lobe. It was shown in this section how to compute the polynomial fit coefficients, depending on the counts, in order to get best accuracy. However, if the methodology presented here is not possible to implement, the AA with flat autocorrelation can be avoided by imposing a threshold for c_{111}.

As an example, for $depth$=3, the application can use only AAs for which $depth$<9 and c_{111}<8.

55.4.7.6.4.4 DMAs

This section describes all the DMAs that the 2.4GHz PHY module generates.

55.4.7.6.5 Application information

This section describes applications supported by the 2.4GHz PHY module.

One of the possible uses of the PHY module is the frames time/frequency synchronization and PDU bits demodulation corresponding to different protocols. As an example, the PHY module supports the packet reception for Bluetooth low energy uncoded (1Mbps and 2 Mbps) and long range (125 kbps and 500 kbps).

Another use of the PHY is the high accuracy time of flight estimation which is used for localization.

55.4.7.7 Transceiver Sequence Manager

55.4.7.7.1 Introduction

55.4.7.7.1.1 Overview

The Transceiver Sequence Manager controls the warmup and warmdown processes for all radio sequences. The TSM provides for a TX sequence, and an RX sequence. For both TX and RX, a warmup and a warmdown sequence is supported. The length of each sequence is programmable, from 1 – 254us. The resolution of the TSM is 1us. Controls for all analog and digital transceiver blocks are provided. Each TSM output enables, or otherwise provides control for, a transceiver-related block. Each TSM output has 4 8-bit registers, with which to control the point at which the output asserts during the warmup (1 register for TX, 1 for RX), and the point at which it deasserts (1 register for TX, 1 for RX). Some TSM outputs, which are known in advance to require identical timing, are “ganged together”, to reduce area and required programming. For DFT, and non-mission-mode validation, each TSM output can be placed under direct software control, using register overrides. Any sequence can be temporarily halted, by setting an optional, programmable breakpoint.

55.4.7.7.1.2 Features

The TSM includes the following features:

- TX warmup and warmdown sequence and RX warmup and warmdown sequence sequence for every controllable output.
- Programmable sequence length from 1 to 254 microseconds for each sequence in 1 microsecond increments.
- Multi-protocol
- Ability to place TSM outputs under software control for test and non-mission mode validation.
- Ability to signal link layers upon PLL unlock or RF_NOT_ALLOWED conditions.

- Fast Warmup Capability for TX and RX
- LPPS Support
- Programmable breakpoint capability to halt any sequence temporarily.

55.4.7.7.2 Functional Description

55.4.7.7.2.1 Sequence Counter

The TSM supports 1 TX and 1 RX sequence. Each sequence consists of 3 phases:

1. WARMUP phase
2. ON phase
3. WARMDOWN phase

The central element of the TSM is an 8-bit counter. The counter is held at 0 during the idle state. From idle state, any sequence can be launched, by an initiating event. (See Section “Sequence Initiation”). At an initiating event, the TSM counter counts up from 0 to a programmed stop point during the WARMUP phase, determined by the END_OF_TX_WU or END_OF_RX_WU register, depending on whether the sequence is TX or RX. At the end-of-warmup “stop point”, the TSM counter holds its count, and the TSM sequence enters the ON phase. The TSM counter will remain in the ON phase, and hold its count, until the initiating event deasserts (See Sequence Termination). When either of these conditions occurs during the ON phase, the TSM will resume counting from the point it was holding during the ON phase, and the sequence will enter the WARMDOWN phase. The counter will continue counting until a programmed stop point is reached. This stop point is determined by the END_OF_TX_WD or END_OF_RX_WD register, depending on whether the sequence is TX or RX. Once this point is reached, the sequence returns to idle, and the TSM counter returns to 0.

The 4 8-bit registers which control the duration of the WARMUP phase (END_OF_TX_WU[7:0] and END_OF_RX_WU[7:0]), and the duration of the WARMDOWN phase (END_OF_TX_WD[7:0] and END_OF_RX_WD[7:0]), reside in the END_OF_SEQ register.

All TSM-controlled outputs are active-high. Any TSM-controlled output can be asserted once during a sequence (either TX or RX sequence), and then deasserted once. Or, the output can be held in a deasserted state for the duration of the sequence. The precise timing for the assertion and deassertion of each TSM-controlled output, for both TX and RX sequences, is determined by 4 8-bit registers assigned to that output (see TSM-Controlled Outputs). The TSM resolution is 1us. This is the update rate for the TSM counter, and sets the granularity with which warmup and warmdown processes can be controlled.

55.4.7.7.2.2 TSM-Controlled Outputs

The TSM-controlled outputs are shown in the table below. In general, each output signal is assigned a unique TSM_TIMING register to control its timing, but in cases where output signals will always be asserted and deasserted at the same time, the signals can share a TSM_TIMING register (e.g., seq_ldo_gang_pup).

1. This signal is inverted with respect to the timing signal
2. This is the pup for the RX peak detector

During the WARMUP and WARMDOWN phases of any sequence, any TSM-controlled output can be programmed to assert once and then deassert once, by programming the timing registers associated with the output. Each output has 4 8-bit timing registers associated with it. The name of the register matches the name of the output:

*OUTPUTNAME*_TX_HI[7:0]

*OUTPUTNAME*_TX_LO[7:0]

*OUTPUTNAME*_RX_HI[7:0]

*OUTPUTNAME*_RX_LO[7:0]

In the case of grouped outputs, the timing registers associated with the signal controlling the group, control timing for the entire group.

During the WARMUP phase of a TX sequence, as the 8-bit TSM counter increments, once the TSM counter equals or exceeds the programmed value of *OUTPUTNAME*_TX_HI[7:0], but is less than the programmed value of *OUTPUTNAME*_TX_LO[7:0], the corresponding TSM output will transition high. During the WARMUP or WARMDOWN phase of the TX sequence, once the TSM counter equals or exceeds the programmed value of *OUTPUTNAME*_TX_LO[7:0], the TSM output will transition low. If the programmed value of *OUTPUTNAME*_TX_HI[7:0], is greater than the length of the TX sequence (set by register END_OF_TX_WD[7:0]), then that signal will never transition high during the TX sequence. A convenient way of ensuring a signal does not assert during a TX sequence, is to set its *OUTPUTNAME*_TX_HI[7:0]=255.

During the WARMUP phase of a RX sequence, as the 8-bit TSM counter increments, once the TSM counter equals or exceeds the programmed value of *OUTPUTNAME*_RX_HI[7:0], but is less than the programmed value of *OUTPUTNAME*_RX_LO[7:0], the corresponding TSM output will transition high. During the WARMUP or WARMDOWN phase of the RX sequence, once the TSM counter equals or exceeds the programmed value of *OUTPUTNAME*_RX_LO[7:0], the TSM output will transition low. If the programmed value of *OUTPUTNAME*_RX_HI[7:0], is greater than the length of the RX sequence (set by register END_OF_RX_WD[7:0]), then that signal will never transition high during the RX sequence. A convenient way of assuring a signal does not assert during a RX sequence, is to set its *OUTPUTNAME*_RX_HI[7:0]=255.

The following diagram depicts the TSM counter, and the control logic used to assert and deassert the TSM-controlled outputs. For clarity, logic for only 2 of the outputs (pll_dig_en, sigma_delta_en) are shown.

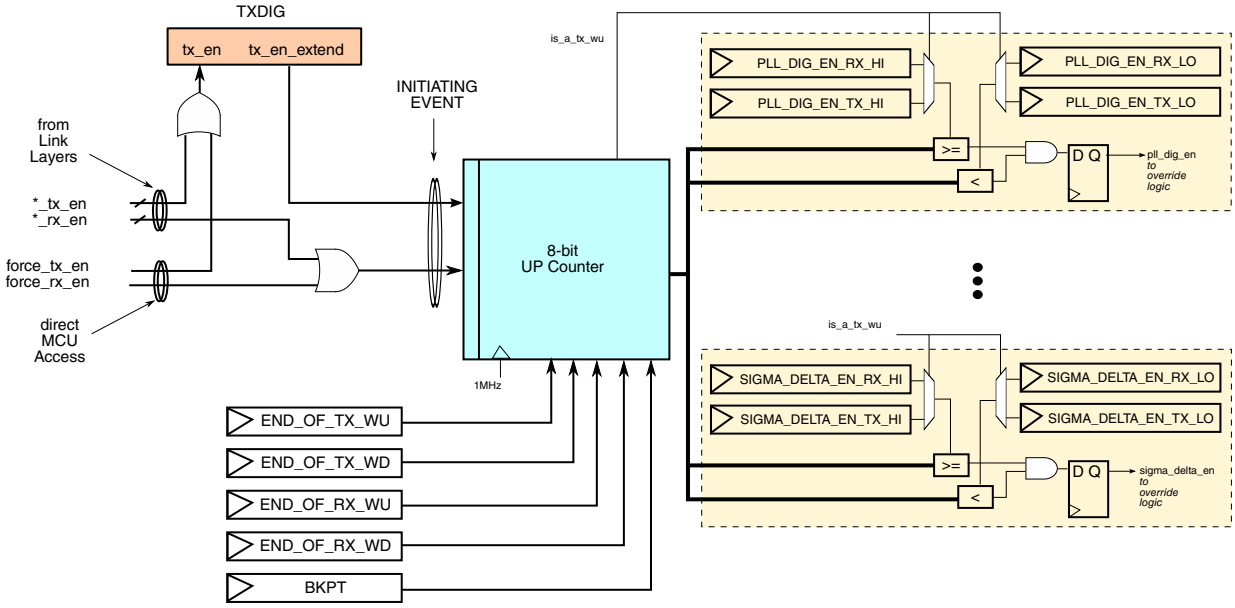

Figure 333. TSM BLOCK DIAGRAM

55.4.7.7.2.3 Timing Registers

There are a set of timing registers for each TSM-controlled output (or, for the signal controlling the group for the “grouped” outputs). Each register set consists of 4 bitfields: one to control the assertion time of the output for TX sequences, one to control the assertion time for RX sequence, one to control the deassertion time for TX sequences, and one to control the deassertion time for RX sequences. For TSM-controlled outputs that are grouped, one set of timing registers controls the timing for all members of the group. For each of these sets, the following table lists the SoC register name, and 4 timing register names associated with each.

SOC REGISTER NAME	BITS [31:24]	BITS [23:16]	BITS [15:8]	BITS [7:0]
TIMINGxx	RX_LO[7:0]	RX_HI[7:0]	TX_LO[7:0]	TX_HI[7:0]

Some of the TSM outputs have relevance for TX sequences only. For those, timing registers are only provided for TX assertion and deassertion times. The RX timings for such outputs are essentially hardwired to 255, meaning there will be no signal assertion during RX sequences.

Some of the TSM outputs have relevance for RX sequences only. For those, timing registers are only provided for RX assertion and deassertion times. The TX timings for such outputs are essentially hardwired to 255, meaning there will be no signal assertion during TX sequences.

55.4.7.7.2.4 Sequence Initiation

The SoC will include one or more protocol engines. Any of the protocol engines, can launch a TSM sequence. Each protocol engine will have an initiating signal for a TX sequence, and another for an RX sequence.

For direct software control, the MCU/Host can initiate a TX sequence warmup directly, by setting the FORCE_TX_EN bit, and later initiate a TX sequence warmdown by clearing the bit. The MCU/Host can initiate a RX sequence warmup directly, by setting the FORCE_RX_EN bit, and later initiate a RX sequence warmdown by clearing the bit. These bits reside in the TSM_CTRL register.

From idle state, the asserting of any initiating event (*source*_tx_en or *source*_rx_en), will begin the TSM WARMUP phase and begin incrementing the TSM counter from 0. The initiating source needs to hold the initiating signal asserted (high) through the course of the WARMUP, and then for the duration of the desired ON phase. Deasserting the initiating signal transitions the TSM to the WARMDOWN phase (see Section “Sequence Termination”).

Needless to say, from idle state, a TX-initiating event (assertion of any TSM *source*_tx_en input) will launch a TX sequence. The TSM output **tx_mode** will go high to indicate a TX sequence is underway. Also, from idle state, an RX-initiating event (assertion of any TSM *source*_rx_en input) will launch an RX sequence. The TSM output **rx_mode** will go high to indicate a RX sequence is underway.

Only 1 initiating source can be allowed to assert at any given time. Under no circumstances should a TX and RX initiating source be asserted simultaneously.

Once a TSM sequence has been launched, the WARMUP phase is entered and TSM counter incrementing will commence. Up-counting will continue until one of the following conditions is met:

1. Deassertion of the initiating event. TSM will transition to WARMDOWN phase
2. tsm_count=END_OF_*SEQ*_WU, where *SEQ*=TX or RX. TSM will transition to ON phase
3. Breakpoint. TSM stay in its current phase and hold its count

A transition from WARMUP to ON phase means TSM will hold its count at END_OF_*SEQ*_WU, where *SEQ*=TX or RX.

A transition from ON to WARMDOWN phase means TSM will cease its hold, and resume counting at END_OF_*SEQ*_WU+1, where *SEQ* = TX or RX. (see Section “Sequence Termination”).

A transition from WARMUP to WARMDOWN phase means the tsm_count will jump to END_OF_*SEQ*_WU+1 (where *SEQ* = TX or RX), and resume counting from there. (see Section “Sequence Termination”).

The 4 8-bit registers which control the duration of the WARMUP phase (END_OF_TX_WU[7:0] and END_OF_RX_WU[7:0]), and the duration of the WARMDOWN phase (END_OF_TX_WD[7:0] and END_OF_RX_WD[7:0]), reside in the END_OF_SEQ register.

55.4.7.7.2.5 Sequence Termination

A sequence may be terminated during the WARMUP on ON phase by deassertion of the initiating event (*source*_tx_en or *source*_rx_en). This will cause a transition to WARMDOWN phase, at which point the TSM counter will resume counting from END_OF_*SEQ*_WU+1 (where *SEQ*=TX or RX).

NOTE

For TX, deassertion of the initiating tx_en event does not cause an immediate transition to TSM WARMDOWN phase. The tx_en deassertion is first recognized by the TXDIG to ramp-down the PA. After the TXDIG completes the PA ramp-down, its tx_en_extend output to the TSM will de-assert causing the TSM to transition to WARMDOWN. See more on PA ramp timing in the next section.

55.4.7.7.2.6 PA Ramp Timing

In previous generation (Gen3.0) of radios, the PA ramp was controlled in the TSM. The PA ramp-up was started near the end of the TSM TX warmup sequence and completed before the end of the TSM TX warmup sequence. The PA ramp-down started at beginning of the TSM TX warmdown sequence and completed before the end of the TSM TX warmdown sequence. In addition to the PA ramp timing, the TSM also output the PA ramp values from a programmable look-up table.

For the latest generation of radio, the PA ramp will be controlled in the TXDIG instead of the TSM. The operation is described as follows.

When a Link Layer asserts *source*_tx_en (or software sets the FORCE_TX_EN bit) to start a TX burst, the TSM TX warmup sequence will begin. Near the end of the TSM TX warmup sequence, a TSM timing signal (tx_dig_en) will signal to the TXDIG to ramp-up the PA and start sending TX data. The TXDIG will also control the PA power-up signal (seq_tx_pa_pup in figure below) to the analog to turn on the PA. After the TXDIG completes the PA ramp-up, it outputs pa_wu_complete to the TSM, and the TSM in turn creates 1us-width pulses tsm_wu_almost_complete and tsm_wu_complete. Note that the TSM count may or may not have reached end_of_tx_wu by the time the TXDIG finishes ramping up the PA; in the example below, the PA ramp-up does not complete until after TSM count has reached end_of_tx_wu. Note also that the figure shows the link layer (or force tx_en signal) is a direct input to the TXDIG, and the TXDIG outputs a tx_en_extend (which asserts at the same time as tx_en) to the TSM; the TXDIG takes no action on assertion of tx_en but the de-assertion is used in ramp-down as described in the next paragraph.

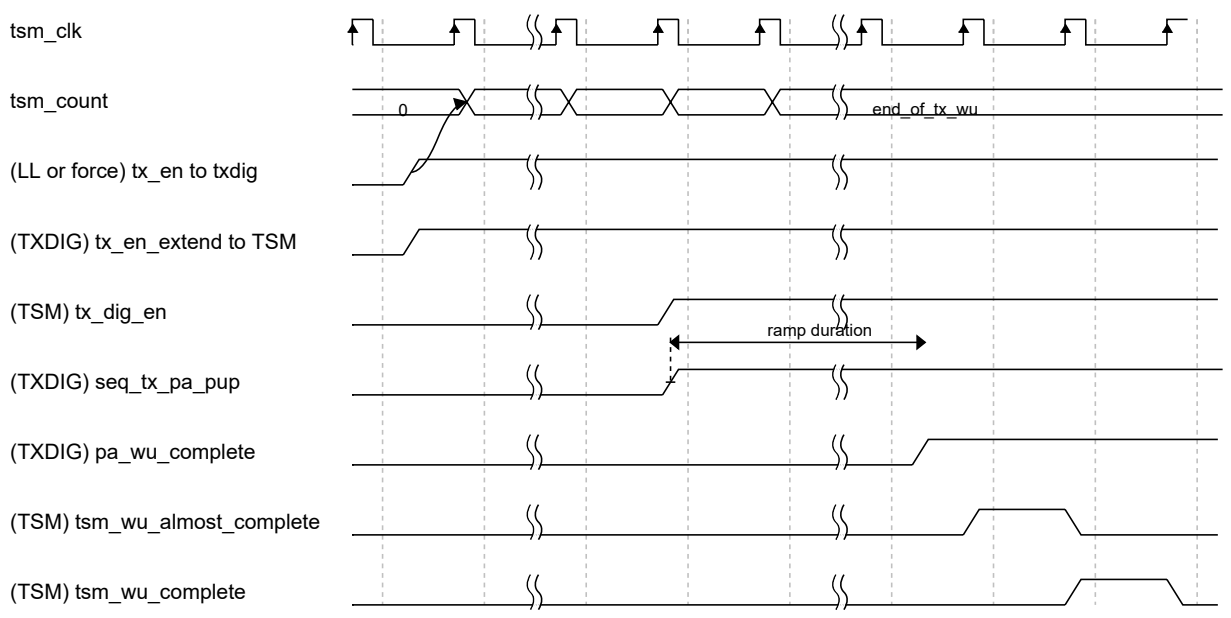

Figure 334. PA Ramp-Up Timing

When the Link Layer deasserts *source*_tx_en (or software clears the FORCE_TX_EN bit) to end a TX burst, the TXDIG will begin to ramp-down the PA. The TSM will not begin its warmdown until after the TXDIG has completed ramp-down of the PA. The TXDIG will provide an output signal (tx_en_extend) to the TSM which asserts at the same time as *source*_tx_en but does not de-assert until after the PA ramp-down has completed by the TXDIG. At that time, the TSM will complete its TX warm-down sequence (deasserting tx_dig_en, and turning off the PLL and other circuits in the analog, etc.) . Since the PA ramp-down is handled in the TXDIG, the TSM TX warm-down timing is expected to be shorter than in previous generation (C90) radios.

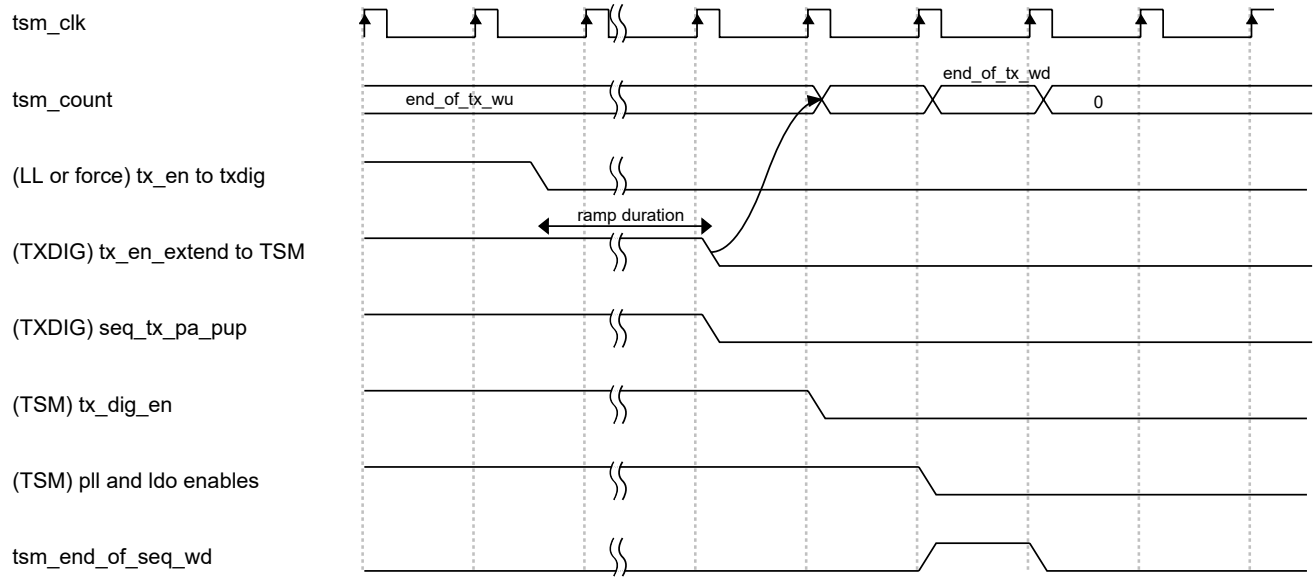

Figure 335. PA Ramp-Down Timing

For all link layers, if a TX PLL unlock or RF_NOT_ALLOWED condition occurs the link layer will need to de-assert the tx_en. Then the PA ramp-down and TSM TX warmdown will proceed as described in the figure above. (See also PLL Unlock and RF_NOT_ALLOWED Conditions)

55.4.7.7.2.7 Overrides

Each of the TSM-controlled outputs has independent override control, except for the 4 GPIO triggers. In addition, two special TSM outputs, tx_mode and rx_mode, also have their own override controls.

Two register bits are assigned to each output, to implement the override function. The bits are named:

*OUTPUTNAME*_OVRD_EN

*OUTPUTNAME*_OVRD

Setting the *OUTPUTNAME*_OVRD_EN=1, allows the *OUTPUTNAME*_OVRD bit to directly control the state of the output. Clearing *OUTPUTNAME*_OVRD_EN=0 returns control of the output to the TSM.

The override bit-pairs reside in the TSM_OVRDyy registers.

Overrides have no effect on TSM operation, TSM counting, sequence initiation, or sequence termination. Overrides may be engaged at any time, during any TSM phase, including during idle state.

55.4.7.7.2.8 Breakpoint

Breakpoint can be used to temporarily suspend a TSM sequence. A breakpoint can be set during the WARMUP or WARMDOWN phase of any TSM sequence. An 8-bit BKPT[7:0] register field resides in the TSM_CTRL register. During a TSM sequence, when the TSM counter matches the BKPT register value, counting stops and the counter holds in its current state. Deassertion of the initiating event will be ignored during the breakpoint. The breakpoint can be lifted by modifying the BKPT[7:0] register. Once the breakpoint is lifted, the TSM proceeds in the phase it was in prior to the breakpoint match, and the TSM counter begins incrementing again from the point at which the breakpoint occurred. Deassertion of the initiaing event will then be recognized and handled as described in Sequence Termination. The default value for BKPT[7:0] is 255, which is greater than the length of any allowed sequence, so a breakpoint will not trigger during a sequence, unless a lower value is programmed.

55.4.7.7.2.9 PLL Unlock and RF_NOT_ALLOWED Conditions

In some situations, it may be desirable to abort an RX or TX sequence. The TSM can detect these situations and alert the link layers. The link layer can then decide to de-assert its rx_en and tx_en outputs to the TSM which causes the sequence to end.

55.4.7.7.2.9.1 PLL Unlock

The TSM can be configured to detect and signal the link layer for any of the following PLL unlock conditions:

1. Coarse Tune Unlock
2. Frequency Target Unlock

The TSM is configured to react to PLL unlock condition via the TSM CTRL register's , ABORT_ON_FREQ_TARG, ABORT_ON_CTUNE,RX_ABORT_DIS and TX_ABORT_DIS bits. Additionally, the table below shows the TSM controlling signal for each the mechanism.

Lock Detect Mechanism	TSM Controlling Signal
Coarse Tune	pll_dig_en (indirect)
Freq. Target	freq_targ_ld_en

55.4.7.7.2.9.2 RF_NOT_ALLOWED

As of the Gen4.5 radio, the RF_NOT_ALLOWED is not qualified by the TSM. The RF_NOT_ALLOWED will signal will be used directly by the link layer(s), which will take appropriate action to de-assert their tx_en or rx_en signal as needed.

55.4.7.7.2.10 TSM RF_ACTIVE Extension

The TSM RF_ACTIVE can be used as the radio's RF_ACTIVE coexistence output. As such, this signal needs to be asserted high a programmable amount of time before a radio event takes place and remains high until either the radio event has been completed or aborted. There should be no glitches/unwanted transitions between successive radio events (e.g., RX->TX or TX->RX). This can be a problem for protocols, such as Bluetooth LE or 802.15.4, which require the transmission of an acknowledge packet shortly after reception and reception of an acknowledge packet shortly after transmission. Bluetooth LE Advertising and Scan states offer other scenarios where closely-spaced (but not adjoining) TX and RX operations are required. The inter-frame spacing between the successive RX and TX operations is long enough such that TSM RF_ACTIVE would normally deassert and reassert between operations, creating the unwanted transitions which must be avoided.

To remedy this, a feature has been added to TSM which allows the TSM RF_ACTIVE output to be optionally extended by a programmable amount, after the nominal TSM sequence completes. The programmable limit is long enough to accommodate the RF_ACTIVE glitch which would otherwise occur using the 802.15.4 192µs turnaround time. The TSM RF_ACTIVE extension will occur for all sequences (TX and RX) for which TSM RF_ACTIVE is programmed to assert, whenever register TSM_SPARE1_EXTEND>0. The hardware mechanism for extending TSM RF_ACTIVE is illustrated in the following diagram:

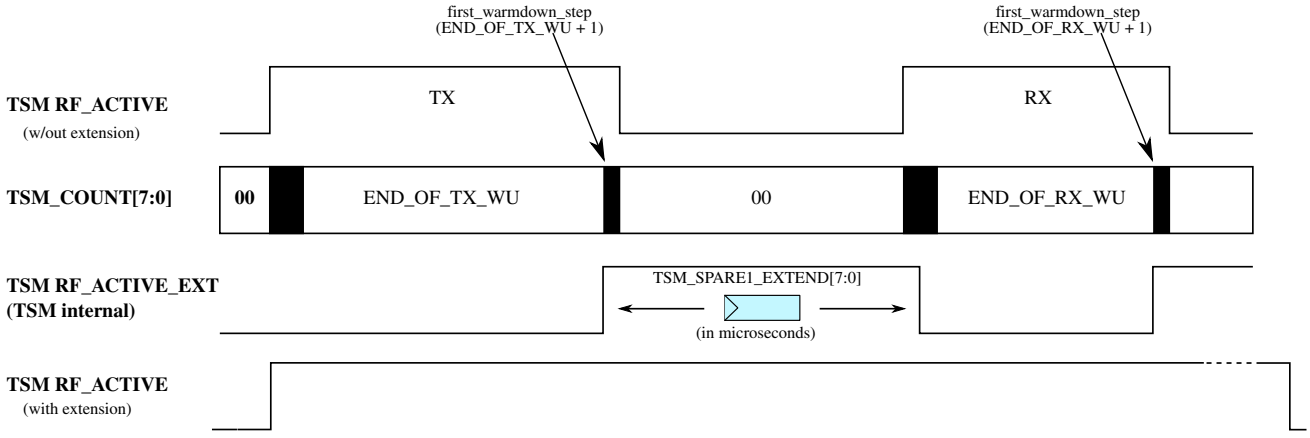

Figure 336. TSM RF_ACTIVE EXTENSION

The trigger for the extension is the TSM's first warmdown step (END_OF_xx_WU + 1), which will be reached whenever the Link Layer deasserts its TX/RX command. If enabled, the extension signal will assert (high) at this point, and will remain high for *TSM_SPARE1_EXTEND* microseconds. The extension signal (TSM RF_ACTIVE_EXT) is logically "OR-ed" with the existing TSM-controlled output TSM RF_ACTIVE, to generate the composite, extended RF_ACTIVE signal. Software can cut short the extension at any time by writing TSM_SPARE1_EXTEND=0. Setting this register to 0 also disables the extension feature from activating on any new TSM sequence. The register TSM_SPARE1_EXTEND[7:0] yields an extension range from 0 to 255µs.

55.4.7.7.2.11 Low Power Preamble Search (LPPS)

To reduce power consumption during 802.15.4 preamble-search receive state, a low-power-preamble-search (LPPS) mode can be optionally enabled. When engaged, the correlators are disabled approximately 50% of the time during preamble search. The same signal used to dynamically enable/disable the correlators, can be used to enable/disable selected analog and RF blocks in tandem, to further reduce power consumption. The LPPS_CTRL register in XCVR space, has one bit to master-enable LPPS mode (LPPS_ENABLE), and several other bits to allow selected analog and RF blocks to be “duty-cycled” in sync with the correlators. For more details on the LPPS algorithm, see Chapter Multi-standard PHY, Section *IEEE Low-power Preamble Search* for more details on the LPPS algorithm.

By default, LPPS mode is not enabled.

During LPPS mode, correlators and RF blocks are duty-cycled with timing controlled by the LPPS signal **lpps_lp_en**, which is a single-wire output from the 802.15.4 demodulator. In general, eligible blocks will be powered off when **lpps_lp_en** is high, and perform normal operation when **lpps_lp_en** is low. Transitions on **lpps_lp_en** will be handled by the TSM in the following ways:

lpps_lp_en 1 → 0:

1. TSM outputs which are programmed to be eligible for LPPS duty-cycling (e.g, those associated with TZA, BBA, ADC) shall be reasserted at this point.
2. TSM shall recycle to a programmable point in the RX warmup. The TSM RECYCLE_COUNT2[7:0] register selects the TSM_COUNT to recycle to.
3. After jumping to the TSM_COUNT indicated in RECYCLE_COUNT2, TSM shall from this point forward execute a Fast RX Warmup (see Section FAST TSM Fast Warmups later in this chapter). For the Fast RX Warmup, the registers LPPS_START_RX[7:0] and LPPS_DEST_RX[7:0] shall be used to program the TSM "jump" start and end points, as defined in the Fast RX Warmup section. The LPPS_START_RX and LPPS_DEST_RX registers reside in the LPPS_CTRL register. These registers are specific to LPPS fast warmups, and do not apply to non-LPPS fast warmups.

lpps_lp_en 0 → 1:

1. TSM outputs which are programmed to be eligible for LPPS duty-cycling (e.g, those associated with TZA, BBA, ADC) shall be deasserted at this point.
2. TSM outputs which are not eligible for LPPS duty-cycling shall remain asserted.

Note that several LPPS timing parameters are configurable (see Chapter Multi-standard PHY, Section *IEEE Low-power Preamble Search*), and LPPS_FILL_COUNT[6:0] is based on the LPPS fast warmup time. Software configuring LPPS parameters, such as LPPS_FILL_COUNT, must calculate the LPPS fast warmup time, in µs, based on the register programming described in the section above. Here is the equation:

LPPS_FAST_WARMUP_DURATION = END_OF_RX_WU - RECYCLE_COUNT2 + 1 - (LPPS_DEST_RX - LPPS_START_RX - 1)

for example,

LPPS_FAST_WARMUP_DURATION = 104 - 28 + 1 - (102 - 40 - 1)

LPPS_FAST_WARMUP_DURATION = 16µs

Note that the penalty for the reduced power consumption in LPPS mode during preamble search, is a slight degradation in receiver sensitivity. Note also that the TSM override bits, also override LPPS functionality. The override bits provide ultimate control over all TSM outputs.

Programming control for LPPS, includes a master-enable register bit for the LPPS state-machine, as well as individual control bits to enable selected analog and digital blocks to be turned on-and-off during LPPS operation. The following table lists the LPPS register bits, and the TSM outputs controlled by each.

Table 457. LPPS Register Controls

LPPS Register Bit	Description
LPPS_ENABLE	Master enable for LPPS mode. Allows correlators to be duty-cycled during Preamble Search, and selected analog and digital blocks to be duty-cycled simultaneously.
LPPS_LNA_MIX_ALLOW	When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: seq_rx_lna_pup, seq_rx_mix_pup , seq_spare1 for peak detector
LPPS_CBPF_ALLOW	When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: seq_cbpf_pup, seq_cbpf_en_dcoc
LPPS_ADC_ALLOW	When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: seq_adc_pup
LPPS_LO_RX_ALLOW	When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: seq_lo_pup_vlo_rx
LPPS_LO_RXDRV_ALLOW	When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: seq_lo_pup_vlo_rxdrv
LPPS_RX_DIG_ALLOW	When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: rx_dig_en
LPPS_RX_PHY_ALLOW	When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: rx_phy_en

55.4.7.7.2.12 FAST and POWERSAVE TSM Warmup and FAST RX2TX Transition

The previous sections illustrate the detailed control and timing generated by the TSM, operating in nominal-timing mode. There are situations that allow for the possibility to streamline and shorten the TSM warmup sequences. These situations arise when the transceiver is operating on the same RF channel for many consecutive transmit and/or receive operations. Multiple closely-spaced TX operations on the same channel allow the HPM calibration to be skipped, after such a calibration is performed once on a given RF channel; similarly, multiple closely spaced RX operations on the same channel allow DC offset calibration to be skipped, after such a calibration is performed once on a given RF channel.

Fast and Power-saving TSM warmups have been devised to accomplish this streamlining. Once engaged, during a fast or power-saving warmup, a portion of the nominal, programmed warmup is bypassed, or skipped over, by instructing the TSM

counter to jump, once it reaches a certain count, to a new count that is not just an increment-by-one. The starting point for the “jump” as well as the destination count, or end point for the “jump”, are TSM programmable registers. There are one pair of start/destination registers for TX, and another for RX, allowing one such jump per sequence.

Power-saving warmups can be used in conjuction with any of the link layers. In a power-saving warmup, the PLL sends a pwrsave_tx_wu_ok (or pwrsave_rx_wu_ok) signal to the TSM to let the TSM known that that the PLL is on the same channel as the previous tx (or rx) channel. For a power-saving warmup, the TSM will insert some idle time after the link layer asserts tx_en (or rx_en) so that the overall time from the link layer asserting tx_en (or rx_en) to when the radio is on-air remains constant. The link layer is therefore unaware that a power-saving warmup has occurred. The power savings benefit is that the analog and calibration circuits are on for a shorter during during warmup.

Fast TSM warmup is required by the link layer. Currently, only the Generic LL supports fast TSM warmups. A fast warmup is similar to a power-saving warmup, except that the TSM does not insert any idle time after the link layers tx_en (or rx_en). So the time from the link layer asserting tx_en (or rx_en) to when the radio is on-air is shorter for a fast warmup. A fast warmup request from the link layer has higher priority than a power-saving warmup ok from the PLL. In fact, the TSM does not qualify a fast warmup request with the pwrsave_tx_wu_ok (or pwrsave_rx_wu_ok) signal from the PLL; the Generic LL programmer must ensure that previous warmup calibrations can be skipped before requesting a fast warmup.

Enables bits provide software with fine control over precisely when fast and power-saving warmups are allowed, versus nominal warmups.

In addition, TSM sequences have in the past been discrete TX or RX operations, with a required software command to initiate the sequence, and a return-to-idle after the sequence is complete, before a new sequence-start command can be issued. For some link layers, it is highly desirable to be able to jump directly from the end of a CCA measurement (CCA = Clear Channel Assessment), which is essentially an RX operation, to a packet transmit operation, without returning the TSM to IDLE in between, if CCA deems the channel to be free. A new TSM transition called “Fast RX2TX” accomplishes this. The Generic or 802.15.4 Link Layer will signal to TSM when to perform such a transition, and TSM will respond by jumping from the RX “ON” phase, to a programmable point within the TX warmup. At the very least, this will allow the re-warmup of the required analog regulators to be skipped, since they can stay on during the transition. Also, since the PLL is staying on the same channel, there is no need to cycle the VCO off, and then on again, so the VCO-related TSM controls can be programmed to maintain their states during the transition. Enable bits provide software with fine control over precisely when a “Fast RX2TX” is allowed, versus a nominal RX-to-IDLE-to-TX ordering of events.

Fast RX2TX can also be combined with a Fast TX Warmup to yield an ultrafast TX warmup sequence, if, as is likely, the RF channel has not changed since the previous TX warmup. In this case, the Fast TX warmup is conditioned by the PLL's pwrsave_tx_wu_ok.

Interaction with other blocks is required to support TSM fast warmup capability. The PLL digital block is responsible for selecting the correct frequency for RF operations, and will keep track of whether consecutive warmup operations utilize the same channel or not; it will signal this information to the TSM. The PLL digital block will maintain such tracking separately for TX and RX warmups. The TSM will then signal back to the PLL digital block when a TX warmup is actually “fast” or not; the PLL digital block will use this information to instruct its state machine to skip HPM calibration. For RX warmups, the TSM will signal to the RX digital block, when to skip DC calibration, and instead use stored values.

The new inter-block signaling to support fast TSM warmups is illustrated in the following diagram, followed by a table which describes the new signaling.

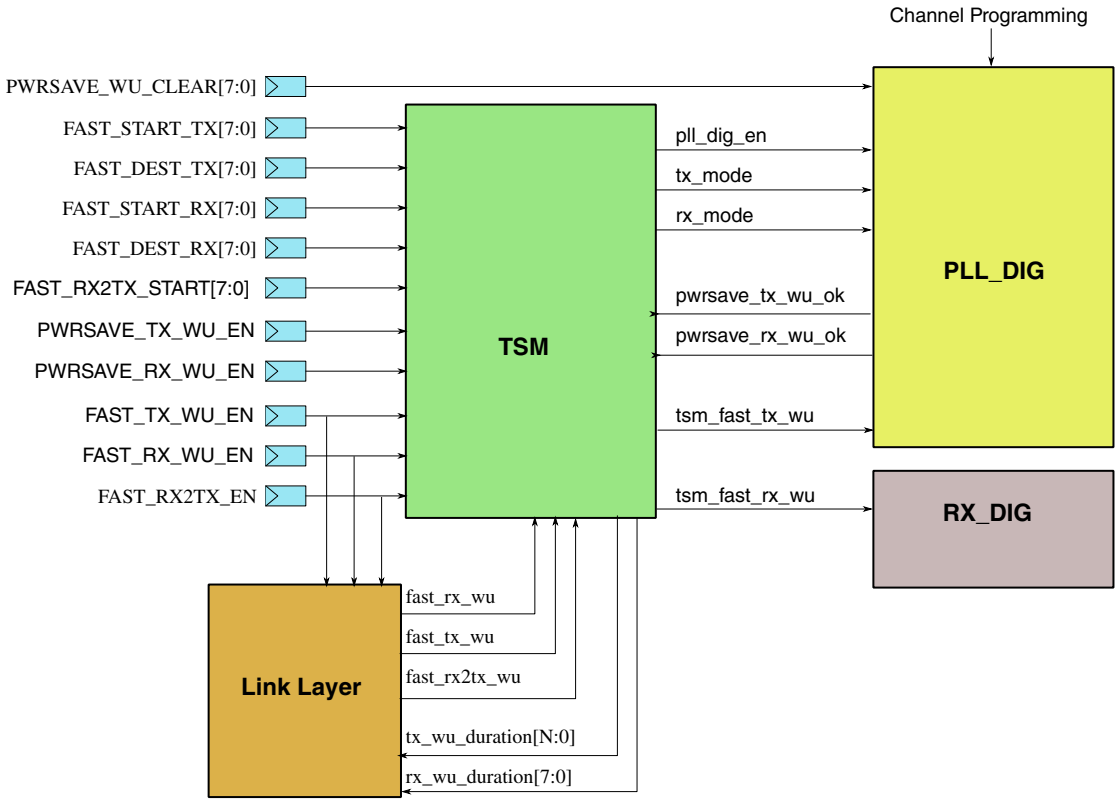

Figure 337. XCVR SIGNALLING TO SUPPORT TSM FAST WARMUPS

"Fast Warmup" Signal	Source	Destination	Description
pll_dig_en	TSM	PLL Digital	Rising edge of this signal used by PLL_DIG to capture the Channel Programming for the current warmup
tx_mode	TSM	PLL Digital	Used in conjunction with pll_dig_en to capture the Channel Programming for TX sequences
rx_mode	TSM	PLL Digital	Used in conjunction with pll_dig_en to capture the Channel Programming for RX sequences
fast_rx_wu	Generic LL	TSM	Link layer requests a Fast RX warmup
fast_tx_wu	Generic LL	TSM	Link layer requests a Fast TX warmup
fast_rx2tx_wu	ZSM (802.15.4) or Generic LL	TSM	The RF channel is free to transmit immediately after

Table continues on the next page...

Table continued from the previous page...

"Fast Warmup" Signal	Source	Destination	Description
			an RX burst. TSM should jump directly from RX "ON" phase to TX "WARMUP" phase, entering at the FAST_RX2TX_START point.
pwrsave_rx_wu_ok	PLL Digital	TSM	Indicates that the Channel Programming on the *current* RX warmup has not changed since the *last* RX warmup
pwrsave_tx_wu_ok	PLL Digital	TSM	Indicates that the Channel Programming on the *current* TX warmup has not changed since the *last* TX warmup
tsm_fast_tx_wu	TSM	PLL Digital	This is a fast or power-saving TX warmup. PLL_DIG should skip calibration.
tsm_fast_rx_wu	TSM	RX Digital	This is a fast or power-saving RX warmup. RX Dig should skip DCOC Cal.
rx_warmup_duration[7:0]	TSM	Link Layer	Indicates the RX warmup time.
tx_warmup_duration[7:0]	TSM	Link Layer	Indicates the TX warmup time, including PA ramp time

TSM Registers to support Fast TSM Warmups and Fast RX2TX are described in the following table.

Field	R/W	Description
PWRSAVE_TX_WU_EN	rw	1: Enable Power-Saving TX Warmup (if pwrsave_tx_wu_ok asserted by PLL_DIG) 0: Disable Power-Saving TX Warmups
PWRSAVE_RX_WU_EN	rw	1: Enable Power-Saving RX Warmup (if pwrsave_rx_wu_ok asserted by PLL_DIG) 0: Disable Power-Saving RX Warmups
PWRSAVE_WU_CLR	rw	This is not used directly by the TSM. It creates a signal to the PLL to clear its wu_ok. It should

Table continues on the next page...

Table continued from the previous page...

Field	R/W	Description
		be set and then cleared by software. 1: Direct the PLL to clear the *wu_ok signals 0: Do nothing
FAST_TX_WU_EN	rw	1: Enable Fast TX Warmup (if fast_tx_wu_ok asserted by PLL_DIG) 0: Disable Fast TX Warmups
FAST_RX_WU_EN	rw	1: Enable Fast RX Warmup (if fast_rx_wu_ok asserted by PLL_DIG) 0: Disable Fast RX Warmups
FAST_RX2TX_EN	rw	1: Enable Fast RX-to-TX transitions (if fast_rx2tx_wu is asserted by ZSM) 0: Disable Fast RX-to-TX transitions
FAST_START_TX[7:0]	rw	During a Fast or Power-Saving TX Warmup, this value represents the starting TSM count for the portion of the warmup that is to be skipped over. If Fast or Power-Saving TX Warmups are enabled, this count will never be reached; its place in the TSM warmup will be replaced by the contents of FAST_DEST_TX[7:0], thereby executing the jump.
FAST_DEST_TX[7:0]	rw	During a Fast or Power-Saving TX Warmup, this value represents the ending TSM count for the portion of the warmup that is to be skipped over. If Fast or Power-Saving TX Warmups are enabled, FAST_START_TX[7:0] will never be reached and will instead be replaced by the contents of this register, thereby executing the jump. Example: FAST_START_TX = 10 FAST_DEST_TX = 15

Table continues on the next page...

Table continued from the previous page...

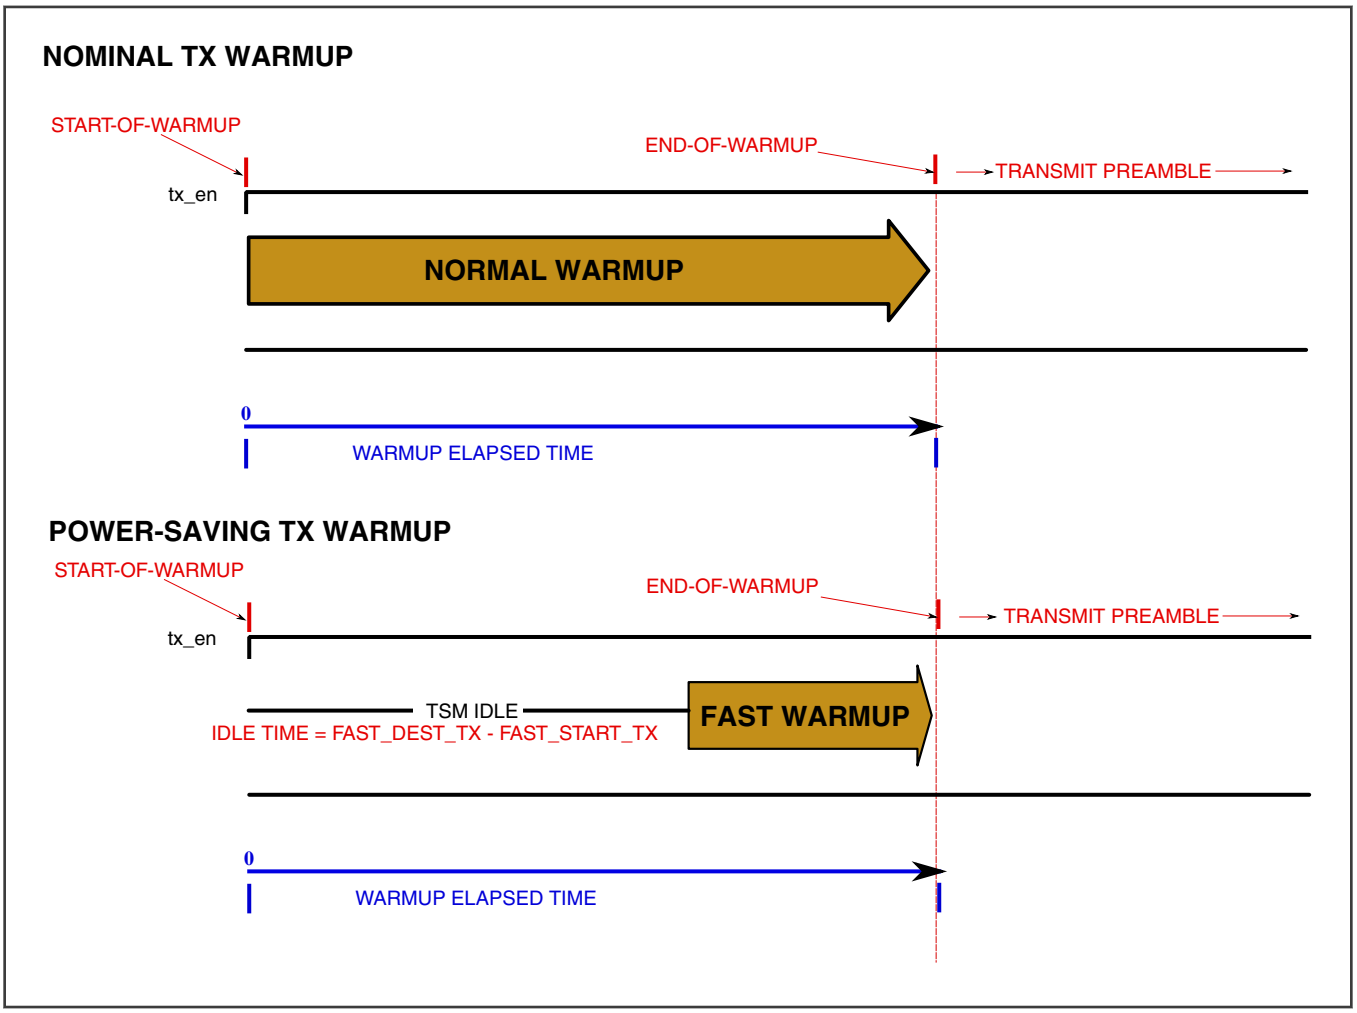
Field	R/W	Description
		The TSM will count as follows: … 7,8,9,15,16,17 …
FAST_START_RX[7:0]	rw	During a Fast or Power-Saving RX Warmup, this value represents the starting TSM count for the portion of the warmup that is to be skipped over. If Fast or Power-Saving RX Warmups are enabled, this count will never be reached; its place in the TSM warmup will be replaced by the contents of FAST_DEST_RX[7:0], thereby executing the jump.
FAST_DEST_RX[7:0]	rw	During a Fast or Power-Saving RX Warmup, this value represents the ending TSM count for the portion of the warmup that is to be skipped over. If Fast or Power-Saving RX Warmups are enabled, FAST_START_RX[7:0] will never be reached and will instead be replaced by the contents of this register, thereby executing the jump. Example: FAST_START_TX = 10 FAST_DEST_TX = 15 The TSM will count as follows: … 7,8,9,15,16,17 …
FAST_RX2TX_START[7:0]	rw	During a Fast RX-to-TX transition (FAST_RX2TX_EN=1) the contents of this register represent the entry point (TSM count) in the TX warmup sequence to which the TSM jumps to when Link Layer asserts fast_rx2tx_wu. The TSM will jump from the RX “ON” phase to the TX “WARMUP” phase, starting at this count.

Software running on the various protocol engines which utilize the TSM to provide access to the channel, need not be aware that the total warmup time has been reduced, when the TSM executes a power-saving warmup, as opposed to a nominal warmup. (With the exception of the Generic LL), Link Layer software expects TSM warmup times to be a fixed constant, actually 2 fixed constants, one for TX warmups and one for RX warmups. Software must account for these TX and RX warmup times when they are scheduling transceiver operations, so that the first symbol of preamble is transmitted at the correct instant for transmit operations, and that the receiver is ready to receive the first symbol of preamble at the correct instant for receive operations. Software views these warmup times as fixed lead times that must be accounted for in advance of a transceiver operation.

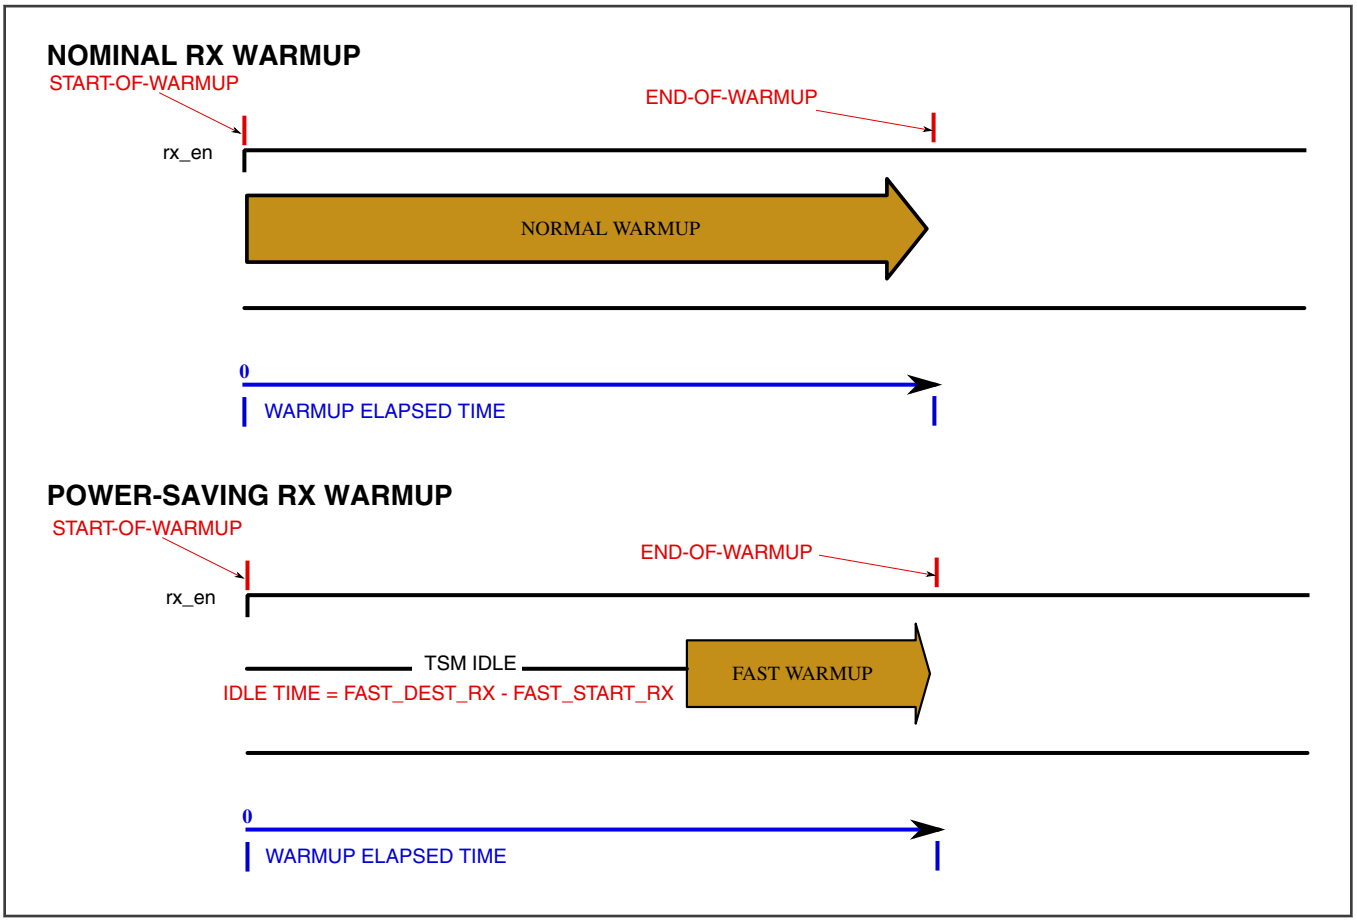
In order to make the power-saving warmup time reduction transparent to software, when a power-saving TSM warmup is executed, the TSM will delay the start of the warmup, by the amount of time skipped by the jump. That keeps the total elapsed time,

from the instant the software launches the TSM sequence, to the point at which the warmup completes, identical for power-saving and nominal warmups.

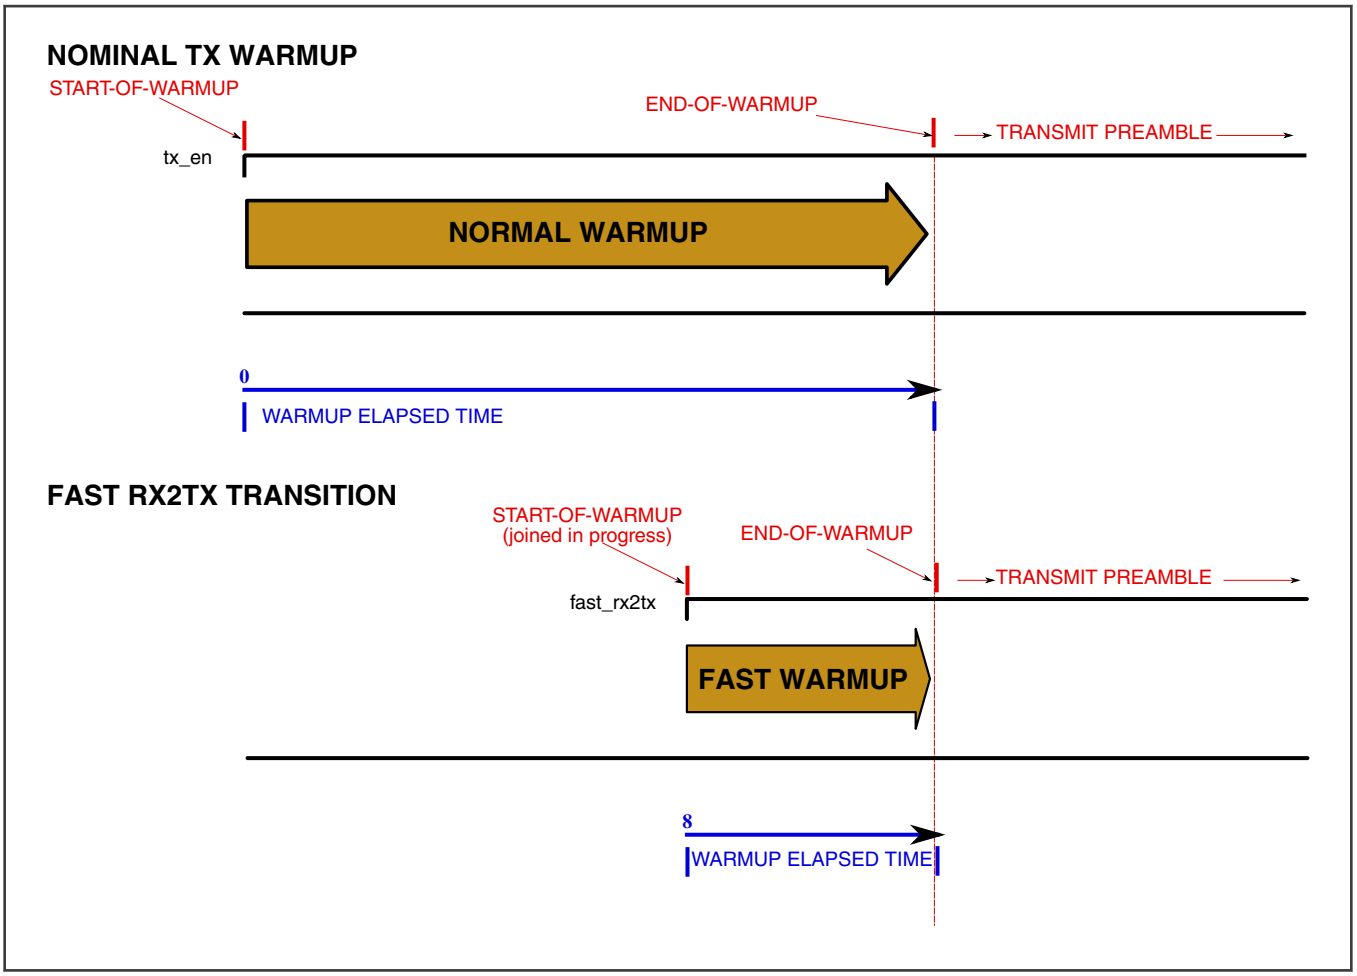
The following diagram illustrates how the TSM delays the start of the Power-saving TX sequence, relative to the nominal TX sequence, so that the delta time between tx_en (TSM launch signal), and the transmission of the first bit of preamble, is the same in either case.



The following diagram illustrates how the TSM delays the start of the Power-saving RX sequence, relative to the nominal RX sequence, so that the delta time between rx_en (TSM launch signal), and the ability to receive first bit of preamble, is the same in either case.



The FAST RX2TX transition is handled differently. The objective in such a transition is to get to the point of transmitting the first bit of preamble ASAP. There is no warmup time that software needs to account for in this case, since the RX-to-TX transition is handled completely by hardware. The following diagram compares a nominal TX warmup, with a foreshortened “Fast RX2TX” warmup.



55.4.7.7.2.13 FAST Transition Support for Ranging Sequence Manager

For the Ranging Sequence Manager (RSM), the TSM supports the following additional features:

- Ability for the RSM to request Fast RX-to-TX transition described in previous section. The RSM outputs a fast_rx2tx_wu signal to the TSM to request this transition
- Fast TX-to-RX feature, analogous to the Fast RX-to-TX feature. The RSM outputs a fast_tx2rx_wu signal to the TSM to request this transition.
- An alternate set of START times for the Fast RX-to-TX and Fast TX-to-RX features. This allows the RSM to use the primary set of START times for its IP (Interlude Period) transitions and the alternate set for its FC (Frequency Change) transitions. The RSM outputs a signal fast_fc_wu to the TSM to select which set to use.
- Ability for the RSM to request FAST RX in conjunction with Fast TX-to-RX transiiton. These use the FAST_START_RX[7:0] and FAST_DEST_RX[7:0] as described in the previous section. The RSM outputs a fast_rx_wu signal to request FAST RX.
- Ability for the RSM to request FAST TX in conjunction with Fast RX-to-TX transiiton. These use the FAST_START_TX[7:0] and FAST_DEST_TX[7:0] as described in the previous section. The RSM outputs a fast_tx_wu signal to request FAST TX.

Refer to Role Swap and Frequency Change Transitions section in the Ranging Sequence Manager topic for more information about RSM use of these TSM features.

The TSM Registers added to support these additional features for the RSM are described in the following table.

Field	R/W	Description
FAST_TX2RX_EN	rw	1: Enable Fast TX-to-RX transitions (if fast_tx2rx_wu is asserted by RSM) 0: Disable Fast TX-to-RX transitions
FAST_TX2RX_START[7:0]	rw	During a Fast TX-to-RX transition (FAST_TX2RX_EN=1) the contents of this register represent the entry point (TSM count) in the RX warmup sequence to which the TSM jumps to when RSM asserts fast_tx2rx_wu with fast_fc_wu=0. The TSM will jump from the TX “ON” phase to the RX “WARMUP” phase, starting at this count.
FAST_RX2TX_START_FC[7:0]	rw	During a Fast RX-to-TX transition (FAST_RX2TX_EN=1) the contents of this register represent the entry point (TSM count) in the TX warmup sequence to which the TSM jumps to when RSM asserts fast_rx2tx_wu with fast_fc_wu=1. (If fast_fc_wu=0, the TSM will use FAST_RX2TX_START[7:0]) The TSM will jump from the RX “ON” phase to the TX “WARMUP” phase, starting at this count.
FAST_TX2RX_START_FC[7:0]	rw	During a Fast TX-to-RX transition (FAST_TX2RX_EN=1) the contents of this register represent the entry point (TSM count) in the RX warmup sequence to which the TSM jumps to when RSM asserts fast_tx2rx_wu with fast_fc_wu=1. (If fast_fc_wu=0, the TSM will use FAST_TX2RX_START[7:0]) The TSM will jump from the TX “ON” phase to the RX “WARMUP” phase, starting at this count.

55.4.7.7.2.14 Programming Restrictions

The following restrictions are imposed on TSM programming. Violating the restrictions may result in unpredictable behavior.

1. The maximum value for END_OF_TX_WU[7:0] is 253
2. The maximum value for END_OF_RX_WU[7:0] is 253
3. The maximum value for END_OF_TX_WD[7:0] is 254
4. The maximum value for END_OF_RX_WD[7:0] is 254
5. END_OF_TX_WD[7:0] – END_OF_TX_WU[7:0] >= 1

6. END_OF_RX_WD[7:0] – END_OF_RX_WU[7:0] >= 1
7. BKPT[7:0] != END_OF_TX_WD[7:0]
8. BKPT[7:0] != END_OF_RX_WD[7:0]
9. For any TSM output: OUTPUTNAME_TX_HI[7:0] <= OUTPUTNAME_TX_LO[7:0]
10. For any TSM output: OUTPUTNAME_RX_HI[7:0] <= OUTPUTNAME_RX_LO[7:0]

Restrictions 9 and 10 above, if violated, will result in the TSM-controlled output held in a deasserted state throughout the sequence.

To guarantee non-assertion of a particular TSM-controlled output throughout the course of a sequence, simply program its OUTPUTNAME_SEQ_HI = OUTPUTNAME_SEQ_LO = 255 (where SEQ = TX or RX).

55.4.7.7.2.15 Interrupts

For debug purposes, TSM has two timing control outputs (tsm_irq0_start_trigger_en and tsm_irq1_stop_trigger_en) which can be used to either generate interrupts to the host processor. Like all other TSM-controlled outputs, the point during the TX or RX warmup at which the interrupt is triggered, is fully programmable.

To use either tsm_irq0_start_trigger_en or tsm_irq1_stop_trigger_en as an interrupt, set the TSM_IRQ0_EN or TSM_IRQ1_EN bit, respectively, in the TSM_CTRL registers. Because the TSM is part of XCVR space, and XCVR space does not have its own interrupt vector, the TSM interrupt is "assigned" to the Link Layer currently in possession of the radio. Each Link Layer controller has in its address space, a TSM_IRQ status bit, as well as a enable bit to allow/disallow the TSM interrupt to assert the Link Layer's interrupt line to the MCU. The TSM_IRQ status bit, as it appears in each Link Layer's address space, is a logical "OR" of the TSM's TSM0_IRQ and TSM1_IRQ. The Link Layer TSM_IRQ is read-only. It can be cleared by clearing both TSM0_IRQ and TSM1_IRQ in the XCVR's XCVR_STATUS register. In the XCVR_STATUS register, TSM0_IRQ and TSM1_IRQ are both write-1-to-clear bits. See the Register Description for each individual Link Layer, for a description of the TSM_IRQ read-only interrupt status bit, and its bit positioning within the Link Layer's address space.

The tsm_irq0_start_trigger_en can also be used as a start trigger source for the Transceiver DMA or Packet RAM Debug mode. The tsm_irq1_stop_trigger_en can also be used as a stop trigger source for the Packet RAM Debug mode.

Fields

Field	Function
31-24 BKPT	TSM Breakpoint Temporarily halt a TSM sequence during the warmup or warmdown phase. When the TSM counter matches the value of BKPT[7:0], breakpoint will take effect and the TSM counter will stop and hold its count. Breakpoint will remain in effect as long as BKPT[7:0] matches the TSM counter value. The TSM Breakpoint can be lifted by modifying the contents of this register. The default value of this register, 0xFF, is greater than the length of the longest possible sequence, so a breakpoint will never be triggered unless BKPT[7:0] is programmed to a value less than the length of sequence.
23-16 TSM_SPARE1_EXTEND	TSM RF_ACTIVE Extension Duration When TSM output RF_ACTIVE is enabled to assert during any TX or RX sequence and TSM_SPARE1_EXTEND[7:0] > 0, this register specifies the number of microseconds for which RF_ACTIVE is to remain asserted beyond the end of the TSM warmdown. This extension is intended to close any gap in the coexistence output RF_ACTIVE that may occur between consecutive TX/RX or RX/TX TSM operations.
15-12 TSM_LL_INHIBIT	TSM Per-Link-Layer Inhibit Nominally, any protocol engine can request TSM to start a TX or RX sequence at any time. In a multiprotocol setting, individual protocol engines can (optionally) be selectively blocked from accessing TSM by setting one of the following bits of TSM_LL_INHIBIT[3:0]: xxx1: Bluetooth LE commands to TSM are inhibited xxx0: Bluetooth LE commands to TSM are permitted

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1xxx: GENERIC_FSK commands to TSM are inhibited 0xxx: GENERIC_FSK commands to TSM are permitted
11 PLL_UNLOCK_IRQ	PLL Unlock IRQ PLL Un-lock Interrupt Status bit. A '1' indicates an unlock event has occurred in the PLL. This is write a '1' to clear bit. 0b - A PLL Unlock Interrupt has not occurred 1b - A PLL Unlock Interrupt has occurred
10 PLL_UNLOCK_IRQ_EN	PLL Unlock Interrupt Enable 0b - allows PLL unlock event to generate an interrupt 1b - A PLL unlock event will set the PLL_UNLOCK_IRQ status bit, but an interrupt is not generated
9 TSM_IRQ1_EN	TSM_IRQ1 Enable/Disable bit TSM_IRQ1 Enable/Disable bit. Intended for debug purposes only. 0b - TSM_IRQ1 is disabled 1b - TSM_IRQ1 is enabled
8 TSM_IRQ0_EN	TSM_IRQ0 Enable/Disable bit TSM_IRQ0 Enable/Disable bit. Intended for debug purposes only. 0b - TSM_IRQ0 is disabled 1b - TSM_IRQ0 is enabled
7 ABORT_ON_FREQ_TARG	Abort On Frequency Target Lock Detect Failure 0b - don't allow TSM abort on Frequency Target Unlock Detect 1b - allow TSM abort on Frequency Target Unlock Detect
6 ABORT_ON_CTUNE	Abort On Coarse Tune Lock Detect Failure 0b - don't allow TSM abort on Coarse Tune Unlock Detect 1b - allow TSM abort on Coarse Tune Unlock Detect
5 RX_ABORT_DIS	Receive Abort Disable RX Abort disable. When set, prevents PLL unlock events during RX sequences from aborting the sequence.
4 TX_ABORT_DIS	Transmit Abort Disable TX Abort disable. When set, prevents PLL unlock events during TX sequences from aborting the sequence.
3	Force Receive Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
FORCE_RX_EN	Direct software control to launch a RX TSM sequence. Initiates RX Warmup on a 0 to 1 transition and RX Warmdown on a 1 to 0 transition. 0b - TSM Idle 1b - TSM executes a RX sequence
2 FORCE_TX_EN	Force Transmit Enable Direct software control to launch a TX TSM sequence. Initiates a TX Warmup sequence on a 0 to 1 transition and a TX Warmdown sequence on a 1 to 0 transition. 0b - TSM Idle 1b - TSM executes a TX sequence
1 TSM_SOFT_RESET	TSM Soft Reset Writing 1 to this bit returns TSM to its IDLE state, with TSM_COUNT=0. Writing 0 to this bit removes the forced-reset condition and resumes normal operation. The bit is not self-clearing. For contingency purposes only 0b - TSM Soft Reset removed. Normal operation. 1b - TSM Soft Reset engaged. TSM forced to IDLE, and holds there until the bit is cleared.
0 —	Reserved

R W	END_OF_TX_WD								END_OF_TX_WU							
Reset	0	1	1	1	0	0	1	0	0	1	1	1	0	0	0	0

Fields

Field	Function
31-24 END_OF_RX_WD	End of RX Warmdown This register defines the point at which the TSM RX sequence warmdown completes, and the TSM returns to idle. The duration of the TSM warmdown phase is determined by: END_OF_RX_WD – END_OF_RX_WU.
23-16 END_OF_RX_WU	End of RX Warmup This register defines the length of the TSM RX warmup sequence. After the assertion of a RX sequence-initiating event, when the TSM counter reaches the count matching this register, it will stop and hold its count, and the TSM will transition from the WARMUP to the ON phase.
15-8 END_OF_TX_WD	End of TX Warmdown This register defines the point at which the TSM TX sequence warmdown completes, and the TSM returns to idle. The duration of the TSM warmdown phase is determined by: END_OF_TX_WD – END_OF_TX_WU.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-0 END_OF_TX_WU	End of TX Warmup This register defines the length of the TSM TX warmup sequence. After the assertion of a TX sequence-initiating event, when the TSM counter reaches the count matching this register, it will stop and hold its count, and the TSM will transition from the WARMUP to the ON phase.

55.4.7.7.3.1.5 WARMUP LATENCY (WU_LATENCY)

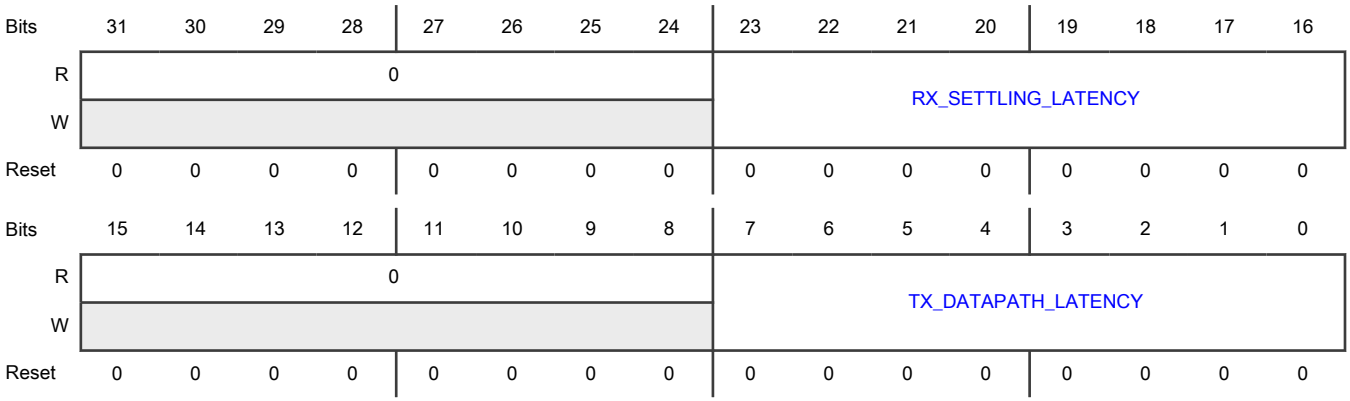
Offset

Register	Offset
WU_LATENCY	Ch

Function

This register contains the RX and TX latency values. These are added to the TSM's warmup duration to provide the Generic link layer a total warmup time.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 RX_SETTLING_LATENCY	RX Settling Latency RX_SETTLING_LATENCY allows for a bulk delay value (in microseconds) to be added to the RX TSM warm-up time for link layer scheduling. The programmed value corresponds to the time that the RX data path may need for RX filters and clocks to settle and/or any post-warm-up RX activities that need to be completed before a valid RF signal can be correctly processed.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-8 —	Reserved
7-0 TX_DATAPATH_LATENCY	TX Datapath Latency TX_DATAPATH_LATENCY allows for a bulk delay value (in microseconds) to be added to the TX TSM warm-up time for link layer scheduling. This value comprises cumulative TX data path processing latency including contributions by RBME, TX-Dig, PLL and Antenna Interface as per TX configuration.

55.4.7.7.3.1.6 TSM RECYCLE COUNT (RECYCLE_COUNT)

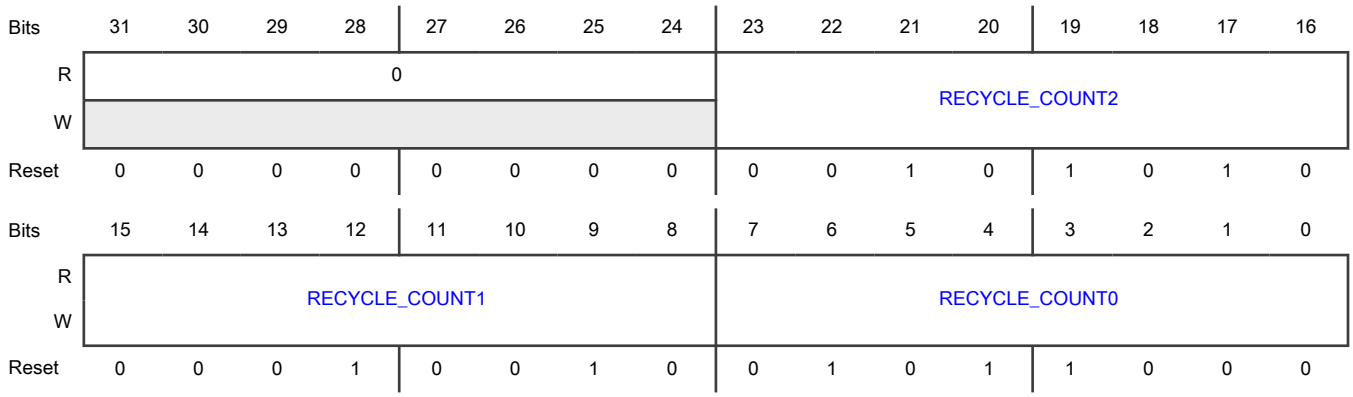
Offset

Register	Offset
RECYCLE_COUNT	10h

Function

This register contains the TSM Recycle "Jump-to" points for the 3 types of TSM Recycle

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 RECYCLE_COUNT2	TSM RX Recycle Count 2 The RECYCLE_COUNT2[7:0] register determines the TSM count value to which the TSM "recycles" when, in LPPS mode, an LPPS power save cycle completes and the receiver is switched back on, necessitating a foreshortened RX warmup. The intention is for this register to be programmed to a TSM

Table continues on the next page...

Table continued from the previous page...

Field	Function
	count value that is just prior to the assertion of rx_lna_en, but there are no restrictions on programming this register. An LPPS recycle is a command from the LPPS state machine to TSM, requesting a jump from the TSM ON phase back to a programmable point in the WARMUP phase, and resume counting from there.
15-8 RECYCLE_COUNT1	TSM RX Recycle Count 1 The RECYCLE_COUNT1 register determines the TSM count value to which the TSM "recycles" when a link layer asserts the tsm_recycle[1] signal. The intention is for RECYCLE_COUNT1 to be programmed to a TSM count value such that the TSM de-asserts, and then re-asserts its "pll_dig_en" output, to effectuate a Dual PAN on-the-fly channel change, but there are no restrictions on programming this register. For 802.15.4 Sequence Manager (ZSM), tsm_recycle[1] is associated with the "RX_PAN1" state. For Generic_FSK Link Layer, tsm_recycle[1] is associated with the "RX_PAN1" state.
7-0 RECYCLE_COUNT0	TSM RX Recycle Count 0 The RECYCLE_COUNT0[7:0] register determines the TSM count value to which the TSM "recycles" when the 802.15.4 Sequence Manager (ZSM) state "RX_CYC" is reached and the ZSM asserts tsm_recycle[0] to TSM. This register also determines the TSM count value to which the TSM recycles when the ZSM state RX_CCCA is reached because tsm_recycle[0] is also asserted in this state. This register also determines the TSM count value to which the TSM recycles when the Generic_FSK Link Layer asserts a tsm_recycle to TSM. The intention is for this register to be programmed to a TSM count value such that the TSM re-asserts its "rx_init" output, but there are no restrictions on programming this register. An RX recycle is a command from any protocol engine to TSM, requesting a jump from the TSM ON phase back to a programmable point in the WARMUP phase, and resume counting from there. A recycle will result from the reception of a packet with bad CRC or one which fails packet-filtering rules, or the end of a CCA operation in Continuous CCA mode which results in a channel indicating "busy".

55.4.7.7.3.1.7 TSM FAST WARMUP CONTROL 1 (FAST_CTRL1)

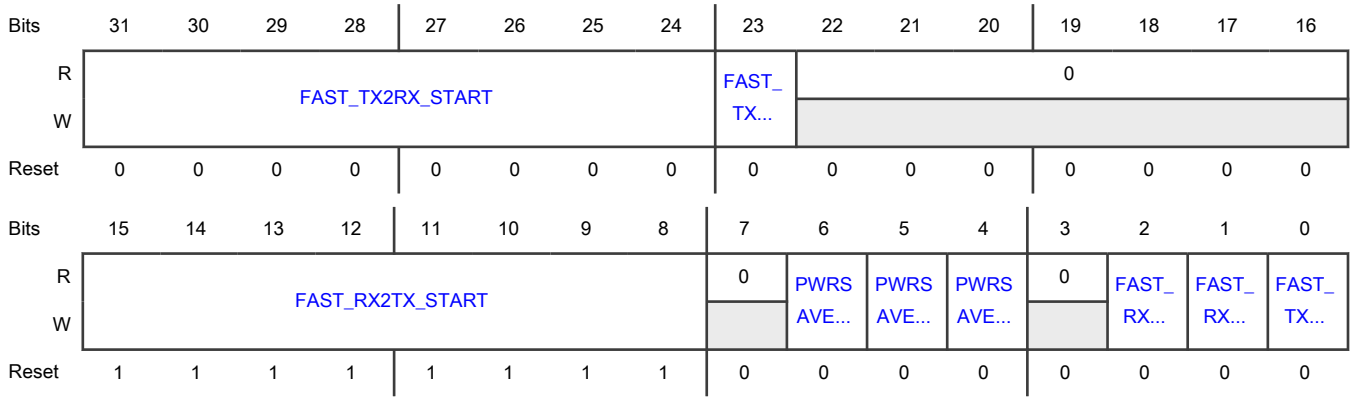
Offset

Register	Offset
FAST_CTRL1	14h

Function

This register provides enabling and control for Fast TSM Mode

Diagram



Fields

Field	Function
31-24 FAST_TX2RX_START	TSM "Jump-to" point for a Fast TSM TX-to-RX Transition. During a Fast TX-to-RX transition (FAST_TX2RX_EN=1), the contents of this register represent the entry point (TSM count) in the RX warmup sequence to which the TSM jumps to when Ranging sequence manager asserts fast_tx2rx_wu. The TSM will jump from the TX “ON” phase to the RX “WARMUP” phase, starting at this count.
23 FAST_TX2RX_EN	Fast TSM TX-to-RX Transition Enable This bit enables a special state transition in the Ranging Sequence Manager, combined with a TSM jump from the TX "ON" phase to the RX "Warmup" phase 0b - Disable Fast TX-to-RX transitions 1b - Enable Fast TX-to-RX transitions (if fast_tx2rx_wu is asserted by Ranging sequence manager)
22-16 —	Reserved
15-8 FAST_RX2TX_START	TSM "Jump-to" point for a Fast TSM RX-to-TX Transition. During a Fast RX-to-TX transition (FAST_RX2TX_EN=1) the contents of this register represent the entry point (TSM count) in the TX warmup sequence to which the TSM jumps to when 802.15.4 ZSM asserts fast_rx2tx_wu. The TSM will jump from the RX “ON” phase to the TX “WARMUP” phase, starting at this count.
7 —	Reserved
6 PWRSAVE_WU_CLEAR	PowerSave TSM Warmup Clear State This bit clears the RF channel memory in the PLL Digital Block, forcing the next TSM TX Warmup to be normal (not powersave), and the next TSM RX Warmup to be normal (not powersave), regardless of whether the RF channel has actually changed or not. This bit is not self-clearing. Write '1' to clear channel memory, then write '0' to proceed with TSM operations.

Table continues on the next page...

Table continued from the previous page...

Field	Function
5 PWRSAVE_RX_WU_EN	Power Save TSM RX Warmup Enable 0b - PowerSave TSM RX Warmups are disabled 1b - PowerSave TSM RX Warmups are enabled, if the RF channel has not changed since the last RX warmup.
4 PWRSAVE_TX_WU_EN	Power Save TSM TX Warmup Enable 0b - PowerSave TSM TX Warmups are disabled 1b - PowerSave TSM TX Warmups are enabled, if the RF channel has not changed since the last TX warmup.
3 —	Reserved
2 FAST_RX2TX_EN	Fast TSM RX-to-TX Transition Enable This bit enables a special state transition in the Link Layer, combined with a TSM jump from the RX "ON" phase to the TX "Warmup" phase, to accelerate the CCA-to-TX transition in the Link Layer autosequences 0b - Disable Fast RX-to-TX transitions 1b - Enable Fast RX-to-TX transitions (if fast_rx2tx_wu is asserted by the Link Layer)
1 FAST_RX_WU_EN	Fast TSM RX Warmup Enable 0b - Fast TSM RX Warmups are disabled 1b - Fast TSM RX Warmups are enabled, if the RF channel has not changed since the last RX warmup, and for Bluetooth LE mode, the RF channel is not an advertising channel.
0 FAST_TX_WU_EN	Fast TSM TX Warmup Enable 0b - Fast TSM TX Warmups are disabled 1b - Fast TSM TX Warmups are enabled, if the RF channel has not changed since the last TX warmup, and for Bluetooth LE mode, the RF channel is not an advertising channel.

55.4.7.7.3.1.8 TSM FAST WARMUP CONTROL 2 (FAST_CTRL2)

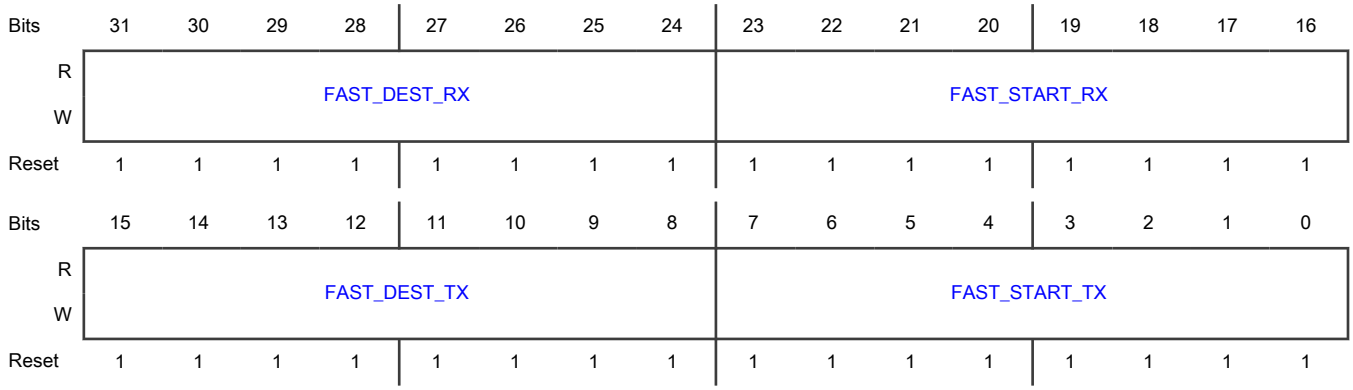
Offset

Register	Offset
FAST_CTRL2	18h

Function

This register provides configuration for Fast TSM Mode

Diagram



Fields

Field	Function
31-24 FAST_DEST_RX	Fast TSM RX "Jump-to" Point During a Fast RX Warmup, this value represents the ending TSM count for the portion of the warmup that is to be skipped over. If Fast RX Warmups are enabled, FAST_START_RX[7:0] will never be reached and will instead be replaced by the contents of this register, thereby executing the jump. Example: FAST_START_RX = 10 FAST_DEST_RX = 15 The TSM will count as follows: … 7,8,9,15,16,17 …
23-16 FAST_START_RX	Fast TSM RX "Jump-from" Point During a Fast RX Warmup, this value represents the starting TSM count for the portion of the warmup that is to be skipped over. If Fast RX Warmups are enabled, this count will never be reached; its place in the TSM warmup will be replaced by the contents of FAST_DEST_RX[7:0], thereby executing the jump.
15-8 FAST_DEST_TX	Fast TSM TX "Jump-to" Point During a Fast TX Warmup, this value represents the ending TSM count for the portion of the warmup that is to be skipped over. If Fast TX Warmups are enabled, FAST_START_TX[7:0] will never be reached and will instead be replaced by the contents of this register, thereby executing the jump. Example: FAST_START_TX = 10 FAST_DEST_TX = 15 The TSM will count as follows: … 7,8,9,15,16,17 …
7-0 FAST_START_TX	Fast TSM TX "Jump-from" Point During a Fast TX Warmup, this value represents the starting TSM count for the portion of the warmup that is to be skipped over. If Fast TX Warmups are enabled, this count will never be reached; its place in the TSM warmup will be replaced by the contents of FAST_DEST_TX[7:0], thereby executing the jump.

55.4.7.7.3.1.9 TSM FAST WARMUP CONTROL 3 (FAST_CTRL3)

Offset

Register	Offset
FAST_CTRL3	1Ch

Function

This register provides enabling and control for Fast TSM Mode

Fields

Field	Function
31-24 FAST_TX2RX_START_FC	TSM "Jump-to" point for RSM's FC TX-to-RX Transition During a Fast TX-to-RX transition (FAST_TX2RX_EN=1), the contents of this register represent the entry point (TSM count) in the RX warmup sequence to which the TSM jumps to when Ranging sequence manager asserts fast_tx2rx_wu and fast_fc_wu. The TSM will jump from the TX “ON” phase to the RX “WARMUP” phase, starting at this count.
23-16 —	Reserved
15-8 FAST_RX2TX_START_FC	TSM "Jump-to" point for RSM's FC RX-to-TX Transition During a Fast RX-to-TX transition (FAST_RX2TX_EN=1) the contents of this register represent the entry point (TSM count) in the TX warmup sequence to which the TSM jumps to when the Ranging Sequence Manager asserts fast_rx2tx_wu and fast_fc_wu. The TSM will jump from the RX “ON” phase to the TX “WARMUP” phase, starting at this count.
7-0 —	Reserved

55.4.7.7.3.1.10 TSM_TIMING00 (TIMING00)

Offset

Register	Offset
TIMING00	20h

Function

This register contains the timing values to control the assertion and deassertion times for both TX and RX sequences for the RF_ACTIVE TSM signal or signal group.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table continued from the previous page...

Field	Function
8 SEQ_DIVN_OPENLOOP_OVRD_EN	Override control for SEQ_DIVN_OPENLOOP 0b - Normal operation. 1b - Use the state of SEQ_DIVN_OPENLOOP_OVRD to override the signal "seq_divn_openloop".
7 SEQ_DIVN_PUP_OVRD	Override value for SEQ_DIVN_PUP When SEQ_DIVN_PUP_OVRD_EN=1, this value overrides the mission mode state of the signal "seq_divn_pup". This bit is ignored when SEQ_DIVN_PUP_OVRD_EN==0.
6 SEQ_DIVN_PUP_OVRD_EN	Override control for SEQ_DIVN_PUP 0b - Normal operation. 1b - Use the state of SEQ_DIVN_PUP_OVRD to override the signal "seq_divn_pup".
5 SEQ_LO_PUP_VLO_TXDRV_OVRD	Override value for SEQ_LO_PUP_VLO_TXDRV When SEQ_LO_PUP_VLO_TXDRV_OVRD_EN=1, this value overrides the mission mode state of the signal "seq_lo_pup_vlo_txdrv". This bit is ignored when SEQ_LO_PUP_VLO_TXDRV_OVRD_EN==0.
4 SEQ_LO_PUP_VLO_TXDRV_OVRD_EN	Override control for SEQ_LO_PUP_VLO_TXDRV 0b - Normal operation. 1b - Use the state of SEQ_LO_PUP_VLO_TXDRV_OVRD to override the signal "seq_lo_pup_vlo_txdrv".
3 SEQ_LO_PUP_VLO_TX_OVRD	Override value for SEQ_LO_PUP_VLO_TX When SEQ_LO_PUP_VLO_TX_OVRD_EN=1, this value overrides the mission mode state of the signal "seq_lo_pup_vlo_tx". This bit is ignored when SEQ_LO_PUP_VLO_TX_OVRD_EN==0.
2 SEQ_LO_PUP_VLO_TX_OVRD_EN	Override control for SEQ_LO_PUP_VLO_TX 0b - Normal operation. 1b - Use the state of SEQ_LO_PUP_VLO_TX_OVRD to override the signal "seq_lo_pup_vlo_tx".
1 SEQ_LO_PUP_VLO_RX_OVRD	Override value for SEQ_LO_PUP_VLO_RX When SEQ_LO_PUP_VLO_RX_OVRD_EN=1, this value overrides the mission mode state of the signal "seq_lo_pup_vlo_rx". This bit is ignored when SEQ_LO_PUP_VLO_RX_OVRD_EN==0.
0 SEQ_LO_PUP_VLO_RX_OVRD_EN	Override control for SEQ_LO_PUP_VLO_RX 0b - Normal operation. 1b - Use the state of SEQ_LO_PUP_VLO_RX_OVRD to override the signal "seq_lo_pup_vlo_rx".

55.4.7.8 Transceiver DMA and Packet RAM Debug Modes

55.4.7.8.1 Introduction

For debug and evaluation purposes, the Radio provides the capability to capture a variety of internal data during the reception process, and store it to either system memory (using Transceiver DMA mode) or radio packet ram (using Packet RAM Debug mode), for analysis and post-processing

55.4.7.8.1.1 Overview

During silicon debug and evaluation, it is often desirable to gain access to data internal to the digital receiver, in order to, for example:

- troubleshoot packet loss issues
- troubleshoot unexpectedly high Bit Error Rate
- fine-tune receiver initialization and configuration parameters

The radio offers 3 methods of accessing such internal data:

1. Transceiver DMA mode
2. Packet RAM Debug mode
3. Digital Test Mux (DTEST)

This section describes the first 2 methods.

Examples of internal data desirable for capture are raw ADC samples, RX digital I and Q outputs, and PHY soft decision data. Transceiver DMA and Packet RAM Debug modes allow a source of internal data to be selected, automate the acquisition of the data, pack the data into a format suitable and optimized for its destination (system or radio memory), implement the interfaces required to access those memories, store the data to memory under program control, and subsequently allow host MCU access to the acquired data for analysis and post-processing. For DMA mode, the SoC's RAM is used via the SoC DMA. For RAM debug mode, the radio packet RAM is made available for this debug mode.

55.4.7.8.1.2 Features

- Captures any of several sources from RX_DIG or PHY
- DMA engine outputs data to an Async FIFO in the SoC which communicates with SoC DMA controller to access system memory
- Packet RAM Debug engine automates transfers to radio memory
- Efficient packing of source data optimized to destination memory dimensions
- Efficient packing of source data optimized to make best use of available bandwidth
- Samples can be decimated by x1, x2, x4, or x8 independently for DMA and Packet RAM
- DMA mask feature allows RSM and LCL_CTRL to specify when samples should be captured
- DMA and Packet RAM engine clocking disabled in mission mode to reduce power
- Simultaneous DMA and Packet RAM Debug operation possible
- Hardware start-triggering capability with several hardware sources
- Start trigger can be delayed by programmable amount up to 2ms (11bits @ 1us resolution)
- Stop-on-trigger capability for Packet RAM Debug

55.4.7.8.1.3 Block Diagram

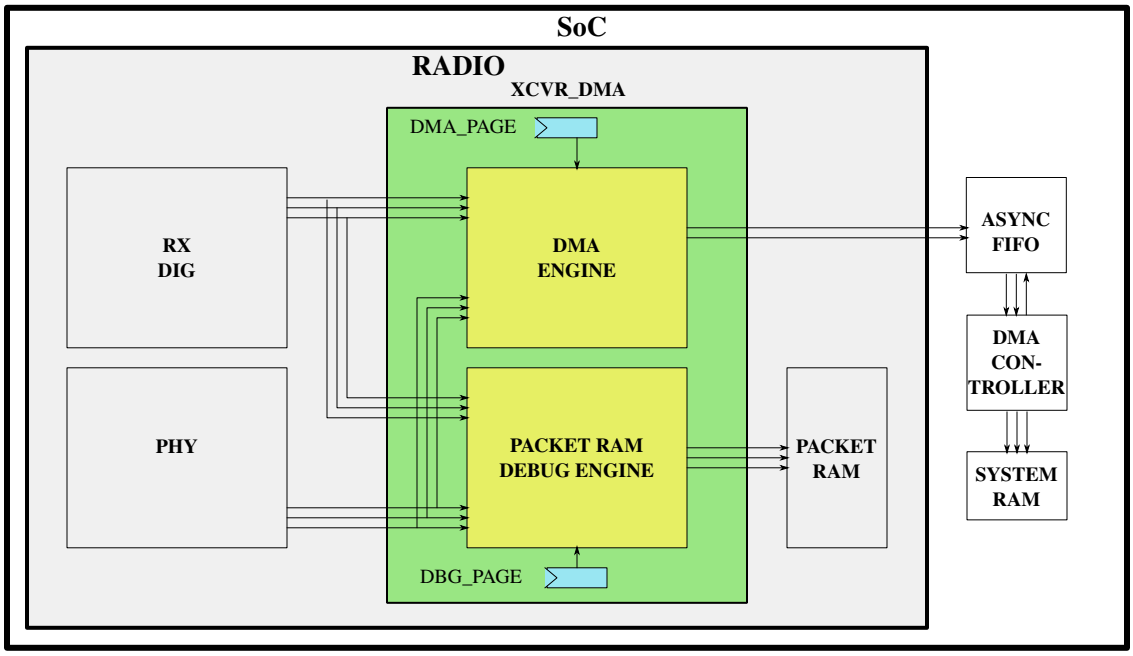

Figure 338. Transceiver DMA and Packet RAM Debug

55.4.7.8.2 Functional Description

55.4.7.8.2.1 Transceiver DMA Mode

Tranceiver DMA mode takes internal receive data from the RX_DIG or PHY, packs the data into an optimal format for bandwidth or RAM dimensions, and hands off the data to an external (SoC) Async FIFO which in turn communicates with the SoC DMA controller for ultimate transfer to system memory. Control and configuration of transceiver DMA operation is governed by the bit fields in the DMA_CTRL register of XCVR address space. These bit fields are referenced in the description that follows. In a typical transceiver DMA debug session, the transceiver DMA hardware performs the following steps:

1. Selects a source of internal data from RX_DIG or PHY for capture based on DMA_PAGE[3:0] setting
2. Waits for a hardware start-trigger, if so configured
3. Waits for a programmable delay (up to 2ms @ 1us resolution), if so configured
4. Uses a defined capture signal from RX_DIG or PHY to latch the internal data into a holding register. Depending on DMA_DEC[1:0], every sample, every other sample, every 4th sample, or every 8th sample will be captured.
5. If capture size is less than 32-bits, packs 2 or more captures of internal data into a 32-bit register until the packing requirements for that DMA_PAGE setting are met
6. Drives 32-bit data along with a valid strobe signal to an SoC Asynchronous FIFO which communites with the SoC DMA controller
7. Repeats steps 3-5 until the debug session is complete (DMA_PAGE set to 0).

If a hardware start-trigger is selected (DMA_START_TRG > 0), the dma engine will wait until the selected triggering event occurs before acquiring any samples; otherwise, acquisition begins as soon as DMA_PAGE is set to a non-zero value.

The maximum DMA transfer rate in this mode is not limited by the radio: the transceiver DMA is capable of sustained 32bit transfers at the reference clock rate, so any limitation would be due to the Async FIFO, DMA, or SoC clocking.

55.4.7.8.2.1.1 PAGE TABLE for 2.4GHz Transceiver Gen4.5

The following table describes the available DMA_PAGE settings. The internal source data selected, the capture signal employed, the data packing method, the OSR setting, and the data rate, are provided for each DMA_PAGE setting.

MNEMONIC	PACKING	CAPTURE SIGNAL	REMARKS
DMAIDLE	---	---	No DMA Activity. All clocks to transceiver DMA hardware gated off.
RXDIG-IQ	{rx_dft_iq_out_q[10:0], rx_mixer_idx[9:5], rx_dft_iq_out_i[10:0], rx_mixer_idx[4:0]}	rx_dft_iq_out_vld	Q and I data captured at various locations in RXDIG. Data is MSB aligned in each 16bit half-word. Check XCVR_RX_DIG->CTRL1[RX_MIXER_IDX_OUT_MODE] for rx_mixer_idx[9:0] mapping.
RXDIG-IQ-ALT	{rx_dft_iq_out_q[10:0], 3'b0, antx_out, crc_fail, rx_dft_iq_out_i[10:0], 3'b0, rx_pd_fnd, aa_sfd_matched}	rx_dft_iq_out_vld	Q and I data captured at various locations in RXDIG plus additional info in the LSBs. I/Q data is MSB aligned in each 16bit half-word.
ADC-IQ	{adc_code_q[10:0], 5'b0, adc_code_i[10:0], 5'b0}	rx_dig_en	Raw ADC capture of I and Q channel. Data is MSB aligned in each 16bit half-word. Bandwidth requirement is 1 word per reference clock cycle.
PHASE	{rx_dft_ph_out[5:0], 2'b0,rx_dft_ph_out[5:0], 2'b0,rx_dft_ph_out[5:0], 2'b0,rx_dft_ph_out[5:0], 2'b0}	rx_dft_ph_out_vld	Sync phase or demod phase (as selected in RXDIG). Newest sample in MSB. Each byte contains a MSB-aligned phase sample.
RSSI-PHASE	{rx_dft_rssi_out[7:0], rx_dig_ph_hi_res[7:0], rx_dft_rssi_out[7:0], rx_dig_ph_hi_res[7:0]}	rx_dft_rssi_ph_hi_res_vld	8bit Narrowband RSSI (rssi, rssi raw, lqi, snr, noise) or Wideband RSSI (rss, rssi raw) plus 8bit high-resolution phase. Newest sample in MS bytes.
MAG-PHASE	{rx_dig_ph_hi_res[7:0], 8'b0, rx_dft_mag_out[11:0], 4'b0}	rx_dft_mag_out_vld	RSSI magnitude + 8bit high-resolution phase.
2P4GHz-PHY	{phy_dma_mux[31:0]}	phy_dma_vld	PHY DMA mux output as selected in PHY
DETERMINISTIC	{counter_q[10:0], 5'b0, counter_i[10:0], 5'b0}	rx_dig_iq_vld	Mimics the RXDIGIQ page, but uses deterministic data for software debug purposes. The Q up-counter start from

Table continues on the next page...

Table continued from the previous page...

MNEMONIC	PACKING	CAPTURE SIGNAL	REMARKS
			0x400, the I up-counter starts from 0x000. The counters reset when dma_page=0, and start counting when the selected trigger fires

55.4.7.8.2.1.2 Example Procedure

The following steps outline the setup and execution of a Transceiver DMA debug session. This example acquires RX DIG I/Q data:

1. Program Receiver for desired protocol
2. If needed, configure RXDIG or PHY to enable the desired DMA output signals from those modules.
3. Enable clocking to the DMA engine by setting DMA_CTRL[DMA_EN]=1
4. Select a DMA start-trigger source, if desired, by setting DMA_CTRL[DMA_START_TRIG] to a non-zero value
5. Select a start-trigger delay value, if desired, by setting DMA_CTRL[DMA_START_DLY] to a non-zero value in microseconds.
6. Select a decimation rate for samples captured, if desired, by setting DMA_CTRL[DMA_DEC] to a non-zero value
7. Program DMA_CTRL[DMA_PAGE]=RXDIGIQ
8. Program the SOC DMA to capture data
9. Start the transceiver's RX sequence by e.g. setting TSM_CTRL[FORCE_RX_EN]=1
10. Begin transmitting RF to the DUT
11. Wait for sufficient RX data to be collected to satisfy the requirements of the debug session. E.g., wait for SOC DMA interrupt
12. Program DMA_CTRL[DMA_PAGE]=0 to terminate the acquisition
13. Download the captured data from system memory

Note: Step 7 (select the DMA_PAGE to enable the DMA engine) should be performed as a sequential, discrete write to the DMA_CTRL register, after steps 3-6 (enabling the clock, and configuring start delay, decimation, and start trigger) have been completed. A single write to DMA_CTRL is permitted for for steps 3-6.

55.4.7.8.2.2 Packet RAM Debug Mode

Packet RAM Debug mode takes internal receive data from the RX_DIG or PHY, packs the data into an format suitable for storage in the radio's Packet RAM, and then directly fills the RAMswith source data, under program control. Control and configuration of Packet RAM Debug operation is governed by the bit fields in the DBG_RAM* register of XCVR address space. These bit fields are referenced in the description that follows. In a typical Packet RAM debug session, the debug hardware performs the following steps:

1. Selects a source of internal data from RX_DIG or PHY for capture based on DBG_PAGE[3:0] setting
2. Waits for a hardware start-trigger, if so configured
3. Waits for a programmable delay (up to 2ms @ 1us resolution), if so configured
4. Uses a defined capture signal from RX_DIG or PHY to latch the internal data into a holding register. Depending on DBG_DEC[1:0], every sample, every other sample, every 4th sample, or every 8th sample will be captured.
5. If capture size is less than 32-bits, packs 2 or more captures of internal data into a 32-bit register until the packing requirements for that DBG_PAGE setting are met

6. Directly accesses the Packet RAM to store the receive data (addressing, write enabling, chip enabling, etc.). The first and last address to use in the ram can be programmed.
7. Repeats steps 3-5 until the debug session is complete: DBG_PAGE set to 0 ; a stop-on-trigger event occurs if so configure; or packet RAM (last address above reached) is full.

The bandwidth to Packet RAM is expected to be higher than Transceiver DMA, since the overhead of DMA-related synchronization and multi-master arbitration can be avoided. The tradeoff is that the total Packet RAM space is smaller than the space available in system memory, restricting the size of the block of data that can be saved.

55.4.7.8.2.2.1 Acquisition

In a typical debug session, the selection of a receive data source is made by setting DBG_PAGE to a non-zero value (see the table below for a description of the debug pages). Setting DBG_PAGE to a non-zero value activates the Packet RAM Debug Engine. The engine has write-only access to the RAM while receive data is being collected. (XCVR host IPS access is not blocked, but should be avoided during acquisition). If a hardware start-trigger is selected (DBG_START_TRG > 0), the debug engine will wait until the selected triggering event occurs before acquiring any samples; otherwise, acquisition begins as soon as DBG_PAGE is set to a non-zero value. Starting at the address indicated by DBG_RAM_FIRST, the RAM will fill with receive data determined by the DBG_PAGE setting. The address for the RAM is always reset to DBG_RAM_FIRST when DBG_PAGE=0.

If a stop-trigger is not selected (DBG_STOP_TRG = 0): When the RAM reaches DBG_RAM_LAST (programmable last address), further write attempts by the debug engine to the RAM are halted, and the DBG_RAM_FULL status bit become set. When sufficient receive data has been acquired to satisfy the requirements of the debug session, the acquisition should be terminated by setting DBG_PAGE=0. The DBG_RAM_FULL and DBG_RAM_STOP status bits are "sticky"; they will remain valid even after DBG_PAGE is set to 0 to end the session. The bits will self-clear when a new acquisition is started.

If a stop-trigger is selected (DBG_STOP_TRG > 0): When the RAM reaches DBG_RAM_LAST address, further write attempts by the debug engine to the RAM are not halted, but the DBG_RAM_FULL status bits do become set. The debug engine will wrap back to the starting address (DBG_RAM_FIRST) and continue filling, until the selected stop-trigger event occurs. When the stop-trigger event occurs, the debug engine will stop filling the RAM immediately, the DBG_STOP_TRIGGERED status bit will become set, and the register DBG_RAM_STOP will hold the address of the last RAM word filled with a valid sample before the trigger. At this point, the acquisition should be terminated by setting DBG_PAGE=0. The DBG_STOP_TRIGGERED and STOP_ADDRESS are "sticky"; they will hold their state even after DBG_PAGE is set to 0 to end the session. DBG_TRIGGERED will self-clear, and DBG_RAM_STOP will reset to 0, when a new acquisition is started by setting DBG_PAGE to a non-zero value.

55.4.7.8.2.2.2 Downloading

As soon as sufficient data has been collected to satisy the requirements of the debug session, DBG_PAGE should be set to 0 to end the acquisition. The receive data stored in RAM may now be downloaded from the Packet RAM for analysis and post-processing.

55.4.7.8.2.2.3 PAGE TABLE for 2.4GHz Transceiver Gen4.5

The DBG_PAGE table settings are the same as the DMA_PAGE table except that the DETERMINISTIC page is not supported for DBG_PAGE

55.4.7.8.2.2.4 Example Procedure

The following steps outline the setup and execution of a Packet RAM debug session. This example acquires RX DIG I/Q data

1. Program Receiver for desired protocol
2. If needed, configure RXDIG or PHY to enable the desired DMA output signals from those modules.
3. Enable clocking to the Packet RAM Debug engine by setting DBG_RAM_CTRL[DBG_EN]=1
4. Select a DBG start-trigger source, if desired, by setting DBG_RAM_CTRL[DBG_START_TRG] to a non-zero value
5. Select a start-trigger delay value, if desired, by setting DBG_RAM_CTRL[DBG_START_DLY] to a non-zero value in microseconds.
6. Select a decimation rate for samples captured, if desired, by setting DBG_RAM_CTRL[DBG_DEC] to a non-zero value

7. Select a DBG stop-trigger source, if desired, by setting DBG_RAM_CTRL[DBG_STOP_TRG] to a non-zero value
8. Program DBG_RAM_ADDR to select the desired starting address (DBG_RAM_FIRST) and ending address (DBG_RAM_LAST) in the RAM
9. Program DBG_RAM_CTRL[DBG_PAGE]=RXDIGIQ
10. Start the transceiver's RX sequence by e.g. setting TSM_CTRL[FORCE_RX_EN]=1
11. Begin transmitting RF to the DUT
12. **If a stop-trigger is selected (DBG_STOP_TRG > 0)** wait for DBG_STOP_TRIGGERED=1, indicating a stop-trigger occurred
13. **If a stop-trigger is not selected (DBG_STOP_TRG = 0)** wait for sufficient RX data to be collected, or poll DBG_RAM_FULL, to satisfy the requirements of the debug session
14. Program DBG_RAM_CTRL[DBG_PAGE]=0 to terminate the acquisition
15. Download the captured data from Packet RAM

Note: Step 9 (select the DBG_PAGE to enable the DBG engine) should be performed as a sequential, discrete write to the DBG_RAM_CTRL register, after steps 3-8 (enabling the clock, and configuring start delay, decimation, start/stop triggers and ram starting address) have been completed. A single write to DBG_RAM_CTRL is permitted for steps 3-7.

55.4.7.8.2.3 DMA Mask

The DMA mask feature allows the XCVR_DMA to remain enabled but only be active when the DMA mask input is asserted high, indicating that there are desirable samples to be captured. The DMA mask input to the Transceiver DMA module is generated by an OR of the DMA mask outputs from the following modules:

- LCL_CTRL:
  - for CTE use case: the DMA mask output ensures that samples are captured during the reference period and during sample slots, but not during switching slots or other times
  - when use with RSM: the DMA mask output is used to avoid capture of samples after the antenna is switched during RSM's PM_RX state
- RSM: the DMA mask output is used to identify samples during RSM FM_RX state, and optionally during PM_RX states (if LCL_CTRL is not enabled during RSM's PM_RX states)

Also note that, for RSM use cases, the Transceiver DMA can remain enabled through an entire RSM event which consists of multiple RX (and TX) bursts; that it, it is not necessary to re-enable the Transceiver DMA for each individual RX burst within an RSM event.

The DMA mask feature in XCVR_DMA is only enabled if the DBG_SIGNAL_VALID_MASK_EN bit (Packet RAM Debug Mode) or DMA_SIGNAL_VALID_MASK_EN bit (Transceiver DMA Mode) bit is set. When enabled, the data valid strobe input selected by DBG_PAGE (Packet RAM Debug Mode) or DMA_PAGE(Transceiver DMA Mode) is AND'ed with the DMA mask input signal so that samples are only captured while the DMA mask signal is high and when there is valid data.

NOTE

The RXDIG also supports a feature to mask its data valid strobe outputs to the Transceiver DMA using the DMA mask signal (OR of RSM and LCL_CTRL DMA mask signals, as indicated above). This RXDIG feature (enabled by setting RXDIG's RX_IQ_PH_OUTPUT_COND bit), can also be combined with RXDIG's IQ phase output average windowing feature to reduce the number of samples which need to be stored to RAM, so this is method is generally preferred over enabling the DMA mask in the Transceiver DMA module. If using the RXDIG feature (RX_IQ_PH_OUTPUT_COND bit set), then the DBG_SIGNAL_VALID_MASK_EN (Packet RAM Debug Mode) and DMA_SIGNAL_VALID_MASK_EN (Transceiver DMA Mode) bits should not be set.

55.4.7.8.2.4 Simultaneous Transceiver DMA and Packet RAM Debug

Transceiver DMA mode and Packet RAM Debug mode are described in the previous sections. The DMA and Debug engines are separate, independent entities, which theoretically allows both to be employed simultaneously. The most practical case for simul operation would be to select an RX_DIG source for DMA_PAGE and a PHY source for DBG_PAGE. During such a simultaneous debug session, RX_DIG data would go to system memory and PHY data to Packet RAM. After acquisition, data would be downloaded from both memories. Post-processing software could consolidate the data and take advantage of the synergy that results from combining data captured simultaneously from multiple sources. (DTEST allows a possible third simultaneous source, beyond the scope of this Block Guide).

In addition, it is also theoretically possible to combine either or both debug modes with mission-mode packet reception, with the caveat that the Packet RAM would not be available to receive mission-mode packet data in such a scenario. (Packet processing, filtering, CRC checking, and Link Layer interrupts don't rely on packet RAM and so would not be impacted by the debug modes). Such a combination has been demonstrated successfully in radio-level simulation, with the following setup:

1. The GEN_FSK Link Layer is engaged in RX mode
2. Transceiver DMA mode is engaged with DMA_PAGE set to PHYPHASE (PHY phase capture)
3. Packet RAM Debug mode is engaged with DBG_PAGE set to DMDSOFT (PHY soft decision data)
4. A GEN_FSK standard packet is received, CRC passes, and GEN_FSK RX_IRQ and SEQ_END_IRQ are asserted (GEN_FSK packet data not stored)
5. RX phase data is downloaded from system memory and verified
6. Demod soft decision data is downloaded from Packet RAM and verified

55.4.7.8.2.5 Start Trigger Sources

Registers DMA_CTRL[DMA_START_TRG] and DBG_RAM_CTRL[DBG_START_TRG], enable a hardware trigger that must assert before acquisition begins, for the transceiver DMA and Packet RAM debug engines, respectively. The same description applies to both registers (i.e., trigger sources are the same), as indicated in the following table:

xxx_START_TRG[3:0]	HARDWARE TRIGGER for 2.4GHz
0	no trigger
1	PHY: pd_fnd_to_ll
2	PHY: aa_fnd_to_ll
3	ZBDEMOD: rx_preamble_det
4	ZBDEMOD: rx_sfd_detect
5	RXDIG: agc_gain_chg
6	TSM: rx_dig_en
7	TSM: tsm_irq0_start_trig
8	CRC pass
9	CRC done (Not used for 15.4 LL)
10	Localization control: pattern match
11	GenericLL: cte_present
12	Ranging sequence manager: dma_trigger

55.4.7.8.2.6 Stop Trigger Sources

Register DBG_RAM_CTRL[DBG_STOP_TRG], enables a hardware trigger such that, when it asserts, acquisition terminates immediately, in Packet RAM debug mode, as indicated in the following table (some of these table entries need discussion):

DBG_STOP_TRG[3:0]	HARDWARE TRIGGER for 2.4GHz
0	no trigger
1	PHY: pd_fnd_to_ll
2	PHY: aa_fnd_to_ll
3	ZBDEMOD: rx_preamble_det
4	ZBDEMOD: rx_sfd_detect
5	RXDIG: agc_gain_chg
6	TSM: rx_dig_en
7	TSM: tsm_irq1_stop_trig
8	CRC fail
9	CRC done (Not used for 15.4 LL)
10	RBME ERROR
11	GenLL: HEADER FAIL
12	TSM: pll unlock

Note: For DBG_STOP_TRIG=11 (HEADER FAIL), register GEN_WHITEN_SZ_THR[REC_BAD_PKT] must be set to 0 (default) to cause an RX recycle on a header violation.

55.4.7.9 Transceiver Antenna and Localization Control

55.4.7.9.1 Introduction

The transceiver supports two antenna control mechanisms: Fast Antenna Diversity (FAD), and Localization Control. FAD allows an optimal choice between two antennaes during the PHY's preamble search. Localization Control refers to direction finding (angle of arrival / angle of departure) and ranging. Only one of these is enabled at any given time.

A high level figure illustrating the transceiver modules involved is shown below. The FAD algorithm is in the PHY, which provides an output to control the antenna through the FAD Common pin interface. The Localization control outputs "lant_lut_gpio[3:0]" (to control an external antenna switch) plus a start trigger and DMA mask signal to the XCVR DMA to facilitate capture of receiver samples. For Bluetooth LE direction finding, the Localization Control module accepts CTE control signals from the Bluetooth LE link layer. For ranging, a Ranging Sequence Manager sequences the transceiver between RX and TX operations across a set of programmable frequencies for the purpose of the capturing phase samples (when tones are transmitted) and RTT measurements (when packets are transmitted) in the receiving device, and also provides a trigger to the Localization Control module for optional antenna switching. In addition, the Localization Control module provides a trigger to the SOC (to be connected to a timer) for time-of-flight timestamping; this trigger is a mux of several signals in the transceiver as shown in the figure. The four FAD outputs and LCL_CTRL's lant_lut_gpio[3:0] outputs go to SOC pins via the RF_GPO muxes described in the Coexistence/FEM/LANT connections section of the Radio Control chapter.

The Localization Control , Ranging Sequence Manager and FAD Common Pin Interface are described in the sections below. For more info on the PHY's FAD algorithm refer to the PHY chapter.

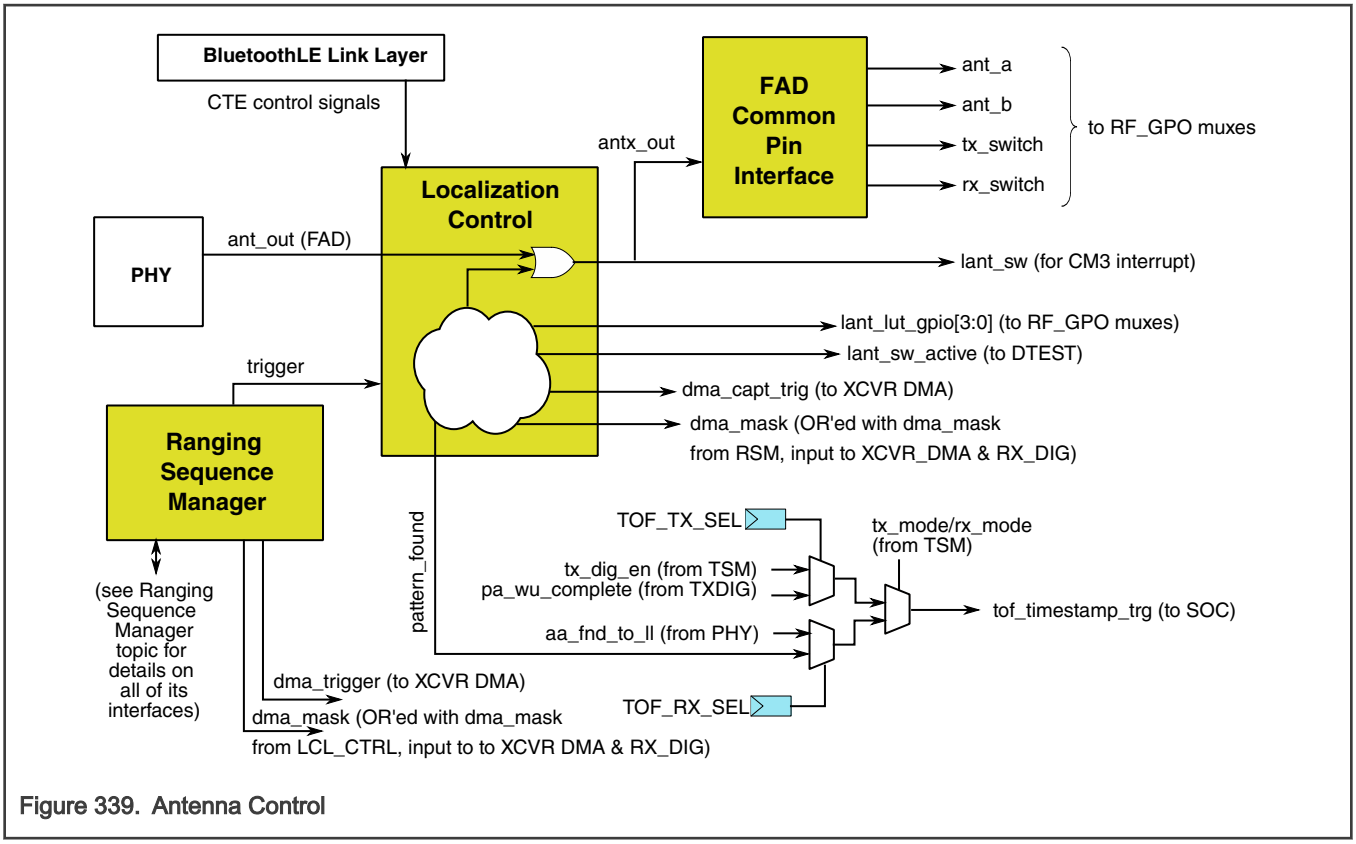

Figure 339. Antenna Control

55.4.7.9.2 Localization Control Module

The LCL_CTRL module implements various controls intended to assist with antenna control and sample capture.

There are 3 significant functions of this module:

1. Scan the bit stream for a pattern
2. Control the switching of the antenna output (lant_lut_gpio[3:0])
3. Provide a data valid mask signal for the XCVR DMA

Within the LCL_CTRL there is pattern matching logic that will assert a pattern found signal when the incoming bit stream matches the pre-programmed pattern. The pattern can be 4, 5, 6, or 8 bytes (setting PM_NUM_BYTES). The pattern must be programmed in the LCL_PM_MSB and LCL_PM_LSB registers and pattern matching must be enabled. If COMP_EN is set, then pattern matching will operate during RX. For pattern matching in TX, both COMP_EN and COMP_TX_EN must be set. The pattern_match output asserts when a pattern match has occurred. For RX, when the pattern_match output asserts the dma_capt_trig to the XCVR_DMA also asserts.

For antenna control, the LCL_CTRL module can be configured using the MODE bit to operate with or without use of the Bluetooth LE Link Layer's Constant Tone Extension (CTE) control signals.

55.4.7.9.2.1 Antenna Control Without Bluetooth LE CTE Signals

For antenna control without using the Bluetooth LE CTE control signals, various settings must be programmed prior to operation. The significant fields are:

- CTE_DUR : Duration of switching activity in doublets, where a doublet = RX/TX_HI_PER + RX/TX_LO_PER
- LANT_INV : When set to 1, the lant_sw signal is inverted
- RX/TX_LCL_EN : Enables antenna switching control in RX and/or TX
- LCL_EN : Enable for the entire LCL_CTRL module

- RX/TX_DELAY_OFF : Extra offset (in samples) to fine tune the RX/TX_DELAY
- RX/TX_DELAY : Delay, in intervals, before antenna switching is to begin
- RX/TX_LO_PER : Number of intervals for which lant_sw should be 0, when switching is active. For RX, RX_LO_PER also indicates the number of intervals that the dma_mask should be 0.
- RX/TX_HI_PER : Number of intervals for which lant_sw should be 1, when switching is active. For RX, RX_HI_PER also indicates the number of intervals that the dma_mask should be 1.
- RX/TX_ANT_TRIG_SEL : Selects the trigger to be observed to begin counting DELAY
- RX/TX_SPINT : Defines the number of samples per interval. This is realized using the sample clock associated with either RX or TX, (typically 4MHz or 8MHz).
- M_ON_DELAY/N_ON_DELAY: The rx/tx_lco_on output will de-assert M_ON_DELAY intervals + N_ON_DELAY doublets earlier than the antenna switching stops.
- LUT_0 to LUT_31: state of lant_lut_gpio[3:0] for the switching activity doublet from 0 to 31
- LUT_WRAP_PTR: Wrap point for the LUT_0 to LUT_31. If programmed to value "N", output will be LUT_0, ..., LUT_N, LUT_0, ...

When enabled, the LCL_CTRL control module begins monitoring the selected trigger source as indicated by RX/TX_ANT_TRIG_SEL. When the trigger occurs, a timer begins. When the timer reaches DELAY+DELAY_OFF, the system will align to the next available sample clock and the antenna switching begins. The switching is described by asserting as 1 for HI_PER, then de-asserting as 0 for LO_PER. One of these cycles is termed a 'doublet'. This initial process is depicted in the figure below.

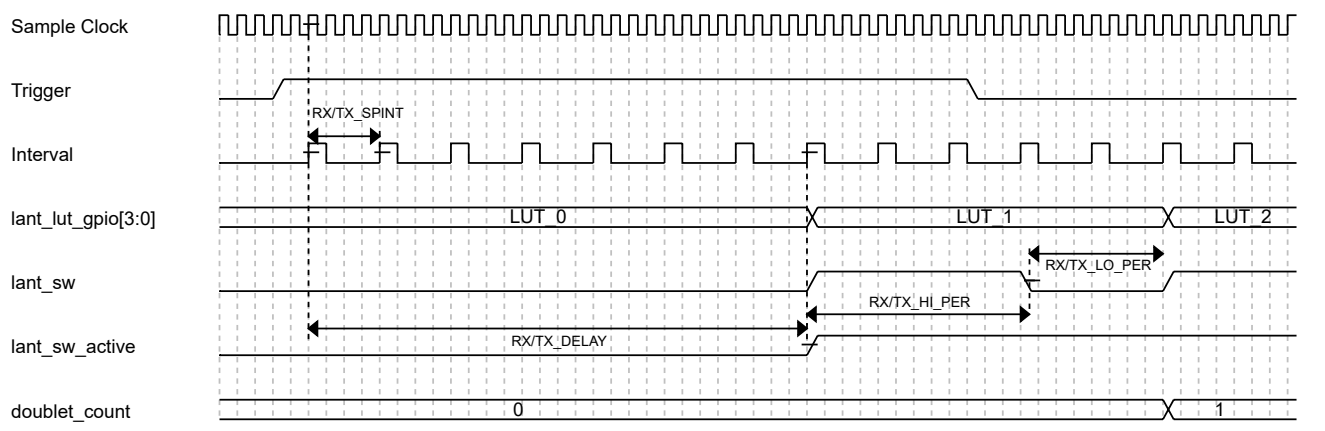

Figure 340. LCL_CTRL startup

After antenna switching has begun, another counter will count the doublets. When the CTE_DUR is reached, switching will stop as depicted in the following figure.

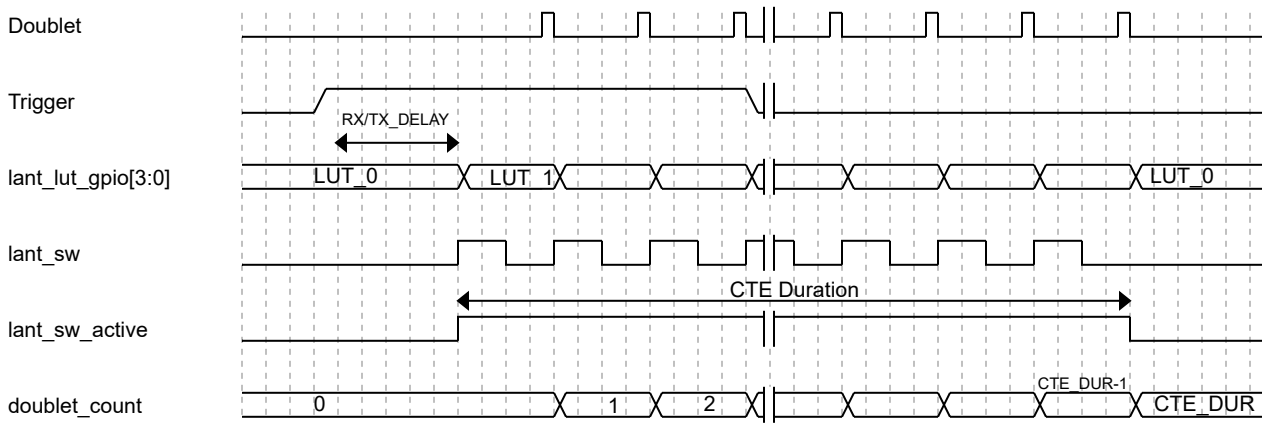

Figure 341. LCL_CTRL shutdown

The LCL_CTLR provides a data valid mask signal for the XCVR DMA so the DMA can avoid capturing unwanted data in the Guard period, and immediately after antenna is switched ("switching slots"). For this feature, there are several additional control settings:

- DMA_MASK_DELAY_OFF: Extra offset (in samples) to fine tune the DMA_MASK_DELAY
- DMA_MASK_DELAY: Delay, in intervals, from RX trigger to the time at which DMA mask asserts
- DMA_MASK_REF_PER: Duration, in intervals, of the reference period after DMA_MASK_DELAY expires during which the dma_mask remains asserted

The following figure depicts the dma_mask signal behavior in a CTE example. As can be seen, the dma_mask allows data to be captured during the reference period and sampling slots while avoid the guard period and switching slots.

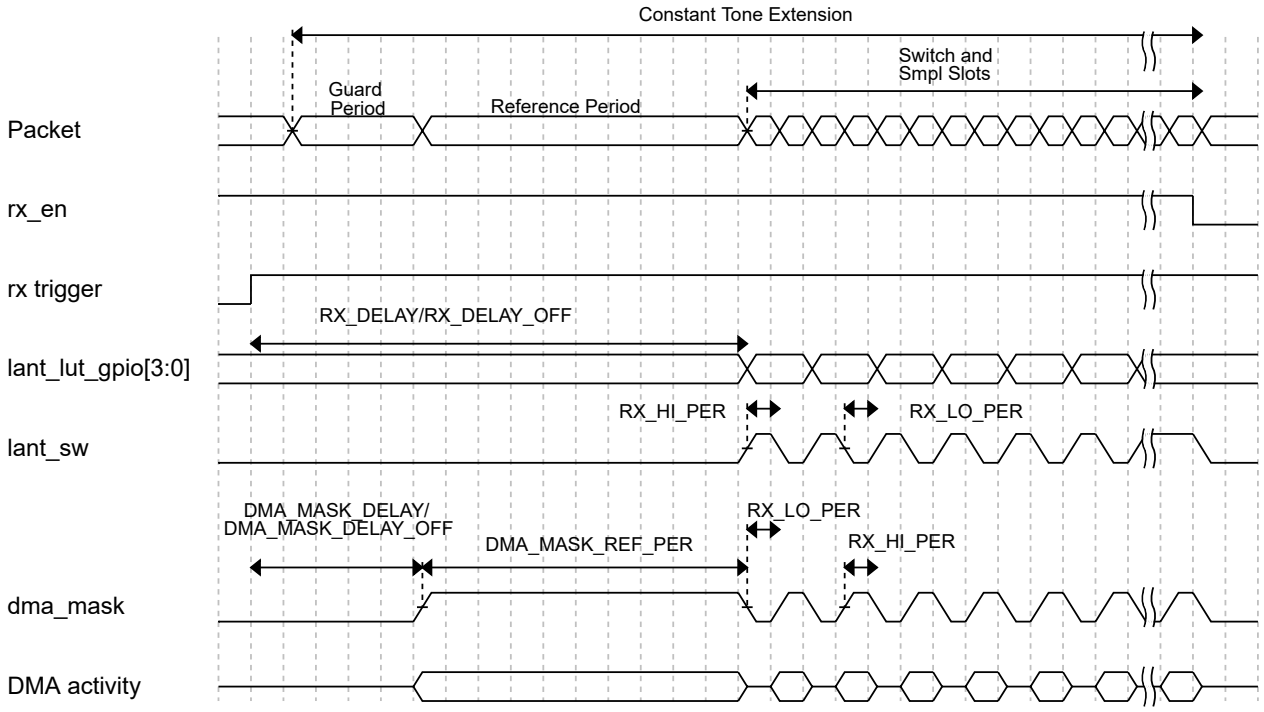

Figure 342. LCL_CTRL dma_mask

55.4.7.9.2.1.1 Antenna Control Used With RSM

Using LCL_CTRL with the RSM is considered a special case of "Antenna Control Without Bluetooth LE CTE Signals."

The RSM's rx and tx trigger output to the LCL_CTRL are expected to be used in this configuration. The RSM will trigger the LCL during it's T_PM (tone exchange) states. Since the RSM supports dynamically switching between 4 different T_PM durations while it is active, the LCL_CTRL include the following registers which are used only in conjunction with RSM:

- RX/TX_LO_PER1-3 : Alternate number of intervals for which lant_sw should be 0, when switching is active. For RX, RX_LO_PER also indicates the number of intervals that the dma_mask should be 0. These are used when RSM signals the LCL_CTRL that it is using T_PM1-3 durations instead of T_PM0 duration. (When T_PM0 duration is used, LCL_CTRL's RX/TX_LO_PER are used.) Refer to Ranging Sequence Manager for more information on T_PM durations.
- RX/TX_HI_PER1-3 : Alternate number of intervals for which lant_sw should be 1, when switching is active. For RX, RX_HI_PER also indicates the number of intervals that the dma_mask should be 1. These are used when RSM signals the LCL_CTRL that it is using T_PM1-3 durations instead of T_PM0 duration. (When T_PM0 duration is used, LCL_CTRL's RX/TX_LO_PER are used.) Refer to Ranging Sequence Manager for more information on T_PM durations.

The figures below illustrate the LCL_CTRL behavior when used with the RSM. Note that the delay from the trigger to the start of antenna switching is different when the RSM is used (as signalled by RSM's "active" output being high) : it includes the LO_PER and HI_PER durations in addition to DELAY/DELAY_OFF. Note that there are two figures for RX: the first one doesn't use DMA_MASK_REF_PER, and the second does.

For Figure 344, the DMA_MASK_REF_PER is not used (programmed to 0). Since the trigger asserts immediately on entry to RSM's T_PM states, the DELAY/DELAY_OFF and DMA_DELAY/DMA_DELAY_OFF values are expected to be programmed to 0 (or very small values), and the DMA mask will be asserted at the end of each LUT_x window.

For Figure 345, the samples captured during the first antenna switching period correspond to DMA_MASK_REF_PER (which would be expected to be programmed to the same value as RX_HI_PER). As compared to the other figure, the DMA mask is centered within the antenna LUT_x window. However, since there is only one DMA_MASK_REF_PER, the logic doesn't support the use of different RX_HI_PER durations / different T_PM durations.

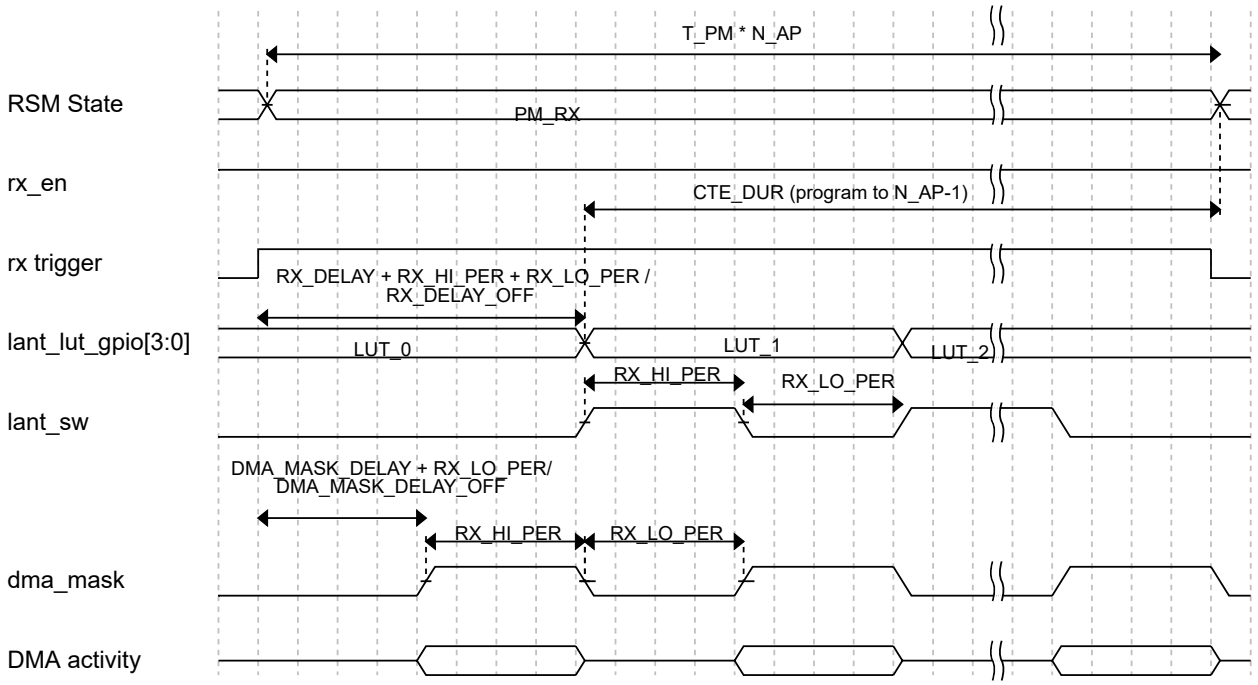

Figure 344. LCL_CTRL Operation with RSM - RX

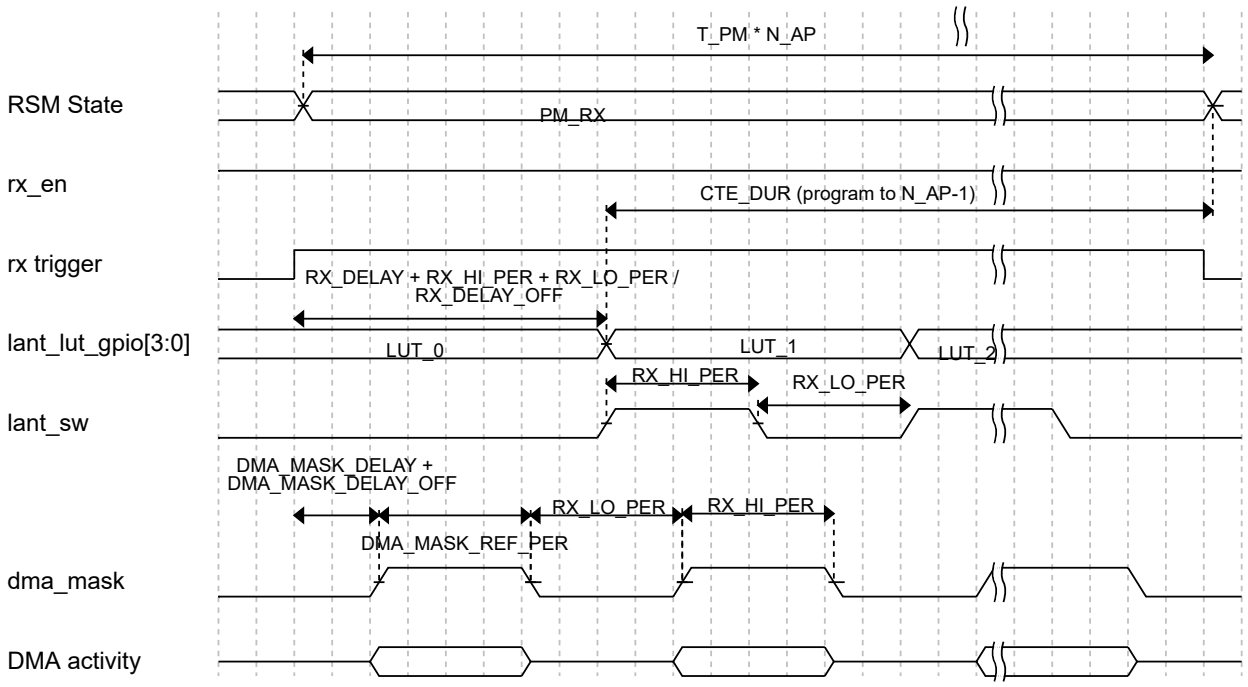

Figure 345. LCL_CTRL Operation with RSM - RX (Alternate Usage)

55.4.7.9.2.2 Antenna Control With Bluetooth LE CTE Signals

In this mode, cte_type[2:0] and cte_sample_dur[2:0] signals from the Bluetooth LE link layer are used to provide configuration of the LCL_CTRL module. The definition for cte_type[2:0] and cte_sample_dur[2:0] are shown in the table below

Table 458. CTE Signal cte_type[2:0]

cte_type[2:0]	Description
0x0	AoA Constant Tone Extension
0x1	AoD Constant Tone Extension with 1us slots
0x2	AoD Constant Tone Extension with 2us slots
0x3	Reserved
0x4	Reserved
0x5	AoD Constant Tone Extension with 4us slots
0x6	AoD Constant Tone Extension with 8us slots
0x7	Reserved

Table 459. CTE Signal cte_sample_dur[2:0]

cte_sample_dur[2:0]	Description
0x0	Reserved

Table continues on the next page...

Table 459. CTE Signal cte_sample_dur[2:0] (continued)

cte_sample_dur[2:0]	Description
0x1	For AoA receive, sampling duration is 1us
0x2	For AoA receive, sampling duration is 2us
0x3	Reserved
0x4	Reserved
0x5	For AoA receive, sampling duration is 4us
0x6	For AoA receive, sampling duration is 8us
0x7	Reserved

For antenna control using the Bluetooth LE CTE control signals, various settings must be programmed prior to operation. The significant fields are:

- LANT_INV : When set to 1, the lant_sw signal is inverted
- RX/TX_LCL_EN : Enables antenna switching control in RX and/or TX. For Bluetooth LE CTE configuration, both bits should be set.
- LCL_EN : Enable for the entire LCL_CTRL module
- RX/TX_DELAY_OFF : Extra offset (in samples) to fine tune the RX/TX_DELAY
- RX/TX_DELAY : Delay, in intervals, before antenna switching is to begin
- RX/TX_ANT_TRIG_SEL : Selects the trigger to be observed to begin counting DELAY
- RX/TX_SPINT : Defines the number of samples per interval. This is realized using the sample clock associated with either RX or TX, (typically 4MHz or 8MHz). For proper operation, RX/TX_SPINT need to be programmed so that the interval is 1us for RX and TX.
- LUT_0 to LUT_31: state of lant_lut_gpio[3:0] for the switching activity doublet from 0 to 31
- LUT_WRAP_PTR: Wrap point for the LUT_0 to LUT_31
- DMA_MASK_REF_PER: Duration, in intervals, of the reference period after DMA_MASK_DELAY expires during which the dma_mask remains asserted. For CTE the reference period is expected to be programmed for 8us.
- DMA_MASK_DELAY_OFF: Extra offset (in samples) to fine tune the DMA_MASK_DELAY
- DMA_MASK_DELAY: Delay, in intervals, from RX trigger to the time at which DMA mask asserts

Note that the following LCL_CTRL fields are not used in this configuration:

- CTE_DUR : In this configuration, the duration is controlled by the Bluetooth LE link layer
- RX/TX_LO_PER : In this configuration, the low period is determined by the CTE control signals
- RX/TX_HI_PER : In this configuration, the high period is determined by the CTE control signals
- M_ON_DELAY/N_ON_DELAY: In this configuration, switching activity stops at the end of the RX or TX burst.
- LANT_BLOCK_RX/TX: In this configuration, for RX lant output is blocked for AoD, and for TX lant output is blocked for AoA

The figures below illustrate the antenna switching operation for Bluetooth LE CTE during Transmit and Receive operations, and an addition figure illustrating the dma_mask behavior for Receive. In the Receive and Transmit figures, three examples of lant_sw / lant_lut_gpio[3:0] behavior are shown for different cte_type (and cte_sample_dur for Receive) input values. In the dma_mask figure, dma_mask and DMA activity behaviors are shown for two example cte_type and cte_sample_dur inputs. Note that these figures show example tx_trigger and rx_trigger signals which assert at the start of the guard period; the actual trigger used in the application (such as "cte_en" from the Bluetooth LE) will likely have different timing so the delays will need to be programmed accordingly.

55.4.7.9.3 Ranging Sequence Manager

The Ranging Sequence Manager (RSM) automates RX and TX operations across a set of frequencies in order to allow two devices to capture samples and other data for distance measurement calculations performed by software. To perform this task, the RSM acts like a small link layer, directing the transceiver to perform RX and TX as needed. The figure and list below shows the modules to which the RSM interfaces:

- To control the RSM's behavior in each frequency step, the RSM reads information stored in the Packet RAM. This consists of the desired frequency (ext_channel_num_ovrd in the figure), frequency calibration information (ext_ctune and ext_hpm_cal_factor in the figure) used by the PLL, and whether the frequency step consists of tone exchanges, packet exchanges, or both. If the ext_ctune info is not used and the PLL performs ctune calibration, then on each frequency change the ctune_best_diff value is saved to Packet RAM by the RSM.
- The RSM provides control signals to the TSM to start receive or transmit operations, to switch between receive and transmit operations, and to end receive and transmit operations.
- For transmit, the RSM uses the tx_mod_disable signal to tell the TXDIG whether to modulate data (packet transmit) or not (tone transmit). For packet transmit, the RSM reads pseudo-noise (PN) info from the Packet RAM and provides the data to transmit to the TXDIG. Note that the RSM does not control the transmit power; that should be programmed in the TXDIG

- When receiving packets, the RSM reads PN info from the Packet RAM which is used by the PHY as the access address (AA) and is also provied as "RTT bits" to the PHY. It also directs the RTT (round trip time) results from the PHY to the Packet RAM
- When receiving tones, the RSM provides a dma_trigger and a dma_mask output for use by the Transceiver DMA module. The dma_trigger asserts whenever RSM's RX_EN or TX_EN bitfields are set. The dma_mask asserts at a programmable delay (DMA_DLY or DMA_DLY0 bitfields) from the start of receive, and remains asserted for a programmable duration (DMA_DUR or DMA_DUR0 bitfields). The delay is programmed to allow the receiver analog and digital time to settle, and the duration programmed for the desired sample capture duration. The RSM also sends a signal to the PLL (ext_rx_lpm_mod_dis in the figure) which indicates that for tone reception the PLL should disable low port modulation and instead use a constant value (programmed in PLL) for high port modulation.
- For ranging operations which use antenna switching, the RSM provides triggers to the Localization Control module; lcl_rx_trigger is used in PM_RX states and lcl_tx_trigger is used in PM_TX states. Since the PM duration can take four different values (T_PM0-3), the RSM also outputs a signal (lcl_alt_reg_sel[1:0]) to the Localization Control module to indicate which T_PM duration is currently being used. Note that if the Localization Control module is used in conjunction with RSM, in PM_RX states the Localization Control module will provide the DMA mask control to the Transceiver DMA and the RSM's DMA mask feature should be disabled. Refer to Antenna Control Used With RSM for more information on LCL_CTRL usage with RSM.
- The RSM "active" output is used by RXDIG and TXDIG in order to keep the Rx/Tx clocks running while the RSM is active. This is required for timestamping continuity for RTT (i.e., the relationship of fine time-stamp to the corresponding integer reference clock timestamp is maintained) as well as tone exchange (i.e., digital downmixing of the IF frequency & CIC clocking randomness do not contribute additional phase jitter). This doesn't require any software configuration except for the RXDIG control bit CIC_CNTR_FREE_RUN_EN which resets to 1, and should remain set to ensure the clocks remain running.

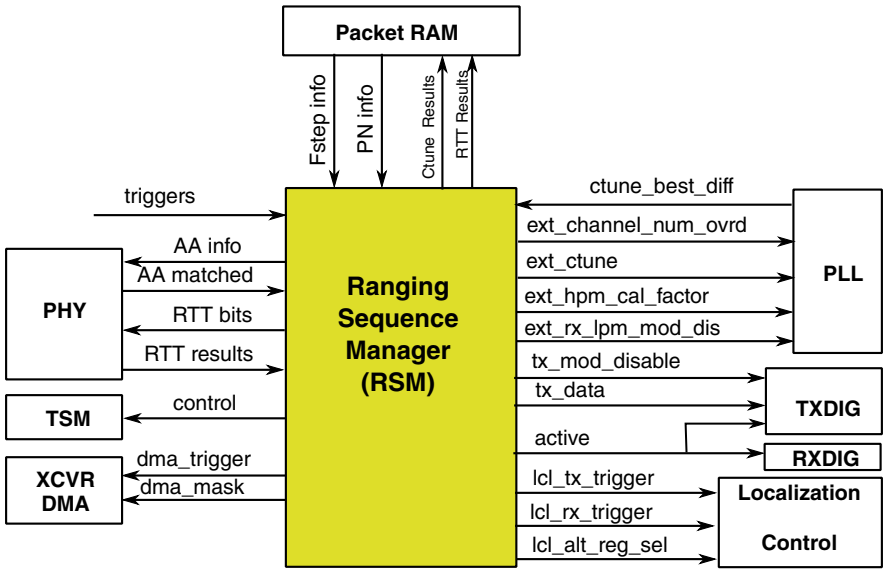

Figure 349. RSM Interfaces

The RSM supports two modes of operation: SQTE (Secure Quick Tone Exchange) and PDE (Phase-based Distance Estimation). These modes, which are described in detail in the following sections, have a good deal in common, including the following:

- The RSM can be configured to begin with a transmit operation (TX_EN bitfield programmed to 1) or receive operation (RX_EN bitfield programmed to 1). These correspond to the Initator and Reflector roles for SQTE, and to Measuring Device (MD) and Reflector Device (RD) roles for PDE, respectively.
- The number of frequency steps is configurable (FREQUENCY_STEP bitfield).
- The durations of the states associated with receive, transmit, frequency change transition and role swap transition (RX to TX or TX to RX) are configurable (T_PM, T_FC, and T_IP2 bitfields), though SQTE has additional configurability (T_IP1 and T_S bitfields).

- The format used for each frequency step is configurable, though for PDE this only includes tone exchanges, while for SQTE this includes tone and/or packet exchanges.

55.4.7.9.3.1 Secure Quick Tone Exchage (SQTE) Mode

The MODE=0 setting is for SQTE, which is shown in the figure below from the Bluetooth LE standards body. In this mode, two devices (one assuming the role of "Initiator" and the other the role of "Reflector") take turns exchanging packets and/or tones. The first set of exchanges are referred to as the Frequency Compensation Step (FCS), which consists of a bidirectional packet exchange and a unidirectional Frequency Measurement (FM) step which is a tone transfer from Reflector to Initiator. The main purpose of FCS is to allow the Initiator to determine the frequency offset of the Reflector with respect to the frequency of the Initiator.

There are a programmable number of SQTE Steps, each of which are individually configured to take one of four formats, as shown in the figure: the FCS step, a Pk-Pk step which only has packet exchange; a Tn-Tn step which only has tone exchange; or a Pk-Tn-Tn-Pk which has both packet and tone exchanges. Usually, the FCS is only used in the first step, but the RSM can be programmed so that it is also used in other steps.

Data is collected during packet reception and tone reception for each "SQTE Step" by both Initiator and Reflector for later post-processing by software. Note that the packets exchanged during SQTE are not normal Bluetooth LE packet; they are comprised of an 8bit (or 16bit for 2Mbps operation) preamble, a 32bit or 64bit pseudo-noise (PN) sequence which is known apriori by both Initiator and Reflector, and a 4bit trailer.

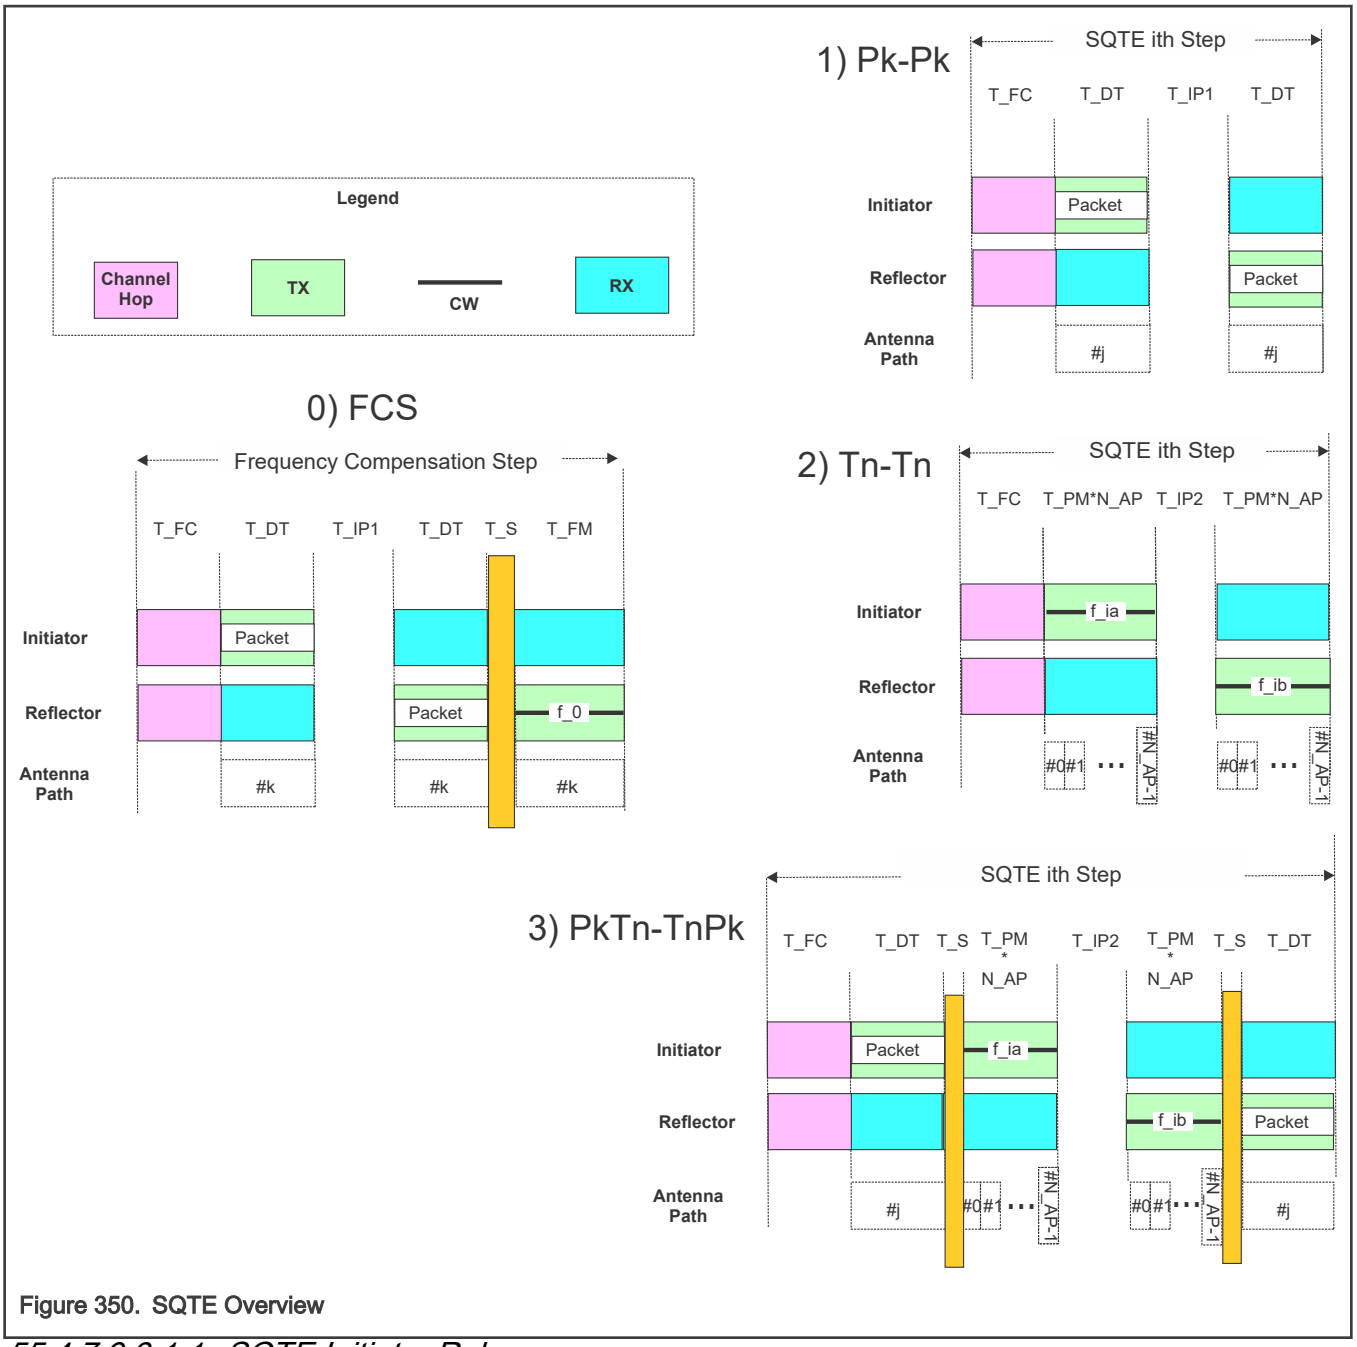

Figure 350. SQTE Overview

55.4.7.9.3.1.1 SQTE Initiator Role

The RSM state diagram below illustrates the RSM states used for SQTE in the Initiator role (TX_EN=1). Some of the states are duplicated in the figure to more clearly show the state transition sequence for the four different step format types (FCS, Pk-Pk, Tn-Tn, and PkTn-Tn-Pk). The states are described as follows:

- IDLE. This is the state the RSM is in after a reset and after a sequence has completed (or been aborted).
- DELAY. If a trigger delay is used, after the selected trigger is recognized, the RSM will stay in the DELAY state for TRIG_DLY microseconds.
- WU (Warmup). The RSM asserts its tx_en output to the TSM and then waits for the TSM's wu_complete signal before leaving this state. The figure shows that WU always transitions to the DT_TX state of the FCS step format but this assumes that the FCS step format is selected for the first frequency step (which is the expected behavior).

- FC_RX2TX (Freqency Change RX-to-TX transition). In this state the RSM directs the TSM to switch from RX to TX mode, change the radio frequency, and start a new step. The nominal duration of this state is T_FC
- DT_TX (Packet Transmit). In this state the RSM directs the transceiver to transmit a "packet" with a preamble, PN data, and a trailer. The duration of this state depends on the RATE and RTT_SEQ_LEN bitfields.
- DT_RX (Packet Receive). In this state the RSM directs the transceiver to receive a "packet" with a preamble, PN data, and a trailer. The nominal duration of this state depends on the RATE and RTT_SEQ_LEN bitfields.
- FM_RX (Tone Receive for FCS). In this state, the RSM directs the transceiver to receive a "tone". The nominal duration of this state is T_FM0 or T_FM1 depending on the t_pm_sel[0] bitfield in the frequency step data stored in Packet RAM.
- PM_RX (Tone Transmit). In this state the TSM directs the transceiver to receive a "tone". The nominal duration of this state is T_PM0, T_PM1, T_PM2, or T_PM3 dependening on the t_p_sel[1:0] bitfield in the frequency step data stored in Packet RAM
- PM_TX (Tone Transmit). In this state the TSM directs the transceiver to transmit a tone. The duration of this state is T_PM0, T_PM1, T_PM2, or T_PM3 dependening on the t_p_sel[1:0] bitfield in the frequency step data stored in Packet RAM
- IP1_TX2RX (Role swap TX-to-RX transition). In this state, the RSM directs the TSM to switch from TX to RX mode. The nominal duration of this state is T_IP1
- IP2_TX2RX (Role swap TX-to-RX transition). In this state, the RSM directs the TSM to switch from TX to RX mode. The nominal duration of this state is T_IP2
- S_TX2TX (Short TX-to-TX transition). In this state, the RSM transitions between packet and tone transmit. The duration of this state is T_S
- S_RX2RX (Short RX-to-RX transition). In this state, the RSM transitions between packet and tone receive. The nominal duration of this state is T_S
- WD (Warmdown). The RSM de-asserts its rx_en or tx_en (depending on what state it was in prior to warmdown) directing the TSM to warm down the transceiver

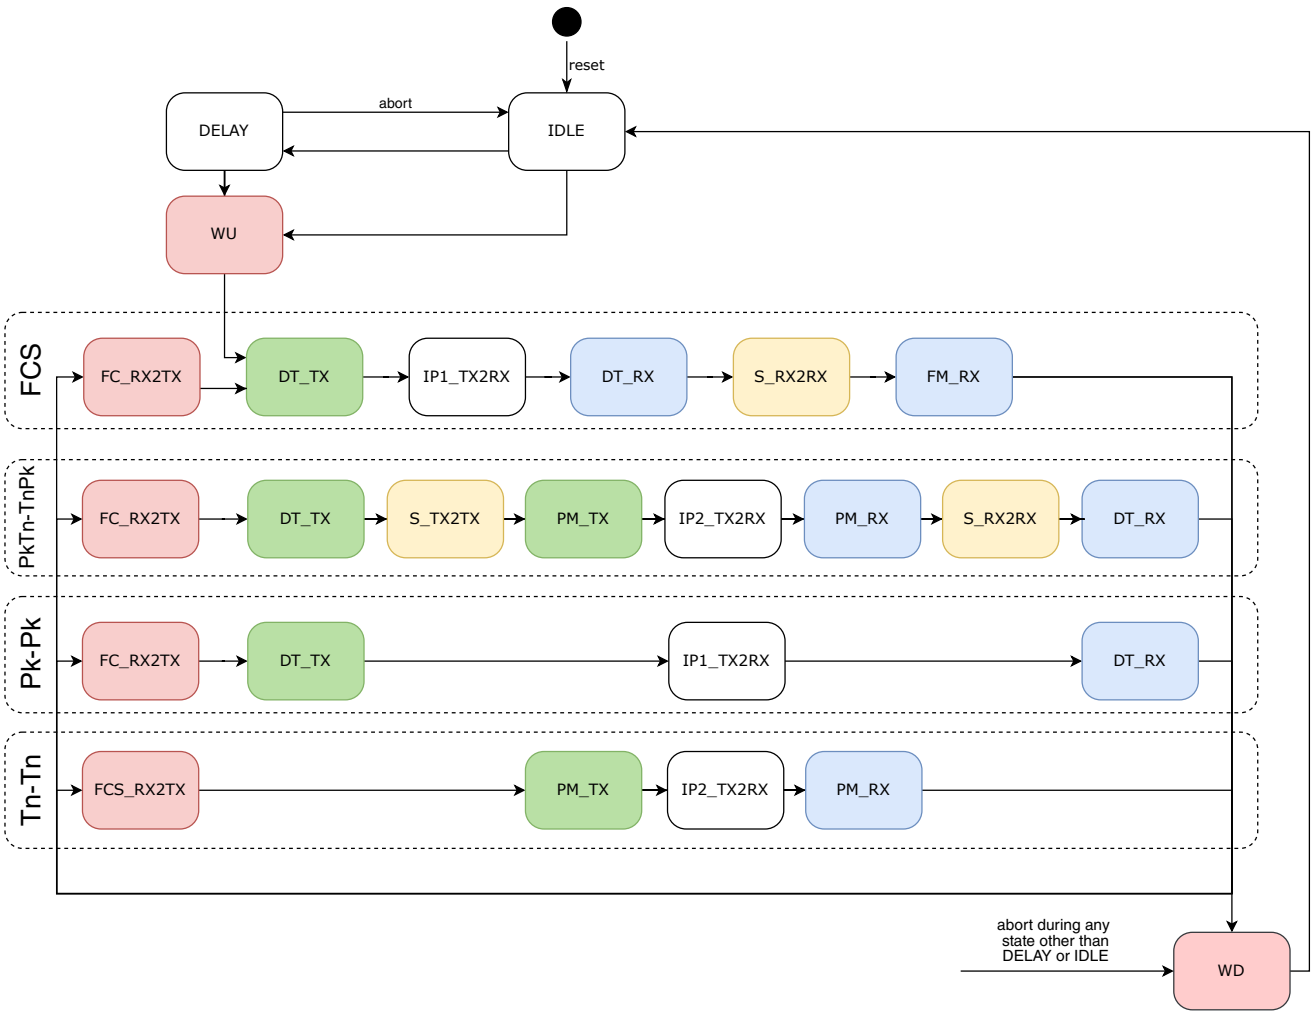

Figure 351. RSM State Transition Diagram for SQTE TX_EN=1 (Initiator role)

Any one of three methods can be used to start RSM operation when the module is configured for SQTE in the Initiator role (TX_EN=1).

1. The RSM is initiated by a hardware trigger (TRIG_SEL>0) which asserts during a previous RX or TX operation controlled by the Bluetooth or Generic LL
2. The RSM is initiated by a software trigger (TRIG_SEL=0)
3. The RSM is initiated immediately (TRIG_DLY=0) by a hardware trigger (TRIG_SEL=seq_spare3) which asserts during a dummy TX operation controlled by the Bluetooth or Generic LL

The figure below shows the timing corresponding to method #1 above. During a previous RX or TX operation controlled by the Bluetooth or Generic LL, a trigger to the is RSM asserted, and then the LL completes it RX or TX operation as usual. Meanwhile, upon recognizing the trigger, the RSM's trigger delay counter starts. After a programmable TRIG_DLY, the RSM will direct the TSM to start a transmit operation with a fast warmup if FAST_FC_TX_WU is set or a normal warmup if not. The state transitions associated with the four frequency step formats when TX_EN=1 are as descibed in the previous state transition diagram figure; note that the timing figure below only shows the Frequency Compensation Step and Pk-Tn-Tn-Pk step formats.

After the last frequency step, the RSM transitions to the WD state where the TSM is warmed down, and then to the IDLE state.

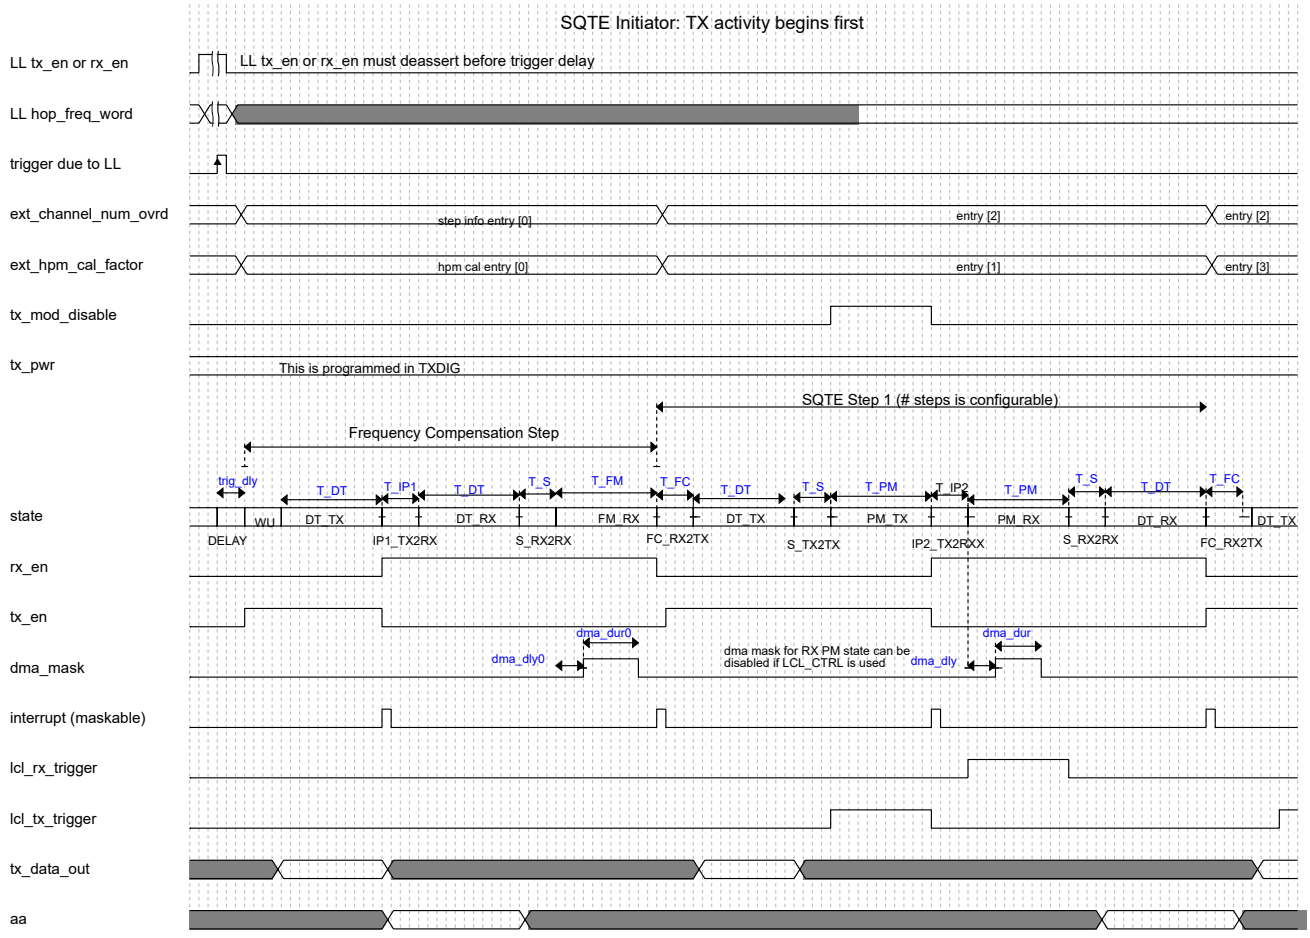

Figure 352. SQTE Mode Timing with TX_EN=1 (Initiator role)

The timing for method #2 (software trigger) is similar to above, but no link layer operation is required. Instead, if TRIG_SEL=0, then the TRIG_DLY counter begins as soon as RSM's TX_EN is programmed to 1.

The timing for method #3 (hardware trigger with dummy LL event) is also similar to above, but differs in the link layer and trigger operation. In this case, the link layer begins a "dummy" TX operation which is only used to trigger the RSM. The RSM trigger for seq_spare3 should be used and the RSM's TRIG_DLY programmed to 0. The TSM should be programmed so that seq_spare3 asserts at time 0. (Seq_spare3 can be programmed to de-assert at any time after 0.) The link layer only needs to assert its "tx_en" signal to the TSM long enough to generate the seq_spare3 trigger to the RSM; after that the link layer can "abort" its TX operation. (Any duration for link layer tx_en from 4us to ~40us should be okay.) The trigger timing for method #2 is shown in the figure below.

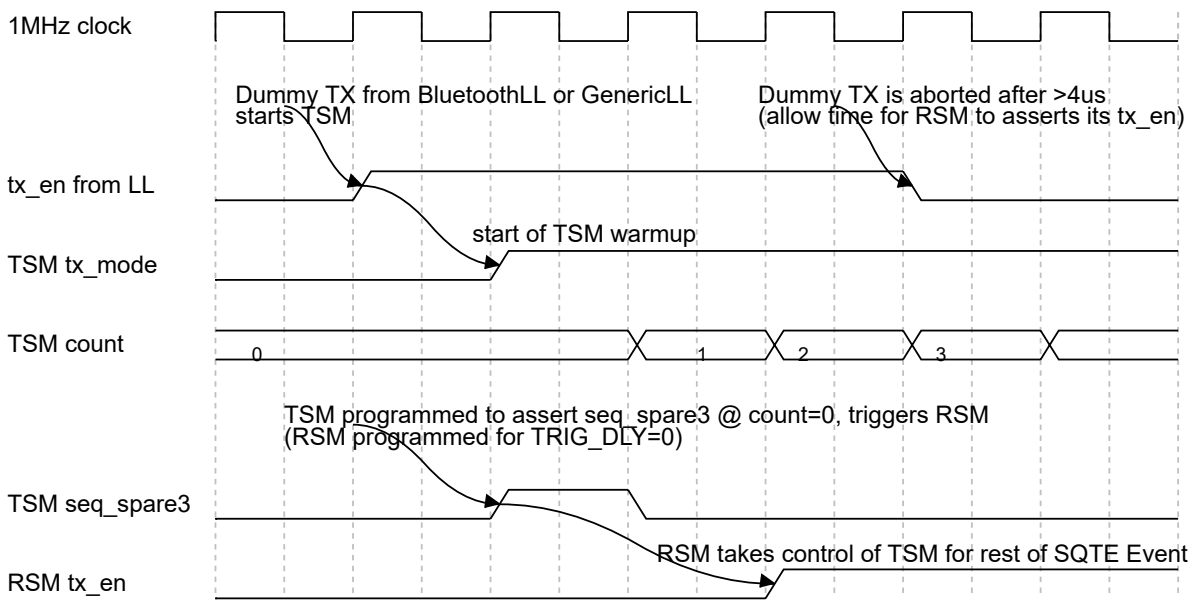

Figure 353. SQTE TX trigger method #3: Dummy LL TX Event for TX_EN=1 (Initiator role)

55.4.7.9.3.1.2 SQTE Reflector Role

The RSM state diagram below illustrates the RSM states used for SQTE in the Reflector role (RX_EN=1). Some of the states are duplicated in the figure to more clearly show the state transition sequence for the four different step format types (FCS, Pk-Pk, Tn-Tn, and PkTn-Tn-Pk). The states are described as follows:

- IDLE. This is the state the RSM is in after a reset and after a sequence has completed (or been aborted).
- DELAY. If a trigger delay is used, after the selected trigger is recognized, the RSM will stay in the DELAY state for TRIG_DLY microseconds.
- WU (Warmup). The RSM asserts its rx_en output to the TSM and then waits for the TSM's wu_complete signal before leaving this state. The figure shows that WU always transitions to the DT_RX state of the FCS step format but this assumes that the FCS step format is selected for the first frequency step (which is the expected behavior).
- FC_TX2RX (Freqency Change TX-to-RX transition). In this state the RSM directs the TSM to switch from TX to RX mode, change the radio frequency, and start a new step. The nominal duration of this state is T_FC
- DT_TX (Packet Transmit). In this state the RSM directs the transceiver to transmit a "packet" with a preamble, PN data, and a trailer. The duration of this state depends on the RATE and RTT_SEQ_LEN bitfields.
- DT_RX (Packet Receive). In this state the RSM directs the transceiver to receive a "packet" with a preamble, PN data, and a trailer. The nominal duration of this state depends on the RATE and RTT_SEQ_LEN bitfields.
- FM_TX (Tone Transmit for FCS). In this state, the RSM directs the transceiver to transmit a "tone". The duration of this state is T_FM0 or T_FM1 depending on the t_pm_sel[0] bitfield in the frequency step data stored in Packet RAM.
- PM_RX (Tone Transmit). In this state the TSM directs the transceiver to receive a "tone". The nominal duration of this state is T_PM0, T_PM1, T_PM2, or T_PM3 dependening on the t_p_sel[1:0] bitfield in the frequency step data stored in Packet RAM
- PM_TX (Tone Transmit). In this state the TSM directs the transceiver to transmit a tone. The duration of this state is T_PM0, T_PM1, T_PM2, or T_PM3 dependening on the t_p_sel[1:0] bitfield in the frequency step data stored in Packet RAM
- IP1_RX2TX (Role swap RX-to-TX transition). In this state, the RSM directs the TSM to switch from RX to TX mode. The nominal duration of this state is T_IP1

- IP2_RX2TX (Role swap RX-to-TX transition). In this state, the RSM directs the TSM to switch from RX to TX mode. The nominal duration of this state is T_IP2
- S_TX2TX (Short TX-to-TX transition). In this state, the RSM transitions between packet and tone transmit. The duration of this state is T_S
- S_RX2RX (Short RX-to-RX transition). In this state, the RSM transitions between packet and tone receive. The nominal duration of this state is T_S
- WD (Warmdown). The RSM de-asserts its rx_en or tx_en (depending on what state it was in prior to warmdown) directing the TSM to warm down the transceiver

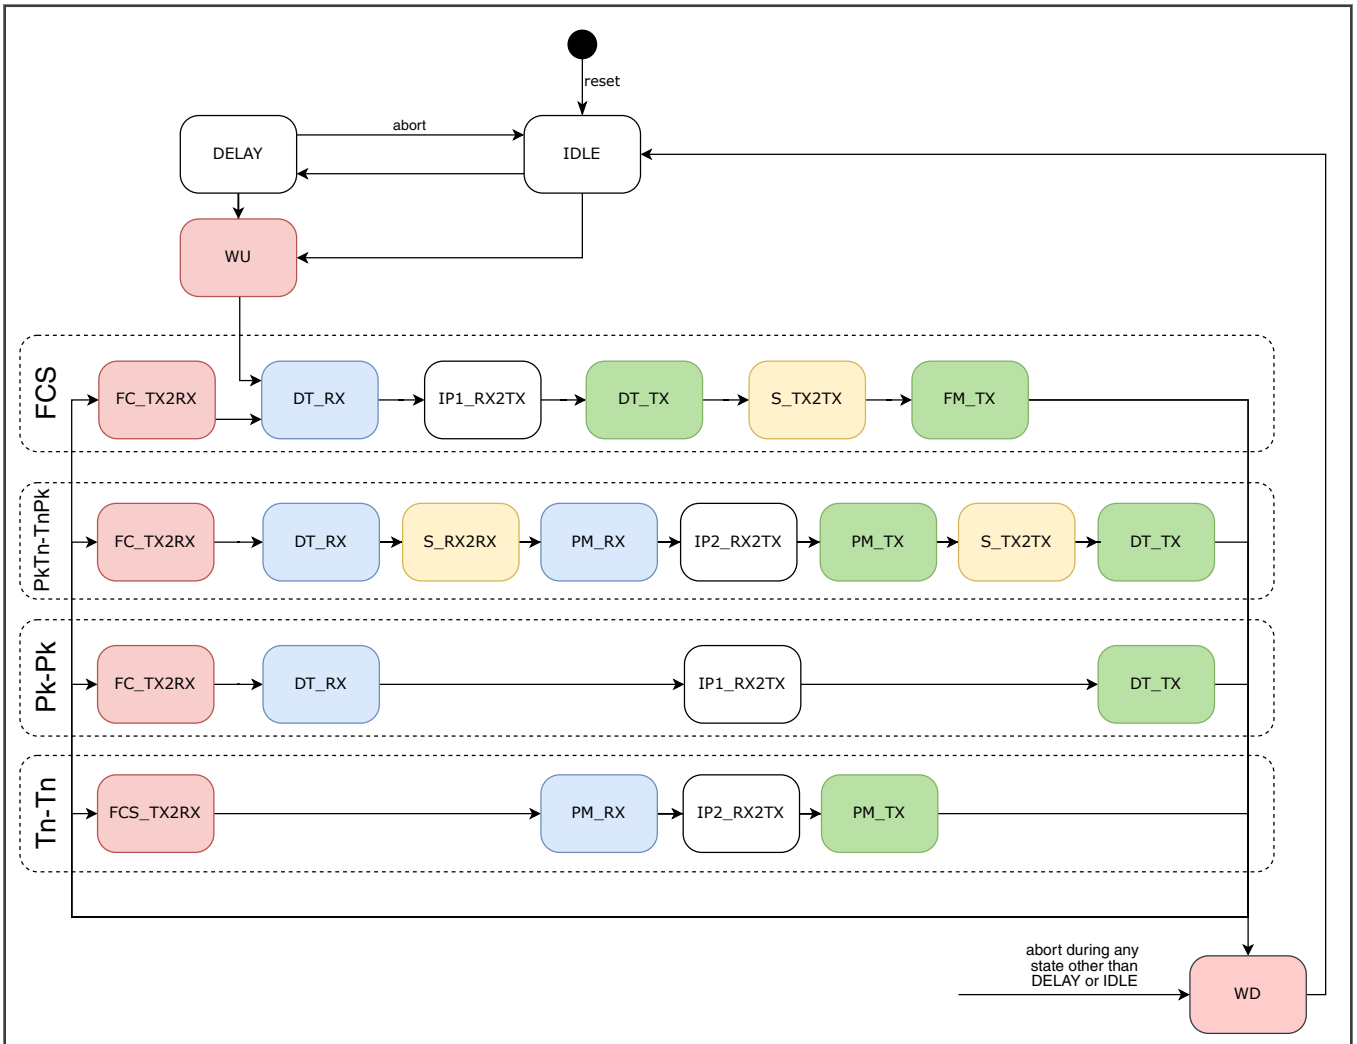

Figure 354. RSM State Transition Diagram for SQTE RX_EN=1 (Reflector role)

Any one of three methods can be used to start RSM operation when the module is configured for SQTE in the Reflector role (RX_EN=1).

1. The RSM is initiated by a hardware trigger (TRIG_SEL>0) which asserts during a previous RX or TX operation controlled by the Bluetooth or Generic LL
2. The RSM is initiated by a software trigger (TRIG_SEL=0)
3. The RSM is initiated immediately (TRIG_DLY=0) by a hardware trigger (TRIG_SEL=seq_spare3) which asserts during a dummy RX operation controlled by the Bluetooth or Generic LL

The figure below shows the timing corresponding to method #1 above. During a previous RX or TX operation controlled by the Bluetooth or Generic LL, a trigger to the is RSM asserted, and then the LL completes it RX or TX operation as usual. Meanwhile, upon recognizing the trigger, the RSM's trigger delay counter starts. After a programmable TRIG_DLY, the RSM will direct the TSM to start a receive operation with a fast warmup if FAST_FC_RX_WU is set or a normal warmup if not. Unless the DT_RX_SYNC_DIS bit is set, then during the FCS RX packet, the RSM will sync the timing using the AA matched signal from the PHY. When SQTE begins with receive, the RSM also utilizes the DMA_DLY0 and DMA_DUR0 to define when and how long dma_mask asserts during the Frequency Error Measurement (T_FM) Step. The state transitions associated with the four frequency step formats when RX_EN=1 are as descibed in the previous state transition diagram figure; note that the timing figure below only shows the Frequency Compensation Step and Pk-Tn-Tn-Pk step formats.

After the last frequency step, the RSM transitions to the WD state where the TSM is warmed down, and then to the IDLE state.

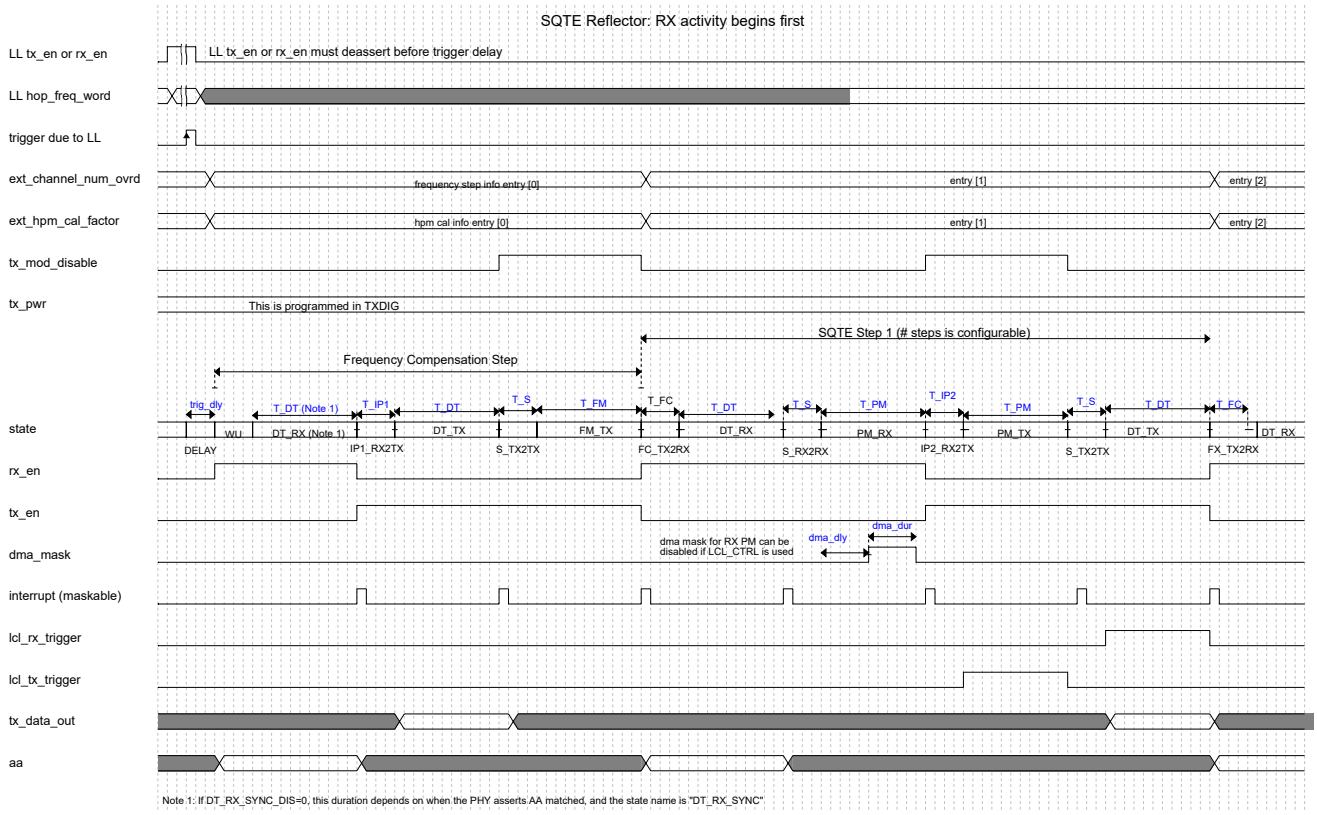

Figure 355. SQTE Timing with RX_EN=1 (Reflector role)

The timing for method #2 (software trigger) is similar to above, but no link layer operation is required. Instead, if TRIG_SEL=0, then the TRIG_DLY counter begins as soon as RSM's RX_EN is programmed to 1.

The timing for method #3 (hardware trigger with dummy LL event) is also similar to above, but differs in the link layer and trigger operation. In this case, the link layer begins a "dummy" RX operation which is only used to trigger the RSM. The RSM trigger for seq_spare3 should be used and the RSM's TRIG_DLY programmed to 0. The TSM should be programmed so that seq_spare3 asserts at time 0. (Seq_spare3 can be programmed to de-assert at any time after 0.) The link layer only needs to assert its "rx_en" signal to the TSM long enough to generate the seq_spare3 trigger to the RSM; after that the link layer can "abort" its RX operation. (Any duration for link layer rx_en from 4us to ~40us should be oky.) The trigger timing for method #2 is shown in the figure below.

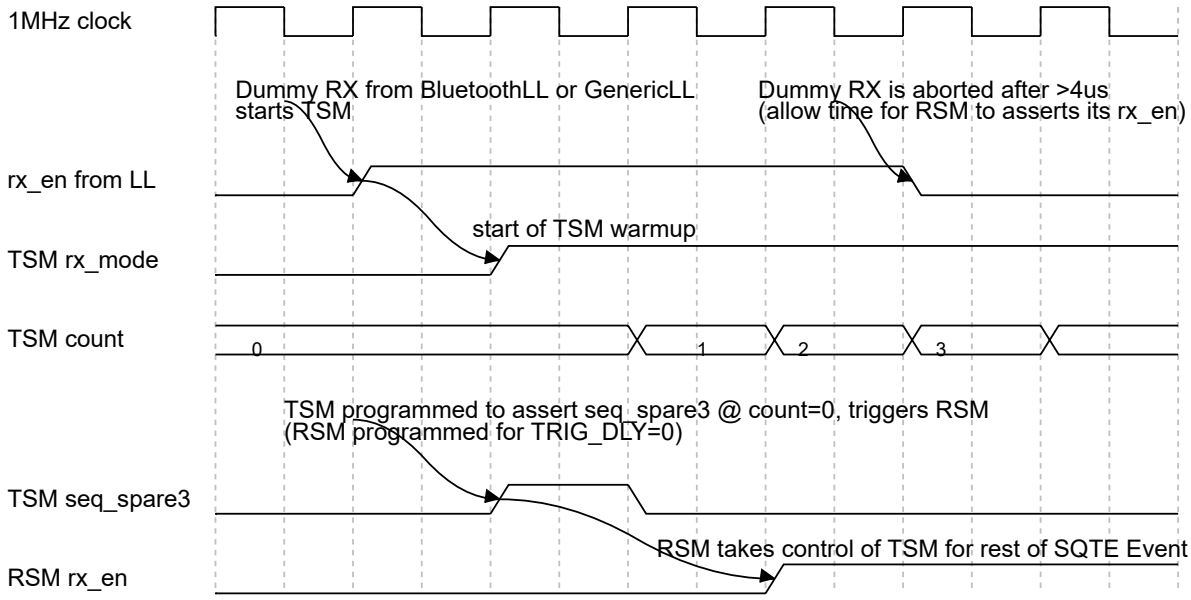

Figure 356. SQTE RX trigger method #3: Dummy LL RX Event for RX_EN=1 (Reflector role)

55.4.7.9.3.2 Phase-based Distance Estimation (PDE) Mode

The MODE=1 setting is for PDE mode. In this mode the transceiver is not warmed down from the LL receive or transmit operation prior to the RSM taking control. Instead, the the RSM is allowed to extend the receive or transmit operation initiated by the LL. For this to work correctly, the frequency used by the LL must match the frequency information in the first set of frequency step information read by the RSM from the Packet RAM (seeConfiguration Stored in Packet RAM).

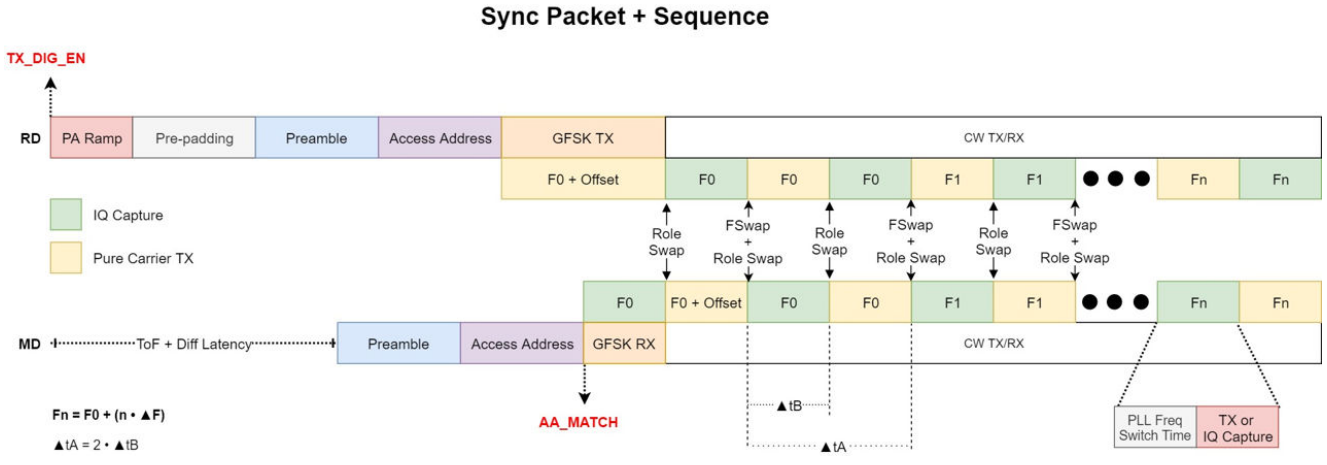

Figure 357. PDE Overview

55.4.7.9.3.2.1 PDE TX_EN=1 (RD Role)

The RSM state diagram below illustrates the RSM states used for PDE with TX_EN=1 (RD Role). Note that unlike SQTE, only one step format (Tn-Tn) is used, so the state diagram is greatly simplified. The states are described as follows:

- IDLE. This is the state the RSM is in after a reset and after a sequence has completed (or been aborted).

- EXT_TX. After the trigger is recognized, the RSM will enter and stay in this state for TRIG_DLY microseconds. During this state, the RSM will assert its tx_en output to the TSM. The link layer continues to control the transceiver at entry to this state, but is expected to de-assert its tx_en output by the time the TRIG_DLY timer expires.
- FC_RX2TX (Freqency Change RX-to-TX transition). In this state the RSM directs the TSM to switch from RX to TX mode, change the radio frequency, and start a new step. The nominal duration of this state is T_FC
- PM_RX (Tone Transmit). In this state the TSM directs the transceiver to receive a "tone". The nominal duration of this state is T_PM0, T_PM1, T_PM2, or T_PM3 dependening on the t_p_sel[1:0] bitfield in the frequency step data stored in Packet RAM
- PM_TX (Tone Transmit). In this state the TSM directs the transceiver to transmit a tone. The duration of this state is T_PM0, T_PM1, T_PM2, or T_PM3 dependening on the t_p_sel[1:0] bitfield in the frequency step data stored in Packet RAM
- IP2_TX2RX (Role swap TX-to-RX transition). In this state, the RSM directs the TSM to switch from TX to RX mode. The nominal duration of this state is T_IP2
- WD (Warmdown). The RSM de-asserts its rx_en or tx_en (depending on what state it was in prior to warmdown) directing the TSM to warm down the transceiver

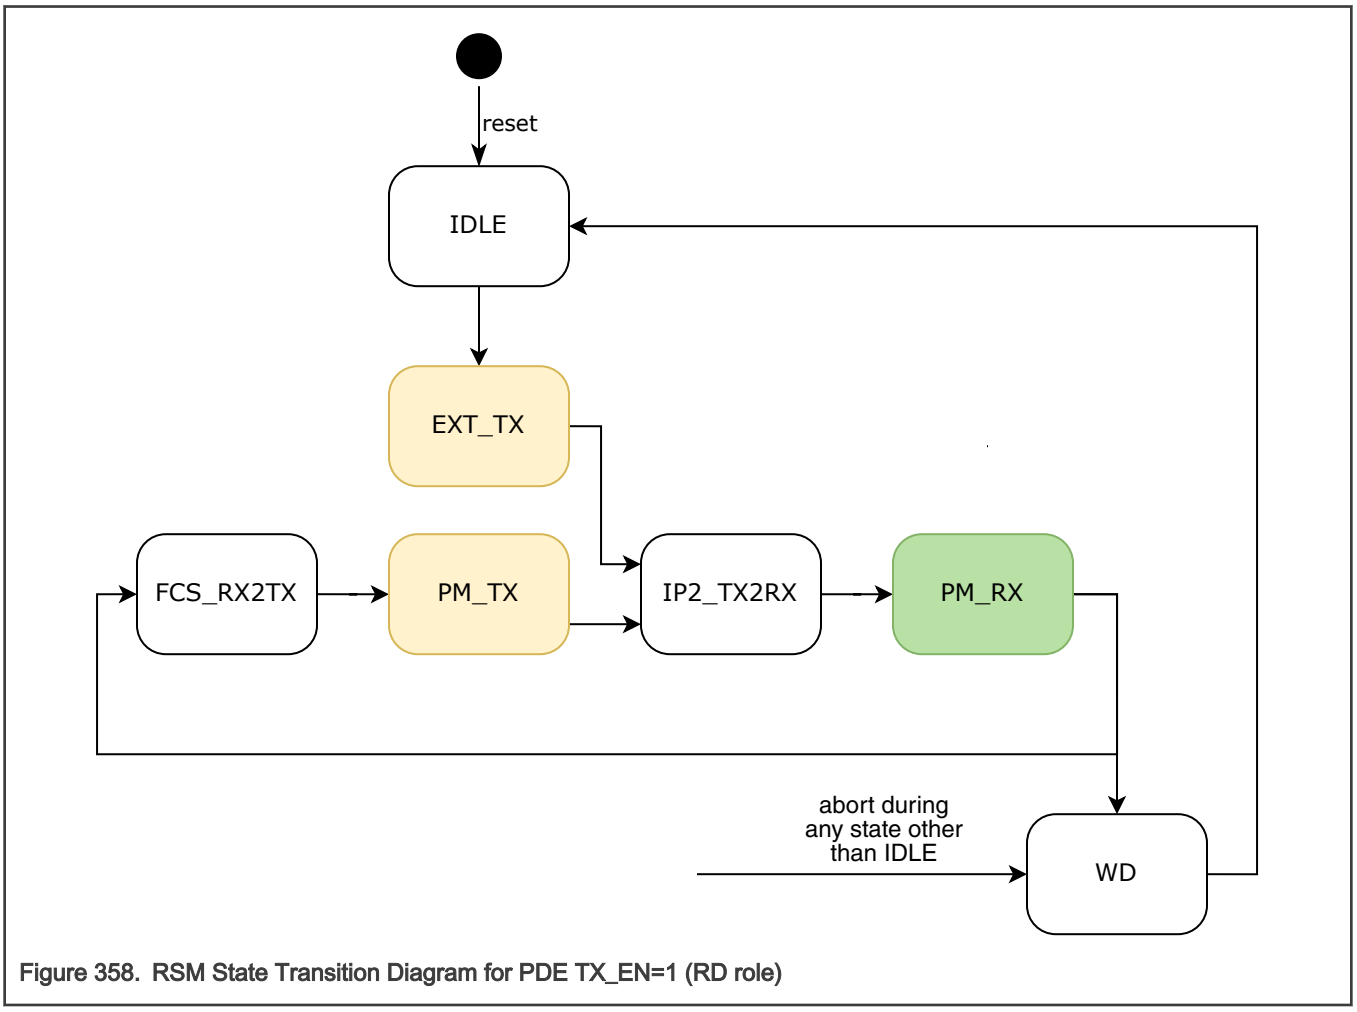

Figure 358. RSM State Transition Diagram for PDE TX_EN=1 (RD role)

The figure below shows PDE operation when the RSM is configured to begin with transmit operation. On assertion of the trigger (for example, TX_DIG_EN from the TSM), the RSM will assert its tx_en signal to keep the transmit operation active until TRIG_DLY expires. By that time, the LL's tx_en should be de-asserted so that the RSM can take full control of the transceiver. When the RSM is configured to begin with transmit, frequency steps occur on RX2TX transitions. Role swaps without frequency changes occur on TX2RX transitions.

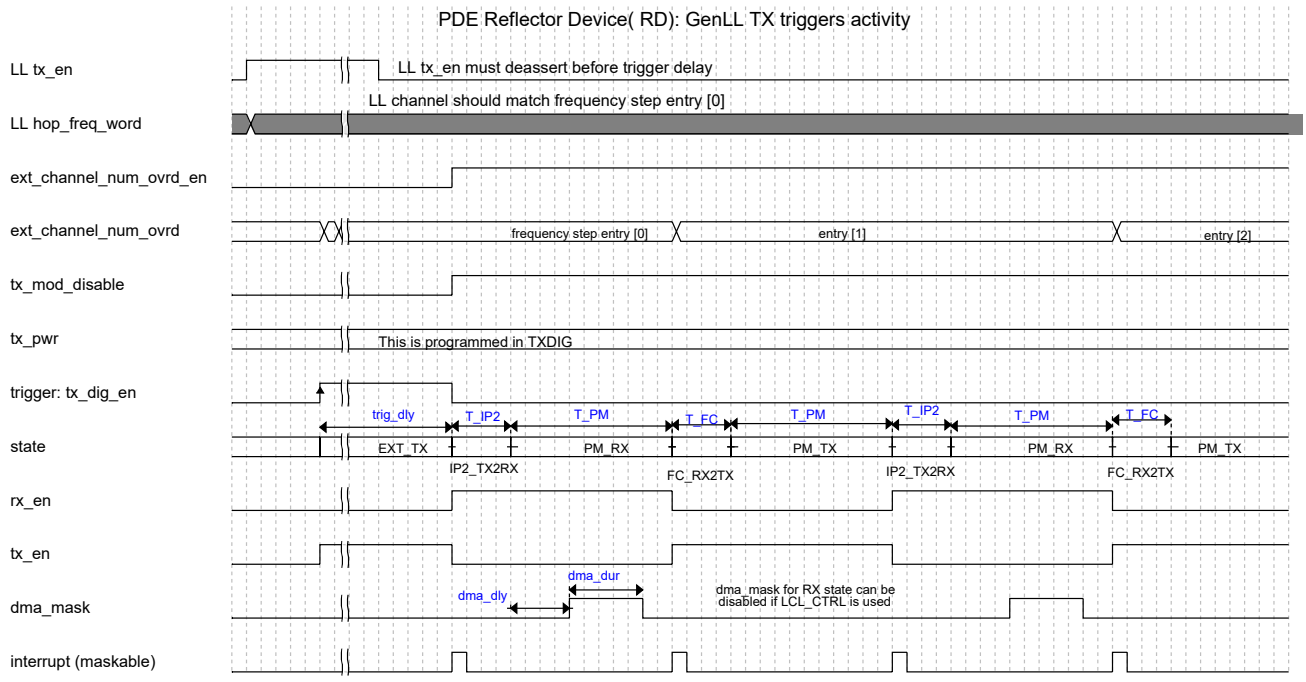

Figure 359. PDE Timing with TX_EN=1 (RD Role)

55.4.7.9.3.2.2 PDE RX_EN=1 (MD Role)

The RSM state diagram below illustrates the RSM states used for PDE with RX_EN=1 (MD Role). Note that unlike SQTE, only one step format (Tn-Tn) is used, so the state diagram is greatly simplified. The states are described as follows:

- IDLE. This is the state the RSM is in after a reset and after a sequence has completed (or been aborted).
- EXT_RX. After the trigger is recognized, the RSM will enter and stay in this state for TRIG_DLY microseconds. During this state, the RSM will assert its rx_en output to the TSM. The link layer continues to control the transceiver at entry to this state, but is expected to de-assert its rx_en output by the time the TRIG_DLY timer expires.
- FC_TX2RX (Freqency Change TX-to-RX transition). In this state the RSM directs the TSM to switch from TX to RX mode, change the radio frequency, and start a new step. The nominal duration of this state is T_FC
- PM_RX (Tone Transmit). In this state the TSM directs the transceiver to receive a "tone". The nominal duration of this state is T_PM0, T_PM1, T_PM2, or T_PM3 dependening on the t_p_sel[1:0] bitfield in the frequency step data stored in Packet RAM
- PM_TX (Tone Transmit). In this state the TSM directs the transceiver to transmit a tone. The duration of this state is T_PM0, T_PM1, T_PM2, or T_PM3 dependening on the t_p_sel[1:0] bitfield in the frequency step data stored in Packet RAM
- IP2_RX2TX (Role swap RX-to-TX transition). In this state, the RSM directs the TSM to switch from RX to TX mode. The nominal duration of this state is T_IP2
- WD (Warmdown). The RSM de-asserts its rx_en or tx_en (depending on what state it was in prior to warmdown) directing the TSM to warm down the transceiver

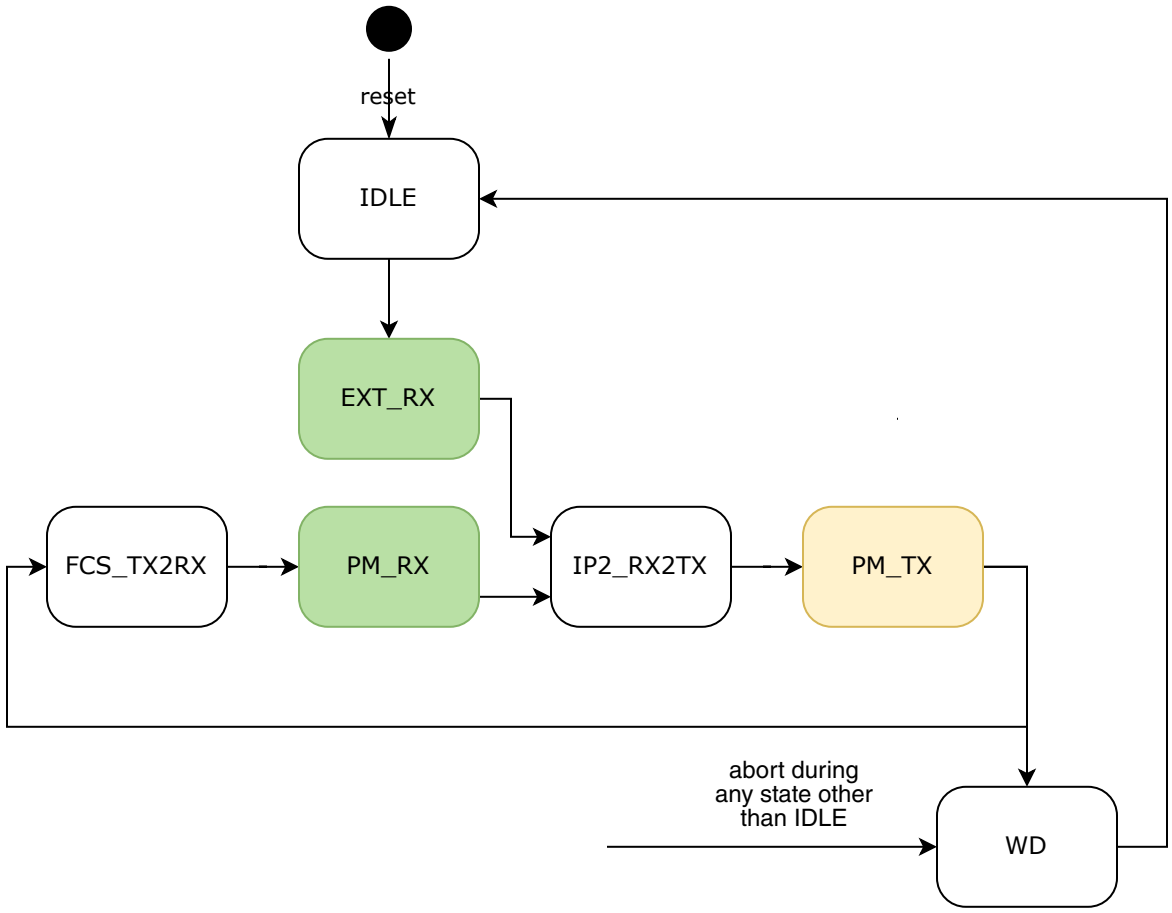

Figure 360. RSM State Transition Diagram for PDE RX_EN=1 (MD role)

The figure below show PDE operation when the RSM is configured to begin with receive operation. On assertion of the trigger (for example, crc_valid), the RSM will assert its rx_en signal to keep the receive operation active until TRIG_DLY expires. By that time, the LL's rx_en should be de-asserted so that the RSM can take full control of the transceiver. When the RSM is configured to begin with receive, frequency steps occur on TX2RX transitions; role swaps without frequency changes occur on RX2TX transitions. When PDE begins with receive, the trigger is also a timing reference for DMA_DLY0 and DMA_DUR0, which define when and how long the dma_mask will be asserted for the initial receive operation.

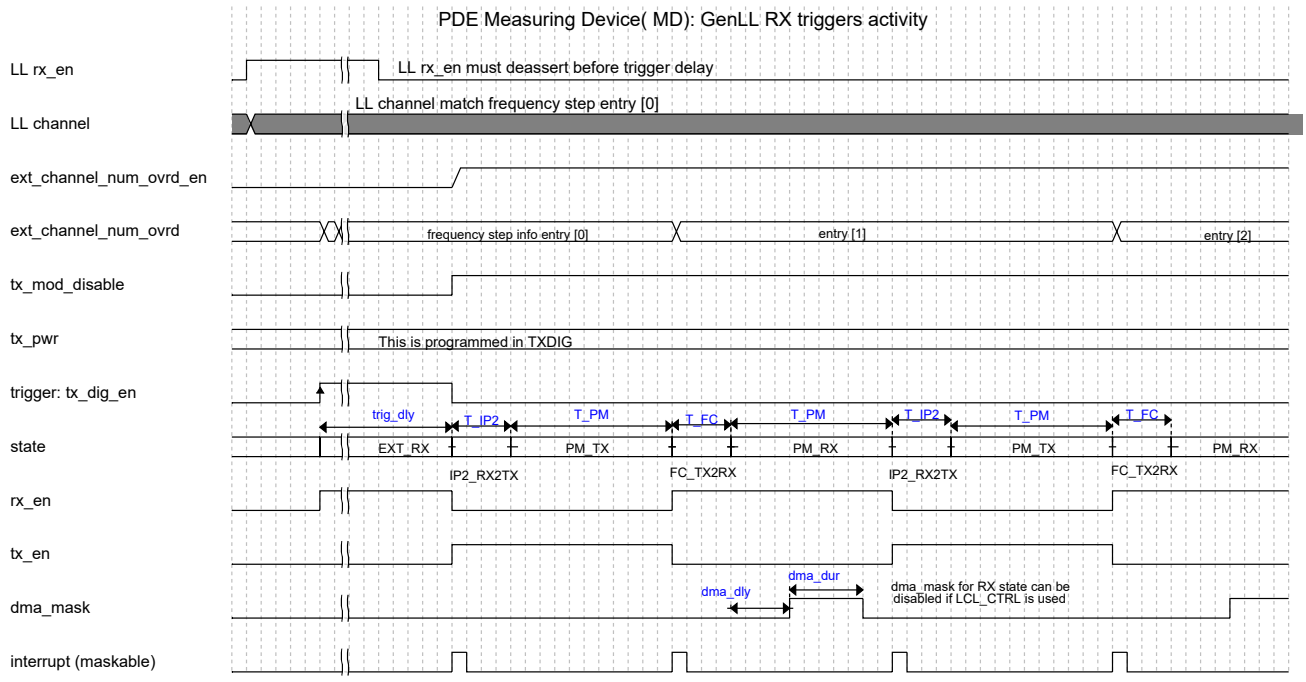

Figure 361. PDE Timing With RX_EN=1 (MD Role)

55.4.7.9.3.3 Programmable Configuration

55.4.7.9.3.3.1 Register Bitfields

The following table describes the control bits used in software configuration of the RSM for PDE and SQTE operation

Table 460. Register Bitfields

Field	Access	Description
MODE	RW	Mode of Operation- 0 - SQTE 1 - PDE
RX_EN	RW	Enables and arms the module for operation starting with Receive. This corresponds to the SQTE "Reflector" role, and the PDE "RD" role. Once set, this bit should remain set until the RSM returns to the IDLE state at the end of the sequence.
TX_EN	RW	Enables and arms the module for operation starting with Transmit. This corresponds to the SQTE "Initiator" role, and the PDE "MD" role. Once set, this bit should remain set until the RSM returns to the IDLE state at the end of the sequence.
RATE	RW	Only used for SQTE. Indicates how the transceiver is configured, and the transfer rate for packets 0 - 1Mbps 1 - 2Mbps

Table continues on the next page...

Table 460. Register Bitfields (continued)

Field	Access	Description
RTT_SEQ_LEN	RW	Only used for SQTE. NOTE that this is programmed in the 2.4GHz PHY. Indicates the length of PN sequence used in packets 0 - 32bits 1 - 64bits
STEPS[7:0]	RW	Number of frequency steps. (For SQTE this also includes the FCS.) The maximum number supported is 128, limited by RX Packet RAM used by RSM. A value of 0 should not be used
T_PM0[5:0], T_PM1[5:0], T_PM2[5:0], and T_PM3[5:0]	RW	PM (phase measurement) durations, units of 10us. 0=10us, ... 0x3F=640us. For SQTE, this is the T_PM*N_AP duration shown in the figures. The T_PM used (T_PM0, T_PM1, T_PM2, or T_PM3) depends on t_pm_sel[1:0] field (see Configuration Stored in Packet RAM)
T_FM0[4:0], T_FM1[4:0]	RW	FM (frequency measurement) duration, units of 10us. 0=10us, ... 0x1F=320us. The T_FM used (T_FM0 or T_FM1) depends on t_pm_sel[0] field (see Configuration Stored in Packet RAM)
T_FC[4:0]	RW	FC (frequency change) duration, units of 5us. 1=5us, ... 0x1F=155us. A value of 0 should not be used
T_IP1[4:0]	RW	Only applies to SQTE. IP1 (interlude period 1) duration, units of 5us. 1=5us, ..., 0x1F=155us. A value of 0 should not be used
T_S[1:0]	RW	Only applies to SQTE. S (short interlude period) duration, units of 5us. 1=5us, 2=10us, 3=15us. A value of 0 should not be used
T_IP2[4:0]	RW	IP2 (interlude period 2) duration, units of 5us. 1=5us, ..., 0x1F=155us. A value of 0 should not be used
FAST_IP_RX_WU	RW	If set, forces TSM to perform a fast RX warmup during IP1_TX2RX and IP2_TX2RX transitions
FAST_IP_TX_WU	RW	If set, forces TSM to perform a fast TX warmup during IP1_RX2TX and IP2_TX2RX transitions
FAST_FC_RX_WU	RW	If set, forces TSM to perform a fast RX warmup during FC_TX2RX transitions (and for SQTE with ipr_rx_en=1 during WU state)
FAST_FC_TX_WU	RW	If set, forces TSM to perform a fast TX warmup during FC_RX2TX transitions (and for SQTE with ipr_tx_en=1 during WU state)
RX_SETTLING_LATENCY	RW	Receiver latency. (From TSM register)
TX_DATA_FLUSH_DLY	RW	TX data flush delay / TX latency. (From TXDIG register)
AA_HAMM[2:0]	RW	Only applies to SQTE. Indicates the Access Address Hamming distance to be used by the PHY when RSM is active
CTUNE	RW	If set, RSM will send coarse tune values read from the Packet RAM to the PLL. If clear, the PLL will perform coarse tune.
HPM_CAL	RW	If set, RSM will send hpm calibration values read from the Packet RAM to the PLL. If clear, the PLL will perform hpm calibration.
TRIG_SEL[2:0]	RW	Selects which trigger to use. If 0, the module is triggered immediately.

Table continues on the next page...

Table 460. Register Bitfields (continued)

Field	Access	Description
TRIG_DLY[10:0]	RW	SQTE mode: delay from trigger to when rx_en or tx_en is asserted, in microseconds PDE mode: delay from trigger to when the first RX2TX or TX2RX transition occurs, in microseconds. For PDE mode, this should be programmed to a value greater than 0.
DMA_DLY[7:0]	RW	Delay from end of RX warmup to assertion of dma_mask signal, in microseconds
DMA_DLY0[7:0]	RW	Same as DMA_DLY[7:0] but used for the SQTE Frequency Measurement (FM) step (in FCS), and for PDE in the handoff from the LL
DMA_DUR[6:0]	RW	Duration of the dma_mask signal, in microseconds. Used in the PM_RX state. NOTE: If used in conjunction with the RXDIG's window averager, to ensure that the same number of samples are captured during each time the dma_mask asserts, the duration should be a multiple of the window averager's duration.
DMA_DUR0[6:0]	RW	Same as DMA_DUR[6:0] but used for the SQTE Frequency Error Measurement Step, and for PDE in the handoff from the LL
DMA_RX_EN	RW	Enable dma_mask to assert in PM_RX State. (Note that the DMA mask is always allowed to assert in the SQTE Frequency Measurement (FM) step in FCS.) This bit is expected to be set in SQTE events where the device does not perform antenna switching (LCL_CTRL is not used).
SW_ABORT	RW	Used to gracefully shut down the module prior to a normal end of sequence. Once set, this bit should remain set until the RSM returns to the IDLE state at the end of the sequence.
DT_RX_SYNC_DIS	RW	Only applies to SQTE, and only used by the Reflector device (RX_EN=1) . Setting this bit disables the auto-sync feature for the Reflector device in the FCS RX packet
DT_RX_SYNC_DLY[3:0]	RW	Only applies to SQTE, and only used by the Reflector device (RX_EN=1) when DT_RX_SYNC_DIS=0. In this configuration the RSM uses the PHY's AA_MATCHED output to sync the Reflector device to the Initiator device's timing. When RTT_SEQ_LEN=0, this corresponds to the delay in microseconds from the PHY's AA_MATCHED to the end of DT_RX duration (the packet duration including preamble and trailer, plus RX_SETTLING_DELAY). The value used for RTT_SEQ_LEN=0 can also be used when RTT_SEQ_LEN=1, though in the latter configuration the RSM internally offsets this value to compensate for the longer packets (since AA_MATCHED uses only the first 32bits of the PN sequence regardless of the PN sequence length).
RX_PHY_EN_MASK_DIS	RW	Only applies to SQTE. If set, the rx_phy_en_mask output is always asserted
SEQ_RCCAL_PUP_MASK_DIS	RW	If set, TSM signal seq_rccal_pup is not modified by RSM. If clear, seq_rccal_pup is masked to 0 for all RSM states except IDLE, WU, and FC
RX_SIGNALS_MASK_DIS	RW	If set, TSM signals dcoc_gain_cfg_en, dcoc_cal_en, seq_bg_pup_ibg_rx, seq_cbpf_en_dcoc, and rx_gang_pup are not modified by RSM. If clear, these signals are masked to 0 during RSM's IP1/IP2_RX2TX states
IRQ_IP1_EN	RW	If set, requests an interrupt at the beginning of the IP1_RX2TX or IP1_TX2RX state
IRQ_IP1	W1C	The bit is set on entry to IP1_RX2TX or IP1_TX2RX states. Write 1 to clear the bit[1].

Table continues on the next page...

Table 460. Register Bitfields (continued)

Field	Access	Description
IRQ_IP2_EN	RW	If set, requests an interrupt at the beginning of the IP2_RX2TX or IP2_TX2RX state
IRQ_IP2	W1C	The bit is set on entry to IP2_TX2RX or IP2_RX2TX states. Write 1 to clear the bit[1].
IRQ_FC_EN	RW	If set, requests an interrupt at the beginning of the FC_RX2TX or FC_TX2RX state
IRQ_FC	W1C	The bit is set on entry to FC_RX2TX or FC_TX2RX states. Write 1 to clear the bit[1].
IRQ_EOS_EN	RW	If set, requests an interrupt at the end of the sequence
IRQ_EOS	W1C	The bit is set to indicate that the sequence is complete. It sets when the RSM transitions from the WD to the IDLE state. Write 1 to clear the bit[1].
IRQ_ABORT_EN	RW	If set, requests an interrupt if the sequence is interrupted due to a PLL abort
IRQ_ABORT	W1C	The bit is set when the sequence is aborted due to pll_abort. This condition can occur during any RSM state except for the IDLE or WD states. Write 1 to clear the bit[1].

1. To clear RSM's W1C bits, RX_EN or TX_EN must be set. It is therefore recommended that software ensures that all the RSM W1C bits are cleared at the end of each RSM sequence prior to clearing RX_EN or TX_EN to disable the module.

55.4.7.9.3.3.2 Configuration Stored in Packet RAM

In addition to the configuration information stored in registers as described in the previous section, the RSM also relies on configuration information stored in the Packet RAM to control the behavior in each individual frequency step. There are 2 separate areas of the Packet RAM used for this configuration information.

First, there is information which is needed for every frequency step. This requires 5bytes per frequency step. It is located in the RX Packet RAM beginning at offset RSM_FSTEP_RAM, and is allocated 640bytes, which limits the maximum STEPS to 128. The frequency step information consists of the following bitfields:

- ext_channel_num_ovrd[15:0]. This defines the frequency to be used for this step. This is decoded by the PLL using the format defined in the PLL's CHAN_MAP[HOP_TBL_CFG_OVRD] bitfield. NOTE: to ensure proper PLL operation when using the RSM, the PLL's CHAN_MAP[CHANNEL_NUM_OVRD] bitfield should be programmed to 0.
- ext_ctune[7:0]. This defines the PLL coarse tune value for this frequency step.
- ext_hpm_cal_factor[12:1]. This defines the 12 MSBs of the PLL high port modulation calibration factor. The LSB, ext_hpm_cal_factor[0], is assigned to 0. Note that this has the same format as PLL's HPM_CAL_FACTOR_MANUAL bitfield
- step_format[1:0]. This 2bit field defines the step format. The values of this are as follows:
  - 00 - Frequency Compensation Step (FCS) format
  - 01 - Pk-Pk format
  - 10 - Tn-Tn format
  - 11 - Pk-Tn-Tn-Pk format.
- t_pm_sel[1:0]. For Tn-Tn and PkTn-Tn-Pk formats, this selects whether T_PM0, T_PM1, T_PM2, or T_PM3 are used for the tone duration in this frequency step : 2'b00 is associated with T_PM0, 2'b01 with T_PM1, 2'b10 with T_PM2, and 2'b11 with T_PM3. For FCS format, t_pm_sel[0] selects whether T_FM0 or T_FM1 is used for this frequency step.

Allowing the coarse tune value and hpm calibration factor for each step to be read from RAM reduces the T_FC duration since the PLL does not have to perform these calibration. Note that even if RSM's CTUNE and HPM_CAL bits are cleared (indicating PLL will perform these calibrations), the step format still consists of 5 bytes.

Table 461. Frequency Step Configuration

Frequency Step	Address Offset	bit 7	bit 6	bit 5	bit 4	bit 3	bit 2	bit 1	bit 0
0	0	ext_channel_num_ovrd[7:0]							
	1	ext_channel_num_ovrd[15:8]							
	2	ext_ctune[7:0]							
	3	ext_hpm_cal_factor[8:1]							
	4	t_pm_sel[1:0]		step_format[1:0]		ext_hpm_cal_factor[12:9]			
1	5	ext_channel_num_ovrd[7:0]							
	6	ext_channel_num_ovrd[15:8]							
	7	ext_ctune[7:0]							
	8	ext_hpm_cal_factor[8:1]							
	9	t_pm_sel[1:0]		step_format[1:0]		ext_hpm_cal_factor[12:9]			
...	...	...							
n	5n	ext_channel_num_ovrd[7:0]							
	5n+1	ext_channel_num_ovrd[15:8]							
	5n+2	ext_ctune[7:0]							
	5n+3	ext_hpm_cal_factor[8:1]							
	5n+4	t_pm_sel[1:0]		step_format[1:0]		ext_hpm_cal_factor[12:9]			

Second, for SQTE steps which have packet exchanges, there is additional information regarding the packet contents. This consists of either 32bits or 64bits, depending on the configured size (RTT_SEQ_LEN) . It is located in the RX Packet RAM beginning at offset RSM_FN_RAM, and is allocated 848bytes, which limits the maximum number of steps with packet exchanges to 106 (32bit PN sequences) or 53 (64bit PN sequences). Each packet exchange consists of the Initiator sending a packet to the Reflector, and the Reflector sending a packet to the Initiator. So, the first word or words stored in Packet RAM are for the Initiator-to-Reflector packet, and the next word or words are for the Reflector-to-Initiator packet. The packet format also includes a 8bit (or 16bit in the case of 2Mbps) preamble and a 4bit trailer. The bit sequence in the preamble and trailer is not read from the Packet RAM; it is determined by hardware based on the PN sequence.

Table 462. PN Configuration for 32bit packets

FCS, Pk-Pk or Pk-Tn-Tn-Pk Step	Address Offset	bits [31:0]
0	0	pn[31:0] for Initiator-to-Reflector packet
	4	pn[31:0] for Reflector-to-Initiator packet
1	8	pn[31:0] for Initiator-to-Reflector packet
	12	pn[31:0] for Reflector-to-Initiator packet
...	...	...
n	8n	pn[31:0] for Initiator-to-Reflector packet
	8n+4	pn[31:0] for Reflector-to-Initiator packet

Table 463. PN Configuration for 64bit packets

FCS, Pk-Pk or Pk-Tn-Tn-Pk Step	Address Offset	bits [31:0]
0	0	pn[31:0] for Initiator-to-Reflector packet
	4	pn[63:32] for Initiator-to-Reflector packet
	8	pn[31:0] for Reflector-to-Initiator packet
	12	pn[63:32] for Reflector-to-Initiator packet
1	16	pn[31:0] for Initiator-to-Reflector packet
	20	pn[63:32] for Initiator-to-Reflector packet
	24	pn[31:0] for Reflector-to-Initiator packet
	28	pn[63:32] for Reflector-to-Initiator packet
...	...	...
n	16n	pn[31:0] for Initiator-to-Reflector packet
	16n+4	pn[63:32] for Initiator-to-Reflector packet
	16n+8	pn[31:0] for Reflector-to-Initiator packet
	16n+12	pn[63:32] for Reflector-to-Initiator packet

55.4.7.9.3.4 Results written to Packet RAM

In the configuration where the PLL performs coarse tune during the RSM operation (CTUNE=0), the RSM will capture the coarse tune best diff value (one byte) and save this to Packet RAM. This will occur on every frequency change operation, and in the case of SQTE during the initial WU state. These results are located in the RX Packet RAM beginning at offset RSM_PCBD_RAM, and is allocated 128bytes, which limits the maximum STEPS to 128.

Table 464. CTUNE Results

Frequency Step	Address Offset	bits [7:0]
0	0	ctune_best_diff[7:0]
1	1	ctune_best_diff[7:0]
...	...	...
n	n	ctune_best_diff[7:0]

For SQTE, during every packet reception, the RSM will save the RTT (round trip time) info from the PHY to Packet RAM. This is a four byte value, which includes 31bits from the PHY (rtt_data[30:0] = {rtt_p_delta[9:0], rtt_ham_dist_sat[1:0], rtt_int_adj[1:0], ha_rtt_cfo[15:0], ha_rtt_found}) and 1bit (rtt_vld) which is 1 if the PHY indicates that the rtt_data[30:0] is valid; otherwise it is 0. These results are saved in the RX Packet RAM beginning at offset RSM_RTT_RAM, and is allocated 424bytes, which limits the maximum number of packet exchanges to 106. Refer to the PHY chapter for more information on rtt_p_delta[9:0], rtt_ham_dist_sat[1:0], rtt_int_adj[1:0], ha_rtt_cfo[15:0], and ha_rtt_found.

Table 465. RTT Results

FCS, Pk-Pk or Pk-Tn-Tn-Pk Step	Address Offset	bit 7	bit 6	bit 5	bit 4	bit 3	bit 2	bit 1	bit 0
0	0	rtt_cfo[5:0]						rtt_found	rtt_vld
	1	rtt_cfo[13:6]							
	2	rtt_p_delta[1:0]		rtt_ham_dist_sat[1:0]		rtt_int_adj[1:0]		rtt_cfo[15:14]	
	3	rtt_p_delta[9:2]							
1	4	rtt_cfo[5:0]						rtt_found	rtt_vld
	5	rtt_cfo[13:6]							
	6	rtt_p_delta[1:0]		rtt_ham_dist_sat[1:0]		rtt_int_adj[1:0]		rtt_cfo[15:14]	
	7	rtt_p_delta[9:2]							
...	...	...							
n	4n	rtt_cfo[5:0]						rtt_found	rtt_vld
	4n+1	rtt_cfo[13:6]							
	4n+2	rtt_p_delta[1:0]		rtt_ham_dist_sat[1:0]		rtt_int_adj[1:0]		rtt_cfo[15:14]	
	4n+3	rtt_p_delta[9:2]							

55.4.7.9.3.5 Role Swap and Frequency Change Transitions

This section provides information on the role swap (changing from receive to transmit or vice versa, from receive packet to receive tone or vice versa, or from transmit packet to transmit tone or vice versa) and frequency change transitions (with or without role swap) and their timings in more detail. These transitions are all intended to be handled by the RSM logic without software involvement; however, as a fallback, it is also possible to trigger interrupts at the beginning of transition states so that software can perform any additional tasks. Note that fewer transitions are supported for PDE than for SQTE, and that the transitions used depends also on the role (whether RX_EN or TX_EN bit is set).

55.4.7.9.3.5.1 TSM Features Utilized

The RSM utilizes several TSM features to control these transitions and to minimize the transition durations: fast RX2TX and fast TX2RX; recycle events; and fast RX and TX warmups. RSM usage of these features is described in the next three paragraphs.

First, for role swap the RSM always directs the Transceiver Sequence Manager (TSM) to perform fast RX2TX and fast TX2RX transitions. In these transitions, the TSM jumps from a recieve (transmit) sequence already warmed up to a programmable starting point in the transmit (receive) sequence. The starting points are programmed in the TSM: FAST_TX2RX_START for IP1_TX2RX or IP2_TX2RX, FAST_TX2RX_START_FC for FC_TX2RX, FAST_RX2TX_START for IP1_RX2TX or IP2_RX2TX, and FAST_RX2TX_START_FC for FC_RX2TX. For the FC_RX2TX and FC_TX2RX, the start value is expected to be programmed such that the TSM's pll_dig_en is de-asserted for 1us and then re-asserted, coincident with new frequency information provided to the PLL from the RSM; for the other transitions a frequency change is not performed, so the start time value should be such that the TSM's pll_dig_en does not de-assert.

Second, for S_RX2RX transitions (which are only used in SQTE), the RSM can direct the TSM using a "recycle0" event. In these transitions, the TSM jumps from a receive sequence already warmed up to a programmable starting point in the receive sequence. The starting count is programmed in the TSM's RECYCLE_COUNT0 bitfield such that rx_dig_en cycles and rx_init pulses to reset the receiver. (Note that S_TX2TX does not require a recycle event; the transmitter is not reset during this transition)

Third, to further minimize the duration of the RX2TX and TX2RX transitions, the RSM can direct the TSM to perform a fast TX or fast RX warmup. Fast RX or TX warmups allow the TSM to skip some TSM counts in the middle of the TSM warmup sequence (after the RX2TX and TX2RX start times described above). For example, during a fast RX warmup the DCOC calibration

time can be skipped. The skip times are programmed in the TSM: FAST_TX_START and FAST_TX_DEST for transmit, and FAST_RX_START and FAST_RX_DEST for receive. The use of fast RX or TX warmups during RSM transitions is an optional feature. It is enabled through the RSM's FAST_IP_TX_WU (for IP1_RX2TX and IP2_RX2TX transitions), FAST_IP_RX_WU (for IP1_TX2RX and IP2_TX2RX transitions), FAST_FC_RX_WU (for FC_TX2RX transitions), and FAST_FC_TX_WU (for FC_RX2TX transitions) bitfields.

In below discussion of the transition timings, the following assumptions are made concerning the configuration of the TXDIG ramp:

- TXDIG is programmed for 1us ramp (PA_RAMP_SEL=2'b01).

NOTE

The 1us ramp setting is a requirement for proper operation of the RSM with the TXDIG

- For PA ramp-up: PAD_DLY (delay from tx_dig_en to PA enable) is assumed to be programmed to 0

The RX2TX transition states (IP1_RX2TX, IP2_RX2TX, and FC_RX2TX) are described as follows:

- The RSM signals to the TSM to initiate a fast RX2TX transition. In response the TSM will change from rx_mode to tx_mode and change its count to FAST_RX2TX_START (IP1_RX2TX, IP2_RX2TX) or FAST_RX2TX_START_FC (FC_RX2TX). FAST_RX2TX_START and FAST_RX2TX_START_FC are programmed in the TSM
- If RSM's FAST_IP_TX_WU bit is set (IP1_RX2TX, IP2_RX2TX) or FAST_FC_TX_WU bit is set (FC_RX2TX), the RSM will also signal to the TSM to perform a fast warmup during the TX warmup. As the TSM count increments it will skip from FAST_TX_START to FAST_TX_DEST (which are programmed in the TSM)
- The TSM reaches the end of warmup when its count reaches END_OF_TX_WU and after the TXDIG has asserted the pa_wu_complete signal.

The time needed for the RX2TX transitions are shown in the table below, where the term "pa_ru" accounts for any additional time after END_OF_TX_WU before the PA ramp-up completes:

- if (RAMP_UP_DLY + 2us >= END_OF_TX_WU - TX_DIG_EN_TX_HI) pa_ru = (RAMP_UP_DLY + 2us) - (END_OF_TX_WU - TX_DIG_EN_TX_HI)
- else pa_ru = 0us

Transition	Time needed for transition	Roles
IP1_RX2TX	(END_OF_TX_WU - FAST_RX2TX_START) - (FAST_DEST_TX - FAST_START_TX)*FAST_IP_TX_WU + pa_ru	SQTE Reflector
IP2_RX2TX	(END_OF_TX_WU - FAST_RX2TX_START) - (FAST_DEST_TX - FAST_START_TX)*FAST_IP_TX_WU + pa_ru	SQTE Reflector, PDE MD
FC_RX2TX	(END_OF_TX_WU - FAST_RX2TX_START_FC) - (FAST_DEST_TX - FAST_START_TX_FC)*FAST_FC_TX_WU + pa_ru	SQTE Initiator, PDE RD

The TX2RX transition states (IP1_TX2RX, IP2_TX2RX, and FC_TX2RX) are described as follows:

- The RSM directs the TXDIG to ramp-down the PA
- The RSM signals to the TSM to initiate a fast TX2RX transition. In response the TSM will change from tx_mode to rx_mode and change its count to FAST_TX2RX_START (IP1_TX2RX, IP2_TX2RX) or FAST_TX2RX_START_FC (FC_TX2RX). FAST_TX2RX_START and FAST_TX2RX_START_FC are programmed in the TSM
- If RSM's FAST_IP_RX_WU bit is set (IP1_TX2RX, IP2_TX2RX) or FAST_FC_RX_WU bit is set (FC_TX2RX), the RSM will also signal to the TSM to perform a fast warmup during the RX warmup. As the TSM count increments it will skip from FAST_RX_START to FAST_RX_DEST (which are programmed in the TSM)
- The TSM reaches the end of warmup when its count reaches END_OF_RX_WU.

The time needed for the TX2RX transitions are shown below. The 2us + TX_DATA_FLUSH_DLY is related to PA ramp-down at the beginning of the transition .

Transition	Time needed for transition	Roles
IP1_TX2RX	(END_OF_RX_WU - FAST_TX2RX_START) - (FAST_DEST_RX - FAST_START_RX)*FAST_IP_RX_WU + 2us + TX_DATA_FLUSH_DLY	SQTE Initiator
IP2_TX2RX	(END_OF_RX_WU - FAST_TX2RX_START) - (FAST_DEST_RX - FAST_START_RX)*FAST_IP_RX_WU + 2us + TX_DATA_FLUSH_DLY	SQTE Inititator, PDE RD
FC_TX2RX	(END_OF_RX_WU - FAST_TX2RX_START_FC) - (FAST_DEST_RX - FAST_START_RX)*FAST_FC_RX_WU + 2us + TX_DATA_FLUSH_DLY	SQTE Reflector, PDE MD

The RX2RX transition state (S_RX2RX) is described as follows.

- The RSM signals to the TSM using recycle0. In response the TSM will change its count to RECYCLE_COUNT0
- The TSM reaches the end of warmup when its count reaches END_OF_RX_WU.

The TX2TX transition state (S_TX2TX), doesn't require a recycle event; the TX_DATA_FLUSH_DLY accounts for the flushing delay in the transition. The time needed for the RX2RX and TX2TX transitions are shown below.

Transition	Time needed for transition	Roles
S_RX2RX	(END_OF_RX_WU - RECYCLE_COUNT0)	SQTE Initiator, SQTE Reflector
S_TX2TX	TX_DATA_FLUSH_DLY	SQTE Initiator, SQTE Reflector

For SQTE, the RSM has to warmup the transceiver from the TSM IDLE state. For SQTE Initiator role, if RSM's FAST_FC_TX_WU bit is set, the RSM will signal to the TSM to perform a fast warmup during the TX warmup. For SQTE Reflector role, if RSM's FAST_FC_RX_WU bit is set, the RSM will signal to the TSM to perform a fast warmup during the RX warmup.

Transition	Time needed for transition	Roles
WU	END_OF_TX_WU - (FAST_DEST_TX - FAST_START_TX)*FAST_FC_TX_WU + pa_ru + 3us	SQTE Initiator (TX warmup)
WU	END_OF_RX_WU - (FAST_DEST_RX - FAST_START_RX)*FAST_FC_RX_WU + 1us	SQTE Reflector (RX warmup)

55.4.7.9.3.5.2 RX and TX Latency Handling

When transmitting, in order to be "on air" beginning at the desired time, it is necessary to account for the latency through the TXDIG and PLL. To account for this, the RSM uses the TXDIG programmable value TX_DATA_FLUSH_DLY which is specified in terms of microseconds. The RSM will shift TX states (DT_TX, FM_TX, PM_TX) to begin earlier in time by TX_DATA_FLUSH_DLY to ensure that transmit information is "on air" at the correct time.

When receiving is it necessary to account for latency through the receiver and PHY. The RSM uses the TSM programmable value RX_SETTLING_LATENCY (which is specified in terms of microseconds) for this. The RSM will extend RX states (DT_RX, FM_RX, PM_RX) by RX_SETTLING_LATENCY to ensure that the last "on air" information during T_DT, T_FM, or T_PM can be processed by the receiver.

These concepts are illustrated in the example figure below for a SQTE step of type Pk-Tn-Tn-Pk. In both Initator and Reflector roles, the TX (DT_TX, FM_TX, and PM_TX) states are shifted early by TX_DATA_FLUSH_DLY with respect to the "nominal time", while the RX (DT_RX, FM_RX, and PM_RX) states are extended by RX_SETTLING_LATENCY.

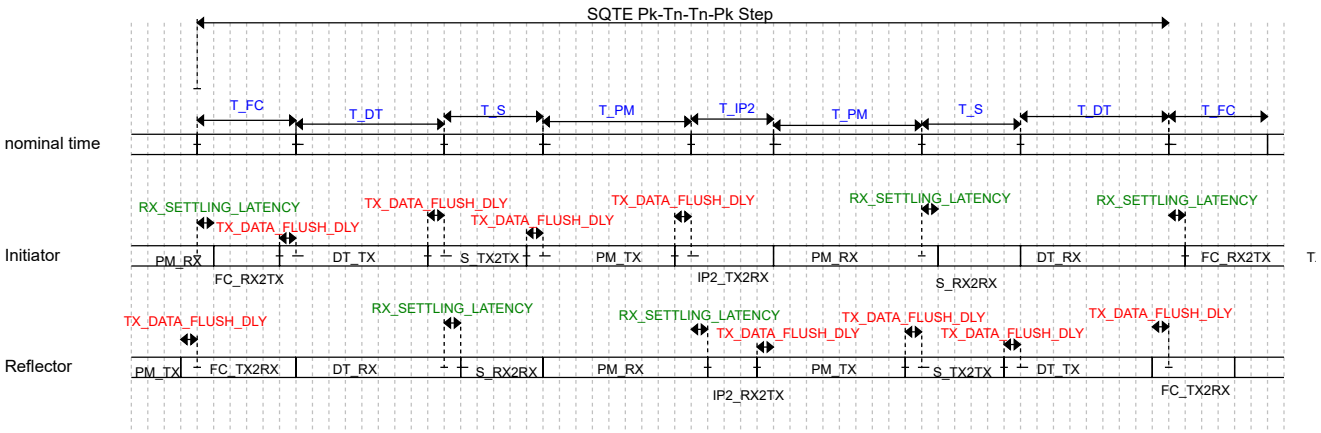

Figure 362. RX and TX Latency

As shown in the timing figure above, after taking into account the RX and TX latencies some of RSM state's durations are different than the "nominal" durations. This is summarized in the table below

Table 466. RSM Actual State Durations

State	Nominal Duration	Actual Duration
FC_RX2TX	T_FC	T_FC - RX_SETTLING_LATENCY - TX_DATA_FLUSH_DLY
IP1_RX2TX	T_IP1	T_IP1 - RX_SETTLING_LATENCY - TX_DATA_FLUSH_DLY
IP2_RX2TX	T_IP2	T_IP2 - RX_SETTLING_LATENCY - TX_DATA_FLUSH_DLY
FC_TX2RX	T_FC	T_FC + TX_DATA_FLUSH_DLY
IP1_TX2RX	T_IP1	T_IP1 + TX_DATA_FLUSH_DLY
IP2_TX2RX	T_IP2	T_IP2 + TX_DATA_FLUSH_DLY
S_RX2RX	T_S	T_S - RX_SETTLING_LATENCY
S_TX2TX	T_S	
PM_RX	T_PM[1]	T_PM[1] + RX_SETTLING_LATENCY
FM_RX	T_FM[2]	T_FM[2] + RX_SETTLING_LATENCY
DT_RX	T_DT[3]	T_DT[3] + RX_SETTLING_LATENCY
PM_TX	T_PM[1]	
FM_TX	T_FM[2]	
DT_TX	T_DT[3]	

1. T_PM0, T_PM1, T_PM2, or T_PM3 depending on t_pm_sel[1:0] for the current step format
2. T_FM0 or T_FM1 depending on t_pm_sel[0] for the current step format
3. T_DT is a function of RATE and RTT_SEQ_LEN programmable bitfields.
   - 1Mbps rate, 32bit rtt_seq_len: 8bit preamble + 32bit data + 4bit trailer = 44us
   - 1Mbps rate, 64bit rtt_seq_len: 8bit preamble + 64bit data + 4bit trailer = 76us
   - 2Mbps rate, 32bit rtt_seq_len: 16bit preamble + 32bit data + 4bit trailer = 26us

- 2Mbps rate, 64bit rtt_seq_len: 16bit preamble + 64bit data + 4bit trailer = 42us

55.4.7.9.3.5.3 Transition Time Summary

The following tables show the transition duration requirements, taking into account the TSM and PA ramp timing, and the TX and RX latency, for different SQTE and PDE roles.

Table 467. SQTE Initiator

Transition Time	Must be programmed to a value no less than
WU[1]	END_OF_TX_WU - (FAST_DEST_TX - FAST_START_TX)*FAST_FC_TX_WU + pa_ru + 3us
T_IP1	IP1_TX2RX - TX_DATA_FLUSH_DLY = (END_OF_RX_WU - FAST_TX2RX_START) - (FAST_DEST_RX - FAST_START_RX)*FAST_IP_RX_WU + 2us
T_S	Maximum of .. S_RX2RX + RX_SETTLING_LATENCY = (END_OF_RX_WU - RECYCLE_COUNT0) + RX_SETTLING_LATENCY S_TX2TX = TX_DATA_FLUSH_DLY
T_IP2	IP2_TX2RX - TX_DATA_FLUSH_DLY = (END_OF_RX_WU - FAST_TX2RX_START) - (FAST_DEST_RX - FAST_START_RX)*FAST_IP_RX_WU + 2us
T_FC	FC_RX2TX + RX_SETTLING_LATENCY + TX_DATA_FLUSH_DLY = (END_OF_TX_WU - FAST_RX2TX_START_FC) - (FAST_DEST_TX - FAST_START_TX)*FAST_FC_TX_WU + pa_ru + RX_SETTLING_LATENCY + TX_DATA_FLUSH_DLY

1. The Warmup transition time is shown here for reference, but there is no programmable "WU" bitfield for this in the RSM programming model

Table 468. SQTE Reflector

Transition Time	Must be programmed to a value no less than
WU[1]	END_OF_RX_WU - (FAST_DEST_RX - FAST_START_RX)*FAST_FC_RX_WU + 1us
T_IP1	IP1_RX2TX + RX_SETTLING_LATENCY + TX_DATA_FLUSH_DLY = (END_OF_TX_WU - FAST_RX2TX_START) - (FAST_DEST_TX - FAST_START_TX)*FAST_IP_TX_WU + pa_ru + RX_SETTLING_LATENCY + TX_DATA_FLUSH_DLY
T_S	Maximum of .. S_RX2RX + RX_SETTLING_LATENCY = (END_OF_RX_WU - RECYCLE_COUNT0) + RX_SETTLING_LATENCY S_TX2TX = TX_DATA_FLUSH_DLY
T_IP2	IP2_RX2TX + RX_SETTLING_LATENCY + TX_DATA_FLUSH_DLY = (END_OF_TX_WU - FAST_RX2TX_START) - (FAST_DEST_TX - FAST_START_TX)*FAST_IP_TX_WU + pa_ru + RX_SETTLING_LATENCY + TX_DATA_FLUSH_DLY

55.4.7.9.4 Fast Antenna Diversity (FAD) Common Pin Interface

55.4.7.9.4.1 Introduction

The Fast Antenna Diversity (FAD) mode, when enabled, allows the optimal choice between two antennae to be selected during the PHY's preamble search. The output of the PHY's FAD algorithm is a 1-bit signal which indicates the selected antenna. This output is provided to the FAD Common Pin Interface logic. Refer to the PHY chapter(s) for more information on the FAD algorithm.

The localization control output (lant_sw) can also be used as the input to the FAD Common Pin Interface instead of the PHY signal, but the primary use case is for FAD.

55.4.7.9.4.2 Common Pin Interface

The FAD Common Pin Interface consists of 4 pins: ANT_A, ANT_B, TX_SWITCH, and RX_SWITCH. All pins are outputs from the device. The switch outputs convey timing information to the external module directly interfacing to the antennae, and they also can be used to control an external LNA or PA, via use of a Front End Module, or FEM. The FAD Common Pin Interface offers multiple configurations that allow for a wide range of FEM control schemes. Each of the 4 FAD-related outputs can be configured to be in FAD or TSM mode; in FAD mode, ANT_A and ANT_B are controlled by the selected FAD algorithm through signal antx_out; in TSM mode, ANT_A and ANT_B are pure timing outputs with programmable timing configurable in the TSM. The 4-bit register FAD_CTRL[FAD_NOT_GPIO] determines whether each FAD-related output is in FAD or TSM mode:

In FAD mode (FAD_NOT_GPIO[0]=1), ANT_A is controlled by the FAD algorithm, modified by the register settings {ANTX_CTRLMODE, ANTX_EN, and ANTX_POL}.

In FAD mode (FAD_NOT_GPIO[1]=1), ANT_B is controlled by the FAD algorithm, modified by the register settings {ANTX_CTRLMODE, ANTX_EN, and ANTX_POL}.

In FAD mode (FAD_NOT_GPIO[2]=1), TX_SWITCH output is derived from TSM output **gpio2_trig_en**, modified by the register settings {ANTX_CTRLMODE, ANTX_EN, and ANTX_POL}.

In FAD mode (FAD_NOT_GPIO[3]=1), RX_SWITCH output is derived from TSM output **gpio3_trig_en**, modified by the register settings {ANTX_CTRLMODE, ANTX_EN, and ANTX_POL}.

In TSM mode, ANT_A and ANT_B become pure TSM timing-controlled outputs, similar to TX_SWITCH and RX_SWITCH, and with independently-controlled timing and capable of providing signalling in TX mode, RX mode, or both; for pins in TSM mode, the ANTX_CTRLMODE, ANTX_EN, and ANTX_POL register settings have no effect.

In TSM mode (FAD_NOT_GPIO[0]=0), ANT_A output is a pure timing signal, derived from TSM output **gpio0_trig_en**.

In TSM mode (FAD_NOT_GPIO[1]=0), ANT_B output is a pure timing signal, derived from TSM output **gpio1_trig_en**.

In TSM mode (FAD_NOT_GPIO[2]=0), TX_SWITCH output is derived from TSM output **gpio2_trig_en**.

In TSM mode (FAD_NOT_GPIO[3]=0), RX_SWITCH output is derived from TSM output **gpio3_trig_en**.

The control register XCVR_CTRL[DEMOD_SEL] determines which FAD algorithm drives the FAD Common Pin Interface: 0b10 = 802.15.4 FAD, 0b01 = FSK FAD.

The state of the antenna selection can be ascertained at any time by reading the FAD_CTRL[ANTX] bit: 0 = ANT_A, 1 = ANT_B.

Antenna selection can be placed under direct software control: Setting the FAD_CTRL[ANTX_OVRD_EN]=1 allows FAD_CTRL[ANTX_OVRD] to substitute for the algorithm-driven antenna selection; in this case, ANTX_OVRD=0 asserts ANT_A, and ANTX_OVRD=1 asserts ANT_B. Note that the algorithm-driven state of the antenna is not lost while ANTX_OVRD_EN=1. The override is temporary, for as long as the override enable is set, and control over antenna state reverts to the antx_out when ANTX_OVRD_EN is cleared to 0. The FAD_CTRL register resides in XCVR space.

The following diagram illustrates the FAD pinout, register controls, and FAD/TSM-mode multiplexing.

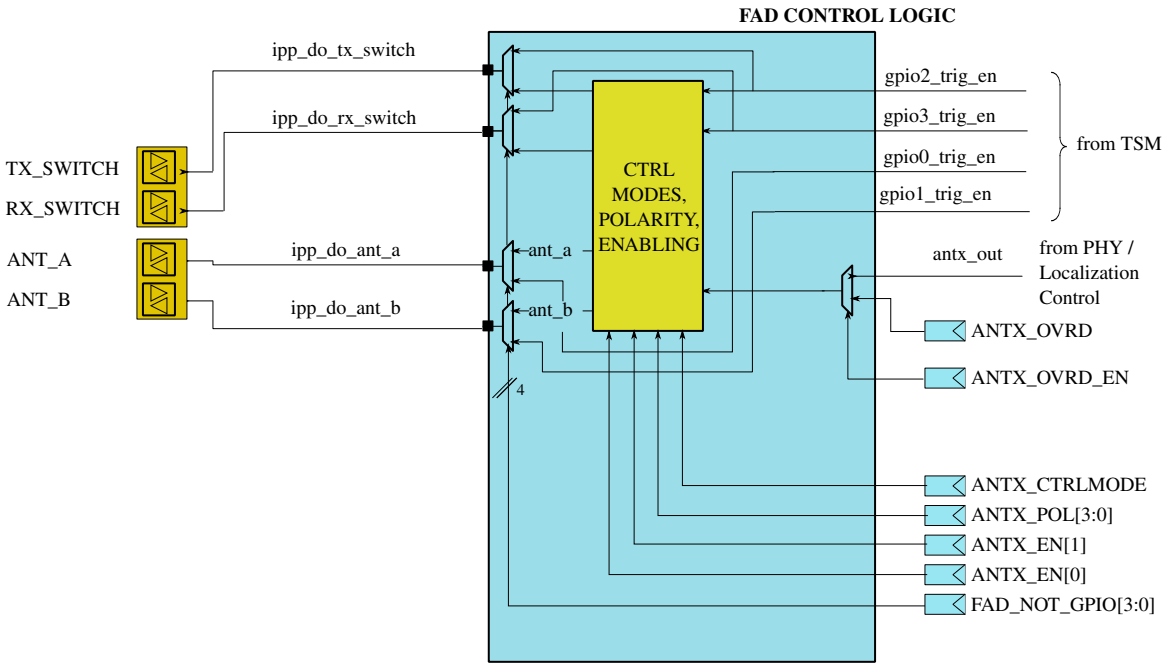

Figure 363. FAD Common Pin Interface

55.4.7.9.4.3 Control Bits

The following table describes the programmable registers which control FAD Common Pin Interface:

Table 471. FAD Common Pin Interface Control Bits

Field	R/W	Description
ANTX_CTRLMODE	rw	**FAD control mode-** selects the single or dual mode **0 : single mode.** ANT_A = NOT(antx) AND(gpio2_trig_en OR gpio3_trig_en) TXSWITCH = gpio2_trig_en RXSWITCH= (gpio2_trig_en OR gpio3_trig_en) **1:dual mode:** ANT_A = NOT(antx) AND(gpio2_trig_en OR gpio3_trig_en) ANT_B = antx AND(gpio2_trig_en OR gpio3_trig_en) TX_SWITCH = gpio2_trig_en RX_SWITCH = gpio3_trig_en
ANTX_EN[1:0]	rw	**FAD Pin Enable-** 00: all disabled

Table continues on the next page...

Table 471. FAD Common Pin Interface Control Bits (continued)

Field	R/W	Description
		01:only RX_SWITCH/TX_SWITCH enabled 10:only ANT_A/ANT_B enabled 11: all enabled
ANTX_POL[3:0]	rw	**Antenna controls mode-** Control the polarity of the FAD pins: ANTX_pol<0>=1 : invert the ANT_A output ANTX_pol<1>=1 : invert the ANT_B output ANTX_pol<2>=1 : invert the TX_SWITCH output ANTX_pol<3>=1 : invert the RX_SWITCH output
FAD_NOT_GPIO[3:0]	rw	**xxx1**: The ANT_A pad is controlled by the antenna-selection algorithm, modified by the register settings above {ANTX_CTRLMODE, ANTX_EN, ANTX_POL} **xxx0**: The ANT_A pad is controlled directly by the TSM output gpio0_trig_en **xx1x**: The ANT_B pad is controlled by the antenna-selection algorithm, modified by the register settings above {ANTX_CTRLMODE, ANTX_EN, ANTX_POL} **xx0x**: The ANT_B pad is controlled directly by the TSM output gpio1_trig_en **x1xx**: The TX_SWITCH pad is controlled by the antenna-selection algorithm, modified by the register settings above {ANTX_CTRLMODE, ANTX_EN, ANTX_POL} **x0xx**: The TX_SWITCH pad is controlled directly by the TSM output gpio2_trig_en **1xxx**: The RX_SWITCH pad is controlled by the antenna-selection algorithm, modified by the register settings above {ANTX_CTRLMODE, ANTX_EN, ANTX_POL} **0xxx**: The RX_SWITCH pad is controlled directly by the TSM output gpio3_trig_en
ANTX	ro	**Antenna Selection State-** The ANTX bit reflects the state of the antx_out signal.
DEMOD_SEL[1:0]	rw	**These bits select the demodulator used during reception. Also select which FAD engine is used to select the antenna-** • 0b00: No demodulator selected

Table continues on the next page...

Table 471. FAD Common Pin Interface Control Bits (continued)

Field	R/W	Description
		• 0b01: Use NXP Multi-standard PHY demodulator, and its FAD engine • 0b10: Use Legacy 802.15.4 demodulator, and the 802.15.4 FAD engine • 0b11: Reserved
ANTX_OVRD_EN	rw	**FAD ANTX Override Enable-** • 0: antx_out controls the antenna selection (mission mode) • 1: ANTX_OVRD controls the antenna selection. 0 = ANT_A, 1 = ANT_B.
ANTX_OVRD	rw	**FAD ANTX Override -** If ANTX_OVRD_EN=1, this bit is used instead of antx_out

55.4.7.9.4.4 FEM Example Use Cases

In 2.4GHz systems, the Radio Frequency (RF) Front-End Module is one of the most critical parts. Acting as an interface between the antenna and RF transceiver, the RF front-end module, or FEM, includes sensitive components such as an antenna Low Noise Amplifier (LNA) , power amplifiers (PA), antenna tuning switches, and a power management unit.

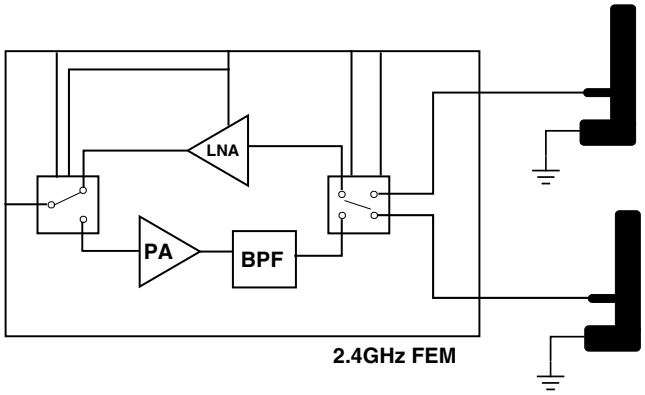

Figure 364. FEM Block Diagram

To accommodate multiple FEM interfaces and control schemes, Fast Antenna Diversity incorporates 2 Antenna Pin Control Modes, which are governed by the register control bit ANTX_CTRLMODE

Some FEM devices use a single input pin to switch the antenna selection. This is called single-mode operation. Operate Fast Antenna Diversity in this mode by programming ANTX_CTRLMODE=0. A timing diagram of single-mode operation is shown below (note: FAD output ANT_B is not used). In this example, one packet is received on Antenna A, followed by another packet received on Antenna B. Both packets require an auto-Acknowledge packet to be transmitted immmediately following reception.

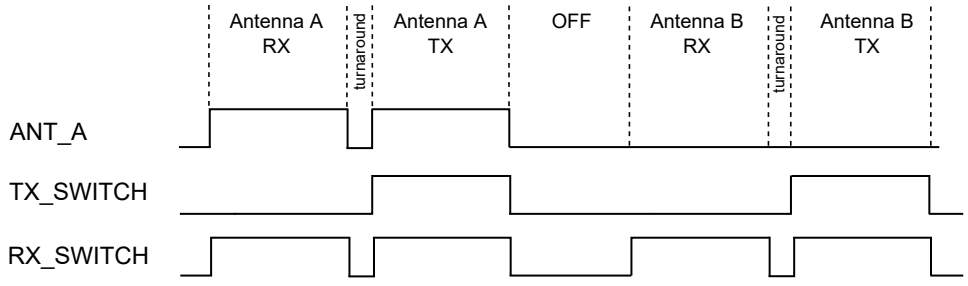

Figure 365. FAD Single Mode Timing

An example FEM Interface diagram, with FAD operated in single mode, is shown below.

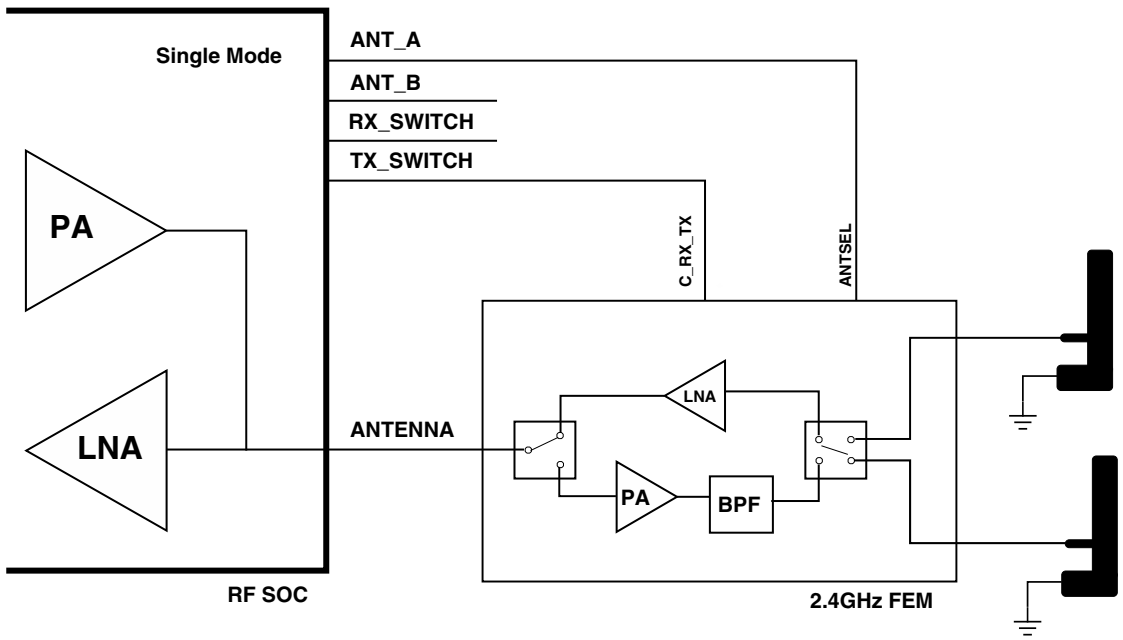

Figure 366. FEM Interface Single Mode

Other FEM devices use 2 input pins to switch the antenna selection. This is called dual-mode operation. Operate Fast Antenna Diversity in this mode by programming ANTX_CTRLMODE=1. A timing diagram of dual-mode operation is shown below. In this example, one packet is received on Antenna A, followed by another packet received on Antenna B. Both packets require an auto-Acknowledge packet to be transmitted immmediately following reception.

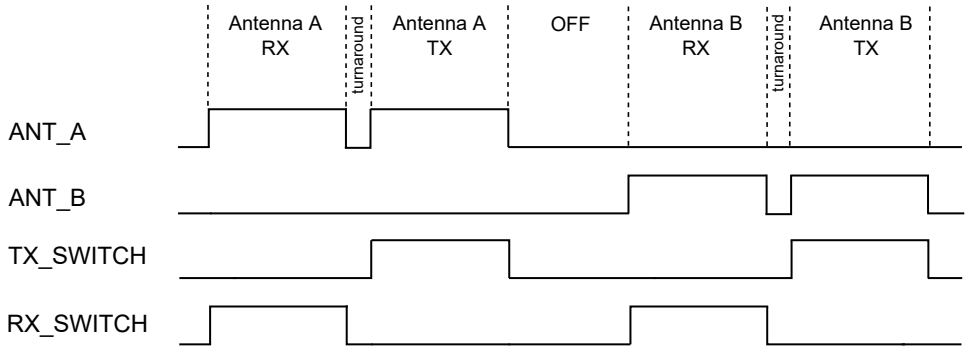

Figure 367. FAD Dual Mode Timing

An example FEM Interface diagram, with FAD operated in dual mode, is shown below.

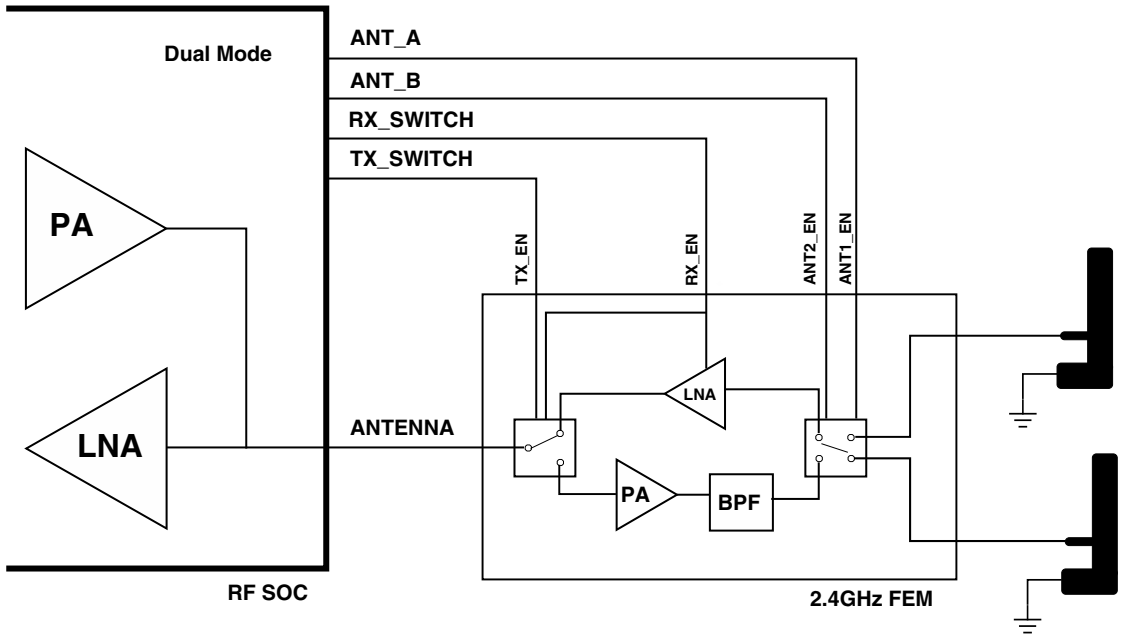

Figure 368. FEM Interface Dual Mode

Other FEM use cases, include external PA only, external LNA only, or external PA plus LNA. In such cases, ANT_A and ANT_B are not required, FAD can be disabled, and TX_SWITCH and RX_SWITCH pins can be operated in TSM mode (pure timing signals). This is called Single Antenna configuration. An example FEM interface diagram illustrating such a use case, is shown below.

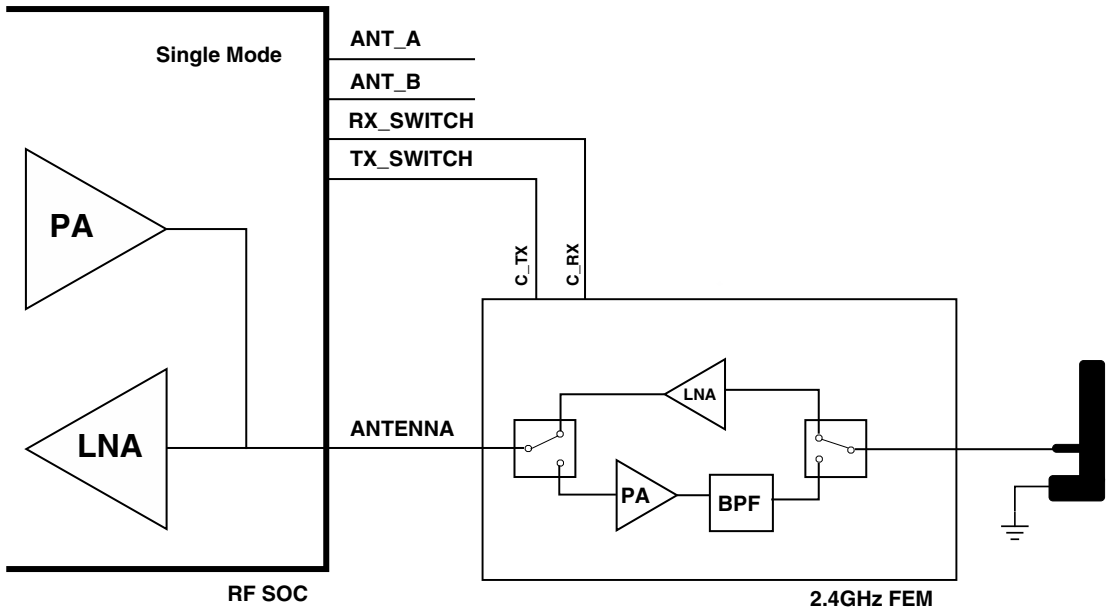

Figure 369. FEM Interface Single Antenna Configuration

55.4.7.10 LDO Calibration

The LDO Calibration module uses a binary search to find the best 6bit calibration code (ldo_cal_trim[5:0]) for the LDO calibration circuit in the analog, and then performs subsequent incremental trims for PLL, VCO and RTXHF LDOs. It is expected that the LDO calibration will be performed on each TX and RX warmup. The entire LDO calibration sequence with incremental calibration requires no more than 8us for all XO reference frequencies supported.

The calibration timing is illustrated in Figure 370 and Figure 371 below.

The calibration sequence is initiated by a TSM control signal (tsm_ldocal_en). The ldo_cal_trim[5:0] is initialized to 6'b10_0000 (6'h20) while the trim codes for the PLL, VCO, RXTXHF and RXTXLF LDOs are intialized to 6'b01_1111 (6'h1F). During each of the 6 steps of the calibration, each bit of the ldo_cal_trim[5:0] is individually set, and a comparator output from the alaog (ldo_trim_cmpout) is used to determine whether the bit should remain set of be cleared. By default, the comparator output signal is captured 2 clk cycles after the ldo_trim_sample signal is de-asserted, but this can also be programmed to 1clk or 3clks if desired. At the end of the 6 steps, the best ldo_cal_trim[5:0] value has been found. The PLL, VCO, RXTXHF and RXTXLF LDO's trim codes are then updated using ldo_cal_trim[5:0] and signed, 4-bit offsets which can be programmed differently for PLL, VCO, RXTXHF and RXTXLF as needed.

The total time needed to determine the ldo_cal_trim is as follows, where LDO_TRIM_SMPL_DLY is a programmable value which is 2 by default but which can also be programmed for values of 1 or 3

1clk + 6*(0.5us + 1clk + LDO_TRIM_SMPL_DLY clks)

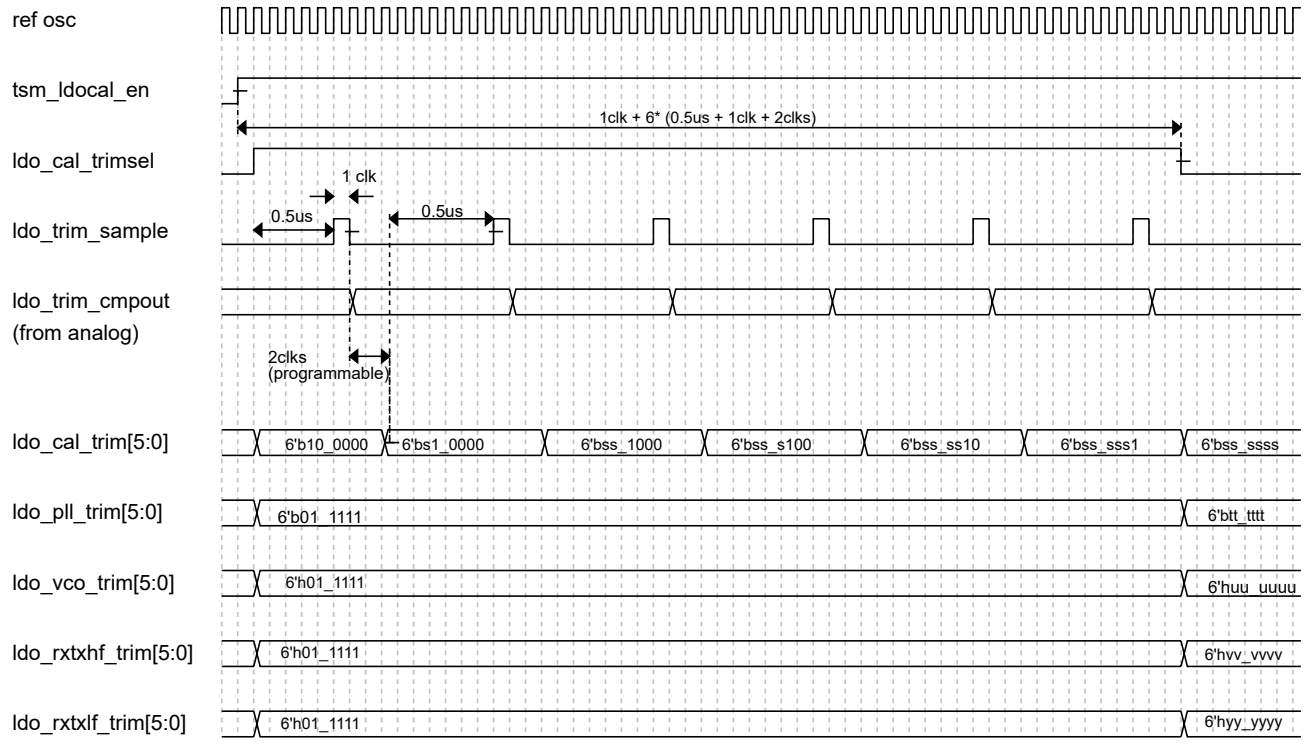

Figure 370. LDO trim part 1: ldo_cal_trim

Incremental calibration allows the PLL, VCO and RXTXHF LDO trim codes to be tested individually and adjusted by +1 trim code value. After the best ldo_trim_code[5:0] has been found from the main calibration, the ldocal module will wait at least 2us but no more than 3us. Following this, trim select signals for the PLL, VCO and RXTXHF LDOs will be sequentially asserted so that the trim code for each of these LDOs can be individually tested. In each case, based on the comparator value the LDO's trim code will either be left as is or incremented by +1 (there is no option to decrease the trim code by 1). Note that the RXTXLF LDO is not incrementally calibrated.

Excluding the +2us wait time before incremental trim, the total time for the incremental calibration is as follows:

3*(0.5us + 1clk + LDO_TRIM_SMPL_DLY clks + 1 clk) + 1 clk

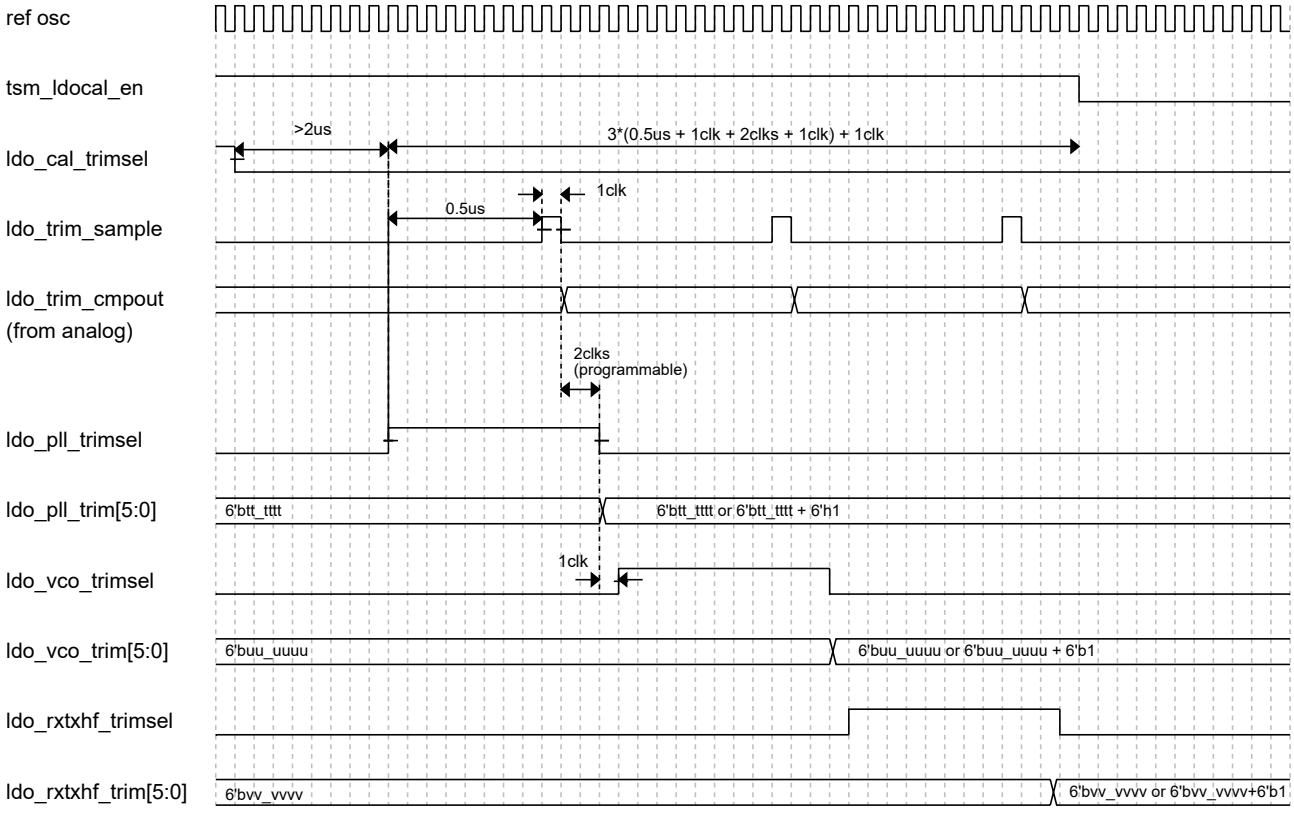

Figure 371. LDO trim part 2: incremental calibrations

The total time for the both parts of the calibrations is as follows:

$ceiling(1clk + 6*(0.5uw + 1clk + LDO_TRIM_SMPL_DLY clks)) + 2us + 3*(0.5us + 1clk + LDO_TRIM_SMPL_DLY clks + 1 clk) + 1 clk

For the default value of LDO_TRIM_SMPL_DLY=2, this is less than 8us for all supported XO frequencies.

Normally, the tsm_ldocal_en remains asserted after the ldo_cal_trim[5:0] has been found in order to perform the incremental calibrations. However, if incremental calibrations are not needed, the tsm_ldocal_en can be de-asserted after ldo_cal_trim[5:0] has been found. This scenario is shown in the figure below. In this case, for the default value of LDO_TRIM_SMPL_DLY=2, only 4us is required for the LDO calibration.

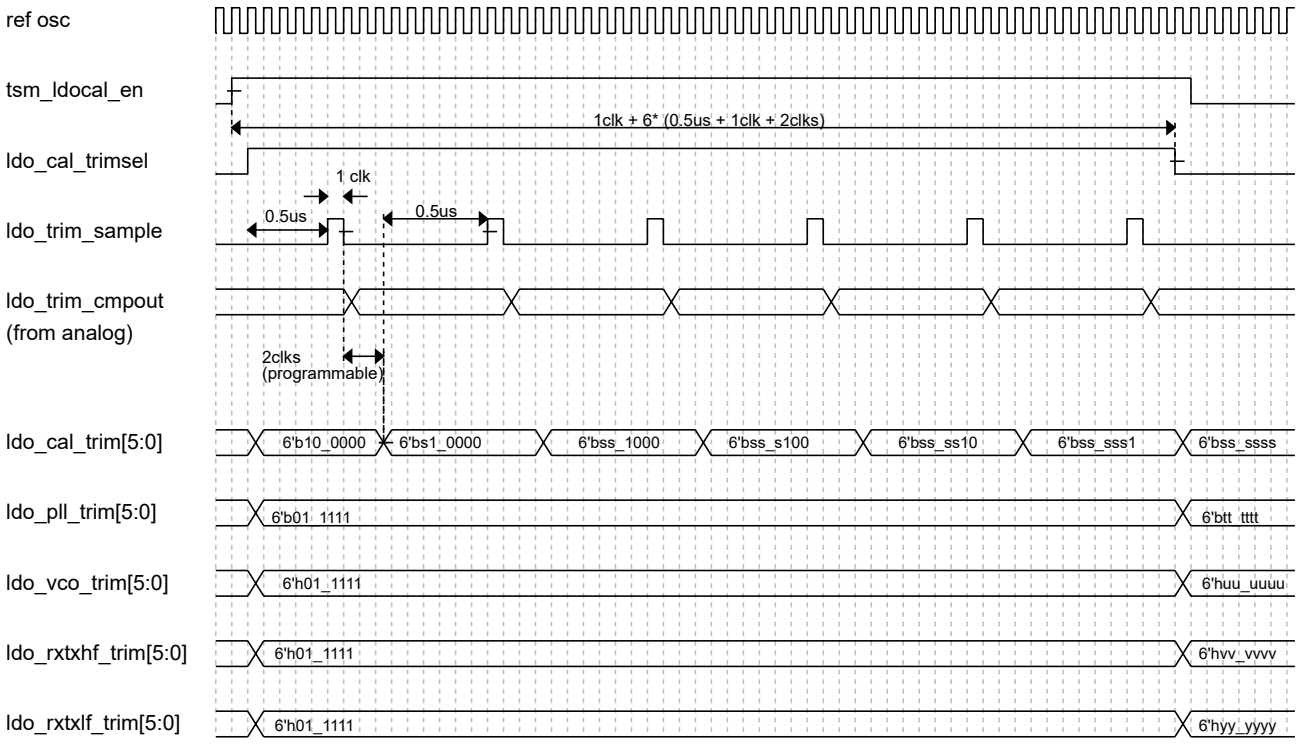

Figure 372. LDO trim without incremental calibrations

55.4.7.11 IPS Fast Overwrite Module

The IPS_FO module provides the capapility to pre-store several address/data pairs that are quickly applied when RX or TX operation begins. Each entry consists of 3 parts:

- Address and config: The ADDR field contains the address to be written, and the ENTRY_TX/RX bits denote if the entry is to be used in TX, RX, or both modes.
- DRS0_DATA: Contains the full 32-bit word that will be written to ADDR as RX/TX begins and the data rate select is 0.
- DRS1_DATA: Contains the full 32-bit word that will be written to ADDR as RX/TX begins and the data rate select is 1.

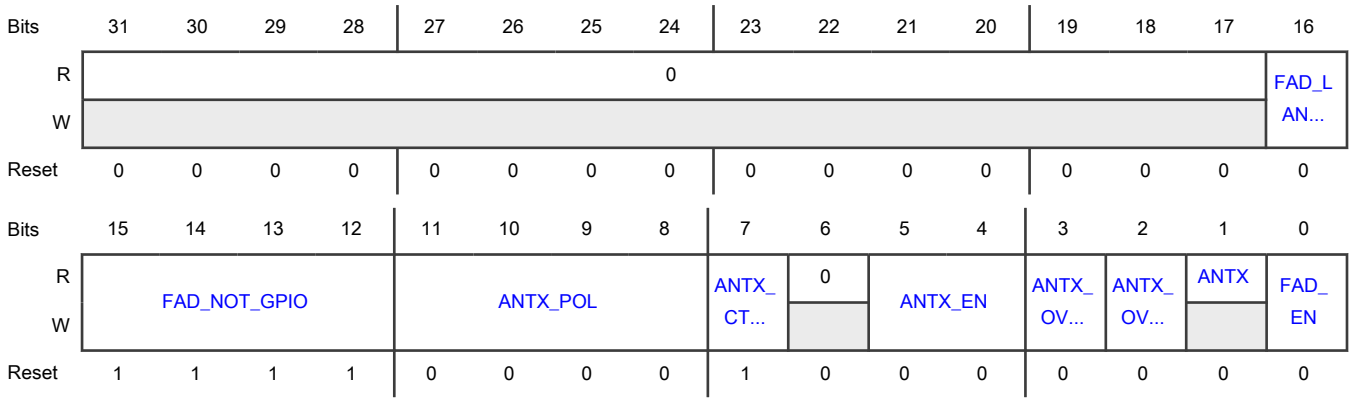
RX_MODE	Indicates an RX transceiver operation is in progress.
13 TSM_BUSY	tsm busy status Indicates TSM is busy or not, active high
12-10 —	Reserved
9 TSM_IRQ1	TSM Interrupt #1 0b - TSM Interrupt #1 is not asserted. 1b - TSM Interrupt #1 is asserted. Write '1' to this bit to clear it.
8 TSM_IRQ0	TSM Interrupt #0 0b - TSM Interrupt #0 is not asserted. 1b - TSM Interrupt #0 is asserted. Write '1' to this bit to clear it.
7-0 TSM_COUNT	TSM_COUNT Reflects the instantaneous value of the TSM counter.

55.4.7.12.2.4 FAD CONTROL (FAD_CTRL)

Offset

Register	Offset
FAD_CTRL	8h

Diagram



Fields

Field	Function
31-17 —	Reserved
16 FAD_LANT_SEL	FAD versus LANT_LUT_GPIO Selector Controls the mux which select whether the LANT_LUT_GPIO[3:0] or the FAD control signals are output to RF_GPO[11:8]. Refer also to the figure in the Coexistence/FEM/LANT connections section of the Radio Control chapter. 0b - LANT_LUT_GPIO[3:0] 1b - {ANT_B, ANT_A, RX_SWITCH, TX_SWITCH}
15-12 FAD_NOT_GPIO	FAD versus GPIO Mode Selector **xxx1** : The ANT_A pad is controlled by the antenna-selection algorithm, modified by the register settings above {ANTX_CTRLMODE, ANTX_EN, ANTX_POL} **xxx0** : The ANT_A pad is controlled directly by the TSM output gpio0_trig_en **xx1x** : The ANT_B pad is controlled by the antenna-selection algorithm, modified by the register settings above {ANTX_CTRLMODE, ANTX_EN, ANTX_POL} **xx0x** : The ANT_B pad is controlled directly by the TSM output gpio1_trig_en **x1xx** : The TX_SWITCH pad is controlled by the antenna-selection algorithm, modified by the register settings above {ANTX_CTRLMODE, ANTX_EN, ANTX_POL} **x0xx** : The TX_SWITCH pad is controlled directly by the TSM output gpio2_trig_en **1xxx** : The RX_SWITCH pad is controlled by the antenna-selection algorithm, modified by the register settings above {ANTX_CTRLMODE, ANTX_EN, ANTX_POL} **0xxx** : The RX_SWITCH pad is controlled directly by the TSM output gpio3_trig_en
11-8 ANTX_POL	FAD Antenna Controls Polarity Control the polarity of the FAD pins: ANTX_POL<0> : This bit currently has no functionality ANTX_POL<1> : This bit currently has no functionality ANTX_POL<2>=1 : invert the TX_SWITCH output ANTX_POL<3>=1 : invert the RX_SWITCH output
7 ANTX_CTRLMODE	Antenna Diversity Control Mode When ANTX_CTRLMODE=1 (dual mode): ANT_A=NOT(ANTX) AND (GPIO3_TRIG_EN OR GPIO2_TRIG_EN) ANT_B=ANTX AND (GPIO3_TRIG_EN OR GPIO2_TRIG_EN) TX_SWITCH=GPIO2_TRIG_EN RX_SWITCH=GPIO3_TRIG_EN

Table continues on the next page...

Table continued from the previous page...

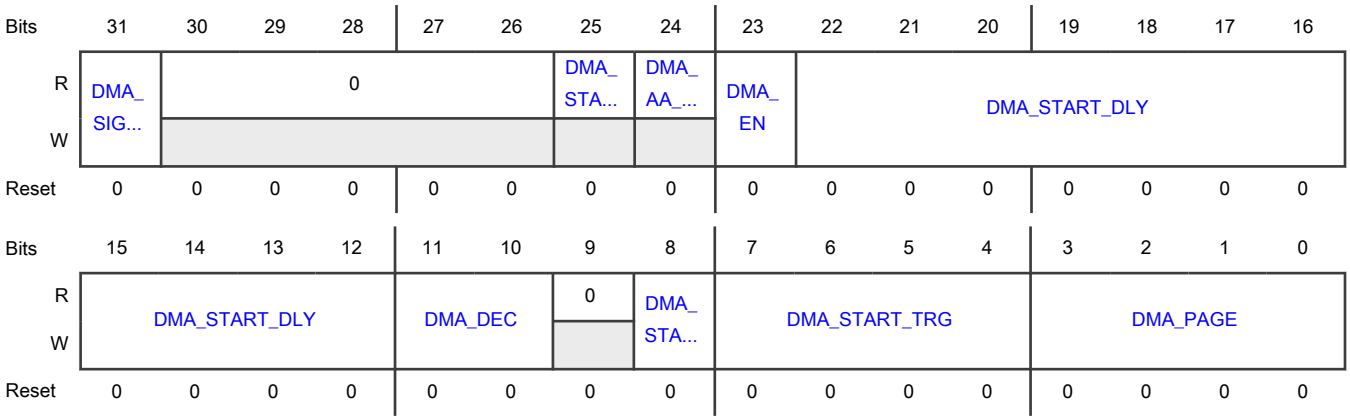
Field	Function
	When ANTX_CTRLMODE=0 (single mode): ANT_A=NOT(ANTX) AND (GPIO3_TRIG_EN OR GPIO2_TRIG_EN) ANT_B=ANTX AND (GPIO3_TRIG_EN OR GPIO2_TRIG_EN) TX_SWITCH=GPIO2_TRIG_EN RX_SWITCH=(GPIO3_TRIG_EN OR GPIO2_TRIG_EN) GPIO2_TRIG_EN and GPIO3_TRIG_EN are outputs of the Transceiver Sequence Manager (TSM). The TSM timing registers associated with GPIO2_TRIG_EN and GPIO3_TRIG_EN should be programmed with the desired TX_SWITCH and RX_SWITCH timing , before enabling Fast Antenna Diversity.
6 —	Reserved
5-4 ANTX_EN	FAD Antenna Controls Enable For any of the 4 FAD-related outputs {ANT_B, ANT_A, RX_SWITCH, TX_SWITCH}, when the associated register control bit (FAD_NOT_GPIO[x]=1) puts that output in FAD mode, ANTX_EN[1:0] determines which pairs of FAD related outputs are enabled: 00b - all disabled (held low) 01b - only RX/TX_SWITCH enabled 10b - only ANT_A/B enabled 11b - all enabled
3 ANTX_OVRD	Antenna State Override Value When ANTX_OVRD_EN=1, the FAD antenna state (ANTX) is overriden by the value of this register; otherwise, antenna state is determined by the 802.15.4 FAD state machine, if XCVR_CTRL[DEMOD_SEL]=0b10, or the FSK PHY FAD state machine if XCVR_CTRL[DEMOD_SEL]=0b01.
2 ANTX_OVRD_EN	Antenna State Override Enable When ANTX_OVRD_EN=1, the FAD antenna state (ANTX) is overriden by the value of the ANTX_OVRD register; otherwise, antenna state is determined by the 802.15.4 FAD state machine, if XCVR_CTRL[DEMOD_SEL]=0b10, or the FSK PHY FAD state machine if XCVR_CTRL[DEMOD_SEL]=0b01.
1 ANTX	Antenna Selection State The ANTX bit reflects the state of antx_out signal.
0 FAD_EN	Fast Antenna Diversity Enable 0b - Fast Antenna Diversity disabled 1b - Fast Antenna Diversity enabled

55.4.7.12.2.5 TRANSCEIVER DMA CONTROL (DMA_CTRL)

Offset

Register	Offset
DMA_CTRL	Ch

Diagram



Fields

Field	Function
31 DMA_SIGNAL_VALID_MASK_EN	DMA Signal Valid Mask Enable **NOTE** This bit should not be set if RXDIG's RX_IQ_PH_OUTPUT_COND bit is set. 0b - Disable use of dma_signal_valid_mask. 1b - Enable use of dma_signal_valid_mask.
30-26 —	Reserved
25 DMA_START_TRIGGERED	DMA Start Trigger Occurred This read-only status bit becomes set, when, during a DMA session (DMA_PAGE > 0), the trigger source selected by DMA_START_TRG[2:0] occurs, with the edge sensitivity selected by DMA_START_EDGE. This bit is cleared when the DMA is re-armed by programming DMA_PAGE to 0 and then to a non-zero value.
24 DMA_AA_TRIGGERED	DMA Access Address triggered This status bit becomes set when the PHY indicates that a Network Address match has occurred. In some cases it may be desirable to delay the start of DMA transfers until such a match occurs; in such cases, software can poll this bit, and once it becomes set, immediately select the desired DMA_PAGE to initiate DMA transfers. This bit is intended for use with DMA_PAGE=GEN4-PHY, but is available on all pages. Its usage is optional.

Table continues on the next page...

Table continued from the previous page...

Field	Function
23 DMA_EN	DMA Enable Setting DMA_EN=1 enables clock gating to the Transciever DMA engine. This bit should be set prior to the start of a DMA session, and remain set for the duration of the session.
22-12 DMA_START_DLY	DMA Start Trigger Delay When a start trigger is used (DMA_START_TRG not equal to 0), the DMA transfers will be delayed by DMA_START_DLY microseconds after the trigger occurs.
11-10 DMA_DEC	DMA Decimation Rate Controls whether every data is captured on every data valid strobe, or only every 2nd, 4th or 8th data valid strobe. 00b - Data is captured on every data valid 01b - Data is captured on every 2nd data valid 10b - Data is captured on every 4th data valid 11b - Data is captured on every 8th data valid
9 —	Reserved
8 DMA_START_EDGE	DMA Start Trigger Edge Selector DMA_START_EDGE selects the edge sensitivity (rising or falling) of the selected start-trigger. 0b - Trigger fires on a rising edge of the selected trigger source 1b - Trigger fires on a falling edge of the selected trigger source
7-4 DMA_START_TRG	DMA Start Trigger Selector The DMA Start Trigger, if desired, can be selected from the sources as shown below 0000b - no trigger 0001b - PHY: pd found 0010b - PHY: aa found 0011b - Zigbee_PHY: pd found 0100b - Zigbee_PHY: sfd detect 0101b - RXDIG: agc_gain_chg 0110b - TSM: rx_dig_en 0111b - TSM: tsm_irq0_start_trig 1000b - CRC pass 1001b - CRC done (Not used for 15.4LL) 1010b - Localization control: pattern match

Fields

Field	Function
31 LCL_MODE	Localization Mode Configure localization control module for GenLL or Bluetooth LE LL. 0b - GenLL configuration. 1b - Bluetooth LE LL configuration.
30 LCL_GPIO_SEL	Localization GPIO Select Reserved. This bit should be programmed to 0
29-25 —	Reserved
24-16 CTE_DUR	Total Switching Duration LCL antenna switching will continue for this many doublets, where a doublet is (RX/TX_HI_PER + RX/TX_LO_PER).

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-12 —	Reserved
11 LANT_BLOCK_RX	Block LANT_SW for RX Setting this bit will cause the Localization Control Module to block its LANT_SW output, for RX. NOTE: the PHY's ant_out will still pass through on the LANT_SW output.
10 LANT_BLOCK_TX	Block LANT_SW for TX Setting this bit will cause the Localization Control Module to block its LANT_SW output, for TX. NOTE: the PHY's ant_out will still pass through on the LANT_SW output.
9-8 PM_NUM_BYTES	Number of Bytes to Match This field indicates how many bytes are used to compare in the bit stream for a pattern match. 00b - 4 bytes 01b - 5 bytes 10b - 6 bytes 11b - 8 bytes
7 LANT_SW_WIGGLE	LANT_SW Wiggle If set, 3 clock pulses will be driven on LANT_SW after the localization control module is triggered, to initialize the SOC TPM.
6 SW_TRIG	Software Trigger. Can be used with either RX or TX Setting this bit will cause a trigger event in RX and TX, depending on the trigger select configuration.
5 COMP_TX_EN	Pattern Matching Enable in TX Normally, pattern matching is used for RX. If it is desired for TX, as well, this bit should be set.
4 COMP_EN	Pattern Matching Enable This enables the pattern matching feature.
3 LANT_INV	Invert Antenna Switch Output
2 RX_LCL_EN	Enable Switching in RX
1 TX_LCL_EN	Enable Switching in TX
0 LCL_EN	Localization Control Module Enable Note: This bit, when 0, will still allow the PHY FAD antenna switch signal to propagate.

6 RSM_FAST_FC_RX_WU	RSM_FAST_FC_RX_WU Forces TSM to fast RX wu during FC_TX2RX and WU state (ipr_rx_en=1).
5 RSM_FAST_IP_TX_WU	RSM_FAST_IP_TX_WU Forces TSM to fast TX wu during IP1_RX2TX and IP2_RX2TX.
4 RSM_FAST_IP_RX_WU	RSM_FAST_IP_RX_WU Forces TSM to fast RX wu during IP1_TX2RX and IP2_TX2RX.
3 RSM_TX_EN	RSM_TX_EN Arms the module for operation starting with TX. Set this bit for SQTE Initiator/PDE MD. Once set, this bit should remain set until the RSM has returned to the IDLE state at the end of the sequence.
2 RSM_RX_EN	RSM_RX_EN Arms the module for operation starting with RX. Set this bit for SQTE Reflector/PDE RD. Once set, this bit should remain set until the RSM has returned to the IDLE state at the end of the sequence.
1 RSM_RATE	RSM_RATE Only used for SQTE. Indicates how the transceiver is configured, and the transfer rate for packets. 0b - 1Mbps 1b - 2Mbps
0 RSM_MODE	RSM_MODE 0b - SQTE 1b - PDE

NOTE: If used in conjunction with the RXDIG's window averager, to ensure that the same number of samples are captured during each time the dma_mask asserts, the duration should be a multiple of the window averager's duration.
15-14 —	Reserved
13 RSM_SEQ_RCCAL_PUP_MASK_DIS	RSM_SEQ_RCCAL_PUP_MASK_DIS If set, disables the seq_rccal_pup_mask output (seq_rccal_pup_mask output will always be 1).
12 RSM_RX_SIGNALS_MASK_DIS	RSM_RX_SIGNALS_MASK_DIS If set, disables the rx_signals_mask output (rx_signals_mask output will always be 1).
11 RSM_RX_PHY_EN_MASK_DIS	RSM_RX_PHY_EN_MASK_DIS Only applies to SQTE. If set, the rx_phy_en_mask output is always asserted. If clear, when the RSM is active the rx_phy_en_mask output is only asserted for packet reception.
10 RSM_DMA_RX_EN	RSM_DMA_RX_EN Enables dma_mask to assert in PM_RX state. (this bit should be cleared if antenna switching / LCL is being used). dma_mask always asserts in SQTE FCS FM state.

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 RSM_CTUNE	RSM_CTUNE If set, RSM will send coarse tune values read from the Packet RAM to the PLL. If clear, the PLL will perform coarse tune calibration
8 RSM_HPM_CAL	RSM_HPM_CAL If set, RSM will send HPM cal values read from the Packet RAM to the PLL. If clear, the PLL will perform HPM calibration
7-5 RSM_AA_HAMM	RSM_AA_HAMM Only applies to SQTE. AA hamming distance to PHY.
4 RSM_DT_RX_SYNC_DIS	RSM_DT_RX_SYNC_DIS Only applies to SQTE. Disables the auto-sync feature for Reflector in FCS RX packet.
3-0 RSM_DT_RX_SYNC_DLY	RSM_DT_RX_SYNC_DLY Only applies to SQTE, and only used by the Reflector device (RX_EN=1) when DT_RX_SYNC_DIS=0. In this configuration the RSM uses the PHY's AA_MATCHED output to sync the Reflector device to the Initiator device's timing. When RTT_SEQ_LEN=0, this corresponds to the delay in microseconds from the PHY's AA_MATCHED to the end of DT_RX duration (the packet duration including preamble and trailer, plus RX_SETTLING_DELAY). The value used for RTT_SEQ_LEN=0 can also be used when RTT_SEQ_LEN=1, though in the latter configuration the RSM internally offsets this value to compensate for the longer packets (since AA_MATCHED uses only the first 32bits of the PN sequence regardless of the PN sequence length).

55.4.8 Radio RAM

55.4.8.1 TX Packet Ram

55.4.8.1.1 RADIO_PACKET_RAM register descriptions

The Radio Packet RAM is directly accessed by various logic blocks in the radio. If software performs an access to Packet RAM concurrently with an access by the radio logic, software reads will be wait-stated but software writes will be ignored. Therefore it the Packet RAM is written by software at a time when the radio logic might be accessing the Packet RAM, it is advisable that software verify the writes were completed successfully by reading the Packet RAM values at the addresses written.

55.4.9 Link Layer Blocks

55.4.9.1 802.15.4 Link Layer

55.4.9.1.1 802.15.4 Link Layer Controller

55.4.9.1.1.1 Introduction

The 802.15.4 Link Layer Controller implements all hardware functionality of the 802.15.4 Link Layer.

55.4.9.1.1.2 Overview

The 802.15.4 Link Layer implementation is divided into software and hardware components. The 802.15.4 Link Layer Controller represents the hardware component of the link layer. Link Layer hardware functionality is further sub-divided into functional blocks. These blocks include:

- Packet Processor block.
- Sequence Manager block.
- Packet Storage block.
- Event Timer block.
- Interrupts block.
- Clear Channel Assessment/Energy Detect/Link Quality Indication block.
- Bit Streaming Mode block.

Together, these blocks implement and accelerate critical functions of the 802.15.4 Link Layer. The non-timing critical functions are implemented in software on a MCU.

55.4.9.1.1.3 Block Diagram

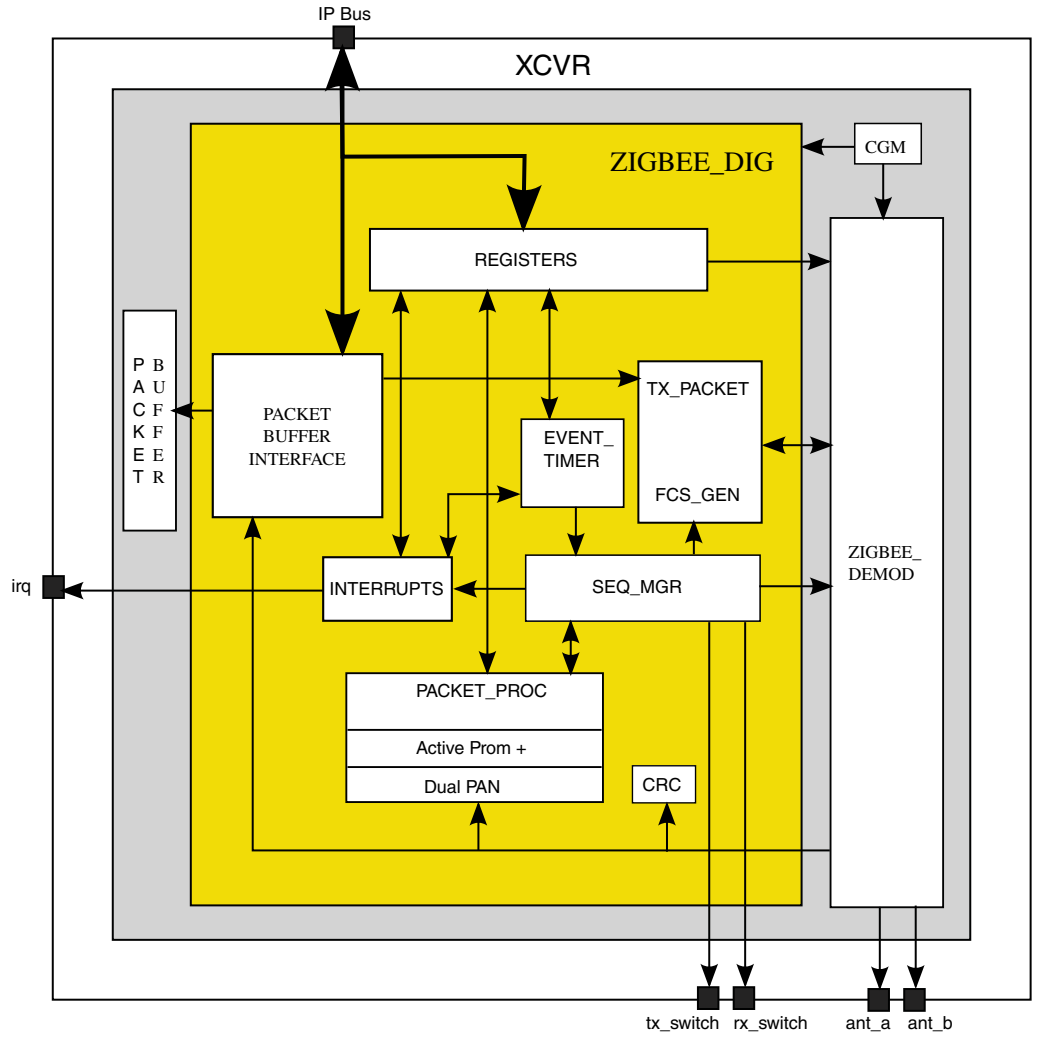

Figure 373. 802.15.4 Link Layer Controller Block Diagram

55.4.9.1.2 Functional Description

55.4.9.1.2.1 Packet Processor

55.4.9.1.2.1.1 Introduction

The 802.15.4 Packet Processor performs sophisticated hardware filtering of the incoming received packet, to determine whether the packet is both PHY- and MAC-compliant, whether the packet is addressed to this device, and if the device is a PAN Coordinator, whether a message is pending for the sending device. The packet processor greatly reduces the packet filtering burden on software, allowing software to tend to higher-layer tasks with a lower latency and smaller software footprint.

Table 472. References

Revision	Title

IEEE Std 802.15.4 -2011	Part 15.4: Low-Rate Wireless Personal Area Networks (LR-WPANs)
IEEE Std 802.15.4e™-2012	Part 15.4: Low-Rate Wireless Personal Area Networks (LR-WPANs) (Amendment to IEEE Std 802.15.4™-2011)
IEEE Std 802.15.4 -2015	Part 15.4: Low-Rate Wireless Personal Area Networks (LR-WPANs) (Amendment to IEEE Std 802.15.4-2011)

55.4.9.1.2.1.1.1 Overview

The 802.15.4 Packet Processor performs aggressive hardware filtering of the incoming packet as it is being received, to increase battery life by not awakening the MCU to process packets which are non-compliant or not addressed to the device, or that violate the 802.15.4 MAC Frame structure. The advanced frame parsing enables the sequence manager to handle complex sequences, by, for example, determining whether a receive frame requires an acknowledge, and generating the Sequence Number for that acknowledge, so that the transmit/receive combination sequence can be executed without any MCU intervention. Finally, the packet processor includes a hardware accelerator that allows the device to handle a critical timing requirement that had been problematic for 8-bit MCU's in the past: the quick-turnaround requirement for an indirect queue-lookup to determine the correct response to an end device sending a data polling request. The packet processor contains a register-based table of end devices which have messages pending, allowing a single-cycle hardware table lookup to be performed, and a minimum-turnaround-time acknowledge packet to be sent to the end device without MCU intervention. The packet processor also includes support for Dual PAN mode, which allows the device to simultaneously reside on 2 networks, with 2 separate IEEE addresses. And the packet processor also supports Active Promiscuous mode, which allows address filtering rules to be bypassed, while still enabling the device to automatically acknowledge packets which are addressed to the device.

55.4.9.1.2.1.1.2 Features

- Aggressive packet filtering to enable long, uninterrupted MCU sleep periods
- Fully compliant with both 2003 and 2006 versions of the 802.15.4 wireless standard
- Supports all Frame Types, including reserved types
- Supports all valid 802.15.4 Frame Lengths
- Enables auto-Tx Acknowledge frames (no MCU intervention) by parsing of Frame Control Field and Sequence Number
- Supports all Source and Destination Address modes, and also PAN ID Compression
- Supports Broadcast address for PAN ID and short address mode
- Supports "Promiscuous" mode, to receive all packets regardless of address- and rules-checking
- Allows Frame Type-specific filtering (e.g., reject all but Beacon frames)
- Supports SLOTTED and non-SLOTTED modes
- Includes special filtering rules for PAN Coordinator devices
- Enables minimum-turnaround TX-Acknowledge frames for data-polling requests by automatically determining message-pending status
- Assists MCU in locating pending messages in its indirect queue for data-polling end devices
- Assists MCU in determining if a poll request originated from a valid child end device
- Makes available to MCU detailed status of frames which fail address- or rules-checking

- Supports Dual PAN mode, allowing the device to exist on 2 PAN's simultaneously
- Supports 2 IEEE addresses for the device
- Supports Active Promiscuous Mode
- Includes provisions to enable software support of 802.15.4e and 802.15.4-2015 frame types and versions

55.4.9.1.2.1.1.3 Block diagram

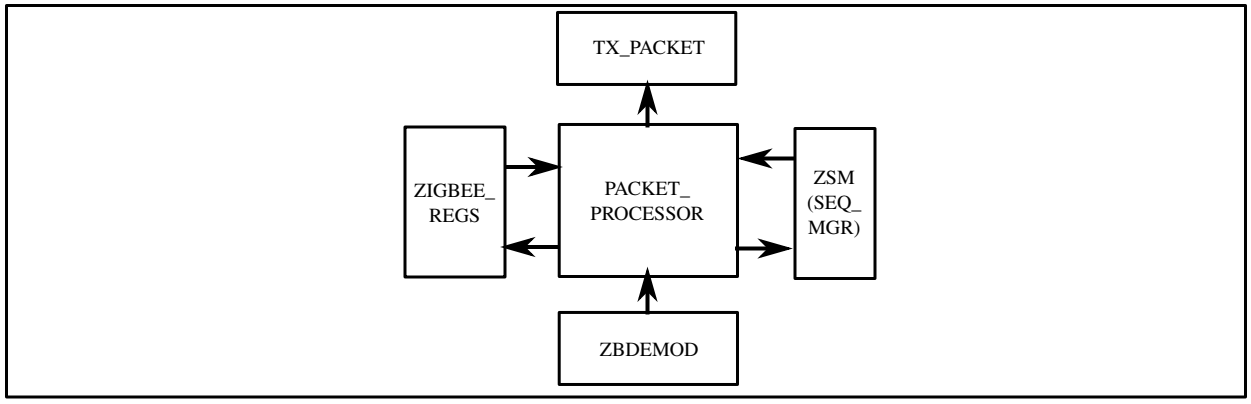

Figure 374. Block diagram

55.4.9.1.2.1.2 Memory Map and register definition

Numerous registers exist to provide configuration and status for the 802.15.4 Packet Processor.

The memory-mapped registers which affect the Packet Processor are described in the table below.

Field	R/W	Description
PI	r	Poll Indication: 1: the received packet was a data request, regardless of whether a source-address table-match occurred, and regardless of whether source-address matching is enabled (see SRCADDR_EN bit); 0: the received packet was not a data request PI is a read-only bit.
SRCADDR	r	If Source Address Management is engaged, meaning at least one of the following bits is set: • SAP0_EN • SAA0_EN • SAP1_EN • SAA1_EN then SRCADDR will be set to 1 if the packet just received is a poll request (PI=1), and at least one of the following conditions is met: • SAP0_EN && SAP0_ADDR_PRESENT

Table continues on the next page...

Table continued from the previous page...

Field	R/W	Description
		• SAA0_EN && SAA0_ADDR_ABSENT • SAP1_EN && SAP1_ADDR_PRESENT • SAA1_EN && SAA1_ADDR_ABSENT If SRCADDR=1, this indicates to SW that the Packet Processor has determined that an auto-TxACK frame must be transmitted with the FramePending subfield of the FrameControlField set to 1. HW will assemble and transmit this Ack packet. If the above conditions are not met, SRCADDR will be cleared to 0.
SAP0_EN	rw	1: Enables SAP0 Partition 0: Disables SAP0 Partition
SAA0_EN	rw	1: Enables SAA0 Partition 0: Disables SAA0 Partition
SAP1_EN	rw	1: Enables SAP1 Partition 0: Disables SAP1 Partition
SAA1_EN	rw	1: Enables SAA1 Partition 0: Disables SAA1 Partition
SAA0_START[6:0]	rw	First Index of SAA0 partition.
SAP1_START[6:0]	rw	First Index of SAP1 partition.
SAA1_START[6:0]	rw	First Index of SAA1 partition.
SAM_CHECKSUM[15:0]		Software-computed source address checksum, to be installed into a table index
SAM_INDEX[6:0]		Contains the table index to be enabled or invalidated. Software must ensure that the index is within the range of the desired partition.
SAM_INDEX_WR	w	For 32-bit writes, SAM_INDEX_WR must be set to indicate that the table entry specified by SAM_INDEX[6:0] is to be written; if SAM_INDEX_WR=0, the table entry is not written, but the SAM_INDEX[6:0] register is updated. For 8-bit writes, this bit is ignored.
SAM_INDEX_EN	w	Enable the index selected by SAM_INDEX[6:0] for searching.
SAM_INDEX_INV	w	Invalidate the index selected by SAM_INDEX[6:0]
FIND_FREE_IDX	w	After modifying Valid bits (enabling or invalidating), write this bit to 1 to force HW to update the “First Free Index” registers to account for the changed Valid bits. This HW update process takes 4us. SW can poll SAM_BUSY to determine when the table update is complete. Write-only bit. Writing 0 to this bit has no effect. Readback value is indeterminate.
SAM_BUSY	r	HW is in the process of updating the Source Address table, either in response to a poll indication from the packet processor, or due to

Table continues on the next page...

Table continued from the previous page...

Field	R/W	Description
		SW setting FIND_FREE_IDX=1. In the latter case, SW should poll SAM_BUSY until low before accessing the “First Free Index” registers. Read-only bit.
INVALIDATE_ALL	w	Writing a 1 to this bit clears all 128 Valid bits. Invalidates the entire table. Write-only bit. Writing 0 to this bit has no effect. Readback value is indeterminate.
SAP0_1ST_FREE_IDX[6:0]	r	First non-enabled (invalid) index in the SAP0 partition. Read-only.
SAA0_1ST_FREE_IDX[6:0]	r	First non-enabled (invalid) index in the SAA0 partition. Read-only.
SAP1_1ST_FREE_IDX[6:0]	r	First non-enabled (invalid) index in the SAP1 partition. Read-only.
SAA1_1ST_FREE_IDX[6:0]	r	First non-enabled (invalid) index in the SAA1 partition. Read-only
PROMISCUOUS	rw	Bypasses most packet filtering. 1: all packet filtering except frame length checking (FrameLength>=5 and FrameLength<=127) is bypassed. 0: normal mode **Note:** Promiscuous Mode is not intended for Sequence TR with RXACKRQD=1 (auto-RXACK mode), because the contents of auto-RXACK packets are not stored in the Packet Buffer. If auto-RXACK packets are to be stored in the PB, use ACTIVE_PROMISCUOUS instead.
PANCORDNTR0	rw	Device is a PAN Coordinator on PAN0. Allows device to receive packets with no destination address, if Source PAN ID matches.
MACPANID0[15:0]	rw	MAC PAN ID for PAN0. The packet processor compares the incoming packet's Destination PAN ID against the contents of this register to determine if the packet is addressed to this device; or if the incoming packet is a Beacon frame, the packet processor compares the incoming packet Source PAN ID against this register. Also, if PANCORDNTR0=1, and the incoming packet has no Destination Address field, and if the incoming packet is a Data or MAC Command frame, the packet processor compares the incoming packet Source PAN ID against this register.
MACSHORTADDRS0[15:0]	rw	MAC Short Address for PAN0, for 16-bit destination addressing mode. The packet processor compares the incoming packet's Destination Address against the contents of this register to determine if the packet is addressed to this device.
MACLONGADDRS0[63:0]	rw	MAC Long Address for PAN0, for 64-bit destination addressing mode. The packet processor compares the incoming packet's Destination Address against the contents of this register to determine if the packet is addressed to this device.
BEACON_FT	rw	1: Beacon frame type enabled.

Table continues on the next page...

Table continued from the previous page...

Field	R/W	Description
		0: reject all Beacon frames
ACK_FT	rw	1: Acknowledge frame type enabled. 0: reject all Acknowledge frames
DATA_FT	rw	1: Data frame type enabled. 0: reject all Data frames
CMD_FT	rw	1: MAC Command frame type enabled. 0: reject all MAC Command frames
LLDN_FT	rw	1: LLDN frame type enabled (Frame Type 4). 0: reject all MAC Command frames
MULTIPURPOSE_FT	rw	1: MULTIPURPOSE frame type enabled (Frame Type 5). 0: reject all MAC Command frames
EXTENDED_FT	rw	1: EXTENDED frame type enabled (Frame Type 7). 0: reject all MAC Command frames
NS_FT	rw	1: Not-specified (reserved) frame type enabled. No packet filtering is performed, except for frame length checking (FrameLength>=5 and FrameLength<=127). 0: reject all reserved frame types
EXTENDED_FCS_CHK	rw	Verify FCS on Frame Type Extended 1: Packet Processor will check FCS at end-of-packet based on packet length derived from PHR, for Frame Type EXTENDED 0: Packet Processor will not check FCS for Frame Type EXTENDED (default)
ACTIVE_PROMISCUOUS	rw	1: Provide Data Indication on all received packets under the same rules which apply in PROMISCUOUS mode, however acknowledge those packets under rules which apply in non-PROMISCUOUS mode 0: normal operation (Default)
FRM_VER_FILTER[3:0]	rw	The incoming packet's Frame Control Field is parsed to obtain the FrameVersion subfield, and that value is compared against this register, in accordance with the following: xxx1: Accept received packets with FrameVersion=00 xx1x: Accept received packets with FrameVersion=01 x1xx: Accept received packets with FrameVersion=10

Table continues on the next page...

Table continued from the previous page...

Field	R/W	Description
		1xxx: Accept received packets with FrameVersion=11 These filtering rules apply to Beacon, Acknowledge, Data, and MAC Command Frame Types, since these frame types require a 2-octet Frame Control Field which embeds a 2-bit FrameVersion subfield. Later frame types introduced in the 802.15.4e addendum (LLDN, Multipurpose) don't guarantee a FrameVersion subfield with the original meaning, so these filtering rules do not apply to these frame types. See registers LLDN_FT and MULTIPURPOSE_FT. For Acknowledge frames, FrameVersion bits are ignored by the Packet Processor, irrespective of FRM_VER_FILTER.
MACPANID1[15:0]	rw	MAC PAN ID for PAN1. The packet processor compares the incoming packet's Destination PAN ID against the contents of this register to determine if the packet is addressed to this device; or if the incoming packet is a Beacon frame, the packet processor compares the incoming packet Source PAN ID against this register. Also, if PANCORDNTR1=1, and the incoming packet has no Destination Address field, and if the incoming packet is a Data or MAC Command frame, the packet processor compares the incoming packet Source PAN ID against this register.
MACSHORTADDRS1[15:0]	rw	MAC Short Address for PAN1, for 16-bit destination addressing mode. The packet processor compares the incoming packet's Destination Address against the contents of this register to determine if the packet is addressed to this device.
MACLONGADDRS1[63:0]	rw	MAC Long Address for PAN1, for 64-bit destination addressing mode. The packet processor compares the incoming packet's Destination Address against the contents of this register to determine if the packet is addressed to this device.
ACTIVE_NETWORK	rw	Selects the PAN on which to transceive, by activating a PAN parameter set (PAN0 or PAN1). In Manual Dual PAN mode (or Single PAN mode), this bit selects the active PAN parameter set (channel and addressing parameters) which governs all autosequences. In Auto Dual PAN mode, this bit selects the PAN on which to begin transceiving, latched at the point at which DUAL_PAN_DWELL register is written. 1: Select PAN1 0: Select PAN0 (Default)
DUAL_PAN_AUTO	rw	Activates automatic Dual PAN operating mode. In this mode, PAN-switching is controlled by hardware at a pre-programmed rate, determined by DUAL_PAN_DWELL. 1: Auto Dual PAN Mode 0: Manual Dual PAN mode (or Single PAN mode). Default.

Field	R/W	Description
LENIENCY[42:0]	rw	The LENIENCY register allows individual packet filtering rules to be overridden, on a rule-by-rule basis. In other words, a specific packet filtering rule, such as an address-mode check, which would result in an incoming packet being rejected, can be overridden by setting the corresponding bit in the LENIENCY register, which would then result in the packet being accepted. This is similar to PROMISCUOUS mode, except that it allows checks to be overridden individually. This will facilitate debug, and potentially allow the device to communicate with devices which may not be 100% MAC-compliant. The mapping of LENIENCY register bits to rules is shown in Appendix B of this document.

55.4.9.1.2.1.3 Functional Description

The packet processor is responsible for receiving symbols from the demodulator, combining them into octets, assembling the octets into packets, filtering the packets in compliance with the 802.15.4 wireless MAC standard, and storing the packets into the Packet Buffer (Packet RAM).

The packet processor parses the incoming packets on-the-fly to determine:

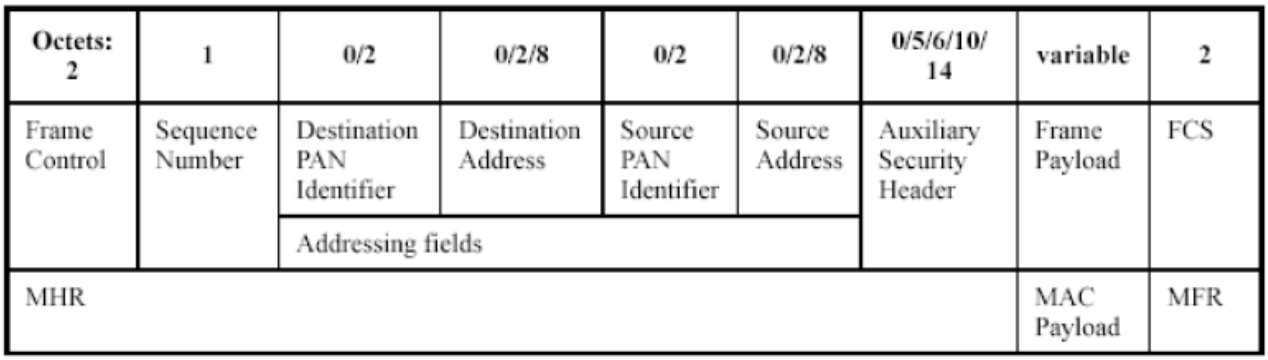
1. whether the packet is MAC-compliant, and if it is,
2. whether the packet is addressed to the end device.

The packet processor performs aggressive filtering on incoming packets, in order to reduce unnecessary MCU wake-ups, to allow longer MCU sleep durations, and to provide sufficient hardware automation so as to enable complex sequences to be executed by the sequence manager. The packet processor also includes hardware support for Dual PAN operation (allowing the device to reside on two networks simultaneously), and for Active Promiscuous mode (allowing the device to receive all packets, but acknowledging only those addressed to the device).

The 802.15.4 packet processor also includes functionality to allow a critical-timing requirement to be met, which in the past has been problematic for low-MIPS 802.15.4 receiving devices: the ability of a coordinator device to respond to a MAC Command data request from an end device, with an Acknowledge frame containing a FramePending bit accurately reflecting the presence of a message for the end device in the coordinator's indirect queue, or the absence of the end device in the coordinator's neighbor table, within the prescribed 192us window. This functionality is described in more detail in the Source Address Matching section.

55.4.9.1.2.1.3.1 Packet Filtering Background

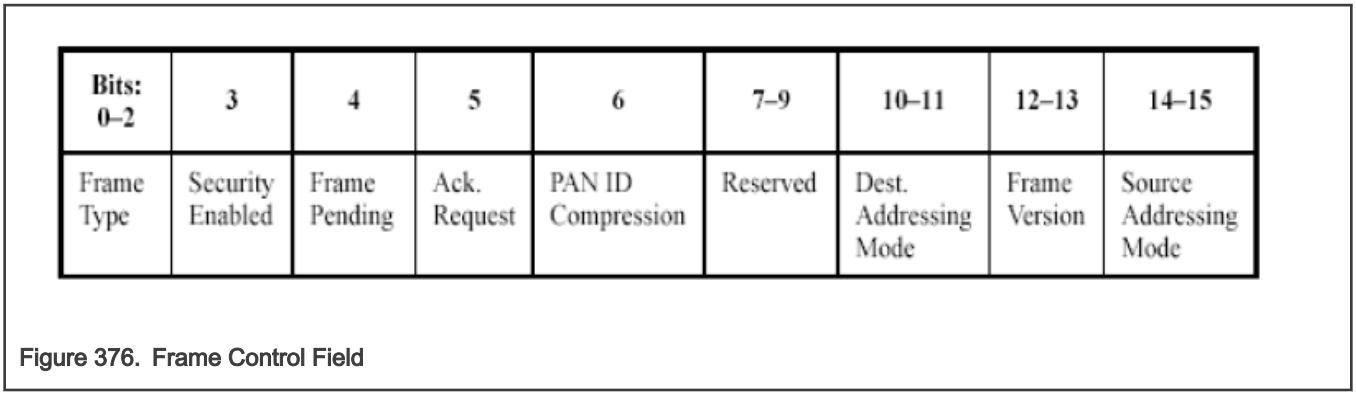
The packet processor parses packets to verify compliance with the 802.15.4 MAC frame format. The basic MAC frame format is shown in the figure below.



Octets: 2	1	0/2	0/2/8	0/2	0/2/8	0/5/6/10/14	variable	2
Frame Control	Sequence Number	Destination PAN Identifier	Destination Address	Source PAN Identifier	Source Address	Auxiliary Security Header	Frame Payload	FCS
		Addressing fields						
MHR							MAC Payload	MFR

Figure 375. MAC Frame Format

The packet processor parses the incoming octets on the fly, as they are received. The Frame Control Field, two octets in length, contains subfields which encode “instructions” on how to parse the remainder of the MHR (MAC Header). The structure of the Frame Control Field is shown in the figure below.



Bits: 0–2	3	4	5	6	7–9	10–11	12–13	14–15
Frame Type	Security Enabled	Frame Pending	Ack. Request	PAN ID Compression	Reserved	Dest. Addressing Mode	Frame Version	Source Addressing Mode

Figure 376. Frame Control Field

The packet processor utilizes the Frame Control Fields subfields in the following manner:

FCF Subfield	Utilization by Packet Processor
FrameType	Interprets the remaining MHR as specific to Beacon, Ack, Data, Command, or Reserved frame types. Each frame type has a unique MHR structure, and so different parsing rules apply.
SecurityEnabled	If SecurityEnabled=1 and FrameVersion>0 (frame versions 2006 and later), an Auxiliary Security Header field will be present in the MHR and will need to be further parsed by the packet processor if this is a MAC Command frame (see Section Source Address Management below). There is no other use of SecurityEnabled by the packet processor.
FramePending	ignored by packet processor
Ack. Request	will be copied into the **pp_ack_request** signal to the sequence manager. An auto-TxAck frame will follow the incoming receive frame if necessary conditions are met
PAN ID Compression	used for addressing mode rules-checking and addressing field parsing.

Table continues on the next page...

Table continued from the previous page...

FCF Subfield	Utilization by Packet Processor
Reserved	ignored by packet processor
Destination Addressing Mode	used for addressing mode rules-checking and addressing field parsing
FrameVersion	For Beacon, Data, and MAC Command frames, FrameVersion is checked against the allowed frame versions according to FRM_VER_FILTER For Acknowledge frames, FrameVersion is ignored. If SecurityEnabled=1 and FrameVersion>0 (frame versions 2006 and later), an Auxiliary Security Header field will be present in the MHR and the MHR will need to be further parsed by the packet processor if this is a MAC Command frame (see Section Source Address Management).
Source Addressing Mode	used for addressing mode rules-checking and addressing field parsing

The Packet Processor parses the FrameType field of the Frame Control Field per the following table:

Frame type value b_2 b_1 b_0	Description
000	Beacon
001	Data
010	Acknowledgment
011	MAC command
100–111	Reserved

Figure 377. Frame Type Field

Directly following the Frame Control Field is the Sequence Number field. The Sequence Number field of the MHR is captured by the packet processor. If an auto-TxAck frame follows the incoming receive frame, the captured Sequence Number will be copied to the transmitted Acknowledge packet, and the Packet Processor will insert FrameVersion=00 into the Frame Control Field of the transmitted frame, regardless of the received FrameVersion subfield of the original frame.

The Addressing Fields follow the Sequence Number. The format of the Addressing Fields depends upon the Source and Destination Addressing Mode subfields of the Frame Control Field. The Addressing Modes are defined in the table below:

Addressing mode value b_1 b_0	Description
00	PAN identifier and address fields are not present.
01	Reserved.
10	Address field contains a 16-bit short address.
11	Address field contains a 64-bit extended address.

Figure 378. Addressing Mode Fields

The packet processor uses these Source and Destination Address Modes shown above, to extract the Source PAN ID and Address (if present), and the Destination PAN ID and Address (if present), from the MHR, according to the table below:

FrameType	Destination Addressing Mode	Source Addressing Mode	PanID-Compression	Addressing Fields
Acknowledge only (reject all other frame types)	0	0	0	None
Data or Command (reject Ack and Beacon frames)	2 or 3	0	0	DstPanID + DstAddr
Beacon (all devices), or Data or Command (PAN Coord Only) (reject Ack frames)	0	2 or 3	0	SrcPanID + SrcAddr
Data or Command (reject Ack and Beacon frames)	2 or 3	2 or 3	0	DstPanID + DstAddr + SrcPanId + SrcAddr
Reject all frames (Illegal as per Section 7.2.2.1.5)	0	0	1	-
Reject all frames (Illegal as per Section 7.2.2.1.5)	2 or 3	0	1	-
Reject all frames	0	2 or 3	1	-

Table continues on the next page...

Table continued from the previous page...

FrameType	Destination Addressing Mode	Source Addressing Mode	PanID-Compression	Addressing Fields
(Illegal as per Section 7.2.2.1.5)				
Data or Command (reject Ack or Beacon frames)	2 or 3	2 or 3	1	DstPanID + DstAddr + SrcAddr
Reject all frames (Illegal as per Section 7.2.2.1.6)	1	-	-	-
Reject all frames (Illegal as per Section 7.2.2.1.8)	-	1	-	-

The Source PAN ID and Address, and Destination PAN ID and Address, extracted by the packet processor, are then checked against the MACPANID, MACSHORTADDRS, and MACLONGADDRS register settings, depending on the FrameType of the incoming packet, to determine:

1. Is the addressing mode combination valid for this frame type?
2. Do the address fields indicate that the packet is indeed addressed to the end device?

The details on how the packet processor answers those 2 questions, are described in the following sections.

55.4.9.1.2.1.3.2 Packet Filtering Detail

The figure below is a high-level representation of the packet filtering performed by the 802.15.4 packet processor. The sections which follow provide more detail on the packet filter implementation.

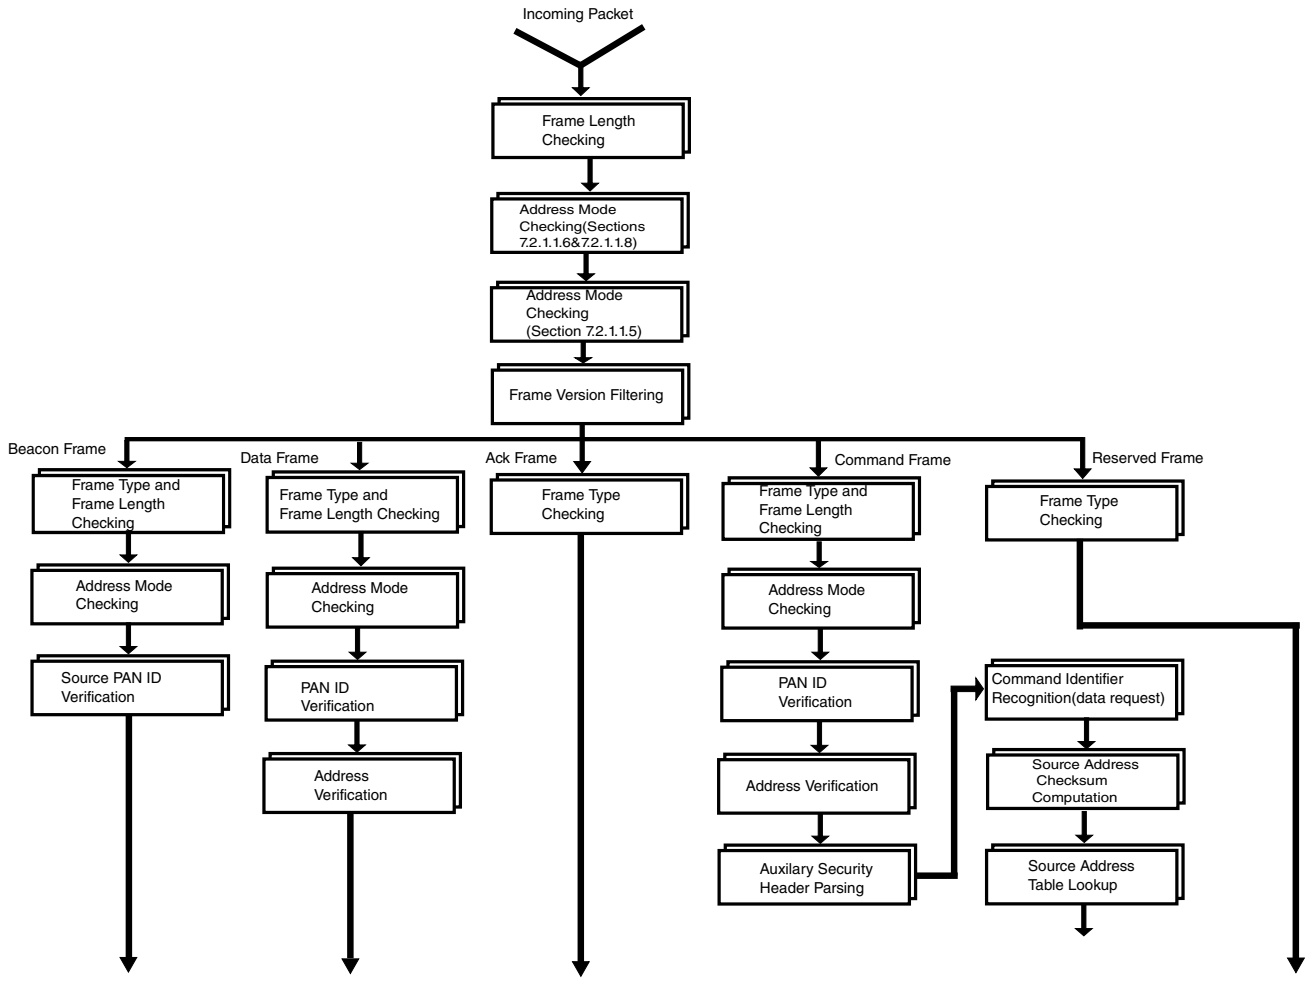


Figure 379. Packet Filtering Flow Diagram

First-Stage Packet Filtering

The first stage of packet filtering examines the incoming packet, and implements basic rule-checking, based on the 2006 version of the 802.15.4 standard, and is applied to *all* frame types. First stage rule-checking is described in the table below:

	Filtering Step	Description
1	Frame Length Checking	Check that all frames are at least 5 octets long (minimum frame length required by the standard), and no longer than 127 octets long (maximum frame length allowed by the standard).
2	Address Mode Checking (Sections 7.2.1.1.6 and 7.2.1.1.8)	Check that neither Source nor Destination Address Mode set to 1 (illegal addressing mode)
3	Address Mode Checking (Section 7.2.1.1.5)	Check for PAN ID Compression enabled, with either Source or Destination Address Mode set to 0 (illegal addressing mode)

Table continues on the next page...

Table continued from the previous page...

	Filtering Step	Description
4	FrameVersion Checking	Check that incoming packet's Frame Version is allowed based on FRM_VER_FILTER setting. (FRM_VER_FILTER is a programmable register, see Register Descriptions Section).

Packets which pass first stage filtering, proceed to the second stage of packet filtering, which is *frame type-specific* filtering. Packets which fail initial rule checking are marked as rejected.

Second-Stage Packet Filtering

The second stage of packet filtering is *frame type-specific*. Different variations of the MAC Header (MHR) apply to different frame types, so different parsing mechanisms apply to each.

Note: In the following section, the following references are to register bits; see Register Description Section for register descriptions: BEACON_FT, ACK_FT, DATA_FT, CMD_FT, NS_FT, PANCORDNTR, MACPANID, MACSHORTADDRS, and MACLONGADDRS.

1) For Beacon frames, these are the basic filtering steps:

- Check that Beacon frames are enabled by software (BEACON_FT)
- Check that FrameLength >= 9
- Check for illegal combinations of PAN ID Compression and Source/Destination Address Modes
- Verify the Source PAN ID matches MACPANID, or that MACPANID = 0xffff.

2) For Acknowledge frames, these are the basic filtering steps:

- Check that Ack frames are enabled by software (ACK_FT)
- If Sequence TR is active and RXACKRQD = 1, check the received Sequence Number matches the transmitted Sequence Number; FrameVersion bits are ignored, as per section 7.2.2.3.1 of the 802.15.4 standard.

Note: It is recommended to use Sequence TR to receive Acknowledge frames, not Sequence R. See Chapter ZSM Sequence Manager, Section Sequence TR (Transmit/Receive).

3) For Data frames, these are the basic filtering steps:

- Check that Data frames are enabled by software (DATA_FT)
- Check that FrameLength >= 9
- Check for illegal combinations of Source and Destination Address Modes
- If PANCORDNTR=0, check for missing Destination Address field or present Source Address field
- If no Destination Address field (PANCORDNTR=1 only), check Source PAN ID matches MACPANID
- If Destination Address present, check Destination PAN ID matches MACPANID or broadcast (0xffff)
- If Short Destination Address field, check address matches MACSHORTADDRS or broadcast (0xffff)
- If Long Destination Address field, check address matches MACLONGADDRS.

4) For MAC Command frames, these are the basic filtering steps:

- Check that Command frames are enabled by software (CMD_FT)
- Check that FrameLength >= 9

- Check for illegal combinations of Source and Destination Address Modes
- If PANCORDNTR=0, check for missing Destination Address field or present Source Address field
- If no Destination Address field (PANCORDNTR=1 only), check Source PAN ID matches MACPANID
- If no Destination Address field (PANCORDNTR=1 only), capture Source PAN ID and Source Address for later use
- If Destination Address present, check Destination PAN ID matches MACPANID or broadcast (0xffff)
- If Short Destination Address field, check address matches MACSHORTADDRS or broadcast (0xffff)
- If Long Destination Address field, check address matches MACLONGADDRS.
- At end of the addressing field, if incoming packet's FrameVersion=0 or SecurityEnabled=0, capture the next octet (Command Identifier)
- At end of the addressing field, if incoming packet's FrameVersion!=0 and SecurityEnabled=1, parse the Auxiliary Security Header, then capture the next octet (Command Identifier)
- If Command Identifier indicates the MAC Command is a data request, compute a "Source Address Checksum" to uniquely identify the sending device.

55.4.9.1.2.1.3.3 Source Address Management

The 802.15.4 wireless MAC standard envisions a scenario whereby an end device may interrogate a coordinator as to whether the coordinator is storing data (i.e., a pending message) for the end device. The situation arises in a beacon-enabled network, when a coordinator includes in its transmitted beacon frame the MAC address of the end device in its "Pending Address Fields". The "Pending Address Fields" are part of the required MAC payload of the beacon frame. The "Pending Address Fields" contain a list of end device addresses for which messages are pending. In this scenario, an end device which finds its address included in the "Pending Address Fields" of the received beacon frame, must respond to the beacon (coordinator) with a MAC Command of type "data request". Alternatively, in non-beacon-enabled networks, an end device may periodically wake up and "poll" a coordinator, to determine if a message is pending for the end device. In either case, the coordinator stores messages for its end devices in its "indirect queue". The coordinator must respond to an incoming MAC Command data request (which *must* have AckRequest=1 in its Frame Control Field), with an Acknowledge frame containing a FramePending subfield indicating the presence (or absence) of a message for the requesting end device, in the coordinator's indirect queue. For a coordinator built around a low-MIPS MCU, a significant amount of MCU time is typically required, simply to ascertain whether a given end device has a message pending or not; the indirect queue can be quite large, and for 8-bit MCU's, the queue must be searched byte-by-byte. This makes it difficult, or impossible, for an underpowered MCU to establish frame-pending status within the 192us RX-to-TX turnaround time required by the standard.

Also, coordinators may include, in software, a "Neighbor Table", the contents of which consist of all the end devices with which the coordinator is in communication. The neighbor table requires periodic maintenance by coordinator (parent) software, as end devices (children) come and go within the network, join different parents, or simply never return. Child tables have limited capacity and parents need to create space for new devices that may show up. A timeout mechanism is the only way that can guarantee that child tables will eventually be cleaned up. Coordinator software must "age out" end devices with which there has not been recent communication. In order for an end device to refresh its status within its parent's Neighbor Table, the end device may periodically send a "keepalive" message in the form of a MAC Data Poll Request. Upon receipt of such a poll request, the parent must search its neighbor table to determine if the source address of the end device is a valid table entry. If the end device exists in the table, an Acknowledgment packet must be transmitted to the end device, with the FramePending subfield set to 0, and coordinator software resets that end device's timeout counter; if the child is not present in the table, an Acknowledgment packet must be transmitted to the end device, with the FramePending subfield set to 1, and the parent device will follow up by transmitting a "Leave Packet" to the end device, instructing the end device to sever its child status with the parent. The end device may opt to rejoin at a later time. Due to the size of the parent's Neighbor table, the search a child's source address can be time consuming, and may not always be possible within the 192us RX-to-TX turnaround time required by the standard.

To alleviate both of these problems, the 802.15.4 packet processor includes hardware acceleration to expedite the source address table search, greatly relieving the software bottleneck during the critical 192us turnaround time. The table search acceleration consists of 2 components: 1) a search for the *presence* of a specific end device's source address, which expedites the process of determining whether a message is pending for the device; and 2) a search for the *absence* of a specific end device's source address, which expedites the process of determining whether the end device is a valid child of the parent.

The packet processor maintains a register table (128 deep, 16-bit wide). The table is divided into multiple partitions, one to perform the “Source Address Present” (SAP) search, and another to perform the “Source Address Absent” (SAA) search. In the SAP partition of the table, coordinator software will store the address of end devices for which it has a message pending; in the SAA partition of the table, coordinator software will store the address of end devices for which it is the parent. To reduce area, the address information is stored in a “compressed” format. Software compresses the address information, and stores it into the table partitions, during a non-critical time. Then, when the coordinator’s packet processor receives a MAC Command data request, it extracts the source address information from the incoming packet, and compresses it using the *same* compression algorithm used by software to populate the source address table. The packet processor performs 2 steps simultaneously:

1. it compares the just-received, compressed source address information, or “checksum”, against all of the enabled entries in the SAP partition of the table. If a match is found in the SAP partition, the packet processor *asserts* the **rx_frame_pending** signal to the transmit block (TX_PACKET), so that an auto-TxAck packet can be sent to the requesting end device, with the FramePending subfield set to 1, indicating that the end device has a message pending in the coordinator’s indirect queue. A message packet from the coordinator to the end device will follow.
2. it compares the just-received, compressed source address information, or “checksum”, against all of the enabled entries in the SAA partition of the table. If *no* match is found in the SAA partition, the packet processor *asserts* the **rx_frame_pending** signal to the transmit block (TX_PACKET), so that an auto-TxAck packet can be sent to the requesting end device, with the FramePending subfield set to 1, indicating that the end device is not a valid child of this parent, and a “Leave Packet” from the coordinator to the end device, will follow.

If neither condition is met, i.e, there is no address match in the SAP partition, and a positive match in the SAA partition, the packet processor *deasserts* the **rx_frame_pending** signal, so that an auto-TxAck packet can be sent indicating to the end device that it has no data pending, and that it remains a valid child of this parent; the end device may then deactivate its receiver immediately. For the packet processor, the entire table lookup occurs in 128 clock cycles, once the last source address octet has been received. The SAP and SAA lookups are performed simultaneously. The checksum is also computed on-the-fly by hardware as the source address octets are received, taking no more than 1 clock cycle per octet. Finally, table-search status is reported to the MCU:

1. after the packet processor completes its SAP table search, the status bit SAP0_ADDR_PRESENT will be set to 1 if a match is found in the SAP partition, and the table index which matched will be indicated in the SAP0_MATCH[6:0] register, to further assist software in locating the relevant message within its indirect queue; if no match is found in the SAP partition, the status bit SAP0_ADDR_PRESENT will be set to 0.
2. after the packet processor completes its SAA table search, the status bit SAA0_ADDR_ABSENT will be set to 1 if *no* match is found in the SAA partition; if a positive match is found in the SAA partition, the status bit SAA0_ADDR_ABSENT will be set to 0, and the table index which matched will be indicated in the SAA0_MATCH[6:0] register, to further assist software in locating the child device within its neighbor table.

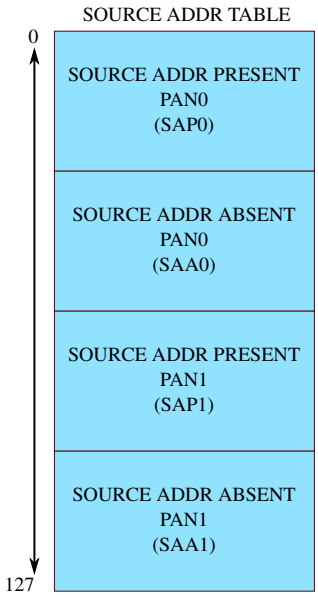
Both features, SAP and SAA acceleration, are optional, and functionally independent. Coordinator software can elect to enable both, either, or neither feature. The control bit SAP0_EN enables SAP acceleration. The control bit SAA0_EN enables SAA acceleration. If either feature is disabled, that table partition (SAP or SAA) is not searched, and so is not a factor in determining FramePending status for the transmitted Acknowledge frame. If *both* features are disabled, FramePending status defaults to software control, and merely tracks the state of the ACK_FRM_PND register bit; in this case software must manage FramePending status for all auto-TxAck frames.

Software can also take direct control of FramePending status for the next auto-TxAck frame at any time (regardless of whether SAP or SAA acceleration is enabled), by setting the ACK_FRM_PND_CTRL bit; in this case, hardware FramePending status will track the state of ACK_FRM_PND.

In order to support Dual PAN mode, a device could theoretically be a PAN Coordinator on both networks. Thus, a coordinator device may need to maintain distinct message pending lists and/or neighbor tables for the 2 PANs. Accordingly, the packet processor further subdivides the Source Address Management table into 4, instead of 2, partitions:

1. SAP0: Source Address Present Partition for PAN0
2. SAA0: Source Address Absent Partition for PAN0
3. SAP1: Source Address Present Partition for PAN1
4. SAA1: Source Address Absent Partition for PAN1

SOURCE ADDRESS TABLE PARTITIONS



Four register control bits enable each partition individually. If a partition is enabled, and a MAC poll request is received on the corresponding PAN (e.g. SAP0 or SAA0 partitions on PAN0), then the partition is searched by the packet processor, looking for a source address match (or absence), and the result of the search affects the FramePending status; if a partition is disabled, the partition is not searched, and will not influence FramePending status. The register bits are described in the table below.

REGISTER NAME	DESCRIPTION
SAP0_EN	Enables SAP0 Partition
SAA0_EN	Enables SAA0 Partition
SAP1_EN	Enables SAP1 Partition
SAA1_EN	Enables SAA1 Partition

For maximum flexibility in supporting all combinations of message-pending status, neighbor-table status, and dual PAN mode, the dividing-line between all the partitions is fully programmable. The SAP0 partition always starts at table index 0. Three registers control the starting point for the other 3 partitions. The starting point is defined the first table index (0-127) of that partition. The registers are described below, along with some software restrictions to ensure table consistency.

REGISTER NAME	DESCRIPTION	RESTRICTIONS
SAA0_START[6:0]	First Index of SAA0 partition.	If SAA0_START=0, then there is no SAP0 partition (SAP0_EN should be set to 0)
SAP1_START[6:0]	First Index of SAP1 partition.	Software must ensure that: **SAP1_START ≥ SAA0_START** If SAP1_START = SAA0_START, then there is no SAA0 partition (SAA0_EN should be set to 0)
SAA1_START[6:0]	First Index of SAA1 partition.	Software must ensure that:

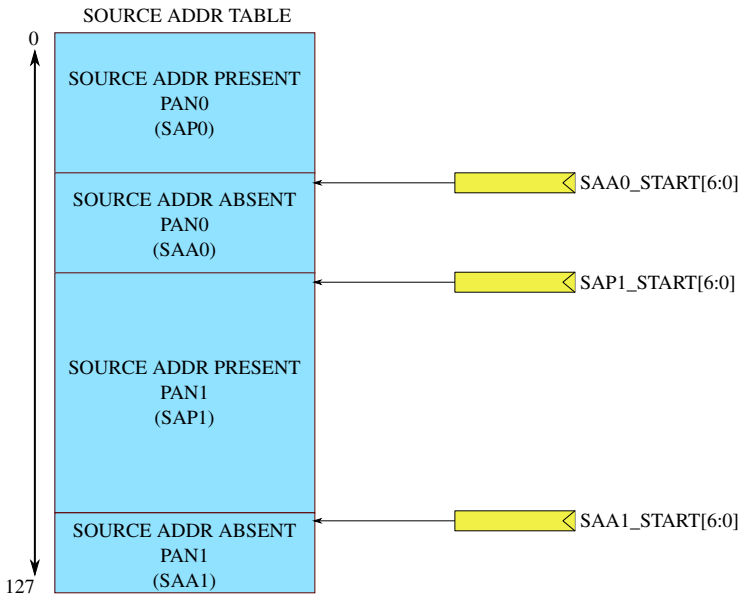
Table continues on the next page...

Table continued from the previous page...

REGISTER NAME	DESCRIPTION	RESTRICTIONS
		SAA1_START ≥ SAP1_START If SAA1_START = SAP1_START, then there is no SAP1 partition (SAP1_EN should be set to 0)

A diagram which depicts one example of how the dividing-line registers affect partitioning of the table, is shown below.

SOURCE ADDRESS TABLE PARTITIONS -- NON-EQUAL SIZES (EXAMPLE)



Each table partition consists of one or more indices, which can be used to store source address checksums. The first index for any partition, is defined by the aforementioned *PARTITION*_START[6:0] register, where *PARTITION*_ is one of {SAP0, SAP1, SAA0, SAA1}. The last index for any partition, is defined by the next higher partition's *PARTITION*_START[6:0] register, minus 1. When populating the table with source address information, software must be sure to select an index that is within the defined range for the partition. For example, when installing a checksum in the SAP1 partition:

SAP1_START ≤ Selected_Index ≤ (SAA1_START – 1)

To populate the table partitions, a 7-bit register SAM_INDEX[6:0] is provided, as well as a "index enable bit", and a "index invalidate" bit. A 16-bit SAM_CHECKSUM[15:0] is provided, into which software will write the computed checksum. Installing a checksum into any partition is referred to as "Enabling an Index", and removing a checksum from any partition is referred to as "Invalidating an Index". A description of the registers is provided in the following table:

REGISTER NAME	DESCRIPTION
SAM_CHECKSUM[15:0]	Software-computed source address checksum, to be installed into a table index
SAM_INDEX[6:0]	Contains the table index to be enabled or invalidated. Software must ensure that the index is within the range of the desired partition.

Table continues on the next page...

Table continued from the previous page...

REGISTER NAME	DESCRIPTION
SAM_INDEX_WR	For 32-bit writes, this must be set to indicate that the table entry specified by SAM_INDEX[6:0] is to be written; if SAM_INDEX_WR=0, the table entry is not written, but the SAM_INDEX[6:0] register is updated. For 8-bit writes, this bit is ignored.
SAM_INDEX_EN	Enable the index selected by SAM_INDEX[6:0] for searching.
SAM_INDEX_INV	Invalidate the index selected by SAM_INDEX[6:0]
FIND_FREE_IDX	After modifying Valid bits (enabling or invalidating), write this bit to 1 to force HW to update the “First Free Index” registers to account for the changed Valid bits. This HW update process takes 4us. SW can poll SAM_BUSY to determine when the table update is complete. Write-only bit. Writing 0 to this bit has no effect. Readback value is indeterminate.
SAM_BUSY	HW is in the process of updating the Source Address table, either in response to a poll indication from the packet processor, or due to SW setting FIND_FREE_IDX=1. In the latter case, SW should poll SAM_BUSY until low before accessing the “First Free Index” registers. Read-only bit.
INVALIDATE_ALL	Writing a 1 to this bit clears all 128 Valid bits. Invalidates the entire table. Write-only bit. Writing 0 to this bit has no effect. Readback value is indeterminate.

All the index-control registers reside within a single 32-bit word, so that a single 32-bit write can store a new checksum in the table, and simultaneously enable, or invalidate, the index. For 32-bit writes, SAM_INDEX_WR must be set to 1 to cause the SAM_CHECKSUM[15:0] to be loaded into the table at the address specified by SAM_INDEX[6:0]. For 32-bit reads, it is necessary first to update SAM_INDEX[6:0] to the desired table index, if it is not already set to the desired index; this requires a write to SAM_INDEX[6:0] with SAM_INDEX_WR=0, so as to not update the table contents. Then, a subsequent 32-bit read will return the table contents at the desired index.

For systems that don’t support 32-bit writes, the register fields should be written in the following order:

1. SAM_INDEX[6:0]
2. SAM_CHECKSUM (the 2 bytes can be written in either order)
3. SAM_INDEX_EN (to enable), or SAM_INDEX_INV (to invalidate)

During operation, when a packet is received and the packet processor searches the table for a source address match, only enabled indices within each partition are searched. Invalidated indices are ignored.

To assist software in finding an available index to store the next source address checksum, the packet processor makes available the following 4 read-only registers:

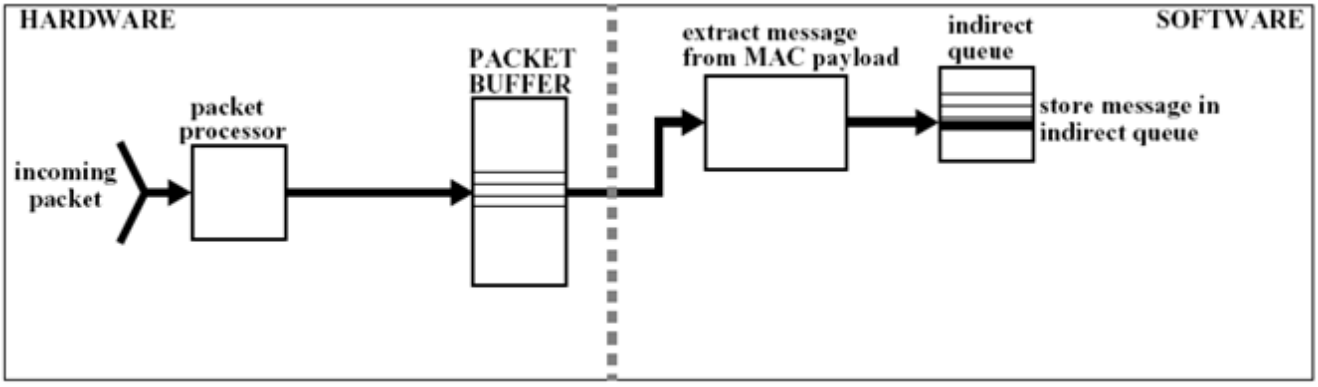
REGISTER NAME	DESCRIPTION
SAP0_1ST_FREE_IDX[6:0]	First non-enabled (invalid) index in the SAP0 partition
SAA0_1ST_FREE_IDX[6:0]	First non-enabled (invalid) index in the SAA0 partition
SAP1_1ST_FREE_IDX[6:0]	First non-enabled (invalid) index in the SAP1 partition
SAA1_1ST_FREE_IDX[6:0]	First non-enabled (invalid) index in the SAA1 partition

Operational Use

The following flow description illustrates how hardware and software interact to utilize the Source Addressing Management feature to facilitate pending-message handling and neighbor table management. This flow assumes both SAP and SAA acceleration are enabled, and Dual PAN mode is in effect. There are 11 sequential steps.

Step 1: Message Packet Reception, Extracting the Message, Indirect Queue Management

A message (data frame) is received by a coordinator. The message is received from one end device, and is intended for another end device. The coordinator's packet processor receives the packet, and stores it in the packet buffer. Coordinator software downloads the packet data from the packet buffer, extracts the message from the MAC payload, and stores the message in its indirect queue.



Step 2: Software computes address checksum

Coordinator software also extracts the destination information (Destination PANID and Destination Address), from the data packet stored in the packet buffer. Software uses this information to compute a 16-bit checksum. This checksum uniquely identifies the sending device, with a high degree of reliability. The checksum is computed according to the following rules:

Destination Addressing Mode	Rule
Mode 2 (short address)	Checksum = (Destination PAN ID + DstAddr[15:0]) % 65536
Mode 3 (long address)	Checksum = (Destination PAN ID + DstAddr[15:0]) % 65536 Checksum = (Checksum + DstAddr[31:16]) % 65536 Checksum = (Checksum + DstAddr[47:32]) % 65536 Checksum = (Checksum + DstAddr[63:48]) % 65536

Step 3: Software populates the address table

Coordinator software chooses an index in the Source Address Table in which it will store the just-computed checksum. If the data packet was received on PAN0, an index in the SAP0 partition should be chosen. Software may consult the register SAP0_1ST_FREE_IDX[6:0] to find the first available index in this partition. If the data packet was received on PAN1, an index in the SAP1 partition should be chosen. Software may consult the register SAP1_1ST_FREE_IDX[6:0] to find the first available index in this partition.

If an index is chosen which is already valid, software should first invalidate the index with the following procedure:

1. Set SAM_INDEX[6:0] to the selected index
2. Set SAM_INDEX_EN=0 and SAM_INDEX_INV=1

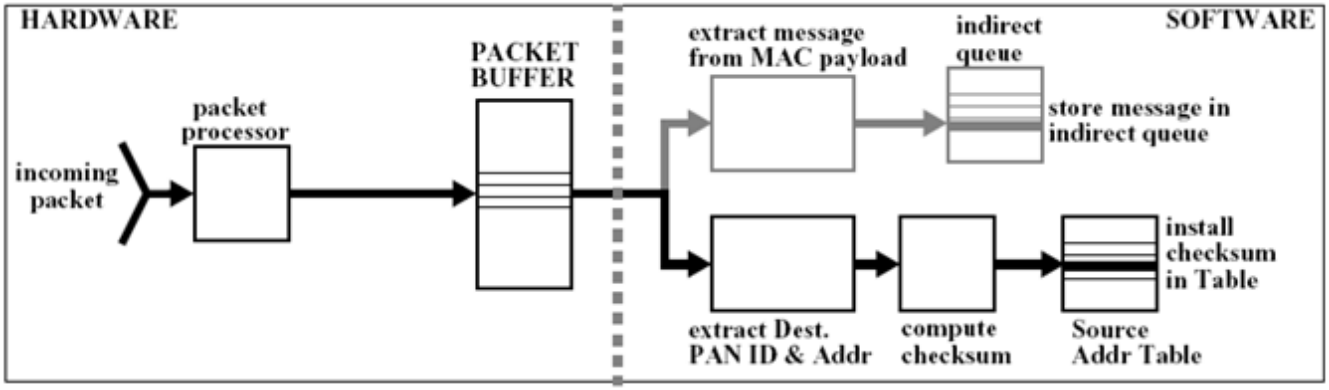
These steps can be performed in a single, 32-bit register write.

To install the source address checksum into the index and enable the index, the following procedure should be used:

1. Program SAM_CHECKSUM[15:0] to the computed checksum
2. Set SAM_INDEX[6:0] to the selected index
3. Set SAM_INDEX_EN=1 and SAM_INDEX_INV=0

These steps can be performed in a single, 32-bit register write.

The index is now enabled, and the packet processor will include it in its search when the next MAC Poll Request is received.



Step 4: Incoming Poll request, Packet Processor parses the Auxiliary Security Header

An incoming packet is received. The packet processor performs routine packet filtering. After determining that the packet is type 'MAC Command', the packet processor must perform additional packet parsing in order to locate the packet's Command Frame Identifier. This is the octet that distinguishes this command as being of type "data request", from other MAC Command types. For the packet processor, this extra parsing is more complex, because the Command Frame Identifier is part of the MAC payload; this is the only scenario where the packet processor is required to parse the payload. This is further complicated by the fact that the revision 2006 (and subsequent) of the 802.15.4 wireless MAC standard, includes a variable-length "Auxiliary Security Header", prior to the MAC payload. This header is only present for FrameVersion > 0, and SecurityEnabled = 1. The packet processor must conditionally parse this header in order to locate the start of the MAC payload, where the Command Frame Identifier is located. The packet processor uses 2 subfields of the Frame Control Field to parse the Auxiliary Security Header (A.S.H.): FrameVersion, and SecurityEnabled. The packet processor parses the Auxiliary Security Header (A.S.H.) according to the following table:

Length of Auxiliary Security Header (Octets)	SecurityEnabled (Frame Control Field)	FrameVersion (Frame Control Field)	KeyIdentifierMode (Security Control Field)	Remarks
0	0	00 or 01	-	If !SecurityEnabled, no ASH regardless of FrameVersion
0	1	00	0	If packet is 2003-compliant, no ASH
5 Security Control (1 octet) + Frame Counter (4 octet)	1	01	0x00	ASH present. Length of ASH computed by HW.
6 Security Control (1 octet) +	1	01	0x01	ASH present. Length of ASH computed by HW.

Table continues on the next page...

Table continued from the previous page...

Length of Auxiliary Security Header (Octets)	SecurityEnabled (Frame Control Field)	FrameVersion (Frame Control Field)	KeyIdentifierMode (Security Control Field)	Remarks
Frame Counter (4 octet) + Key Identifier (1 octet)				
10 Security Control (1 octet) + Frame Counter (4 octet) + Key Identifier (5 octet)	1	01	0x2	ASH present. Length of ASH computed by HW.
14 Security Control (1 octet) + Frame Counter (4 octet) + Key Identifier (9 octet)	1	01	0x3	ASH present. Length of ASH computed by HW.
-	-	10 or 11	-	HW will handle these FrameVersion's indentically to FrameVersion 01

The contents of the A.S.H. are irrelevant to the packet processor; only its length is important. This is because the octet which immediately follows the A.S.H. is the Command Frame Identifier. This is all the packet processor needs to know.

Step 5: Hardware extracts the Command Frame Identifier

After parsing the A.S.H. (if present), the next octet in the MAC payload, in accordance with the 802.15.4 standard, is the Command Frame Identifier.

Command frame identifier	Command name	RFD		Subclause
		Tx	Rx	
0x01	Association request	X		5.3.1
0x02	Association response		X	5.3.2
0x03	Disassociation notification	X	X	5.3.3
0x04	Data request	X		5.3.4
0x05	PAN ID conflict notification	X		5.3.5
0x06	Orphan notification	X		5.3.6
0x07	Beacon request			5.3.7
0x08	Coordinator realignment		X	5.3.8
0x09	GTS request			5.3.9
0x0a–0xff	Reserved			—

The packet processor checks to see if the Command Frame Identifier = 0x4. If it is not, packet processing for this frame is complete, the remainder of the packet is received, without inspection by the packet processor, and is stored the packet buffer. If the Command Frame Identifier = 0x4, then this is a data request, and assuming the prior rules-checking and address-checking on this packet have already passed, then the Source Address Matching function will be applied to this packet, continuing in STEP 6.

Step 6: Hardware Computes the Source Address Checksum

The packet processor uses the received Source PAN ID and Source Address for this packet to compute a 16-bit Source Address checksum. This checksum uses precisely the same algorithm that software uses to compute its Address checksum (see STEP 2), except that the *Source* PAN ID and address are used, rather than the Destination PAN ID and address. This checksum uniquely identifies the sending device, with a high degree of reliability. Note if the incoming packet's Frame Control Field has the PANIDCompression subfield asserted, the packet processor will substitute "Destination PAN ID" for "Source PAN ID" in the computation, since Source PAN ID will not be present under these circumstances.

Step 7: Hardware performs "Source Address Present" Table Search

If the MAC poll request was received on PAN0, and SAP0_EN=1 to enable searches of the PAN0 "Source Address Present" partition, the packet processor uses its Source Address checksum to look for a match in the SAP0 partition of the table. Only table entries that are enabled, are compared against (see STEP 3); table indices which are not enabled, are ignored in the search.

If a single table match is found (i.e., 1 software-computed checksum in SAP0 partition matches the hardware-computed checksum for the incoming packet), this means that there is a message for this requestor in the coordinator's message queue. For a SAP0 match, the packet processor takes these 2 steps:

1. Set SAP0_ADDR_PRESENT=1
2. Set SAP0_MATCH[6:0] to the index which matched

If multiple table matches are found (i.e., more than 1 software-computed checksum in the SAP0 partition matches the hardware-computed checksum for the incoming packet), this means that there are multiple messages for this requestor in the coordinator's message queue. In this case, the packet processor takes the same steps as for a single match, with the SAP0_MATCH[6:0] register being set to the lowest-value matching index (i.e., the smallest number) within the SAP0 partition.

If no source address match is found in the SAP0 table search, the packet processor will set SAP0_ADDR_PRESENT=0.

If, on the other hand, the MAC poll request was received on PAN1, and SAP1_EN=1 to enable searches of the PAN1 “Source Address Present” partition, the packet processor uses its Source Address checksum to look for a match in the SAP1 partition of the table. Only table entries that are enabled, are compared against (see STEP 3); table indices which are not enabled, are ignored in the search.

If a single table match is found (i.e., 1 software-computed checksum in SAP1 partition matches the hardware-computed checksum for the incoming packet), this means that there is a message for this requestor in the coordinator’s message queue. For a SAP1 match, the packet processor takes these 2 steps:

1. Set SAP1_ADDR_PRESENT=1
2. Set SAP1_MATCH [6:0] to the index which matched

If multiple table matches are found (i.e., more than 1 software-computed checksum in the SAP1 partition matches the hardware-computed checksum for the incoming packet), this means that there are multiple messages for this requestor in the coordinator’s message queue. In this case, the packet processor takes the same steps as for a single match, with the SAP1_MATCH[6:0] register being set to the lowest-value matching index (i.e., the smallest number) within the SAP1 partition.

If no source address match is found in the SAP1 table search, the packet processor will set SAP1_ADDR_PRESENT=0.

Step 8: Hardware performs “Source Address Absent” Table Search

If the MAC poll request was received on PAN0, and SAA0_EN=1 to enable searches of the PAN0 “Source Address Absent” partition, the packet processor uses its Source Address checksum to look for a match in the SAA0 partition of the table. Only table entries that are enabled, are compared against (see STEP 3); table indices which are not enabled, are ignored in the search.

If one (or more) table match is found (i.e., a software-computed checksum in SAA0 partition matches the hardware-computed checksum for the incoming packet), this means that the end device which sent the poll request is a valid child of this parent. For a SAA0 match, the packet processor takes these 2 steps:

1. Set SAA0_ADDR_ABSENT=0
2. Set SAA0_MATCH[6:0] to the first index which matched

If *no* source address match is found in the SAA0 table search, the packet processor will set SAA0_ADDR_ABSENT=1.

If, on the other hand, the MAC poll request was received on PAN1, and SAA1_EN=1 to enable searches of the PAN1 “Source Address Absent” partition, the packet processor uses its Source Address checksum to look for a match in the SAA1 partition of the table. Only table entries that are enabled, are compared against (see STEP 3); table indices which are not enabled, are ignored in the search.

If one (or more) table match is found (i.e., a software-computed checksum in SAA1 partition matches the hardware-computed checksum for the incoming packet), this means that the end device which sent the poll request is a valid child of this parent. For a SAA1 match, the packet processor takes these 2 steps:

1. Set SAA1_ADDR_ABSENT=0
2. Set SAA1_MATCH[6:0] to the first index which matched

If *no* source address match is found in the SAA1 table search, the packet processor will set SAA0_ADDR_ABSENT=1.

Step 9: Hardware determines FramePending status

The packet processor maintains an internal flag called **rx_frame_pending**, which is sent to the TX_PACKET block after every received packet, to directly control the state of the FramePending subfield of the Frame Control Field in the upcoming auto-TxAck frame (if enabled with AUTOACK=1).

If the Source Address Management feature is completely disabled, i.e.,

SAP0_EN = SAA0_EN = SAP1_EN = SAA1_EN = 0

then the packet processor will set the **rx_frame_pending flag** to the value of the ACK_FRM_PND register, putting the state of FramePending under direct software control.

Otherwise, if *any* of the following conditions are met, the packet processor will set its **rx_frame_pending** flag to 1:

1. The MAC Poll Request was received on PAN0, SAP0_EN=1, and SAP0_ADDR_PRESENT=1
2. The MAC Poll Request was received on PAN1, SAP1_EN=1, and SAP1_ADDR_PRESENT=1
3. The MAC Poll Request was received on PAN0, SAA0_EN=1, and SAA0_ADDR_ABSENT=1
4. The MAC Poll Request was received on PAN1, SAA1_EN=1, and SAA1_ADDR_ABSENT=1

If none of the conditions are met, **rx_frame_pending** flag will be set to 0.

Step 10: Receive interrupt RXIRQ

The packet processor receives the remainder of the packet, and verifies the FCS. Assuming the CRC check passes, the RXIRQ interrupt is issued. In the coordinator software's RXIRQ Interrupt Service Routine, software can determine if the received packet was a MAC Poll Request by reading the PI bit of the IRQSTS register. If PI=0, the received packet was not a poll request, and no action relating to Source Address Matching need be taken.

Otherwise, if *either* SAP0_ADDR_PRESENT=1 or SAP1_ADDR_PRESENT=1, an auto-TxAck packet is being sent with the FramePending subfield set to 1, so software should follow up by constructing a data packet (or packets) for the requesting end device, with a payload consisting of the message for this device which had been stored in the coordinator's indirect queue.

Also, if *either* SAA0_ADDR_ABSENT=1 or SAA1_ADDR_ABSENT=1, an auto-TxAck packet is being sent with the FramePending subfield set to 1, so software should follow up by constructing a "Leave Message" for the requesting end device.

Step 11: Software disables the spent index

In the final step, coordinator software must disable (invalidate) the index which was just used to locate and send the stored message to the requesting end device. To disable the index:

1. Set SAM_INDEX[6:0] to the selected index
2. Set SAM_INDEX_EN=0 and SAM_INDEX_INV=1

At this point, the disabled index is now an available table entry, which can be used to install a new Address checksum for another message in the indirect queue.

55.4.9.1.2.1.3.4 Dual PAN Mode

In the past, radio transceivers designed for 802.15.4 applications allow a device to associate to one and only one PAN (Personal Area Network), at any given time. The Packet Processor includes hardware support for a device to reside on two networks simultaneously. In optional Dual PAN mode, the device will alternate between the 2 PAN's, under hardware or software control. Hardware support for Dual PAN operation consists of 2 sets of PAN and IEEE addresses for the device, 2 different channels (one for each PAN), a programmable timer to automatically switch PAN's (including on-the-fly channel-changing) without software intervention, control bits to configure and enable Dual PAN mode, and read-only bits to monitor status in Dual PAN mode. A device can be configured to be a PAN Coordinator on either network, both networks, or neither.

For the purpose of defining a "PAN" in the context of Dual PAN mode, two sets of network parameters are maintained. In this document, "PAN0" and "PAN1" will be used to refer to the 2 PAN's. Each parameter set uniquely identifies a PAN for Dual PAN mode. These parameters are:

PAN0	PAN1
CHANNEL_NUM0	CHANNEL_NUM1
MACPANID0 (16-bit register)	MACPANID1 (16-bit register)

Table continues on the next page...

Table continued from the previous page...

PAN0	PAN1
MACSHORTADDRS0 (16-bit register)	MACSHORTADDRS1 (16-bit register)
MACLONGADDRS0 (64-bit registers)	MACLONGADDRS1 (64-bit registers)
PANCORDNTR0 (1-bit register)	PANCORDNTR1 (1-bit register)

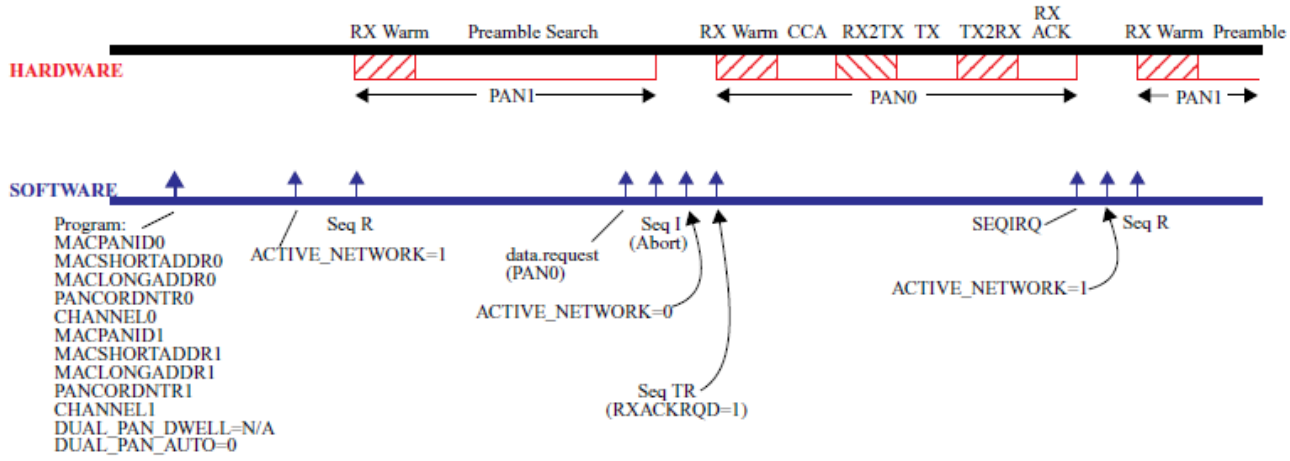
During device initialization, if Dual PAN mode is to be utilized, software will program both parameters sets, to configure the hardware for operation on two networks.

Two modes are available for Dual PAN operation: manual and automatic.

Manual Dual PAN

In manual Dual PAN mode, software controls which PAN is selected for transmission and reception, at all times. Software populates both PAN network parameter-set registers listed above. Software then selects a PAN to begin transmission or reception. A single control bit **ACTIVE_NETWORK**, selects the PAN. To select PAN0, **ACTIVE_NETWORK** should be set to 0; to select PAN1, **ACTIVE_NETWORK** should be set to 1. Software then initiates an autosequence by writing the appropriate value to XCVSEQ (PHY_CTRL1 Register). At any point, software can elect to switch to the alternate PAN. To do so, software aborts the sequence (if one is active) by writing XCVSEQ=IDLE. Software then toggles **ACTIVE_NETWORK**, and restarts a new sequence with XCVSEQ. Software is responsible for aborting and initiating sequences. Hardware is responsible for warming up the transceiver on the selected channel (CHANNEL_NUM0 or CHANNEL_NUM1), and performing address-filtering on the selected network's address parameters (PANCORDNTR, MacPanID, Short Address, and/or IEEE address). Software overhead is significantly reduced in this mode, since there is no need to re-program all of the the PAN-select registers every time the PAN is toggled in Dual PAN mode; only a single bit (**ACTIVE_NETWORK**) need be written. For manual Dual PAN operation, **DUAL_PAN_AUTO** should be set to 0.

The following diagram depicts Dual PAN operation in manual mode. In this example, software populates both PAN parameters sets during initialization. In this example, software elects to initiate packet reception on PAN1, so **ACTIVE_NETWORK** is set to 1. Software initiates the Sequence R by writing to XCVSEQ. Hardware warms up the receiver on CHANNEL_NUM1 and enters preamble-search. In this example, no packet is received, but a data request from higher-level software requires a switch to PAN0. Software responds by aborting the reception by writing Sequence I to XCVSEQ. Software then sets **ACTIVE_NETWORK** to 0 to select PAN0. In the example, software initiates a Sequence TR. Hardware warms up the receiver for CCA on CHANNEL_NUM0, performs CCA (channel is idle), warms down the receiver, and warms up the transmitter on CHANNEL_NUM0, transmits the requested packet, warms down the transmitter and warms up the receiver again (as per the autosequence) on CHANNEL_NUM0, to receive the acknowledge packet. The acknowledge packet is received and the autosequence completes successfully with RXIRQ and SEQIRQ. Software elects to resume packet reception on PAN1 (which was in progress before the data request). Software toggles **ACTIVE_NETWORK** back to 1, and re-initiates Sequence R.



Auto Dual PAN

In automatic Dual PAN mode, hardware is responsible for alternating the selected PAN, at a pre-programmed interval. Software programs a "PAN dwell time", which determines the amount of time during which the hardware will receive on a given PAN. This is done by programming the **DUAL_PAN_DWELL** register. Software sets the **DUAL_PAN_AUTO** bit to 1 for automatic Dual PAN operation, and sets **ACTIVE_NETWORK** to correspond to the PAN on which it desires packet reception to begin. Software then initiates a Sequence R. Hardware warms up the receiver on the selected PAN, and begins preamble search. When the dwell time expires, assuming preamble and SFD have not been detected, hardware will switch to the alternate PAN. This includes an on-the-fly channel change. Once switched to the alternate PAN, hardware will use the address filtering parameters (PANCORDNTR, MacPanID, Short Address, and/or IEEE address) programmed for the alternate PAN. Once the dwell time expires on the alternate PAN, assuming preamble and SFD have not been detected, hardware will switch back to the original PAN. This process will repeat indefinitely, until one of the following occurs:

1. A packet is successfully received (address match and CRC valid).
2. Software aborts the Sequence R
3. A TMR3 RX timeout, which automatically aborts the Sequence R
4. A PLL unlock automatically aborts the Sequence R (if unlock aborting is enabled)

If the hardware PAN dwell timer expires *during* a packet reception (i.e., preamble and SFD have been detected during a Sequence R), the PAN-switch will be delayed until the packet is completely received. If the packet is received successfully (address match and CRC valid), the receive sequence will terminate with RXIRQ and SEQIRQ (if an auto-Acknowledge was requested and enabled, the sequence will complete after the Acknowledge packet was transmitted, and TXIRQ will also be set, in addition to RXIRQ and SEQIRQ); the PAN switch will occur at this point, after the Sequence has returned to IDLE.

If the received packet fails FCS (CRC check), or, if the packet was not intended for the device (address mismatch), the hardware will toggle the PAN, and return to preamble-search on the new PAN.

If the hardware PAN dwell timer expires during a state *other* than RX preamble search during Sequence R (i.e., if expiration occurs during TX, CCA, ED, Sequence TR, or any warmup or transitional state), PAN-switch will be delayed until either:

1. Preamble Search state is reached during a Sequence R (not Sequence TR)
2. Sequence returns to IDLE.

At any point, software can elect to interrupt the automatic Dual PAN operation, by aborting the sequence with a XCVSEQ=IDLE, and the setting the **DUAL_PAN_AUTO** bit to 0. In response, hardware will freeze the current state of the dwell timer, and capture the currently-selected PAN, so that hardware-controlled PAN alternation can resume where it left off, later. Software can then tend to that tasks that caused the Dual PAN interruption. When software wants to resume Dual PAN operation, it then sets **DUAL_PAN_AUTO**=1, and re-initiates Sequence R. Hardware will resume the dwell timer from the point it was

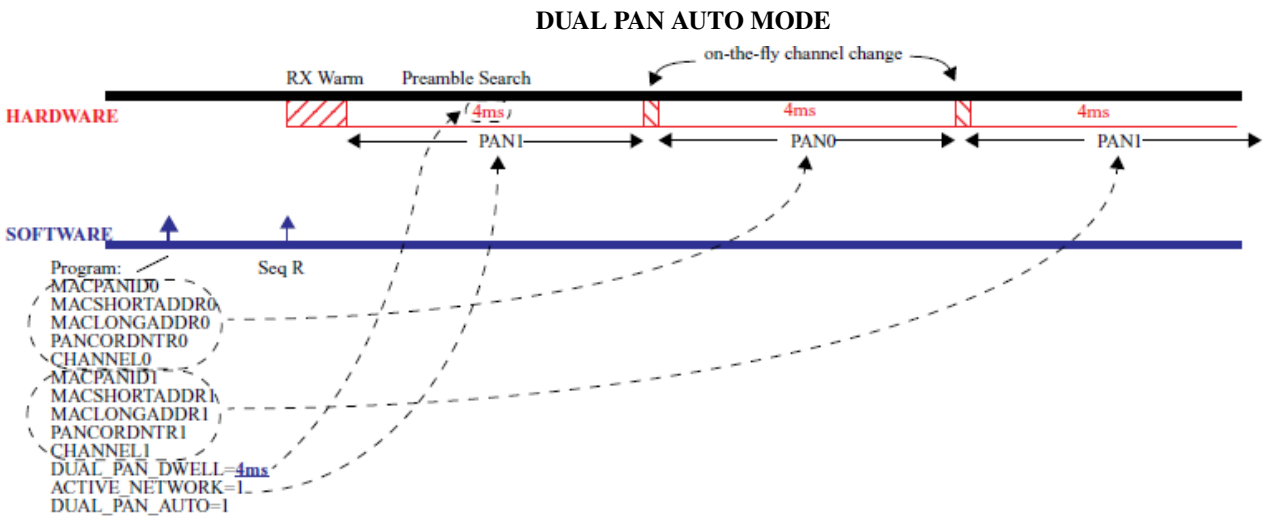
frozen earlier, on the same PAN, and will warmup the receiver to receive on the PAN which was being monitored before the interruption. Hardware will dwell on that PAN until the timer expires, and then switch PAN's (assuming no preamble and SFD detected, subject to the conditions listed above). Software can always determine the selected PAN at any time, in any mode, by reading **CURRENT_NETWORK** bit. If **DUAL_PAN_AUTO**=0, then **CURRENT_NETWORK** = **ACTIVE_NETWORK**. If **DUAL_PAN_AUTO**=1, then **CURRENT_NETWORK** is controlled by hardware.

To initiate auto Dual PAN operation for the first time, or to reset the dwell timer to its programmed value and allow software to select the initial PAN for auto Dual PAN operation, software should program the desired initial PAN to **ACTIVE_NETWORK** (0 for PAN0, 1 for PAN1), and then program the desired dwell time into the **DUAL_PAN_DWELL** register. Hardware always responds to a write to **DUAL_PAN_DWELL**, by resetting the dwell timer to its programmed value, and selecting the initial PAN for auto Dual PAN operation, based on the state of **ACTIVE_NETWORK**. A write to **DUAL_PAN_DWELL**, always re-initializes the DWELL TIMER to the programmed value. If a write to **DUAL_PAN_DWELL** occurs during an autosequence, the DWELL TIMER will begin counting down immediately. If a write to **DUAL_PAN_DWELL** occurs when there is no autosequence underway, the DWELL TIMER will not begin counting until the next autosequence begins; it will begin counting at the start of the autosequence warmup. Under all circumstances, **DUAL_PAN_AUTO** must be asserted to allow the DWELL TIMER to count. If **DUAL_PAN_AUTO**=0, the DWELL TIMER will freeze and hold its state, until **DUAL_PAN_AUTO**=1. However, a write to **DUAL_PAN_DWELL** will still initialize the DWELL TIMER to its programmed value, regardless of the state of **DUAL_PAN_AUTO**.

At any point during auto Dual PAN mode, software can ascertain the PAN currently being serviced by hardware, by reading the **CURRENT_NETWORK** bit. Software can also determine the time-remaining in the current dwell, by reading the **DUAL_PAN_REMAIN** Register.

In auto Dual PAN mode, software retains responsibility for initiating and aborting sequences. There is no provision for hardware-initiated sequences. TMR2 may be used to initiate an autosequence at a future time. TMR3 may be used as an RX hardware-abort mechanism.

The following diagram depicts Dual PAN operation in automatic mode. In this example, software populates both PAN parameters sets during initialization. In this example, software wants to initiate packet reception in auto Dual PAN mode, on PAN1, so **ACTIVE_NETWORK** is set to 1. For auto Dual PAN operation, software programs the desired PAN-switching interval into **DUAL_PAN_DWELL** register, in this case, 4ms. Software initiates the Sequence R by writing to XCVSEQ. The dwell timer begins counting as soon as the receiver warmup begins. Hardware warms up the receiver on CHANNEL_NUM1 (since PAN1 was selected as the initial PAN in this example), and begins preamble search. If a packet is received during this interval, hardware applies PAN1 address filtering. In this example, no preamble is detected at the point at which the dwell timer expires. So, at this point, hardware executes a PAN-switch to PAN0. which includes an on-the-fly channel change. The on-the-fly channel change requires approximately 93us and no preamble detection is possible during this "blind spot". (For more details on how the hardware executes the Dual PAN on-the-fly channel change, see Chapter ZSM Sequence Manager, Section Dual PAN Mode.) After the PAN switch, hardware resumes preamble search on CHANNEL_NUM0, and applies PAN0 address filtering if a packet is received. In this example, no preamble is detected at the point at which the dwell timer expires. So, at this point, hardware performs a PAN-switch back to PAN1. And so on and so forth.



Two-PAN-one-channel

A special case occurs if a device is operating in Dual PAN mode (either Auto or Manual mode), and both PAN's occupy the same channel; in other words, CHANNEL_NUM0=CHANNEL_NUM1. In this case, hardware will detect this condition automatically, and apply both sets of address-filtering parameters simultaneously. Hardware will provide Data Indication if the received packet matches either the PAN0 address parameter set {**MACPANID0, MACSHORTADDRS0, MACLONGADDRS0, PANCORDNTR0**}, or the PAN1 address parameter set {**MACPANID1, MACSHORTADDRS1, MACLONGADDRS1, PANCORDNTR1**}. At Data Indication, two status bits can be queried by software to quickly determine on which PAN the packet was received, **RECD_ON_PAN0** or **RECD_ON_PAN1**. In the "Two-PAN-one-channel" scenario, it is possible for a packet to satisfy both sets of addressing parameters (PAN0 and PAN1). When this happens, both **RECD_ON_PAN0** and **RECD_ON_PAN1** will be set. In the "Two-PAN-one-channel" scenario, the **CURRENT_NETWORK** bit should be ignored, since both networks are simultaneously active.

If Dual PAN mode is not to be utilized, **ACTIVE_NETWORK** should be maintained at 0 (default) to select the PAN0 parameters for transceiving. In single PAN operation, the PAN1 parameter registers need not be programmed, and can be used as scratchpad. CHANNEL_NUM1 should not be programmed, and should instead be left in its default state, if Dual PAN mode is not in use.

Dual PAN Channel Override

In Dual PAN mode, in case there is a need to generate a frequency which may be offset from the 16 prescribed 5MHz-spaced channels, to, for example, avoid interference on one of the Dual PAN channels, a method has been provided to do that, by designating one of the two PAN channels to use the transceiver's set of direct frequency-programming registers, instead of CHANNEL_NUMx. Programming the direct frequency-programming registers – integer, numerator, and denominator, allows an RF frequency to be selected with much more precision than the 5MHz granularity of the 802.15.4 mapped-channel registers, CHANNEL_NUM0 and CHANNEL_NUM1. This is referred to as "Dual PAN Channel Override". For more details on this feature, see Chapter ZSM Sequence Manager, Section Dual PAN Channel Override.

55.4.9.1.2.1.3.5 Active Promiscuous Mode

Functional description

The 802.15.4 Wireless Medium Access Control (MAC) and Physical Layer (PHY) Specifications for Low-Rate Wireless Personal Area Networks (WPANs) defines the following behavior for Promiscuous Mode operation:

> "In promiscuous mode, the MAC sublayer shall pass all frames received after the first filter directly to the upper layers without applying any more filtering or processing."

Where first level filtering is described as:

> "For the first level of filtering, the MAC sublayer shall discard all received frames that do not contain a correct value in their FCS field in the MFR (see 7.2.1.9)"

Promiscuous mode allows a device to receive and process all 802.15.4 frames which pass FCS check (CRC), regardless of whether or not they are addressed to the device. This allows a device to receive and process all valid traffic on a network. In Promiscuous mode, the Packet Processor will provide a Data Indication on all such packets. This capability allows a simple network sniffer to be constructed, which can display comprehensive packet data for all packets transmitted on a network within receiving range of the device.

Since a device operating in promiscuous mode is designed to do so discreetly, automatic acknowledgement of all received packets is inhibited, regardless of the state of the Ack Request field in the Frame Control Field of the received packet; otherwise, the sniffing device would be acknowledging received frames for which it was not the addressee.

The Packet Processor features an "Active Promiscuous Mode". In this mode, the Packet Processor will process packets according to the same rules that it applies to Promiscuous mode, except that it will automatically transmit an acknowledgement packet *for frames that are addressed to the device*. In other words, in Active Promiscuous mode, if the received frame meets all the address and packet filtering requirements that would have applied in non-promiscuous mode, an acknowledgement packet will be transmitted; a Data Indication will still be provided for all valid packets (those which pass FCS check). Note that all existing packet processor rules governing transmission of acknowledge packets, are still in effect; i.e., AUTOACK bit of the PHY_CTRL1 Register must be set to 1, and the Ack Request field in the Frame Control Field of the received packet must be set to 1.

The Packet Processor can be also programmed to provide a Data Indication for packets which fail FCS check, by setting CRC_MSK=0. Received packets which fail FCS check are never acknowledged, under any circumstances.

Special Handling for Broadcast Packets

Special rules apply to received packets which contain a broadcast PAN Identifier (0xffff), and/or a broadcast short address (0xffff). According to the 802.15.4 standard,

> “For valid frames that are not broadcast, if the Frame Type subfield indicates a data or MAC command frame and the Acknowledgment Request subfield of the Frame Control field is set to one, the MAC sublayer shall send an acknowledgment frame."

An exception is made for received packets which contain a broadcast PAN Identifier, and a long address which matches the device’s IEEE address. Such packets are acknowledged, because the IEEE address uniquely identifies the device, regardless of PAN. This special case will apply also in Active Promiscuous mode; such packets will be acknowledged. The following diagram describes the packet processor’s "acknowledgement decision" for all permutations of broadcast indicators in the received packet’s addressing fields.

ACKNOWLEDGE-ON-BROADCAST (ALL PERMUTATIONS)

DESTINATION ADDRESS MODE	PAN ID = !BROADCAST DSTADDR = !BROADCAST	PAN ID = !BROADCAST DSTADDR = BROADCAST	PAN ID = BROADCAST DSTADDR = BROADCAST	PAN ID = BROADCAST DSTADDR = !BROADCAST
SHORT	ACK	NO ACK	NO ACK	NO ACK
LONG	ACK			ACK

Special Handling for Broadcast Packets

The Packet Processor features an autosequence to automatically receive, and verify, Acknowledge Frames after a Transmit frame has been sent by the device. This is accomplished by programming a Sequence TR with RXACKRQD=1. During normal operation, these receive Acknowledge Frames are not stored in the Packet Buffer. They are merely checked for matching Sequence Number and Frame Version, with a Data Indication issued for a valid match on both. In Active Promiscuous Mode, receive Acknowledge frames *will* be stored into the Packet Buffer, just like any other received frame. This saves software from having to re-construct the contents of the Acknowledge packet, from the contents of the packet which was originally transmitted. Ordinary Promiscuous Mode should therefore not be used with Sequence TR with RXACKRQD=1. Use Active Promiscuous instead.

55.4.9.1.2.1.3.6 Provisions to Enable Software Support for 802.15.4e and 802.15.4-2015

Addendum 802.15.4e to the 802.15.4-2011 standard introduces 3 new variations on the 802.15.4 MAC Frame Structure:

1. FrameVersion=2 (Frame Types: Beacon, Acknowledge, Data, and MAC Command)
2. LLDN Frame Type
3. Multipurpose Frame Type

In addition, the 802.15.4-2015 revision to the standard introduces a new Frame Type: Extended (Frame Type = 0b111).

All three of the “4e-compliant packets”, as well as the Extended Frame Type, modify the format and definition of the Frame Control Field in such a way as to render parsing of the MHR by the packet processor impossible, without major upgrades to the hardware. For example, the packet processor hardware does not support 8-bit (simple) addressing, nor Sequence Number Suppression.

As in interim solution, provisions have been added to the packet processor to allow these new packet variations to be recognized and conditionally admitted (Data Indication to software). Three new Frame Type control bits, and a modification of the Frame Version Filtering bits, are included in the Packet Processor, and affect hardware packet parsing as indicated in the following table:

REGISTER	DEFINITION
FRM_VER_FILTER[3:0]	Frame Version selector. The incoming packet's Frame Control Field is parsed to obtain the FrameVersion subfield, and that value is compared against this register, in accordance with the following: xxx1: Accept received packets with FrameVersion=00 xx1x: Accept received packets with FrameVersion=01 x1xx: Accept received packets with FrameVersion=10 1xxx: Accept received packets with FrameVersion=11 These filtering rules apply to Beacon, Acknowledge, Data, and MAC Command Frame Types, since these frame types require a 2-octet Frame Control Field which embeds a 2-bit FrameVersion subfield. Later frame types introduced in the 802.15.4e addendum (LLDN, Multipurpose) don't guarantee a FrameVersion subfield with the original meaning, so these filtering rules do not apply to those frame types. See registers LLDN_FT and MULTIPURPOSE_FT.
LLDN_FT	1: LLDN frame type enabled (Frame Type 4) 0: reject all LLDN frames
MULTIPURPOSE_FT	1: Multipurpose frame type enabled (Frame Type 5) 0: reject all Multipurpose frames
EXTENDED_FT	1: Extended frame type enabled (Frame Type 7) 0: reject all Extended frames

The Extended Frame Type does not comply with the General MAC Frame Format, which is shown in the following diagram:

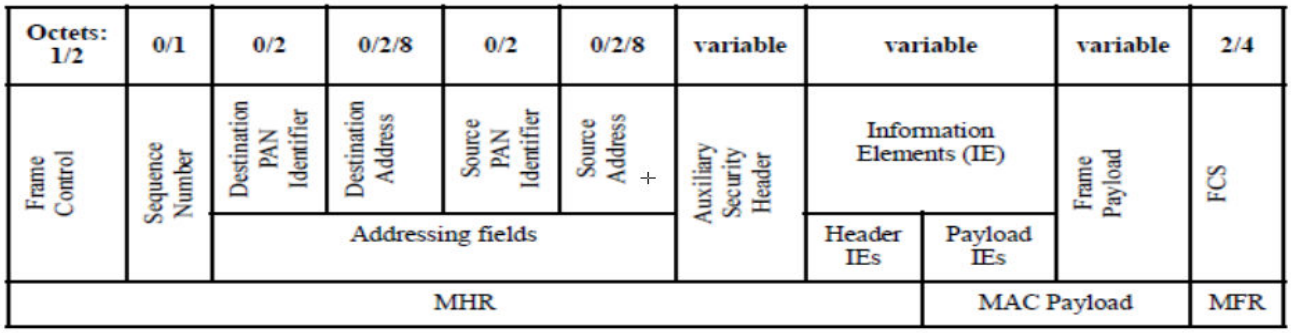


Figure 380. General MAC Frame Format

Instead, the Extended Frame has its own unique format, which is shown in the following diagram:

Bits: 0-2	3-5	variable
Frame Type	Extended Frame Type	Extended Frame Payload

Figure 381. Extended Frame Format

Because the Extended Frame Payload, which is not defined in the 802.15.4-2015 revision to the standard, would be intended to contain and fully specify the FCS, the Packet Processor will not be able to verify FCS on received packets with Frame Type Extended. FCS checking will need to be implemented in software.

Note: If the EXTENDED_FT bit is set to enable Data Indication on packets of Frame Type Extended, software should expect a substantial increase in the frequency of notifications, as a consequence of the lack of hardware verification of FCS, which will have implications for software workload as well as power consumption in the SoC.

When the packet processor receives any of the 4e-compliant frames, if the corresponding control bit is set, the hardware will skip Stage 2 filtering, and merely verify FCS. If FCS passes, the packet processor will notify software of the packet, without inspection of the addressing fields or payload. For such packets, software will be responsible for parsing the MHR and payload sections of the frame. If the corresponding control bit is not set, the packet processor will reject the received packet and there will be no Data Indication.

When the packet processor receives a packet of Frame Type Extended, if the EXTENDED_FT bit is set, the hardware will skip Stage 2 filtering, and after the entire packet is received, the packet processor will merely notify software of the packet, without inspection of the Extended Frame Type bits or the Extended Frame Payload. For such packets, software will be responsible for parsing the Extended Frame Type and the Extended Frame Payload sections of the frame. If the corresponding control bit is not set, the packet processor will reject the received packet and there will be no Data Indication.

Like all existing frames prior to 802.15.4e and 802.15.4-2015, a received frame may require an acknowledgement. In the case of the new 802.15.4e and 802.15.4-2015 frames, the required timing for the acknowledge frame transmission, has been modified. The acknowledgement no longer immediately follows the packet reception. For this reason, upon reception of any of these 4e-compliant 2015-compliant packets, the packet processor will cancel any auto-ACK transmission, regardless of the state of the PHY_CTRL[AUTOACK] bit and AR field of the received packet's Frame Control Field. Software will be responsible for constructing the acknowledgment packet and transmitting it at the appropriate time using a Sequence T.

To help expedite software processing of the 4e- and 2015-compliant Frame Types and Versions, additional status bits have been added to the 802.15.4 register set, which are described in the following table:

STATUS BIT	RESIDES IN REGISTER	DEFINITION
ENH_PKT_STATUS	IRQSTS	1: The last packet received was 4e- or 2015-compliant (SW should query the RX_FRAME_FILTER register for additional status bits) 0: The last packet received was neither 4e- nor 2015-compliant
BEACON_FV2_RECD	RX_FRAME_FILTER	1: The last packet received was a FrameType Beacon with FrameVersion 2 0: The last packet received was not a FrameType Beacon with FrameVersion 2
DATA_FV2_RECD	RX_FRAME_FILTER	1: The last packet received was a FrameType Data with FrameVersion 2

Table continues on the next page...

Table continued from the previous page...

		0: The last packet received was not a FrameType Data with FrameVersion 2
ACK_FV2_RECD	RX_FRAME_FILTER	1: The last packet received was a FrameType Acknowledge with FrameVersion 2 0: The last packet received was not a FrameType Acknowledge with FrameVersion 2
CMD_FV2_RECD	RX_FRAME_FILTER	1: The last packet received was a FrameType MAC Command with FrameVersion 2 0: The last packet received was not a FrameType MAC Command with FrameVersion 2
LLDN_RECD	RX_FRAME_FILTER	1: The last packet received was a FrameType LLDN 0: The last packet received was not a FrameType LLDN
MULTIPURPOSE_RECD	RX_FRAME_FILTER	1: The last packet received was a FrameType Multipurpose with FrameVersion 2 0: The last packet received was not a FrameType Multipurpose
EXTENDED_RECD	RX_FRAME_FILTER	1: The last packet received was a FrameType Extended 0: The last packet received was not a FrameType Extended

The new status bits are mapped into the 802.15.4 Address space as shown in the diagram below:

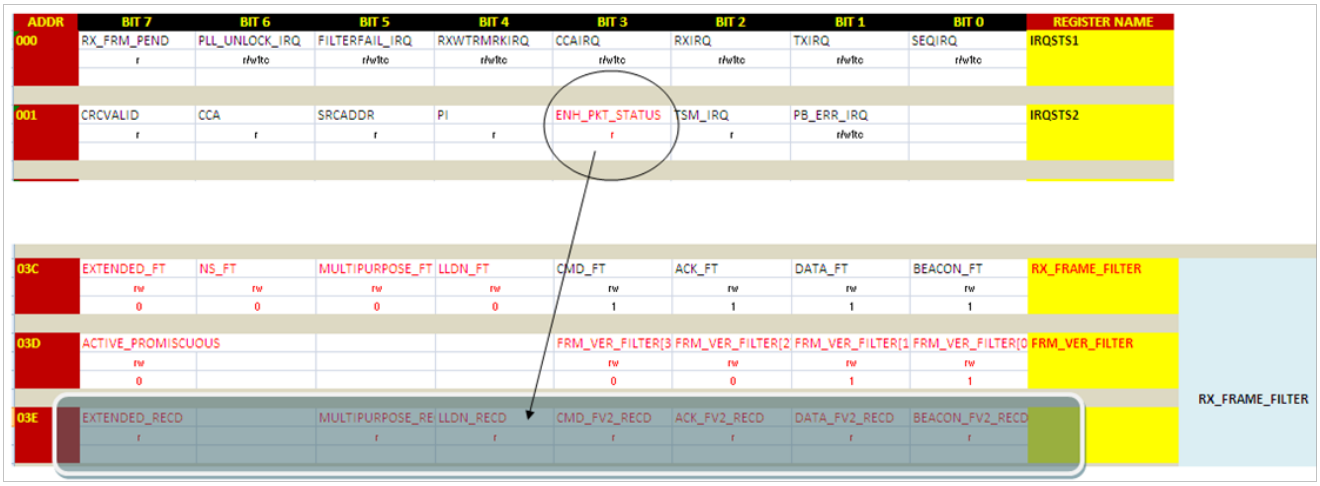

Figure 382. Enhanced Packet Status Bits

55.4.9.1.2.1.3.7 Clocks

Packet Processor is a fully synchronous module. It has a single clock input **clk_250khz**. The clock frequency, 250KHz, is the 802.15.4 bit rate. This clock input is driven by a divide-down of the RF Oscillator, generated in the CRM (Clocks and Resets module). The Packet Processor has no asynchronous interfaces.

55.4.9.1.2.1.3.8 Reset

The Packet Processor has a single, active-low, asynchronous reset input: **rst_b** . At integration, this reset should be tied to the master reset for the entire transceiver. There are no special reset requirements.

55.4.9.1.2.1.3.9 Interrupts

The Packet Processor does not generate any interrupts.

55.4.9.1.2.1.3.10 Appendix A

FILTERFAIL CODES

A description of the FILTERFAIL codes can be found in the following table.

FILTERFAIL CODE BIT	REASON FOR FILTERFAIL
[0]	Fails Stage 1 Frame Length Checking (FL < 5 or FL > MAXFRAMELENGTH) **Note:** FL < 3 will not generate an SFD, so this bit will not be set
[1]	Fails Stage 1 Section 7.2.1.1.6 or Section 7.2.1.1.8 Checking (DST_ADDR_MODE or SRC_ADDR_MODE = 1)
[2]	For frame version 0 or 1, fails Stage 1 Section 7.2.1.1.5 Checking (Illegal PAN_ID_COMPRESSION Usage); For frame version 2, fails Stage 1 checking not supported cases in 802.15.4-2015 Table 7-2, see leniency[40] for the not supported cases.
[3]	Fails Stage 1 Frame Version Checking
[4]	Fails Stage 2 Auto-RxAck Checking (Illegal Ack Frame Format in Sequence TR)
[5]	Fails Stage 2 Frame Type Checking (Incorrect Frame Filter Bit setting)
[6]	Fails Stage 2 Frame Length Checking (Illegal Beacon, Data, or Cmd FL)
[7]	Fails Stage 2 Addressing Mode Checking (Illegal Addressing Mode for Beacon, Data, OR Cmd)
[8]	Fails Stage 2 Sequence Number Matching (Sequence TR Only)
[9]	Fails Stage 2 PAN ID or Address Checking (Beacon, Data, or Cmd)

55.4.9.1.2.1.3.11 Appendix B

LENIENCY BITS

The Packet Processor performs filtering on all received packets, in order to determine whether the packet is intended for the device. The packet filtering is based on rules. In case any of the packet filtering rules need to be overridden, a 43-bit "leniency register" has been provided. When the leniency register is programmed to its default value (0), all hardware packet filtering rules are in effect, and if an incoming packet violates any rule, a "Filter Fail" will occur (packet will be rejected). When a given leniency register bit is asserted, the packet filtering rule assigned to that bit will not be in effect, and if any incoming packet violates that rule (but no other rules), then a "Filter Fail" will not occur, the packet will not be rejected, the packet will be treated as "intended for the device", and software will be notified of the incoming packet. The table below shows the assignment of leniency bits to packet filtering rules.

LENIENCY BIT	PACKET FILTERING RULE OVERRIDDEN
leniency[0]	Override Stage 1 Frame Length Checking (FL < 5 or FL > MAXFRAMELENGTH)

leniency[1]	Override Stage 1 Section 7.2.1.1.6 Checking (DST_ADDR_MODE = 1)
leniency[2]	Override Stage 1 Section 7.2.1.1.8 Checking (SRC_ADDR_MODE = 1)
leniency[3]	Override Stage 1 Section 7.2.1.1.5 Checking (Illegal PAN_ID_COMPRESSION Usage)
leniency[4]	Override Stage 2 Auto-RxAck Checking (Illegal Ack Frame Format in Sequence TR)
leniency[5]	Override Stage 2 Frame Length Checking (Illegal Beacon, Data, or Cmd FL)
leniency[6]	Override Stage 2 Beacon Frame Address Mode Violations
leniency[7]	Override Stage 2 Data Frame Address Mode Violations
leniency[8]	Override Stage 2 MAC Command Frame Address Mode Violations
leniency[9]	Override Stage 2 Sequence Number Matching
leniency[10]	Override Stage 2 Filter for DST_ADDR_MODE_NONE/SRC_ADDR_MODE_SHORT (Beacon Only)
leniency[11]	Override Stage 2 Filter for DST_ADDR_MODE_NONE/SRC_ADDR_MODE_SHORT (Data and MAC Command Only)
leniency[12]	Override Stage 2 Dst PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_NONE (Data and MAC Command Only)
leniency[13]	Override Stage 2 Dst Short Addr Filter for DST_ADDR_MODE_SHORT/ SRC_ADDR_MODE_NONE (Data and MAC Command Only)
leniency[14]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_SHORT/ PAN_ID_COMPRESSION (Beacon Only)
leniency[15]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_SHORT/ PAN_ID_COMPRESSION (Data and MAC Command Only)
leniency[16]	Override Stage 2 Dst Short Addr Filter for DST_ADDR_MODE_SHORT/ SRC_ADDR_MODE_SHORT/PAN_ID_COMPRESSION (Data and MAC Command Only)
leniency[17]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_SHORT/ NO_PAN_ID_COMPRESSION (Beacon Only)
leniency[18]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_SHORT/ NO_PAN_ID_COMPRESS ION (Data and MAC Command Only)
leniency[19]	Override Stage 2 Dst Addr Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_SHORT/ NO_PAN_ID_COMPRESSION (Data and MAC Command Only)
leniency[20]	Override Stage 2 Src PAN ID Filter for DST_ADDR_MODE_NONE/SRC_ADDR_MODE_LONG/ NO_PAN_ID_COMPRESSION (Beacon Only)
leniency[21]	Override Stage 2 Src PAN ID Filter for DST_ADDR_MODE_NONE/SRC_ADDR_MODE_LONG/ NO_PAN_ID_COMPRESSION (Data and MAC Command Only)
leniency[22]	Override Stage 2 Dst PAN ID Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_NONE (Data and MAC Command Only)
leniency[23]	Override Stage 2 Dst Long Addr Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_NONE (Data and MAC Command Only)

Table continues on the next page...

Table continued from the previous page...

LENIENCY BIT	PACKET FILTERING RULE OVERRIDDEN
leniency[24]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_LONG/ PAN_ID_COMPRESSION (Beacon Only)
leniency[25]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_LONG/ PAN_ID_COMPRESSION (Data and MAC Command Only)
leniency[26]	Override Stage 2 Dst Long Addr Filter for DST_ADDR_MODE_SHORT/ SRC_ADDR_MODE_LONG/PAN_ID_COMPRESSION (Data and MAC Command Only)
leniency[27]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_SHORT/ PAN_ID_COMPRESSION (Beacon Only)
leniency[28]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_SHORT/ PAN_ID_COMPRESSION (Data and Mac Command Only)
leniency[29]	Override Stage 2 Dst Long Addr Filter for DST_ADDR_MODE_LONG/ SRC_ADDR_MODE_SHORT/PAN_ID_COMPRESSION (Data and Mac Command Only)
leniency[30]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_LONG/ NO_PAN_ID_COMPRESSION (Beacon Only)
leniency[31]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_LONG/ NO_PAN_ID_COMPRESSION (Data and MAC Command Only)
leniency[32]	Override Stage 2 Short Addr Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_LONG/ NO_PAN_ID_COMPRESSION (Data and MAC Command Only)
leniency[33]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_SHORT/ NO_PAN_ID_COMPRESSION (Beacon Only)
leniency[34]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_SHORT/ NO_PAN_ID_COMPRESSI ON (Data and MAC Command Only)
leniency[35]	Override Stage 2 Long Addr Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_SHORT/ NO_PAN_ID_COMPRESSION (Data and MAC Command Only)
leniency[36]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_LONG (Beacon Only)
leniency[37]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_LONG (Data and MAC Command Only)
leniency[38]	Override Stage 2 Long Addr Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_LONG (Data and MAC Command Only)
leniency[39]	Allow an auto-TxAck frame to be sent, after a receive frame which has all of the following parameters: 1. Destination PAN ID = Broadcast (0xFFFF) 2. Destination Address = !Broadcast (not 0xFFFF) 3. Destination Address Mode = Short Nominally, the SEQ_MGR inhibits auto-TxAck on such frames.
leniency[40]	Override Stage 1 for frame version 2 not supported cases in 802.15.4-2015 Table 7-2. See detail in Chapter "Enhanced Acknowledgment (Enh-Ack) Support".

Table continues on the next page...

Table continued from the previous page...

LENIENCY BIT	PACKET FILTERING RULE OVERRIDDEN
leniency[41]	Override Stage 2 Auto-RxAck Checking (Illegal EnhAck Frame Format in Sequence TR). 1. The received PAN ID Compression matches the transmitted PAN ID Compression 2. The received Sequence Number Suppression matches the transmitted Sequence Number Suppression 3. The received Destination Address Mode matches the transmitted Source Address Mode
leniency[42]	Override Stage 2 Auto-RxAck Checking (Illegal EnhAck Frame Format in Sequence TR). 1. The Destination Address field, when present, shall contain the value of the Source Address field from the frame that is being acknowledged. 2. The Destination PAN ID, when present, contains the value from the Source PAN ID field from the frame that is being acknowledged.

55.4.9.1.2.2 Sequence Manager

55.4.9.1.2.2.1 Introduction

This Section describes the 802.15.4 Sequence Manager.

55.4.9.1.2.2.1.1 Overview

The 802.15.4 Sequence Manager (ZSM) is a hardware state machine which controls the timing of all transmit, receive, and CCA operations for the 802.15.4 Link Layer. The ZSM manages high-level 802.15.4 required timing (autosequences), and interfaces directly with a lower-level, protocol-neutral sequence manager called the Transceiver Sequence Manager (TSM), which manages the direct control of the digital, analog, and RF components of the 2.4GHz transceiver. See the TSM Chapter for more details.

For each digital and analog element in the 2.4GHz transceiver, the ZSM and TSM operate seamlessly and collaboratively, to perform some or all of the following functions:

- activation
- deactivation
- initialization
- mode transitions
- initiating calibration routines
- clock enabling and disabling
- interrupt triggering and status generation

Designed into the ZSM are a variety of complex sequences, called autosequences, which are sequential concatenations of simpler, building-block sequences. The hardware autosequences provide the following advantages:

- smaller SW memory footprint: HW automates operations previously done by SW
- increases MCU sleep times, reducing current consumption
- handles timing-critical sequences (rx-to-tx), e.g., data-polling, not possible in SW

Sequences can be initiated by software directly, or alternatively, can be initiated automatically at the expiration of a hardware timer. The general parameters of the sequences can be programmed by software prior to initiating the sequences. Such parameters allow software to select, for example:

- whether CCA is required ahead of a transmit sequence
- whether an automatic Ack frame should be transmitted after a receive sequence

- slotted vs. unslotted mode
- type of CCA (e.g., Energy Detect, CCA Mode 2)
- whether the device is a PAN Coordinator or not
- whether the device resides on 2 networks simultaneously (Dual PAN mode)

The ZSM also includes support for Dual PAN Mode, and Active Promiscuous Mode.

55.4.9.1.2.2.1.2 Features

- Supports complex sequences
- Unburdens software by automating many transceiver operations
- Data-polling accelerator hardware enables critical-timing sequences
- Includes Continuous CCA for low-latency-transmit applications
- Includes capability to conditionally perform CCA prior to every transmit operation
- Includes capability to conditionally transmit an Ack frame after every receive operation
- Supports software- or timer-initiated sequences
- Fully supports 2003 and 2006 versions of the 802.15.4 standard
- Supports slotted and unslotted modes
- Supports beacon-enabled and non-beacon-enabled networks
- Supports orderly transceiver shutdown on PLL unlock event
- Increases software visibility by making SEQ_STATE state readable
- Supports Dual PAN Mode, including on-the-fly channel changing
- Supports Active Promiscuous Mode

55.4.9.1.2.2.1.3 Modes and operations

The ZSM controls, coordinates, and automates all 802.15.4 transceiver operations within the 2.4GHz radio. Software selects the desired sequence, sets the general parameters, and (optionally) configures a hardware timer to trigger the sequence at a precise time in the future. Subsequently, the MCU can enter a low-power state, or tend to other activities, while the sequence manager state machine conducts the programmed transceiver operations. When the sequence completes, an interrupt alerts the MCU. At this point the MCU can check the completion status of the sequence, download received data from the packet buffer, and then prepare the next sequence. Sequences can be simple transceiver operations. For example, transmit one frame, or, perform a CCA on a channel. Alternatively, the sequence manager supports complex sequences, which use simple operations as building blocks, strung together in a back-to-back fashion, with precise timing intervals between operations. For example, a “TR” sequence calls for a transmit frame followed by a receive frame. For complex sequences, interrupts can optionally be generated at the completion of each stage of the sequence, providing greater visibility for the MCU into the timeline of the sequence. Software can determine the precise state of the sequence manager state machine at any time. Software can opt to abort a sequence at any time; when this happens, the sequence manager will return to its IDLE state in an orderly fashion.

55.4.9.1.2.2.1.4 Block diagram

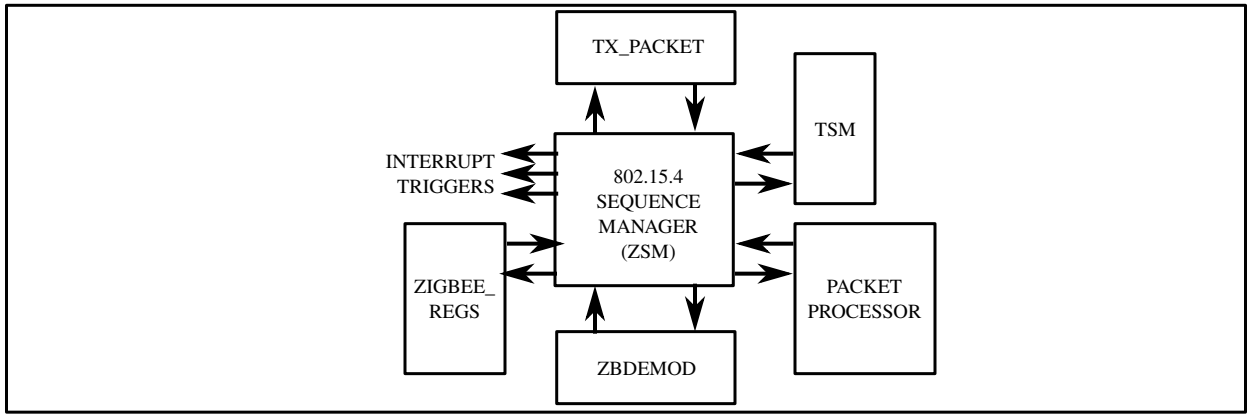

Figure 383. Block diagram

55.4.9.1.2.2.2 Memory Map and register definition

Numerous registers exist to provide configuration and status for the 802.15.4 Sequence Manager. See table below.

<table>
<tr><th>Field</th><th>R/W</th><th>Description</th></tr>
<tr><td>XCVSEQ</td><td>rw</td><td>The Transceiver Sequence Selector register selects a sequence for the sequence manager to execute. Sequence initiation can be immediate, or scheduled (see TMRTRIGEN). A write of XCVSEQ=IDLE will abort any ongoing sequence. A write of XCVSEQ=IDLE must always be performed after a sequence is complete, and before a new sequence is programmed. Any write to XCVSEQ other than XCVSEQ=IDLE during an ongoing sequence, shall be ignored. The mapping of XCVSEQ to sequence types is as follows:
<table>
<tr><th>XCVSEQ</th><th>SEQUENCE</th><th>DESCRIPTION</th></tr>
<tr><td>0</td><td>I</td><td>IDLE</td></tr>
<tr><td>1</td><td>R</td><td>RECEIVE</td></tr>
<tr><td>2</td><td>T</td><td>TRANSMIT</td></tr>
<tr><td>3</td><td>C</td><td>CCA</td></tr>
<tr><td>4</td><td>TR</td><td>TRANSMIT/RECEIVE</td></tr>
<tr><td>5</td><td>CCCA</td><td>CONTINUOUS CCA</td></tr>
</table></td></tr>
<tr><td>TMRTRIGEN</td><td>rw</td><td>Timer2 Trigger Enable.
1: allow timer TC2 (or TC2') to initiate a preprogrammed sequence (see XCVSEQ register).
0: programmed sequence initiates immediately upon write to XCVSEQ.</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

Field	R/W	Description
CCABFRTX	rw	CCA Before TX. Applies only to Sequences T and TR, ignored during all other sequences. 1: at least one CCA measurement is required prior to the transmit operation (see also SLOTTED). 0: no CCA required, transmit operation begins immediately.
SLOTTED	rw	Slotted Mode, for beacon-enabled networks. Applies only to Sequences T, TR, and R, ignored during all other sequences. Used, in concert with CCABFRTX, to determine how many CCA measurements are required prior to a transmit operation. Also used during R sequence to determine whether the ensuing transmit acknowledge frame (if any) needs to be synchronized to a backoff slot boundary.
RXACKRQD	rw	Receive Acknowledge Frame required. Applies only to Sequence TR, ignored during all other sequences. 1: A receive Ack frame follows the transmit frame. 0: An ordinary receive frame (not an Ack frame) follows the transmit frame.
AUTOACK	rw	Auto Acknowledge Enable. Applies only to Sequence R and Sequence TR, ignored during other sequences. 1: sequence manager will follow a receive frame with an automatic hardware-generated Tx Ack frame, assuming other necessary conditions are met. 0: sequence manager will not follow a receive frame with a Tx Ack frame, under any conditions; the sequence will terminate after the receive frame.
CRC_MSK	rw	CRC Mask. 1: sequence manager requires CRCVALID=1 at the end of the received frame in order for the receive operation to complete successfully; if CRCVALID=0, sequence manager will return to preamble-detect mode after the last octet of the frame has been received. 0: sequence manager ignores CRCVALID and considers the receive operation complete after the last octet of the frame has been received.
PROMISCUOUS	rw	Prevents auto-TxAck on received packets 1: promiscuous mode, no auto-TxAck 0: auto-TxAck allowed, depending on other conditions.
CCATYPE[1:0]	rw	Clear Channel Assessment Type. Selects one of four possible functions for CCA or ED, per below. (See Chapter CCA/ED/LQI for more details). 00: ENERGY DETECT 01: CCA MODE 1

Table continues on the next page...

Table continued from the previous page...

Field	R/W	Description
		10: CCA MODE 2 11: CCA MODE 3
TC3TMOUT	rw	1: Allow a TMR3 timeout to abort any RX operation 0: Don't allow a TMR3 timeout to abort any RX operation See Appendix A for more details on how autosequences are affected by a TMR3 timeout
SEQ_STATE[4:0]	r	This read-only register reflects realtime 802.15.4 Sequence Manager (ZSM) state
ACTIVE_PROMISCUOUS	rw	1: Provide Data Indication on all received packets under the same rules which apply in PROMISCUOUS mode, however acknowledge those packets under rules which apply in non-PROMISCUOUS mode 0: normal operation (Default)
ACTIVE_NETWORK	rw	Selects the PAN on which to transceive, by activating a PAN parameter set (PAN0 or PAN1). In Manual Dual PAN mode (or Single PAN mode), this bit selects the active PAN parameter set (channel and addressing parameters) which governs all autosequences. In Auto Dual PAN mode, this bit selects the PAN on which to begin transceiving, latched at the point at which DUAL_PAN_DWELL register is written. 1: Select PAN1 0: Select PAN0 (Default)
DUAL_PAN_AUTO	rw	Activates automatic Dual PAN operating mode. In this mode, PAN-switching is controlled by hardware at a pre-programmed rate, determined by DUAL_PAN_DWELL. 1: Auto Dual PAN Mode 0: Manual Dual PAN mode (or Single PAN mode). Default. Whenever DUAL_PAN_AUTO=0, CURRENT_NETWORK=ACTIVE_NETWORK at all times. In other words, software directly controls which PAN is selected. Whenever DUAL_PAN_AUTO=1, CURRENT_NETWORK is controlled by hardware
CURRENT_NETWORK	r	This read-only bit indicates which PAN is currently selected by hardware in automatic Dual PAN mode 1: PAN1 is selected 0: PAN0 is selected
DUAL_PAN_DWELL[7:0]	rw	Channel Frequency Dwell Time. In Auto Dual PAN mode, hardware will toggle the PAN, after dwelling on the current PAN for the interval described below (assuming Preamble/SFD not detected). A write to

Table continues on the next page...

Table continued from the previous page...

<table>
<tr><th>Field</th><th>R/W</th><th>Description</th></tr>
<tr><td></td><td></td><td>DUAL_PAN_DWELL, always re-initializes the DWELL TIMER to the programmed value. If a write to DUAL_PAN_DWELL occurs during an autosequence, the DWELL TIMER will begin counting down immediately. If a write to DUAL_PAN_DWELL occurs when there is no autosequence underway, the DWELL TIMER will not begin counting until the next autosequence begins; it will begin counting at the start of the sequence warmup.

<table>
<tr><th>PRESCALER (bits [1:0])</th><th>TIMEBASE (bits [7:2])</th><th>RANGE (min) - (max)</th></tr>
<tr><td>00</td><td>0.5ms</td><td>0.5 - 32ms</td></tr>
<tr><td>01</td><td>2.5ms</td><td>2.5 - 160ms</td></tr>
<tr><td>10</td><td>10ms</td><td>10 - 640ms</td></tr>
<tr><td>11</td><td>50ms</td><td>50ms - 3.2seconds</td></tr>
</table>

A write to DUAL_PAN_DWELL also causes the value of ACTIVE_NETWORK to get latched into the hardware. This latched value will be the starting point for the automatic dual-pan mode (i.e., start on PAN0 or on PAN1). The starting value takes effect immediately (if sequence is underway and DUAL_PAN_AUTO=1), or is otherwise delayed until sequence starts and DUAL_PAN_AUTO=1.</td></tr>
<tr><td>DUAL_PAN_REMAIN[5:0]</td><td></td><td>This read-only register indicates time remaining before next PAN switch in auto Dual PAN mode. The units for this register, depend on the PRESCALER setting (bits [1:0]) in the DUAL_PAN_DWELL register, according to the following table:

<table>
<tr><th>DUAL_PAN_DWELL PRESCALER</th><th>DUAL_PAN_REMAIN UNITS</th></tr>
<tr><td>00</td><td>0.5ms</td></tr>
<tr><td>01</td><td>2.5ms</td></tr>
<tr><td>10</td><td>10ms</td></tr>
<tr><td>11</td><td>50ms</td></tr>
</table>

The readback value indicates that between N-1 and N timebase units remain until the next PAN switch. For example, a DUAL_PAN_REMAIN readback value of 3, with a DUAL_PAN_DWELL PRESCALER setting of 2 (10ms), indicates that between 20ms (2*10ms) and 30ms (3*10ms), remain until the next automatic PAN switch.</td></tr>
<tr><td>RECD_ON_PAN0</td><td>r</td><td>Indicates the packet which was just received, was received on PAN0.</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

Field	R/W	Description
		In Dual PAN mode operating on 2 different channels, RECD_ON_PAN0 will be set if CURRENT_NETWORK=0 when the packet was received, regardless of FILTERFAIL status. In DUAL PAN mode operating with same channel on both networks, CURRENT_NETWORK will be ignored and RECD_ON_PAN0 will be set only if a valid packet was received on PAN0 (PAN0's FILTERFAIL_FLAG is deasserted).
RECD_ON_PAN1	r	Indicates the packet which was just received, was received on PAN1. In Dual PAN mode operating on 2 different channels, RECD_ON_PAN1 will be set if CURRENT_NETWORK=1 when the packet was received, regardless of FILTERFAIL status. In DUAL PAN mode operating with same channel on both networks, CURRENT_NETWORK will be ignored and RECD_ON_PAN1 will be set only if a valid packet was received on PAN1 (PAN1's FILTERFAIL_FLAG is deasserted).
ACKDELAY[5:0]	rw	Provides a fine-tune adjustment of the time delay between Rx warmdown and the beginning of Tx warmup for an Tx Acknowledge packet. ACKDELAY register will apply to both SLOTTED and UNSLOTTED TxAck, but only to TxAck (not T sequences). This is a two's complement value. The minimum permissible value is -19 (0x2D). Values less than -19 will lead to unexpected results. Resolution = 2us. Range = +/- 62us. Default = 0x0. Max ACKDELAY = 0x1F. Min ACKDELAY = 0x2d.
TXDELAY[5:0]	rw	Provides a fine-tune adjustment of the time delay between post-CCA Rx warm-down and the beginning of Tx warm-up for an Tx (non-Ack) packet. TXDELAY register will apply in both SLOTTED and UNSLOTTED modes, but only to T sequences (e.g., T, TR, and T(R)), not TxAck operations. This is a two's complement value. The minimum permissible value is -19 (0x2D). Values less than -19 will lead to unexpected results. Resolution = 2us. Range = +/- 62us. Default = 0x0. Max TXDELAY = 0x1F. Min TXDELAY = 0x2d

Table continues on the next page...

Table continued from the previous page...

Field	R/W	Description
CLR_NEW_SEQ_INHIBIT	rw	when asserted, overrides the automatic hardware locking of the programmed XCVSEQ while an autosequence is underway. Asserting this feature will allow software to change the programmed autosequence “on-the-fly”, without aborting and returning to idle between sequences. Overriding the hardware lockout of XCVSEQ should be used with caution, since the Sequence Manager is not designed (or verified) for manual state transitions between one type of autosequence and other (i.e., Sequence T -> Sequence R).
NO_RX_RECYCLE	rw	when asserted, prevents the Sequence Manager from automatically re-starting the receiver when a packet is received which results in a FilterFail or CRC failure. Normally, the Sequence Manager jumps to the RX_CYC state, and then resumes from there with a new Rx warmup, in search of a new packet. When this bit is set, the Sequence Manager will instead return to idle state, and issue a SEQIRQ, after a FilterFail or CRC failure.
LATCH_PREAMBLE	rw	1: Make PREAMBLE_DET and SFD_DET bits of PHY_STS Register “sticky”, i.e., occurrences of preamble and SFD detection are latched and held until the start of the next autosequence 0: Don’t make PREAMBLE_DET and SFD_DET bits of PHY_STS Register “sticky”, i.e, these status bits reflect the realtime, dynamic state of preamble_detect and sfd_detect. (default)
XCVSEQ_ACTUAL[2:0]	r	indicates the programmed sequence that has been recognized by the Sequence Manager. Takes into account the fact that sequence-change commands from software are ignored while a sequence is underway (see new_seq_inhibit bit). Read-only bits.
SEQ_IDLE	r	when asserted, indicates that the Sequence Manager is in its idle state. Read-only bit.
NEW_SEQ_INHIBIT	r	when asserted, indicates that a new programmed autosequence has commenced (TMR2 match has occurred if TMRTRIGEN=1). Once this bit is asserted, software is blocked from commanding any new autosequences (other than Sequence I to abort the current sequence), until the current sequence completes. Hardware will ignore a sequence-change command from software while this bit is asserted. Hardware will automatically deassert this bit once the sequence completes. Read-only bit.
RX_TIMEOUT_PENDING	r	when asserted, indicates that a TMR3 timeout (RX timeout) flag has been set by Hardware, but the Sequence Manager has not yet aborted because an RX operation is not currently underway. This would be the case, for example, during a Sequence TR, if a TMR3 timeout were to occur during the transmit operation of this sequence; the sequence would not be aborted by Hardware until the receive operation begins. This bit will always be 0 if TC3TMOUT=0. Read-only bit.

Table continues on the next page...

Table continued from the previous page...

Field	R/W	Description
RX_MODE	r	indicates that an RX operation is in progress. CCA and ED operations are considered RX operations. Read-only bit.
TMR2_SEQ_TRIG_ARMED	r	when asserted, indicates that TMR2 has been programmed and is armed to trigger a new autosequence, when Sequence Manager timer-triggering mode is selected (i.e., TMRTRIGEN=1). When timer-triggering mode is selected, TMR2 must be re-programmed (using either T2CMP or T2), in advance of each new sequence. Once TMR2 is programmed, this bit will be asserted, and will remain asserted until the new sequence commences (at TMR2 match). Hardware will deassert this bit when the new sequence starts. When TMRTRIGEN=0, this bit should be ignored. Read-only bit.
SW_ABORTED	r	when asserted, indicates that the autosequence has terminated due to an Software abort. Software can abort any programmed autosequence by writing Sequence I to XCVSEQ. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. Read-only bit.
TC3_ABORTED	r	when asserted, indicates that the autosequence has terminated due to an TC3 (TMR3) timeout during a receive operation. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. Read-only bit.
PLL_ABORTED	r	when asserted, indicates that the autosequence has terminated due to an PLL unlock event. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. Read-only bit.
CCCA_BUSY_CNT[5:0]	r	For Sequence CCCA mode only, this register indicates the number of “busy” CCA attempts which occurred during the autosequence, before the channel was detected to be idle. This register can also be read in real-time (during the autosequence) to determine how many busy CCA attempts have occurred to that point. The register saturates at 63 (i.e, if there are more than 63 busy attempts, the register will continue to read 63). This register is automatically cleared to zero by hardware when the next autosequence commences. Read-only register.
SEQ_T_STATUS[5:0]	r	Status of the just-completed (or ongoing) Sequence T or Sequence TR autosequence. This register is valid at all times during, and after, the Sequence T or Sequence TR. Not valid for other types of autosequences. This is a read-only register. The bits of this register map to status, according to the following table: [0] 1st CCA complete (CCABFRTX=1) [1] 2nd CCA complete (SLOTTED=1) [2] Tx operation complete [3] Rx Recycle occurred (Sequence TR only)

Table continues on the next page...

Table continued from the previous page...

Field	R/W	Description
		[4] Rx operation complete (Sequence TR only) [5] TxAck operation complete(Sequence TR only)
CONTINUOUS_EN	rw	Enable Continuous TX or RX mode (testmode). See Appendix B.
SLOT_PRELOAD[7:0]	rw	This register represents the number that gets loaded into the slot_timer at SFD detect, which ultimately determines when the next slot boundary will occur. Due to processing delays within the analog front-end and digital modem, the point at which SFD is detected by the modem, is delayed relative to over-the-air timing. Since this timing may not be known prior to until actual silicon, and since this is such a critical timing parameter for slotted operations, it has been made programmable. The default value is 0x74. This timing parameter is critical for the Sequence R autosequence in slotted mode, when an automatic TxAck is required.

55.4.9.1.2.2.3 Functional description

This section describes the supported sequences in more detail. All sequences can be initiated by software directly (instantaneously) by writing the desired sequence to the XCVSEQ register, with the TMRTRIGEN bit deasserted. Alternatively, software can schedule the initiation of a sequence at a precise time in the future, by programming the desired start time into the T2CMP (or T2PRIMECMP) timer compare register, and setting the TMRTRIGEN bit. The XCVSEQ register field is writable and readable, so software can read this register to determine which sequence it had programmed earlier. After the sequence completes (SEQIRQ interrupt), software should set the XCVSEQ to IDLE (0x0), before initiating a new sequence. If the sequence-complete interrupt (SEQIRQ) is masked, software can determine when the sequence is complete by polling the SEQ_STATE register, until it returns to SEQ_IDLE (0x0). While a sequence is ongoing, software can abort the sequence at any time by writing IDLE (0x0) to XCVSEQ; the sequence manager state machine will respond with an orderly return to the SEQ_IDLE state, and a SEQIRQ will be generated. While a sequence is underway, software should not attempt to change XCVSEQ (other than aborting the sequence as previously described); the sequence manager will ignore all mid-sequence attempts to change XCVSEQ. As mentioned previously, software should write the IDLE value to XCVSEQ before changing sequences. If TMR2 triggering is enabled (TMRTRIGEN=1), after the scheduled sequence is automatically launched at TMR2 match, and then completes, software must re-arm TMR2 triggering by writing to either T2CMP, or T2PRIMECMP. At least the LS byte of one of these registers must be written to re-arm. This hardware interlock is designed to prevent the inadvertent re-triggering of sequences, which would otherwise occur after the 24-bit Event Timer rolls over.

The supported sequences are shown in the following table.

Table 473. Supported Sequences

XCVSEQ	Sequence	Description
0	I	Idle
1	R	Receive Sequence - conditionally followed by a TxAck
2	T	Transmit Sequence
3	C	Standalone CCA
4	TR	Transmit /Receive Sequence - transmit unconditionally followed by either an R or RxAck

Table continues on the next page...

Table 473. Supported Sequences (continued)

XCVSEQ	Sequence	Description
5	CCCA	Continuous CCA - sequence completes when channel is idle
6	Reserved	
7	Reserved	

All sequences can be aborted by a PLL unlock detection. The unlock detection is qualified by the sequence manager; in other words, an unlock detection during the early stages of the PLL warmup is expected, and is not allowed to abort the sequence at that point. The primary rationale for the PLL unlock abort, is to prevent transmission on an incorrect, or unstable, frequency during a transmit operation, or to increase battery life by not prolonging a receive or CCA operation that is bound to fail. Software can disable the PLL unlock auto-abort. See Sequence Aborting.

55.4.9.1.2.2.3.1 Supported Sequences

55.4.9.1.2.2.3.1.1 Sequence I (Idle)

When the IDLE value is written to XCVSEQ, the sequence manager goes to its SEQ_IDLE state. If not already in SEQ_IDLE, the sequence manager executes an orderly warmdown to return to SEQ_IDLE. A SEQIRQ interrupt is then issued. Writing IDLE value to XCVSEQ is the proper way to abort a sequence.

When a sequence is aborted in this way (called a software abort), the SW_ABORTED bit of the ABORT_STS register in 802.15.4 space, will become set. This bit will be self-cleared at the start of the next autosequence.

55.4.9.1.2.2.3.1.2 Sequence R (Receive)

Sequence R is the basic receive sequence. Sequence R can be used to receive all types of 802.15.4 PHY- and MAC-compliant frames, including reserved frame types. However, reception of Acknowledge frames is not recommended using Sequence R. This is because reception of an Acknowledge frame, usually follows a transmitted frame, with a designated Sequence Number, so that the received Acknowledge frame can be verified for the matching Sequence Number. In a standalone Sequence R, there is no Sequence Number to verify against, so any Acknowledge frame is merely transferred to the Packet Buffer. (Note: the appropriate way to receive Acknowledge frames is with Sequence TR, with the RXACKRQD bit asserted). Using Sequence R, *all* frames which pass frame-filtering rules and CRC check, are transferred to the Packet Buffer.

The basic execution of a successful Sequence R is as follows:

- MCU writes TC2 compare value to the desired initiation time, and sets TMRTRIGEN (optional)
- MCU writes XCVSEQ=R
- Wait for TC2 match (if TMRTRIGEN=1)
- SEQ_MGR executes RxWarmup
- Preamble Detected
- SFD Detected
- FrameLength octet received, transferred to Packet Buffer
- *N* additional octets received (*N* = FrameLength), transferred to Packet Buffer. *Note if (FrameLength > 127), then N = 127.*
- If frame-filtering rules and CRC check pass:
- ---> RXIRQ interrupt issued
- ---> SEQ_MGR executes RxWarmdown
- ---> If received Frame Control Field indicates AckRequest=1
- ---- ---> SEQ_MGR executes TxWarmup

- ---- ---> an Ack frame is transmitted using the received Sequence Number
- ---- ---> SEQ_MGR executes TxWarmdown
- SEQIRQ interrupt issued

When Sequence R is initiated, the ZSM sequence manager warms up the receiver (analog and digital elements), via the TSM (Transceiver Sequence Manager). After warmup is complete, timer TMR3 can be enabled as a “bracketing” timer (software option). If a TMR3 timer match occurs, and software has asserted the TC3TMOUT bit, the sequence manager will warm down the receiver and return to SEQ_IDLE state. Assuming no TMR3 timeout, reception proceeds in preamble-search mode. Once a preamble is detected, reception continues in SFD-search mode. At this point, the sequence manager’s slot timer is activated. This is because a slotted “transmit acknowledge” frame (TxAck) may be required later in this sequence. The slot timer is loaded with the following value (in us):

Slot Timer Preload = 160 + TXWARMUPTIME + (2*ACKDELAY).

The 160 term arises because, at the point of SFD detection, we are exactly 10 symbols into the backoff slot, and the symbol period is 16us. The slot timer will count up and eventually rollover at 319, to 0. (There are 320us in a backoff slot). The receiver receives the next octet (FrameLength). Starting with this octet, and continuing through the remainder of the frame, each octet that is received is transferred to Packet Buffer. After each octet is transferred to Packet Buffer, the Packet Buffer address is incremented by 1. The next 2 octets (Frame Control Field) are then received, which are parsed to obtain the AckRequest field, and the FrameVersion field. The next octet is then received (SequenceNumber), and stored. The remainder of the frame, determined by FrameLength, is then received. As the octets are received, the packet data is parsed and subjected to packet-filtering rules (see Chapter Packet Processor). If any of the packet-filtering rules fail, or if the CRC check on the FCS field fails, the sequence manager will return the receiver to preamble-search mode, after the last octet has been received and transferred to Packet Buffer. Assuming the packet-filtering rules and CRC pass, an interrupt (RXIRQ) is issued to the MCU. At this point, the sequence manager must determine if a TxAck is required. A TxAck is required if the following 3 conditions are all met:

- AUTOACK=1 (register bit)
- PROMISCUOUS=0 (register bit)
- The received FrameControlField has AckRequest=1

If these conditions are met, and SLOTTED mode is not in effect, the sequence manager loads its TxAck timer with the following value (in us):

TxAck Timer Preload = 192 - TXWARMUPTIME - 2*ACKDELAY

The 192us is the non-slotted RX-to-TX turnaround requirement in the 802.15.4 standard. The TXWARMUPTIME takes into account the fact that the TxAck timer must expire early for the Tx warmup to be complete at exactly the 192us point. The ACKDELAY is a signed, fine-tune adjustment to the TxAck transmission time (+/- 62us).

If SLOTTED mode is in effect, the slot timer was previously loaded (at SFD detect), but the sequence manager needs to determine how much time is left in the current backoff slot. If less than 192us remain, the sequence manager must wait an *additional* backoff slot before initiating the Ack transmission. So it sets a flag indicating it must allow the slot counter to rollover an additional iteration.

Finally, at TxAck timer expiration (in non-SLOTTED mode), or at the qualified rollover of the slot timer (in SLOTTED mode), a Tx warmup is initiated. The conclusion of the Tx warmup will coincide precisely with a backoff slot boundary if SLOTTED mode is in effect. The sequence manager will then initiate the transmission of the Ack frame. The entire Ack frame will be built up by hardware; the Packet Buffer is not used for the auto-TxAck feature. The hardware will insert the following parameters into the Ack frame’s Frame Control Field:

Table 474. Frame Control Field for Hardware-generated Auto-TxAck Frame

FCF Field	Value
FrameType	Acknowledge
SecurityEnabled	0
FramePending	Determined by the Packet Processor.

Table continues on the next page...

Table 474. Frame Control Field for Hardware-generated Auto-TxAck Frame (continued)

FCF Field	Value
	(see Packet Processor Chapter, Source Address Management.)
AckRequest	0
PanIDCompression	0
Reserved (bits 7-9)	000
DstAddrMode	0
FrameVersion	0
SrcAddrMode	0

The Sequence Number for the Ack packet, will be the Sequence Number obtained from the previously received frame.

After the Ack frame has been transmitted, the sequence manager will issue a TXIRQ interrupt, and then perform a Tx warmdown. Finally, a SEQIRQ interrupt will be issued, and the sequence manager returns to SEQ_IDLE state.

55.4.9.1.2.2.3.1.3 Sequence T (Transmit)

Sequence T is the basic, standalone transmit sequence. Sequence T can be used to transmit all types of 802.15.4 PHY- and MAC-compliant frames. However, transmission of Acknowledge frames is not recommended using Sequence T. This is because transmission of an Acknowledge frame, usually follows a received frame, with a designated Sequence Number. The ZSM sequence manager automates the transmission of an Ack frame which follows a received frame, using Sequence R with the AUTOACK bit asserted. This is the recommended method for transmitting an Ack frame. This is especially beneficial, because the transmitted Ack frame octets are generated by hardware, and so no setup of a transmit packet in Packet Buffer, is required. However, sequence manager hardware does not prohibit Ack frames using Sequence T.

Sequence T allows for the insertion of 1 or 2 CCA (clear channel assessment) measurements prior to transmission, to ensure that the selected channel is idle. The CCA-before-TX feature is governed by two register bits, CCABFRTX and SLOTTED. All CCA measurements must indicate channel-idle, in order for the sequence manager to proceed to transmission; if the channel is determined by CCA to be busy, the sequence manager will terminate the sequence without a transmission. The number of CCA measurements attempted by the sequence manager, and the timing of the measurements, is shown in the following table.

Table 475. Timing of CCA Operations for Sequence T

CCABFRTX	SLOTTED	Number of CCA measurements	Timing of Initiation of CCA measurement #1	Timing of Initiation of CCA measurement #2	Timing of First Bit of Transmitted Frame (assumes channel idle)
0	X	0	-	-	Immediately follows TxWarmup
1	0	1	Immediately follows RxWarmup	-	Immediately follows RxWarmdown and TxWarmup
1	1	2	Immediately follows RxWarmup	320us after Initiation of CCA measurement #1	320us after Initiation of CCA measurement #2

Any CCA mode can be used for Sequence T and Sequence TR (CCA Modes 1, 2, and 3 are available. See Chapter CCA/ED/LQI). Software must configure the CCATYPE bits prior to initiating the autosequence, to select the CCA Mode.

The basic execution of a successful Sequence T is as follows:

- MCU writes TC2 compare value to the desired initiation time, and sets TMRTRIGEN (optional)
- MCU sets CCABFRTX if one or more CCA's are required prior to transmit
- MCU sets SLOTTED if in slotted mode (2 CCA's will be attempted)
- MCU writes XCVSEQ=T
- Wait for TC2 match (if TMRTRIGEN=1)
- If CCABFRTX=1 :
- ---> SEQ_MGR executes RxWarmup
- ---> SEQ_MGR initiates CCA measurement (takes 128us)
- ---> if CCA indicates channel busy, sequence terminates, CCAIRQ & SEQIRQ issued
- ---> otherwise, if CCA indicates channel idle:
- ---- ---> if SLOTTED=0, SEQ_MGR executes a RxWarmdown, followed by a TxWarmup
- ---- ---> if SLOTTED=1, SEQ_MGR initiates a 2nd CCA, 320us after initiating 1st CCA.
- ---- ---> if SLOTTED=1, and channel busy, sequence terminates, CCAIRQ & SEQIRQ issued
- ---- ---> if SLOTTED=1, and channel idle, SEQ_MGR executes a RxWarmdown, followed by a TxWarmup
- if SLOTTED=1, SEQ_MGR waits until 320us elapse after 2nd CCA initiation
- SEQ_MGR executes TxWarmup
- Preamble transmitted
- SFD transmitted
- FrameLength octet is obtained from Packet Buffer Address 0, and transmitted
- CRC engine is reset
- *N* additional octets are obtained from Packet Buffer and transmitted (*N* = FrameLength - 2)
- Each octet that is transmitted, is shifted through the CRC engine

- After Mth octet transmitted, FCS is available from CRC engine.
- FCS lower octet transmitted
- FCS upper octet transmitted
- SEQ_MGR issues TXIRQ
- SEQ_MGR executes TxWarmdown
- SEQ_MGR issues SEQIRQ

When Sequence T is initiated, the sequence manager first must determine if one or more CCA measurements are required. If CCABFRTX bit is asserted, the sequence manager warms up the receiver (analog and digital elements), via the TSM (Transceiver Sequence Manager). Immediately after the conclusion of the warmup, a CCA measurement is initiated. The CCA measurement takes 128us. If CCA indicates the channel is busy, the sequence manager warms down the receiver, issues CCAIRQ and SEQIRQ interrupts, and terminates the sequence. If, however, CCA indicates the channel is idle, the sequence manager inspects the SLOTTED bit to determine what to do next. If the SLOTTED bit is clear, the sequence manager issues a CCAIRQ interrupt, and then executes a warmdown of the receiver. If, however, the SLOTTED bit is set, the sequence manager does not issue a CCAIRQ interrupt; instead, the sequence manager initiates a second CCA measurement, precisely 320us after the initiation of the first CCA. This 320us interval is timed by the slot timer, which had been preloaded with 320 (microseconds) at the instant that Rx warmup was complete. At the conclusion of the second CCA, the sequence manager issues a CCAIRQ. If the second CCA indicates the channel is busy, the sequence manager warms down the receiver, issues a SEQIRQ interrupt, and terminates the sequence. If, however, CCA indicates the channel is idle, the sequence manager executes a warmdown of the receiver. Prior to executing the warmdown, the sequence manager reloads the slot timer, in order to precisely schedule the ensuing transmission. This time, the slot timer is loaded with a smaller value, in order to account for the fact that the timer must expire early in order to trigger the Tx warmup, which must complete at precisely the next backoff slot boundary. Thus, this time the slot timer is preloaded with:

Slot Timer Preload = 320 - TXWARMUPTIME + (2*TXDELAY).

The 320us is the duration of the backoff slot. The TXWARMUPTIME takes into account the fact that the TxAck timer must expire early for the Tx warmup to be complete at exactly the 320us point. The TXDELAY is a signed, fine-tune adjustment to the TxAck transmission time (+/- 62us).

If the SLOTTED bit is asserted, once the slot timer expires, the sequence manager executes a Tx warmup. The conclusion of this warmup coincides with the backoff slot boundary. If the SLOTTED bit is deasserted, the sequence manager does not wait for the slot timer, and instead executes a Tx warmup immediately after the Rx warmdown.

At this point, the sequence manager begins the transmit operation. The preamble and SFD are transmitted first. The preamble and SFD octets are generated by hardware, and are not included in the Packet Buffer. Then, the FrameLength octet is obtained from the Packet Buffer (address 0), and the buffer address pointer is incremented by one. The FrameLength octet is transmitted. The CRC engine is reset at this point. The FrameLength octet is used to determine how many more octets remain in the Packet Buffer. The number of remaining octets is:

Number of octets remaining in Tx buffer = FrameLength - 2

This is because the final 2 octets of the transmit frame constitute the FCS (Frame Check Sequence), and this value is hardware-computed. Thus, FCS is not part of the Tx buffer. Each of the octets in the Tx buffer is transmitted, and simultaneously shifted through CRC, to generate the FCS field. Once the Tx buffer is drained and all of its octets transmitted, the 2 FCS octets are transmitted, starting with the least significant octet. At this point, the transmit operation is complete. The sequence manager issues a TXIRQ interrupt. The sequence manager then executes a complete Tx warmdown, and follows up with a SEQIRQ interrupt. The sequence manager returns to SEQ_IDLE state.

55.4.9.1.2.2.3.1.4 Sequence C (CCA)

Sequence C is the standalone CCA sequence. During Sequence C, the sequence manager executes a Clear Channel Assessment (CCA). The result of the CCA measurement is reported back to software in the CCA bit of the IRQSTS2 Register. The CCA bit indicates either a busy channel (1), or an idle channel (0).

The basic execution of a Sequence C is as follows:

- MCU writes TC2 compare value to the desired initiation time, and sets TMRTRIGEN (optional)
- MCU writes XCVSEQ=C
- Wait for TC2 match (if TMRTRIGEN=1)
- SEQ_MGR asserts one of {**cca1_en, cca2_en, cca3_en, ed_en** } to CCA_DIG
- SEQ_MGR executes RxWarmup, via Transceiver Sequence Manager
- SEQ_MGR initiates CCA measurement by asserting **rx_cca_en** to CCA_DIG
- SEQ_MGR waits for CCA to complete
- CCA bit is set to the CCA status (1=busy 0=idle)
- CCAIRQ interrupt issued
- SEQ_MGR executes RxWarmdown
- SEQIRQ interrupt issued

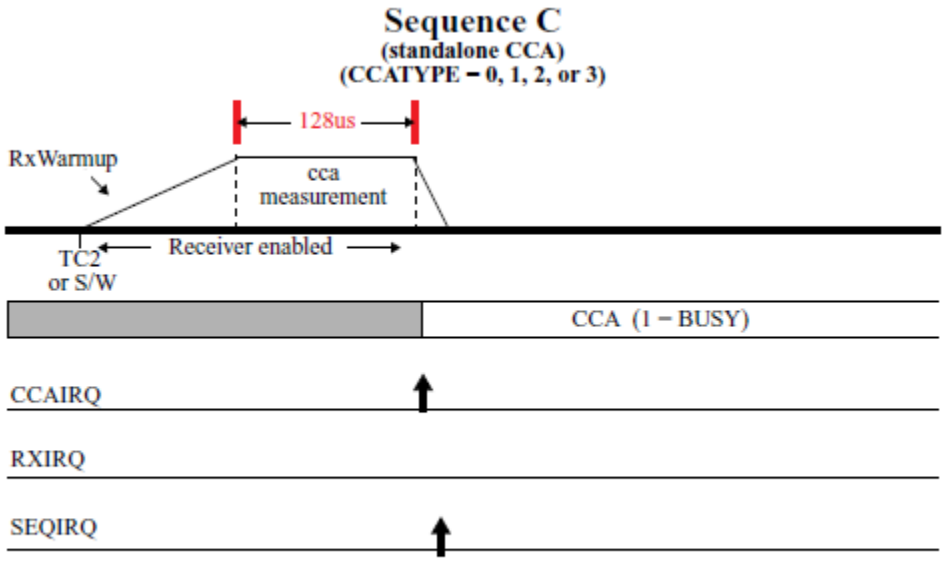
When Sequence C is initiated, the sequence manager asserts one of 4 control signals to CCA_DIG, based on which CCA or ED mode is programmed into CCATYPE[1:0]. The mapping of CCATYPE[1:0] to control signal is shown in the following table:

CCATYPE[1:0]	CCA_DIG CONTROL SIGNAL
00	ed_en
01	cca1_en
10	cca2_en
11	cca3_en

The asserted control signal will remain asserted for the duration of the Sequence C. The sequence manager warms up the receiver (analog and digital elements), via the Transceiver Sequence Manager (TSM). The TC3 “bracketing” timer has no effect on the sequence manager during Sequence C, so it cannot abort the sequence. At the completion of the warmup, the sequence manager initiates the CCA by asserting the **rx_cca_en** signal to CCA_DIG. While CCA is enabled, the CCA_DIG measures and averages the energy or signal on the channel. At the completion of the CCA process, the CCA bit is set to the status of the channel (idle or busy). The CCAIRQ is issued, the receiver is warmed down, the SEQIRQ is issued, and the sequence manager returns to SEQ_IDLE state.

Any CCATYPE setting may be used for Sequence C.

Sequence C Timing Diagrams



55.4.9.1.2.2.3.1.5 Sequence TR (Transmit/Receive)

Sequence TR is a combination Transmit/Receive sequence. The sequence is executed as a concatenation of 1 transmit operation followed by 1 receive operation, with a minimum TX-to-RX turnaround time in between. There are 2 permutations of Sequence TR, depending on the RXACKRQD bit. For both permutations, the Sequence T which constitutes the first half of a Sequence TR, is identical to the standalone Sequence T (XCVSEQ=2). This means that the transmit operation can be slotted or unslotted, and can be preceded by 1 or 2 CCA measurements, depending on the state of the CCABFRTX and SLOTTED bits.

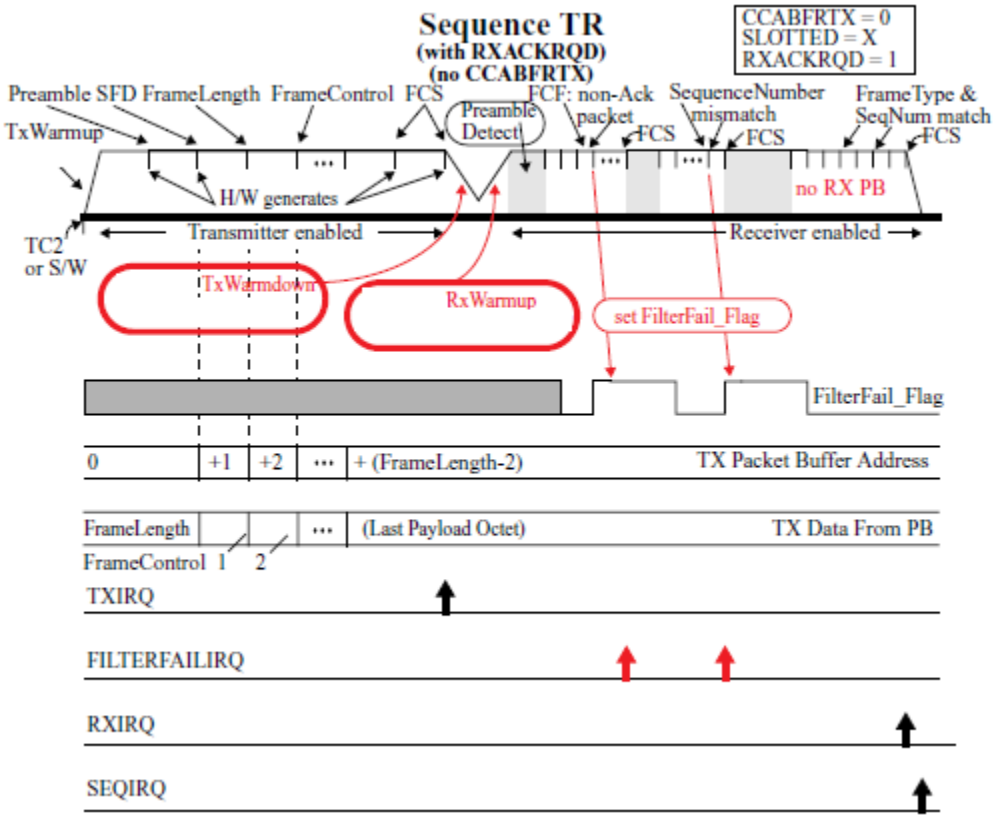
If RXACKRQD=0, then Sequence TR is executed as a Sequence T followed by a Sequence R, with a minimum TX-to-RX turnaround time in between. The Sequence R, which constitutes the second half of the Sequence TR, is identical to the standalone Sequence R (XCVSEQ=1). This means that the receive operation can be followed by an automatic, hardware-generated transmit Acknowledge frame, if all the necessary conditions are met. As with basic Sequence R, data for a successful receive operation is always transferred to Packet Buffer.

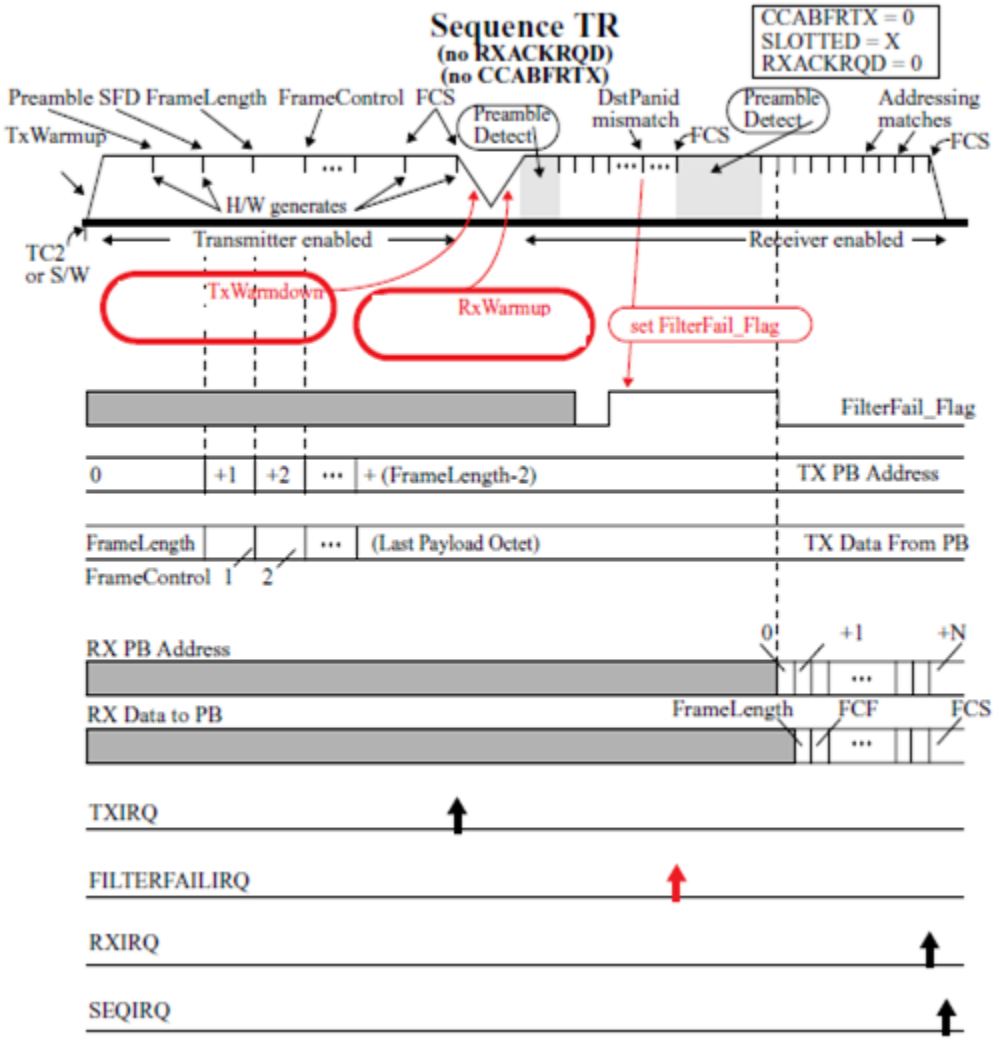
If RXACKRQD=1, then Sequence TR is executed as a Sequence T followed by a Receive-Acknowledge-Only frame. This type of receive operation is special, and not the same as a standalone Sequence R. The Ack-only receive operation filters all incoming frames, looking only for an Acknowledge frame whose Sequence Number matches the Sequence Number which was transmitted in the Sequence T portion of the sequence. All non-matching frames are discarded, and after each non-matching frame, the sequence manager will return the receiver to preamble-detect mode. This receive operation will continue until the matching Ack frame is received. Since this is a Receive-Acknowledge-Only operation, and not a Sequence R, there will be no receive octets transferred to Packet Buffer (an exception is made if ACTIVE_PROMISCUOUS=1; if so, all receive octets are transferred to the Packet Buffer, even for the Receive-Acknowledge-Only frame). The sequence will end with a RXIRQ interrupt, which indicates that the matching Ack frame was successfully received.

Needless to say, if during the transmit operation of a Sequence TR, an Acknowledge frame is being requested of the receiving end device (Frame Control Field: AckRequest=1), then Sequence TR with RXACKRQD=1 is the appropriate procedure. (Using Sequence TR with *RXACKREQ=0* is *not* recommended for this scenario, since there is no Sequence Number matching.)

Conversely, if during the transmit operation of a Sequence TR, an Acknowledge frame is *not* being requested of the receiving end device (Frame Control Field: AckRequest=0), then Sequence TR with RXACKRQD=1 should *never* be used, since a receive acknowledge frame will not be forthcoming. Instead, use Sequence TR with RXACKRQD=0, or simply Sequence T, if no followup receive frame is expected.

Sequence TR Timing Diagrams





55.4.9.1.2.2.3.1.6 Sequence CCCA (Continuous CCA)

Sequence CCCA is the Continuous CCA sequence. This sequence is designed to accommodate situations where channel availability may be infrequent, or low-duty-cycle, and a device needs to be able to transmit at the earliest available opportunity. During Sequence CCCA, the sequence manager repeats CCA measurements continuously until a channel-idle condition is found. The interval between the end of one CCA measurement, and the start of the next, is 63us. The actual interval between consecutive CCA measurements (i.e., from measurement-start to measurement-start), in the CCCA sequence, is 193us. After each CCA iteration, the CCA bit (IRQSTS2 Register) is set to the result of the measurement. As long as the CCA bit is high (busy) at the end of the iteration, the sequence manager will initiate a new measurement. Unlike Sequence C (standalone CCA), there is no CCAIRQ interrupt generated at the end of each CCA measurement, until the channel-idle condition is detected, at which point CCAIRQ is issued. The SLOTTED bit has no effect on this sequence. A Sequence CCCA will be aborted by the ZSM Sequence Manager if a TMR3 match occurs, and TC3TMOUT=1. CCA Modes 1, 2, or 3, can be used for Continuous CCA.

The basic execution of a Sequence CCCA is as follows:

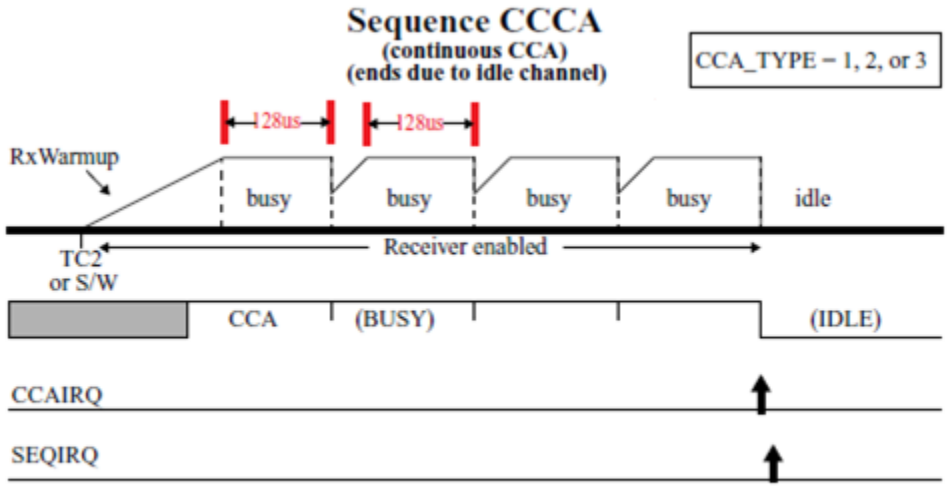
- MCU writes TC2 compare value to the desired initiation time, and sets TMRTRIGEN (optional)
- MCU writes XCVSEQ=CCCA
- Wait for TC2 match (if TMRTRIGEN=1)
- SEQ_MGR asserts one of {**cca1_en, cca2_en, cca3_en** } to CCA_DIG

- SEQ_MGR executes RxWarmup
- SEQ_MGR initiates CCA measurement by asserting **rx_cca_en** to CCA_DIG
- SEQ_MGR waits for CCA to complete
- CCA bit is set to the CCA status (1=busy 0=idle)
- If CCA=1, initiate a new CCA measurement immediately and repeat the previous 4 steps
- If CCA=0, CCAIRQ is issued
- SEQ_MGR executes RxWarmdown
- SEQIRQ interrupt issued

Note: The CCA bit (IRQSTS2 register) may change dynamically during the CCA measurement, and are only considered valid (and sampled by the Sequence Manager), at the end of the CCA measurement; therefore the user should not continuously poll CCA during CCCA and be expecting continuously-valid results

Note: The user can continuously monitor progress of the Sequence CCCA by reading the CCCA_BUSY_CNT register.

Sequence CCCA Timing Diagrams

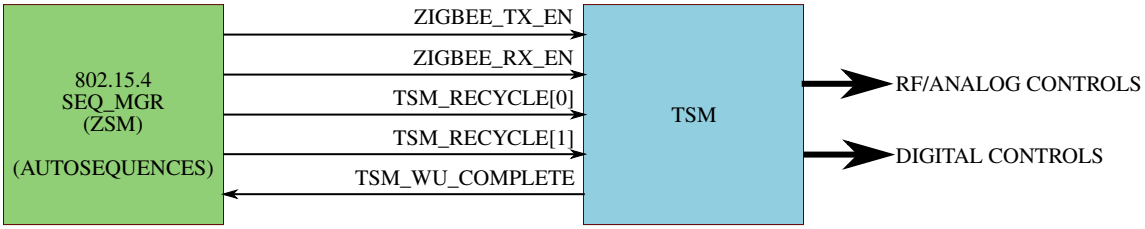


55.4.9.1.2.2.3.2 ZSM/TSM Interaction

The 802.15.4 Sequence Manager (ZSM) controls high-level autosequence timing, but offloads low level warmup and warmdown tasks to a dedicated, protocol-neutral Transceiver Sequence Manager, or TSM (see TSM Chapter). The ZSM initiates high-level functions, such as a CCA measurement operation or a transmit acknowledge operation, by commanding the TSM to execute an RX warmup, a TX warmup, a RX warmdown, a TX warmdown, or an RX recycle. Based on these commands, TSM generates the precise timing to control all of the digital, analog, and RF components of the TX and RX chains. The TSM is fully programmable, allowing all of the enabling and control signals to the transceiver components to be independently scheduled with 1us precision. TSM also allows all enable and control signals to be optionally overridden at any time, giving software complete control of each transceiver block, and ultimately the entire warmup/warmdown process if desired.

The ZSM and TSM sequence managers operate on the same clock domain, and both have 1us resolution. The TSM is fully programmable, while the ZSM is largely hardwired, with a few key exceptions. In the ZSM/TSM relationship, ZSM is the master and TSM is the slave. The key ZSM/TSM interface signaling is shown below:

ZSM/TSM INTERFACE SIGNALS



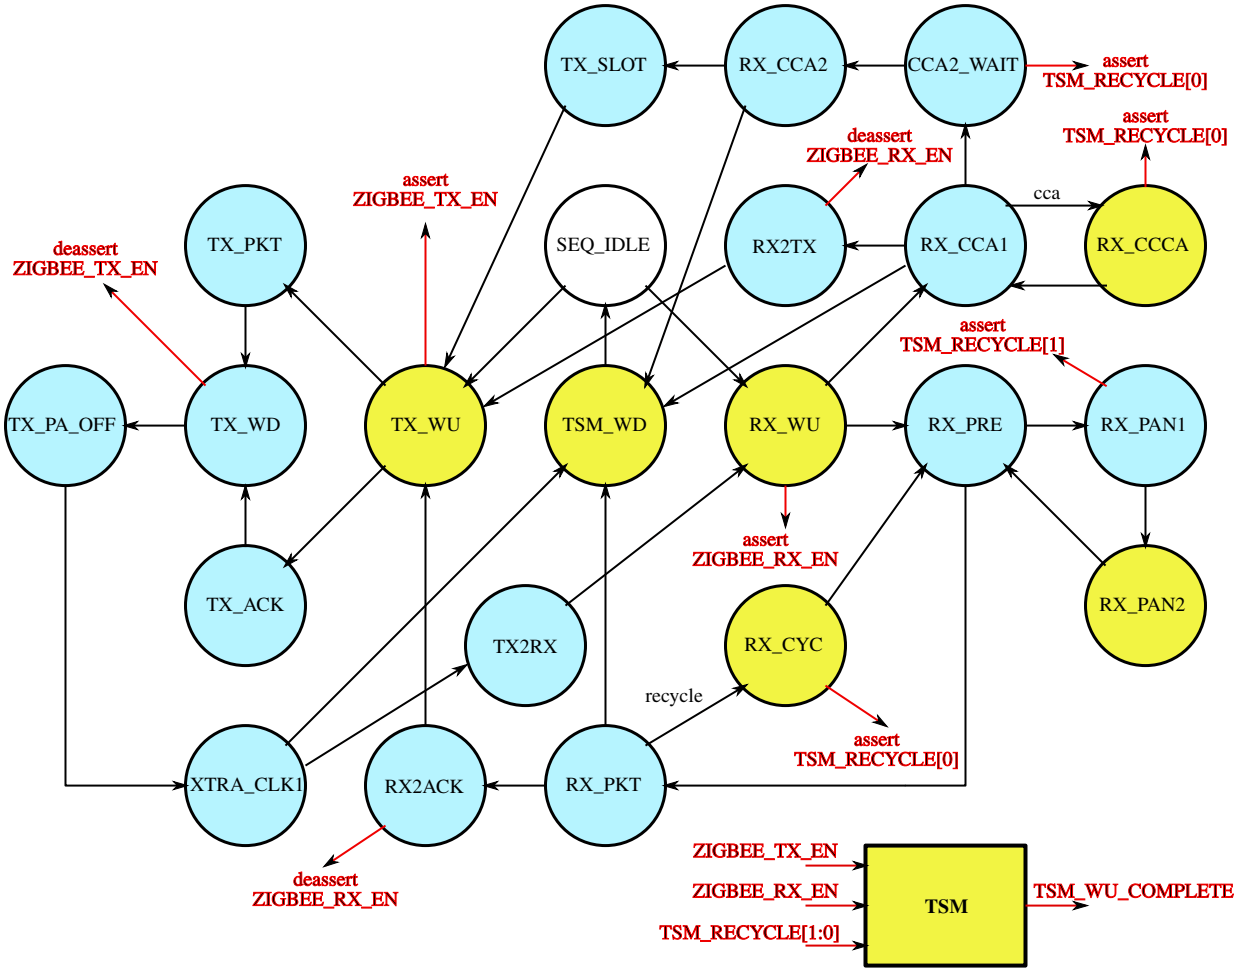
A description of the interface signals is provided in the table below.

ZSM/TSM INTERFACE SIGNAL	DESCRIPTION
ZIGBEE_TX_EN	A low-to-high transition initiates a TSM TX warmup, starting 1us after the transition. A high-to-low transition initiates a TSM TX warmdown, starting 1us after the transition.
ZIGBEE_RX_EN	A low-to-high transition initiates a TSM RX warmup, starting 1us after the transition. A high-to-low transition initiates a TSM RX warmdown, starting 1us after the transition.
TSM_RECYCLE[0]	This signal asserts in the ZSM RX_CYC state, and causes the TSM to jump from its “ON” phase, back to a point in the TSM RX warmup determined by the TSM’s RECYCLE_COUNT0[7:0] register in XCVR space. This process is used to execute an RX recycle. This signal is also asserted in the ZSM RX_CCCA state, with the same response by the TSM. This process is used to re-initialize the CCA function during Continuous CCA (CCCA) operations.
TSM_RECYCLE[1]	This signal asserts in the ZSM RX_PAN1 state, and causes the TSM to jump from its “ON” phase, back to a point in the TSM RX warmup determined by the TSM’s RECYCLE_COUNT1[7:0] register in XCVR space. This process is used to re-initialize the PLL digital on a new RF channel, during a Dual PAN mode on-the-fly channel change.
TSM_WU_COMPLETE	For the ZSM states which assert ZIGBEE_TX_EN or ZIGBEE_RX_EN, this 1us-wide signal from the TSM indicates that the warmup is complete, and the ZSM is now free to advance to its next state. The TSM_WU_COMPLETE is asserted 1us before the actual end of sequence, which is determined by the END_OF_TX_WU[7:0] register for TX warmup, and the END_OF_RX_WARMUP[7:0] register for RX warmup.

55.4.9.1.2.2.3.3 ZSM State Diagram

A ZSM state diagram is shown below. The states in yellow, are ZSM states which require interaction with the TSM. For example, a TSM control signal is asserted or deasserted, and/or a wait for warmup-complete from TSM is required; the assertions of the TSM control signals are shown in red. The states in blue have no interaction with TSM, so the timing of these states, and the transitions between such states, are governed by the ZSM itself.

802.15.4 SEQUENCE MANAGER AND TSM INTERACTION



Each ZSM state is represented in the hardware by a 5-bit state vector. The ZSM state can be monitored at any time by way of the read-only SEQ_STATE[4:0] register in 802.15.4 space. The mapping of ZSM state names to state vectors is shown in the table below:

ZSM STATE	VECTOR
SEQ_IDLE	0x00
RX_WU	0x10
RX_PRE	0x14
RX_PKT	0x15

55.4.9.1.2.2.3.5 Dual PAN Mode

Dual PAN On-the-fly Channel Change

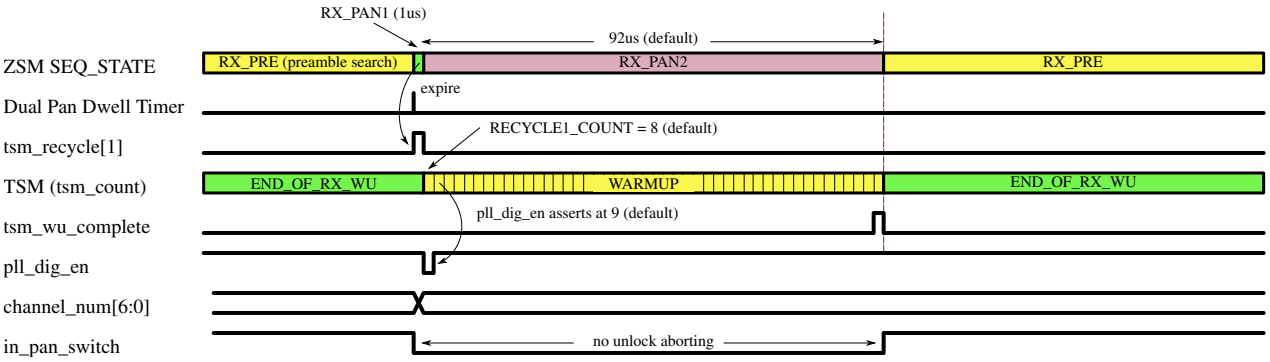
The 802.15.4 Sequence Manager (ZSM) supports Dual PAN mode, which allows the device to reside on 2 networks simultaneously, switching back and forth between the 2 networks under software, or hardware control. (See Packet Processor Chapter, Section Dual PAN Mode for more details on Dual PAN mode).

In Automatic Dual PAN Mode, the device must switch from one network to another under hardware control, at a software-programmed rate. Since the 2 networks often occupy different channels (frequencies), the sequence manager supports an "on-the-fly channel change", whereby, during a Sequence R, in preamble-search state (RX_PRE), the sequence manager will request the TSM to toggle **pll_dig_en** and switch to a new RF channel, wait out a PLL settling time, and then resume preamble search on the new channel. The entire on-the-fly channel change consumes 93us (based on default TSM programming), and consumes 2 ZSM states. The first state (RX_PAN1) issues **tsm_recycle[1]** to the TSM, which causes TSM to jump from its "ON" phase, back to the tsm_count value which is programmed into the RECYCLE_COUNT1[7:0] register in XCVR space. Based on the default programming for RECYCLE1_COUNT, along with the default programming for the TSM timing registers, this TSM recycle will cause the TSM to jump back to the point 1us before **pll_dig_en** is asserted, resulting in a 1us-long deassertion of **pll_dig_en**. The TSM will resume counting from that point, which will re-assert **pll_dig_en**, and the ZSM will simultaneously select the alternate Dual Pan channel. Meanwhile, the ZSM will advance to RX_PAN2 state and wait there pending **tsm_wu_complete** from the TSM. The TSM will resume counting until it once again until it reaches END_OF_RX_WU[7:0], and then will return to its ON phase. At the end of the TSM RX warmup, TSM will issue **tsm_wu_complete** to ZSM, which will return ZSM to RX_PRE (preamble search) state.

Normally, during RX sequences, the PLL is monitored for unlock conditions, and if such an unlock were to occur, the ZSM would abort the RX sequence by deasserting ZIGBEE_RX_EN to TSM. During RX_PAN1 and RX_PAN2 states, ZSM asserts **in_pan_switch** to the transceiver, which indicates that PLL unlock detection should be temporarily suspended while the channel change and subsequent PLL re-lock takes place. Once the ZSM transitions from RX_PAN2 state back to RX_PRE, ZSM will deassert **in_pan_switch** to resume PLL unlock monitoring.

As mentioned, the entire on-the-fly channel change consumes 93us, based on default TSM programming. This 93us represents a short "blind spot" during which preamble detection can't occur, while the device switches from one RF frequency to another. See diagram below.

ZSM DUAL PAN ON-THE-FLY CHANNEL CHANGE



Dual PAN Channel Override

When using Dual PAN mode, the channels are assigned to the 2 PAN's by programming the CHANNEL_NUM0[6:0] and CHANNEL_NUM1[6:0] registers in 802.15.4 space. This method allows a channel number, from 11 to 26, to be programmed into each register, and the channel number is processed downstream into the necessary Integer, Numerator, and Denominator components, required to generate the correct RF frequencies (see PLL Digital Chapter).

In Dual PAN mode, in case there is a need to generate a frequency which may be offset from the 16 prescribed 5MHz-spaced channels, to, for example, avoid interference on one of the Dual PAN channels, a method has been provided to do that, by designating one of the two PAN channels to use the transceiver's set of direct frequency-programming registers, instead of CHANNEL_NUMx. Programming the direct frequency-programming registers – integer, numerator, and denominator, allows an

RF frequency to be selected with much more precision than the 5MHz granularity of the 802.15.4 mapped-channel registers, CHANNEL_NUM0 and CHANNEL_NUM1.

Two bits have been provided in 802.15.4 space to realize this feature: ZB_DP_CHAN_OVRD_SEL and ZB_DP_CHAN_OVRD_EN. When ZB_DP_CHAN_OVRD_EN=1, this enables one of the Dual PAN channels to use the direct frequency programming. The ZB_DP_CHAN_OVRD_SEL bit determines *which* channel uses the direct programming, according to the following table:

ZB_DP_CHAN_OVRD_EN	ZB_DP_CHAN_OVRD_SEL	PAN0 Frequency Determined by …	PAN1 Frequency Determined by …
0	X	CHANNEL_NUM0[6:0]	CHANNEL_NUM1[6:0]
1	0	DIRECT FREQUENCY PROGRAMMING	CHANNEL_NUM1[6:0]
1	1	CHANNEL_NUM0[6:0]	DIRECT FREQUENCY PROGRAMMING

Direct Frequency Programming is accomplished by setting the PLL's Integer, Numerator, and Denominator registers to the appropriate values for the desired RF frequency. These registers are in XCVR address space, and are shown in the following table:

DIRECT FREQUENCY PROGRAMMING PARAMETER	REGISTER NAME (XCVR SPACE)	REGISTER MNEMONIC
Integer	LPM_INTG[6:0]	PLL_LP_SDM_CTRL1
Numerator	LPM_NUM[27:0]	PLL_LP_SDM_CTRL2
Denominator	LPM_DENOM[27:0]	PLL_LP_SDM_CTRL3

See the PLL Digital Chapter for RF frequency programming details.

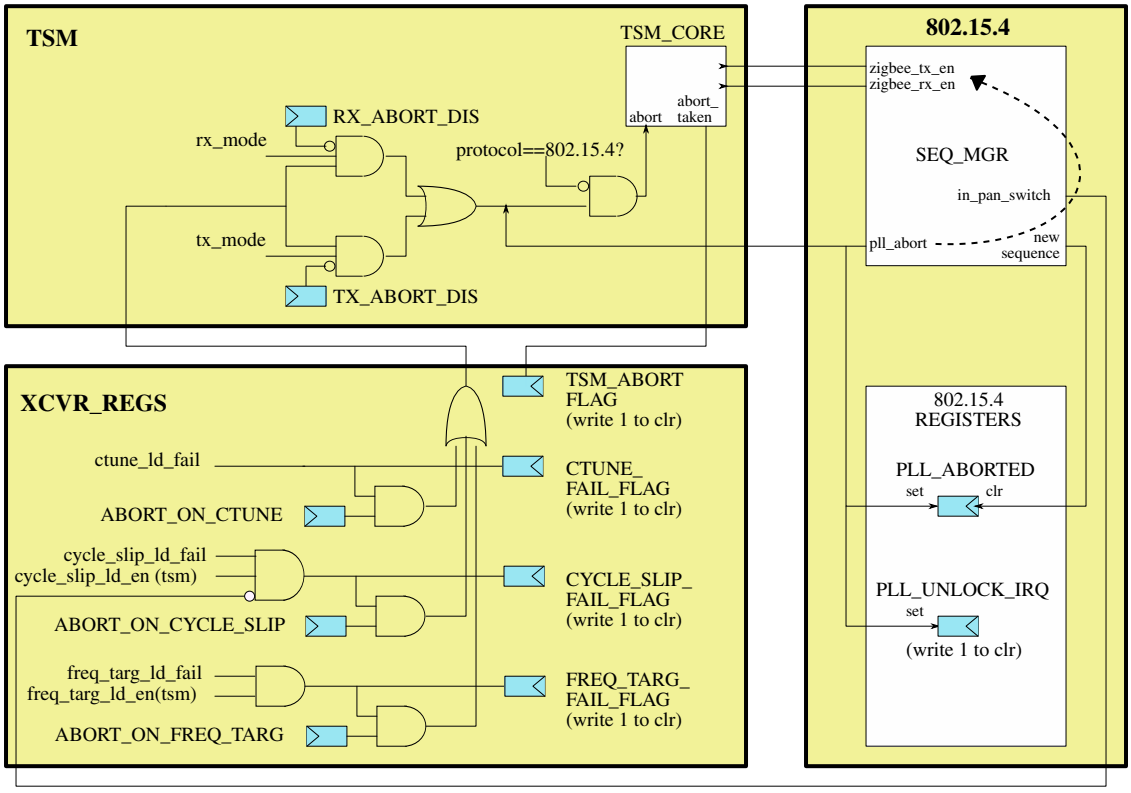
In Dual PAN automatic mode, if ZB_DP_CHAN_OVRD_EN=1, when the hardware switches to the PAN selected by ZB_DP_CHAN_OVRD_SEL as a direct-programming channel, the CHANNEL_NUMx[6:0] register is ignored and the directly programmed frequency is used instead; when the hardware switches back to the other channel, the CHANNEL_NUMx[6:0] register is used once again.

55.4.9.1.2.2.3.6 Sequence Aborting

All 802.15.4 sequences can be aborted by a PLL unlock detection. The unlock detection is qualified by the ZSM sequence manager; in other words, an unlock condition during the early stages of the PLL warmup is expected, and is not allowed to abort the sequence at that point. The primary rationale for the PLL unlock abort is to prevent transmission on an incorrect, or unstable, frequency during a transmit operation, or to increase battery life by not prolonging a receive or CCA operation that is bound to fail. Software can disable the PLL unlock auto-abort.

When a PLL unlock event occurs during a 802.15.4 autosequence, the TSM's abort facilities are not used, to allow the ZSM to handle the unlock condition directly, as shown in the following diagram:

802.15.4 PLL UNLOCK HANDLING



The combined-abort signal is blocked from reaching the TSM, and instead is routed to the 802.15.4 Sequence Manager (ZSM). This is due to the fact that the ZSM already includes abort-handling logic, which is being re-used from previous Freescale/NXP 802.15.4 products. Keeping the unlock handling intact, facilitates the porting of software from one NXP 802.15.4 product to the next.

For 802.15.4, the logic which determines which ZSM states allow aborting, is designed into the ZSM state machine. Not all states require an abort-on-unlock. When an unlock event occurs during a ZSM state that requires an abort, the ZSM will deassert its initiating signal to TSM (zigbee_tx_en or zigbee_rx_en), which results in a de facto abort, similar to a TSM-generated abort. For a ZSM abort, the PLL_UNLOCK_IRQ bit will become set, as will the PLL_ABORTED bit. The PLL_UNLOCK_IRQ bit is of type write-1-to-clear, and resides in the IRQSTS1 register of 802.15.4 space. The PLL_ABORTED bit is a read-only bit, and resides in the ABORT_STS register of 802.15.4 space; it will self-clear at the start of the next autosequence.

55.4.9.1.2.2.3.7 Clocks

The ZSM sequence manager use 2 clocks.

The main clock is **seq_mgr_clk**. This clock establishes the sequence manager timebase (1us), and runs the sequence manager state machine and auxiliary timers.

A secondary clock is “**ck”,** which is a gated 32mhz clock from the reference oscillator. This clock is used only for low-latency processing of a few incoming signals, such as the issuing of XCVSEQ sequence commands through the IPS bus interface, which can occur at a rate faster than 1us.

The **seq_mgr_clk** and **ck** derive from the same 32MHz source. Thus, these 2 clocks are in the same clock domain, and will be balanced (skew-controlled) during clock-tree synthesis. The **seq_mgr_clk** will be generated in the CRM. All inputs to the sequence manager are also in this same clock domain, including all the TSM interface signals, and the IPS bus-based control registers; there are no clock-domain-crossings or asynchronous interfaces in the ZSM sequence manager.

55.4.9.1.2.2.3.8 Reset

The 802.15.4 Sequence Manager has a single, active-low, asynchronous reset input: **rst_b** . At integration, this reset should be tied to the master reset for the entire transceiver. There are no special reset requirements.

55.4.9.1.2.2.3.9 Interrupts

The 802.15.4 Sequence Manager generates 4 interrupt "triggers":

1. rxirq_trig
2. txirq_trig
3. ccairq_trig
4. filterfail_irq_trig

These triggers are not a direct interrupts to the MCU, but are used to set individual 802.15.4 Interrupt Status bits to become 4 of the 12 802.15.4 Link Layer interrupt sources which, if enabled, will result in the 802.15.4 interrupt **ipi_int_zigbee** being asserted to the MCU. These 4 interrupt triggers will assert the 802.15.4 Interrupt Status Bits RXIRQ, TXIRQ, CCAIRQ, and FILTERFAIL_IRQ, respectively. All of these Interrupt Status Bits reside in the IRQSTS1 register of 802.15.4 Address Space. See Section Interrupts for more details on how the 802.15.4 Link Layer interrupt sources are consolidated into a single MCU interrupt line.

55.4.9.1.2.2.3.10 Appendix A

Effect of Timer TMR3 on Sequence Manager

Timer TMR3 can be used as a “bracketing” timer, to abort certain sequences after a software-determined timeout period. This timeout mechanism is enabled by setting the TC3TMOUT bit to 1. If TC3TMOUT=0, then the abort mechanism is disabled, and timer TMR3 functions merely as a software timer.

Timer TMR3’s hardware-abort functions are summarized in the following table.

Table 476. TMR3 Hardware Abort Functions

SEQUENCE	TC3TMOUT=0	TC3TMOUT=1
I	S/W timer	S/W timer
R	S/W timer	Abort sequence
T	S/W timer	S/W timer
C	S/W timer	S/W timer
TR	S/W timer	Abort sequence, (during receive operation only)
CCCA	S/W timer	Abort sequence

55.4.9.1.2.2.3.11 Appendix B

Continuous TX and RX Modes

Setting the bit CONTINUOUS_EN enables continuous transmission or reception, determined by which type of sequence is subsequently activated using the XCVSEQ register (i.e., Sequence T or Sequence R). Continuous TX and RX modes are designed to be used in tandem; i.e., two communicating devices, one serving as a continuous transmitter, and the other serving as a continuous receiver. The CONTINUOUS_EN resides in the SEQ_MGR_CTRL register of 802.15.4 address space. A description of the continuous TX and RX modes follows:

Continuous TX Mode

Continuous TX mode instructs the Sequence Manager to stay in a transmitting state forever (TX_PKT state), rather than shutting down the sequence after the 802.15.4 packet has been transmitted. In Continuous TX mode, data to be transmitted must be pre-established in the Packet Buffer prior to initiating a Sequence T. In Continuous TX mode, the first byte of the Packet Buffer

determines the length of the buffer, in bytes. In this mode, when the end of the buffer is reached, instead of transmitting FCS (CRC bytes), the TX modem circles back to the 2nd byte of the buffer (the byte after the length byte), and re-transmits the remainder of the buffer again, and this repeats continuously, until one of the following events occurs:

1) CONTINUOUS_EN is deasserted by SW

2) SW aborts the Sequence T by writing Sequence I to XCVSEQ

3) An PLL Unlock occurs, aborting the Sequence

To prepare for Continuous TX mode, the following steps should be taken:

1) Write the “length” byte to the first byte of the Packet Buffer

2) Write the remaining Packet Buffer contents (a total of “length” bytes)

3) Assert the CONTINUOUS_EN bit

4) Start the Transmit Sequence by writing Sequence T to XCVSEQ.

After Continuous TX mode has been entered, the SEQ_STATE register can be monitored to verify the Sequence Manager has reached the TX_PKT state, and remains in this state.

Continuous RX Mode

Continuous RX mode instructs the Sequence Manager to stay in a receiving state forever (RX_PKT state), rather than shutting down the sequence after a 802.15.4 packet has been received. For continuous RX mode, it is assumed that another device has been deployed as a continuous transmitter. The length of the continuous transmitter’s TX buffer, will also be the length of the continuous receiver’s RX buffer. For the receiver, in Continuous RX mode, the length of the buffer is determined by the DUAL_PAN_DWELL register. (Needless to say, Continuous RX mode should not be engaged simultaneously with Dual PAN mode, since DUAL_PAN_DWELL is serving an alternate purpose). For Continuous RX mode, DUAL_PAN_DWELL should be programmed to the same value as the “length” byte of the continuous transmitter’s TX buffer. See step 2) above, for Continuous TX mode. In Continuous RX mode, the first byte received (after Preamble and SFD), will be the “length” byte, which can be read from the RX_FRM_LEN register of the receiving device. (It is up to the user to guarantee that this length byte on the TX device matches the contents of the DUAL_PAN_DWELL register on the RX devices, by correctly programming the 2 devices). Each subsequent byte which is received, will be written to the next sequential address of the Packet Buffer, starting at PB address 0. When the number of received bytes matches the contents of DUAL_PAN_DWELL register, the Packet Buffer’s address generation logic will circle back to PB address 0, and store the next received byte to this location. Then, each subsequent received byte, will be written to the next sequential address of the Packet Buffer. In this way, the contents of TX buffer on the continuous transmitter, will be identical to the contents of the RX buffer on the continuous receiver (assuming no reception errors). To prepare for Continuous RX mode, the following steps should be taken:

1) Program DUAL_PAN_DWELL register with the contents of the “length” byte of the continuously-transmitting device’s TX Buffer

2) Assert the CONTINUOUS_EN bit

3) Start the Receive Sequence by writing Sequence R to XCVSEQ.

After Continuous RX mode has been entered, the SEQ_STATE register can be monitored to verify the Sequence Manager has reached the RX_PKT state, and remains in this state. The contents of the Packet Buffer can also be observed in realtime, to verify they match the contents of the TX device’s TX buffer. The Sequence Manager will remain in the RX_PKT state until one of the following events occurs:

1) CONTINUOUS_EN is deasserted by SW

2) SW aborts the Sequence R by writing Sequence I to XCVSEQ

3) An PLL Unlock occurs, aborting the Sequence

55.4.9.1.2.3 Packet Storage

The 802.15.4 Link Layer has access to a Packet Buffer to store data to be transmitted, and to receive incoming packet data. The 802.15.4 Link Layer software prepares data to be transmitted, by loading the octets, in order, into the Packet Buffer (Zigbee LL

TX_RAM Buffer). After reception, the octets received over the air are stored into the Packet Buffer (Zigbee LL RX_RAM Buffer), in the order they are received. The Packet Buffer contains separate spaces for TX and RX data, so incoming receive octets don't overwrite previously-loaded content intended for transmission. The Packet Buffer is large enough to accommodate the longest 802.15.4 packet, 127 bytes, for both transmit and receive.

The 802.15.4 Packet Buffer is contained within the multi-protocol Packet RAM. In the Packet RAM, space has been allocated for 802.15.4 packets, with separate spaces for TX and RX. The Packet RAM is 64 bits wide, so the 802.15.4 Link Layer controller hardware will address the RAM in an interleaved fashion as it stores octets to, or fetches octets from, the RAM-based packet buffer. The 802.15.4 TX buffer space begins at TX_RAM_BASE_ADDR, and 802.15.4 RX buffer space begins at RX_RAM_BASE_ADDR. Separate TX and RX spaces means that incoming RX packets don't overwrite TX packet data.

In addition, the 802.15.4 Link Layer controller includes acceleration for Source Address Matching (see Section Source Address Management). The hardware acceleration includes a Source Address Table, which is 128 entries by 16 bits wide. This table begins at TX_RAM_BASE_ADDR+0x100.

During packet reception, the MCU is allowed to access the RX packet buffer, in order to download the packet while it's being received, if so desired. In cases where both the MCU and the 802.15.4 Link Layer controller attempt to access RX packet buffer during reception, internal hardware arbitration is provided to delay the MCU access until 802.15.4 Link Layer completes its access.

During packet reception, the MCU is allowed to access the Source Address Table. Access to he Source Address Table is indirect, and is performed through the 802.15.4 Register Interface, specifically by programming SAM_TABLE register with the index of the table entry to be written or read, and the desired checksum in the case of write accesses. Because accesses to Source Address Table consist of discrete writes to 802.15.4 registers, and not long burst accesses, arbitration shall be able to accommodate Link Layer read accesses to the table while the Host access is underway, by delaying the Host access until the Link Layer completes.

During packet transmission MCU access to TX_RAM Buffer is also allowed. Arbitration shall be able to accommodate Link Layer read accesses to the TX RAM Buffer while the Host access is underway, by delaying the Host access until the Link Layer completes. This is very useful when sending enhanced ACK frames. But the 802.15.4 softwaremust not alter the Source Address Table once transmission has begun.

Arbitration

Arbitration hardware has been provided to allow the MCU to download data from the RX RAM Buffer while the packet is being received, in order to allow a headstart on software packet processing, if required by the application. Arbitration hardware has also been provided to allow the MCU to write data to the TX RAM Buffer while the packet is being sent, in order to allow software packet preparation, if required by the application. In the SoC, there is no provisions to wait the MCU on IPS or APB bus accesses to the radio. Therefore, in case of simultaneous access attempts by the MCU and the 802.15.4 Link Layer to the TX/RX RAM Buffer, arbitration hardware delays the MCU access to the TX/RX RAM Buffer until Link Layer completes its access. In the intended scenario, 802.15.4 software sets a RX watermark interrupt, and on this interrupt, proceeds to download the contents of the Packet RX buffer in RX RAM Buffer.

55.4.9.1.2.4 Memory Mapping

In the SoC memory map, space has been allocated to 802.15.4. Within the SoC, peripherals are allocated memory space in 4KB blocks, called IPS slots. 802.15.4 occupies one such slot. 802.15.4 address space consists of the 802.15.4 registers, as well as the Packet Buffer (RAM), which is memory-mapped into 802.15.4 memory space. The partitioning of address space for 802.15.4 is shown in the diagram below.

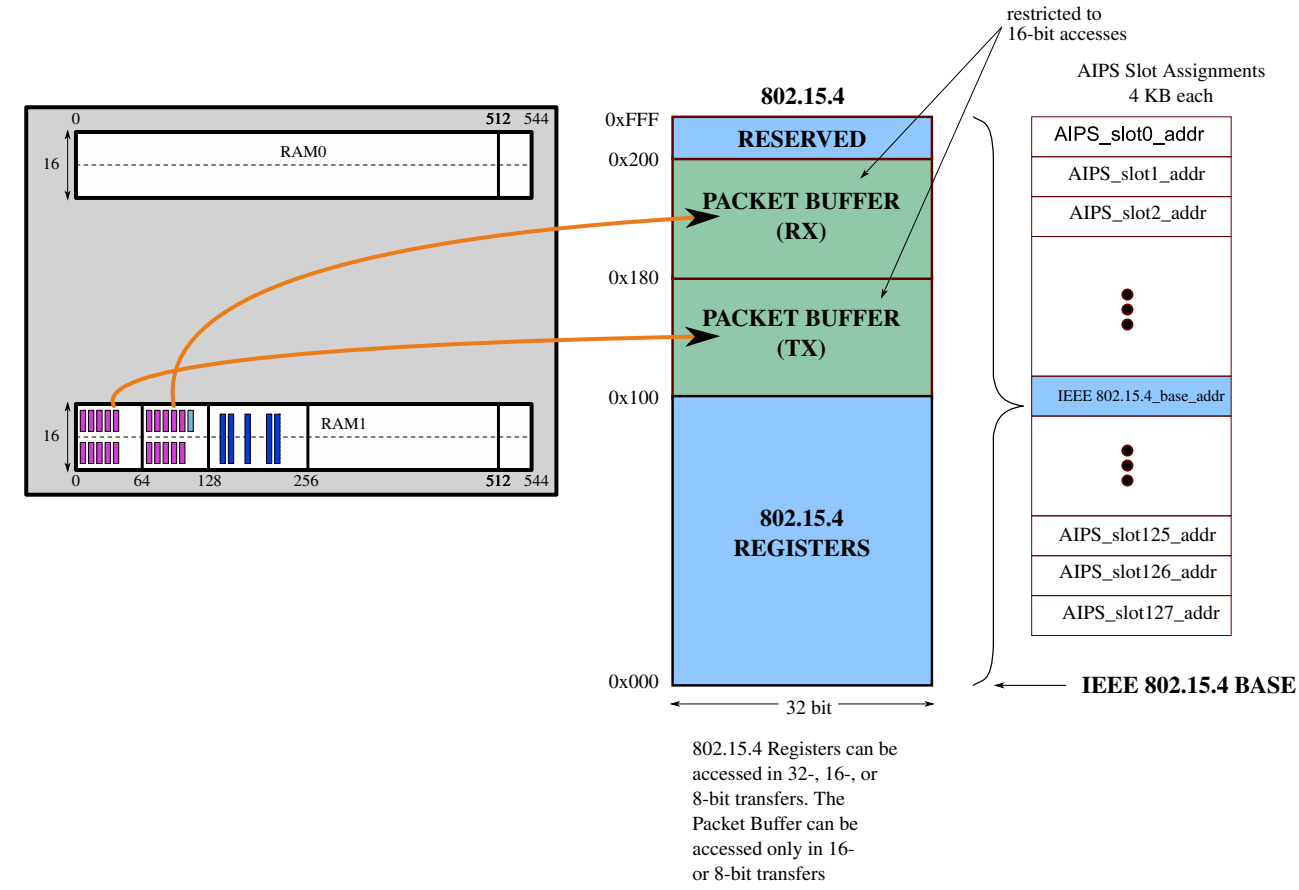


Figure 384. 802.15.4 MEMORY MAPPING

NOTE

See AIPS Memory Map for specific memory assignments details.

The Packet Buffer (RAM), is accessible by the MCU in 16-, or 8-bit accesses. The 802.15.4 Registers are accessible in 32-, 16-, or 8-bit accesses. The Source Address Table partition in RAM, is not accessible directly by the MCU, but via a prescribed protocol using the 802.15.4 SAM_TABLE register (see Section Source Address Management). Therefore, the table is not memory-mapped directly into 802.15.4 address space.

55.4.9.1.2.5 Event Timer

OVERVIEW

The 802.15.4 Link Layer Controller contains an internal Event Timer block that manages link layer timing.

The Event Timer consists of a prescaler and a 24-bit counter which increment whenever the 32MHz reference oscillator is operating (i.e., the controller is not in Deep Sleep Mode). Interrupts to the MCU may be generated when the current time of the counter matches several pre-determined values set in programmable registers. The current time is accessible at any time via a read operation, as well as, programmable via a write operation.

The Event Timer provides the following functions:

- Timer to generate current system time
- Interrupt generation at pre-determined system times

- Abort an RX sequence at pre-determined system time
- Latches timestamp value during packet reception
- Initiates timer-triggered sequences

Note: The Event Timer is actually a 28-bit value, with 24 integer bits and 4 fractional bits. For most operations involving the Event Timer, such as interrupt-generation and sequence-triggering, only the integer portion need be considered, and the fractional component can be ignored. Extended-precision (28-bit) Event Timer operations are required only to realize the increased accuracy required for entering and exiting Deep Sleep Mode. See Section Extended Precision Event Timer below.

EVENT TIMER TIME BASE

The Event Timer's base clock (tmr_clk) is derived from a prescaler which is clocked by the 32MHz crystal source. The prescaler provides a counter input frequency of 62.5KHz, which sets the granularity and resolution of the current time. The 24-bit counter automatically rolls over upon reaching its maximum value, yielding a maximum possible Event Timer duration of 268.436 seconds.

READING CURRENT TIME

"Current Time" is defined as the value of the Event Timer internal counter. This 24-bit value can be read as the upper 3 bytes of the EVENT_TMR register. The EVENT_TMR register resides at at address ZLL_BASE + 0x8, so the upper 3 bytes begin at ZLL_BASE + 0x9. The 24-bit value represents the integer component of the 28-bit Event Timer, which is all that is needed for most Event Timer operations. (For accessing the extended precision Event Timer, see Section Extended Precision Event Timer below.)

SETTING CURRENT TIME

"Current Time" is defined as the value of the Event Timer internal counter. This 24-bit value is available as the upper 3 bytes of the EVENT_TMR register. The EVENT_TMR register resides at at address ZLL_BASE + 0x8, so the upper 3 bytes begin at ZLL_BASE + 0x9. The current time is programmable, but does not have to be programmed. In the reset condition, the current time is set to zero. Current time advances from zero at the tmr_clk clock rate and rolls over to zero after reaching its maximum value.

The Event Timer can be updated in one of 2 ways:

EVENT_TMR_LD: Write the desired new EVENT_TMR value into the EVENT_TMR field of the EVENT_TMR register (upper 3 bytes), with the EVENT_TMR_LD bit set.

EVENT_TMR_ADD: Write the desired *increment* to the EVENT_TMR value into the EVENT_TMR field of the EVENT_TMR register (upper 3 bytes), with the EVENT_TMR_ADD bit set. The increment will be added to the current value of EVENT_TMR to become the new EVENT_TMR value. Since the Event Timer value is 24-bits, the addition is modulo 2^{24}.

Needless to say, EVENT_TMR_LD and EVENT_TMR_ADD are mutually exclusive, and no more than 1 of these bits should be set.

The 24-bit value represents the integer component of the 28-bit Event Timer, which is all that is needed for most Event Timer operations. (For accessing and updating the extended precision Event Timer, see Section Extended Precision Event Timer below.)

LATCHING THE TIMESTAMP

During packet reception, the 802.15.4 link layer controller has the ability generate a timestamp, or to latch a copy of the "current time" while continuing to increment its internal counter. This timestamp value latched within the Event Timer corresponds to the beginning of a receive packet where the actual packet data begins after the SFD (Start-of-Frame-Delimiter) has been received. The timestamp[23:0] can be accessed by reading the read-only register of the same name, TIMESTAMP, which resides at address ZLL_BASE + 0xC. Once the timestamp has been latched, it shall remain valid until the *next* SFD detection.

EVENT TIMER COMPARATORS

There are four 24-bit timer compare fields:

1. T1CMP[23:0] at address ZLL_BASE + 0x10
2. T2CMP[23:0] at address ZLL_BASE + 0x14
3. T3CMP[23:0] at address ZLL_BASE + 0x1C
4. T4CMP[23:0] at address ZLL_BASE + 0x20

And a special 16-bit timer compare field, for situations where the upper byte of EVENT_TMR is a don't-care.

- T2PRIMECMP[15:0] at address ZLL_BASE + 0x18

The TMR2IRQ status bit, can be set by a match to T2CMP or T2PRIMECMP. If register bit TC2PRIME_EN=1 (PHY_CTRL register, address ZLL_BASE + 0x04), then TMR2IRQ becomes set by a match to T2PRIMECMP (16-bit compare); if TC2PRIME_EN=0, then TMR2IRQ becomes set by a match to T2CMP (24-bit compare).

Each timer comparator has a enable bit that enables or disables the compare function. The enable bit is written to a 1 to enable the corresponding comparator, and the default condition is the timer compare disabled (reset to 0):

1. TMR1CMP_EN (for T1CMP)
2. TMP2CMP_EN (for T2CMP and T2PRIMECMP)
3. TMR3CMP_EN (for T3CMP)
4. TMR4CMP_EN (for T4CMP)

If a timer comparator is enabled using its associated bit, the corresponding interrupt status bit (TMRxIRQ) will be set by a timer compare match to its respective TxCMP register. If a timer comparator is disabled using its associated bit, the corresponding interrupt status bit (TMRxIRQ) will not be set by a timer compare match to its respective TxCMP register.

When enabled, all four fields can be continuously compared to the current value of the Event Timer counter. When a match occurs, the following corresponding internal status flags assert:

1. TMR1IRQ (T1CMP match)
2. TMR2IRQ (T2CMP or T2PRIMECMP match)
3. TMR3IRQ (T3CMP match)
4. TMR4IRQ (T4CMP match)

These 4 status bits all reside in the IRQSTS register at address ZLL_BASE + 0x0. The 4 interrupt status bits are write-1-to-clear. The status bit remains set until a 1 is written to the bit location in the IRQSTS register. Writing 0 to the bit, or reading the bit, will not change its state.

When a comparator match occurs and the internal status flag asserts, the following interrupt masks can enable an interrupt on the ipi_int_zigbee line to the MCU:

1. TMR1MSK, applies to TMRQ1IRQ
2. TMR2MSK, applies to TMRQ2IRQ
3. TMR3MSK, applies to TMRQ3IRQ
4. TMR4MSK, applies to TMRQ4IRQ

If the interrupt mask is set to 1 (masked), the respective interrupt status bit, TMRxIRQ, will not cause an interrupt on the ipi_int_zigbee line. If the interrupt mask is set to 0 (enabled), the respective interrupt status bit, TMRxIRQ, will cause an interrupt on ipi_int_zigbee. Timer mask bits, TMRxMSK, have no effect on the state of the TMRxIRQ interrupt status bits; they only allow (or prevent) the respective TMRxIRQ bit from generating an interrupt to the MCU on ipi_int_zigbee.

INTENDED EVENT TIMER USAGE

It is intended that the system utilize the current time value and the timer compare functions of the Event Timer to schedule system events, including:

1. Generating time-based interrupts
2. Aborting an RX operation
3. Triggering transceiver operations

GENERATING TIME-BASED INTERRUPTS

Generating time-based interrupts is accomplished by setting timer compare values relative to the current time, allowing the Event Timer counter to increment until a timer compare match is generated, and using this match to generate an interrupt to the host. The general procedure is as follows:

1. Disable the timer compare: set TMRxCMP_EN=0

2. Enable the timer compare interrupt mask: set TMRxMSK=1
3. Read the current time value from EVENT_TMR register
4. Determine an offset to this value to equal desired future time.
5. Write to EVENT_TMR register with the EVENT_TMR field set to this offset, and set EVENT_TMR_ADD=1
6. Re-enable the timer compare: set TMRxCMP_EN=1
7. Unmask the timer compare interrupt mask: set TMRxMSK=0
8. Wait for TMRxIRQ
9. After TMRxIRQ, program the appropriate TMRxCMP_EN bit to disable the compare function. If this is not done, the compare function will continue to run and generate another interrupt every time the counter rolls over and again matches the comparator.

USING T3CMP TO ABORT AN RX OPERATION

The Event Timer provides a timer-based mechanism to automatically abort an RX operation. The 802.15.4 link layer is put into an RX operation when XCVSEQ[2:0] (PHY_CTRL register, address ZLL_BASE + 0x4) is set to 0x01. An RX autosequence will commence, and will begin a search for preamble. Software can program in advance, a hardware timeout to occur, such that the RX autosequence can be automatically aborted by hardware after a certain amount of time elapses without a packet being detected. The general procedure is as follows:

1. Read the current time value from EVENT_TMR register
2. Add an offset to this value to equal desired future time to abort the RX operation.
3. Program register T3CMP[23:0] to value future time.
4. Program TC3TMOUT=1, (PHY_CTRL Register, address ZLL_BASE + 0x4) to 1, to enable hardware aborting of the RX operation.
5. Program XCVSEQ=1, to start the RX autosequence
6. When current time equals T3CMP[23:0], the 802.15.4 Sequence Manager aborts the RX autosequence, and the Sequence Manager returns to SEQ_IDLE state. The SEQIRQ interrupt status bit (IRQSTS Register, address ZLL_BASE + 0x0) will be set, and the TMR3IRQ interrupt status bit will also be set. The RXIRQ interrupt status bit will not be set, since no packet was received before the timeout. In the SEQ_CTRL_STATUS register (address ZLL_BASE + 0x78), the TC3_ABORTED status bit will also be asserted to indicate that the type of abort that occurred was a TMR3 timeout. This bit will self-clear at the start of the next autosequence.

As mentioned above, TMR3 with TC3TMOUT=1 can be used to abort an RX operation. Such an RX operation can be entered by launching a Sequence R (XCVSEQ=1), and can also be entered by launching a Sequence TR (XCVSEQ=4); after the TX operation of a Sequence TR completes, an RX operation begins, and can be aborted using this method. In addition, a Continuous CCA autosequence (XCVSEQ=5) can be aborted using this method. When a TMR3 timeout occurs with TC3TMOUT=1 during transceiver operations other than those listed above, TMR3 will not abort the autosequence, and TMR3 becomes merely a software timer, capable of setting TMR3IRQ and interrupting the MCU. The table below shows the effect of TMR3 timeouts on the 802.15.4 autosequences:

Table 477. TMR3 Hardware Abort Functions

SEQUENCE	TC3TMOUT=0	TC3TMOUT=1
I	S/W timer	S/W timer
R	S/W timer	Abort sequence
T	S/W timer	S/W timer
C	S/W timer	S/W timer
TR	S/W timer	Abort sequence, (during receive operation only)
CCCA	S/W timer	Abort sequence

USING T2CMP OR T2PRIMECMP TO TRIGGER TRANSCEIVER OPERATIONS

The Event Timer provides a timer-based mechanism to automatically launch a transceiver autosequence. Using this method, a sequence can be scheduled for time in the future, and the MCU can be put into a reduced power state, without the need to wake up at the appropriate time to start the autosequence. The general procedure is as follows.

1. Read the current time value from EVENT_TMR register.
2. Add an offset to this value to equal desired future time to launch the autosequence.
3. For a 24-bit compare, program register T2CMP[23:0] to value future time, and set TC2PRIME_EN=0. For a 16-bit compare, program register T2PRIMECMP[15:0] to value future time, and set TC2PRIME_EN=1. Set TMRTRIGEN=1 and program the desired autosequence into XCVSEQ[2:0]. The Sequence Manager will not launch the sequence immediately because it sees TMRTRIGEN=1.
4. When current time equals T2CMP[23:0] (for a 24-bit compare), or T2PRIMECMP[15:0] (for a 16-bit compare), the Sequence Manager will launch the scheduled autosequence in accordance with the XCVSEQ[2:0] field. The TMR2IRQ interrupt status bit will become set simultaneous with the autosequence launch.
5. The MCU can wake up at this point (if TMR2MSK=0), or can elect to continue in low-power state until the autosequence completes, at which time SEQIRQ will become set. If SEQMSK=0, then SEQIRQ will interrupt the MCU at the completion of the transceiver operation.

EXTENDED PRECISION EVENT TIMER

For most 802.15.4 transceiver operations referencing the Event Timer, the 24-bit precision and the 62.5KHz update rate (16µs period) are sufficient. However, the required precision for maintaining the 802.15.4 timebase is tighter: 1 microsecond, instead of 16. As long as the 32MHz reference oscillator is running there is no difficulty maintaining that precision. However, when the link layer has to enter low-power state, and the reference oscillator must be switched off, and alternate clock source must be temporarily employed to keep the timebase running. This low power state is known as Deep Sleep Mode, or DSM. The alternate clock source, a 32KHz crystal oscillator, is equally as precise as the reference oscillator, but with a much longer period. At the instant the reference oscillator is turned off and the switchover to the 32KHz is made, the EVENT_TMR becomes frozen at its current state. After a period of DSM, when the precisely-programmed wakeup point is reached, the reference oscillator, which has been previously restarted, is re-engaged by the link layer, and the EVENT_TMR resumes counting where it left off. The precise duration of time for which the EVENT_TMR was frozen, is known to software, based on DSM programming parameters. The EVENT_TMR must be corrected for this "time slept", by adding to it an amount equal to "time slept", in microseconds (hence the requirement for microsecond precision). After the precise correction is made, the EVENT_TMR is now up-to-date, as if the DSM entry/exit had never happened, and all previously scheduled events will occur on time, within 1µs precision.

To realize the required microsecond precision, the actual Event Timer has been expanded to 28 bits, with 24 integer bits and 4 fractional bits, as shown in the diagram below.

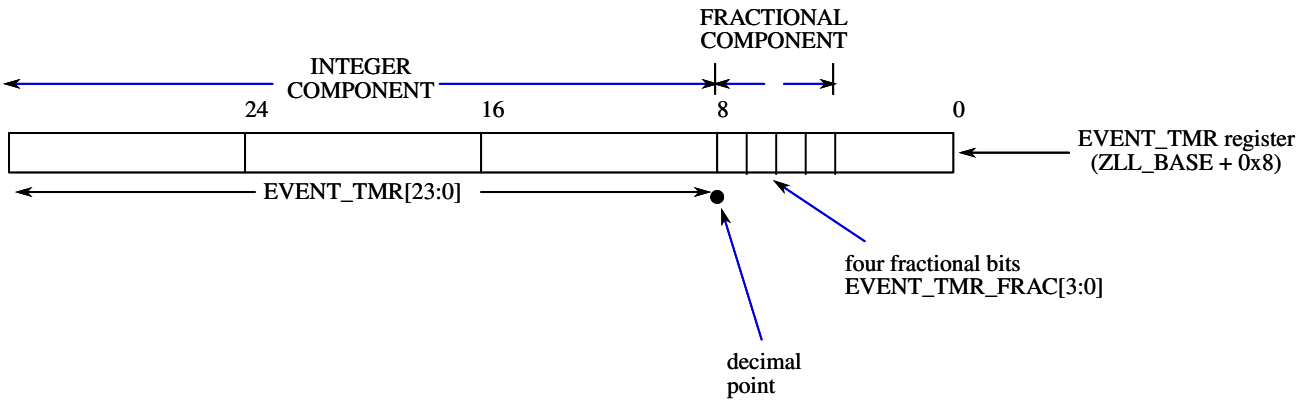

Figure 385. Event Timer Integer and Fractional Components

The 24-bit integer component is the EVENT_TMR value that has been referenced earlier in this section; most 802.15.4 operations require only the integer component, and the fractional component can be ignored. When the fractional bits are not required, writes

to EVENT_TMR register (read-modify-write operations) with EVENT_TMR_LD=1 should leave the fractional bits unchanged. Transceiver operations which reference the EVENT_TMR (i.e., automatic sequence launching, and RX sequence aborting), reference only the integer component, as shown below.

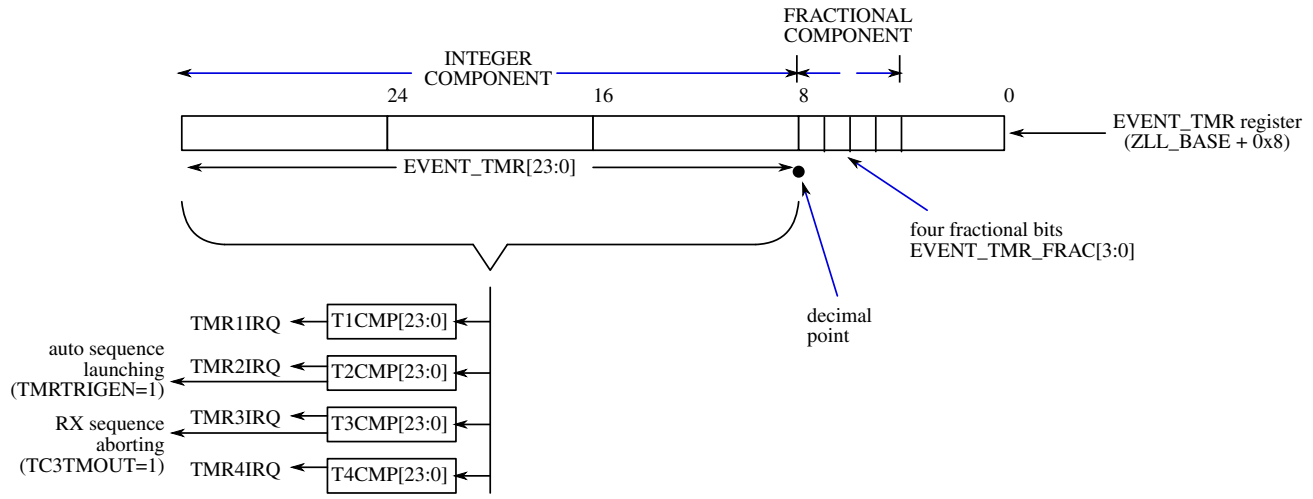

Figure 386. Event Timer Hardware Referencing

However, software EVENT_TMR updates to correct for "time slept" after a DSM cycle must make use of the full precision, including the fractional bits, in order to maintain microsecond accuracy. For example, say a DSM cycle was just completed in which the EVENT_TMR was frozen for exactly 163µs. The 163µs must be "added back" to the EVENT_TMR.

In this case the integer component is:

integer(163µs / 16µs) = **10**

And the fractional component is the remainder x 16:

(163µs / 16µs) - integer(163µs / 16µs) = 3/16 x 16 = **3**

So the value written to the EVENT_TMR with the EVENT_TMR_ADD bit set, accounting for the bit shifts to align to the integer and fractional components of the EVENT_TMR register, is:

(10 $lt;< 8) | (3 $lt;< 4), *or,*

EVENT_TMR = (10 $lt;< 8) | (3 $lt;< 4) | EVENT_TMR_ADD;

This operation adds 163µs to the EVENT_TMR current time, and after the update has occurred, the 802.15.4 timebase has been restored, as if no DSM cycle had occurred, within 1µs accuracy.

55.4.9.1.2.6 Simultaneous CCA/RX

The 802.15.4 Link Layer controller features an autosequence that precedes a packet transmission with a CCA (Clear Channel Assessment), to ensure the channel is idle before transmitting. If the CCA indicates a busy channel, the autosequence ends after the CCA, without transmitting. In slotted mode, 2 CCA measurements take place, with the start points for the measurements 320us apart. Both must indicate an idle channel for transmission to proceed.

During intervals of severe network congestion, high node density, and packets which are heavily fragmented, the situation can arise where Device A is preparing to transmit a packet, or fragment, and performing pre-transmit CCA, and during the CCA, Device B attempts to transmit another packet or fragment to Device A. Previous NXP 802.15.4 transceivers were unable to receive a packet during CCA, so Device B's packet will be missed by Device A. For the Gen3 2.4GHz radio, the capability to receive-during-CCA has been added to 802.15.4. This capability is referred to as "Simultaneous CCA/RX".

To enable this capability, 3 enhancements have been made to the digital receiver and the 802.15.4 sequence manager:

1. CCA Mode 2 Algorithm Separated from 802.15.4 Demodulator

2. New 802.15.4 State Machine Transitions
3. New TSM Fast RX-to-TX Capability

1. Separated CCA Mode 2 Algorithm

One reason for the lack of prior support, is that the CCA Mode 2 algorithm has been tightly integrated with the 15.4 demodulator, so that both functions cannot simultaneously co-exist. The Gen3 digital receiver separates these functions, removing the CCA Mode 2 impediment to Simultaneous CCA/RX. See Chapter *Receiver Digital Module*, Section *IEEE 802.15.4 CCA mode 2*. (CCA Mode 1 does not utilize the demodulator, so such impediment exists.)

The legacy CCA Mode 2 hardware has been retained as a back-up. The control bit USE_DEMOD_CCA2 selects between legacy (1) and new CCA Mode 2 (0). This bit must be set to 0 to utilize Simultaneous CCA/RX. The following table summarizes the programmability associated with CCA Mode 2. The third column references table *IEEE 802.15.4 CCA mode 2 parameters* in Chapter *Receiver Digital Module*, Section *IEEE 802.15.4 CCA mode 2*

REGISTER NAME	ADDRESS SPACE	ASSOCIATED CCA MODE 2 PARAMETER	DESCRIPTION
USE_DEMOD_CCA2	XCVR	n/a	CCA Mode 2 hardware selector. • 0: use new CCA Mode 2 • 1: use demodulator-based (legacy) CCA Mode 2
CCA2_CORR_THRESH[7:0]	802.15.4	zb_cca2_thresh_corr[7:0]	Threshold used to compare correlation products. **Note:** this register is shared between the new and legacy CCA Mode 2 hardware
CCA2_CNT_THRESH[9:0]	XCVR	zb_cca2_thresh_cnt[9:0]	Threshold to compare count of correlation products exceeding CCA2_CORR_THRESH[7:0]
CCA2_SYM_THRESH[9:0]	XCVR	zb_cca2_thresh_sym[9:0]	Threshold used to detect repetition sequence addresses corresponding to correlation products that exceed CCA2_CORR_THRESH[7:0]
CCA2_REF_SEQ[7:0]	XCVR	zb_cca2_ref_seq[7:0]	Selection of the sequence addresses to be used.
CCA2_INTERVAL[1:0]	XCVR	zb_cca2_duration[1:0]	Specifies the CCA2 measurement window duration: • 0x00 - 64 µs • 0x01 - 128 µs • 0x02 - 256 µs • 0x03 - 512 µs

Note: Set CCA2_DURATION=0x01 (128us) for 802.15.4 operation.

2. New 802.15.4 State Machine Transitions

Using Simultaneous CCA/RX, the 802.15.4 Link Layer controller needs to be able to anticipate preamble, and even SFD detection, during the states in which it is taking CCA measurement. Those states are RX_CCA1, for non-slotted, and RX_CCA2, for slotted operation. If preamble and/or SFD is detected in those states, the 802.15.4 sequence manager needs to transition to a packet reception state, and then receive the packet in its entirety as if the called sequence was Sequence R. To address this, these new state transitions have been added to the 802.15.4 Sequence Manager (ZSM) state machine:

- RX_CCA1 -> RX_PRE (preamble detected during 1st CCA but no SFD)
- RX_CCA1 -> RX_PKT (preamble + SFD detected during 1st CCA)
- RX_CCA2 -> RX_PRE (preamble detected during 2nd CCA but no SFD)
- RX_CCA2 -> RX_PKT (preamble + SFD detected during 1st CCA)

The following diagram highlights the new ZSM state transitions, in red:

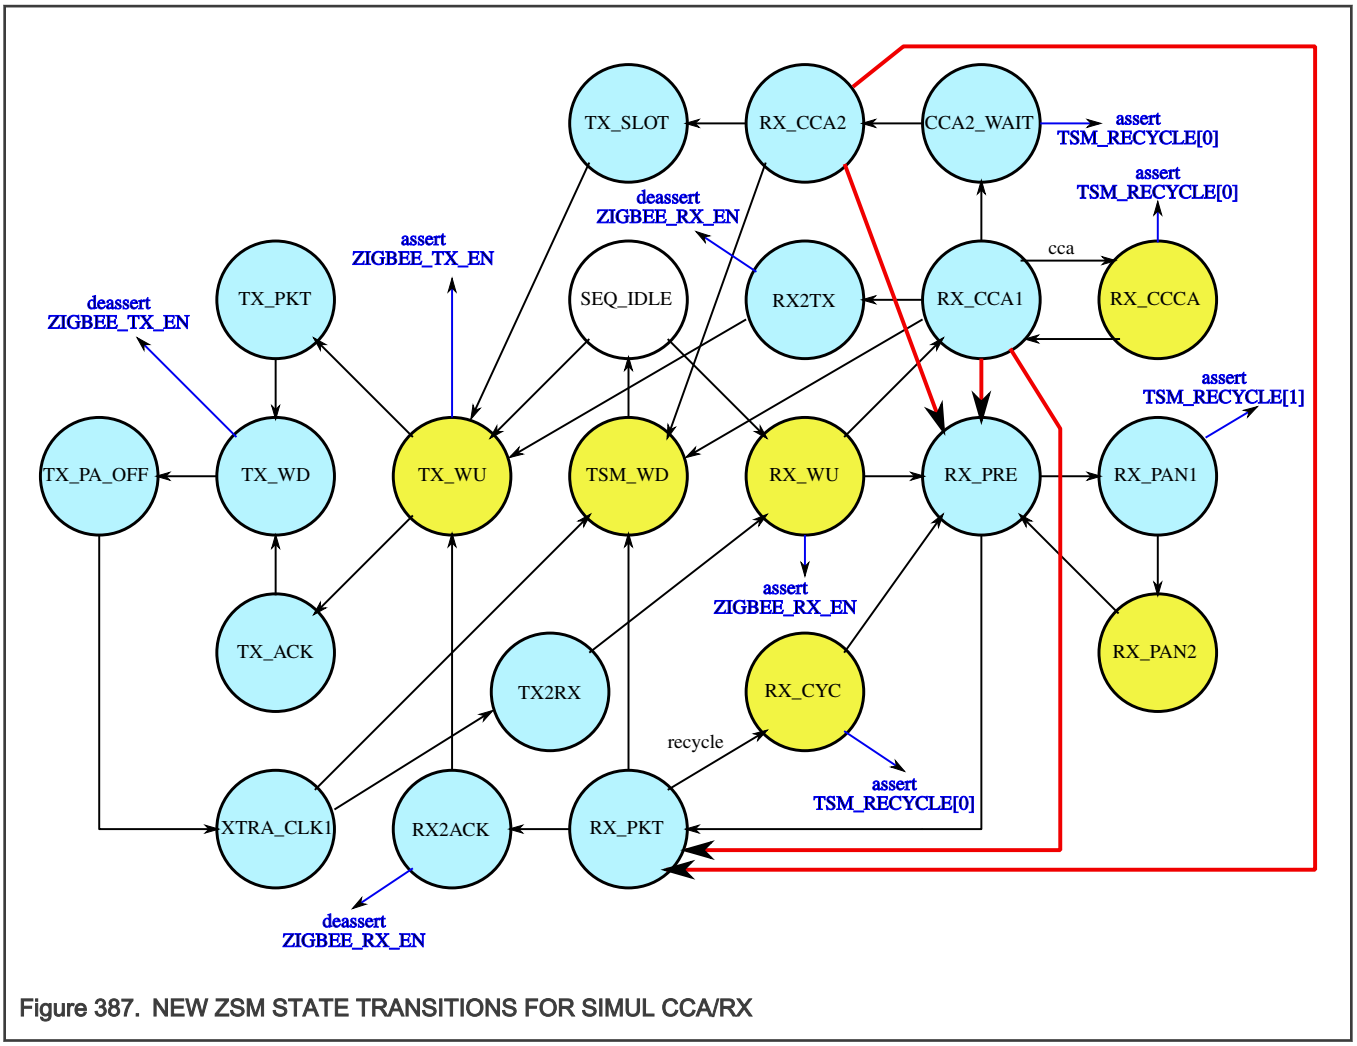

Figure 387. NEW ZSM STATE TRANSITIONS FOR SIMUL CCA/RX

False preambles may occur during the CCA states as well. False preambles occur when the 802.15.4 demodulator detects a sufficient number of consecutive 0 symbols to meet the preamble threshold, but the symbol which follows is neither a '0' nor a '7'. False preambles result in the 802.15.4 demodulator signal sfd_rst asserting either during, or after, the CCA state. If a false preamble is declared *within* the 128µs CCA window, then the fact that there was a false preamble has no bearing on the channel status, the CCA measurement determines channel status, as usual. If the false preamble is declared *after* the CCA window, the

channel is assessed to be busy and the autosequence terminates without transmission, because the scheduled transmission time has been missed.

In defining the Simultaneous CCA/RX operation, 9 "scenarios", or cases, were developed to help ensure correct hardware response to various permutations of preamble and SFD arrival times, preamble falsing, channel status, and RX packet goodness. These scenarios were used to guide the hardware design, for each of the 3 CCA modes, and for mode 3, both boolean combinations. The 9 scenarios are listed in the table below, with the correct hardware response indicated. The hardware response consists of a sequence of state transitions, as well as assertion (or non-assertion) of the various 802.15.4 interrupts. The final combination of asserted interrupts assists software in determining what transpired during the autosequence, and therefore what must be done next.

SCENARIO	#1	#2	#3	#4	#5	#6	#7	#8	#9
CHANNEL IDLE @ 128us	1	0	0	0	0	0	0	0	0

Figure 388. SIMUL CCA/RX SCENARIOS

A single register bit enables Simultaneous CCA/RX mode: SIMUL_CCA_RX. This bit resides in the CCA_CTRL register in 802.15.4 address space. By default SIMUL_CCA_RX=0, meaning that the new ZSM transitions are inhibited. Set this bit to 1, to enable the new transitions. Simultaneous CCA/RX works with any CCA Mode (1, 2, or 3), and works for both non-slotted (single CCA before TX) and slotted (2 CCA before TX) modes.

Note that to use the Simultaneous CCA/RX feature, software (not just hardware) needs to anticipate packet reception during a Sequence T (not just a Sequeunce TR). This may not exist today, since prior to Gen3, the 802.15.4 controller did not have this capability.

3. New TSM Fast RX-to-TX Capability

The 802.15.4 Sequence Manager (ZSM), makes use of the radio's all-protocol Transceiver Sequence Manager (TSM) to execute TX and RX warmup and warmdown sequences; TSM handles low-level commanding, with precise, programmable timing, of the analog and digital blocks in the transmit and receive chains, absolving the higher-level sequence managers from this responsibility. TSM sequences have, in the past, been discrete TX or RX operations, with a required software command to initiate the sequence, and a return-to-idle after the sequence is complete, before a new sequence-start command can be issued. For 802.15.4 Simultaneous CCA/RX mode, it is highly desirable to be able to jump directly from the end of a CCA measurement, which is essentially an RX operation, to a packet transmit operation, without returning the TSM to IDLE in between, if CCA deems the channel to be free. A new TSM transition called Fast RX2TX accomplishes this. The 802.15.4 ZSM will signal to TSM when to perform such a transition, and TSM will respond by jumping from the RX ON phase, to a programmable point within the TX warmup. See Chapter *Transceiver Sequence Manager*, Section *FAST TSM Warmup and FAST RX2TX Transition* for more details on this TSM feature, and a description of the ZSM -> TSM signaling required to execute such a transition.

A single register bit enables TSM Fast RX-to-TX: FAST_RX2TX_EN. This bit resides in the TSM_FAST_CTRL1 register in XCVR address space. By default FAST_RX2TX_EN=0, meaning that this TSM capability is inhibited, and RX-to-TX transitions remain discrete RX and TX sequences (legacy).

Once enabled with FAST_RX2TX_EN=1, the ZSM will request a TSM Fast RX-to-TX warmup, by asserting fast_rx2tx_wu, when all of the following conditions are met:

- 802.15.4 autosequence is T or TR
- Pre-TX CCA is enabled with CCABFRTX=1
- ZSM state is RX_CCA1 (non-slotted or slotted) or RX_CCA2 (slotted mode only)
- 128µs measurement timeout expires
- Neither preamble-detect nor SFD-detect are *currently* asserted
- Channel is deemed idle (CCA=0)

The TSM will respond to fast_rx2tx_wu by jumping from the "ON" phase of the RX operation to the "WARMUP" phase of the TX operation at the programmed point. Simultaneously, ZSM must jump to its TX_WU state to wait for the TX warmup to complete. This requires 2 new state transitions, to enable the Simultaneous CCA/RX feature, shown in red in the diagram below:

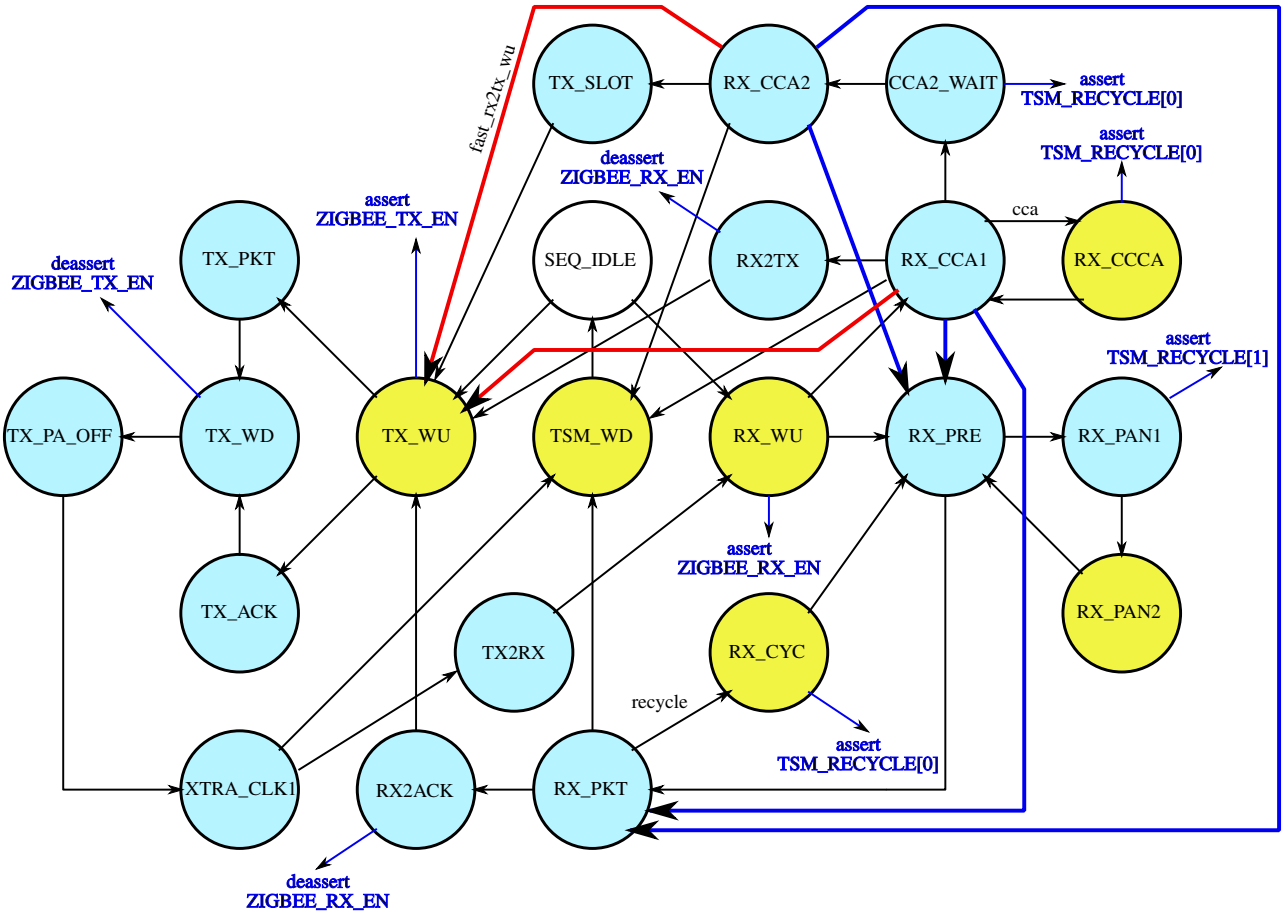

Figure 389. ZSM STATE TRANSITIONS FOR FAST RX2TX

Once the TX warmup completes, the 802.15.4 controller will transmit the packet as per the Sequence T command.

55.4.9.1.2.7 Manual DSM

When the 802.15.4 Link Layer anticipates long periods of inactivity, the Link Layer controller can be put into a Deep Sleep Mode (DSM), where all of its clocks are turned off. In addition, the 802.15.4 Link Layer can be configured to optionally turn off the RF Oscillator, if it is not otherwise needed by the SoC. Deep Sleep Mode results in dramatic power savings. The procedure described below, is called Manual DSM.

To make Manual DSM possible, the transceiver incorporates a low-frequency, high-precision Deep Sleep Timer, TIMER. This timer is clocked by a crystal-referenced 32.768KHz oscillator. The timer is 24-bit wide, yielding a 8.5 minute rollover (the maximum length of a deep sleep period).

The hardware to implement DSM within the SoC, is partitioned across several modules, and several power domains. This is to allow the maximum achievable power savings, by retaining full voltage for only those modules which need to be active in DSM, and placing the remaining modules in “state retention” mode. The diagram below depicts the partitioning of DSM hardware across the various modules, including the 802.15.4 Link Layer Controller.

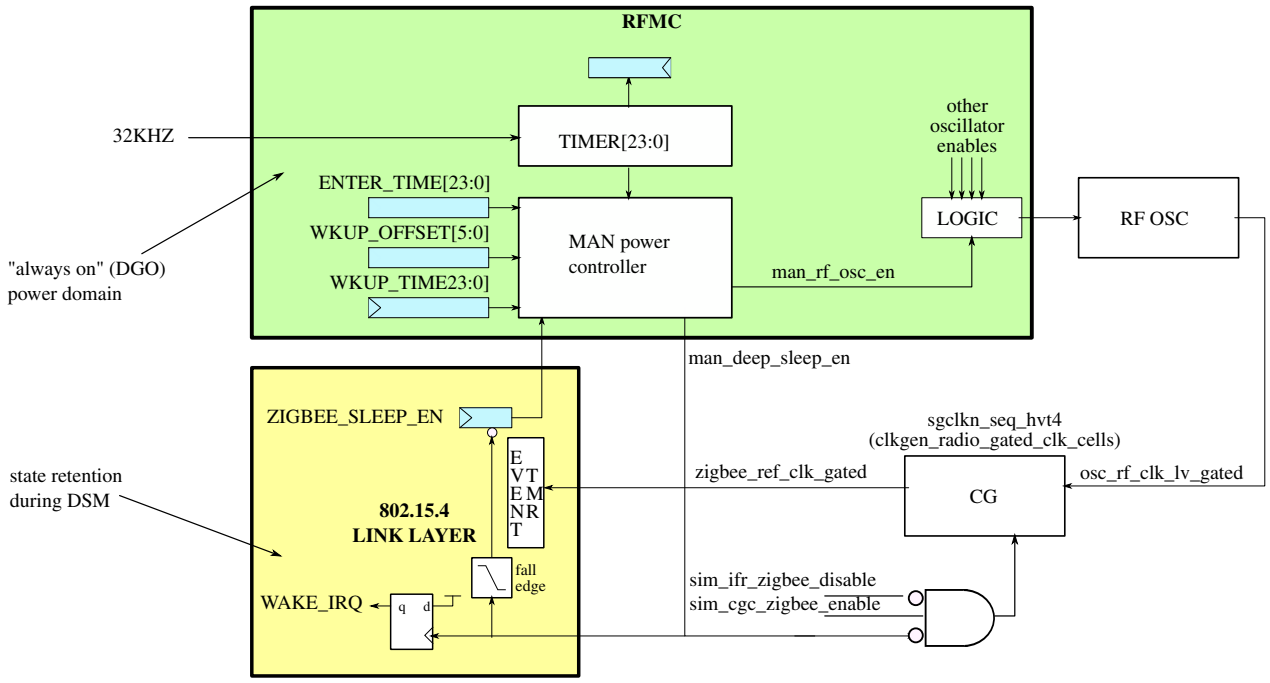

Figure 390. MANUAL DSM BLOCK DIAGRAM

The concept behind Manual DSM, as it is implemented for 802.15.4, is to allow the 802.15.4 timebase to be maintained for a period of time, while the RF Oscillator is turned off and much of the SoC is placed in state-retention. During DSM, the timebase management is temporarily transferred from the 802.15.4 EVENT_TMR to the low-power TIMER, and after DSM exit, timebase management is transferred back to the EVENT_TMR, under software control. During DSM, the EVENT_TMR is frozen. The total time spent in DSM is known to software, so that upon exiting DSM, the EVENT_TMR can be updated to correct for the precise amount of time it was frozen.

DSM entry and exit, and RF Oscillator re-start during Manual DSM, are governed by 5 registers, as described in the table below.

Field	R/W	Description
ENTER_TIME[23:0]	rw	If ZIG_SLEEP_REQUEST=1, enter DSM & freeze EVENT_TMR when ENTER_TIME matches TIMER. **NOTE** This register resides in WOR Address Space
WKUP_OFFSET[5:0]	rw	Determines the power and RF oscillator re-start times relative to WKUP_TIME **NOTE** This register resides in RFMC Address Space

Table continues on the next page...

Table continued from the previous page...

Field	R/W	Description
WKUP_TIME[23:0]	rw	Exit Deep Sleep Mode, and resume EVENT_TMR, when WKUP_TIME matches TIMER **NOTE** This register resides in WOR Address Space
ZIG_SLEEP_REQUEST	w	Enable a match on ENTER_TIME[23:0] to TIMER[23:0], to enter Deep Sleep Mode, by writing a 1 to this bit. Cancel a pending sleep request by writing a 0 to it, if already set, at least 2 32.768KHz clock cycles prior to ENTER_TIME[23:0]
TIMER[23:0]	r	Current State of the 32KHz Sleep Timer **NOTE** This register resides in RFMC Address Space

Procedure

The procedure to schedule a Manual DSM cycle (entry/exit) as well as to program the desired RF Oscillator re-start time, and the calculation to restore the 802.15.4 EVENT_TMR after a DSM cycle, is described below.

1. Software determines the future time at which it would like to enter DSM, by reading the TIMER, computing the number of 32KHz clock cycles remaining until the desired DSM start-time, and writing this value into ENTER_TIME register. The value programmed into ENTER_TIME should be no fewer than 4 clocks greater (in the future) than the current time as read from TIMER.
2. Software determines the future time at which it would like to exit DSM, by computing the number of 32KHz clock cycles remaining until the desired DSM exit-time, and writing this value into WKUP_TIME register.
3. Software writes a 1 to DSM_CTRL[ZIG_SLEEP_REQUEST]. This bit resides in 802.15.4 address space. This bit is write-only and always reads back 0. Writing this bit to 1 enables a DSM cycle to commence using the values programmed into ENTER_TIME and WKUP_TIME.
4. MCU can go into a low power state.
5. When TIMER = ENTER_TIME, the EVENT_TMR will be clock-gated so that it will remain frozen at its current count. The RF Oscillator will be turned off (unless overridden due to a non-802.15.4-related SoC requirement)
6. All hardware in the low-voltage domain will be placed into state-retention, or other low-power state.
7. When TIMER = WKUP_TIME, clocking of the 802.15.4 Link Layer Controller will resume and the EVENT_TMR will be ungated (allowed to resume counting).
8. Software computes the time that the SoC was in DSM (and hence the time the EVENT_TMR was frozen), in microseconds, with the equation:

   (WKUP_TIME – ENTER_TIME) / 32768 * 1000000

9. Software increments the 802.15.4 EVENT_TMR by this amount, by writing this value to the EVENT_TMR register with EVENT_TMR_ADD=1. **Note:** The 802.15.4 EVENT_TMR has an integer component (24 bits) and a fractional component (4 bits). The fractional component provides the microsecond precision to the Event Timer, so both components need to be accounted for when compensating for the DSM "time slept".
10. On the next 1MHz clock edge, the EVENT_TMR has been restored to where it would have been, had no DSM occurred, with 1.0-microsecond accuracy.

Note that the 1.0-microsecond accuracy quoted above, assumes an ideal 32.768KHz source. Any ppm error in the 32.768KHz source will degrade the microsecond accuracy proportionally to the magnitude of the error.

Once ZIG_SLEEP_REQUEST has been set to 1 to request Manual DSM, the request can be cancelled by writing a 0 to the bit. The cancellation must be performed at least 2 32.768KHz before the ENTER_TIME[23:0] match to TIMER[23:0] to avoid a race condition to enter DSM.

The following timing diagram depicts an 802.15.4-driven DSM entry/exit cycle.

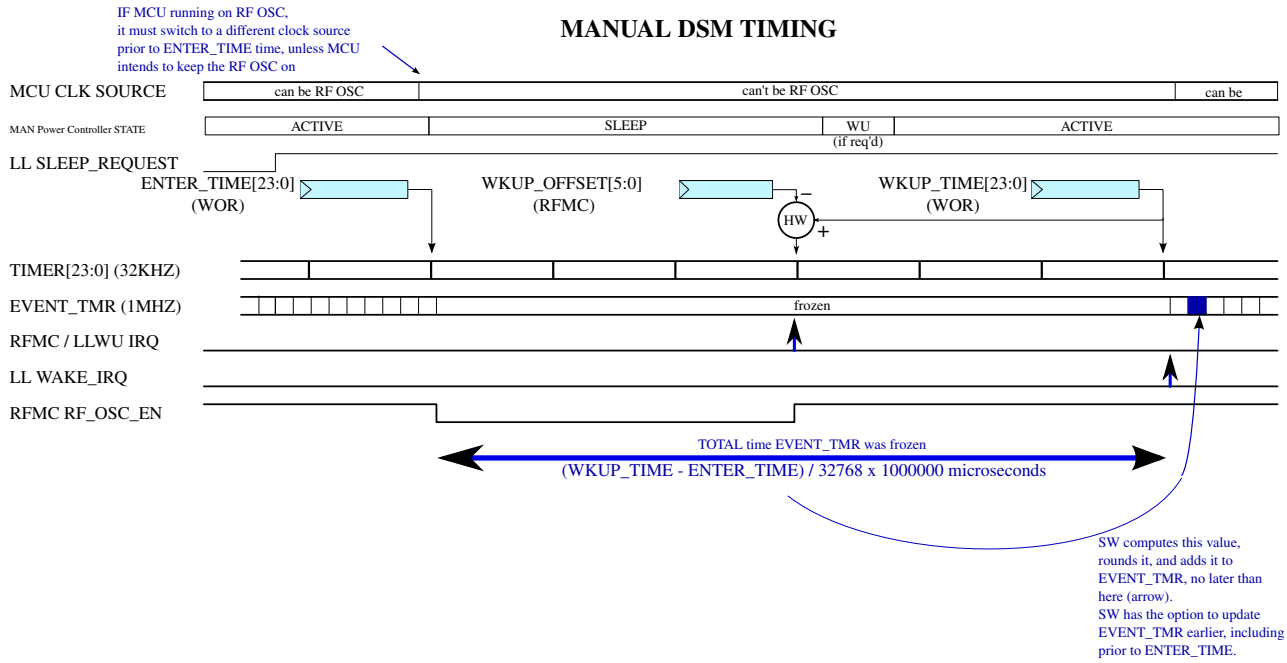

Figure 391. 802.15.4 DEEP SLEEP TIMING

DSM Early Exit

Circumstances may arise where the Manual DSM cycle may occasionally need to be cut short, due to circumstances beyond the control of the radio. When this happens, the SoC, starting with the MCU, is awakened out of its low power state, long before the RFMC TIMER reaches WKUP_TIME. Therefore, software handling the event which triggered the wakeup, will determine if the radio needs to be awakened as well. If this is the case, software will advance the WKUP_TIME setting to a point in the near future, but no fewer than 4 32KHz clock cycles beyond the current time ascertained by reading TIMER. So, to execute a Manual DSM Early Exit, software shall read TIMER, add +4 to the value, and write the sum to the WOR WKUP_TIME register. Software shall then wait for the 802.15.4 WAKE_IRQ interrupt, which will assert once the full radio wakeup from the low power state has completed. Software should then take whatever steps are necessary to configure the radio to respond to the conditions which triggered the early exit. Servicing of a DSM early exit interrupt is beyond the scope of this document.

55.4.9.1.2.8 Wake-On-Radio

The 802.15.4 Link Layer can take advantage of the automated sequence- and DSM-scheduling provided by Wake-On-Radio. Wake-On-Radio is one of two DSM control schemes that can be selected for 802.15.4, as an alternative to Manual DSM. See Chapter *Wake-On-Radio*.

Several changes to the 802.15.4 Link Layer Controller have been made to support Wake-On-Radio.

Interrupt WAKE_IRQ has been made dual-purpose. If Wake-On-Radio is disabled, i.e., WOR_CTRL[WOR_EN]=0, or Wake-On-Radio not assigned to 802.15.4, WAKE_IRQ performs its legacy function for Manual DSM. (See Section Manual DSM). If Wake-On-Radio is enabled, i.e., WOR_EN=1, and assigned to 802.15.4, this interrupt becomes WOR_IRQ, and has new functionality specific to Wake-On-Radio. See Chapter *Wake-On-Radio*, Section *Interrupt Management*, for more details on the meaning, and handling of WOR_IRQ.

In addition to WOR_IRQ, numerous interface changes have been made to support Wake-On-Radio. The changes allow, for example, WOR to manage 802.15.4's RF interrupts, inhibit timestamp updates, etc. The added port signals are listed in the table below, along with a description or each:

WAKE-ON-RADIO INTERFACE SIGNAL	DIRECTION	DESCRIPTION
wor_event_tmr_add[27:0]	WOR -> 802.15.4	The Event Timer "Addback" value computed by WOR to compensate for the amount of time Event Timer was frozen during DSM
wor_addback	WOR -> 802.15.4	A 1µs-long pulse commanding the 802.15.4 Event Timer to auto-increment by the the amount appearing on wor_event_tmr_add[27:0]
wor_force_wake_irq	WOR -> 802.15.4	Force WOR_IRQ to assert, due to an occurrence of one of the 3 WOR_IRQ interrupt triggers
wor_block_wake_irq	WOR -> 802.15.4	Inhibit the legacy WAKE_IRQ assertion when WOR_EN=1 (this interrupt becomes WOR_IRQ)
tx_start_ext	WOR -> 802.15.4	A 1µs-long pulse to the 802.15.4 command decoder to initiate a WOR-driven TX sequence
rx_start_ext	WOR -> 802.15.4	A 1µs-long pulse to the 802.15.4 command decoder to initiate a WOR-driven RX sequence
seq_stop_ext	WOR -> 802.15.4	A 1µs-long pulse to the 802.15.4 command decoder to stop (abort) a WOR-driven RX sequence
wor_allow_irq	WOR -> 802.15.4	Inhibits RF interrupts, so that interrupt assertions can be managed based on WOR descriptor settings. Controlled dynamically by the WOR state machine.
timestamp_inhibit	WOR -> 802.15.4	In Wake-On-Radio, the legacy 802.15.4 TIMESTAMP register becomes WOR TIMESTAMP0 (timestamp for SLOT0).

Table continues on the next page...

Table continued from the previous page...

WAKE-ON-RADIO INTERFACE SIGNAL	DIRECTION	DESCRIPTION
		This signal blocks this register from updating on SLOTS 1-3
wake_irq_trig	WOR <- 802.15.4	WOR uses this signal to cancel ZIG_SLEEP_REQUEST and transition from IN_DSM -> COMP_ADDBACK state
event_tmr[27:0]	WOR <- 802.15.4	802.15.4 Event Timer, used by WOR for timestamp capture
event_tmr_plus_1[27:0]	WOR <- 802.15.4	802.15.4 Event Timer + 1, used by WOR to schedule RF operation starts and stops
tx_irq_trig	WOR <- 802.15.4	TXIRQ trigger, indicates the completion of a packet transmission, used by WOR to transition out of WAKE_SEQ_END state
rx_irq_trig	WOR <- 802.15.4	RXIRQ trigger, indicates the completion of a good packet reception, used by WOR to transition out of WAKE_SEQ_END state
rx_status_for_wor[2:0]	WOR <- 802.15.4	Internal RX status signals used by WOR to formulate TIMESTAMPx_STS[2:0]
timestamp_clk_en	WOR <- CGM <- 802.15.4	Timestamp clock gate enable, the resultant clock is used by WOR to update the TIMESTAMP1,2, and 3 registers

55.4.9.1.2.9 CCA/ED/LQI

55.4.9.1.2.9.1 Introduction

CCA/ED/LQI block resides inside 802.15.4 demodulator top. The purpose of this block is to perform the following operations: 1) Clear Channel Assessment: Modes 1, 2 and 3, 2) Energy Detection and 3) Link Quality Indicator.

This block takes RSSI value, as an input, for computations related to CCA modes 1 and 3, Energy Detection and LQI. For CCA2, this block takes output of 802.15.4 correlators for detecting an 802.15.4 signal in the channel of interest.

At the output, it provides a signal called (cca) to indicate if the channel of interest is busy (cca=1) or idle (cca=0), the final computed energy value (cca1_ed_fnl) and Link Quality Indicator (LQI) value. The cca signal is further used to generate cca interrupt, according to the set interrupt mask. The cca1_ed_fnl is a signed 8 bit value that can be read back as a register. LQI is an unsigned 8 bit value that is written at the end of each valid packet that is received and is available to be read in the packet buffer.

55.4.9.1.2.9.1.1 Block diagram

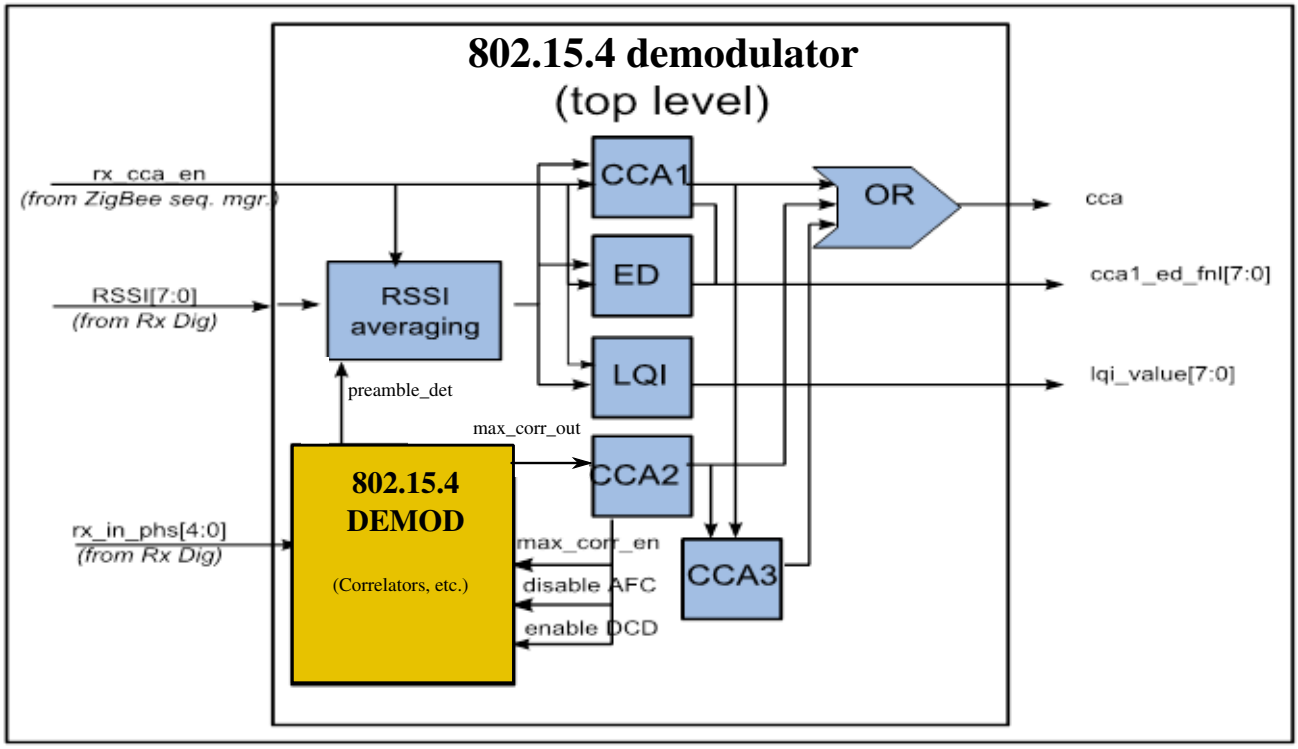

Figure 392. Block diagram

55.4.9.1.2.9.2 Memory Map and register definition

Field	R/W	Description
LQI_VALUE[7:0]	r	8-bit LQI value of each Rx packet
CCA1_ED_FNL[7:0]	r	8-bit signed value to indicate last energy detected
CCA1_THRESH[7:0]	rw	8-bit signed value to be compared against averaged signed RSSI value from Rx DIG block, to determine channel busy or idle
LQI_OFFSET_COMP[7:0]	rw	8-bit value to offset average of signed RSSI value coming from Rx DIG, in order to compute 8-bit LQI value.
CCA3_AND_NOT_OR	rw	This register bit controls how CCA1 and CCA2 are combined to assert CCA3 mode: 1 : CCA1 AND CCA2 0: CCA1 OR CCA2
CCA2_MIN_NUM_CORR_THRESH[2:0]	rw	3-bit value to compare against number of correlation peaks within CCA2 time.
CCA2_NUM_CORR_PEAKS[3:0]	r	4-bit value indicating number of correlation peaks detected in last CCA2 run

Table continues on the next page...

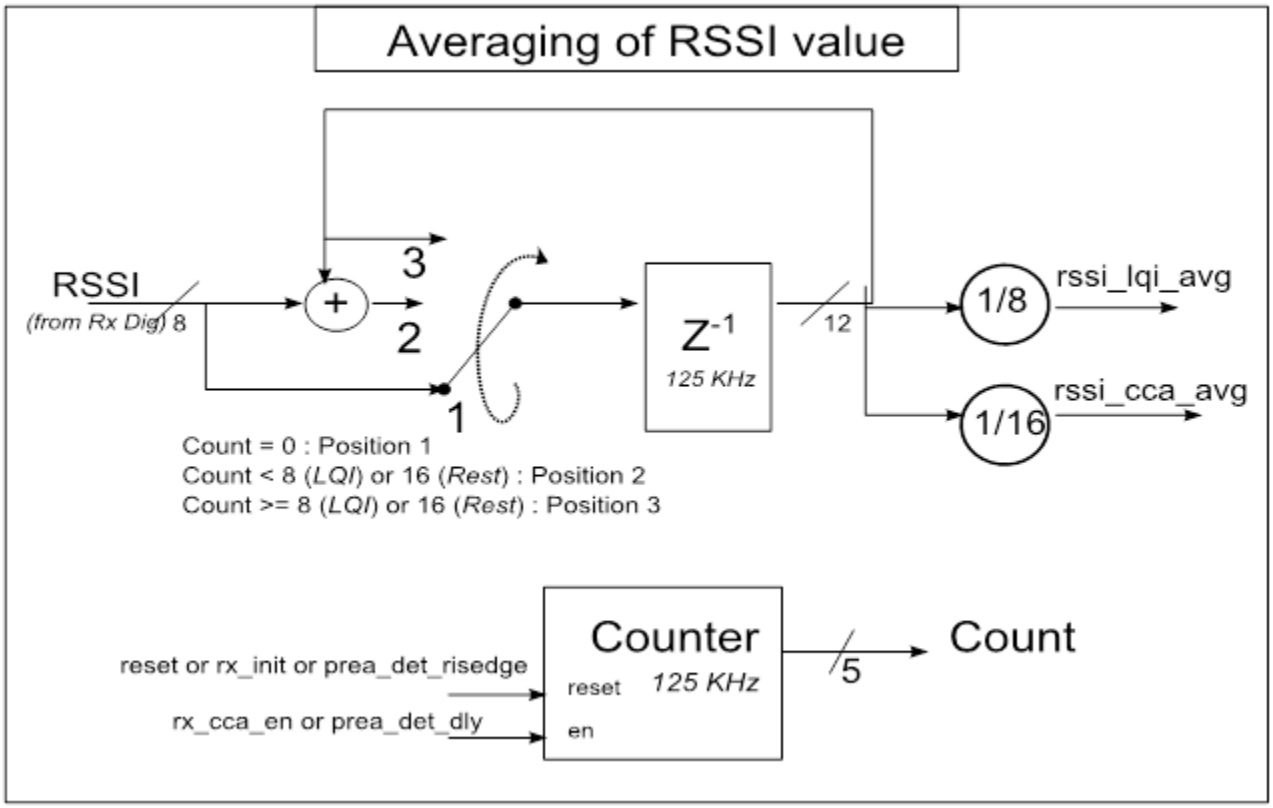
Table continued from the previous page...

Field	R/W	Description
CCA2_CORR_THRESH[7:0]	rw	8-bit value to be compared against correlation peak value during CCA2 operation.
LQI_START_AT_SFD	rw	Defines starting point for LQI computation during packet reception 1: Begin computing LQI at SFD detect (new for KW41) 0: Begin computing LQI at preamble detect (legacy)

55.4.9.1.2.9.3 Functional description

The following sections describe functional details of the module.

55.4.9.1.2.9.3.1 RSSI Averaging



The above picture shows how RSSI is averaged. 8-bit signed RSSI value from Rx Dig block is averaged for 128 us for CCA1/2/3/ED sequences. For LQI, it is averaged for 64 us. In both cases, the RSSI value is sampled at 125 KHz rate.

55.4.9.1.2.9.3.2 CCA1

When the 802.15.4 link layer is set up to perform CCA1 operation, rx_cca_en signal is asserted at the end of Rx warm up by the 802.15.4 Sequence Manager (ZSM). After rx_cca_en is asserted high, at the end of 128 us, i.e. count = 16, rssi_cca_avg is compared against 8-bit signed register cca1_thresh to assess CCA as follows:

If rssi_cca_avg >= cca1_thresh, CCA1 = 1, i.e. channel is busy.

Else CCA1 = 0, i.e. channel is idle.

55.4.9.1.2.9.3.3 CCA2

When the 802.15.4 link layer is set up to perform CCA2 operation, rx_cca_en signal is asserted at the end of Rx warm up by the 802.15.4 Sequence Manager (ZSM). During CCA2 operation, differential chip detection is enabled and automatic frequency correction is disabled, in order to receive correlation peaks related to all available 16 802.1.5.4 symbols. The signal max_corr_en is held high, in order to refresh maximum correlator value after each symbol period. 128 us after rx_cca_en is asserted high, i.e. count = 16, the number of maximum correlation peaks are counted which exceeded the value cca2_corr_thresh register. If the number of correlation peaks exceeds minimum desired number of correlation peaks (programmable register: cca2_num_corr_peaks), cca2 is asserted high to indicate the channel is busy and low otherwise, to indicate channel is idle.

55.4.9.1.2.9.3.4 CCA3

CCA mode 3 is a combination of CCA1 and CCA2. There are 2 combinations in which CCA mode 3 operates, based on the register setting of CCA3_AND_NOT_OR: 1) CCA1 OR CCA2 2) CCA1 AND CCA2. When the 802.15.4 link layer is set to perform CCA3, both CCA1 and CCA2 operations, as mentioned above and decides if the channel is busy or idle, according to the desired combination (i.e. AND/OR).

55.4.9.1.2.9.3.5 Energy Detection

During Energy Detection operation, the demodulator is expected to average RSSI value (from Rx_DIG) for 128 us, as mentioned above in the block diagram. At the end of 128 us, the register CCA1_ED_FNL is updated with this average energy value. Energy detection is similar to CCA1. Unlike CCA1, busy/idle signal is not generated.

55.4.9.1.2.9.3.6 Link Quality Indicator

LQI maps RSSI value (from Rx_DIG) to values between 0x00 and 0xFF, as shown in the following block diagram. Upon preamble detect, RSSI value is averaged for 64 us and mapped to LQI value. This latched LQI value is available in the register LQI_VALUE. Packet processor also appends this LQI value at the end of packet buffer.

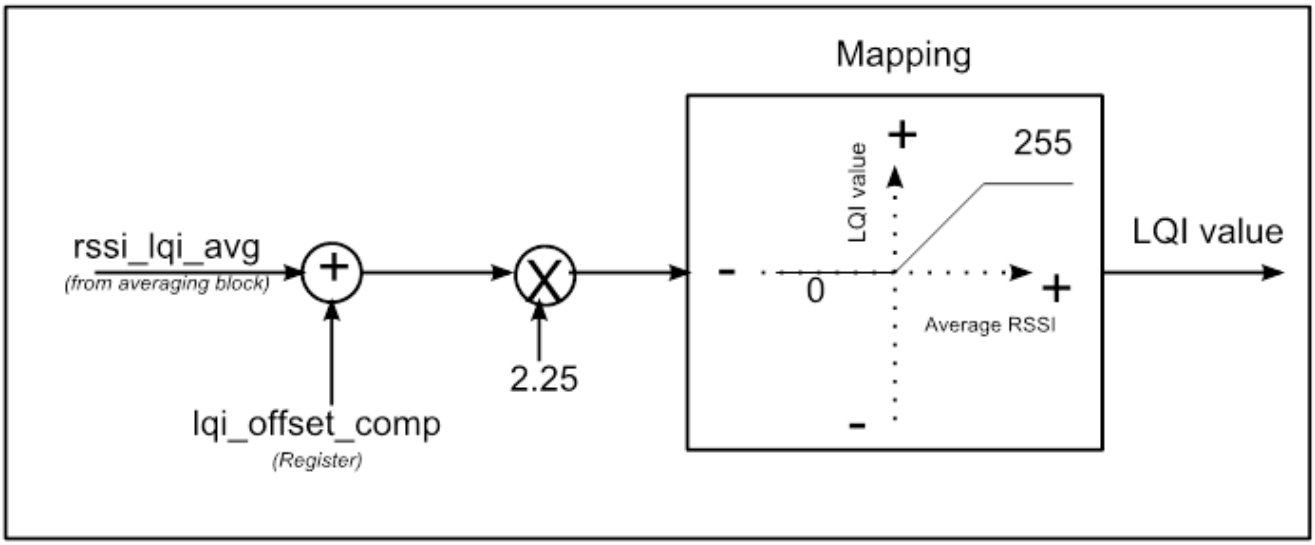


Figure 393. LQI Computation

The following picture shows an example of mapped LQI, when the register LQI_OFFSET_COMP is programmed to decimal value of 102.

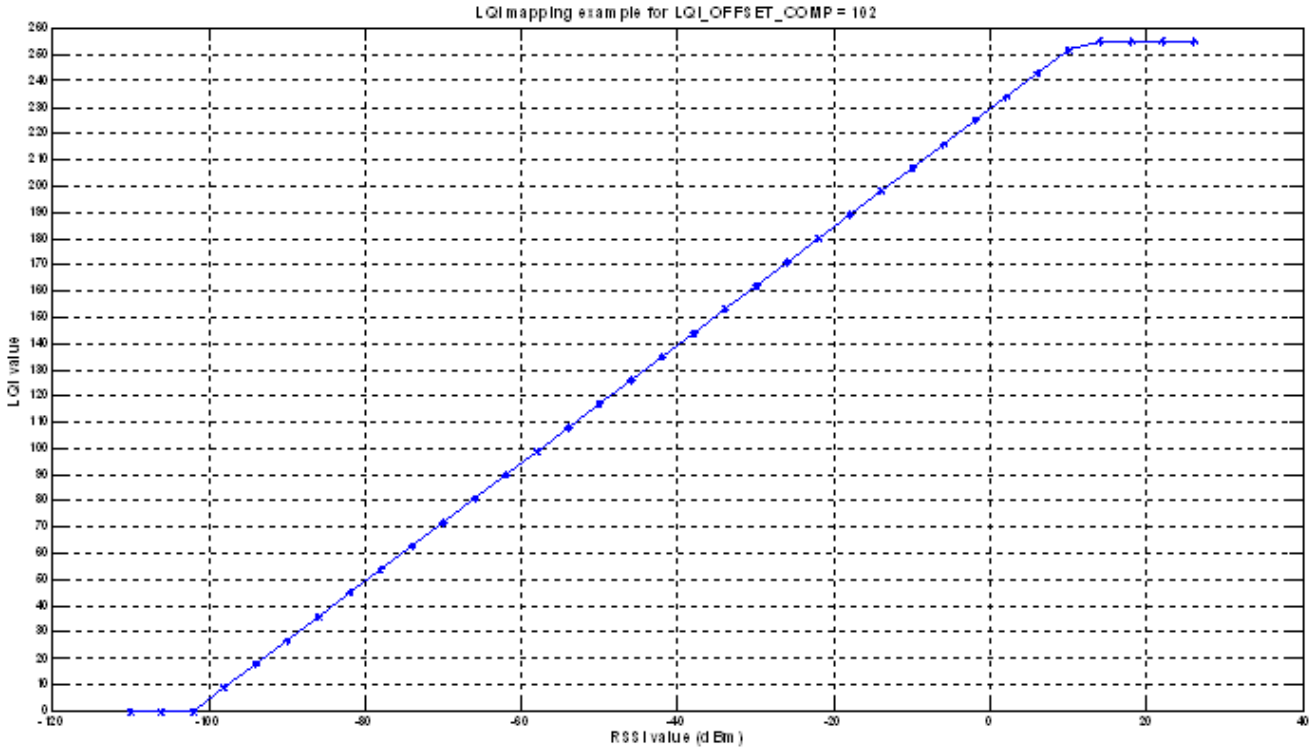

Figure 394. Plot of LQI vs. RSSI

55.4.9.1.2.9.3.7 Clocks

The CCA/ED/LQI module is a fully synchronous module. It has a single clock input **clk32m**. This clock input is driven by the RF Oscillator. The CCA/ED/LQI module has no asynchronous interfaces or clock domain crossings.

55.4.9.1.2.9.3.8 Reset

The CCA/ED/LQI module has a single, active-low, asynchronous reset input: **resetb** . At integration, this reset should be tied to the master reset for the entire transceiver. There are no special reset requirements.

55.4.9.1.2.9.3.9 Interrupts

The CCA/ED/LQI module does not generate any interrupts.

55.4.9.1.2.10 Fast Antenna Diversity (FAD)

FAD ALGORITHM

The Fast Antenna Diversity (FAD) mode, when enabled, will allow the choice between two antennae to be selected during the preamble search. By continually monitoring the received signal the FAD block will select the first antenna on which the received signal has a correlation factor above a predefined, programmable, threshold. This threshold is register programmable. The FAD accomplishes the antenna selection by sequentially switching between the two antenna testing for the presence of a suitably strong s0 symbol, the first antenna to reach this condition is then selected for the reception of the packet.

The first antenna is monitored for a period equal to 1 symbol, T_s = 16µs, then the antenna monitoring is switched to the second antenna, T_a = 8µs. T_a is required to allow for the external pin diodes to turn on/off to select the antenna. $T_s + T_a$ = 24µs which allows enough time to be able to test both antenna within the first 4 preamble symbols, $T_{fad} = 3 \times T_a + 2 \times T_s$ = 56µs, thus T_{fad} $lt; 4 x T_s $lt; 64µs.

The FAD will continually switch between the two antenna until one is found which a sufficiently strong s0 detection. By virtue of the fact that the FAD operation covers less than four s0 symbols before the antenna is selected still allows the symbol demodulator to then detect at least four s0 symbols before declaring "Preamble Detect".

The symbol correlator runs during the T_a period to calculate the max correlation factor for the antenna Cx. However since T_c is not guaranteed to coincide with 1 unique symbol T_s the correlation must be able to work across symbols. To accomplish this the correlator will rotate the s0 PN chip code through its 32 combinations in order to find the s0 symbol split across two adjacent symbols.

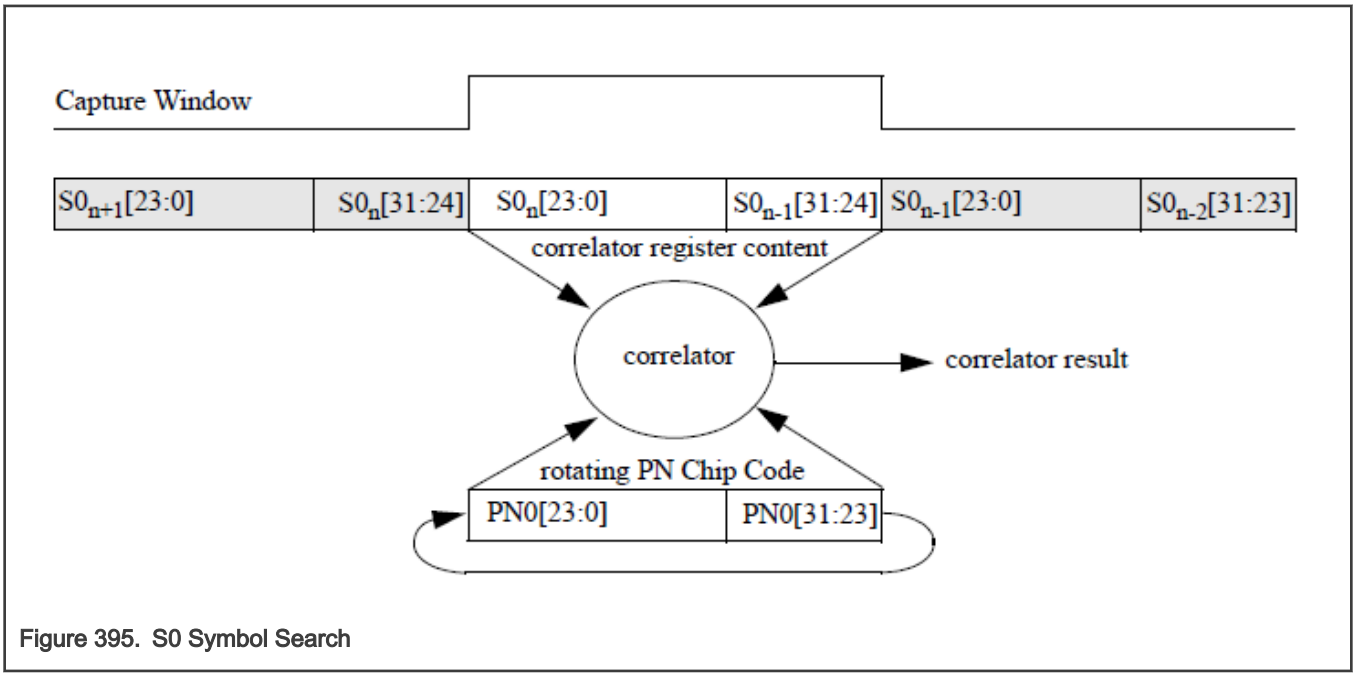

Figure 395. S0 Symbol Search

When the S0 PN Chip code becomes aligned to the Symbol data within the correlator register a correlation peak is produced that is used to determine the Antenna has a sufficiently strong signal to be selected.

It is not possible to choose between Antenna with the highest correlation factor, since indeed 1 antenna could receive no signal and thus is not distinguishable from a clear channel. This being the case, the first antenna that meets the requirements, correlation factor above the defined threshold, is selected.

When a correlator peak is detected, a second check is done ½ symbol later. A new peak should be detected with the rotation equal to ½ symbols ±2 chips. If it is the case the channel is validated and the classical *CORR_NVAL* consecutive S0 is used to certify a correct preamble, where *CORR_NVAL* is the programmable number of consecutive S0 symbols required to declare preamble detected.

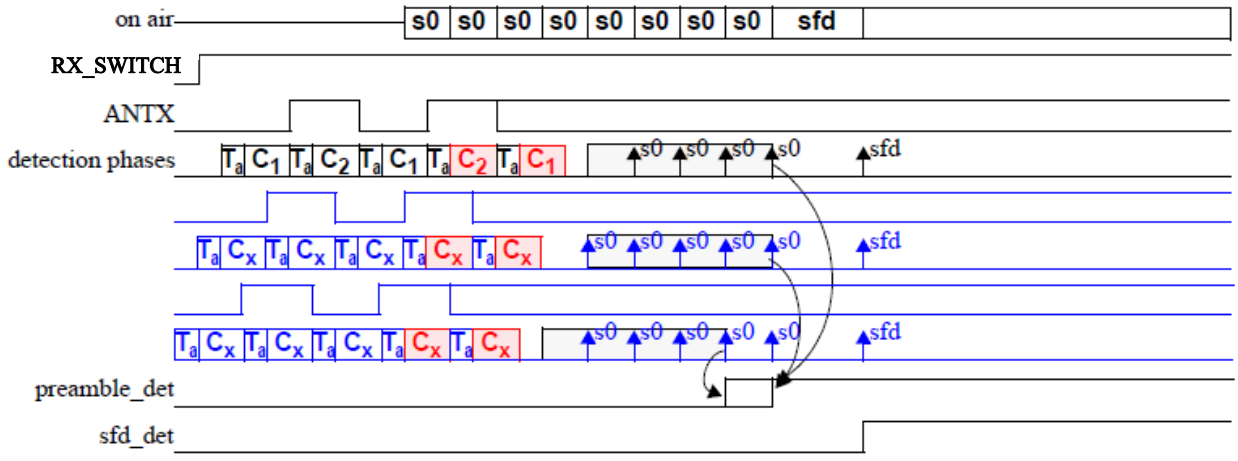

Figure 396. FAD Switching

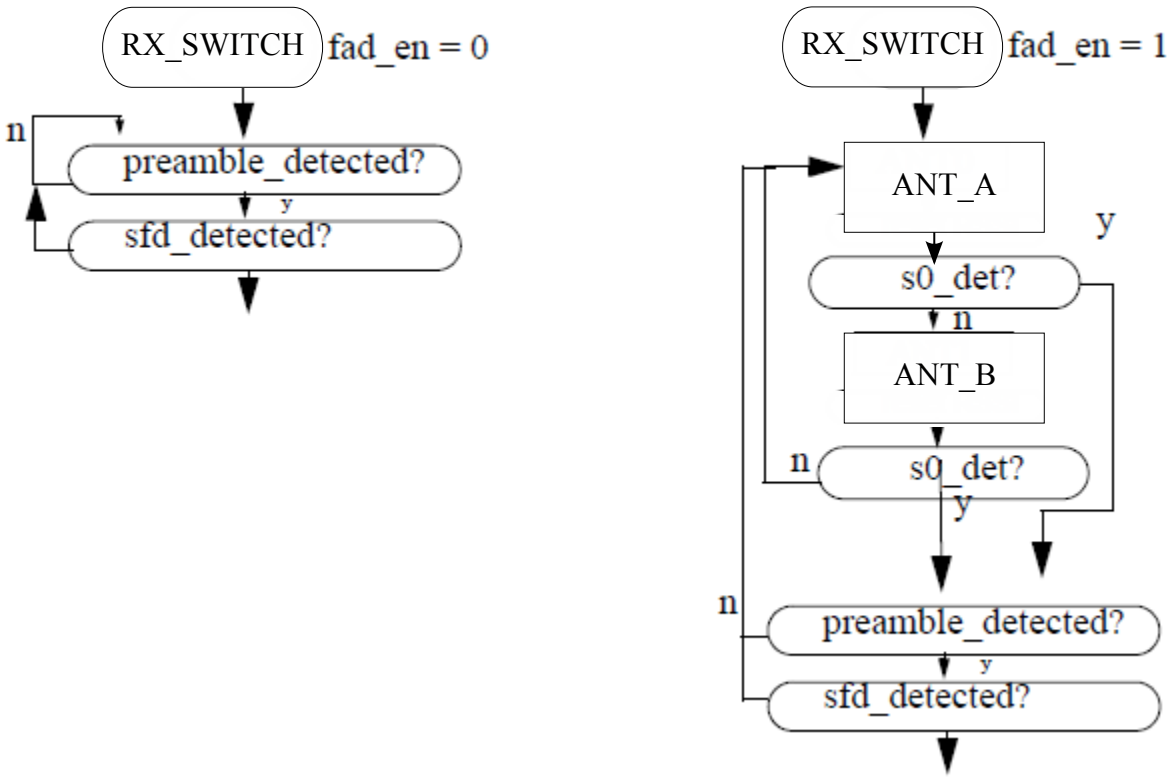

Figure 397. FAD Decision Flow Diagram

The choice of the antenna is also used for the transmit. Since the antx_out value (the last antenna selected by the FAD algorithm) is kept after the end of the receive, the following TX will use the last best antenna found during the last receive. This is true also for any ensuing CCA or ED RX frame; the antenna selected will be the one selected by the FAD algorithm during the last successful preamble search. So a CCA will search for an empty channel on the best antenna chosen at the last RX. When FAD is enabled (FAD_CTRL[FAD_EN]=1), the state of the antenna can be ascertained at any time by reading the FAD_CTRL[ANTX] bit: 0 = ANT_A, 1 = ANT_B. When FAD_CTRL[FAD_EN]=0, antenna selection is placed under direct software control, and the value written to the FAD_CTRL[ANTX] bit becomes the selected antenna: 0 = ANT_A, 1 = ANT_B. The FAD_CTRL register resides in XCVR space.

FAD PIN INTERFACE

55.4.9.1.2.11 Interrupts

55.4.9.1.2.11.1 Introduction

This section describes the 802.15.4 Interrupt Architecture.

Revision	Date	Author	Changes
0.1	04-28-2014	D. Brown	Copy-over from Coconino
0.2	10-24-2015	D. Brown	Updated for KW41

The 802.15.4 Link Layer has a single, active high, interrupt line (ipi_int_zigbee) to the MCU. Internally, the Link Layer has 13 interrupt sources, as shown in the following table:

802.15.4 Interrupt Sources
SEQIRQ
TXIRQ
RXIRQ
CCAIRQ
RXWTRMRKIRQ

TMR4IRQ
WAKE_IRQ
TSM_IRQ

Any or all of the interrupt sources, can be enabled to cause an assertion on ipi_int_zigbee. Each interrupt source has its own interrupt status bit in 802.15.4 register space. Each interrupt source is individually maskable (each has its own MASK bit), so that each interrupt source can be individual enabled to trigger an assertion on ipi_int_zigbee. There is also a global interrupt mask, TRCV_MSK, which can enable/disable all ipi_int_zigbee assertions by programming a single masking bit. All interrupt status bits (except TSM_IRQ) use a write-1-to-clear protocol. Interrupt status bits are not affected by reads. The ipi_int_zigbee pin is a level-sensitive interrupt indicator to the MCU; on an interrupt, ipi_int_zigbee will remain asserted until all active interrupt sources are cleared or masked.

55.4.9.1.2.11.1.1 Features

- 13 interrupt sources (interrupt status bits)
- each interrupt source individually maskable
- each interrupt source is individually write-1-to-clear.
- interrupts remain asserted until cleared.

55.4.9.1.2.11.2 Memory Map and register definition

Numerous register bits are provided to control 802.15.4 interrupt behaviour. The registers referred to below (IRQSTS1, IRQSTS2, IRQSTS3, PHY_CTRL2, PHY_CTRL3, and PHY_CTRL4) all reside in the 802.15.4 Address space.

Field	R/W	Description	Default

Field	R/W	Description	Default
T2CMP[23:0]	rw	TMR2 compare value. If TMR2CMP_EN=1 and the Event Timer matches this value, TMR2IRQ is set.	0xFFF
T2PRIMECMP[15:0]	rw	TMR2-prime compare value. If TMR2CMP_EN=1 and TC2PRIME_EN=1 and the lower 16 bits of Event Timer matches this value, TMR2IRQ is set.	0xFF
T3CMP[23:0]	rw	TMR3 compare value. If TMR3CMP_EN=1 and the Event Timer matches this value, TMR3IRQ is set.	0xFFF
T4CMP[23:0]	rw	TMR4 compare value. If TMR4CMP_EN=1 and the Event Timer matches this value, TMR4IRQ is set.	0xFFF
TMR1CMP_EN	rw	1: Allow an Event Timer Match to T1CMP to set TMR1IRQ 0: Don't allow an Event Timer Match to T1CMP to set TMR1IRQ	0
TMR2CMP_EN	rw	1: Allow an Event Timer Match to T2CMP or T2PRIMECMP to set TMR2IRQ 0: Don't allow an Event Timer Match to T2CMP or T2PRIMECMP to set TMR2IRQ	0
TMR3CMP_EN	rw	1: Allow an Event Timer Match to T3CMP to set TMR3IRQ 0: Don't allow an Event Timer Match to T3CMP to set TMR3IRQ	0
TMR4CMP_EN	rw	1: Allow an Event Timer Match to T4CMP to set TMR4IRQ 0: Don't allow an Event Timer Match to T4CMP to set TMR4IRQ	0
TC2PRIME_EN	rw	1: Allow a match of the lower 16 bits of Event Timer to T2PRIMECMP to set TMR2IRQ 0: Don't allow a match of the lower 16 bits of Event Timer to T2PRIMECMP to set TMR2IRQ	0
RX_WTR_MARK[7:0]	rw	Receive byte count (octets) needed to trigger a RXWTRMRKIRQ interrupt . A setting of 0 generates an interrupt at end of the Frame Length field (first byte after SFD). A setting of 1 generates an interrupt after the first byte of Frame Control Field, etc.	0xFF

NOTE

For the standalone Block Guide shell project the DIL reference is commented out so that register tables will not show up in the project until they are explicitly included (see the .ditamap file).

55.4.9.1.2.11.3 Functional description

55.4.9.1.2.11.3.1 Interrupt Status Bit Structure

The 802.15.4 Link Layer has 13 interrupt sources, each represented in the register map by an interrupt status bit. All interrupt status bits share a common, generic structure. If a particular interrupt source is enabled, a "TRIGGERING EVENT" for that interrupt source, will always set the status bit. A write-1-to-clear input from the IPS bus, will clear the status bit, but only if there is not a simultaneous triggering event. The triggering event prevails over a software clear attempt, if both events coincide. The clock gate guarantees that the status bit only sees a clock when either a triggering event occurs, or a write-1-to-clear pulse arrives

from the IPS bus. This reduces interrupt status bit power consumption to an absolute minimum. The common interrupt status bit structure is shown in the following diagram.

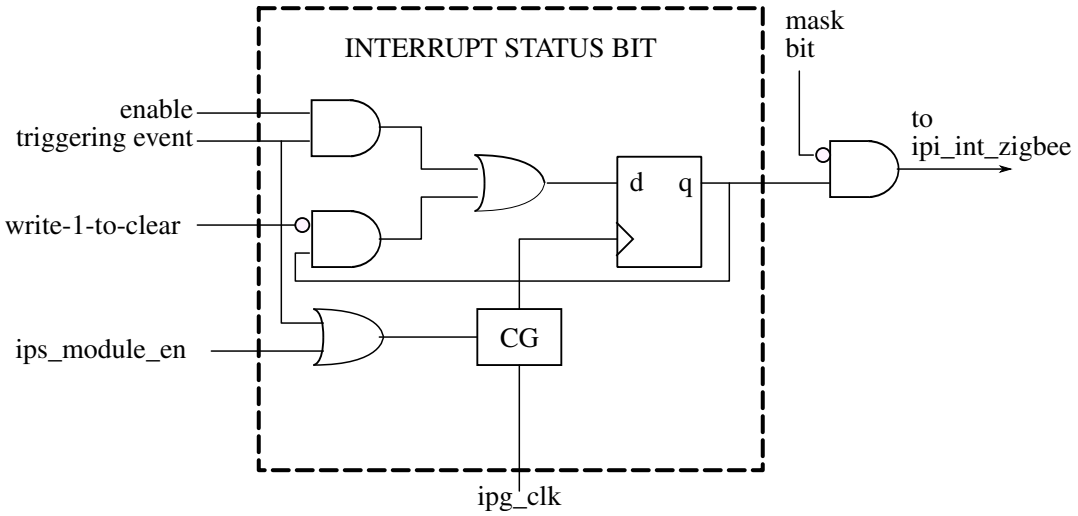

Figure 398. Interrupt Status Bit

Note that for any 802.15.4 interrupt source, if the triggering event occurs, the Interrupt Status Bit will be set regardless of the state of the corresponding MASK bit. If any of the 13 interrupts is to be ignored, software should set the corresponding MASK bit, and apply the appropriate bit mask when reading the IRQSTS1, IRQSTS2, or IRQSTS3 register, to mask out the unwanted status bit.

55.4.9.1.2.11.3.2 802.15.4 Interrupt Architecture

The 13 802.15.4 interrupt sources (status bits) are combined with their individual MASK bits, and then logically OR'ed together, in sum-of-products fashion, to generate single line to the MCU: ipi_int_zigbee. A global mask bit, TRCV_MSK, can enable or disable ipi_int_zigbee altogether. There is no prioritization of interrupt sources, they all have equal weight. The ipi_int_zigbee output is a level-sensitive indicator and will remain asserted until all interrupt status bits are cleared (or the corresponding mask bits set). The following diagram depicts the 802.15.4 Interrupt Architecture.

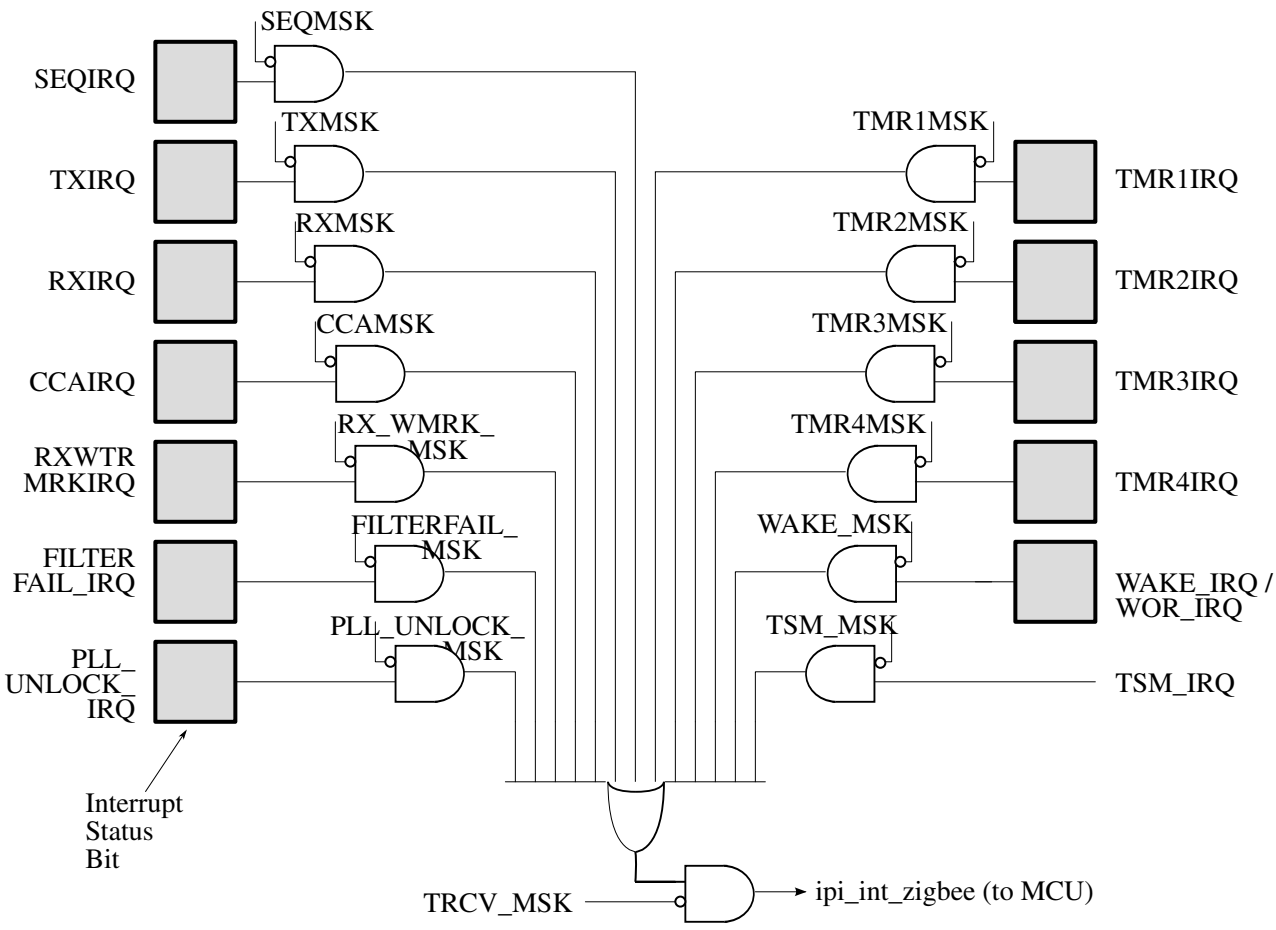

Figure 399. 802.15.4 Interrupt Architecture

55.4.9.1.2.11.3.3 Clearing Interrupts

All interrupt status bit use a write-1-to-clear protocol. Writing a '1' to the interrupt status bit, in the IRQSTS1, IRQSTS2, or IRQSTS3 register, clears the offending interrupt. Writing a '0' to an interrupt status bit has no effect on the bit. Interrupt status bits are not affected by reads.

Note: The TSM interrupt is an exception from the interrupt-clearing rules stated above. See Section TSM Interrupt below.

55.4.9.1.2.11.3.4 Timer Interrupts

The 802.15.4 Link Layer features a 24-bit Event Timer (see Section Event Timer). The Link Layer has 4 Timer interrupts (TMR1IRQ, TMR2IRQ, TMR3IRQ, and TMR4IRQ), each with its own 24-bit compare register (T1CMP, T2CMP, T3CMP, and T4CMP), and each with its own compare enable (TMR1CMP_EN, TMR2CMP_EN, TMR3CMP_EN, and TMR4CMP_EN). For each timer compare enable, if the bit is set, a match on the respective 24-bit compare value to the Event Timer will cause the corresponding interrupt status bit to become set. If the compare enable is low, Event Timer matches won't cause the corresponding interrupt status bit to become set.

In addition, a 16-bit T2PRIMECMP compare value is provided, along with a compare-enable bit: TC2PRIME_EN. When TC2PRIME_EN is set (and TMR2CMP_EN is also set), a match on T2PRIMECMP with the *lower 16 bits of Event Timer*, will cause TMR2IRQ to become set, rather than a full 24-bit compare.

55.4.9.1.2.11.3.5 PLL Unlock Interrupt

When an PLL unlock event occurs during a 802.15.4 autosequence, the PLL_UNLOCK_IRQ status bit will become set. The ZSM Sequence Manager will begin monitoring for PLL unlock only after a complete transceiver warmup has occurred; unlocks which occur during warmup will not cause a PLL_UNLOCK_IRQ. A PLL unlock which occurs after the warmup period, can be enabled to cause a sequence abort. (See Section Sequence Aborting for more details).

55.4.9.1.2.11.3.6 Filterfail Interrupt

Filterfail interrupt will occur during packet reception, when a packet fails filtering rules. On a Filterfail interrupt, the FILTERFAIL_CODE register can be read to ascertain more information about the nature of the filter failure. Filterfail interrupt is not expected to be widely used in mission modes; it has been provided primarily for debug purposes.

55.4.9.1.2.11.3.7 RX Watermark Interrupt

RX Watermark interrupt will occur during packet reception, when the number of received bytes matches the contents of the RX_WTR_MARK register, minus 1. For the purpose of defining RX_WTR_MARK, the first byte received is the Frame Length field (PHR). The second byte received is the least-significant byte of Frame Control Field, etc. For example, to cause an RX Watermark Interrupt to occur after the 10th received byte, set RX_WTR_MARK=11.

55.4.9.1.2.11.3.8 CCA Interrupt

CCA interrupts occur at the end of CCA and ED measurement intervals. The presence, and timing, of CCA interrupts varies based on which autosequence is engaged. See Chapter ZSM Sequence Manager, Section Supported Sequences for more details on when to expect a CCAIRQ for each of the relevant autosequences (Sequences C, T, TR, and CCCA).

55.4.9.1.2.11.3.9 RX Interrupt

RX interrupts occur at the end of an RX operation. An RX operation can be a standalone Sequence R, or the “R” portion of a Sequence TR. An RXIRQ, in combination with a SEQIRQ, is considered a “Data Indication”. RX interrupts are not generated on packets which fail FCS (CRC check), or fail packet filtering. Either of these two conditions results in an RX recycle back to the preamble-search state. To prevent RX recycling on packets which fail filtering or FCS, set the NO_RX_RECYCLE bit of the SEQ_MGR_CTRL register to 1. To receive a Data Indication (including RXIRQ) on packets which fail CRC, clear the CRC_MSK bit of the PHY_CTR2 register to 0. To inhibit packet filtering and enable Data Indication on packets which would otherwise fail packet filtering rules, set the PROMISCUOUS bit of the PHY_CTRL4 register to 1.

55.4.9.1.2.11.3.10 TX Interrupt

TX interrupts occur at the end of a TX operation. An TX operation can be a standalone Sequence T, the “T” portion of a Sequence TR, or the auto-TXACK portion of a Sequence R with AUTOACK=1.

55.4.9.1.2.11.3.11 Sequencer Interrupt

The Sequencer Interrupt (SEQIRQ), indicates that an autosequence has completed, and the 802.15.4 Sequence Manager has returned to its idle state. A SEQIRQ will *always* occur at the end of an autosequence, even if the autosequence terminated abnormally (such as a Software Abort, a TC3 Timeout, or a PLL Unlock Abort). **Note:** the ABORT_STS register can be read to determine which of these abnormal terminations occurred, if any. The SEQIRQ always occurs whenever the Sequence Manager transitions from non-idle to idle state. When SEQIRQ occurs, software can be sure that the Sequence Manager is in its idle state, and a new sequence can be programmed immediately.

55.4.9.1.2.11.3.12 TSM Interrupt

TSM_IRQ is a debug feature, enabling the Transceiver Sequence Manager (TSM) to generate an interrupt at any point in a TX or RX Warmup. TSM is a multipurpose hardware resource shared by all of the protocol engines in the SoC. Thus, TSM does not have its own interrupts; its interrupts are assigned to whichever link layer controller is currently executing an RF operation. The 802.15.4 interrupt TSM_IRQ is asserted when the TSM interrupt is enabled in the transceiver's TSM_CTRL register, and the TSM interrupt asserts during an 802.15.4 TX or RX Warmup. The TSM Interrupt status bit in the IRQSTS register of 802.15.4 space is read-only. It is a logical OR of the 2 TSM_IRQ interrupt status bits of the XCVR_STATUS register in XCVR address space. and the asserted status bit(s) should be cleared there. There is no intended mission-mode use for TSM_IRQ. See the TSM Chapter for more details.

55.4.9.1.2.11.3.13 Wake Interrupt

For Manual DSM: This is WAKE_IRQ. A WAKE_IRQ will be triggered when the 802.15.4 Link Layer Controller has awoken from a Manual DSM (Deep Sleep Mode) cycle. WAKE_IRQ indicates that the RF Oscillator has been restarted, and the 802.15.4 EVENT_TMR has resumed counting.

For Wake-On-Radio:: This is WOR_IRQ. This interrupt will become set when 802.15.4 has been assigned to Wake-On-Radio, and one or more of the following Wake-On-Radio conditions occurs:

1. A Wake-On-Radio slot of type "NO_RF" has completed, and MCU wakeup is requested in the descriptor
2. A Wake-On-Radio maximum slot count has been reached
3. A Wake-On-Radio Early Exit condition has been encountered

See Chapter *Wake-On-Radio* for more details

55.4.9.1.2.12 Wifi Coexistence

Provisions have been made to allow for the 2.4GHz transceiver to coexist in the same space as a WiFi transceiver IC, which shares the same frequency band. The coexistence scheme designates the WiFi transceiver as the master, and the 2.4GHz transceiver as the slave. The objective of the coexistence strategy is to prevent both the WiFi and 2.4GHz transceivers transmitting simultaneously; a configuration option exists to also prevent the 2.4GHz transceiver from receiving when the WiFi transceiver owns the RF channel.

A very basic mechanism is used in cases where 2.4GHz radio does not generate requests, but instead defers to the WiFi transceiver to grant permission to use the medium. The WiFi IC generates a signal, RF_NOT_ALLOWED. If this signal is asserted, then 2.4GHz radio does not perform any communication. When this signal is de-asserted, then 2.4GHz radio is free to perform communications. In case the signal RF_NOT_ALLOWED is de-asserted when 2.4GHz radio has already initiated the transmission/reception of a packet then the 2.4GHz radio must stop its activity immediately .

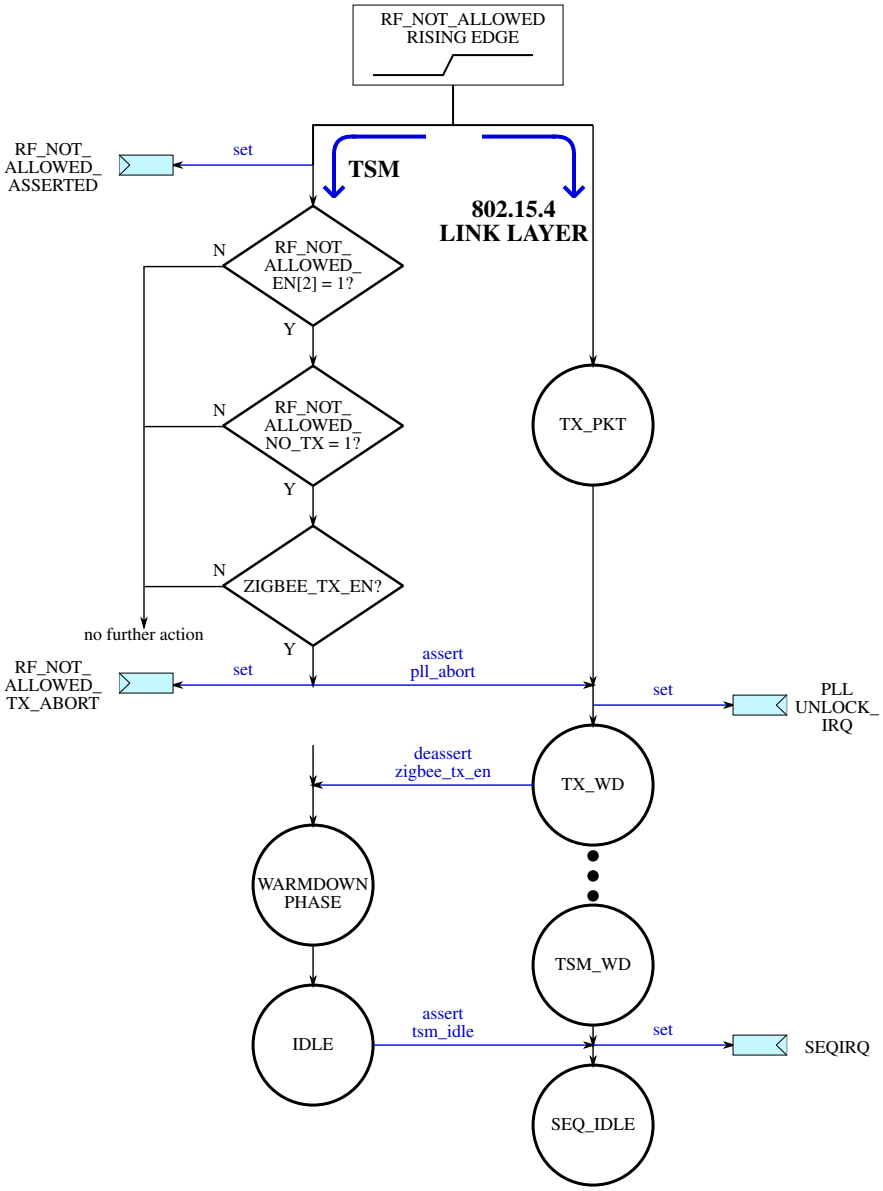
When RF_NOT_ALLOWED aborting is enabled, the 802.15.4 Link Layer hardware must respond to RF_NOT_ALLOWED assertions, by aborting any autosequence which is currently underway, and Link Layer software must not initiate any new autosequences until RF_NOT_ALLOWED has been deasserted. The hardware response must be handled autonomously by the Link Layer, with no MCU intervention required, because the RF_NOT_ALLOWED assertions can occur during a Wake-On-Radio timeslot which has been designated as "no-MCU-wakeup" in the slot's descriptor. In this scenario, the aborting of the autosequence occurs without any assistance from, or notification of, the MCU.

In the multi-protocol 2.4GHz radio, RF_NOT_ALLOWED aborting can be individually enabled/disabled for each protocol engine. For 802.15.4, RF_NOT_ALLOWED_EN[2] is the associated enable control bit. This bit resides in the COEX_CTRL register in XCVR address space. When this bit is 0, transitions on RF_NOT_ALLOWED are ignored by the 802.15.4 Link Layer hardware; when this bit is 1, the 802.15.4 Link Layer hardware will monitor RF_NOT_ALLOWED at all times, and abort any active autosequence which is underway when an assertion on the pin occurs. The complete hardware response to RF_NOT_ALLOWED assertions is described below.

Additional control over RF_NOT_ALLOWED aborting is provided by the RF_NOT_ALLOWED_NO_TX and RF_NOT_ALLOWED_NO_RX control bits. If RF_NOT_ALLOWED_NO_TX=1, then an RF_NOT_ALLOWED abort will occur only if an 802.15.4 autosequence is active, and currently executing a TX operation (zigbee_tx_en=1); 802.15.4 autosequence TX operations will not be aborted if RF_NOT_ALLOWED_NO_TX=0. If RF_NOT_ALLOWED_NO_RX=1, then an RF_NOT_ALLOWED abort will occur only if an 802.15.4 autosequence is active, and currently executing an RX operation (zigbee_rx_en=1); 802.15.4 autosequence RX operatons will not be aborted if RF_NOT_ALLOWED_NO_RX=0. The RF_NOT_ALLOWED_NO_TX and RF_NOT_ALLOWED_NO_RX control bits reside in the COEX_CTRL register.

For the purposes of triggering a hardware abort, the *pll_abort* input to the 802.15.4 Sequence Manager (ZSM) is used. This is because the hardware response to the RF_NOT_ALLOWED assertion is identical to that of a PLL unlock event. This also means that, when RF_NOT_ALLOWED aborting is enabled for 802.15.4, the PLL_UNLOCK_IRQ interrupt status bit, will be dual purpose: it will not only indicate a PLL unlock condition, but also a RF_NOT_ALLOWED abort. PLL aborting and RF_NOT_ALLOWED aborting are enabled separately, with the COEX_CTRL register maintaining the control bits required for the latter. The status bits for RF_NOT_ALLOWED aborting are also available in COEX_CTRL, so that software will be able to distinguish the source of the PLL_UNLOCK_IRQ, in case both PLL and RF_NOT_ALLOWED aborting are enabled.

The sequence of events which results in a hardware abort of an 802.15.4 TX operation triggered by an assertion on RF_NOT_ALLOWED, is a collaboration between the TSM (Transceiver Sequence Manager) and the 802.15.4 Sequence Manager (ZSM), as shown in the following diagram.



Upon assertion on RF_NOT_ALLOWED, the TSM sets the RF_NOT_ALLOWED_ASSERTED status bit in COEX_CTRL, then checks that the conditions for a hardware abort are all met:

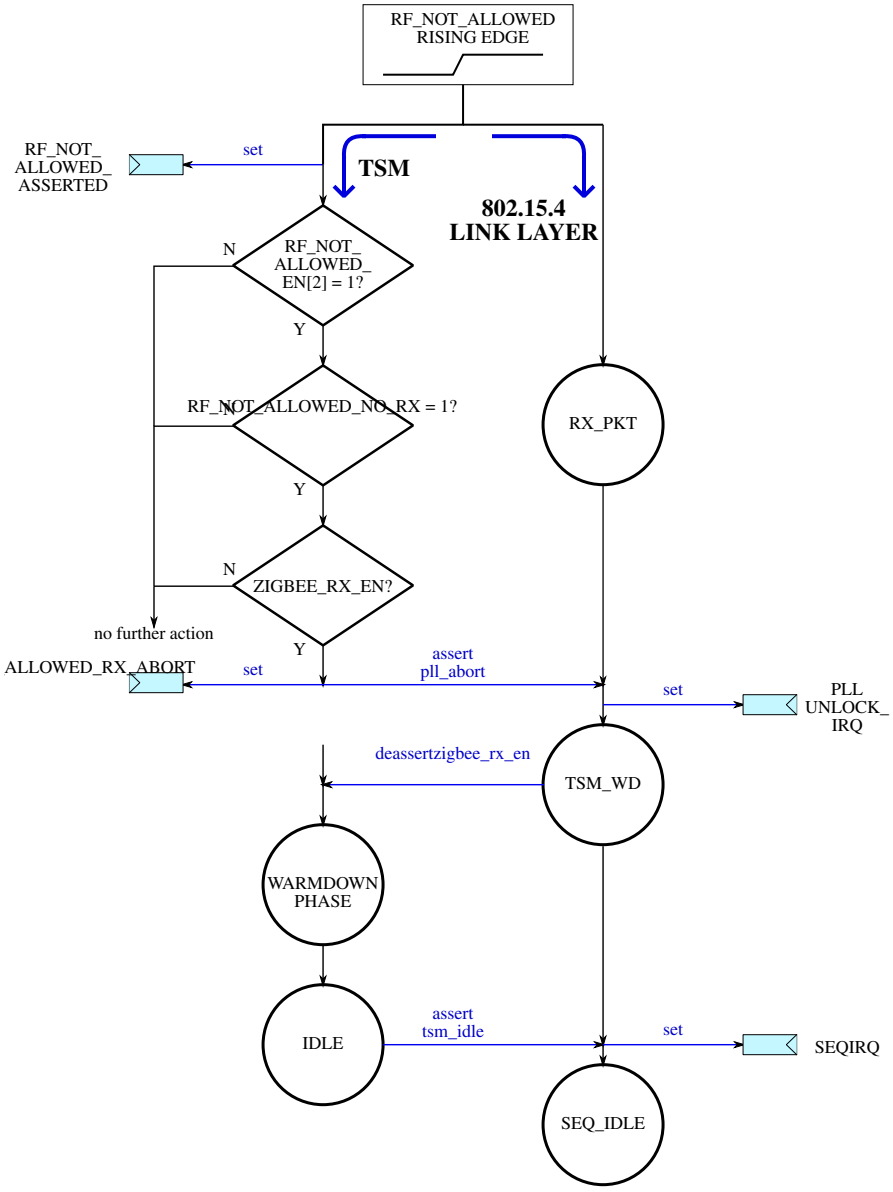
- RF_NOT_ALLOWED_EN[2] = 1, which enables 802.15.4 to respond to RF_NOT_ALLOWED events
- RF_NOT_ALLOWED_NO_TX = 1, which enables TX operations to be aborted

- zigbee_tx_en = 1, TX request to TSM from 802.15.4 ZSM, indicating TX operation in progress

If all conditions are not met, no further action is taken. Otherwise, the TSM sets COEX_CTRL[RF_NOT_ALLOWED_TX_ABORT], and also asserts *pll_unlock* to the 802.15.4 ZSM Sequence Manager. The ZSM responds by asserting IRQSTS1[PLL_UNLOCK_IRQ] in 802.15.4 space. ZSM enters TX_WD state, which deasserts zigbee_tx_en to the TSM. This initiates the TSM TX warmdown, while the ZSM simultaneously steps through its TX warmdown sequence of states. ZSM enters TSM_WD to wait for TSM to return to idle. Once this occurs, ZSM asserts IRQSTS1[SEQIRQ] and returns to its SEQ_IDLE state. Three status bits are now set to indicate to software that the source of the abort was an RF_NOT_ALLOWED assertion:

- IRQSTS1[PLL_UNLOCK_IRQ]
- COEX_CTRL[RF_NOT_ALLOWED_ASSERTED]
- COEX_CTRL[RF_NOT_ALLOWED_TX_ABORT]

The sequence of events which results in a hardware abort of an 802.15.4 RX operation triggered by an assertion on RF_NOT_ALLOWED, is shown in the following diagram.



Upon assertion on RF_NOT_ALLOWED, the TSM sets the RF_NOT_ALLOWED_ASSERTED status bit in COEX_CTRL, then checks that the conditions for a hardware abort are all met:

- RF_NOT_ALLOWED_EN[2] = 1, which enables 802.15.4 to respond to RF_NOT_ALLOWED events
- RF_NOT_ALLOWED_NO_RX = 1, which enables RX operations to be aborted
- zigbee_rx_en = 1, RX request to TSM from 802.15.4 ZSM, indicating RX operation in progress

If all conditions are not met, no further action is taken. Otherwise, the TSM sets COEX_CTRL[RF_NOT_ALLOWED_RX_ABORT], and also asserts *pll_unlock* to the 802.15.4 ZSM Sequence Manager. The ZSM responds by asserting IRQSTS1[PLL_UNLOCK_IRQ] in 802.15.4 space. ZSM enters TSM_WD state, which deasserts zigbee_rx_en to the TSM. This initiates the TSM RX warmdown. ZSM waits in the TSM_WD to wait for TSM to return to idle. Once this occurs, ZSM asserts IRQSTS1[SEQIRQ] and returns to its SEQ_IDLE state. Three status bits are now set to indicate to software that the source of the abort was an RF_NOT_ALLOWED assertion:

- IRQSTS1[PLL_UNLOCK_IRQ]
- COEX_CTRL[RF_NOT_ALLOWED_ASSERTED]
- COEX_CTRL[RF_NOT_ALLOWED_RX_ABORT]

The complete set of control and status bits in the COEX_CTRL register is described in the following table:

Field	R/W	Description
RF_NOT_ALLOWED_EN	RW	The coexistence input RF_NOT_ALLOWED can be enabled to selectively abort TX or RX sequences, with individual enables for each supported protocol, subject also to the state of the RF_NOT_ALLOWED_NO_TX and RF_NOT_ALLOWED_NO_RX control bits, according to the following table: **xxx1**: RF_NOT_ALLOWED assertions are enabled to abort Bluetooth LE TX and RX sequences **xxx0**: RF_NOT_ALLOWED assertions are not enabled to abort Bluetooth LE TX and RX sequences **xx1x**: RF_NOT_ALLOWED assertions are enabled to abort ANT TX and RX sequences **xx0x**: RF_NOT_ALLOWED assertions are not enabled to abort ANT TX and RX sequences **x1xx**: RF_NOT_ALLOWED assertions are enabled to abort 802.15.4 TX and RX sequences **x0xx**: RF_NOT_ALLOWED assertions are not enabled to abort 802.15.4 TX and RX sequences **1xxx**: RF_NOT_ALLOWED assertions are enabled to abort GENERIC_FSK TX and RX sequences **0xxx**: RF_NOT_ALLOWED assertions are not enabled to abort GENERIC_FSK TX and RX sequences
RF_NOT_ALLOWED_NO_TX	RW	TX Sequences will be aborted by RF_NOT_ALLOWED assertions, if the appropriate RF_NOT_ALLOWED_EN[x] bit is set.
RF_NOT_ALLOWED_NO_RX	RW	RX Sequences will be aborted by RF_NOT_ALLOWED assertions, if the appropriate RF_NOT_ALLOWED_EN[x] bit is set.
RF_NOT_ALLOWED_ASSERTED	R/W1TC	RF_NOT_ALLOWED has gone from not asserted, to asserted, since the last time this bit was cleared

Table continues on the next page...

RF_NOT_ALLOWED_TX_ABORT	R/W1TC	An TX sequence has been aborted since the last time this bit was cleared
RF_NOT_ALLOWED_TX_ABORT	R/W1TC	An TX sequence has been aborted since the last time this bit was cleared
RF_NOT_ALLOWED	R	Reflects the instantaneous state of the RF_NOT_ALLOWED pin,

55.4.9.1.2.13 Enhanced Acknowledgment (Enh-Ack) Support

This device supports to send Enh-Ack frame, acknowledging to a frame version 2 of DATA or MAC Data Request Command packet. By the combination of Destination Address Mode, Source Address Mode and PAN ID Compression, the 802.15.4-2015 protocol specifies 14 possible packet structures in its Table 7-2. According to specific application scenarios, this device defines case 5 and 9 ~ 14 are legal, as shown in the Figure 400. Other cases will be filtered out by default unless LENIENCY[40] is set.

Figure 401. Supported Address Modes of ACK Frame

The Enh-Ack frame is formatted as illustrated in Figure 402, also can be found in Figure 7-16 in IEEE Std 802.15.4-2015.

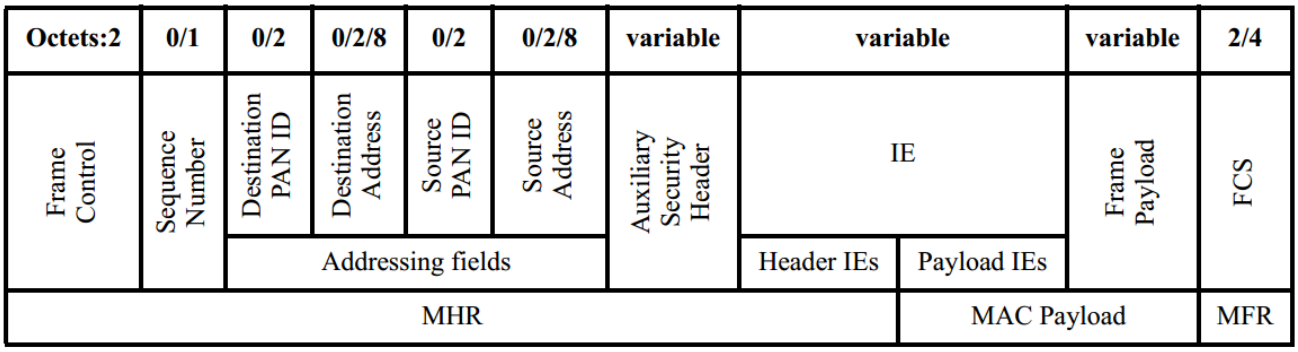

Figure 402. Enh-Ack frame format

The Frame Control field of the Enh-Ack frame is formatted as illustrated in Figure 403, also can be found in Figure 7-2 in IEEE Std 802.15.4-2015.

Bits: 0–2	3	4	5	6	7	8	9	10–11	12–13	14–15
Frame Type	Security Enabled	Frame Pending	AR	PAN ID Compression	Reserved	Sequence Number Suppression	IE Present	Destination Addressing Mode	Frame Version	Source Addressing Mode

Figure 403. Frame Control Field of Enh-Ack

Enh-Ack is much more complicated than Imm-Ack because it may contain IEs and Frame Payload Field, and it also introduces data decryption and encryption. This makes it very difficult to achieve a turnaround time of 192us in pure software or pure hardware. So the entire Enh-Ack process is completed through software and hardware cooperation.

The main idea is that the software is responsible for decrypting, analyzing received packets and forming the Enh-Ack packet(Full-Enh-Ack). At the turnaround time, the hardware automatically sends the Full-Enh-Ack. If the software cannot prepare the Full-Enh-Ack in time, the hardware will send an Empty-Enh-Ack frame. After the hardware sends Empty-Enh-Ack, the software will send a complete Enh-Ack packet, which is Full-Enh-Ack.

According to the requirements of 802.15.4 -2015 spec for Enh-Ack frame format, the fields in Full-Enh-Ack and Empty-Enh-Ack frame are as follows:

In the Full-Enh-Ack:

- The Frame Control field:
  - The Frame Type is b010, Acknowledgment type
  - The Frame Version is b10.
  - Security Enabled field shall be set if security feature is enabled.
  - If the Enh-Ack frame is being sent in response to a received either a Data frame or Data Request command the Frame Pending field is calculated by the Source Address Management process; If the Enh-Ack frame is being sent in response to another type of MAC command, the Frame Pending field is zero.
  - The AR field is zero.
  - The PAN ID compression field and Sequence Number Compression field shall be set to be the same value as the corresponding fields in the Frame Control field of the frame that is being acknowledged.
  - The IEs present field shall be set to one if IEs are included in the Enh-Ack frame.
  - The Destination Addressing Mode field shall contain the value of the Source Addressing Mode field in the Frame Control field of the frame that is being acknowledged.
  - The Source Addressing mode field shall be set as appropriate for the address of the device transmitting the Enh-Ack frame.
- The Sequence Number field, when present shall contain the value of the sequence number received in the frame for which the acknowledgment is to be sent.
- The Source Address field, when present, is from MACSHORTADDRS0(if CURRENT_NETWORK is 0) or MACSHORTADDRS1(if CURRENT_NETWORK is 1) when EMPTY_SRC_ADDR_MODE is 2; or is from MACLONGADDRS0(if CURRENT_NETWORK is 0) or MACLONGADDRS1(if CURRENT_NETWORK is 1) when EMPTY_SRC_ADDR_MODE is 3.
- The Source PAN ID field, when present, is from MACPANID0 (if CURRENT_NETWORK is 0) or MACPANID1(if CURRENT_NETWORK is 1).

- The Destination Address field, when present, shall contain the value of the Source Address field from the frame that is being acknowledged. The Destination PAN ID, when present, contains the value from the Source PAN ID field from the frame that is being acknowledged.
- The Auxiliary Security Header, IE and Frame Payload may be included.

Because Empty-Enh-Ack is a simplified format, compared with Full-Enh-Ack, there are some *differences*.

- The Frame Control field:
  - The Frame Type is b010, Acknowledgment type.
  - The Frame Version is b10.
  - *Security Enabled field is 0, indicating the Enh-Ack frame is not protected. (when EMPTY_SECURITY_ENABLED_OVRD_EN is 1, this field tracks the EMPTY_SECURITY_ENABLED_OVRD bit)*
  - *The Frame Pending field is 1, indicating that there will be a Full-Enh-Ack frame after the Empty-Enh-Ack frame. (when ACK_FRM_PND_CTRL is 1, this field tracks the ACK_FRM_PND bit)*
  - The AR field is zero
  - The PAN ID compression field and Sequence Number Compression field shall be set to be the same value as the corresponding fields in the Frame Control field of the frame that is being acknowledged.
  - *The IEs present field is 0, indicating there is no IEs field in the Empty-Enh-Ack*
  - The Destination Addressing Mode field shall contain the value of the Source Addressing Mode field in the Frame Control field of the frame that is being acknowledged
  - *The Source Addressing mode field is from register EMPTY_SRC_ADDR_MODE, which should be 2 or 3 only.*
- The Sequence Number field, when present shall contain the value of the sequence number received in the frame for which the acknowledgment is to be sent.
- The Source Address field, when present, is from MACSHORTADDRS0(if CURRENT_NETWORK is 0) or MACSHORTADDRS1(if CURRENT_NETWORK is 1) when EMPTY_SRC_ADDR_MODE is 2; or is from MACLONGADDRS0(if CURRENT_NETWORK is 0) or MACLONGADDRS1(if CURRENT_NETWORK is 1) when EMPTY_SRC_ADDR_MODE is 3.
- The Source PAN ID field, when present, is from MACPANID0 (if CURRENT_NETWORK is 0) or MACPANID1(if CURRENT_NETWORK is 1).
- The Destination Address field, when present, shall contain the value of the Source Address field from the frame that is being acknowledged. The Destination PAN ID, when present, contains the value from the Source PAN ID field from the frame that is being acknowledged.
- *The Auxiliary Security Header, IE and Frame Payload are not exist.*

The key steps/points of the Enhanced Acknowledgment flow are as follows.

- The hardware provides a mechanism to ensure that the software can read and write RAM during the process of receiving and sending packets.
- The hardware provides RXWTRMRKIRQ, which can provide an interrupt indication when receiving any number bytes of packets, by software configuration.
- During the receiving process, by dynamically configuring the RX_WTR_MARK register, software no longer waits until the entire packet is received, but after a part of the packet is written into RAM by the hardware. The purpose of this is to enable the software to start decrypting and parsing the package in advance.
- After received the unencrypted MHR and parsed the Frame Version 2, the hardware checks whether the packet is sent to this device and whether it complies with the 802.15.4 -2015 spec. The detailed parsing flow is show in Figure 404. For stage "Address Mode Checking(Valid case in Table 7-2)", it checks if the frame type is Beacon, MAC Command or DATA, check if it is a valid case in Figure 400; if the frame type is ACK, check if it is a valid case in Figure 401. Other rule-checking for each

stage is described in Packet Filtering Detail. If the packet does not pass the parsing flow, the hardware may abort process and set FILTERFAIL_IRQ. Software should also abort its process when received FILTERFAIL_IRQ.

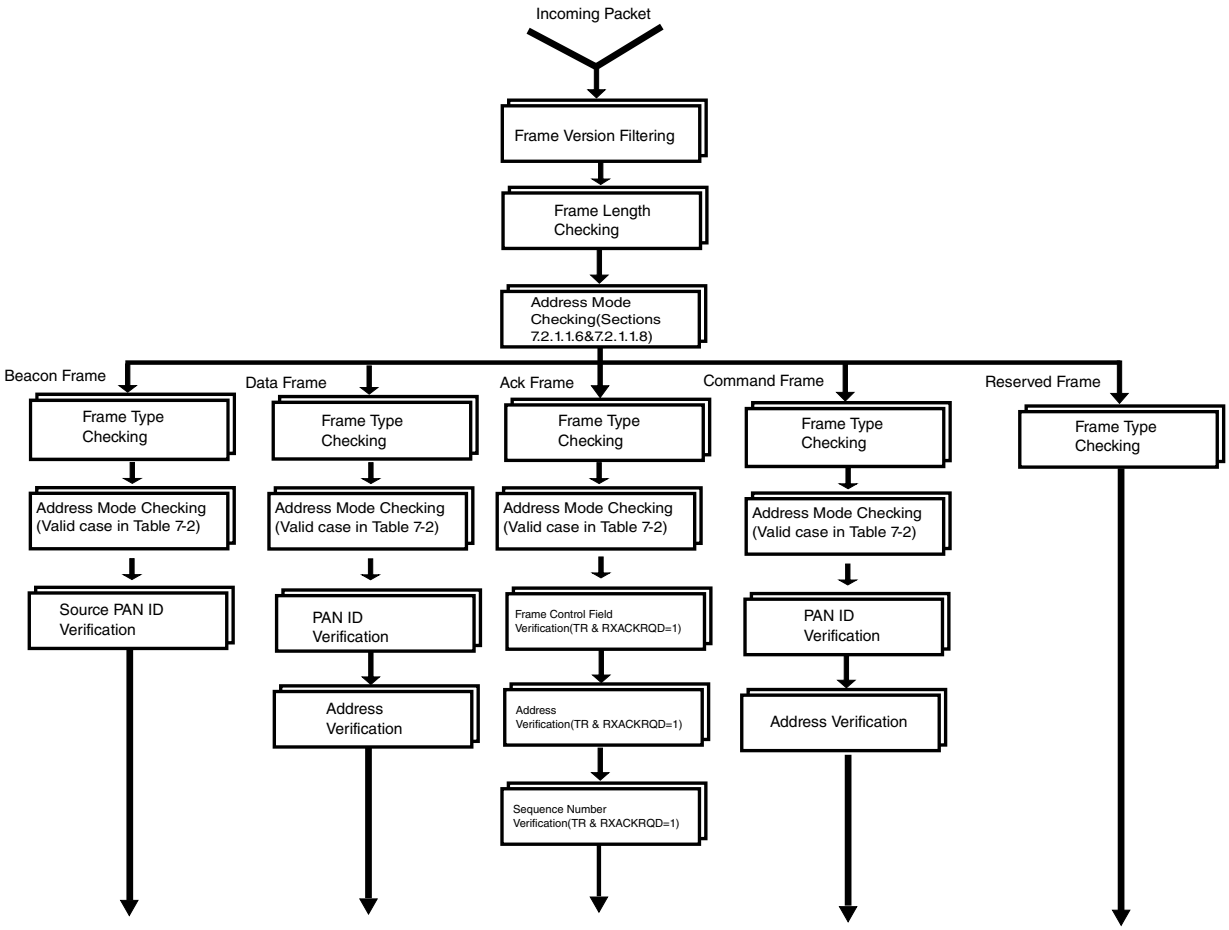

Figure 404. Packet Filtering Flow Diagram of Frame Version 2

- If received DATA or MAC Command packet, the hardware will automatically perform the Source Address Management process if it is enabled, and calculate Frame Pending field, put it in register HW_FRAME_PENDING. This bit will be placed in the Frame Pending field of Enh-Ack, if the software further parses the packet is a MAC Data Request Command or DATA type packet. Otherwise, Enh-Ack's Frame Pending field is 0 and HW_FRAME_PENDING is not used.
- Software may also do some additional rule checks and can abort the process on fail.
- If data authenticity is enabled, software also checkes the data authenticity by message integrity code(MIC). If fail, the software can abort the process.
- At the end of packet, the CRC check is performed by hardware. If CRC fails, the auto acknowledge process is aborted. There are two cases if CRC fails. For each case, the software will be notified to be aborted: Case 1. if NO_RX_RECY CLE is 0 (by default), hardware automaticly recycles and RECYC_IRQ is asserted; Case 2. if NO_RX_RECY CLE is 1, RXIRQ and SEQIRQ are asserted. Software aborts if register CRCVALID is 0.
- If the received packet meets the following conditions, the software starts to prepare the Enh-Ack packet and hardware starts to schedule the acknowledge time.
  - the Frame Version is 2
  - the AR field is 1
  - the Frame Type is DATA or MAC Command

  - filtering flow check pass
  - MIC check pass
  - CRC check pass
- At the 192us turnaround time, if no software abort, hardware starts sending Preamble(4 bytes) and SFD(1 byte), which lasts for 160us. So from the receipt of the last CRC bit, there is a total of 352us for the software to prepare the Enh-Ack packet.
- The software needs to prepare the Length Field first, because this is the first field to be sent after Preamble and SFD. After writing Length Field to RAM, the software needs to set register SW_LEN_RDY to 1.
- After the SFD is sent, the SW_LEN_RDY is used by the hardware to check whether the software Enh-Ack package has been assembled. If SW_LEN_RDY is 1, the hardware continues to read the Full-Enh-Ack from RAM and send it to the air; else, hardware will send an unencrypted Empty-Enh-Ack packet with the correct MHR, but no IEs and Frame Payload. At the same time, the hardware will generate an EMPTY_ACK_IRQ if enabled.
- While the hardware is sending Full-Enh-Ack's Length Field, the software can continue to calculate and write the rest of the packet into RAM.
- Due to possible software and hardware race conditions, before sending the Header IE field(HIE), the hardware has a checkpoint. If the HIE exists in the Enh-Ack packet, after writing the HIE into the RAM, the software needs to set the register SW_HIE_RDY to 1. This SW_HIE_RDY is used by the hardware to check whether the software is capable of completing the HIE and other reset Fields.
- The register SW_MHR_LENGTH is used by the software to tell the hardware the specific location of the HIE in the packet.
- If SW_HIE_RDY is checked as 1, the hardware continues to read bytes from RAM and send them to air; Otherwise, hardware aborts the sequence and generates an interrupt ACK_ABORT_IRQ if enabled.
- When the last byte of the Full-Enh-Ack or Empty-Enh-Ack is sent according to the length specified by the Length field, the sequence completes with the TXIRQ set.

Just like the usage of RXACKRQD bit in Imm-Ack, it can also be used in Enh-Ack. If RXACKRQD=1, then Sequence TR is executed as a Sequence T followed by a Receive-Acknowledge-Only frame. This type of receive operation is special, and not the same as a standalone Sequence R. The Ack-only receive operation filters all incoming frames, looking only for an Enh-Ack frame if the frame version is 2. And the Enh-Ack frame should pass the following checks which is also shown in Figure 404.

- Frame Control field check (can be overridden by leniency[41])
  - The received PAN ID Compression matches the transmitted PAN ID Compression
  - The received Sequence Number Suppression matches the transmitted Sequence Number Suppression
  - The received Destination Address Mode matches the transmitted Source Address Mode
- Address Field check (can be overridden by leniency[42])
  - The Destination Address field, when present, shall contain the value of the Source Address field from the frame that is being acknowledged.
  - The Destination PAN ID, when present, contains the value from the Source PAN ID field from the frame that is being acknowledged
- Sequence Number Check(same as Imm-Ack, can be overridden by leniency[9])

All non-matching frames are discarded, and after each non-matching frame, the sequence manager will return the receiver to preamble-detect mode. This receive operation will continue until the matching Enh-Ack frame is received. Unlike Imm-Ack, the hardware will put the entire Enh-Ack frame in RAM. Because Enh-Ack may contain other information required by the software.

Fields

Field	Function
31 —	Reserved
30-24 RX_FRAME_LENGTH	Receive Frame Length Contents of the PHR (PHY header), or FrameLength field, of the most recently received packet. Read-only.
23 TMR4MSK	Timer Comparator 4 Interrupt Mask bit 0b - allows interrupt when comparator matches event timer count 1b - Interrupt generation is disabled, but a TMR4IRQ flag can be set
22 TMR3MSK	Timer Comparator 3 Interrupt Mask bit 0b - allows interrupt when comparator matches event timer count 1b - Interrupt generation is disabled, but a TMR3IRQ flag can be set
21 TMR2MSK	Timer Comparator 2 Interrupt Mask bit 0b - allows interrupt when comparator matches event timer count 1b - Interrupt generation is disabled, but a TMR2IRQ flag can be set
20 TMR1MSK	Timer Comparator 1 Interrupt Mask bit 0b - allows interrupt when comparator matches event timer count 1b - Interrupt generation is disabled, but a TMR1IRQ flag can be set
19 TMR4IRQ	Timer 4 IRQ Timer Comparator 4 Interrupt Status bit: Indicates T4CMP comparator value matched event timer counter. This is write '1' to clear bit
18 TMR3IRQ	Timer 3 IRQ Timer Comparator 3 Interrupt Status bit: Indicates T3CMP comparator value matched event timer counter. This is write '1' to clear bit
17 TMR2IRQ	Timer 2 IRQ Timer Comparator 2 Interrupt Status bit: Indicates comparator value matched event timer counter. This flag is shared between the T2CMP (24-bit) and T2PRIMECMP (16-bit) compare registers. This is write '1' to clear bit
16 TMR1IRQ	Timer 1 IRQ Timer Comparator 1 Interrupt Status bit: Indicates T1CMP comparator value matched event timer counter. This is write '1' to clear bit
15 CRCVALID	CRC Valid Status Code Redundancy Check Valid: This flag indicates the compare result between the FCS field, in the most-recently received frame, and the internally calculated CRC value. This flag is cleared at next receiver warm up.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Rx FCS != calculated CRC (incorrect) 1b - Rx FCS = calculated CRC (correct)
14 CCA	CCA Status Channel IDLE/BUSY indicator. This indicator is valid at CCAIRQ and also at SEQIRQ. This flag is cleared at next receiver warm up. 0b - IDLE 1b - BUSY
13 SRCADDR	Source Address Match Status If Source Address Management is engaged, meaning at least one of the following bits is set: SAP0_EN SAA0_EN SAP1_EN SAA1_EN Then SRCADDR will be set to 1 if the packet just received is a poll request (PI=1), *and* at least one of the following conditions is met: SAP0_EN and SAP0_ADDR_PRESENT SAA0_EN and SAA0_ADDR_ABSENT SAP1_EN and SAP1_ADDR_PRESENT SAA1_EN and SAA1_ADDR_ABSENT If SRCADDR=1, this indicates to SW that the Packet Processor has determined that an auto-TxACK frame must be transmitted with the FramePending subfield of the FrameControlField set to 1. HW will assemble and transmit this Ack packet. If the above conditions are not met, SRCADDR will be cleared to 0.
12 PI	Poll Indication 0b - the received packet was not a data request 1b - the received packet was a data request, regardless of whether a Source Address table match occurred, or whether Source Address Management is enabled or not
11 ENH_PKT_STATUS	Enhanced Packet Status 0b - The last packet received was neither 4e- nor 2015-compliant 1b - The last packet received was 4e- or 2015-compliant (RX_FRAME_FILTER register should be queried for additional status bits)
10 TSM_IRQ	TSM IRQ TSM Interrupt Request 0b - A TSM Interrupt has not occurred

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - A TSM Interrupt has occurred
9 ARB_GRANT_DEASSERTION_IRQ	arb_grant Deassertion IRQ arb_grant(!RF_NOT_ALLOWED) Deassertion Interrupt Status bit. A '1' indicates an arb_grant deassertion event has occurred. This is write a '1' to clear bit. 0b - An arb_grant Deassertion Interrupt has not occurred 1b - An arb_grant Deassertion Interrupt has occurred
8 WAKE_IRQ	WAKE Interrupt Request Wake Interrupt. The RFMC TIMER has matched the WOR WKUP_TIME register, and DSM has exited. The 802.15.4 EVENT_TMR has resumed counting. 0b - A Wake Interrupt has not occurred 1b - A Wake Interrupt has occurred
7 RX_FRM_PEND	RX Frame Pending Status of the frame pending bit of the frame control field for the most-recently received packet. Read-only.
6 PLL_UNLOCK_IRQ	PLL Unlock IRQ PLL Un-lock Interrupt Status bit. A '1' indicates an unlock event has occurred in the PLL. This is write a '1' to clear bit. 0b - A PLL Unlock Interrupt has not occurred 1b - A PLL Unlock Interrupt has occurred
5 FILTERFAIL_IRQ	Filter Fail IRQ Receiver Packet Filter Fail Interrupt Status bit. A '1' indicates that the most-recently received packet has been rejected due to elements within the packet. This is write a '1' to clear bit. In Dual PAN mode, FILTERFAIL_IRQ applies to either or both networks, as follows: **A:** If PAN0 and PAN1 occupy different channels and CURRENT_NETWORK=0, FILTERFAIL_IRQ applies to PAN0. **B:** If PAN0 and PAN1 occupy different channels and CURRENT_NETWORK=1, FILTERFAIL_IRQ applies to PAN1. **C:** If PAN0 and PAN1 occupy the same channel, FILTERFAIL_IRQ is the logical 'AND' of the individual PANs' Filter Fail status. 0b - A Filter Fail Interrupt has not occurred 1b - A Filter Fail Interrupt has occurred
4 RXWTRMRKIRQ	Receive Watermark IRQ Receiver Byte Count Water Mark Interrupt Status bit. A '1' indicates that the number of bytes specified in the RX_WTR_MARK register has been reached. This is write a '1' to clear bit.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - A Receive Watermark Interrupt has not occurred 1b - A Receive Watermark Interrupt has occurred
3 CCAIRQ	CCA IRQ Clear Channel Assessment Interrupt Status bit. A '1' indicates completion of CCA operation. This is write '1' to clear bit. 0b - A CCA Interrupt has not occurred 1b - A CCA Interrupt has occurred
2 RXIRQ	RX IRQ Receiver Interrupt Status bit. A '1' indicates the completion of a receive operation. This is write a '1' to clear bit. 0b - A RX Interrupt has not occurred 1b - A RX Interrupt has occurred
1 TXIRQ	TX IRQ Transmitter Interrupt Status bit. A '1' indicates the completion of a transmit operation. This is write a '1' to clear bit. 0b - A TX Interrupt has not occurred 1b - A TX Interrupt has occurred
0 SEQIRQ	Sequencer IRQ Sequence-end Interrupt Status bit. A '1' indicates the completion of an autosequence. This interrupt will assert whenever the Sequence Manager transitions from non-idle to idle state, for any reason. This is write a '1' to clear bit. 0b - A Sequencer Interrupt has not occurred 1b - A Sequencer Interrupt has occurred

55.4.9.1.3.1.3 PHY CONTROL (PHY_CTRL)

Offset

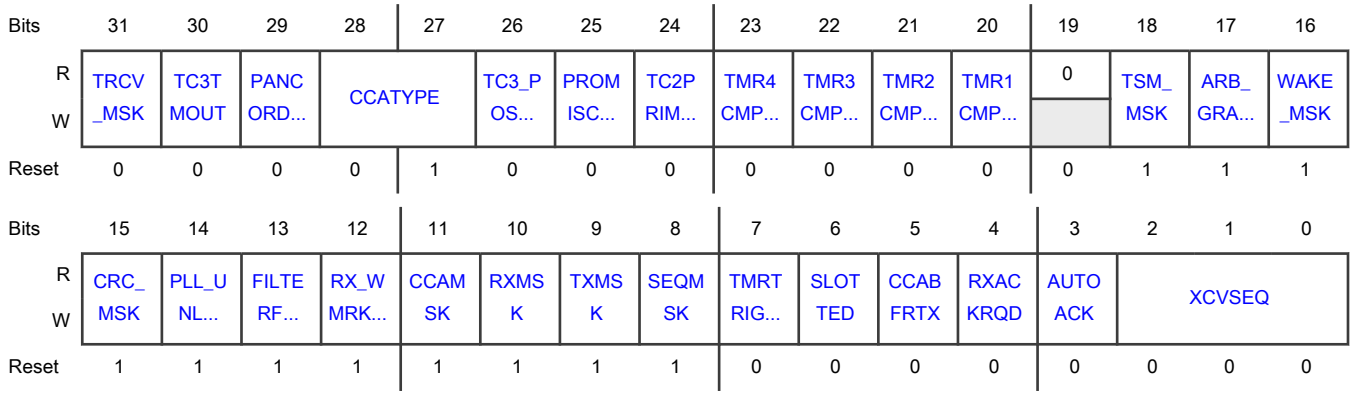
PHY_CTRL	4h

Function
PHY Control Register

Diagram



Fields

Field	Function
31 TRCV_MSK	Transceiver Global Interrupt Mask Transceiver Global Interrupt Mask 0b - Enable any unmasked interrupt source to assert zigbee interrupt 1b - Mask all interrupt sources from asserting zigbee interrupt
30 TC3TMOUT	TMR3 Timeout Enable TMR3 Timeout Enable 0b - TMR3 is a software timer only 1b - Enable TMR3 to abort Rx or CCCA operations.
29 PANCORDNTR0	Device is a PAN Coordinator on PAN0 Device is a PAN Coordinator on PAN0. Allows device to receive packets with no destination address, if Source PAN ID matches.
28-27 CCATYPE	Clear Channel Assessment Type Clear Channel Assessment Type. Selects one of four possible functions for CCA or Energy Detect, per below. 00b - ENERGY DETECT 01b - CCA MODE 1 10b - CCA MODE 2 11b - CCA MODE 3
26 TC3_POSTPONE_ON_SFD	Postpone TC3 Timeout On SFD Enable If this bit is set, if a TMR3 timeout occurs while a packet is being received (*rx_sfd_detect* = 1), the timeout-related abort will be deferred until the packet reception is completed. If the packet is good, HW will signal Data Indication; otherwise the 802.15.4 ZSM (Sequence Manager) will return to SEQ_IDLE and await further commanding.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - TC3 Abort will occur on TMR3 timeout, regardless of rx_sfd_detect 1b - TC3 Abort will be deferred on TMR3 timeout if rx_sfd_detect is asserted; otherwise the TC3 Abort will occur immediately
25 PROMISCUOUS	Promiscuous Mode Enable Bypasses most packet filtering. 0b - normal mode 1b - all packet filtering except frame length checking (FrameLength>=5 and FrameLength<=127) is bypassed.
24 TC2PRIME_EN	Timer 2 Prime Compare Enable 0b - Don't allow a match of the lower 16 bits of Event Timer to T2PRIMECMP to set TMR2IRQ 1b - Allow a match of the lower 16 bits of Event Timer to T2PRIMECMP to set TMR2IRQ
23 TMR4CMP_EN	Timer 4 Compare Enable 0b - Don't allow an Event Timer Match to T4CMP to set TMR4IRQ 1b - Allow an Event Timer Match to T4CMP to set TMR4IRQ
22 TMR3CMP_EN	Timer 3 Compare Enable 0b - Don't allow an Event Timer Match to T3CMP to set TMR3IRQ 1b - Allow an Event Timer Match to T3CMP to set TMR3IRQ
21 TMR2CMP_EN	Timer 2 Compare Enable 0b - Don't allow an Event Timer Match to T2CMP or T2PRIMECMP to set TMR2IRQ 1b - Allow an Event Timer Match to T2CMP or T2PRIMECMP to set TMR2IRQ
20 TMR1CMP_EN	Timer 1 Compare Enable 0b - Don't allow an Event Timer Match to T1CMP to set TMR1IRQ 1b - Allow an Event Timer Match to T1CMP to set TMR1IRQ
19 —	Reserved
18 TSM_MSK	Mask generating interrupt from TSM 0b - allows assertion of a TSM interrupt to generate a zigbee interrupt 1b - Assertion of a TSM interrupt will set the TSM_IRQ status bit, but a zigbee interrupt is not generated
17 ARB_GRANT_DEASSERTION_MSK	arb_grant Deassertion Interrupt Mask 0b - allows arb_grant deassertion event to generate a zigbee interrupt 1b - An arb_grant deassertion event will set the ARB_GRANT_DEASSERTION_IRQ status bit, but a zigbee interrupt is not generated

Table continues on the next page...

Table continued from the previous page...

Field	Function
16 WAKE_MSK	Mask wakeup from DSM 0b - Allows a wakeup from DSM to generate a zigbee interrupt 1b - Wakeup from DSM will set the WAKE_IRQ status bit, but a zigbee interrupt is not generated
15 CRC_MSK	CRC Mask CRC Mask 0b - sequence manager ignores CRCVALID and considers the receive operation complete after the last octet of the frame has been received. 1b - sequence manager requires CRCVALID=1 at the end of the received frame in order for the receive operation to complete successfully; if CRCVALID=0, sequence manager will return to preamble-detect mode after the last octet of the frame has been received.
14 PLL_UNLOCK_MSK	PLL Unlock Interrupt Mask 0b - allows PLL unlock event to generate a zigbee interrupt 1b - A PLL unlock event will set the PLL_UNLOCK_IRQ status bit, but a zigbee interrupt is not generated
13 FILTERFAIL_MSK	FilterFail Interrupt Mask FilterFail Interrupt Mask 0b - allows Packet Processor Filtering Failure to generate a zigbee interrupt 1b - A Packet Processor Filtering Failure will set the FILTERFAIL_IRQ status bit, but a zigbee interrupt is not generated
12 RX_WMRK_MSK	RX Watermark Interrupt Mask RX Watermark Interrupt Mask 0b - allows a Received Byte Count match to the RX_WTR_MARK threshold register to generate a zigbee interrupt 1b - A Received Byte Count match to the RX_WTR_MARK threshold register will set the RXWTRMRKIRQ status bit, but a zigbee interrupt is not generated
11 CCAMSK	CCA Interrupt Mask CCA Interrupt Mask 0b - allows completion of a CCA operation to generate a zigbee interrupt 1b - Completion of a CCA operation will set the CCA status bit, but a zigbee interrupt is not generated
10 RXMSK	RX Interrupt Mask 0b - allows completion of a RX operation to generate a zigbee interrupt 1b - Completion of a RX operation will set the RXIRQ status bit, but a zigbee interrupt is not generated

Table continued from the previous page...

Field	Function
9 TXMSK	TX Interrupt Mask 0b - allows completion of a TX operation to generate a zigbee interrupt 1b - Completion of a TX operation will set the TXIRQ status bit, but a zigbee interrupt is not generated
8 SEQMSK	Sequencer Interrupt Mask 0b - allows completion of an autosequence to generate a zigbee interrupt 1b - Completion of an autosequence will set the SEQIRQ status bit, but a zigbee interrupt is not generated
7 TMRTRIGEN	Timer2 Trigger Enable 0b - programmed sequence initiates immediately upon write to XCVSEQ. 1b - allow timer TC2 (or TC2') to initiate a preprogrammed sequence (see XCVSEQ register).
6 SLOTTED	Slotted Mode Slotted Mode, for beacon-enabled networks. Applies only to Sequences T, TR, and R, ignored during all other sequences. Used, in concert with CCABFRTX, to determine how many CCA measurements are required prior to a transmit operation. Also used during R sequence to determine whether the ensuing transmit acknowledge frame (if any) needs to be synchronized to a backoff slot boundary.
5 CCABFRTX	CCA Before TX Applies only to Sequences T and TR, ignored during all other sequences. 0b - no CCA required, transmit operation begins immediately. 1b - at least one CCA measurement is required prior to the transmit operation (see also SLOTTED).
4 RXACKRQD	Receive Acknowledge Frame required Applies only to Sequence TR, ignored during all other sequences. 0b - An ordinary receive frame (any type of frame) follows the transmit frame. 1b - A receive Ack frame is expected to follow the transmit frame (non-Ack frames are rejected).
3 AUTOACK	Auto Acknowledge Enable Applies only to Sequence R and Sequence TR, ignored during other sequences 0b - sequence manager will not follow a receive frame with a Tx Ack frame, under any conditions; the autosequence will terminate after the receive frame. 1b - sequence manager will follow a receive frame with an automatic hardware-generated Tx Ack frame, assuming other necessary conditions are met.
2-0 XCVSEQ	802.15.4 Transceiver Sequence Selector The Transceiver Sequence Selector register selects an autosequence for the sequence manager to execute. Sequence initiation can be immediate, or scheduled (see TMRTRIGEN). A write of XCVSEQ=IDLE will abort any ongoing sequence. A write of XCVSEQ=IDLE must always be performed

Table continues on the next page...

Table continued from the previous page...

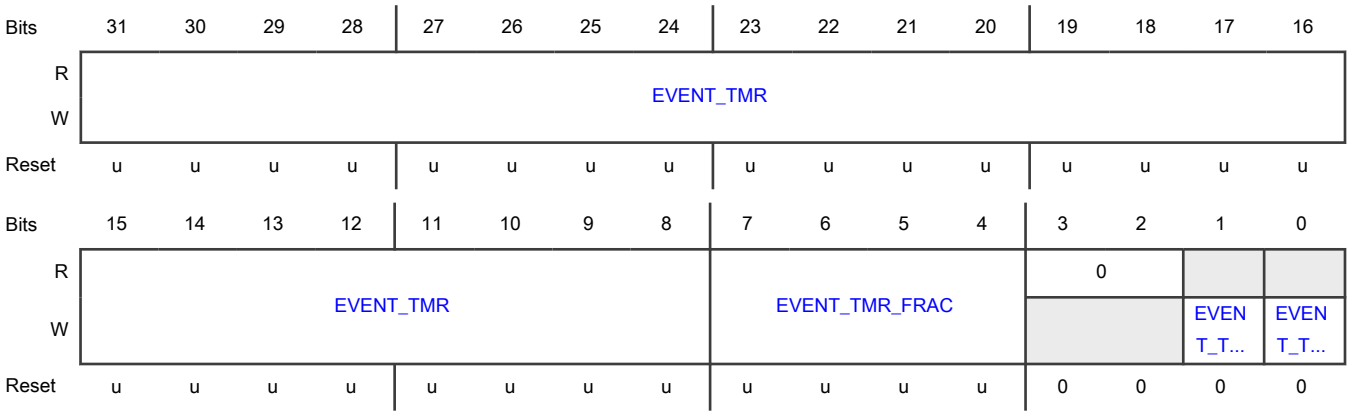
Field	Function
	after a sequence is complete, and before a new sequence is programmed. Any write to XCVSEQ other than XCVSEQ=IDLE during an ongoing sequence, shall be ignored. The mapping of XCVSEQ to sequence types is as follows: 000b - I (IDLE) 001b - R (RECEIVE) 010b - T (TRANSMIT) 011b - C (CCA) 100b - TR (TRANSMIT/RECEIVE) 101b - CCCA (CONTINUOUS CCA) 110b - Reserved 111b - Reserved

55.4.9.1.3.1.4 EVENT TIMER (EVENT_TMR)

Offset

Register	Offset
EVENT_TMR	8h

Diagram



Fields

Field	Function
31-8 EVENT_TMR	Event Timer Integer Component

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The EVENT_TMR represents a 28-bit number with 24 Integer bits and 4 Fractional bits. This field is the integer component, which appears to the left of the decimal point. Most 802.15.4 operations which relate to the Event Timer require only the integer component.
7-4 EVENT_TMR_FRAC	Event Timer Fractional Component The EVENT_TMR represents a 28-bit number with 24 Integer bits and 4 Fractional bits. This field is the fractional component, which appears to the right of the decimal point. The fractional component can be ignored for most 802.15.4 operations which relate to the Event Timer; it has been provided only to allow for microsecond accuracy when software updates the Event Timer after a long period of DSM (sleep) mode
3-2 —	Reserved
1 EVENT_TMR_ADD	Event Timer Add Enable Increments the Event Timer by the values written to the EVENT_TMR[23:0] and EVENT_TMR_FRAC[3:0] fields of this register.
0 EVENT_TMR_LD	Event Timer Load Enable Loads the Event Timer with the values written to the EVENT_TMR[23:0] and EVENT_TMR_FRAC[3:0] fields of this register.

15 EXTENDED_FCS_CHK	Verify FCS on Frame Type Extended 0b - Packet Processor will not check FCS for Frame Type EXTENDED (default) 1b - Packet Processor will check FCS at end-of-packet based on packet length derived from PHR, for Frame Type EXTENDED
14 ACTIVE_PROMISCUOUS	Active Promiscuous 0b - normal operation 1b - Provide Data Indication on all received packets under the same rules which apply in PROMISCUOUS mode, however acknowledge those packets under rules which apply in non-PROMISCUOUS mode
13-12	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
11-8 FRM_VER_FILTER	Frame Version selector. The incoming packet's Frame Control Field is parsed to obtain the FrameVersion subfield, and that value is compared against this register, in accordance with the following: xxx1: Accept received packets with FrameVersion=00 xx1x: Accept received packets with FrameVersion=01 x1xx: Accept received packets with FrameVersion=10 1xxx: Accept received packets with FrameVersion=11 These filtering rules apply to Beacon, Acknowledge, Data, and MAC Command Frame Types, since these frame types require a 2-octet Frame Control Field which embeds a 2-bit FrameVersion subfield. Later frame types introduced in the 802.15.4e addendum (LLDN, Multipurpose) don't guarantee a FrameVersion subfield with the original meaning, so these filtering rules do not apply to these frame types. See registers LLDN_FT and MULTIPURPOSE_FT. For Acknowledge frames, FrameVersion bits are ignored by the Packet Processor, irrespective of FRM_VER_FILTER.
7 EXTENDED_FT	Extended Frame Type Enable 0b - reject all Extended frames 1b - Extended frame type enabled (Frame Type 7).
6 NS_FT	"Not Specified" Frame Type Enable This bit enables reception of all Frame Types not covered by the other _FT bits in this register. 0b - reject all "Not Specified" frames 1b - Not-specified (reserved) frame type enabled. Applies to Frame Type 6. No packet filtering is performed, except for frame length checking (FrameLength>=5 and FrameLength<=127). No AUTOACK is transmitted for this Frame Type
5 MULTIPURPOSE_FT	Multipurpose Frame Type Enable 0b - reject all Multipurpose frames 1b - Multipurpose frame type enabled (Frame Type 5).
4 LLDN_FT	LLDN Frame Type Enable 0b - reject all LLDN frames 1b - LLDN frame type enabled (Frame Type 4).
3 CMD_FT	MAC Command Frame Type Enable 0b - reject all MAC Command frames 1b - MAC Command frame type enabled.
2	Ack Frame Type Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
ACK_FT	0b - reject all Acknowledge frames 1b - Acknowledge frame type enabled.
1 DATA_FT	Data Frame Type Enable 0b - reject all Beacon frames 1b - Data frame type enabled.
0 BEACON_FT	Beacon Frame Type Enable 0b - reject all Beacon frames 1b - Beacon frame type enabled.

Field	Function
31-0 MACLONGADDRS1_MSB	MAC LONG ADDRESS for PAN1 MSB MAC Long Address for PAN1, for 64-bit destination addressing mode. The packet processor compares the incoming packet's Destination Address against the contents of this register to determine if the packet is addressed to this device.

55.4.9.1.3.1.24 DUAL PAN CONTROL (DUAL_PAN_CTRL)

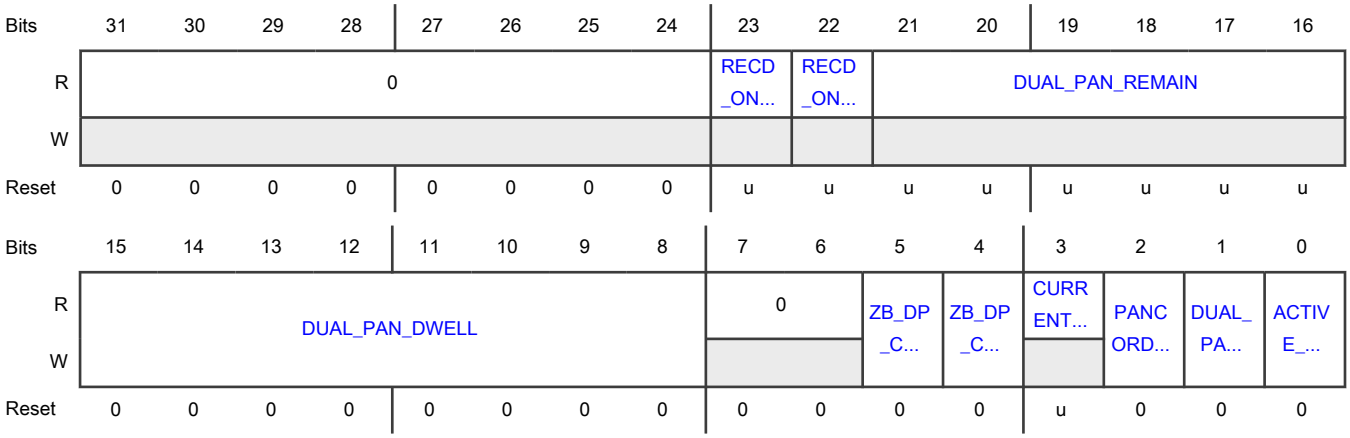
Offset

Register	Offset
DUAL_PAN_CTRL	60h

Function

Dual PAN Control Register

Diagram



Fields

Field	Function
31-24 —	Reserved
23 RECD_ON_PAN1	Last Packet was Received on PAN1 Indicates the packet which was just received, was received on PAN1. In Dual PAN mode operating on 2 different channels, RECD_ON_PAN1 will be set if CURRENT_NETWORK=1 when the packet was received, regardless of FILTERFAIL status. In DUAL PAN mode operating with same channel on both networks, CURRENT_NETWORK will be ignored and RECD_ON_PAN1 will be set only if a valid packet was received on PAN1 (PAN1's FILTERFAIL_FLAG is deasserted). RECD_ON_PAN1 remains valid until the start of the next autoseqeuence.
22 RECD_ON_PAN0	Last Packet was Received on PAN0 Indicates the packet which was just received, was received on PAN0. In Dual PAN mode operating on 2 different channels, RECD_ON_PAN0 will be set if CURRENT_NETWORK=0 when the packet was received, regardless of FILTERFAIL status. In DUAL PAN mode operating with same channel on both networks, CURRENT_NETWORK will be ignored and RECD_ON_PAN0 will be set only if a valid packet was received on PAN0 (PAN0's FILTERFAIL_FLAG is deasserted). RECD_ON_PAN0 remains valid until the start of the next autoseqeuence.
21-16 DUAL_PAN_REMAIN	Time Remaining before next PAN switch in auto Dual PAN mode This read-only register indicates time remaining before next PAN switch in auto Dual PAN mode. The units for this register, depend on the PRESCALER setting (bits [1:0]) in the DUAL_PAN_DWELL register. Tthe units are the same as the TIMEBASE determined by the prescaler, as per the following table: DUAL_PAN_DWELL[1:0]=0b00 (TIMEBASE=0.5ms) DUAL_PAN_REMAIN UNITS=0.5ms DUAL_PAN_DWELL[1:0]=0b01 (TIMEBASE=2.5ms) DUAL_PAN_REMAIN UNITS=2.5ms

Table continues on the next page...

Table continued from the previous page...

Field	Function
	DUAL_PAN_DWELL[1:0]=0b10 (TIMEBASE=10ms) DUAL_PAN_REMAIN UNITS=10ms DUAL_PAN_DWELL[1:0]=0b11 (TIMEBASE=50ms) DUAL_PAN_REMAIN UNITS=50ms The readback value indicates that between N-1 and N timebase units remain until the next PAN switch. For example, a DUAL_PAN_REMAIN readback value of 3, with a DUAL_PAN_DWELL PRESCALER setting of 2 (10ms), indicates that between 20ms (2*10ms) and 30ms (3*10ms), remain until the next automatic PAN switch.
15-8 DUAL_PAN_DWELL	Dual PAN Channel Frequency Dwell Time Channel Frequency Dwell Time. In Auto Dual PAN mode, hardware will toggle the PAN, after dwelling on the current PAN for the interval described below (assuming Preamble/SFD not detected). A write to DUAL_PAN_DWELL, always re-initializes the DWELL TIMER to the programmed value. If a write to DUAL_PAN_DWELL occurs during an autosequence, the DWELL TIMER will begin counting down immediately. If a write to DUAL_PAN_DWELL occurs when there is no autosequence underway, the DWELL TIMER will not begin counting until the next autosequence begins; it will begin counting at the start of the sequence warmup. DUAL_PAN_DWELL[1:0] select the timebase for the dwell time. There are 4 options: DUAL_PAN_DWELL[1:0]=0b00 --> TIMEBASE=0.5ms DUAL_PAN_DWELL[1:0]=0b01 --> TIMEBASE=2.5ms DUAL_PAN_DWELL[1:0]=0b10 --> TIMEBASE=10ms DUAL_PAN_DWELL[1:0]=0b11 --> TIMEBASE=50ms DUAL_PAN_DWELL[7:2] select how many multiples of the time base to use, from 1 (DUAL_PAN_DWELL[7:2]=0) to 64 (DUAL_PAN_DWELL[7:2]=63). Given those definitions, the table below specifies the minimum and maximum dwell times for each TIMEBASE option: DUAL_PAN_DWELL[1:0]=0b00 --> MIN_DWELL=0.5ms MAX_DWELL=32ms DUAL_PAN_DWELL[1:0]=0b01 --> MIN_DWELL=2.5ms MAX_DWELL=160ms DUAL_PAN_DWELL[1:0]=0b10 --> MIN_DWELL=10ms MAX_DWELL=640ms DUAL_PAN_DWELL[1:0]=0b11 --> MIN_DWELL=50ms MAX_DWELL=3.2seconds A write to DUAL_PAN_DWELL also causes the value of ACTIVE_NETWORK to get latched into the hardware. This latched value will be the starting point for the automatic dual-pan mode (i.e., start on PAN0 or on PAN1). The starting value takes effect immediately (if sequence is underway and DUAL_PAN_AUTO=1), or is otherwise delayed until sequence starts and DUAL_PAN_AUTO=1.
7-6 —	Reserved
5 ZB_DP_CHAN_OVRD_SEL	Dual PAN Channel Override Selector This bit works with **ZB_DP_CHAN_OVRD_EN** to allow one of the two Dual PAN channels to use Direct Frequency programming. See description for **ZB_DP_CHAN_OVRD_EN** .
4	Dual PAN Channel Override Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
ZB_DP_CHAN_OVRD_EN	In Dual PAN mode, in case there is a need to generate a frequency which may be offset from the 16 prescribed 5MHz-spaced channels, to, for example, avoid interference on one of the Dual PAN channels, a method has been provided to accomplish that, by designating one of the two PAN channels to use the transceiver's set of direct frequency-programming registers, instead of CHANNEL_NUMx. Programming the direct frequency-programming registers -- integer, numerator, and denominator, allows an RF frequency to be selected with much more precision than the 5MHz granularity of the Zigbee mapped-channel registers, CHANNEL_NUM0 and CHANNEL_NUM1. Two bits have been provided in 802.15.4 space to realize this feature: ZB_DP_CHAN_OVRD_SEL and ZB_DP_CHAN_OVRD_EN. When ZB_DP_CHAN_OVRD_EN=1, this enables one of the Dual PAN channels to use the direct frequency programming. The ZB_DP_CHAN_OVRD_SEL bit determines which channel uses the direct programming, according to the following: If ZB_DP_CHAN_OVRD_EN=0, then PAN0 frequency is determined by register CHANNEL_NUM0[6:0] and PAN1 frequency is determined by register CHANNEL_NUM1[6:0]. If ZB_DP_CHAN_OVRD_EN=1 and ZB_DP_CHAN_OVRD_SEL=0, then PAN0 frequency is determined by DIRECT FREQUENCY PROGRAMMING and PAN1 frequency is determined by register CHANNEL_NUM1[6:0]. If ZB_DP_CHAN_OVRD_EN=1 and ZB_DP_CHAN_OVRD_SEL=1, then PAN0 frequency is determined by register CHANNEL_NUM0[6:0] and PAN1 frequency is determined by DIRECT FREQUENCY PROGRAMMING. **NOTE** Direct Frequency Programming is accomplished by setting the PLL's Integer, Numerator, and Denominator registers to the appropriate values for the desired RF frequency.
3 CURRENT_NETWORK	Indicates which PAN is currently selected by hardware This read-only bit indicates which PAN is currently selected by hardware in automatic Dual PAN mode 0b - PAN0 is selected 1b - PAN1 is selected
2 PANCORDNTR1	Device is a PAN Coordinator on PAN1 Device is a PAN Coordinator on PAN1. Allows device to receive packets with no destination address, if Source PAN ID matches.
1 DUAL_PAN_AUTO	Activates automatic Dual PAN operating mode Activates automatic Dual PAN operating mode. In this mode, PAN-switching is controlled by hardware at a pre-programmed rate, determined by DUAL_PAN_DWELL. 0: Manual Dual PAN mode (or Single PAN mode). 1: Auto Dual PAN Mode Whenever DUAL_PAN_AUTO=0, CURRENT_NETWORK=ACTIVE_NETWORK at all times. In other words, software directly controls which PAN is selected. Whenever DUAL_PAN_AUTO=1, CURRENT_NETWORK is controlled by hardware.
0	Active Network Selector

Table continues on the next page...

Table continued from the previous page...

Field	Function
ACTIVE_NETWORK	Selects the PAN on which to transceive, by activating a PAN parameter set (PAN0 or PAN1). In Manual Dual PAN mode (or Single PAN mode), this bit selects the active PAN parameter set (channel and addressing parameters) which governs all autosequences. In Auto Dual PAN mode, this bit selects the PAN on which to begin transceiving, latched at the point at which DUAL_PAN_DWELL register is written. 0b - Select PAN0 1b - Select PAN1

55.4.9.1.3.1.27 SOURCE ADDRESS MANAGEMENT TABLE (SAM_TABLE)

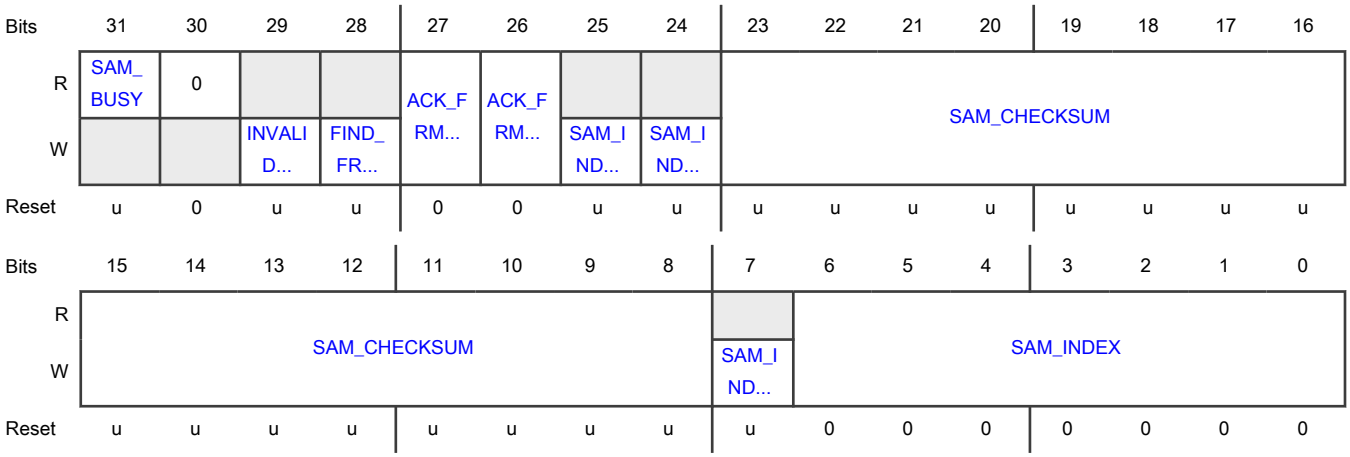
Offset

Register	Offset
SAM_TABLE	6Ch

Function

Source Address Management Table

Diagram



Fields

Field	Function
31 SAM_BUSY	SAM Table Update Status Bit

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Hardware is in the process of updating the Source Address table, either in response to a poll indication from the packet processor, or due to software setting FIND_FREE_IDX=1. In the latter case, software should poll SAM_BUSY until low before accessing the "First Free Index" registers. Read-only bit.
30 —	Reserved
29 INVALIDATE_ALL	Invalidate Entire SAM Table Writing a 1 to this bit clears all 128 Valid bits. Invalidates the entire table. Write-only bit. Writing 0 to this bit has no effect. Readback value is indeterminate.
28 FIND_FREE_IDX	Find First Free Index After modifying Valid bits (enabling or invalidating), write this bit to 1 to force hardware to update the "First Free Index" registers to account for the changed Valid bits. This hardware update process takes 4us. Software can poll SAM_BUSY to determine when the table update is complete. Write-only bit. Writing 0 to this bit has no effect. Readback value is indeterminate.
27 ACK_FRM_PND_CTRL	Manual Control for AutoTxAck FramePending field 0b - the FramePending field of the Frame Control Field of the next automatic TX acknowledge packet is determined by hardware 1b - the FramePending field of the Frame Control Field of the next automatic TX acknowledge packet tracks ACK_FRM_PEND
26 ACK_FRM_PND	State of AutoTxAck FramePending field when SAM Accelleration is Disabled Software can take manual control of the FramePending field of the Frame Control Field of the next automatic TX acknowledge packet, by setting ACK_FRM_PND_CTRL=1; in that case FramePending will track the state of this bit. The FramePending field also tracks this bit if Source Address Management is completely disabled, i.e., SAP0_EN=SAA0_EN=SAP1_EN=SAA1_EN=0 Otherwise, the FramePending field is determined by Source Address Management (SAM) hardware.
25 SAM_INDEX_EN	Enable the SAM table index selected by SAM_INDEX
24 SAM_INDEX_INV	Invalidate the SAM table index selected by SAM_INDEX
23-8 SAM_CHECKSUM	Software-computed source address checksum, to be installed into a table index Software-computed source address checksum, to be installed into a table index. The value on SAM_CHECKSUM[15:0] can be installed into the table with a single, atomic 32-bit write; in that case, the write data would contain the desired SAM_INDEX[6:0] and SAM_CHECKSUM[15:0], and SAM_INDEX_WR=1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If SAM_INDEX_WR=0, then the SAM_INDEX[6:0] register is written, but the checksum is *not* written to the table. The readback value of SAM_CHECKSUM[15:0] is the contents of the SAM Table at the location pointed to by SAM_INDEX[6:0]. To readback from a specific table index, software should first write the desired index to SAM_INDEX[6:0], and then read back the checksum from the table on SAM_CHECKSUM[15:0].
7 SAM_INDEX_WR	Enables SAM Table Contents to be updated For 32-bit writes, SAM_INDEX_WR must be set to indicate that the table entry specified by SAM_INDEX[6:0] is to be written; if SAM_INDEX_WR=0, the table entry is not written, but the SAM_INDEX[6:0] register is updated. For 8-bit writes, this bit is ignored.
6-0 SAM_INDEX	Contains the SAM table index to be enabled or invalidated Contains the table index to be enabled or invalidated. Software must ensure that the index is within the range of the desired partition.

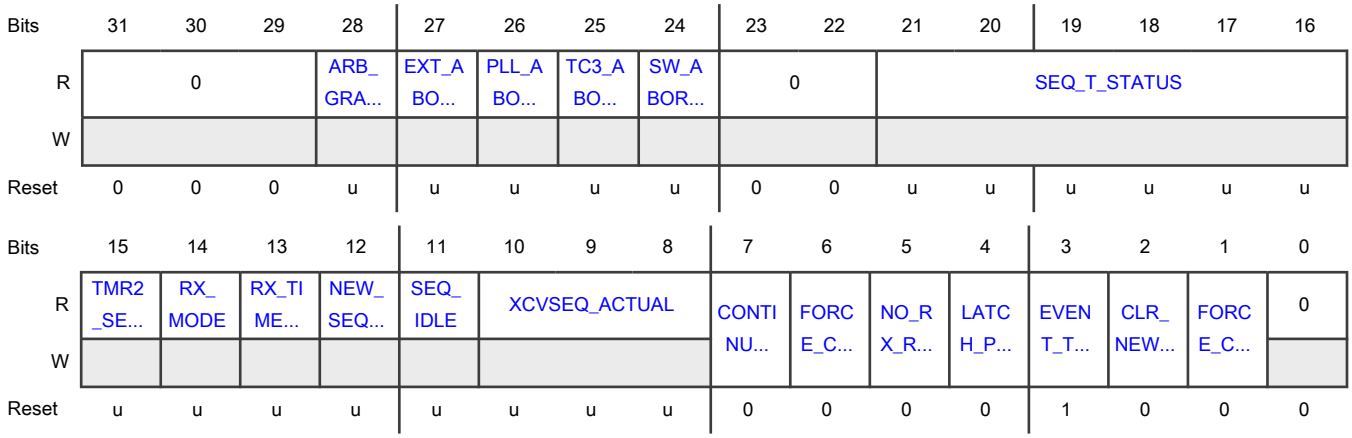
55.4.9.1.3.1.30 SEQUENCE CONTROL AND STATUS (SEQ_CTRL_STS)

Offset

Register	Offset
SEQ_CTRL_STS	78h

Diagram



Fields

Field	Function
31-29 —	Reserved
28 ARB_GRANT_DEASSERTION_ABORTED	Autosequence has terminated due to an arb_grant deassertion event when asserted, indicates that the autosequence has terminated due to an arb_grant deassertion event. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. Read-only bit.
27 EXT_ABORTED	Autosequence has terminated due to a Wake-On-Radio command when asserted, indicates that the autosequence has terminated due to an external event, such as a Wake-On-Radio stop command. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. Read-only bit.
26 PLL_ABORTED	Autosequence has terminated due to an PLL unlock event when asserted, indicates that the autosequence has terminated due to an PLL unlock event. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. Read-only bit.
25 TC3_ABORTED	autosequence has terminated due to an TMR3 timeout when asserted, indicates that the autosequence has terminated due to an TC3 (TMR3) timeout during a receive operation. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. Read-only bit.
24 SW_ABORTED	Autosequence has terminated due to a Software abort. when asserted, indicates that the autosequence has terminated due to an Software abort. Software can abort any programmed autosequence by writing Sequence I to XCVSEQ. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. Read-only bit.
23-22	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
21-16 SEQ_T_STATUS	Status of the just-completed or ongoing Sequence T or Sequence TR Status of the just-completed (or ongoing) Sequence T or Sequence TR autosequence. This register is valid at all times during, and after, the Sequence T or Sequence TR. Not valid for other types of autosequences. This is a read-only register. The bits of this register map to status, according to the following table: [0] 1st CCA complete (CCABFRTX=1) [1] 2nd CCA complete (SLOTTED=1) [2] Tx operation complete [3] Rx Recycle occurred (Sequence TR only) [4] Rx operation complete (Sequence TR only) [5] TxAck operation complete(Sequence TR only)
15 TMR2_SEQ_TRIG_ARMED	indicates that TMR2 has been programmed and is armed to trigger a new autosequence when asserted, indicates that TMR2 has been programmed and is "armed" to trigger a new autosequence, when Zigbee Sequence Manager timer-triggering mode is selected (i.e., TMRTRIGEN=1). When timer-triggering mode is selected, TMR2 must be re-programmed (using either T2CMP or T2PRIMECMP), in advance of each new sequence. Once TMR2 is programmed, this bit will be asserted, and will remain asserted until the new sequence commences (at TMR2 match). Hardware will deassert this bit when the new sequence starts. When TMRTRIGEN=0, this bit should be ignored. Read-only bit.
14 RX_MODE	RX Operation in Progress when asserted, this Sequence Manager Output indicates that an RX operation is in progress. An RX operation can be part of a complex transmit autosequence such as a Sequence TR. CCA and ED operations are considered RX operations, during which rx_mode is asserted. Read-only bit.
13 RX_TIMEOUT_PENDING	Indicates a TMR3 RX Timeout is Pending when asserted, indicates that a TMR3 timeout (RX timeout) flag has been set by Hardware, but the Sequence Manager has not yet aborted because an RX operation is not currently underway. This would be the case, for example, during a Sequence TR, if a TMR3 timeout were to occur during the transmit operation of this sequence; the sequence would not be aborted by Hardware until the receive operation begins. This bit will always be 0 if TC3TMOUT=0. Read-only bit.
12 NEW_SEQ_INHIBIT	New Sequence Inhibit When asserted, indicates that a new programmed autosequence has commenced (TMR2 match has occurred if TMRTRIGEN=1). Once this bit is asserted, software is blocked from commanding any "new" autosequences (other than Sequence I to abort the current sequence), until the current sequence completes. Hardware will ignore a sequence-change command from software while this bit is asserted. Hardware will automatically deassert this bit once the sequence completes. Read-only bit.
11 SEQ_IDLE	ZSM Sequence Idle Indicator

Table continues on the next page...

Table continued from the previous page...

Field	Function
10-8 XCVSEQ_ACTUAL	Indicates the programmed sequence that has been recognized by the ZSM Sequence Manager Reflects the programmed sequence that has been recognized by the Zigbee Sequence Manager. Takes into account the fact that sequence-change commands from software are ignored while a sequence is underway (see NEW_SEQ_INHIBIT). Read-only bits.
7 CONTINUOUS_EN	Enable Continuous TX or RX Mode Continuous Mode Enable (Continuous TX or RX). **Note:** Dual PAN mode should not be engaged in Continuous TX or RX modes. 0b - normal operation 1b - Continuous TX or RX mode is enabled (depending on XCVSEQ setting).
6 FORCE_CRC_ERROR	Induce a CRC Error in Transmitted Packets 0b - normal operation 1b - Force the next transmitted packet to have a CRC error
5 NO_RX_RECYCLE	Disable Automatic RX Sequence Recycling when asserted, prevents the Zigbee Sequence Manager (ZSM) from automatically re-starting (recycling) the receiver when a packet is received which results in a FilterFail or CRC failure. Normally, on a RX recycle, the ZSM returns to the RX_WU (warmup) state, and then resumes from there with a new, foreshortened, Rx warmup, in search of a new preamble. When this bit is set, the Sequence Manager will instead return to idle state, and issue a SEQIRQ, after a FilterFail or CRC failure.
4 LATCH_PREAMBLE	Stickiness Control for Preamble Detection 0b - Don't make PREAMBLE_DET and SFD_DET bits of PHY_STS (SEQ_STATE) Register "sticky", i.e, these status bits reflect the realtime, dynamic state of preamble_detect and sfd_detect 1b - Make PREAMBLE_DET and SFD_DET bits of PHY_STS (SEQ_STATE) Register "sticky", i.e., occurrences of preamble and SFD detection are latched and held until the start of the next autosequence
3 EVENT_TMR_DO_NOT_LATCH	Overrides the automatic hardware latching of the Event Timer when asserted, overrides the automatic hardware latching of the Event Timer that prevents the timer from updating while software reads the 3 Event Timer bytes. This allows the Event Timer LS byte to continue to update without reading the upper 2 bytes. Overriding the automatic latching of the Event Timer should be used with caution, as it can allow the Event Timer lower bytes to get out-of-sync with the upper bytes. However, it can be useful when polling the Event Timer LS byte for a value that is just a few counts in the future.
2 CLR_NEW_SEQ_INHIBIT	Overrides the automatic hardware locking of the programmed XCVSEQ while an autosequence is underway when asserted, overrides the automatic hardware locking of the programmed XCVSEQ while an autosequence is underway. Asserting this feature will allow software to change the programmed autosequence "on-the-fly", without aborting and returning to idle between sequences. Overriding the hardware lockout of XCVSEQ should be used with caution, since the Sequence Manager is not designed (or verified) for manual state transitions between one type of autosequence and other (i.e., Sequence T -> Sequence R).

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 FORCE_CLK_ON	Force On 802.15.4 phy_gck Force On 802.15.4 phy_gck 0b - Allow TSM to control 802.15.4 phy_gck, for minimum power consumption (default) 1b - Force on 802.15.4 phy_gclk at all times, for debug purposes only
0 —	Reserved

55.4.9.1.3.1.31 ACK DELAY (ACKDELAY)

Offset

Register	Offset
ACKDELAY	7Ch

Function

Provides a fine-tune adjustment of the time delay between Rx warmdown and the beginning of Tx warmup for an autoTxAck packet.

Field	Function
31-27 —	Reserved
26-25	FAST_TX_WD_DELAY

Table continues on the next page...

Table continued from the previous page...

Field	Function
FAST_TX_WD_DELAY	Provides a fine-tune adjustment of the time delay from the beginning of Tx warmdown to the end of Tx warmdown when FAST_TX_WD_EN is set to 1.
24 FAST_TX_WD_EN	Fast TX_WD enable/disable When this bit is enabled, the Zigbee squence manager executes the fast TX warmdown sequence by bypassing TX_PA_OFF and XTAL_CLK1 and jumping from TX_WD to TSM_WD directly. 0b - Disable fast Tx warmdown sequence. 1b - Enable fast Tx warmdown sequence.
23-22 —	Reserved
21-16 RXDELAY	RX Delay Provides a fine-tune adjustment of the time delay between Tx warmdown and the beginning of Rx warmup for TR sequence. RXDELAY register will apply to both SLOTTED and UNSLOTTED TR sequence. This is an unsigned value. Resolution = 2us. Range = 3 - 127us. Max RXDELAY = 0x3F. Min RXDELAY = 0x01.
15-14 —	Reserved
13-8 TXDELAY	TX Delay Provides a fine-tune adjustment of the time delay between post-CCA Rx warm-down and the beginning of Tx warm-up for an Tx (non-Ack) packet. TXDELAY register will apply in both SLOTTED and UNSLOTTED modes, but only to T sequences (e.g., T, TR, and T(R)), not TxAck operations. This is a two's complement value. The minimum permissible value is -19 (0x2D). Values less than -19 will lead to unexpected results. Resolution = 2us. Range = +/- 62us. Max TXDELAY = 0x1F. Min TXDELAY = 0x2D.
7 —	Reserved
6-0 ACKDELAY	ACK Delay

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Provides a fine-tune adjustment of the time delay between Rx warmdown and the beginning of Tx warmup for an Tx Acknowledge packet. ACKDELAY register will apply to both SLOTTED and UNSLOTTED TxAck, but only to TxAck (not T sequences). This is a two's complement value. Resolution = 2us. Range = -128 - 126us. Max ACKDELAY = 0x3F. Min ACKDELAY = 0x40.

Fields

Field	Function
31-8 —	Reserved
7-0 RX_WTR_MARK	RECEIVE WATER MARK Receive byte count (octets) needed to trigger a RXWTRMRKIRQ interrupt . A setting of 0 generates an interrupt at end of the Frame Length field (first byte after SFD). A setting of 1 generates an interrupt after the first byte of Frame Control Field, etc.

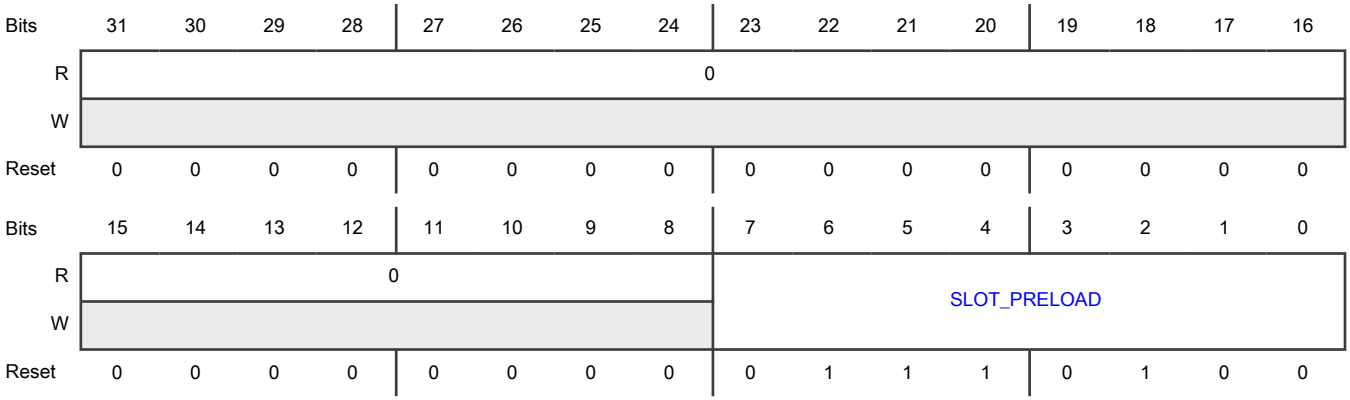
55.4.9.1.3.1.34 SLOT PRELOAD (SLOT_PRELOAD)

Offset

Register	Offset
SLOT_PRELOAD	8Ch

Function
Slotted Mode Preload

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SLOT_PRELOAD	Slotted Mode Preload This register represents the number that gets loaded into the slot_timer at SFD detect, which ultimately determines when the next slot boundary will occur. Due to processing delays within the analog front-end and digital modem, the point at which SFD is detected by the modem, is delayed relative to over-the-air timing. This register setting compensates for that delay. This timing parameter is critical for the Sequence R autosequence in slotted mode, when an automatic TxAck is required.

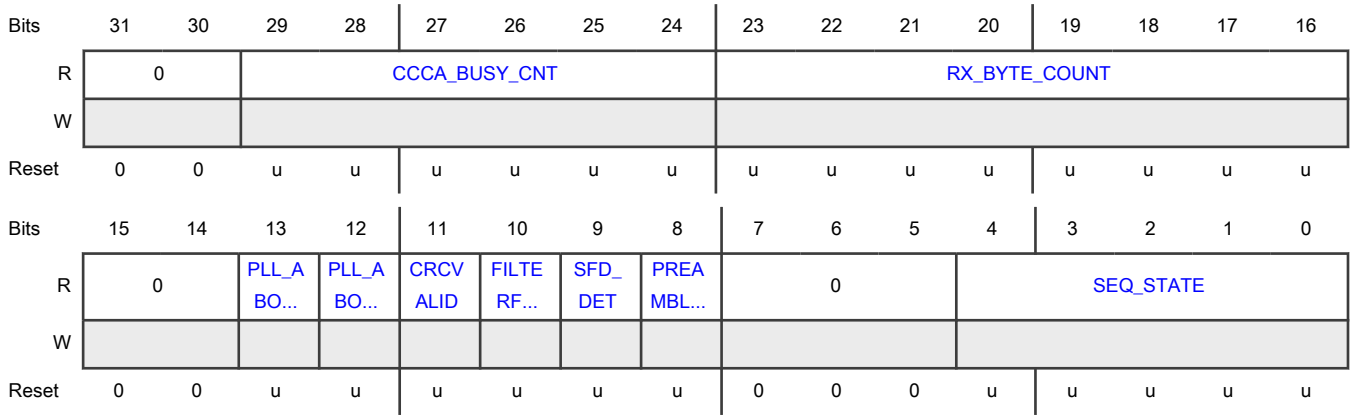
55.4.9.1.3.1.35 802.15.4 SEQUENCE STATE (SEQ_STATE)

Offset

Register	Offset
SEQ_STATE	90h

Function
802.15.4 Sequence State Register

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 CCCA_BUSY_CNT	Number of CCA Measurements resulting in Busy Channel For Sequence CCCA mode only, this register indicates the number of "busy" CCA attempts which occurred during the autosequence, before the channel was detected to be idle. This register can also be read in real-time (during the autosequence) to determine how many busy CCA attempts have occurred to that point. The register saturates at 63 (i.e, if there are more than 63 busy attempts, the register will continue to read 63). This register is automatically cleared to zero by hardware when the next autosequence commences. Read-only register.
23-16 RX_BYTE_COUNT	Realtime Received Byte Count During packet reception, this read-only register is a real-time indicator of the number of bytes that have been received. This register will read 0 until SFD and PHR have been received. It will read 1 after the first byte of Frame Control Field has been received, etc.
15-14 —	Reserved
13 PLL_ABORTED	Autosequence has terminated due to an PLL unlock event when asserted, indicates that the autosequence has terminated due to an PLL unlock event. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. This bit is a read-only mirror of the register bit of the same name in the ABORT_STS (SEQ_CTRL_STS) register.
12 PLL_ABORT	Raw PLL Abort Signal This bit reflects the instantaneous, consolidated status of the PLL unlock detection circuits; if asserted high, indicates that at least one of the three PLL unlock detect mechanisms is currently reporting an unlocked condition.
11	CRC Valid Indicator

Table continues on the next page...

Table continued from the previous page...

Field	Function
CRCVALID	Cyclic Redundancy Check Valid: This flag indicates the compare result between the FCS field, in the most-recently received frame, and the internally calculated CRC value. This flag is cleared at next receiver warm up. 0b - Rx FCS != calculated CRC (incorrect) 1b - Rx FCS = calculated CRC (correct)
10 FILTERFAIL_FLAG_SEL	Consolidated Filter Fail Flag 0: The incoming, or just-received packet, passed packet filtering rules. 1: The incoming, or just-received packet, failed packet filtering rules When FILTERFAIL_FLAG_SEL=1, a non-zero FILTERFAIL_CODE is present (see FILTERFAIL_CODE registers). In Dual PAN mode, FILTERFAIL_FLAG_SEL applies to either or both networks, as follows: **A:** If PAN0 and PAN1 occupy different channels and CURRENT_NETWORK=0, FILTERFAIL_FLAG_SEL applies to PAN0. **B:** If PAN0 and PAN1 occupy different channels and CURRENT_NETWORK=1, FILTERFAIL_FLAG_SEL applies to PAN1. **C:** If PAN0 and PAN1 occupy the same channel, FILTERFAIL_FLAG_SEL is the logical 'AND' of the individual PANs' FILTERFAIL_FLAG bits.
9 SFD_DET	SFD Detected 0: an 802.15.4 preamble-and-SFD have not been detected. 1: An 802.15.4 preamble-and-SFD have been detected. The function of this read-only bit depends on the setting of the LATCH_PREAMBLE bit of the SEQ_MGR_CTRL register. If LATCH_PREAMBLE=1, any preamble-and-SFD detection during a Sequence R (even false detections), will set this bit, and it will remain set (sticky) until the start of the next autosequence. If LATCH_PREAMBLE=0, this bit is not sticky, and reflects the instantaneous state of the SFD-detection circuit; for false SFD, the bit will clear when the false nature of the SFD is recognized (i.e., an RX recycle). When LATCH_PREAMBLE=0, SFD_DET should be considered valid only while an autosequence is underway.
8 PREAMBLE_DET	Preamble Detected 0: an 802.15.4 preamble has not been detected. 1: An 802.15.4 preamble has been detected. The function of this read-only bit depends on the setting of the LATCH_PREAMBLE bit of the SEQ_MGR_CTRL register. If LATCH_PREAMBLE=1, any preamble detection during a Sequence R (even false detections), will set this bit, and it will remain set (sticky) until the start of the next autosequence. If LATCH_PREAMBLE=0, this bit is not sticky, and reflects the instantaneous state of the preamble-detection circuit; for false preambles, the bit will clear when the false nature of the preamble is recognized. When LATCH_PREAMBLE=0, PREAMBLE_DET should be considered valid only while an autosequence is underway.

0 ENHACK_EN	Enhanced Acknowledgment Enable 0b - Enhanced acknowledgment is disabled. 1b - Enhanced acknowledgment is enabled.

55.4.9.2 Generic FSK Link Layer

55.4.9.2.1 Introduction

The Generic FSK protocol enables radio operation using a custom GFSK/GMSK or MSK modulation format achieved by programming a set of PHY variables such as BT product, modulation index and modulation filter co-efficients (such that max frequency deviation <= 500kHz). Generic FSK mode also offers a highly configurable packet structure, variable bit rate transmission and reception, some limited packet processing, and interface to a RAM-based Packet Buffer.

55.4.9.2.1.1 Overview

The Generic FSK Link Layer Controller provides the interface between Generic FSK software, and the transceiver hardware. The interface consists of an IP bus-based set of registers, which provide command, control, and status to Generic FSK software. The Link Layer controller features programmability that allows for a highly configurable packet structure, defining the lengths, bit ordering, and contents of individual packet fields, defining the start and end points for whitening, CRC, and providing for some primitive parsing of the packet header. The Link Layer Controller implements a Sequence Command Set consisting of 20 commands; a command decoder to interpret the commands in realtime as they are received from Generic FSK software, and to provide the necessary control signals to the radio's Transceiver Sequence Manager (TSM); a high-precision timebase based on an external crystal-based oscillator; an Interrupt Control Unit; finite state machines to control the transmission and reception of Generic FSK packets; controls for CRC generation (TX) and verification (RX); controls for data whitening; interface to RAM-based Packet Buffer for packet storage; and provisions for entering and exiting low-power Deep Sleep Mode.

55.4.9.2.1.2 Features

- Highly configurable packet structure
- Optimized Sequence Command Set
- High-precision timebase to maintain network timing
- Two timer-compare mechanisms for Interrupt Generation and Sequence Launching
- Hardware automation for packet transmit and receive, CRC and Whitening
- Up to 4 Network Addresses to synchronize to, can be 8-bit, 16-bit or 32-bit
- Packet Lengths up to 2047 Bytes
- Support complex auto-sequence, like CCA before TX, Auto-ACK, TR.
- Many operating modes can support the sending and receiving of multiple protocol packets, such as 802.15.4, Bluetooth LE, etc.
- Generic test mode(GTM)
- Deep Sleep Mode support

Field	Function
	C: If PAN0 and PAN1 occupy the same channel, FILTERFAIL_IRQ is the logical 'AND' of the individual PANs' Filter Fail status. 0b - A Filter Fail Interrupt has not occurred. 1b - A Filter Fail Interrupt has occurred.
12 PHRFFAIL_IRQ	Received Frame PHR Fail Interrupt Asserts when the received frame fails at BCH check or Parity check, for LECIM FSK and SUN FSK Mode Switch frame only. 0b - Received frame PHR Fail Interrupt is not asserted. 1b - Received frame PHR Fail Interrupt is asserted.
11 ACK_IRQ	Auto ACK Interrupt Asserts when RX finishes, and an auto ACK frame is needed. Software may need to write packet RAM to prepare the ACK frame. 0b - Auto ACK Interrupt is not asserted. 1b - Auto ACK Interrupt is asserted.
10 CRC_VALID	CRC Valid CRC Valid indicator for RX packets. This bit becomes valid at RX_IRQ, and remains valid until the start of the next RX TSM sequence.
9 TSM_IRQ	TSM Interrupt Indicates TSM0_IRQ or TSM1_IRQ is set in XCVR_STATUS. Clear the bits there. For debug purposes. 0b - TSM0_IRQ and TSM1_IRQ are both clear. 1b - Indicates TSM0_IRQ or TSM1_IRQ is set in XCVR_STATUS.
8 RX_WATERMARK_IRQ	RX Watermark Interrupt Asserts when RX Byte Counter == RX_WATERMARK[12:0] 0b - RX Watermark Interrupt is not asserted. 1b - RX Watermark Interrupt is asserted.
7 WAKE_IRQ	Wake Interrrupt **For Manual DSM:** This is WAKE_IRQ. A WAKE_IRQ will be triggered when the GENERIC_FSK Link Layer Controller has awoken from a Manual DSM (Deep Sleep Mode) cycle. WAKE_IRQ indicates that the RF Oscillator has been restarted, and the GENERIC_FSK EVENT_TMR has resumed counting. **For Wake-On-Radio:** This is WOR_IRQ. See Section **Wake-On-Radio**. 0b - Wake Interrupt is not asserted. 1b - Wake Interrupt is asserted.
6	PLL Unlock Interrupt

Table continues on the next page...

Table continued from the previous page...

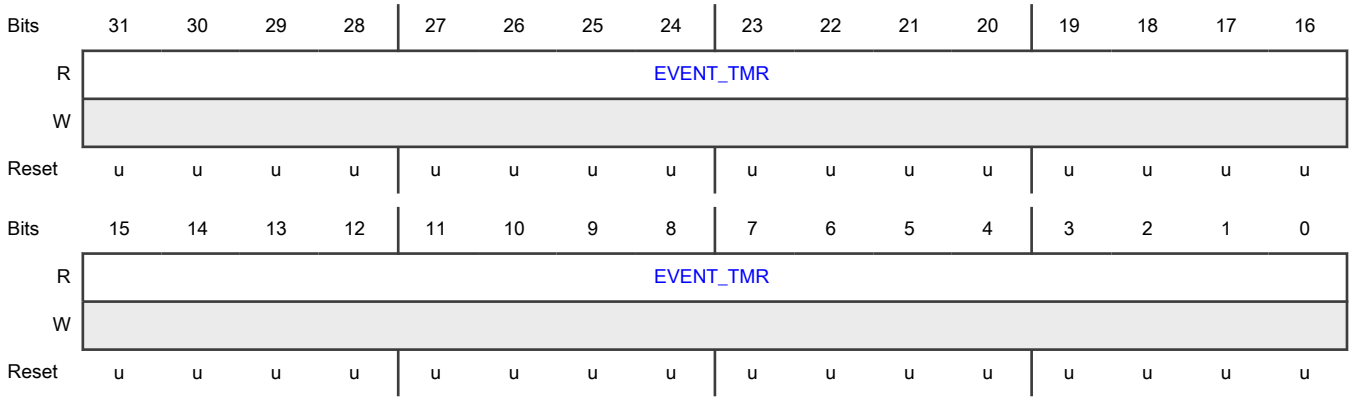
Field	Function
PLL_UNLOCK_IRQ	An unlock event has occurred. 0b - PLL Unlock Interrupt is not asserted. 1b - PLL Unlock Interrupt is asserted.
5 T2_IRQ	Timer2 (T2) Compare Interrupt 0b - Timer2 (T2) Compare Interrupt is not asserted. 1b - Timer2 (T2) Compare Interrupt is asserted.
4 T1_IRQ	Timer1 (T1) Compare Interrupt 0b - Timer1 (T1) Compare Interrupt is not asserted. 1b - Timer1 (T1) Compare Interrupt is asserted.
3 NTW_ADR_IRQ	Network Address Match Interrupt A Network Address Match has occurred. 0b - Network Address Match Interrupt is not asserted. 1b - Network Address Match Interrupt is asserted.
2 RX_IRQ	RX Interrupt The RX sequence has completed with a successful packet reception. 0b - RX Interrupt is not asserted. 1b - RX Interrupt is asserted.
1 TX_IRQ	TX Interrupt The TX sequence has completed with a successful packet transmission. 0b - TX Interrupt is not asserted. 1b - TX Interrupt is asserted.
0 SEQ_END_IRQ	Sequence End Interrupt Will assert when any TX or RX sequence ends for any reason. 0b - Sequence End Interrupt is not asserted. 1b - Sequence End Interrupt is asserted.

55.4.9.2.2.1.3 EVENT TIMER (EVENT_TMR)

Offset

Register	Offset
EVENT_TMR	4h

Diagram



Fields

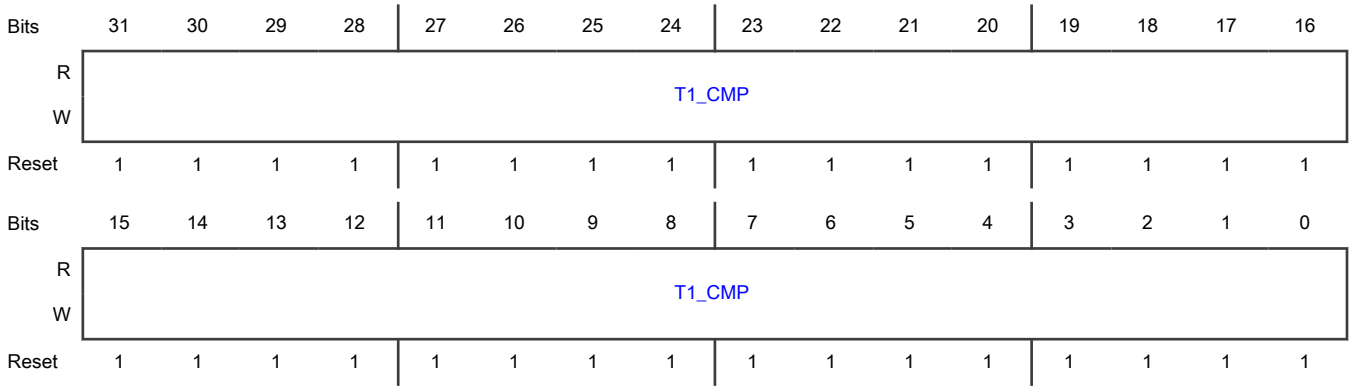
Field	Function
31-0 EVENT_TMR	Event Timer Event Timer can be read in these byte locations. To update the Event Timer, either: 1. Write the desired EVENT_TMR to register EVENT_TMR_LD[31:0], or, 2. Write the desired EVENT_TMR increment amount to regiter EVENT_TMR_ADD[31:0]. **Note:** for EVENT_TMR_ADD, EVENT_TMR[31:0] is a signed, two's-complement value.

55.4.9.2.2.1.4 T1 COMPARE (T1_CMP)

Offset

Register	Offset
T1_CMP	8h

Diagram



Fields

Field	Function
31-0 T1_CMP	Timer1 (T1) Compare Value Timer1 (T1) Compare Value. Can be used to generate T1_IRQ and/or launch Sequence Commands

55.4.9.2.2.1.5 T2 COMPARE (T2_CMP)

Offset

Register	Offset
T2_CMP	Ch

Diagram

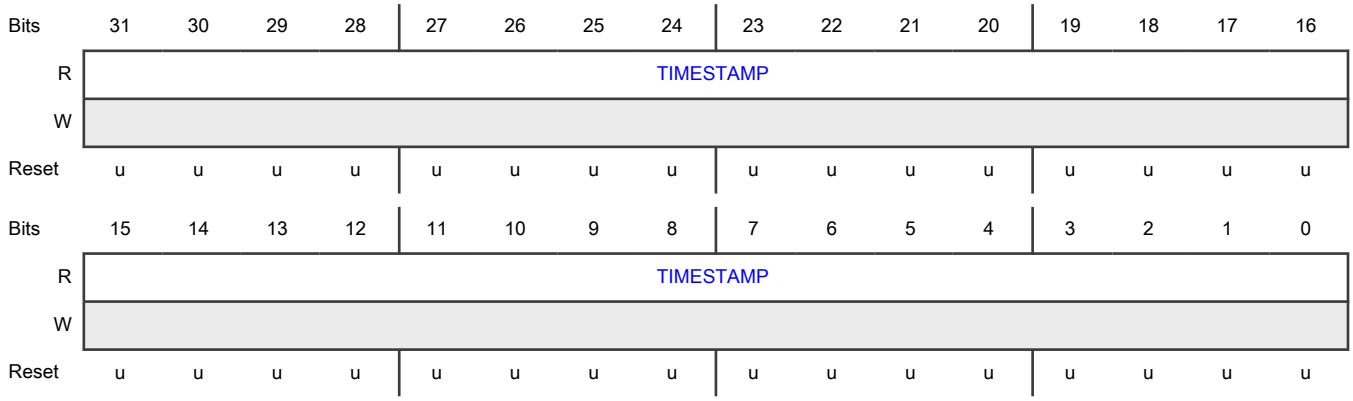
Field	Function
31-0 T2_CMP	Timer2 (T2) Compare Value Timer2 (T2) Compare Value. Can be used to generate T2_IRQ and/or launch Sequence Commands

55.4.9.2.2.1.6 TIMESTAMP (TIMESTAMP)

Offset

Register	Offset
TIMESTAMP	10h

Diagram



Fields

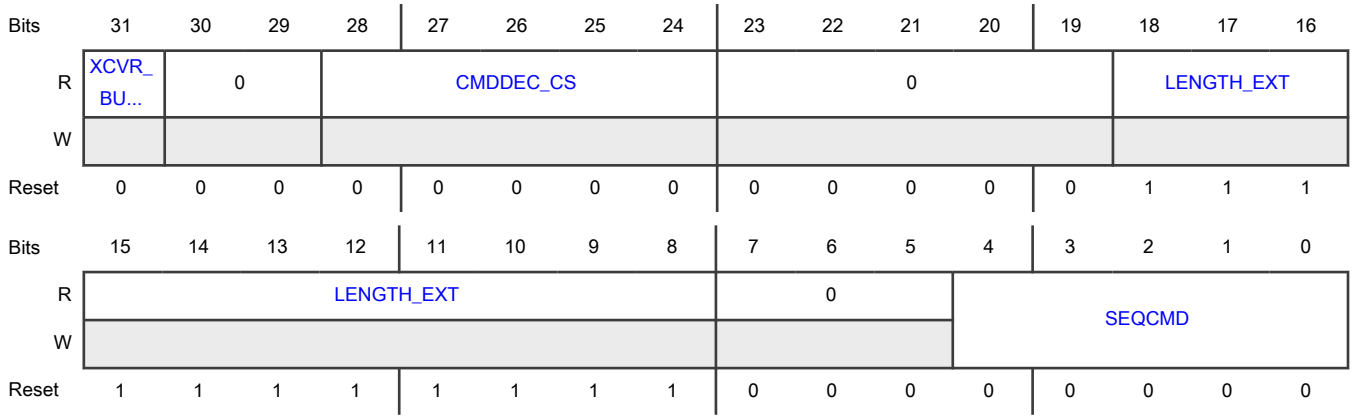
Field	Function
31-0 TIMESTAMP	Received Packet Timestamp Received Packet Timestamp. Captured at NTW_ADR_IRQ.

55.4.9.2.2.1.7 TRANSCEIVER CONTROL (XCVR_CTRL)

Offset

Register	Offset
XCVR_CTRL	14h

Diagram



Fields

Field	Function
31 XCVR_BUSY	Transceiver Busy For multi-protocol arbitration, XCVR_BUSY=1 indicates an RX or TX operation is underway, by either GENERIC_FSK, or some other protocol. 0b - IDLE 1b - BUSY
30-29 —	Reserved
28-24 CMDDEC_CS	Command Decode Current State of the Command Decoder FSM (debug only). Also named as SEQ_STATE.
23-19 —	Reserved
18-8 LENGTH_EXT	Extracted Length Field The read-only register reflects the contents of the LENGTH field of the Header of the most-recently received packet. This is the raw, unmodified LENGTH field, as it appears in the received bit stream, unmodified by LENGTH_ADJ or any other parameter.
7-5 —	Reserved
4-0 SEQCMD	Sequence Commands, also named as "XCVSEQ(Transceiver Sequence)" 0_0000b - Same as command ABORT 0_0001b - TX Start Now 0_0010b - TX Start @ T1 Timer Compare Match (EVENT_TMR = T1_CMP) 0_0011b - TX Start @ T2 Timer Compare Match (EVENT_TMR = T2_CMP) 0_0100b - TX Cancel -- Cancels pending TX events but do not abort a TX-in-progress 0_0101b - RX Start Now 0_0110b - RX Start @ T1 Timer Compare Match (EVENT_TMR = T1_CMP) 0_0111b - RX Start @ T2 Timer Compare Match (EVENT_TMR = T2_CMP) 0_1000b - RX Stop @ T1 Timer Compare Match (EVENT_TMR = T1_CMP) 0_1001b - RX Stop @ T2 Timer Compare Match (EVENT_TMR = T2_CMP) 0_1010b - RX Cancel -- Cancels pending RX events but do not abort a RX-in-progress 0_1011b - Abort All - Cancels all pending events and abort any sequence-in-progress 0_1100b - TR Start Now 0_1101b - TR Start @ T1 Timer Compare Match (EVENT_TMR = T1_CMP)

Table continues on the next page...

Table continued from the previous page...

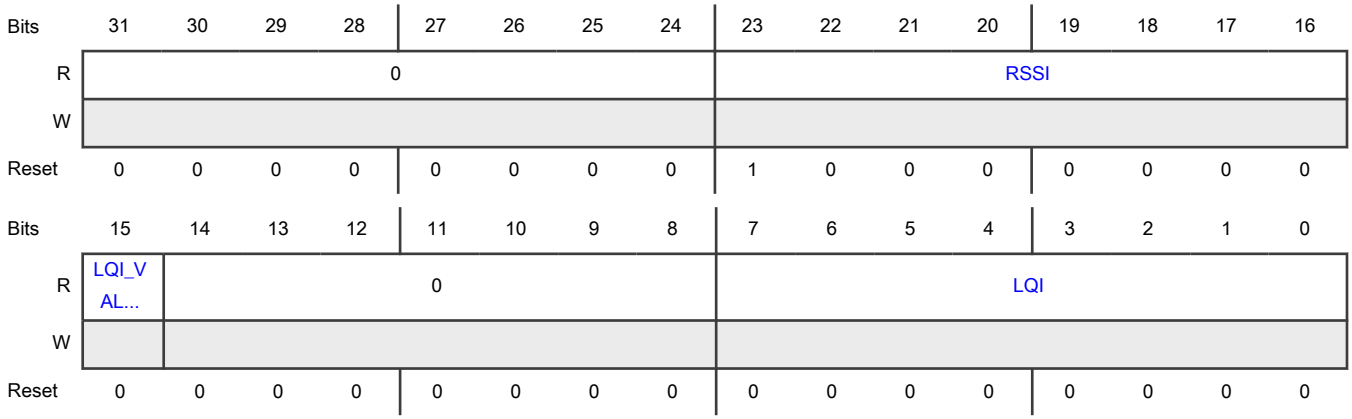
Field	Function
	0_1110b - TR Start @ T2 Timer Compare Match (EVENT_TMR = T2_CMP) 0_1111b - TR Cancel -- Cancels pending TR events but do not abort a TR-in-progress 1_0000b - CCA Start Now 1_0001b - CCA Start @ T1 Timer Compare Match (EVENT_TMR = T1_CMP) 1_0010b - CCA Start @ T2 Timer Compare Match (EVENT_TMR = T2_CMP) 1_0011b - CCA Cancel -- Cancels pending CCA events but do not abort a CCA-in-progress

55.4.9.2.2.1.8 TRANSCEIVER STATUS (XCVR_STS)

Offset

Register	Offset
XCVR_STS	18h

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 RSSI	RSSI Value Received Signal Strength Indicator, in dBm
15 LQI_VALID	LQI Valid Indicator

Table continues on the next page...

Table continued from the previous page...

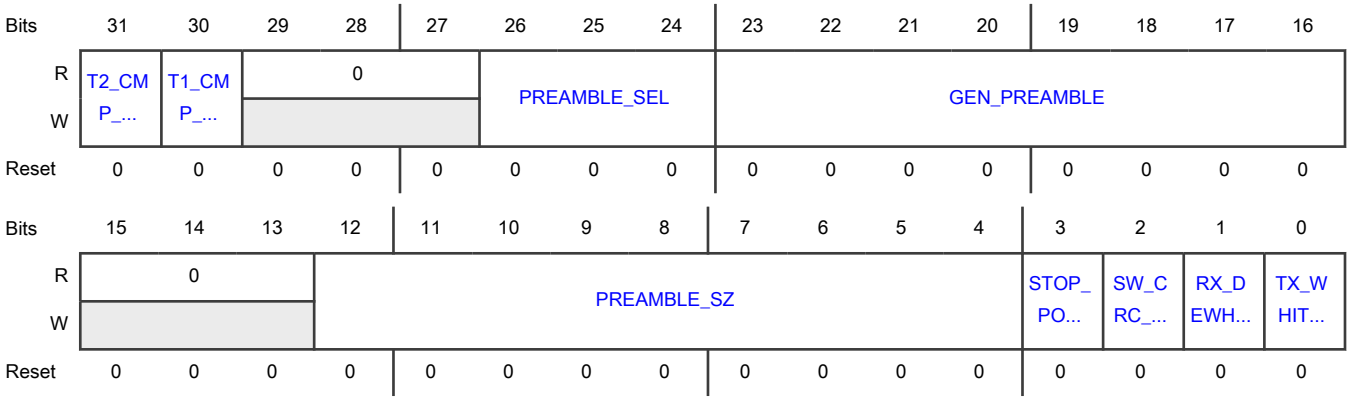
Field	Function
	LQI Valid indicator for RX packets. This bit becomes set when the LQI computation completes for the packet currently being received, and remains set for the remainder of the packet. 0b - LQI is not yet valid for RX packet. 1b - LQI is valid for RX packet.
14-8 —	Reserved
7-0 LQI	Link Quality Indicator This field is valid when LQI_VALID=1. LQI is a unsigned, unitless value.

55.4.9.2.2.1.9 TRANSCEIVER CONFIGURATION (XCVR_CFG)

Offset

Register	Offset
XCVR_CFG	1Ch

Diagram



Fields

Field	Function
31 T2_CMP_EN	Timer2 (T2) Compare Enable Enable Timer Compare #2 (T2_CMP) to generate T2_IRQ and/or execute Sequence Commands.
30 T1_CMP_EN	Timer1 (T1) Compare Enable Enable Timer Compare #1 (T1_CMP) to generate T1_IRQ and/or execute Sequence Commands.

Table continues on the next page...

Table continued from the previous page...

Field	Function
29-27 —	Reserved
26-24 PREAMBLE_SEL	Preamble Select Select the Preamble pattern. 000b - The controller hardware selects the preamble pattern based on the first transmitted bit of Network Address, such that the last bit of preamble is the opposite polarity from the first bit of Network Address, forcing a bit transition at this boundary. 001b - Preamble is programmed by register GEN_PREAMBLE[7:0] 010b - Preamble is 0b01 011b - Preamble is 0b10
23-16 GEN_PREAMBLE	Preamble pattern The repeated byte of the preamble when PREAMBLE_SEL[2:0] is 001b.
15-13 —	Reserved
12-4 PREAMBLE_SZ	Preamble Size Number of Octets(PREAMBLE_SEL is 0 or 1) or two-bits(PREAMBLE_SEL is 2 or 3) = PREAMBLE_SZ + 1, where 0 <= PREAMBLE_SZ <= 511
3 STOP_POSTPONE_ON_AA	Postpone Stop Command Timeout On Access Address Match Enable If this bit is set, if a RX STOP condition occurs, due to an Event Timer match to a previously issued RX_STOP_T1 or RX_STOP_T2 sequence command, while a packet is being received (*NTW_ADR_MCH* = 1), the timeout-related abort will be deferred untl the packet reception is completed. If the packet is good, HW will signal Data Indication; otherwise the Sequence Manager will return to IDLE and await further commanding. 0b - STOP Abort will occur on RX_STOP_T1 or RX_STOP_T1 Event Timer match, regardless of NTW_ADR_MCH 1b - STOP Abort will be deferred on RX_STOP_T1 or RX_STOP_T1 Event Timer match, if NTW_ADR_MCH is asserted; otherwise the RX_STOP Abort will occur immediately
2 SW_CRC_EN	Software CRC Enable Software override of the HW-computed CRC for TX. Software must write CRC to Packet Buffer (RAM)
1 RX_DEWHITEN_DIS	RX De-Whitening Disable Disable all de-whitening on RX packets
0	TX Whitening Disable

Table continues on the next page...

Table continued from the previous page...

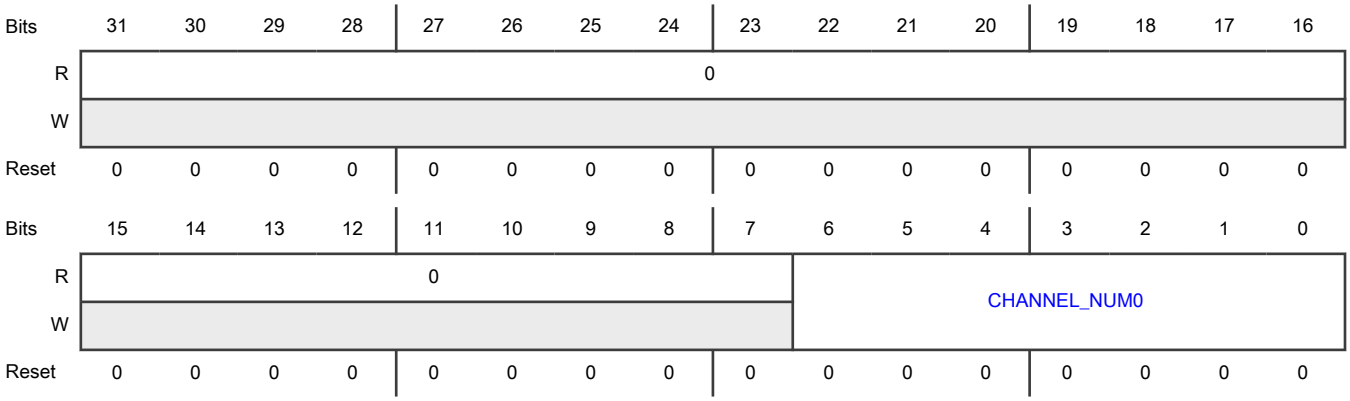
Field	Function
TX_WHITEN_DIS	Disable all whitening on TX packets

55.4.9.2.2.1.10 CHANNEL NUMBER 0 (CHANNEL_NUM0)

Offset

Register	Offset
CHANNEL_NUM0	20h

Diagram



Fields

Field	Function
31-7 —	Reserved
6-0 CHANNEL_NUM0	Channel Number for PAN0 This is the mapped channel number used to transmit and receive packets. If Dual PAN is engaged, this register applies to PAN0. Formula: F = (2360 + CHANNEL_NUM0) [in MHz]

55.4.9.2.2.1.11 TRANSMIT POWER (TX_POWER)

Offset

Register	Offset
TX_POWER	24h

Diagram

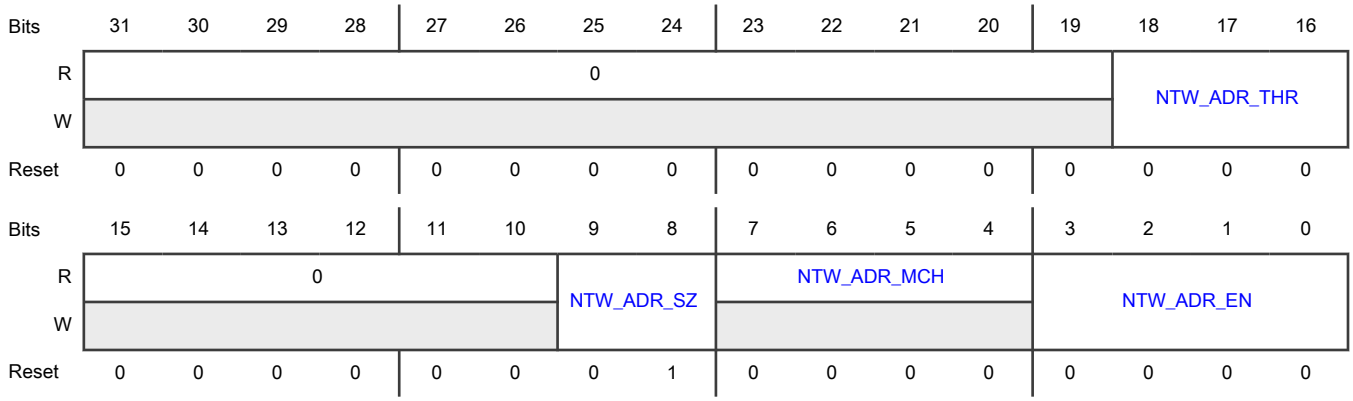
5-0 TX_POWER	Transmit Power PA Power Level.

55.4.9.2.2.1.12 NETWORK ADDRESS CONTROL (NTW_ADR_CTRL)

Offset

Register	Offset
NTW_ADR_CTRL	28h

Diagram



Fields

Field	Function
31-19 —	Reserved
18-16 NTW_ADR_THR	Network Address Threshold Number of Tolerated bit errors for Network Address 0/1/2/3
15-10 —	Reserved
9-8 NTW_ADR_SZ	Network Address Size 00b - Network Address 0/1/2/3 requires a 8-bit correlation 01b - Network Address 0/1/2/3 requires a 16-bit correlation 10b - Network Address 0/1/2/3 requires a 24-bit correlation 11b - Network Address 0/1/2/3 requires a 32-bit correlation
7-4 NTW_ADR_MCH	Network Address Match Indicates which of the 4 Network Addresses has matched in the PHY. Valid during an RX sequence at the point of match, and remains asserted until either: 1. The next RX sequence begins (if the current packet passed CRC and header filtering), or, 2. An RX recycle to Network Address search (if the current packet failed CRC or header filtering) 0001b - Network Address 0 has matched 0010b - Network Address 1 has matched 0100b - Network Address 2 has matched 1000b - Network Address 3 has matched
3-0 NTW_ADR_EN	Network Address Enable Enable Network Address N for PHY correlation, where 0 ≤ N ≤ 3. Any bit combination can be set. 0001b - Enable Network Address 0 for correlation 0010b - Enable Network Address 1 for correlation 0100b - Enable Network Address 2 for correlation 1000b - Enable Network Address 3 for correlation

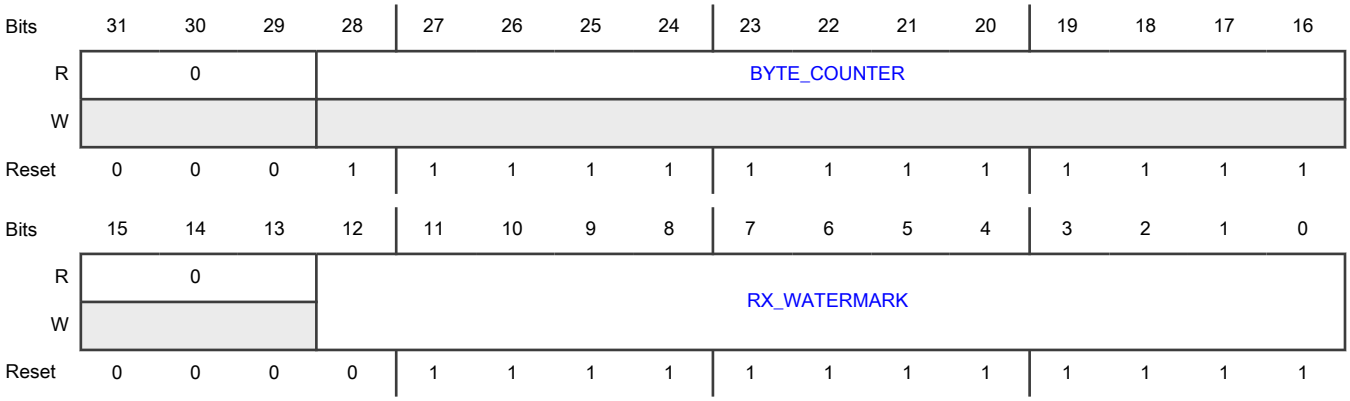
55.4.9.2.2.1.17 RECEIVE WATERMARK (RX_WATERMARK)

Offset

Register	Offset
RX_WATERMARK	3Ch

Diagram



Fields

Field	Function
31-29 —	Reserved
28-16 BYTE_COUNTER	Byte Counter Reflects the current Byte Count, for TX and RX. This is a signed, twos-complement value. For values less than zero, indicates the preamble transmission is underway (TX only). A value of 0 indicates the first octet of Network Address is being transmitted or received. A value of 1 indicates the second octet of Network Address is being transmitted or received. Etc. When AA_PLAYBACK_CNT is 0, there is no Network Address sent to link layer, so a value of 0 indicates the first octet of H0 or LENGTH field; for TX, AA_PLAYBACK_CNT does not effect.
15-13 —	Reserved
12-0	Receive Watermark

Table continues on the next page...

Table continued from the previous page...

Field	Function
RX_WATERMARK	Sets the trigger for RX_WATERMARK_IRQ. Trigger the RX_WATERMARK_IRQ when: RX Byte Counter == RX_WATERMARK[12:0]

55.4.9.2.2.1.18 DSM CONTROL (DSM_CTRL)

Offset

Register	Offset

R W	SLOT_PRELOAD															
Reset	0	0	0	0	0	0	1	0	1	0	1	0	1	0	0	0

Fields

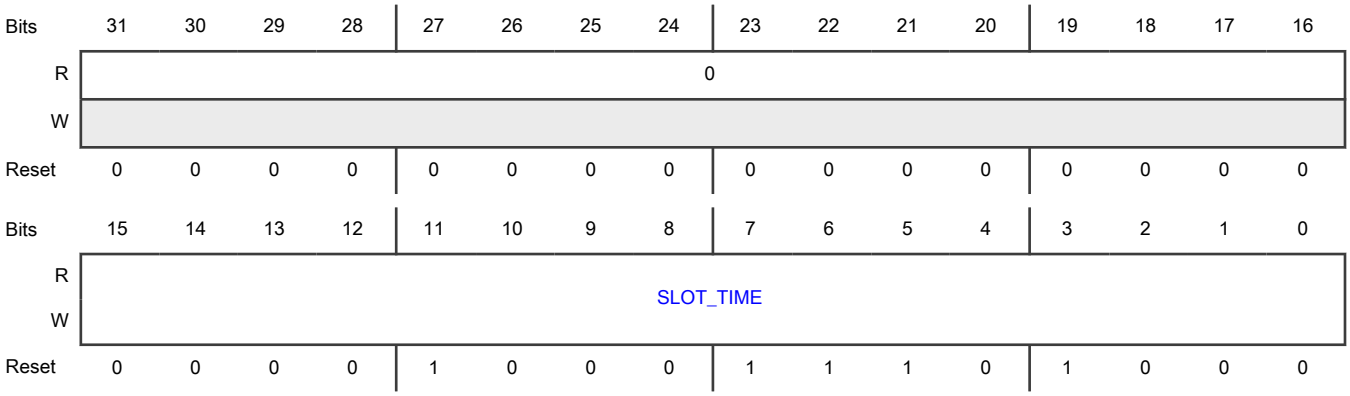
Field	Function
31-16 —	Reserved
15-0 SLOT_PRELOAD	Slotted Mode Preload This register represents the number that gets loaded into the slot_timer at SFD detect, which ultimately determines when the next slot boundary will occur. Due to processing delays within the analog front-end and digital modem, the point at which SFD is detected by the modem, is delayed relative to over-the-air timing. This register setting compensates for that delay. This timing parameter is critical for the Sequence R autosequence in slotted mode, when an automatic TxAck is required.

55.4.9.2.2.1.21 SLOT TIME (SLOT_TIME)

Offset

Register	Offset
SLOT_TIME	4Ch

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 SLOT_TIME	Duration of the Backoff Slot This register represents the time duration of the backoff slot, which is calculated by the constant *aUnitBackoffPeriod* in IEEE Std 802.15.4-2015. For all PHYs except SUN PHYs operating in the 920 MHz band, *aTurnaroundTime* + *aCcaTime*. For SUN PHYs operating in the 920 MHz band, *aTurnaroundTime* + *phyCCADuration*.

55.4.9.2.2.1.22 TURNAROUND TIME (TURNAROUND_TIME)

15-0 TURNAROUND_TIME	RX-to-TX or TX-to-RX turnaround time This register represents the RX-to-TX or TX-to-RX turnaround time, which is calculated by the constant *aTurnaroundTime* in IEEE Std 802.15.4-2015.

55.4.9.2.2.1.23 ACK DELAY (ACKDELAY)

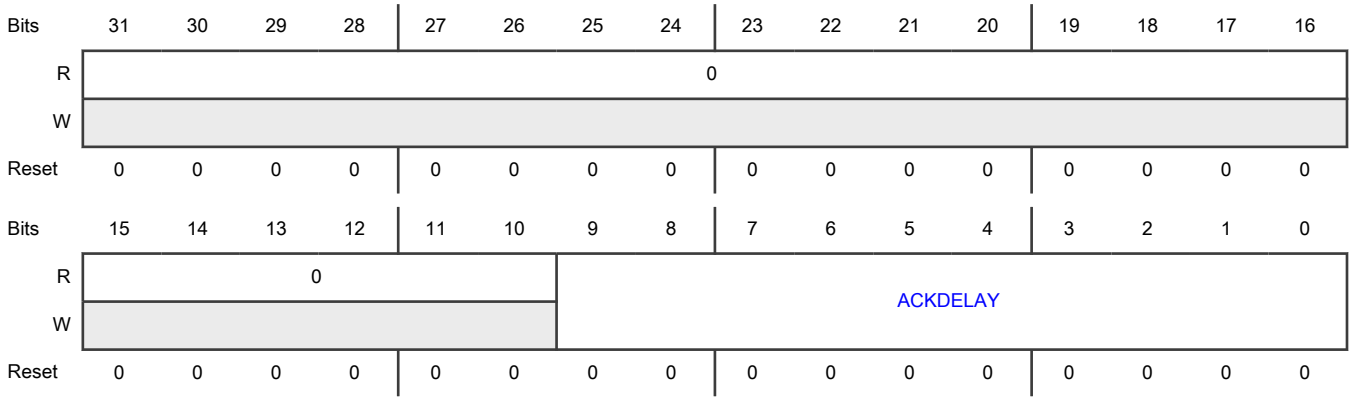
Offset

Register	Offset
ACKDELAY	54h

Function

Provides a fine-tune adjustment of the time delay between Rx warmdown and the beginning of Tx warmup for an autoTxAck packet.

Diagram



Fields

Field	Function
31-10 —	Reserved
9-0 ACKDELAY	ACK Delay Provides a fine-tune adjustment of the time delay between Rx warmdown and the beginning of Tx warmup for an Tx Acknowledge packet. ACKDELAY register will apply to both SLOTTED and UNSLOTTED TxAck, but only to TxAck (not T sequences). This is a two's complement value. Resolution = 1us.

55.4.9.2.2.1.24 RX DELAY (RXDELAY)

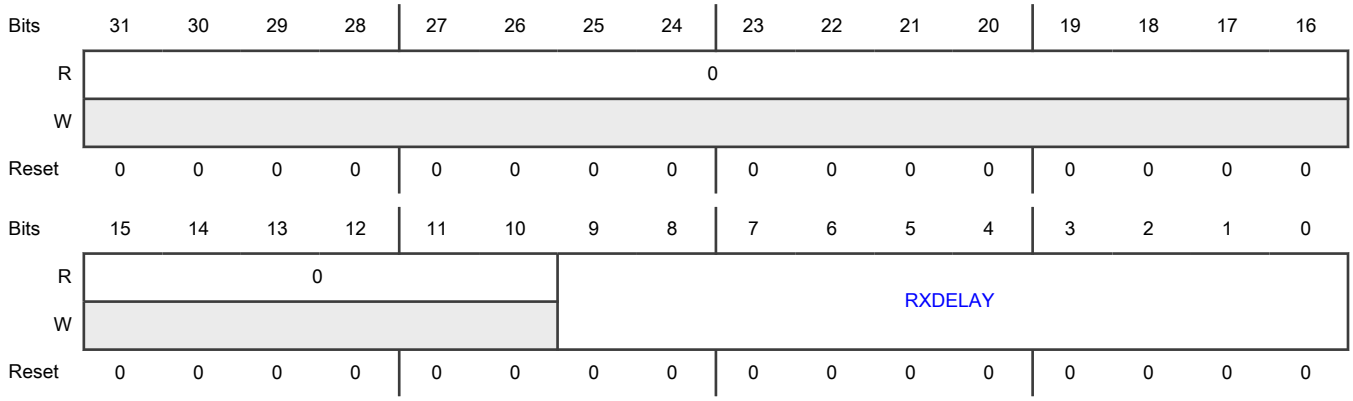
Offset

Register	Offset
RXDELAY	58h

Function

Provides a fine-tune adjustment of the time delay between Tx warmdown and the beginning of Rx warmup in a TR sequence.

Diagram



Fields

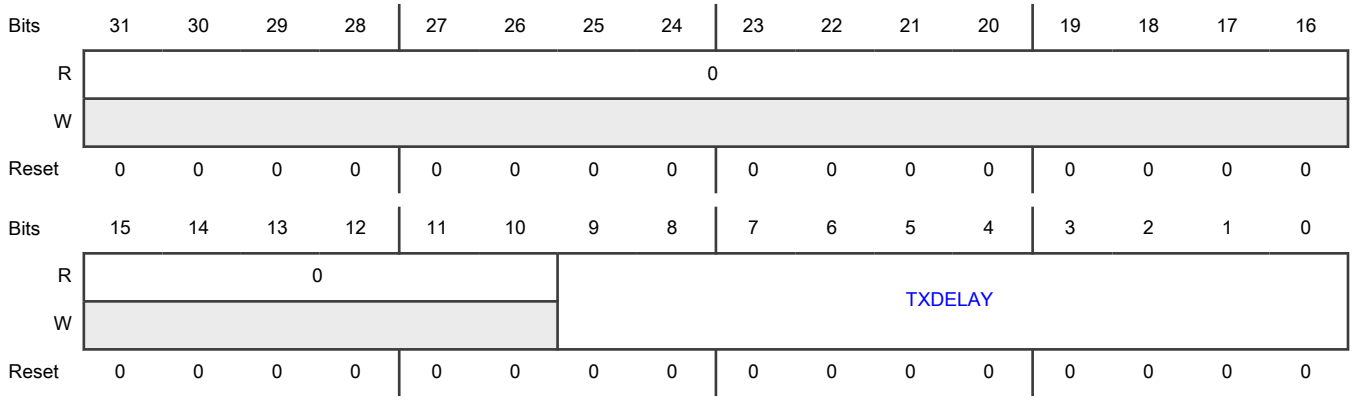
Field	Function
31-10 —	Reserved
9-0 RXDELAY	RX Delay Provides a fine-tune adjustment of the time delay between Tx warm-down and the beginning of Rx warm-up in a TR sequence. RXDELAY register will apply in both SLOTTED and UNSLOTTED modes. This is a two's complement value. Resolution = 1us.

55.4.9.2.2.1.25 TX DELAY (TXDELAY)

Offset

Register	Offset
TXDELAY	5Ch

Diagram



Fields

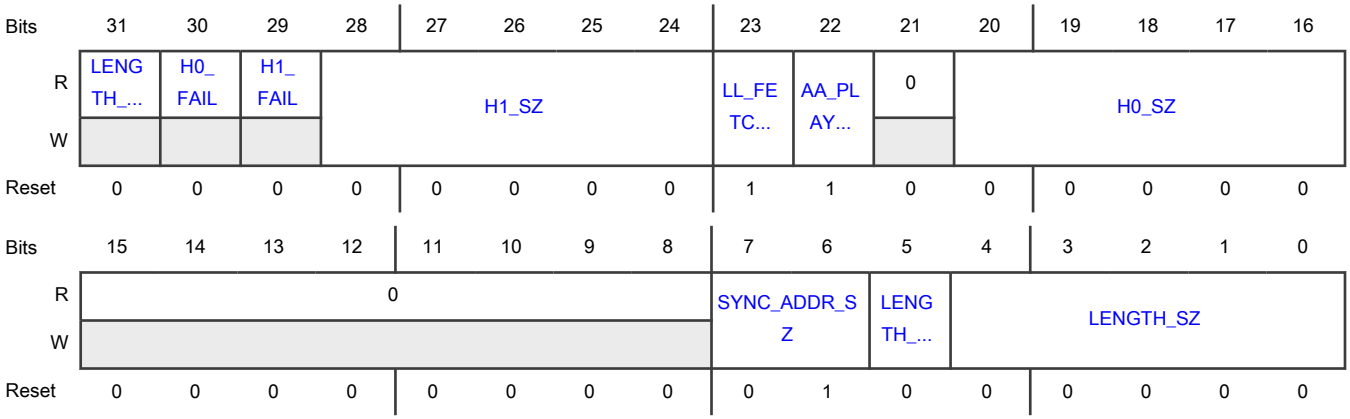
Field	Function
31-10 —	Reserved
9-0 TXDELAY	TX Delay Provides a fine-tune adjustment of the time delay between post-CCA Rx warm-down and the beginning of Tx warm-up for an Tx (non-Ack) packet. TXDELAY register will apply in both SLOTTED and UNSLOTTED modes, but only to T sequences (e.g., T, TR, and T(R)), not TxAck operations. This is a two's complement value. Resolution = 1us.

55.4.9.2.2.1.26 PACKET CONFIGURATION (PACKET_CFG)

Offset

Register	Offset
PACKET_CFG	60h

Diagram



Fields

Field	Function
31 LENGTH_FAIL	Maximum Length Violated Status Bit For packets received with REC_BAD_PKT=1, LENGTH_FAIL indicates the extracted LENGTH header field exceeded LENGTH_MAX
30 H0_FAIL	H0 Violated Status Bit For packets received with REC_BAD_PKT=1, H0_FAIL indicates the received H0 header field violates the H0_MASK/H0_MATCH pattern

Table continues on the next page...

Table continued from the previous page...

Field	Function
29 H1_FAIL	H1 Violated Status Bit For packets received with REC_BAD_PKT=1, H1_FAIL indicates the received H1 header field violates the H1_MASK/H1_MATCH pattern
28-24 H1_SZ	H1 Size Length of H1 in bits; 0 ≤ H1_SZ ≤ 16
23 LL_FETCH_AA	Link layer fetches AA from PHY When AA_PLAYBACK_CNT is 0, link layer can fetch AA from PHY 0b - Link layer does not fetch AA from PHY 1b - Link layer fetches AA from PHY when AA_PLAYBACK_CNT is 0
22 AA_PLAYBACK_CNT	AA PLAYBACK COUNT AA is playback to Link layer 0b - AA is not through CRC and not playback to Link layer. 1b - AA is through CRC and palyback to Link Layer.
21 —	Reserved
20-16 H0_SZ	H0 Size Size of H0 in bits; 0 ≤ H0_SZ ≤ 16
15-8 —	Reserved
7-6 SYNC_ADDR_SZ	Sync Address Size Number of Octets = SYNC_ADDR_SZ + 1, 0 ≤ SYNC_ADDR_SZ ≤ 3. **NOTE** When AA_PLAYBACK_CNT = 0, the Sync Address is not played out when receive. At this case, SYNC_ADDR_SZ is ignored by link layer.
5 LENGTH_BIT_ORD	LENGTH Bit Order Bit order for the LENGTH field of the header 0b - LS Bit First 1b - MS Bit First
4-0 LENGTH_SZ	LENGTH Size Size of LENGTH field of the header, in bits; 0 ≤ LENGTH_SZ ≤ 16

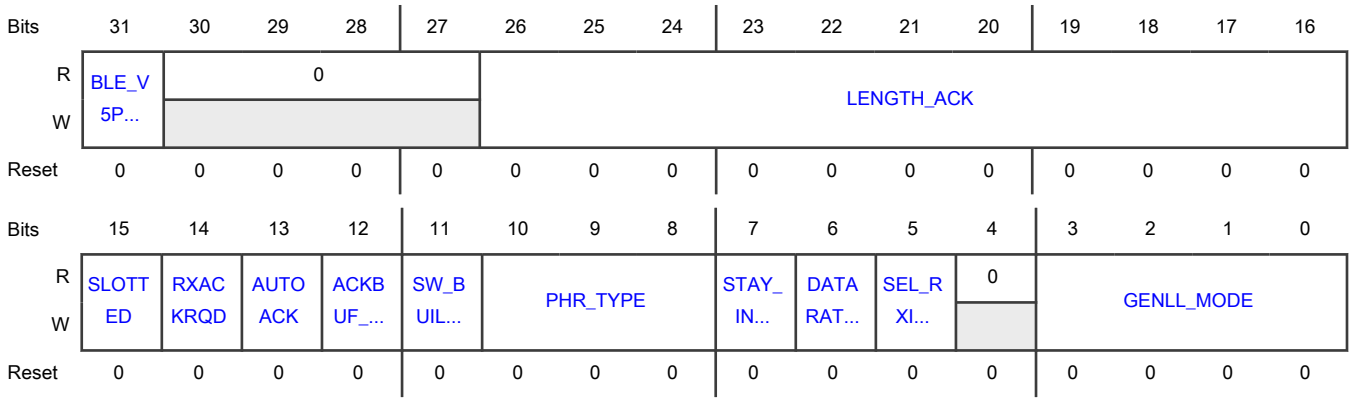
31-0 EVENT_TMR_ADD	Event Timer Add A write access of this register increments EVENT_TMR by the contents of EVENT_TMR_ADD[31:0]. This is a signed addition.

55.4.9.2.2.1.38 ENHANCED FEATURES (ENH_FEATURE)

Offset

Register	Offset
ENH_FEATURE	90h

Diagram



Fields

Field	Function
31 BLE_V5P1_CTE_EN	Bluetooth LE version 5.1 CTE feature enable 0b - Do not support Bluetooth LE version 5.1 CTE feature. 1b - Support Bluetooth LE version 5.1 CTE feature, which means the link layer hardware can parse the CTE field length and extend the RX_EN signal accordingly.
30-27 —	Reserved
26-16 LENGTH_ACK	Length of the ACK frame(or part of the ACK frame) in RAM In GLL mode, it is programed into the LENGTH field in PHR. So, if ACK's payload length is Payload_length, LENGTH_ACK = Payload_length + CRC_SZ - LENGTH_ADJ. In FAN-LL mode, when SW_BUILD_ACK=0, it is the length of ASH and IEs field in PHR. In GTM mode, it is the length of the test packet payload.
15 SLOTTED	Slotted Mode Slotted Mode, for beacon-enabled networks. Applies only to Sequences T, TR, and R, ignored during all other sequences. Used, in concert with CCABFRTX, to determine how many CCA measurements are required prior to a transmit operation. Also used during R sequence to determine whether the ensuing transmit acknowledge frame (if any) needs to be synchronized to a backoff slot boundary.
14 RXACKRQD	Receive Acknowledge Frame required Applies only to Sequence TR, ignored during all other sequences. 0b - An ordinary receive frame (any type of frame) follows the transmit frame. 1b - A receive Ack frame is expected to follow the transmit frame (non-Ack frames are rejected).
13 AUTOACK	Auto Acknowledge Enable Applies only to Sequence R and Sequence TR, ignored during other sequences 0b - sequence manager will not follow a receive frame with a Tx Ack frame, under any conditions; the autosequence will terminate after the receive frame. 1b - sequence manager will follow a receive frame with an automatic hardware-generated Tx Ack frame, assuming other necessary conditions are met.
12 ACKBUF_SEL	ACK frame is in 64-byte dedicated RAM or TX buffer RAM 0b - ACK frame is in 64-byte dedicated RAM 1b - ACK frame is in TX buffer RAM
11 SW_BUILD_ACK	Software builds the ACK packet in RAM 0b - Hardware builds part of or the whole of the auto ACK frame 1b - Software builds the whole auto ACK frame in RAM.
10-8 PHR_TYPE	PHR Type Specify the PHR type in PAN or FAN mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
	000b - The packet type is GFSK 001b - The packet type is MSK 010b - The packet type is SUN FSK 011b - The packet type is LECIM FSK
7 STAY_IN_RX	Stay in receive Enable the ability to recycle and stay in receive even after an RX_IRQ, to avoid the full RX re-warmup. 0b - Linklayer will warmdown after an RX_IRQ 1b - Linklayer will recycle and stay in receive even after an RX_IRQ.
6 DATARATE_CONFIG_SEL	Select the data rate configuration bank 0b - Select the data rate as per configuration bank 0 1b - Select the data rate as per configuration bank 1
5 SEL_RXIRQ	Select the RX IRQ assert time **NOTE** This bit must not be changed when RX or TX are active. Unpredictable behavior will ensue. 0b - RX_IRQ is asserted at the end of RX_PKT state. 1b - RX_IRQ is asserted at the end of RXEN_DLY state. This to be used for delaying RX_IRQ to accept TERM2 bits in Bluetooth LE-LR and CTE bits as needed.

30	Promiscuous Mode Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
PROMISCUOUS	Bypasses most packet filtering. 0b - normal mode 1b - all packet filtering except frame length checking (FrameLength>=5) is bypassed.
29 FILTER_FAIL_IGNORE	Filter Fail Ignore If set, assert RX_IRQ even when filter fail. 0b - RX_IRQ will not be asserted when filter fail. 1b - RX_IRQ will be asserted when filter fail.
28 RXCYC_SEL	Rx Recycle Time Select 0b - Recycle when fail happens. 1b - Recycle when Rx done and fail happens.
27-24 —	Reserved
23 EXTENDED_RECD	Extended Packet Received 0b - The last packet received was not Frame Type EXTENDED 1b - The last packet received was Frame Type EXTENDED, and EXTENDED_FT=1 to allow such packets.
22 FRAGMENT_RECD	Fragment Packet Received 0b - last packet received was not Frame Type FRAGMENT 1b - The last packet received was Frame Type FRAGMENT, and FRAGMENT_FT=1 to allow such packets.
21 MULTIPURPOSE_RECD	Multipurpose Packet Received 0b - last packet received was not Frame Type MULTIPURPOSE 1b - The last packet received was Frame Type MULTIPURPOSE, and MULTIPURPOSE_FT=1 to allow such packets.
20 LLDN_RECD	LLDN Packet Received 0b - The last packet received was not Frame Type LLDN 1b - The last packet received was Frame Type LLDN, and LLDN_FT=1 to allow such packets.
19 FV2_CMD_RECD	Frame Version 2 MAC Command Packet Received 0b - The last packet received was not Frame Type MAC Command with Frame Version 2 1b - The last packet received was Frame Type MAC Command with Frame Version 2, and FRM_VER_FILTER[2]=1 to allow such packets
18	Frame Version 2 Acknowledge Packet Received

Table continues on the next page...

Table continued from the previous page...

Field	Function
FV2_ACK_RECD	0b - The last packet received was not Frame Type Ack with Frame Version 2 1b - The last packet received was Frame Type Ack with Frame Version 2, and FRM_VER_FILTER[2]=1 to allow such packets
17 FV2_DATA_RECD	Frame Version 2 Data Packet Received 0b - The last packet received was not Frame Type Data with Frame Version 2 1b - The last packet received was Frame Type Data with Frame Version 2, and FRM_VER_FILTER[2]=1 to allow such packets
16 FV2_BEACON_RECD	Frame Version 2 Beacon Packet Received 0b - The last packet received was not Frame Type Beacon with Frame Version 2 1b - The last packet received was Frame Type Beacon with Frame Version 2, and FRM_VER_FILTER[2]=1 to allow such packets
15 EXTENDED_FCS_CHK	Verify FCS on Frame Type Extended 0b - Packet Processor will not check FCS for Frame Type EXTENDED (default) 1b - Packet Processor will check FCS at end-of-packet based on packet length derived from PHR, for Frame Type EXTENDED
14-13 —	Reserved
12-9 FRM_VER_FILTER	Frame Version selector. The incoming packet's Frame Control Field is parsed to obtain the FrameVersion subfield, and that value is compared against this register, in accordance with the following: xxx1: Accept received packets with FrameVersion=00 xx1x: Accept received packets with FrameVersion=01 x1xx: Accept received packets with FrameVersion=10 1xxx: Accept received packets with FrameVersion=11 These filtering rules apply to Beacon, Acknowledge, Data, and MAC Command Frame Types only, since these frame types require a 2-octet Frame Control Field which embeds a 2-bit FrameVersion subfield. For Acknowledge frames, FrameVersion bits are ignored by the Packet Processor, irrespective of FRM_VER_FILTER.
8 NS_FT	"Not Specified" Frame Type Enable This bit enables reception of all Frame Types not covered by the other _FT bits in this register. 0b - reject all "Not Specified" frames 1b - Not-specified (reserved) frame type enabled. Applies to Frame Type 6. No packet filtering is performed, except for frame length checking (FrameLength>=5 and FrameLength<=127). No AUTOACK is transmitted for this Frame Type
7	Extended Frame Type Enable

Table continues on the next page...

Table continued from the previous page...

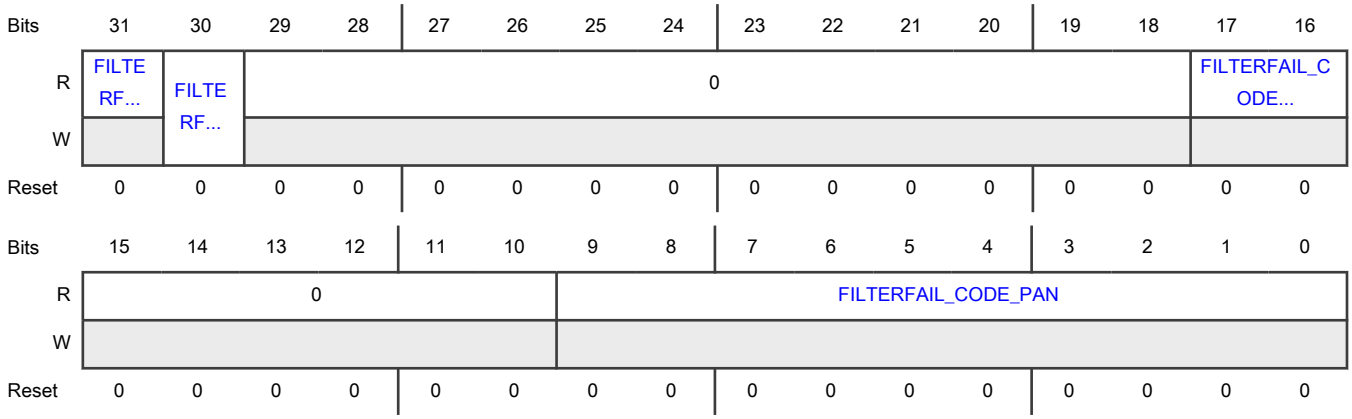
Field	Function
EXTENDED_FT	0b - reject all Extended frames 1b - Extended frame type enabled (Frame Type 7).
6 FRAGMENT_FT	Fragment Frame Type Enable 0b - reject all Fragment frames 1b - Fragment frame type enabled (Frame Type 6).
5 MULTIPURPOSE_FT	Multipurpose Frame Type Enable 0b - reject all Multipurpose frames 1b - Multipurpose frame type enabled (Frame Type 5).
4 LLDN_FT	LLDN Frame Type Enable 0b - reject all LLDN frames 1b - LLDN frame type enabled (Frame Type 4).
3 CMD_FT	MAC Command Frame Type Enable 0b - reject all MAC Command frames 1b - MAC Command frame type enabled.
2 ACK_FT	Ack Frame Type Enable 0b - reject all Acknowledge frames 1b - Acknowledge frame type enabled.
1 DATA_FT	Data Frame Type Enable 0b - reject all Beacon frames 1b - Data frame type enabled.
0 BEACON_FT	Beacon Frame Type Enable 0b - reject all Beacon frames 1b - Beacon frame type enabled.

55.4.9.2.2.1.40 FILTER FAIL CODE (FILTERFAIL_CODE)

Offset

Register	Offset
FILTERFAIL_CODE	98h

Diagram



Fields

Field	Function
31 FILTERFAIL_FLAG_SEL	Consolidated Filter Fail Flag 0: The incoming, or just-received packet, passed packet filtering rules. 1: The incoming, or just-received packet, failed packet filtering rules When FILTERFAIL_FLAG_SEL=1, a non-zero FILTERFAIL_CODE is present (see FILTERFAIL_CODE registers). In Dual PAN mode, FILTERFAIL_FLAG_SEL applies to either or both networks, as follows: **A:** If PAN0 and PAN1 occupy different channels and CURRENT_NETWORK=0, FILTERFAIL_FLAG_SEL applies to PAN0. **B:** If PAN0 and PAN1 occupy different channels and CURRENT_NETWORK=1, FILTERFAIL_FLAG_SEL applies to PAN1. **C:** If PAN0 and PAN1 occupy the same channel, FILTERFAIL_FLAG_SEL is the logical 'AND' of the individual PANs' FILTERFAIL_FLAG bits.
30 FILTERFAIL_PAN_SEL	PAN Selector for Filter Fail Code 0b - FILTERFAIL_CODE_PAN/FILTERFAIL_CODE_FAN will report the FILTERFAIL status of PAN0 1b - FILTERFAIL_CODE_PAN/FILTERFAIL_CODE_FAN will report the FILTERFAIL status of PAN1
29-18 —	Reserved
17-16 FILTERFAIL_CODE_FAN	Filter Fail Code When in FAN Mode Code inidicating what condition, or conditions, caused the Packet Processor to reject the just-received packet in FAN mode. The bits of FILTERFAIL_CODE_FAN indicate the reason for packet rejection.
15-10 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
9-0 FILTERFAIL_CODE_PAN	Filter Fail Code When in PAN Mode Code inidicating what condition, or conditions, caused the Packet Processor to reject the just-received packet in PAN mode. The bits of FILTERFAIL_CODE_PAN indicate the reason for packet rejection.

55.4.9.2.2.1.41 LENIENCY LSB (LENIENCY_LSB)

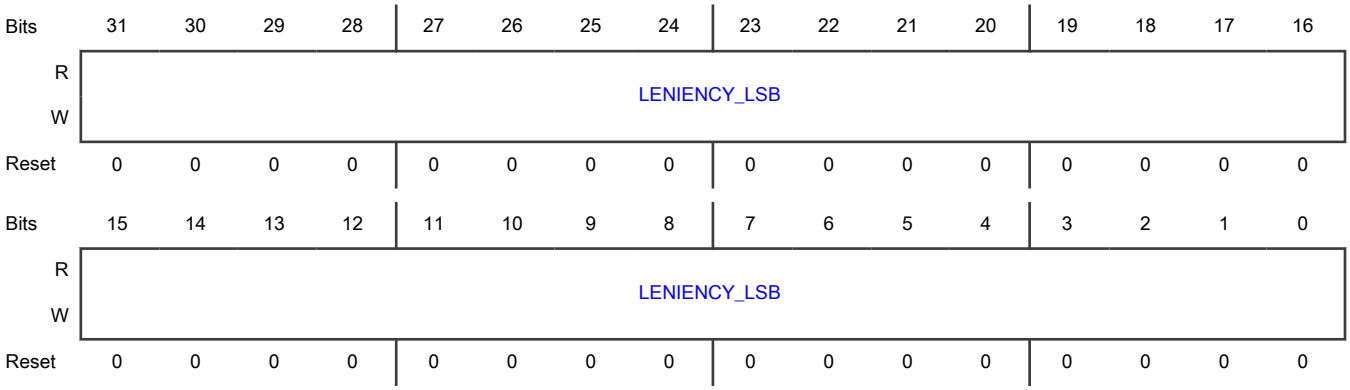
Offset

Register	Offset
LENIENCY_LSB	9Ch

Function

Packet Processor Leniency Bits (LSB)

Diagram



Fields

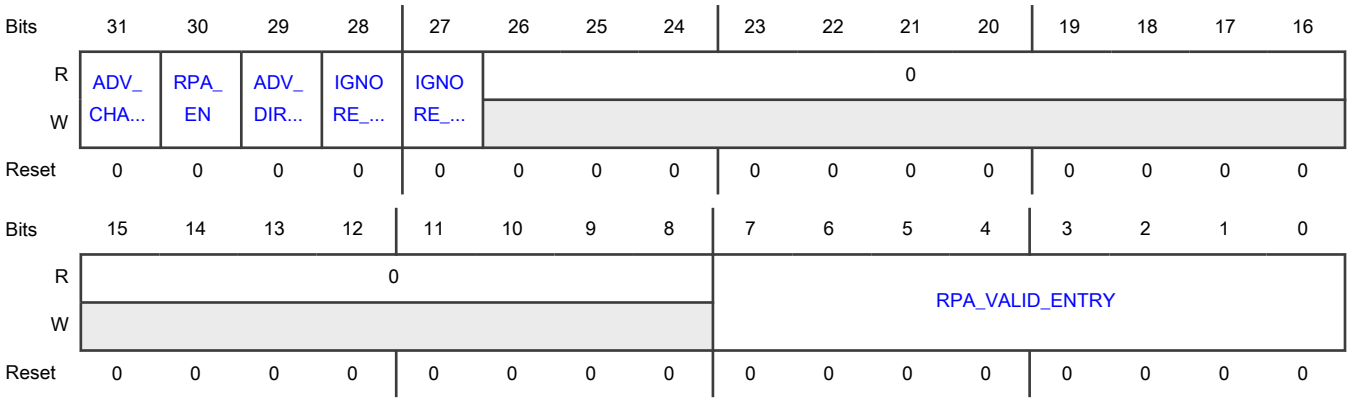
Field	Function
31-0 LENIENCY_LSB	Leniency LSB Register The Packet Processor performs filtering on all received packets, in order to determine whether the packet is intended for the device. The packet filtering is based on rules. In case any of the packet filtering rules need to be overriden, a 45-bit "leniency register" has been provided. When the leniency register is programmed to its default value (0), all hardware packet filtering rules are in effect, and if an incoming packet violates any rule, a "Filter Fail" will occur (packet will be rejected). When a given leniency register bit is asserted, the packet filtering rule assigned to that bit will not be in effect, and if any incoming packet violates that rule (but no other rules), then a "Filter Fail" will not occur, the packet will not be rejected, the packet will be treated as "intended for the device", and software will be notified of the incoming packet.

55.4.9.2.2.1.42 RPA CONTROL (RPA_CTRL)

Offset

Register	Offset
RPA_CTRL	9Ch

Diagram



Fields

Field	Function
31 ADV_CHANNEL_EN	0b - The packet to be received is in Data Channel PDU. 1b - The packet to be received is in Advertising Channel PDU.
30 RPA_EN	0b - The RPA check is disabled. 1b - The RPA check is enabled.
29 ADV_DIRECT_IND_SENT	When set, it means the link layer is advertiser who has sent an ADV_DIRECT_IND. This bit is used by hardware to bypass the white list check when received a CONNECT_IND or SCAN_REQ. In this case, the peer address and peer address type are to be compared with the register DIRECT_PEER_ADDRESS and DIRECT_PEER_ADDRESS_TYPE.
28 IGNORE_DIRECT_FAIL	0b - link layer aborts the Rx process when DIRECT_ID_FAIL_IRQ 1b - link layer ignores DIRECT_ID_FAIL_IRQ.
27 IGNORE_RPA_FAIL	0b - link layer aborts the Rx process when LOCAL_RPA_FAIL_IRQ or PEER_RPA_FAIL_IRQ 1b - link layer ignores LOCAL_RPA_FAIL_IRQ and PEER_RPA_FAIL_IRQ.
26-8 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-0 RPA_VALID_ENTRY	Here bits [7:0] corresponds to validity of 8th to 1st entry in RPA list respectively. Value "1" means the entry is valid, "0" means invalid.

55.4.9.2.2.1.45 DUAL PAN CONTROL (DUAL_PAN_CTRL)

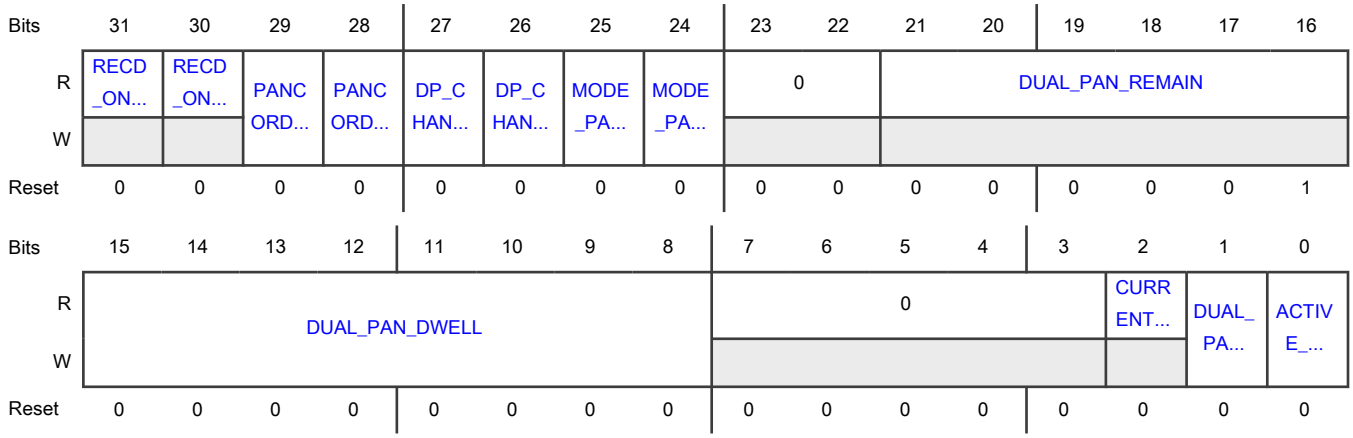
Offset

Register	Offset
DUAL_PAN_CTRL	A4h

Function

Dual PAN Control Register

Diagram



Fields

Field	Function
31 RECD_ON_PAN1	Last Packet was Received on PAN1 Indicates the packet which was just received, was received on PAN1. In Dual PAN mode operating on 2 different channels, RECD_ON_PAN1 will be set if CURRENT_NETWORK=1 when the packet was received, regardless of FILTERFAIL status. In DUAL PAN mode operating with same channel on both networks, CURRENT_NETWORK will be ignored and RECD_ON_PAN1 will be set only if a valid packet was received on PAN1 (PAN1's FILTERFAIL_FLAG is deasserted). RECD_ON_PAN1 remains valid until the start of the next autoseqeuence.
30 RECD_ON_PAN0	Last Packet was Received on PAN0 Indicates the packet which was just received, was received on PAN0. In Dual PAN mode operating on 2 different channels, RECD_ON_PAN0 will be set if CURRENT_NETWORK=0 when the packet was received, regardless of FILTERFAIL status. In DUAL PAN mode operating with same channel on both networks, CURRENT_NETWORK will be ignored and RECD_ON_PAN0 will be set only if a valid packet was received on PAN0 (PAN0's FILTERFAIL_FLAG is deasserted). RECD_ON_PAN0 remains valid until the start of the next autoseqeuence.
29 PANCORDNTR1	Device is a PAN Coordinator on PAN1 Device is a PAN Coordinator on PAN1. Allows device to receive packets with no destination address, if Source PAN ID matches.

Table continues on the next page...

Table continued from the previous page...

Field	Function
28 PANCORDNTR0	Device is a PAN Coordinator on PAN0 Device is a PAN Coordinator on PAN0. Allows device to receive packets with no destination address, if Source PAN ID matches.
27 DP_CHAN_OVRD_SEL	Dual PAN Channel Override Selector This bit works with **DP_CHAN_OVRD_EN** to allow one of the two Dual PAN channels to use Direct Frequency programming. See description for **DP_CHAN_OVRD_EN**.
26 DP_CHAN_OVRD_EN	Dual PAN Channel Override Enable In Dual PAN mode, in case there is a need to generate a frequency which may be offset from the 16 prescribed 5MHz-spaced channels, to, for example, avoid interference on one of the Dual PAN channels, a method has been provided to accomplish that, by designating one of the two PAN channels to use the transceiver's set of direct frequency-programming registers, instead of CHANNEL_NUMx. Programming the direct frequency-programming registers -- integer, numerator, and denominator, allows an RF frequency to be selected with much more precision than the 5MHz granularity of the Zigbee mapped-channel registers, CHANNEL_NUM0 and CHANNEL_NUM1. Two bits have been provided in 802.15.4 space to realize this feature: DP_CHAN_OVRD_SEL and DP_CHAN_OVRD_EN. When DP_CHAN_OVRD_EN=1, this enables one of the Dual PAN channels to use the direct frequency programming. The DP_CHAN_OVRD_SEL bit determines which channel uses the direct programming, according to the following: If DP_CHAN_OVRD_EN=0, then PAN0 frequency is determined by register CHANNEL_NUM0[6:0] and PAN1 frequency is determined by register CHANNEL_NUM1[6:0]. If DP_CHAN_OVRD_EN=1 and DP_CHAN_OVRD_SEL=0, then PAN0 frequency is determined by DIRECT FREQUENCY PROGRAMMING and PAN1 frequency is determined by register CHANNEL_NUM1[6:0]. If DP_CHAN_OVRD_EN=1 and DP_CHAN_OVRD_SEL=1, then PAN0 frequency is determined by register CHANNEL_NUM0[6:0] and PAN1 frequency is determined by DIRECT FREQUENCY PROGRAMMING. **NOTE** Direct Frequency Programming is accomplished by setting the PLL's Integer, Numerator, and Denominator registers to the appropriate values for the desired RF frequency.
25 MODE_PAN1	PAN1 Mode Select For Hybrid Dual PAN Mode, select the PAN1 Mode 0b - PAN1 is in PAN mode 1b - PAN1 is in FAN mode
24 MODE_PAN0	PAN0 Mode Select For Hybrid Dual PAN Mode, select the PAN0 Mode 0b - PAN0 is in PAN mode 1b - PAN0 is in FAN mode
23-22	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
21-16 DUAL_PAN_REMAIN	Time Remaining before next PAN switch in auto Dual PAN mode This read-only register indicates time remaining before next PAN switch in auto Dual PAN mode. The units for this register, depend on the PRESCALER setting (bits [1:0]) in the DUAL_PAN_DWELL register. Tthe units are the same as the TIMEBASE determined by the prescaler, as per the following table: DUAL_PAN_DWELL[1:0]=0b00 (TIMEBASE=0.5ms) DUAL_PAN_REMAIN UNITS=0.5ms DUAL_PAN_DWELL[1:0]=0b01 (TIMEBASE=2.5ms) DUAL_PAN_REMAIN UNITS=2.5ms DUAL_PAN_DWELL[1:0]=0b10 (TIMEBASE=10ms) DUAL_PAN_REMAIN UNITS=10ms DUAL_PAN_DWELL[1:0]=0b11 (TIMEBASE=50ms) DUAL_PAN_REMAIN UNITS=50ms The readback value indicates that between N-1 and N timebase units remain until the next PAN switch. For example, a DUAL_PAN_REMAIN readback value of 3, with a DUAL_PAN_DWELL PRESCALER setting of 2 (10ms), indicates that between 20ms (2*10ms) and 30ms (3*10ms), remain until the next automatic PAN switch.
15-8 DUAL_PAN_DWELL	Dual PAN Channel Frequency Dwell Time Channel Frequency Dwell Time. In Auto Dual PAN mode, hardware will toggle the PAN, after dwelling on the current PAN for the interval described below (assuming Preamble/SFD not detected). A write to DUAL_PAN_DWELL, always re-initilizes the DWELL TIMER to the programmed value. If a write to DUAL_PAN_DWELL occurs during an autosequence, the DWELL TIMER will begin counting down immediately. If a write to DUAL_PAN_DWELL occurs when there is no autosequence underway, the DWELL TIMER will not begin counting until the next autosequence begins; it will begin counting at the start of the sequence warmup. DUAL_PAN_DWELL[1:0] select the timebase for the dwell time. There are 4 options: DUAL_PAN_DWELL[1:0]=0b00 --> TIMEBASE=0.5ms DUAL_PAN_DWELL[1:0]=0b01 --> TIMEBASE=2.5ms DUAL_PAN_DWELL[1:0]=0b10 --> TIMEBASE=10ms DUAL_PAN_DWELL[1:0]=0b11 --> TIMEBASE=50ms DUAL_PAN_DWELL[7:2] select how many multiples of the time base to use, from 1 (DUAL_PAN_DWELL[7:2]=0) to 64 (DUAL_PAN_DWELL[7:2]=63). Given those definitions, the table below specifies the minimum and maximum dwell times for each TIMEBASE option: DUAL_PAN_DWELL[1:0]=0b00 --> MIN_DWELL=0.5ms MAX_DWELL=32ms DUAL_PAN_DWELL[1:0]=0b01 --> MIN_DWELL=2.5ms MAX_DWELL=160ms DUAL_PAN_DWELL[1:0]=0b10 --> MIN_DWELL=10ms MAX_DWELL=640ms DUAL_PAN_DWELL[1:0]=0b11 --> MIN_DWELL=50ms MAX_DWELL=3.2seconds A write to DUAL_PAN_DWELL also causes the value of ACTIVE_NETWORK to get latched into the hardware. This latched value will be the starting point for the automatic dual-pan mode (i.e., start on PAN0 or on PAN1). The starting value takes effect immediately (if sequence is underway and DUAL_PAN_AUTO=1), or is otherwise delayed until sequence starts and DUAL_PAN_AUTO=1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-3 —	Reserved
2 CURRENT_NETWORK	Indicates which PAN is currently selected by hardware This read-only bit indicates which PAN is currently selected by hardware in automatic Dual PAN mode 0b - PAN0 is selected 1b - PAN1 is selected
1 DUAL_PAN_AUTO	Activates automatic Dual PAN operating mode Activates automatic Dual PAN operating mode. In this mode, PAN-switching is controlled by hardware at a pre-programmed rate, determined by DUAL_PAN_DWELL. 0: Manual Dual PAN mode (or Single PAN mode). 1: Auto Dual PAN Mode Whenever DUAL_PAN_AUTO=0, CURRENT_NETWORK=ACTIVE_NETWORK at all times. In other words, software directly controls which PAN is selected. Whenever DUAL_PAN_AUTO=1, CURRENT_NETWORK is controlled by hardware.
0 ACTIVE_NETWORK	Active Network Selector Selects the PAN on which to transceive, by activating a PAN parameter set (PAN0 or PAN1). In Manual Dual PAN mode (or Single PAN mode), this bit selects the active PAN parameter set (channel and addressing parameters) which governs all autosequences. In Auto Dual PAN mode, this bit selects the PAN on which to begin transceiving, latched at the point at which DUAL_PAN_DWELL register is written. 0b - Select PAN0 1b - Select PAN1

1 SAA0_EN	Enables SAA0 Partition of the SAM Table 0b - Disables SAA0 Partition 1b - Enables SAA0 Partition
0 SAP0_EN	Enables SAP0 Partition of the SAM Table 0b - Disables SAP0 Partition 1b - Enables SAP0 Partition

55.4.9.2.2.1.68 SOURCE ADDRESS MANAGEMENT TABLE (SAM_TABLE)

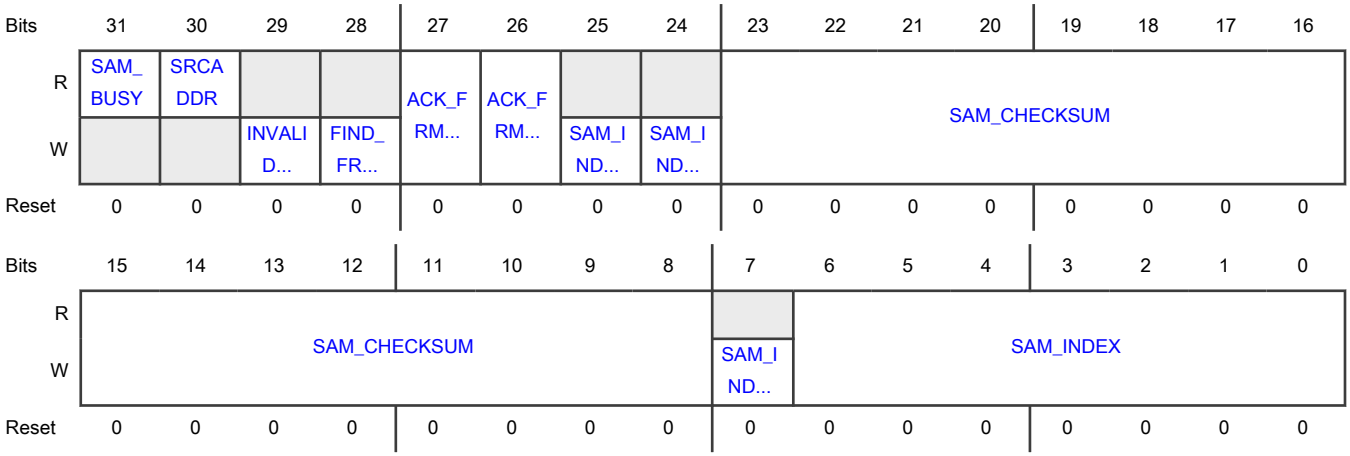
Offset

Register	Offset
SAM_TABLE	D8h

Function

Source Address Management Table

Diagram



Fields

Field	Function
31 SAM_BUSY	SAM Table Update Status Bit Hardware is in the process of updating the Source Address table, either in response to a poll indication from the packet processor, or due to software setting FIND_FREE_IDX=1. In the latter case, software should poll SAM_BUSY until low before accessing the "First Free Index" registers. Read-only bit.
30 SRCADDR	Source Address Match Status If Source Address Management is engaged, meaning at least one of the following bits is set: SAP0_EN SAA0_EN SAP1_EN SAA1_EN Then SRCADDR will be set to 1 if the packet just received is a poll request (PI=1), *and* at least one of the following conditions is met: SAP0_EN and SAP0_ADDR_PRESENT SAA0_EN and SAA0_ADDR_ABSENT SAP1_EN and SAP1_ADDR_PRESENT SAA1_EN and SAA1_ADDR_ABSENT If SRCADDR=1, this indicates to SW that the Packet Processor has determined that an auto-TxACK frame must be transmitted with the FramePending subfield of the FrameControlField set to 1. HW will assemble and transmit this Ack packet. If the above conditions are not met, SRCADDR will be cleared to 0.
29 INVALIDATE_ALL	Invalidate Entire SAM Table Writing a 1 to this bit clears all 128 Valid bits. Invalidates the entire table. Write-only bit. Writing 0 to this bit has no effect. Readback value is indeterminate.
28 FIND_FREE_IDX	Find First Free Index After modifying Valid bits (enabling or invalidating), write this bit to 1 to force hardware to update the "First Free Index" registers to account for the changed Valid bits. This hardware update process takes 4us. Software can poll SAM_BUSY to determine when the table update is complete. Write-only bit. Writing 0 to this bit has no effect. Readback value is indeterminate.
27 ACK_FRM_PND_CTRL	Manual Control for AutoTxAck FramePending field 0b - the FramePending field of the Frame Control Field of the next automatic TX acknowledge packet is determined by hardware 1b - the FramePending field of the Frame Control Field of the next automatic TX acknowledge packet tracks ACK_FRM_PEND
26 ACK_FRM_PND	State of AutoTxAck FramePending field when SAM Accelleration is Disabled Software can take manual control of the FramePending field of the Frame Control Field of the next automatic TX acknowledge packet, by setting ACK_FRM_PND_CTRL=1; in that case FramePending will

Table continues on the next page...

Table continued from the previous page...

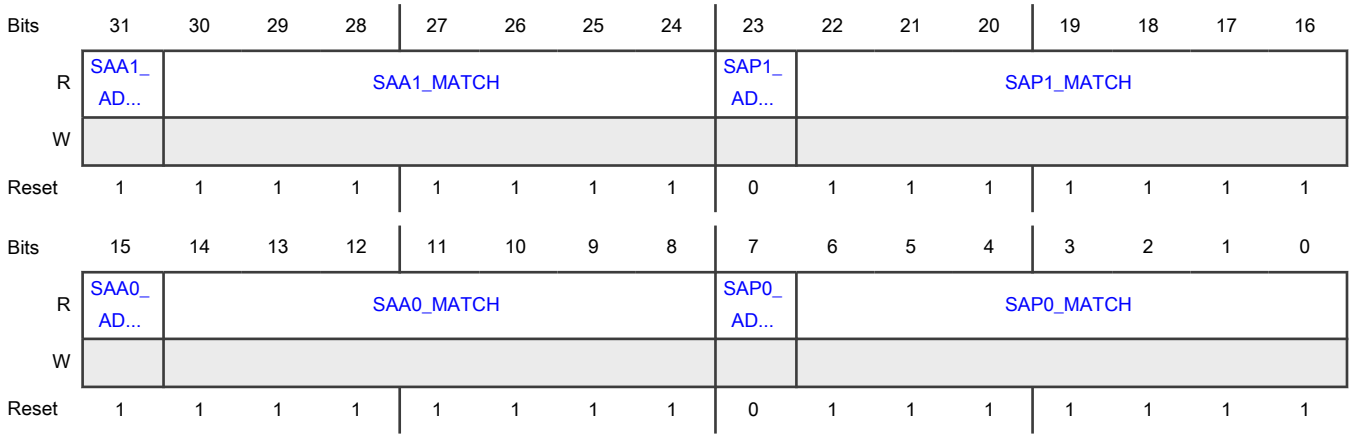
Field	Function
	track the state of this bit. The FramePending field also tracks this bit if Source Address Management is completely disabled, i.e., SAP0_EN=SAA0_EN=SAP1_EN=SAA1_EN=0 Otherwise, the FramePending field is determined by Source Address Management (SAM) hardware.
25 SAM_INDEX_EN	Enable the SAM table index selected by SAM_INDEX
24 SAM_INDEX_INV	Invalidate the SAM table index selected by SAM_INDEX
23-8 SAM_CHECKSUM	Software-computed source address checksum, to be installed into a table index Software-computed source address checksum, to be installed into a table index. The value on SAM_CHECKSUM[15:0] can be installed into the table with a single, atomic 32-bit write; in that case, the write data would contain the desired SAM_INDEX[6:0] and SAM_CHECKSUM[15:0], and SAM_INDEX_WR=1. If SAM_INDEX_WR=0, then the SAM_INDEX[6:0] register is written, but the checksum is *not* written to the table. The readback value of SAM_CHECKSUM[15:0] is the contents of the SAM Table at the location pointed to by SAM_INDEX[6:0]. To readback from a specific table index, software should first write the desired index to SAM_INDEX[6:0], and then read back the checksum from the table on SAM_CHECKSUM[15:0].
7 SAM_INDEX_WR	Enables SAM Table Contents to be updated For 32-bit writes, SAM_INDEX_WR must be set to indicate that the table entry specified by SAM_INDEX[6:0] is to be written; if SAM_INDEX_WR=0, the table entry is not written, but the SAM_INDEX[6:0] register is updated. For 8-bit writes, this bit is ignored.
6-0 SAM_INDEX	Contains the SAM table index to be enabled or invalidated Contains the table index to be enabled or invalidated. Software must ensure that the index is within the range of the desired partition.

55.4.9.2.2.1.69 SOURCE ADDRESS MANAGEMENT MATCH (SAM_MATCH)

Offset

Register	Offset
SAM_MATCH	DCh

Diagram



Fields

Field	Function
31 SAA1_ADDR_ABSENT	A Checksum Match is Absent in the SAP1 Partition of the SAM Table
30-24 SAA1_MATCH	Index in the SAA1 Partition of the SAM Table corresponding to the first checksum match
23 SAP1_ADDR_PRESENT	A Checksum Match is Present in the SAP1 Partition of the SAM Table
22-16 SAP1_MATCH	Index in the SAP1 Partition of the SAM Table corresponding to the first checksum match
15 SAA0_ADDR_ABSENT	A Checksum Match is Absent in the SAA0 Partition of the SAM Table
14-8 SAA0_MATCH	Index in the SAA0 Partition of the SAM Table corresponding to the first checksum match
7 SAP0_ADDR_PRESENT	A Checksum Match is Present in the SAP0 Partition of the SAM Table
6-0 SAP0_MATCH	Index in the SAP0 Partition of the SAM Table corresponding to the first checksum match

This is write a '1' to clear bit. 0b - An arb_grant Deassertion Interrupt has not occurred 1b - An arb_grant Deassertion Interrupt has occurred

55.4.9.2.3 Functional Description

55.4.9.2.3.1 Packet Configuration

The Generic FSK Link Layer Controller provides the capability to configure the over-the-air packet structure by way of a set of programmable registers. The Generic FSK packet has a consistent structure, which consists of various elements which are transmitted and received in fixed order. Most of the packet elements have associated configurability, which allows

software to pre-configure, for example, the size of the element (in number of bits, or octets), or bit ordering of the element. In addition, the generic structure defines a variable-length header, for which some (optional) primitive parsing is provided, allowing hardware to differentiate packets based on header-bit settings, into compliant and non-compliant packets. Data Indication is provided on compliant packets only. Non-complaint packets are discarded. By default, all packet elements are transmitted and received LSB-first.

The Generic FSK Link Layer Controller supports a packet structure based on the following template:

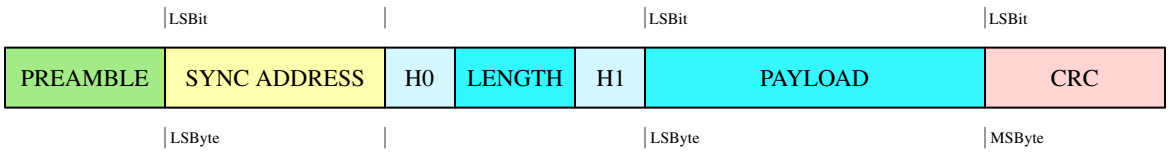

Figure 405. GENERIC_FSK Packet Structure

The Generic_FSK Link Layer controller transmits and receives packets which conform to the format shown above. The elements of the packet are transmitted in received in the order shown, although some of the packet elements may be optionally skipped, depending on the configuration options chosen.

The following diagram depicts the register configurability associated with the Preamble, Sync Address, H0, Length, and H1 elements of the packet structure.

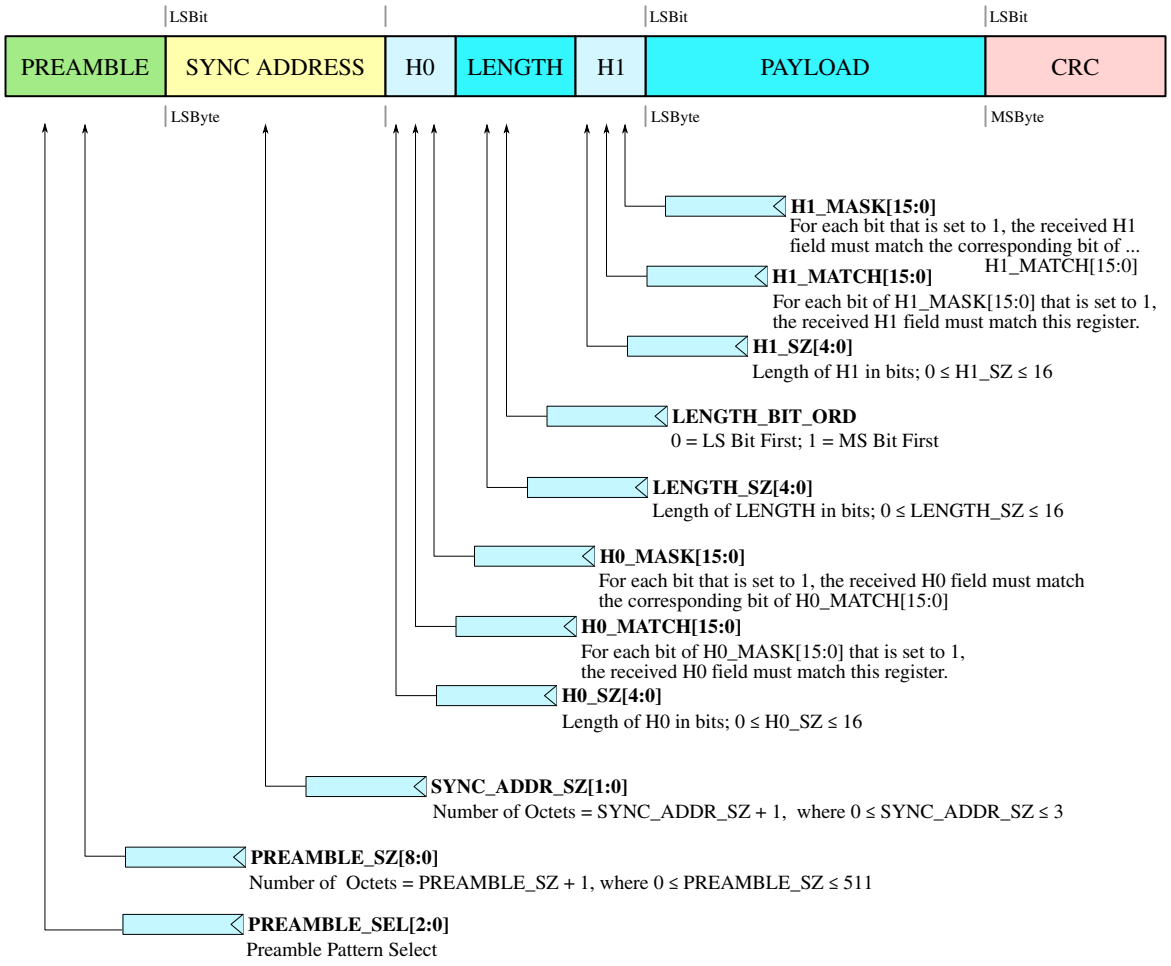

Figure 406. Packet Structure Definitions (Part 1)

The following diagram depicts the register configurability associated with the Payload and CRC elements of the packet structure.

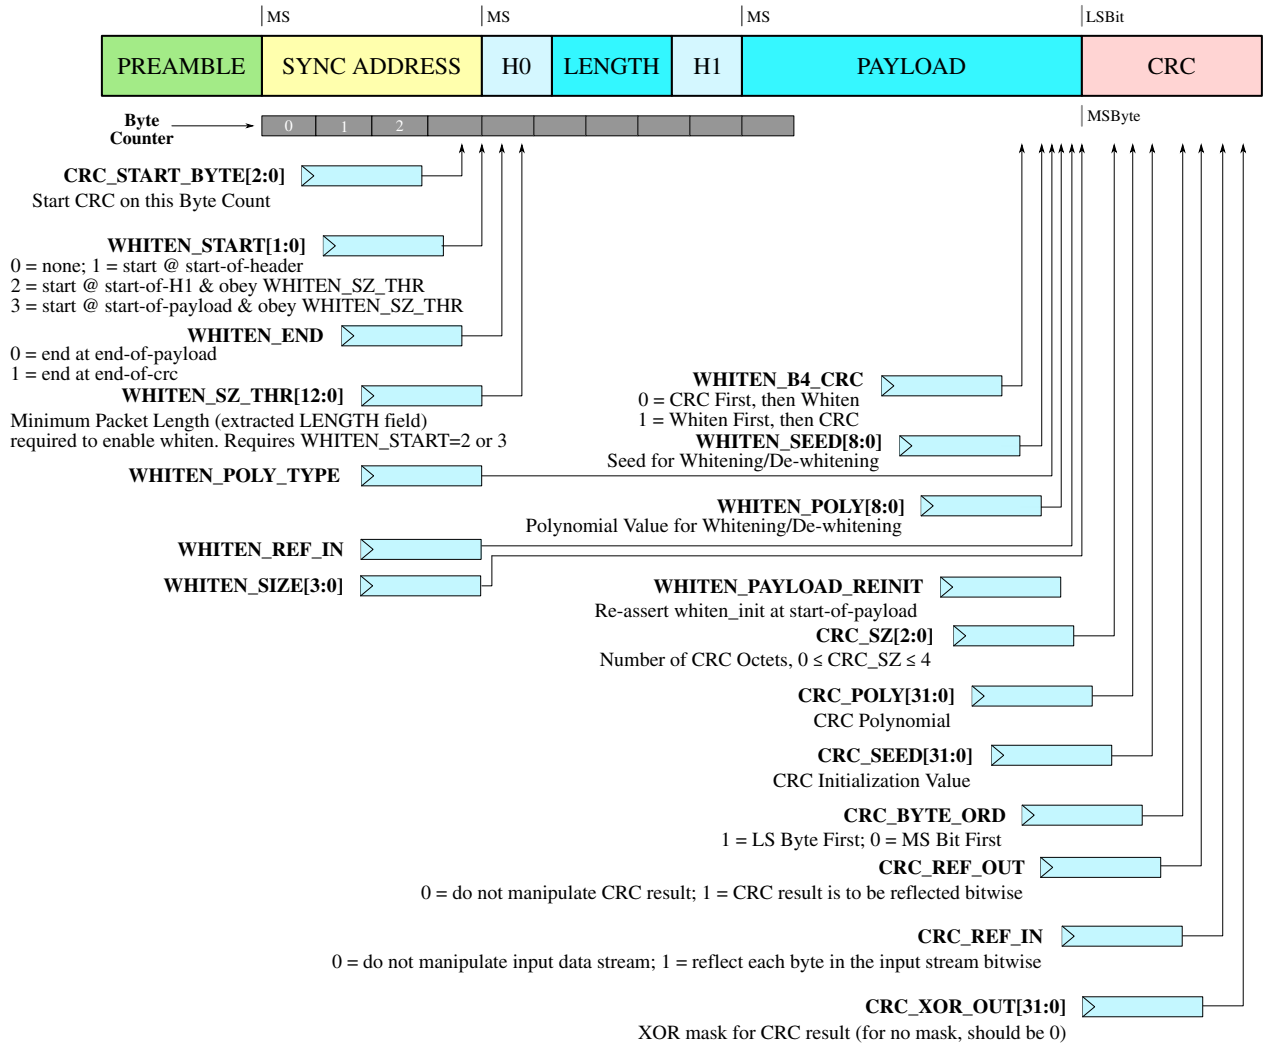

Figure 407. Packet Structure Definitions (Part 2)

The following subsections describe each of the packet elements, and the configurability associated with each.

PREAMBLE

When PREAMBLE_SEL=0x0, the preamble pattern is 0x55 or 0xAA. Like all packet elements, preamble is transmitted LSB first. The Sync Address, which immediately follows the preamble, determines which of the 2 preamble options is selected by hardware: the controller hardware selects the preamble pattern based on the first transmitted bit of Network Address, such that the last bit of preamble is the opposite polarity from the first bit of Network Address, forcing a bit transition at this boundary. The number of octets of preamble is programmable, via the PREAMBLE_SZ[2:0] register, with a range from 1 to 8 octets. A setting of PREAMBLE_SZ=0 yields a single preamble octet, whereas a setting of PREAMBLE_SZ=7 yields 8 octets. For transmission, the Generic FSK BYTE_COUNTER will be negative during preamble transmission. If PREAMBLE_SZ=0 (1 preamble octet), BYTE_COUNTER will be -1 while the single preamble octet is being transmitted. If PREAMBLE_SZ=7 (8 octets), BYTE_COUNTER will be -8 during the first preamble octet, -7 during the next, and so on and so forth, until the eighth and final octet, during which the BYTE_COUNTER will be -1. Unlike most packet elements, the preamble is generated and shifted out by hardware (only preamble and CRC are hardware-generated); there is no software setup required, and preamble does not appear in the Packet Buffer TX buffer. During reception, the Link Layer controller does not receive preamble, since preamble detection is performed by the PHY; preamble does not appear in the Packet Buffer RX buffer.

When PREAMBLE_SEL=0x1, the preamble pattern is fixed to register GEN_PREAMBLE[7:0], regardless of the Sync Address.

When PREAMBLE_SEL=0x2 or 0x3, the preamble pattern is fixed to 0b01 or 0b10, regardless of the Sync Address. At this case, PREAMBLE_SZ is the two-bits number not the byte number. If PREAMBLE_SZ=7 (8 two-bits), BYTE_COUNTER will be -8 during the first preamble two-bits, -7 during the next, and so on and so forth, until the eighth and final two-bits, during which the BYTE_COUNTER will be -1.

SYNC (NETWORK) ADDRESS

Sync Address, known synonymously as Network Address or Access Address depending on the protocol in use, is the second packet element transmitted by the Link Layer controller, and the first element received. In a network of associated devices, all devices generally share a common Network Address. The first bit of Network Address determines the preamble selection for transmission, as noted above. For TX, Network Address is the first packet element programmed into the Packet Buffer TX buffer, in LSB-first format. For RX, Network Address is also the first element stored into the Packet Buffer RX buffer, in LSB-first format. The register NTW_ADR_SZ[1:0] determines the length, in octets, of the Network Address field in the packet structure. A setting of NTW_ADR_SZ=0 yields a single-octet Network Address, whereas a setting of NTW_ADR_SZ=3 yields 4 octets. For reception, up to four unique Network Addresses are supported. Any combination of the 4 can be simultaneously searched for. Network Address correlation is performed in the PHY. Multiple Network Address capability allows GENERIC_FSK devices to be associated to more than one network simultaneously, if the network topology supports it; this feature also enables multi-protocol operation. Each of the 4 Network Address options has its own enable bit, NTW_ADR_EN[x]; when the enable bit for a Network Address is set to 1, the PHY is instructed to search for that Network Address pattern in the demodulated data, and when the enable bit is set to 0, the PHY will disregard that pattern. Each of the 4 Network Address options shares one NTW_ADR_SZ register, to program its octet size during reception. Additionally, each of the 4 Network Address options shares one register NTW_ADR_THR[2:0], which determine the number of bit errors that can be tolerated by the PHY during Network Address correlation to the respective Network Address option. Finally, when the PHY detects a match to one of the 4 Network Address options, with a number of bit errors less than or equal to the threshold programmed into NTW_ADR_THR, a read only status bit, NTW_ADR_MCH[x] becomes set, indicating which of the 4 patterns matched. After a match has been detected, the PHY shall hold NTW_ADR_MCH[x] valid (sticky), until the next receiver warmup, or the next RX recycle. (Specifically, the TSM output rx_init clears the NTW_ADR_MCH[x] bits; TSM will assert this signal during either an RX warmup or a recycle). A table listing the registers which apply to Network Address Management, for each of the 4 Network Address options, is shown below.

NTW_ADR PATTERN REGISTER	NTW_ADR ENABLE BIT	NTW_ADR SIZE REGISTER	NTW_ADR THRESHOLD REGISTER	NTW_ADR PATTERN-MATCH STATUS BIT
NTW_ADR_0[31:0]	NTW_ADR_EN[0]	NTW_ADR_SZ[1:0]	NTW_ADR_THR[2:0]	NTW_ADR_MCH[0]
NTW_ADR_1[31:0]	NTW_ADR_EN[1]	NTW_ADR_SZ[1:0]	NTW_ADR_THR[2:0]	NTW_ADR_MCH[1]
NTW_ADR_2[31:0]	NTW_ADR_EN[2]	NTW_ADR_SZ[1:0]	NTW_ADR_THR[2:0]	NTW_ADR_MCH[2]
NTW_ADR_3[31:0]	NTW_ADR_EN[3]	NTW_ADR_SZ[1:0]	NTW_ADR_THR[2:0]	NTW_ADR_MCH[3]

For Network Addresses of size less than 4 octets, the PHY expects the desired pattern to occupy the least-significant byte positions of the NTW_ADR_x register. Unused byte positions may be filled with any value.

NOTE

When programming the NTW_ADR_x, NTW_ADR_EN[x], NTW_ADR_SZ, and NTW_ADR_THR for any RX operation, the following software restrictions apply:

1. All NTW_ADR_x patterns which are enabled by their respective NTW_ADR_EN[x]=1 must be unique (disabled NTW_ADR_x registers need not follow this restriction).
2. Given restriction #1 above, not only must the patterns be unique, but the bit patterns of NTW_ADR_x and NTW_ADR_y must differ by an amount greater than the bit-error threshold, i.e., NTW_ADR_THR.

These restrictions are designed to preclude multiple, simultaneous pattern matches during a pattern search. Results are indeterminate if the restrictions are violated.

When the PHY detects a pattern match on any enabled NTW_ADR_x during reception, and asserts NTW_ADR_MCH[x], the GENERIC_FSK Link Layer Controller shall assert NTW_ADR_IRQ. The NTW_ADR_IRQ is the Link Layer's first indication that

a packet is being received. After any NTW_ADR_IRQ assertion, a packet will be received and stored into the Packet Buffer RX buffer.

HEADER

The packet header is comprised of H0, LENGTH, and H1, in that order. Each of the 3 fields of the header has programmable length, from 0 to 16 bits. A size of zero for any of the header components infers that the component is skipped in the packet structure. Although the size of the individual H0, LENGTH, and H1 components need not be aligned to a byte boundary, the overall header must be byte-aligned. That is, the sum of the sizes (in bits) of H0, LENGTH, and H1, must be a integer multiple of 8 bits. This is a software restriction, a violation of which may result in indeterminate behavior.

For GENERIC_FSK protocol, the purpose of the header is twofold:

1. To frame the LENGTH field, so that LENGTH can be extracted and interpreted by the GENERIC_FSK packet processor, so as to determine how and when perform the required bit-stream processing on the data. In most wireless protocols with regular structures, the LENGTH field is embedded within the packet header, but its positioning, number of LENGTH bits, bit ordering, and interpretation can differ. The GENERIC_FSK configurability thus provides support for a wide range of header formats, yielding a high likelihood that most current and future packet formats and LENGTH fields will be parsable by the GENERIC_FSK Link Layer controller.
2. To provide rudimentary packet filtering on the non-LENGTH header bits, namely H0 and H1. Screening of packets based on H0 and/or H1 bit comparisons can reduce power consumption, by avoiding notification to the host processor on received packets that do not comply with pre-configured H0 and/or H1 bitmasks, enabling longer MCU sleep durations.

The header components, and their configurability options, are further described below.

H0

H0 is an optional header packet element. Its length in bits is determined by register H0_SZ[4:0]. Legal values for H0_SZ are:

0 <= H0_SZ <= 16

If H0 is present (non-zero size), it can be filtered-on by the GENERIC_FSK packet processor; each bit of H0 can be forced to match a programmable bitmask, or ignored. Every bit of H0 that is forced to match the bitmask, must match; otherwise, the packet is rejected. The registers H0_MATCH[15:0] and H0_MASK[15:0] control H0 filtering. For every bit of H0_MASK that is set to one, the received bit in the H0 portion of the header must match the corresponding bit of H0_MATCH. Bits of H0_MASK which are cleared, do not require a match of received data bits to H0_MATCH bits. If any bit of received data which is qualified with H0_MASK[x]=1 fails to match its corresponding H0_MATCH[x] bit, the H0_FAIL register status bit will be set, an RX recycle will occur, and the host processor will not be notified. (The recycle operation will self-clear the H0_FAIL bit). For debug purposes, the control bit REC_BAD_PKT has been provided. If REC_BAD_PKT=1 and a H0-mismatch occurs, the RX recycle is prevented, the full packet is received, the MCU is notified, and the H0_FAIL flag stays asserted. In this case, the H0-fail flag will stay asserted until the next RX warmup (specifically, rx_init clears the bit).

The equation for H0_FAIL is thus:

H0_FAIL = [$H0_{received}$^H0_MATCH[15:0]) & H0_MASK > 0

LENGTH

LENGTH is an optional header packet element. Its length in bits is determined by the register LENGTH_SZ[4:0]. Legal values for LENGTH_SZ are:

0 <= LENGTH_SZ <= 16

If LENGTH is present (non-zero size), its value determines the number of octets remaining in the packet after the header is complete, that is, PAYLOAD octets plus CRC octets, as depicted below.

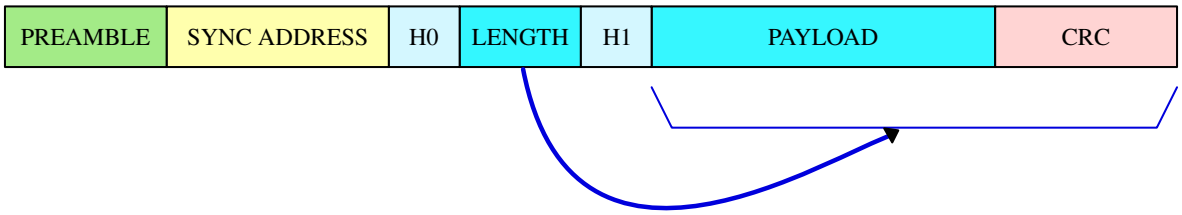

Figure 408. LENGTH Field Interpretation with No LENGTH_ADJ

For example, if the payload consists of 16 octets, and CRC is 4 octets, the LENGTH field of the header should be set to 20. The packet processor will extract the packet length from the LENGTH field of the header, and use this information to determine the timing of the CRC, Whitening control signals, as well as end-of-packet interrupt triggering.

In case a protocol exists for which the LENGTH field is to be interpreted differently, a configurability option has been provided to compensate for this. Hypothetically, this could happen, for example, in a proprietary packet structure, in which LENGTH is to be defined to represent PAYLOAD only, excluding CRC. The register LENGTH_ADJ, allows a fixed offset to be applied to the extracted LENGTH field, such that the sum of LENGTH + LENGTH_ADJ represents the number of PAYLOAD + CRC octets, as depicted below:

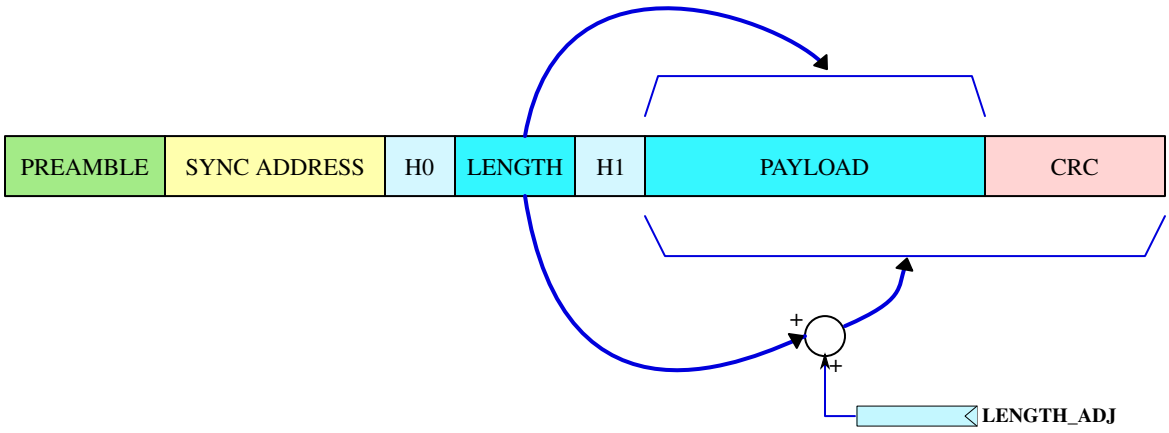

Figure 409. LENGTH Field Interpretation with LENGTH_ADJ

Applying the previous example, if, using a proprietary format, LENGTH were to be defined as payload-length only, LENGTH would be set to 16. In order for the packet processor to correctly time the CRC and Whitening control signals, etc., the LENGTH_ADJ register should be programmed to 4 in this case, so that the packet processor would operate on a 20-octet "PAYLOAD + CRC" PDU. The LENGTH_ADJ register represents a signed value, so that negative offsets can be applied. The legal range for LENGTH_ADJ is:

-1024 <= LENGTH_ADJ <= 1023

The LENGTH field could be ordered MSB first or LSB first. The packet processor must be able to accommodate either case, in order to extract the LENGTH field properly from the header, so a configurability option has been provided. The register bit LENGTH_BIT_ORD specifies the bit order. If LENGTH_BIT_ORD=0, ordering is LSB-first, as shown below.

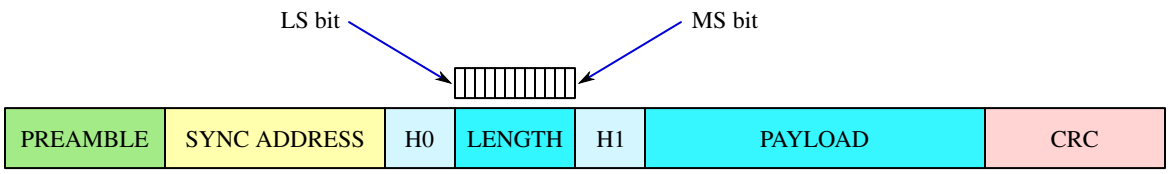

Figure 410. LENGTH Bit Ordering (LSB First)

If LENGTH_BIT_ORD=1, ordering is MSB-first, as shown below.

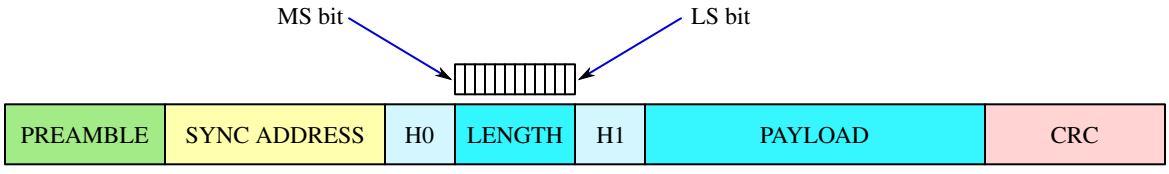

Figure 411. LENGTH Bit Ordering (MSB First)

If LENGTH_SZ=0, then LENGTH is not present in the header. The packet processor interprets this as LENGTH=0. If, in this case, LENGTH_ADJ=0 also, the packet processor interprets this to mean that the packet ends with the last bit of H1, and there are no PAYLOAD or CRC octets (CRC_SZ should be programmed to 0 in this case). There is no CRC verification in this scenario. If, in this case, LENGTH_SZ=0, meaning an empty payload field, but a CRC check is desired, CRC_SZ should be programmed to the desired number of CRC octets, and LENGTH_ADJ should be programmed to the same value: LENGTH_ADJ = CRC_SZ.

For GENERIC_FSK, valid payload lengths are from 0 to 2047 octets, i.e.,

0 <= LENGTH <= 2047

If LENGTH_ADJ is non-zero, then the maximum limit of 2047 applies to the sum of LENGTH and LENGTH_ADJ, i.e.,

0 <= (LENGTH + LENGTH_ADJ) <= 2047

A restriction on LENGTH_ADJ follows:

If the packet ends immediately after the LENGTH field of the header, i.e., H1_SZ=0 and there is neither payload nor CRC, then LENGTH_ADJ must be set to 0.

Although the LENGTH field has a maximum size of 16 bits, since the maximum receivable packet size is 2047 bytes, any received LENGTH bits above bit [10] are ignored by the packet processor, which effectively clamps LENGTH at 2047 bytes. There may be cases where it is desirable to limit the maximum received packet length to values less than 2047, so that received packets whose extracted LENGTH field indicates to be larger than a pre-set limit, are rejected by the packet processor. A configurability option has been provided for this, the register LENGTH_MAX[6:0]. The LENGTH_MAX setting configures a pre-set limit on the extracted LENGTH field, in multiples of 16 octets. A special case exists for LENGTH_MAX=0 (the register default), which implies no hardware-limiting; this setting should be used to allow reception of full-length 2047-octet packets. If LENGTH_MAX=1, packets with LENGTH >= 16 octets are rejected. If LENGTH_MAX=2, packets with LENGTH >= 32 octets are rejected. If LENGTH_MAX=127 (the maximum setting) packets with LENGTH >= 2032 octets are rejected. To determine compliance with LENGTH_MAX, the packet processor compares the LENGTH_MAX register with the extracted LENGTH field directly, not the adjusted length (LENGTH + LENGTH_ADJ). If a packet is received during which the extracted LENGTH field exceeds the LENGTH_MAX setting, the LENGTH_FAIL register status bit will be set, an RX recycle will occur, and the host processor will not be notified. (The recycle will self-clear the LENGTH_FAIL bit). For debug purposes, the control bit REC_BAD_PKT has been provided. If REC_BAD_PKT=1 and a LENGTH_MAX violation occurs, the RX recycle is prevented, the full packet is received, the MCU is notified, and the LENGTH_FAIL flag stays asserted. In this case, the LENGTH_FAIL flag will stay asserted until the next RX warmup (specifically, rx_init clears the bit).

H1

H1 is an optional header packet element. Its length in bits is determined by register H1_SZ[4:0]. Legal values for H1_SZ are 0 ≤ H1_SZ ≤ 16. If H1 is present (non-zero size), it can be filtered-on by the GENERIC_FSK packet processor; each bit of H1 can be forced to match a programmable bitmask, or ignored. Every bit of H1 that is forced to match the bitmask, must match; otherwise, the packet is rejected. The registers H1_MATCH[15:0] and H1_MASK[15:0] control H1 filtering. For every bit of H1_MASK that is set to one, the received bit in the H1 portion of the header must match the corresponding bit of H1_MATCH. Bits of H1_MASK which are cleared, do not require a match of received data bits to H1_MATCH bits. If any bit of received data which is qualified with H1_MASK[x]=1 fails to match its corresponding H1_MATCH[x] bit, the H1_FAIL register status bit will be set, an RX recycle will occur, and the host processor will not be notified. (The recycle will self-clear the H1_FAIL bit). For debug purposes, the control bit REC_BAD_PKT has been provided. If REC_BAD_PKT=1 and a H1-mismatch occurs, the RX recycle is prevented, the full packet is received, the MCU is notified, and the H1_FAIL flag stays asserted. In this case, the H1-fail flag will stay asserted until the next RX warmup (specifically, rx_init clears the bit).

The equation for H1_FAIL is thus:

H1_FAIL = [$H1_{received}$^H1_MATCH[15:0]) & H1_MASK > 0

PAYLOAD

In the GENERIC_FSK packet structure, the payload directly followed the header. For transmission, payload bytes are serialized, and transmitted, LSB first, in order, as they are received from the Packet Buffer interface. During reception, payload bytes are received LSB first, undergo serial-to-parallel conversion to octets, 4 octets are packed into a 32-bit word, and the word is transferred to memory via Packet Buffer. For both TX and RX, since the packet processor interprets the extracted LENGTH to represent the number of Payload + CRC octets, the actual number of payload octets is computed from the following equation:

Number_of_Payload_Octets = ($LENGTH_{extracted}$ + LENGTH_ADJ – CRC_SZ)

For TX, payload bytes are subjected to whitening . They are also shifted through CRC to compute a CRC checksum value. Whitening and CRC computing are all optional. For RX, payload bytes are subjected to de-whitening and CRC verification. De-whitening and CRC verification are all optional. For both TX and RX, (de-)whitening can precede CRC, or follow it. For more details on CRC, whitening, see Section Bitstream Processing.

CRC

In the GENERIC_FSK packet structure, the CRC field directly followed the payload. The size of the CRC field, in octets, is set by the CRC_SZ register. The valid range for CRC_SZ is:

0 <= CRC_SZ <= 4

For both TX and RX, the portion of the packet which are subjected to CRC is programmable, via the register CRC_START_BYTE[3:0]. The register CRC_START_BYTE programs the absolute byte count of the first byte for which CRC shifting is desired. The CRC_START_BYTE value is referenced to the GENERIC_FSK Byte Counter. The Byte Counter starts at 0 for the first octet of Sync Address, and increments octet-for-octet henceforth, until the last octet of CRC is transmitted or received. An example of CRC_START_BYTE programming is shown below.

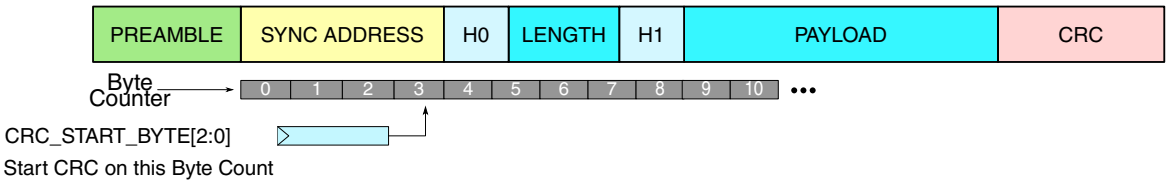

Figure 412. CRC Start Byte

In this example

SYNC_ADDR_SZ = 4

Header Size = 4 i.e. (H0_SZ + LENGTH_SZ +H1_SZ)/8 = 4

To initiate CRC shifting at the start of Sync Address, program CRC_START_BYTE = 0

To initiate CRC shifting at the start of Header, program CRC_START_BYTE = 4

To initiate CRC shifting at the start of Payload, program CRC_START_BYTE = 9

The CRC_START_BYTE should not be programmed so large as to exceed the length of the PDU; that is, larger than extracted LENGTH – CRC_SZ. If CRC_SZ=0, program CRC_START_BYTE=0.

For more details on how the GENERIC_FSK packet processor controls the CRC generation and verification processes, see Section Bitstream Processing.

EXAMPLE

A real-world example follows, describing how the GENERIC_FSK Link Layer packet configuration can be applied to transmit and receive packets which conforms to, e.g., IEEE 802.15.4-2015 SUN FSK PHY packet format.

IEEE 802.15.4-2015 SUN FSK PHY header(PHR) is as follows.

Table 478. Format of the PHR(without mode switching) for MR-FSK

Bit string index	0	1-2	3	4	5-15
Bit mapping	MS	R_1-R_0	FCS	DW	L_{10}-L_0
Field Name	Mode Switch	Reserved	FCS Type	Data Whitening	Frame Length

The GENERIC_FSK Link Layer controller supports such a header format, and can be programmed to transmit and receive packets which conform to it. To correctly size and order the GENERIC_FSK header elements so as to conform with this header format:

1. The LENGTH field ends the header, so there is no H1 (H1_SZ=H1_MASK=0)
2. The 5 bits which precede LENGTH in the header, are grouped into H0 (H0_SZ=5)
3. The size of the LENGTH field is 11 bits (LENGTH_SZ=11)
4. The LENGTH is specified as MSB-first (LENGTH_BIT_ORD=1)

For this example, we would like to leverage the H0-filtering capability built into the GENERIC_FSK Link Layer to screen the 802.15.4-2015 SUN FSK header, to require that the bit fields in the received packet comply with the following conditions:

1. MS (Mode Switch, bit [0] of header) = 0
2. DW (Data Whitening, bit [4]) = 1
3. FCS (FCS Type, bit [3]) = 1 (Four-octet FCS)
4. Bits [1] and [2] are marked as Reserved, to be ignored on reception

Given these parameters, the following diagram shows how we would program the GENERIC_FSK Link Layer controller to accept this packet configuration, and then screen H0 accordingly:

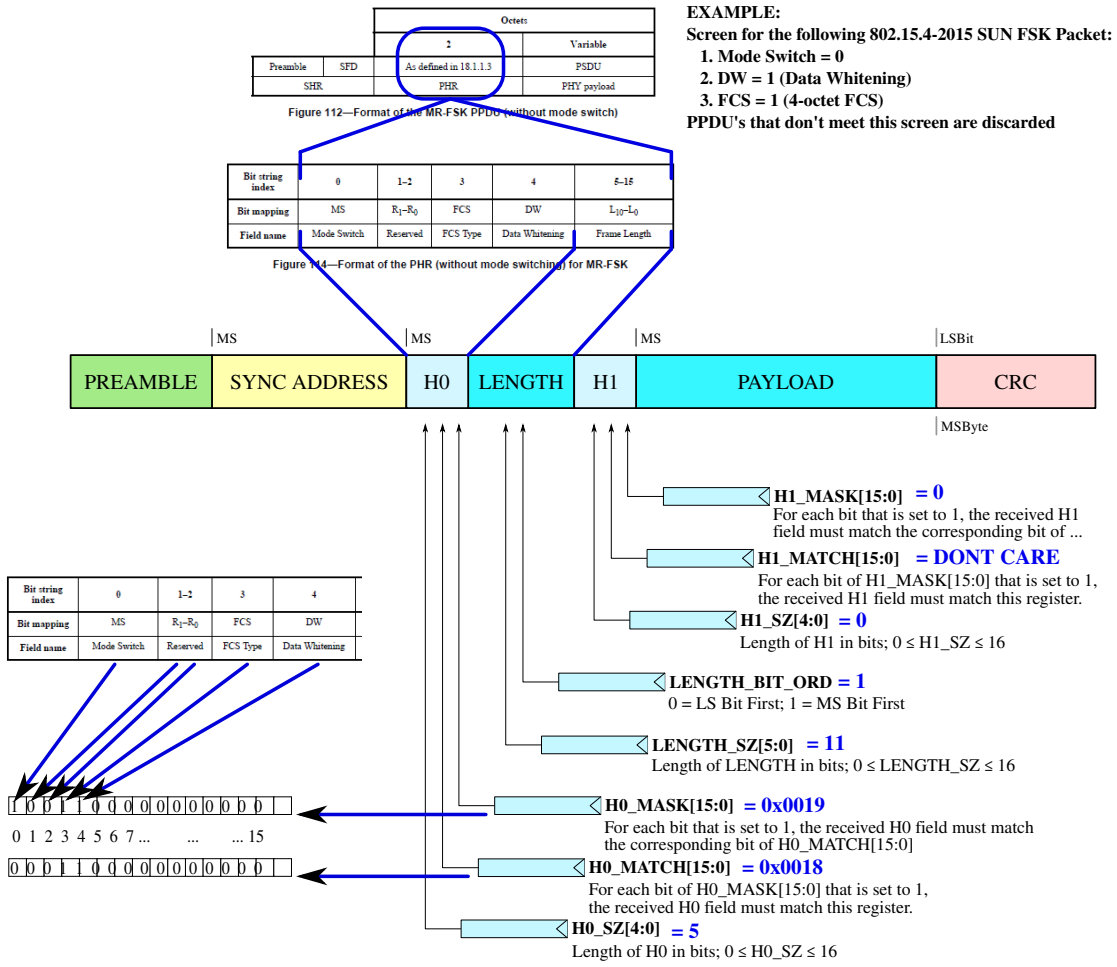

Figure 413. GENERIC FSK PACKET STRUCTURE AS APPLIED TO 802.15.4-2015 SUN FSK PHR

Received packets which meet the H0 filtering screen are fully received, and Data Indication is provided to the host processor. Packets which fail the screen result in an RX recycle, and no notification to the host.

55.4.9.2.3.2 Bitstream Processing

The CRC/Whitener block is inside RBME.

The GENERIC_FSK Link Layer controller provides control for CRC verification and Data De-whitening as the packet is being received.

The RBME provides control for CRC generation and Data Whitening as the packet is being transmitted.

The following diagram provides another perspective of bitstream processing.

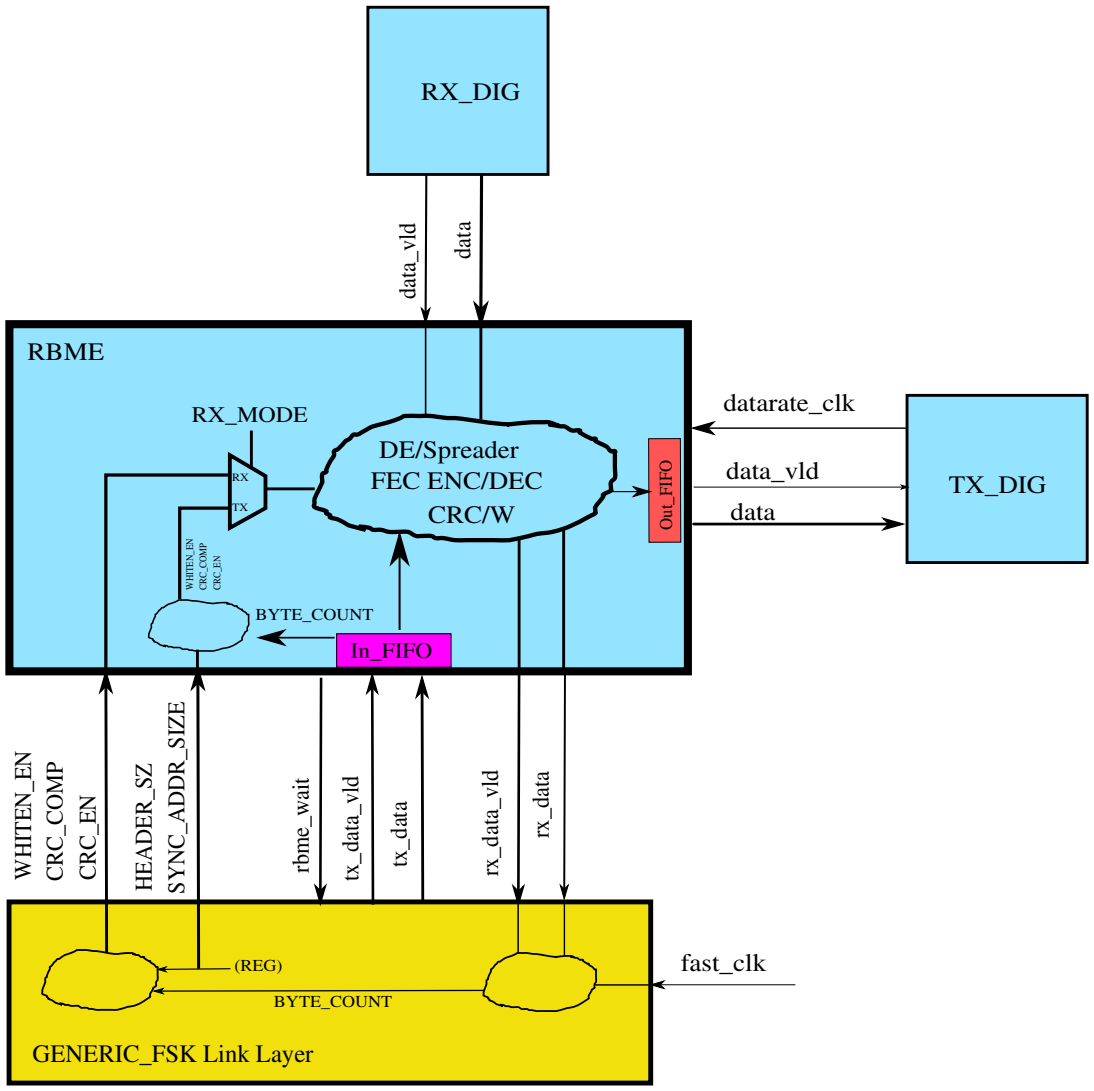

Figure 414. Basic Bitstream Between RBME and Link Layer

The following sections provide more detail on how CRC and whitening, are controlled, and describes the configuration options associated with each.

CRC & WHITENING

The GENERIC_FSK Link Layer controller dynamically manages CRC verification process (for RX), RBME manages the CRC generation process (for TX), by way of 3 timing signals that it asserts to the CRC/Whitener module.

The CRC engine in the CRC/Whitener block shall only shift incoming bits (data_in) through its LFSR when all the following conditions are met:

1. crcw_init=0
2. crc_en=1
3. tx_data_in_vld=1 (signal is data_in_vld at the CRC/Whitener)

The CRC/Whitener shall only shift bits out of its CRC LFSR, to the TX digital block, when all the following conditions are met:

1. crcw_init=0
2. crc_comp=1

3. tx_data_in_vld=1 (signal is data_in_vld at the CRC/Whitener)

The GENERIC_FSK Link Layer and RBME use the extracted LENGTH field of the packet, as well as the registers which control the size of the individual packet elements, in order to determine when to assert the CRC-related control signals, **crc_en** and **crc_comp**. This is true for both transmission and reception.

The calculations used by the GENERIC_FSK Link Layer to determine when to assert the CRC-related control signals are summarized in the Figure 415.

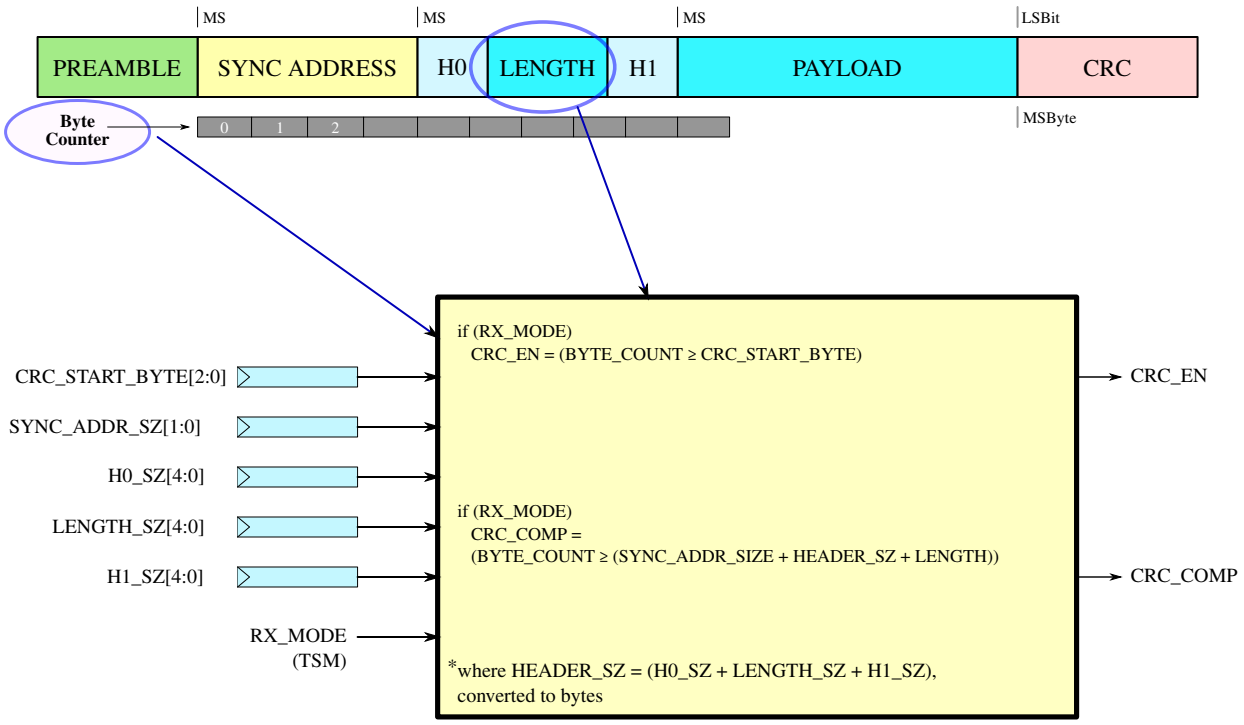

Figure 415. CONTROL OF CRC IN LINK LAYER (RX)

The calculations used by the RBME to determine when to assert the CRC related control signals are summarized in the Figure 416.

Note, the RBME and Link Layer has their own BYTE_COUNT, for TX and RX respectively.

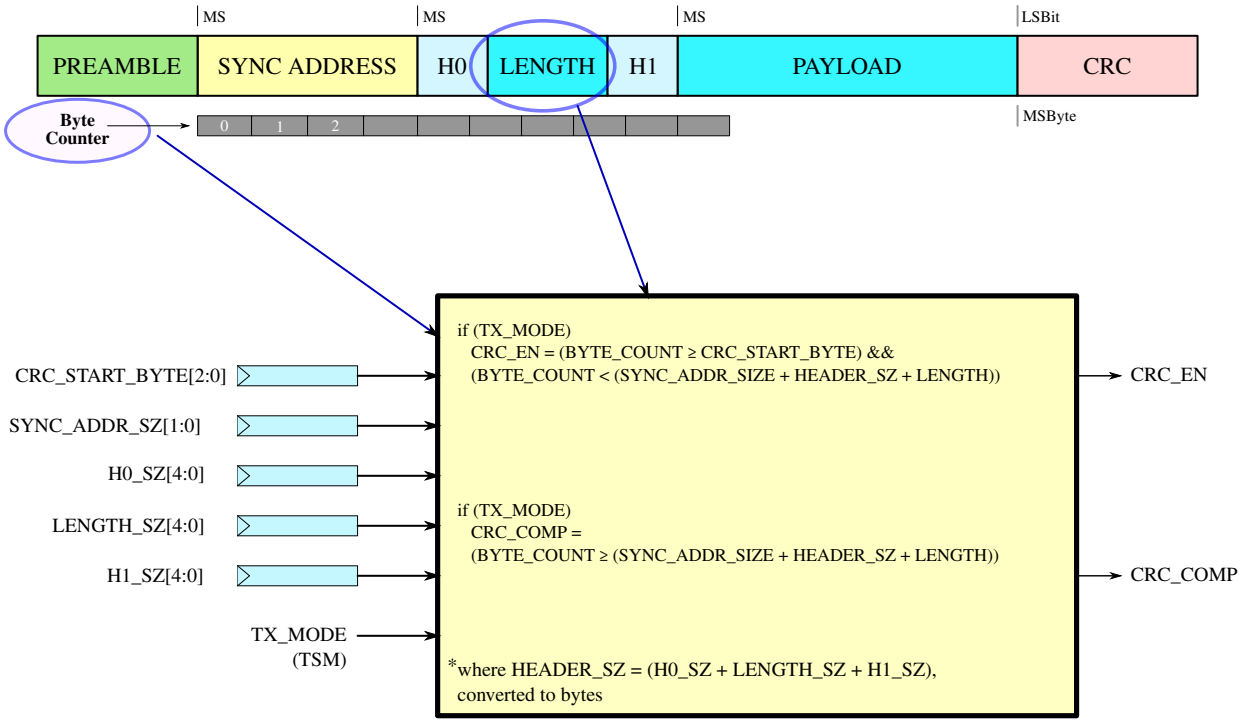

Figure 416. CONTROL OF CRC IN RBME (TX)

Likewise, the Link Layer controller and RBME optionally enables whitening and de-whitening of the packet bitstream, and controls the portions of the packet which are subjected to whitening. For both TX and RX, the portion of the packet which are subjected to whitening/de-whitening is programmable; the following table describes the 3 registers which determine which elements of the packet bitstream are whitened/de-whitened.

REGISTER NAME	FUNCTIONAL DESCRIPTION
WHITEN_START[1:0]	**0**: No whitening/de-whitening **1**: Begin whitening/de-whitening at the start of the header (H0) field, regardless of packet length. **2**: Begin whitening/de-whitening at the start of the header H1 field, but only if the extracted length field meets or exceeds WHITEN_SZ_THR, i.e., ($LENGTH_{extracted}$ >= WHITEN_SZ); otherwise, there is no whitening/de-whitening of the bitstream **3**: Begin whitening/de-whitening at the start of the PAYLOAD, but only if the extracted length field meets or exceeds WHITEN_SZ_THR, i.e., ($LENGTH_{extracted}$ >= WHITEN_SZ); otherwise, there is no whitening/de-whitening of the bitstream
WHITEN_END	**0**: Whitening/de-whitening ends with the last bit of the last PAYLOAD byte

Table continues on the next page...

Table continued from the previous page...

REGISTER NAME	FUNCTIONAL DESCRIPTION
	1: Whitening/de-whitening ends with the last bit of the last CRC byte
WHITEN_SZ_THR[12:0]	If WHITEN_START=2 or WHITEN_START=3, apply whitening/de-whitening at the point determined by WHITEN_START, but only if the extracted LENGTH field of the packet meets or exceeds this WHITEN_SZ_THR threshold; if LENGTHextracted < WHITEN_SZ_THR, there is no whitening/de-whitening of the bitstream. If WHITEN_START < 2, this register has no effect.

The GENERIC_FSK Link Layer controller dynamically manages the data whitening process (for TX), and de-whitening (for RX), via 2 timing signals that it asserts to the CRC/Whitener module.

The Whitening/de-whitening engine in the CRC/Whitener block shall only shift incoming bits (data_in) through its LFSR when all the following conditions are met:

1. crcw_init=0
2. whiten_en=1
3. tx_data_in_vld=1 (signal is data_in_vld at the CRC/Whitener)

The GENERIC_FSK Link Layer and RBME use the extracted LENGTH field of the packet, as well as the registers which control the size of the individual packet elements, in order to determine when to assert the whitening-related control signal, whiten_en. This is true for both transmission and reception.

The calculations used to determine when to assert whiten_en control signals are summarized in the following diagram.

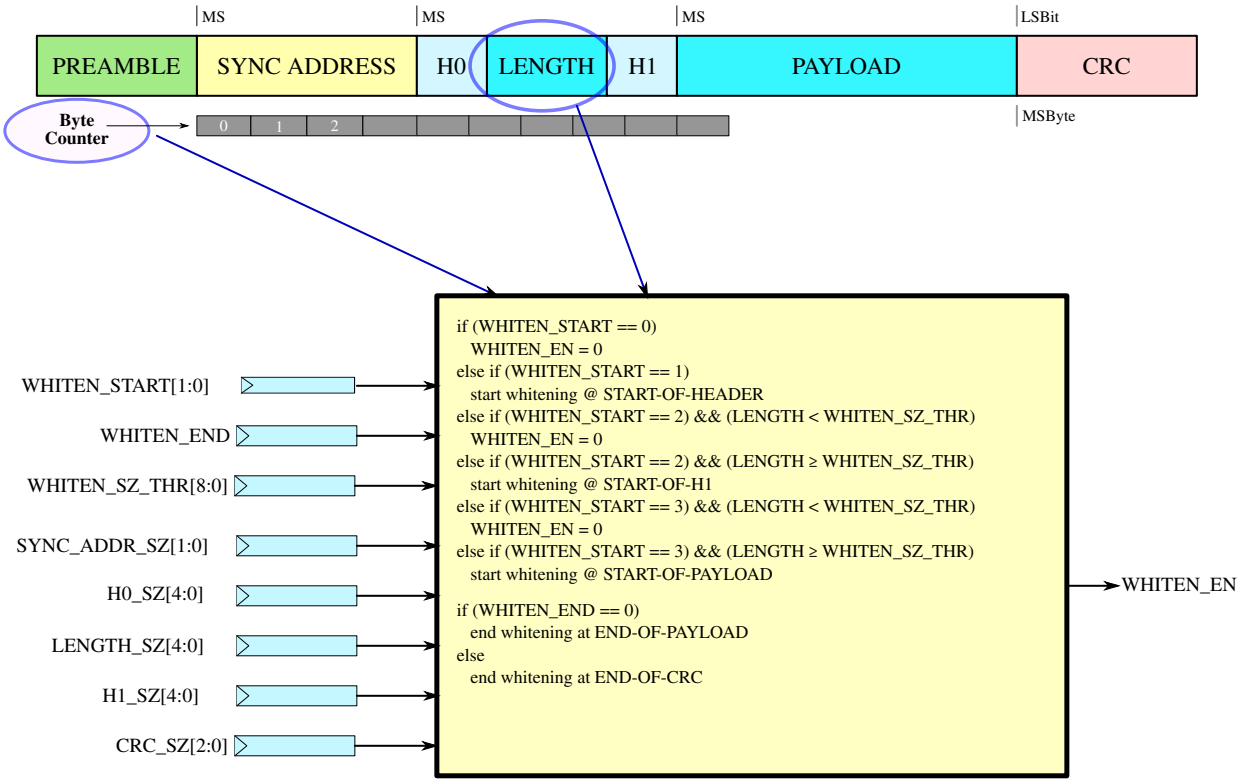

Figure 417. CONTROL OF WHITENING (TX and RX)

The order in which CRC and whitening are performed, is configurable, via the static register bit WHITEN_B4_CRC. This bit is programmed in the RBME, and sent to the CRC/Whitening engine to control the ordering. The following table describes how the bitstream is processed for both settings of WHITEN_B4_CRC, for both TX and RX.

	TX	RX
WHITEN_B4_CRC=1	In the CRC/Whitener, the CRC engine shifts in data bits which have been whitened first through the whitener LSFR. The entire post-whitened bitstream is then transmitted to the TX Digital.	Since the entire bitstream, including CRC, has been pre-whitened, the incoming bitstream from the PHY is shifted directly through the CRC LFSR to verify the checksum. The entire bitstream is simultaneously de-whitened by the whitener LFSR and shifted out to the Link Layer.
WHITEN_B4_CRC=0	In the CRC/Whitener, the CRC engine shifts in data bits which have not been whitened. Whitening is performed on the CRC LFSR output. The entire post-whitened bitstream is then transmitted to the TX Digital.	The entire bitstream is de-whitened first by the whitener LFSR, and then shifted through the CRC LFSR to verify the checksum. The entire de-whitened bitstream is simultaneously shifted out to the Link Layer.

A diagram depicting an example of bitstream processing flow during packet transmission, with WHITEN_B4_CRC=1 (the register default), is shown below.

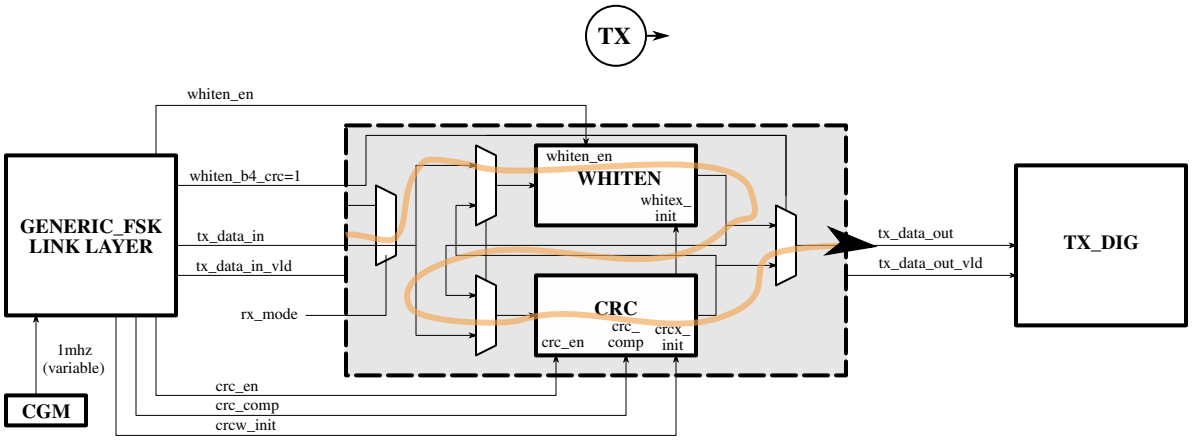

Figure 418. Whitening Before CRC (TX)

A diagram depicting an example of bitstream processing flow during packet reception, with WHITEN_B4_CRC=1, is shown below.

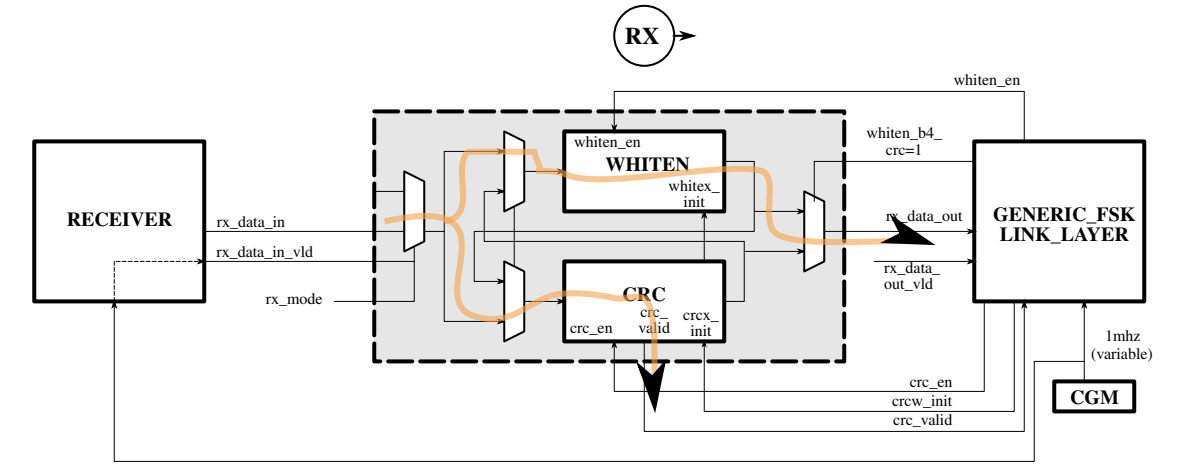

Figure 419. Whitening Before CRC (RX)

A timing diagram depicting a real-world example of TX bitstream processing timing is shown below. In this example, the desired start point for CRC shifting is the start of Network Address, so CRC_START_BYTE=0. The desired start point for whitening is the start of the header (H0), so WHITEN_START=1. It is also desired to stop whitening after the last bit of the last PAYLOAD byte, so WHITEN_END=0.

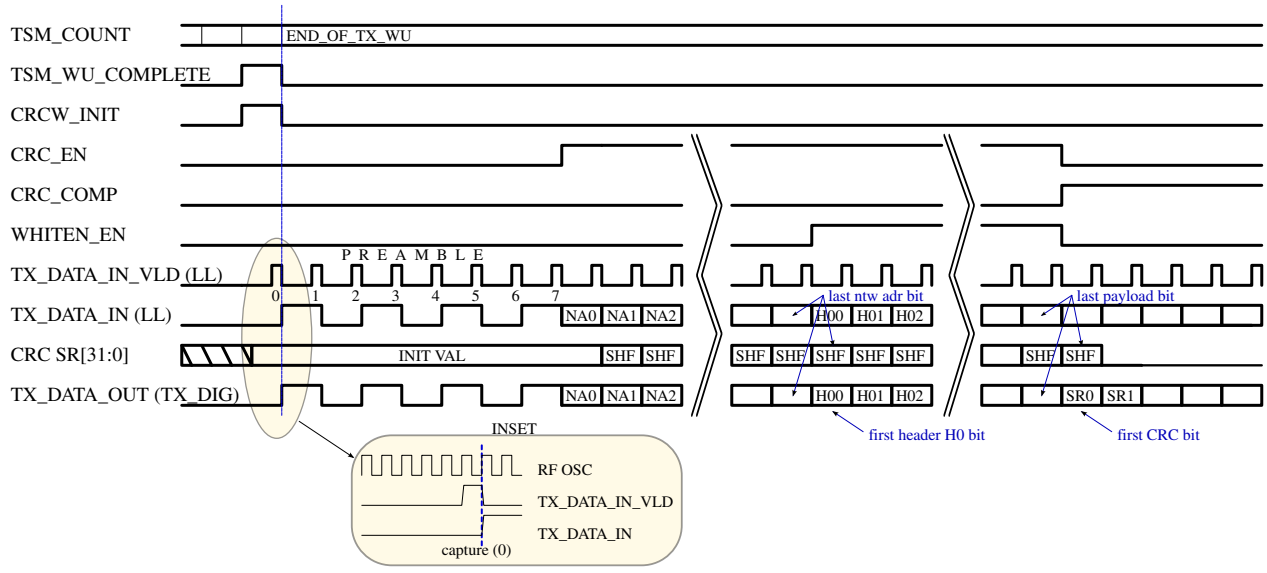

Figure 420. BIT STREAM PROCESSING CRC AND WHITENING TX TIMING

The bitstream depicted in the previous timing diagram, with CRC and whitening applied, is shifted out to the TX digital block, and transmitted over the air. A receiving device, will receive and process this same bitstream, by applying de-whitening, and verifying CRC on the de-whitened bitstream. The CRC and whitening parameters (registers) would be programmed to the receiving device, identically to how they are programmed for the transmitting device, specifically:

CRC_START_BYTE=0

WHITEN_START=1

WHITEN_END=0

A similar timing diagram depicting this RX bitstream processing timing, is shown below.

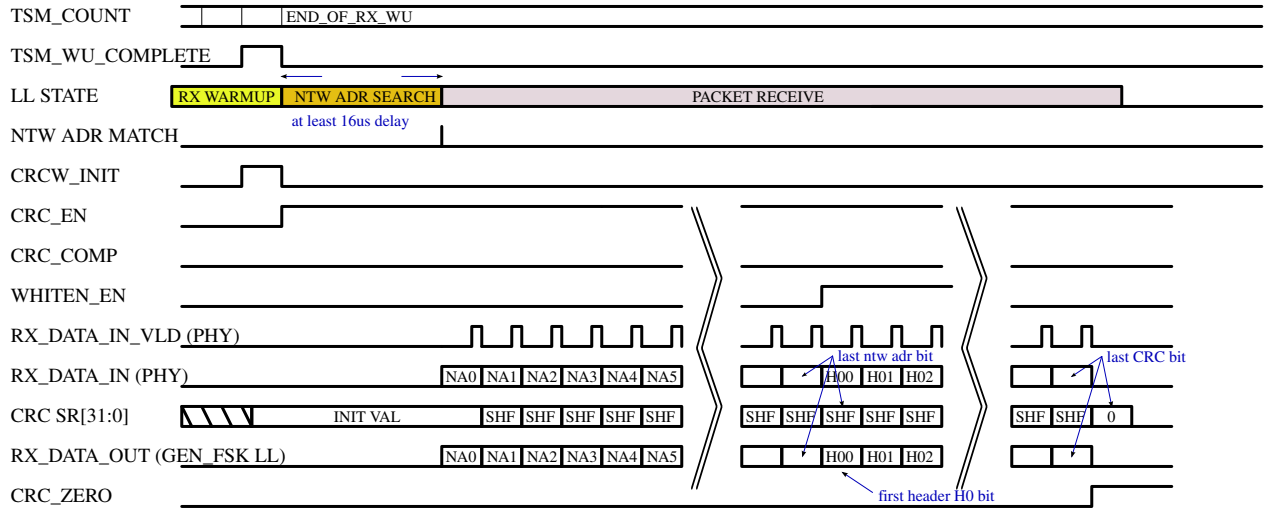

Figure 421. BIT STREAM PROCESSING CRC AND WHITENING RX TIMING

The GENERIC_FSK Link Layer controller provides a special whitening option, that causes the whitening LFSR to be re-initialized at the start of the PAYLOAD. The register bit WHITEN_PAYLOAD_REINIT, when 1, will result in the LFSR being re-initialized to its programmed initial state, determined by WHITEN_SEED[8:0], coincident with the first bit of the first byte of PAYLOAD. This applies to both TX and RX. When WHITEN_PAYLOAD_REINIT=0, there is no such re-initialization. This feature is only relevant when whitening/de-whitening is programmed to start before the PAYLOAD, i.e., WHITEN_START=1 or WHITEN_START=2.

The RBME provides a number of other configurability options, which affect the internal operation of the CRC engine, and not the Link Layer controller. A listing of these registers which affect CRC internal operation, appears in the table below. For more details on how these registers affect CRC operation, see the CRC/Whitener Chapter.

CRC-related Register	Brief Description
CRC_POLY[31:0]	CRC Polynomial 1: XOR exists in the bit's feedback path 0: no XOR in the bit's feedback path
CRC_SEED[31:0]	CRC Initialization Value
CRC_BYTE_ORD	0: LS Byte First 1: MS Byte First
CRC_REF_IN	0: do not manipulate input data stream 1: reflect each byte in the input stream bitwise
CRC_REF_OUT	0: do not manipulate CRC result 1: CRC result is to be reflected bitwise (operated on entire word)
CRC_XOR_OUT[31:0]	XOR mask for CRC result (for no mask, should be 0)

Similarly, there are a number of configurable whitening options provided by the RBME, which affect the internal operation of the whitening engine, and not the Link Layer controller. A listing of these registers which affect whitener internal operation, appears in the table below. For more details on how these registers affect whitener operation, see the CRC/Whitener Chapter.

Whitener-related Register	Brief Description
WHITEN_ POLY[8:0]	Polynomial Value for Whitening/De-whitening
WHITEN_POLY_TYPE	Whiten polynomial type. A Fibonacci type LFSR is used with the whiten polynomial if this bit is asserted. Otherwise, a Galois type LFSR is used.
WHITEN_SEED[31:0]	Initialization Value for Whitening/De-whitening
WHITEN_SIZE[3:0]	Whitener Length
WHITEN_REF_IN	The input data stream is reflected, bit-wise, per byte, if this bit is asserted. Bit 7 becomes bit 0, bit 6 becomes bit 1, etc. This bit will only cause the reflection of the payload data bits as they are used in the whiten calculation and will not cause any change in the output bit order.

55.4.9.2.3.3 Fixed Packet Length

The GENERIC_FSK Link Layer controller expects a stream of consecutive bits specifying the length of the packet, to be transmitted and received over-the-air, as part of the packet bitstream, with the length specification typically encoded into the packet header, as shown below.

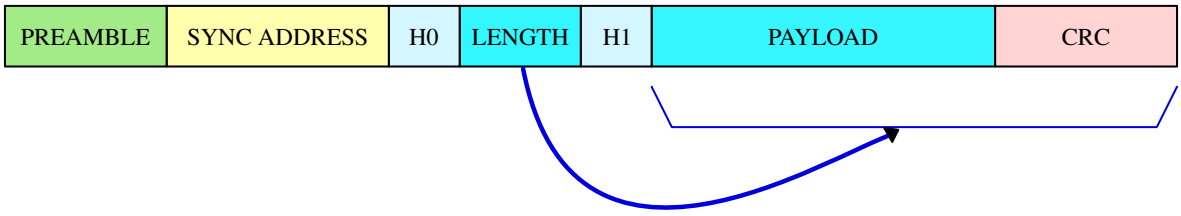

Figure 422. PACKET STRUCTURE WITH LENGTH FIELD IN HEADER

Some protocols don't include any length instructions in the packet header, as shown below.

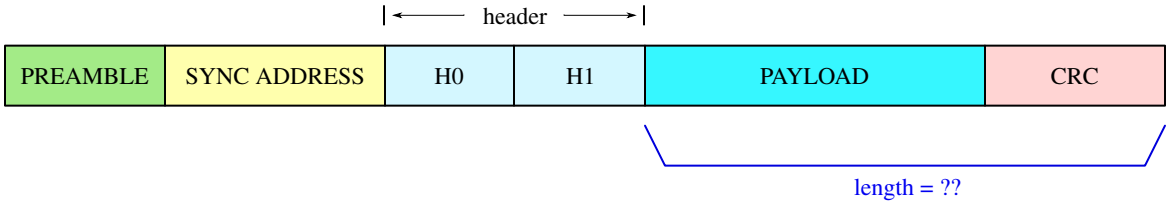

Figure 423. PACKET STRUCTURE WITH NO LENGTH FIELD IN HEADER

And, some protocols may not include a header at all.

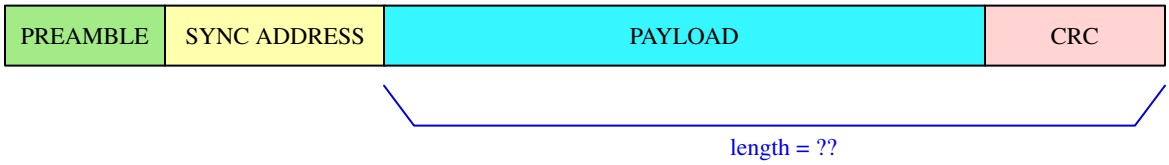

Figure 424. PACKET STRUCTURE WITH NO HEADER

In the aforementioned cases, another method of specifying length to the GENERIC_FSK Link Layer hardware must be employed. In both cases, if the length is not specified as part of the over-the-air bitstream, then GENERIC_FSK software must know the length in advance of the TX or RX operation, or know how to calculate it. So GENERIC_FSK software will provide this information to the hardware, in advance of the TX or RX operation, by programming the following registers:

- PACKET_CFG[LENGTH_SZ] = 0 : instructs the hardware that there is no LENGTH info in the packet header, and thus forces the hardware to use LENGTH_ADJ for packet length
- PACKET_CFG[LENGTH_ADJ] = ??? : program the desired (known) length of PAYLOAD + CRC
- CRC_CFG[CRC_SZ] = ??? : program the desired number of CRC octets

As an example, a packet is to be transmitted or received using the GENERIC_FSK Link Layer hardware. The packet has no header, but the length of the payload is known in advance to be 57 octets, and the number of CRC octets is 3. In this case, LENGTH_ADJ is programmed to 60 (57 + 3) and CRC_SZ is programmed to 3, as shown below.

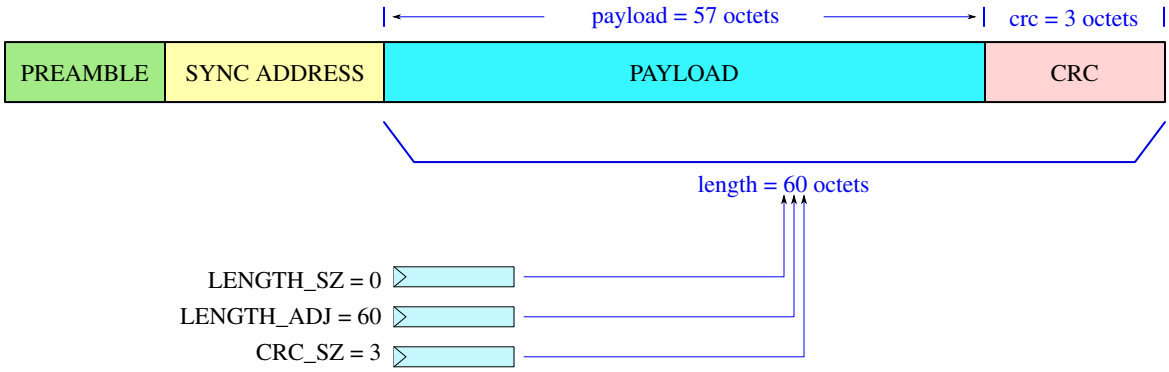

Figure 425. PACKET STRUCTURE WITH NO HEADER AND FIXED PACKET LENGTH

55.4.9.2.3.4 Packet Storage

The GENERIC_FSK Link Layer has access to a Packet Buffer (also known as Packet RAM), to store data to be transmitted, and to receive incoming packet data. The GENERIC_FSK Link Layer software prepares data to be transmitted, by loading the octets, in order, into the Packet Buffer. After reception, the octets received over the air are stored into the Packet Buffer, in the order they are received. The Packet Buffer contains separate spaces for TX and RX data, so incoming receive octets don't overwrite previously-loaded content intended for transmission. The Packet Buffer is large enough to accommodate the longest GENERIC_FSK packet, 2047 octets, plus header and CRC octets, for either transmit or receive.

The GENERIC_FSK Packet Buffer is contained within the multi-protocol Packet RAM. When operating in GENERIC_FSK mode, the entire Packet RAM is allocated to the GENERIC_FSK packet buffer. Separate TX and RX buffers within the consolidated RAM means that incoming RX packets don't overwrite TX packet data. Because the Packet RAM is 32/64bits wide, the GENERIC_FSK Link Layer controller hardware will address the consolidated RAM in an interleaved fashion as it stores octets to, or fetches octets from, the RAM-based packet buffer.

During packet reception, the MCU is allowed to access the RX packet buffer of the consolidated RAM, in order to download the packet while it's being received, if so desired. In cases where both the MCU and the GENERIC_FSK Link Layer controller attempt to simultaneously access the RAM during reception, internal hardware arbitration is provided to delay the MCU access until the GENERIC_FSK Link Layer completes its access to the RAM. Link Layer accesses complete in a single reference oscillator clock period, so one and only 1 wait state shall be inserted on the IPS bus whenever access attempts coincide.

During packet transmission, MCU access to the consolidated RAM is not allowed. The GENERIC_FSK software must program the TX buffer before commanding a TX operation, and must not access the RAM during the transmission.

As mentioned previously, incoming receive data lands in the RX section of the Packet Buffer. Nominally, a newly received packet will overwrite the contents of the previously received packet (the TX section of the Packet Buffer remains intact). Software can inhibit receive-packet overwriting of the RX section of the Packet Buffer contents by setting the PB_PROTECT bit in the PACKET_RAM_CTRL register. When this bit is set, incoming receive data will be blocked from overwriting the existing contents of the RX section of the Packet Buffer. This will block RX packet overwriting, but will not inhibit TX content loading of the TX section of the Packet Buffer.

GENERIC_FSK software must not attempt to access the Packet RAM unless GENERIC_FSK Link Layer is the controlling Link Layer.

When using another Link Layer, if the GENERIC_FSK Link Layer software attempts to access the Packet RAM via the GENERIC_FSK IPS bus, the access attempt will fail, as described below:

1. RAM contents shall not be altered on a GENERIC_FSK write attempt
2. Readback data on a GENERIC_FSK read attempt shall be indeterminate
3. The **ips_xfr_err** shall be asserted on the GENERIC_FSK IPS bus

55.4.9.2.3.5 Send and Receive multiple packets

The feature of "Send and Receive multiple packets" is enabled by setting the register MULT_PKT_EN.

To support this, the Tx and Rx RAM are divided into segments with same size. The segment size is defined by register SEG_SZ.

The first packet received is stored in the Segment 0. The second packet is stored in Segment 1, and so on. Register PKT_INDEX is initially 0 and is automatically increased by 1 after successfully received a packet. So PKT_INDEX has two meanings: the number of packet received; the segment number to store the next coming packet.

Tx is like the Rx process. The first packet to sent is placed in Segment 0. After transmitted the first packet, the PKT_INDEX is automatically increased to 1, and so on. So PKT_INDEX has two meanings in Tx: the number of packet sent; the segment number to send the next packet.

User should monitor the PKT_INDEX to avoid it moves to outside of Tx/Rx RAM.

User should write RESET_PKT_IDX to clear the PKT_INDEX to 0 before the round of packet reception.

Figure 426 shows an example of 8 packets. After received or sent 8 packets, the PKT_INDEX is increased to 8. If user wants to start another around, the PKT_INDEX should be cleared to 0.

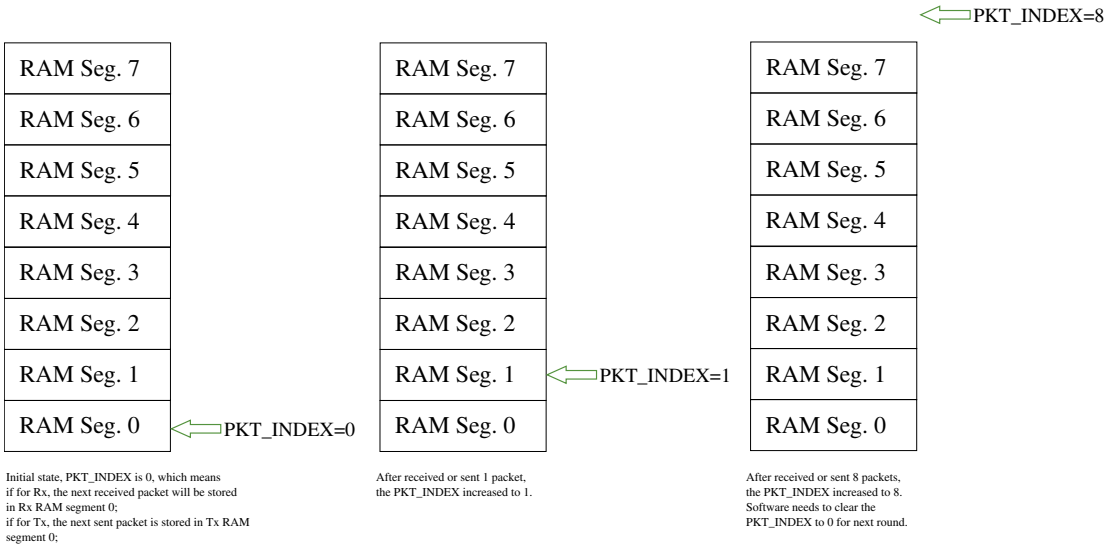

Figure 426. Send or Receive 8 packets

Notes:

1. If a packet is recieved with error, like CRC fail, and this fail causes the link layer to recycle, the PKT_INDEX will not be increased. This means link layer ignores the current received packet
2. For Rx with AutoACK case, the PKT_INDEX is increased after Rx is done. The AutoACK packet is not effected by PKT_INDEX. It is always in the dedicated RAM.
3. For TR case, the PKT_INDEX is increased after the TR sequence end. The T and R sequence use the same PKT_INDEX to detemine the segment to send or receive a packet.

55.4.9.2.3.6 Timebase

The GENERIC_FSK Link Layer includes a dedicated, 32-bit multi-purpose Event Timer (EVENT_TMR), that is updated at a 1 MHz rate. The EVENT_TMR maintains the timebase for all GENERIC_FSK-related activities, except during intervals of Deep Sleep Mode. The clock source for the EVENT_TMR is a high-precision, crystal-referenced RF Oscillator, which can be either 32MHz or 26MHz. The RF Oscillator is divided down to 1MHz for GENERIC_FSK in the Clocks Generation Module (CGM). To reduce power consumption to a minimum, most of the GENERIC_FSK Link Layer Controller runs off this 1MHz clock. The exceptions are the Register IP bus interface, Command Decoder, and Interrupt Control Unit, parts of which must run at the IP bus frequency.

The 32-bit EVENT_TMR running at 1 MHz rolls over (wraps around) approximately every 4295 seconds.

The EVENT_TMR count can be read at any time, via the register of the same name. A 32-bit read is recommended to ensure coherency of the 4 bytes that make up the counter. No synchronization to the IP bus is required.

If the EVENT_TMR needs to be updated (changed), this can be done by writing the new, desired EVENT_TMR value to the register EVENT_TMR_LD. The update to EVENT_TMR will take effect at the next 1MHz clock edge.

If it is desired to increment the EVENT_TMR by a known amount, this can be done by writing the desired increment value to the EVENT_TMR_ADD register. The increment value is 32-bit signed, thus enabling a decrement function as well. The update to EVENT_TMR will take effect immediately. The EVENT_TMR_ADD avoids the necessity to perform an read-modify-write operation to the EVENT_TMR to adjust its value; this facilitates accurate restoration of the EVENT_TMR state after a period of Deep Sleep Mode.

Two 32-bit timer-compare registers are provided, T1_CMP and T2_CMP.

GENERIC_FSK software may load T1_CMP with a future EVENT_TMR count value. When EVENT_TMR reaches the T1_CMP value, either (or both) of the following events can be triggered:

1. T1_IRQ (Interrupt)
2. Sequence Command Trigger (can automatically launch or stop a transceiver operation)

Similarly, GENERIC_FSK software may load T2_CMP with a future EVENT_TMR count value. When EVENT_TMR reaches the T2_CMP value, either (or both) of the following events can be triggered:

1. T2_IRQ(Interrupt)
2. Sequence Command Trigger (can automatically launch or stop a transceiver operation)

For either type of T1-triggered events to be enabled, i.e., interrupt or sequence-launch, set T1_CMP_EN=1 after loading T1_CMP with the desired value. If T1_CMP_EN=1, the T1_IRQ interrupt status bit will always become set on a T1 timer match. (Whether or not T1_IRQ generates an GENERIC_FSK Interrupt to the MCU depends on the settings of T1_IRQ_EN and GENERIC_FSK_IRQ_EN, see section: Interrupts). If T1_CMP_EN=0, neither an interrupt nor a sequence command can be triggered by a T1 match.

For either T2-triggered events to be enabled, i.e., interrupt or sequence launch, set T2_CMP_EN=1 after loading T2_CMP with the desired value. If T2_CMP_EN=1, the T2_IRQ interrupt status bit will always become set on a T2 timer match. (Whether or not T2_IRQ generates a GENERIC_FSK Interrupt to the MCU depends on the settings of T2_IRQ_EN and GENERIC_FSK_IRQ_EN, see Section: Interrupts). If T2_CMP_EN=0, neither an interrupt nor a sequence command can be triggered by a T2 match.

See Section Interrupts for a description of how the Link Layer Controller manages the T1 and T2 interrupts, and how software can clear them.

See Section Sequence Manager for a description on how to launch and stop sequences on T1 and T2 timer matches.

55.4.9.2.3.7 Sequence Manager

55.4.9.2.3.7.1 Introduction

This Section describes the Generic Link Layer Sequence Manager (GSM).

55.4.9.2.3.7.1.1 Overview

The GSM is a hardware state machine which controls the timing of all transmit, receive, and CCA operations for the Link Layer.

Designed into the GSM are a variety of complex sequences, called autosequences, which are sequential concatenations of simpler, building-block sequences. The hardware autosequences provide the following advantages:

- smaller SW memory footprint: HW automates operations previously done by SW
- increases MCU sleep times, reducing current consumption
- handles timing-critical sequences (rx-to-tx), e.g., data-polling, not possible in SW

Sequences can be initiated by software directly, or alternatively, can be initiated automatically at the expiration of a hardware timer. The general parameters of the sequences can be programmed by software prior to initiating the sequences. Such parameters allow software to select, for example:

- whether CCA is required ahead of a transmit sequence
- whether an automatic Ack frame should be transmitted after a receive sequence
- slotted vs. unslotted mode
- whether the device is a PAN Coordinator or not
- whether the device resides on 2 networks simultaneously (Dual PAN mode)

55.4.9.2.3.7.1.2 Features

- Supports many working modes, defined by register GENLL_MODE
- Supports complex sequences
- Unburdens software by automating many transceiver operations
- Data-polling accelerator hardware enables critical-timing sequences
- Includes capability to conditionally perform CCA prior to every transmit operation
- Includes capability to conditionally transmit an Ack frame after every receive operation
- Supports software- or timer-initiated sequences
- Broad support of 2FSK/GFSK PHYs in IEEE 802.15.4-2015
- Supports slotted and unslotted modes
- Supports orderly transceiver shutdown on PLL unlock event
- Increases software visibility by making SEQ_STATE state readable
- Supports Dual PAN Mode, including on-the-fly channel changing

55.4.9.2.3.7.1.3 Modes and operations

The GSM controls, coordinates, and automates all transceiver operations within the 2.4GHz radio. Software selects the desired sequence, sets the general parameters, and (optionally) configures a hardware timer to trigger the sequence at a precise time in the future. Subsequently, the MCU can enter a low-power state, or tend to other activities, while the sequence manager state machine conducts the programmed transceiver operations. When the sequence completes, an interrupt alerts the MCU. At this point the MCU can check the completion status of the sequence, download received data from the packet buffer, and then prepare the next sequence. Sequences can be simple transceiver operations. For example, transmit one frame, or, perform a CCA on a channel. Alternatively, the sequence manager supports complex sequences, which use simple operations as building blocks, strung together in a back-to-back fashion, with precise timing intervals between operations. For example, a "TR" sequence calls for a transmit frame followed by a receive frame. For complex sequences, interrupts can optionally be generated at the completion of each stage of the sequence, providing greater visibility for the MCU into the timeline of the sequence. Software can determine the precise state of the sequence manager state machine at any time. Software can opt to abort a sequence at any time; when this happens, the sequence manager will return to its IDLE state in an orderly fashion.

55.4.9.2.3.7.2 Functional Description

The GSM provides a command set of transceiver commands, which can be used to launch and stop sequences. Software can issue sequence commands by writing to the SEQCMD(XCVSEQ) field of the XCVR_CTRL register. The SEQCMD field always reads back what was previously written by software, enabling software to quickly recall the last command written. The sequence commands are as listed in the table below:

SEQCMD[3:0]	COMMAND	DESCRIPTION
0x0	IDLE	Abort All - Cancels all pending events and abort any sequence-in-progress
0x1	TX_START_NOW	TX Start Now
0x2	TX_START_T1	TX Start @ T1 Timer Compare Match (EVENT_TMR = T1_CMP)
0x3	TX_START_T2	TX Start @ T2 Timer Compare Match (EVENT_TMR = T2_CMP)
0x4	TX_CANCEL	TX Cancel -- Cancels pending TX events but do not abort TX-in-progress[1]
0x5	RX_START_NOW	RX Start Now
0x6	RX_START_T1	RX Start @ T1 Timer Compare Match (EVENT_TMR = T1_CMP)
0x7	RX_START_T2	RX Start @ T2 Timer Compare Match (EVENT_TMR = T2_CMP)
0x8	RX_STOP_T1	RX Stop @ T1 Timer Compare Match (EVENT_TMR = T1_CMP)
0x9	RX_STOP_T2	RX Stop @ T2 Timer Compare Match (EVENT_TMR = T2_CMP)
0xA	RX_CANCEL	RX Cancel -- Cancels pending RX events but do not abort RX-in-progress[2]
0xB	ABORT	Abort All - Cancels all pending events and abort any sequence-in-progress
0xC	TR_START_NOW	TR Start Now
0xD	TR_START_T1	TR Start @ T1 Timer Compare Match (EVENT_TMR = T1_CMP)
0xE	TR_START_T2	TR Start @ T2 Timer Compare Match (EVENT_TMR = T2_CMP)
0xF	TR_CANCEL	TR Cancel -- Cancels pending TR events but do not abort TR-in-progress[3]
0x10	CCA_NOW	CCA Start Now
0x11	CCA_START_T1	CCA Start @ T1 Timer Compare Match (EVENT_TMR = T1_CMP)
0x12	CCA_START_T2	CCA Start @ T2 Timer Compare Match (EVENT_TMR = T2_CMP)
0x13	CCA_CANCEL	CCA Cancel -- Cancels pending CCA events but do not abort CCA-in-progress[4]

1. TX-in-progress implies TX Warmup is complete, and packet transmission is underway (i.e., command decoder state = TX_PKT)
2. RX-in-progress implies RX Warmup is complete, and Network Address search or packet reception is underway (i.e., command decoder state = RX_PKT)
3. TR-in-progress implies TX Warmup is complete, and packet transmission is underway (i.e., command decoder state = TX_PKT). For CCA+TX case, if cancel command is issued at CCA phase, then need to wait CCA complete, the following TX is cancelled.
4. CCA-in-progress implies RX Warmup is complete(i.e., command decoder state = RX_CCA1/RX_CCA2/CCA2_WAIT))

As described above, sequences can be launched immediately (actually on the next 1MHz clock edge) by issuing one of the following commands:

- TX_START_NOW
- RX_START_NOW
- TR_START_NOW

- CCA_START_NOW

Alternatively, sequences can be scheduled to launch (or stop) in the future on a T1 timer compare, by loading T1_CMP with the desired launch time (relative to the EVENT_TMR), setting T1_CMP_EN=1, and then issuing one of the following commands:

- TX_START_T1
- RX_START_T1
- RX_STOP_T1
- TR_START_T1
- CCA_START_T1

Similarly, sequences can be scheduled to launch (or stop) in the future on a T2 timer compare, by loading T2_CMP with the desired launch time (relative to the EVENT_TMR), setting T2_CMP_EN=1, and then issuing one of the following commands:

- TX_START_T2
- RX_START_T2
- RX_STOP_T2
- TR_START_T2
- CCA_START_T2

Any transceiver sequence that has been launched, either immediately (by way of the *_NOW commands), or in the future (by way of the *_T1 or *_T2 commands), can be terminated immediately by issuing the ABORT/IDLE command. This is true whether or not the sequence has actually begun, or is merely pending because the T1- (or T2-) match has not yet occurred. In either case, this is called a software abort. The ABORT/IDLE command will terminate any active sequence and cancel any pending events.

Regarding the issuance of sequence commands, both immediate and timer-triggered, software should be mindful of the following Guidelines and Restrictions:

PROGRAMING GUIDELINES AND RESTRICTIONS	
1	T1 can only be assigned to 1 function at a time {TX_START, RX_START, RX_STOP, TR_START, CCA_START}. Once assigned to a function, attempts to change the assignment will be ignored
2	T2 can only be assigned to 1 function at a time {TX_START, RX_START, RX_STOP, TR_START, CCA_START}. Once assigned to a function, attempts to change the assignment will be ignored
3	To change a T1- or T2- assignment, do one of the following first: **a.** issue an ABORT or IDLE command **b.** issue an TX_CANCEL command if T1 (or T2) is already assigned to TX_START, and the sequence has not yet started **c.** issue an RX_CANCEL command if T1 (or T2) is already assigned to RX_START or RX_STOP, and the sequence has not yet started **d.** issue an TR_CANCEL command if T1 (or T2) is already assigned to TR_START, and the sequence has not yet started **e.** issue an CCA_CANCEL command if T1 (or T2) is already assigned to CCA_START, and the sequence has not yet started

Table continues on the next page...

Table continued from the previous page...

PROGRAMING GUIDELINES AND RESTRICTIONS	
4	T1 and T2 should not be assigned to the same function (results are indeterminate)
5	If T1 and T2 are both assigned to functions, then T1_CMP shall not be equal to T2_CMP (results are indeterminate)
6	If any TX or RX or TR or CCA sequence is underway (e.g., TSM not idle), the ongoing sequence will not be interrupted or perturbed by any of the following: **a.** a T1 timer-match with T1 assigned to a function. The sequence trigger will be ignored, but the associated "pending" status bit will be cleared. **b.** a T2 timer-match with T2 assigned to a function. The sequence trigger will be ignored, but the associated "pending" status bit will be cleared. **c.** a TX_START_NOW or RX_START_NOW or TR_START_NOW or CCA_START_NOW command. Both commands will be ignored

The GSM controls high-level autosequence timing, but offloads low level warmup and warmdown tasks to a dedicated, protocol-neutral Transceiver Sequence Manager, or TSM (see TSM Chapter). The GSM initiates high-level functions, such as a CCA measurement operation or a transmit acknowledge operation, by commanding the TSM to execute an RX warmup, a TX warmup, a RX warmdown, a TX warmdown, or an RX recycle. Based on these commands, TSM generates the precise timing to control all of the digital, analog, and RF components of the TX and RX chains. The TSM is fully programmable, allowing all of the enabling and control signals to the transceiver components to be independently scheduled with 1us precision. TSM also allows all enable and control signals to be optionally overridden at any time, giving software complete control of each transceiver block, and ultimately the entire warmup/warmdown process if desired.

The GSM and TSM sequence managers operate on the same clock domain, and both have 1us resolution. The TSM is fully programmable, while the GSM is largely hardwired, with a few key exceptions. In the GSM/TSM relationship, GSM is the master and TSM is the slave. The key GSM/TSM interface signaling is shown below:

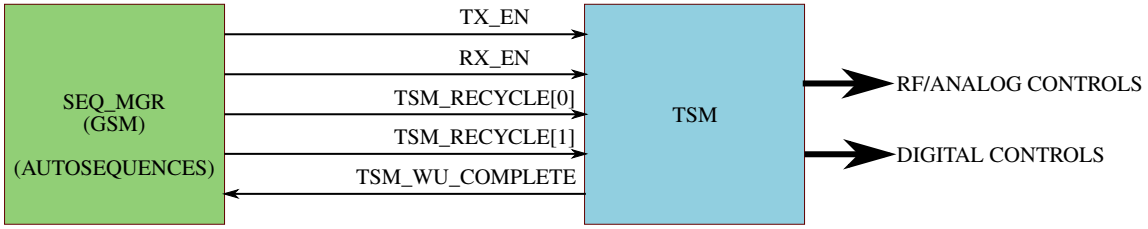

Figure 427. GSM/TSM INTERFACE SIGNALS

A description of the interface signals is provided in the table below.

GSM/TSM INTERFACE SIGNAL	DESCRIPTION
TX_EN	A low-to-high transition initiates a TSM TX warmup, starting 1us after the transition. A high-to-low transition initiates a TSM TX warmdown, starting 1us after the transition.
RX_EN	A low-to-high transition initiates a TSM RX warmup, starting 1us after the transition. A high-to-low transition initiates a TSM RX warmdown, starting 1us after the transition.

Table continues on the next page...

Table continued from the previous page...

GSM/TSM INTERFACE SIGNAL	DESCRIPTION
TSM_RECYCLE[0]	This signal asserts in the GSM RX_CYC state, and causes the TSM to jump from its "ON" phase, back to a point in the TSM RX warmup determined by the TSM's RECYCLE_COUNT0[7:0] register in XCVR space. This process is used to execute an RX recycle.
TSM_RECYCLE[1]	This signal asserts in the GSM RX_PAN1 state, and causes the TSM to jump from its "ON" phase, back to a point in the TSM RX warmup determined by the TSM's RECYCLE_COUNT1[7:0] register in XCVR space. This process is used to re-initialize the PLL digital on a new RF channel, during a Dual PAN mode on-the-fly channel change.
TSM_WU_COMPLETE	For the GSM states which assert TX_EN or RX_EN, this 1us-wide signal from the TSM indicates that the warmup is complete, and the GSM is now free to advance to its next state. The TSM_WU_COMPLETE is asserted 1us before the actual end of sequence, which is determined by the END_OF_TX_WU[7:0] register for TX warmup, and the END_OF_RX_WU[7:0] register for RX warmup.

The Command Decoder also maintains an set of status bits, that make it easy for Link Layer software to track, not only state, but pending events; that is, timer-linked events scheduled for future triggering. These status bits reside in the SEQ_STS register. A description of these bits is provided in the table below.

SEQSTS[12:0]	BIT	DESCRIPTION
TX_START_T1_PEND	[0]	TX Sequence will start @ next T1 Match
TX_START_T2_PEND	[1]	TX Sequence will start @ next T2 Match
TX_IN_WARMUP	[2]	TX Sequence in TSM Warmup
TX_IN_PROGRESS	[3]	TX Packet Transmission Currently Underway
TX_IN_WARMDN	[4]	TX Sequence in TSM Warmdown
RX_START_T1_PEND	[5]	RX Sequence will start @ next T1 Match
RX_START_T2_PEND	[6]	RX Sequence will start @ next T2 Match
RX_STOP_T1_PEND	[7]	RX Sequence will stop @ next T1 Match
RX_STOP_T2_PEND	[8]	RX Sequence will stop @ next T2 Match
RX_IN_WARMUP	[9]	RX Sequence in TSM Warmup
RX_IN_SEARCH	[10]	RX Sequence in Network Address Search
RX_IN_PROGRESS	[11]	RX Packet Reception Currently Underway
RX_IN_WARMDN	[12]	RX Sequence in TSM Warmdown
TR_START_T1_PEND	[13]	TR Sequence will start @ next T1 Match
TR_START_T2_PEND	[14]	TR Sequence will start @ next T2 Match
CCA_START_T1_PEND	[15]	CCA Sequence will start @ next T1 Match
CCA_START_T2_PEND	[16]	CCA Sequence will start @ next T2 Match

The GSM state diagram is shown below.

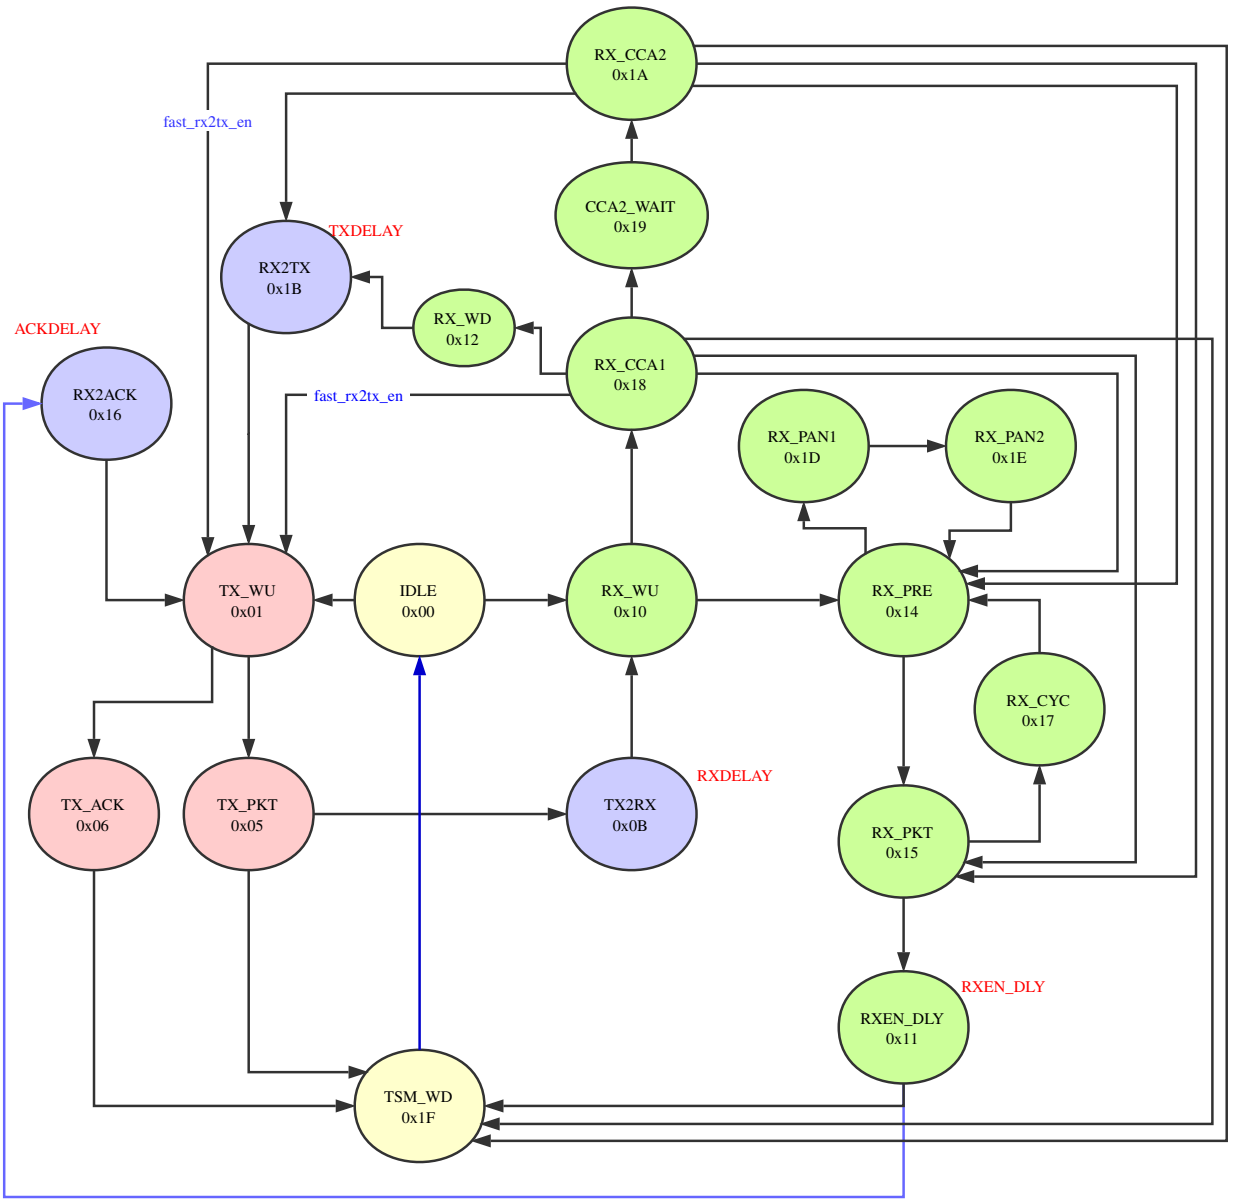

Figure 428. GSM State Diagram

Each GSM state is represented in the hardware by a 5-bit state vector. The GSM state can be monitored at any time by way of the read-only SEQ_STATE[4:0] register. The mapping of GSM state names to state vectors is shown in the table below:

GSM STATE	VECTOR
SEQ_IDLE	0x00
RX_WU	0x10

Table continues on the next page...

Table continued from the previous page...

GSM STATE	VECTOR
RX_PRE	0x14
RX_PKT	0x15
RX2ACK	0x16
RX_CYC	0x17
RX_PAN1	0x1D
RX_PAN2	0x1E
RX_CCA1	0x18
CCA2_WAIT	0x19
RX_CCA2	0x1A
RX_WD	0x12
RX2TX	0x1B
TX_WU	0x01
TX_PKT	0x05
TX_ACK	0x06
TX2RX	0x0B
TSM_WD	0x1F

55.4.9.2.3.7.2.1 Supported Sequences

55.4.9.2.3.7.2.1.1 Sequence I (Idle)

When the IDLE/ABORT value is written to XCVSEQ, the sequence manager goes to its SEQ_IDLE state. If not already in SEQ_IDLE, the sequence manager executes an orderly warmdown to return to SEQ_IDLE. A SEQIRQ interrupt is then issued. Writing IDLE/ABORT value to XCVSEQ is the proper way to abort a sequence.

When a sequence is aborted in this way (called a software abort), the SW_ABORTED bit will become set. This bit will be self-cleared at the start of the next autosequence.

55.4.9.2.3.7.2.1.2 Sequence R (Receive)

Sequence R can be lunched by command RX_START_*. Sequence R is the basic receive sequence.

In GLL mode, sequence R can be used to receive all frames.

In PAN mode, sequence R can be used to receive all types of PHY- and MAC-compliant frames, including reserved frame types. However, reception of Acknowledge frames is not recommended using Sequence R. This is because reception of an Acknowledge frame, usually follows a transmitted frame, with a designated Sequence Number, so that the received Acknowledge frame can be verified for the matching Sequence Number. In a standalone Sequence R, there is no Sequence Number to verify against, so any Acknowledge frame is merely transferred to the Packet RAM. (Note: the appropriate way to receive Acknowledge frames is with Sequence TR, with the RXACKRQD bit asserted). Using Sequence R, *all* frames which pass frame-filtering rules and CRC check, are transferred to the Packet RAM.

In FAN mode, sequence R can be used to receive all types of PHY- and FAN-compliant frames. Same as in PAN mode, it is recommended to use TR to receive Acknowledge frames.

The basic execution of a successful Sequence R in GLL/PAN/FAN mode is as follows:

- SEQ_MGR executes RxWarmup
- SFD Detected and received, transferred to Packet RAM
- Payload and CRC bytes received, transferred to Packet RAM.
- If no H0/H1/LENGTH violation and CRC check pass:
- And if frame-filtering rules(PAN rule) and PHR check pass:(PAN mode)
- And if frame-filtering rules(FAN rule) and PHR check pass:(FAN mode)
- ---> RXIRQ interrupt issued
- ---> SEQ_MGR executes RxWarmdown
- ---> If AUTOACK=1
- ---> And if received Frame Control Field indicates AckRequest=1 (PAN/FAN mode)
- ---- ---> SEQ_MGR executes TxWarmup
- ---- ---> an Ack frame is transmitted (programmed in Packet RAM) (GLL mode)
- ---- ---> an imm-Ack frame is transmitted using the received Sequence Number (PAN mode)
- ---- ---> an Enh-Ack frame is transmitted, with IEs and ASH field programmed in Packet RAM (FAN mode)
- ---- ---> SEQ_MGR executes TxWarmdown
- SEQIRQ interrupt issued

When Sequence R is initiated, the GSM sequence manager warms up the receiver (analog and digital elements), via the TSM (Transceiver Sequence Manager). Once a SFD is detected, the sequence manager's slot timer is activated. This is because a slotted "transmit acknowledge" frame (TxAck) may be required later in this sequence. The slot timer is loaded with the following value (in us):

Slot Timer Preload = SLOT_TIME - (PREAMBLE + SFD) + ACKDELAY

The slot timer will count down and eventually rollover at to 0, then to (SLOT_TIME-1). (There are SLOT_TIME us in a backoff slot).

The receiver receives the SFD octets . Starting with this octet, and continuing through the remainder of the frame, each octet that is received is transferred to Packet RAM. After each octet is transferred to Packet RAM, the Packet RAM address is incremented by 1.

During the reception, link layer will check the healthy of frame:

- CRC (all modes)
- H0/LENGTH_MAX/H1 violation (all modes)
- BCH/Parity fail (PAN/FAN mode)
- PAN packet-filtering rules (PAN mode)
- FAN packet-filtering rules (FAN mode)

Assuming no fail, an interrupt (RXIRQ) is issued to the MCU.

At this point, the sequence manager must determine if a TxAck is required. A TxAck is required if the following conditions are all met:

- AUTOACK=1 (register bit) (all modes)
- PROMISCUOUS=0 (register bit) (FAN and PAN mode)
- The received FrameControlField has AckRequest=1 (FAN and PAN mode)

If these conditions are met, and SLOTTED mode is not in effect, the sequence manager loads its TxAck timer with the following value (in us):

TxAck Timer Preload = TURNAROUND_TIME + ACKDELAY - TXWARMUPTIME

The TURNAROUND_TIME is the non-slotted RX-to-TX turnaround requirement in the 802.15.4 standard. The TXWARMUPTIME takes into account the fact that the TxAck timer must expire early for the Tx warmup to be complete at exactly the TURNAROUND_TIME us point. The ACKDELAY is a signed, fine-tune adjustment to the TxAck transmission time (+/-).

If SLOTTED mode is in effect, the slot timer was previously loaded (at SFD detect), but the sequence manager needs to determine how much time is left in the current backoff slot. If less than TURNAROUND_TIME remain, the sequence manager must wait an *additional* backoff slot before initiating the Ack transmission. So it sets a flag indicating it must allow the slot counter to rollover an additional iteration.

Finally, at TxAck timer expiration (in non-SLOTTED mode), or at the qualified rollover of the slot timer (in SLOTTED mode), a Tx warmup is initiated. The conclusion of the Tx warmup will coincide precisely with a backoff slot boundary if SLOTTED mode is in effect. The sequence manager will then initiate the transmission of the Ack frame.

In GLL mode, entire Ack frame should be programmed by software in Packet RAM.

In FAN mode, software should program ASH and IEs field in the Packet RAM and point out their total length in register LENGTH_ACK. The other part of the Enh-Ack frame are built up by hardware.

In PAN mode, entire Ack frame will be built up by hardware. The hardware will insert the following parameters into the Ack frame's Frame Control Field:

Table 479. Frame Control Field for Hardware-generated Auto-TxAck Frame (PAN Mode)

FCF Field	Value
FrameType	Acknowledge
SecurityEnabled	0
FramePending	Determined by the Packet Processor. (see Packet Processor Chapter, Source Address Management)
AckRequest	0
PanIDCompression	0
Reserved (bits 7-9)	000
DstAddrMode	0
FrameVersion	0
SrcAddrMode	0

The Sequence Number for the Ack packet, will be the Sequence Number obtained from the previously received frame.

Table 480shows the register bits used to control the Auto-Ack sequence in different modes.

Table 480. Auto-Ack Behavior and Register Setting(AUTOACK=1, SLOTTED=0/1)

Mode	GENLL_MODE[3:0]	SW_BUILD_ACK	ACKBUFSEL	LENGTH_ACK[10:0]	ACK Condition
GLL-ACK	0x0	0	ACK frame's SFD/H0/H1 field is from received frame. LENGTH field is from LENGTH_ACK.	Payload length + CRC_SZ - LENGTH_ADJ	1. Pass CRC 2. Pass H0/H1/LENGTH_MAX check (No SAM)

Table continues on the next page...

Table 480. Auto-Ack Behavior and Register Setting(AUTOACK=1, SLOTTED=0/1) (continued)

Mode	GENLL_ MODE[3:0]	SW_BUILD_ ACK	ACKBUFSEL	LENGTH_ACK[10:0]	ACK Condition
			0: Payload is in 64-byte dedicated RAM. 1: Payload is in TX RAM.		
		1	ACK frame's SFD/H0/H1/LENGTH/ Payload field is from RAM 0: ACK frame is in 64-byte dedicated RAM. 1: ACK frame is in TX RAM.	Not used	
Imm-ACK	0x1 or 0x3	0	ACK frame's SFD is from received. HW build the PHR according to PHR type HW build the payload HW does not access RAM	Not used	1. Pass CRC 2. Pass H0/H1/LENGTH_MAX check 3. Pass PHR check 4. Is MAC-compliant 5. Is addressed to the device 6. Is DATA or CMD frame (Do SAM when is a data polling CMD frame)
		1	ACK frame's SFD/H0/H1/LENGTH/ Payload field is from RAM 0: ACK frame is in 64-byte dedicated RAM. 1: ACK frame is in TX RAM.	Not used	
Enh-ACK	0x2 or 0x3	0	ACK frame's SFD is from received HW build the PHR according to PHR type HW build part of the Payload 0: ASH and IEs is in 64-byte dedicated RAM. 1: ASH and IEs is in TX RAM.	ASH/IEs length	1. Pass CRC 2. Pass H0/H1/LENGTH_MAX check 3. Pass PHR check 4. Is FAN-compliant 5. Is addressed to the device (No SAM since FAN use DATA frame only.)
		1	ACK frame's SFD/H0/H1/LENGTH/ Payload field is from RAM 0: ACK frame is in 64-byte dedicated RAM. 1: ACK frame is in TX RAM.	Not used	

After the Ack frame has been transmitted, the sequence manager will issue a TXIRQ interrupt, and then perform a Tx warmdown. Finally, a SEQIRQ interrupt will be issued, and the sequence manager returns to SEQ_IDLE state.

Sequence R Timing Diagrams

The following timing diagram depicts an example of "good" packet reception, highlighting the following events:

1. AUTOACK=0, so no auto-TxAck
2. Software loads T2_CMP with desired RX start time, sets T2_CMP_EN=1
3. Software schedules RX sequence with RX_START_T2 command
4. EVENT_TMR matches T2_CMP, RX sequence starts automatically
5. Network Address search, followed by NTW_ADR_IRQ interrupt, TIMESTAMP capture

6. Packet reception, Generic_FSK LL write octets to Packet RAM
7. CRC verification passes, and no H0, H1, or LENGTH_MAX violations(GLL/PAN/FAN mode)
8. PHR verification passes(PAN/FAN mode)
9. Payload verification passes PAN rules(PAN mode)
10. Payload verification passes FAN rules(FAN mode)
11. RX_IRQ asserted, Packet RX RAM valid, RSSI valid
12. SEQ_END_IRQ asserts after TSM returns to IDLE (RX warmdown complete)

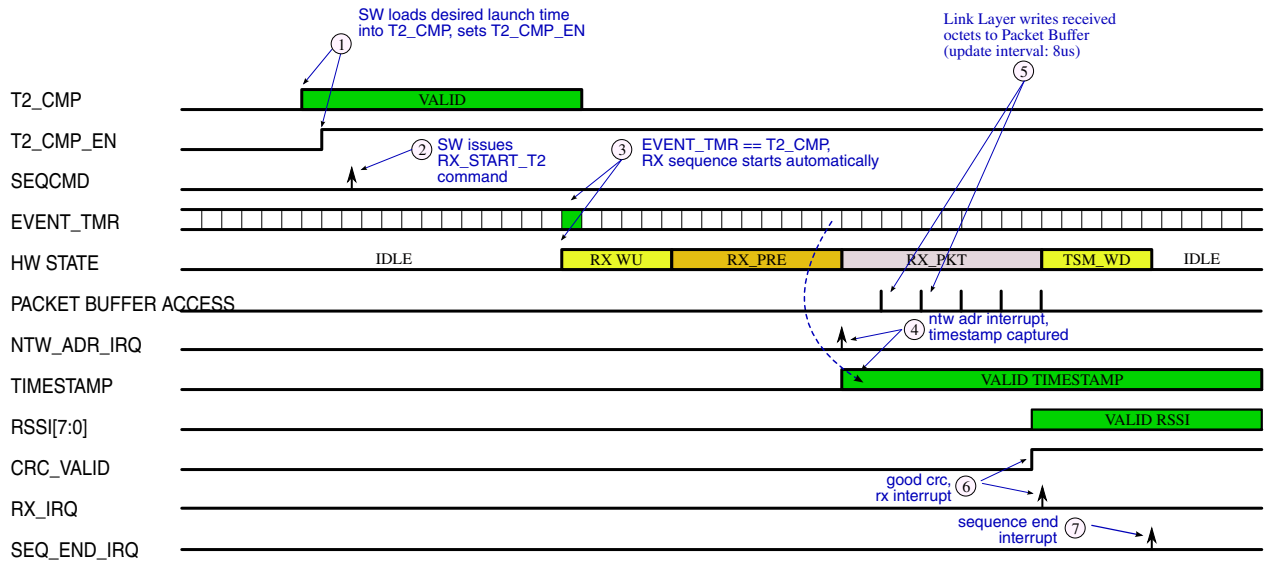

Figure 429. SEQUENCE R: LAUNCH VIA T2 TIMER, GOOD PACKET, AUTOACK=0 (All Modes)

The following timing diagram depicts an example of "good" packet reception, highlighting the following events:

1. Register RXEN_DLY is not zero and RXEN_DLY_OVERRIDE is one. After the last byte(determined by LENGTH field) of packet is received, the RX_EN signal will delay (RXEN_DLY +1) microseconds to de-assert
2. RX_IRQ asserted after the last byte(determined by LENGTH field) of packet is received.(if SEL_RXIRQ=0)
3. After extra packet received, RX_IRQ is asserted(if SEL_RXIRQ=1), GSM jumps to TSM_WD from RXEN_DLY.
4. SEQ_END_IRQ asserts after TSM returns to IDLE (RX warmdown complete)
5. **This RX mode is particularly suitable for protocols that have other fields after the CRC field. For example, the CTE(Constant Tone Extension) field in the Bluetooth LE 5.1 protocol.**

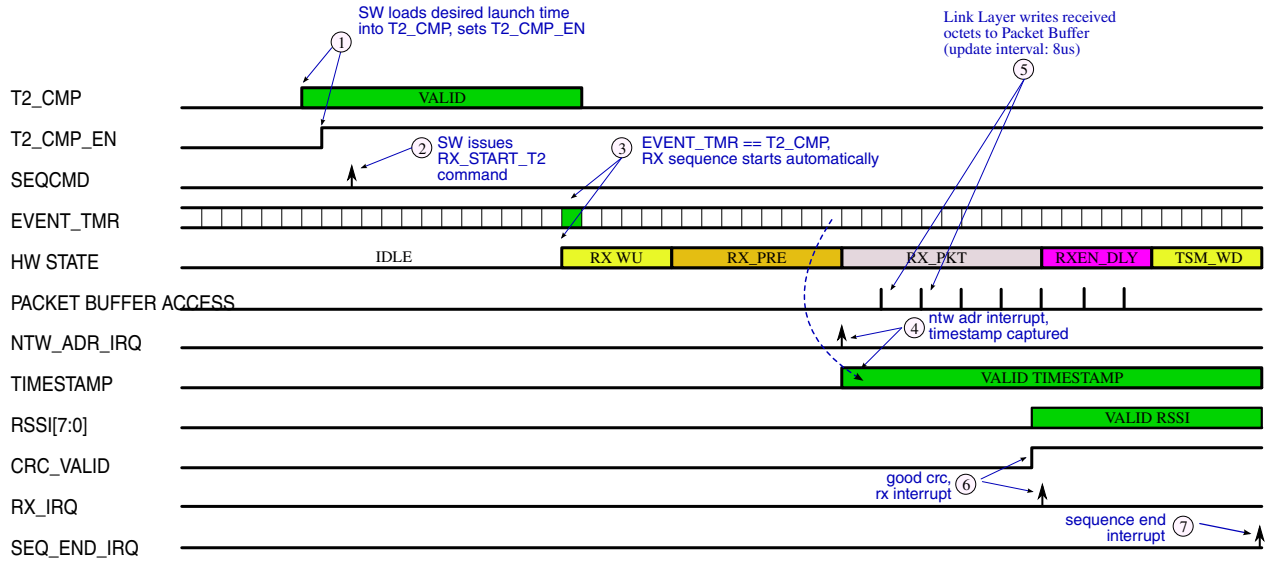

Figure 430. SEQUENCE R: RXEN DELAY (All Modes)

The following timing diagram depicts an example of "good" packet reception, highlighting the following events:

1. Register STAY_IN_RX is 1.
2. After packet received with CRC valid, GSM jumps to RX_CYC after RX_IRQ
3. This avoid the full RX re-warmup to facilitate sniffer SW.

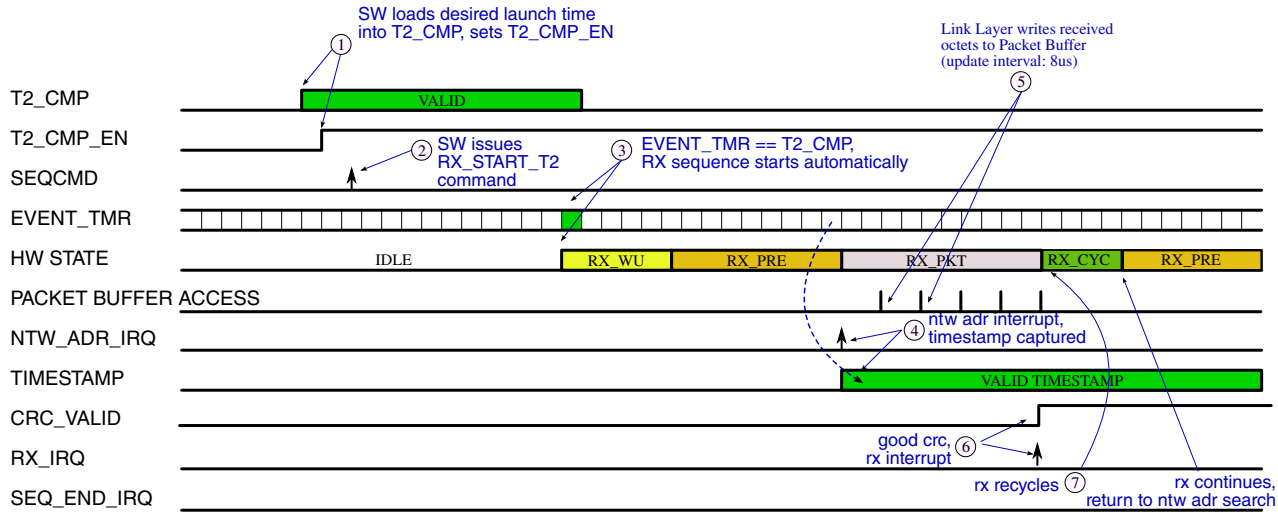

Figure 431. SEQUENCE R: STAY IN RX (All Modes)

The following timing diagram depicts an example of GENERIC_FSK "bad" packet reception, highlighting the following events:

1. Software loads T2_CMP with desired RX start time, sets T2_CMP_EN=1
2. Software schedules RX sequence with RX_START_T2 command

3. EVENT_TMR matches T2_CMP, RX sequence starts automatically
4. Network Address search, followed by NTW_ADR_IRQ interrupt, TIMESTAMP capture
5. Packet reception, Generic_FSK LL write octets to Packet RAM
6. CRC verification fails, no CRC_VALID, no RX_IRQ, RX Recycle
7. No SEQ_END_IRQ, return to Network Address Search

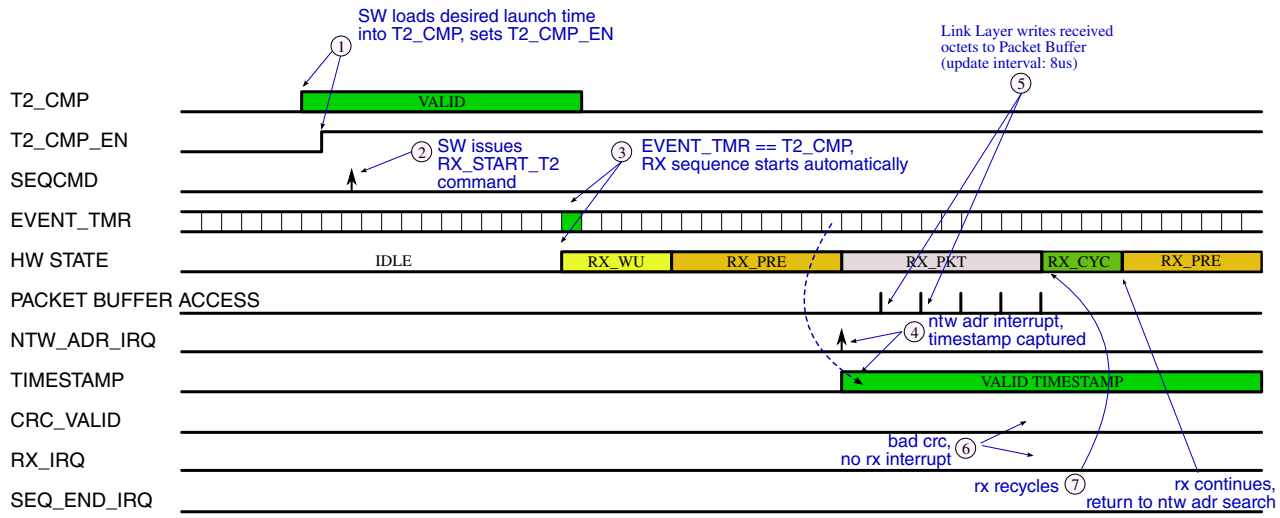

Figure 432. R SEQUENCE: LAUNCH VIA T2 TIMER, BAD PACKET, RX RECYCLE(All Modes)

The following timing diagram depicts a GENERIC_FSK RX search operation, which fails to detect a Network Address before timing out. The following events are highlighted:

1. Software loads T1_CMP with desired RX start time, sets T1_CMP_EN=1
2. Software loads T2_CMP with desired RX stop time, sets T2_CMP_EN=1
3. Software schedules RX sequence start with RX_START_T1 command
4. Software schedules RX sequence end with RX_STOP_T2 command
5. EVENT_TMR matches T1_CMP, RX sequence starts automatically
6. EVENT_TMR matches T2_CMP, RX sequence goes into warmdown automatically
7. SEQ_END_IRQ asserts to indicate TSM has returned to IDLE. No NTW_ADR_IRQ, No RX_IRQ.

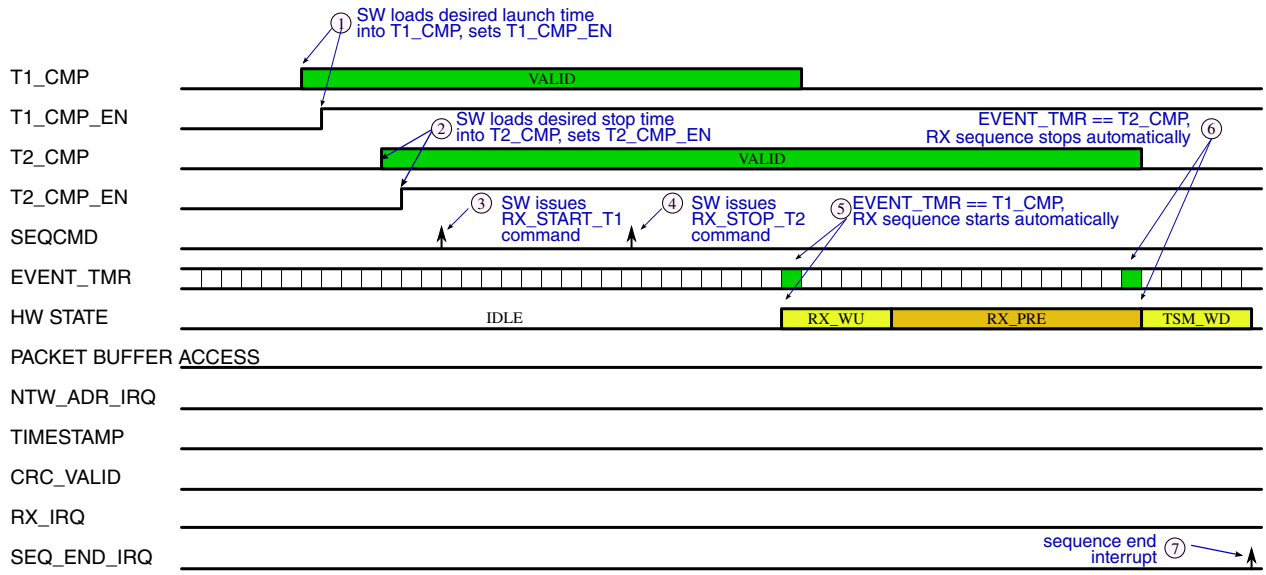

Figure 433. R SEQUENCE: SLAVE CHANNEL SEARCH, LAUNCH VIA T1, STOP VIA T2 (All Modes)

The following timing diagram depicts the GSM state transition of the Auto-Ack in PAN mode, highlighting the following events:

1. The Imm-Ack is built by hardware (SW_BUILD_ACK=0)
2. The Rx to TX time is TURNAROUND_TIME+ACKDELAY(±) (SLOTTED=0)
3. RX_IRQ is asserted when RX ends, TX_IRQ is asserted when TX ends, SEQ_END_IRQ is asserted when sequence finishes.

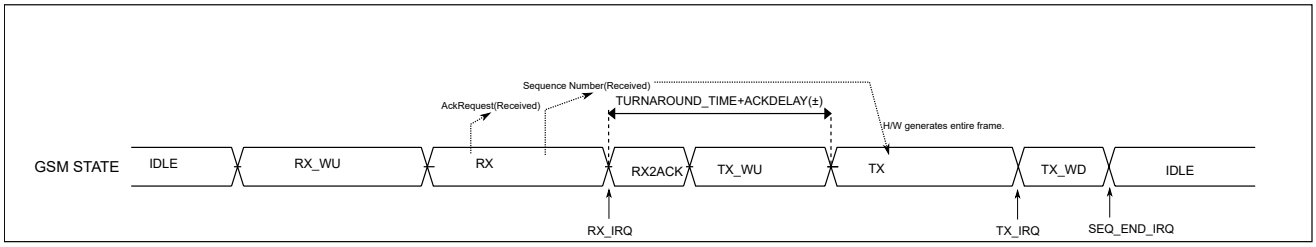

Figure 434. SEQUENCE R: Imm-Ack, SW_BUILD_ACK=0, SLOTTED=0, No SAM (PAN Mode)

The following timing diagram depicts the GSM state transition of the Auto-Ack in PAN mode, highlighting the following events:

1. The Imm-Ack is built by software in Packet RAM (SW_BUILD_ACK=1)
2. The Imm-Ack can be built by software at ACK_IRQ or any time before TX_PKT
3. ACK_IRQ are asserted when RX ends.

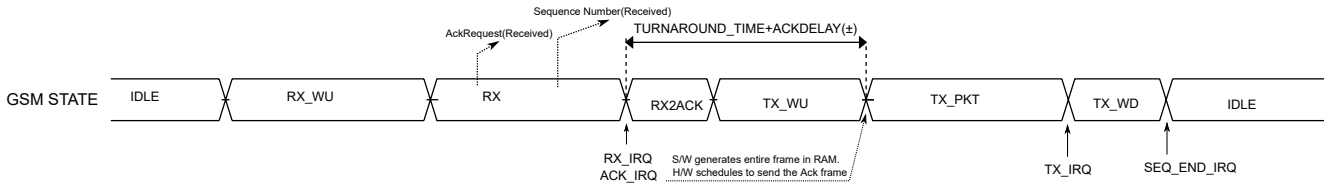

Figure 435. SEQUENCE R: Imm-Ack, SW_BUILD_ACK=1, SLOTTED=0, No SAM (PAN Mode)

The following timing diagram depicts the GSM state transition of the Auto-Ack in PAN mode, highlighting the following events:

1. The received frame is a data polling CMD frame, so Source Address Management is trigged.

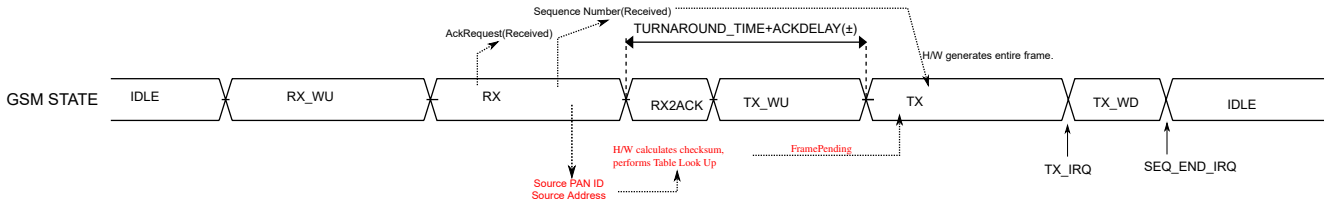

Figure 436. SEQUENCE R: Imm-Ack, SLOTTED=0, With SAM (PAN Mode)

The following timing diagram depicts the GSM state transition of the Auto-Ack in PAN mode, highlighting the following events:

1. The Slot Timer is preloaded at SFD detected with value SLOT_PRELOAD.
2. In Slot Mode, if the time between the RX END and next slot boundary is smaller than TURNAROUND_TIME, Link Layer will Tx-Ack at the next 2 slot boundary.

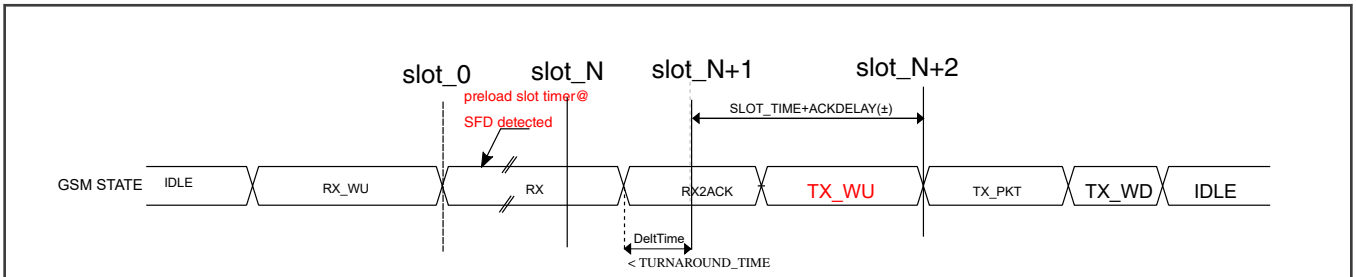

Figure 437. SEQUENCE R: Imm-Ack, SLOTTED=1, CASE 1(PAN Mode)

The following timing diagram depicts the GSM state transition of the Auto-Ack in PAN mode, highlighting the following events:

1. The Slot Timer is preloaded at SFD detected with value SLOT_PRELOAD.
2. In Slot Mode, if the time between the RX END and next slot boundary is larger than or equal to TURNAROUND_TIME, Link Layer will Tx-Ack at the next slot boundary.

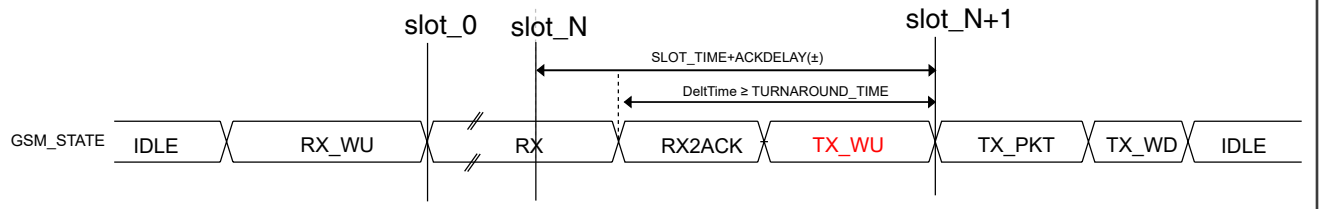

Figure 438. SEQUENCE R: Imm-Ack, SLOTTED=1, CASE 2 (PAN Mode)

55.4.9.2.3.7.2.1.3 Sequence T (Transmit)

Sequence T can be lunched by command TX_START_*. Sequence T is the basic, standalone transmit sequence.

Sequence T can be used to transmit all types of 802.15.4 PHY- and MAC-compliant frames. However, transmission of Acknowledge frames is not recommended using Sequence T. This is because transmission of an Acknowledge frame, usually follows a received frame, with a designated Sequence Number. The GSM sequence manager automates the transmission of an Ack frame which follows a received frame, using Sequence R with the AUTOACK bit asserted. This is the recommended method for transmitting an Ack frame. This is especially beneficial, because the transmitted Ack frame octets are generated by hardware, and so no setup of a transmit packet in Packet RAM, is required. However, sequence manager hardware does not prohibit Ack frames using Sequence T.

Sequence T allows for the insertion of 1 or 2 CCA (clear channel assessment) measurements prior to transmission, to ensure that the selected channel is idle. The CCA-before-TX feature is governed by two register bits, CCABFRTX and SLOTTED. All CCA measurements must indicate channel-idle, in order for the sequence manager to proceed to transmission; if the channel is determined by CCA to be busy, the sequence manager will terminate the sequence without a transmission. The number of CCA measurements attempted by the sequence manager, and the timing of the measurements, is shown in the following table.

Table 481. Timing of CCA Operations for Sequence T

CCABFRTX	SLOTTED	Number of CCA measurements	Timing of Initiation of CCA measurement #1	Timing of Initiation of CCA measurement #2	Timing of First Bit of Transmitted Frame (assumes channel idle)
0	X	0	-	-	Immediately follows TxWarmup
1	0	1	Immediately follows RxWarmup	-	Immediately follows RxWarmdown and TxWarmup
1	1	2	Immediately follows RxWarmup	SLOT_TIME us after Initiation of CCA measurement #1	SLOT_TIME us after Initiation of CCA measurement #2

CCA mode 1 can be used for Sequence T and Sequence TR.

The basic execution of a successful Sequence T is as follows:

- MCU sets CCABFRTX if one or more CCA's are required prior to transmit
- MCU sets SLOTTED if in slotted mode (2 CCA's will be attempted)
- MCU writes XCVSEQ = RX_START_*

- Wait for T1 or T2 match (if RX_START_T*)
- If CCABFRTX=1 :
- ---> SEQ_MGR executes RxWarmup
- ---> SEQ_MGR initiates CCA measurement (takes CCA_TIME us (CCA_TIME = SLOT_TIME - TURNAROUND_TIME))
- ---> if CCA indicates channel busy, sequence terminates, CCAIRQ & SEQIRQ issued
- ---> otherwise, if CCA indicates channel idle:
- ---- ---> if SLOTTED=0, SEQ_MGR executes a RxWarmdown, followed by a TxWarmup
- ---- ---> if SLOTTED=1, SEQ_MGR initiates a 2nd CCA, SLOT_TIME us after initiating 1st CCA.
- ---- ---> if SLOTTED=1, and channel busy, sequence terminates, CCAIRQ & SEQIRQ issued
- ---- ---> if SLOTTED=1, and channel idle, SEQ_MGR executes a RxWarmdown, followed by a TxWarmup
- if SLOTTED=1, SEQ_MGR waits until SLOT_TIME us elapse after 2nd CCA initiation
- SEQ_MGR executes TxWarmup
- Preamble transmitted
- SFD are obtained from Packet RAM and transmitted
- Payload are obtained from Packet RAM and transmitted
- After Payload octet transmitted, FCS is available from CRC engine.
- SEQ_MGR issues TXIRQ
- SEQ_MGR executes TxWarmdown
- SEQ_MGR issues SEQIRQ

When Sequence T is initiated, the sequence manager first must determine if one or more CCA measurements are required.

If CCABFRTX bit is asserted, the sequence manager warms up the receiver (analog and digital elements), via the TSM (Transceiver Sequence Manager). Immediately after the conclusion of the warmup, a CCA measurement is initiated. The CCA measurement takes CCA_TIME us. If CCA indicates the channel is busy, the sequence manager warms down the receiver, issues CCAIRQ and SEQIRQ interrupts, and terminates the sequence. If, however, CCA indicates the channel is idle, the sequence manager inspects the SLOTTED bit to determine what to do next.

If the SLOTTED bit is clear, the sequence manager issues a CCAIRQ interrupt, and then executes a warmdown of the receiver.

If, however, the SLOTTED bit is set, the sequence manager does not issue a CCAIRQ interrupt; instead, the sequence manager initiates a second CCA measurement, precisely SLOT_TIME us after the initiation of the first CCA. This SLOT_TIME us interval is timed by the slot timer, which had been preloaded with SLOT_TIME (microseconds) at the instant that Rx warmup was complete.

At the conclusion of the second CCA, the sequence manager issues a CCAIRQ. If the second CCA indicates the channel is busy, the sequence manager warms down the receiver, issues a SEQIRQ interrupt, and terminates the sequence. If, however, CCA indicates the channel is idle, the sequence manager executes a warmdown of the receiver. Prior to executing the warmdown, the sequence manager reloads the slot timer, in order to precisely schedule the ensuing transmission. This time, the slot timer is loaded with a smaller value, in order to account for the fact that the timer must expire early in order to trigger the Tx warmup, which must complete at precisely the next backoff slot boundary. Thus, this time the slot timer is preloaded with:

Slot Timer Preload = TURNAROUND_TIME - TXWARMUPTIME + TXDELAY.

The SLOT_TIME us is the duration of the backoff slot. The TXWARMUPTIME takes into account the fact that the TxAck timer must expire early for the Tx warmup to be complete at exactly the SLOT_TIME us point. The TXDELAY is a signed, fine-tune adjustment to the TxAck transmission time.

If the SLOTTED bit is asserted, once the slot timer expires, the sequence manager executes a Tx warmup. The conclusion of this warmup coincides with the backoff slot boundary. If the SLOTTED bit is deasserted, the sequence manager does not wait for the slot timer, and instead executes a Tx warmup immediately after the Rx warmdown.

At this point, the sequence manager begins the transmit operation. After the transmit operation is complete. The sequence manager issues a TXIRQ interrupt. The sequence manager then executes a complete Tx warmdown, and follows up with a SEQIRQ interrupt. The sequence manager returns to SEQ_IDLE state.

Sequence T Timing Diagrams

The following timing diagram depicts an example of packet transmission, highlighting the following events:

1. No CCA before TX
2. Software stores packet octets into Packet RAM, to be transmitted
3. Software loads T1_CMP with desired TX start time, sets T1_CMP_EN=1
4. Software schedules TX sequence with TX_START_T1 command
5. EVENT_TMR matches T1_CMP, TX sequence starts automatically
6. Link Layer reads octets from Packet RAM **and sends to RBME when requested**
7. Packet is transmitted at the end of TX_WU
8. TX_IRQ asserts after last bit of packet transmitted
9. SEQ_END_IRQ asserts after TSM returns to IDLE (TX warmdown complete)

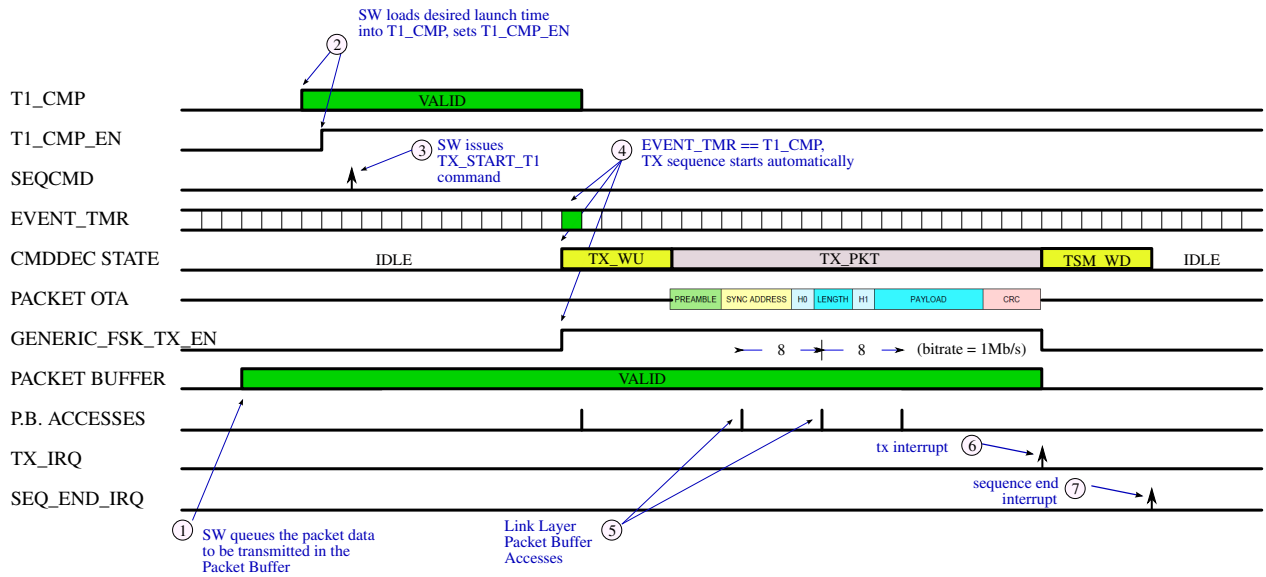

Figure 439. SEQUENCE T: LAUNCH VIA T1 TIMER

The following timing diagram depicts the GSM state transition of Tx, highlighting the following events:

1. Un-slotted mode with CCA before TX
2. The CCA measurement takes CCA_TIME us, the result shows IDLE channel
3. After CCA Rx warmdown, Link Layer inserts TXDELAY time (positive or zero) before Tx warmup
4. CCA_IRQ is asserted when CCA ends, TX_IRQ is asserted when Tx ends, SEQ_END_IRQ is asserted when sequence finishes

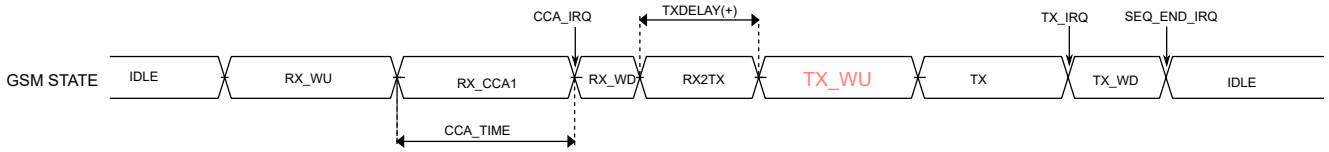

Figure 440. SEQUENCE T: Unslotted CCABFRTX, Channel is IDLE

The following timing diagram depicts the GSM state transition of Tx, highlighting the following events:

1. FAST_RX2TX_EN=1, enables TSM Fast RX-to-TX
2. Link Layer assert fast_rx2tx_wu to TSM, requests a Fast RX-to-TX warmup
3. The TSM will respond to fast_rx2tx_wu by jumping from the "ON" phase of the RX operation to the "WARMUP" phase of the TX operation at the programmed point.
4. Simultaneously, GSM jumps to its TX_WU state to wait for the TX warmup to complete.

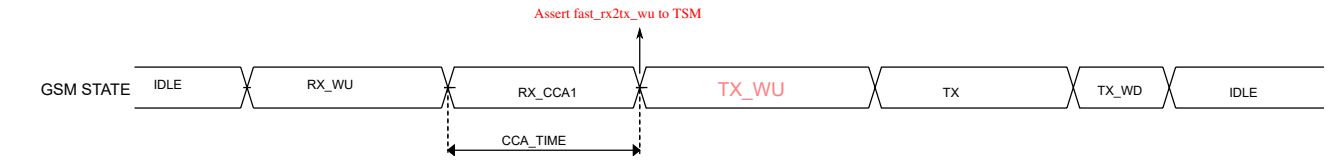

Figure 441. SEQUENCE T: Unslotted CCABFRTX, Channel is IDLE, TSM FAST RX-to-TX

The following timing diagram depicts the GSM state transition of Tx, highlighting the following events:

1. Slotted mode with CCA before TX
2. CCA_IRQ is asserted after 2nd CCA is done
3. Link Layer sends out the packet at next slot boundary(TXDELAY(±))

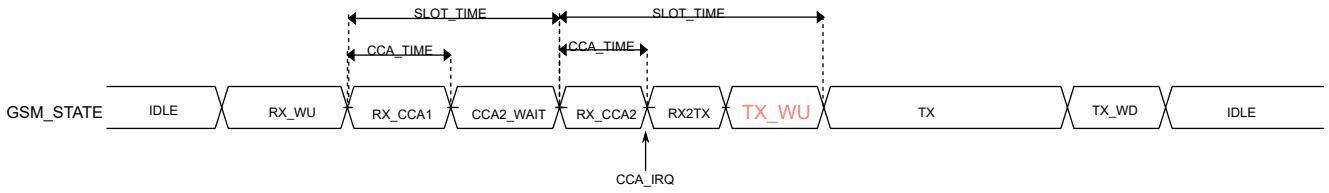

Figure 442. SEQUENCE T: Slotted CCABFRTX, Channel is IDLE

55.4.9.2.3.7.2.1.4 Sequence C (CCA)

CCA/ED/LQI

The CCA/ED/LQI block resides inside RX DIG. The purpose of this block is to perform the following operations:

1. Clear Channel Assessment: Modes 1
2. Energy Detection
3. Link Quality Indicator

This block takes RSSI value, as an input, for computations related to CCA modes 1, Energy Detection and LQI.

At the output, it provides a signal called (cca) to indicate if the channel of interest is busy (cca=1) or idle (cca=0), the final computed energy value (cca1_ed_fnl) and Link Quality Indicator (LQI) value.

The cca signal is further used to generate cca interrupt, according to the set interrupt mask. The cca1_ed_fnl is a signed 8 bit value that can be read back as a register. LQI is an unsigned 8 bit value that is written at the end of each valid packet that is received and is available to be read in the packet buffer.

Sequence C

Sequence C can be lunched by command CCA_START_*. Sequence C is the standalone CCA sequence.

During Sequence C, the sequence manager executes a Clear Channel Assessment (CCA). The result of the CCA measurement is reported back to software in the CCA bit. The CCA bit indicates either a busy channel (1), or an idle channel (0).

The basic execution of a Sequence C is as follows:

- MCU writes XCVSEQ=CCA_START_*
- Wait for T1 or T2 match (if CCA_START_T*)
- SEQ_MGR asserts one of **cca1_en** to CCA_DIG
- SEQ_MGR executes RxWarmup, via Transceiver Sequence Manager
- SEQ_MGR initiates CCA measurement by asserting **rx_cca_en** to CCA_DIG
- SEQ_MGR waits for CCA to complete (**CCA_TIME=SLOT_TIME - TURNAROUND_TIME**)
- CCA bit is set to the CCA status (1=busy 0=idle)
- CCAIRQ interrupt issued
- SEQ_MGR executes RxWarmdown
- SEQIRQ interrupt issued

The asserted control signal **cca1_en** will remain asserted for the duration of the Sequence C. The sequence manager warms up the receiver (analog and digital elements), via the Transceiver Sequence Manager (TSM). At the completion of the warmup, the sequence manager initiates the CCA by asserting the **rx_cca_en** signal to CCA_DIG. While CCA is enabled, the CCA_DIG measures and averages the energy or signal on the channel. At the completion of the CCA process, the CCA bit is set to the status of the channel (idle or busy). The CCAIRQ is issued, the receiver is warmed down, the SEQIRQ is issued, and the sequence manager returns to SEQ_IDLE state.

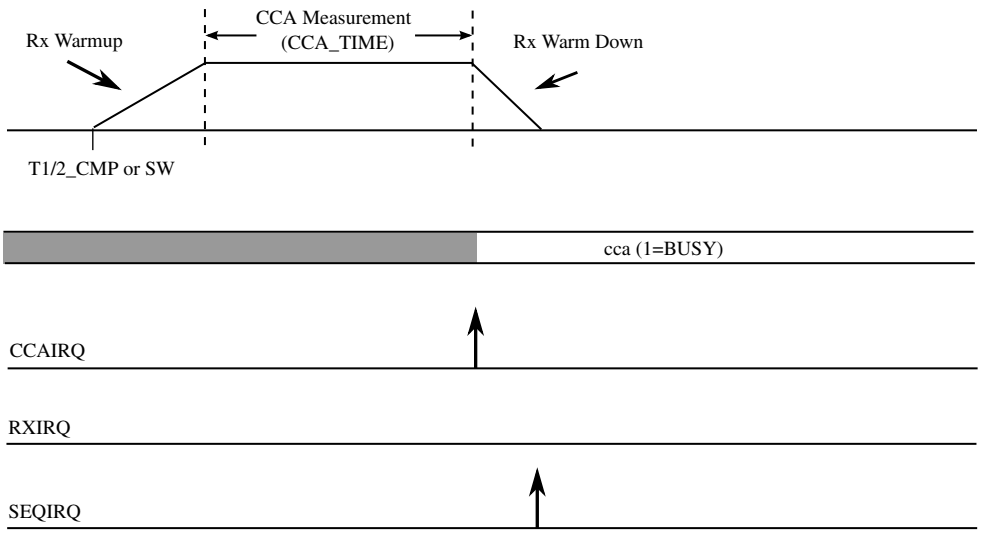

Figure 443. Sequence C Timing Diagrams

55.4.9.2.3.7.2.1.5 Sequence TR (Transmit/Receive)

Sequence TR can be lunched by command TR_START_*. Sequence TR is a combination Transmit/Receive sequence.

The sequence is executed as a concatenation of 1 transmit operation followed by 1 receive operation, with a minimum TX-to-RX turnaround time in between.

In PAN and FAN mode, there are 2 permutations of Sequence TR, depending on the RXACKRQD bit. For both permutations, the Sequence T which constitutes the first half of a Sequence TR, is identical to the standalone Sequence T (XCVSEQ=TX_START_*). This means that the transmit operation can be slotted or unslotted, and can be preceded by 1 or 2 CCA measurements, depending on the state of the CCABFRTX and SLOTTED bits.

If RXACKRQD=0, then Sequence TR is executed as a Sequence T followed by a Sequence R, with a minimum TX-to-RX turnaround time in between. The Sequence R, which constitutes the second half of the Sequence TR, is identical to the standalone Sequence R (XCVSEQ=RX_START_*). This means that the receive operation can be followed by an automatic, hardware-generated transmit Acknowledge frame, if all the necessary conditions are met. As with basic Sequence R, data for a successful receive operation is always transferred to Packet Buffer.

If RXACKRQD=1, then Sequence TR is executed as a Sequence T followed by a Receive-Acknowledge-Only frame. This type of receive operation is special, and not the same as a standalone Sequence R. The Ack-only receive operation filters all incoming frames, looking only for an Acknowledge frame whose Sequence Number matches the Sequence Number which was transmitted in the Sequence T portion of the sequence. All non-matching frames are discarded, and after each non-matching frame, the sequence manager will return the receiver to preamble-detect mode. This receive operation will continue until the matching Ack frame is received. Since this is a Receive-Acknowledge-Only operation, and not a Sequence R, there will be no receive octets transferred to Packet Buffer. The sequence will end with a RXIRQ interrupt, which indicates that the matching Ack frame was successfully received.

Needless to say, if during the transmit operation of a Sequence TR, an Acknowledge frame is being requested of the receiving end device (Frame Control Field: AckRequest=1), then Sequence TR with RXACKRQD=1 is the appropriate procedure. (Using Sequence TR with *RXACKREQ=0* is *not* recommended for this scenario, since there is no Sequence Number matching.)

Conversely, if during the transmit operation of a Sequence TR, an Acknowledge frame is *not* being requested of the receiving end device (Frame Control Field: AckRequest=0), then Sequence TR with RXACKRQD=1 should *never* be used, since a receive acknowledge frame will not be forthcoming. Instead, use Sequence TR with RXACKRQD=0, or simply Sequence T, if no followup receive frame is expected.

In GLL mode, there is nothing to check against to the received Acknowledge frame, so RXACKRQD is not used.

Sequence TR Timing Diagrams

The following timing diagram depicts the GSM state transition of TR, highlighting the following events:

1. Unslotted mode
2. The TX-to-RX time is TURNAROUND_TIME+RXDELAY(±)
3. TX_IRQ is asserted when TX ends, RX_IRQ is asserted when RX ends, SEQ_END_IRQ is asserted when sequence finishes.

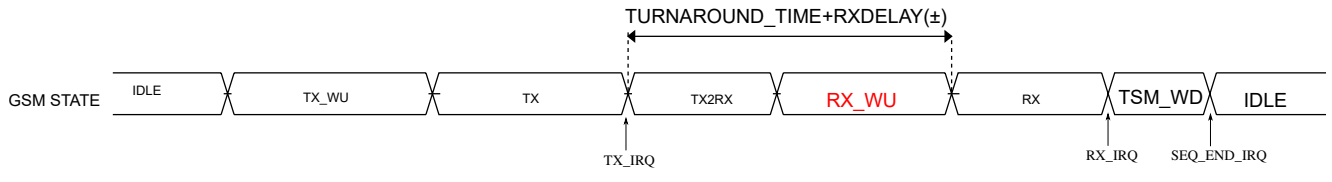

Figure 444. SEQUENCE TR: UNSLOTTED

The following timing diagram depicts the GSM state transition of TR, highlighting the following events:

1. Slotted mode

2. The time between the TX END and next slot boundary is smaller than TURNAROUND_TIME, Link Layer starts to receive at next 2 slot boundary (RXDELAY(±))

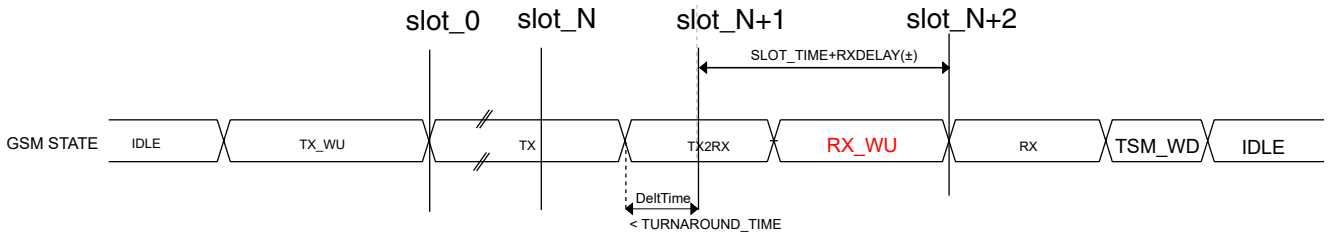

Figure 445. SEQUENCE TR: SLOTTED, CASE 1

The following timing diagram depicts the GSM state transition of TR, highlighting the following events:

1. Slotted mode
2. The time between the TX END and next slot boundary is larger than or equal to TURNAROUND_TIME, Link Layer starts to receive at next slot boundary (RXDELAY(±))

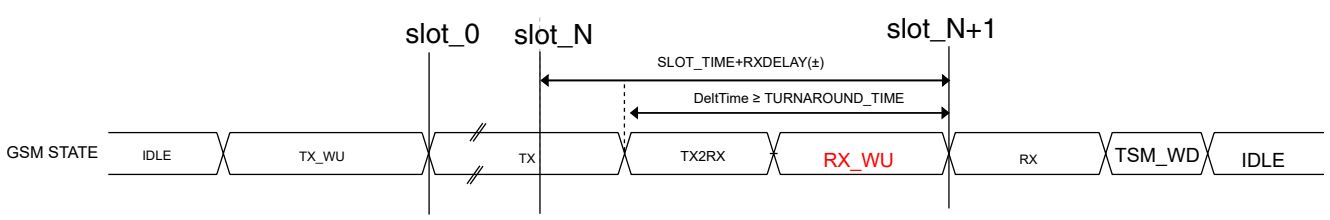

Figure 446. SEQUENCE TR: SLOTTED, CASE 2

55.4.9.2.3.7.2.2 Dual PAN Mode

Dual PAN On-the-fly Channel Change

The Sequence Manager (GSM) supports Dual PAN mode, which allows the device to reside on 2 networks simultaneously, switching back and forth between the 2 networks under software, or hardware control. (See Dual PAN Modefor more details on Dual PAN mode).

In Automatic Dual PAN Mode, the device must switch from one network to another under hardware control, at a software-programmed rate. Since the 2 networks often occupy different channels (frequencies), the sequence manager supports an "on-the-fly channel change", whereby, during a Sequence R, in preamble-search state (RX_PRE), the sequence manager will request the TSM to toggle **pll_dig_en** and switch to a new RF channel, wait out a PLL settling time, and then resume preamble search on the new channel. The entire on-the-fly channel change consumes 93us (based on default TSM programming), and consumes 2 GSM states. The first state (RX_PAN1) issues **tsm_recycle[1]** to the TSM, which causes TSM to jump from its "ON" phase, back to the tsm_count value which is programmed into the RECYCLE_COUNT1[7:0] register in XCVR space. Based on the default programming for RECYCLE1_COUNT, along with the default programming for the TSM timing registers, this TSM recycle will cause the TSM to jump back to the point 1us before **pll_dig_en** is asserted, resulting in a 1us-long deassertion of **pll_dig_en**. The TSM will resume counting from that point, which will re-assert **pll_dig_en**, and the GSM will simultaneously select the alternate Dual Pan channel. Meanwhile, the GSM will advance to RX_PAN2 state and wait there pending **tsm_wu_complete** from the TSM. The TSM will resume counting until it once again until it reaches END_OF_RX_WU[7:0], and then will return to its ON phase. At the end of the TSM RX warmup, TSM will issue **tsm_wu_complete** to GSM, which will return GSM to RX_PRE (preamble search) state.

Normally, during RX sequences, the PLL is monitored for unlock conditions, and if such an unlock were to occur, the GSM would abort the RX sequence by deasserting RX_EN to TSM. During RX_PAN1 and RX_PAN2 states, GSM asserts **in_pan_switch** to the transceiver, which indicates that PLL unlock detection should be temporarily suspended while the channel change and subsequent PLL re-lock takes place. Once the GSM transitions from RX_PAN2 state back to RX_PRE, GSM will deassert **in_pan_switch** to resume PLL unlock monitoring.

As mentioned, the entire on-the-fly channel change consumes 93us, based on default TSM programming. This 93us represents a short "blind spot" during which preamble detection can't occur, while the device switches from one RF frequency to another. See diagram below.

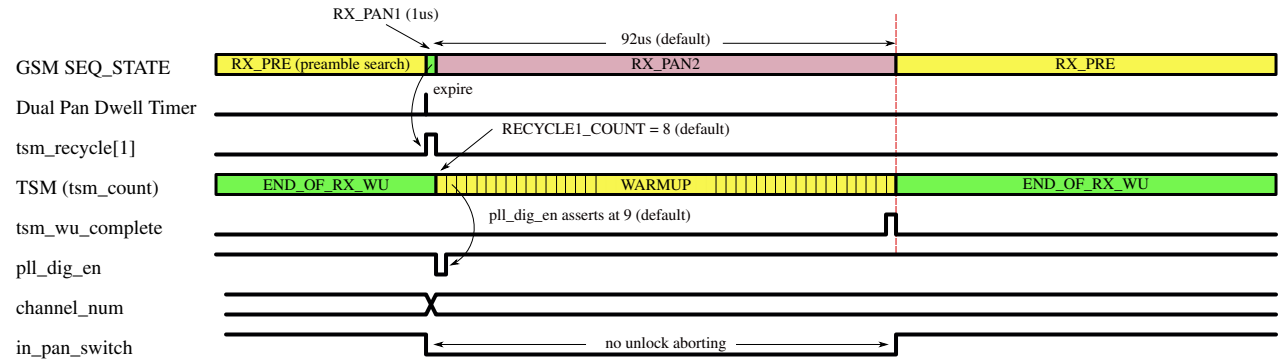

Figure 447. GSM Dual PAN on-the-fly Channel Change

Dual PAN Channel Override

When using Dual PAN mode, the channels are assigned to the 2 PAN's by programming the CHANNEL_NUM0[6:0] and CHANNEL_NUM1[6:0] registers. The channel number is processed downstream into the necessary Integer, Numerator, and Denominator components, required to generate the correct RF frequencies (see PLL Digital Chapter).

In Dual PAN mode, in case there is a need to generate a frequency which may be offset from the 16 prescribed 5MHz-spaced channels, to, for example, avoid interference on one of the Dual PAN channels, a method has been provided to do that, by designating one of the two PAN channels to use the transceiver's set of direct frequency-programming registers, instead of CHANNEL_NUMx. Programming the direct frequency-programming registers – integer, numerator, and denominator, allows an RF frequency to be selected with much more precision than the 5MHz granularity of the 802.15.4 mapped-channel registers, CHANNEL_NUM0 and CHANNEL_NUM1.

Two bits have been provided to realize this feature: DP_CHAN_OVRD_SEL and DP_CHAN_OVRD_EN. When DP_CHAN_OVRD_EN=1, this enables one of the Dual PAN channels to use the direct frequency programming. The DP_CHAN_OVRD_SEL bit determines *which* channel uses the direct programming, according to the following table:

Table 482. Dual PAN Channel Override

DP_CHAN_OVRD_EN	DP_CHAN_OVRD_SEL	PAN0 Frequency Determined by …	PAN1 Frequency Determined by …
0	X	CHANNEL_NUM0	CHANNEL_NUM1
1	0	DIRECT FREQUENCY PROGRAMMING	CHANNEL_NUM1
1	1	CHANNEL_NUM0	DIRECT FREQUENCY PROGRAMMING

Direct Frequency Programming is accomplished by setting the PLL's Integer, Numerator, and Denominator registers to the appropriate values for the desired RF frequency. These registers are in XCVR address space, and are shown in the following table:

Table 483. Direct Frequency Programming

DIRECT FREQUENCY PROGRAMMING PARAMETER	REGISTER NAME (XCVR SPACE)	REGISTER MNEMONIC
Integer	LPM_INTG[6:0]	PLL_LP_SDM_CTRL1
Numerator	LPM_NUM[27:0]	PLL_LP_SDM_CTRL2
Denominator	LPM_DENOM[27:0]	PLL_LP_SDM_CTRL3

See the PLL Digital Chapter for RF frequency programming details.

In Dual PAN automatic mode, if DP_CHAN_OVRD_EN=1, when the hardware switches to the PAN selected by DP_CHAN_OVRD_SEL as a direct-programming channel, the CHANNEL_NUMx register is ignored and the directly programmed frequency is used instead; when the hardware switches back to the other channel, the CHANNEL_NUMx register is used once again.

Hybrid Dual PAN Mode

Dual PAN Mode can be in Hybrid Mode by configuring the register GENLL_MODE. In Hybrid Mode, the two PAN can be one in PAN mode and another in FAN mode, as shown in the following table:

Table 484. Hybrid Dual PAN Mode

MODE_PAN0	MODE_PAN1	PAN0 Mode	PAN1 Mode
0	0	PAN mode	PAN mode
0	1	PAN mode	FAN mode
1	0	FAN mode	PAN mode
1	1	FAN mode	FAN mode

55.4.9.2.3.7.2.3 Simultaneous CCA/RX

The Link Layer controller features an autosequence that precedes a packet transmission with a CCA (Clear Channel Assessment), to ensure the channel is idle before transmitting. If the CCA indicates a busy channel, the autosequence ends after the CCA, without transmitting. In slotted mode, 2 CCA measurements take place, with the start points for the measurements SLOT_TIME apart. Both must indicate an idle channel for transmission to proceed.

During intervals of severe network congestion, high node density, and packets which are heavily fragmented, the situation can arise where Device A is preparing to transmit a packet, or fragment, and performing pre-transmit CCA, and during the CCA, Device B attempts to transmit another packet or fragment to Device A. The capability to receive-during-CCA is referred to as "Simultaneous CCA/RX".

Using Simultaneous CCA/RX, the Link Layer controller needs to be able to anticipate preamble, and even SFD detection, during the states in which it is taking CCA measurement. Those states are RX_CCA1, for non-slotted, and RX_CCA2, for slotted operation. If preamble and/or SFD is detected in those states, the sequence manager needs to transition to a packet reception state, and then receive the packet in its entirety as if the called sequence was Sequence R. To address this, these new state transitions have been added to the Sequence Manager state machine:

- RX_CCA1 -> RX_PRE (preamble detected during 1st CCA but no SFD)
- RX_CCA1 -> RX_PKT (preamble + SFD detected during 1st CCA)
- RX_CCA2 -> RX_PRE (preamble detected during 2nd CCA but no SFD)
- RX_CCA2 -> RX_PKT (preamble + SFD detected during 1st CCA)

False preambles may occur during the CCA states as well. False preambles occur when the demodulator detects a sufficient number of consecutive symbols to meet the preamble threshold, but the symbol which follows is not right SFD. False preambles

result in the demodulator signal sfd_rst asserting either during, or after, the CCA state. If a false preamble is declared within the CCA time window, then the fact that there was a false preamble has no bearing on the channel status, the CCA measurement determines channel status, as usual. If the false preamble is declared after the CCA window, the channel is assessed to be busy and the autosequence terminates without transmission, because the scheduled transmission time has been missed

In defining the Simultaneous CCA/RX operation, 9 "scenarios", or cases, were developed to help ensure correct hardware response to various permutations of preamble and SFD arrival times, preamble falsing, channel status, and RX packet goodness. These scenarios were used to guide the hardware design, for each of the 3 CCA modes, and for mode 3, both boolean combinations. The 9 scenarios are listed in the table below(**take the CCA_TIME 128us as example**), with the correct hardware response indicated. The hardware response consists of a sequence of state transitions, as well as assertion (or non-assertion) of the various 802.15.4 interrupts. The final combination of asserted interrupts assists software in determining what transpired during the autosequence, and therefore what must be done next.

Table 485. SIMUL CCA/RX SCENARIOS(*CCA_TIME is 128us in table*)

#	Scenario	Auto Sequence Ends After	Mode Switch to SFD Search Occurs At	Mode Switch to PKT Reception Occurs At	CCAIRQ?	RXIRQ?	TXIRQ?
1	Channel IDLE @ 128us	TX	--	--	Yes(CCA=0)	No	Yes
2	Channel Busy @ 128us	CCA	--	--	Yes(CCA=1)	No	No
3	Preamble Asserted During CCA SFD_RST Occurs During CCA Channel Otherwise IDLE @128us	TX	--	--	Yes(CCA=0)	No	Yes
4	Preamble Asserted During CCA SFD_RST Occurs During CCA Channel Otherwise Busy @128us	CCA	--	--	Yes(CCA=1)	No	No
5	Preamble Asserted @128us SFD Not Asserted @128us SFD_RST Asserts Later (False PRE)	SFD_RST	128us	--	Yes(CCA=1)	No	No
6	Preamble Asserted @128us SFD Not Asserted @128us SFD Asserts Later (Bad PKT)	RX	128us	--	Yes(CCA=1)	No	No
7	Preamble Asserted @128us SFD_RST Asserted @ 128us (Bad PKT)	RX	--	SFD DET	Yes(CCA=1)	No	No
8	Preamble Asserted @128us SFD Not Asserted @128us SFD Asserts Later (Good PKT)	RX	128us	--	Yes(CCA=1)	Yes	No
9	Preamble Asserted @128us SFD Asserted @128us(Good PKT)	RX	--	SFD DET	Yes(CCA=1)	Yes	No

A single register bit enables Simultaneous CCA/RX mode: SIMUL_CCA_RX. Simultaneous CCA/RX works with both nonslotted (single CCA before TX) and slotted (2 CCA before TX) modes.

Note that to use the Simultaneous CCA/RX feature, software (not just hardware) needs to anticipate packet reception during a Sequence T (not just a Sequeunce TR)

55.4.9.2.3.8 Work Modes

The Generic Link Layer work modes are controlled by register bits GENLL_MODE[3:0] . With proper setting, Generic Link Layer and RBME can support to receive and send different kinds of packet, like 802.15.4, FCP, Bluetooth LE packets.

- The default mode is called Generic Link Layer mode(**GLL mode**). GLL mode is the most basic mode, all commands and sequences can be used in GLL mode.
- The PAN, FAN modes are to support GFSK, MSK, SUN FSK, and LECIM FSK in the 802.15.4 protocol. In these modes, the PHRs are parsed and checked according to the protocol. Both modes also check whether the payload complies with the 802.15.4 MAC frame format. The difference is that in PAN mode, link layer only supports frames with frame version less than 2, and supports Imm-Ack frame sending and receiving. While in FAN mode, link layer supports FAN protocol-specific frame, and supports Enh-Ack frame only.
- The link layer can work in Dual PAN mode when in PAN or FAN mode. In this case, both PANs are in PAN mode or both PANs are in FAN mode. When configured to Hybrid Dual PAN Mode, one PAN can be in PAN mode while the other can be in FAN mode.
- Link layer can also work in FCP/Bluetooth LE mode.
- The test mode (GTM mode) is also supported.

55.4.9.2.3.8.1 802.15.4 Protocol Support

The link layer supports to parse the IEEE 802.15.4-2015 FSK/GFSK mode packet header when configured in PAN or FAN mode. The objective is to be able to parse the PHR field and identify when to mode switch, extract the PSDU configuration and verify the health of the header. It is intended to support the FSK/GFSK modes as specified for GFSK, MSK, SUN-FSK and LECIM-FSK PHYs.

The 4 PHR structures are shown as Figure 448

Figure 448. PPDU Mapping to Link Layer Packet Structure

Software should configure the register PHR_TYPE[2:0] to select the proper PHR type before Tx or Rx.

For SUN FSK, user should put the **uncoded network address in NTW_ADR_0 or NTW_ADR_2** and put the **coded network address in NTW_ADR_1 or NTW_ADR_3**.

And also software should configure the related registers to correctly work with different PHRs, as shown in Table 486.

GEN_PREAMBLE[7:0]	As needed		
NTW_ADR_SZ[1:0]	According to SFD length		
SYNC_ADDR_SZ[1:0]	According to SFD length		
H0_SZ[4:0]	0	• 5 (MS=0) • 16 (MS=1)	5
LENGTH_SZ[4:0]	7	• 11(MS=0) • 0 (MS=1)	11
H1_SZ[4:0]	1	0	
LENGTH_BIT_ORD	1 - MS Bit First 0 - LS Bit First		
LENGTH_ADJ[10:0]	0		
AA_PLAYBACK_CNT	0 - Access Address will not play back to Link Layer		
RXEN_DLY[9:0]	0		
PHR_TYPE[2:0]	• 000b - The packet type is GFSK • 001b - The packet type is MSK	010b - The packet type is SUN FSK	011b - The packet type is LECIM FSK

For SUN FSK PHR, there will be two cases: one is mode switch PPDU and the other is PPDU without mode switch. LL distinguishes between the two modes by the "Mode Switch (MS)" bit received. If MS=1, then link layer hardware will override the H0_SZ to 16, override LENGTH_SZ to 0. And if MS=0, then link layer hardware will override the H0_SZ to 5 and override the LENGTH_SZ to 11.

For SUN FSK PHR (MS=0) and LECIM FSK PHR type, when Rx, link layer hardware will override the CRC_SZ and WHITEN_START register according to the received FCS Type and Data Whitening bits. That is when FCS Type = 0, CRC_SZ is 4; when FCS Type = 1, CRC_SZ is 2. And when Data Whitening = 0, WHITEN_START=0; when Data Whitening = 1, WHITEN_START=3. When Tx, the PHR is programmed in Packet RAM by software. The FCS Type and Data Whitening bits in PHR should align with the CRC_SZ and WHITEN_START registers. When link layer is performing an auto-Ack sequence, the FCS Type and Data Whitening bits are automatically calculated by hardware according to the CRC_SZ and WHITEN_START registers.

When Rx, for SUN FSK(MS=1), RBME will do the BCH correction and Parity check for the PHR and it will send out the corrected result and fail/pass flag to link layer. If the flag shows pass, an interrupt flag MS_IRQ will be set in IRQ_CTRL register. If MS_IRQ_EN=1, then the interrupt will occur. The PHR[10:0] will be saved into PHR_MISC register for software read. For LECIM FSK, link layer will check the Parity bit. When either fail happens, BCH fail or Parity fail, the PHRFAIL_IRQ will be set and RX_IRQ

will not set. if PHRFAIL_IRQ_EN=1, then the fail interrupt will occur. If PHR_FAIL_IGNORE =1, RX_IRQ will be set even for a received packet which fails PHR verification.

When Tx, for SUN FSK(MS=1), RBME will do the BCH encode and Parity calculation, and fill the Checksum and Parity Check bits in PHR. For LECIM FSK, the Parity bit is calculated by software and programmed into the Packet RAM.

When auto-Ack, the Parity bit for LECIM FSK are calculated by link layer hardware.

55.4.9.2.3.8.1.1 Packet Processor

55.4.9.2.3.8.1.1.1 Introduction

The Packet Processor works in PAN or FAN mode.

In PAN mode, the Packet Processor performs sophisticated hardware filtering of the incoming received packet, to determine whether the packet is both PHY- and MAC-compliant, whether the packet is addressed to this device, and if the device is a PAN Coordinator, whether a message is pending for the sending device.

In FAN mode, the Packet Processor checks whether the received packet passes the rules in FAN standard.

The packet processor greatly reduces the packet filtering burden on software, allowing software to tend to higher-layer tasks with a lower latency and smaller software footprint.

55.4.9.2.3.8.1.1.1.1 Overview

The Packet Processor performs aggressive hardware filtering of the incoming packet as it is being received, to increase battery life by not awakening the MCU to process packets which are non-compliant or not addressed to the device, or that violate the 802.15.4 MAC Frame structure.

The advanced frame parsing enables the sequence manager to handle complex sequences, by, for example, determining whether a receive frame requires an acknowledge, and generating the Sequence Number for that acknowledge, so that the transmit/receive combination sequence can be executed without any MCU intervention.

Finally, the packet processor includes a hardware accelerator that allows the device to handle a critical timing requirement that had been problematic for 8-bit MCU's in the past: the quick-turnaround requirement for an indirect queue-lookup to determine the correct response to an end device sending a data polling request.

The packet processor contains a register-based table of end devices which have messages pending, allowing a single-cycle hardware table lookup to be performed, and a minimum-turnaround-time acknowledge packet to be sent to the end device without MCU intervention.

The packet processor also includes support for Dual PAN mode, which allows the device to simultaneously reside on 2 networks, with 2 separate IEEE addresses.

55.4.9.2.3.8.1.1.1.2 Features

- Aggressive packet filtering to enable long, uninterrupted MCU sleep periods

- Fully compliant with both 2003 and 2006 versions of the 802.15.4 wireless standard
- Supports all Frame Types, including reserved types
- Enables auto-Tx Acknowledge frames (no MCU intervention) by parsing of Frame Control Field and Sequence Number
- Supports all Source and Destination Address modes, and also PAN ID Compression
- Supports Broadcast address for PAN ID and short address mode
- Supports "Promiscuous" mode, to receive all packets regardless of address- and rules-checking
- Allows Frame Type-specific filtering (e.g., reject all but Beacon frames)
- Supports SLOTTED and non-SLOTTED modes
- Includes special filtering rules for PAN Coordinator devices
- Enables minimum-turnaround TX-Acknowledge frames for data-polling requests by automatically determining message-pending status
- Assists MCU in locating pending messages in its indirect queue for data-polling end devices
- Assists MCU in determining if a poll request originated from a valid child end device
- Makes available to MCU detailed status of frames which fail address- or rules-checking
- Supports Dual PAN mode, allowing the device to exist on 2 PAN's simultaneously
- Supports 2 IEEE addresses for the device
- Includes provisions to enable software support of 802.15.4-2015 frame types and versions
- **Supports FAN standard DATA and ACK frame filter.**

55.4.9.2.3.8.1.1.2 Functional Description

The packet processor is responsible for receiving symbols from the demodulator, combining them into octets, assembling the octets into packets, filtering the packets in compliance with the 802.15.4 wireless MAC standard, and storing the packets into the Packet Buffer (Packet RAM).

The packet processor parses the incoming packets on-the-fly to determine:

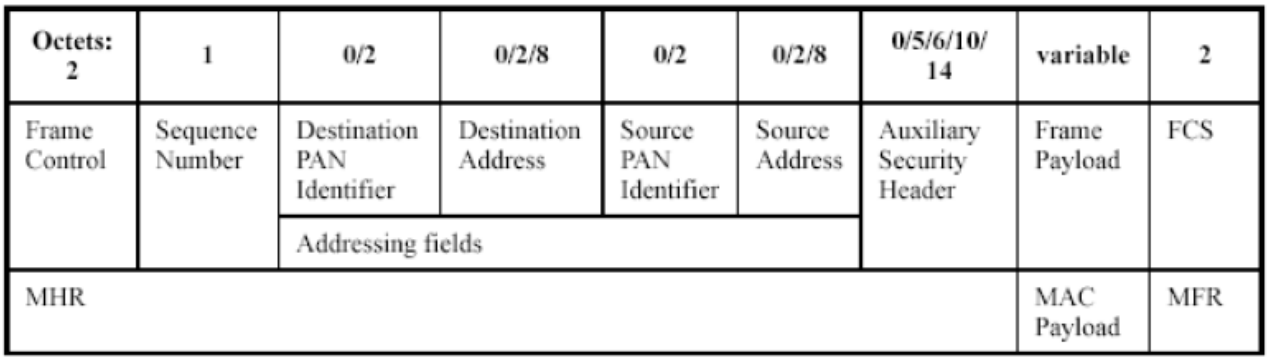
1. whether the packet is MAC-compliant, and if it is,
2. whether the packet is addressed to the end device.

The packet processor performs aggressive filtering on incoming packets, in order to reduce unnecessary MCU wake-ups, to allow longer MCU sleep durations, and to provide sufficient hardware automation so as to enable complex sequences to be executed by the sequence manager. The packet processor also includes hardware support for Dual PAN operation (allowing the device to reside on two networks simultaneously).

The packet processor also includes functionality to allow a critical-timing requirement to be met, which in the past has been problematic for low-MIPS receiving devices: the ability of a coordinator device to respond to a MAC Command data request from an end device, with an Acknowledge frame containing a FramePending bit accurately reflecting the presence of a message for the end device in the coordinator's indirect queue, or the absence of the end device in the coordinator's neighbor table, within the prescribed turnaround time window. This functionality is described in more detail in the Source Address Management

55.4.9.2.3.8.1.1.2.1 Packet Filtering Background

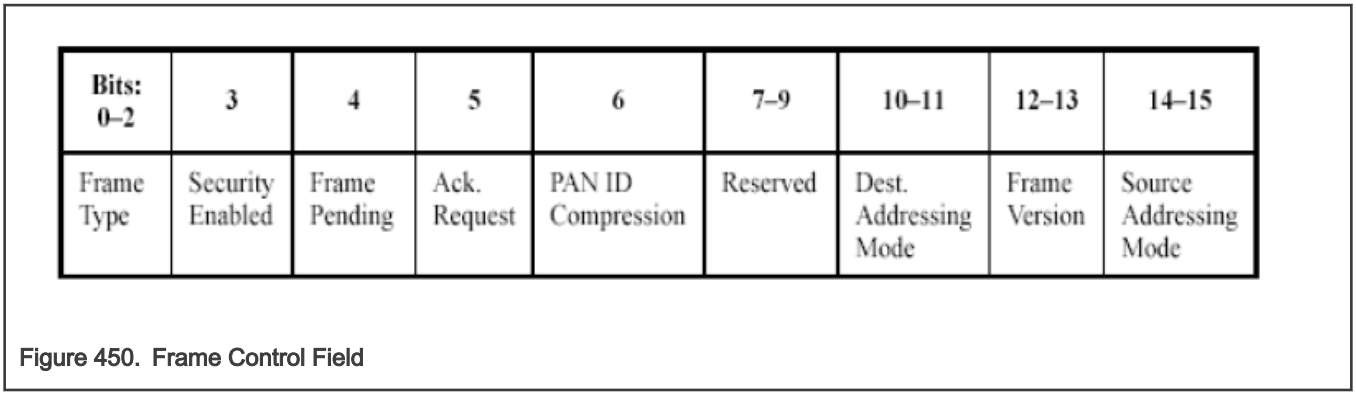
The packet processor parses packets to verify compliance with the 802.15.4 MAC frame format. The basic MAC frame format is shown in the figure below.



Octets: 2	1	0/2	0/2/8	0/2	0/2/8	0/5/6/10/14	variable	2
Frame Control	Sequence Number	Destination PAN Identifier	Destination Address	Source PAN Identifier	Source Address	Auxiliary Security Header	Frame Payload	FCS
		Addressing fields						
MHR							MAC Payload	MFR

Figure 449. MAC Frame Format

The packet processor parses the incoming octets on the fly, as they are received. The Frame Control Field, two octets in length, contains subfields which encode "instructions" on how to parse the remainder of the MHR (MAC Header). The structure of the Frame Control Field is shown in the figure below.



Bits: 0–2	3	4	5	6	7–9	10–11	12–13	14–15
Frame Type	Security Enabled	Frame Pending	Ack. Request	PAN ID Compression	Reserved	Dest. Addressing Mode	Frame Version	Source Addressing Mode

Figure 450. Frame Control Field

The packet processor utilizes the Frame Control Fields subfields in the following manner:

FCF Subfield	Utilization by Packet Processor
FrameType	Interprets the remaining MHR as specific to Beacon, Ack, Data, Command, or Reserved frame types. Each frame type has a unique MHR structure, and so different parsing rules apply.
SecurityEnabled	If SecurityEnabled=1 and FrameVersion>0 (frame versions 2006 and later), an Auxiliary Security Header field will be present in the MHR and will need to be further parsed by the packet processor if this is a MAC Command frame (see Section Source Address Management). There is no other use of SecurityEnabled by the packet processor.
FramePending	ignored by packet processor
Ack. Request	will be copied into the **pp_ack_request** signal to the sequence manager. An auto-TxAck frame will follow the incoming receive frame if necessary conditions are met
PAN ID Compression	used for addressing mode rules-checking and addressing field parsing.

Table continues on the next page...

Table continued from the previous page...

FCF Subfield	Utilization by Packet Processor
Reserved	ignored by packet processor
Destination Addressing Mode	used for addressing mode rules-checking and addressing field parsing
FrameVersion	For Beacon, Data, and MAC Command frames, FrameVersion is checked against the allowed frame versions according to FRM_VER_FILTER For Acknowledge frames, FrameVersion is ignored. If SecurityEnabled=1 and FrameVersion>0 (frame versions 2006 and later), an Auxiliary Security Header field will be present in the MHR and the MHR will need to be further parsed by the packet processor if this is a MAC Command frame (see SectionSource Address Management).
Source Addressing Mode	used for addressing mode rules-checking and addressing field parsing

The Packet Processor parses the FrameType field of the Frame Control Field per the following table:

Frame type value b_2 b_1 b_0	Description
000	Beacon
001	Data
010	Acknowledgment
011	MAC command
100–111	Reserved

Figure 451. Frame Type Field

Directly following the Frame Control Field is the Sequence Number field. The Sequence Number field of the MHR is captured by the packet processor. If an auto-TxAck frame follows the incoming receive frame, the captured Sequence Number will be copied to the transmitted Acknowledge packet, and the Packet Processor will insert FrameVersion=00 into the Frame Control Field of the transmitted frame, regardless of the received FrameVersion subfield of the original frame.

The Addressing Fields follow the Sequence Number. The format of the Addressing Fields depends upon the Source and Destination Addressing Mode subfields of the Frame Control Field. The Addressing Modes are defined in the table below:

Addressing mode value b_1 b_0	Description
00	PAN identifier and address fields are not present.
01	Reserved.
10	Address field contains a 16-bit short address.
11	Address field contains a 64-bit extended address.

Figure 452. Addressing Mode Fields

The packet processor uses these Source and Destination Address Modes shown above, to extract the Source PAN ID and Address (if present), and the Destination PAN ID and Address (if present), from the MHR, according to the table below:

FrameType	Destination Addressing Mode	Source Addressing Mode	PanID-Compression	Addressing Fields
Acknowledge only (reject all other frame types)	0	0	0	None
Data or Command (reject Ack and Beacon frames)	2 or 3	0	0	DstPanID + DstAddr
Beacon (all devices), or Data or Command (PAN Coord Only) (reject Ack frames)	0	2 or 3	0	SrcPanID + SrcAddr
Data or Command (reject Ack and Beacon frames)	2 or 3	2 or 3	0	DstPanID + DstAddr + SrcPanId + SrcAddr
Reject all frames (Illegal as per Section 7.2.2.1.5)	0	0	1	-
Reject all frames (Illegal as per Section 7.2.2.1.5)	2 or 3	0	1	-
Reject all frames	0	2 or 3	1	-

Table continues on the next page...

Table continued from the previous page...

FrameType	Destination Addressing Mode	Source Addressing Mode	PanID-Compression	Addressing Fields
(Illegal as per Section 7.2.2.1.5)				
Data or Command (reject Ack or Beacon frames)	2 or 3	2 or 3	1	DstPanID + DstAddr + SrcAddr
Reject all frames (Illegal as per Section 7.2.2.1.6)	1	-	-	-
Reject all frames (Illegal as per Section 7.2.2.1.8)	-	1	-	-

The Source PAN ID and Address, and Destination PAN ID and Address, extracted by the packet processor, are then checked against the MACPANID, MACSHORTADDRS, and MACLONGADDRS register settings, depending on the FrameType of the incoming packet, to determine:

1. Is the addressing mode combination valid for this frame type?
2. Do the address fields indicate that the packet is indeed addressed to the end device?

The details on how the packet processor answers those 2 questions, are described in the following sections.

55.4.9.2.3.8.1.1.2.2 Packet Filtering Detail

The figure below is a high-level representation of the packet filtering performed by the 802.15.4 packet processor. The sections which follow provide more detail on the packet filter implementation.

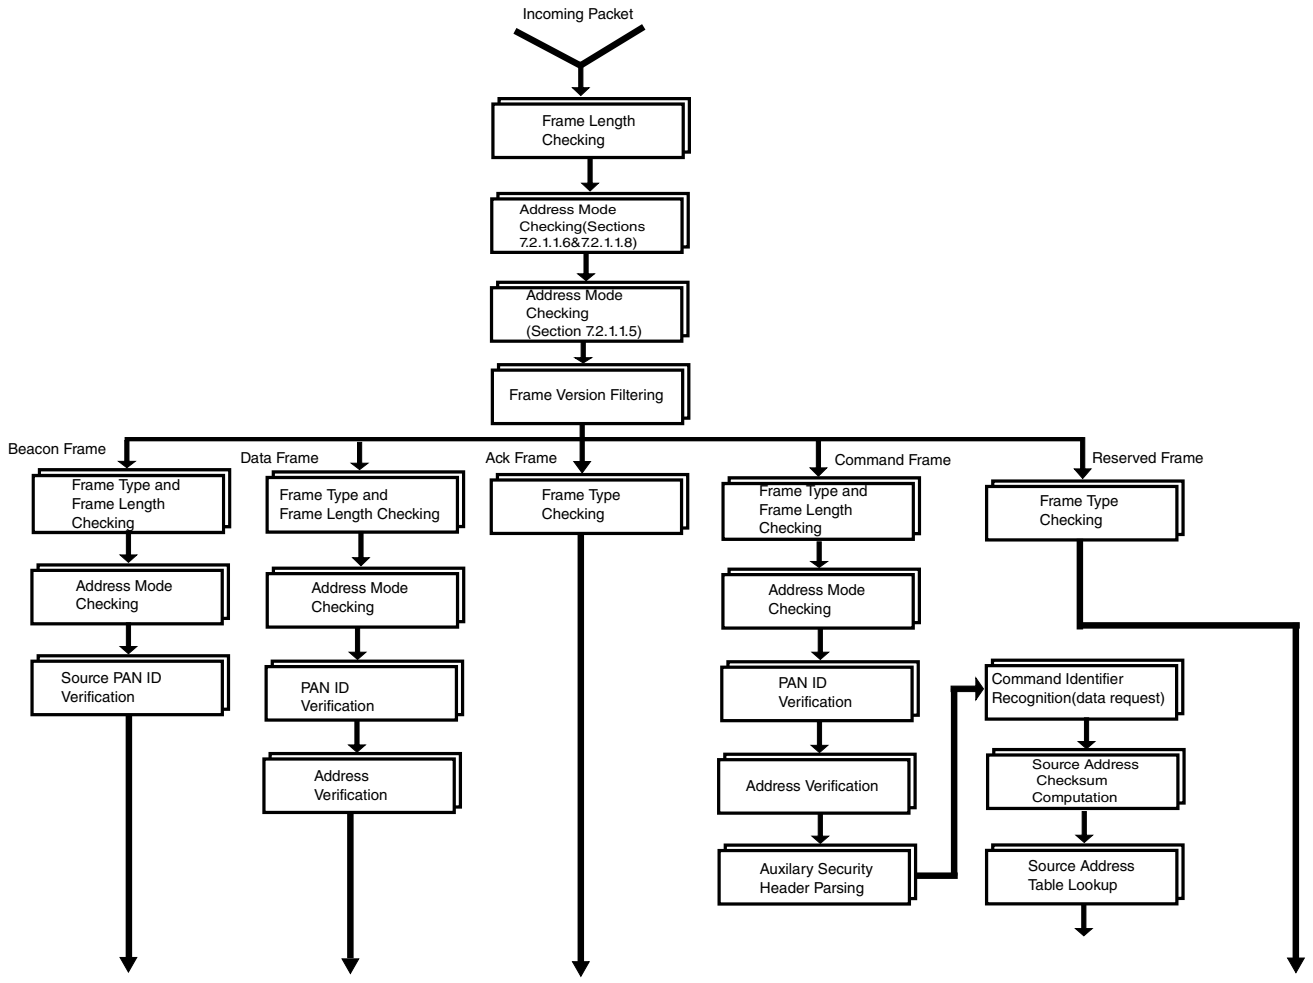


Figure 453. Packet Filtering Flow Diagram

First-Stage Packet Filtering

The first stage of packet filtering examines the incoming packet, and implements basic rule-checking, based on the 2006 version of the 802.15.4 standard, and is applied to *all* frame types. First stage rule-checking is described in the table below:

	Filtering Step	Description
1	Frame Length Checking	Check that all frames are at least 3 octets payload (not include FCS field).
2	Address Mode Checking (Sections 7.2.1.1.6 and 7.2.1.1.8)	Check that neither Source nor Destination Address Mode set to 1 (illegal addressing mode)
3	Address Mode Checking (Section 7.2.1.1.5)	Check for PAN ID Compression enabled, with either Source or Destination Address Mode set to 0 (illegal addressing mode)
4	FrameVersion Checking	Check that incoming packet's Frame Version is allowed based on FRM_VER_FILTER setting. (FRM_VER_FILTER is a programmable register, see Register Descriptions Section).

Packets which pass first stage filtering, proceed to the second stage of packet filtering, which is *frame type-specific* filtering. Packets which fail initial rule checking are marked as rejected.

Second-Stage Packet Filtering

The second stage of packet filtering is *frame type-specific*. Different variations of the MAC Header (MHR) apply to different frame types, so different parsing mechanisms apply to each.

Note: In the following section, the following references are to register bits; see Register Description Section for register descriptions: BEACON_FT, ACK_FT, DATA_FT, CMD_FT, NS_FT, PANCORDNTR, MACPANID, MACSHORTADDRS, and MACLONGADDRS.

1) For Beacon frames, these are the basic filtering steps:

- Check that Beacon frames are enabled by software (BEACON_FT)
- Check that Payload Length >= 7
- Check for illegal combinations of PAN ID Compression and Source/Destination Address Modes
- Verify the Source PAN ID matches MACPANID, or that MACPANID = 0xffff.

2) For Acknowledge frames, these are the basic filtering steps:

- Check that Ack frames are enabled by software (ACK_FT)
- If Sequence TR is active and RXACKRQD = 1, check the received Sequence Number matches the transmitted Sequence Number; FrameVersion bits are ignored, as per section 7.2.2.3.1 of the 802.15.4 standard.

Note: It is recommended to use Sequence TR to receive Acknowledge frames, not Sequence R. See Chapter Sequence Manager, Section.Sequence TR (Transmit/Receive)

3) For Data frames, these are the basic filtering steps:

- Check that Data frames are enabled by software (DATA_FT)
- Check that Payload Length >= 7
- Check for illegal combinations of Source and Destination Address Modes
- If PANCORDNTR=0, check for missing Destination Address field or present Source Address field
- If no Destination Address field (PANCORDNTR=1 only), check Source PAN ID matches MACPANID
- If Destination Address present, check Destination PAN ID matches MACPANID or broadcast (0xffff)
- If Short Destination Address field, check address matches MACSHORTADDRS or broadcast (0xffff)
- If Long Destination Address field, check address matches MACLONGADDRS.

4) For MAC Command frames, these are the basic filtering steps:

- Check that Command frames are enabled by software (CMD_FT)
- Check that Payload Length >= 7
- Check for illegal combinations of Source and Destination Address Modes
- If PANCORDNTR=0, check for missing Destination Address field or present Source Address field
- If no Destination Address field (PANCORDNTR=1 only), check Source PAN ID matches MACPANID
- If no Destination Address field (PANCORDNTR=1 only), capture Source PAN ID and Source Address for later use
- If Destination Address present, check Destination PAN ID matches MACPANID or broadcast (0xffff)
- If Short Destination Address field, check address matches MACSHORTADDRS or broadcast (0xffff)
- If Long Destination Address field, check address matches MACLONGADDRS.

- At end of the addressing field, if incoming packet's FrameVersion=0 or SecurityEnabled=0, capture the next octet (Command Identifier)
- At end of the addressing field, if incoming packet's FrameVersion!=0 and SecurityEnabled=1, parse the Auxiliary Security Header, then capture the next octet (Command Identifier)
- If Command Identifier indicates the MAC Command is a data request, compute a "Source Address Checksum" to uniquely identify the sending device.

55.4.9.2.3.8.1.1.2.3 Source Address Management

The 802.15.4 wireless MAC standard envisions a scenario whereby an end device may interrogate a coordinator as to whether the coordinator is storing data (i.e., a pending message) for the end device. The situation arises in a beacon-enabled network, when a coordinator includes in its transmitted beacon frame the MAC address of the end device in its "Pending Address Fields". The "Pending Address Fields" are part of the required MAC payload of the beacon frame. The "Pending Address Fields" contain a list of end device addresses for which messages are pending. In this scenario, an end device which finds its address included in the "Pending Address Fields" of the received beacon frame, must respond to the beacon (coordinator) with a MAC Command of type "data request". Alternatively, in non-beacon-enabled networks, an end device may periodically wake up and "poll" a coordinator, to determine if a message is pending for the end device. In either case, the coordinator stores messages for its end devices in its "indirect queue". The coordinator must respond to an incoming MAC Command data request (which *must* have AckRequest=1 in its Frame Control Field), with an Acknowledge frame containing a FramePending subfield indicating the presence (or absence) of a message for the requesting end device, in the coordinator's indirect queue. For a coordinator built around a low-MIPS MCU, a significant amount of MCU time is typically required, simply to ascertain whether a given end device has a message pending or not; the indirect queue can be quite large, and for 8-bit MCU's, the queue must be searched byte-by-byte. This makes it difficult, or impossible, for an underpowered MCU to establish frame-pending status within the RX-to-TX turnaround time required by the standard.

Also, coordinators may include, in software, a "Neighbor Table", the contents of which consist of all the end devices with which the coordinator is in communication. The neighbor table requires periodic maintenance by coordinator (parent) software, as end devices (children) come and go within the network, join different parents, or simply never return. Child tables have limited capacity and parents need to create space for new devices that may show up. A timeout mechanism is the only way that can guarantee that child tables will eventually be cleaned up. Coordinator software must "age out" end devices with which there has not been recent communication. In order for an end device to refresh its status within its parent's Neighbor Table, the end device may periodically send a "keepalive" message in the form of a MAC Data Poll Request. Upon receipt of such a poll request, the parent must search its neighbor table to determine if the source address of the end device is a valid table entry. If the end device exists in the table, an Acknowledgment packet must be transmitted to the end device, with the FramePending subfield set to 0, and coordinator software resets that end device's timeout counter; if the child is not present in the table, an Acknowledgment packet must be transmitted to the end device, with the FramePending subfield set to 1, and the parent device will follow up by transmitting a "Leave Packet" to the end device, instructing the end device to sever its child status with the parent. The end device may opt to rejoin at a later time. Due to the size of the parent's Neighbor table, the search a child's source address can be time consuming, and may not always be possible within the RX-to-TX turnaround time required by the standard.

To alleviate both of these problems, the 802.15.4 packet processor includes hardware acceleration to expedite the source address table search, greatly relieving the software bottleneck during the critical turnaround time. The table search acceleration consists of 2 components: 1) a search for the *presence* of a specific end device's source address, which expedites the process of determining whether a message is pending for the device; and 2) a search for the *absence* of a specific end device's source address, which expedites the process of determining whether the end device is a valid child of the parent.

The packet processor maintains a register table (128 deep, 16-bit wide). The table is divided into multiple partitions, one to perform the "Source Address Present" (SAP) search, and another to perform the "Source Address Absent" (SAA) search. In the SAP partition of the table, coordinator software will store the address of end devices for which it has a message pending; in the SAA partition of the table, coordinator software will store the address of end devices for which it is the parent. To reduce area, the address information is stored in a "compressed" format. Software compresses the address information, and stores it into the table partitions, during a non-critical time. Then, when the coordinator's packet processor receives a MAC Command data request, it extracts the source address information from the incoming packet, and compresses it using the *same* compression algorithm used by software to populate the source address table. The packet processor performs 2 steps simultaneously:

1. it compares the just-received, compressed source address information, or "checksum", against all of the enabled entries in the SAP partition of the table. If a match is found in the SAP partition, the packet processor *asserts* the **rx_frame_pending** signal to the transmit block (TX_PACKET), so that an auto-TxAck packet can be sent to the requesting end device, with the FramePending subfield set to 1, indicating that the end device has a message pending in the coordinator's indirect queue. A message packet from the coordinator to the end device will follow.
2. it compares the just-received, compressed source address information, or "checksum", against all of the enabled entries in the SAA partition of the table. If *no* match is found in the SAA partition, the packet processor *asserts* the **rx_frame_pending** signal to the transmit block (TX_PACKET), so that an auto-TxAck packet can be sent to the requesting end device, with the FramePending subfield set to 1, indicating that the end device is not a valid child of this parent, and a "Leave Packet" from the coordinator to the end device, will follow.

If neither condition is met, i.e., there is no address match in the SAP partition, and a positive match in the SAA partition, the packet processor *deasserts* the **rx_frame_pending** signal, so that an auto-TxAck packet can be sent indicating to the end device that it has no data pending, and that it remains a valid child of this parent; the end device may then deactivate its receiver immediately. For the packet processor, the entire table lookup occurs in 128 clock cycles, once the last source address octet has been received. The SAP and SAA lookups are performed simultaneously. The checksum is also computed on-the-fly by hardware as the source address octets are received, taking no more than 1 clock cycle per octet. Finally, table-search status is reported to the MCU:

1. after the packet processor completes its SAP table search, the status bit SAP0_ADDR_PRESENT will be set to 1 if a match is found in the SAP partition, and the table index which matched will be indicated in the SAP0_MATCH[6:0] register, to further assist software in locating the relevant message within its indirect queue; if no match is found in the SAP partition, the status bit SAP0_ADDR_PRESENT will be set to 0.
2. after the packet processor completes its SAA table search, the status bit SAA0_ADDR_ABSENT will be set to 1 if *no* match is found in the SAA partition; if a positive match is found in the SAA partition, the status bit SAA0_ADDR_ABSENT will be set to 0, and the table index which matched will be indicated in the SAA0_MATCH[6:0] register, to further assist software in locating the child device within its neighbor table.

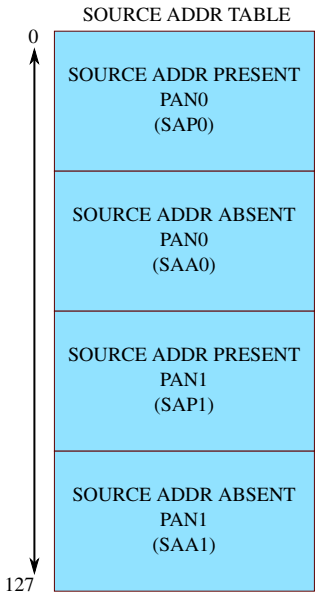
Both features, SAP and SAA acceleration, are optional, and functionally independent. Coordinator software can elect to enable both, either, or neither feature. The control bit SAP0_EN enables SAP acceleration. The control bit SAA0_EN enables SAA acceleration. If either feature is disabled, that table partition (SAP or SAA) is not searched, and so is not a factor in determining FramePending status for the transmitted Acknowledge frame. If *both* features are disabled, FramePending status defaults to software control, and merely tracks the state of the ACK_FRM_PND register bit; in this case software must manage FramePending status for all auto-TxAck frames.

Software can also take direct control of FramePending status for the next auto-TxAck frame at any time (regardless of whether SAP or SAA acceleration is enabled), by setting the ACK_FRM_PND_CTRL bit; in this case, hardware FramePending status will track the state of ACK_FRM_PND.

In order to support Dual PAN mode, a device could theoretically be a PAN Coordinator on both networks. Thus, a coordinator device may need to maintain distinct message pending lists and/or neighbor tables for the 2 PANs. Accordingly, the packet processor further subdivides the Source Address Management table into 4, instead of 2, partitions:

1. SAP0: Source Address Present Partition for PAN0
2. SAA0: Source Address Absent Partition for PAN0
3. SAP1: Source Address Present Partition for PAN1
4. SAA1: Source Address Absent Partition for PAN1

SOURCE ADDRESS TABLE PARTITIONS



Four register control bits enable each partition individually. If a partition is enabled, and a MAC poll request is received on the corresponding PAN (e.g. SAP0 or SAA0 partitions on PAN0), then the partition is searched by the packet processor, looking for a source address match (or absence), and the result of the search affects the FramePending status; if a partition is disabled, the partition is not searched, and will not influence FramePending status. The register bits are described in the table below.

REGISTER NAME	DESCRIPTION
SAP0_EN	Enables SAP0 Partition
SAA0_EN	Enables SAA0 Partition
SAP1_EN	Enables SAP1 Partition
SAA1_EN	Enables SAA1 Partition

For maximum flexibility in supporting all combinations of message-pending status, neighbor-table status, and dual PAN mode, the dividing-line between all the partitions is fully programmable. The SAP0 partition always starts at table index 0. Three registers control the starting point for the other 3 partitions. The starting point is defined the first table index (0-127) of that partition. The registers are described below, along with some software restrictions to ensure table consistency.

REGISTER NAME	DESCRIPTION	RESTRICTIONS
SAA0_START[6:0]	First Index of SAA0 partition.	If SAA0_START=0, then there is no SAP0 partition (SAP0_EN should be set to 0)
SAP1_START[6:0]	First Index of SAP1 partition.	Software must ensure that: **SAP1_START ≥ SAA0_START** If SAP1_START = SAA0_START, then there is no SAA0 partition (SAA0_EN should be set to 0)
SAA1_START[6:0]	First Index of SAA1 partition.	Software must ensure that:

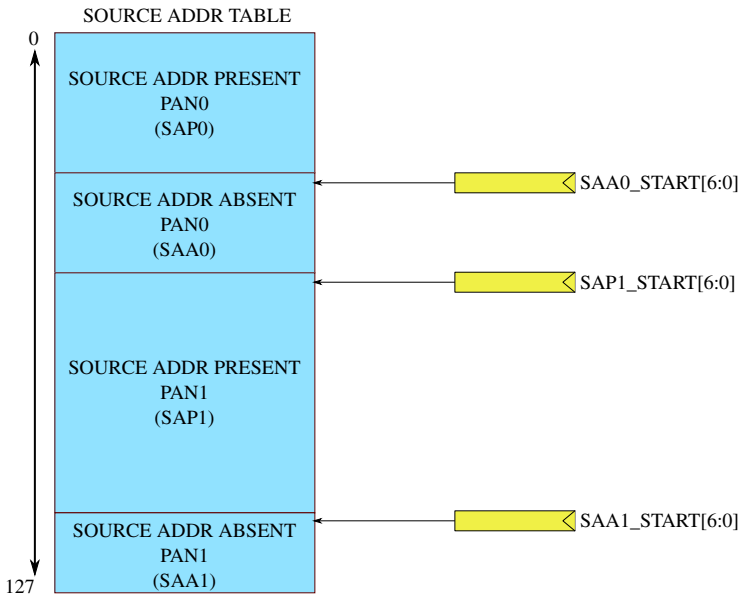
Table continues on the next page...

Table continued from the previous page...

REGISTER NAME	DESCRIPTION	RESTRICTIONS
		SAA1_START ≥ SAP1_START If SAA1_START = SAP1_START, then there is no SAP1 partition (SAP1_EN should be set to 0)

A diagram which depicts one example of how the dividing-line registers affect partitioning of the table, is shown below.

SOURCE ADDRESS TABLE PARTITIONS -- NON-EQUAL SIZES (EXAMPLE)



Each table partition consists of one or more indices, which can be used to store source address checksums. The first index for any partition, is defined by the aforementioned *PARTITION*_START[6:0] register, where *PARTITION*_ is one of {SAP0, SAP1, SAA0, SAA1}. The last index for any partition, is defined by the next higher partition's *PARTITION*_START[6:0] register, minus 1. When populating the table with source address information, software must be sure to select an index that is within the defined range for the partition. For example, when installing a checksum in the SAP1 partition:

SAP1_START ≤ Selected_Index ≤ (SAA1_START – 1)

To populate the table partitions, a 7-bit register SAM_INDEX[6:0] is provided, as well as a "index enable bit", and a "index invalidate" bit. A 16-bit SAM_CHECKSUM[15:0] is provided, into which software will write the computed checksum. Installing a checksum into any partition is referred to as "Enabling an Index", and removing a checksum from any partition is referred to as "Invalidating an Index". A description of the registers is provided in the following table:

REGISTER NAME	DESCRIPTION
SAM_CHECKSUM[15:0]	Software-computed source address checksum, to be installed into a table index
SAM_INDEX[6:0]	Contains the table index to be enabled or invalidated. Software must ensure that the index is within the range of the desired partition.

Table continues on the next page...

Table continued from the previous page...

REGISTER NAME	DESCRIPTION
SAM_INDEX_WR	For 32-bit writes, this must be set to indicate that the table entry specified by SAM_INDEX[6:0] is to be written; if SAM_INDEX_WR=0, the table entry is not written, but the SAM_INDEX[6:0] register is updated. For 8-bit writes, this bit is ignored.
SAM_INDEX_EN	Enable the index selected by SAM_INDEX[6:0] for searching.
SAM_INDEX_INV	Invalidate the index selected by SAM_INDEX[6:0]
FIND_FREE_IDX	After modifying Valid bits (enabling or invalidating), write this bit to 1 to force HW to update the "First Free Index" registers to account for the changed Valid bits. This HW update process takes 4us. SW can poll SAM_BUSY to determine when the table update is complete. Write-only bit. Writing 0 to this bit has no effect. Readback value is indeterminate.
SAM_BUSY	HW is in the process of updating the Source Address table, either in response to a poll indication from the packet processor, or due to SW setting FIND_FREE_IDX=1. In the latter case, SW should poll SAM_BUSY until low before accessing the "First Free Index" registers. Read-only bit.
INVALIDATE_ALL	Writing a 1 to this bit clears all 128 Valid bits. Invalidates the entire table. Write-only bit. Writing 0 to this bit has no effect. Readback value is indeterminate.

All the index-control registers reside within a single 32-bit word, so that a single 32-bit write can store a new checksum in the table, and simultaneously enable, or invalidate, the index. For 32-bit writes, SAM_INDEX_WR must be set to 1 to cause the SAM_CHECKSUM[15:0] to be loaded into the table at the address specified by SAM_INDEX[6:0]. For 32-bit reads, it is necessary first to update SAM_INDEX[6:0] to the desired table index, if it is not already set to the desired index; this requires a write to SAM_INDEX[6:0] with SAM_INDEX_WR=0, so as to not update the table contents. Then, a subsequent 32-bit read will return the table contents at the desired index.

For systems that don't support 32-bit writes, the register fields should be written in the following order:

1. SAM_INDEX[6:0]
2. SAM_CHECKSUM (the 2 bytes can be written in either order)
3. SAM_INDEX_EN (to enable), or SAM_INDEX_INV (to invalidate)

During operation, when a packet is received and the packet processor searches the table for a source address match, only enabled indices within each partition are searched. Invalidated indices are ignored.

To assist software in finding an available index to store the next source address checksum, the packet processor makes available the following 4 read-only registers:

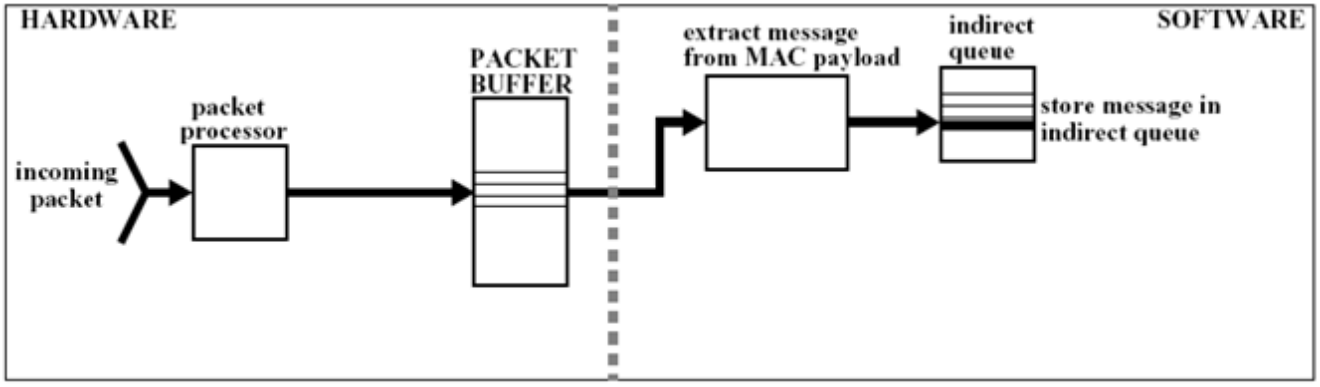
REGISTER NAME	DESCRIPTION
SAP0_1ST_FREE_IDX[6:0]	First non-enabled (invalid) index in the SAP0 partition
SAA0_1ST_FREE_IDX[6:0]	First non-enabled (invalid) index in the SAA0 partition
SAP1_1ST_FREE_IDX[6:0]	First non-enabled (invalid) index in the SAP1 partition
SAA1_1ST_FREE_IDX[6:0]	First non-enabled (invalid) index in the SAA1 partition

Operational Use

The following flow description illustrates how hardware and software interact to utilize the Source Addressing Management feature to facilitate pending-message handling and neighbor table management. This flow assumes both SAP and SAA acceleration are enabled, and Dual PAN mode is in effect. There are 11 sequential steps.

Step 1: Message Packet Reception, Extracting the Message, Indirect Queue Management

A message (data frame) is received by a coordinator. The message is received from one end device, and is intended for another end device. The coordinator's packet processor receives the packet, and stores it in the packet buffer. Coordinator software downloads the packet data from the packet buffer, extracts the message from the MAC payload, and stores the message in its indirect queue.



Step 2: Software computes address checksum

Coordinator software also extracts the destination information (Destination PANID and Destination Address), from the data packet stored in the packet buffer. Software uses this information to compute a 16-bit checksum. This checksum uniquely identifies the sending device, with a high degree of reliability. The checksum is computed according to the following rules:

Destination Addressing Mode	Rule
Mode 2 (short address)	Checksum = (Destination PAN ID + DstAddr[15:0]) % 65536
Mode 3 (long address)	Checksum = (Destination PAN ID + DstAddr[15:0]) % 65536 Checksum = (Checksum + DstAddr[31:16]) % 65536 Checksum = (Checksum + DstAddr[47:32]) % 65536 Checksum = (Checksum + DstAddr[63:48]) % 65536

Step 3: Software populates the address table

Coordinator software chooses an index in the Source Address Table in which it will store the just-computed checksum. If the data packet was received on PAN0, an index in the SAP0 partition should be chosen. Software may consult the register SAP0_1ST_FREE_IDX[6:0] to find the first available index in this partition. If the data packet was received on PAN1, an index in the SAP1 partition should be chosen. Software may consult the register SAP1_1ST_FREE_IDX[6:0] to find the first available index in this partition.

If an index is chosen which is already valid, software should first invalidate the index with the following procedure:

1. Set SAM_INDEX[6:0] to the selected index
2. Set SAM_INDEX_EN=0 and SAM_INDEX_INV=1

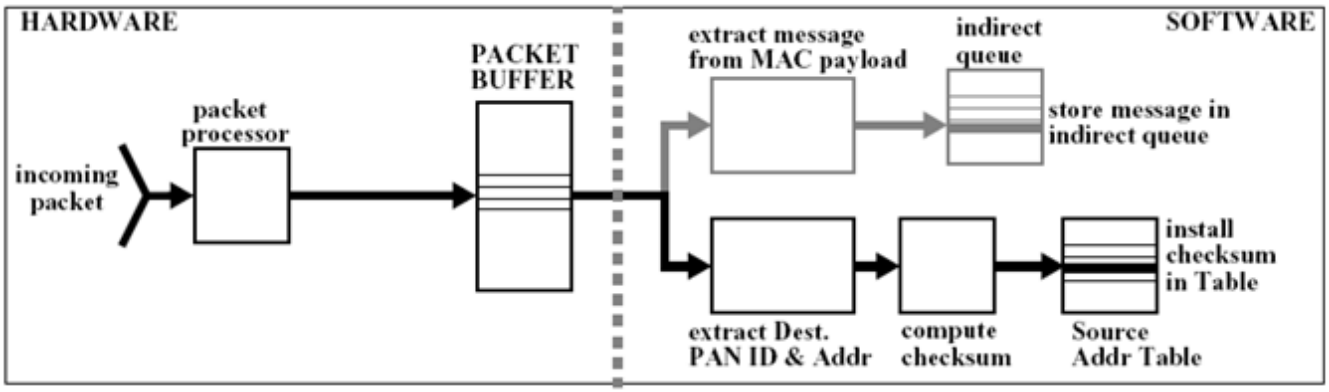
These steps can be performed in a single, 32-bit register write.

To install the source address checksum into the index and enable the index, the following procedure should be used:

1. Program SAM_CHECKSUM[15:0] to the computed checksum
2. Set SAM_INDEX[6:0] to the selected index
3. Set SAM_INDEX_EN=1 and SAM_INDEX_INV=0

These steps can be performed in a single, 32-bit register write.

The index is now enabled, and the packet processor will include it in its search when the next MAC Poll Request is received.



Step 4: Incoming Poll request, Packet Processor parses the Auxiliary Security Header

An incoming packet is received. The packet processor performs routine packet filtering. After determining that the packet is type 'MAC Command', the packet processor must perform additional packet parsing in order to locate the packet's Command Frame Identifier. This is the octet that distinguishes this commandas being of type "data request", from other MAC Command types. For the packet processor, this extra parsing is more complex, because the Command Frame Identifier is part of the MAC payload; this is theonly scenario where the packet processor is required to parse the payload. This is further complicated by the fact that the revision 2006 (and subsequent) of the 802.15.4 wireless MAC standard, includes a variable-length "Auxiliary Security Header", prior to the MAC payload. This header is only present for FrameVersion > 0, and SecurityEnabled = 1. The packet processor must conditionally parse this header in order to locate the start of the MAC payload, where the Command Frame Identifier is located. The packet processor uses 2 subfields of the Frame Control Field to parse the Auxiliary Security Header (A.S.H.): FrameVersion, and SecurityEnabled. The packet processor parses the Auxiliary Security Header (A.S.H.) according to the following table:

Length of Auxiliary Security Header (Octets)	SecurityEnabled (Frame Control Field)	FrameVersion (Frame Control Field)	KeyIdentifierMode (Security Control Field)	Remarks
0	0	00 or 01	-	If !SecurityEnabled, no ASH regardless of FrameVersion
0	1	00	0	If packet is 2003-compliant, no ASH
5 Security Control (1 octet) + Frame Counter (4 octet)	1	01	0x00	ASH present. Length of ASH computed by HW.
6 Security Control (1 octet) +	1	01	0x01	ASH present. Length of ASH computed by HW.

Table continues on the next page...

Table continued from the previous page...

Length of Auxiliary Security Header (Octets)	SecurityEnabled (Frame Control Field)	FrameVersion (Frame Control Field)	KeyIdentifierMode (Security Control Field)	Remarks
Frame Counter (4 octet) + Key Identifier (1 octet)				
10 Security Control (1 octet) + Frame Counter (4 octet) + Key Identifier (5 octet)	1	01	0x2	ASH present. Length of ASH computed by HW.
14 Security Control (1 octet) + Frame Counter (4 octet) + Key Identifier (9 octet)	1	01	0x3	ASH present. Length of ASH computed by HW.
-	-	10 or 11	-	HW will handle these FrameVersion's indentically to FrameVersion 01

The contents of the A.S.H. are irrelevant to the packet processor; only its length is important. This is because the octet which immediately follows the A.S.H. is the Command Frame Identifier. This is all the packet processor needs to know.

Step 5: Hardware extracts the Command Frame Identifier

After parsing the A.S.H. (if present), the next octet in the MAC payload, in accordance with the 802.15.4 standard, is the Command Frame Identifier.

Command frame identifier	Command name	RFD		Subclause
		Tx	Rx	
0x01	Association request	X		5.3.1
0x02	Association response		X	5.3.2
0x03	Disassociation notification	X	X	5.3.3
0x04	Data request	X		5.3.4
0x05	PAN ID conflict notification	X		5.3.5
0x06	Orphan notification	X		5.3.6
0x07	Beacon request			5.3.7
0x08	Coordinator realignment		X	5.3.8
0x09	GTS request			5.3.9
0x0a–0xff	Reserved			—

The packet processor checks to see if the Command Frame Identifier = 0x4. If it is not, packet processing for this frame is complete, the remainder of the packet is received, without inspection by the packet processor, and is stored the packet buffer. If the Command Frame Identifier = 0x4, then this is a data request, and assuming the prior rules-checking and address-checking on this packet have already passed, then the Source Address Matching function will be applied to this packet, continuing in STEP 6.

Step 6: Hardware Computes the Source Address Checksum

The packet processor uses the received Source PAN ID and Source Address for this packet to compute a 16-bit Source Address checksum. This checksum uses precisely the same algorithm that software uses to compute its Address checksum (see STEP 2), except that the *Source* PAN ID and address are used, rather than the Destination PAN ID and address. This checksum uniquely identifies the sending device, with a high degree of reliability. Note if the incoming packet's Frame Control Field has the PANIDCompression subfield asserted, the packet processor will substitute "Destination PAN ID" for "Source PAN ID" in the computation, since Source PAN ID will not be present under these circumstances.

Step 7: Hardware performs "Source Address Present" Table Search

If the MAC poll request was received on PAN0, and SAP0_EN=1 to enable searches of the PAN0 "Source Address Present" partition, the packet processor uses its Source Address checksum to look for a match in the SAP0 partition of the table. Only table entries that are enabled, are compared against (see STEP 3); table indices which are not enabled, are ignored in the search.

If a single table match is found (i.e., 1 software-computed checksum in SAP0 partition matches the hardware-computed checksum for the incoming packet), this means that there is a message for this requestor in the coordinator's message queue. For a SAP0 match, the packet processor takes these 2 steps:

1. Set SAP0_ADDR_PRESENT=1
2. Set SAP0_MATCH[6:0] to the index which matched

If multiple table matches are found (i.e., more than 1 software-computed checksum in the SAP0 partition matches the hardware-computed checksum for the incoming packet), this means that there are multiple messages for this requestor in the coordinator's message queue. In this case, the packet processor takes the same steps as for a single match, with the SAP0_MATCH[6:0] register being set to the lowest-value matching index (i.e., the smallest number) within the SAP0 partition.

If no source address match is found in the SAP0 table search, the packet processor will set SAP0_ADDR_PRESENT=0.

If, on the other hand, the MAC poll request was received on PAN1, and SAP1_EN=1 to enable searches of the PAN1 "Source Address Present" partition, the packet processor uses its Source Address checksum to look for a match in the SAP1 partition of the table. Only table entries that are enabled, are compared against (see STEP 3); table indices which are not enabled, are ignored in the search.

If a single table match is found (i.e., 1 software-computed checksum in SAP1 partition matches the hardware-computed checksum for the incoming packet), this means that there is a message for this requestor in the coordinator's message queue. For a SAP1 match, the packet processor takes these 2 steps:

1. Set SAP1_ADDR_PRESENT=1
2. Set SAP1_MATCH [6:0] to the index which matched

If multiple table matches are found (i.e., more than 1 software-computed checksum in the SAP1 partition matches the hardware-computed checksum for the incoming packet), this means that there are multiple messages for this requestor in the coordinator's message queue. In this case, the packet processor takes the same steps as for a single match, with the SAP1_MATCH[6:0] register being set to the lowest-value matching index (i.e., the smallest number) within the SAP1 partition.

If no source address match is found in the SAP1 table search, the packet processor will set SAP1_ADDR_PRESENT=0.

Step 8: Hardware performs "Source Address Absent" Table Search

If the MAC poll request was received on PAN0, and SAA0_EN=1 to enable searches of the PAN0 "Source Address Absent" partition, the packet processor uses its Source Address checksum to look for a match in the SAA0 partition of the table. Only table entries that are enabled, are compared against (see STEP 3); table indices which are not enabled, are ignored in the search.

If one (or more) table match is found (i.e., a software-computed checksum in SAA0 partition matches the hardware-computed checksum for the incoming packet), this means that the end device which sent the poll request is a valid child of this parent. For a SAA0 match, the packet processor takes these 2 steps:

1. Set SAA0_ADDR_ABSENT=0
2. Set SAA0_MATCH[6:0] to the first index which matched

If *no* source address match is found in the SAA0 table search, the packet processor will set SAA0_ADDR_ABSENT=1.

If, on the other hand, the MAC poll request was received on PAN1, and SAA1_EN=1 to enable searches of the PAN1 "Source Address Absent" partition, the packet processor uses its Source Address checksum to look for a match in the SAA1 partition of the table. Only table entries that are enabled, are compared against (see STEP 3); table indices which are not enabled, are ignored in the search.

If one (or more) table match is found (i.e., a software-computed checksum in SAA1 partition matches the hardware-computed checksum for the incoming packet), this means that the end device which sent the poll request is a valid child of this parent. For a SAA1 match, the packet processor takes these 2 steps:

1. Set SAA1_ADDR_ABSENT=0
2. Set SAA1_MATCH[6:0] to the first index which matched

If *no* source address match is found in the SAA1 table search, the packet processor will set SAA0_ADDR_ABSENT=1.

Step 9: Hardware determines FramePending status

The packet processor maintains an internal flag called **rx_frame_pending**, which is sent to the TX_PACKET block after every received packet, to directly control the state of the FramePending subfield of the Frame Control Field in the upcoming auto-TxAck frame (if enabled with AUTOACK=1).

If the Source Address Management feature is completely disabled, i.e.,

SAP0_EN = SAA0_EN = SAP1_EN = SAA1_EN = 0

then the packet processor will set the **rx_frame_pending flag** to the value of the ACK_FRM_PND register, putting the state of FramePending under direct software control.

Otherwise, if *any* of the following conditions are met, the packet processor will set its **rx_frame_pending** flag to 1:

1. The MAC Poll Request was received on PAN0, SAP0_EN=1, and SAP0_ADDR_PRESENT=1
2. The MAC Poll Request was received on PAN1, SAP1_EN=1, and SAP1_ADDR_PRESENT=1
3. The MAC Poll Request was received on PAN0, SAA0_EN=1, and SAA0_ADDR_ABSENT=1
4. The MAC Poll Request was received on PAN1, SAA1_EN=1, and SAA1_ADDR_ABSENT=1

If none of the conditions are met, **rx_frame_pending** flag will be set to 0.

Step 10: Receive interrupt RXIRQ

The packet processor receives the remainder of the packet, and verifies the FCS. Assuming the CRC check passes, the RXIRQ interrupt is issued. In the coordinator software's RXIRQ Interrupt Service Routine, software can determine if the received packet was a MAC Poll Request by reading the PI bit of the IRQSTS register. If PI=0, the received packet was not a poll request, and no action relating to Source Address Matching need be taken.

Otherwise, if *either* SAP0_ADDR_PRESENT=1 or SAP1_ADDR_PRESENT=1, an auto-TxAck packet is being sent with the FramePending subfield set to 1, so software should follow up by constructing a data packet (or packets) for the requesting end device, with a payload consisting of the message for this device which had been stored in the coordinator's indirect queue.

Also, if *either* SAA0_ADDR_ABSENT=1 or SAA1_ADDR_ABSENT=1, an auto-TxAck packet is being sent with the FramePending subfield set to 1, so software should follow up by constructing a "Leave Message" for the requesting end device.

Step 11: Software disables the spent index

In the final step, coordinator software must disable (invalidate) the index which was just used to locate and send the stored message to the requesting end device. To disable the index:

1. Set SAM_INDEX[6:0] to the selected index
2. Set SAM_INDEX_EN=0 and SAM_INDEX_INV=1

At this point, the disabled index is now an available table entry, which can be used to install a new Address checksum for another message in the indirect queue.

55.4.9.2.3.8.1.1.2.4 Dual PAN Mode

In the past, radio transceivers designed for 802.15.4 applications allow a device to associate to one and only one PAN (Personal Area Network), at any given time. The Packet Processor includes hardware support for a device to reside on two networks simultaneously. In optional Dual PAN mode, the device will alternate between the 2 PAN's, under hardware or software control. Hardware support for Dual PAN operation consists of 2 sets of PAN and IEEE addresses for the device, 2 different channels (one for each PAN), a programmable timer to automatically switch PAN's (including on-the-fly channel-changing) without software intervention, control bits to configure and enable Dual PAN mode, and read-only bits to monitor status in Dual PAN mode. A device can be configured to be a PAN Coordinator on either network, both networks, or neither.

For the purpose of defining a "PAN" in the context of Dual PAN mode, two sets of network parameters are maintained. In this document, "PAN0" and "PAN1" will be used to refer to the 2 PAN's. Each parameter set uniquely identifies a PAN for Dual PAN mode. These parameters are:

PAN0	PAN1
CHANNEL_NUM0	CHANNEL_NUM1
MACPANID0 (16-bit register)	MACPANID1 (16-bit register)

Table continues on the next page...

Table continued from the previous page...

PAN0	PAN1
MACSHORTADDRS0 (16-bit register)	MACSHORTADDRS1 (16-bit register)
MACLONGADDRS0 (64-bit registers)	MACLONGADDRS1 (64-bit registers)
PANCORDNTR0 (1-bit register)	PANCORDNTR1 (1-bit register)

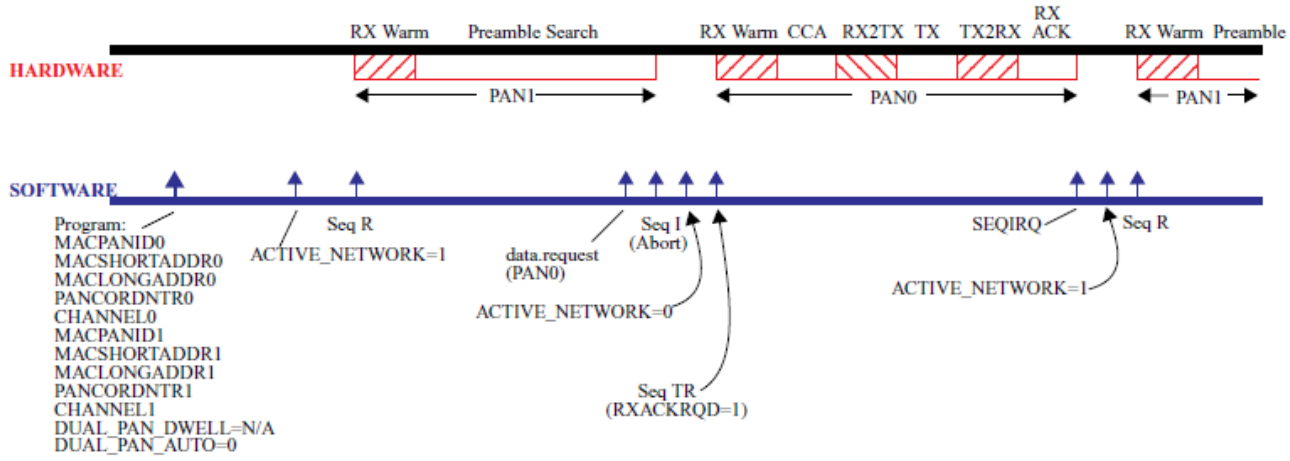
During device initialization, if Dual PAN mode is to be utilized, software will program both parameters sets, to configure the hardware for operation on two networks.

Two modes are available for Dual PAN operation: manual and automatic.

Manual Dual PAN

In manual Dual PAN mode, software controls which PAN is selected for transmission and reception, at all times. Software populates both PAN network parameter-set registers listed above. Software then selects a PAN to begin transmission or reception. A single control bit **ACTIVE_NETWORK**, selects the PAN. To select PAN0, **ACTIVE_NETWORK** should be set to 0; to select PAN1, **ACTIVE_NETWORK** should be set to 1. Software then initiates an autosequence by writing the appropriate value to XCVSEQ (PHY_CTRL1 Register). At any point, software can elect to switch to the alternate PAN. To do so, software aborts the sequence (if one is active) by writing XCVSEQ=IDLE. Software then toggles **ACTIVE_NETWORK**, and restarts a new sequence with XCVSEQ. Software is responsible for aborting and initiating sequences. Hardware is responsible for warming up the transceiver on the selected channel (CHANNEL_NUM0 or CHANNEL_NUM1), and performing address-filtering on the selected network's address parameters (PANCORDNTR, MacPanID, Short Address, and/or IEEE address). Software overhead is significantly reduced in this mode, since there is no need to re-program all of the PAN-select registers every time the PAN is toggled in Dual PAN mode; only a single bit (**ACTIVE_NETWORK**) need be written. For manual Dual PAN operation, **DUAL_PAN_AUTO** should be set to 0.

The following diagram depicts Dual PAN operation in manual mode. In this example, software populates both PAN parameters sets during initialization. In this example, software elects to initiate packet reception on PAN1, so **ACTIVE_NETWORK** is set to 1. Software initiates the Sequence R by writing to XCVSEQ. Hardware warms up the receiver on CHANNEL_NUM1 and enters preamble-search. In this example, no packet is received, but a data request from higher-level software requires a switch to PAN0. Software responds by aborting the reception by writing Sequence I to XCVSEQ. Software then sets **ACTIVE_NETWORK** to 0 to select PAN0. In the example, software initiates a Sequence TR. Hardware warms up the receiver for CCA on CHANNEL_NUM0, performs CCA (channel is idle), warms down the receiver, and warms up the transmitter on CHANNEL_NUM0, transmits the requested packet, warms down the transmitter and warms up the receiver again (as per the autosequence) on CHANNEL_NUM0, to receive the acknowledge packet. The acknowledge packet is received and the autosequence completes successfully with RXIRQ and SEQIRQ. Software elects to resume packet reception on PAN1 (which was in progress before the data request). Software toggles **ACTIVE_NETWORK** back to 1, and re-initiates Sequence R.



Auto Dual PAN

In automatic Dual PAN mode, hardware is responsible for alternating the selected PAN, at a pre-programmed interval. Software programs a "PAN dwell time", which determines the amount of time during which the hardware will receive on a given PAN. This is done by programming the **DUAL_PAN_DWELL** register. Software sets the **DUAL_PAN_AUTO** bit to 1 for automatic Dual PAN operation, and sets **ACTIVE_NETWORK** to correspond to the PAN on which it desires packet reception to begin. Software then initiates a Sequence R. Hardware warms up the receiver on the selected PAN, and begins preamble search. When the dwell time expires, assuming preamble and SFD have not been detected, hardware will switch to the alternate PAN. This includes an on-the-fly channel change. Once switched to the alternate PAN, hardware will use the address filtering parameters (PANCORDNTR, MacPanID, Short Address, and/or IEEE address) programmed for the alternate PAN. Once the dwell time expires on the alternate PAN, assuming preamble and SFD have not been detected, hardware will switch back to the original PAN. This process will repeat indefinitely, until one of the following occurs:

1. A packet is successfully received (address match and CRC valid).
2. Software aborts the Sequence R
3. A PLL unlock automatically aborts the Sequence R (if unlock aborting is enabled)

If the hardware PAN dwell timer expires *during* a packet reception (i.e., preamble and SFD have been detected during a Sequence R), the PAN-switch will be delayed until the packet is completely received. If the packet is received successfully (address match and CRC valid), the receive sequence will terminate with RXIRQ and SEQIRQ (if an auto-Acknowledge was requested and enabled, the sequence will complete after the Acknowledge packet was transmitted, and TXIRQ will also be set, in addition to RXIRQ and SEQIRQ); the PAN switch will occur at this point, after the Sequence has returned to IDLE.

If the received packet fails FCS (CRC check), or, if the packet was not intended for the device (address mismatch), the hardware will toggle the PAN, and return to preamble-search on the new PAN.

If the hardware PAN dwell timer expires during a state *other* than RX preamble search during Sequence R (i.e., if expiration occurs during TX, CCA, ED, Sequence TR, or any warmup or transitional state), PAN-switch will be delayed until either:

1. Preamble Search state is reached during a Sequence R (not Sequence TR)
2. Sequence returns to IDLE.

At any point, software can elect to interrupt the automatic Dual PAN operation, by aborting the sequence with a XCVSEQ=IDLE, and the setting the **DUAL_PAN_AUTO** bit to 0. In response, hardware will freeze the current state of the dwell timer, and capture the currently-selected PAN, so that hardware-controlled PAN alternation can resume where it left off, later. Software can then tend to that tasks that caused the Dual PAN interruption. When software wants to resume Dual PAN operation, it then sets **DUAL_PAN_AUTO**=1, and re-initiates Sequence R. Hardware will resume the dwell timer from the point it was frozen earlier, on the same PAN, and will warmup the receiver to receive on the PAN which was being monitored before

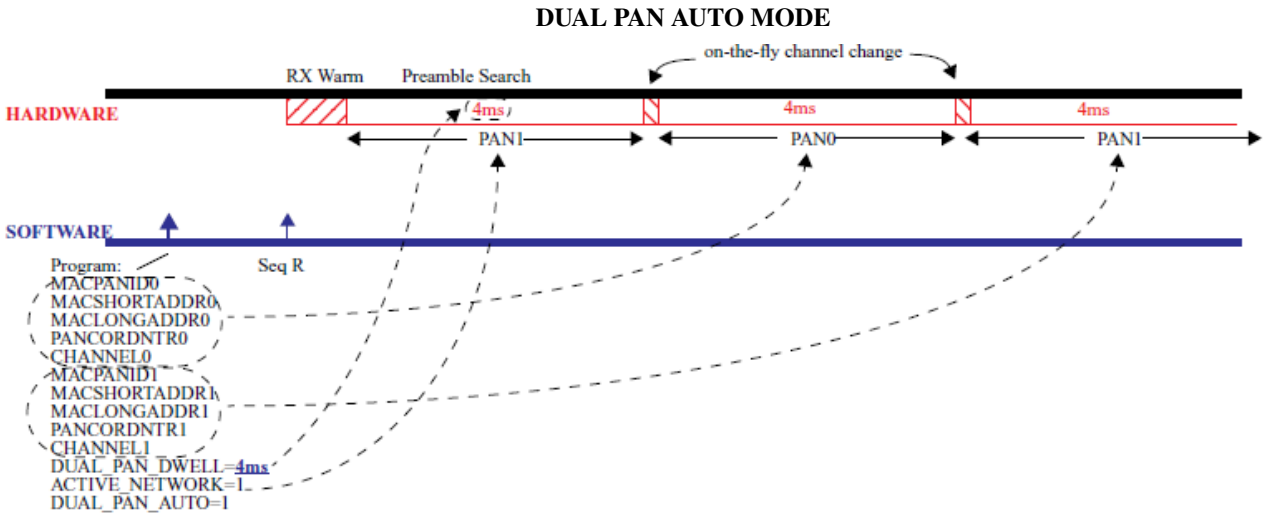
the interruption. Hardware will dwell on that PAN until the timer expires, and then switch PAN's (assuming no preamble and SFD detected, subject to the conditions listed above). Software can always determine the selected PAN at any time, in any mode, by reading **CURRENT_NETWORK** bit. If **DUAL_PAN_AUTO**=0, then **CURRENT_NETWORK** = **ACTIVE_NETWORK**. If **DUAL_PAN_AUTO**=1, then **CURRENT_NETWORK** is controlled by hardware.

To initiate auto Dual PAN operation for the first time, or to reset the dwell timer to its programmed value and allow software to select the initial PAN for auto Dual PAN operation, software should program the desired initial PAN to **ACTIVE_NETWORK** (0 for PAN0, 1 for PAN1), and then program the desired dwell time into the **DUAL_PAN_DWELL** register. Hardware always responds to a write to **DUAL_PAN_DWELL**, by resetting the dwell timer to its programmed value, and selecting the initial PAN for auto Dual PAN operation, based on the state of **ACTIVE_NETWORK**. A write to **DUAL_PAN_DWELL**, always re-initilizes the DWELL TIMER to the programmed value. If a write to **DUAL_PAN_DWELL** occurs during an autosequence, the DWELL TIMER will begin counting down immediately. If a write to **DUAL_PAN_DWELL** occurs when there is no autosequence underway, the DWELL TIMER will not begin counting until the next autosequence begins; it will begin counting at the start of the autosequence warmup. Under all circumstances, **DUAL_PAN_AUTO** must be asserted to allow the DWELL TIMER to count. If **DUAL_PAN_AUTO**=0, the DWELL TIMER will freeze and hold its state, until **DUAL_PAN_AUTO**=1. However, a write to **DUAL_PAN_DWELL** will still initialize the DWELL TIMER to its programmed value, regardless of the state of **DUAL_PAN_AUTO**.

At any point during auto Dual PAN mode, software can ascertain the PAN currently being serviced by hardware, by reading the **CURRENT_NETWORK** bit. Software can also determine the time-remaining in the current dwell, by reading the **DUAL_PAN_REMAIN** Register.

In auto Dual PAN mode, software retains responsibility for initiating and aborting sequences. There is no provision for hardware-initiated sequences.

The following diagram depicts Dual PAN operation in automatic mode. In this example, software populates both PAN parameters sets during initialization. In this example, software wants to initiate packet reception in auto Dual PAN mode, on PAN1, so **ACTIVE_NETWORK** is set to 1. For auto Dual PAN operation, software programs the desired PAN-switching interval into **DUAL_PAN_DWELL** register, in this case, 4ms. Software initiates the Sequence R by writing to XCVSEQ. The dwell timer begins counting as soon as the receiver warmup begins. Hardware warms up the receiver on CHANNEL_NUM1 (since PAN1 was selected as the initial PAN in this example), and begins preamble search. If a packet is received during this interval, hardware applies PAN1 address filtering. In this example, no preamble is detected at the point at which the dwell timer expires. So, at this point, hardware executes a PAN-switch to PAN0. which includes an on-the-fly channel change. The on-the-fly channel change requires approximately 93us and no preamble detection is possible during this "blind spot". (For more details on how the hardware executes the Dual PAN on-the-fly channel change, see Chapter GSM Sequence Manager, Section Dual PAN Mode.) After the PAN switch, hardware resumes preamble search on CHANNEL_NUM0, and applies PAN0 address filtering if a packet is received. In this example, no preamble is detected at the point at which the dwell timer expires. So, at this point, hardware performs a PAN-switch back to PAN1. And so on and so forth.



Two-PAN-one-channel

A special case occurs if a device is operating in Dual PAN mode (either Auto or Manual mode), and both PAN's occupy the same channel; in other words, CHANNEL_NUM0=CHANNEL_NUM1. In this case, hardware will detect this condition automatically, and apply both sets of address-filtering parameters simultaneously. Hardware will provide Data Indication if the received packet matches either the PAN0 address parameter set {**MACPANID0, MACSHORTADDRS0, MACLONGADDRS0, PANCORDNTR0**}, or the PAN1 address parameter set {**MACPANID1, MACSHORTADDRS1, MACLONGADDRS1, PANCORDNTR1**}. At Data Indication, two status bits can be queried by software to quickly determine on which PAN the packet was received, **RECD_ON_PAN0** or **RECD_ON_PAN1**. In the "Two-PAN-one-channel" scenario, it is possible for a packet to satisfy both sets of addressing parameters (PAN0 and PAN1). When this happens, both **RECD_ON_PAN0** and **RECD_ON_PAN1** will be set. In the "Two-PAN-one-channel" scenario, the **CURRENT_NETWORK** bit should be ignored, since both networks are simultaneously active.

If Dual PAN mode is not to be utilized, **ACTIVE_NETWORK** should be maintained at 0 (default) to select the PAN0 parameters for transceiving. In single PAN operation, the PAN1 parameter registers need not be programmed, and can be used as scratchpad. CHANNEL_NUM1 should not be programmed, and should instead be left in its default state, if Dual PAN mode is not in use.

Dual PAN Channel Override

In Dual PAN mode, in case there is a need to generate a frequency which may be offset from the 16 prescribed 5MHz-spaced channels, to, for example, avoid interference on one of the Dual PAN channels, a method has been provided to do that, by designating one of the two PAN channels to use the transceiver's set of direct frequency-programming registers, instead of CHANNEL_NUMx. Programming the direct frequency-programming registers – integer, numerator, and denominator, allows an RF frequency to be selected with much more precision than the 5MHz granularity of the 802.15.4 mapped-channel registers, CHANNEL_NUM0 and CHANNEL_NUM1. This is referred to as "Dual PAN Channel Override". For more details on this feature, see Chapter GSM Sequence Manager, Section Dual PAN Channel Override.

55.4.9.2.3.8.1.1.2.5 Promiscuous Mode

Functional description

Promiscuous Mode are defined in PAN mode and FAN mode.

The 802.15.4 Wireless Medium Access Control (MAC) and Physical Layer (PHY) Specifications for Low-Rate Wireless Personal Area Networks (WPANs) defines the following behavior for Promiscuous Mode operation:

> "In promiscuous mode, the MAC sublayer shall pass all frames received after the first filter directly to the upper layers without applying any more filtering or processing."

Where first level filtering is described as:

> "For the first level of filtering, the MAC sublayer shall discard all received frames that do not contain a correct value in their FCS field in the MFR (see 7.2.1.9)"

Promiscuous mode allows a device to receive and process all 802.15.4 frames which pass FCS check (CRC), regardless of whether or not they are addressed to the device. This allows a device to receive and process all valid traffic on a network. In Promiscuous mode, the Packet Processor will provide a Data Indication on all such packets. This capability allows a simple network sniffer to be constructed, which can display comprehensive packet data for all packets transmitted on a network within receiving range of the device.

In PAN mode, promiscuous mode will bypass the filtering rules described in Packet Filtering Detail.

In FAN mode, promiscuous mode will bypass the filtering rules described in FAN Mode Filter.

Since a device operating in promiscuous mode is designed to do so discreetly, automatic acknowledgement of all received packets is inhibited, regardless of the state of the Ack Request field in the Frame Control Field of the received packet; otherwise, the sniffing device would be acknowledging received frames for which it was not the addressee.

Special Handling for Auto Receive Acknowledge Frame

The Packet Processor features an autosequence to automatically receive, and verify, Acknowledge Frames after a Transmit frame has been sent by the device. This is accomplished by programming a Sequence TR with RXACKRQD=1. During normal operation, these receive Acknowledge Frames are not stored in the Packet Buffer. They are merely checked for matching Sequence Number and Frame Version, with a Data Indication issued for a valid match on both. Promiscuous Mode should therefore **NOT** be used with Sequence TR with RXACKRQD=1.

55.4.9.2.3.8.1.1.2.6 Provisions to Enable Software Support 802.15.4-2015

Legacy frame types as specified in 802.15.4, such as LLDN Frame Type, Multipurpose Frame Type, , as well as the Extended Frame Type, Fragment Frame Type, modify the format and definition of the Frame Control Field in such a way as to render parsing of the MHR by the packet processor impossible, without major upgrades to the hardware. For example, the packet processor hardware does not support 8-bit (simple) addressing, nor Sequence Number Suppression.

As in interim solution, provisions have been added to the packet processor to allow these new packet variations to be recognized and conditionally admitted (Data Indication to software). Three new Frame Type control bits, and a modification of the Frame Version Filtering bits, are included in the Packet Processor, and affect hardware packet parsing as indicated in the following table:

REGISTER	DEFINITION
FRM_VER_FILTER[3:0]	Frame Version selector. The incoming packet's Frame Control Field is parsed to obtain the FrameVersion subfield, and that value is compared against this register, in accordance with the following: xxx1: Accept received packets with FrameVersion=00 xx1x: Accept received packets with FrameVersion=01 x1xx: Accept received packets with FrameVersion=10 1xxx: Accept received packets with FrameVersion=11 These filtering rules apply to Beacon, Acknowledge, Data, and MAC Command Frame Types only, since these frame types require a 2-octet Frame Control Field which embeds a 2-bit FrameVersion subfield.
LLDN_FT	1: LLDN frame type enabled (Frame Type 4) 0: reject all LLDN frames
MULTIPURPOSE_FT	1: Multipurpose frame type enabled (Frame Type 5) 0: reject all Multipurpose frames
EXTENDED_FT	1: Extended frame type enabled (Frame Type 7) 0: reject all Extended frames
FRAGMENT_FT	1: Fragment/Frak frame type enabled (Frame Type 6) 0: reject all Fragment/Frak frames

The Extended Frame Type does not comply with the General MAC Frame Format, which is shown in the following diagram:

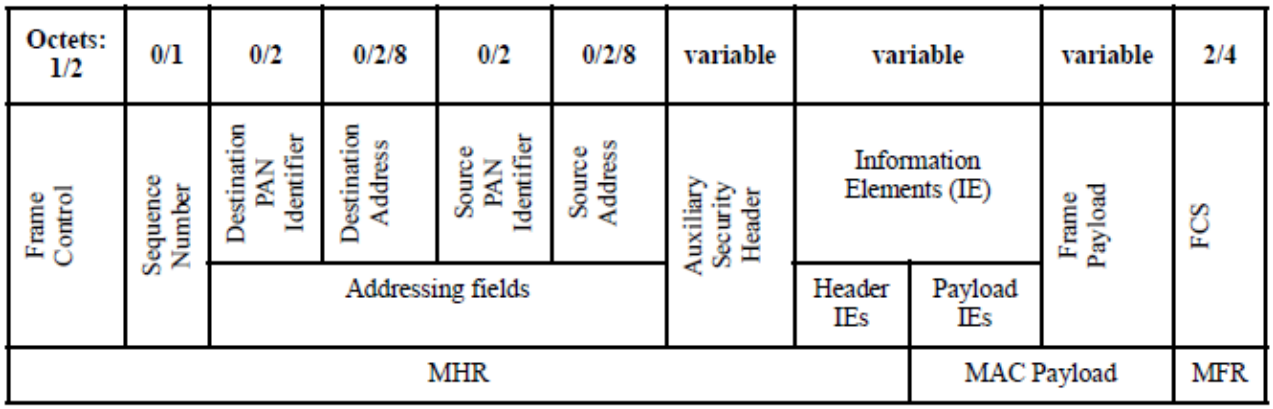


Figure 86—General MAC frame format

Figure 454. General MAC Frame Format

Instead, the Extended Frame has its own unique format, which is shown in the following diagram:

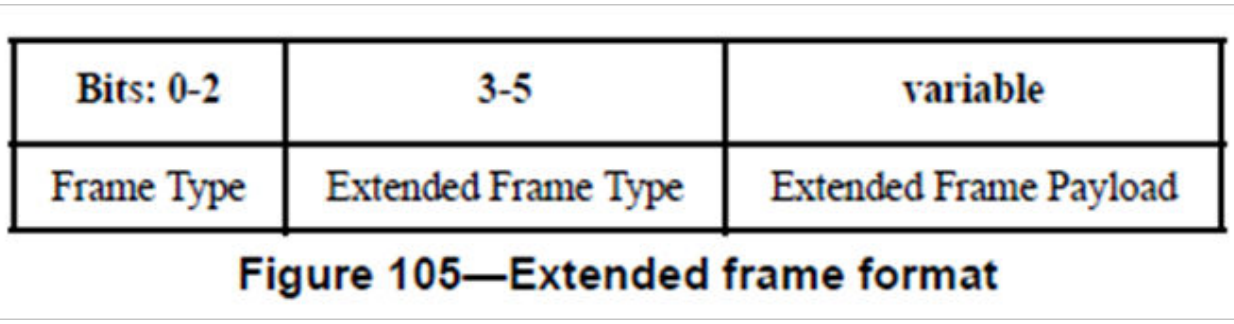

Figure 105—Extended frame format

Figure 455. Extended Frame Format

Because the Extended Frame Payload, which is not defined in the 802.15.4-2015 revision to the standard, would be intended to contain and fully specify the FCS, the Packet Processor will not be able to verify FCS on received packets with Frame Type Extended. FCS checking will need to be implemented in software.

Note: If the EXTENDED_FT bit is set to enable Data Indication on packets of Frame Type Extended, software should expect a substantial increase in the frequency of notifications, as a consequence of the lack of hardware verification of FCS, which will have implications for software workload as well as power consumption in the SoC.

When the packet processor receives any of the legacy frames, if the corresponding control bit is set, the hardware will skip Stage 2 filtering, and merely verify FCS. If FCS passes, the packet processor will notify software of the packet, without inspection of the addressing fields or payload. For such packets, software will be responsible for parsing the MHR and payload sections of the frame. If the corresponding control bit is not set, the packet processor will reject the received packet and there will be no Data Indication.

When the packet processor receives a packet of Frame Type Extended, if the EXTENDED_FT bit is set, the hardware will skip Stage 2 filtering, and after the entire packet is received, the packet processor will merely notify software of the packet, without inspection of the Extended Frame Type bits or the Extended Frame Payload. For such packets, software will be responsible for parsing the Extended Frame Type and the Extended Frame Payload sections of the frame. If the corresponding control bit is not set, the packet processor will reject the received packet and there will be no Data Indication.

Like all existing frames prior to 802.15.4-2015, a received frame may require an acknowledgement. In the case of the 802.15.4-2015 frames, the required timing for the acknowledge frame transmission, has been modified. The acknowledgement no longer immediately follows the packet reception. For this reason, upon reception of any of these 2015-compliant packets, the packet processor will cancel any auto-ACK transmission, regardless of the state of the PHY_CTRL[AUTOACK] bit and AR

field of the received packet's Frame Control Field. Software will be responsible for constructing the acknowledgment packet and transmitting it at the appropriate time using a Sequence T.

To help expedite software processsing of the 2015-compliant Frame Types and Versions, additional status bits have been added to the 802.15.4 register set, which are described in the following table:

STATUS BIT	RESIDES IN REGISTER	DEFINITION
ENH_PKT_STATUS	RX_FRAME_FILTER	1: The last packet received was 2015-compliant (SW should query the RX_FRAME_FILTER register for additional status bits) 0: The last packet received was not 2015-compliant
BEACON_FV2_RECD	RX_FRAME_FILTER	1: The last packet received was a FrameType Beacon with FrameVersion 2 0: The last packet received was not a FrameType Beacon with FrameVersion 2
DATA_FV2_RECD	RX_FRAME_FILTER	1: The last packet received was a FrameType Data with FrameVersion 2 0: The last packet received was not a FrameType Data with FrameVersion 2
ACK_FV2_RECD	RX_FRAME_FILTER	1: The last packet received was a FrameType Acknowledge with FrameVersion 2 0: The last packet received was not a FrameType Acknowledge with FrameVersion 2
CMD_FV2_RECD	RX_FRAME_FILTER	1: The last packet received was a FrameType MAC Command with FrameVersion 2 0: The last packet received was not a FrameType MAC Command with FrameVersion 2
LLDN_RECD	RX_FRAME_FILTER	1: The last packet received was a FrameType LLDN 0: The last packet received was not a FrameType LLDN
MULTIPURPOSE_RECD	RX_FRAME_FILTER	1: The last packet received was a FrameType Multipurpose with FrameVersion 2 0: The last packet received was not a FrameType Multipurpose
EXTENDED_RECD	RX_FRAME_FILTER	1: The last packet received was a FrameType Extended 0: The last packet received was not a FrameType Extended
FRAGMENT_RECD	RX_FRAME_FILTER	1: The last packet received was a FrameType Fragment 0: The last packet received was not a FrameType Fragment

55.4.9.2.3.8.1.1.2.7 FAN Mode Filter

The Packet Processor supports to filter the DATA and ACK frame in FAN standard which is based on 802.15.4-2015. Only Data and Enhanced Acknowledge frames are used in FAN mode.

The following table summarizes the frame format used in FAN.

	Frame Control, Octets: 2											1	8	2	8	6	Variable	4
	Bit:0-2	3	4	5	6	7	8	9	10-11	12-13	14-15							
	Frame Type	Security	Frame Pending	AR	PAN ID Compression	Reserved	Sequence Number Suppression	IEs Present	Destination Addressing Mode	Version	Source Addressing Mode	Sequence Number	Destination Address	Source PAN ID	Source Address	ASH	IE	FCS
PA	1	0	0	0	0	0	1	1	0	2	3	N	N	Y	Y	N	Y	Y
PAS	1	0	0	0	1	0	1	1	0	2	3	N	N	N	Y	N	Y	Y
PC	1	1	0	0	0	0	1	1	0	2	3	N	N	Y	Y	Y	Y	Y
PCS(same as PA)	1	0	0	0	0	0	1	1	0	2	3	N	N	Y	Y	N	Y	Y
unicast ULAD	1	1	0	0/1	1	0	0/1	1	3	2	0/3	Y/N	Y	N	Y/N	Y	Y	Y
broadcast ULAD	1	1	0	0	0	0	0	1	0	2	3	Y	N	Y	Y	Y	Y	Y
Acknowledgement	2	1	0	0	1	0	1	1	3	2	3	N	Y	N	Y	Y	Y	Y
EAPOL	1	0	0	0	1	0	0	1	3	2	3	Y	Y	N	Y	N	Y	Y

Figure 456. Frame Type in FAN

The Packet Processor checks the following rules:

1. Auto-RxAck Checking (in Sequence TR)
    a. Received Destination Address == Device's Address
    b. Received Source Address = Transmitted Destination Address
    c. Received Frame Control filed is same as WiSUN spec
2. Data or ACK frame format check
    a. Received Destination Address == Device's Address
    b. Frame Version field should be b10
    c. IEs Present field should be 1
    d. Frame Type should be DATA or ACK

55.4.9.2.3.8.1.1.2.8 Appendix A

FILTERFAIL CODES

A description of the FILTERFAIL_PAN codes can be found in the following table.

FILTERFAIL CODE_PAN BIT	REASON FOR FILTERFAIL
[0]	Fails Stage 1 Frame Length Checking (FL < 5) **Note:** FL < 3 will not generate an SFD, so this bit will not be set
[1]	Fails Stage 1 Section 7.2.1.1.6 or Section 7.2.1.1.8 Checking (DST_ADDR_MODE or SRC_ADDR_MODE = 1)
[2]	Fails Stage 1 Section 7.2.1.1.5 Checking (Illegal PAN_ID_COMPRESSION Usage)
[3]	Fails Stage 1 Frame Version Checking
[4]	Fails Stage 2 Auto-RxAck Checking (Illegal Ack Frame Format in Sequence TR)
[5]	Fails Stage 2 Frame Type Checking (Incorrect Frame Filter Bit setting)
[6]	Fails Stage 2 Frame Length Checking (Illegal Beacon, Data, or Cmd FL)
[7]	Fails Stage 2 Addressing Mode Checking (Illegal Addressing Mode for Beacon, Data, OR Cmd)
[8]	Fails Stage 2 Sequence Number Matching (Sequence TR Only)
[9]	Fails Stage 2 PAN ID or Address Checking (Beacon, Data, or Cmd)

A description of the FILTERFAIL_FAN codes can be found in the following table.

FILTERFAIL CODE_FAN BIT	REASON FOR FILTERFAIL
[0]	Fails Stage 2 Auto-RxAck Checking (Illegal Ack Frame Format in Sequence TR)
[1]	Fails Stage 2 Received frame has Destination Address != Device's Address or Frame Version field != b10 or IEs Present field != 1 or Frame Type != DATA or ACK

55.4.9.2.3.8.1.1.2.9 Appendix B

LENIENCY BITS

The Packet Processor performs filtering on all received packets, in order to determine whether the packet is intended for the device. The packet filtering is based on rules. In case any of the packet filtering rules need to be overriden, a 45-bit "leniency register" has been provided. When the leniency register is programmed to its default value (0), all hardware packet filtering rules are in effect, and if an incoming packet violates any rule, a "Filter Fail" will occur (packet will be rejected). When a given leniency register bit is asserted, the packet filtering rule assigned to that bit will not be in effect, and if any incoming packet violates that rule (but no other rules), then a "Filter Fail" will not occur, the packet will not be rejected, the packet will be treated as "intended for the device", and software will be notified of the incoming packet. The table below shows the assignment of leniency bits to packet filtering rules.

LENIENCY BIT	PACKET FILTERING RULE OVERRIDDEN
leniency[0]	Override Stage 1 Frame Length Checking (FL < 5)
leniency[1]	Override Stage 1 Section 7.2.1.1.6 Checking (DST_ADDR_MODE = 1)
leniency[2]	Override Stage 1 Section 7.2.1.1.8 Checking (SRC_ADDR_MODE = 1)
leniency[3]	Override Stage 1 Section 7.2.1.1.5 Checking (Illegal PAN_ID_COMPRESSION Usage)
leniency[4]	Override Stage 2 Auto-RxAck Checking (Illegal Ack Frame Format in Sequence TR)
leniency[5]	Override Stage 2 Frame Length Checking (Illegal Beacon, Data, or Cmd FL)
leniency[6]	Override Stage 2 Beacon Frame Address Mode Violations
leniency[7]	Override Stage 2 Data Frame Address Mode Violations
leniency[8]	Override Stage 2 MAC Command Frame Address Mode Violations
leniency[9]	Override Stage 2 Sequence Number Matching
leniency[10]	Override Stage 2 Filter for DST_ADDR_MODE_NONE/SRC_ADDR_MODE_SHORT (Beacon Only)
leniency[11]	Override Stage 2 Filter for DST_ADDR_MODE_NONE/SRC_ADDR_MODE_SHORT (Data and MAC Command Only)
leniency[12]	Override Stage 2 Dst PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_NONE (Data and MAC Command Only)

Table continues on the next page...

Table continued from the previous page...

LENIENCY BIT	PACKET FILTERING RULE OVERRIDDEN
leniency[13]	Override Stage 2 Dst Short Addr Filter for DST_ADDR_MODE_SHORT/ SRC_ADDR_MODE_NONE (Data and MAC Command Only)
leniency[14]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_SHORT/ PAN_ID_COMPRESSION (Beacon Only)
leniency[15]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_SHORT/ PAN_ID_COMPRESSION (Data and MAC Command Only)
leniency[16]	Override Stage 2 Dst Short Addr Filter for DST_ADDR_MODE_SHORT/ SRC_ADDR_MODE_SHORT/PAN_ID_COMPRESSION (Data and MAC Command Only)
leniency[17]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_SHORT/ NO_PAN_ID_COMPRESSION (Beacon Only)
leniency[18]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_SHORT/ NO_PAN_ID_COMPRESS ION (Data and MAC Command Only)
leniency[19]	Override Stage 2 Dst Addr Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_SHORT/ NO_PAN_ID_COMPRESSION (Data and MAC Command Only)
leniency[20]	Override Stage 2 Src PAN ID Filter for DST_ADDR_MODE_NONE/SRC_ADDR_MODE_LONG/ NO_PAN_ID_COMPRESSION (Beacon Only)
leniency[21]	Override Stage 2 Src PAN ID Filter for DST_ADDR_MODE_NONE/SRC_ADDR_MODE_LONG/ NO_PAN_ID_COMPRESSION (Data and MAC Command Only)
leniency[22]	Override Stage 2 Dst PAN ID Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_NONE (Data and MAC Command Only)
leniency[23]	Override Stage 2 Dst Long Addr Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_NONE (Data and MAC Command Only)
leniency[24]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_LONG/ PAN_ID_COMPRESSION (Beacon Only)
leniency[25]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_LONG/ PAN_ID_COMPRESSION (Data and MAC Command Only)
leniency[26]	Override Stage 2 Dst Long Addr Filter for DST_ADDR_MODE_SHORT/ SRC_ADDR_MODE_LONG/PAN_ID_COMPRESSION (Data and MAC Command Only)
leniency[27]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_SHORT/ PAN_ID_COMPRESSION (Beacon Only)
leniency[28]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_SHORT/ PAN_ID_COMPRESSION (Data and Mac Command Only)
leniency[29]	Override Stage 2 Dst Long Addr Filter for DST_ADDR_MODE_LONG/ SRC_ADDR_MODE_SHORT/PAN_ID_COMPRESSION (Data and Mac Command Only)
leniency[30]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_LONG/ NO_PAN_ID_COMPRESSION (Beacon Only)
leniency[31]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_LONG/ NO_PAN_ID_COMPRESSION (Data and MAC Command Only)

Table continues on the next page...

Table continued from the previous page...

LENIENCY BIT	PACKET FILTERING RULE OVERRIDDEN
leniency[32]	Override Stage 2 Short Addr Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_LONG/ NO_PAN_ID_COMPRESSION (Data and MAC Command Only)
leniency[33]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_SHORT/ NO_PAN_ID_COMPRESSION (Beacon Only)
leniency[34]	Override Stage 2 PAN ID Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_SHORT/ NO_PAN_ID_COMPRESSI ON (Data and MAC Command Only)
leniency[35]	Override Stage 2 Long Addr Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_SHORT/ NO_PAN_ID_COMPRESSION (Data and MAC Command Only)

leniency[39]	Allow an auto-TxAck frame to be sent, after a receive frame which has all of the following parameters: 1. Destination PAN ID = Broadcast (0xFFFF) 2. Destination Address = !Broadcast (not 0xFFFF) 3. Destination Address Mode = Short Nominally, the SEQ_MGR inhibits auto-TxAck on such frames.
leniency[40]	Override FAN mode Ack frame filter for Received Destination Address == Device's Address
leniency[41]	Override FAN mode Ack frame filter for Received Source Address = Transmitted Destination Address
leniency[42]	Override FAN mode Ack frame filter for Received Frame Control filed is same as WiSUN spec
leniency[43]	Override FAN mode filter for Data frame Received Destination Address = Device's Address
leniency[44]	Override FAN mode filter for Frame Version field should be b10, IEs Present field should be 1 and Frame Type should be DATA or ACK

55.4.9.2.3.8.2 FCP(Frame delimiter before CRC Protocol) Protocol Support

The FCP package structure and its mapping relationship with the GENLL package structure is shown in Figure 457.

The Device Address, Control and Data Payload are mapping to PAYLOAD. User should set H0_SZ=0,H1_SZ=0, LENGTH_SZ=0, and use LENGTH_ADJ to inform the length of (Device Address + Control + Data Payload + CRC-CCITT). Standard fixed sized packets have a total length of 18bytes. Advanced Burst packets can be 19, 27 or 35 bytes. The sizes for all packets are pre-determined and will be specified by the FCP stack prior to each Tx/Rx.

Bit ordering when defining packets conforms to a Big Endian approach. First bit transmitted over the air is the MSB. So register LENGTH_BIT_ORD should set to 1.

Pre-amble is either 0xAA or 0x55 depending on the MSB of the Network Address. If MSB of Network Address is 1, preamble is 0xAA, otherwise the preamble is 0x55.

Network Address is programmable by FCP stack and transmitted in big-endian byte-order. This is the sync word of the RF packet in which corresponding FCP receivers are configured to sync on when trying to receive FCP packets.

Device Address specified and by FCP stack. Address configurable by host interface.

Control byte specified and controlled by FCP stack. Packet sequencing control.

Data payload specified and controlled by FCP stack. Data contents altered by host interface.

CRC-CCITT of packet calculated from Network Address (inclusive) to Data Payload (inclusive). Initial value is 0xFFFF with polynomial (X^16+X^12+X^5+1). CRC is to be transmitted in big-endian byteorder. **CRC_START_BYTE[2:0] in RBME should set to 0.**

Whitening is done to avoid long sequences of 0s or 1s and can be performed by the FCP stack SW or the HW (if it is capable). Whitening is perfomed by XORing against a pseudo-random number sequence generated from a 9-bit pseudo-random number generator with the following polynomial X^9+X^5+X^0.

- Whitening is only applied to the Device Address, Control and Data Payload. The other parts of the packet are not whitened. **So WHITEN_START[1:0] in RBME should set to 0x3.**
- Whitening is performed for any packet that is larger than the standard 18 byte packet (any packet where the Data Payload is larger than 8 bytes).
- Whitening is performed prior to CRC Generation and dewhitening is performed after the CRC is checked.

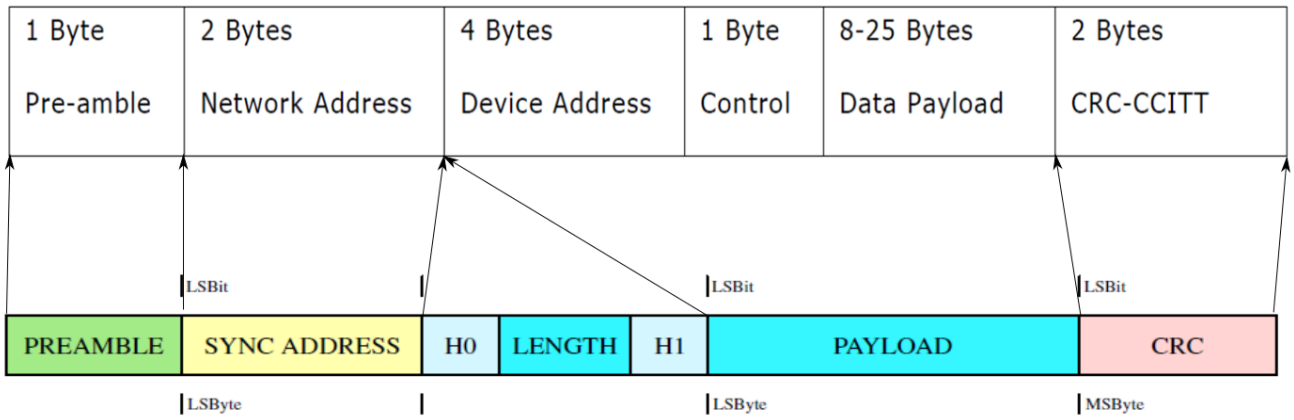

Figure 457. FCP Packet Format and Mapping to Generic Link Layer Format

Table 488 shows the register configuration for the FCP emulation.

Table 488. Link Layer Register Configuration for FCP Emulation

Register	Value
GENLL_MODE[3:0]	0x6 - FCP Mode
PREAMBLE_SZ[8:0]	0x000 - 1 octet preamble
PREAMBLE_SEL[2:0]	000b - The controller hardware selects the preamble pattern based on the first transmitted bit of Network Address, such that the last bit of preamble is the opposite polarity from the first bit of Network Address, forcing a bit transition at this boundary.
GEN_PREAMBLE[7:0]	Not used
NTW_ADR_SZ[1:0]	01b - Network Address 0/1/2/3 requires a 16-bit correlation
SYNC_ADDR_SZ[1:0]	01b - Network Address is 16-bit

Table continues on the next page...

Table 488. Link Layer Register Configuration for FCP Emulation (continued)

Register	Value
H0_SZ[4:0]	0
LENGTH_SZ[4:0]	0
H1_SZ[4:0]	0
LENGTH_BIT_ORD	0 - MS Bit First
LENGTH_ADJ[10:0]	Device Address + Control + Data Payload + CRC-CCITT
AA_PLAYBACK_CNT	1 - Access Address will play back to Link Layer
RXEN_DLY[9:0]	0

55.4.9.2.3.8.3 Bluetooth LE Protocol Support

- Bluetooth LE 5.0 packet format for the LE uncoded PHY

  The following packet format is defined for the LE Uncoded PHYs (LE 1M and LE 2M) and is used for both advertising channel packets and data channel packets. This packet format is shown in Figure 458. Each packet consists of four mandatory fields. The mandatory fields are Preamble, Access Address, PDU, and CRC.

  When a packet is transmitted on either the primary or secondary advertising channel, the PDU shall be the Advertising Channel PDU as defined in Figure 460. When a packet is transmitted on the data physical channel, the PDU shall be the Data Channel PDU as defined in Figure 462.

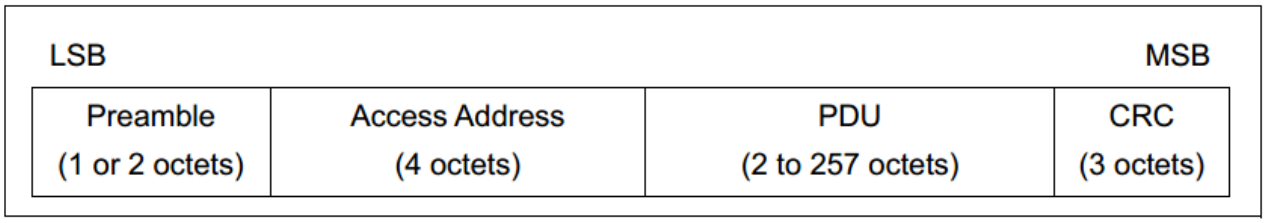

Figure 458. Link Layer packet format for the LE Uncoded PHYs

- Bluetooth LE 5.0 packet format for the LE coded PHY

  The following packet format is defined for the LE Coded PHY and is used for both advertising channel packets and data channel packets. This packet format is shown in Figure 459 .

  Each packet consists of the Preamble, FEC block 1, and FEC block 2. The Preamble is not coded. The FEC block 1 consists of three fields: Access Address, Coding Indicator (CI), and TERM1. The CI field determines which coding scheme is used for FEC block 2. The FEC block 2 consists of three fields: PDU, CRC, and TERM2.

  When a packet is transmitted on either the primary or secondary advertising channel, the PDU shall be the Advertising Channel PDU as defined in Figure 460. When a packet is transmitted on the data physical channel, the PDU shall be the Data Channel PDU as defined in Figure 462.

  When TX, RBME will pad CI, TERM1 and TERM2 into the packet.

  When RX, Link Layer will only get PDU, CRC from RBME.

  Users can also set RXEN_DLY_OVERRIDE to 1 and use RXEN_DLY to override the hardware calculation result. The waveform is show in Figure 430.

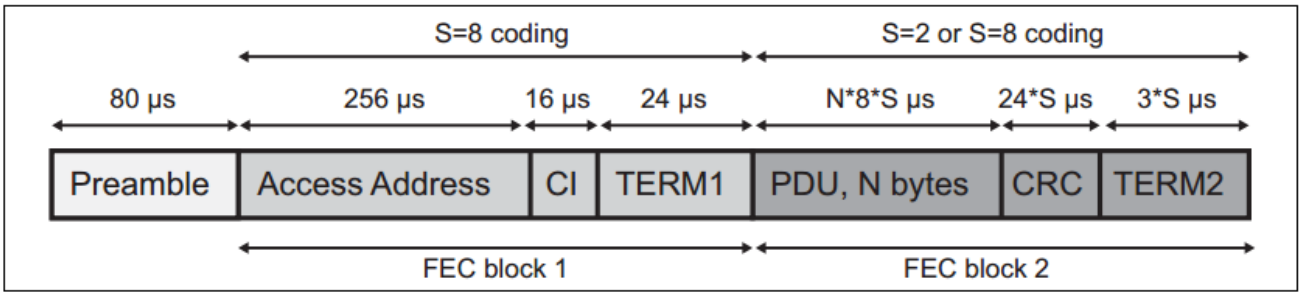

Figure 459. Link Layer packet format for the LE Coded PHY

- Advertising channel PDU

  The advertising channel PDU has a 16-bit header and a variable size payload. Its format is as shown in Figure 460. The 16-bit Header field of the advertising channel PDU is as shown in Figure 461.

  The Length field of the advertising channel PDU header indicates the payload field length in octets. The valid range of the Length field shall be 1 to 255 octets.

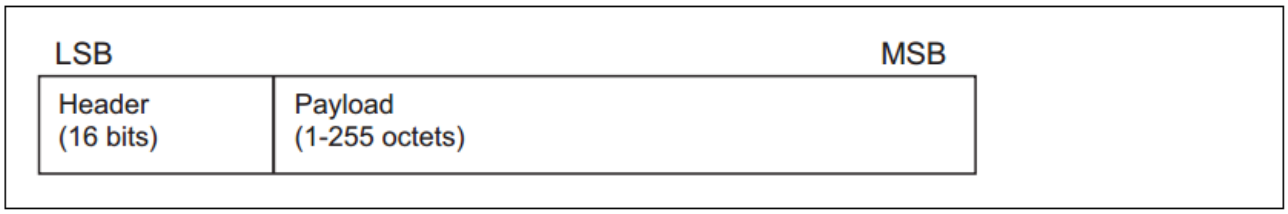

Figure 460. Advertising channel PDU

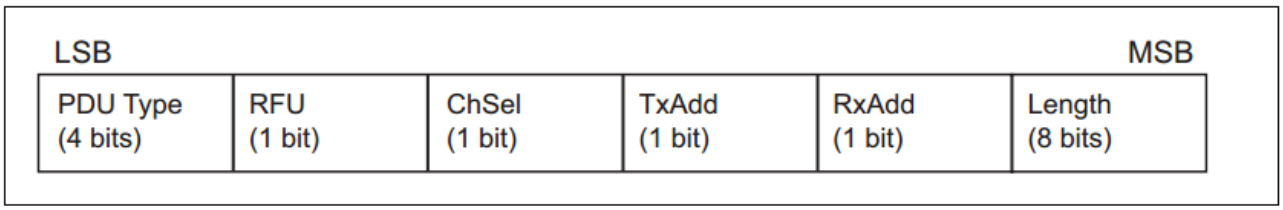

Figure 461. Advertising channel PDU Header

- Data channel PDU

  The Data Channel PDU has a 16 bit header, a variable size payload, and may include a Message Integrity Check (MIC) field. The Data Channel PDU is as shown in Figure 462. The Header field of the Data Channel PDU is as shown in Figure 463.

  The Length field of the Header indicates the length of the Payload and MIC if included. The length field has the range of 0 to 255 octets. The Payload field shall be less than or equal to 251 octets in length. The MIC is 4 octets in length.

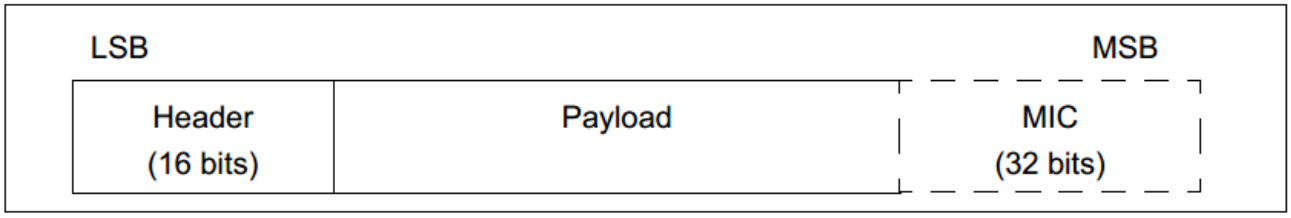

Figure 462. Data Channel PDU

Header					
LLID (2 bits)	NESN (1 bit)	SN (1 bit)	MD (1 bit)	RFU (3 bits)	Length (8 bits)

Figure 463. Data channel PDU header

- Bluetooth LE 5.1 packet format for the LE uncoded PHYs

  Be different with Bluetooth LE 5.0, the CRC is followed by an optional Constant Tone Extension field, which consists of a constantly modulated series of unwhitened 1s. The constant Tone Extension field is not included in CRC or MIC calculations.

  When TX, TX_DIG adds the CTE field.

  When RX, the CTE field can be received by Link Layer, using the RX_EN delay feature. LL hardware will recognize the uncoded packet and automatically calculate the duration of CTE according to the PDU type and CTETime field parsed, and expand the RX_EN signal accordingly. Users can also set RXEN_DLY_OVERRIDE to 1 and use RXEN_DLY to override the hardware calculation result. The waveform is shown in Figure 430.

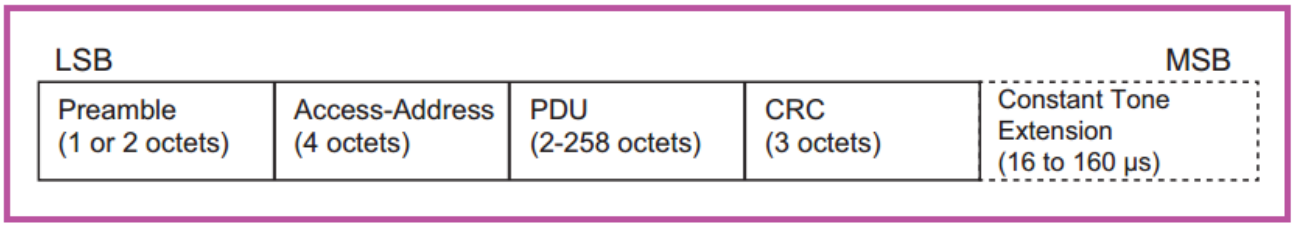

Figure 464. Link Layer packet format for the LE Uncoded PHY (Bluetooth LE 5.1)

To map the Bluetooth LE packet format to the generic packet format, just map the Length to the LENGTH field and the other 8 bits in the Header to the H0 field. Table 489 shows the register configuration for the Bluetooth LE emulation.

Table 489. Link Layer Register Configuration for Bluetooth LE Emulation

Register	Value
GENLL_MODE[3:0]	• 0x9 - Bluetooth LE Uncoded Mode • 0xA - Bluetooth LE LR Mode • 0xB - Bluetooth LE Concurrent Mode (RX configuration only; TX uses either Bluetooth LE Uncoded or Bluetooth LE LR configuration)

Table continues on the next page...

Table 489. Link Layer Register Configuration for Bluetooth LE Emulation (continued)

Register	Value
PREAMBLE_SZ[8:0]	• 0x000 - 1 octet preamble • 0x001 - 2 octets preamble
PREAMBLE_SEL[2:0]	001b - Preamble is programmed by register GEN_PREAMBLE[7:0]
GEN_PREAMBLE[7:0]	As needed
NTW_ADR_SZ[1:0]	11b - Network Address 0/1/2/3 requires a 32-bit correlation
SYNC_ADDR_SZ[1:0]	11b - Network Address is 32-bit
H0_SZ[4:0]	8
LENGTH_SZ[4:0]	8
H1_SZ[4:0]	0 or 8(TX of Bluetooth LE 5.1 Data Channel PDU with CTE)
LENGTH_BIT_ORD	0 - LS Bit First
LENGTH_ADJ[10:0]	3 - Same as CRC_SZ[2:0] (RBME register)
AA_PLAYBACK_CNT	0 - Access Address will not play back to Link Layer
BLE_V5P1_CTE_EN	When set, hardware will parse the CTE field as defined in Bluetooth LE V5.1 specification
RXEN_DLY_OVERRIDE	Override the hardware calculation result for the duration of TERM2 or CTE
RXEN_DLY[9:0]	When not zero and RXEN_DLY_OVERRIDE is set, the RX_EN signal will delay (RXEN_DLY +1) microseconds to de-assert after payload is received. The delay time range is from 2~1024 microseconds.
SEL_RXIRQ	• 0: RX_IRQ is asserted at the end of RX_PKT state • 1: RX_IRQ is asserted at the end of RXEN_DLY state(only if RX_EN is delayed).

CTE duration and parsing and signal cte_present resolve process:

- When RXEN_DLY_OVERRIDE=1, it means for all the RX process, there will be a delay defined by RXEN_DLY[9:0];
- — If BLE_V5P1_CTE_EN==1, cte_present=1 in the whole RX process
  — Otherwise, cte_present=0
- When RXEN_DLY_OVERRIDE=0, hardware will decide the RX_EN delay time.
- — If Bluetooth LE coded packet is received(i.e., internal signal phy_mode[2:0]=1), RX_EN is not delayed.
  — If Bluetooth LE uncoded packet is received(i.e., phy_mode[2:0]=2),
  — ◦ If it is Bluetooth LE 5.0 use case(BLE_V5P1_CTE_EN=0), no RX_EN delay
    ◦ If it is Bluetooth LE 5.1 use case(BLE_V5P1_CTE_EN=1),
    ◦ ▪ If received data channel PDU (ADV_CHANNEL_EN=0) , as shown in Figure 465
      ▪ • If [CP] =0, then on-the-fly change H1_SIZE to 0, no RX_EN delay
        • If [CP] =1, then on-the-fly change H1_SIZE to 8, and get the [CTETime] as the RX_EN Delay; cte_present=1 when parsed
      ▪ If received advertising channel PDU(ADV_CHANNEL_EN=1) , as shown in Figure 466
      ▪ • If the [Extended Header Length]=0, no RX_EN delay

- If the [Extended Header Length]>0, get the [CTEInfo] (if exists), and get the [CTETime] as the RX_EN Delay; cte_present=1 when parsed

NOTE

1. The [CTETime] field defines the length of the Constant Tone Extension in 8 us units. The value of the [CTETime] field shall be between 2 and 20 inclusive; all other values are reserved for future use. But LL will not check the length range.
2. Once asserted, cte_present will not be de-asserted even CRC fails. Register bit CRC_IGNORE can be used in debug cases to bypass the CRC pass condition.
3. If CRC fail and CRC_IGNORE=0, LL will recycle according to its inherent behavior.

55.4.9.2.3.8.3.1 RPA and White List

The format of the resolvable private address is shown in Figure 469.

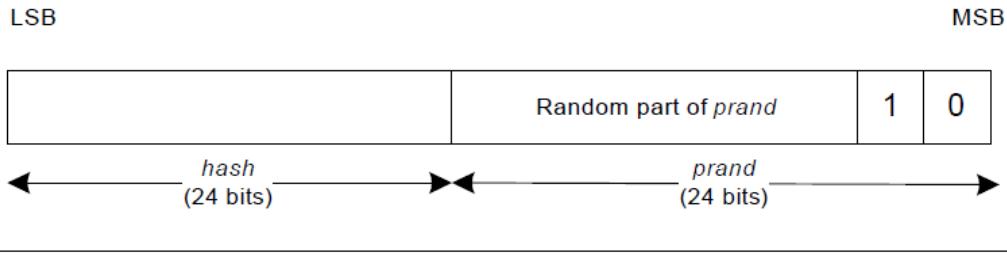

Figure 469. Format of resolvable private address

Private device address generation

The resolvable private address is generated with the Identity Resolving Key (IRK) and a randomly generated 24-bit number(prand).

The hash is generated using the function *ah* as *hash = ah(IRK, prand)*.

The prand and hash are concatenated to generate the resolvable private address in the following manner:

resolvable private address = hash || prand

The least significant octet of hash becomes the least significant octet of RPA and the most significant octet of prand becomes the most significant octet of RPA.

Private device address resolution

A resolvable private address may be resolved if the corresponding device's IRK is available using this procedure. If a resolvable private address is resolved, the device can associate this address with the peer device.

A localHash value is generated as *localHash = ah(IRK, prand)*

The localHash value is then compared with the hash value extracted from RPA. If the localHash value matches the extracted hash value, then the identity of the peer device has been resolved.

If a device has more than one stored IRK, the device repeats the above procedure for each stored IRK to determine if the received resolvable private address is associated with a stored IRK, until either address resolution is successful for one of the IRKs or all have been tried.

The RPA resolution and White List check are related with advertising channel PDUs. Register ADV_CHANNEL_EN is to indicate that it is to receive an advertising channel PDU.

Linklayer supports resolvable private address(RPA) resolution during Rx process when register RPA_EN is enabled.

There are 8 entries for the RPA resolution in RAM. Each entry includes the fields: Peer IRK[127:0], Local IRK[127:0], Peer_Identity_Address[47:0], Peer_Identity_Address_Type, Peer_RPA[47:0], Local_RPA[47:0]. The organization of these fields are shown in Figure 470.

Register RPA_VALID_ENTRY[7:0] defines that if the entry is valid or not. If the entry is not valid, it is bypassed during RPA search and resolution.

When RPA_EN is asserted, and the received Peer Address is resolvable, the address is first be searched in the PRPA list. If the address is found in the PRPA list, the address is resolved and register PEER_RESOLVED_INDEX[3:0] returns matched index of the entry. If the address is not in the PRPA list, link layer resolves the address with Peer IRK, one by one. If the address is resolved by one of the Peer IRK, register PEER_RESOLVED_INDEX[3:0] returns matched index of the entry. Link layer will also update the received peer address to the PRPA list.

If the peer address is not resolved, PEER_RESOLVED_INDEX[3:0] returns 0xF and interrupt flag PEER_RPA_FAIL_IRQ is asserted. In this case, if register PEER_RPA_FAIL_IRQ_EN is set, the interrupt is generated to the host. If register IGNORE_RPA_FAIL is set, the link layer continues to receive the whole packet; otherwise, the link layer aborts.

When RPA_EN is asserted, and the received Local Address is resolvable, the address is first be searched in the LRPA list. If the address is found in the LRPA list, the address is resolved and register LOCAL_RESOLVED_INDEX[3:0] returns matched index of the entry. If the address is not in the LRPA list, link layer resolves the address with Local IRK, one by one. If the address is resolved by one of the Local IRK, register LOCAL_RESOLVED_INDEX[3:0] returns matched index of the entry. Link layer will also update the received peer address to the LRPA list.

If the local address is not resolved, LOCAL_RESOLVED_INDEX[3:0] returns 0xF and interrupt flag LOCAL_RPA_FAIL_IRQ is asserted. In this case, if register LOCAL_RPA_FAIL_IRQ_EN is set, the interrupt is generated to the host. If register IGNORE_RPA_FAIL is set, the link layer continues to receive the whole packet; otherwise, the link layer aborts.

Figure 470. RPA entry organization in RAM

Link layer supports White List search and filter during Rx process when register WL_EN is enabled.

There are 2 White Lists in RAM, WL0 and WL1. Each White List has 32 entries. Register WL_SEL is used to select which White List is used for the search.

Each entry includes fields WL_Device_Address[47:0] and WL_Device_Address_Type, as shown in Figure 471.

For each White List, there is a register WL_VALID_ENTRY[31:0] to enable the 32 entries. Once disabled, the entry is skipped during the search.

If RPA is resolved, the Peer_Identity_Address[47:0] and Peer_Identity_Address_Type are searched in the White List. If RPA is not enabled or no RPA entry is valid, the received Peer Address and its type are directly searched in the White List.

After search, if there is an entry matches the address to be searched, the register WL_MATCH_INDEX[5:0] returns the matched index of the entry.

If there is no entry matched or all entries are invalid, WL_MATCH_INDEX[5:0] returns the 0x3F value, and interrupt flag WL_FAIL_IRQ is asserted. In this case, if register WL_FAIL_IRQ_EN is set, the interrupt is generated to the host. If register IGNORE_WL_FAIL is set, the link layer continues to receive the whole packet; otherwise, the link layer aborts.

Byte Addr	Entry #	White List 0

Figure 471. White List 0 and White List 1 in RAM

For each type of PDUs that needs to do RPA check and WL check, the hardware tasks are summarized in Figure 472.

If the received PDU Type is "0011b" or "0101b" regarding to an ADV_DIRECT_IND PDU, the resolved Peer identity address and address type are not searched in WL, but are compared with register DIRECT_PEER_ADDR[47:0] and DIRECT_PEER_ADDR_TYPE. This case is indicated by set the register ADV_DIRECT_IND_SENT.

If the comparison result is a mismatch, interrupt flag DIRECT_ID_FAIL_IRQ is asserted. In this case, if register DIRECT_ID_FAIL_IRQ_EN is set, the interrupt is generated to the host. If register IGNORE_DIRECT_FAIL is set, the link layer continues to receive the whole packet; otherwise, the link layer aborts.

55.4.9.2.3.8.4 Generic Link Layer Test Mode (GTM)

Objective

Generic Test Mode (GTM) is a special test mode with the objective to facilitate time-efficient testing of the Packet Error Rate (PER) for the PHY modes available to the Generic Link Layer. The goal of this mode is to test the radio's TX and RX physical layer and front-end quality assisted by the link layer without necessarily involving complicated link layer processing.

The key objective of this test mode are as follows:

- To make PER testing on NXP radios using Generic Link Layer easy for both internal and external (customer) usage, and
- To minimize the complications in a PER test setup by reducing the need of external triggering and provision of accounting for good (passing CRC), bad (failing CRC) and missing packets on the receiving end.

Generic Test Mode (GTM) Requirements

The GTM HW will facilitate the following simplified testing of RX and TX PHY performances using either a signal analyzer (for TX), a vector signal generator (for RX) and using two NXP radios (where one is configured as TX, while the other is configured as RX). Note that it is conceived that the GTM implementation would leverage the link layer infrastructure as much as possible minimizing the need of additional register space to support GTM programming.

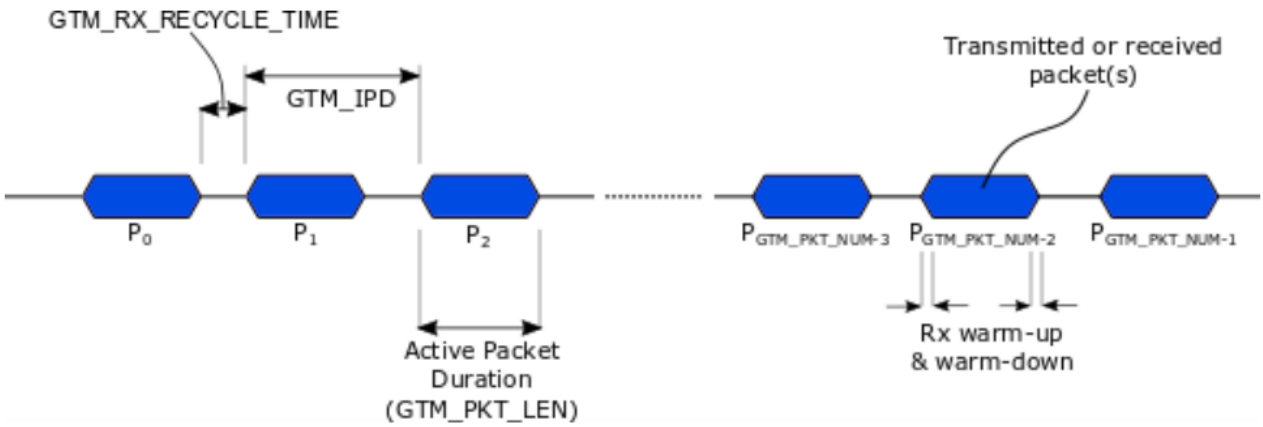

Figure 473. PACKET INTERVALS IN GTM mode

GTM Packet Structure

The packet structure in GTM mode is shown as below, where H0[7:0] = {4'h0, GTM_PDU_TYP}. So in GTM mode, register H0_SZ should be set to 8.

Figure 474. GTM PACKET STRUCTURE

Where

Table 490. GTM PACKET FIELDS

Field	Definition
PREAMBLE	Packet Preamble as supported by Gen-LL. Default size is 1 octet with preamble pattern chosen based on 1st bit of SYNC ADDRESS
SYNC ADDRESS	From registers NTW_ADR_*X*, when NTW_ADR_EN[*X*]==1. When more than one NTW_ADR_EN[*X*] is enabled, NTW_ADR_EN[0] has the highest priority. NTW_ADR*X*_SZ and SYNC_ADDR_SZ should be same value. Default size is 4 octets. It is recommended to use the same default SYNC ADDRESS value as is used by Bluetooth-LE DTM, with default transmission order of '10010100 10000010 01101110 10001110'.
GTM_PDU_TYP	From register GTM_PDU_TYPE[3:0] (reused from MACLONGADDRS1_LSB[27:24]) 0000b PRBS9 Sequence 0001b Programmable 8-bit Pattern (from register GTM_PDU[7:0], reused from MACSHORTADDRS1[7:0]) 0010b PRBS-13 Sequence 0011b PRBS-15 Sequence 0100b Programmable 32-bit Pattern (from register GTM_PDU[31:0], reused from {MACSHORTADDRS1,MACPANID1}) 0101b Programmable packet from Packet RAM (in this case, PKT_LEN is ignored) Others reserved
RES	It is reserved. (0000b)

Table continues on the next page...

Table 490. GTM PACKET FIELDS (continued)

Field	Definition
PKT_LEN	The PKT_LEN is the content of the LENGTH field. When LENGTH_ADJ=0, PKT_LEN means the length of (PAYLOAD + CRC); When LENGTH_ADJ = CRC_SZ, PKT_LEN means the length of PAYLOAD. The PKT_LEN size is controlled by register LENGTH_SZ, the value can be 8 or 16-bit. The PKT_LEN value is controlled by register GTM_PKT_LEN[10:0] (reused from LENGTH_ACK[10:0]). The GTM_PKT_LEN[10:0] value overflows the LENGTH_SZ is ignored. The default packet allocation will be 8 bits and the default value will be 39 octets (same as Bluetooth LE DTM)
GTM_PDU	A string of transmission bits as defined above by GTM_PDU_TYP, which are sent out by default in the same order as Bluetooth-LE.
CRC	All CRC computational combinations defined by Gen-LL are possible. Default size will be 3 octets and the computation will be configured to be the same as Bluetooth-LE, i.e.,

Generic Test Mode Transmit (GTM-TX)

In GTM-TX mode, Generic LL would allow for the following configurability for the radio driver SW:

- Program GENLL_MODE[3:0] to 0xF to enable the GTM mode
- Program PHY modulation parameters
- Program the type and size of the preamble to be used for the packet (PREAMBLE_SZ and PREAMBLE_SEL)
- Program a test mode Access Address (or SFD). All size of the AA/SFD supported by the Gen-LL shall be supported. (NTW_ADR_EN[*X*] , NTW_ADR_*X*, NTW_ADR_SZ and SYNC_ADDR_SZ)
- Program a fixed length for the Packet size in octets (PKT_LEN).
- Program the type of payload (GTM_PDU).
- Program the Bit manipulation engine (BME) configuration to be used, e.g., CRC, whitening, FEC, encoding, repetition or spreading, etc. blocks and processing order be configured as per the desired test configuration.
- Program the interpacket duration (register GTM_IPD[19:0], reused from MACLONGADDRS1_MSB[19:0]).
- Program the number of packets to be sent (register GTM_PKT_NUM[11:0]), reused from MACLONGADDRS1_LSB[11:0]).
- Program the delay time between 1st Tx warmup time and GTM_IN_TX asserted (register GTM_RX_RECYCLE_TIME[19:0], reused from MACLONGADDRS0_MSB[19:0]; This register has different meaning in GTM RX mode)

Once configured, GTM_TX mode will operate as follows:

- Write a "1" to register GTM_IN_TX to trigger the start of the GTM-TX mode.
  - Clear GTM_PKT_COUNT at initial
  - Gen-LL transmits the 1st sequence after GTM_RX_RECYCLE_TIME
  - Gen-LL transmits sequence after every GTM_IPD duration for GTM_PKT_NUM times.
  - Note that for each packet transmission, the TX would warm-up, transmit the packet and warm-down
- After requisite number of TX packets are sent, i.e., GTM_PKT_COUNT == GTM_PKT_NUM; the GTM_IN_TX bit would be de-asserted and GTM_TX would stop.
- The following figure shows the GTM TX timing. The GTM_PKT_PUR represents the transmitted packet duration, where *GTM_PKT_DUR = sizeof(PREAMBLE+AA+H0+LEN+GTM_PDU+CRC)*symbol_time*

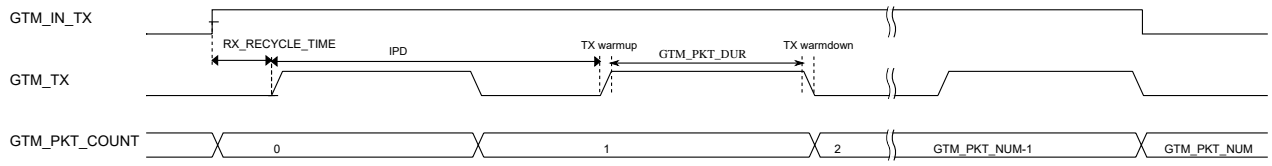

Figure 475. GTM TX Processing

Generic Test Mode Receive (GTM-RX)

For GTM-RX, it is conceived that Gen-LL and BME for the receiver are correctly configured as per the test configuration. This includes

- Program GENLL_MODE[3:0] to 0xF to enable the GTM mode
- Program the register FIRST_SFD2WD, which means the time between the force Rx warmdown and first SFD found. It is possibly the longest packet duration plus some margin.
- Program the register RX_RECYCLE_TIME, which means the time between the force Rx warmdown and Rx warmup.
- Program the register GTM_IPD, same as the GTM Tx side.
- Write a "1" to register GTM_IN_RX to trigger the start of the GTM-RX scan mode. This bit should also clear all GTM packet counters (GTM_GOOD_PKT_COUNT, GTM_BAD_PKT_COUNT and GTM_PKT_COUNT).
- The receiver will wait for the first correctly AA/SFD matched packet. This initiates the GTM-RX state machine.
- Every packet for which AA/SFD match happens should increment the GTM_PKT_COUNT.
- Once GTM_PKT_COUNT == GTM_PKT_NUM, GTM_IN_RX bit should be de-asserted and the periodic RX recycling by the GTM state machine should stop.
- If register ***GTM_PKT_COUNT_CHECK_DIS*** is programmed, then
  - The check GTM_PKT_COUNT == GTM_PKT_NUM is disabled
  - In this case the GTM test would be disabled by SW based time-out
  - As now there is no limit on the upper bound on GTM_PKT_COUNT due to a pre-programmed GTM_PKT_NUM, the counter can possibly overflow GTM_PKT_NUM. The counter will have saturation but not roll over in this case.
- If the packet is successfully received, processed by BME and passes the payload CRC. It is considered a good packet and the GTM_GOOD_PKT_COUNT is incremented.
- If the packet is not successfully received due to corrupted packet length or an unrecoverable bit error causing the packet to fail the payload CRC, or there is a header(H0/Length/H1) check fail or there is no AA matched, it is considered a bad packet and the GTM_BAD_PKT_COUNT is incremented.
- GTM_GOOD_PKT_COUNT and GTM_BAD_PKT_COUNT should be incremented based on CRC pass/fail only and setting a Gen-LL configuration such as CRC_IGNORE should not effect it.
- After receiving either a good or a bad packet, Gen-LL should recycle the receiver after GTM_RX_RECYCLE_TIME, where GTM_RX_RECYCLE_TIME is the time required by the receiver to warm-down and warm-up with some additional timing margins to receive the next packet. As an example, for a radio having a warm-up time of 110us and a warm-down time of 10us, GTM_RX_RECYCLE_TIME ≥ 150us.
- If for a packet, AA/SFD was not detected for a duration of GTM_IPD - GTM_RX_RECYCLE_TIME, it is considered that the packet was missed, GTM_PKT_COUNT is incremented and the receiver is recycled.
- In case the receiver decodes the incoming packets length incorrectly to be too long, although AA/SFD will be matched (causing the GTM_PKT_COUNT to be incremented), RX may stay in the demodulation state during the entire GTM_IPD - GTM_RX_RECYCLE_TIME duration. In this scenario, the receiver is recycled at the scheduled time and the GTM_BAD_PKT_COUNT is incremented as well.

- If register ***GTM_IPD_CHECK_DIS*** is programmed, then,
  - GTM_IPD duration enforcement is disabled
  - After each packet received, Link layer will recycle after "GTM_RX_RECYCLE_TIME"
- The packet statistics are collected as follows:
  - Number of Good CRC Packets = GTM_GOOD_PKT_COUNT
  - Number of Bad CRC Packets = GTM_BAD_PKT_COUNT
  - Number of Missed Packets = GTM_PKT_NUM - (GTM_GOOD_PKT_COUNT + GTM_BAD_PKT_COUNT)
- The following figure shows the normal GTM RX timing.

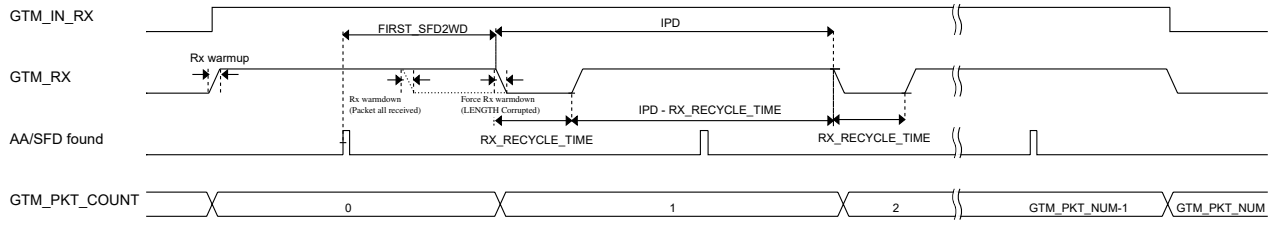

Figure 476. GTM RX Processing

The following figure shows the GTM RX timing with GTM_IPD_CHECK_DIS=1.

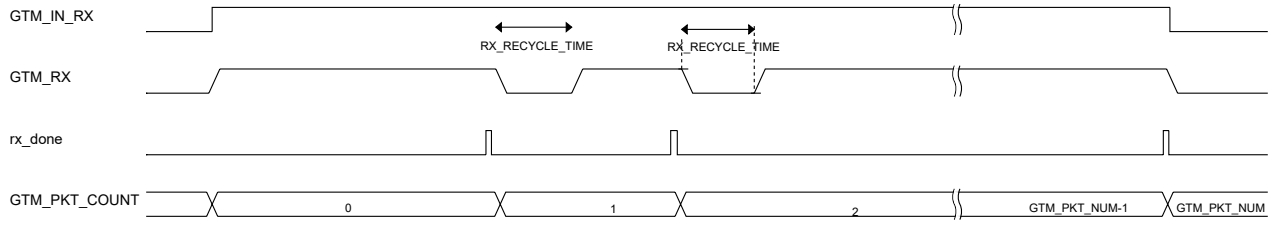

Figure 477. GTM RX Processing with GTM_IPD_CHECK_DIS=1

The following table summarizes the registers used in GTM.

Table 491. Link Layer Registers Used in GTM

Register	RX Side ?	TX Side ?	Description	Reused From
GENLL_MODE[3:0]	X	X	Link layer Mode Select, 1111b - GTM Mode	/
GTM_PDU[31:0]		X	8bits(GTM_PDU_TYP is 0001b) or 32 bits (GTM_PDU_TYP is 0100b) GTM PDU Pattern	{MACSHORTADDRS1, MACPANID1}
GTM_PDU_TYPE[3:0]		X	GTM PDU Type	MACLONGADDRS1[27:24]
GTM_IPD_CHECK_DIS	X		• GTM_IPD duration enforcement is disabled	MACLONGADDRS1[30]

Table continues on the next page...

Table 491. Link Layer Registers Used in GTM (continued)

Register	RX Side ?	TX Side ?	Description	Reused From
			• After each packet received, Link layer will recycle after "GTM_RX_RECYCLE_TIME"	
GTM_PKT_COUNT_CHECK_DIS	X		• The check GTM_PKT_COUNT == GTM_PKT_NUM is disabled; In this case the GTM test would be disabled by SW based time-out; • As now there is no limit on the upper bound on GTM_PKT_COUNT due to a pre-programmed GTM_PKT_NUM, the counter can possibly overflow GTM_PKT_NUM. The counter will have saturation but not roll over in this case.	MACLONGADDRS1[31]
GTM_PKT_NUM[11:0]	X	X	The total number of packets to be sent or received	MACLONGADDRS1[11:0]

55.4.9.2.3.9 Interrupts

Interrupt Status Bit Structure

The Generic FSK Link Layer Controller has 15 interrupt sources, each represented in the register map by an interrupt status bit. All interrupt status bits share a common, generic structure. If a particular interrupt source is enabled, a "TRIGGERING EVENT" for that interrupt source, will always set the status bit. A write-1-to-clear input from the IPS bus, will clear the status bit, but only if there is not a simultaneous triggering event. The triggering event prevails over a software clear attempt, if both events coincide. An integrated clock gate guarantees that the status bit only sees a clock when either a triggering event occurs, or a write-1-to-clear pulse arrives from the IPS bus. This reduces interrupt status bit power consumption to an absolute minimum. (Note: the TSM_IRQ does not have an associated status bit in the Link Layer Controller; its status bit resides in the Transceiver Sequence Manager, or TSM).

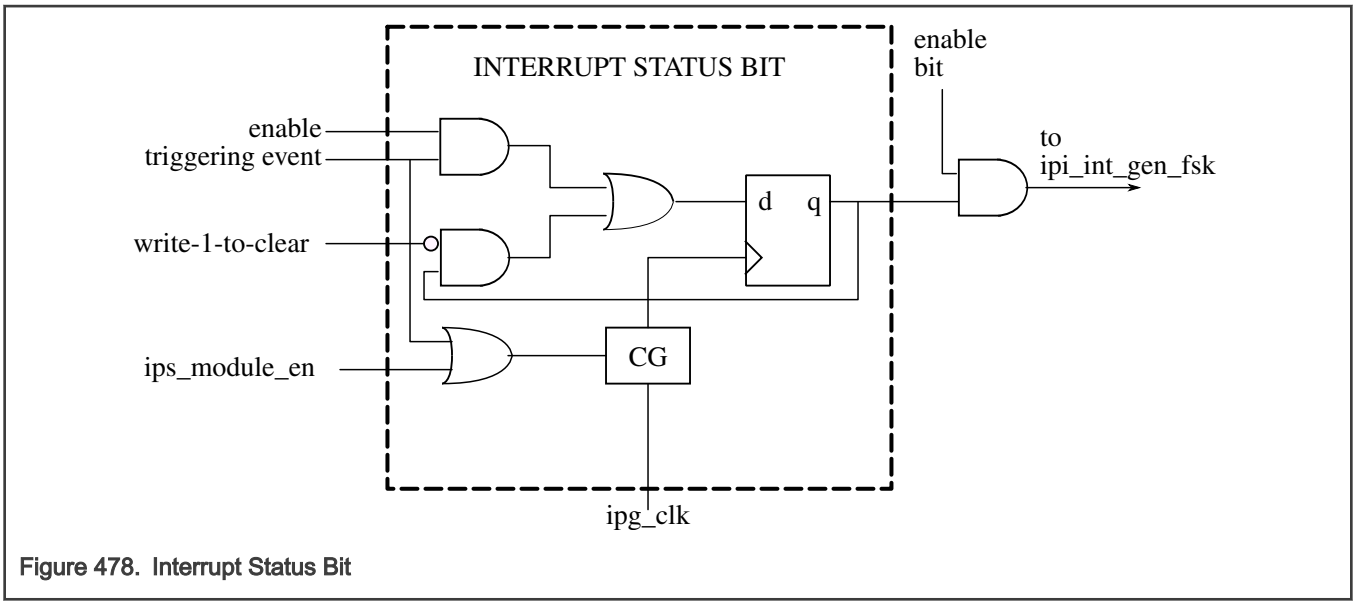

Figure 478. Interrupt Status Bit

Each GENERIC_FSK interrupt status bit, has an ENABLE bit associated with it. The name of the enable bit tracks the name of the interrupt source, with the string "_EN" appended at the end. Note that for any GENERIC_FSK interrupt source, if the triggering event occurs, the Interrupt Status Bit will be set regardless of the state of the corresponding ENABLE bit. If any of the 15 interrupts is to be ignored, software should clear the corresponding ENABLE bit, and apply the appropriate bit mask when reading the IRQ_CTRL register, to mask out the unwanted status bit.

GENERIC_FSK Interrupt Architecture

The 10 interrupt sources (status bits) are combined with their individual ENABLE bits, and then logically OR'ed together, in sum-of-products fashion, to generate single interrupt line to the MCU: **ipi_int_gen_fsk**. A global mask bit, GENERIC_FSK_IRQ_EN, can enable or disable **ipi_int_gen_fsk** altogether. There is no prioritization of interrupt sources; they have equal weight. The **ipi_int_gen_fsk** output is a level-sensitive indicator and will remain asserted until all interrupt status bits are cleared (or the corresponding ENABLE bits cleared). The following diagram depicts the GENERIC_FSK Interrupt Architecture.

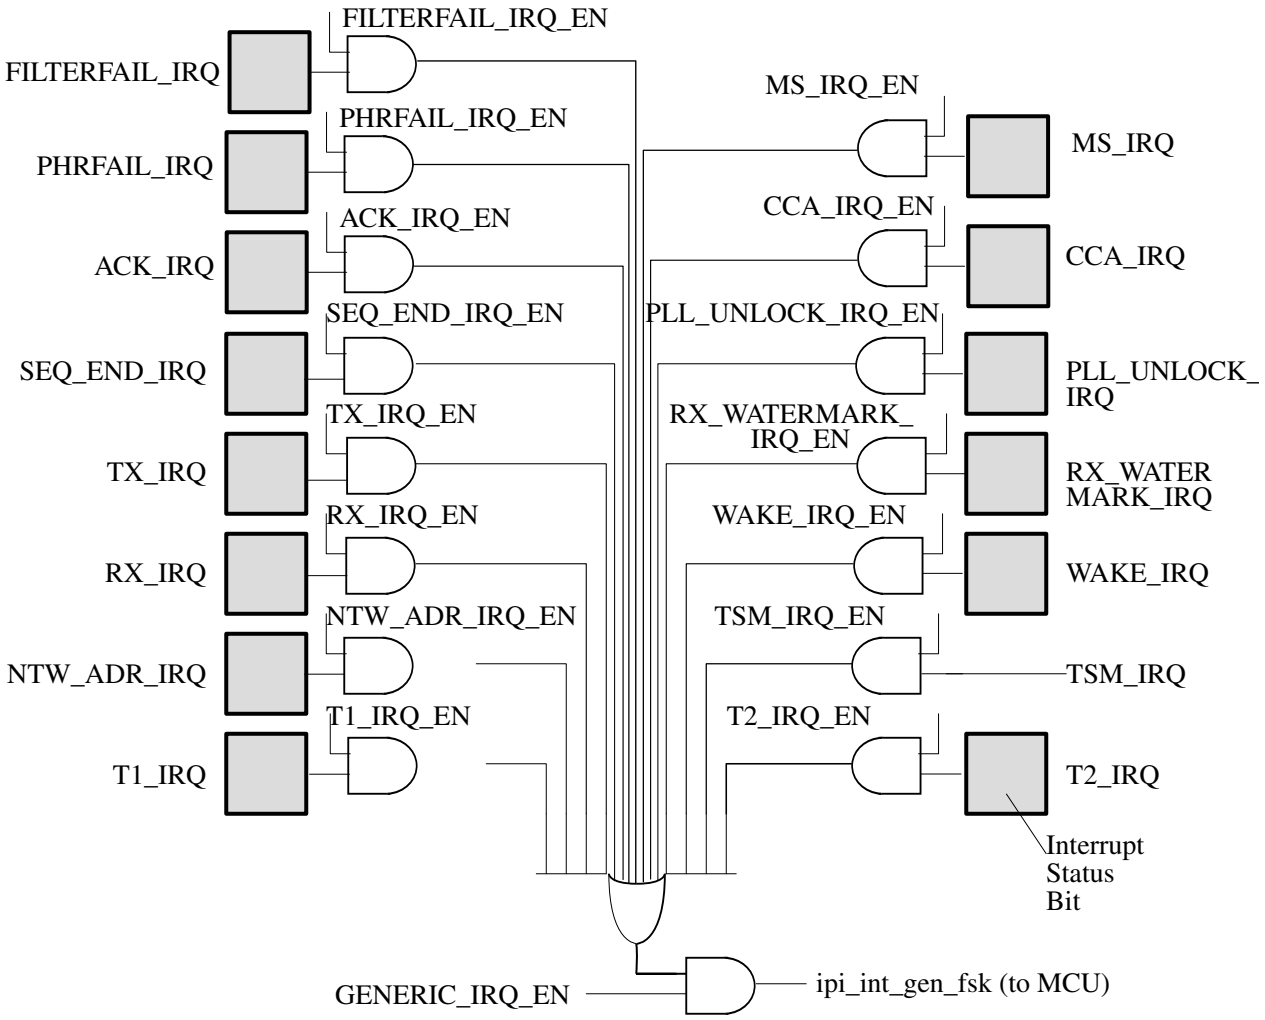

Figure 479. GENERIC_FSK Interrupt Architecture

Clearing Interrupts

All interrupt status bit use a write-1-to-clear protocol. Writing a '1' to the interrupt status bit, in the IRQ_CTRL register, clears the offending interrupt. Writing a '0' to an interrupt status bit has no effect on the bit. Interrupt status bits are not affected by reads.

GENERIC FSK Interrupt Sources

The following table describes the GENERIC_FSK Interrupt Sources

Interrupt	Description
T1_IRQ, T2_IRQ	The GENERIC_FSK Link Layer features a 24-bit Event Timer, which runs at a rate of 1MHz. The Link Layer has 2 Timer interrupts (T1_IRQ, T2_IRQ), each with its own 24-bit compare register (T1_CMP, T2_CMP), and each with its own compare enable (T1_CMP_EN, T2_CMP_EN). For each timer compare enable, if the bit is set, a match on the respective 24-bit compare value to the Event Timer will cause the corresponding interrupt status bit to become set. If the compare enable is

Table continues on the next page...

Table continued from the previous page...

Interrupt	Description
	not set, Event Timer matches won't cause the corresponding interrupt status bit to become set.
TX_IRQ	TX interrupt occurs at the end of a TX operation.
RX_IRQ	RX interrupt occurs at the end of a successful RX packet reception. A successful packet reception implies CRC was verified to be good, H0 matching passed, H1 matching passed, and received packet length did not violate pre-set limits. Nominally, RX interrupts are not generated on packets which fail CRC check, or which failure the H0, H1 or LENGTH limits. A received packet with a failed CRC check or a H0, H1, or LENGTH violation, results in an RX recycle back to the Network Address Search state. To receive a Data Indication (RX_IRQ) on packets which fail CRC, set the bit CRC_IGNORE=1. H0 and H1 matching, and LENGTH limiting, are under SW control.
NTW_ADR_IRQ	A Network Address Match has occurred on an enabled Network Address. At NTW_ADR_IRQ, a timestamp is captured by transferring the current contents of the EVENT_TMR into the TIMESTAMP register. Software can determined which Network Address matched by querying the NTW_ADR_MCH[3:0] field of the NTW_ADR_CTRL register.
SEQ_END_IRQ	The Sequence End Interrupt (SEQ_END_IRQ), indicates that a transceiver operation (TX or RX) has completed, and the Command Decoder State Machine, and the Transceiver Sequence Manager (TSM), have returned to their respective IDLE states. A SEQ_END_IRQ will always occur at the end of a sequence, even if the sequence terminated abnormally (such as a Software Abort, or a PLL Unlock Abort). A SEQ_END_IRQ always occurs whenever the Command Decoder FSM transitions from any non-idle to IDLE state. When SEQ_END_IRQ occurs, software can be sure that the Command Decoder and TSM are in their idle state, and a new sequence can be programmed.
RX_WATERMARK_IRQ	RX Watermark interrupt will occur during packet reception, when the number of received bytes, as indicated by the read-only BYTE_COUNTER register, matches the contents of the RX_WATERMARK register. For the purpose of defining RX_WTR_MARK, the first byte received (BYTE_COUNTER = 0) is the first byte of Network Address; the second byte received (BYTE_COUNTER = 1) is the second byte of Network Address, etc. To cause an RX Watermark Interrupt to occur after a 2-byte Network Address has been received, set RX_WTR_MARK=1. By default, RX_WATERMARK is set to a value larger than the longest supported GENERIC_FSK packet length, so an RX_WATERMARK_IRQ won't be triggered under these conditions.

Table continues on the next page...

Table continued from the previous page...

Interrupt	Description
PLL_UNLOCK_IRQ	When an PLL unlock event occurs during an transceiver operation, and the transceiver has been configured to automatically abort sequences on PLL unlock events, the PLL_UNLOCK_IRQ status bit will become set. The Transceiver Sequence Manager (TSM) will begin monitoring for PLL unlock only after the PLL has been given sufficient time to achieve lock; A PLL unlock which occurs after the warmup period, can be enabled to cause a sequence abort. Individual enables are provided for TX and RX sequences. (See the TSM Chapter for more details).
WAKE_IRQ	**For Manual DSM:** This is WAKE_IRQ. A WAKE_IRQ will be triggered when the GENERIC_FSK Link Layer Controller has awoken from a Manual DSM (Deep Sleep Mode) cycle. WAKE_IRQ indicates that the RF Oscillator has been restarted, and the GENERIC_FSK EVENT_TMR has resumed counting. **For Wake-On-Radio:**: This is WOR_IRQ. See Section Wake-On-Radio
TSM_IRQ	TSM_IRQ is a debug feature, enabling the Transceiver Sequence Manager (TSM) to generate an interrupt at any point in a TX or RX Warmup. TSM is a multipurpose hardware resource shared by all of the protocol engines in the SoC. Thus, TSM does not have its own interrupts; its interrupts are assigned to whichever link layer controller is currently executing an RF operation. TSM Interrupt Status bits reside in Transceiver (XCVR) Address Space, and can be cleared there. There is no intended mission-mode use for TSM_IRQ. See the TSM Chapter for more details.
ACK_IRQ	ACK_IRQ is asserted when RX finishes, and an auto ACK frame is scheduled to TX. At this time, software may need to write packet RAM to prepare the ACK frame or part of the ACK frame.
PHRFFAIL_IRQ	PHRFFAIL_IRQ is asserted when the received frame fails at BCH check or Parity check, for LECIM FSK and SUN FSK Mode Switch frame only.
FILTERFAIL_IRQ	FILTERFAIL_IRQ indicates that the most-recently received packet has been rejected due to elements within the packet. In Dual PAN mode, FILTERFAIL_IRQ applies to either or both networks, as follows: A: If PAN0 and PAN1 occupy different channels and CURRENT_NETWORK=0, FILTERFAIL_IRQ applies to PAN0.

Table continues on the next page...

Table continued from the previous page...

Interrupt	Description
	B: If PAN0 and PAN1 occupy different channels and CURRENT_NETWORK=1, FILTERFAIL_IRQ applies to PAN1. C: If PAN0 and PAN1 occupy the same channel, FILTERFAIL_IRQ is the logical 'AND' of the individual PANs' Filter Fail status.
CCA_IRQ	CCA_IRQ indicates completion of CCA operation
MS_IRQ	MS_IRQ indicates a mode switch frame is received with no BCH or Parity error.

55.4.9.2.3.10 Memory Mapping

In the SoC memory map, space has been allocated to GENERIC_FSK. Within the SoC, peripherals are allocated memory space in 4KB blocks, called IPS slots. GENERIC_FSK occupies one such slot. GENERIC_FSK address space consists of the GENERIC_FSK registers. The partitioning of address space for GENERIC_FSK is shown in the diagram below.

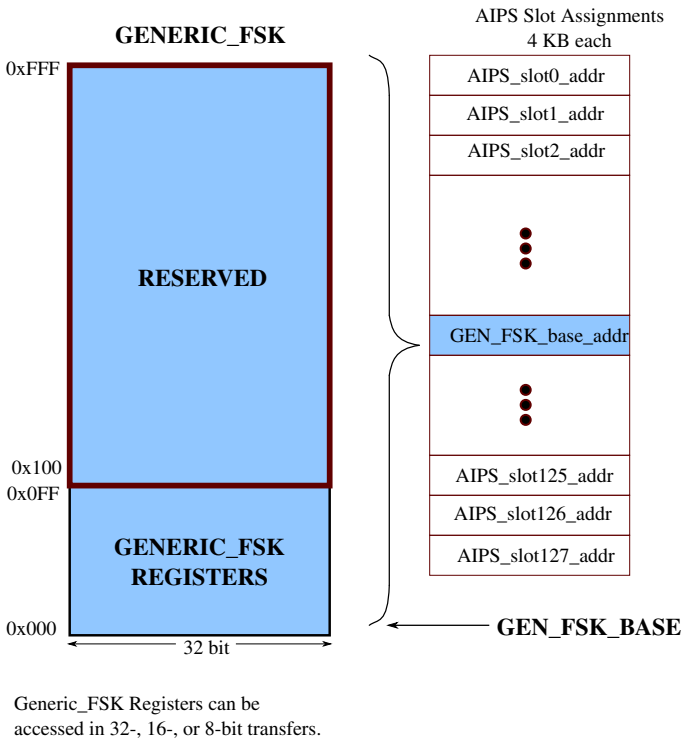

Figure 480. GENERIC_FSK MEMORY MAPPING

NOTE

See AIPS Memory Map for specific memory assignments details.

All registers within GENERIC_FSK memory space, are accessible by the MCU in 8-, 16-, or 32-bit accesses. For efficiency, 32-bit accesses are recommended.

55.4.9.2.3.11 Manual DSM

When the GENERIC_FSK Link Layer anticipates long periods of inactivity, the Link Layer controller can be put into a Deep Sleep Mode (DSM), where all of its clocks are turned off. In addition, the GENERIC_FSK Link Layer can be configured to optionally turn off the RF Oscillator, if it is not otherwise needed by the SoC. Deep Sleep Mode results in dramatic power savings. The procedure described below, is called Manual DSM.

To make Manual DSM possible, the transceiver incorporates a low-frequency, high-precision Deep Sleep Timer, TIMER. This timer is clocked by a crystal-referenced 32.768KHz oscillator. The timer is 24-bit wide, yielding a 8.5 minute rollover (the maximum length of a deep sleep period).

The hardware to implement DSM within the SoC, is partitioned across several modules, and several power domains. This is to allow the maximum achievable power savings, by retaining full voltage for only those modules which need to be active in DSM, and placing the remaining modules in "state retention" mode. The diagram below depicts the partitioning of DSM hardware across the various modules, including the GENERIC_FSK Link Layer Controller.

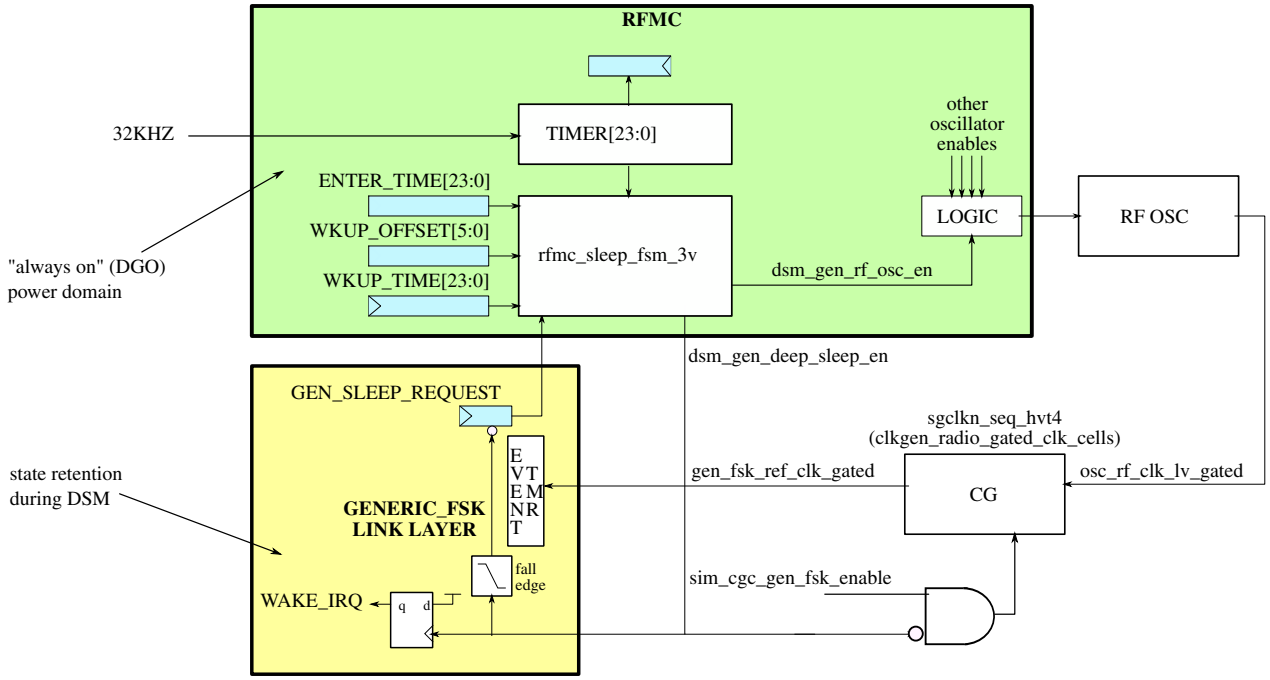

Figure 481. MANUAL DSM BLOCK DIAGRAM

The concept behind Manual DSM, as it is implemented for GENERIC_FSK, is to allow the GENERIC_FSK timebase to be maintained for a period of time, while the RF Oscillator is turned off and much of the SoC is placed in state-retention. During DSM, the timebase management is temporarily transferred from the GENERIC_FSK EVENT_TMR to the low-power TIMER, and after DSM exit, timebase management is transferred back to the EVENT_TMR, under software control. During DSM, the EVENT_TMR is frozen. The total time spent in DSM is known to software, so that upon exiting DSM, the EVENT_TMR can be updated to correct for the precise amount of time it was frozen.

DSM entry and exit, and RF Oscillator re-start during Manual DSM, are governed by 5 registers, as described in the table below.

Field	R/W	Description
ENTER_TIME[23:0]	rw	If GEN_SLEEP_REQUEST=1, enter DSM & freeze EVENT_TMR when ENTER_TIME matches TIMER.

Table continues on the next page...

Table continued from the previous page...

Field	R/W	Description
		NOTE This register resides in RFMC Address Space
WKUP_OFFSET[5:0]	rw	Determines the power and RF oscillator re-start times relative to WKUP_TIME **NOTE** This register resides in RFMC Address Space
WKUP_TIME[23:0]	rw	Exit Deep Sleep Mode, and resume EVENT_TMR, when WKUP_TIME matches TIMER **NOTE** This register resides in RFMC Address Space
GEN_SLEEP_REQUEST	w	Enable a match on ENTER_TIME[23:0] to TIMER[23:0], to enter Deep Sleep Mode, by writing a 1 to this bit. Cancel a pending sleep request by writing a 0 to it, if already set, at least 2 32.768KHz clock cycles prior to ENTER_TIME[23:0]
TIMER[23:0]	r	Current State of the 32KHz Sleep Timer **NOTE** This register resides in RFMC Address Space

Procedure

The procedure to schedule a Manual DSM cycle (entry/exit) as well as to program the desired RF Oscillator re-start time, and the calculation to restore the GENERIC_FSK EVENT_TMR after a DSM cycle, is described below.

1. Software determines the future time at which it would like to enter DSM, by reading the TIMER, computing the number of 32KHz clock cycles remaining until the desired DSM start-time, and writing this value into ENTER_TIME register. The value programmed into ENTER_TIME should be no fewer than 4 clocks greater (in the future) than the current time as read from TIMER.
2. Software determines the future time at which it would like to exit DSM, by computing the number of 32KHz clock cycles remaining until the desired DSM exit-time, and writing this value into WKUP_TIME register.
3. Software writes a 1 to DSM_CTRL[GEN_SLEEP_REQUEST]. This bit resides in GENERIC_FSK address space. Writing this bit to 1 enables a DSM cycle to commence using the values programmed into ENTER_TIME and WKUP_TIME.
4. MCU can go into a low power state (e.g., STOP, VLPS, or VLLSx)
5. When TIMER = ENTER_TIME, the EVENT_TMR will be clock-gated so that it will remain frozen at its current count. The RF Oscillator will be turned off (unless overridden due to a non-Generic-related SoC requirement)
6. All hardware not in the low-voltage domain will be placed into state-retention, or other low-power state.

7. When TIMER = WKUP_TIME, clocking of the GENERIC_FSK Link Layer Controller will resume and the EVENT_TMR will be ungated (allowed to resume counting).
8. Software computes the time that the SoC was in DSM (and hence the time the EVENT_TMR was frozen), in microseconds, with the equation:

   (WKUP_TIME - ENTER_TIME) / 32768 * 1000000
9. Software increments the GENERIC_FSK EVENT_TMR by this amount, by writing this value to EVENT_TMR[23:0] register with EVENT_TMR_ADD=1.
10. On the next 1MHz clock edge, the EVENT_TMR has been restored to where it would have been, had no DSM occurred, with 1.0-microsecond accuracy.

Note that the 1.0-microsecond accuracy quoted above, assumes an ideal 32.768KHz source. Any ppm error in the 32.768KHz source will degrade the microsecond accuracy proportionally to the magnitude of the error.

Once GEN_SLEEP_REQUEST has been set to 1 to request Manual DSM, the request can be cancelled by writing a 0 to the bit. The cancellation must be performed at least 2 32.768KHz before the ENTER_TIME[23:0] match to TIMER[23:0] to avoid a race condition to enter DSM.

The following timing diagram depicts an GENERIC_FSK-driven DSM entry/exit cycle.

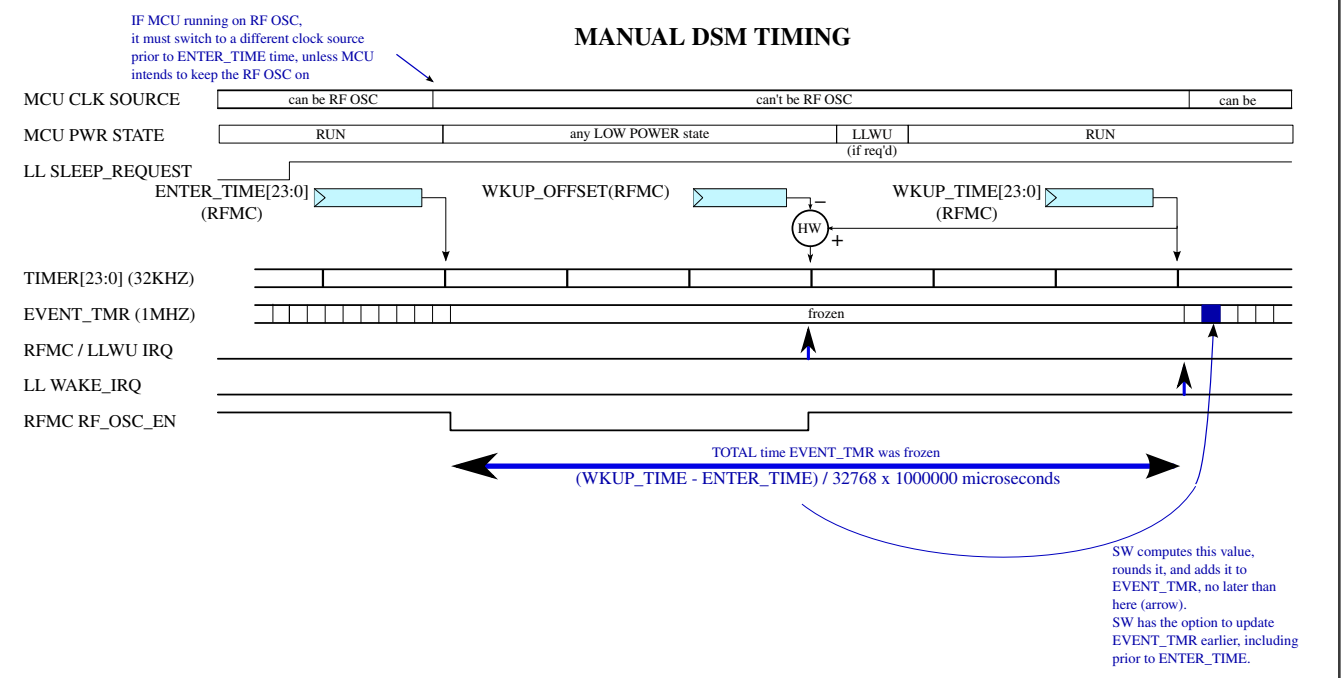

Figure 482. GENERIC_FSK DEEP SLEEP TIMING

DSM Early Exit

Circumstances may arise where the Manual DSM cycle may occasionally need to be cut short, due to circumstances beyond the control of the radio. When this happens, the SoC, starting with the MCU, is awakened out of its low power state, long before the RFMC TIMER reaches WKUP_TIME. Therefore, software handling the event which triggered the wakeup, will determine if the radio needs to be awakened as well. If this is the case, software will advance the WKUP_TIME setting to a point in the near future, but no fewer than 4 32KHz clock cycles beyond the current time ascertained by reading TIMER. So, to execute a Manual DSM Early Exit, software shall read TIMER, add +4 to the value, and write the sum to the RFMC WKUP_TIME register. Software shall then wait for the GENERIC_FSK WAKE_IRQ interrupt, which will assert once the full radio wakeup from the low power state has completed. Software should then take whatever steps are necessary to configure the radio to respond to the conditions which triggered the early exit. Servicing of a DSM early exit interrupt is beyond the scope of this document.

55.4.9.2.3.12 Wake-On-Radio

The GENERIC_FSK Link Layer can take advantage of the automated sequence- and DSM-scheduling provided by Wake-On-Radio. Wake-On-Radio is one of two DSM control schemes that can be selected for GENERIC_FSK, as an alternative to Manual DSM. See Chapter *Wake-On-Radio*.

Several changes to the GENERIC_FSK Link Layer Controller have been made to support Wake-On-Radio.

Interrupt WAKE_IRQ has been made dual-purpose. If Wake-On-Radio is disabled, i.e., WOR_CTRL[WOR_EN]=0, or Wake-On-Radio not assigned to GENERIC_FSK, WAKE_IRQ performs its legacy function for Manual DSM. (See Section Manual DSM). If Wake-On-Radio is enabled, i.e., WOR_EN=1, and assigned to GENERIC_FSK, this interrupt becomes WOR_IRQ, and has new functionality specific to Wake-On-Radio. See Chapter *Wake-On-Radio*, Section *Interrupt Management*, for more details on the meaning, and handling of WOR_IRQ. The Interruptssection of this chapter describes the dual-purpose nature of WAKE_IRQ / WOR_IRQ.

In addition to WOR_IRQ, numerous interface changes have been made to support Wake-On-Radio. The changes allow, for example, WOR to manage GENERIC_FSK's RF interrupts, inhibit timestamp updates, etc. The added port signals are listed in the table below, along with a description or each:

WAKE-ON-RADIO INTERFACE SIGNAL	DIRECTION	DESCRIPTION
wor_event_tmr_add[23:0]	WOR -> GENERIC_FSK	The Event Timer "Addback" value computed by WOR to compensate for the amount of time Event Timer was frozen during DSM
wor_addback	WOR -> GENERIC_FSK	A 1µs-long pulse commanding the GENERIC_FSK Event Timer to auto-increment by the the amount appearing on wor_event_tmr_add[23:0]
wor_force_wake_irq	WOR -> GENERIC_FSK	Force WOR_IRQ to assert, due to an occurrence of one of the 3 WOR_IRQ interrupt triggers
wor_block_wake_irq	WOR -> GENERIC_FSK	Inhibit the legacy WAKE_IRQ assertion when WOR_EN=1 (this interrupt becomes WOR_IRQ)
tx_start_ext	WOR -> GENERIC_FSK	A 1µs-long pulse to the GENERIC_FSK command decoder to initiate a WOR-driven TX sequence
rx_start_ext	WOR -> GENERIC_FSK	A 1µs-long pulse to the GENERIC_FSK command decoder to initiate a WOR-driven RX sequence
seq_stop_ext	WOR -> GENERIC_FSK	A 1µs-long pulse to the GENERIC_FSK command decoder to stop (abort) a WOR-driven RX sequence
wor_allow_irq	WOR -> GENERIC_FSK	Inhibits RF interrupts, so that interrupt assertions can be managed based on WOR descriptor settings. Controlled dynamically by the WOR state machine.
timestamp_inhibit	WOR -> GENERIC_FSK	In Wake-On-Radio, the legacy GENERIC_FSK TIMESTAMP register

Table continues on the next page...

Table continued from the previous page...

WAKE-ON-RADIO INTERFACE SIGNAL	DIRECTION	DESCRIPTION
		becomes WOR TIMESTAMP0 (timestamp for SLOT0). This signal blocks this register from updating on SLOTS 1-3
wake_irq_trig	WOR <- GENERIC_FSK	WOR uses this signal to cancel GEN_SLEEP_REQUEST and transition from IN_DSM -> COMP_ADDBACK state
event_tmr[23:0]	WOR <- GENERIC_FSK	GENERIC_FSK Event Timer, used by WOR for timestamp capture
event_tmr_plus_1[23:0]	WOR <- GENERIC_FSK	GENERIC_FSK Event Timer + 1, used by WOR to schedule RF operation starts and stops
tx_irq_trig	WOR <- GENERIC_FSK	TXIRQ trigger, indicates the completion of a packet transmission, used by WOR to transition out of WAKE_SEQ_END state
rx_irq_trig	WOR <- GENERIC_FSK	RXIRQ trigger, indicates the completion of a good packet reception, used by WOR to transition out of WAKE_SEQ_END state
rx_status_for_wor[2:0]	WOR <- GENERIC_FSK	Internal RX status signals used by WOR to formulate TIMESTAMPx_STS[2:0]. **NOTE** See Section Timestamp Status for Wake-On-Radio following this table
timestamp_clk_en	WOR <- CGM <- GENERIC_FSK	Timestamp clock gate enable, the resultant clock is used by WOR to update the TIMESTAMP1,2, and 3 registers

Timestamp Status for Wake-On-Radio

The GENERIC_FSK Link Layer has 5 methods for filtering and screening packets as they are being received:

H0 filtering

H1 filtering

LENGTH_MAX filtering

PHR filtering(PAN or FAN mode)

MAC rule filtering(PAN or FAN mode)

In Normal operation, when one or more of the filtering rules are violated, an RX recycle will occur immediately after the header, and the cause of the filtering violation (status bit) will not be preserved. In addition, the final CRC status can't be known at the point of recycle. In Wake-On-Radio operation, The TIMESTAMPx_STS[1] bit reflects CRC status, and TIMESTAMPx_STS[2] bit reflects Packet Filter status. For an RX recycle at the end of the packet header, the GENERIC_FSK Link Layer won't be able to provide the necessary signalling to Wake-On-Radio in order to properly set those 2 bits of each TIMESTAMPx_STS register, so these bits should be considered invalid. To render them valid, set the GENERIC_FSK PACKET_CFG[REC_BAD_PKT]=1, which will force reception of the entire packet, including CRC, before recycling. Set RX_FRAME_FILTER[FILTER_FAIL_IGNORE] to ignore MAC rule filtering fail and set PHR_MISC[PHR_FAIL_IGNORE] to ignore PHR filtering rule fail. This will allow the Wake-On-Radio TIMESTAMPx_STS[2:1] bits to yield valid information.

55.4.9.2.3.13 Multi-protocol Arbitration

The GENERIC_FSK Link Layer controller may be included in an SoC that includes similar controllers for other protocols (e.g., Bluetooth Low Energy). GENERIC_FSK may be required to operate simultaneously with other protocols on the SoC, and there are scenarios where both protocol engines require access to the RF channel at the same time.

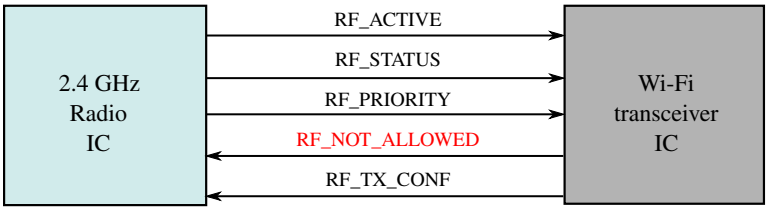
To assist in software arbitration between GENERIC_FSK and other protocols, the read-only status but XCVR_BUSY has been included in the XCVR_STS register. When this bit is set, this indicates that the RF channel is currently in use (TSM is busy), by one of the Radio's four link layer controllers. When this bit it clear, the RF channel is available to GENERIC_FSK (TSM is idle).

55.4.9.2.3.14 Wifi Coexistence

Provisions have been made to allow for the 2.4GHz transceiver to coexist in the same space as a WiFi transceiver IC, which shares the same frequency band. The coexistence scheme designates the WiFi transceiver as the master, and the 2.4GHz transceiver as the slave. The objective of the coexistence strategy is to prevent both the WiFi and 2.4GHz transceivers transmitting simultaneously; a configuration option exists to also prevent the 2.4GHz transceiver from receiving when the WiFi transceiver owns the RF channel.

The 2.4GHz Radio IC support the coexistence interface signals as shown in the figure below, though in a typical application only a subset of these are used.

The WiFi IC generates a signal, RF_NOT_ALLOWED. If this signal is asserted, then 2.4GHz radio does not perform any communication. When this signal is de-asserted, then 2.4GHz radio is free to perform communications.



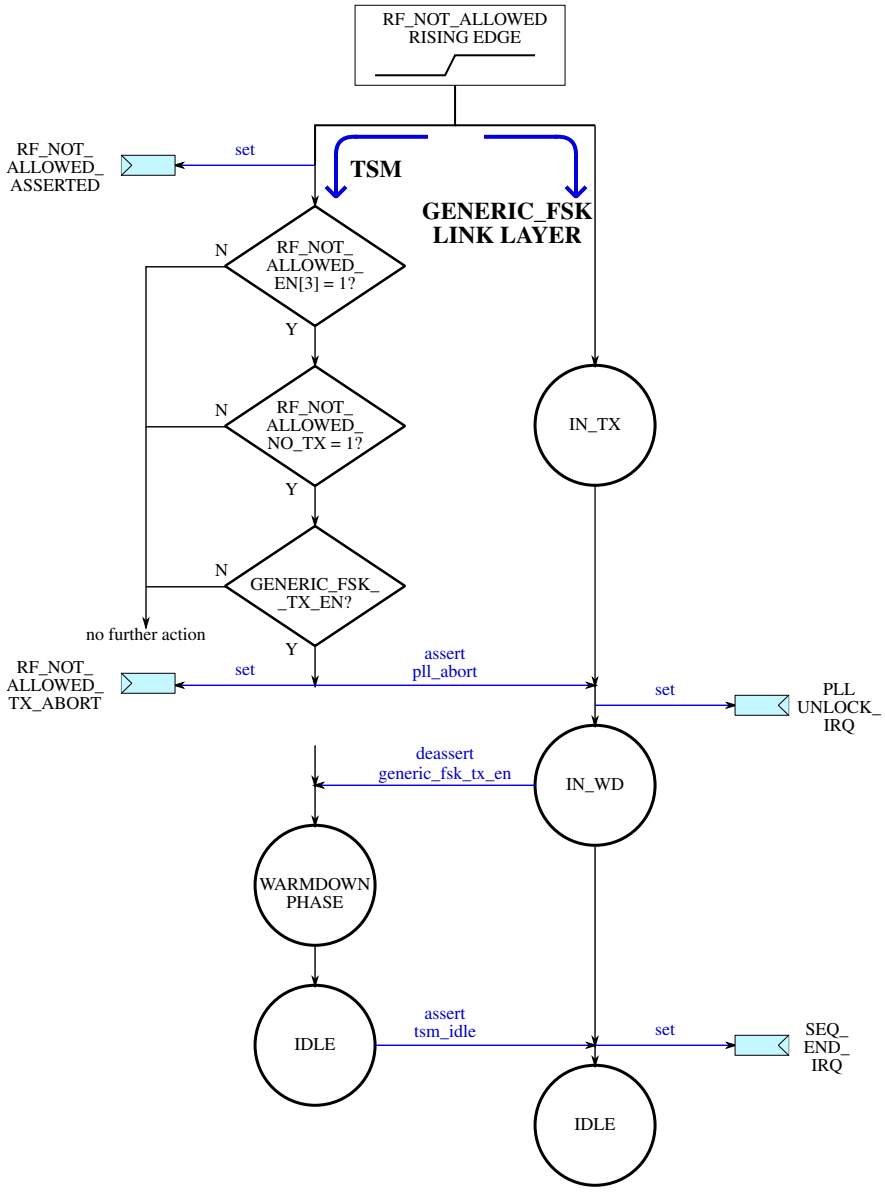
When RF_NOT_ALLOWED aborting is enabled, the GENERIC_FSK Link Layer hardware must respond to RF_NOT_ALLOWED assertions, by aborting any TX or RX sequence which is currently underway, and Link Layer software must not initiate any new sequences until RF_NOT_ALLOWED has been deasserted. The hardware response must be handled autonomously by the Link Layer, with no MCU intervention required. This is because the RF_NOT_ALLOWED assertions can occur during a Wake-On-Radio timeslot which has been designated as "no-MCU-wakeup" in the slot's descriptor. In this scenario, the aborting of the sequence occurs without any assistance from, or notification of, the MCU.

In the multi-protocol 2.4GHz radio, RF_NOT_ALLOWED aborting can be individually enabled/disabled for each protocol engine. For GENERIC_FSK, RF_NOT_ALLOWED_EN[3] is the associated enable control bit. This bit resides in the COEX_CTRL register in XCVR address space. When this bit is 0, transitions on RF_NOT_ALLOWED are ignored by the GENERIC_FSK Link Layer hardware; when this bit is 1, the GENERIC_FSK Link Layer hardware will monitor RF_NOT_ALLOWED at all times, and abort any active sequence which is underway when an assertion on the pin occurs. The complete hardware response to RF_NOT_ALLOWED assertions is described below.

Additional control over RF_NOT_ALLOWED aborting is provided by the RF_NOT_ALLOWED_NO_TX and RF_NOT_ALLOWED_NO_RX control bits. If RF_NOT_ALLOWED_NO_TX=1, then an RF_NOT_ALLOWED abort will occur only if a GENERIC_FSK TX sequence is underway (generic_fsk_tx_en=1). GENERIC_FSK TX sequences will not be aborted if RF_NOT_ALLOWED_NO_TX=0. If RF_NOT_ALLOWED_NO_RX=1, then an RF_NOT_ALLOWED abort will occur only if GENERIC_FSK RX sequence is underway (generic_fsk_rx_en=1). GENERIC_FSK RX sequences will not be aborted if RF_NOT_ALLOWED_NO_RX=0. The RF_NOT_ALLOWED_NO_TX and RF_NOT_ALLOWED_NO_RX control bits reside in the COEX_CTRL register.

For the purposes of triggering a hardware abort, the *pll_abort* input to the GENERIC_FSK Link Layer hardware is used. This is because the hardware response to the RF_NOT_ALLOWED assertion is identical to that of a PLL unlock event. This also means that, when RF_NOT_ALLOWED aborting is enabled for GENERIC_FSK the PLL_UNLOCK_IRQ interrupt status bit, will be dual purpose: it will not only indicate a PLL unlock condition, but also a RF_NOT_ALLOWED abort. PLL aborting and RF_NOT_ALLOWED aborting are enabled separately, with the COEX_CTRL register maintaining the control bits required for the latter. The status bits for RF_NOT_ALLOWED aborting are also available in COEX_CTRL, so that software will be able to distinguish the source of the PLL_UNLOCK_IRQ, in case both PLL and RF_NOT_ALLOWED aborting are enabled.

The sequence of events which results in a hardware abort of an GENERIC_FSK TX operation triggered by an assertion on RF_NOT_ALLOWED, is a collaboration between the TSM (Transceiver Sequence Manager) and the GENERIC_FSK Link Layer hardware, as shown in the following diagram.



Upon assertion on RF_NOT_ALLOWED, the TSM sets the RF_NOT_ALLOWED_ASSERTED status bit in COEX_CTRL, then checks that the conditions for a hardware abort are all met:

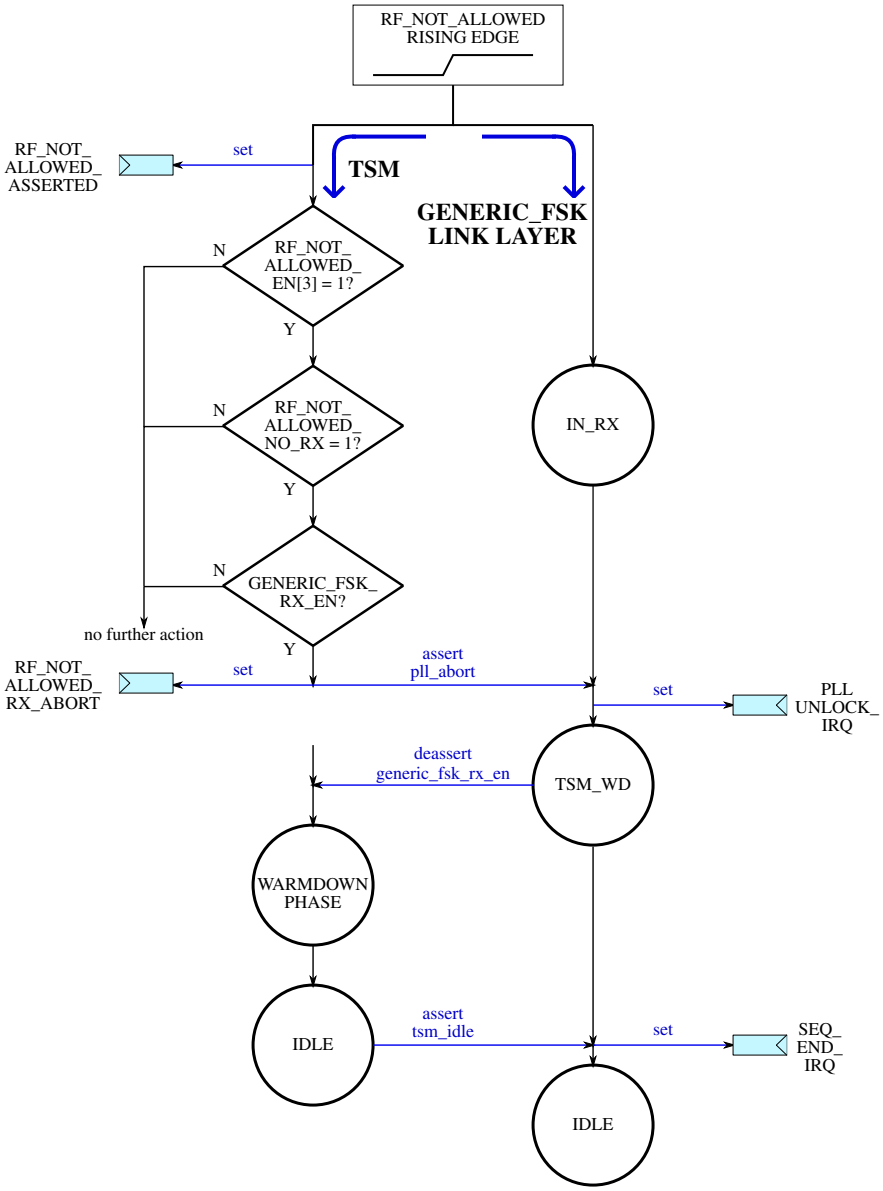
- RF_NOT_ALLOWED_EN[3] = 1, which enables GENERIC_FSK to respond to RF_NOT_ALLOWED events
- RF_NOT_ALLOWED_NO_TX = 1, which enables TX operations to be aborted
- generic_fsk_tx_en = 1, TX request to TSM from GENERIC_FSK, indicating TX operation in progress

If all conditions are not met, no further action is taken. Otherwise, the TSM sets COEX_CTRL[RF_NOT_ALLOWED_TX_ABORT], and also asserts *pll_unlock* to the GENERIC_FSK Link Layer hardware. GENERIC_FSK responds by asserting IRQ_CTRL[PLL_UNLOCK_IRQ] in GENERIC_FSK address space. GENERIC_FSK enters IN_WD state, which deasserts generic_fsk_tx_en to the TSM. This initiates the TSM TX warmdown. GENERIC_FSK holds in IN_WD to wait for TSM to return to idle. Once this occurs, GENERIC_FSK asserts IRQ_CTRL[SEQ_END_IRQ] and returns to its IDLE state. Three status bits are now set to indicate to software that the source of the abort was an RF_NOT_ALLOWED assertion:

- IRQ_CTRL[PLL_UNLOCK_IRQ]
- COEX_CTRL[RF_NOT_ALLOWED_ASSERTED]

- COEX_CTRL[RF_NOT_ALLOWED_TX_ABORT]

The sequence of events which results in a hardware abort of an GENERIC_FSK RX sequence triggered by an assertion on RF_NOT_ALLOWED, is shown in the following diagram.



Upon assertion on RF_NOT_ALLOWED, the TSM sets the RF_NOT_ALLOWED_ASSERTED status bit in COEX_CTRL, then checks that the conditions for a hardware abort are all met:

- RF_NOT_ALLOWED_EN[3] = 1, which enables GENERIC_FSK to respond to RF_NOT_ALLOWED events
- RF_NOT_ALLOWED_NO_RX = 1, which enables RX operations to be aborted
- generic_fsk_rx_en = 1, RX request to TSM from GENERIC_FSK, indicating RX operation in progress

If all conditions are not met, no further action is taken. Otherwise, the TSM sets COEX_CTRL[RF_NOT_ALLOWED_RX_ABORT], and also asserts *pll_unlock* to the GENERIC_FSK Link Layer hardware. GENERIC_FSK responds by asserting IRQ_CTRL[PLL_UNLOCK_IRQ] in GENERIC_FSK address space. GENERIC_FSK enters IN_WD state, which deasserts generic_fsk_rx_en to the TSM. This initiates the TSM TX warmdown. GENERIC_FSK holds in IN_WD to wait for TSM to return to idle. Once this occurs, GENERIC_FSK asserts IRQ_CTRL[SEQ_END_IRQ] and returns to its IDLE state. Three status bits are now set to indicate to software that the source of the abort was an RF_NOT_ALLOWED assertion:

- IRQSTS1[PLL_UNLOCK_IRQ]
- COEX_CTRL[RF_NOT_ALLOWED_ASSERTED]
- COEX_CTRL[RF_NOT_ALLOWED_RX_ABORT]

Chapter 56
Data Stream Buffer (DSB)

56.1 Introduction

The Data Stream Buffer (DSB) module captures streaming data from the radio and transfers the data to system memory with minimal intervention from a host processor. The hardware microarchitecture includes:

- An internal FIFO for temporary storage of the data stream
- A small Direct Memory Access (DMA) controller that performs:
  - Destination address calculations
  - Data-movement operations

The block diagram of DSB is shown in the figure below.

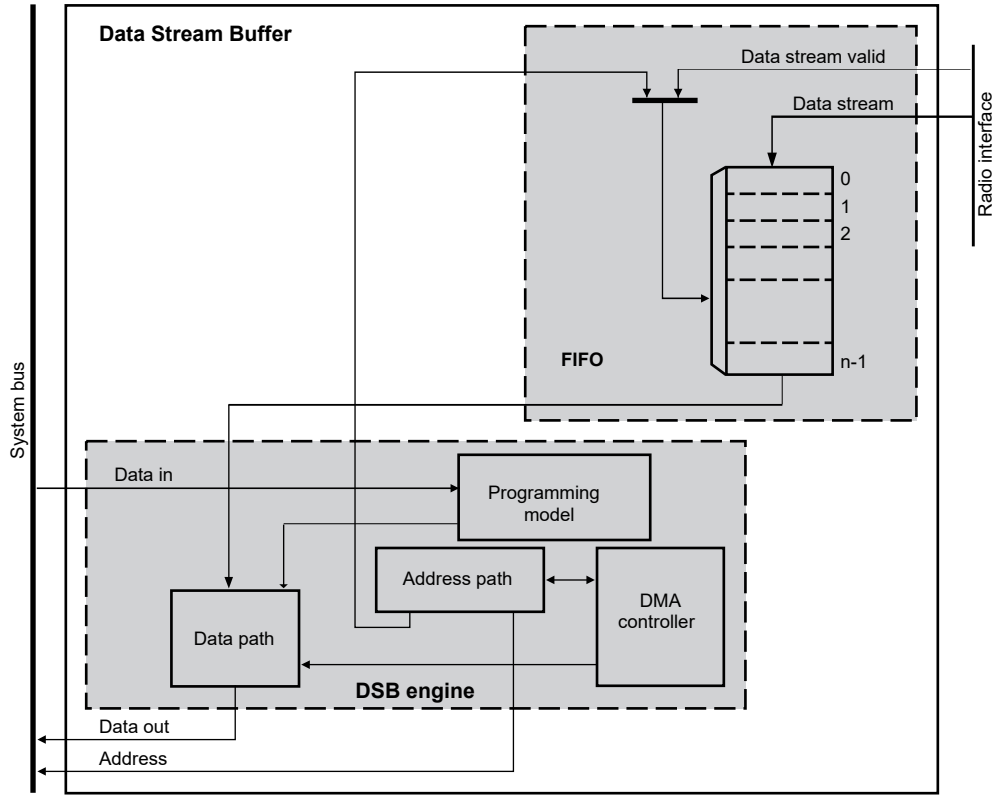


Figure 483. DSB block diagram

56.2 Memory map/register definition

The programming model of DSB is partitioned into four parts:

- The first part, Control/Status, defines a number of registers providing overall control functions.
- The second part corresponds to the interrupt status.

- The third part corresponds to the FIFO attributes.
- The fourth part corresponds to the FIFO read data.

DMA initialization

Before enabling the DMA logic, you must initialize the control fields of DMA with the appropriate transfer profile.

Reserved memory and bit fields

- Reading reserved bits in a register returns the value of zero.
- Writes to reserved bits in a register are ignored.
- Reading a reserved memory location returns undefined.
- Writes to a reserved memory location is ignored.

56.2.1 DSB register descriptions

56.2.1.1 DSB memory map

DSB0 base address: 4004_1000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Control Register (CSR)	32	RW	0000_0000h
4h	Interrupt Request Status Register (INT)	32	RW	0000_0000h
8h	Watermark Configuration Register (WMC)	32	RW	1000_0000h
Ch	FIFO Read Data Register (RDATA)	32	R	0000_0000h
10h	DMA Destination Address Register (DADDR)	32	RW	0000_0000h
14h	DMA Transfer Count Register (XCR)	32	RW	0000_0000h

56.2.1.2 Control Register (CSR)

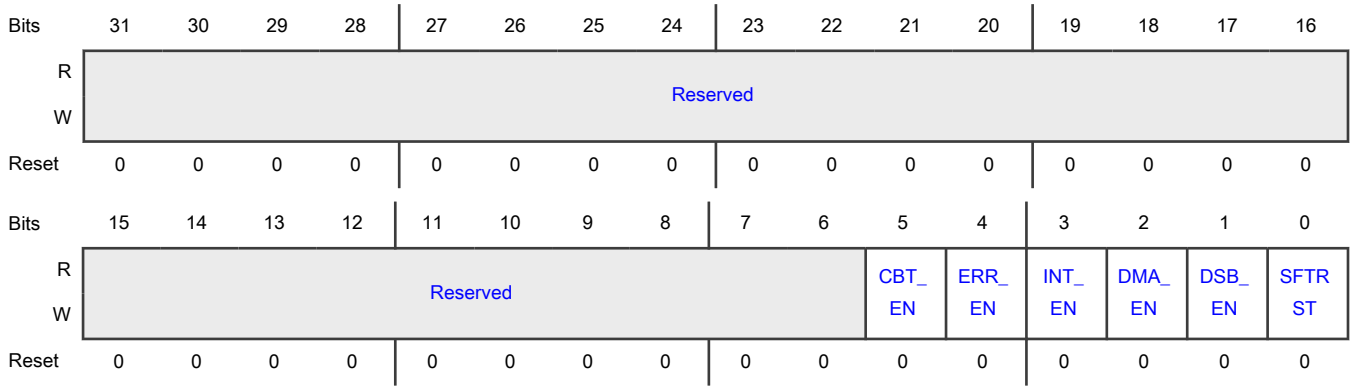
Offset

Register	Offset
CSR	0h

Function

The CSR register defines the basic operating configuration of DSB.

Diagram



Fields

Field	Function
31-6 —	Reserved
5 CBT_EN	Continuous Burst Transfer Enable When enabled, continuous burst transfer streams data from the FIFO to the system bus until either the FIFO is empty or the transfer count, XCR[TCNT], has been achieved. The continous data transfer is executed as a single, undefined length burst transfer. When disabled, the burst transfer length is equal to the watermark value WMC[WMRK]. 0b - Continuous burst transfer mode is disabled. 1b - Continuous burst transfer mode is enabled.
4 ERR_EN	Error Interrupt Request Enable 0b - Error interrupt requests on overflow, underrun, or bus error are disabled. 1b - Error interrupt requests on overflow, underrun, or bus error are enabled.
3 INT_EN	Interrupt Request Enable 0b - Interrupt requests on data ready or DMA done are disabled. 1b - Interrupt requests on data ready or DMA done are enabled. Interrupt requests on data ready or DMA done are enabled. When the DMA is enabled (CSR[DMA_EN]=1), INT_EN enables interrupt requests when the packet transfer is complete (INT[DONE]=1). Otherwise, INT_EN enables interrupt requests when data is ready (INT[DRDY]=1).
2 DMA_EN	DMA Transfer Enable 0b - DMA transfers are disabled. 1b - DMA transfers are enabled.
1 DSB_EN	Data Stream Buffer Enable 0b - Buffer is disabled. 1b - Buffer is enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 SFTRST	Soft Reset 0b - No operation. 1b - Reset the data stream buffer.

56.2.1.3 Interrupt Request Status Register (INT)

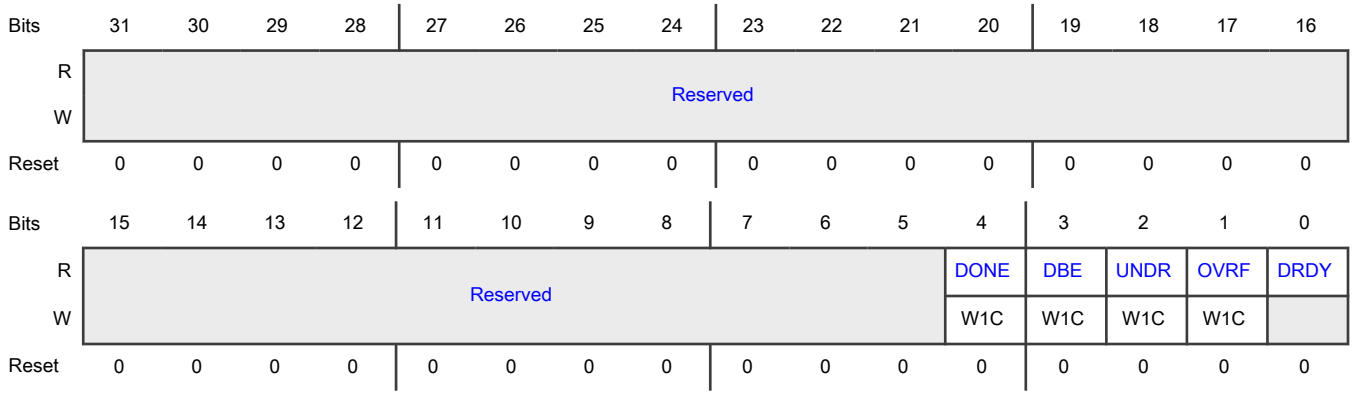
Offset

Register	Offset
INT	4h

Function

The INT register shows the current state of the interrupt service request sources for DSB.

Diagram



Fields

Field	Function
31-5 —	Reserved
4 DONE	DMA Packet Transfer Complete 0b - Packet transfer not done; CCNT less than TCNT 1b - Packet transfer is done; TCNT 32-bit words transferred
3 DBE	Destination Bus Error 0b - No destination bus error

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - The last recorded error is bus error on a write
2 UNDR	Underrun Error 0b - No underrun error 1b - The last recorded error is an underrun on a read
1 OVRF	Overflow Error 0b - No overflow error 1b - The last recorded error is a buffer overflow
0 DRDY	Data Ready 0b - No data to read (watermark has not been reached) 1b - Data is ready to read (watermark has been reached)

56.2.1.4 Watermark Configuration Register (WMC)

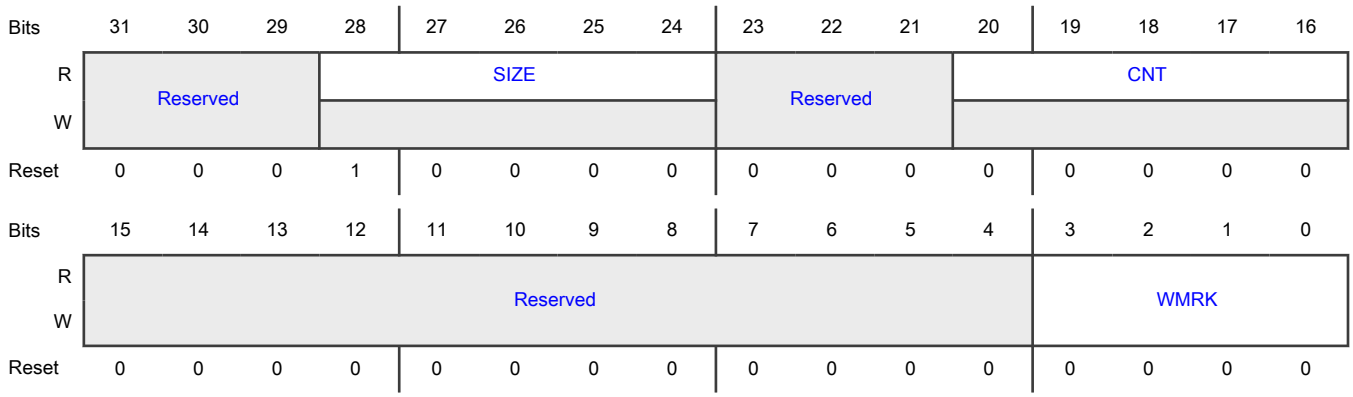
Offset

Register	Offset
WMC	8h

Function

The WMC register controls the DMA operations of DSB and indicates data is available via the INT[DRDY] bit. The WMC register shows the depth of the data stream FIFO and the number of elements written into the FIFO.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-24 SIZE	FIFO size The FIFO size indicates the number of elements the FIFO can hold.
23-21 —	Reserved
20-16 CNT	FIFO Count The FIFO Count indicates the number of elements currently in the FIFO.
15-4 —	Reserved
3-0 WMRK	Watermark DSB starts DMA transfers, if enabled, and sets DRDY when the number of elements in the FIFO is equal to or greater than the watermark value.

56.2.1.5 FIFO Read Data Register (RDATA)

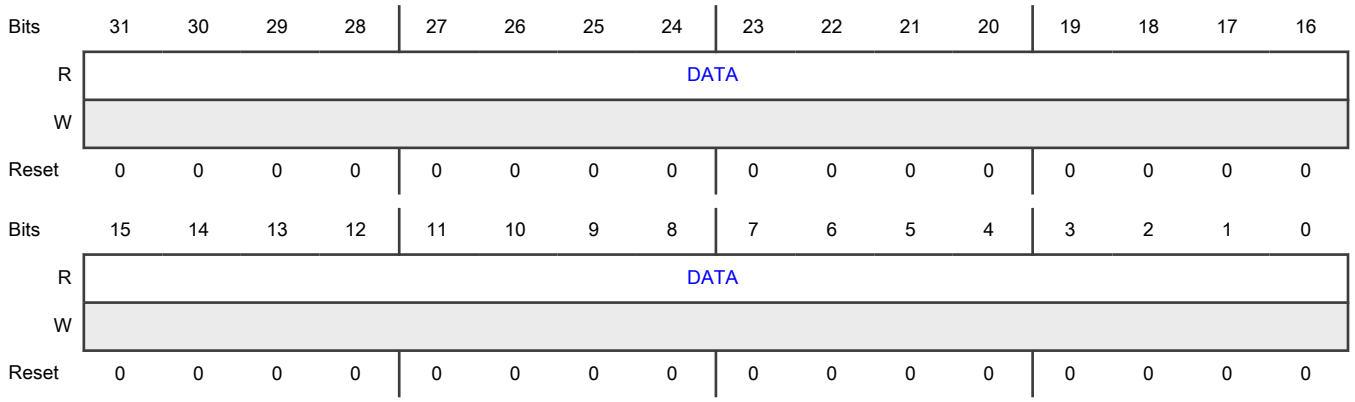
Offset

Register	Offset
RDATA	Ch

Function

The RDATA register is a read-only register that presents the next element in the FIFO. Reading the RDATA register pops the element off the FIFO stack.

Diagram



Fields

Field	Function
31-0 DATA	FIFO Data Read data from FIFO.

56.2.1.6 DMA Destination Address Register (DADDR)

Offset

Register	Offset
DADDR	10h

Function

The DADDR register is the target address in system memory where the FIFO data is transferred to upon reaching the watermark value. The transfer profile to the destination address is undefined length INCR burst, 32-bits per beat. The number of beats is equal to the watermark value until TCNT is reached. This byte address register automatically increments by four after each transfer beat.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	DADDR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DADDR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 DADDR	Destination Address Destination address for the DMA transfer.

56.2.1.7 DMA Transfer Count Register (XCR)

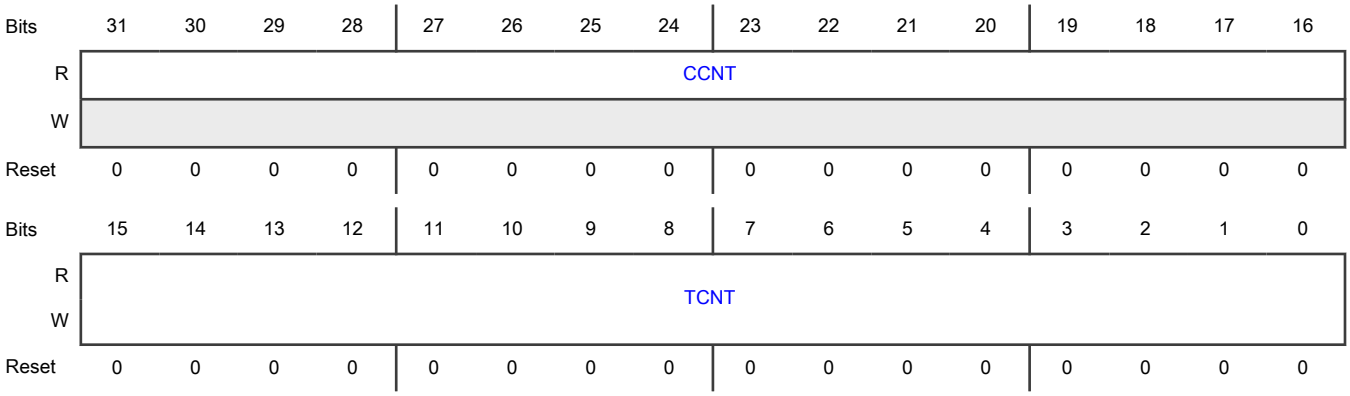
Offset

Register	Offset
XCR	14h

Function

The XCR register indicates the required and actual number of 32-bit words that the internal DMA controller transfers.

Diagram



Fields

Field	Function
31-16 CCNT	Current Transfer Count The current number of elements transferred to system memory.
15-0 TCNT	Total Transfer Count The required total number of elements to transfer to system memory. When the CCNT equals the TCNT: • DSB disables, • DMA operations stop, • any remaining data discards in the FIFO, • the CCNT resets to zero, • an optional DONE interrupt request generates.

56.3 Initialization/application information

This section discusses initialization of DSB and its programming considerations.

To use the internal DMA engine to transfer streaming radio data to system memory, initialize the transfer profile before enabling DSB. Follow the below procedure:

1. Initialize the DADDR with the destination buffer location in system memory.
2. Set the required total transfer count, TCNT, with the total packet length (in 32-bit words).
3. Set the watermark threshold value, WMRK, in the WMC register.
4. Set the DMA_EN bit.
5. Set the INT_EN bit and ERR_EN bit for interrupts on error or packet transfer completion.
6. Set the DSB_EN bit when ready to receive the data stream.

For example:

1. DADDR = 0x80004000 (system memory location)

2. TCNT = 0x1000 (16 KB of data)
3. WMRK = 0x8 (1/2 of the 16 element depth)
4. DMA_EN = 1, INT_EN = 1, ERR_EN = 1
5. DSB_EN = 1

NOTE

Real-time deadline analysis should be performed to ensure that DSB has sufficient system resources to meet all deadlines with respect to transferring the radio data stream to system memory.

Chapter 57
RF Core Mode Controller (RF_CMC)

57.1 Introduction

The Radio Core Mode Controller (RF_CMC) provides the following functions:

- Provides the enable to radio FRO module, which is sequenced off at low power entry, and on at low power exit
- Controls the low power sequencing for the radio flash via Q-channel interface.
- Conditions the low power entry requests from the NBU and WOR (for WOR and MAN) to wait until the NBU/CM3 is ready and the radio flash has entered low power
- On exit from Power Down or Deep Power Down low power modes, holds the radio LV in reset until the radio flash has finished its initialization.
- Creates XTAL ready interrupt for CM3
- Provides programmable control for TPM2 (clock control and input channel selection)
- Generates ifr_ld_en associated with the radio flash IFR outputs
- Implements SOC Core status registers
- Implements RAM related control registers (power controls)

The RF_CMC's logic uses the IPS/APB clock provided by the radio FRO module. It does not use the XTAL clock or the 32.768KHz clock.

57.2 Block Diagram

The following diagram gives a high-level overview of the RF_CMC.

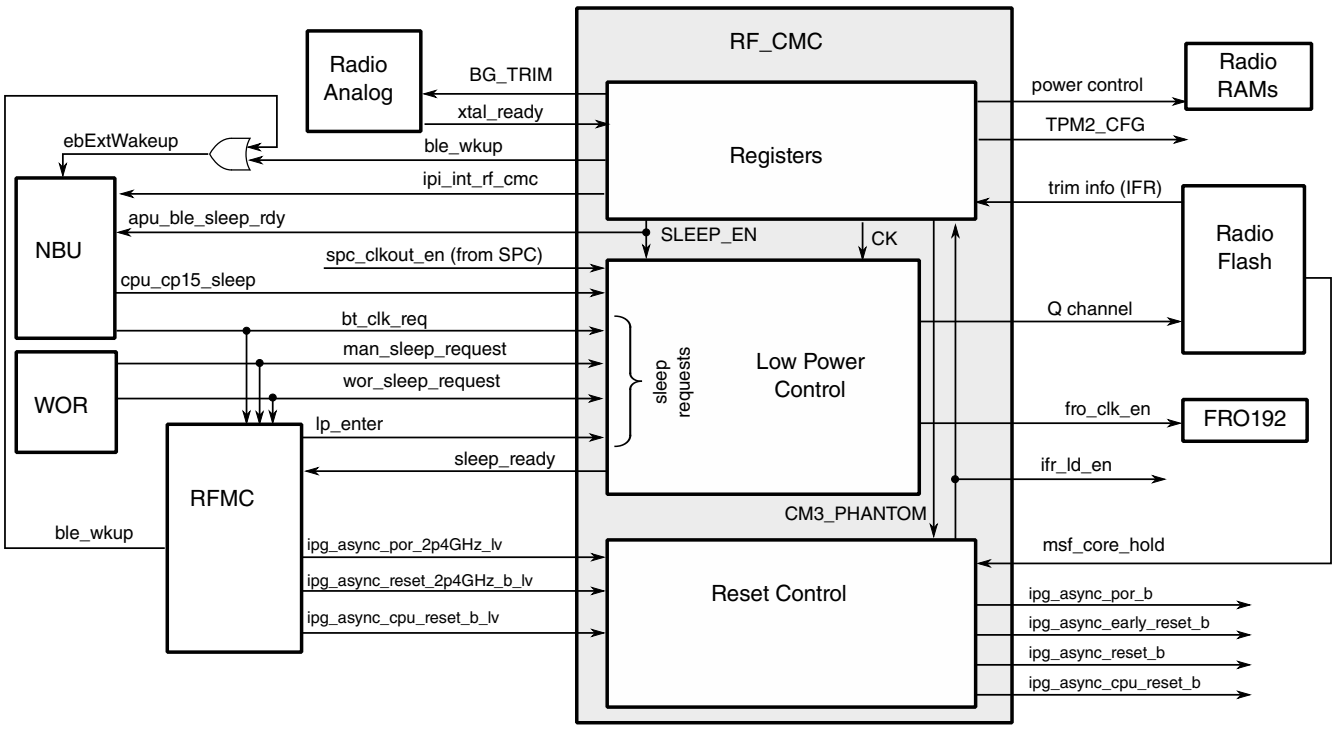


Figure 484. RF_CMC Block Diagram

57.3 Memory Map and Registers

57.3.1 RF_CMC register descriptions

57.3.1.1 RF_CMC memory map

RF_CMC1 base address: 4898_3000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Radio Low Power Control Register (RADIO_LP)	32	RW	0000_0000h
4h	SOC Low Power Control and Status Register (SOC_LP)	32	RW	0000_0000h

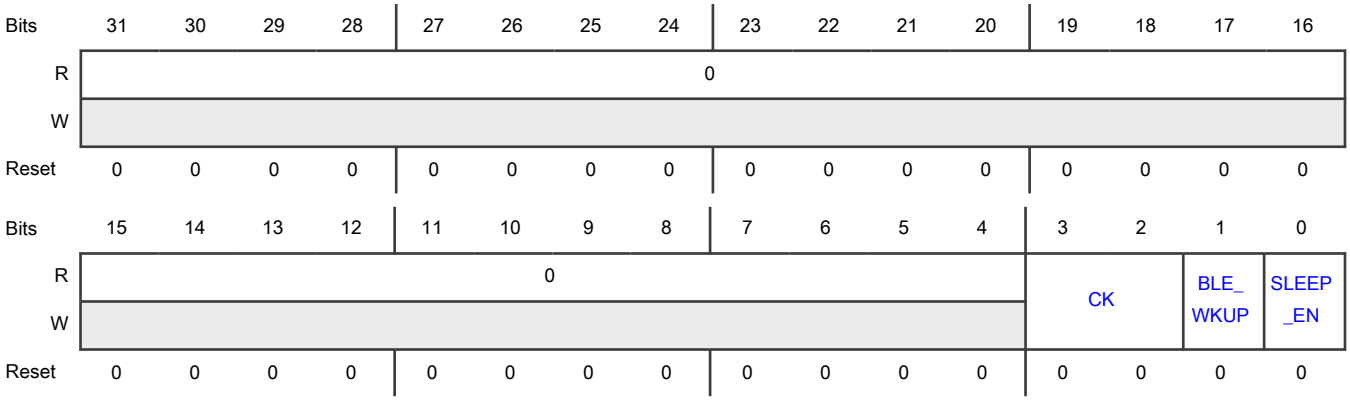
57.3.1.2 Radio Low Power Control Register (RADIO_LP)

Offset

Register	Offset
RADIO_LP	0h

Diagram



Fields

Field	Function
31-4 —	Reserved
3-2 CK	Clock Control These bits provide additional configuration for the RF_CMC 00b - Normal configuration. When NBU CPU executes WFI and SLEEP_EN=1 (or if NBU CPU reset is asserted), and a sleep request from RFMC (LP_ENTER) NBU, MAN or WOR is asserted, the flash is put in low power, the sleep_rdy to RFMC asserts and the FRO will be disabled. 01b - Configuration where NBU, FRO and flash are not used. When NBU CPU reset is asserted, or NBU CPU executes WFI and SLEEP_EN=1, the flash will be placed in low power, the FRO disabled, the sleep_rdy to RFMC will assert and the NBU CM3 and AHB clocks will be gated off. The RF_CMC and NBU CPU will be without a clock until the next reset, but low power requests (RFMC LP_ENTER, MAN or WOR) will by accepted by RFMC since RF_CMC's sleep_rdy output will remain asserted. 10b - Configuration where NBU CPU is not used but FRO and flash can still be used. When NBU CPU reset is asserted, or NBU CPU executes WFI and SLEEP_EN=1, the clock to the NBU CPU will be gated. When RFMC (LP_ENTER), MAN or WOR request sleep, the flash is put in low power, the sleep_rdy to RFMC asserts and the FRO will be disabled as in configuration 00.
1 BLE_WKUP	Bluetooth Wakeup

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Software control bit which can be used to force the NBU to assert its bt_clk_req output. Note that this bit is OR'ed with RFMC's BLE_WKUP bit; the output of that OR is connected to the NBU's ebExtWakeup input.
0 SLEEP_EN	Sleep Enable Software control bit which gates all sleep entry requests. Software should clear this bit if it is not ready to enter sleep, and set it when it is ready. This bit does not automatically clear on low power exit. This bit is also input to NBU as "apu_ble_slp_rdy".

57.4 Functional description

57.4.1 Reset Control

The Reset control module performs the following functions

- On exit from Power Down or Deep Power Down low power modes, holds the radio LV in reset until the radio flash has finished its initialization.
- Supports CM3_PHANTOM feature which can hold CM3 in reset
- Generates the flash ifr_ld_en used to capture the radio flash IFR outputs

57.4.2 Low Power Control

The Low Power control module performs the following functions

- Provides the enable to radio FRO module, which is sequenced off at low power entry, and on at low power exit using the spc_clkout_en signal. The FRO can also be gated off in the CK=01 configuration
- Controls the low power sequencing for the radio flash via Q-channel interface.
- Creates a sleep_rdy signal to the RFMC. This signal must be asserted before the RFMC will accept a request to enter low power mode.

The RF_CMC supports the following low power configurations, selected by the programmable CK bits.

- CK=00. This is the normal/default configuration. When NBU CPU executes WFI and SLEEP_EN=1 (or if NBU CPU reset is asserted), and a sleep request from RFMC (LP_ENTER) NBU, MAN or WOR is asserted, the flash is put in low power, then the sleep_rdy to RFMC asserts and the FRO will be disabled.
- CK=01. This configuration supports use cases where NBU, FRO and flash are not used. When NBU CPU reset is asserted, or NBU CPU executes WFI and SLEEP_EN=1, the flash will be placed in low power, then the FRO disabled, the sleep_rdy to RFMC will assert and the NBU CM3 and AHB clocks will be gated off. Note the following behavior in the configuration after the FRO is disabled:
  - Read/write access to RF_CMC's registers will not be possible
  - RF_CMC's sleep_rdy output will remain asserted, so low power requests from RFMC (LP_ENTER), MAN or WOR will be immediately accepted by RFMC
  - If will not be possible to reprogram the RAM_RM registers, but the RAM control logic will still respond correctly to voltage select changes
- CK=10. Configuration where NBU CPU is not used but FRO and flash can still be used. When NBU CPU reset is asserted, or NBU CPU executes WFI and SLEEP_EN=1, the clock to the NBU CPU will be gated. When RFMC (LP_ENTER), MAN or WOR request sleep, the flash is put in low power, then the sleep_rdy to RFMC asserts and the FRO will be disabled as in configuration 00.</brief_description>

Chapter 58
Radio Flash

58.1 Introduction

The Radio Flash is the wrapper that contains 256 KB flash and FMC. It manages accesses performed by the bus masters of the system to the radio flash memory.

58.2 Memory Map and register definition

This section includes the Radio Flash module memory map and detailed descriptions of all registers.

58.2.1 RadioFlash register descriptions

58.2.1.1 RadioFlash memory map

RF_FMCCFG base address: 4898_2000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Radio Flash Memory Controller Configuration Register (RFMCCFG)	32	RW	0000_0000h

58.2.1.2 Radio Flash Memory Controller Configuration Register (RFMCCFG)

Offset

Register	Offset
RFMCCFG	0h

Function

The flash controller needs to be idle when writing to the RFMCCFG register associated with Flash memory. This means no read/erase/execute/etc operations from the Flash memory should be made while writing to the RFMCCFG register. Changing controller configuration while active can cause undesired results.

Chapter 59
FRO Clock Generator (FRO192M)

59.1 Overview

The FRO192 module provides the system clocks for the Radio Mode Controller.

59.1.1 Block Diagram

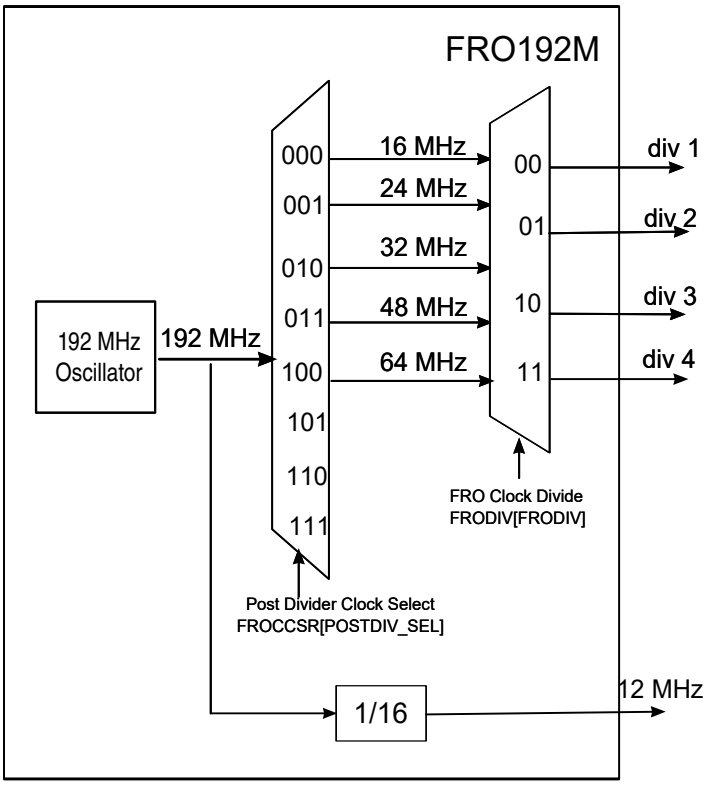

Figure 485. Clock Generator block diagram

59.1.2 Features

Key features of the FRO192 module are:

- Programmable post-divider for up to 5 different frequency ranges

59.2 Functional description

59.2.1 Modes of operation

The following table describes the modes available for FRO192.

Table 492. Operating modes

Mode	Entry	Exit	Description
Reset	POR Warm Reset Disabled	Reset Deassertion	FRO192 is reset.
Run	Enabled	POR Warm Reset Disabled	FRO192 is allowed to run and generate an output clock.
Disabled	Disabled	Run	FRO192 is held in a reset state and waiting to be enabled to switch over to Run mode.

59.2.2 Interrupts

FRO192 does not support any interrupts.

59.2.3 Clocks

FRO192 registers and logic are clocked by the slow bus clock.

The following table describes the clocks of FRO192.

Table 493. Clocks and their description

Clock	Type	Description
Slow Bus Clock	Input	FRO192 register read/write clock source.
FRO Bus Clock	Output	FRO192 Div Clock/FRODIV output divided system clock.
Fixed_clk	Output	FRO192 fixed 12 MHz output clock source.

59.3 External signals

This module has no external signals.

59.4 Initialization

By default, FRO192 is disabled and enabled by external block. It requires no initialization.

59.5 Memory Map/Register Definition

This section includes the memory map and register definition.

59.5.1 FRO192 clock generator register descriptions

- For any writeable registers, only 32-bit writes are allowed. 8-bit or 16-bit writes will result in transfer errors.

59.5.1.1 FRO192 memory map

FRO192M0 base address: 4898_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	FRO192 Clock Control Status Register (FROCCSR)	32	RW	0000_2001h

Field	Function
14-12 POSTDIV_SEL	Post Divider Clock Select This field selects the correct post divider to generate selected output frequenc clock. Output frequency options supported are 64 MHz, 48 MHz, 32 MHz, 24 MHz, and 16 MHz. Divide values can be changed while FRO192 is enabled 000b - FRO 16MHz Range selected. 001b - FRO 24MHz Range selected 010b - FRO 32MHz Range selected 011b - FRO 48MHz Range selected 100b - FRO 64MHz Range selected 101b - RESERVED. Not Supported 110b - RESERVED. Not Supported 111b - RESERVED. Not Supported
11-2 —	Reserved
1-0 FRODIV	FRO Clock Divide This field indicates the status of the FRODIV Divider. 00b - Divide by 1 01b - Divide by 2 10b - Divide by 3 11b - Divide by 4

59.5.1.3 FRO192 Divide Register (FRODIV)

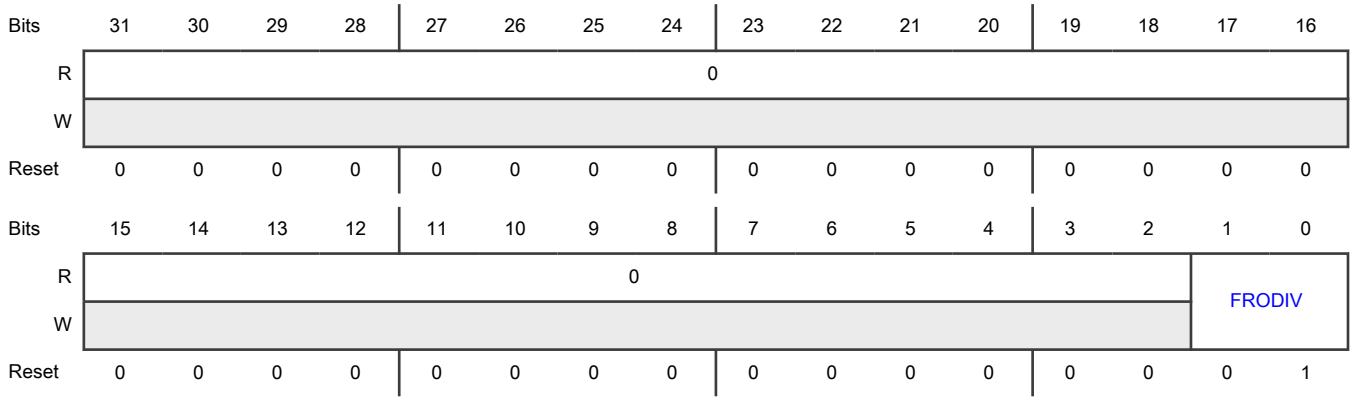
Offset

Register	Offset
FRODIV	4h

Function

This register divides the output of the POSTDIV_SEL to generate the a system clock source.

Diagram



Fields

Field	Function
31-2 —	Reserved
1-0 FRODIV	FRO Clock Divide This read/write field select the clock divider ratio for POSTDIV_SEL output clock. Used to generate the system clock source. 00b - Divide by 1 01b - Divide by 2 10b - Divide by 3 11b - Divide by 4

Legal information

Definitions

Draft — A draft status on a document indicates that the content is still under internal review and subject to formal approval, which may result in modifications or additions. NXP Semiconductors does not give any representations or warranties as to the accuracy or completeness of information included in a draft version of a document and shall have no liability for the consequences of use of such information.

Disclaimers

Limited warranty and liability — Information in this document is believed to be accurate and reliable. However, NXP Semiconductors does not give any representations or warranties, expressed or implied, as to the accuracy or completeness of such information and shall have no liability for the consequences of use of such information. NXP Semiconductors takes no responsibility for the content in this document if provided by an information source outside of NXP Semiconductors.

In no event shall NXP Semiconductors be liable for any indirect, incidental, punitive, special or consequential damages (including - without limitation - lost profits, lost savings, business interruption, costs related to the removal or replacement of any products or rework charges) whether or not such damages are based on tort (including negligence), warranty, breach of contract or any other legal theory.

Notwithstanding any damages that customer might incur for any reason whatsoever, NXP Semiconductors' aggregate and cumulative liability towards customer for the products described herein shall be limited in accordance with the Terms and conditions of commercial sale of NXP Semiconductors.

Right to make changes — NXP Semiconductors reserves the right to make changes to information published in this document, including without limitation specifications and product descriptions, at any time and without notice. This document supersedes and replaces all information supplied prior to the publication hereof.

Suitability for use — NXP Semiconductors products are not designed, authorized or warranted to be suitable for use in life support, life-critical or safety-critical systems or equipment, nor in applications where failure or malfunction of an NXP Semiconductors product can reasonably be expected to result in personal injury, death or severe property or environmental damage. NXP Semiconductors and its suppliers accept no liability for inclusion and/or use of NXP Semiconductors products in such equipment or applications and therefore such inclusion and/or use is at the customer's own risk.

Applications — Applications that are described herein for any of these products are for illustrative purposes only. NXP Semiconductors makes no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

Customers are responsible for the design and operation of their applications and products using NXP Semiconductors products, and NXP Semiconductors accepts no liability for any assistance with applications or customer product design. It is customer's sole responsibility to determine whether the NXP Semiconductors product is suitable and fit for the customer's applications and products planned, as well as for the planned application and use of customer's third party customer(s). Customers should provide appropriate design and operating safeguards to minimize the risks associated with their applications and products.

NXP Semiconductors does not accept any liability related to any default, damage, costs or problem which is based on any weakness or default in the customer's applications or products, or the application or use by customer's third party customer(s). Customer is responsible for doing all necessary testing for the customer's applications and products using NXP Semiconductors products in order to avoid a default of the applications and the products or of the application or use by customer's third party customer(s). NXP does not accept any liability in this respect.

Terms and conditions of commercial sale — NXP Semiconductors products are sold subject to the general terms and conditions of commercial sale, as published at https://www.nxp.com/profile/terms, unless otherwise agreed in a valid written individual agreement. In case an individual agreement is concluded only the terms and conditions of the respective agreement shall apply. NXP Semiconductors hereby expressly objects to applying the customer's general terms and conditions with regard to the purchase of NXP Semiconductors products by customer.

Export control — This document as well as the item(s) described herein may be subject to export control regulations. Export might require a prior authorization from competent authorities.

Suitability for use in non-automotive qualified products — Unless this document expressly states that this specific NXP Semiconductors product is automotive qualified, the product is not suitable for automotive use. It is neither qualified nor tested in accordance with automotive testing or application requirements. NXP Semiconductors accepts no liability for inclusion and/or use of non-automotive qualified products in automotive equipment or applications.

In the event that customer uses the product for design-in and use in automotive applications to automotive specifications and standards, customer (a) shall use the product without NXP Semiconductors' warranty of the product for such automotive applications, use and specifications, and (b) whenever customer uses the product for automotive applications beyond NXP Semiconductors' specifications such use shall be solely at customer's own risk, and (c) customer fully indemnifies NXP Semiconductors for any liability, damages or failed product claims resulting from customer design and use of the product for automotive applications beyond NXP Semiconductors' standard warranty and NXP Semiconductors' product specifications.

Translations — A non-English (translated) version of a document, including the legal information in that document, is for reference only. The English version shall prevail in case of any discrepancy between the translated and English versions.

Security — Customer understands that all NXP products may be subject to unidentified vulnerabilities or may support established security standards or specifications with known limitations. Customer is responsible for the design and operation of its applications and products throughout their lifecycles to reduce the effect of these vulnerabilities on customer's applications and products. Customer's responsibility also extends to other open and/or proprietary technologies supported by NXP products for use in customer's applications. NXP accepts no liability for any vulnerability. Customer should regularly check security updates from NXP and follow up appropriately.

Customer shall select products with security features that best meet rules, regulations, and standards of the intended application and make the ultimate design decisions regarding its products and is solely responsible for compliance with all legal, regulatory, and security related requirements concerning its products, regardless of any information or support that may be provided by NXP.

NXP has a Product Security Incident Response Team (PSIRT) (reachable at PSIRT@nxp.com) that manages the investigation, reporting, and solution release to security vulnerabilities of NXP products.

NXP B.V. — NXP B.V. is not an operating company and it does not distribute or sell products.

Trademarks

Notice: All referenced brands, product names, service names, and trademarks are the property of their respective owners.

NXP — wordmark and logo are trademarks of NXP B.V.

AMBA, Arm, Arm7, Arm7TDMI, Arm9, Arm11, Artisan, big.LITTLE, Cordio, CoreLink, CoreSight, Cortex, DesignStart, DynamIQ, Jazelle, Keil, Mali, Mbed, Mbed Enabled, NEON, POP, RealView, SecurCore, Socrates, Thumb, TrustZone, ULINK, ULINK2, ULINK-ME, ULINK-PLUS, ULINKpro, µVision, Versatile — are trademarks and/or registered trademarks of Arm Limited (or its subsidiaries or affiliates) in the US and/or elsewhere. The related technology may be protected by any or all of patents, copyrights, designs and trade secrets. All rights reserved.

Bluetooth — the Bluetooth wordmark and logos are registered trademarks owned by Bluetooth SIG, Inc. and any use of such marks by NXP Semiconductors is under license.

Matter, Zigbee — are developed by the Connectivity Standards Alliance. The Alliance's Brands and all goodwill associated therewith, are the exclusive property of the Alliance.
